KIDNEYWEEK 2015

KIDNEYWEEK 2015
San Diego, CA • Nov 3-8

JASN Abstract Supplement

Abstract Publication
More than 4,300 abstracts are published in this supplement. Abstracts are arranged by the abstract type**, then by presentation date*, and then by chronological publication number. Abstracts with a "PUB" number will not be presented at the ASN Annual Meeting.

* TH = Thursday, FR = Friday, SA = Saturday
** OR = Oral, PO = Poster, PUB = Publication Only

The presenting author's name is underlined. For the poster sessions, the publication numbers and poster board numbers are the same.

Abstract Author Index
The Author Index lists all abstract authors in alphabetical order. To locate an abstract, first reference the abstract type (OR, PO, or PUB) and then the presentation day (TH, FR, or SA), and then the chronological publication number.

Abstract Keyword Index
The Keyword Index lists major keywords from each abstract in alphabetical order. To locate an abstract, first reference the abstract type (OR, PO, or PUB) and then the presentation day (TH, FR, or SA), and then the chronological publication number.

Abstract Reference Format
To cite abstracts in this publication, please use the following format: Author Names: Abstract Title [Abstract]. J Am Soc Nephrol 26, 2015: Page(s).

Abstract Experts
Abstract submissions were rigorously reviewed and graded by multiple experts. ASN thanks the abstract category chairs and reviewers for assistance with the abstract process. The *Onsite Program* lists all abstract experts.

Abstract Disclaimer and Copyright
The Abstract Issue of JASN® contains proprietary information belonging to the American Society of Nephrology (ASN). It is published as a service for the personal, noncommercial, and informational use only of its members and Kidney Week participants. Any commercial use is strictly prohibited. ASN's program materials and publications facilitate scientific discourse for educational purposes. ASN accepts no responsibility for any products, presentations, opinions, statements, or positions expressed, and inclusion of such material within Kidney Week and other ASN publications, or online postings does not constitute an endorsement by ASN.

ASN General Information

Kidney Week Program and Presentations
The Kidney Week 2015 program, which can be found in the *Onsite Program*, includes:

- Plenary Sessions
- Basic/Clinical Science Sessions
- Clinical Practice Sessions
- Translational Sessions
- Special Sessions
- Educational Symposia
- Oral Abstract Sessions
- Poster Sessions

Disclosure Statement
ASN requires all individuals in a position to control content for Kidney Week 2015 to complete a disclosure form. Responses are listed on the ASN website (www.asn-online.org/kidneyweek/faculty) and on the Kidney Week 2015 mobile app.

Program Builder
All abstracts and the complete Kidney Week 2015 program are viewable online through the Program Builder at www.asn-online.org/KidneyWeek with features including keyword search and PDA download.

Dapagliflozin Reduces Albuminuria Over 2 Years in Diabetic Patients with Renal Impairment Bergur V. Stefansson,[2] Paola Fioretto,[1] Eva K.A. Johnsson,[2] Valerie A. Cain,[3] David Sjostrom.[2] *[1]Univ of Padova, Italy; [2]AZ, Mölndal, Sweden; [3]AZ, Wilmington.*

Background: Pooled clinical data has shown reductions in albuminuria during dapagliflozin (DAPA) treatment. This analysis explored the long term effect of DAPA on albuminuria and renal safety.

Methods: This is a post hoc analysis of patients with CKD3 and albuminuria (³30 mg/g) from study NCT00663260. Percent change in urinary albumin:creatinine ratio (UACR) was evaluated up to 104 weeks. At baseline 57 placebo (PBO), 53 DAPA 5 mg and 56 DAPA 10 mg patients were identified.

Results: The baseline (BL) median (range) values for UACR, mg/g, were PBO: 180 (30 to 9262), DAPA 5 mg: 397 (31 to 4970) and DAPA 10 mg: 179 (32 to 4792). The corresponding mean (SD) values for eGFR, mL/min/1.73 m^2, were: 45.1 (9.37), 43.9 (8.96) and 44.1 (11.1), respectively. A reduction in UACR was already evident at Week 1. At 104 weeks the mean (95% CI) PBO-corrected reduction in UACR was –44% (–71, 9.0) and –57% (–77, –20) for DAPA 5 and 10 mg, respectively. After adjusting for changes in blood pressure, HbA1c and eGFR, the reductions were largely maintained. During the 104 week study period 7% of PBO patients regressed to normoalbuminuria, the corresponding numbers for DAPA 5 and 10 mg were 19 and 18%, respectively. After a transient decrease in eGFR in DAPA-treated patients, the DAPA 5 and 10 mg groups showed PBO-corrected 104 week changes of 2.1 (–1.3, 5.5) and –0.7 (–4.0, 2.6) mL/min/1.73 m^2. Renal adverse events (AEs) were more common in DAPA 10 mg treated subjects (10.7%) than in DAPA 5 mg (1.9%) or PBO treated (3.5%) subjects, many were due to increased creatinine. There was no increase in serious AEs related to renal impairment in the DAPA 10 mg group (1.8%) compared with the PBO group (1.8%).

Conclusions: Dapagliflozin reduces UACR for up to 2 years in subjects with CKD3, without increases in serious renal AEs. The UACR reduction remained present after adjustments for changes in blood pressure, HbA1c and eGFR, indicating a direct renal effect independent of changes in these variables.

Structural Predictors of Loss of Renal Function in Type 2 Diabetes Gudeta D. Fufaa,[1] E. Jennifer Weil,[1] Kevin V. Lemley,[2] William Knowler,[1] Frank C. Brosius,[3] Berne Yee,[4] Michael Mauer,[5] Robert G. Nelson.[1] *[1]NIDDK; [2]Univ of Southern California; [3]Univ of Michigan; [4]Southwest Kidney Inst; [5]Univ of Minnesota.*

Background: Diabetes is the leading cause of kidney failure in the US, but the early structural determinants of renal function loss in type 2 diabetes are poorly defined. We examined the association between morphometrically-determined renal structural variables and renal function loss in 111 Pima Indians with type 2 diabetes who volunteered for a research kidney biopsy and for annual measurement of glomerular filtration rate (GFR, iothalamate).

Methods: Renal function loss was defined as ≥40% loss of GFR from baseline. Associations with renal function loss were evaluated by Cox proportional-hazards regression. Hazard ratios (HR) were reported per 1 SD increment for each morphometric variable.

Results: Of the 111 participants (82% women, baseline mean age 46 years, diabetes duration 16 years, HbA1c 9.4%, GFR 147 ml/min, and median albumin/creatinine ratio [ACR] 41 mg/g), 51 (46%) developed renal function loss during a median follow-up of 6.6 years (IQR=3.1-9.0). Higher mesangial fractional volume (HR=2.33, 95% CI 1.63-3.33), percent global sclerosis (HR=1.57, 95% CI 1.18-2.09), non-podocyte cell number per glomerulus (HR=1.49, 95% CI 1.08-2.05), GBM width (HR=1.45, 95% CI 1.04-2.04), lower glomerular filtration surface density (HR=0.61, 95% CI 0.41-0.93), and reduced endothelial fenestrations (HR=0.67, 95% CI 0.47-0.94) were each associated with loss of renal function after adjustment for baseline age, sex, duration of diabetes, HbA1c and GFR. Although power was reduced when 14 participants with baseline GFR <90 ml/min were excluded from the analysis, baseline structure still predicted renal function loss.

Conclusions: Quantitative measures of glomerular structure predict loss of renal function in type 2 diabetes.

Mitotic Catastrophe in Diabetic Nephropathy Masanori Hara,[1] Helen Liapis.[2] *[1]Dept of Pediatrics, Yoshida Hospital, Tsubame, Niigata, Japan; [2]Nephropath, Little Rock, AR.*

Background: Podocytopenia is involved in the progression of diabetic nephropathy. Apoptosis is thought to be a major mechanism for loss of podocytes. However, apoptotic podocytes (Podo) are not seen in renal biopsy specimens with diabetes. Instead mitotic catastrophe (MC) is a newly recognized form of podocyte death characterized by Podo multinucleation, aberrant mitotic spindles and micronucleoli. Because injured podocytes may die and released in the urine, in this study we sought to quantitate MC in urine samples from diabetic patients.

Methods: Urine samples from patients with diabetes type 2 (n=41, microalbuminuria 8, macroalbuminuria 33) were used. All samples were evaluated for the presence of urinary Podo by immunofluorescence (IF) using anti-podocalyxin (PCX) antibody and the only PCX positive Podo (PCX-podo) were selected for further immunohistochemical study. Urine sediments were double or triple stained by IF using antibodies against various podocyte antigens such as 1) PCX, nephrin, podocine and GLEPP1 (podocyte markers), 2) macrophages, and panleucocytes (leucocyte markers), 3) cytokeratin 8 (parietal epithelial marker), 4) Annexin V, cleaved caspase-3 and Tunel assay (apoptosis markers), and 5) phosphorylated vimentin (cell mitosis marker). Nucleus was stained with hematoxylin or DAPI.

Results: The PCX-podo showed various nuclear morphology such as 1) mononucleated, normal shape (8.7%), 2) mononucleated, large and abnormal shape (3.8 %), 3) multinucleated with or without micronucleoli (40.2%) 4) single nucleus and fragmented nuclei (10.9%) and 5) numerous fragmented nuclei (31.0%). We considered 2) and 3) as definitive MC, and 4) and 5) suspected MC. Apoptotic bodies were not found. 50% of PCX-podo were positve for GLEPP 1, while none of PCX-podo were positive for nephrin and podocine. None of PCX-podo were positive for leucocyte and parietal epithelial cell markers, annexin V, cleaved caspase-3 and Tunel assay. 10 % of PCX-podo were positive for phosphorylated vimentin.

Conclusions: Urine from diabetic patients contains a significant number of urinary Podo with MC and no Podos with apoptotic bodies. Our results indicate that the majority of urine podocytes in diabetic patients may be due to MC and not to apoptosis.

TH-OR004

Advanced Glycation End Products Predict Loss of Renal Function and Correlate with Diabetic Nephropathy Lesions in Type 2 Diabetes Pierre Jean Saulnier,[1] Kevin M. Wheelock,[1] William Knowler,[1] Robert G. Nelson,[1] Paul James Beisswenger,[2] Scott K. Howell.[2] *[1]NIDDK; [2]PreventAGE Healthcare.*

Background: We examined the associations of serum advanced glycation end-products (AGEs) with loss of renal function and with the structural lesions of diabetic nephropathy in a post-hoc analysis of a clinical trial of renoprotection with losartan in Pima Indians with type 2 diabetes (ClinicalTrials.gov number, NCT00340678).

Methods: Free AGEs were measured at baseline in 168 subjects by LC triple quadrupole mass spectrometry. Glomerular filtration rate (GFR, iothalamate) was measured annually, and kidney biopsies were performed in 109 of the subjects 6 years later. Loss of renal function was defined as ≥40% loss of GFR from baseline. Multivariable associations between AGEs and loss of renal function were examined by Cox proportional-hazards regression, and between AGEs and morphometric variables by linear regression, after adjustment for age, sex, diabetes duration, HbA1c, treatment, albumin/creatinine ratio (ACR), and GFR. Hazard ratios (HR) were reported per doubling for each AGE. Linear regression results were reported as the difference in the structural measurement in SD units per doubling of AGE.

Results: Of the 168 subjects (73% women, mean age 41±11 years, diabetes duration 11±6 years, HbA1c 9.2±2.3%, median GFR=165 ml/min(IQR=135-190), and median ACR=31 mg/g (IQR=14-76)), 104 (62%) lost ≥40% of their renal function during a median follow-up of 8.0 years (IQR=4.9-13.1). After multivariable adjustment, higher concentrations of carboxyethyllysine (CEL) and methylglyoxal hydroimidazolones (MGH1) were associated with loss of renal function (HR for CEL=1.7, 95% CI 1.1-2.5; HR for MGH1=1.3, 95% CI 1.1-1.7). MGH1 (β=0.23, P=0.018) and CEL (β=0.36, P=0.033) were also positively associated with mesangial fractional volume, and MGH1 (β=-0.27, P=0.009) and 3DG hydroimidazolone (3DGH) (β=-0.27, P=0.047) were inversely associated with total filtration surface per glomerulus.

Conclusions: Higher baseline dicarbonyl-derived AGEs are associated with loss of renal function and its structural correlates, including increased mesangial fractional volume and the corresponding loss of total filtration surface per glomerulus.

TH-OR005

Serum Amyloid A and Increased Risk of End-Stage Renal Disease and Death in Diabetic Kidney Disease Brad Dieter,[1] Sterling Mcpherson,[2] Maryam Afkarian,[3] Ian H. De Boer,[3] Rajnish Mehrotra,[3] Rick L. Meek,[3] Katherine R. Tuttle.[1,3] *[1]Providence Health Care, Spokane, WA; [2]Washington State Univ, Spokane, WA; [3]Univ of Washington, Seattle, WA.*

Background: Serum amyloid A (SAA) activates inflammation and apoptosis in kidney cells. SAA is also increased in the blood, urine, and kidneys of mice and people with DKD. The objective of this study was to determine if SAA adds to risk prediction models for death and end-stage renal disease (ESRD) in DKD.

Methods: Serum SAA was measured in a longitudinal cohort with type 2 diabetes and prevalent DKD, defined by urine protein-to-creatinine ratio >0.5 g/g (n=135). Cox-proportional hazard models tested whether SAA was associated with a composite primary outcome of death and ESRD, adjusting for age, sex, race, hemoglobin A1c, diabetes duration, body mass index, renin-angiotensin system inhibitor use, systolic and diastolic blood pressure, albuminuria and estimated glomerular filtration rate (eGFR). Improvement in risk prediction was assessed by receiver-operating curves (ROC), goodness-of-fit, and Akaike's Information Criterion (AIC).

Results: Participants were 73% Mexican-American (99/135) with mean (SD) age of 57 (7.4) years, 55% male (75/135), mean eGFR 56 (22) ml/min/1.73m^2, and median (IQR) urine albumin-to-creatinine of 1.9 (0.7-3.9) g/g. The incident rate for the primary outcome was 44 % (60/135). Risk of the composite primary outcome was higher in the 3rd tertile of SAA (>1.0 ug/ml) compared to the 1st tertile (<0.55 ug/ml): adjusted HR=3.7, 95 % CI 1.7–8.3, p<0.001. The risk of death was markedly increased in the 3rd versus 1st tertile of SAA: adjusted HR 8.2, 95% CI 2.7-24.2, p<0.001. The C-statistic, generated from ROC curves, improved predictive ability of the model for the primary outcome (0.71 and 0.74, without versus with SAA). Goodness-of-fit and AIC also improved with inclusion of SAA.

Conclusions: In DKD, higher serumSAA concentration is associated with increased risk of death and ESRD. SAA improves risk prediction when added to traditional risk factors. SAA is a candidate biomarker that may advance DKD risk assessment and is a potential therapeutic target.

Biomarkers of Early Decline in Renal Function: A Translational Study in Type 2 Diabetes Jennifer W. Xu,[1] Carla Cavallin,[1] Sona Haku,[1,2] Michael S. Simonson.[1] *[1]Nephrology and Hypertension, Univ Hospitals Case Medical Center and CWRU School of Medicine, Cleveland, OH; [2]Dept of Medical Science and Cardiorenal Medicine, Yokohama City Univ Graduate School of Medicine, Yokohama, Japan.*

Background: Kidney disease in type 2 diabetes (DKD) is the leading cause of end-stage renal disease. Early detection and treatment of DKD can prevent or slow progression to end-stage disease, but identifying early decline in renal function can be problematic because albuminuria is insensitive. In a Phase I preclinical exploratory study we measured the performance of candidate biomarkers from mouse models of early renal function decline.

Methods: Patients with type 2 diabetes (median baseline eGFR = 80.3 + 29.5 ml/min/1.73m^2) were recruited into training (n=56) and independent, non-overlapping test (n=37) groups. Biomarkers were measured in spot urine collections by ELISA, and performance was assessed as area under the receiver operating characteristic curve (AUC) with adjustment for clinical covariates of DKD.

Results: For classifying participants with baseline early renal function decline (eGFR 90 – 60) vs normal function (i.e., >90), the highest performing biomarkers were: transforming growth factor b (TGFb, AUC + SD, 0.827 + 0.070), interleukin-6 (IL-6, 0.815 + 0.065) and endothelin-1 (ET-1, 0.720 + 0.082; all $P < 0.01$ compared to ACR, 0.465 + 0.093 and angiotensinogen 0.465 ± 0.090). Performance was validated in the independent test group. AUCs were unchanged after multivariate adjustment for age, sex, race, duration of diabetes, HbA1c, hypertension, cardiovascular disease, body mass index, and use of angiotensin converting enzyme inhibitors or receptor blockers. In participants with eGFR 90 – 60 at baseline, TGFb, IL-6 and ET-1 predicted a composite renal outcome at 5 years (eGFR < 60 OR ESRD) better than ACR (0.769 ± 0.105, 0.690 ± 0.128, and 0.793 ± 0.091, all $P <$ 0.05 versus ACR, 0.520 ±0.119).

Conclusions: Urine levels of TGFb, IL-6 or ET-1 may identify patients with early renal function decline and aid development of novel therapeutics.

Primary Prevention of Albuminuria Using Renin-Angiotensin-System Inhibitors in Patients with Type 2 Diabetes: A Systematic Review and Meta-Analysis Frederik I. Persson,[1] Bianca Hemmingsen,[2] Morten Lindhardt,[1] Peter Rossing,[1,3,4] Hans-Henrik Parving.[3,5] *[1]Steno Diabetes Center, Gentofte, Denmark; [2]Copenhangen Trial Unit, Copenhagen Univ Hospital, Copenhagen, Denmark; [3]HEALTH, Univ of Aarhus, Aarhus, Denmark; [4]Novo Nordisk Foundation for Basic and Metabolic Research, Univ of Copenhagen, Copenhagen, Denmark; [5]Dept of Medical Endocrinology, Rigshospitalet, Copenhagen Univ Hospital, Copenhagen, Denmark.*

Background: Early prevention of diabetic nephropathy by way of blocking the renin angiotensin system (RAS) in patients with normoalbuminuria seems rational, but trials have so far shown conflicting results. The present meta-analysis was undertaken to investigate if such treatment can prevent development of microalbuminuria and also to assess whether available trials can provide sufficient information for such conclusions.

Methods: We searched MEDLINE, EMBASE and the Cochrane Library for double-masked randomised controlled trials, with a population of patients with type 2 diabetes and normoalbuminuria, comparing angiotensin enzyme inhibitors (ACEi) or angiotensin receptor blockers (ARB) to placebo. At least one year of follow-up was considered reasonable for the development of micro- or macroalbuminuria, and studies had to have at least 50 participants in each arm. Random and fixed effect models were performed as well as trial sequential analysis.

Results: Six trials were identified and included in the analysis (n=16921). Overall risk of bias was low. In a fixed model analysis ACE or ARB treatment was superior to placebo in relation to development of microalbuminuria, relative risk 0.84 (95% CI 0.79, 0.88) p<0.001, I^2 23%, risk difference -0.04 (-0.05, -0.03), p= 0.001. Similar results were seen with the random model approach. Trial sequential analysis revealed a Z-value of 6.53 and an information size of 4163 patients (O'Brien twosided 5% boundaries).

Conclusions: Sufficient trial data are available for the meta-analysis to conclude that in patients with type 2 diabetes and normoalbuminuria, ACEinhibitors or ARBs reduces the risk for development of microalbuminuria.

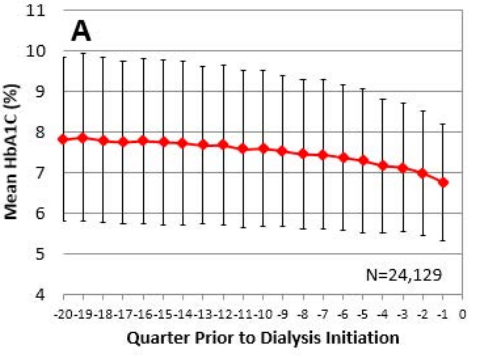
TH-OR008

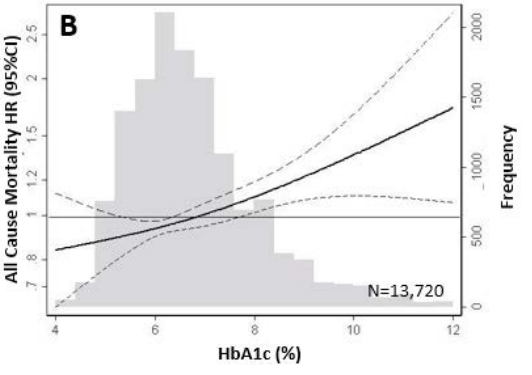
The Impact of Pre-ESRD Glycemic Status on Early Post-ESRD Mortality Among U.S. Veterans: A Transition of Care in CKD Study Connie Rhee,[1] Elani Streja,[1] Melissa Soohoo,[1] Jennie Jing,[1] Danh V. Nguyen,[1] Steven M. Brunelli,[2] Gregory Brent,[3] Csaba P. Kovesdy,[4] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]DaVita Clinical Research; [3]UCLA; [4]UTHSC.*

Background: In the general population randomized controlled trials show no benefit and possible harm with intensive glycemic targets in diabetics. Non-dialysis dependent (NDD) CKD and ESRD patients experience both hypo- and hyperglycemia through multifactorial pathways, and studies of glycemic status and mortality in dialysis patients have shown mixed findings. Little is known about the net effect of kidney dysfunction on glucose homeostasis in NDD-CKD patients transitioning to dialysis, and how pre-ESRD glycemic status impacts early post-ESRD mortality.

Methods: We first examined the longitudinal trajectory of glycemic status defined by HbA1c during the 5-year pre-ESRD prelude period among veterans with NDD-CKD transitioning to dialysis from 10/2007-9/2011. In a subcohort of patients with at least one HbA1c measure during the 6 month prelude period, we then examined HbA1c levels averaged over 6 months as a continuous predictor of all-cause mortality using restricted cubic spline analysis. Associations with mortality in the first 3 months of ESRD were estimated using Cox models adjusted for age, sex, race, ethnicity, ESRD cause, and geographic region.

Results: Among 24,129 veterans transitioning to dialysis, there was a decline in mean HbA1c over the 5 year prelude period. Among 13,720 patients with at least one HbA1c in the 6 month prelude period, higher HbA1c was monotonically associated with a higher risk of post-ESRD death.





Conclusions: In veterans transitioning to dialysis there is a steady decline in HbA1c as they approach ESRD. Higher HbA1c levels in the pre-ESRD period are associated with higher early post-ESRD mortality. Further studies are needed to determine if glycemic-lowering strategies in the pre-ESRD period improves post-ESRD outcomes.

TH-OR009

Glycemic Markers and 2-Year Diabetic Hemodialysis Outcomes from the Glycemic Indices in Dialysis Evaluation Study Mark E. Williams,[1] Neal Mittman,[2] Lin Ma,[3] Julia I. Brennan,[4] Chinu M. Jani,[4] Curtis D. Johnson,[4] Franklin W. Maddux,[3] Eduardo K. Lacson.[3,5] *[1]Joslin Diabetes Center, Boston, MA; [2]Kidney Care of Brooklyn and Queens, Brooklyn, NY; [3]Fresenius Medical Care North America, Waltham, MA; [4]Spectra Laboratories, Rockleigh, NJ; [5]Physician, Lexington, MA.*

Background: Initial results from the GIDE (Glycemic Indices in Dialysis Evaluation) Study have added to concerns about sole reliance on hemoglobin (Hgb) A1c in patients with diabetes on hemodialysis (HD). We reported correlations of HgbA1c with nontraditional glycemic markers [albumin-adjusted and unadjusted fructosamine (AlbF; F) and glycated albumin (GA) or percent GA (%GA)]. One-year results indicated a potential association only with high AlbF and outcomes. We report here two-year outcomes.

Methods: 1,424 active HD patients with DM from 26 FMCNA facilities with glycemic markers from Jan-March 2013 were followed until April, 2015. Poor glycemic control was based on: HgbA1c >7% (sensitivity analysis>8%), AlbF ≥ 974 µmol/g, F > 285µmol/L, %GA >15.7%, and GA> 300 µmol/L. Standard and Time-dependent (TD) Cox models with adjustment for age, sex, race, ethnicity, vintage, BMI, HD catheter, and baseline comorbid illnesses were utilized to determine associations between each dichotomized glycemic index and hospitalization/death outcomes.

Results: Poor glycemic control was found in 28% according to HgbA1c>7% (13% for HgbA1c>8%), but 35% by AlbF, 87% by F, 81% by %GA, and 68% by GA. Elevated AlbF was significantly associated with 2-year hospitalization [Standard Cox: Hazard Ratio (HR)=1.66, 95% CI (1.28,2.15), p=0.0001; TD Cox: HR=1.83, 95% CI (1.37,2.44), p<0.0001] and mortality [Standard Cox: HR=1.53, 95% CI (1.21,1.93), p=0.0004; TD Cox: HR=1.65, 95% CI (1.28,2.13), p=0.0001]. For all other glycemic indices, there were no such associations, at the proposed thresholds for glycemic control.

Conclusions: A strong association between poor glycemic control, determined by elevated AlbF, and worse 2-year hospitalization and mortality risks has emerged from the GIDE study data. Future analyses will include longer follow-up, use of continuous values for glycemic indices, and cardiovascular mortality outcomes.

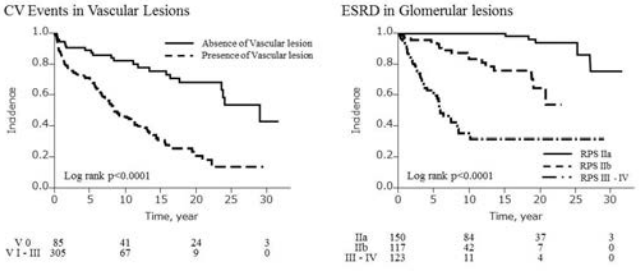
TH-OR010

Renal Biopsy for Diabetic Nephropathy Is Useful for the Prediction of Cardiovascular Events – 10-Year Follow Up Katsuhiko Morimoto, Ken-ichi Samejima, Masaru Matsui, Yasuhiro Akai, Miho Tagawa, Yoshihiko Saito. *First Dept of Internal Medicine, Nara Medical Univ, Kashihara, Japan.*

Background: Diabetic nephropathy has a higher risk of cardiovascular (CV) events and end-stage renal disease (ESRD). However, the association between renal histopathology, especially vascular lesion, and CV risk in diabetic nephropathy remains to be elucidated. We investigated the relationship between the glomerular or vascular lesions of renal specimen and CV events or ESRD in the patients with biopsy-proven diabetic nephropathy.

Methods: Three hundred ninety patients with biopsy-proven diabetic nephropathy with type 2 diabetes were enrolled in this retrospective study. According to the Renal Pathological Society (RPS) classification, the glomerular lesions were divided into three groups as IIa, IIb, and III – IV and vascular lesions were classified into 2 groups according to the absence or presence of vascular involvement.

Results: The background features were as follows: mean age of 57.7 ± 11.3 years old, the average observation period of 9.3 ± 8.0 years. During the observation period 164 patients had outcome of CV events and 71 patients reached ESRD. In Kaplan-Meier survival analysis, significant difference among different glomerular lesion class and vascular class was observed in terms of CV events and ESRD, respectively.



In Cox proportional hazard analysis, presence of vascular lesion in the renal tissue was an independent risk factor for the development of CV events (HR 2.12 [1.27 to 3.70]) and glomerular lesion was NOT associated with CV events. Glomerular lesions in the renal tissue was an independent risk factor for the development of ESRD (IIb vs. IIa, HR 6.44 [2.39 to 20.7]; III – IV vs. IIa, HR 12.1 [4.46 to 39.2]) and vascular lesion was NOT associated with renal outcome.

Conclusions: Vascular lesion of renal tissue had predictive value for the development of CV events.

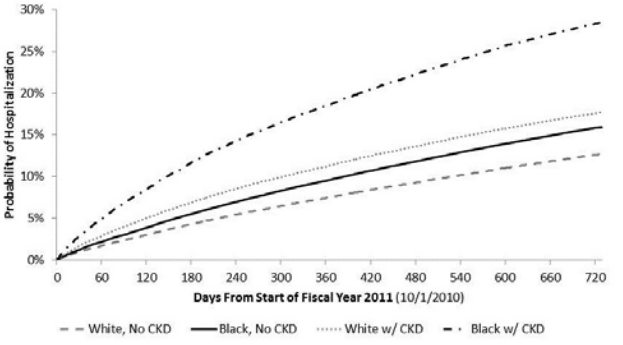
TH-OR011

Racial Differences in Hospitalization Rates Among U.S. Veterans with and without Chronic Kidney Disease Jennifer L. Bragg-Gresham,[1] Hal Morgenstern,[1] Neil R. Powe,[2] Deidra C. Crews,[3] Nilka Rios Burrows,[4] Sharon Saydah,[4] Kara Zivin,[1] Rajiv Saran.[1] *[1]KECC & SPH, Univ of Michigan, Ann Arbor, MI; [2]Univ of California, San Francisco, CA; [3]Johns Hopkins Univ, Baltimore, MD; [4]Centers for Disease Control and Prevention, Atlanta, GA.*

Background: To elucidate potential racial disparities, we examined hospitalization rates for black and white veterans with and without CKD, utilizing the Veterans Affairs Health System.

Methods: This cohort study included 2.6 million black and white veterans who attended ³1 outpatient visit, had a serum creatinine value during the baseline period (10/1/09-9/31/10), and had no indication of ESRD on 9/31/10. Cox regression was used to estimate the combined effects of race and CKD status on first hospitalization during the next 2 years, adjusting for age, gender, comorbidities, and prior hospitalization during the baseline period. CKD was defined by clinical diagnosis or eGFR <60 ml/min/1.73m^2.

Results: Black patients were younger with a higher prevalence of diabetes, but lower prevalence other comorbidities, including hypertension. Although the overall prevalence of CKD at baseline was higher in whites (21.0% vs. 15.8%), the prevalence of a clinical diagnosis was higher in blacks (11.8% vs. 9.4%). The rate of first hospitalization was greater for blacks in both persons with and without CKD (HR=1.30, 95% CI: 1.29-1.31 & HR=1.16, 95% CI: 1.15-1.17, respectively). The 2-year risk of hospitalization was greatest (27.9%) in black patients with CKD, compared with the other groups (figure; p for interaction <0.001).



Conclusions: In an integrated health-care system with presumably less disparity in access to care between racial groups, the 2-year risk of hospitalization was greater for blacks than for whites, especially among patients with CKD. Further research is warranted to better understand these differences.

Funding: Other U.S. Government Support

Optimal Endpoint Definition for Transition in Albuminuria Stage in Clinical Trials Tobias Felix Kröpelin,[1] Dick de Zeeuw,[1] Rudolf W. Bilous,[2] Giuseppe Remuzzi,[3] Hans-Henrik Parving,[4] Hiddo Jan Lambers Heerspink.[1] *[1]Clinical Pharmacy and Pharmacology, UMCG, Groningen; [2]Newcastle Univ, United Kingdom; [3]IRCCS Mario Negri Inst for Pharmacological Research, Ospedale Papa Giovanni XXIII, Bergamo, Italy; [4]Medical Endocrinology, Univ of Copenhagen, Denmark.*

Background: Albuminuria transition (normo- to micro- to macroalbuminuria) is used as an endpoint in clinical trials that assess renoprotective drug efficacy. Current definitions vary between trials in: number of urine collections, requirement of a confirmation visit, if yes at what time, and the requirement of an additional percentage albuminuria change when transitions occur. We assessed the impact of these variations.

Methods: We used 3 clinical trials that tested the effect of RAS intervention on albuminuria class transition in diabetic patients (BENEDICT, DIRECT, IRMA 2). We assessed the drug effect per trial using varying transition definitions: 1) class transition based on either 1, 2, or 3 consecutively collected urine samples prior to each study visit, 2) based on a single urine sample confirmed by a next visit (within 2 - 8 weeks, next planned visit), 3) class transition and 10 - 40% increase in albuminuria.

Results: Neither increasing the number of urines collected at a visit, nor the inclusion of a confirmation visit, nor the time to the confirmation visit, nor the addition of a percentage albuminuria change altered the average drug effect or standard error.

	Single visit			Single urine +
	One urine	Two urines	Three urines	confirmation visit
	HR (SE) [95% CI]	HR (SE) [95% CI]	HR (SE) [95% CI]	HR (SE) [95% CI]
BENEDICT	0.75 (0.21) [0.50 - 1.12]	0.73 (0.22) [0.48 - 1.12]	0.66 (0.23) [0.42 - 1.04]	0.68 (0.34) [0.35 - 1.32]
DIRECT	0.95 (0.06) [0.84 - 1.07]	0.96 (0.07) [0.84 - 1.10]		0.95 (0.14) [0.73 - 1.24]
IRMA 2	0.55 (0.20) [0.37 - 0.82]			0.64 (0.38) [0.30 - 1.35]

Conclusions: Our results suggest that the optimal transition endpoint for a clinical trial measuring a drug effect can use a single urine collection per study visit. It needs to be tested whether more frequent study visits with albuminuria measurement would improve precision of the drug effect, as suggested in our previous work on quantitative albuminuria change (Kropelin 2014).

TH-OR013

CKD and Risk for Gastrointestinal Bleeding: The Atherosclerosis Risk in Communities (ARIC) Study Junichi Ishigami, Morgan Grams, Rakhi Naik, Josef Coresh, Kunihiro Matsushita. *Johns Hopkins Univ.*

Background: Patients on dialysis have increased risk for gastrointestinal (GI) bleeding. However, GI bleeding risk across the full spectrum of CKD has not been comprehensively investigated.

Methods: We studied 11,143 participants in the ARIC Study, a bi-ethic community-based cohort. Baseline CKD measures (eGFR and ACR) were assessed at visit 4 (1996-

1998), and follow-up was continued through 2011. The primary outcome was hospitalization with relevant ICD codes of upper- or lower-GI bleeding. Cox regression models were used to estimate incident rate and hazard ratios of GI bleeding, respectively.

Results: A total of 693 hospitalizations related to GI bleeding was observed during a median follow-up of 13.9 years (incident rate 4.9 per 1,000 person-years). After adjusting for potential confounders, both lower eGFR and higher ACR were independently associated with increased risk of GI bleeding (Table). Compared to eGFR ≥90 ml/min/1.73m^2, the association was particularly strong in eGFR <30 ml/min/1.73m^2 (HR 8.37 [5.04-13.88] in Model 2), but eGFR between 30-60 also reached significance (HR 1.55 [1.16-2.06]). Compared to ACR <10 mg/g, both microalbuminuria (30-299 mg/g) and macroalbuminuria (³300 mg/g) were associated with 2-2.5 greater hazard of GI bleeding (HR 2.14 [1.69-2.72] and 2.40 [1.59-3.62], respectively, in Model 2). Of note, high-normal albuminuria (10-29 mg/g) was also significantly associated with GI bleeding (HR 1.36 [1.09-1.70]). These results were largely consistent even after adjusting for each of kidney measures (Model 3) or accounting for cardiovascular events and incident dialysis during follow-up.

Conclusions: Both low eGFR (<60 but especially <30 ml/min/1.73m^2) and high ACR (particularly ³30 but also ³10 mg/g), were associated with incidence of GI bleeding, warranting clinical attention for GI bleeding risk among persons with even mild to moderate CKD.

Table: Hazard ratios of GI bleeding events according to eGFR and ACR categories

	Model1	Model2	Model3
eGFR category (ml/min/1.73m^2)			
Events/N		226/4703	
90-	reference	reference	reference
Events/N		378/5648	
60-89	1.23 (1.03-1.46)	1.19 (1.00-1.42)	1.18 (0.99-1.41)
Events/N		72/735	
30-59	1.92 (1.45-2.53)	1.55 (1.16-2.06)	1.42 (1.06-1.91)
Events/N		17/57	
0-30	12.15 (7.39-19.97)	8.37 (5.04-13.88)	6.40 (3.49-11.77)
ACR category (mg/gCre)			
Events/N		460/8798	
0-9	reference	reference	reference
Events/N		101/1307	
10-29	1.53 (1.23-1.90)	1.36 (1.09-1.70)	1.37 (1.10-1.71)
Events/N		91/730	
30-299	2.56 (2.04-3.21)	2.14 (1.69-2.72)	2.05 (1.61-2.61)
Events/N		28/197	
300-	3.63 (2.47-5.34)	2.40 (1.59-3.62)	1.57 (0.98-2.52)

Model 1 was adjusted for age, race and gender. Model 2 was adjusted for Model 1 plus aspirin use, anticoagulant agents use, hypertension, diabetes, BMI, history of CVD, alcohol consumption, smoking status and education level. Model 3 was adjusted for ACR/eGFR in addition to Model 2.

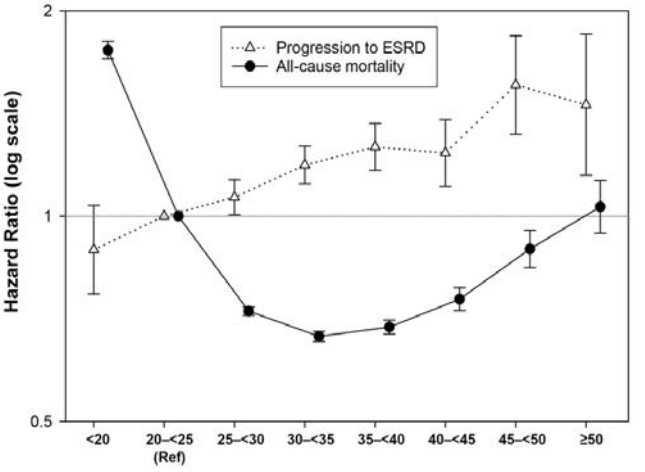
Association of Body Mass Index with Clinical Outcomes in Non Dialysis Dependent Chronic Kidney Disease: A Systematic Review and Meta-Analysis

Seyed-foad Ahmadi,[1] Golara Zahmatkesh,[1] Emad Ahmadi,[1] Elani Streja,[5] Connie Rhee,[1] Luca De Nicola,[3] Roberto Minutolo,[3] Ana C. Ricardo,[4] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]UTHSC; [3]Second Univ Napoli, Italy; [4]Univ Illinois, Chicago; [5]Harvard.*

Background: Previous studies have not shown a consistent link between body mass index (BMI) and outcomes such as mortality and kidney disease progression in non-dialysis dependent (NDD) CKD patients. We therefore aimed to complete a systematic review and meta-analysis on this subject.

Methods: We searched MEDLINE, EMBASE, Web of Science, CINAHL, and Cochrane CENTRAL, and screened 7,123 retrieved studies for inclusion. Two investigators independently selected studies using predefined criteria and assessed each study's quality using the Newcastle-Ottawa Quality Assessment Scale. We meta-analyzed the results based on BMI classification by WHO.

Results: Ten studies with a total sample size of 484,906 were included in the systematic review presenting generally heterogeneous results. Through re-analysis of the largest reported study and quantitative data synthesis, we observed that in Stages 3–5 CKD, being underweight was associated with higher death risk while being overweight or obese class I was associated with lower death risk; however, obesity classes II or III were not associated with death risk. In addition, re-analysis of the largest available study showed that higher BMI was associated with incrementally higher risk of kidney disease progression; however, this association was attenuated in our pooled results. For earlier stages of CKD, we could not complete meta-analyses as the studies were sparse and had heterogeneous BMI classifications and/or referent BMI groups.



Conclusions: Patients with stage 3–5 CKD have a differential association between obesity classes I–III and mortality compared with the general population, indicating an obesity paradox in the CKD population.

Risk Factors for Cognitive Impairment in Chronic Kidney Disease – The Brain in Kidney Disease Study

Anne M. Murray,[1,6] Elizabeth J. Bell,[1] David S. Knopman,[2] Yelena Slinin,[3,4] Robert N. Foley,[3] David Tupper.[5] *[1]Minneapolis Medical Research Foundation; [2]Dept of Neurology, Mayo Clinic; [3]Nephrology Div, U of Minnesota; [4]VA Medical Center; [5]Neuropsychology Section, Hennepin County Medical Center (HCMC); [6]Geriatrics Div, HCMC.*

Background: Cognitive impairment (CI) in patients with chronic kidney disease (CKD) poses a substantial public health burden. The extent that factors beyond estimated glomerular filtration rate (eGFR) contribute to the increased risk of CI in CKD has not been adequately measured.

Methods: We used cross-sectional data from the baseline exam (2011-2015) of the BRain IN Kidney disease study. Level of CI was determined using an algorithm based on neuropsychological tests that incorporates the DSM-IV dementia criteria. We assessed the relation between baseline characteristics and moderate to severe CI (yes/no) using logistic regression, controlling for potential confounding variables: age, gender, race, education, diabetes, hypertension, smoking status, cholesterol, BMI, and eGFR.

Results: The CKD cohort includes 422 community-dwelling participants (mean age=70, mean eGFR=34) with eGFR <60 mL/min/1.73 m^2 but not on dialysis. Of these, 149 had CI at baseline. Prior stroke, phosphorus ≥4.5 mg/dL and African American race were associated with a higher risk of CI. EGFR, markers of inflammation (TNFα and IL-6) and microalbuminuria (UACR), cholesterol and hemoglobin were not associated with CI.

Conclusions: We identified elevated phosphorus, prior stroke and African American race as potential risk factors for CI in community-dwelling CKD patients. Phosphorus is a potentially modifiable risk factor. Longitudinal analyses are needed to confirm these findings and identify potential preventive interventions against CI.

Adjusted odds ratios for CI		
Characteristics	**Unit change**	**Odd ratios (95% confidence intervals)**
EGFR	–10 ml/min/1.73 m^2	1.19 (0.99-1.44)
Prior stroke	Yes vs no	1.89 (1.09-3.27)
UACR	100 mg/g	1.01 (0.99-1.03)
TNFα	3 pg/mL	1.02 (0.87-1.20)
IL-6	6 pg/mL	1.17 (0.94-1.44)
Phosphorus	≥4.5 mg/dL vs <4.5	2.42 (1.15-5.10)
Cholesterol	–45 mg/dL	1.26 (0.99-1.61)
Hemoglobin	<10.5 g/dL vs ≥10.5	1.56 (0.64-3.82)
African American	Yes vs no	4.86 (2.44-9.64)

Increased Risk of Incident Chronic Kidney Disease, Cardiovascular Disease and Mortality in Diabetic Patients with Comorbid Depression

Miklos Zsolt Molnar,[2] Marta Novak,[1] Istvan Mucsi,[1] Jun Ling Lu,[2] Kamyar Kalantar-Zadeh,[3] Csaba P. Kovesdy.[2,4] *[1]Univ Health Network, Univ of Toronto, Toronto, ON, Canada; [2]Univ of Tenessee Health Sciences Center, Memphis, TN; [3]Univ of California, Irvine, CA; [4]Veterans Affairs Medical Center, Memphis, TN.*

Background: Depressed patients with diabetes have worse diabetes self-care and worse clinical outcomes. Here we aimed to determine the association of depression and the risk of incident CKD, cardio-vascular (CV) outcomes and all-cause mortality in a population of US veterans with diabetes mellitus (DM).

Methods: From a nationally representative prospective cohort of over 3 million US veterans with baseline estimated glomerular filtration rate (eGFR) ≥60 ml/min/1.73m^2, we identified 933,211 diabetic patients. The associations between depression and outcomes 1): incident CKD; 2): incident coronary heart disease [CHD]; 3): incident ischemic stroke; 4): all-cause mortality were assessed using the Kaplan-Meier method, and Cox proportional hazard models.

Results: Mean age was 64±11 years, 97% were male and 18% African-American. Depression was present in 340,806 patients at enrollment. Depressed patients were somewhat younger (61±11 versus 65±11 years), had slightly higher eGFR (84±15 versus 81±14 ml/min/1.73m^2) but had somewhat more comorbidities at baseline. During a median follow-up of 7.3 years, 180,343 patients (19%) developed CKD. The presence of depression at enrollment was associated with 20% higher risk of incident CKD (adjusted hazard ratio [aHR] and 95% confidence interval [CI]: 1.20 (1.19-1.21)). Similarly, depression was associated with 35% higher risk of incident stroke (aHR and 95% CI: 1.35 (1.32-1.39), 24% higher risk of incident CHD (aHR and 95% CI: 1.24 (1.22-1.27) and 25% higher risk of all cause mortality (aHR and 95% CI: 1.25 (1.24-1.26) during the follow-up.

Conclusions: Comorbid depression is associated with increased risk of developing CKD in diabetic patients. Similarly, the presence of depression is associated with worse CV outcomes. Appropriate intervention studies are needed to determine if treating depression in patients with diabetes would prevent CKD and CV disease.

Cardiorespiratory Fitness and Neurocognitive Function in Older Adults with Chronic Kidney Disease

Daniel E. Weiner,[3] Lindsay J. Lajoie,[1,2] Eamon F. Fleming,[3] Dylan R. Kirn,[2] Shari R. Waldstein,[4] Jason Kisser,[4] Kieran Reid,[2] Roger A. Fielding,[2] Stephen L. Seliger.[5] *[1]Friedman School of Nutrition, Tufts Univ; [2]Human Nutrition Research Center on Aging, Tufts Univ; [3]Tufts Medical Center; [4]Univ of Maryland Baltimore County; [5]Univ of Maryland School of Medicine.*

Background: Chronic kidney disease (CKD) is associated with an increased risk for neurocognitive impairment in older adults, while greater cardiorespiratory fitness (CRF) is associated with better neurocognitive function among healthy older adults. This relationship has not been adequately explored in patients with CKD. This study examines whether CRF, as measured by VO_2peak, is associated with neurocognitive function in older adults with CKD stage 3b-4.

Methods: Baseline data from a multi-center randomized controlled trial of exercise training was used. The Mini-Mental State Exam (MMSE), Digit Symbol Substitution Test (DSST), Montreal Cognitive Assessment (MoCA), Trail Making Test Part A (TMT-Part A), and Trail Making Test Part B (TMT-Part B) were utilized to quantify neurocognitive function. The association between VO_2peak and neurocognitive function was assessed using multiple linear regression, adjusted for age, sex, and education level.

Results: Among 71 participants, with mean age 68.4±7.74 years and mean eGFR=33.2±10.6 ml/min/1.73m^2, higher VO_2peak was associated with better performance on the MMSE (β=0.08, p=0.04), and DSST (β=0.75, p=0.03). While not statistically significant, directionality was similar for other cognitive tests, including the MoCA (β=0.12, p=0.20), TMT-Part A (β=-0.47, p=0.30) and TMT-Part B (β=-1.39, p=0.38).

Conclusions: Better cardiorespiratory fitness, as assessed by VO_2peak, is associated with better performance on several neurocognitive tests in older adults with advanced CKD. Further research is needed to better understand the underlying mechanisms of this relationship and whether improved fitness can modify cognitive performance.

TH-OR018

Low Birth Weight and Risk of Progression to End Stage Renal Disease in IgA Nephropathy

Paschal Joseph Ruggajo,[1,2] Einar Svarstad,[2] Sabine Leh,[3] Hans-Peter Marti,[2] Anna Reisaeter,[4] Bjorn Egil Vikse.[2] *[1]Dept of Internal Medicine, MUHAS, Dar es Salaam, Tanzania, United Republic of; [2]Dept of Clinical Medicine, Univ of Bergen, Bergen, Norway; [3]Dept of Pathology, Haukeland Univ Hospital, Bergen, Norway; [4]Dept of Transplantation Medicine, Rikshospitalet, Oslo Univ Hospital, Oslo, Norway.*

Background: Low Birth Weight (LBW) is a surrogate for fetal undernutrition and is associated with impaired nephron development in utero. Low birth weight is associated with fewer and larger glomeruli and increased risk of hypertension and renal disease in later life. In this study, we investigate whether low birth weight (LBW) and low birth weight for gestational age (LBW-GA) predict progression to ESRD in IgAN patients.

Methods: The Medical Birth Registry has recorded medical data for all births in Norway since 1967 and the Norwegian Renal Registry has recorded all patients With ESRD since 1980. From the Norwegian Kidney Biopsy Registry we retrieved all patients who had been diagnosed with IgAN from 1988-2013. These registries were linked and we analysed risk of progression to ESRD associated with LBW (defined as less than the 10th percentile of gender-specific birth weight) and/or LBW-GA (defined as less than the 10th percentile of birth weight for gestational age) by regression statistics.

Results: We included 471 patients, of whom 74 (15.7%) developed ESRD. As compared to patients without LBW, patients with LBW had a hazard ratio (HR) of 2.0 (95% confidence interval 1.0-3.7) for the total cohort, HR 2.2 (1.1-4.4) for males and HR 1.3 (0.30-5.8) for females. Corresponding HRs for LBW-GA were 2.2 (1.1-4.2), 2.7 (1.4-5.5) and 0.8 (0.10-5.9). After adjustments for eGFR at time of diagnosis, the association was lost. Further analyses showed that as compared to patients who were neither LBW nor LBW-GA, patients who were LBW-GA but not LBW had a HR of 1.3 (0.39-4.0), patients who were LBW but not LBW-GA had a HR of 1.4 (0.51-3.9) and patients who were both LBW and LBW-GA had a HR of 3.2 (1.5-6.8).

Conclusions: Among IgAN patients, having had low birth weight or low birth weight for gestational age predicted progression to ESRD. The association was only significant in male patients.

TH-OR019

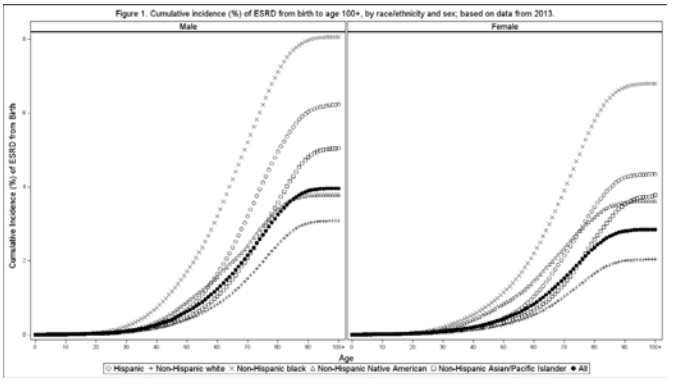
Risks of End-Stage Renal Disease (ESRD) in the United States

Patrick J. Albertus,[1] Hal Morgenstern,[1] Bruce M. Robinson,[1,2] Rajiv Saran.[1] *[1]Univ of Michigan; [2]Arbor Research Collaborative for Health.*

Background: Although incidence rates of ESRD are reported routinely by the USRDS, these are not directly relevant for individuals or providers. The objective of this study was to utilize incidence rate information to estimate the short- and long-term *risk* of ESRD by age, sex and race/ethnicity.

Methods: Using data from 2000 and 2013, risks/cumulative incidences were estimated using DevCan software developed principally to estimate risk of cancer diagnosis. This method uses a competing-risk framework by constructing a hypothetical cohort followed from birth to death. Incidence and mortality rates of ESRD were obtained from the USRDS and all-cause mortality rates from CDC-Wonder.

Results: Among males, the lifetime risk of ESRD from birth using 2013 data was 3.08% for non-Hispanic (NH) whites, 8.06% for NH blacks, 3.80% for NH Native Americans, 5.05% for NH Asians/Pacific Islanders, and 6.23% for Hispanics. Among females, the lifetime risks were 2.03% for NH whites, 6.80% for NH blacks, 3.63% for NH Native Americans, 3.78% for NH Asian/Pacific Islanders, and 4.34% for Hispanics. The 10-year risk was highest at age 70 at 1.52% for males and 1.03% for females. Comparing risk estimates based on 2013 data to 2000 data, the lifetime risk of ESRD from birth increased from 3.53% to 3.96% in males and decreased from 2.96% to 2.85% in females, but these changes were not uniform across racial/ethnic groups.



Conclusions: The risk of ESRD in the U.S. varies substantially among racial/ethnic groups for both sexes. Lifetime risks increased a little during the previous decade in males, but decreased slightly in females. The statistical approach used in this study could be applied routinely to USRDS data to estimate the probability of individuals being diagnosed with ESRD. To be most useful in clinical practice, this application will require additional data elements (e.g., comorbidities, CKD stage).

TH-OR020

The Relevance of Systolic Blood Pressure to Renal Progression: Observations from the Study of Heart and Renal Protection (SHARP)

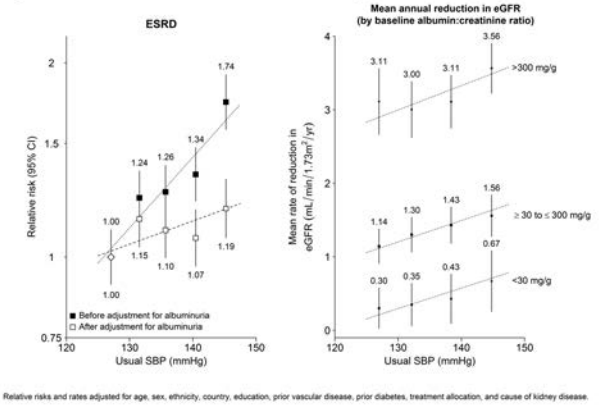
Natalie Staplin, William G. Herrington. *On behalf of the SHARP Collaborative Group. CTSU, Univ of Oxford.*

Background: Meta-analysis of intensive versus standard blood pressure (BP) lowering trials has demonstrated that lower BP reduces the risk of end-stage renal disease (ESRD), but there is uncertainty about optimal BP targets in chronic kidney disease (CKD), particularly in those without albuminuria.

Methods: Systolic blood pressure (SBP), creatinine and renal outcomes were assessed 6 monthly for 5 years among 6245 SHARP participants not on dialysis at baseline of whom 2137 (33%) developed ESRD. Regression models adjusted for confounders assessed the relevance of usual SBP to ESRD and to annual rate of change in CKD-EPI eGFR. High BP may cause or be caused by albuminuric CKD, so analyses were performed with and without adjustment for albuminuria.

Results: Each 20 mmHg higher usual SBP was associated with an average increase of 71% in the risk of ESRD (adjusted hazard ratio [HR] 1.71, 95% CI 1.50-1.95). The risk of ESRD was substantially attenuated, but remained statistically significant, after adjustment for albuminuria (HR 1.18, 1.02-1.35). Among those with at least 3 creatinine measurements, each 20 mmHg higher usual SBP was associated with a 1.3 (95% CI 1.0-1.6) mL/min/1.73m^2/year greater mean decline in eGFR, which reduced to 0.7 (0.4-1.0) after adjustment for albuminuria. Mean rate of reduction in eGFR was similar irrespective of baseline albuminuria (macroalbuminuria 0.7 [0.1-1.3]; microalbuminuria 0.6 [0.2-1.0]; normoalbuminuria 0.6 [0.1-1.1]).

Figure: Relevance of SBP to ESRD and annual rate of change in eGFR



Relative risks and rates adjusted for age, sex, ethnicity, country, education, prior vascular disease, prior diabetes, treatment allocation, and cause of kidney disease.

Conclusions: In CKD, the true relevance of SBP to renal progression is difficult to quantify precisely as the relative risks are substantially attenuated by adjustment for albuminuria (which may not be appropriate if this is on the causal pathway). Nevertheless, after such adjustment, higher SBP is significantly associated with renal progression irrespective of the presence or absence of albuminuria.

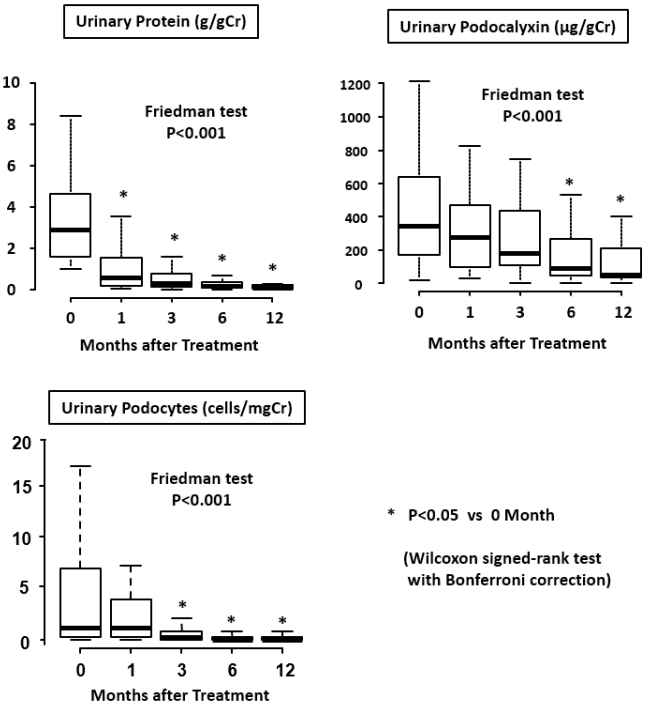
The Significance of Urinary Podocalyxin Level and Urinary Podocyte Number in Lupus Nephritis: A Longitudinal Study

Keiju Hiromura,[1] Hiroshi Kajiyama,[2] Hidekazu Ikeuchi,[1] Junya Suwa,[1] Daisuke Ikuma,[2] Toru Sakairi,[1] Yoriaki Kaneko,[1] Akito Maeshima,[1] Hiroyuki Kurosawa,[3] Yoshiaki Hirayama,[3] Masanori Hara,[4] Toshihide Mimura,[2] Yoshihisa Nojima.[1] *[1]Dept of Medicine and Clinical Science, Gunma Univ, Japan; [2]Dept of Rheumatology and Applied Immunology, Saitama Medical Univ, Japan; [3]Denki Kagaku Kogyo K.K., Japan; [4]Dept of Pediatrics, Yoshida Hospital, Japan.*

Background: Podocalyxin sheds in urine from injured podocytes. We have previously reported that urinary podocalyxin levels (U-PCX) and urinary podocytes numbers (U-POD) were highly elevated in active lupus nephritis (LN) before treatment (Arthritis Rheum, 2013, 65:10 S377). In the current study, we examined the changes of U-PCX and U-POD levels after treatment and the impact of baseline U-PCX and U-POD on the response to treatment.

Methods: Patients with active LN (n=37), whose urinary protein levels (U-Prot) >1.0 g/gCr and who required initiation or intensification of treatment, were examined. Early proteinuric remission was defined as U-Prot <0.3g/g/Cr at 3 months, which was observed in 15 patients.

Results: Although the significant improvement of U-Prot was observed at 1 month after treatment, U-PCX and U-POD decreased more gradually (Fig). A weakly positive correlation was found between U-PCX and U-POD (R=0.363, P=0.027), but not between U-Prot and U-PCX or U-POD. Multivariate logistic regression analysis showed that U-Prot ³3g/gCr, U-PCX >600 mg/gCr and U-POD £1cell/mgCr) at baseline were risk factors for not achieving early proteinuric remission (OR32.4, 95%CI 2.8-373.2, P=0.005; OR 24.9, 95%CI 1.3-455.2, P=0.030; OR 13.9, 1.2-161.2, P=0.036; respectively). The combination of U-Prot <3g/gCr and U-PCX <600mg/gCr at baseline predicted early proteinuric remission (sensitivity 80%, specificity 86%, PPV 80%, NPV 86%).



Conclusions: U-PCX and U-POD would be novel biomarkers of podocyte injury in LN.

Funding: Government Support - Non-U.S.

TH-OR022

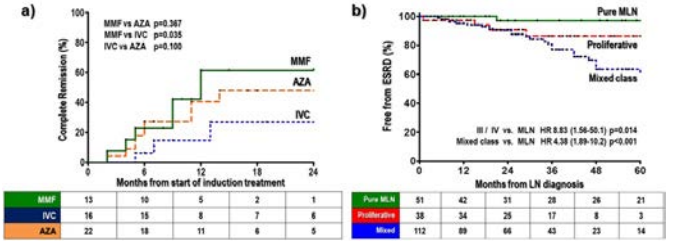
Mycophenolate Mofetil, Azathioprine and Intravenous Cyclophosphamide Are Effective for Treatment of Pure Membranous Lupus Nephritis in Hispanic Population

Juan M. Mejia-Vilet, Ricardo Correa-Rotter. *Dept of Nephrology, National Science and Nutrition Inst Salvador Zubirán, Mexico City, Distrito Federal, Mexico.*

Background: Membranous lupus nephritis (MLN) accounts for 10-20% of renal biopsy diagnosis in SLE patients. Its optimal treatment remains uncertain.

Methods: Treatment of 51 patients with biopsy proven MLN was retrospectively evaluated. Response to therapy and outcome were compared to those with proliferative (III or IV, n=38) and mixed-class LN (III+V / IV+V, n=112).

Results: Fifty one patients with MLN were distributed by induction drug in 3 groups: MMF (mean 2.6±0.4g/day), IV cyclophosphamide (5.4g/m^{2}BSA accumulative dose), azathioprine (mean 2.1±0.6 mg/kg/d). Median follow-up was 44 months (IQR 15-94). At presentation, patients in IVC group had a trend to worse urinary protein to creatinine ratio (uPCR) and a longer time from symptoms to start of treatment. Complete remission rates at 6, 12 and 24 months were 23.1, 61.5 and 61.5% for MMF, 6.2, 14.8 and 26.9% for IVC and 27.3, 40.5 and 47.9 for AZA. MMF induction was superior to IVC on Kaplan-Meier analysis (HR 5.42, 95% CI 1.38-21.2, p=0.03), but after Cox multivariate analysis there was only a trend to a better complete remission with MMF (HR 3.65, 95% CI 0.94-14.2, p=0.061). There were no differences between groups in adverse effects and thrombotic events. Only two MLN patients developed ESRD on follow-up. When compared with an historical cohort, patients with proliferative (HR 8.83, 1.56-50.1, p=0.014) and mixed histological classes (HR 4.38, 1.89-10.2, p<0.001) were more likely to develop ESRD.



Conclusions: Mycophenolate mofetil, IVC and AZA are effective for induction treatment of MLN. At our center, there is a trend to treat severe nephrotic patients with IVC and less severe cases with MMF or AZA. MLN has a similar rate of response to treatment and better long-term outcome than proliferative and mixed classes.

TH-OR023

Impact of Tabalumab on the Kidney in Lupus: Results from Two Phase 3 Clinical Trials Brad H. Rovin,[1] Mary Anne Dooley,[2] Jai Radhakrishnan,[3] Ellen M. Ginzler,[4] Tammy Forrester,[5] Pamela W. Anderson.[5] *[1]Ohio State Univ, Columbus, OH; [2]Univ of North Carolina, Chapel Hill, NC; [3]Columbia Univ, New York, NY; [4]SUNY Downstate, Brooklyn, NY; [5]Eli Lilly & Company, Indianapolis, IN; [6]Eli Lilly & Company, Indianapolis, IN.*

Background: Tabalumab (TAB) is a monoclonal antibody that neutralizes membrane and soluble B-cell activating factor. Two 52-week, randomized, double-blinded, placebo (PBO)-controlled Phase 3 trials evaluated the safety and efficacy of TAB for non-renal disease in lupus.

Methods: Patients with moderate-severe active lupus, but without severe active lupus nephritis (ie, urine protein/creatinine ratio [uPCR] of >200 mg/mmol or estimated creatinine clearance of <30 mL/min) were randomized 1:1:1 to TAB (120 mg subcutaneously [SC] every 4 weeks [Q4W] or 120 mg SC every 2 weeks [Q2W]) or PBO for 52 weeks. Serum creatinine (SCr), glomerular filtration rate (GFR), uPCR, and renal adverse events were determined monthly. Data were analyzed for the intent-to-treat (ITT) population and for ITT patients with a baseline uPCR >20 mg/mmol (ITT+uPCR) using an ANCOVA model.

Results: The trials enrolled 2262 patients. Baseline demographics, lupus disease activity, use of lupus drugs, SCr, GFR, and uPCR were similar among treatment arms. In the ITT and ITT+uPCR populations, there were no differences between treatment arms in baseline-to-endpoint change in SCr, GFR, or uPCR. Renal adverse events were not different among treatment arms.

ITT	**Tab Q2W N=597**	**Tab Q4W N=583**	**PBO N=575**
ΔSCr	.54±10.7	.11±9.8	.31±11.4
p-value vs PBO	.549	.897	
ΔGFR	.17±17.6	.63±14.8	.38±16.6
p-value vs PBO	.622	.805	
ΔuPCR	.44±53.4	-.30±51.6	1.87±44.4
p-value vs PBO	.718	.517	
ITT+uPCR			
ΔSCr	1.68±13.0	1.42±12.1	2.73±14.4
p-value vs PBO	.471	.655	
ΔGFR	-.87±18.9	.29±16.0	-2.14±20.7
p-value vs PBO	.604	.559	
ΔuPCR	-12.52±85.8	-9.08±111.8	-7.53±102.9
p-value vs PBO	.383	.434	

Conclusions: Compared to PBO, TAB did not significantly affect SCr, GFR, or uPCR over 52 weeks in ITT or ITT+PCR patients. There were no significant renal safety signals.

Evaluation and Validation of a Biomarker Panel in ANCA-Associated Renal Vasculitis Andreas Kronbichler, Julia Kerschbaum, Georg Gründlinger, Johannes Leierer, Gert J. Mayer, Michael Rudnicki. *Internal Medicine IV, Nephrology and Hypertension, Innsbruck, Austria.*

Background: Emerging studies in ANCA-associated vasculitis revealed markers of disease activity. The aim of the study was to evaluate and validate encouraging markers identified by literature search and the creation of respective panels.

Methods: 161 marker molecules were identified by a systematic literature review. ELISA assays were performed to validate a panel of biomarkers in an independent cross-sectional cohort of patients with renal involvement. Active vasculitis as assessed by BVAS v3 was defined as BVAS v3 ≥ 1 and inactive disease as BVAS v3 of 0. Statistical analysis was performed with SPSS 21 ® and the Salford Predictive Modeler 7.0® was used to generate a biomarker panel.

Results: Our review indicated increased expression of monocyte chemotactic protein (MCP)-1, sC5bC9, C3a and C5a in urine, whereas GM-CSF, sFlt1, CRP, IL-17A, C5a, hyaluronan, C3a and IL-18 bp were identified to be diversely regulated in active and inactive disease in blood samples. Our cross-sectional analysis revealed increased expression of CRP, C5a, C3a, IL-18 bp in blood and C5a and MCP-1 in urine samples during active AAV (all p<0.05).

	Units	Active	Remission	p-value
CRP	mg/l	18.7	6.4	<0.001
sFlt1	ng/ml	0.8	0.8	0.737
C3a	ng/ml	253	135	<0.001
C5a	ng/ml	10.2	6.2	0.006
IL-17A	pg/ml	0.8	0.3	0.115
IL-18 bp	ng/ml	8.5	5.2	0.007
Hyaluronan	ng/ml	43.3	46.3	0.894
MCP-1 urine	ng/ml	2.4	0.4	<0.001
C5a urine	ng/ml	0.4	0.0	0.010
sC5bC9 urine	ng/ml	0.0	0.0	0.639
C3a urine	ng/ml	0.0	0.0	0.384

Table 1. The respective biomarker with a mean expression is given in active and inactive disease. CRP, C3a, C5a, IL-18 bp in plasma as well as MCP-1 and C5a in urine yielded significance (all p<0.05).

Creation of a biomarker panel yielded a sensitivity and specificity of 76% (AUC 0.89) when CRP and urinary MCP-1 were added.

Conclusions: We could find a significant increase in CRP, C3a, C5a, IL-18 bp in blood and MCP-1 and C5a in urine samples. Moreover, we propose a biomarker panel comprising CRP and urinary MCP-1 in patients with ANCA-associated renal vasculitis. Further investigations to confirm our results are desired, including the reliability to predict renal relapses.

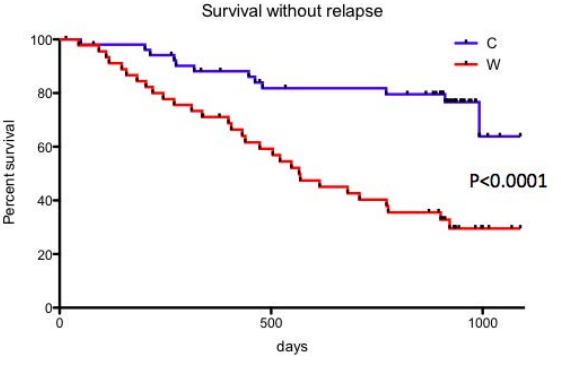
TH-OR025

Randomized Controlled Trial of Treatment Withdrawal in the Remission Phase of ANCA Vasculitis: The REMAIN Study Alexandre Karras,[1,4] Marten Segelmark,[3,4] David R.W. Jayne.[2,4] *[1]Nephrology, HEGP Hospital, Paris, France; [2]Nephrology, Addenbrooke's Hospital, Cambridge, United Kingdom; [3]Dept of Nephrology, Linköping Univ, Sweden; [4]On behalf of the EUVAS Study Group.*

Background: After induction of remission, continuation of immunosuppressive and glucocorticoid therapy is recommended in ANCA-associated vasculitis (AAV), to reduce the risk of relapse. The optimal duration of immunosuppression (IS) for maintenance of remission is unknown.

Methods: The REMAIN study is a prospective, randomized trial conducted by the European Vasculitis Study (EUVAS) group. AAV patients were included after induction of remission with Cyclophosphamide/Prednisone (PRED) and initiation of remission maintenance therapy with azathioprine (AZA). They were randomized (1:1) at month 18, to receive either AZA/PRED until 48 months from onset of therapy (continuation group, C) or to discontinue IS by 24 months (withdrawal group, W). The primary endpoint was the rate of relapses during 30-months follow-up.

Results: 121 patients were included, 45% had antiMPO ANCA. At randomization, median Screat was 15 mg/l, ANCA remained detectable in 56%, median AZA dose was 98 mg/day, median PRED dose 5.5 mg/day. The rate of relapse was higher in the W than in the C group (66% vs 22%, p<0.0001, OR 6.83, CI 2.79-16.69).



ANCA positivity at randomization was associated with higher relapse risk (51% vs 31%, p=0.04, OR 2.31, CI 1.02-5.29). Renal function, ANCA specificity (MPO vs PR3) or age were not predictive of relapse. IS-related severe adverse events were more frequent in the C group (9 vs 2) but this group had better renal outcome (0 vs 5 ESRD cases).

Conclusions: Prolonged remission maintenance therapy with AZA/PRED beyond 24 months after diagnosis reduced relapse rate. Continuation of immunosuppression was associated with better renal survival but not with improvement of overall patient survival.

TH-OR026

Pharmacogenetics of Rituximab in ANCA Associated Vasculitis

Federico Alberici,[1] Rona M. Smith,[1] Mariana G. Fonseca,[1] Lisa C. Willcocks,[1] Rachel B. Jones,[1] James E. Peters,[1] Augusto Vaglio,[2] Renato Alberto Sinico,[4] Julia U. Holle,[11] Bo Baslund,[6] Annette Bruchfeld,[3] Iva Gunnarsson,[3] Sophie Ohlsson,[7] Vladimir Tesar,[8] Zdenka Hruskova,[8] Maria C. Cid,[9] Thomas Neumann,[10] Paul Anthony Lyons,[1] Kenneth GC Smith,[1] David R.W. Jayne.[1] *[1]Dept of Medicine, Univ of Cambridge, United Kingdom; [2]Univ Hospital of Parma, Italy; [3]Karolinska Inst, Sweden; [4]AO San Carlo Borromeo, Milano, Italy; [5]Rigshospitalet, Denmark; [6]Lund Univ, Sweden; [7]Charles Univ, Czech Republic; [8]Hospital Clinic of Barcelona, Spain; [9]Univ of Jena, Germany; [10]Klinikum Bad Bramstedt, Germany.*

Background: Rituximab(RTX) is effective for induction and maintenance of remission in ANCA associated vasculitis(AAV); however optimal dosing approach is still unclear, relapse is common after discontinuation and predictors of response do not exist. This study assesses potential genetic determinants of response to RTX in AAV.

Methods: We included AAV-patients treated with RTX from European centers (primary cohort) and UK(replication cohort). Genotyping of 18 single nucleotide polymorphisms(SNPs) identified according to a biological rationale was performed using TaqMan and Sequenom platforms. End points were treatment failure rate(TF) 6 months after RTX and time to TF or relapse(TTR). Bonferroni correction was applied.

Results: 213 patients were enrolled in the primary and 109 in the replication cohorts. A SNP in the *TNFSF13B* gene region(BAFF) was associated to TTR in the primary (HR12.4,p=$7x10^{-04}$) and replication cohorts (HR5.4,p=0.0024). Meta-analyses showed an association with both end-points.

	Primary cohort		Replication cohort		Meta-analysis	
	OR-HR	p	OR	p	OR-HR	p
TF at 6 months	8	0.07	9.8	0.009	9.2	0.006
TTR	12.4	$7x10^{-04}$	5.4	0.002	7.3	$5.2x10^{-06}$

Carriers of the risk genotype had higher rate of detectable B cells 6 months after RTX (50%vs14%,p=0.0146). The association was restricted to patients historically PR3-ANCA positive (TF risk-OR 9,p=0.0141;TTR-HR 8.2,p=$8.7x10^{-06}$) while in the MPO-ANCA subgroup an association with a SNP in chromosome 4 was identified (TF risk,p=0.03;TTR,p=0.0238).

Conclusions: We have identified a SNP that may predict response to RTX in AAV. Our results may suggest a role for this SNP in modulating BAFF levels.

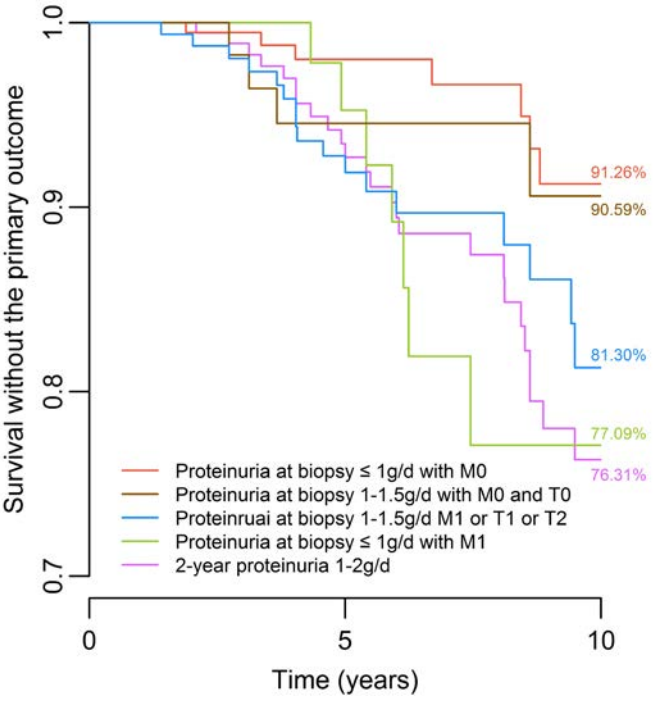
The MEST Score in IgA Nephropathy: Implications for Clinical Management

Sean Barbour,[1,2,7] Gabriela Espino-Hernandez,[2,7] Heather N. Reich,[3,7] Rosanna Coppo,[4,7] Ian Roberts,[5,7] John Feehally,[6,7] Daniel C. Cattran.[3,7] *[1]Univ of BC; [2]BC Renal Agency; [3]Univ of Toronto; [4]Univ of Turin; [5]Oxford Univ; [6]Leicester General Hospital; [7]For the Oxford Derivation, North American Validation and VALIGA Consortia.*

Background: The MEST score from the Oxford classification of IgA nephropathy (IgAN) is independently associated with renal outcome. Current risk stratification in IgAN requires clinical data over 2 years of follow-up. Using modern prediction tools, we examined whether combining MEST with cross-sectional clinical data at biopsy provides earlier risk prediction in IgAN than our current best methods that use 2 years of follow-up data.

Methods: We used a cohort of 901 adults with IgAN from the Oxford derivation, North American validation and VALIGA studies to analyze the risk of a 50% decrease in eGFR or ESRD using Cox regression models. Median follow-up was 5.6yrs. We considered the following covariates: clinical data at biopsy (eGFR, proteinuria, MAP) with or without MEST, and 2-year clinical data alone (2-year average of proteinuria/MAP, eGFR at biopsy). Prediction was assessed using the AIC, R^2, NRI, IDI, C-statistic and calibration curves.

Results: There was significant improvement in prediction by adding MEST to clinical data at biopsy, and the combination predicted the outcome as well as using 2-year clinical data alone. Results did not change in subgroups treated or not with RAS blockade or immunosuppression. The figure provides examples of how using MEST with clinical data at biopsy can identify high or low risk groups compared to using 2-year clinical data alone.



Conclusions: These results demonstrate that combining MEST with cross-sectional clinical data at biopsy provides earlier risk prediction in IgAN than our current best methods, and should allow modification of treatment based on risk assessment using data readily available at the time of biopsy.

Effects of Tonsillectomy Combined with Steroid Pulse Therapy upon IgA Nephropathy Depending on Proteinuria Status at Diagnosis

Hiroyuki Komatsu,[1] Shouichi Fujimoto,[1] Yuji Sato,[1] Akihiro Fukuda,[1] Yoshinari Yasuda,[2] Takashi Yasuda,[3] Tetsuya Kawamura,[4] Seiichi Matsuo.[2] *[1]Univ of Miyazaki, Miyazaki, Japan; [2]Univ of Nagoya, Nagoya, Aichi, Japan; [3]St. Marianna Univ School of Medicine, Kanagawa, Japan; [4]Jikei Univ School of Medicine, Tokyo, Japan.*

Background: Little is known about the effects of tonsillectomy combined with steroid pulse therapy on IgA nephropathy (IgAN) with a hard end-point and long-term observation. We therefore examined the effects of the combined therapy on renal outcomes of IgAN in a large, nationwide cohort study in Japan.

Methods: We divided 669 of 1,174 patients who were diagnosed with IgAN between 2002 and 2004 into three groups based on their having mild (0.50 - 0.99 g/day; n = 258), moderate (1.00 - 1.99 g/day, n = 225), or severe (≥ 2.00 g/day; n = 186) proteinuria at diagnosis. Ratios of decline in renal function and urinary remission were compared among the three groups after receiving combined, steroid or conservative therapy during a mean follow-up of 6.2 ± 3.4 years.

Results: The ratio of urinary remission at final observation was significantly higher in the groups given combined, than steroid or conservative therapy (mild proteinuria: 63% vs. 46% and 42%; moderate proteinuria, 52% vs. 44% and 23%; severe proteinuria, 43% vs. 33% and 16%, respectively). In contrast, the ratio of a 50% increase in serum creatinine decreased more groups given combined, than steroid or conservative therapy (mild proteinuria, 3.7% vs. 10.8% and 14.6%; moderate proteinuria, 7.6% vs. 6.5% and 19.8%; severe proteinuria, 16.7% vs. 25.0% and 36.8%, respectively). Cox proportional hazards models revealed that the combined therapy significantly prevented a 50% increase in serum creatinine compared with conventional therapy in the groups with moderate and severe proteinuria (hazards ratio, 3.64 and 3.09, respectively).

Conclusions: Tonsillectomy combined with steroid pulse therapy induces urinary remission and prevents the decline in renal function in patients with moderate and severe proteinuria.

TH-OR029

Pregnancy and IgA Nephropathy: Renal, Maternal and Fetal Outcomes

Sehoon Park, Kyung Don Yoo, Dong Ki Kim, Kwon Wook Joo, Chun Soo Lim, Yon Su Kim, Hajeong Lee. *Dept of Internal Medicine, Seoul National Univ Hospital.*

Background: Impact of pregnancy on long term renal prognosis of IgA nephropathy (IgAN) remains controversial. Also, there are few information about maternal and fetal outcomes of pregnancy in IgAN women.

Methods: This study included women with biopsy proven IgAN from 1979 to 2013 and all mothers with delivery record from 1999 to 2014 in Seoul National University Hospital.

A survey was done by medical chart review and telephone poll. Primary outcome for kidney was end-stage renal disease (ESRD) progression and doubling of serum creatinine. Maternal outcomes were preeclampsia, gestational hypertension, and proteinuria. Fetal outcomes were preterm birth, fetal death and fetal growth restriction (FGR). Matched analysis was done by 2:1 propensity score matching (PSM).

Results: A total of 803 IgAN women were enrolled including 88 patients with 166 pregnancy experiences. In addition, 15,028 women with 17,432 pregnancies were enrolled as control. After PSM, no significant difference of baseline parameters was found between matched groups. For renal outcome, pregnancy affect neither ESRD progression nor creatinine doubling in overall IgAN women. However, renal progression was accelerated by pregnancy (HR, 2.90; 95% CI, 1.171–7.179, $P = 0.023$) in IgAN women with moderate kidney dysfunction (eGFR <60). In maternal outcome, pregnancy of IgAN showed more proteinuria, gestational hypertension, and preeclampsia than normal pregnancies. Moreover, risks of fetal death and FGR were elevated. We found that this adverse pregnancy outcomes of IgAN patients occurred inversely to their pregestational kidney function. Unexpectedly, this trend started even from preserved pregestational renal function (eGFR <75), not from advanced renal dysfunction.

Conclusions: We demonstrated pregnancy accelerated renal progression in IgAN women with impaired kidney function. Moreover, we found that IgAN women suffered from a substantial burden of pregnancy even in those with relatively preserved pregestational renal function.

TH-OR030

Semaphorin 3F (SEMA3F) Expression Is Reduced in Pregnancy Complicated by Preeclampsia (PE) Giovanni Stallone, Adelaide Di Lorenzo, Giuseppe S. Netti, Barbara Infante, Francesca Bruno, Pantaleo Greco, Maria Matteo, Stefania Carlucci, Federica Trezza, Giuseppe Grandaliano. *Medical and Surgical Sciences, Univ of Foggia, Foggia, Italy.*

Background: PE, characterized by the new onset of hypertension and proteinuria after 20 weeks of gestation, affects 2-10% of pregnancies worldwide. It is characterized by an ineffective remodeling of maternal vessels perfusing the placenta. SEMA3F is a well-known anti-angiogenic mediator. We aimed to investigate whether SEMA3F placenta expression and serum and amniotic levels are modulated in PE.

Methods: To this purpose, we performed an observational single center, cohort study in the period from March 2013 to July 2014. We enrolled 132 consecutive pregnant women (PE n=13), undergoing an elective cesarean section (cross-sectional study) and 150 consecutive pregnant women undergoing amniocentesis for routine clinical indications at 16-18 week of gestation (perspective study). SEMA3F concentration was evaluated in maternal peripheral blood, venous umbilical blood and amniotic fluid at the time of delivery in the first group. In addition, in this group we examined placental SEMA3F protein expression. We then investigated amniotic fluid SEMA3F level at 16-18 weeks of gestation in the second group of pregnants.

Results: SEMA3F placenta expression was significantly reduced in PE (Control 3.2±.3 vs. PE 1.3±.6AU, p=.01). In addition, SEMA3F level at the time of delivery was significantly lower in serum (2.0±.4 vs 2.9±.6 ng/mL, p=.04), amniotic fluid (133.6±41.9 vs 202.4±102.2 ng/mL, p=.01) and cord blood (.58±.27 vs .92±.20 ng/mL, p=.02) of PE patients compared with normal pregnant women. SEMA3F level in maternal serum was significantly associated with placental weight (R^2=.802; p<.001) and newborn weight (R^2=.532; p<.001) at birth. In the prospective cohort study 14 women developed PE. In this setting, SEMA3F level in the amniotic fluid was lower in women developing PE compared to women with a normal pregnancy (12.9±8.1 vs 30.1±8.0 ng/mL, p<.01).

Conclusions: Our findings demonstrate, for the first time, that SEMA3F expression is significantly reduced in PE and support the hypothesis that SEMA3F amniotic fluid levels might represent a biomarker of PE.

TH-OR031

Efficacy in Diabetic Nephropathy in a Phase 2 Clinical Trial of Chemokine Receptor 2 Inhibitor CCX140-B Richard J. Glassock,[1] Elena Henkel,[2] Heidrun Mehling,[3] Christoph Hasslacher,[4] Ioanna Gouni-Berthold,[5] Vladimir Tesar,[6] Antonia Potarca,[7] Pirow Bekker,[7] Thomas J. Schall.[7] *[1]David Geffen School of Med; [2]Technical Univ; [3]Free Univ; [4]Univ Heidelberg; [5]Univ of Cologne; [6]Charles Univ; [7]ChemoCentryx.*

Background: The orally administered inhibitor of C-C chemokine receptor 2 (CCR2) CCX140-B blocks the deleterious effects of monocyte chemoattractant protein-1, including macrophage infiltration, podocyte injury and dysfunction. The aim was to test CCX140-B in diabetic nephropathy (DN).

Methods: This is a randomized, one-year clinical trial. Primary efficacy measure: change in urinary albumin:creatinine ratio (UACR) over 52 wks. Eligible patients were on stable ACE inhibitor or ARB, and anti-diabetic treatment for ≥8 wks prior to entry, with UACR 100-3000 mg/g creatinine, HbA1c 6-10%, and eGFR ³25 mL/min/1.73 m². Patients were stratified based on baseline UACR and eGFR, and then randomized to receive placebo, 5 mg, or 10 mg CCX140-B once daily (QD) plus standard of care (SOC) for 52 wks.

Results: 332 pts were enrolled. Baseline characteristics (mean±SD): 63±8 yrs, 77% males, BMI 33±5 kg/m², duration of diabetes 16±8 yrs, UACR (geo mean) 461 (range 77-2922) mg/g, eGFR 60±24 mL/min/1.73 m². The primary endpoint was met: 5 mg CCX140-B QD plus SOC showed a statistically significant (p=0.01) reduction in UACR compared to SOC alone. The maximum effect (24% reduction) was at 12 wks, with sustained reduction in UACR over the full year. 10 mg CCX140-B QD did not provide further improvement in UACR vs. 5 mg. CCX140-B treatment showed an improvement in fasting plasma glucose (-1.12 mmol/L). In a covariate analysis, CCX140-B was effective on UACR across patient groups. In a pre-specified subgroup with high baseline UACR (>800 mg/g creatinine), CCX140-B resulted in a placebo-corrected 28% improvement in albuminuria over 52 wks, and a slower rate of decline in eGFR. CCX140-B did not affect systemic BP or body weight, and appeared to be well tolerated with a low overall dropout rate (10%).

Conclusions: CCX140-B improved albuminuria over 52 weeks in a broad patient population. Patients with high baseline UACR may benefit most from CCX140-B treatment, relevant for design of a renal endpoint study.

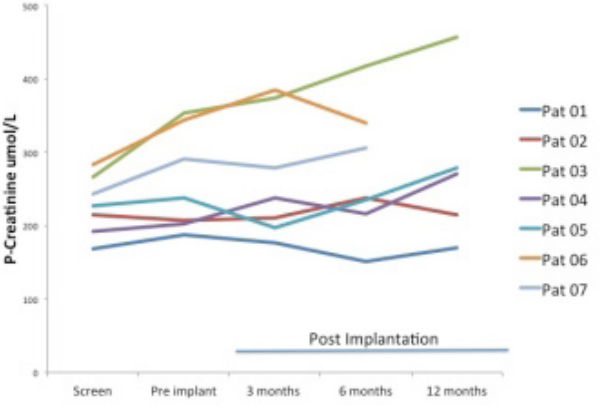
TH-OR032

A First in Human Study of Implantation of Neo-Kidney Augment, an Autologous Selected Renal Cell Population, in Type-2 Diabetic CKD Stage 3-4 Patients Peter Stenvinkel,[1] Torbjörn Lundgren,[1] Jonas Wadstrom,[1] Pontus Blomberg,[1] Torkel Brismar,[1] Randal K. Detwiler.[2] *[1]Karolinska Univ Hospital, Sweden; [2]Univ of North Carolina.*

Background: Animal models of CKD show that a selected population of bioactive renal cells (Selected Renal Cells; SRC) can be delivered to the kidney through intra-parenchymal injection resulting in a decrease in disease progression. We have used a laparoscopic technique to perform the first-in-human study with Neo-Kidney Augment (NKA).

Methods: 7 male type-2 diabetic (108±11kg) patients (63±6yrs) with CKD were selected. After evaluation of renal function and radiology they underwent renal biopsy. Two cores were shipped to the manufacturing plant for cell isolation, culture and product preparation. NKA was shipped back to the clinical centre (44-87d after biopsy) and injected into the left kidney.

Results: Implantation of 8 mL NKA was uneventful. 1 postop complication was observed (ileocecal volvolus). Infectious complications were observed in 3 patients during the first 3 months. Antihypertensive medication has been reduced in 3/7 during the first 6 months. Creatinine has remained stable at 6 and 12 months after autologous renal cell implantation in 6/7 patients. In one patient a rise in s-creatinine has, at least partly, been due to prostatic hypertrophy. 2 patients have only been followed for 6 months. Kidney volume was stable at 3, 6, and 12 m (n5).



Conclusions: NKA was safely implanted in 7 diabetic CKD patients. Complications after the implantations in this population were found to be related to the surgical procedure. Longer follow-up and a larger number of patients is needed to reveal if this novel technique can arrest progression of CKD and delay the start of renal replacement therapy. Perioperative findings indicate that image-guided percutaneous techniques ("reversed biopsy") could facilitate the procedure in this patient group.

TH-OR033

Selective Inhibition of CCR2/5 Chemokine Receptors Reduces Macroalbuminuria in Subjects with Type 2 Diabetes and Overt Nephropathy Jeremy D. Gale,[1] Steven A. Gilbert,[1] Samuel S. Blumenthal,[2] Tom Elliott,[4] Pablo E. Pergola,[3] Kosalaram Goteti,[1] Douglas Girgenti,[1] Willem H. Scheele,[1] Robert Webster,[1] Christelle Huguet Perros.[1] *[1]Pfizer Inc, Cambridge, MA; [2]Zablocki VAMC, Milwaukee, WI; [3]Renal Associates PA, San Antonio, TX; [4]BCDiabetes, Vancouver, Canada.*

Background: Recruitment, infiltration and activation of inflammatory cells appears important in diabetic nephropathy (DN). Inhibition of MCP-1/CCR2 receptor pathways may have renoprotective effects in DN and clinical data support a potential protective role of CCR5 receptors. Our hypothesis was that combined blockade of CCR2 and CCR5 receptors could decrease proteinuria in subjects with nephropathy.

Methods: The effect on albuminuria of the novel and specific dual CCR2/5 receptor antagonist, PF-04634817, was assessed in a multinational, randomized, double-blind, placebo-controlled, parallel group trial of subjects with Type 2 diabetes and overt nephropathy already receiving ACEi and/or ARB. Subjects with eGFR 20-75 mL/min/1.73m² and urinary albumin creatinine ratio (UACR) >300mg/g (33.9 mg/mmol) at baseline were assigned to receive PF-04634817 200mg (150mg if baseline eGFR <30 mL/min/1.73m²) or placebo (3:1), orally, once daily for 12 weeks.

Results: 226 subjects (mean UACR of 180.78 ± 160.53 mg/mmol Cr and mean eGFR of 41.46 ± 12.64 ml/min/1.73 m² at baseline) were randomised. A modest placebo-adjusted

reduction in UACR of 8% (95% CI -9% to 23%) was observed in response to treatment with PF-04634817 using the pre-defined primary assessment of efficacy (Bayesian analysis with informative prior). Ad hoc analysis, of those with eGFR <60 mL/min/1.73m^2 at baseline, showed a placebo-adjusted reduction of UACR approaching 19%. However, interpretation of subgroups are difficult due to the 3:1 randomization and the presence of data outliers. Adverse events (AEs) were mostly mild, the most common treatment-related AEs being nausea, acne and diarrhoea.

Conclusions: The efficacy of PF-04634817 to reduce UACR in this study appears modest, although may be greater in a subset of subjects with more advanced disease. This profile combined with good safety supports further investigation of its potential as a novel therapeutic strategy to improve renal outcome in DN.

TH-OR034

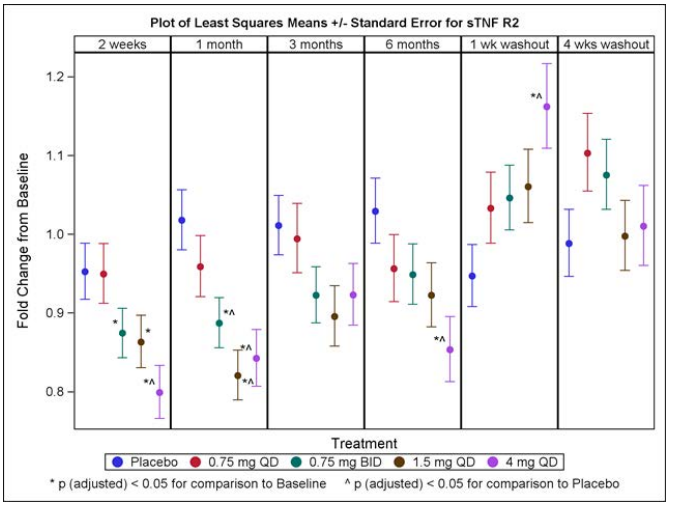
Baricitinib in Diabetic Kidney Disease: Biomarker Analysis from a Phase 2, Randomized, Double-Blind, Placebo-Controlled Study

Frank C. Brosius,[1] Katherine R. Tuttle,[2] Sharon G. Adler,[3] Matthias Kretzler,[1] Ravindra L. Mehta,[4] James A. Tumlin,[5] Kevin L. Duffin,[6] Joseph V. Haas,[6] Jiajun Liu,[6] Maria E. Silk,[6] William Macias,[6] Jonathan M. Janes.[6] *[1]Univ MI Med Sch, Ann Arbor; [2]Univ WA Sch Med, Spokane; [3]LA BioMed, Torrance; [4]Univ CA, San Diego; [5]Univ TN Coll Med, Chattanooga; [6]Eli Lilly & Co, IN.*

Background: New therapies for diabetic kidney disease (DKD) are needed as standard care (SC) fails to prevent progressive DKD. Baricitinib (bari) is an oral Janus Kinase (JAK)1/JAK2 inhibitor. The study met its primary endpoint of significantly reduced urine albumin/creatinine ratio (UACR) at 6 months (mo) in diabetics with albuminuria despite SC.[a]

Methods: To examine effects of bari treatment (tx) on key secondary endpoints: 24h urine protein; [3]30% UACR decrease; inflammatory biomarkers: urinary interferon gamma-induced protein-10 (IP-10), monocyte chemoattractant protein-1 (MCP-1), and plasma soluble tumor necrosis factor receptor (sTNFR) 1&2. Type 2 diabetics at high-risk for progressive DKD on SC were randomized to bari 0.75mg QD (n=25), 0.75mg BID (n=26), 1.5mg QD (n=26), 4mg QD (n=25), or placebo (PBO;n=27) for 6 mo.

Results: Reductions in 24h proteinuria compared with PBO were observed at 6 mo of bari tx (LSM ratio vs PBO for 0.75mg BID, 1.5mg QD, 4mg QD; 0.59, 0.58, 0.60, resp. p<.05). Benefits were maintained during a 1-2 mo washout period. The proportion with [3]30% UACR decline was increased by bari tx. IP-10, MCP-1, and sTNFR 1&2 decreased in a numerically dose-dependent manner. Estimated glomerular filtration rate by cystatin C was unchanged. At 6 mo, only 4mg bari had decreased hemoglobin vs PBO (-1.0±0.35 g/dL). No other safety concerns were observed.



Conclusions: Analysis of proteinuria and inflammatory biomarkers supports efficacy of bari in high-risk DKD. Data suggest an anti-inflammatory tx response encouraging further study of bari in DKD. [a]Tuttle et al, ADA Jun 2015, Post. 114-LB.

Patiromer Lowers Serum K$^+$ and Prevents Recurrent Hyperkalemia in CKD Patients ≥65 Years of Age on RAAS Inhibitors

Matthew R. Weir,[1] David A. Bushinsky,[2] Martha Mayo,[3] Dahlia Garza,[3] Yuri Stasiv,[3] Daniel J. Wilson,[3] Susan Arthur,[3] Lance Berman,[3] George L. Bakris.[4] *[1]Univ of Maryland; [2]Univ of Rochester; [3]Relypsa, Inc; [4]Univ of Chicago.*

Background: Older pts are at risk for hyperkalemia (HK) due to comorbid diseases and K$^+$-altering medications. The active moiety of patiromer is a nonabsorbed K$^+$ -binder. We present a prespecified subgroup analysis in pts ≥65 yr with CKD and HK on RAASi from a 2-part, single-blind, phase 3 patiromer trial (OPAL-HK).

Methods: Pts (n=243) with baseline (BL) serum K$^+$ (s-K$^+$) 5.1 to <6.5 mEq/L received patiromer (4.2 or 8.4 g BID) in a 4-wk treatment phase (part A); then pts with BL s-K$^+$ 5.5 to <6.5 mEq/L by central lab (n=107) were randomized to continue patiromer or switch to placebo (PBO) in an 8-wk withdrawal phase (part B). Primary endpoints were Ds-K$^+$ from BL at 4 wk in part A and between-group difference in Ds-K$^+$ from part B BL to part B wk 4.

Results: 131 (54%) pts were ≥65 yr at BL. Consistent with overall results, primary endpoints were significant for pts ≥65 yr (Table). Overall and in pts ≥65 yr, 76% and 73%, respectively, had s-K$^+$ 3.8 to <5.1 mEq/L (2° endpoint) at part A wk 4. More PBO pts (p<0.001) developed recurrent HK in part B. In all pts, mild-moderate constipation was the most common AE in part A (11%).

Conclusions: Patiromer significantly reduced s-K$^+$ in pts ≥65 yr and, vs. PBO, maintained control of s-K$^+$.

Table. Primary Endpoint Results (mEq/L)

Treatment Phase			
	Mean±SE BL S-K$^+$	Mean ΔS-K$^+$±SE (95% CI)	
Overall (n=237)[a]	5.58±0.03	-1.01±0.03 (-1.07, -0.95) p<0.001	
≥65 yr (n=126)[a]	5.56±0.04	-1.01±0.05 (-1.10, -0.92) p<0.001	
Withdrawal Phase			
	Median ΔS-K$^+$ (25th, 75th Percentile) from BL to Wk 4[b]		Between-Group Difference in Median ΔS-K$^+$ (95% CI)
	PBO	Patiromer	
Overall (n=107)	0.72 (0.22, 1.22) *n*=52	0.00 (-0.30, 0.30) *n*=55	0.72 (0.46, 0.99) p<0.001[c]
≥65 yr (n=60)	0.81 (0.51, 1.48) *n*=31	0.00 (-0.35, 0.30) *n*=29	0.81 (0.49, 1.14) p<0.001[c]

[a]Excludes 6 (overall) and 5 (≥65 yr) pts with no s-K$^+$ value at wkly visit after Day 3. [b]Or earlier timepoint if pt first had s-K$^+$ <3.8 mEq/L or ≥5.5 mEq/L. [c]Between-group difference in mean ranks of change.

The Microalbminuria Intervention Study: Effects of Different Losartan Combination Antihypertensive Therapy in Patients with CKD, MIDLAND-CKD

Yoshinari Yasuda,[1] Takeyuki Hiramatsu,[2] Seiichi Matsuo,[1] Shoichi Maruyama.[1] *[1]CKD Initiatives/Nephrol/CAMCR, Nagoya Univ, Nagoya, Aichi, Japan; [2]Nephrol, Konankosei Hosp, Konan, Aichi, Japan.*

Background: GUARD study reported that ACEI with a diuretic resulted in a greater reduction in albuminuria compared to ACEI and calcium channel blocker (CCB), however GFR significantly declined in ACEI and diuretic group and superiority between diuretics and CCB in combination with ACEI remains controversial. In addition the effect of combination antihypertensive therapy with ARB has not been fully evaluated. Thus the effect to reduce albuminuria were studied between amlodipine and HCTZ in combination with losartan, ARB.

Methods: Study design was randomized control trial. Eligible subjects were hypertensive CKD patients (aged 20-79) treated with ACEI or ARB more than 2 months, BP 140/90 mmHg and above, and suspected albuminuria. Suspected albuminuria was defined as albuminuria creatinine ratio (ACR) greater than 30 mg/gCr in an single spot urinalysis, or ± and above in urine dipstick test more than 2 times within 1 year. Exclusion criteria were renal insufficiency, prescription of CCB/diuretics, cardiovascular events within 6 months, abnormal liver function, and uncontrolled diabetes/hyperuricemia within 3 months. Written informed consent were obtained from all patients. This study was approved by the ethical committee and registered to UMIN (ID: 000004062). Patients were randomly assigned to group A (losartan and amlodipine) or B (compounding agent of losartan and HCTZ12.5mg) for 6 months.

Results: 48 and 46 patients were assigned to group A and B. There was no significant difference in patient characteristics between 2 groups at baseline, and BP were well controlled in both groups. ACR were decreased in both groups at 3 and 6 months without statistical significance. Among patients with ACR 30mg/gCr and above, ACR was significantly decreased in group B compared to A at 3 and 6 months (-17.5 ± 77.4 vs -56.3 ± 37.3 %, p<0.01 and -27.8 ± 63.4 vs -63.8 ± 34.0 %, p<0.01). DeGFR were not significantly different in 2 groups.

Conclusions: Compounding agent of losartan and HCTZ was superior to losartan and amlodipine treatment in hypertensive CKD patients with albuminuria.

Blood Pressure and Renal Outcomes in Diabetic Kidney Disease: Results from the VA NEPHRON-D Trial David J. Leehey,[1] Jane Hongyuan Zhang,[2] Nicholas Emanuele,[1] Adam Whaley-Connell,[3] Paul M. Palevsky,[4] Robert F. Reilly,[5] Peter Guarino,[2] Linda F. Fried.[4] *[1]Edward Hines, Jr. Veterans Affairs (VA) Hospital, Hines, IL; [2]Cooperative Studies Program Coordinating Center, VA Connecticut Healthcare System, West Haven, CT; [3]Harry S. Truman Memorial VA Hospital, Columbia, MO; [4]VA Pittsburgh Healthcare System, Pittsburgh, PA; [5]VA North Texas Healthcare System, Dallas, TX; [6]VA NEPHRON-D Study Group.*

Background: Proteinuric diabetic kidney disease (DKD) frequently progresses to end-stage renal disease (ESRD). Control of blood pressure (BP) delays progression, but the optimal BP to improve outcomes remains unclear. The objective of this analysis was to evaluate the relationship between BP and renal outcomes in proteinuric DKD.

Methods: BP data from all 1448 randomized participants in the VA NEPHRON-D study were included in a post-hoc analysis. The effects of mean on-treatment BP on the primary endpoint (decline in the estimated GFR (eGFR), ESRD, or death), renal endpoint (decline in eGFR or ESRD), rate of eGFR decline, and mortality were measured.

Results: In univariate analyses, both mean systolic BP (SBP) and mean diastolic BP (DBP) were strongly associated ($p < 0.001$) with the primary endpoint. After multivariate adjustment, the hazard of developing the primary endpoint increased as mean SBP rose from < 120 to > 150 mmHg (p=0.018); a significant increase in hazard ratio was seen when mean SBP was > 140 mmHg. There was also a significant effect of mean DBP on the hazard of developing the primary endpoint (p=0.005), with an increase in hazard ratio when mean DBP was > 80 mmHg. Associations between BP and both renal endpoint and rate of eGFR decline were similar to those with the primary endpoint. No effect of BP on mortality was observed, possibly because of the limited number of mortality events.

Conclusions: In patients with proteinuric DKD, mean SBP > 140 mmHg and mean DBP > 80 mmHg were associated with worse renal outcomes.

Funding: Veterans Administration Support

TH-OR038

Hemoglobin (HGB) Response in a Phase 2b Study of AKB-6548 for the Treatment of Anemia in Patients with Non-Dialysis Dependent Chronic Kidney Disease (NDD-CKD) Bruce S. Spinowitz,[1] Pablo E. Pergola,[2] Volker H. Haase,[3] Tasha M. Farmer,[4] Charlotte S. Hartman,[4] Bradley J. Maroni.[4] *[1]New York Hospital Queens, Flushing, NY; [2]Renal Associates PA and Univ of Texas Health Sciences Center, San Antonio, TX; [3]Vanderbilt Univ, Nashville, TN; [4]Akebia Therapeutics, Inc., Cambridge, MA.*

Background: AKB-6548 is a novel, once-daily, oral hypoxia-inducible factor prolyl-hydroxylase inhibitor (HIF-PHI) that preferentially stabilizes HIF-2α. Studies have shown AKB-6548 produces physiologic increases in erythropoietin, enhances iron mobilization and utilization, and produces a dose dependent increase in HGB.

Methods: A randomized, double-blind, placebo-controlled study assessed HGB response of AKB-6548 over 20 weeks in CKD subjects with anemia. 210 subjects were enrolled into one of 3 groups: 1) ESA naïve with HGB £10.5 g/dL, 2) previously treated with ESA with HGB £10.5 g/dL, or 3) actively treated with ESA with HGB ≥9.5 and £12.0 g/dL, and randomized (2:1) to once daily AKB-6548 or placebo. Primary endpoint was percent of subjects with mean HGB of ³11.0 g/dL or increase in HGB by ³1.2 g/dL from baseline.

Results: Overall, 54.9% of AKB-6548 vs. 10.3% of placebo subjects met the primary endpoint (p=0.0001) and mean change in HGB at end of treatment was 0.84 g/dL in the AKB-6548 group as compared to 0.02 g/dL in the placebo group (p=0.0054 at Week 2, p<0.0001 all time points Week 4 and beyond). HGB responses in the Naïve and Previously Treated groups were similar to each other and the overall group. In subjects converting from active ESA, AKB-6548 maintained a stable HGB throughout the study. HGB response with AKB-6548 was associated with an increase in reticulocytes and TIBC, and a decrease in serum hepcidin and ferritin across all three treatment groups. AKB-6548 was generally well tolerated and overall adverse events were balanced between treatment groups (74.6% vs. 73.6%).

Conclusions: AKB-6548, a novel HIF-PHI being developed for the treatment of anemia of CKD, raised and maintained HGB, while increasing iron mobilization and utilization, providing a more physiologic approach to the treatment of renal anemia. This study forms the basis for future Phase 3 studies.

Anemia Correction with Roxadustat Improves Health Related Quality of Life (HRQOL) in Chronic Kidney Disease (CKD) Patients Lynda Szczech, Stefan Hemmerich, Anatole Besarab, Khalil Georges Saikali, Lona Poole, Kin-Hung Peony Yu, Thomas B. Neff. *FibroGen, San Francisco, CA.*

Background: The hypoxia-inducible factor prolyl hydroxylase inhibitor roxadustat is being developed for treatment of CKD anemia.This analysis of two phase 2 trials was undertaken to assess the effect of roxadustat on HRQOL in non-dialysis (NDD) and dialysis dependent (DD) CKD.

Methods: HRQOL was assessed by SF-36 and FACT-An questionnaires in efficacy-evaluable populations in 2 open-label studies, CKD-NDD (041) and ESA-naïve incident CKD-DD (053). HRQOL was assessed at baseline (BL), 8 and 16 wks [end of treatment (EOT)] in 041 and at BL, 8 and 12 wks (EOT) in 053 [mean±SE changefrom BL (Δ)]. Missing data were imputed by last observation carried forward.

Results: Data from 141 subjects with CKD-NDD and 55 subjects with CKD-DD were available. In both populations, SF-36 physical component summary and FACT-An scores improved compared to BL (p=0.005 & 0.001, CKD-NDD; p=0.01 & 0.02, CKD-DD). SF-36 vitality norm-based domain scores (NBDS) and FACT-An anemia score increased by an average of >4 points. Benefits were seen particularly among those with low BL scores. In Study 053, subjects with BL SF-36 Physical Functioning NBDS <35 experienced a mean increase of 8.7 (p=0.005) and those with BL Vitality NBDS <50 increased by 6.7 (p<0.0001). Subjects with BL FACT-An Anemia score<55 increased 10.3 (p=0.0001), and those with BL FACT-An Total Score<135 increased 16.0 (p=0.0005).

Population (Study) (n)	Instrument	HRQOL Domains	Baseline	Δ at EOT	P-value
NDD (041) (n=141)	SF-36	Physical Functioning NBDS	37.7±1.0	1.4±0.7	0.04
		Vitality NBDS	48.1±1.1	4.3±0.9	<0.0001
	FACT-An	Physical Well Being	21.7±0.4	1.0±0.3	0.0004
		Anemia	54.8±1.3	4.3±1.0	<.0001
DD (053) (n=55)	SF-36	Physical Functioning NBDS	40.0±1.4	3.9±1.0	0.0002
		Vitality NBDS	47.3±1.5	3.7±1.2	0.003
	FACT-An	Physical Well Being	19.3±0.8	1.6±0.7	0.03
		Anemia	52.4±2.1	4.9±1.6	0.003

Conclusions: Roxadustat consistently improved mean HRQOL sub- and summary scores. Improvements were greatest in subjects with low BL scores. Roxadustat is currently being evaluated in phase 3 trials in which HRQOL is further explored.

TH-OR040

Hepcidin Response to Intravenous (IV) or Oral Iron in the Randomized FIND-CKD Trial of Patients with Non-Dialysis Dependent CKD (ND-CKD) Carlo A. Gaillard,[1] Andreas H. Bock,[2] Fernando Carrera,[3] Kai-Uwe Eckardt,[4] David B. Van Wyck,[5] Sukhvinder Singh Bansal,[6] Bernard Roubert,[7] Maureen Cronin,[7] Simon D. Roger,[8] Iain C. Macdougall.[6] *[1]Uni. of Groningen, Groningen, Netherlands; [2]Kantonsspital, Aarau, Switzerland; [3]Eurodial, Leiria, Portugal; [4]Uni. of Erlangen-Nuremberg, Erlangen, Germany; [5]Davita Healthcare Partners, Denver, CO; [6]King's College Hospital, London, United Kingdom; [7]Vifor Pharma Ltd, Glattbrugg, Switzerland; [8]Renal Research, Gosford, NSW, Australia.*

Background: Hepcidin is the key regulator of iron homeostasis but its temporal response to iron therapy, and response to IV vs oral iron therapy, are unexplored.

Methods: In the 56-week, open-label, multicenter, prospective, randomized FIND-CKD study, 626 anemic patients with ND-CKD and iron deficiency not receiving ESA therapy were randomized (1:1:2) to IV ferric carboxymaltose (FCM), targeting higher (400–600µg/L) or lower (100–200µg/L) ferritin, or oral iron. In a subset of patients enrolled in the UK, serum hepcidin was measured centrally by a validated liquid chromatography tandem mass spectrometry assay.

Results: 61 patients provided baseline and ³1 post-baseline hepcidin values. Mean (SD) baseline hepcidin level was 4.0(3.5), 7.3(6.4) and 6.5(5.6) ng/mL in the high ferritin FCM, low ferritin FCM and oral iron groups. The mean (SD) endpoint value (i.e. the last post-baseline value) was 26.0(9.1),15.7(7.7) and 16.3(11.0) ng/mL, respectively. The increase in hepcidin from baseline was smaller with low ferritin FCM and with oral iron vs high ferritin FCM up to week 52 (all p<0.05). Correlations were significant between the post-baseline increases in hepcidin and ferritin (r=0.70, p<0.0001), TSAT (r=0.42, p=0.0008) or hemoglobin (r=0.30, p=0.0295) using endpoint values across all groups. The increase in hepcidin levels over the 12-month study generally mirrored the cumulative iron dose in all groups.

Conclusions: These prospective, 1-year data from a randomized trial show that hepcidin levels rose in response to either IV or oral iron therapy, but that the speed and extent of the rise was greatest with IV iron targeting a higher ferritin level. Oral iron and IV iron targeting a lower ferritin level resulted in similar hepcidin levels.

TH-OR041

Isolation of Live Nephron Progenitors Cells Expressing Six2+ and Cited1+ from Human Embryonic Kidneys and Amniotic Fluid Laura Perin,[1] Stefano Da Sacco,[1] Astgik Petrosyan,[1] Matthew Edward Thornton,[2] Brendan Grubbs,[2] Roger E. De Filippo.[1] *[1]Urology, Children's Hospital Los Angeles, Los Angeles, CA; [2]Univ of Southern California, Los Angeles, CA.*

Background: In the developing kidney, formation of new nephrons relies on a small population of self renewing progenitors co-expressing Six2 and Cited1. Unfortunately, despite their essential role in the renal formation, direct isolation and expansion of human nephrogenic progenitor cells has not been successfully achieved and our knowledge is mostly based on rodent models. We have identified a small niche of Six2+Cited1+ cells within human amniotic fluid (hAF) and in this project we report for the first time the isolation and characterization of this population from both hAF and human embryonic kidneys (hEK).

Methods: Six2+ Cited1+ live cells from hAF and hEK were sorted using Smartflare RNA probes. RNAseq on positive and negative selections was performed immediately after sorting to evaluate their genetic profile without the confounding effects of cell culture. Integration into developing renal structures was assessed. Potential for a glomerular fate was tested by differentiation toward podocyte lineage.

Results: Six2+Cited1+ cells were successfully isolated from hEK (0.17%) and hAF (0.2%). RNASeq confirmed expression of genes such as Six2, Cited1, Osr1, suggesting a nephrogenic signature. Clones and subclones were derived and expanded for many passages in specific nephrogenic media maintaining Six2 and Cited1 expression. These populations were able to integrate in developing renal structures when co-cultured with dissociated/re-aggregated hEK. Differentiation into podocyte-like cells was evaluated by expression of specific markers including WT1 and nephrin, deposition of collagen IV alpha3-4-5 and functional response to angiotensin II.

Conclusions: Our preliminary results suggest the possibility of deriving and expanding for the first time, Six2+Cited1+ cells from hEK as well as from an exogenous source of cells like hAF without genetic manipulation. This system might represent an accessible and novel source of nephron progenitors that can guide studies of renal cell specification, thus increasing our knowledge on human renal development.

Novel Noninvasive Source of Kidney Progenitor Cells with Potential to Differentiate into Podocytes Fanny Oliveira Arcolino,[1] Silvia Zia,[1] Katharina Held,[1] Joris Vriens,[1] Elli Papadimitriou,[3] Benedetta Bussolati,[3] Anke Raaijmakers,[1,2] Karel Allegaert,[1] Jan A. Deprest,[1] Jaan Toelen,[1,2] Lambertus P.W.J. Van den Heuvel,[1,4] Elena N. Levtchenko.[1,2] *[1]Development and Regeneration, Catholic Univ Leuven, Leuven, Belgium; [2]Dept of Pediatrics, Univ Hospitals Leuven, Leuven, Belgium; [3]Dept of Molecular Biotechnology and Health Sciences, Univ of Turin, Turin, Italy; [4]Dept of Pediatric Nephrology, Radboud UMC, Nijmegen, Netherlands.*

Background: Recently, subpopulations of cells from amniotic fluid (AF) and adult urine were shown to express kidney progenitor cell features with multipotential of differentiation. We aimed to study urine of preterm neonates born before the completion of nephrogenesis for the presence of kidney neonatal stem/progenitor cells (nKSPC) and the ability of these cells to differentiate into functional podocytes.

Methods: Clonal cell lines were characterized as KSPC and KSPC-derived podocytes by gene expression analyses using quantitative rt-PCR and protein expression by flow cytometry and immunofluorescence. Podocytes differentiation was induced by incubation of cells in medium containing retinoic acid and vitamin D. Function of podocytes was assessed by albumin endocytosis and calcium influx assays. Results were compared to conditionally immortalized podocytes (ciPodocytes) and podocytes differentiated from amniotic fluid stem cells (AFSC) and adult urine progenitor cells (aUPC).

Results: nKSPCs expressed mesenchymal stem cell markers and kidney progenitor cell markers as SIX2, CD24, CD133, Vimentin and CITED1 maintaining these characteristics up to passage 17. nKSPC-derived podocytes presented mesenchymal-to-epithelial transition and acquired arborized cytoplasm comparable to ciPodocytes. Cells presented up-regulation of podocyte-specific genes and proteins and were able to endocytose albumin and uptake calcium via transient receptor potential cation channel, subfamily C, member 6 (TRPC6).

Conclusions: Preterm neonatal urine represents a novel noninvasive source of self-reviewing kidney progenitor cells with potential to differentiate into functional podocytes and may be a promising tool for regenerative medicine aiming kidney repair and a model for studying renal disease.

TH-OR043

Pluripotent, Non-Tumorigenic, Human Muse Cells Integrate into Glomerulus to Recover Function in a Chronic Kidney Disease Mouse Model Nao Uchida,[1] Naonori Kumagai,[1] Yoshiaki Kondo,[2] Shigeo Kure.[1] *[1]Pediatrics, Tohoku Univ School of Medicine, Sendai, Miyagi, Japan; [2]Healthcare Services Management, Nihon Univ School of Medicine, Tokyo, Japan.*

Background: As availability of transplantable kidneys is limited, stem/progenitor cell therapy replenishing new glomerular cells may be helpful; several pluripotent stem cell types have been studied, including non-tumorigenic Muse cells, collectable from the bone marrow as stage-specific embryonic antigen (SSEA)-3(+) cells. Here the effect of intravenously injected human Muse cells on a chronic kidney disease (CKD) mice model was evaluated.

Methods: Muse SSEA-3(+) and non-Muse SSEA-3(-) cells were isolated from bone marrow-derived mesenchymal stem cells (MSCs) using fluorescence-activated cell sorter. CKD was induced by intravenously injecting doxorubicin into severe combined immunodeficient (SCID), Balb/c mice, mimicking human focal segmental glomerulosclerosis. A week later, 2×10^4 cells of Muse, or non-Muse cells, or sterile vehicle were infused via the tail vein.

Results: In vitro, Muse cells showed specific migration activity toward the serum from CKD mice. After three weeks of renal lineage induction, Muse cells expressed WT1, while no signals were detected in non-Muse cells. In CKD-SCID mice, intravenously injected Muse cells migrated and integrated into the glomerulus, replacing a certain number of glomerular cells by differentiating into WT1-, podocin-, megsin-, and CD31-positive cells. This led to functional recovery, particularly in creatinine clearance at 7 weeks. In CKD-Balb/c mice, WT1(+)- and CD31(+)-Muse cells were recognized in the glomerulus at 5 weeks without immunosuppressant, whereas majority of these were rejected by 7 weeks. Significant functional recovery was observed for urine protein, creatinine clearance, and plasma creatinine compared with the vehicle group at 5 weeks. Attenuated glomerular sclerosis, interstitial fibrosis, and podocyte loss was noted in both models.

Conclusions: Muse cells are unique from other pluripotent stem cells in their high integration rate into the damaged glomerulus simply by intravenous injection, non-tumorigenicity, and differentiation in vivo into glomerular cells that mediate functional recovery.

TH-OR044

Patient-Derived Induced Pluripotent Stem Cell (iPSC) Modeling of Genetic Renal Disease (GRD) Andrew John Mallett,[1,3,4] Barbara Maier,[1,2] Pei Xuan Er,[1,2] Minoru Takasato,[1,2] Jane Sun,[5] Ernst J. Wolvetang,[5] Stephen I. Alexander,[6] Cas Simons,[1] Melissa H. Little.[1,2,7] *[1]Inst for Molecular Bioscience, The Univ of Queensland, Brisbane, Australia; [2]Murdoch Children's Research Inst, Melbourne, Australia; [3]Kidney Health Service & Conjoint Kidney Research Laboratory, Royal Brisbane and Women's Hospital, Australia; [4]School of Medicine, UQ, Australia; [5]Australian Inst of Bioengineering and Nanotechnology, UQ, Australia; [6]Dept of Nephrology, Children's Hospital at Westmead, Australia.*

Background: The reprogramming of somatic cells into iPSCs provides potential to model human diseases in vitro, as has been demonstrated in the cardiac and neuronal fields. Nephrology has not yet benefited from these advancements primarily due to lack of a robust kidney differentiation protocol.

Methods: We aimed to generate and characterize iPSCs from patients with different GRDs. Families with clinically diagnosed GRD were recruited from a Renal Genetics Clinic for concurrent research-based massively parallel sequencing (MPS) and iPSC generation. One affected and unaffected member of each family was recruited. To establish transgene-free iPSC lines, fibroblasts were isolated via skin biopsy and reprogrammed using non-integrating Sendai virus (21day protocol).

Results: 7 families (14 participants) were recruited with a variety of GRD diagnoses. Fibroblast culture was successful in 6 families. Established iPSC lines have typical hESC-like morphology and express pluripotency markers after 4 (TRA1-60) and 15 passages (NANOG). Moreover, iPCS lines have cleared the Sendai virus vectors, as confirmed by RT PCR after only 7 passages. G-band analysis of 2 lines from each isolation confirmed that each of the derived lines had maintained the normal karyotype after reprogramming. Paired patient and control iPSC are being redifferentiated towards kidney employing an established protocol. Renal organoids will be analyzed using IF, FACS and transcriptional profiling.

Conclusions: Patient derived iPSC have been generated and renal redifferentiation commenced. We hope to uncover the biological consequences of novel genetic variants causing GRD as identified via MPS, thereby beginning to explain patient phenotypes and disease pathogenesis.

TH-OR045

Multi-Segmented Nephron Organoids Derived from Human Pluripotent Stem Cells Model Kidney Development and Injury Ryuji Morizane, Albert Q. Lam, Benjamin S. Freedman, Seiji Kishi, M. Todd Valerius, Joseph V. Bonventre. *Medicine, Brigham and Women's Hospital, Boston, MA.*

Background: Kidney differentiation from human pluripotent stem cells (hPSCs) is limited by the inability to generate complete nephrons, which has inhibited efforts to model kidney development and disease. One important problem is the low efficiency of SIX2+ nephron progenitor cell (NPC) generation by published protocols. We hypothesized that more precise recapitulation of the stages of *in vivo* metanephric development with hPSCs would result in the generation of more pure populations of NPCs with the capacity to form nephrons.

Methods: We developed a chemically defined protocol to direct the differentiation of hPSCs into NPCs that form multi-segmented nephron structures in 2D and 3D organoids, mimicking the stages of *in vivo* nephrogenesis: late primitive streak (PS), posterior intermediate mesoderm (IM), SIX2+ metanephric mesenchyme (NPCs), renal vesicles (RVs), and nephrons. hPSC-derived nephron organoids were tested for the ability to model kidney development and injury.

Results: Efficient differentiation of hPSCs into late PS followed by WT1+HOXD11+ posterior IM enabled the induction of SIX2+SALL1+WT1+PAX2+ NPCs with **~90%** efficiency within 9 days. Treatment with Wnt and FGF signals induced differentiation into PAX8+LHX1+ RVs, which spontaneously differentiated into multi-segmented nephron

structures containing podocytes (Nephrin+PODXL+WT1+, foot process formation shown by EM), proximal tubules (LTL+CDH6+AQP1+), loops of Henle (CDH1+THP+), and distal tubules (CDH1+BRN1+) in an organized, contiguous arrangement in both 2D and 3D culture. Inhibition of Notch signaling during organoid formation resulted in specific defects in proximal tubules, indicating that nephron organoids model kidney development. Moreover, treatment with the nephrotoxins, gentamicin or cisplatin, induced KIM-1 expression in LTL+ tubules in a dose dependent manner.

Conclusions: We developed a novel method to differentiate hPSCs into NPCs with **~90%** efficiency within **9 days** of differentiation. NPCs formed organized, contiguous, multi-segmented nephron structures in 2D and 3D organoids, which could be used to model kidney development and injury.

TH-OR046

A Developmentally Plastic Adult Mouse Kidney Cell Line Spontaneously Generates Multiple Adult Kidney Structures Tomoko Obara. *Cell Biology, Univ of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Background: Diabetic nephropathy (DN) is the leading cause of end stage renal disease (ESRD) in the US. Although the precise causes are not well understood, DN is characterized by fibrosis within the glomeruli and tubular interstitium. Dialysis and kidney transplantation are currently the only successful therapies for ESRD. The renal transplantation approach suffers from donor shortages and complications of immune rejection. New therapies for renal replacement are needed. At this time the derivation of kidney lineage cells from either mouse or human induced pluripotent stem cells leads to limited nephron-like structures. To date, no one has been able to regenerate or model functional nephrons from normal or diseased kidneys.

Methods: In this study, we explored the utility of the absence of the epigenetic regulator ARID3a an adult mouse kidney cell line (KKPS5) for generating nephron structures in both *in vitro* and *in vivo* model systems.

Results: We discovered that KKPS5 acquires renal progenitor surface markers as an alternative cell source and further develop into multicellular nephron-like structures within a few days in 3-D matrigel. Moreover, when these cells are engrafted into immunocompromised medaka adult kidney they formed mouse nephron structures. We are unaware of the existence of other cell lines that exhibit this unique multipotent property.

Conclusions: These data implicate KKPS5 cells provide a unique advantage for exploring kidney development. Moreover, we predict our findings will be relevant for future therapeutic manipulations in kidney disease.

Decellularized Renal Extracellular Matrix Scaffolds Serve as 3D Biological Templates for Regeneration of Nephron Structures by Human Kidney Cells Joseph S. Uzarski,[1] Carol Ann Deaton,[2] Heather Hilary Ward,[2] Angela Wandinger-Ness,[3] Jason Wertheim.[1] *[1]Dept of Surgery, Northwestern Univ Feinberg School of Medicine, Chicago, IL; [2]Dept of Internal Medicine, Univ of New Mexico HSC, Albuquerque, NM; [3]Dept of Pathology, Univ of New Mexico HSC, Albuquerque, NM.*

Background: An alternative to current renal replacement therapy options aims to utilize renal tissues developed *ex vivo* using patient-derived cells for implantation to augment or replace failing kidneys. Our objective was to characterize the phenotypic effects of culturing particular populations of human nephron-derived cells within 3D decellularized renal extracellular matrix scaffolds (ECMs) as a step toward regenerating functional nephrons.

Methods: Rat kidneys were perfused antegrade with detergents to completely remove the autologous cells. The resultant renal ECMs were injected arterially with select populations of immortalized or primary human renal epithelial or progenitor cells (RPC) and cultured using specialized perfusion bioreactors. We compared proliferation, metabolism, gene expression, and morphological adaptation in cells derived from different nephron components.

Results: Epithelial cells infused into ECMs dispersed in periglomerular tubules. Distal tubule-derived RCTE cells formed patent, polarized E-cadherin+ tubular structures, and steadily proliferated over 1 week of perfusion culture. Proximal tubule-derived RPTE cells similarly distributed in the tubular space, with some cells found in glomeruli and Bowman's capsules. Both epithelial lines showed downregulation of EMT markers S100A4 and vimentin after culture within renal ECMs. After 7 days, kidney-specific-cadherin was upregulated in RPTE cells. Injury markers KIM-1 and CD24 were downregulated in RCTE cells alone. Cadaver-derived CD133/1+ RPC formed tubular structures within renal ECMs, and gradually decreased proteolytic KIM-1 shedding over 7 days.

Conclusions: We conclude that renal ECMs have inductive properties that may eventually be used in concert with exogenous biological or chemical stimuli to promote differentiation of stem or progenitor cells into mature, functional nephron-specific epithelial cells.

Systems Biology of Polycystic Kidney Disease Suggests It Is a Metabolic Disease Luis F. Menezes, Fang Zhou, Gregory G. Germino. *NIDDK, National Insts of Health, Bethesda, MD.*

Background: The major gene mutated in autosomal dominant polycystic kidney disease was identified over 20 years ago yet its function remains poorly understood. We have used a systems-based approach to examine the effects of acquired loss of *Pkd1* in an orthologous mouse model of human ADPKD as the kidneys transition from normal to cystic state.

Methods: A total of 135 *Pkd1*^{cko};Tg(Cre/Esr1) mice animals in which *Pkd1* knockout was induced by tamoxifen at P40 were harvested between P100 and P210 and kidney/body weight curves were fitted for males and females separately. Gene expression in 80 kidneys was analyzed with Illumina arrays, followed by differential gene expression and network analysis. Predictions were tested using: 1) metabolite and complex lipids profiling in 14 male kidneys; 2) diet manipulations in 33 *Pkd1*^{cko};Tg(Cre/Esr1) mice induced at P7 and harvested at P21 and in 52 P*kd1*^{cko}; Tg(Cdh16-cre) mice harvested at P14.

Results: We found in the P40-induction model that females were significantly protected from cystic kidney disease but had more severe cystic liver disease. Furthermore, the transcriptional profiles of normal male and female kidneys differed almost as much as those of normal and cystic kidneys and the differentially expressed gene modules were enriched for genes involved in lipid metabolism. Gene ontology of the differentially expressed genes common to both sexes showed enrichment for metabolic pathways. Metabolic and lipid profiling confirmed differences in cystic kidneys. We also found that the P7- and P40-induced mice share common transcriptional signatures, suggesting similar mechanisms of cyst initiation and growth. Finally, we showed that a modest change in the lipid composition of diet could significantly affect the progression of disease.

Conclusions: Gene expression and network analysis accompanied by global metabolites and complex lipid profiling suggested that metabolic status could be a major regulator of disease susceptibility. By manipulating the lipid content of mouse diets we corroborate this hypothesis and suggest that metabolic pathways are a major component of polycystic kidney disease, possibly underlying some of the sex effects.

Smyd2 Synergistically Activates STAT3 and NF-κB and Represses p53 to Promote Cyst Growth Xiaoyan Li, Lucy Fan, Xia Zhou, James P. Calvet, Xiaogang Li. *Kidney Inst, Univ of Kansas Medical Center, Kansas City, KS.*

Background: Protein methylation has emerged as a post-translational modification that exerts key roles in defining protein functions, at the level of signaling mediators and at the level of epigenetic regulation of transcription, in polycystic kidney disease (PKD). Smyd2, as a SET-domain-containing histone (lysine) methyltransferase, methylates both histone and non-histone proteins, including PKD associated p53, Rb and HSP90. However, the roles and underlying mechanisms of Smyd2 in regulating cyst development remain unknown.

Methods: To understand the role of Smyd2 in cyst growth in vivo, we generated *Pkd1* and *Smyd2* double conditional knockout mice (*Pkd1*$^{flox/flox}$*:Smyd2*$^{flox/flox}$*:Ksp-Cre*), and we treated *Pkd1*$^{nl/nl}$ mutant mice with the Smyd2 specific inhibitor, AZ505. To identify novel Smyd2 target genes involved in cystogenesis, we performed ChIP-seq analysis.

Results: We found that knockout of Smyd2 or inhibition of Smyd2 with AZ505 delayed cyst growth as seen by decreased cystic index, kidney weight (KW)/body weight (BW) ratios, blood urea nitrogen (BUN) levels, cyst lining epithelial cell proliferation, and increased cyst lining epithelial cell apoptosis in *Pkd1* mutant mice (all $p < 0.01$). We further found that *Pkd1* and *Smyd2* double knockout mice lived longer, to a mean age of 25 days, while Pkd1 knockout mice died at a mean age of 17 days ($p < 0.001$). We found that STAT3 and the p65 subunit of NF-κB are novel non-histone substrates of Smyd2, which methylates and activates them leading to increased cystic epithelial cell proliferation and survival. Smyd2 also regulates cystic epithelial cell apoptosis by repressing p53 activity and expression. Further, we identified novel Smyd2 target genes, including the primary cilia associated Ahi1 (Abelson helper integration site 1) gene and HYDIN gene, by ChIP-seq analysis, which may connect Smyd2 signaling to the ciliopathy hypothesis in PKD.

Conclusions: Smyd2 promotes renal cyst growth in ADPKD through STAT3 and NF-κB signaling as well as p53 and ciliopathy associated signaling. Targeting Smyd2 in cystic renal epithelial cells may be a viable new therapy for ADPKD.

Novel Insights into Polycystin-1 Function from the *Xenopus* Pronephric Kidney Oliver Wessely, Uyen Tran. *Cellular & Molecular Medicine, Cleveland Clinic, Cleveland, OH.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is caused by mutations in Polycystin-1 (PKD1) or Polycystin-2 (PKD2). PKD1 is a large transmembrane, mechanoreceptor-like protein that forms multiprotein complexes at focal adhesions, cell–cell junctions and cilia. It is thought to transmit a signal to PKD2, which in turn releases calcium. Studies in mouse and other model organisms have led to the prevailing hypothesis that Polycystin-1 and Polycystin-2 regulate a range of cellular pathways, which together ensure that renal epithelial tubules establish and maintain a correct diameter. While there has been significant progress over the years, the molecular mechanism of PKD1 action is still obscure.

Methods: To address the function of PKD1 we used the *Xenopus* pronephros as a model for PKD. We knocked down Pkd1 expression using antisense morpholino oligomers and characterized the kidney by morphology, histology, immunofluorescence and *in*

situ hybridization. To identify functional domains we subsequently re-expressed Pkd1 and fragments, thereof. Finally, we performed molecular analysis and binding assays to understand the underlying mechanism.

Results: *Xenopus* embryos lacking Pkd1 develop a PKD phenotype characterized by the formation of fluid-filled edema, dilated tubules, randomization of the mitotic spindle angle and increased DNA instability. This phenotype could be restored by re-expression of the intracellular domain of Pkd1. Moreover, structure-function analysis demonstrate that the G-protein binding domain is critically important for this activity. Based on this result, we performed binding studies with all the G-protein alpha subunits and demonstrated that Pkd1 recruits a very select subset of G-protein alpha subunits. The importance of this interaction was then subsequently validated by epistasis experiments in *Xenopus*.

Conclusions: Together, the data support the hypothesis that the intracellular domain of PKD1 recruits G-proteins and that this interaction is critical for its function.

A Forward Genetic Screen Identifies a Calcium-Regulated Mitochondrial Metabolite Carrier as a Downstream Target of Polycystin-2 Alexis Hofherr,[1] Claudia Seger,[1] Terry J. Watnick,[2] Michael Kottgen.[1] *[1]Dept of Medicine, Univ Medical Center Freiburg, Germany; [2]Univ of Maryland.*

Background: Polycystin-2 (aka TRPP2) is a cation channel that localizes to primary cilia and regulates developmental programs ranging from tubular morphogenesis to establishment of left-right (LR) asymmetry. Loss of TRPP2 results in polycystic kidney disease and randomized LR asymmetry. TRPP2-mediated calcium signals are thought to regulate morphogenesis. But the molecular events translating these calcium signals into morphogenetic programs are unknown.

Methods: To identify evolutionarily conserved core constituents of the TRPP2 signaling pathway, we conducted an unbiased forward genetic screen in *D. melanogaster* for mutants that phenocopy the TRPP2 loss of function phenotype. To test the conservation of newly identified genes in vertebrates, the function of candidate genes was investigated in zebrafish. The molecular function of genes was studied in mIMCD3 cells using TALEN-mediated gene deletion in combination with metabolomics.

Results: We identified a calcium-dependent mitochondrial metabolite carrier (MC) as a downstream target of TRPP2 in a large-scale mutagenesis screen for mutants that phenocopy loss of TRPP2 in *D. melanogaster*. Calcium regulation of this MC appears to be critical, since loss of MC in flies was rescued by wt MC, but not by MC with EF-hand mutations, which abolish calcium binding. In zebrafish, TRPP2 is essential for the establishment of LR asymmetry. We show that MC is also required for the determination of LR asymmetry in zebrafish. Rescue experiments in flies and zebrafish suggest that MC acts downstream of TRPP2, which is consistent with the calcium-dependence of this carrier. To investigate the molecular function of MC and TRPP2, we deleted the genes in mIMCD3 cells. Metabolomic analyses showed that TRPP2- and MC-deficient cells display impaired mitochondrial metabolism and concordant changes of several metabolites which may contribute to morphogenetic signaling processes.

Conclusions: We show that a calcium-dependent mitochondrial metabolite carrier acts in a conserved pathway linking TRPP2-mediated ciliary calcium signals to mitochondrial metabolism *in vivo*.

Modeling Polycystic Kidney Disease Cystogenesis with Genome-Modified Human Pluripotent Stem Cells Benjamin S. Freedman,[1,2,3,5] Theodore I. Steinman,[1,2,4,5] Jing Zhou,[1,2,4,5] Joseph V. Bonventre.[1,2,4,5] *[1]Brigham and Women's Hospital; [2]Harvard Medical School; [3]Univ of Washington School of Medicine; [4]Beth Israel Deaconess Medical Center; [5]Harvard PKD Center.*

Background: Human pluripotent stem cells (hPSCs) can self-renew extensively and differentiate into diverse tissues, including tubules expressing kidney markers. To date, however, no study has demonstrated a phenotype in these tubules relevant to kidney disease. Using the CRISPR/Cas9 genome editing system, we tested the ability of hPSC-derived kidney cells to model features of polycystic kidney disease (PKD) cystogenesis.

Methods: Cas9 nuclease and guide RNAs targeting *PKD1* or *PKD2* were transfected into hPSCs. Chromatogram analysis and immunoblotting indicated biallelic, frame-shift mutations at target sites and the absence of the corresponding full-length proteins. hPSCs were treated with specific growth factors to direct stepwise differentiation into kidney progenitor cells ($SIX2^+PAX2^+$) and subsequently proximal tubules (LTL^+LRP2^+). PKD hPSCs and derived tubules were inspected for cystogenesis phenotypes, compared to unmodified control cultures of otherwise identical genetic background.

Results: PKD hPSCs exhibited self-renewal and pluripotency characteristics comparable to isogenic controls, and differentiated into tubular organoids with similar efficiencies. Interestingly, in PKD hPSC cultures, we observed formation of large, translucent, cyst-like structures alongside tubules. Cyst-lining epithelia reacted strongly with LTL and surrounded hollow interior compartments devoid of cells. Time-lapse imaging revealed that cysts arose from a small minority of differentiating tubular structures. Importantly, isogenic control hPSCs, plated and differentiated in an identical manner to the PKD hPSCs, did not form cysts.

Conclusions: Our findings suggest that PKD-specific cyst formation from tubules can be reproducibly modeled in a minimal system *in vitro*. Cysts arise from both $PKD1^{-/-}$ or $PKD2^{-/-}$ hPSCs, but not from parental hPSCs of otherwise identical genetic background. Genome-modified hPSCs represent a new, human model in which to investigate PKD pathophysiology, with potential for 'clinical trials in a dish' to evaluate candidate therapeutics.

TH-OR053

Inactivation of Ift88 Gene Rescues the Phenotype in a Genetic Model of Autosomal Dominant Polycystic Kidney Disease Jing Zhou,[1] Wassim El-jouni,[1] Xiaogang Shen,[1,2] Maoqing Wu,[1] Ivan Barrera,[1] Azadeh Tabari,[1] Nadeem Haque,[1] Ilyas Yambayev.[1] *[1]Renal Div, Harvard Center for Polycystic Kidney Disease Research, Renal Devision, Brigham and Women's Hospital and Harvard Medical School, Boston, MA; [2]Nephrology Div, Zhejiang Provincial People's Hospital, Hangzhou, Zhejiang Province, China.*

Background: Mutations in *PKD1* and *PKD2* genes are responsible for autosomal dominant polycystic kidney disease, the most common life threatening genetic disease in humans. The gene products polycystin-1 (PC1) and -2 (PC2) are localized to the primary cilia and function as a receptor channel complex on the primary cilia.

Methods: To create an animal model for ADPKD, we deleted an exon encoding part of the pore region of PC2 in mice using the Cre-loxP system. To test the ciliary function of polycystins, we genetically disrupted cilia in mice with a mutation in *Pkd2* by creating *Ift88* and *Pkd2* double knockout mice. Mice were induced at post-developmental stages and renal phenotypes were analyzed by histology. Western analyses and immunostaining methods were performed to evaluate protein levels and expression patterns.

Results: A protective effect in cystic lesions was observed in kidneys from *Pkd2.Ift88* double knockout mice when compared with Pkd2 single knockouts. Disruption of PC2 was validated in both *Pkd2* single knockouts and *Pkd2.Ift88* double knockout mice. To examine if there is ciliogenesis defects due to the inactivation of PC2 and Ift88, we examine the length of cilia in kidneys from both *Pkd2* single knockout and *Pkd2* and *Ift88* double knockout mice. An increase in cilium length was detected in Pkd2 knockout mice, compared with wild type mice. A significant reduction of the number and length of cilia were found in Ift88 and Pkd2 double knockout mice. Ift88 knockout in the double knockout mice was also confirmed by western blot analyses. Comparative analyses of signaling events in both single and double knockout mice suggest the mammalian target of rapamycin (mTOR) pathway is activated in the early stage of cyst formation of Pkd2 single knockouts and its aberrant activation is rescued in Pkd2 knockout mice with Ift88 inactivation.

Conclusions: Inactivation of IFT88 rescues the polycystic phenotype in a genetic mouse model of ADPKD. mTOR signal pathway, a cilium-mediated pathway, appears to be involved.

TH-OR054

Other Signaling Pathways Rapidly Compensate for Loss of mTORC1 in Driving Cystic Kidney Disease Florian Grahammer,[1] Gerd Walz,[1,2] Tobias B. Huber.[1,2,3] *[1]Renal Div, Univ Medical Center Freiburg, Freiburg, Germany; [2]BIOSS Center for Biological Signalling Studies, Albert-Ludwigs Univ Freiburg, Freiburg, Germany; [3]Center for Systems Biology (ZBSA), Albert-Ludwigs Univ Freiburg, Freiburg, Germany.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the leading monogenetic cause of end-stage renal disease. In both mice and humans, cystic kidney disease is consistently linked to an activation of the mTORC1 pathway. Yet, the utility of mTORC1 inhibitors to treat patients with ADPKD remains controversial despite promising preclinical data.

Methods: To conclusively define the cell-intrinsic role of mTORC1 for cyst development, the essential mTORC1 scaffolding protein Raptor was selectively inactivated in renal tubular cells lacking cilia due to deletion of *Kif3A*.

Results: In comparison to a rapid onset of cyst formation and renal failure in mice with defective ciliogenesis alone, both renal function and overall survival were strikingly improved in mice additionally lacking *Raptor*. However, eventually these mice succumbed to cystic kidney disease despite mTORC1 inactivation. In-depth transcriptome analysis showed a rapid activation of other growth-promoting pathways, overriding the effects of mTORC1 deletion.

Conclusions: Our findings indicate that cystic kidney disease can adopt bypass mechanisms frequently observed in drug-resistant cancers. Thus future clinical trials will need to consider combinatorial or sequential therapies to improve efficacy in patients with cystic kidney disease.

ANKS3 Mutation in Nephronophtisis Patients Leads to Cilia and Cytoskeleton Defects In Vitro and In Vivo in Zebrafish Gweltas Odye,[1] Marion H. Delous,[1] Valentina Grampa,[1] Line De grande,[1] Anita Becker-heck,[2] Emilie Filhol,[1] Pauline Krug,[3] Flora Silbermann,[1] Bertrand Knebelmann,[3] Andreas W. Sailer,[2] Pierre Saint-mezard,[2] Alexandre Benmerah,[1] Sophie Saunier.[1] *[1]Inserm U1163, Imagine Inst, Paris Descartes Univ, France; [2]Novartis Inst for Biomedical Research, Switzerland; [3]APHP Necker Hospital, France.*

Background: Nephronophthisis (NPH) is an heterogeneous autosomal recessive renal ciliopathy that represents the major hereditary cause of end stage renal disease in children. Causative genes encode NPHP proteins which localize at the primary cilium and in some cases at cell-cell junctions. Among these genes, *ANKS6* is known for its implication in kidney development and mutations contribute to NPHP phenotype in humans.

Results: Using NGS, we identified a homozygous mutation (c.806 C>T, p.P269L) in *ANKS3*, in three siblings affected by late onset NPH with hepatic fibrosis. *ANKS3* encodes a SAM domain and Ankyrin repeat containing protein which interacts with ANKS6, NEK8 and NPHP3, three NPHP proteins located at the Inversin 'Invs' compartment (proximal part of the cilium) that controls essential ciliary signaling pathways during development and tissue homeostasis (Wnt/PCP). Surprisingly, ANKS3 did not localize at the Invs compartment but in apical cytoplasmic aggregates in tubular renal cells or at the basal body in fibroblasts. We provide evidence that the p.P269L mutation led to cilia length defects in patient's fibroblasts and *Anks3* knockdown IMCD3 cells, associated with disorganization of the Invs compartment. Moreover, it affects the interaction of ANKS3 with NPHP1 and led to defects in tight-junction and lumen formation in 3D culture, reminiscent of *NPHP1* knockdown. We next generated an *ANKS3* zebrafish mutant (TALEN) that exhibits laterality defects and lethality by 2-3 weeks. Analyses within the Kupffer's vesicle revealed normal number and length of cilia but motility defects likely explaining the laterality phenotype observed in mutant fish.

Conclusions: Altogether, these results indicate that ANKS3 plays a dual function, in controlling the composition of the Invs compartment and in epithelial morphogenesis, supporting the causative effect of the mutation in the NPH patients.

SDCCAG8 Regulates Ciliogenesis by Mediating Endosomal Vesicle Docking to the Basal Body Merlin Airik,[1] Rannar Airik,[1] Jang W. Cho,[1] Markus Schueler,[1] Friedhelm Hildebrandt.[1,2] *[1]Div of Nephrology, Boston Children's Hospital, Boston, MA; [2]Howard Hughes Medical Inst, Chevy Chase, MD.*

Background: Mutations in *SDCCAG8* gene cause a retinal-renal ciliopathy with BBS-like features in affected humans (1). Our previous characterization of the orthologous *Sdccag8*-mouse model recapitulated the retinal-renal degeneration phenotypes and identified impaired DNA damage response signaling as an underlying disease mechanism in the kidney (2). However, several other phenotypic features of *Sdccag8*$^{gt/gt}$ mice remained unexplored. Here we have extended our studies of SDCCAG8 function.

Methods: Immunofluorescence analysis was performed on mouse embryo cryosections and hTERT-RPE cell line. To identify SDCCAG8 interacting proteins at the centrosome we employed a proteomic strategy using stable isotope labeling with amino acids in cell culture (SILAC). Co-immunoprecipitation assay was performed in HEK293 cells.

Results: *Sdccag8*$^{gt/gt}$ mice have defective neural tube patterning and structural abnormalities of the skeleton, suggesting impaired Hedgehog (Hh) signaling. In cell culture studies we show that loss of *Sdccag8* affects ciliogenesis and interferes with Hh signaling. Using SILAC-assay combined with co-immunoprecipitation and immunofluorescence studies we demonstrate that SDCCAG8 interacts with centriolar satellite (OFD1, AZI1), endosomal sorting complex proteins (RABEP2, ERC1) and non-muscle myosin motors (MYH9, MYH10, MYH14).

Conclusions: SDCCAG8 function is required for ciliogenesis and Hedhehog signaling. Our study identifies several novel components of the basal body, that interact with SDCCAG8. Together, our analysis suggests that SDCCAG8 function at the basal body is required for coupling endosomal vesicles and molecular motors to facilitate ciliogenesis.

TH-OR057

Characterization of Cystic Kidneys in Mice Deficient in the Polarity Proteins DLG1 and CASK Steven Daniel Funk, Jinzhi Wang, Moe Mahjoub, Jeffrey H. Miner. *Renal Div, Washington Univ School of Medicine, St. Louis, MO.*

Background: Polycystic kidney disease involves dysregulation of tubular proliferation and cellular polarity leading to cystogenesis. Deletion of various apico-basal and planar cell polarity (PCP) proteins in mice, including members of the membrane-associated guanylate kinase (MAGUK) family, is sufficient for cystogenesis. DLG1-deficient mice exhibit PCP defects but only occasional unilateral renal agenesis or hypoplasia. Co-deletion or hypomorphic expression of DLG1 and CASK in nephron progenitors (via Six2Cre) induces hypoplasia and cystogenesis, respectively. This work aimed to characterize the cystic phenotype in DLG1+/-; CASK-/- mice.

Methods: DLG1+/-; CASK-/- kidneys were analyzed histologically by immunohistochemistry, western blotting, and qRT-PCR at various ages. Additionally, for mechanistic insight we employed a model of cystogenesis in which cell-permeant cAMP (8-Br-cAMP) drives tubular dilation in cultured embryonic kidneys through luminal fluid flux.

Results: DLG1+/-; CASK-/- mice exhibit cysts as early as 90 days with severe but variable pathology by 9 months. Analysis of DLG1+/-; CASK-/- tubule segments indicates proximal tubule origin of cysts and dysregulation of matrix proteins, but with preservation of apico-basal polarity. Ciliary length was up to 2-fold longer in the majority of DLG1+/-; CASK-/- tubules, but was longer only in dilated DLG1-/-; CASK-/- tubules. Curiously, whereas 8-Br-cAMP induced dilations in wild-type embryonic renal tubules, DLG1+/- or -/-; CASK-/- embryonic kidneys did not exhibit tubular dilations.

Conclusions: Our data indicate that DLG1 and CASK co-regulate renal development as well as homeostasis of renal epithelium independently of apico-basal polarity. IHC analysis revealed molecular features consistent with PKD phenotypes, with an unusual elongation of cilia. A cAMP-stimulated model of cystogenesis revealed a failure in PKA-dependent tubular dilations in DLG1+/- or -/-; CASK-/- embryonic kidneys. Coupled with cilia elongation and PKA effects on ciliary function, these results indicate a previously unrecognized regulation of PKA by MAGUK family members in the kidney.

TH-OR058

Serum Leptin, Pre-Existing Vascular Disease, and Arteriovenous Fistula Maturation Failure Jwa-kyung Kim,[1] Sun Ryoung Choi,[2] Mi jin Park,[3] Sung gyun Kim.[1] *[1]Internal Medicine, Hallym Univ Sacred Heart Hospital, Kidney Research Inst, Anyang, Republic of Korea; [2]Internal Medicine, Shamyook Medical Center, Seoul, Republic of Korea; [3]Clinical immunology, Hallym Univ Sacred Heart Hospital, Anyang, Republic of Korea.*

Background: Pre-existing vascular diseases is one of the important causes of maturation failure of arteriovenous fistula (AVF). Recently, a growing proportion of incident dialysis patients are obese, and leptin is regarded as a pivotal mediator between obesity and cardiovascular disease. This study evaluated the association between serum leptin and pre-existing vascular disease and AVF maturation failure in patients with end-stage renal disease (ESRD).

Methods: Vein samples from 62 patients were collected at the time of AVF creation near the site of AV anastomosis**.** Histological (hematoxylin and eosin, and trichrome staining), immunohistochemical and morphometric (smooth muscle actinin [SMA], vimentin and desmin) studies were performed. AVF maturation failure was defined as an AVF not possible to use successfully for hemodialysis by the third month after its creation despite radiological or surgical interventions.

Results: Mean age was 63.3 ± 13.7 years and the prevalence of obesity (BMI ³25 kg/m^2) was 49.1%. Mean serum leptin levels were 2.10 ± 1.41 pg/mL (log transformed), and patients in the highest leptin tertile had significantly increased BMI, higher triglyceride, interleukin-6, and hs-CRP levels (P<001). AVF maturation failure occurred in 21 (35.6%) patients, and the failure rate progressively increased from the lowest to the highest leptin tertile (p<0.001). On histological examinations, increased leptin tertiles were closely associated with intimal hyperplasia (13.3±4.5 vs. 18.2±5.2 vs. 30.3±14.3 mm in each tertile) as well as medial fibrosis. In addition, the majority of cells within the neointima were positive for SMA and vimentin and negative for desmin, suggesting a myofibroblast phenotype. Interestingly, a number of vascular sections in lowest leptin tertile also had desmin-positive contractile smooth muscle cells.

Conclusions: Obesity related fistula maturation failure may be mediated by higher serum leptin level - associated preexisting vascular diseases in ESRD patients.

TH-OR059

Time-Dependent Endothelial Dysfunction following Arteriovenous Fistula Creation Timmy C. Lee, Jennifer S. Pollock. *Univ of Alabama at Birmingham.*

Background: Vascular endothelial function plays a critical role in arteriovenous fistula (AVF) remodeling and neointimal hyperplasia development. The goal of our study was to characterize the natural history of endothelial dysfunction following AVF creation.

Methods: AVFs were created using an end to side anastomosis between the femoral vein and artery in 12-16 week old Sprague-Dawley rats. Contralateral vessels served as controls. Rats were sacrificed at 1, 7, 14, and 21 days after AVF creation and vein and artery collected for morphometric analysis. Segments from the arterial anastomosis were isolated at these time points and mounted on wire myographs to assess endothelial-dependent and -independent function by concentration-response curves to acetylcholine (Ach) and sodium nitroprusside (SNP), respectively.

Results: Maximal relaxation to Ach was significantly decreased at 7 days compared to the contralateral control (29±12% vs 110±15%; p=0.006) (figure 1), but endothelial-dependent function was fully restored by 21 days (94±2% vs 93±2%; p=0.598).

Percent (%) Maximal Relaxation						
Time Point of Sacrifice (Days) Post AVF Creation	AVF Relaxation to ACh (Endothelial-dependent response) (Mean% ± SEM)	Control Vessel Relaxation to ACh (Endothelial-dependent response) (Mean% ± SEM)	P-value	AVF Relaxation to SNP (Endothelial-independent response) (Mean% ± SEM)	Control Vessel Relaxation to SNP (Endothelial-independent response) (Mean% ± SEM)	P-value
1 day (n=4)	61±22	92±3	0.205	107±5	99±1	0.162
7 day (n=4)	29±12	110±15	0.006	93±5	94±6	0.895
14 day (n=4)	43±25	90±3	0.168	98±2	101±3	0.349
21 day (n=4)	94±2	93±2	0.592	84±6	99±2	0.047

Endothelial-independent response to SNP was similar to the contralateral control artery at 1, 7, and 14 day time points, suggesting an adequate smooth muscle cell response necessary for vasodilation. However, at 21 days vascular relaxation to SNP was impaired compared to control (84±6% vs 99±2%; p=0.047), suggesting smooth muscle dysfunction. Our morphometric analysis showed that the greatest change in amount of arterial and venous intimal hyperplasia occurs in the 1st 7 days following AVF creation.

Conclusions: Creation of AVF results in a time-dependent endothelial dysfunction worse 7 days after creation. Therapies targeted at restoring endothelial function via increasing nitric oxide production shortly after AVF creation may help improve AVF remodeling and inhibit neointimal hyperplasia. Late changes in endothelial-independent vascular function following AVF creation needs further evaluation.

TH-OR060

Is Preoperative Vein Morphology Associated to Vascular Access Outcome? Maria Guedes Marques,[1] Raquel Pina,[1] Joaquim Ferreira,[1] Pedro Maia,[1] Teresa Mendes,[1] Emanuel Ferreira,[1] Helena Pinto,[1] Nuno Oliveira,[1] Ana Belmira,[1] Luís Freitas,[2] Armando Carreira,[1] Mário Campos.[2] *[1]CHUC - Hospital Geral; [2]CHUC - HUC.*

Background: Vascular access (VA) stenosis is histologically characterized as neointimal hyperplasia (NH).Smooth muscle cells initially proliferate in media, and migrate to the intima where endothelial cell proliferation and angiogenesis occur. Venous NH has been primarily associated with hemodynamic stress, surgical injury, grafts and cannulation. According to recent data, uremia is likely to exacerbate endothelial dysfunction and predispose to NH before VA creation. Primary end point was to evaluate preoperative vein morphology and how it would affect VA outcome. Secondary end points were to found if other demographic and clinical factors could also have any impact.

Methods: Transversal observational study performed in 26 patients with end-stage-renal-disease. Venous specimens obtained during VA creation were evaluated for intimal inflammatory infiltrate/angiogenesis, media abnormalities and intima/global wall thickness. Postoperative clinical function and demographic parameters recorded.

Results: The majority of patients were male (84.6%); age 71.4±15.1y; 57.7% diabetic; 50.0% had central venous catheter at surgery time; maturation occurred in 53.8%. Intimal angiogenesis and media abnormality were both seen in 66.7% of patients in which VA didn't maturate, but only in 14.3% and 21.4% of the ones that maturated, respectively. Chi-square analysis showed that both previous findings were significantly associated with VA failure (p 0.006 and p 0.020). Intimal and global wall thicknesses were 0.0607±0.0715 and 0.7000±0.2228mm in maturated VA; 0.2600±0.2442 and 1.0318±0.3227mm in nonmaturated VA, respectively (p 0.006 and p 0.005). Gender, age, diabetic status and catheter presence didn't affect VA function.

Conclusions: Preexisting venous thickness, intimal angiogenesis and media abnormalities predispose to postoperative VA nonmaturation. It is possible that uremia and other pre-dialysis factors may contribute to preexisting venous abnormalities which, independently of the future hemodynamic stress, predispose patients to more aggressive NH after VA creation, contributing to inferior outcomes.

The Effect of Far Infrared Therapy on the Maturation of Newly Created Arteriovenous Fistula and the Parameters of Inflammation, Endothelial Function and Oxidative Stress in Patients with Advanced Chronic Kidney Disease Chih-Ching Lin. *Div of Nephrology, Dept of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan.*

Background: We had demonstrated that far infrared (FIR) therapy could improve the access flow and unassisted patency of arteriovenous fistula (AVF) in prevalent HD patients; however, the effect of FIR on the endothelial function as well as the markers of inflammation and oxidative stress of the newly created AVF is unknown.

Methods: We enrolled patients with advanced chronic kidney disease (CKD) by the definition of eGFR <20 ml/min/1.73m2. Patients were randomly and equally allocated to FIR group (receiving FIR therapy for 40 minutes thrice weekly for 3 months) and control group (without FIR therapy). This study is aimed to evaluate (1) the effect of newly-created AV access on the markers of inflammation (hsCRP), endothelial function [asymmetric dimethyl arginine (ADMA) and L-arginine], and oxidative stress [serum malondialdehyde (MDA), serum advanced oxidation protein products (AOPPs), blood glutathione (GSH), erythrocyte glutathione peroxidase (GPx), and erythrocyte superoxide dismutase (SOD) activities], (2) the effect of FIR on access flow and the levels of the above-mentioned inflammatory, endothelial and oxidative stress markers in patients with advanced CKD in the first 3 months after the creation of AVF.

Results: Totally, 122 advanced CKD patients finished this study with 60 in FIR group and 62 in control group. In comparison with control patients, the patients in FIR group had lower mean values of incremental change of the plasma concentrations of hs-CRP (-0.68±0.93 vs. 0.39±0.46 mg/L, P=0.04) and ADMA (-0.10±0.05 vs. 0.02±0.05, P=**0.02)** but a higher incremental change of blood glutathione (2.45±2.23 vs. -0.44±0.67, P=0.031) and access flow of AVF from 1st to 3rd month.

Conclusions: In patients with advanced stages of CKD, AVF malfunction is associated with a higher level of plasma hs-CRP, ADMA and a lower level of blood glutathione at baseline, which could be improved by FIR therapy. Henceforth, FIR therapy improves blood flow and the maturation of AVF possibly through the mechanism of correcting inflammation, endothelial dysfunction and oxidative stress.

Use of Arteriovenous Fistula/Graft Access for Continuous Renal Replacement Therapy: A Single Center Experience Anas Al Rifai, Nidhi Sukul, Michael Heung. *Internal Medicine-Nephrology, Univ of Michigan, Ann Arbor, MI.*

Background: Use of arteriovenous fistula or graft (AVF/AVG) access is widely considered to be contraindicated for continuous renal replacement therapy (CRRT), yet insertion of hemodialysis (HD) catheters can carry high risk of complications in critically ill endstage renal disease (ESRD) patients. Here we report our single-center experience with using AVF/AVG access for CRRT.

Methods: Retrospective review of 43 consecutive hospitalized ESRD patients on maintenance HD who received CRRT in 2012. After exclusions (16 catheter-dependent at admission, 4 with AVF/AVG thrombosis before CRRT start), our cohort consisted of 23 patients. Data collection included patient and treatment characteristics, and access outcomes.

Results: Mean+SD age was 57±15 yrs, 48% were male, and median HD duration was 54 months (range 8-300); 14 (61%) patients had AVF and 9 (39%) had AVG. Most (83%) patients required vasopressor support at CRRT start. Mental status at CRRT initiation showed 35% to be oriented and following commands, 9% awake but confused, and 56% sedated. Median duration of AVF/AVG use for CRRT was 4 days (range 2-34). Complications related to use of the AVF/AVG for CRRT (with subsequent requirement of HD catheter placement) developed in 3 patients (13%): hematoma in 2 patients with AVF and thrombosis of AVG in 1 patient. All 3 patients with complications had documented pre-existing access problems; 1 had known subclavian vein stenosis and 2 required access intervention within the previous 1 year. Of these three patients, 1 was awake and confused while the other 2 were sedated. Among them, 1 required blood product transfusion for line insertion and 1 developed a catheter-associated bloodstream infection. Of the cohort, 16 (70%) patients survived to hospital discharge; among the survivors, AVF/AVG access was functional at the time of discharge in 15 (94%) patients.

Conclusions: Our experience suggests that use of AVF/AVG for CRRT is feasible with a relatively low complication rate and low risk of access failure. This approach may aid in avoiding the potential complications associated with HD catheter insertion in ESRD patients with a functioning vascular access.

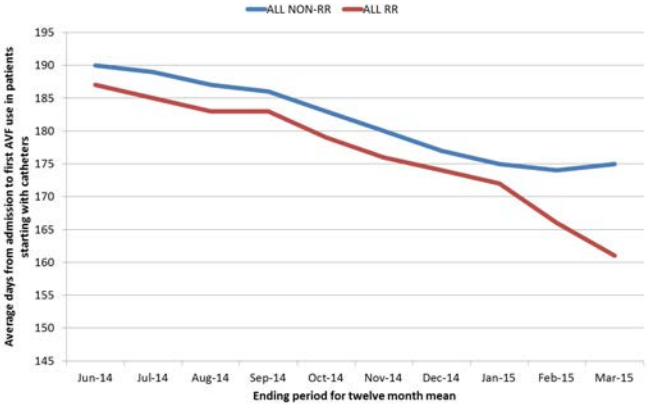
TH-OR063

Improvements in Time to Fistula Use in Incident Hemodialysis Patients in the Rapid Response Pilot Program Karen G. Butler, John W. Larkin, Deborah J. Brouwer-Maier, Sandra Bodin, Michelle L. Gilliland, Michele Inglese, Lillian A. Pryor, Len A. Usvyat, Dugan Maddux, Franklin W. Maddux. *Clinical Innovation Initiatives, Fresenius Medical Care North America (FMCNA), Waltham, MA.*

Background: It is known that use of a catheter hemodialysis (HD) access is associated with increased morbidity and mortality, as compared to arteriovenous fistulas (AVFs) and grafts (AVGs). FMCNA has initiated the Rapid Response (RR) pilot program in an attempt to improve time to use of AVF accesses in incident HD (iHD) patients who initiated dialysis with a catheter. The aim of this study was to determine if the RR program is associated with improvements in AVF access use in iHD patients.

Methods: In September 2014, 59 clinics initiated the RR pilot program. Clinics were selected by high census (>95 patients) and high catheter rates (>30%). The program consisted of sequential, educational modules designed to build awareness of catheter exposure, engage staff in standardized and simplified vascular access monitoring, and address lack of AVF maturation as a root cause of high catheter rates. All patients initiating dialysis with a catheter access were followed. Non-RR clinics in the same geographical location were randomly identified for controls. To determine the change in time to AVF use, the mean time to AVF use over 12 months at the end of each month from June 2014 to March 2015 was calculated.

Results: 5,248 and 4,159 iHD patients starting dialysis with a catheter at RR and non-RR clinics were included in this analysis. The mean time to AVF use was reduced in RR clinics after initiation of the program in September of 2014, as compared to control clinics (p<0.05).



Conclusions: This study demonstrates improvements associated with time to AVF use in incident patients initiating HD with a catheter access at clinics participating in the RR program.

TH-OR064

Impact of Poverty and Health Care Insurance on Arteriovenous Fistula Use Among Incident Hemodialysis Patients Deepti S. Moon,[1] Rahul M. Jindal,[2] Frank P. Hurst,[2] Christina M. Yuan,[1] Lawrence Agodoa,[3] Kevin C. Abbott,[1] Robert Nee.[1] *[1]Nephrology, Walter Reed National Military Medical Center, Bethesda, MD; [2]Uniformed Services Univ of the Health Sciences, Bethesda, MD; [3]NIDDK, National Insts of Health, Bethesda, MD.*

Background: We assessed the association of area and individual-level indicators of poverty and types of health care insurance on arteriovenous fistula (AVF) use among incident end stage renal disease (ESRD) patients initiated on hemodialysis (HD).

Methods: In this retrospective cohort study using the United States Renal Data System database, we identified 669,206 patients initiated on maintenance HD from January 1, 2007 through December 31, 2012. We assessed the Medicare-Medicaid dual eligibility status as an indicator of individual-level poverty and ZIP code-level median household income (MHI) data obtained from the 2010 United States Census. We conducted logistic regression of AVF use at start of dialysis as the outcome variable, as reported on the Medical Evidence Form 2728.

Results: The proportions of dual-eligible and non-dual eligible patients who initiated HD with an AVF were 12.53% and 16.17%, respectively ($p<0.001$). Dual-eligibility was associated with significantly lower likelihood of AVF use upon initiation of HD (adjusted odds ratio [aOR] 0.91; 95% confidence interval [CI] 0.90-0.93). Patients in the lowest area-level MHI quintile had an aOR 0.97 (95% CI 0.95-0.99) compared to those in higher quintile levels. However, dual eligibility and area-level MHI were not significant in patients with Veterans Affairs (VA) coverage.

Conclusions: Individual and area level measures of poverty were independently associated with lower likelihood of AVF use at the start of HD, the only exception being patients with VA healthcare benefits. Efforts to improve incident AVF use may require focusing on pre-ESRD care to be successful. A Subset of CD64^{+} F4/80^{high} CD11b^{int} CD11c^{int} Macrophages Protects against Chronic Ischemic Kidney Injury Amrutesh Puranik,[1] Sonu Kashyap,[3] Mark A. Jensen,[4] Bruce Knudsen,[3] John R. Woollard,[2] Tyra Witt,[7] Stephen C. Textor,[2] Jeremy Stuart Duffield,[5] Joseph P. Grande,[3] Rob Simari,[6] Lilach O. Lerman.[2] *[1]Dept of Anesthesiology, Mayo Clinic, Rochester, MN; [2]Div of Nephrology & Hypertension, Mayo Clinic, Rochester, MN; [3]Laboratory Medicine & Pathology, Mayo Clinic, Rochester, MN; [4]Dept of Rheumatology, Mayo Clinic, Rochester, MN; [5]Biogen, Cambridge, MA; [6]Univ of Kansas, Kansas City, KS; [7]Cardiac Regeneration Program, Mayo Clinic, Rochester, MN.*

Background: Macrophages (Mfs) have been implicated in both progression and resolution of renal injury. We tested the hypothesis that a specific Mfs subtype regulates fibrosis in chronic murine ischemic renal artery stenosis (RAS).

Methods: After 28 days of unilateral RAS in mice, stenotic kidneys were harvested and 3 Mfs populations (Figure 1), black circles) quantified using polychromatic flow cytometry by expression of the CD11b, CD11c, F4/80, MHCII, CD64, MerTK, Ly6c & CD206. Mouse macrophages were ablated using I.P injections of liposomal clodronate (2/week for 28 days), and macrophage populations were flow-sorted to study gene expression using Taqman low-density arrays.

Results: RAS induced hypertension and post-stenotic kidney atrophy, and increased the total Mfs numbers in each population. Ablation with clodronate aggravated fibrosis (figure1 bottom graph), and increased expression of proinflammatory transcripts for Il6, Ifng, Il1b, Tnfa, and Nos2. Clodronate selectively ablated a sub-population of CD64^{+}F4/80^{+}CD11b^{int}CD11c^{int} macrophages ([figure1 middle panel, right), while other populations remained intact. In healthy controls, gene expression studies on this population demonstrate significantly higher levels of genes typically expressed by tissue-resident Mfs (such as Myo7a, Nln, Slc48a, Pla2g15, Spi1, Csf1r, Pon3, Tlr4, Cebpa, Mafb, Hbp1 Mertk and Fcgr1), than monocyte-derived Mfs (figure1, circles 1 and 2) (CD64^{+}F4/80^{+}CD11b^{hi}CD11c$^{hi/-}$). Flow sorted CD64^{+}F4/80^{+}CD11b^{int}CD11c^{int} macrophages from RAS kidneys showed increased levels of Mertk, Arg1, Agtr2, Csf1, Il10, Igf1, Angpt1 and Vegfa, factors involved in inhibiting inflammation and promoting regeneration. These factors were down-regulated upon clodronate treatment.

Conclusions: CD64^{+}F4/80^{+}CD11b^{int}CD11c^{int} macrophages represent a novel population of protective kidney-resident macrophages that regulate the injury response in chronic kidney ischemia.

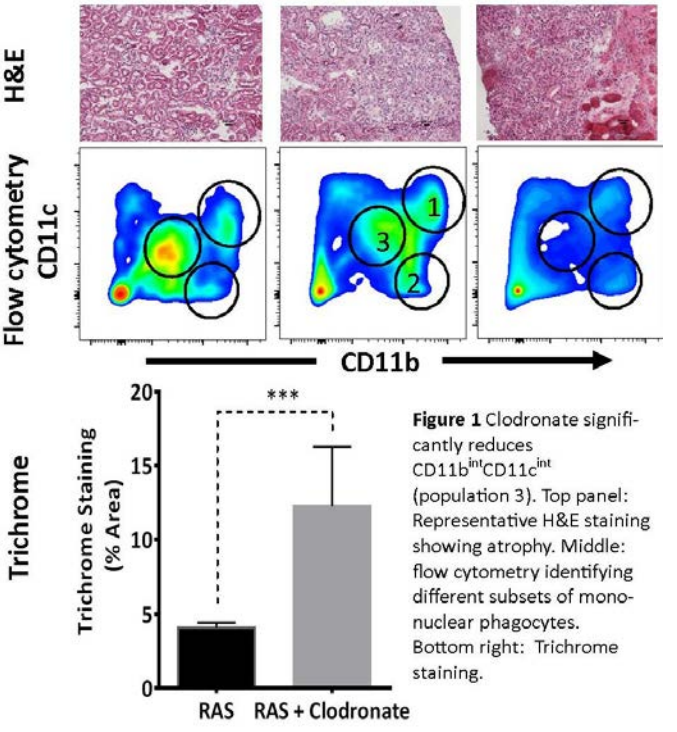

Figure 1 Clodronate significantly reduces CD11b^{int}CD11c^{int} (population 3). Top panel: Representative H&E staining showing atrophy. Middle: flow cytometry identifying different subsets of mononuclear phagocytes. Bottom right: Trichrome staining.

TH-OR066

Spliced XBP1 Rescues Renal Interstitial Inflammation due to Loss of *Sec63* in Collecting Ducts Yasunobu Ishikawa,[1] Sorin V. Fedeles,[1] Rachel Gallagher,[1] Stefan Somlo.[1,2] *[1]Internal Medicine, Yale Univ School of Medicine, New Haven, CT; [2]Genetics, Yale Univ School of Medicine, New Haven, CT.*

Background: *SEC63* is one of two genes which cause human autosomal dominant polycystic liver disease, and is located in the membrane of the endoplasmic reticulum (ER). A number of disease states alter ER function and result in ER stress, thus initiating the unfolded protein response (UPR). UPR is mediated by three major stress sensors, IRE1α, PERK and ATF6. In particular, IRE1α is the most conserved of the three branches and phosphorylation of IRE1α results in spliced XBP1 (XBP1s), a transcription factor that activates transcription of chaperones and proteins involved in ER-associated degradation. We have shown that loss of *Sec63* and *Xbp1* in collecting ducts causes phosphorylation of IRE1α and progressive renal interstitial inflammation leading to CKD (ASN, 2014 TH-OR162). It is known that phosphorylated IRE1α activates NFkβ, JNK and NALP3 inflammasome. In the current work we investigated the interaction of the SEC63 and IRE1-XBP1 pathways and their role in CKD.

Methods: Animal models used in this study: WT (wild type), SKO (*Sec63$^{fl/fl}$;Pkhd1-cre*), DKO (*Sec63$^{fl/fl}$;Xbp1$^{fl/fl}$;Pkhd1-cre*) and TKO (*Sec63$^{fl/fl}$;Xbp1$^{fl/fl}$;Ire1a$^{fl/fl}$;Pkhd1-cre)*, as well as *DKO;Nalp3$^{-/-}$* and DKO expressing a cre activated *ROSA-XBP1s* allele. The kidneys were removed and analyzed at P70.

Results: Analysis of NFkβ and JNK phosphorylation states were no different between WT, SKO and DKO. The histology in WT and SKO kidneys appeared normal. In contrast, DKO mice showed many inflammatory cells in the renal interstitium with decline in renal function. By removing *Ire1a* and *Nalp3$^{-/-}$*, respectively, on the DKO background did not rescue the inflammation nor ameliorate decline in renal function. In addition, double knockout of *Sec63* and *Ire1α* in the collecting duct also resulted in renal interstitial inflammation similar to what was observed in the DKO kidneys. Re-expression of a human XBP1 transgene that produces spliced XBP1 on the DKO background rescued the inflammatory phenotype.

Conclusions: Spliced XBP1 rescues renal interstitial inflammation due to loss of *Sec63* in collecting ducts.

TH-OR067

Specific Deletion of Rictor in Macrophages Ameliorates Macrophage Activation and Obstructive Nephropathy in Mice Jiafa Ren, Chunsun Dai. *Nanjing Medical Univ.*

Background: Rictor/mTORC2 signaling is activated in both tubular and interstitial cells in mouse kidneys with obstructive nephropathy. Our published studies reported that Rictor/mTORC2 signaling mediates TGFb1-induced fibroblast activation and kidney fibrosis. Regarding the critical role for macrophages infiltration in kidney fibrosis, deciphering the role and mechanisms for mTORC2 signaling in macrophage activation and its contribution to kidney fibrosis are very necessary.

Methods: In this study, a mouse model with tamoxifen-induced macrophage-specific deletion of Rictor and primary cultural macrophages from bone marrow were employed.

Results: Here, we found that Rictor/mTORC2 signaling was activated in the kidney interstitial F4/80+ macrophages in mice with UUO nephropathy. A mouse model with tamoxifen-induced macrophage-specific deletion of Rictor was generated. Compared with their control littermates, the knockout kidneys developed less kidney injury, interstitial extracelluar matrix deposition and macrophage infiltration at 2 weeks after UUO surgery. In the primary cultured macrophages, compared with wild type cells, cell proliferation stimulated by M-CSF treatment was similar, whereas cell migration was markedly inhibited in Rictor-deleted macrophages. Additionally, the mRNA abundance for arginase 1, fizz1, and YM1 were largely induced in wild type macrophages treated with IL4, which were much less in Rictor-deleted macrophages.

Conclusions: Together, these results suggest that Rictor/mTORC2 signaling plays an important role for promoting macrophage activation and contributes to the development of kidney fibrosis.

Non-HLA Antibodies Targeting Angiotensin II Type 1 Receptor and Endothelin-1 Type A Receptor Induce mTOR Signaling and Endothelial Injury in Human Microvascular Endothelium

Duska Dragun, Oskar Wischnewski, Rusan Catar, Angelika Kusch. *Nephrology and Intensive Care Medicine, Charité Universitätsmedizin Berlin, Berlin, Germany.*

Background: Functional non-HLA antibodies (Abs) targeting G protein-coupled receptors Angiotensin II Type 1 (AT1R) and Endothelin-1 Type A receptor (ETAR) are implicated in pathogenesis of renal transplant vasculopathy. Both antibodies activate canonic G-protein related ERK 1/2. The molecular link between receptor stimulation and development of vascular obliterative lesion has not been fully established. We hypothesized the involvement of PI3K/Akt downstream signaling target mTOR and assessed functional consequences of AT1R- and ETAR-activation by non-HLA Abs.

Methods: Human microvascular endothelial cells were stimulated with AT1R-Ab and ETAR-Ab containing IgG from patients with obliterative vasculopathy. Phospho-specific antibodies against ERK and mTOR downstream targets were used to assess activation of mTORC1 and mTORC2. Scratch assay was employed to study effect of non-HLA-antibodies on wound healing. Involvement of AT1R/ETAR activation in non-HLA antibody downstream signaling was addressed by use of specific inhibitors for AT1R (Valsartan) and ETAR (Sitaxentan).

Results: Signaling activity of both, mTORC1 and mTORC2, was increased after short and long term treatment with patient IgG compared to cells treated with IgG from healthy controls. This effect could be inhibited by preincubating the cells with specific inhibitors of AT1R and ETAR. Both, activation of mTORC1 and mTORC2 were PI3K-dependent and independent from ERK-activation. mTOR inhibitor rapamycin completely abolished non-HLA Abs induced activation of mTORC1 and in addition mTORC2 after long term treatment. Impaired wound healing by non-HLA Abs could be restored by either use of specific AT1R or ETAR inhibitors.

Conclusions: We provide evidence that functional targeting AT1R and ETAR antibodies induce mTORC1 and mTORC2 signalling which is independent of canonic ERK 1/2 activation in human microvascular endothelium. Our data on impaired AT1R and ETAR-dependent wound healing induced by non-HLA Abs may provide a translational rationale for therapeutic AT1R and mTOR inhibitors in patients with non-HLA Abs.

Memory Effector T Cells and OX40 Signaling Could Contribute to Chronic T-Cell Mediated Rejection

Claudia Curci,[1] Fabio Sallustio,[1] Grazia Serino,[1] Giuseppe De Palma,[1] Mirko Trpevski,[1] M. Rossini,[2] Loreto Gesualdo,[2] Marco Quaglia,[3] Paolo Rigotti,[4] Francesco Paolo Schena.[1] *[1]C.A.R.S.O. Consortium, Bari, Italy; [2]Univ of Bari, Bari, Italy; [3]Univ of Eastern Piedmont, Novara, Italy; [4]Univ of Padua, Padua, Italy.*

Background: Chronic T-cell Mediated Rejection (TCMR) is characterized by the reduction of vessel lumen with marked intimal thickening, fibrous hyperplasia and a large component of leukocyte infiltrate. Aim of our work was the study of gene expression profile in renal tissue, including the cellular infiltrate, in chronic TCMR.

Methods: We performed transcriptomics study using RNA extracted from archival formalin-fixed and paraffin-embedded (FFPE) renal biopsies obtained from 21 patients with chronic TCMR and 10 with acute TCMR. Controls were renal tissue samples from 52 cadaveric donors (CD). Genome-wide expression profiles were generated by Illumina platform. Real-Time PCR and immunofluorescence were used for validation of the identified transcripts.

Results: Using a FC³2 and a FDR<0.05, we identified 164 genes differentially expressed in renal tissue of patients with chronic and 165 genes differentially expressed in acute TCMR, compared to CDs. Partial Least Square showed a clear difference in the gene expression of the three groups of biopsies. The study of gene pathways showed up-regulation of OX40 signaling, that is involved in the differentiation of $CD8^+$ memory effector T cell, and up-regulation of KLRG1, BLIMP1 and CD25 that characterized short-lived memory effector T cells. Interestingly, we found that OX40 signaling was specific only for chronic TCMR. Next, the validation study forOX40, KLRG1, BLIMP1 demonstrated that these genes were expressed by $CD8^+$ T cells in chronic but not in acute TCMR.

Conclusions: Our data suggest, for the first time, the involvement of memory committed $CD8^+$ effector T cells specifically in chronic TCMR. The generation of memory effector T cells is mediated by OX40 pathway, that may be considered a potential target for specific treatment of chronic TCMR of kidney graft.

Dendritic Cell-Targeted CD40 DNA Vaccination Suppresses Th17 and Ameliorates Renal Injury in Experimental Autoimmune Glomerulonephritis

Qing Li,[1] Qi Cao,[1] Chengshi Wang,[1] Xin M. Wang,[2] Yuan Min Wang,[3] Stephen I. Alexander,[3] Yiping Wang,[1] David C. Harris.[1] *[1]Centre for Transplant and Renal Research, Westmead Millennium Inst, The Univ of Sydney, Sydney, Australia; [2]Flow Cytometry Facility, Westmead Millennium Inst, The Univ of Sydney, Sydney, Australia; [3]Centre for Kidney Research, Children's Hospital at Westmead, Sydney, Australia.*

Background: The CD40-CD154 co-stimulatory pathway is critical for T cell activation in autoimmune disease. Our group previously found that blocking this pathway using CD40 DNA vaccine enhanced by targeting dendritic cell receptor DEC205 prevent the development of Heymann nephritis. In this study, we used DEC-CD40 DNA vaccine to treat the disease and explored its effect on Th17-mediated pathogenesis of experimental autoimmune glomerulonephritis (EAG).

Methods: The rat EAG model was established by NC1 protein injection, and DEC-CD40 vaccination was administered at week3 and week6 after NC1 injection. Renal function and histology were assessed at week12. Th subsets, key transcription factors and relevant cytokines in kidneys, spleens and lymph nodes were examined.

Results: Administration of DEC-CD40 DNA vaccine at week3 and week6 after NC1 injection reduced renal structural and functional injury in EAG. DEC-CD40 vaccination reduced the number of Th17 cells and inhibited Th17 immune responses in kidney, spleen and lymph nodes, but did not alter the number of Th1, Th2 and Treg cells. Early and late treatment showed similar effects on kidney injury and Th17 immune responses, indicating DEC-CD40 vaccination has both preventative and therapeutic roles in EAG. Serum from rats with DEC-CD40 suppressed Th17 in vitro, but not Th1 differentiation. B cell activation and M1 macrophage polarization were inhibited when co-cultured with Th17 cells induced with DEC-CD40-EAG serum but not EAG serum.

Conclusions: DNA vaccine encoding CD40 and targeting dendritic cells ameliorates renal injury in both early and late stages of experimental autoimmune glomerulonephritis. Its preventative and therapeutic effect was associated with suppression of Th17 differentiation and Th17-dependent B cell activation as well as M1 macrophage polarization.

Funding: Government Support - Non-U.S.

Pharmacologic Targeting of Sirtuin-1 (Sirt1) Enhances Treg Function, Markedly Prolongs Renal Allograft Survival and Protects against Renal Allograft Dysfunction

Ulf H. Beier,[1] Zhonglin Wang,[2] Tricia Bhatti,[1] Wayne W. Hancock,[1] Matthew H. Levine.[2] *[1]Children's Hospital of Philadelphia, Philadelphia, PA; [2]Univ of Pennsylvania, Philadelphia, PA.*

Background: Published data show that the pharmacologic regulation of Foxp3+ T-regulatory (Treg) function provides safer, more consistent, potent and less expensive options than Treg-based cell therapy involving injection of short-lived Tregs at one or more times post-transplant (Tx). In the case of sirtuins biology, conditional deletion of the Sirt1 gene within Foxp3+ T-regulatory (Treg) cells augments Foxp3 acetylation and Treg suppressive function, and enhances heterotopic cardiac allograft survival.However, such data remain of uncertain translational significance until tested in life-supporting models using pharmacologic approaches in normal recipients. We now report such data.

Methods: To this end, C57BL/6 mice were engrafted with BALB/c kidneys (i.e. full MHC-mismatch) and underwent native nephrectomy, and blood chemistries, renal function and hematocrit were monitored weekly thereafter.

Results: Allograft recipients were divided into two groups, and treated with either a Sirt1 inhibitor, EX-527 (1 mg/kg/d for 14 days), or vehicle control. We found that allograft survival at 100 days post-Tx was 87.5% in the EX-527 group, but only 28.6% in control mice (P=0.037, Mantel-Cox test). Moreover, at 100 days post-Tx, the EX-527 treated group had lower BUN (71 ± 2.7 vs. 90 ± 3.6 mg/dL, P<0.001) and serum creatinine levels (0.33 ± 0.04 vs. 0.58 ± 0.02 mg/dL, P<0.001) than survivors in the control group. Histologic analysis of renal allografts retrieved after 100 days showed less allograft fibrosis (p=0.03) and less inflammation (p=0.01) in the EX-527 treated vs. control groups, respectively.

Conclusions: Pharmacologic inhibition of Sirt1 is effective at prolonging allograft survival and function. These data provide clear evidence that pharmacologic regulation of Treg function is of demonstrable value in stringent allograft models, and provide a compelling rationale for testing of Sirt1 inhibitors in pre-clinical models.

TH-OR072

A Novel IL-2 and IL-33 Hybrid Cytokine for Lupus Glomerulonephritis (GN) Therapy Rahul Sharma, Marta Stremska, Chao Dai, Hongyang Wang, Saleh Mohammad, Sheethal Jose, Sun-sang J. Sung, Shu man Fu. *CIIR, Univ of Virginia, Charlottesville, VA.*

Background: Autoimmune Lupus GN is caused by T-cell and immune complex (IC) mediated inflammation resulting in renal dysfunction. Low interleukin (IL)-2 levels and T-regulatory cell (Treg) deficiency is implicated in lupus GN. Based on our findings that (a) IL-2, which is critical for Tregs, also regulates the expression of ST2 (receptor for IL-33-a Th2 promoting cytokine) and (b) a major subset of Tregs express ST2; we hypothesized that both IL-2 and IL-33 will be beneficial for treating lupus GN by simultaneously promoting Tregs and Th2. Further, linking IL-2 and IL-33 in a single molecule will target Tregs more efficiently.

Methods: We made a recombinant hybrid cytokine (IL233) bearing activities of IL-2 and IL-33 and tested its efficacy to treat GN using lupus prone NZM2328 female mice, in which disease was accelerated by injection of IFNα-expressing adenovirus (Ad-IFNα). NZM2328 females were injected with saline or 66pmoles/day of IL233 or IL2/IL33 alone or in combination for 5-days before Ad-IFNα injection.

Results: IL233 and the IL-2 and IL-33 combination protected 80% and 60% mice respectively from severe proteinuria and mortality, whereas 80% of mice treated with saline or IL-2 or IL-33 alone succumbed to severe proteinuria. IL233 treatment induced robust and sustained increase in Tregs. Renal histology of mice that succumbed to proteinuria showed glomerular hypertrophy, mesangial expansion and leukocytic infiltration, which were absent in IL233 treated mice. While complement deposition was similar, IL233 treated mice showed reduced IC deposits and skewing towards IgG2b compared to predominantly IgG2a deposits in the control mice. Further, treatment with IL233 (66pmoles/day for 5days) of mice with established proteinuria (100-300mg/dL for 2 consecutive weeks) induced persistent remission in 9 out of 11 mice, which survived beyond 10 months of age, when 70% of the NZM2328 females die of severe proteinuria. IL233 treated mice had higher circulating IgG2b without any symptoms of allergic diseases.

Conclusions: IL233 hybrid cytokine can prevent and reverse lupus GN by enhancing Tregs and bears therapeutic potential.

TH-OR073

Interleukin-27 Has Potential Predictive Role in the Onset of Post-Transplant Malignancies Paola Pontrelli,[1] F. Rascio,[2] Giovanni Stallone,[2] Matteo Accetturo,[1] Margherita Gigante,[1] Giuseppe Castellano,[1] Barbara Infante,[2] Gianluigi Zaza,[3] Loreto Gesualdo,[1] Giuseppe Grandaliano.[2] *[1]Dept of Emergency and Organ Transplantation, Univ of Bari, Italy; [2]Dept of Medical and Surgical Sciences, Univ of Foggia, Italy; [3]Dept of Medicine, Univ of Verona, Italy.*

Background: Malignancies are the third leading cause of mortality among transplant recipients and their incidence is increasing. Although the role of the immune system in the development of malignancies is known, the mechanisms of tumor escape remain unclear. Aim of the study was to evaluate the differences in transcriptomic profiles of peripheral blood mononuclear cells (PBMC) in subjects who developed post-transplant malignancies (PTM, n=8) compared to transplanted patients without malignancies (ctrl-Tx, n=8).

Methods: The two patients' groups were comparable for the main clinical/demographic features and all patients were receiving calcineurin inhibitors (CNI), mycophenolate and steroids. Transcriptomic profiles of PBMC were assessed by microarray (Agilent technologies), analyzed by statistical and functional pathway analysis and validated by qPCR in an independent set of patients (PTM n=9; ctrl-Tx n=13).

Results: The comparison between PTM and ctrl-Tx (Fold-change>1.5), revealed that 4,363 genes were differentially expressed. Among them, the most down-regulated gene was interleukin (IL)-27 (fold-change (FC):-10.88), a cytokine produced by antigen presenting cells, which regulates anti-tumor immunity promoting the cytotoxic T lymphocytes activity and the natural killer cells activation. qPCR confirmed a significant reduction of IL-27 expression level in PTM patient compared to ctrl-Tx ($p<.05$). Since the treatment with mTOR inhibitors (mTORi) is associated to a reduce cancer risk in transplant recipients, we investigated whether mTORi may influence IL-27 expression in vivo. Interestingly, IL-27 gene expression was significantly higher in transplant recipients receiving an mTORi (n=8) compared to those with a CNI-based therapy ($p=.009$).

Conclusions: Our data stress the role of the immune system in the onset of cancer and suggest that IL-27 might represent a useful marker in order to stratify patients at risk of developing post-transplant malignancies.

Translation of Anti-Fibrotic MicroRNA Strategies into a Mouse Model of Chronic Allograft Dysfunction Celina Schauerte,[1] Song Rong,[2] Michael Mengel,[3] Hermann G. Haller,[2] Thomas Thum,[1] Johan Lorenzen.[1,2] *[1]Inst of Molecular and Translational Therapeutic Strategies (IMTTS), Hannover Medical School, Germany; [2]Div of Nephrology & Hypertension, Hannover Medical School, Germany; [3]Dept of Laboratory Medicine & Pathology, Univ of Alberta, Canada.*

Background: Chronic allograft dysfunction (CAD) is characterized by fibrotic remodeling, renal injury and chronic inflammation. Pro-fibrotic microRNA-21 (miR-21) was shown to be upregulated in CAD. This study investigates miR-21-inhibition in an evaluated murine model of CAD.

Methods: Allogenic kidney transplantation (NTx) was performed from male C57BL/6 into female Balb/c mice. Recipient mice were treated at day -1 and day 7 either with LNA-21 (miR-21 inhibitor) or LNA-SCR (control) (20mg/kg BW, i.p.). Six weeks after NTx, kidneys were harvested and analyzed e.g. by qRT-PCR, PAS and Sirius Red staining. Potential signal mechanisms were validated *in vitro* using renal fibroblast cell line NRK49F and macrophage-like cell line RAW264.7.

Results: We determined increased expression levels of markers for fibrosis (aSMA, Col1a2, Col3, FSP-1), inflammation (IL-6, MIP-1, IL-1β) and injury (NGAL, KIM-1) in transplanted kidneys which were rescued by miR-21 inhibition. Moreover, Sirius Red staining revealed significantly less fibrosis development due to miR-21 inhibition. Besides, BANFF chronic rejection score was decreased in allografts of LNA-21 treated mice. The miR-21 promoter region harbors a putative binding site of transcription factor STAT3, which is activated by IL-6. We identified upregulated IL-6 expression and secretion in LPS activated RAW264.7 and hypothesized, that infiltrating immune cells produce and secrete cytokines that might affect resident renal cells causing fibrosis and injury. Co-culture assays confirmed a crosstalk between RAW264.7 and NRK49F with increased expression levels of IL-6, CTGF and miR-21 in NRK49F. Similar results were observed due to IL-6 treatment of NRK49F.

Conclusions: In our murine model of CAD allograft rejection is preserved by inhibition of miR-21 due to less inflammation and fibrosis thereby suggesting a new and essentially needed anti-fibrotic treatment strategy against CAD.

TH-OR075

Regulation of the Apical Cotransporter NKCC2 by a Novel Kinase: TNIK Paulo S. Caceres,[1,2] Pablo A. Ortiz.[1,2] *[1]Hypertension & Vascular Research, Henry Ford Hospital, Detroit, MI; [2]Physiology, Wayne State Univ, Detroit, MI.*

Background: The apical cotransporter NKCC2 mediates NaCl absorption by the thick ascending ascending limb (TAL), maintaining blood pressure. Abnormally enhanced NKCC2 activity contributes to salt-sensitive hypertension. Phosphorylation of NKCC2 at amino terminal (NH_2) threonines 96,101 (Thr-96,101) increases its activity. Trafficking of NKCC2 to the apical surface also regulate TAL NaCl absorption. Only the kinases SPAK and OSR1 have been shown to target Thr-96,101. Identifying additional kinases that target NKCC2 will help understand the role of Thr-96,101 in the regulation of NKCC2. To identify additional kinases, we performed a targeted proteomics screen using a GST-NH_2-NKCC2 fusion protein as bait in pull down assays from TAL protein lysates. We found that the Traf2 and NCK interacting kinase (TNIK) binds the NH_2terminus of NKCC2. The role of TNIK in renal function and NKCC2 regulation is unknown. We hypothesized that TNIK phosphorylates NKCC2 at Thr-96,101 and stimulates surface NKCC2 expression in TALs.

Methods: We measured NKCC2-TNIK interaction by co-immunoprecipitation in rat TAL lysates. To determine whether TNIK directly phosphorylates NKCC2, we incubated the NH_2 terminus of NKCC2 with recombinant TNIK and measured NKCC2 phosphorylation at Thr-96,101. We generated TNIK knockout mice ($TNIK^{-/-}$), obtained TALs and measured total NKCC2, phosphorylation at Thr-96,101 and surface NKCC2 by surface biotinylation.

Results: We observed TNIK expression in isolated perfused TALs. NKCC2 and TNIK co-immunoprecipitate in TAL lysates and TNIK directly phosphorylates NKCC2 at Thr-96,101 in vitro. In TALs from $TNIK^{-/-}$ mice on a normal diet, total NKCC2 expression was decreased by 32±9% ($p<0.05$) and phospho/total NKCC2 was decreased by 23±6% ($p<0.05$). In $TNIK^{-/-}$ mice fed a low Na diet, phospho/total NKCC2 was decreased by 51±9% ($p<0.05$). The surface/intracelluar NKCC2 ratio was decreased by 58±4% ($p<0.01$) in $TNIK^{-/-}$ mice.

Conclusions: TNIK is a new kinase that interacts with NKCC2 in TALs, it phosphorylates NKCC2 at Thr-96,101 and mediates total and surface NKCC2 expression in vivo. This represent a novel pathway in the field of renal ion transport.

Golgi Alpha1,2-Mannosidase IA Promotes the Efficient Degradation of NKCC2 and Its Disease Causing Mutants Kamel Laghmani, Sylvie Demaretz, Nadia Defontaine, Elie Seaayfan. *Centre de Recherche des Cordeliers, INSERM/UPMC/CNRS - U1138, ERL8228, Equipe 3, Paris, France.*

Background: Mutations in the apically located Na-K-2Cl cotransporter, NKCC2, lead to type I Bartter syndrome, and inherited kidney disorder associated with salt wasting, hypokalemia, and metabolic alkalosis. We have previously shown that wild type (WT) NKCC2 protein and its mutants are subject to regulation by the endoplasmic reticulum-associated degradation (ERAD). The aim of the present study was to identify the protein partners involved in ERAD of NKCC2.

Methods: To identify novel NKCC2-interacting proteins, we screened a kidney cDNA library through yeast two-hybrid using NKCC2 C-terminus as bait. NKCC2 protein expression was monitored in transiently transfected OKP and HEK cells, using immunoblot and confocal imaging. NKCC2 stability was assessed by cycloheximide chase assay.

Results: We identified Golgi alpha1, 2-mannosidase IA (MANIA) as a specific binding partner of NKCC2. In addition to ER mannosidases, recent reports revealed that Golgi-situated α-1, 2-mannosidases may also contribute to the ERAD of glycoproteins. Co-immunoprecipitation and co-immunolocalization experiments confirmed NKCC2-MANIA interaction in renal cells. They also showed that MANIA association involves mainly the immature form of NKCC2. MANIA co-expression decreased total cellular WT NKCC2 protein in a dose dependent manner. Cycloheximide chase assay showed that in cells over expressing MANIA, NKCC2 maturation is impaired. Importantly, MANIA co-expression had a more profound effect on the disease-associated NKCC2 folding mutants, A508T and Y998X (>90%). The MANIA induced reductions in NKCC2 expression were offset by the proteasome inhibitor MG132. Finally, kifunensine and 1-deoxymannojirimycin, two potent inhibitors of alpha1, 2-mannosidases, reproduced MG132 effect on NKCC2 regulation.

Conclusions: Our data demonstrate the presence of a MANIA mediated ERAD pathway in renal cells promoting retention and/or degradation of misfolded NKCC2 proteins. They suggest a model whereby, Golgi MANIA contributes to ERAD of NKCC2, by promoting the retention, recycling, and ERAD of misfolded proteins that initially escape protein quality control surveillance within the ER.

Inhibition of Mitochondrial Complex-1 Prevents the Downregulation of NKCC2 and ENaCα in Obstructive Nephropathy Zhanjun Jia,[1,2] Yue Zhang,[1] Ying Sun,[1] Guixia Ding,[1] Songming Huang,[1] Aihua Zhang.[1] *[1]Nephrology, Nanjing Children Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China; [2]Nanjing Key Laboratory of Pediatrics.*

Background: Ureteral obstruction with subsequent hydronephrosis is a common clinical complication. Downregulation of renal sodium transporters in obstructed kidneys could contribute to impaired urine concentrating capability and salt waste following the release of a ureteral obstruction. This study was undertaken to investigate the role of mitochondrial complex-1 inhibition in modulating sodium transporters in obstructive nephrophthy.

Methods: C57BL/6 mice were subjected to the sham surgery or unilateral ureteral obstruction (UUO) for 7 days. Then kidney tissues were harvested for the analyses.

Results: Following UUO, sodium transporters including NHE3, α-Na-K-ATPase, NCC, NKCC2, p-NKCC2, ENaCα, and ENaCγ were remarkably reduced by 60-90% contrasting to unaltered expression of ENaCβ, as determined by qRT-PCR, Western blotting, and immunohistochemistry. This global downregulation of sodium transporters was accompanied by striking reduction of mitochondrial DNA copy number (mtDNA), mitochondrial transcription factor (mTFAM), and mitochondria-encoded NADH dehydrogenase 1 (mtNd1) indicating a mitochondrial abnormality. Strikingly, specific inhibition of mitochondrial complex-1 by rotenone (500ppm in diet) completely abolished the downregulation of NKCC2, p-NKCC2, and ENaCα without affecting other sodium transporters. To study the potential mechanisms mediating the rotenoen effects on sodium transporters, we examined a number of known sodium modulators, including PGE2, ET1, Ang II, natriuretic peptides (ANP, BNP, and CNP), and nitric oxide synthases (iNOS, nNOS, and eNOS) and found that all of them were strikingly elevated by 3 to 80 folds except for nNOS in obstructed kidneys. However, after rotenone administration, only BNP with a 80-fold increase and iNOS with a 4-fold increase but not others were significantly reduced by 62% and 96%, respectively.

Conclusions: These findings demonstrated a substantial role of mitochondrial dysfunction in mediating the downregulation of NKCC2 and ENaCα in obstructive nephropathy, possibly via iNOS-derived nitric oxide and BNP.

NLRP3 Inflammasome Activation Confers the Resistance to Loop Diuretics in Proteinuric Kidney Disease Aihua Zhang,[1,2] Yibo Zhuang,[1] Guixia Ding,[1] Songming Huang,[1] Zhanjun Jia.[1,2] *[1]Nephrology Dept, Nanjing Children Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China; [2]Nanjing Key Laboratory of Pediatrics.*

Background: The resistance to loop diuretics is a known phenomenon in proteinuric patients, particularly in the patients with nephrotic syndrome. However, the pathogenic mechanisms remain elusive.

Methods: Kidney biopsy specimens of proteinuric patients and mouse kidney tissues from albumin overloaded mice (daily i.p injection of albumin for 12 days) were analyzed.

Results: In the present study, we analyzed Na-K-Cl cotransporter (NKCC2, target of loop diuretics) expression in proteinuric patient kidneys via immunohistochemistry (IHC) and found a significant NKCC2 downregulation which was negatively correlated with proteinuria severity. Interestingly, in NKCC2 positive tubules (thick ascending limb, TAL), NLRP3 inflammasome was strikingly elevated and showed a positive correlation with proteinuria severity. These findings suggested a possibility that proteinuria may suppress NKCC2 expression via a NLRP3 inflammasome-mediated mechanism. To validate this hypothesis, NLRP3 WT and KO mice were subjected to albumin overload. Strikingly, albumin overload in WT mice resulted in a robust reduction of NKCC2 by 80% as determined by Western blotting, qRT-PCR, and IHC in accord with a specific induction of NLRP3 in TAL. Meanwhile, the downstream components of NLRP3 inflammasome including caspase-1, IL-1β, and IL-18 were remarkably activated. Importantly, such a reduction of NKCC2 was entirely abolished in NLRP3 KO mice. In primary cultures of renal tubular cells, albumin markedly reduced NKCC2, indicating a direct effect of albumin on NKCC2 dysregulation. In addition, WT mice with albumin overload displayed a remarkable resistance to loop diuretic furosemide (NKCC2 inhibitor), which was completely reversed by NLRP3 invalidation.

Conclusions: These novel findings demonstrated that albuminuria-stimulated NLRP3 inflammasome is highly responsible for the impaired response to loop diuretics via suppressing NKCC2 expression in proteinuric kidney diseases. This may also offer novel, effective therapeutic targets for dealing with the resistance to loop diuretics in proteinuric patients.

TH-OR079

Targeted Knockin of Constitutively Active SPAK (CA-SPAK) in the Early Distal Convoluted Tubule (DCT) Causes Hyperkalemic Hypertension P. Richard Grimm,[1] Richard A. Coleman,[1] Eric J. Delpire,[2] Paul A. Welling.[1] *[1]Physiology, Univ of Maryland SOM, Baltimore, MD; [2]Anesthesiology, Vanderbilt Univ SOM, Nashville, TN.*

Background: Familial Hyperkalemic Hypertension (FHHt) is caused by aberrant gain in WNK function, leading to hyperactivation of the thiazide-sensitive sodium chloride co-transporter, NCC, and alterations in other salt transport pathways. SPAK is thought to be the key arbiter of WNK-NCC signaling in the DCT; upon activation by WNK1/4-phosphorylation (S383 and T243), SPAK phosphorylates NCC to stimulate salt reabsorption. Here, we explore if constitutive activation of SPAK in the DCT is sufficient to produce FHHt.

Methods: Knockin-CA-SPAK lox/lox mice were created by inserting a SPAK phosphomimetic mutant (T243E and S383D) between Lox-P sites in the first exon of the SPAK gene, using homologous recombination. Upon Cre-Lox recombination, these mice express CA-SPAK under the control of the endogenous SPAK promoter. To drive DCT1-specific expression of CA-SPAK in the kidney, mice expressing Cre-recombinase under the parvalbumin promoter (Parv-Cre+) were crossed with the CA-SPAK lox/lox mice. The phenotypes of DCT-specific CA-SPAK knockin (CA-SPAK KI) were compared to matched wild-type (WT) controls.

Results: As observed by immunofluoresent-confocal microscopy, CA-SPAK was specifically targeted to parvalbumin positive tubules in CA-SPAK KI mice, consistent with DCT1-specific expression. CA-SPAK KI mice displayed significantly greater amounts of phosphorylated NCC than WT even though the abundance of CA-SPAK and WT-SPAK were comparable, verifying the constitutively active nature of the knockin. Telemetric measurements of blood-pressure (BP) revealed the CA-SPAK KI mice are hypertensive despite low renin and aldosterone levels. Elevated BP was further exacerbated by high salt diet and ameliorated by hydrochlorothiazide (HCTZ). CA-SPAK KI also displayed HCTZ-remediable metabolic acidosis, and elevated plasma potassium levels, comparable to mouse models of WNK FFHT.

Conclusions: Targeted expression of CA-SPAK in the DCT1 phenocopies FHHt, underscoring the chief role of SPAK-dependent activation of NCC in early distal tubule in the pathogenesis of the disease.

Generation and Analysis of Knock-In Mice Carrying Pseudohypoaldosteronism Type II-Causing Mutations in the Cullin 3 Gene Yuya Araki, Tatemitsu Rai, Eisei Sohara, Takayasu Mori, Yuichi Inoue, Eriko Kikuchi, Shinichi Uchida. *Dept of Nephrology, Tokyo Medical and Dental Univ, 1-5-45 Yushima, Bunkyo, Tokyo, Japan.*

Background: Pseudohypoaldosteronism type II (PHAII) is a hereditary hypertensive disease caused by mutations in four different genes: *WNK1* and *4*, *KLHL3*, and *cullin 3* (*Cul3*). Cul3 and KLHL3 form an E3 ligase complex that ubiquitinates and reduces WNK4 protein. However, the molecular pathogenesis of PHAII caused by mainly intronic *Cul3* mutations is unclear. In cultured cells and human leukocytes, PHAII-causing *Cul3* mutations result in the skipping of exon 9, producing a mutant Cul3 protein lacking 57 amino acids (Δ403–459). However, whether this phenomenon occurs in the kidneys and is responsible for the pathogenesis of PHAII *in vivo* is unknown.

Methods: We generated knock-in mice carrying a mutation in the C terminus of intron 8 of *Cul3*, c.1207 -1G>A, which corresponds to a PHAII-causing mutation in the human *Cul3* gene.

Results: Heterozygous $Cul3^{G(-1)A/+}$ knock-in mice did not exhibit PHAII phenotypes, and the skipping of exon 9 was not observed in their kidneys. However, the level of Cul3 mRNA expression in the kidneys of heterozygous knock-in mice was approximately half that of wild-type mice. Furthermore, homozygous knock-in mice were nonviable, similar to *Cul3* knockout mice, suggesting that the mutant allele does not produce Cul3 mRNA lacking exon 9, but behaves like a knockout allele in this mouse model. These data suggest that the production of the mutant Cul3 may be necessary and important for the pathogenesis of PHAII.

Conclusions: Our findings highlight the pathogenic role of mutant Cul3 protein and provide insight to explain why intronic PHAII-causing mutations in *Cul3*, which has numerous binding partners in addition to KLHL3, cause only kidney-specific PHAII phenotypes.

TH-OR081

Disruption of SPAK/OSR1 Reveal Their Critical Roles in Potassium Homeostasis Mohammed Zubaerul Ferdaus, Andrew Terker, James A. McCormick. *Dept of Medicine, Div of Nephrology & Hypertension, Oregon Health & Science Univ, Portland, OR.*

Background: The WNK-SPAK/OSR1 pathway has been shown to play a key role in ion homeostasis, regulation of extracellular fluid volume, and blood pressure (BP). STE20 (sterile20)/SPS1-related proline/alanine-rich kinase (SPAK) and oxidative stress-responsive kinase-1 (OSR1) activate the renal cotransporters NKCC2 and NCC by phosphorylation. SPAK knockout mice (SPAK-KO) and OSR1 knockout mice display mild renal phenotypes, and may compensate for each other. We therefore generated SPAK-KO/inducible renal OSR1-KO mice (DKO) to compare the effects of deleting both kinases with SPAK deletion alone.

Methods: To examine the effects of disrupting both SPAK and OSR1, we manipulated dietary sodium (Na) and potassium (K), and analyzed levels of phospho-NCC (pNCC) and phospho-NKCC2 (pNKCC2) and other relevant proteins. We also measured plasma and urine electrolytes, and the BP of SPAK-KO and DKO mice on different diets using telemetry.

Results: We found that DKO had lower pNCC (48% on low Na, p=0.02 & 40% on low K diet, $p=5X10^{-7}$) and pNKCC2 (56% on low Na, p=0.04 & 57% on low K diet, p=0.002) than SPAK-KO (100%). On normal diet we found lower pNCC in DKO (40%, p=0.01) than in SPAK-KO but surprisingly no difference in pNKCC2. Total-NKCC2 and total-NCC levels did not differ between the strains on any diet except on low K diet where total-NCC was lower in DKO (74%, p=0.003) than in SPAK-KO. Surprisingly, levels of pS126-NKCC2, a non-SPAK/OSR1 target site, were lower in DKO (52%, p=0.0003) on normal diet. DKO displayed lower plasma potassium than SPAK-KO mice on normal (3.35 vs 3.71 mmol/L, p=0.05), low Na (2.83 vs 3.44 mmol/L, p=0.00001) and low K (2.08 vs 3.11 mmol/L, $p=6X10^{-8}$) diet. Unexpectedly, urinary Na did not differ between strains, and DKO did not show lower BP than SPAK-KO.

Conclusions: Our data suggest that SPAK/OSR1 play more important roles in K homeostasis than in Na and BP homeostasis. Even after disrupting SPAK/OSR1, there was NKCC2 phosphorylation at sites reported to be SPAK/OSR1-dependent, suggesting alternative pathways for phosphorylation at these sites. Finally, disruption of SPAK/OSR1 reduced levels of pS126-NKCC2.

TH-OR082

Inducible Kidney-Specific KCNJ10 Knockout Mice Show a Salt Losing Phenotype Catherina A. Cuevas,[1] James A. McCormick,[1] Andrew Terker,[1] Chao-Ling Yang,[1] WenHui Wang,[3] David H. Ellison.[1] *[1]Dept of Medicine, Oregon Health & Science Univ, Portland, OR; [2]Portland VA Medical Center, Oregon Health & Science Univ, Portland, OR; [3]Pharmacology, New York Medical College, Valhalla, NY.*

Background: Missense mutations of KCNJ10 cause EAST/SeSAME syndrome, which is characterized by epilepsy, ataxia, sensorineural deafness and a salt-wasting tubulopathy resembling Gitelman syndrome. KCNJ10 encodes the Kir4.1 potassium channel, which resides in the basolateral membrane of the distal nephron. $KCNJ10^{-/-}$ mice have a severe phenotype and die during the first two weeks of life, limiting the useful of this model. Results obtained in young mice show reduced basolateral K^+ conductance, sodium chloride transporter (NCC) and SPAK (Ste20-related proline alanine rich kinase) abundances. Here, we determine the renal phenotype of kidney-specific $KCNJ10^{-/-}$ adult mice.

Methods: Doxycycline-inducible kidney-specific $KCNJ10^{-/-}$ mice were generated using the TetOn/CreLoxP system under the control of Pax8 promoter. Doxycycline was administered for two weeks in the drinking water (0.2 mg/ml in 5% sucrose) of 2 month old mice. Biochemical parameters were assayed in urine, blood or renal tissue in KS-$KCNJ10^{-/-}$ mice after two weeks of the end of doxycycline treatment.

Results: Kir4.1 was absent in the KS-$KCNJ10^{-/-}$ mice, which displayed hypokalemia, hypochloremia with metabolic alkalosis, hypocalciuria, polyuria, and renal loss of sodium and potassium ($P<0.05$). At protein level, we observed that disruption of KCNJ10 decreased the expression of NCC and pNKCC2 (Na^+-K^+-Cl^- cotransporter) without affecting the levels of WNK4 (with no lysine kinase 4) and SPAK.

Conclusions: In conclusion, disruption of KCNJ10 in adult mice induces a severe renal phenotype highlighted by hypokalemic metabolic alkalosis and renal loss of sodium with hypocalciuria. In contrast to constitutive $KCNJ10^{-/-}$ mice in which decreased of NCC and SPAK abundance may be explained by a reduction in DCT mass, the disruption of KCNJ10 in adult mice causes a sodium wasting phenotype accompanied by decreased NCC and NKCC2 abundances. suggesting a more widespread tubulopathy involving both DCT and TAL in our model.

TH-OR083

HIV Vpr Antagonizes Mineralocorticoid Receptor Activity, Explaining Salt Wasting Koji Okamoto, Hewang Lee, Jeffrey B. Kopp, Shashi Shrivastav. *Kidney Section, NIDDK, NIH, Bethesda, MD.*

Background: Patients with HIV-associated-nephropathy (HIVAN) present with proteinuria but often lack edema, suggesting renal Na wasting. We have shown that the HIV accessory protein Vpr binds transcriptional regulators including the glucocorticoid-receptor and PPAR-g and b/d. We investigated whether Vpr regulates mineralocorticoid-receptor (MR) activity.

Methods: We have developed transgenic mice that express Vpr in proximal tubules (PEPCK/rtTA-X-TetOp/Vpr). Wild type and transgenic mice were fed a high protein diet for 2 weeks to induce transgene expression. After 6 days on a Na deficient diet, urine and kidneys were obtained. A human distal cortical tubular (DCT) cell line was exposed to soluble Vpr (100 ng/mL) and aldosterone (10^{-8} mM).

Results: On low salt diet, Vpr transgenic mice, compared to wild-type mice, manifested renal Na wasting (28±3 vs 15±2 mmol/g body weight/d) and an increased fractional Na excretion (2.0% vs 0.7%). We examined renal RNAexpression of the thiazide-sensitive cotransporter (TSC), NHE, ATP1A1, NKCC2, NaPi-2A and only TSC was decreased in Vpr mice. As TSC expression is regulated by MR, we focused the effect of Vpr on MR function. In a promoter reporter assay in CV1 cells, Vpr reduced aldosterone-stimulated MMTV and TSC promoter activity. We hypothesized that Vpr binds MR and inhibits its transcriptional activity. Using immunoprecipitation, we found that Vpr, but not Vpr with LXXLL motif mutations, bound recombinant MR. We reasoned that the interaction between Vpr and MR might interfere with the folding of the MR signal peptide, preventing nuclear entry, or might prevent MR from binding to promoter sequences. We performed WB using nuclear extracts from DCT cells and IHC, following exposure to Vpr and/or aldosterone. Vpr inhibited nuclear entry of MR. Using genome-wide ChIP sequencing with MR antibody in distal tubules cell line with aldosterone±Vpr, we found that the peak signal of TSC promoter was disappeared after treatment with Vpr.

Conclusions: Vpr binds MR and inhibits MR transcriptional activity, providing a molecular mechanism for renal salt wasting in HIVAN.

TH-OR084

The Sodium/Proton Exchanger NHA2 Is a Novel Regulator of Sodium, Calcium and Blood Pressure Homeostasis in the Distal Convoluted Tubule of the Kidney Manuel Andreas Anderegg,[1,2] Giuseppe Albano,[1,2] Ganesh Pathare,[1,2] Daniel G. Fuster.[1,2] *[1]Divison of Nephrology, Hypertension and Clinical Pharmacology, Univ of Bern, Bern, Switzerland; [2]Dept of Clinical Research, Univ of Bern, Bern, Switzerland; [3]Dept of Anatomy, Univ of Zürich, Zürich, Switzerland.*

Background: NHA2 (also known as SLC9B2) is a sodium/proton exchanger expressed in the kidney, but its function there remains unknown.

Methods: We performed in vitro and in vivo experiments to elucidate the physiological role of NHA2 in the kidney.

Results: We found NHA2 expression restricted to distal convoluted tubules in both murine and human kidney. By confocal imaging, NHA2 had an apical to subapical tubular localization. Blood pressure, measured by invasive telemetry, was significantly lower in NHA2 KO mice compared to WT mice on low, normal and high sodium diets. In addition, NHA2 KO mice exhibited normocalcemic hypocalciuria with reduced plasma PTH but unaltered 1,25-OH Vitamin D3 levels. Interestingly, immunoblotting of kidney lysates revealed reduced phosphorylation of the sodium/chloride co-transporter (NCC) in NHA2 KO mice. Similarly, phosphorylation of SPAK, as well as the abundance of WNK4, kinases regulating NCC phosphorylation, was reduced in kidney lysates of KO mice, compared with those of WT mice. In line with these findings, NHA2 KO mice exhibited a reduced natriuretic response to hydrochlorothiazide compared to WT mice. In the DCT cell line $mpkDCT_4$, stimulation of NCC phosphorylation was reduced upon siRNA mediated knockdown of NHA2 compared with control siRNA treated cells. In addition, knockdown of NHA2 led to a decreased WNK4 abundance and an increase of WNK4 ubiquitylation.

Conclusions: These results indicate that the renal phenotype observed in vivo upon loss of NHA2 is a result of increased degradation and therefore reduced abundance of WNK4 in the kidney.

Together, our data reveal the sodium/proton exchanger NHA2 as a novel regulator of calcium, sodium and blood pressure homeostasis in the distal convoluted tubule of the kidney.

Funding: Government Support - Non-U.S.

TH-OR085

Transgenic Mice Expressing APOL1-G0 or APOL1-G2 in Podocytes Do Not Develop Kidney Disease Leslie A. Bruggeman,[1] Zhenzhen Wu,[1] Liping Luo,[1] Sethu M. Madhavan,[1] Martha Konieczkowski,[1] Paul E. Drawz,[2] L. Barisoni,[3] John R. Sedor,[1] John F. O'Toole.[1] *[1]Medicine, MetroHealth Medical Center, Case Western Reserve Univ, Cleveland, OH; [2]Medicine, Univ of Minnesota, Minneapolis, MN; [3]Pathology, Univ of Miami, Miami, FL.*

Background: Variants in Apolipoprotein L1 (APOL1) associate with non-diabetic kidney diseases in African Americans, however, the mechanism of renal injury associated with APOL1 risk variants remains unknown.

Methods: Since APOL1 is present only in humans and some other primates, we created transgenic mice (FVB/N strain) expressing the reference allele of APOL1 (G0) and a risk variant (G2) in podocytes using the Nephrin promoter. Mice were phenotyped for APOL1 expression, podocyte injury, and renal disease.

Results: Numerous founders for both G0 (n=29) and G2 (n=8) were obtained and progeny transmitted the transgenes consistent with Mendelian expectations. Founders and offspring expressed variable levels of APOL1 in podocytes, but even in the highest expressing G0 and G2 mice, markers for necrosis, apoptosis, or autophagic cell death were not identified in podocytes. Aged (~300days) G0 and G2 mice did not develop spontaneous kidney pathology, proteinuria, or azotemia. An unexpected phenotype in G0 and G2 founders and their offspring was sporadic seizures and sudden death during pregnancy. Pregnant mice from both G0 and G2 models exhibited hallmarks of preeclampsia including hypertension, proteinuria, glomerular endothelial damage, and elevated sFlt-1 levels. APOL1 was expressed in placental tissues, confirming prior reports of placental expression of Nephrin and APOL1.

Conclusions: Constitutive expression of the APOL1 G0 and G2 protein in vivo was not cytotoxic to podocytes regardless of expression level, mimicking the observations in humans that APOL1 risk genotypes are insufficient to cause kidney disease in the absence of an additional stressor. The preeclampsia phenotype was not variant-dependent and may represent placental injury related to ectopic transgene expression, however, a role for APOL1 in placental function may warrant further investigation.

TH-OR086

Kidney Disease Associated Variants of Apolipoprotein L1 Changes Conformational Dynamics of the C-Terminal Domain Sethu M. Madhavan,[1] John F. O'Toole,[1] Martha Konieczkowski,[1] Zhenzhen Wu,[1] Yaping Gu,[1] Leslie A. Bruggeman,[1] Matthias Buck,[2] John R. Sedor.[1,2] *[1]Medicine, MetroHealth System; [2]Physiology and Biophysics, Case Western Reserve Univ, Cleveland, OH.*

Background: *APOL1* risk variants associate with non-diabetic kidney diseases in African Americans; however, the mechanisms of variant APOL1-mediated kidney injury remain unknown. We have shown a SNARE protein VAMP8 interacts with the C-terminus of APOL1; *APOL1* variants change the C-terminal amino acid sequence and attenuate this interaction. Given this, we hypothesize that the structures of variant APOL1s are altered and disrupt protein interactions.

Methods: We modeled the 3D structure of the APOL1 C-terminus (residues 305-398) with the threading program ITASSER. We expressed the C-terminus of APOL1 with and without variants, (G0: reference, G1: S342G & I384M, and G2: del388-389NY) and used circular dichroism (CD) spectroscopy to experimentally verify the predicted secondary structure. Molecular Dynamics (MD) simulations assessed conformational behavior over time of G0, G1 and G2. PyMOL software modeled the APOL1:VAMP8 interaction.

Results: The computationally modeled structures of G0, G1, and G2 (residues 305-398) initially overlapped as three α-helices folded into a bundle, linked by short loops, and CD spectroscopy confirmed the predicted alpha helical content. APOL1-G0 adopted an "open" conformation in MD simulations (over 40 ns) while the G1 and G2 variants both remained in a "closed" conformation, assessed as Cα deviation from starting structure. Fluctuations of the Cas over the last 10 ns and principal component analysis of protein motion also demonstrated increased mobility of the G0 C-terminus compared to G1 and G2. *De novo* formation of intramolecular H-bonds mediated the structural stability of G1 and G2. The APOL1-G0:VAMP8 interaction is most stable with a 3:1 stoichiometry and does not involve the G1 and G2 residues.

Conclusions: APOL1-G0 adopts an "open" conformation but G1 and G2 both generate a "closed" C-terminal conformation, which limits protein interactions and explains attenuation of the APOL1:VAMP8 interaction. Kidney disease induced by G1 and G2 may result from protein conformational changes that limit interactions with SNARE proteins.

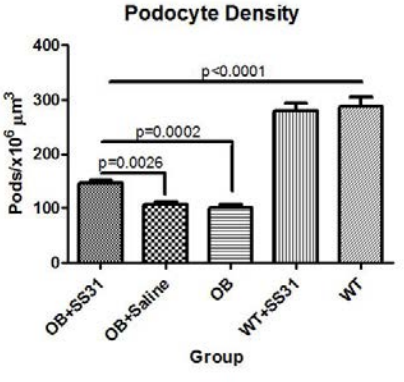
SS-31, a Peptide Targeting Mitochondria, Restores Podocytes in Diabetic Nephropathy (DN) in BTBR *ob/ob* Mice Minseob Eom,[1] Anna Batorsky,[1] Hazel H. Szeto,[2] Dao-fu Dai,[1] Kelly L. Hudkins,[1] Charles E. Alpers.[1] *[1]Pathology, Univ of Washington School of Medicine, Seattle, WA; [2]Pharmacology, Weill Cornell Medical College, New York, NY.*

Background: SS-31 is a novel peptide that selectively binds to cardiolipin in the inner mitochondrial membrane, where it prevents cardiolipin peroxidation and protects mitochondrial structure. We investigated the renoprotective effects of SS-31 in the BTBR *ob/ob* mice with advanced DN.

Methods: 18 week male diabetic BTBR *ob/ob* and wild type (WT) mice were randomly assigned to 5 groups:*ob/ob* with infusion of SS-31 via osmotic pump for 6 weeks, *ob/ob* with saline infusion, untreated *ob/ob*, WT, and WT with SS-31 infusion. Podocyte density, mesangial matrix (% tuft area occupied by collagen IV matrix), and glomerular macrophages were quantified by morphometry and immunohistochemistry.

Results: Podocyte density, diminished in *ob/ob* mice, was significantly restored in *ob/ob* with SS-31 infusion (147.2 ± 6.33 podocytes/$10^6\mu m^3$) compared with saline treated *ob/ob* mice (107.6 ± 4.78) or untreated mice (100.5 ± 6.14) (p=0.0026 & 0.0002).



Mesangial matrix was reduced in the *ob/ob* with SS-31 treatment (30.9 ± 0.61 %) compared to *ob/ob* with saline treated (45.2 ± 2.15) and untreated mice (46.5 ± 1.29) (p<0.0001). Macrophage infiltration was lower in *ob/ob* treated with SS-31 (1.3 ± 0.36 cells/glomerulus) than untreated *ob/ob* (1.9 ± 0.36) (p=0.02). Albumin-creatinine ratio was decreased in *ob/ob* with SS-31 (276.8 ± 60.14 mg/mg), compared with the untreated *ob/ob* (671.8 ± 250.60), but results were not statistically significant.

Conclusions: Podocyte density was restored and mesangial matrix decreased in SS-31 treated diabetic *ob/ob* mice, compared to saline treated and untreated controls. SS-31, currently in human clinical trials for other diseases, may be useful in treatment of DN and potentially other glomerular diseases in which podocytes are lost.

Genetic and Pharmaceutical Targeting of GSK3β in Podocytes Reinforces the Nrf2 Antioxidant Response and Ameliorates Podocytopathy and Proteinuria Sijie Zhou,[1] Yan Ge,[1] Zhangsuo Liu,[2] Rujun Gong.[1] *[1]Nephrology, Brown Medical School; [2]Nephrology, The First Affiliated Hospital of Zhengzhou Univ, China.*

Background: Evidence suggests that the GSK3β dictated Nrf2 nuclear exclusion and degradation is pivotal for switching off the self-protective antioxidant response following injury. This study aimed to examine the role of the GSK3β regulated Nrf2 antioxidant response in podocyte pathobiology.

Methods: The regulatory effect of GSK3β on Nrf2 response was examined in cultured podocytes and in a murine model of adriamycin nephropathy by genetic targeting of GSK3β or by using SB216763, a selective small molecule inhibitor of GSK3.

Results: In cultured podocytes, adriamycin injury caused cell death, concomitant with GSK3 hyperactivity and minimal Nrf2 activation. Inhibition of GSK3 by SB216763 exerted a prosurvival effect, which was dependent on the enhanced Nrf2 antioxidant response, marked by increased expression and nuclear accumulation of Nrf2 and elevated production of the Nrf2-target hemoxygenase-1. Ectopic expression of the kinase-dead mutant of GSK3β, the isoform of GSK3 predominantly expressed in glomerular podocytes, reinforced the Nrf2 antioxidant response upon adriamycin injury and prevented cellular death. Conversely, GSK3β overactivity induced by a constitutively active mutant resulted in a blunted Nrf2 response and exacerbated podocyte death following adriamycin injury, which could be abolished by SB216763. In adriamycin injured mice, genetic targeting of GSK3β by the doxycycline inducible podocyte specific knockout or pharmaceutical targeting by SB216763 attenuated albuminuria and ameliorated podocytopathic lesions, including glomerulosclerosis, loss of podocyte markers, *de novo* expression of podocyte injury marker desmin and ultrastructural changes of podocytes, like foot process effacement. This beneficial outcome was likely attributable to the enhanced Nrf2 response in podocytes, because trigonelline, a selective antagonist of Nrf2, largely abrogated the proteinuria reducing and podoprotective effect.

Conclusions: The GSK3β regulated Nrf2 antioxidant response might represent a novel therapeutic target to protect podocytes and treat proteinuric glomerulopathies.

Ablation of Podocyte-Derived Wnts Aggravates Proteinuria and Kidney Injury Dong Zhou,[1] Haiyan Fu,[1] Roderick J. Tan,[2] Youhua Liu.[1] *[1]Dept of Pathology, Univ of Pittsburgh, Pittsburgh, PA; [2]Dept of Medicine, Univ of Pittsburgh, Pittsburgh, PA.*

Background: Activation of canonical Wnt signaling has been implicated in podocyte injury and proteinuria. However, as Wnts are secreted extracellular signal proteins, whether podocyte-derived Wnts are obligatory for developing proteinuria remains elusive. Wntless (Wl), a cargo receptor protein, is required for the secretion of Wnt proteins.

Methods: We generated conditional knockout mice in which Wl was specifically deleted in podocytes by using the Cre-LoxP system. The mice were subjected to adriamycin administration, and urine and kidney were analyed at 7 days and 21 days, respectively. We utilized another proteinuric kidney disease model by chronic infusion of angiotensin II for 4 weeks.

Results: Mice with podocyte-specific ablation of Wl (podo-Wl-/-) developed normally. No albuminuria or overt pathologic lesions was observed up to 6 months of age, suggesting that Wl is dispensable for podocyte maturation, survival, and function under normal physiologic conditions. However, after adriamycin treatment for 7 days, podo-Wl-/- mice developed more severe podocyte injury and albuminuria than their control littermates. Surprisingly, ablation of Wl resulted in even more profound upregulation of β-catenin, accompanied by reduction and aberrant distribution of nephrin, Wilms tumor 1 (WT1), synaptopodin, and podocalyxin. In chronic injury induced by adriamycin or Ang II infusion, increased albuminuria, aggravated podocyte lesions and extracellular matrix deposition were evident in Podo-Wl-/- mice. Mechanistically, specific ablation of Wl in podocyte caused significant down-regulation of Dickkopf-3 expression. Meanwhile, NFAT1, a key downstream mediator in non-canonical Wnt signaling, was largely inhibited in Podo-Wl-/- mice after ADR injection.

Conclusions: These results indicate that podocyte-derived Wnts may play an important role in protecting podocytes from injury by repressing canonical Wnt/β-catenin signaling via promoting Dickkopf-3 expression and activating non-canonical pathway.

TH-OR090

Blockade of Wnt/β-Catenin Signaling Exhibits Superior Therapeutic Efficacy Than RAS Inhibition in CKD Zhen Li,[1] Lili Zhou,[1] Xue Hong,[1] Youhua Liu.[1,2] *[1]Div of Nephrology, Nanfang Hospital, Southern Medical Univ, Guangzhou, Guangdong, China; [2]Dept of Patholgy, Univ of Pittsburgh, Pittsburgh, PA.*

Background: CKD has become a public health problem worldwide. Treatment options for CKD are limited and ineffective, underscoring enormous unmet medical need. The mainstay of clinical therapy for CKD is inhibition of renin-angiotensin system (RAS), using angiotensin-converting enzyme inhibitor (ACEI) or angiotensin II type 1 receptor (AT1) blocker (ARB). However, current therapy with RAS inhibition is insufficient, partially because of compensatory upregulation of renin expression. Thus it is paramount to develop new therapeutic strategy with better outcomes.

Methods: Using two mouse models of CKD induced by adriamycin (ADR) or unilateral ischemic/reperfusion injury (UIRI), we directly compared the therapeutic efficacy of small-molecule Wnt/β-catenin inhibitor ICG-001 with trandolapril (ACEI) alone, or the combination of trandolapril and losartan (ARB). The effect of renin on fibroblast activation was also assessed in vitro.

Results: Compared to ACEI, or ACEI plus ARB, ICG-001 displayed superior therapeutic efficacy in both models. ICG-001 almost completely abolished proteinuria, ameliorated glomerular injury and fibrotic lesions and reduced serum creatinine in ADR nephropathy, whereas trandolapril, or trandolapril plus losartan only displayed as 50% efficacy as ICG-001. Similar results were obtained in UIRI model. We found that ICG-001 completely abolished renal expression of all RAS components including angiotensinogen, renin, ACE and AT1 in both models. However, trandolapril or trandolapril plus losartan actually induced angiotensinogen and renin expression in the kidneys. In vitro, incubation of kidney interstitial fibroblasts (NRK-49F) with renin protein induced fibronectin expression, and this effect was dependent on ERK-1/2 activation. Losartan did not block renin-induced fibronectin expression, suggesting that renin elicited its effect by an angiotensin II-independent mechanism.

Conclusions: Our studies demonstrate that blockade of Wnt/β-catenin, the master upstream regulator of all RAS genes, has superior therapeutic efficacy for the treatment of CKD than RAS inhibition.

TH-OR091

Distinct Populations of FOXD1-Derived Renal Interstitial Cells Regulate Erythropoietin Production Hanako Kobayashi, Volker H. Haase. *Medicine, Vanderbilt Univ, Nashville, TN.*

Background: In adults, the kidney is the main physiologic production site of erythropoietin (EPO), a hypoxia-inducible factor (HIF)-2-regulated hormone that is essential for normal erythropoiesis. However, renal EPO producing cells (REPCs) are poorly characterized and their histogenetic origin is ill-defined.

Methods: To investigate the hypoxic regulation of renal EPO, we targeted the EPO/HIF-2/prolyl-4-hydroxylase domain (PHD) oxygen-sensing pathway in renal interstitial cells using *Foxd1-Cre* transgenic mice and simultaneously labeled REPCs with green fluorescent protein (GFP). FOXD1 is expressed in embryonic stromal cells that give rise to renal pericytes and peritubular interstitial fibroblasts.

Results: In order to determine to what degree FOXD1-lineage cells contribute to EPO homeostasis, *Epo* or *Hif2a* were deleted (*Foxd1-Epo*$^{-/-}$ or *Foxd1-Hif2a*$^{-/-}$). As expected, *Foxd1-Epo*$^{-/-}$ and *Foxd1-Hif2a*$^{-/-}$ mice developed anemia. While pharmacologic PHD inhibition and hypoxia exposure (10% O_2 for 2 days) increased renal *Epo* mRNA and serum EPO (sEPO) levels in control mice, the renal EPO response was completely abrogated in both mutants, demonstrating that REPCs are exclusively derived from FOXD1-expressing stroma. To investigate the role of individual PHDs, we inactivated PHD1, PHD2 and/or PHD3 in FOXD1-lineage cells and used multi-color fluorescent *in situ* hybridization for a detailed characterization of the REPC pool. Deletion of PHD2 alone (*Foxd1-Phd2*$^{-/-}$), but not of PHD1 or PHD3, was sufficient to induce *Epo* in a subpopulation of GFP^{+} interstitial cells (0.8 ± 0.5% in control vs. 39.0 ± 5.5% in *Foxd1-Phd2*$^{-/-}$ mutants). However, EPO synthesis was induced in additional GFP^{+} *Phd2*$^{-/-}$ cells following hypoxia exposure or PHD3 deletion (73.0 ± 4.1% and 64.1 ± 8.4% respectively).

Conclusions: Our genetic studies demonstrate that REPCs consist of at least two distinct subpopulations, a) a PHD2-sensitive cell population and b) a subpopulation, in which in addition to PHD2 inactivation, hypoxia and/or PHD3 inactivation are required for EPO induction. In summary our data suggest that REPCs are entirely FOXD1 stroma-derived and are heterogeneous with regard to HIF-2-dependent oxygen sensing and their ability to synthesize EPO.

microRNA-21 in Human Glomerular Aging Christopher Lund O'Connor, Yifan Wu, Harkamal Singh Jhajj, Jeffrey B. Hodgin, Markus Bitzer. *Internal Medicine, Univ of Michigan, Ann Arbor, MI.*

Background: Loss of podocytes is sufficient to cause progressive glomerulosclerosis (the podocyte depletion hypothesis). We have recently shown that podocytes loss and glomerular hypertrophy are critical phenotypes of normal human aging (Hodgin, Bitzer, et al. JASN 2015) and that lack of miR-21 accelerates podocyte loss in murine models of glomerular injury. We now explore the role of miR-21 in aging of human and mouse glomeruli.

Methods: Kidney tissue samples were collected from 41 patients who underwent unilateral nephrectomy at the University of Michigan. 10 computer-assisted glomerular morphometric parameters were assessed in formalin fixed paraffin embedded sections by standard chemical and immunohistochemical stains. Gene expression profiles (Affymetrix human ST 2.1) and small RNA expression (Illumina tru-seq) were generated from RNA isolated from micro-dissected glomeruli and corresponding tubulointerstitium of the same individuals. Associations between gene expression and quantitative phenotypes were then determined. In addition miR-21 deficient mice and wild type littermates (C57BL/6J and DBA/2J; n≥6 for each genotype) were aged to in excess of two years and assessed for the same morphometric parameters.

Results: In human kidneys podocyte density declined with age and was significantly associated with increases in mesangial index (p=0.003), podocyte cytoplasmic size (p=<0.001) and focal global glomerulosclerosis (FGGS) (p=0.009). FGGS was significantly associated with interstitial fibrosis (p=0.006). miR-21 expression in glomeruli is positively correlated with podocyte density (p=0.041) and inversely correlated with mesangial index (p=0.02) and podocyte size (p=0.01). miR-21 expression increases with age in murine kidneys and miR-21-null mice exhibited decreased podocyte density (p=<0.001) and increased mesangial index (p=0.001) compared to wildtype littermates.

Conclusions: Both humans and mice experience an age-associated loss of loss of podocytes, and a concomitant increase in podocyte size and mesangial index. In mice miR-21 ameliorates phenotypes of glomerular aging. Candidate transcripts targeted by miR-21 that may mediate the observed phenotypes are being explored.

Murine Double Minute-2 Inhibition Ameliorates Established Crescentic Glomerulonephritis Dana Thomasova, Shrikant R. Mulay, Simone Romoli, Santhosh Kumar Vr, Jyaysi Desai, Hans J. Anders. *Nephrologisches Zentrum, Medizinische Klinik und Poliklinik IV, Klinikum der Univ München, Munich, Germany.*

Background: Rapidly progressive glomerulonephritis (RPGN) is characterized by glomerular necroinflammation and crescent formation. The E3-ubiquitin ligase murine double minute (MDM)-2 is a non-redundant element of NF-κB signalling and the negative regulator of p53-mediated cell cycle arrest. We hypothesized that the MDM2 would drive crescentic GN via NF-κB-dependent glomerular inflammation and via p53-dependent parietal epithelial cell (PEC) hyperproliferation.

Methods: We used injection of 75 µl of sheep anti-rat anti-GBM serum in C57BL/6 wild type and p53-deficient mice to induce crescentic GN and injection of MDM2 inhibitor nutlin-3a or vehicle every alternate day starting on day –1 for pre-emptive or day +1 for therapeutic intervention. Evaluation was performed 7 days after antiserum injection. For in vitro studies murine glomerular endothelial cells and PECs were transfected with MDM2 or p53 siRNA and anlysed with qPCR or proliferation assay.

Results: The pre-emptive MDM2 blockade with nutlin-3a ameliorated all aspects of crescentic GN such as vascular necrosis, podocyte loss, glomerular crescent formation, albuminuria, as well as inflammation, preventing cytokine induction, and recruitment of glomerular leukocytes and macrophages. MDM2 inhibition with nutlin-3a had identical protective effects in p53 knockout mice, with the exception of crescent formation. In vitro experiments confirmed the MDM2 requirement for induction of NFκB-dependent cytokines in murine glomerular endothelial cells as well as the p53-dependency of MDM2-mediated PEC proliferation. To evaluate MDM2 blockade as a therapeutic intervention in RPGN, we treated mice with established GN with nutlin-3a. Delayed onset of nutlin-3a treatment was equally protective as the pre-emptive treatment in abrogating crescentic GN.

Conclusions: The pathogenic effects of MDM2 are mostly p53-independent, associated with NFκB activation and increased intraglomerular inflammation, but the p53-dependent function of MDM2 regulates the PEC proliferation and crescent formation.We therefore propose MDM2 blockade as a potential novel therapy in RPGN.

The Bone Marrow Initiates and Propagates suPAR-Mediated Kidney Disease Eunsil Hahm,[1] Changli Wei,[1] Isabel Fernandez,[1] Jing Li,[1] Nicholas J. Tardi,[1] Shikha Wadhwani,[1] Vineet Gupta,[1] Sanja Sever,[2] Jochen Reiser.[1] *[1]Dept of Internal Medicine, Rush Univ Medical Center, Chicago, IL; [2]Div of Nephrology, Massachusetts General Hospital, Charlestown, MA.*

Background: Proteinuria is a hallmark of glomerular kidney dysfunction, seen in both, native and post-transplant focal segmental glomerulosclerosis (FSGS). Systemic soluble urokinase plasminogen activator receptor (suPAR) is implicated in FSGS, yet the origin of suPAR in FSGS remains unclear.

Methods: Humanization techniques, adoptive transfer, cell depletion, ELISA, flow cytometry, histology, and electron microscopy were performed.

Results: Here we report that bone marrow (BM) myeloid progenitor cells (MPCs) are responsible for the production of suPAR, resulting in kidney damage and proteinuria. Using a xenograft mouse model, we found that engraftment of CD34^{+} peripheral blood mononuclear cells (PBMCs), but not CD34^{-} PBMCs, from patients with recurrent FSGS into immunocompromised mice resulted in an expansion of Gr-1^{lo} murine BM myeloid cells, leading to proteinuria and FSGS-like glomerulopathy. Furthermore, adoptive transfer experiments demonstrated that Gr-1^{lo} BM myeloid cells are capable of causing suPAR-mediated proteinuria and therefore transmitting disease in healthy mice. We immunophenotypically characterized uPAR^{+}Sca-1^{+}Gr-1^{lo} cells as "diseased" BM myeloid progenitor cells (MPCs), which are responsible for the production of suPAR competent to investigate kidney damage and proteinuria.

Conclusions: Collectively, these results reveal a novel connection between bone marrow and kidney, and implicate myeloid progenitor cells as initiators of glomerular dysfunction with particular relevance to post-transplant FSGS.

C-Reactive Protein and Myeloid Derived Suppressor Cells in Acute Kidney Injury

Alexander J. Szalai, Melissa A. Pegues. *Dept of Medicine, The Univ of Alabama at Birmingham, Birmingham, AL.*

Background: Myeloid derived suppressor cells (MDSCs) are best known for their anti-proliferative effects on immune cells. Their contribution in renal cell carcinoma and chronic kidney disease has been investigated and their association with kidney transplant survival documented, but their role in acute kidney injury (AKI) has not been studied. Renal ischemia reperfusion injury (IRI) is a frequent cause of AKI: the former triggering a systemic inflammatory response that leads to increased blood levels of C-reactive protein (CRP), a biomarker of worsened outcomes. Recently, using a CRP transgenic mouse (CRPtg) model of renal IRI, we provided direct evidence that CRP is causal in AKI, i.e. its expression exacerbates renal IRI. The purpose of the present study was to determine if this harmful effect of CRP was propelled by increased infiltration of inflammatory cells into the injured kidneys.

Methods: We compared myeloid cell populations in the kidneys of wild type (WT), human CRP transgenic (CRPtg), and CRP deficient ($CRP^{-/-}$) mice subjected to bilateral renal IRI.

Results: In $CRP^{-/-}$, which were nearly refractory to renal IRI, there was almost complete absence of MDSCs of the granulocytic subtype (g-MDSC; $Gr\text{-}1^{+}CD11b^{+}Ly6g^{high}Ly6c^{low}$ cells identified by flow cytometry of kidney digest cells) in the injured kidneys. In stark contrast in CRPtg, wherein renal IRI was exaggerated, there was an abundance of g-MDSCs in the injured kidneys. Using *in vitro* T-cell proliferation assays we confirmed that these renal g-MDSCs were suppressive and *in vivo* in CRPtg, depletion of g-MDSCs prior to renal IRI (using anti-Gr-1 antibody) reduced serum/urine biomarkers of AKI. Importantly, CRPtg treated with an antisense oligonucleotide that specifically lowered human CRP levels, showed both dramatic improvement in renal biomarkers of AKI and dramatic reduction in renal infiltration of g-MDSCs after AKI.

Conclusions: To our knowledge these are the first data showing that (i) g-MDSCs contribute to the renal response to IRI and that (ii) CRP amplifies this contribution. By reducing g-MDSC infiltration into the injured kidney, CRP lowering therapy might be an effective treatment option for AKI.

C-Reactive Protein Promotes AKI by Impairing TEC Regeneration via the CD32-Smad3-P27 Dependent Inhibition of CKD2/Cyclin E Mechanism

Xiao Ru Huang,[1] Weiyan Lai,[2] Ying Tang,[3] Tan-qi Lou,[2] Hui Y. Lan.[1] *[1]Dept of Medicine & Therapeutics, Li Ka Shing Inst of Health Sciences, and Shenzhen Research Inst, The Chinese Univ of Hong Kong, Hong Kong, China; [2]Dept of Nephrology, The Third affiliated Hospital of Sun Yat-Sen Univ, Guangzhou, China; [3]Dept of Nephrology, Sun Yat-Sen Memorial Hospital of Sun Yat-Sen Univ, Guangzhou, China.*

Background: We have previous shown that C-reactive protein (CRP) plays a pathogenic role in acute kidney injury (AKI) by inhibiting tubular epithelial cell (TEC) regeneration. The present study tested a hypothesis that CRP may promote AKI via Smad3-p27 dependent inhibition of CKD2/cylin E-mediated TEC regeneration in vivo and in vitro.

Methods: The hypothesis was examined in a mouse model of AKI induced in human CRP transgenic/Smad3 knockout (CRP-Tg/Smad3-KO), CRP-Tg/Smad3-WT, CRP-WT/Smad3-KO, and CRP-WT/Smad3-WT mice by clamping bilateral renal arteries for 40 minutes and in cultured HK-2 TEC line.

Results: After 24 hours of AKI, CRP-WT/Smad3-WT showed a significant increase in serum levels of creatinine and severe tubular necrosis, which was further enhanced in CRP-Tg/Smad3-WT mice but blunted in CRP-Tg/Smad3-KO and CRP-WT/Smad3-KO mice. Further studies revealed that enhanced AKI in CRP-Tg/Smad3-WT mice was associated with a marked activation of TGF-b/Smad3, upregulation of p27, and inactivation of CKD2 kinase, thereby reducing cyclin E expression and impairing TEC proliferation as determined by BrdU incorporation and PCNA. In contrast, deletion of Smad3 in CRP-Tg mice prevented the development of AKI as demonstrated by normalizing serum levels of creatinine and suppressing the Smad3-p27 pathway, thereby promoting CKD2/cyclin E-dependent TEC proliferation. In vitro studies confirmed these findings that CRP acted through its receptor CD32b to activate Smad3 signaling via both TGF-b-dependent and ERK/MAPK crosstalk pathway. Furthermore, we also found that activated Smad3 then bound directly to p27 to suppress CKD2/cyclin E-dependent TEC proliferation, which was inhibited by a Smad3 inhibitor (SIS3).

Conclusions: CRP promotes AKI by impairing the TEC regeneration via the CD32-Smad3-p27 mediated inhibition of CKD2/cyclin E mechanism.

Peptidyl Arginine Deiminase-4 Exacerbates Ischemic Acute Kidney Injury by Finding NEMO

May M. Rabadi, Mihwa Kim, Kevin M. Brown, H. Thomas Lee. *Anesthesiology, Columbia Univ, New York, NY.*

Background: Ischemic acute kidney injury (AKI) is a devastating clinical problem without effective therapy. We recently showed that peptidylarginine deiminase-4 (PAD4) that converts peptidylarginine to peptidylcitrulline plays a critical role in ischemic AKI by promoting renal tubular inflammation. We hypothesized that PAD4 induces renal inflammation and exacerbates AKI by citrullinating IKKγ (also known as NFkB Essential MOdulator or NEMO) and promoting renal tubular pro-inflammatory NFkB signaling. Furthermore, we tested whether targeted NEMO inhibition attenuates renal inflammation and protects against ischemic AKI.

Methods: We first tested whether recombinant human PAD4 (1-10 mg/ml) directly citrullinates human recombinant NEMO or NEMO in human proximal tubule (HK-2) cells. We also tested whether NEMO neutralization with NEMO binding peptide (NBP, 10 μM) attenuates rPAD4-mediated nuclear NFkB translocation and induction of pro-inflammatory mRNAs in HK-2 cells. Finally, after Columbia IACUC approval, we tested whether NEMO neutralization (5 mg/kg) in mice attenuates rPAD4-mediated exacerbation of 20 min ischemic AKI and renal inflammation.

Results: rPAD4 directly citrullinated NEMO in a cell free system as well as in HK-2 cells. In addition, rPAD4 directly caused nuclear NFkB-p65 subunit translocation which was attenuated by NEMO neutralization. Furthermore, NEMO neutralization significantly attenuated rPAD4-mediated induction of pro-inflammatory genes (MCP-1 by 59±11%, MIP-2 by 43±10%, TNF-α by 59±12% and IL-8 by 83±3%) in HK-2 cells ($P<0.05$, N=5-8). Finally, NEMO neutralization significantly attenuated rPAD4-mediated exacerbation of ischemic AKI (rPAD+veh Cr(mg/dL)=2.4±0.4 vs. rPAD+NBP Cr=1.2±0.1, N=6, $P<0.01$) and renal inflammation (assessed with pro-inflammatory gene expression, neutrophil infiltration) in mice.

Conclusions: Our studies show that PAD4 exacerbates ischemic AKI and inflammation by promoting renal tubular NFkB activity via NEMO citrullination. Furthermore, we show that NEMO inhibition attenuates kidney injury and reduces the inflammatory response after renal IR injury. Selective NEMO neutralization may serve as a potential therapy for this devastating clinical problem.

Severity, Frequency and Prevalence of Proximal Tubule Injury Determines Renal Prognosis

Koji Takaori,[1] Jin Nakamura,[1] Tadashi Yamamoto,[2] Kumar Sharma,[3] Motoko Yanagita.[1] *[1]Nephrology, Kyoto Univ, Kyoto, Japan; [2]Structural Pathology, Niigata Univ, Niigata, Japan; [3]Center for Renal Translational Medicine and Inst of Metabolomic Medicine, Univ of California San Diego, Sandiego, CA.*

Background: Acute kidney injury (AKI) increases the risk to develop chronic kidney disease (CKD) and end-stage renal disease, whereas the mechanisms linking AKI to CKD remain unclear. Because proximal tubule injury is the mainstay of AKI, we postulated that proximal tubule injury triggers several features of CKD.

Methods: We generated a novel mouse model to induce selective proximal tubule-specific adjustable injury by inducing the expression of diphtheria toxin receptor (DTR) in proximal tubules with variable prevalence (*Ndrg1CreERT2:iDTR* mice). For in vitro analysis, we utilized co-culture of renal fibroblasts and tubular epithelial cells.

Results: Administration of high-dose diphtheria toxin (DT) faithfully causes severe proximal tubule-specific injury, associated with interstitial fibrosis and reduction of erythropoietin production. Mild proximal tubule injury from a single hit triggers reversible fibrosis, whereas repeated mild injuries cause sustained interstitial fibrosis, inflammation, glomerulosclerosis and atubular glomeruli. Fibroblasts co-cultured with damaged tubular cells exhibited the induction of extracellular matrix and inflammatory genes, supporting the crosstalk between these two cell types. Proximal tubule-specific injury also triggers distal tubule injury, implying the proximal-distal tubule crosstalk.

Conclusions: Our data provide new evidence that proximal tubule injury triggers several features of CKD, and that the severity, frequency and prevalence of proximal tubule injury determine the progression to CKD. Our results indicate that fibrosis after AKI is secondary to tubular injury, and that treatment of fibrosis itself might not be enough to halt AKI-to-CKD progression. There is an urgent need to develop therapeutic strategies to protect proximal tubules from repeated injury and to restore healthy proximal tubular function.

Proximal Tubule Necroptosis Is Mediated by Mixed Lineage Kinase Domain Like (MLKL) In Vivo and Ex Vivo Andreas Linkermann,[1] Nina Himmerkus,[2] Ina Maria Schiessl,[3] Hans J. Anders,[4] Joel M. Weinberg,[5] Alberto Ortiz,[6] James M. Murphy,[7] Ulrich Kunzendorf,[1] Jan H. Braesen,[8] Markus Bleich,[2] Stefan Krautwald.[1] *[1]Clinic for Nephrology and Hypertension, Univ of Kiel, Kiel, Germany; [2]Dept of Physiology, Univ of Kiel, Kiel, Germany; [3]Inst for Physiology, Univ of Regensburg, Regensburg, Germany; [4]Medizinische Klinik und Poliklinik IV, LMU Munich, Munich, Germany; [5]Dept of Internal Medicine, Univ of Michigan, Ann Arbor, MI; [6]Unidad de Dialisis, Fundacion Jimenez Diaz, Madrid, Spain; [7]Div of Cell Signalling and Death, Walter and Eliza Hall Insitute of Medical Research, Parkville, Australia; [8]Dept of Pathology, Unversity of Hanover, Hanover, Germany.*

Background: RIPK3-dependent necroptosis is of critical relevance for many diseases including hypoxic organ damage in AKI (Linkermann and Green, NEJM 2014). However, the putative downstream mediators, such as mixed lineage kinase domain like (MLKL) have not been investigated in detail, but may trigger local tissue Inflammation in a process referred to as necroinflammation (Linkermann et al, NRI 2014). Ferroptosis, an iron dependent cell death, is thought not to be affected by MLKL.

Methods: We employed video-monitoring of microperfused freshly isolated renal tubules, intravital microscopy, biochemistry, and diverse *in vivo* models of AKI and SIRS in wild type, MLKL-deficient- and RIPK3-deficient mice in the presence of newly developed necrostatins and ferrostatins.

Results: MLKL-deficient mice exhibit stronger protection against all investigated models of AKI in direct comparison to RIPK3-deficient mice. In SIRS models, RIPK3 and MLKL-ko mice are protected compared to wild type littermates, but there is no statistically significant difference between these two. In intravital microscopy, MLKL-ko, unlike RIPK3-ko, do not exhibit wider peritubular capillaries compared to wild type, but the perfusion is increased due to increased flow. In isolated renal tubules, erastin-induced synchronized renal tubular necrosis was significantly attenuated in MLKL-ko mice.

Conclusions: We identify MLKL as a master regulator of AKI and SIRS. In contrast to RIPK3, which exclusively functions in necroptosis, MLKL might affect ferroptosis.

TH-OR100

NMN, a NAD+ Precursor, Can Rescue the Age-Associated Susceptibility to Cisplatin Induced Acute Kidney Injury in a SIRT1-Dependent Manner Yi Guan, Chuanming Hao. *Dept of Nephrology, Huashan Hospital, Shanghai, China.*

Background: AKI is a common critical condition, the incidence of which increases with age. SIRT1, a NAD^+-dependent deacetylase, has been shown to have beneficial effect on both life span and renal health. NMN is a NAD^+ precursor involved in NAD^+ recycle and SIRT1 activity. This study explores the role of SIRT1 and NMN in age-associated AKI, and mechanism by which SIRT1 deficiency aggravates AKI.

Methods: Age-associated susceptibility to AKI was investigated using 3 month-old and 20 month-old 129 mice. The role of SIRT1 in AKI was examined using SIRT1 heterozygotes. AKI was induced by cisplatin(20mg/kg). Kidney damage was assessed by BUN, kidney histology and Tunel assay. Mitochondria was examined by electronic microscope. The signaling pathway involved was explored by microarray and validated by Q-PCR, western blot and co-IP.

Results: After exposed to cisplatin, the 20-month-old mice had a more severe acute kidney injury than 3-month-old. In the aged mice, the kidney NAD^+ level was only 30% of that in the young (5.9±2.5vs19.9±5.9 pmol/mg protein), accompanied by reduced SIRT1 expression. SIRT1 deficiency($SIRT1^{+/-}$) also significantly aggravated cisplatin-induced AKI compared to SIRT1 intact littermates. Severe mitochondrial dysfunction and cell damage was observed in proximal tubules of the AKI aged mice and SIRT1 knockouts. NMN, provided from the same day as cisplatin for 4days, markedly attenuated renal damage(BUN 78.31±18.16vs148.7±9.136, P<0.001). The effect of exogenous NMN was substantially reduced in SIRT1 deficient mice, suggesting that the protective effect of NMN was dependent on SIRT1 activity. Microarray suggests that JNK pathway is a critical signaling pathway associated with SIRT1 deficiency. Activation of JNK was validated by Q-PCR and Western blot. Co-IP experiment revealed DUSP16, a JNK dephosphorylase, might be regulated by SIRT1.

Conclusions: (1)In aged kidney, NAD^+ level and SIRT1 expression is reduced, resulting in increased age-associated susceptibility to AKI;(2)Supplementation of NMN, a NAD^+ precursor and a metabolite of a lipid lowering drug Niacin, rescued cisplatin-induced AKI;(3)JNK activation is associated with increased renal injury in SIRT1 deficient animals.

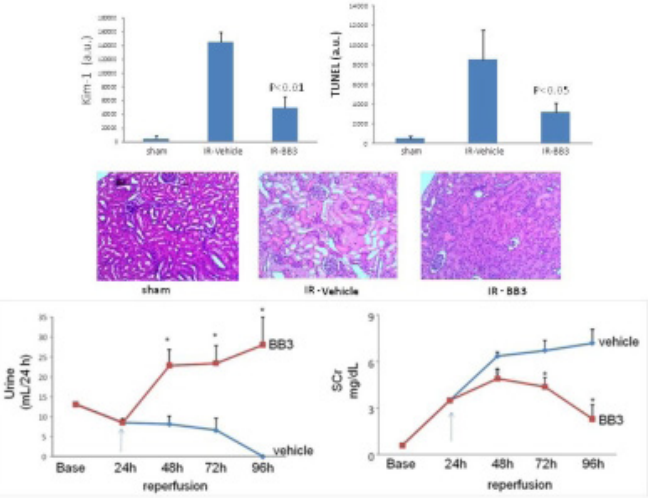
Therapeutic Effects of BB3, a Small Molecule Hepatocyte Growth Factor Mimetic, in Kidney Reperfusion Injury Prakash Narayan, Bin Duan, Xingxi Peng, Kai Jiang, Latha Paka, Michael A. Yamin, Itzhak D. Goldberg. *Angion Biomedica Corp.*

Background: Activation of the hepatocyte growth factor (HGF)/cMet pathway is therapeutic in ischemia-reperfusion (IR)-related acute kidney injury (AKI). However poor half-life makes clinical use of recombinant protein therapy in settings such as AKI or kidney transplantation (Tx) challenging. We investigated the effects of a unique and novel small molecule with HGF-like activities, BB3, in models of AKI and Tx. BB3 selectively phosphorylates cMet and triggers the HGF/cMet pathway in multiple *in vitro* assays.

Methods: IR: Adult male rats had 60 min normothermic renal artery occlusion. At reperfusion, the contralateral kidney was excised. BB3 (2 mg/kg) was administered QD starting at 24 hour into reperfusion. Tx: Kidneys from adult male Lewis rats were cold-preserved (~4°C) for 4 hr and transplanted into syngeneic recipients whose native kidneys were excised. BB3 (2.0 mg/kg, QD) was administered until sacrifice on Day 14.

Results: IR: Treatment with BB3, starting 24 hr after reperfusion, increased tubular cMet phosphorylation *in vivo* 3.5-fold (p<0.01). BB3 decreased tubular expression of kidney injury marker-1 (KIM-1), decreased tubular apoptosis, enhanced preservation of tubular integrity, improved urine output and reduced serum creatinine (figure1) Tx: BB3 improved recipient survival (60% vs 30% for control) and mitigated renal dysfunction (e.g., Day 7 SCr: 0.84 mg/dL vs 2.72 mg/dL for control; p<0.05).



Conclusions: Starting as late at 24 hour after AKI, activation of the HGF/cMet pathway with BB3 mitigates renal injury and improves renal function. These data together with the expanded window for therapeutic intervention support the use of BB3 in Angion's Phase 2 GUARD study in AKI patients and Phase 3 GIFT study in kidney Tx recipients presenting with delayed graft function. CRP Exacerbates Ischemia-Reperfusion Injury in the Kidney by Down-Regulating Autophagy Ao Bian,[1] Mingjun Shi,[1] Brianna Flores,[1] Nancy Gillings,[1] Orson W. Moe,[1,2,3] Ming Chang Hu.[1,2] *[1]Charles and Jane Center for Mineral Metabolism and Clinical Research, UT Southwestern Medical Center; [2]Dept of Internal Medicine, UT Southwestern Medical Center; [3]Physiology, UT Southwestern Medical Center, Dallas, TX.*

Background: C-reactive protein (CRP), an acute biomarker, was recently reported to be closely associated with poor renal function in patients with acute kidney injury (AKI), but its pathogenic role in ischemic kidney injury remains unclear.

Methods: To examine the *in vivo* effect of CRP on autophagy in AKI induced by renal ischemia-reperfusion injury (IRI), we mated transgenic CRP overexpressing mice (*CRP*) with a autophagy reporter mouse (*LC-3-GFP*) to generate the combination mouse line (*CRP;LC-3-GFP*). *In vivo*: Mice were studied 2 days after IRI. *Ex vivo*: Renal tubules were isolated from *LC-3-GFP* mice at baseline for primary culture. *In vitro*: OK cells transfected with LC-3-GFP were used. The *ex vivo* and *in vitro* studies complement the *in vivo* study to define the direct effect of CRP on the kidney.

Results: Compared with *LC-3-GFP* mice, *CRP;LC-3-GFP* mice had higher serum creatinine (P<0.05), more tubular necrosis, and higher NGAL expression in the kidney after IRI. CRP addition exacerbated H_2O_2-increased LDH release from both primary cultured renal tubules and OK cells (P<0.01 respectively). Immunoblots showed lower LC-3 II/I ratio and higher p62, markers of autophagic flux, in the kidneys of *CRP;LC-3-GFP* compared to *LC-3-GFP* mice after IRI, and in primary culture of renal tubules and OK cells treated with CRP + H_2O_2 compared to H_2O_2 alone. Immunohistochemistry showed much fewer LC-3-GFP puncta in kidneys of *CRP;LC3-GFP* compared to *LC-3-GFP* mice after IRI. Similarly, CRP addition reduced LC-3-GFP puncta induced by H_2O_2 in primary cultured renal tubules and in OK cells transfected with LC-3-GFP plasmid. Autophagy inducers (rapamycin and LiCl) rescued the impaired autophagy and blunted the LDH release from OK cells treated with CRP + H_2O_2 (P<0.05).

Conclusions: CRP renders the kidney more susceptible to ischemic/oxidative injury by down-regulation of autophagy flux. Autophagy inducer repairs down-regulated autophagy triggered by CRP and protects the kidney against ischemia reperfusion injury.

TH-OR103

Signal Inhibitory Regulatory Protein-α Regulates Pathologic Reactive Oxygen Species Generation in Acute Kidney injury Natasha M. Rogers,[1,2] Daniel N. Meijles,[1] Patrick J. Pagano,[1] Jeffrey S. Isenberg.[1] *[1]Vascular Medicine Inst, Univ of Pittsburgh, Pittsburgh, PA; [2]Starzl Transplant Inst, Univ of Pittsburgh, Pittsburgh, PA.*

Background: Ischemia reperfusion injury (IRI) is a major cause of acute kidney injury mediated by oxidative stress. We recently reported that signal regulatory inhibitory protein (SIRP)-α is expressed by renal tubular epithelial cells (TEC), that the protein thrombospondin-1 (TSP1) is increased following renal IRI, and TSP1 binds to SIRPα. However, it is unclear how TSP1-SIRPα signaling contributes to IRI pathophysiology.

Methods: Wild-type (WT) mice, and SIRPα mutant ($SIRPa^{mut}$) mice lacking cytoplasmic recruitment domains, underwent bilateral renal IRI followed by assessment of renal function and biomolecular analysis after 24 h reperfusion. Murine WT and $SIRPa^{mut}$ TEC were studied *in vitro*. Mice were also irradiated and rescued with WT or $SIRPa^{mut}$ bone marrow.

Results: IRI resulted in elevated serum creatinine in WT mice which was mitigated in $SIRPa^{mut}$ animals (2.3±0.5 *versus* 0.98±0.4 mg/dl, $p<0.01$). Changes in renal function reflected improvements in renal histology, including tubular necrosis and inflammatory infiltrate. TSP1 was expressed to a similar degree in all mice post-IRI. Measurement of reactive oxygen species (ROS) in kidney demonstrated a 3-fold increase in superoxide in WT mice post-IRI ($p<0.001$) but no increase in $SIRPa^{mut}$mice when compared to sham. Expression of 3-nitrotyrosine protein modification was reduced in $SIRPa^{mut}$ compared to WT mice, although total renal expression of NADPH oxidase 1 and 2 were unchanged. *In vitro*, WT TEC displayed upregulation of ROS in response to TSP1 ($p<0.01$), which was not reflected in $SIRPa^{mut}$ cells. SIRPα is expressed by all renal cells, and chimeric mice were generated to explore differences in cell compartment contribution to IRI. $SIRPa^{mut}$ mice, regardless of hematopoietic reconstitution, were fully protected against renal dysfunction, tubular damage and ROS generation following IRI.

Conclusions: These data provide evidence for a role for SIRPα promoting renal IRI through generation of pathologic ROS, and blockade of SIRPα may provide a therapeutic target to modify IR-mediated damage.

"Urine Sediment" the Ignored Treasure Chest in the Search for Biomarkers in Acute Kidney Injury Nithin Karakala,[1] Juan Carlos Q. Velez,[1] Michael G. Janech,[1] Joseph Alge,[1] John M. Arthur.[2] *[1]Div.of Nephrology, MUSC, Charleston, SC; [2]Div Nephrology, UAMS, Little Rock, AR.*

Background: In the last decade novel urine biomarkers have been identified in urine supernatant. Urine sediment is extensively used in clinical practice for microscopy but has not been used for AKI biomarker discovery. We examined whether urine sediment from can be used to identify biomarkers and determine the proportion of sediment proteins that originate from brush border (BB), and mitochondria (MX).

Methods: Urine samples from patients admitted to the medical ICU at the Medical University of South Carolina were collected from 8 patients (4 without AKI and 4 with AKIN stage 3 AKI at the time of collection). The urine was centrifuged to separate sediment from supernatant. We performed liquid chromatography, tandem mass spectrometry (LC MS/MS) on each sediment and supernatant sample. We estimated the relative abundance of brush border, and mitochondrial proteins using Exponentially Modified Protein Abundance Index (emPAI). Database of BB, and MX proteins were used to identify BB and MX proteins from our experiment. The molar fraction of each protein in the sample relative to the total moles of all proteins in the sample was calculated for each protein. We used this to determine the percent of moles of protein for BB, and MX proteins in the sediment.

Results: We identified 479 proteins in sediment (396 from the AKI 3 and 430 in No AKI). We identified 556 proteins from the no AKI samples, 239 proteins were present only in the sediment and 126 were identified only in the supernatant. In AKI 3 samples we identified 570 proteins, 169 proteins were unique to the sediment and 174 to the supernatant. The molar abundance percentage of BB proteins in the AKI 3 sediment and no AKI 3 sediment was 3.7 and 27.6% and MX proteins was 2.7 and 14.6% respectively.

Conclusions: We have developed an LC MS/MS technique for proteomic analysis of urine sediment. Urine sediment from no AKI and AKI 3 have proteins that are not found in supernatant. These proteins are potential biomarkers. As a percent of the molar amount of protein BB and MX is markedly less in AKI sediment. This finding has implication for the pathophysiology of shedding of renal tubular material in AKI.

TH-OR105

FGF23 Drives Progression of Chronic Kidney Disease in Mice Olena Andrukhova,[1] Svetlana Slavic,[1] Sathish Kumar Murali,[1] William G. Richards,[2] Reinhold Erben.[1] *[1]Dept of Biomedical Sciences, Univ of Veterinary Medicine, Vienna, Austria; [2]Dept of Metabolic Disorders, Amgen Thousand Oaks, Thousand Oaks, CA.*

Background: Circulating fibroblast growth factor 23 (FGF23) is associated with disease progression in patients with chronic kidney disease (CKD).

Methods: Here, we elucidate the role of Fgf23 and its co-receptor Klotho in pathogenesis of CKD in mice by a dual approach, using genetic loss-of-function together with pharmacological inhibition models. CKD was induced by 5/6 nephrectomy in 3-month-old wild-type (WT) mice, vitamin D receptor (VDR) mutant mice, $Fgf23^{-/-}$/$VDR^{\Delta/\Delta}$, and $Klotho^{-/-}$/$VDR^{\Delta/\Delta}$ compound mutant mice. All mice were kept on a rescue diet to prevent secondary hyperparathyroidism in VDR mutant mice. Sham-operated (SHAM) mice served as controls. In addition, SHAM and CKD WT, VDR, and Klotho/VDR mice were treated with low dose anti-FGF23 antibody (anti-FGF23Ab, 50 µg/mouse, 2 times/week) over 8 weeks.

Results: Genetic ablation of Fgf23 in Fgf23/VDR compound mutant or treatment of WT and VDR CKD mice with anti-FGF23Ab partially or completely protected against the CKD-induced weight loss, increase in mortality, reduction in glomerular filtration rate, albuminuria, volume expansion, hypernatremia, hypercalcemia, hypertension, and left ventricular functional impairment observed in untreated and vehicle-treated WT and VDR mice. Anti-FGF23Ab treatment of Klotho/VDR CKD mice, which were characterized by the highest circulating Fgf23 concentrations among all CKD groups, reduced mortality and slowed disease progression in these mice to levels found in Fgf23/VDR mutants, demonstrating that Fgf23 also has Klotho independent effects at high circulating levels. Genetic or pharmacological ablation of Fgf23 prevented hypercalcemia and volume overload in CKD mice by down-regulating renal sodium-transporting molecules, and increasing urinary excretion of sodium and calcium.

Conclusions: Collectively, our data suggest that elevated Fgf23 contributes to the pathogenesis of CKD in a vitamin D hormone- and partially Klotho-independent manner. Hence, our study may provide a mechanistic explanation for the association between circulating FGF23 and disease progression in CKD patients.

In Vivo Role of Klotho in the Renal Proximal Tubules Noriko Ide,[1] Hannes Olauson,[3] Tadatoshi Sato,[1] Junichi Hanai,[2] Tobias E. Larsson,[3] Beate Lanske.[1] *[1]Dept of Oral Medicine, Infection, and Immunity, Harvard School of Dental Medicine, Boston, MA; [2]Dept of Medicine, Div of Nephrology, Interdisciplinary Medicine and Biotechnology, Medicine, Boston, MA; [3]Div of Renal Medicine, CLINTEC, Karolinska Inst, Stockholm, Sweden.*

Background: Klotho is predominantly expressed in the distal tubules, but also in proximal tubules to regulate calcium and phosphate reabsorption, respectively. Global and total-nephron specific Klotho deletion both cause mineral disorder and premature aging. Klotho ablation from only distal tubules resulted in a mild phenotype indicating a key role for Klotho in proximal tubules.

Methods: No single Cre strain provided effective Klotho deletion in all proximal tubular segments. Therefore, three proximal tubule-specific Klotho knock-out mouse models were generated and compared by crossing PEPCK (phosphoenolpyruvate carboxykinase)-, KAP (Kidney androgen-regulated protein)-, or SLC34a1 (sodium phosphate cotransporter-2a1)-cre with $Klotho^{fl/fl}$(KL) mice.

Results: Klotho deletion was confirmed by qPCR, Western, and IHC. FGF23-Klotho signaling regulates phosphate homeostasis, so mineral parameters and regulatory factors were measured. In PEPCK-KL and SLC34a1-KL mice, urine phosphate excretion significantly decreased. This was not clearly detected in KAP-KL mice, despite increased renal NaPi2a mRNA and protein levels. Challenge of KL-KAP mice with high phosphate diet resulted in a significant decrease of urine phosphate excretion compared with WT. Serum phosphate level remained normal in all mouse lines. In summary, Klotho deletion in renal proximal tubules leads to a slightly decreased phosphate excretion with no changes in serum phosphate levels.

Conclusions: We demonstrate a role for Klotho in renal proximal tubules. Importantly, while global and total-nephron deletion of Klotho result in a severe phenotype, deletion in either distal or proximal renal tubules alone results in only minor changes in mineral homeostasis. This suggests a more integrated and organized cooperation between these two loci. These results are the first to show an interdependent relationship of Klotho in the distal and proximal tubules.

TH-OR107

The Increased Bone Fibroblast Growth Factor 23 Expression Is Mediated by the Fibroblast Growth Factor Receptor in Experimental Uremia Ronen Levi, Alia Hassan, Karina Durlacher, Justin Silver, Tally Naveh-Many. *Minerva Center for Calcium and Bone Metabolism, Nephrology, Hadassah Hebrew Univ Medical Center, Jerusalem, Israel.*

Background: Serum FGF23 is markedly elevated in CKD and has been associated with poor long-term outcomes. FGF23 expression is increased by activation of the FGF receptor 1 (FGFR1) in rats with normal renal function and in vitro in UMR106 osteoblast-like cells. We now demonstrate a role for FGFR in the regulation of FGF23 in a mouse model of acute kidney injury (AKI) due to high dose folic acid (FA), in rats with adenine high phosphorus induced CKD and in UMR106 osteoblast like cells.

Methods: Mice were injected with 250 mg/kg folic acid ip to induce AKI and sacrificed at 3 and 6 h. The FGFR inhibitor PD173074 was given to the mice 1 h before FA. Rats were fed an adenine high phosphorus diet for 14 d and PD173074 given for the last 2 d of the diet. Serum biochemistry, FGF23 and PTH levels were analyzed and calvaria FGF23 mRNA measured by qRT-PCR. FGF2 and PD173074 were added to UMR106 cells for 24 and 48 h and FGF23 mRNA levels measured.

Results: FA increased serum BUN and phosphate levels as expected from 3 h. Calvaria FGF23 mRNA and serum FGF23 levels were increased 2-3-fold at 6 h. PTH levels increased 6-fold from 3 h after FA. The FGFR inhibitor PD173074 prevented the FA induced increase in both FGF23 mRNA and serum levels but had no effect on serum PTH levels. A more prolonged uremia due to an adenine high phosphorus diet for 14 d resulted in high levels of serum PTH (30-fold increase) and FGF23 (3.5-fold increase). PD173074 decreased

serum FGF23 and mRNA levels with no effect on PTH in the adenine high phosphorus induced uremic rats. Addition of FGF2 to UMR106 cells increased FGF23 expression that was also prevented by PD173074.

Conclusions: A derangement in FGF-23 regulation starts early in the course of AKI, is in part independent of the increase in serum PTH and involves activation of FGFR. This is the first demonstration that activation of FGFR is important to the high levels of FGF23 in both acute and chronic experimental uremia. FGFR in the osteocyte may be activated by locally produced canonical FGFs such as FGF2.

TH-OR108

Acute and Chronic Inflammation Raises the Blood Levels of FGF23 in Normal Mice Shweta Bansal,[1,2] William E. Friedrichs,[1] Chakradhar Velagapudi,[1] Sherry L. Werner,[1,2] Paolo Fanti.[1,2] *[1]Medicine/Renal, Univ of Texas Health Sciences Center at San Antonio, San Antonio, TX; [2]Renal Section, South Texas Veterans Healthcare System, San Antonio, TX.*

Background: High levels of FGF23 are not fully explained by abnormal mineral metabolism in CKD. We and others found association of FGF23 with inflammation in CKD patients, but knowledge about the role of inflammation in FGF23 regulation is limited.

Methods: Inflammation was induced in FBV mice as follows (n=5 each Gr): **Gr1-acute inflammation**: single IP injection of 3.3 µg/kg of LPS (E.Coli 0111:B4) or vehicle control (Vh); **Gr2-chronic pulsatile inflammation**: daily IP injections of 3.3 µg/kg of LPS x 2 weeks; **Gr3-chronic persistent inflammation**: SQ insertion of pellets releasing 2 mg/kg/day of LPS plus Vh daily injection x 2 weeks; and **Gr4-acute on chronic inflammation**: SQ LPS pellets x 2 weeks and single IP LPS injection before sacrifice. Plasma FGF23 (c-term) and TNFα levels and spleen weight measured at sacrifice.

Results: In **Gr1,** FGF23 levels were 0.5±0.1 ng/ml 5 hours after LPS injection vs. 0.2±0.04 ng/ml in Vh (p=0.001). In **Gr2**, FGF23 was 0.2±0.02 ng/ml after 2-week daily LPS injections vs. 0.14±0.04 in Vh (p=0.02). In **Gr3,** FGF23 was 0.8±0.6 after 2-weeks LPS pellet vs. 0.14±0.04 ng/ml in Vh (p=0.04). In **Gr4**, FGF23 was the highest i.e.,1.3±0.7 after 2-week LPS pellets and single LPS injection, vs. 0.14±0.04 in Vh (p=0.006). TNFα levels rose significantly in Gr3 and Gr4 vs. Vh (respectively 11±0.8, 14±0.8, and 8.0±0.8 pg/ml). Spleen weights were significantly higher in Gr3 and Gr4 as further indication of presence of inflammation. Summary: Both acute and chronic exposure to LPS caused inflammation and stimulated the synthesis of FGF23. The effects of acute and chronic LPS exposure seemed to be synergistic.

Conclusions: Inflammation raises the FGF23 levels in FVB mice. The inflammation experienced by the Gr4 mice mimics events in CKD, where low-grade chronic inflammation is often aggravated by sporadic acute inflammation, e.g., caused by infections or translocation of inflammatory agents across the gut barrier. More studies are needed to delineate the role of inflammation in the regulation of FGF23 in the context of CKD.

FGF23 Directly Targets Hepatocytes to Promote Inflammation in CKD Saurav Singh,[1] Alexander Grabner,[1] Karla J. Schramm,[1] Christopher Yanucil,[1] Alexis J. Sloan,[1] Ansel P. Amaral,[1,2] Myles S. Wolf,[2] Christian Faul.[1] *[1]Dept of Medicine, Univ of Miami Miller School of Medicine, Miami, FL; [2]Dept of Medicine, Northwestern Univ Feinberg School of Medicine, Chicago, IL.*

Background: Chronic inflammation is a hallmark of chronic kidney disease (CKD), and biomarkers of inflammation are strong predictors of poor clinical outcome. The molecular mechanisms underlying the interrelationship between deterioration of renal function and amplification of the inflammatory state are unknown. CKD patients develop marked elevations in circulating levels of the phosphorus-regulating hormone, fibroblast growth factor (FGF) 23. Our recent data indicates that FGF23 directly induces cardiac injury by activating FGF receptor (FGFR) 4 in cardiac myocytes, independent of α-klotho. Since hepatocytes express high levels of FGFR4, we postulate that FGF23 can directly target the liver.

Methods: Using HepG2 cells, a hepatocellular carcinoma cell line, and primary mouse hepatocytes, we analyzed signal transduction and expression of inflammatory cytokines, including C-reactive protein (CRP) and interleukin-6 (IL-6) upon FGF23 treatment. FGF23 was injected intravenously into wild-type mice for 5 days, and FGFR4 knockout mice were fed a 2% phosphorus diet for 12 weeks. 5/6 nephrectomized rats were administered with an FGFR4-specific blocking antibody.

Results: FGF23 induces expression of inflammatory cytokines in hepatocytes by activating calcineurin/NFAT signaling in an FGFR4-dependent and α-klotho-independent manner. Elevation of serum FGF23 in wild-type mice via injections of recombinant FGF23 or administration of a high phosphate diet increases CRP levels in liver and blood. High phosphate diet does not elevate CRP expression in FGFR4 knockout mice. Pharmacological FGFR4 blockade reduces the expression of CRP in rats with CKD.

Conclusions: We provide a causative link between FGF23 elevations and the induction of an inflammatory response in the liver, and suggest a novel mechanism to explain the development of chronic inflammation in patients with CKD. Pharmacologic FGFR4 blockade might have anti-inflammatory effects in CKD.

TH-OR110

Differential Effects of Calcitriol on FGF23/Klotho System and LVH in Experimental Uremia Maren Leifheit-Nestler,[1] Laura Hermann,[1] Dagmar-Christiane Fischer,[2] Dieter Haffner.[1] *[1]Dept of Pediatric Kidney, Liver and Metabolic Diseases, Hannover Medical School, Hannover, Germany; [2]Dept of Pediatrics, Univ Hospital Rostock, Rostock, Germany.*

Background: Vitamin D (vitD) deficiency and excess of circulating FGF23 are significant contributors to cardiovascular (CV) mortality in CKD patients. *In vivo*, vitD metabolites downregulate genes involved in the development of left ventricular hypetrophy (LVH). However, vitD is a known stimulator of FGF23 synthesis in the bone, and thus, may have paradoxical effects on the CV phenotype in CKD. Here, we investigated the effects of vitD on the FGF23 signaling cascade mediated LVH in experimental uremia.

Methods: 5/6 nephrectomized rats (Nx) were treated with vitD for 4 and 10 weeks, and compared with controls. Heart tissue was determined for gene/protein expression of the FGF23 signaling pathway, pathological cardiac remodeling, and LVH. Cardiomyocyte cross-sectional area was quantified by immunofluorescence microscopy. Renal Klotho expression was investigated by quantitative real-time PCR.

Results: Cardiac Fgf23 levels, *Fgfr1* and *Fgfr4* mRNA, and LVH were increased significantly in 5/6Nx rats compared with controls. The calcineurin-NFAT signaling pathway was activated in uremia demonstrated by enhanced calcineurin accompanied by a strong reduction of phosphorylated NFAT protein. Pro-hypertrophic genes were increased in myocardial tissue of 5/6Nx rats. In general, vitD treatment of 5/6Nx rats resulted in reduced cardiomyocyte cross-sectional area. Although, cardiac Fgf23 levels, and *Fgfr1* and *Fgfr4* mRNA were further stimulated by vitD, vitD treated 5/6Nx rats showed reduced activation of NFAT ameliorating cardiac remodeling processes and LVH. Interestingly, renal *Klotho* expression was markedly reduced in uremic animals, and almost normalized after vitD treatment.

Conclusions: Cardiac FGF23 levels are enhanced in experimental uremia, and associated with LVH. VitD enhances NFAT phosphorylation and thereby blocks pathological remodeling processes induced by FGF23. In addition, vitD restores renal *Klotho* expression, and consequently enhances soluble Klotho, which may further be cardioprotective via binding to and neutralizing FGF23 in the heart.

TH-OR111

FGFR4 Activation Is Sufficient to Induce LVH in Mice Alexander Grabner,[1] Karla J. Schramm,[1] Saurav Singh,[1] Christopher Yanucil,[1] Alexis J. Sloan,[1] Ansel P. Amaral,[1,2] Christian Faul.[1] *[1]Medicine, Univ of Miami Miller School of Medicine, Miami, FL; [2]Medicine, Northwestern Univ Feinberg School of Medicine, Chicago, IL.*

Background: Previously, we demonstrated that fibroblast growth factor (FGF) 23 is a causal factor in the pathogenesis of left ventricular hypertrophy (LVH). FGF23 directly targets cardiac myocytes via FGF receptors (FGFR) and activates calcineurin/NFAT signaling. Mammals express four FGFR isoforms (FGFR1-4). Using two loss-of-function approaches (delivery of a blocking antibody in a rat model of chronic kidney disease (CKD) and gene deletion in mice), we could show that FGFR4 is required for the development of LVH in rodents with high FGF23. To confirm this finding in a gain-of-function approach, we studied a genetic knock-in mouse model carrying a FGFR4 mutation (G385R) that causes constitutive and ligand-independent activation of FGFR4.

Methods: We studied 6 months old homozygous FGFR4-G385R knock-in mice and wild type littermates. LVH was assessed by echocardiography, H&E staining of cardiac cross sections, and cross sectional area of individual myocytes. We analyzed cardiac fibrosis by Picrosirius Red staining and qPCR. Activation of calcineurin/NFAT signaling in cardiac tissue was studied by qPCR and Western blot analysis, and serum levels of cleaved FGF23 were determined by ELISA.

Results: Compared to wild type littermates, FGFR4-G385R mice develop LVH as evident by significantly increased LV wall thickness, cross sectional myocyte area and ejection fraction. FGFR4-G385R hearts are not fibrotic, and show a significant elevation of NFAT target gene expression. Although serum FGF23 levels were increased in FGFR4-G385R mice, the elevation did not correlate with the cardiac phenotype.

Conclusions: Activation of FGFR4 per se is sufficient to induce LVH in mice independently of serum FGF23 levels. We postulate that FGFR4 is part of a novel pro-hypertrophic signaling pathway in the heart that could be activated in patients with cardiomyopathies. FGFR4 blockade might not only serve as a novel pharmacological intervention for LVH in CKD patients with elevated FGF23, but also in patients with primary cardiac disease and increased FGFR4 activity in the heart.

TH-OR112

Downregulation of Thrombomodulin Expression in Endothelial Cells by Fibroblast Growth Factor-23 and Klotho Kenji Tanaka,[1] Yoko Oyama,[2] Tancharoen Salunya.[3] *[1]Internal Medicine, Suiyukai, Kashihara, Nara, Japan; [2]Dept of Laboratory and Vascular Medicine, Kagoshima Univ Graduate School of Medical and Dental Sciences, Kagoshima, Japan; [3]Dept of Pharmacology, Faculty of Dentistry, Mahidol Univ, Bangkok, Thailand.*

Background: Chronic kidney disease (CKD) is regarded as a state of excessive fibroblast growth factor-23 (FGF-23) and a Klotho (KL) deficiency. Moreover, the increased mortality risk in CKD patients associated with cardiovascular disease and endothelial dysfunction. Increasing evidence demonstrates that thrombomodulin (TM)

plays an important role in endothelial barrier. The mechanism responsible for the linkage of FGF-23 underlying endothelial damage in these patients is unclear. Here we report a downregulation of membrane TM in human umbilical vein endothelial cells (HUVEC) after FGF-23/ KL stimulation.

Methods: HUVECs were cultured in endothelial basal medium with supplement. SDS-PAGE analysis was performed to confirm the dose dependent effect of FGF-23 on TM expression in HUVECs, and to confirm the effect of KL. Next, membrane TM expression was performed by flow cytometry to confirm the effect of FGF-23 in HUVEC cell surface. Finally, immunofluorescence (IF) staining for TM expression on HUVECs was performed. Cells were visualized by double staining for TM expression and nucleus.

Results: SDS-PAGE and flow cytometry analysis shows that TM expression was markedly decreased when HUVECs were stimulated with 10 ng/ml FGF-23/ KL whereas this effect was less pronounced upon 1 ng/ml FGF-23/ KL treatment and that KL stimulation for 12 and 16 hours induced TM production significantly as compared to the controls and FGF-23 and FGF-23/ Klotho -treated cells. IF staining shows that TM is expressed on the cell surface in control cells while this number was dramatically increased after KL stimulation and that TM expression was reduced after FGF-23 and FGF-23/ KL stimulation.

Conclusions: TM is constitutively expressed in HUVEC and is suppressed by FGF-23 and FGF-23/ KL dose-dependently. Our results imply that TM response by FGF-23/ KL is a possible mechanism that leads to vascular complications in CKD patients.

TH-OR113

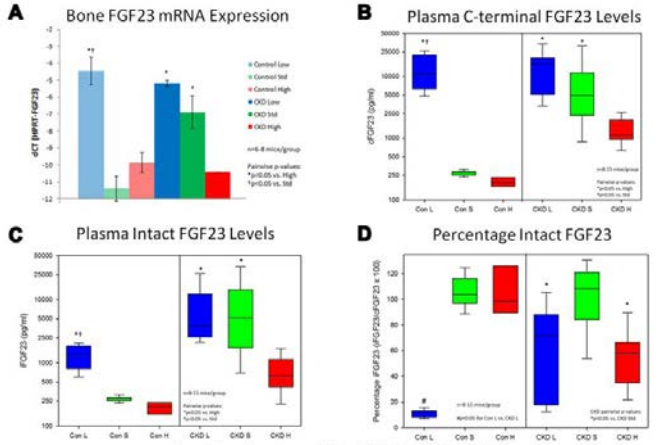
Iron Status Affects FGF23 Production and Metabolism in Mice with Chronic Kidney Disease Mark Hanudel,[1] Kristine Joy Chua,[2] Katherine Wesseling-Perry,[1] Elizabeta Nemeth,[2] Tomas Ganz,[2] Isidro B. Salusky.[1] *[1]Pediatrics, UCLA, Los Angeles, CA; [2]Center for Iron Disorders, UCLA, Los Angeles, CA.*

Background: Iron deficiency anemia and elevated FGF23 levels occur early in CKD. In mice with normal renal function, iron deficiency upregulates FGF23 expression, resulting in higher circulating FGF23 levels. However, the impact of iron status on FGF23 production and metabolism in CKD is unknown.

Methods: Wild type (WT) and hepcidin knockout (HKO) C57BL/6 mice were fed diets that did or did not contain adenine (which induces CKD), with low iron (4 ppm), standard iron (335 ppm), or high iron (10,000 ppm) concentrations. The standard iron diet was sufficient to iron load the HKO mice. Mice were on the diets for 8 weeks post-weaning, then sacrificed (n=8-15 mice/group). We measured plasma C-terminal FGF23 (cFGF23) and intact FGF23 (iFGF23); BUN, phosphorus, CBC; liver iron; and bone FGF23 mRNA expression. Multiple linear regression modeling was performed to assess the independent effects of iron and phosphorus on FGF23 in CKD.

Results: In both the Control and CKD cohorts, the low iron groups had the highest FGF23 mRNA expression and highest cFGF23 levels. Among the WT CKD mice, the high iron group had the lowest serum phosphorus levels, lowest cFGF23 levels, and a lower percentage iFGF23, possibly secondary to iron sufficiency and/or normophosphatemia. The HKO CKD standard iron group had higher liver iron content, lower FGF23 mRNA expression, and lower cFGF23 levels than the WT CKD standard iron group. In the CKD mice (n=57), serum phosphorus was independently associated with higher cFGF23 levels and higher percentage iFGF23; and liver iron was independently associated with lower cFGF23 levels and higher percentage iFGF23.

Conclusions: In mice with CKD, iron status affects FGF23 production and metabolism, independent of the effects of serum phosphorus.



Association of predictor variables with log cFGF23 in CKD mice:

Predictor Variable	Coefficient (95% CI)	p-value	Adjusted R^2	n
Standardized Serum Phosphorus	0.23 (0.10, 0.36)	0.001	0.29	57
Standardized Liver Iron	-0.17 (-0.30, -0.04)	0.013		

Association of predictor variables with percentage intact FGF23 in CKD mice:

Predictor Variable	Coefficient (95% CI)	p-value	Adjusted R^2	n
Standardized Serum Phosphorus	13.7 (3.9, 23.3)	0.008	0.13	57
Standardized Liver Iron	11.4 (1.7, 21.1)	0.025

TH-OR114

Tenapanor, an NHE3 Inhibitor, Reduces Serum Phosphate in Patients with CKD Stage 5D and Hyperphosphatemia Geoffrey A. Block,[1] David P. Rosenbaum,[2] Maria Leonsson Zachrisson,[3] Magnus Åstrand,[3] Susanne Johansson,[3] Mikael Knutsson,[3] Anna Maria Langkilde.[3] *[1]Denver Nephrology, Denver, CO; [2]Ardelyx Inc., Fremont, CA; [3]AstraZeneca R&D, Mölndal, Sweden.*

Background: Tenapanor (AZD1722), a first-in-class small molecule with minimal systemic availability, is an inhibitor of the Na^+/H^+ exchanger NHE3. Healthy volunteer studies show that tenapanor treatment increases stool sodium and phosphate and concomitantly reduces urinary sodium and phosphate. This double-blind, dose-finding study (NCT02081534) examined the effect of tenapanor on serum phosphate in patients with CKD stage 5D (hemodialysis).

Methods: After a 1–3-week washout of phosphate binders, 162 patients with baseline serum phosphate 6.0–<10.0 mg/dL and ³1.5 mg/dL increase from pre-washout levels were randomized to placebo or one of six tenapanor groups (1, 3, 10 or 30 mg bid, or 3 or 30 mg qd) for 4 weeks. Blood samples were collected weekly. The primary endpoint was change in serum phosphate from baseline. Dose–response analysis was a secondary endpoint.

Results: Tenapanor treatment resulted in dose-dependent reductions in serum phosphate (Table), with a significant difference between the treatment groups (p=0.012, ANCOVA). Gastrointestinal AEs were more common with tenapanor than with placebo, with higher doses associated with higher rates of diarrhea.

		Serum phosphate, mg/dL		
	N[a]	Baseline	End of treatment	Change from baseline
Tenapanor				
1 mg bid	23	7.55 (1.00)	7.02 (1.90)	−0.43 (1.55)
3 mg bid	21	7.32 (1.01)	6.19 (1.51)	−1.09 (1.39)
10 mg bid	23	7.92 (1.06)	6.14 (1.90)	−1.76 (2.02)
30 mg bid	26[b]	7.76 (1.18)	5.80 (2.04)	−2.00 (2.01)
3 mg qd	22	7.73 (1.28)	7.14 (2.21)	−0.57 (1.76)
30 mg qd	21	7.61 (0.85)	6.32 (1.77)	−1.09 (1.47)
Placebo	26	7.87 (1.49)	7.28 (1.71)	−0.58 (1.80)

[a]Randomized patients; [b]n=25 for data in table.
Data are mean (SD).

Conclusions: Tenapanor provided clinically and statistically significant reductions in serum phosphate. Higher doses of tenapanor were associated with higher rates of diarrhea, as expected based on its additional pharmacodynamic effect on stool sodium. Once- or twice-daily administration of tenapanor may offer a new treatment mechanism to reduce serum phosphate in patients with CKD.

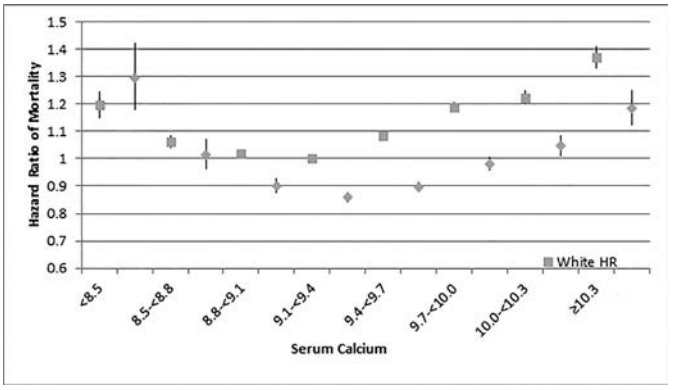
Racial Differences in Association of Serum Calcium with Mortality and Incident Cardio- and Cerebrovascular Events Jun Ling Lu,[1] Miklos Zsolt Molnar,[1] Jennie Z. Ma,[2] Lekha K. George,[1] Kamyar Kalantar-Zadeh,[3] Csaba P. Kovesdy.[1,4] *[1]Univ of Tennessee Health Science Center, Memphis, TN; [2]Univ of Virginia, Charlottesville, VA; [3]Univ of California, Irvine, CA; [4]VA Medical Center, Memphis, TN.*

Background: In CKD patients, both high and low serum calcium (CA) is associated with higher mortality. Calcium metabolism is different in African American (AA) vs. white individuals. It is unclear if CA is associated with mortality and vascular events in patients with normal kidney function and if such association differs by race.

Methods: We examined racial differences in associations between corrected CA and mortality or incident coronary disease (CHD) and stroke in a national cohort of 1,967,685 US veterans with eGFR >60ml/min/1.73m^2. We used multivariable Cox proportional hazards models with interaction terms for CA and race, adjusted for age, BMI, social-economics, eGFR, BP, comorbidities, and medications.

Results: The mean age (SD) was 60.6(13.5), and the mean eGFR (SD) was 83.3 (15.4) ml/min/1.73m^2. 15.5% of patients were AA, with a mean baseline CA of 9.5±0.4 mg/dl. Over a median follow-up of 8.2-years, there were 47,790 (15.7%) deaths, 8,129 (2.7%) strokes, and 6,175 (2.0%) CHD events in AA, compared to 299,137 (21.1%), 30,300(2.1%) and 34,304(2.4%) events in whites. A U-shaped association between CA and mortality was present in both races, but AA patients experienced lower risk relative to white patients with CA>8.8mg/dl (Figure, p<0.01 for interaction). No associations were found between CA and CHD/stroke in either race.



Conclusions: Both higher and lower CA are associated with higher mortality in patients with normal kidney function. AA patients appear to experience relatively lower risk of death compared to white patients when CCA≥8.8 mg/dl, but this could not be attributed to differences in incident occlusive vascular events.

Relevance of LDL Cholesterol and C-Reactive Protein to Cardiovascular Risk Among Patients with Chronic Kidney Disease – Results from the Study of Heart and Renal Protection

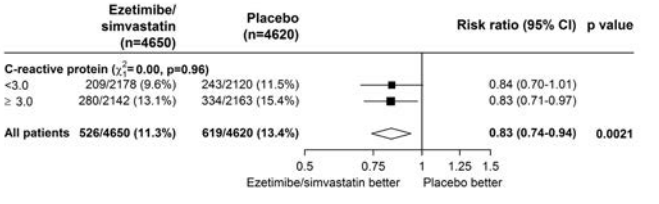
Ben Storey. *On behalf of the SHARP Collaboration Group, Univ of Oxford.*

Background: Previous observational studies have found J-shaped relationships between LDL-C and cardiovascular risk among patients with CKD and suggested this association may be modified by inflammation: that it is positive in the absence of inflammation but negative in its presence. Conversely, other studies suggest that statins may be most effective in people with inflammation.

Methods: SHARP was a randomised controlled trial of LDL-C lowering with ezetimibe/simvastatin (E/S) in 9270 patients with CKD. Hazard ratios (HR) for all atherosclerotic vascular events (AVE) over 4.9 years were estimated with Cox regression. The effect of E/S on major atherosclerotic events (MAE) was estimated in the presence and absence of inflammation; defined as CRP ³3mg/L (the study median) or in a sensitivity analysis as CRP >10 mg/L and/or albumin <36 g/L (90th & 10th centiles in 3rd NHANES respectively).

Results: Among all patients, usual LDL-C was positively, and approximately log-linearly, associated with risk of AVE (HR per 1 mmol/L [39 mg/dL] higher LDL-C 1.38 [95% CI 1.22-1.56]). Compared to patients with low CRP, patients with high CRP were at higher risk, but the relationship between LDL-C and AVE risk was similar in both groups (HR per mmol/L 1.29 [1.07-1.54] and 1.43 [1.21-1.69] respectively, p for interaction=0.58). E/S was similarly effective at reducing MAE in patients with low and high CRP. (Rate Ratio 0.84 and 0.83 respectively, p for heterogeneity=0.96). Sensitivity analyses gave similar results.

Figure: Effect of allocation to E/S on major atherosclerotic events, by level of CRP



Conclusions: LDL-C was positively associated with risk of AVE irrespective of baseline inflammation. Furthermore, lowering LDL-C with E/S was similarly effective in the presence or absence of inflammation. While CRP is associated with vascular risk, it does not modify the association between LDL-C and risk nor the efficacy of lowering LDL-C.

Utilization of Statin Medications in Non-Dialysis Dependent Chronic Kidney Disease (CKD) Patients

Holly J. Kramer,[1] Talar Markossian,[1] Nicholas Burge,[2] Benjamin Ling,[1] Julia Koval,[1] David J. Leehey,[2] Kevin Stroupe.[2] *[1]Loyola Univ Chicago; [2]Hines VA Medical Center.*

Background: KDIGO and KDOQI guidelines recommend statin medications for adults age ≥ 50 years with non-dialysis dependent chronic kidney disease (CKD) due to demonstrated benefits of statins in reducing the risk for cardiovascular events and mortality for these patients. Results from few empirical studies suggest that statins are underused for CKD patients.

Methods: Retrospective analysis of U.S. Department of Veterans Affairs Healthcare System (VA) national databases to determine statin use in patients with non-dialysis dependent CKD. Patients with non-dialysis dependent CKD stages 3-5 with no history of kidney transplantation were included in the analysis. Statin use was ascertained from pharmacy dispensing records in 2012 and 2013.

Results: Approximately sixty percent of patients with non-dialysis dependent CKD were prescribed statins. Among patients prescribed statins in 2012, 11.0% lacked statin prescriptions during 2013. Statin use varied by age (33.9% ≤50, 53.0% 50-59, 64.6% 60-74, 58.0% ≥ 75 years). Table 1 shows the frequency of statin use by CKD stage and by presence of comorbidities.

Characteristics (%)	CKD Stage undetermined (n=147, 508)	CKD Stage 3A (n=457, 528)	CKD Stage 3B (n=194, 470)	CKD Stage 4 (n=51, 299)	CKD Stage 5 (n=13, 999)
	% Using statin	% Using statin	% Using statin	% Using statin	% Using statin
	62.6	57.8	61.6	61.3	53.6
Comorbidities	% using statin by comorbidity	% using statin by comorbidity	% using statin by comorbidity	% using statin by comorbidity	% using statin by comorbidity
Coronary artery disease	80.6	82.9	83.2	82.5	76.5
Diabetes	75.1	70.5	71.2	70.4	61.8
Heart Failure	75.5	71.7	71.2	71.4	65.6
Myocardial infarction	82.8	77.6	77.5	77.2	73.0
Peripheral artery disease	77.5	72.9	73.1	72.5	66.3
Stroke	74.9	71.2	71.4	71.2	64.9

Conclusions: Despite KDIGO and KDOQI guidelines recommending statins for adults with non-dialysis dependent CKD, statin use is suboptimal in adults with CKD receiving care in the VA health system. Interventions are needed to increase knowledge regarding the clinical importance of statin use in adults with non-dialysis dependent CKD.

Associations of Conventional Echocardiographic Measures with Incident Heart Failure and Mortality: The Chronic Renal Insufficiency Cohort Study

Ruth F. Dubin,[1] Amanda Hyre Anderson,[2] Wei Yang,[2] Alan S. Go,[3] Martin Keane,[4] Rajat Deo,[2] Nisha Bansal,[5] Raymond R. Townsend,[2] Michael Shlipak.[1] *[1]Univ of California, San Francisco/SF VAMC; [2]Univ of Pennsylvania School of Medicine; [3]Kaiser Permanente, California; [4]Temple Univ School of Medicine; [5]Univ of Washington.*

Background: Heart failure (HF) is the most common cardiac complication for patients with chronic kidney disease (CKD). Left ventricular hypertrophy (LVH) develops early in CKD, but studies have not adequately evaluated the association of left ventricular mass index (LVMI) with HF incidence among men and women with CKD.

Methods: We evaluated two-dimensional echocardiograms among 2964 participants of the Chronic Renal Insufficiency (CRIC) Study without cardiovascular disease (CVD). LVMI was calculated using the linear method, indexed to height and analyzed using gender-specific quartiles. The primary outcomes of incident HF and all-cause mortality were adjudicated;HF analyses were censored for death.

Results: Among 2964 participants, 45% were women, 54% were non-white race, mean(SD) age was 59±11years, mean(SD) eGFR was 44±17ml/min/1.73m² at baseline. Over a median[IQR] follow up of 6.6 [5.7-7.6] years, 262 participants developed incident HF, and 470 participants died. In both men and women, LVMI was a strong, independent predictor of incident HF and mortality, even after adjustment for BNP and troponin T.

	Hazard Ratio (95% CI)*			
	Q1*	Q2	Q3	Q4
Heart Failure				
Men	Ref	1.9(0.68-5.4)	3.1(1.2-8.3)	3.5(1.3-9.5)
Women	Ref	1.2(0.43-3.4)	2.5 (0.9-6.7)	5.1(1.8-14)
Death				
Men	Ref	1.3(0.8-2.2)	1.7(1.0-2.9)	1.7(1.0-3.0)
Women	Ref	1.3(0.7-2.5)	2.2(1.1-4.4)	3.1(1.5-6.4)

* Model adjusted for: age, race, site, comorbidities, medications, proteinuria, eGFR, hemoglobin, PTH, FGF-23, BNP, Troponin T

There was no significant interaction for gender in this association, but the LVMI-HF association was stronger in persons without diabetes: per SD LVMI, HR[95%CI] 1.3[1.1-1.6] with diabetes and 2.2[1.6-2.8] without diabetes (p for interaction:0.01).

Conclusions: Among persons with CKD and without history of CVD, LVMI is a strong predictor of incident HF and death, even after adjustment for major cardiovascular biomarkers.

Prevalence and Prognostic Significance of Apparent Treatment Resistant Hypertension in Chronic Kidney Disease: A Report from the CRIC Study

George Thomas,[1] Dawei Xie,[2] Hsiang-Yu Chen,[2] Amanda Hyre Anderson,[2] Lawrence J. Appel,[2] Carolyn S. Brecklin,[2] Paul E. Drawz,[2] John M. Flack,[2] Edgar R. Miller,[2] Susan P. Steigerwalt,[2] Raymond R. Townsend,[2] Matthew R. Weir,[2] Jackson T. Wright,[2] Mahboob Rahman.[2] *[1]Cleveland Clinic, Cleveland, OH; [2]CRIC Investigators.*

Background: While hypertension is common in patients with chronic kidney disease (CKD), the association between apparent treatment resistant hypertension (ATRH) and clinical outcomes is not well studied in this population.

Methods: We analyzed data on 3367 hypertensive participants in the Chronic Renal Insufficiency Cohort (CRIC) to determine prevalence, associations, and clinical outcomes of ATRH in non-dialysis CKD patients. ATRH was defined as blood pressure ³140/90 mm Hg on ³3 antihypertensives, or use of ≥4 antihypertensives with BP at goal at baseline.

Results: The prevalence of ATRH was 40.4%. Older age, male gender, black race, diabetes, and higher BMI were independently associated with significantly higher odds of having ATRH. Compared to participants without ATRH, after adjustment for common covariates, participants with ATRH had a higher risk of clinical events (composite of myocardial infarction (MI), stroke, peripheral arterial disease (PAD), congestive heart failure (CHF), and all-cause mortality) (HR [95% CI]): (1.38 [1.22,1.56]); renal events (ESRD or 50% decline in GFR) (1.28 [1.11,1.46]); CHF (1.77 [1.44,2.16)]; and all-cause mortality (1.24 [1.06,1.45]). The subset of participants with ATRH and BP at goal on ≥ 4 medications also had significantly higher risk of composite of MI, stroke, PAD, CHF, and all-cause mortality (HR [95% CI]) (1.30 [1.12, 1.51]) and CHF (1.68 [1.32, 2.12]) compared to those without ATRH. The association between ATRH and CHF and renal outcomes differed depending on baseline GFR (interaction ($p<0.05$); ATRH was associated with significantly higher risk for CHF and renal events only among those with GFR ³30 ml/min/1.73 m^2.

Conclusions: Our findings show that ATRH is common, and associated with high risk of adverse outcomes in a cohort of patients with CKD.

Aryl Hydrocarbon Receptor Is Activated during Chronic Kidney Disease and Is Associated with Mortality

Stephane Burtey,[1,2] Laetitia Dou,[1] Marion Sallée,[1,2] Claire Cerini,[1] Noemie Jourde-chiche,[1,2] Bertrand Gondouin,[1,2] Michael S. Denison,[3] Philippe Brunet.[1,2] *[1]Aix-Marseille Univ; [2]AP-HM; [3]UC Davis.*

Background: Aryl hydrocarbon receptor (AhR) is a transcription factor activated by numerous pollutants, like dioxin. Its activation is associated with cardiovascular risk. Indoxyl sulfate (IS) and indole-3 acetic acid (IAA) are uremic toxins associated with mortality in chronic kidney disease (CKD). They are agonists of AhR. Our goal was to study the activation of AhR in patients with CKD and its association with mortality.

Methods: We included 96 non-diabetic patients with CKD (50 patients with stage 3-5 CKD and 46 patients with stage 5D) and 32 controls without CKD matched for age and gender. The median follow up was 966 days. Activation of AhR by serum was evaluated by a Chemical Activated LUciferase gene eXpression assay (CALUX) and was expressed in arbitrary units (AU). In a subset of 20 patients with CKD stage 5D and 17 controls we performed RT-qPCR to study whole blood expression of AhR target genes (*CYP1A1*, *CYP1B1* and *AHRR*).

Results: The sera of patients with CKD stage 5D and CKD stage 3-5 activated AhR (means: 53.6 and 45.6 AU; 95% CI [45.6-61.6] and [32.6-58.7] respectively) compared to sera from controls (mean: 2.1 AU; 95% CI [0.5-3.8]). The activating effect of CKD serum was reduced by the addition of an AhR antagonist (CH-223191) in the CALUX assay. The expression of AhR target genes was increased in patients with CKD stage 5D compared to controls. In stage 3-5 CKD patients, AhR serum activity was inversely correlated with eGFR ($r=-0.59$, $p<0.0001$). All-cause mortality (log-Rank $p=0.01$) and cardiovascular mortality (log-Rank $p=0.047$) were increased in patients with an AhR serum activity above the median (44 AU) compared to patients with value below.

Conclusions: Serum from patients with CKD activates AhR, this ability is associated with mortality. Furthermore, AhR is activated in vivo in patients with CKD. Serum AhR activation is a new biomarker to predict the cardiovascular risk of patient with CKD. It is also an attractive target to develop new therapy.

Funding: Government Support - Non-U.S.

Associations of Urine Kidney Injury Biomarkers and All-Cause Mortality in the CRIC Study

Meyeon Park,[1] Chi-yuan Hsu,[1] Alan S. Go,[2] Dawei Xie,[3] Xiaoming Zhang,[3] Sushrut S. Waikar,[4] Joseph V. Bonventre,[4] Josef Coresh,[5] Robert G. Nelson,[6] Harold I. Feldman,[3] Paul L. Kimmel,[6] Vasan S. Ramachandran,[7] Kathleen D. Liu.[1] *[1]UCSF; [2]Kaiser Permanente of Northern California; [3]U. of Pennsylvania; [4]Harvard; [5]Welch Center for Prevention; [6]NIH; [7]Boston Univ.*

Background: Among individuals with CKD, we hypothesized that ongoing kidney injury would associate with an increased risk of death. We tested this hypothesis in the Chronic Renal Insufficiency Cohort (CRIC) study.

Methods: Urine kidney injury molecule-1 (KIM-1), neutrophil gelatinase associated lipocalin (NGAL), N-acetyl-beta-D-glucosaminidase (NAG), and liver fatty acid-binding protein (LFABP) were measured in 2466 CRIC subjects. Cox proportional hazards models were used to examine the association between biomarker concentrations indexed to urinary creatinine and death.

Results: Mean age of study participants was 59.5 (± 10.8) years; 46% were women, 43% were white, 38% were black. 50% had diabetes mellitus and 34% had cardiovascular (CV) disease. After adjustment for baseline eGFR, albuminuria, age, sex, race, CV comorbidities, and medications, those in the highest quintile (Q5, >2290.3 pg/g) of KIM-1/Cr levels and in the highest two quintiles of NGAL/Cr (Q5, > 64 ng/g, Q4, >20.2 ng/g) relative to the lowest (Q1 KIM-1/Cr <661.3 pg/g, Q1 NGAL/Cr <2.6 ng/g) had an increased risk of death [KIM-1/Cr Q5 v. Q1, hazard ratio (HR) 1.6 (1.1-2.3); NGAL/Cr Q5 v. Q1 HR 1.8 (1.2-2.8); Q4 v. Q1 HR 1.5 (1-2.2)]. Both analytes were also associated with death when levels were expressed as a continuous variable [HR per log SD increase of KIM-1/Cr=1.21 (1.06-1.39); HR per log SD increase of NGAL/Cr=1.22 (1.07, 1.39)]. NAG/Cr was associated with death in the continuous analysis only [HR per log SD increase of NAG/Cr=1.2 (1.04-1.37)]. LFABP/Cr was not associated with death.

Conclusions: Urine KIM-1/Cr, NGAL/Cr, and NAG/Cr are independently associated with increased risk of death in individuals with CKD. Kidney tubular injury may mark processes related to mortality risk in individuals with CKD.

TH-OR122

Endogenous Klotho Is Expressed in Human Heart and May Associated with Fibrosis

Qinghua Liu,[1,2] Tzongshi Lu,[1] Qiying Dai,[1] David M. Charytan,[1] Daniel Zehnder,[3] Li-Li Hsiao.[1] *[1]Renal Div, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Dept of Nephrology, The First Affiliated Hospital, Sun Yat-sen Univ, Guangzhou, China; [3]Univ Hospital Coventry and Warwickshire NHS Trust, Coventry, UK.*

Background: Cardiovascular disease is the major risk factor for patients with CKD. Emerging evidence suggests that fibroblast growth factor 23 (FGF23) is associated with left ventricular hypertrophy and cardiovascular events in ESRD patients. Klotho and fibroblast growth factor receptor (FGFR) serve as co-receptors for FGF23. We previously showed that endogenous Klotho is expressed in human arteries, and that CKD is a state of Klotho deficiency, but whether human heart expresses Klotho and whether Klotho levels is correlated with kidney function or cardiac fibrosis in CKD patients is unknown.

Methods: Human atrial appendage specimens were collected during cardiac surgery from individuals with and without CKD. Estimated glomerular filtration rate (eGFR) was calculated using the Modification of Diet in Renal Disease equation. CKD was defined as eGFR<60 ml/min/1.73 m^2. Fibrosis was quantified digitally using trichrome stained sections. Paraffin embedded cardiac tissue was obtained commercially. Western blot and immunohistochemical assay were used to detect protein expressions of Klotho, FGF23 and FGFR3. Klotho mRNA expression was assessed with RT-PCR.

Results: We confirmed that FGF23 is expressed in human heart. Our results show that endogenous Klotho and its co-receptor FGFR3 are expressed in human atrial appendage and left ventricle both in protein and mRNA levels. Our results also showed that cardiac fibrosis is negatively correlated with eGFR. And the endogenous Klotho levels in the heart is significantly suppressed with decreasing eGFR and increasing cardiac fibrosis.

Conclusions: We show for the first time that endogenous Klotho expressed in human heart and that Klotho suppression is associated with the degree of cardiac fibrosis and kidney function, suggesting the endogenous Klotho may have an association with cardiac fibrosis with possible involvement of FGF23.

TH-OR123

Circulating TNF Receptors Predicts Cardiovascular Disease in CKD Patients

Eunjin Bae,[1] Jung Nam An,[2] Jin Ho Hwang,[3] Dong Ki Kim,[1] Chun Soo Lim,[2] Jung Tak Park,[4] Shin-Wook Kang,[4] Yon Su Kim,[1] Jung Pyo Lee.[2] *[1]Internal Medicine, Seoul National Univ College of Medicine, Seoul, Republic of Korea; [2]Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul, Republic of Korea; [3]Internal Medicine, Chung-Ang Univ Hospital, Seoul, Republic of Korea; [4]Internal Medicine, Yonsei Univ College of Medicine, Seoul, Republic of Korea.*

Background: Cardiovascular disease (CVD) is the main public health problem in patients with CKD. However, there is no definite biomarker for predicting CVD morbidity and mortality in CKD. The aim of this study is to evaluate the role of circulating tumor necrosis factor receptors (cTNFRs) as a predictor of CVD risk in CKD patients.

Methods: We recruited 1,078 patients with CKD from 11 centers prospectively between 2006 and 2012. The levels of cTNFR1 and cTNFR2 were determined by performing enzyme-linked immunosorbent assay (ELISA). The correlation coefficient between cTNFRs and various values was measured using a Pearson's correlation test. Cox regression analysis was used to calculate the hazard ratio (HR) of CVD.

Results: Among a total of 1,078 patients, 57.2% was men and mean age was 50.4±15.7 years. 261 participants (24.2%) had DM. The mean serum creatinine was 1.9±1.0 mg/dL, UPCR was 2.2±2.7 g/g creatinine, hs-CRP was 0.6±2.4 mg/dL, cTNFR1 was 271±917 and cTNFR2 was 5687±3878 pg/ml. Serum cTNFR2 was correlated with the cTNFR1 (r=0.827), each other. In addition, age, BMI, UPCR, and eGFR were significantly correlated with cTNFR1 (r=0.43 for age, r=0.15 for BMI, r=0.20 for UPCR, r=–0.63 for eGFR; p<0.001 for all). Similar correlations were observed with the cTNFR1. For the mean follow-up duration of 4 years, 51 patients experienced CVD event. Participants with CVD were older and had lower eGFR level, higher SBP, higher cTNFRs level than those without CVD. In cox proportional hazard analyses, cTNFR1 (HR 1.907, 95% CI 1.025-3.550, p=0.0042) and cTNFR2 (HR 2.271, 95% CI 1.269-4.065, p value=0.006) predicted risk for CVD even after adjustment for clinical covariates, such as UPCR, eGFR, hs-CRP.

Conclusions: cTNFR1 and 2 associate with CVD and other risk factors in CKD, independent of eGFR and UPCR. Furthermore, cTNFRs could be relevant predictors for CVD in CKD patients.

TH-OR124

Fibroblast Growth Factor 23 and Risk of Atrial Fibrillation in Chronic Kidney Disease: The CRIC Study Rupal Mehta,[1] Xuan Cai,[1] Jungwha Lee,[1] Nisha Bansal,[2] Julia J. Scialla,[2] James H. Sondheimer,[2] Rajat Deo,[2] Jing Chen,[2] L. Lee Hamm,[2] Ana C. Ricardo,[2] Mahboob Rahman,[2] Sankar D. Navaneethan,[2] Alan S. Go,[2] Harold I. Feldman,[2] Tamara Isakova,[1] Myles S. Wolf.[1] *[1]Northwestern Univ; [2]CRIC Study.*

Background: Levels of fibroblast growth factor 23 (FGF23) are elevated in chronic kidney disease (CKD) and are strongly associated with cardiovascular disease and mortality. Atrial fibrillation (AF) is a common complication in CKD that is associated with poor outcomes, but whether FGF23 is an independent risk factor for AF in CKD is unknown.

Methods: We tested the associations of FGF23 with AF in cross-sectional and longitudinal analyses of 3879 participants in the Chronic Renal Insufficiency Cohort Study who had baseline FGF23 measurements. For longitudinal time-to-incident AF analyses, we excluded the 660 individuals with AF at baseline. Incident AF was adjudicated based on review of hospital records and yearly electrocardiograms.

Results: Mean estimated glomerular filtration rate (eGFR) was 44.3 ± 15.0 ml/min/1.73m^2 and median C-terminal FGF23 was 146 RU/ml (interquartile range 96, 239 RU/ml). In multivariable logistic regression models, higher FGF23 expressed continuously and in quartiles was associated with greater prevalence of AF (Table 1). Over a median follow up of 7 years, 248 incident AF events occurred. In multivariable-adjusted Cox proportional hazards models, elevated baseline FGF23 was a risk factor for incident AF (Table 2). These associations remained significant across strata of sex, race, prior heart failure, and eGFR. When FGF23 was expressed in quartiles or in models that censored individuals at end-stage renal disease onset (loss of 55 incident AF events), FGF23 was no longer associated with incident AF.

Effects of Cyclosporine on Renal Handling of Divalent Cations in Claudin 16-Deficient Mice Hoora Drewell,[1] Tilman Breiderhoff,[2] Dominik Müller,[3] Michael Fähling,[4] Sebastian Bachmann,[1] Kerim Mutig.[1] *[1]Anatomy, Charité-Universitätsmedizin, Berlin, Germany; [2]Physiology, Charité-Universitätsmedizin, Berlin, Germany; [3]Pediatric Nephrology, Charité-Universitätsmedizin, Berlin, Germany; [4]Vegetative Physiology, Charité-Universitätsmedizin, Berlin, Germany.*

Background: Calcineurin inhibitors tacrolimus and cyclosporine are instrumental for immunosuppression after organ transplantation but cause substantial renal side effects including hypomagnesemia and hypercalciuria. The tight junctions protein Claudin 16 (Cldn16) mediates paracellular reabsorption of divalent cations along the cortical thick ascending limb and has been implicated in the adverse effects of cyclosporine. We have compared effects of cyclosporine in wild-type (WT) and Cldn16-deficient (Cldn16-/-) mice.

Methods: Mice received cyclosporine (25 mg/kg) for 7 days and their kidney performance was analysed in metabolic cages. Expression of distal transport proteins has been studied by quantitative PCR and immunoblotting.

Results: Physiological analysis revealed baseline hypomagnesemia and hypercalciuria in Cldn16-/- mice. Administration of cyclosporine induced marked hypomagnesemia in WT mice but did not significantly alter plasma magnesium levels in Cldn16-/- mice. In contrast, cyclosporine-induced increase in urinary calcium was significantly stronger in Cldn16-/- mice compared to WT controls alongside more pronounced decrease of plasma calcium levels in Cldn16-/- mice. Cyclosporine stimulated distal sodium transporters leading to sodium retention in both genotypes.

Conclusions: In sum, our data corroborate the pivotal role of Cldn16 in the renal magnesium and calcium handling and suggest that Cldn16 may be involved in the cyclosporine-induced renal magnesium loss and hypomagnesemia, since genetic deletion of Cldn16 prevented these effects. In contrast, the strong manifestation of cyclosporine-induced hypercalciuria in Cldn16-/- mice suggests that cyclosporine may affect transcellular calcium reabsorption pathways rather than the Cldn16-mediated paracellular transport.

***Ogr1* and Acid-Induced Hypercalcuria** Pedro Henrique Imenez Silva,[1] Kessara Chan,[1] Marie-Gabrielle Ludwig,[2] Jürg Andreas Gasser,[2] Timothy R. Arnett,[3] Olivier Bonny,[4] Klaus Seuwen,[2] Carsten A. Wagner.[1] *[1]Inst of Physiology, Univ of Zurich, Zurich, Switzerland; [2]Novartis Insts for Biomedical Research, Basel, United Kingdom; [3]Dept of Cell and Developmental Biology, Univ College London, London, United Kingdom; [4]Dept of Pharmacology and Toxicology, Univ of Lausanne, Lausanne, Switzerland.*

Background: The Ovarian cancer G-protein coupled Receptor 1 OGR1 (GPR68) is an extracellular proton activated GPCR that stimulates inositol triphosphate (IP_3) production and increases intracellular Ca^{2+} levels. However, the physiological roles of OGR1 are not well established. In this work we aimed to identify the roles of OGR1 in acid-base and mineral balance.

Methods: Wild type (OGR1$^{+/+}$) and an OGR1 mice-deficient model (OGR1$^{-/-}$) were subjected to metabolic acidosis (280 mM NH4Cl) or non-acidotic control condition for 1 and 7 days and basic physiological parameters were collected from blood and urine. Several organs were isolated such as kidneys, intestine, brain, heart, etc. in order to extract RNA and perform RT-PCR/real time PCR. Kidneys were also used for protein extraction/western blotting.

Results: OGR1 mRNA was found in many organs including kidney where mRNA was detected in all nephron segments. No acid-base modifications were observed in OGR1$^{-/-}$ mice, except for a higher plasma pH in the 1 day metabolic acidosis group (7.20 ± 0.04 vs 7.12 ± 0.03, p<0.05). As was expected, metabolic acidosis caused an increase in calcium and magnesium excretion in OGR1$^{+/+}$, but this was not observed in OGR1$^{-/-}$. The mRNA levels of proteins involved in Ca^{2+} and Mg^{2+} reabsorption like Calbindin D28k, TRPV5/6, TRPM6/7 and Claudins 16 and 19 were not altered in OGR1$^{-/-}$. The protein expression of TRPV5, the main apical distal convoluted tubule route for calcium, was 2.4 - fold increased (p<0.001) in OGR1$^{-/-}$ under metabolic acidosis which may explain the diminished Ca^{2+} excretion in these mice.

Conclusions: OGR1 is involved in the hypermagnesuria and hypercalciuria developed during metabolic acidosis, by a mechanism involving the Ca^{2+} channel, TRPV5.

Conditional NFAT5 Knockout Causes Impaired Urinary Concentrating Ability with Renal Diabetes Insipidus and Hypernatremia without Renal Medullary Injury Christoph Kueper,[1] Franz Xaver Beck,[1] Zoran Popovic,[2] Hermann-Josef Groene,[2] Bernhard K. Krämer,[3] Wolfgang Neuhofer.[3] *[1]Cellular Physiology, Univ of Munich, Munich, Germany; [2]Molecular Pathology, German Cancer Research Inst, Heidelberg, Germany; [3]Div of Nephrology, Univ Hospital Mannheim, Mannheim, Germany.*

Background: This study addressed the effects of inducible deletion of NFAT5 in adult mice on the expression of components of urinary concentration, i.e. AQP-2, ClC-K1, barttin, and UT-A1. In parallel, NFAT5-dependent osmoprotective genes AR, HSP70, and others were determined along with renal functional, morphological, and systemic parameters.

Methods: Mice with tamoxifen-inducible deletion of NFAT5 were established. At the age of 3-4 weeks, conditional NFAT5 KO mice or control animals were fed with a diet

containing tamoxifen for further 3-4 weeks. Subsequently, the expression of NFAT5 target genes was determined by qRT-PCR, Western blot analysis, and immunohistochemistry in different kidney zones in animals with free access to water or in mice that were water deprived for 24 h. Urine and blood electrolyte and urea concentrations were determined by standard methods.

Results: Adult mice with conditional deletion of NFAT5 showed 80-90% reduced expression of NFAT5 in all tissues tested, particularly in renal medullary regions. Accordingly, the NFAT5 target genes AQP-2, ClC-K1, barttin, UT-A1, AR, and HSP70 were substantially downregulated. Consistently, these NFAT5-deficient mice had renal diabetes insipidus with reduced urinary concentrating ability, dehydration, and hypernatremia, particularly following water deprivation. In contrast to constitutive NFAT5 knockout animals, inducible deletion in adult mice was not associated with renal medullary injury or hydronephrosis.

Conclusions: Deletion of NFAT5 causes renal diabetes insipidus-like phenotype by diminished expression of genes essential for urinary concentration. Despite reduced expression of osmoprotective genes in the renal medulla, histological evidence of medullary cellular injury was not detectable. The lack of damage might be a consequence of diminished medullary interstitial sodium chloride and urea concentrations, and hence reduced osmotic stress in this kidney region.

FR-OR004

Effect of Concurrent P2Y2 Receptor Deletion and P2Y12 Receptor Blockade on Lithium-Induced Nephrogenic Diabetes Insipidus in Mice Yue Zhang, Kristina M. Heiney, Bellamkonda K. Kishore. *Internal Medicine, Univ of Utah & VA Med Ctr, Salt Lake City, UT.*

Background: Chronic lithium (Li) administration for bipolar disorder causes nephrogenic diabetes insipidus (NDI), characterized by polyuria, natriuresis and kaliuresis, resulting in a debilitating condition. Previously we reported that mice lacking ATP/UTP-activated P2Y2 receptor are significantly, but not completely resistant to Li-induced polyuria. Recently in a mouse model we observed that pharmacological blockade of ADP-activated P2Y12 receptor offers near complete amelioration of Li-induced polyuria. However, there were differences between these two approaches in terms of natriuresis, kaliuresis and blood Li levels. Hence, we tested the concurrent effect of both in mice.

Methods: Groups (n = 5 to 7) of age-matched adult wild type B6D2 (WT) and syngeneic P2Y2-R knockout (KO) mice were fed Li-added diet (40 mmol LiCl/kg food) ad libitum, with or without administration of clopidogrel bisulfate (CLPD; 80 mg/kg bw/day) in drinking water for 14 days and euthanized. Twenty-four hour urine samples were collected prior to and toward the end of the experimental period. Blood samples were collected at euthanasia.

Results: Compared to Li-fed WT mice: (i) Li-fed KO mice had ~50% less polyuria associated with significant amelioration of Li-induced natriuresis and kaliuresis; and (ii) Li-fed WT mice treated with CLPD had near complete amelioration of polyuria, but had no effect on Li-induced natriuresis and kaliuresis. Interestingly, Li-fed KO mice concurrently treated with CLPD showed significant amelioration of natriuresis and kaliuresis, in addition to almost complete suppression of polyuria. P2Y2-R deletion had no effect on blood Li levels, whereas P2Y12-R blockade caused modest, but significant increase in blood Li levels. However, the concurrent approach neutralized the effect of P2Y12-R blockade on blood Li levels.

Conclusions: Our results demonstrate that concurrent blockade of P2Y2 and P2Y12 receptors has the potential for better outcomes in amelioration of Li-induced NDI without causing a rise in blood Li levels. By proper optimization of CLPD dose, it should be possible to achieve better control of all parameters of NDI.

The V-ATPase B1 Subunit Polymorphism p.E161K Is Associated with Impaired Urinary Acidification in Recurrent Stone Formers Daniel G. Fuster,[1,3] Nasser Dhayat,[1,3] Giuseppe Albano,[1,3] Andreas Pasch,[1,3] Bruno Vogt,[1,3] Orson W. Moe.[2] *[1]Nephrology, Hypertension and Clinical Pharmacology, Univ Hospital of Bern, Bern, Switzerland; [2]Div of Nephrology, UT Southwestern Medical Center, Dallas, TX; [3]Dept of Clinical Research, Univ of Bern, Bern, Switzerland.*

Background: Mutations in the V-ATPase B1 subunit gene ATP6V1B1 cause autosomal-recessive distal renal tubular acidosis. We previously identified a single nucleotide polymorphism (SNP) in the human V-ATPase B1 subunit (c.481G>A; p.E161K) that displayed greatly diminished pump function in vitro.

Methods: To investigate the impact of this p.E161K SNP on urinary acidification in vivo, we conducted a genotype-phenotype analysis of recurrent stone formers in the Dallas and Bern kidney stone registries.

Results: 32 of 555 (5.77 %) of the patients examined were heterozygous for the p.E161K SNP, the remaining 523 patients (94.23%) carried two wild-type alleles. Adjusted for sex, age, BMI and dietary acid and alkali intake, p.E161K SNP carriers had a tendency to higher urinary pH under a random diet (6.31 versus 6.09; p=0.089). Under an instructed low calcium and sodium diet, urinary pH was higher in p.E161K SNP carriers (6.555 versus 6.005; p<0.005). Kidney stones of p.E161K carriers were significantly more likely to contain calcium phosphate than stones of wild-type patients. In acute ammonium chloride loading, p.E161K carriers displayed a higher trough urinary pH(5.34 vs 4.89; p=0.01) than wild-type patients. 14.58 % of wild-type patients and 52.38% of p.E161K carriers were unable to acidify their urine below 5.3 and thus had incomplete distal renal tubular acidosis.

Conclusions: In summary, our data indicate that recurrent stone formers with the V-ATPase B1 subunit p.E161K SNP exhibit a urinary acidification deficit with an increased prevalence of calcium phosphate containing kidney stones. The burden of E161K heterozygosity may be a forme fruste of distal RTA.

Proximal Tubule-Specific Glutamine Synthetase Deletion Alters Basal and Acidosis-Stimulated Renal Ammonia Excretion Hyun-Wook Lee,[1] Gunars Osis,[1] Mary E. Handlogten,[1] Jill W. Verlander,[1] I. David Weiner.[1,2] *[1]Renal Div, Univ of Florida, Gainesville, FL; [2]Nephrology and Hypertension, NF/SGVHS, Gainesville, FL.*

Background: Glutamine synthetase (GS) mediates the recycling of NH_4^+ and glutamate back to glutamine. In the kidney, the majority of GS is expressed in the proximal tubule where it may decrease net ammoniagenesis and limit ammonia available for net acid excretion. This study's purpose was to determine the role of proximal tubule (PT) GS in normal acid-base homeostasis and in the renal response to metabolic acidosis.

Methods: We generated mice with proximal tubule-specific glutamine synthetase deletion (PT-GS-KO) by using Cre-loxP techniques. PT-GS-KO mice had loxP sites flanking exons 1 and 7 ($GS^{fl/fl}$) and expressed Cre-recombinase under control of the phospho*enol*pyruvate carboxykinase (PEPCK) promoter (PEPCK-Cre). Control (C) mice were $GS^{fl/fl}$ but PEPCK-Cre negative.

Results: Immunoblot analysis showed PT-GS-KO decreased GS protein expression by 47 ± 4% in the cortex and 89 ± 1% in the outer stripe of the outer medulla; immunohistochemistry showed efficient and specific PT GS deletion with occasional residual GS-positive cells. Under basal conditions, proximal tubule GS deletion increased urinary ammonia excretion: 102 ± 10 vs 75 ± 8 mmol/day in PT-GS-KO and C mice, respectively, consistent with our hypothesis that GS deletion increases net ammoniagenesis and thereby increases ammonia excretion. However, ammonia excretion after acid loading for 7 days increased similarly in PT-GS-KO and C mice during the first 4 days of acid loading but on days 5-7 was significantly less, by ~33%, in PT-GS-KO as compared to C mice. In acid-loaded mice, adaptive responses to PT-GS-KO included increased expression of cortical phosphate-dependent glutaminase (PDG), PEPCK, and the glutamine transporter, SN1, compared to C.

Conclusions: We conclude: 1) proximal tubule GS expression contributes to both basal and acidosis-stimulated renal ammonia excretion; and, 2) elimination of the contribution of proximal tubule GS downregulation to enhance ammoniagenesis during acid-loading is partially compensated for by adaptive increases in PDG, PEPCK and SN1 expression.

FR-OR007

The B1 H^+-ATPase (Atp6v1b1) Subunit Is Required for Non-Type A Intercalated Cell Function and Defense against Alkalosis Soline Bourgeois, Jana Kovacikova, Carsten A. Wagner. *Inst of Physiology, Univ of Zurich, Zurich, Switzerland.*

Background: The final urine pH is fine-tuned by type A and non-type A intercalated cells (IC) along the connecting tubule (CNT) and collecting duct (CCD) involving the action of vacuolar H-ATPases. Mutations in the B1 subunit of H-ATPase (ATP6V1B1) in man cause distal renal tubular acidosis due to its importance in acid secretion by type A-ICs. Non-type A-IC also express the vacuolar H^+-ATPases containing the B1 subunit isoform at their luminal and/or basolateral plasma membrane together with the luminal Cl^-/HCO_3^- exchanger pendrin. The main function of non-type A-ICs is the excretion of bicarbonate during metabolic alkalosis. However, the function of the B1 isoform in non-type A-ICs has remained elusive.

Methods: We studied the metabolic behaviour of B1 deficient mice during an alkali load induced by a 4-day desoxycorticosterone (DOCA, 2 mg/mouse s.c) and 0.28M NaHCO3 treatment in the drinking water.

Results: Induction of metabolic alkalosis resulted in a more pronounced alkalosis in B1 deficient mice associated with increased blood bicarbonate, hypokalemia, and hypochloremia. Furthermore, while, pendrin localization was preserved, total pendrin expression was reduced and pendrin activity was altered in B1 deficient mice whereas the relative abundance of pendrin expressing cells was increased. In parallel, H^+-ATPase activity in non-type A-IC from ex vivo microperfused cortical collecting duct was strongly reduced. Finally, the E and A subunits of H-ATPase did not associate with the basolateral domain of B1 deficient non-type A-ICs leading to the non-association of V_1 domain while basolateral expression of a4 subunit, part of the V0 domain, was not disrupted.

Conclusions: Thus, the B1 subunit is required for the formation of a complete and functional basolateral H^+-ATPases complexes and is critical for normal non-type A-IC function cells during alkalosis.

FR-OR008

Comparing the Effect of Combination of Acetazolamide and Hydrochlorothiazide Followed by Furosemide versus Combination of Hydrochlorothiazide and Furosemide Followed by Furosemide in Treating Refractory Edema Associated with Nephrotic Syndrome: A Randomized, Double-Blind Trial Mohammad Kazem Fallahzadeh,[1] Mohammad Amin Fallahzadeh,[2] Banafshe Dormanesh,[3] Jamshid Roozbeh,[2] Mohammad Hossein Fallahzadeh,[2] Mohammad Mahdi Sagheb.[2] *[1]Baylor Univ Medical Center, Dallas, TX; [2]Shiraz Univ of Medical Sciences, Shiraz, Islamic Republic of Iran; [3]AJA Univ of Medical Sciecnes, Tehran, Islamic Republic of Iran.*

Background: The Cl/HCO3 exchanger pendrin and Na/Cl cotransporter (NCC) play important role in distal tubule salt reabsorption. A recent animal study has shown simultaneous inhibition of pendrin and NCC by acetazolamide and hydrochlorothiazide, respectively results in significant diuresis. The aim of this study was to evaluate the efficacy of combination of acetazolamide and hydrochlorothiazide followed by furosemide in treatment of refractory edema associated with nephrotic syndrome.

Methods: In this randomized, double-blind trial we enrolled 20 patients with nephrotic syndrome who had refractory edema despite receiving maximum furosemide dose. All patients had GFR>60 ml/min/1.73m^2. After a 2-week washout period when patients received no diuretics, they were randomly assigned to 2 equal groups. Group 1 received 250-mg oral acetazolamide and 50-mg oral hydrochlorothiazide daily for 1 week. Group 2 received 40 mg oral furosemide and 50-mg oral hydrochlorothiazide daily for 1 week. Then patients in both groups received 40-mg oral furosemide daily for 2 weeks. The primary outcome was the amount of change in weight from baseline to the end of the treatment phase.

Results: Although weight reduction occurred in both groups, it was significantly higher in group 1 as compared to group 2 at the end of first week (-1.4±0.52 vs. -0.65±0.41 kg, p=0.004) and of third week of treatment phase (-3±0.94 vs. -1.15±0.47 kg, p=0.001). Increase in 24-hour urine volume was also significantly higher in group 1 at the end of treatment phase. Serum Na and K levels were in reference range in all the patients during the treatment phase.

Conclusions: Combination of acetazolamide and hydrochlorothiazide followed by furosemide may be a novel and safe diuretic therapy in refractory edema associated with nephrotic syndrome.

FR-OR009

Tissue Na^+ in Chronic Kidney Disease and Effect of Renal Transplantation on Na^+ Stores Christoph Kopp,[1] Jonathan Jantsch,[5] Anke Dahlmann,[1] Peter Linz,[2] Daniela Amslinger,[2] Matthias Hammon,[3] Kai-Uwe Eckardt,[1] Friedrich C. Luft,[6] Jens Titze.[2,4] *[1]Nephrology and Hypertension, Univ Hospital Erlangen, Germany; [2]Junior Research Group II, Interdisciplinary Center for Clinical Research, Erlangen, Germany; [3]Radiology, Univ Hospital Erlangen, Germany; [4]Clinical Pharmacology, Vanderbilt Univ, Nashville; [5]Clinical Microbiology and Hygiene, Univ Hospital Regensburg, Germany; [6]Experimental and Clinical Research Center, Max-Delbrück Center, Berlin, Germany.*

Background: Diminished kidney function as occurs in Chronic Kidney Disease (CKD) causes salt sensitive hypertension. By using ^{23}Na-Magnetic Resonance Imaging (^{23}Na-MRI) technology we recently could detect Na^+ storage in humans, which was associated with hypertension. Whether impaired Na^+ excretion in CKD results in tissue Na^+ accumulation and if kidney transplantation affects tissue Na^+ stores is not known.

Methods: We recruited 32 patients with CKD Stage 4 and 5 prior to preemptive living donor transplantation or dialysis treatment and 30 age- and gender-matched control subjects. ^{23}Na-MRI at 3Tesla was used to quantify muscle and skin Na^+ of the lower leg before kidney transplantation/dialysis as well as 3 and 6 months after living donor transplantation. Additionally, clinical parameters including blood pressure as well as blood and urine samples were assessed.

Results: Compared to healthy control subjects, CKD-patients showed increased muscle and skin Na^+ content (skin 15.8 ± 3.6 vs. 23.1 ± 8.2, p<0.001; muscle 15.8 ± 1.8 vs. 21.0 ± 3.9, p<0.001). Despite these differences in tissue Na^+, serum Na^+ concentration did not vary between both groups. Restoration of kidney function by successful renal transplantation in 15 CKD patients was accompanied by reduced blood pressure (mean arterial pressure 104 ± 12 vs. 94 ± 11, p <0.01) and mobilization of tissue Na^+ from muscle (21.4 ± 3.1 vs. 18.4 ± 2.9, p<0.01) and skin (24.4 ± 6.2 vs. 19.2 ± 4.5, p<0.01) 6 months post-transplantation.

Conclusions: Accelerated sodium storage occurs in pre-dialysis patients with CKD that could be reversed by successful kidney transplantation. Reduction of tissue Na^+ after kidney transplantation was associated with better blood pressure control.

FR-OR010

Small-Molecule Inhibitors of Pendrin (SLC26a4) Augment the Diuretic Action of Furosemide Onur Cil, Cristina Esteva-Font, Joseph-Anthony Tapia Tan, Puay Wah Phuan, Peter Michael Haggie, Alan S. Verkman. *Depts of Medicine and Physiology, Univ of California San Francisco, San Francisco, CA.*

Background: Pendrin (Slc26a4) is a chloride/bicarbonate exchanger expressed in type-B and non-A, non-B intercalated cells of connecting tubule and cortical collecting duct, where it mediates Cl^- absorption and modulates ENaC function by changing luminal HCO_3^- concentration. Under normal conditions, pendrin has a minimal role in renal salt metabolism; pendrin knock-out mice and patients with Pendred Syndrome (caused by loss-of-function *Slc26a4* mutations) do not manifest salt wasting. Previous studies demonstrated that double knock-out of pendrin with other renal salt transporters causes increased urine output, volume depletion and salt wasting. It has been hypothesized that pendrin may attenuate diuretic-induced salt loss.

Methods: A cell-based high-throughput screen was established to identify pendrin inhibitors involving fluorescence plate reader measurement of chloride influx in epithelial cells stably coexpressing human pendrin and a chloride-sensing fluorescent protein. Screening of ~30,000 drug-like small molecules produced three chemical classes of pendrin inhibitors with IC50 down to 1 μM. The pendrin inhibitors were administered to mice intraperitoneally (10 mg/kg) either alone or with low (5 mg/kg), intermediate (10 mg/kg) or high (20 mg/kg) dose furosemide. Urine was collected in metabolic cages for 3 hours after injection, and blood was collected afterwards.

Results: In furosemide-treated mice pendrin inhibitors of two chemically different classes produced an approximate 40% increase in urine output and osmolar clearance, without changing urine osmolality. The compounds had no effect in mice when administered alone. LC/MS analysis showed predicted therapeutic inhibitor concentrations in blood and urine.

Conclusions: Our findings suggest pendrin inhibition as a novel approach to amplify the diuretic action of loop diuretics. Such combination therapy might enhance diuresis and salt excretion for treatment of hypertension and edema, including diuretic-resistant edema.

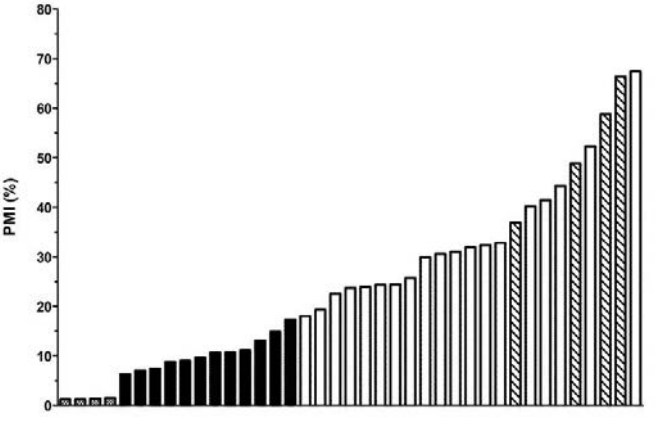
FR-OR011

Increased Synthesis of Liver Erythropoietin in Patients with Chronic Kidney Disease Sophie M. De Seigneux,[1] Stine Lundby,[2] Patrick Saudan,[1] Pierre-Yves F. Martin,[1] Carsten Lundby.[2] *[1]Service of Nephrology, Univ of Geneva; [2]Inst of Physiology, Univ of Zurich.*

Background: Anemia of chronic kidney disease (CKD) is thought to be related to impaired renal erythropoietin (Epo) production. Epo may be synthetized by the kidney but also by the liver in humans. Epo glycosylation pattern is dependent on its synthesizing cell, thereby indicating its origin. Here we tested the hypothesis that synthesis of Epo from non-kidney cells increases to compensate for insufficient renal Epo production in patients with moderate CKD.

Methods: We determined plasma [Epo] levels and Epo glycosylation patterns in 19 moderate non-dialyzed CKD patients (stage III-IV) and compared these to values obtained in healthy volunteers, rhEPO and umbilical cord plasma (liver derived Epo mainly).

Results: Despite higher Epo levels (15.75 (11.3 - 24.2) IU/L) compared to healthy controls (8.4 (7.56 - 8.98) IU/L, p<0.01), CKD patients were moderately anemic ([Hb]: 113 ± 11 g/dl). Half of the patients presented higher Epo levels than expected from the calculated values corrected for anemia. Glycosylation was increased in CKD patients (34 ± 12 %; measured as percent migrated isoform, PMI,open bars) when compared to healthy controls (8.6 ± 1 %; p<0.01, black bars) and rhEpo samples (1.4± 1.4 p<0.01, hatched bars), whereas the pattern did not differ from umbilical cord plasma (55 ± 10 %, p >0.05, lined filled bars) which is known to contain mainly liver derived Epo.



Renal function correlated strongly to glycosylation pattern assessed by PMI (R=-0.8, p<0.01), with patients having lowest eGFR diplaying higher Epo PMI values, indicating a larger part of liver derived Epo.

Conclusions: These results suggest that 1) moderate CKD patients exhibit preserved Epo levels despite declining renal function 2) this may be achieved by increasing liver Epo synthesis and 3) Epo originating from liver seems less erythropoietic.

Associations Among Erythroferrone and Biomarkers of Erythropoiesis and Iron Metabolism, and Treatment of Long-Term Erythropoiesis-Stimulating Agents in Patients on Hemodialysis Hirokazu Honda,[1] Yasuna Kobayashi,[2] Shoko Onuma,[3] Keigo Shibagaki,[4] Toshitaka Yuza,[4] Keiichi Hirao,[5] Toshinori Yamamoto,[2] Naohisa Tomosugi,[6] Takanori Shibata.[3] *[1]Div of Nephrology, Dept of Medicine, Showa Univ Koto Toyusu Hospital, Tokyo, Japan; [2]Div of Clinical Pharmacy, Dept of Pharmacotherapeutics, Showa Univ, School of Pharmacy, Tokyo, Japan; [3]Dept of Preventive Medicine, Showa Univ, School of Medicine; [4]Shibagaki Dialysis Clinic Jiyugaoka, Tokyo, Japan; [5]Shibagaki Dialysis Clinic Togoshi, Tokyo, Japan; [6]Kanazawa Medical Univ, Kanazawa, Japan.*

Background: The present study aimed to identify associations between erythroferrone (ERFE), a regulator of hepcidin 25, and biomarkers of erythropoiesis and iron metabolism. We also investigated the effects of the erythropoiesis-stimulating agents (ESA), continuous erythropoietin receptor activator (CERA) and darbepoetin-α (DA), on ERFE production in patients on hemodialysis (HD).

Methods: Blood samples were obtained from 59 patients before HD sessions on day 0 (baseline) for baseline cross-sectional analysis. Twenty patients who were injected with either CERA (N = 10) or DA (N = 10) at the end of the dialysis week (day 0), who were not iron-deficient (ferritin < 100 ng/mL and transferrin saturation < 20%) and had hemoglobin levels > 9 g/dL were selected from among the 59 patients. Blood was sampled serially before HD sessions on days 3, 5, 7 from patients on DA and on the same days and day 14 from those on CERA to assess impact of ESA on iron metabolism including ERFE.

Results: Levels of ERFE correlated inversely with those of hepcidin 25 and ferritin, and positively with soluble transferrin receptor. The hepcidin 25: ERFE ratio and hepcidin 25 levels positively correlated with ferritin levels. Levels of ERFE significantly increased from day 3 of treatment with DA and CERA and decreased by days 7 and 14, respectively. Levels of hepcidin 25 were decreased by ESA in accordance as those of ERFE increased.

Conclusions: Erythroferrone might be associated with iron metabolism in patients on HD. Both DA and CERA increased levels of ERFE that regulated hepcidin 25 and led to iron mobilization from body stores during erythropoiesis.

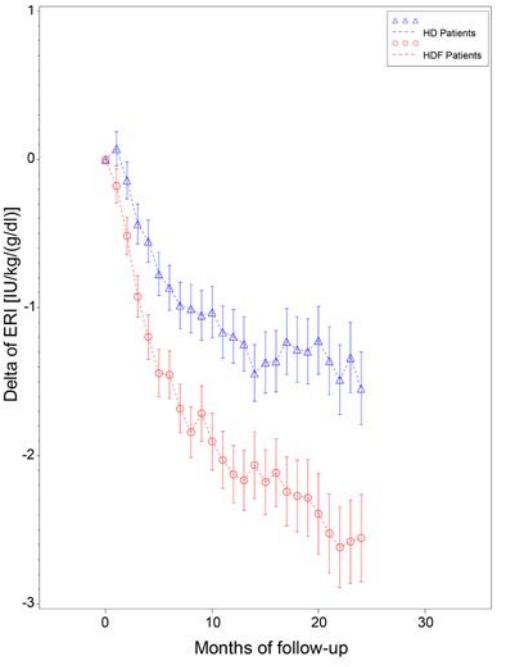
FR-OR013

Dynamics of ESA Resistance Index in Incident Hemodiafiltration and High-Flux Hemodialysis Patients Daniele Marcelli, Inga Bayh, Aileen Grassmann, Laura Scatizzi, Katharina Brand, Bernard J. Canaud. *Fresenius Medical Care, Bad Homburg, Germany.*

Background: Hemodiafiltration (HDF), combining diffusion and convection, provides efficient blood detoxification over a wide molecular weight range that may include erythropoiesis inhibiting agents. Study aim: to compare ESA resistance index (ERI) in incident HDF and high-flux hemodialysis (HD) patients. ERI is the weekly weight-adjusted ESA dose (U/kg/week) divided by hemoglobin level (g/dl).

Methods: 20,694 incident patients (7,674 HDF; 13,020 HD,) from 436 NephroCare clinics in 20 countries with ≥6 mths follow-up were studied between January 1 2007 and December 31 2013. Baseline (BL) was 6 mths after dialysis initiation; follow-up was 1.35±0.69 yrs. Exclusion criteria: BL presence of metastatic tumors, malnourishment (BMI <18.5 kg/m^2), treatment via catheter, age <18 years, less/more than thrice weekly dialysis, modality switch in month before BL, and missing ESA dose after BL. After propensity score matching to reduce bias by indication, a total of 6,568 patients (3,284 in each arm) remained.

Results: At BL, HDF patients had a non-significant higher ERI than HD patients (7.79 vs 7.48 IU/kg/(g/dl)) (p=0.06). ERI decreased by 0.087 IU/kg/(g/dl) per mth in HDF patients and significantly less in HD patients (0.050 IU/kg/(g/dl) per mth). The difference between both groups increased by 0.036 IU/kg/(g/dl) per mth. At 8.4 mths of follow-up, ERI was lower in HDF patients compared to HD patients. The delta ERI for each time interval versus BL also reveals ERI change dynamics (Figure).



Conclusions: ERI progressively decreased during the first 24 months on dialysis, but more sharply and to a great extent in the HDF group compared to the HD group. The dynamics of ERI change over the first year on dialysis may explain why previous studies encountered difficulties in recognizing ERI trends when various dialysis vintages are grouped together.

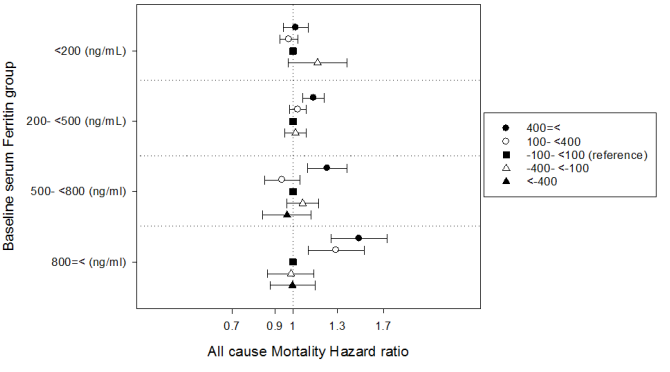
FR-OR014

Serum Ferritin Variations and Mortality in Incident Hemodialysis Patients Tae Hee Kim,[1] Joline L.T. Chen,[1,2] Elani Streja,[1] Connie Rhee,[1] Yoshitsugu Obi,[1] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]VA Long Beach; [3]UTHSC.*

Background: Previous studies on maintenance hemodialysis (MHD) patients have shown that higher serum ferritin may be associated with inflammation and higher mortality. Additional studies have shown that serum ferritin increase sharply in the first year of MHD and gradually increase over time. However, associations between changes in serum ferritin levels over the first 6 months of dialysis and mortality are unknown. We hypothesized that a rapid rise in serum ferritin is associated with higher risk of mortality.

Methods: In a cohort of 93,996 incident MHD patients receiving treatment from a large dialysis organization during 2007-2011, we examined mortality associations of change in serum ferritin from baseline patient quarter (first 91 days from dialysis start) to subsequent quarters using Cox proportional hazard models. Models were adjusted for demographics, comorbidities, markers of the malnutrition and inflammation complex (MICS) and intravenous iron dose. Serum ferritin change was divided into five strata: (<-400, -400 to <-100, -100 to <100, 100 to <400, and ≥400 ng/ml over 3 months). Associations were examined across strata of baseline serum ferritin (<200, 200 to <500, 500 to <800 and ≥800 ng/ml).

Results: Patients were 63±15 years old, 44% female, 32% African-American, and 60% diabetic. In patients with baseline serum ferritin ³200 ng/ml, a rise in serum ferritin ≥400 ng/ml/quarter was associated with higher all-cause mortality during the 5-year follow-up compared with no change in serum ferritin (-100 to <100 ng/ml).



Conclusions: Rapid rise in serum ferritin levels >400 ng/ml/quarter during the first 6-months after MHD initiation is associated with higher 5-year mortality in patients with elevated baseline serum ferritin. Studies evaluating the conditions influencing these serum ferritin changes and their associations with mortality are needed.

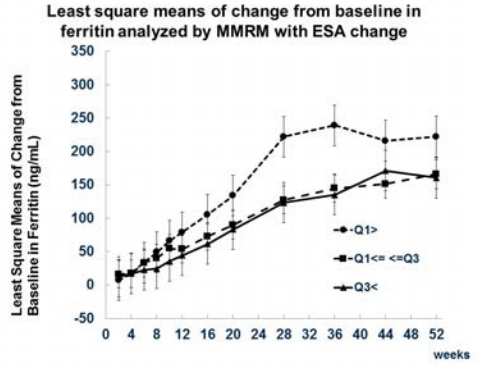
Decreasing ESA Dosage Can Be a Factor of the Increase in Ferritin Under the Administration of Ferric Citrate with Improving ESA Resistance Index

Keitaro Yokoyama,[1] Takashi Akiba,[2] Masafumi Fukagawa,[3] Masaaki Nakayama,[4] Hideki N. Hirakata.[5] *[1]Div of Nephrology and Hypertension, Jikei Univ School of Medicine, Tokyo, Japan; [2]Dept of Blood Purification, Kidney Center, Tokyo Women's Medical Univ, Tokyo, Japan; [3]Div of Nephrology, Endocrinology and Metabolism, Tokai Univ School of Medicine, Isehara, Japan; [4]Dept of Nephrology, Hypertension, Diabetology, Endocrinology, and Metabolism, Fukushima Medical Univ School of Medicine, Fukushima, Japan; [5]Japanese Red Cross, Fukuoka Hospital, Fukuoka, Japan.*

Background: Ferric citrate (an iron based phosphate binder) controlled serum phosphorus with lower concentrations and reduced the doses for ESA and intravenous iron in HD patients. Also, serum ferritin concentrations had a tendency to increase (Phase 3 trial).

Methods: To explore potential factors associated with an increase in ferritin values, data from the 52-week phase3 clinical study in Japanese HD patients were analyzed by a mixed model for repeated measurement (MMRM) including variables that were selected based on the results of correlation, simple linear regression, and multiple regression analyses. In addition, ESA resistance index (ERI) was analyzed to determine factors which contribute to it based on the result from the MMRM.

Results: The factor of the increase in ferritin was associated with not only the dosage of ferric citrate but also the degree of decrease in ESA dosage (Q1>: dosage was decreased in the course of study. Q1≤ to £Q3: dosage was not changed. Q3<: dosage was increased.).



In subjects whose ESA dosage was decreased in the course of the study, the ERI went lower by the administration of ferric citrate in spite of that initial dosage of ESA and ERI were higher than other subjects group.

Conclusions: Decreasing ESA dosage might increase serum ferritin level under the administration of ferric citrate with improving ERI.

Triferic Maintains Hemoglobin and Iron Balance Long Term: Open-Label Phase III Extension Studies

Carrie D. Guss, Raymond D. Pratt, Ajay Gupta, Vivian H. Lin. *R&D, Rockwell Medical Inc., Wixom, MI.*

Background: The objective of the Phase 3 extension studies was to confirm the safety of Triferic administered via dialysate for up to 18 months of treatment and to assess hemoglobin and iron status.

Methods: Patients who completed the Phase 3 randomized controlled treatment studies (RCT) could continue in the open-label (OL) extension studies for up to 18 months of combined participation. In the OL extensions, patients received ESA according to their site protocol and IV iron could be administered for presumed development of iron deficiency.

Results: Approximately 70% of patients completed the pivotal RCT and enrolled in the OL extension, providing a total of 412 patient-years of exposure to Triferic. Triferic reliably administered iron with each hemodialysis treatment. The average pre-HD to post-HD increment in serum total iron concentration was 96.2 ± 44.20 mg/dL. Chronic administration of Triferic maintained Hgb levels within the target range of 9.5 to 11.5 g/dL during the study. ESA requirements and CHr also remained stable from study baseline throughout the study. Pre-dialysis serum iron values were maintained at baseline levels. Serum ferritin concentrations declined from 372.8 ± 236.78 mg/L at OL study entry to 305.2 ± 219.36 mg/L at End of Treatment (EoT). Fewer patients who had received Triferic in the RCT studies required supplemental IV iron (48%) than patients who had received placebo (58%). OL long term safety was similar to the RCT results. The most frequent AE was procedural hypotension, occurring in 34.8% of patients. When adjusted for exposure, the rates of adverse events in the OL study were similar to those observed in the RCT.

Conclusions: Triferic administered long term (up to 18 months) reliably delivered iron with every treatment. Triferic administered via dialysate maintained Hgb while not increasing iron stores or increasing ESA doses. The safety profile was similar to that observed in the pivotal Phase 3 RCT studies. No anaphylaxis was observed in over 45,000 individual doses administered in this program.

FR-OR017

Longer Sustained Reduction of Serum Hepcidin Level (Hep) During the Treatment of Anemia with Epoetin Beta Pegol (CERA) as Compared to Epoetin Beta (rEPO) in Predialysis Stage-5 CKD Patients

Yusuke Kuroki,[1] Koji Mitsuiki,[1] Yuko Yoshida,[1] Hokuto Arase,[1] Kaneyasu Nakagawa,[1] Hideki Yotsueda,[1] Hideki N. Hirakata,[1] Naohisa Tomosugi.[2] *[1]Nephrology & Dialysis Center, Fukuoka Red Cross Hospital, Fukuoka, Japan; [2]Kanazawa Medical Univ.*

Background: Efficient iron utilization is required in ESA-induced erythropoiesis in CKD patients, Hep being a key factor to modulate iron turn-over in this situation. In the present study, changes in Hep and the related iron markers were examined before and after CERA administration in comparison with rEPO in pre-dialysis ESA-naïve stage 5 CKD patients.

Methods: Twenty-three patients were subjected to the study; age 70±13 [SD] y/o, m/f=15/8, DM/nonDM=10/13, eGFR 14±5 ml/min/1.73m^2, Hb 9.7±1.1 g/dl. They were assigned randomly to 2 groups, being treated with either rEPO (n=13) or CERA (n=10). Their baseline data were as follows; Hb 9.8 ± 0.9 (rEPO) vs. 9.6 ± 1.3 (CERA) g/dl, serum iron (SFe) 75 ± 25 vs. 77 ± 17 mg/dl, TSAT 28 ± 8 vs. 31 ± 9 %, ferritin 129 ± 117 vs. 173 ± 91 ng/ml, albumin 3.7 ± 0.5 vs. 3.6 ± 0.6 g/dl, IL-6 3.2 ± 2.8 vs. 3.8 ± 2.3 pg/ml, hs CRP 1038 ± 2539 vs. 1730 ± 4191ng/ml, and Hep 34 ± 19 vs. 52 ± 29 ng/ml, respectively. ESA was given in the morning, SFe and Hep were measured before and on the 2nd, 4th, 7th, 14th and 28th day. On the first day, circadian variation of SFe and Hep was evaluated. Hematological parameters, TSAT and ferritin were measured before and on the 28th day.

Results: Hep level was highest at 3 pm on the first day. Hb rose significantly in both group in associated with steep decrease in Hep in rEPO, being 34±19 to 7.7±8.5, and was returned to the baseline in 14 days. In CERA, Hep reduction was also observed but the trend was mild from 52±29 to 27±17 ng/ml on the 14th days. The decrease in Hep correlated significantly with the increase in reticulocyte production index, a marker of erythropoietic output, in all patients (r=0.66, p<0.01). These changes were associated with the significant decrease in SFe.

Conclusions: CERA has a sustained suppressive effect on Hep, which might contribute to its longer erythropoietic activity via enhancing iron utilization.

FR-OR018

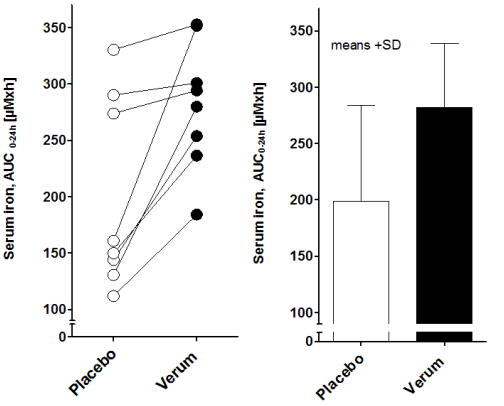
Clinical Pharmacology, Efficacy, and Safety of the Anti-Hepcidin Spiegelmer Lexaptepid Pegol

Iain C. Macdougall,[1] Enric Vilar,[2] Helmut Reichel,[3] Joachim H. Beige,[4] Leela Goldstein,[1] Frank Schwöbel,[5] Luciana Summo,[5] Kai Riecke.[5] *[1]Dpt. of Renal Medicine, King's College Hospital, London, United Kingdom; [2]Lister Hospital, Stevenage, United Kingdom; [3]Nephrological Center Villingen Schwenningen, Germany; [4]Hospital St. Georg, Leipzig, Germany; [5]NOXXON Pharma AG, Berlin, Germany.*

Background: Elevated hepcidin is frequent in hemodialysis patients and contributes to ESA-resistant anemia. Inhibiting hepcidin may therefore reduce resistance to ESA therapy and improve anemia. The anti-hepcidin L-RNA-Aptamer (Spiegelmer®) lexaptepid pegol binds and inactivates hepcidin and is in development for treatment of anemia.

Methods: We studied the pharmacological effects on iron metabolism, on anemia, and the safety of lexaptepid in 109 healthy subjects and patients with myeloma/lymphoma or on hemodialysis. A trial in dialysis patients with functional iron deficiency is ongoing.

Results: Lexaptepid increased iron concentrations and prevented the serum iron decrease after endotoxin challenge in healthy subjects. In patients with myeloma / lymphoma and functional iron deficiency, 2 doses/week of lexaptepid over 1 month increased hemoglobin by ³1 g/dL in patients with low reticulocyte Hb and high soluble transferrin receptor. In ESA-hyporesponsive dialysis patients, cross-over comparison with placebo showed increases in serum iron concentrations following lexaptepid administration, consistent with its anti-hepcidin action.



The recruitment of hemodialysis patients for twice weekly treatment with lexaptepid for one month is ongoing in a randomized controlled trial. Lexaptepid was well tolerated by healthy subjects and patients.

Conclusions: Lexaptepid was safe and well tolerated and showed pharmacodynamic activity in healthy subjects and ESA-hyporesponsive dialysis patients as well as signs of efficacy in anemic cancer patients with functional iron deficiency.

FR-OR019

Neutrophil Gelatinase-Associated Lipocalin (NGAL) Is Associated with Iron Status in Anemic Patients with Chronic Kidney Disease Min Jung Kim,[1] Il Young Kim,[1] Soo Bong Lee,[1] Joo Hui Kim,[1] Dong Won Lee,[1] Su Min Park,[2] Jong Man Park,[2] Woo Jin Jung,[2] Sang Heon Song,[2] Eun Young Seong,[2] Harin Rhee,[2] Ihm Soo Kwak.[2] *[1]Internal Medicine, Pusan National Univ Yangsan Hospital, Yangsan, Republic of Korea; [2]Internal Medicine, Pusan National Univ Hospital, Busan, Republic of Korea.*

Background: Iron deficiency anemia is common in patients with chronic kidney disease (CKD). Neutrophil gelatinase-associated lipocalin (NGAL) is known as a biomarker of acute kidney injury and predictor of the progression of CKD. In addition, recent studies have shown that NGAL is associated with iron metabolism by binding siderophores, small molecules containing iron. We investigated whether serum NGAL levels is associated with iron status in CKD patients with anemia.

Methods: This study included 257 CKD patients [estimated glomerular filtration rate (eGFR) < 60 ml/min/1.73m^2] who had anemia at the time of study enroll (hemoglobin levels < 13.0 g/dl in males and < 12.0 g/dl in females). The associations between serum NGAL and iron status [iron, total iron binding capacity, ferritin, transferrin saturation (TSAT)], eGFR, albumin, uric acid, lipid profile, calcium, phosphate, and C-reactive protein (CRP) were assessed.

Results: The CKD patients with TSAT ≤ 30 % had lower serum NGAL values than those with TSAT > 30% (274.9 ± 228.3 vs. 394.7 ± 232.2 ng/ml). In univariate analysis, serum NGAL correlated with eGFR (r = -0.367, P < 0.001), CRP (r = 0.253, P < 0.001), TSAT (r = 0.296, P < 0.001), and ferritin (r = 0.259, P < 0.001). In multivariate regression analysis, TSAT (β = 0.370, P < 0.001) was independently associated with serum NGAL in addition to CRP (β = 0.268, P < 0.001) and eGFR (β = -0.365, P < 0.001). However, ferritin lost its association with serum NGAL (β = 0.093, P = 0.132).

Conclusions: This study suggests serum NGAL is associated with iron status in anemic patients with CKD. Further studies are needed to demonstrate the role of NGAL in the assessment of iron deficiency and in the management of iron therapy for CKD patients.

FR-OR020

Safety and Hemoglobin Effect of Sotatercept, Administered Intravenously and Subcutaneously, for Maintenance of Hemoglobin in Hemodialysis Subjects: Interim Analysis of a Phase 2 Study Frank Dellanna,[1] Francisco Maduell,[2] Joan Fort,[3] Xavier Warling,[4] Hem N. Singh,[5] William T. Smith.[5] *[1]DaVita Nephrology, Duesseldorf, Germany; [2]Hospital Clinic of Barcelona, Barcelona, Spain; [3]Vall d'Hebron Univ Hospital, Barcelona, Spain; [4]Citadelle Regional Hospital Center, Liege, Belgium; [5]Celgene Corporation, Warren, NJ.*

Background: An ongoing randomized study is evaluating intravenous (IV) and subcutaneous (SC) sotatercept, an ActRIIA-IgG1 fusion protein ligand trap, for maintenance of hemoglobin (Hb) after switching from a prior erythropoietin-stimulating agent (ESA) in end-stage kidney disease (ESKD) subjects on hemodialysis (HD).

Methods: In part 1 of a 2-part phase 2 study, ESA-responsive ESKD/HD subjects with Hb between 10 and 12 g/dL were switched from ESA and randomized to open-label sotatercept (IV: 0.1 and 0.2 mg/kg; SC: 0.13 and 0.26 mg/kg) given every 14 days for up to 8 doses; a third dose group level of IV and SC is enrolling. Pharmacokinetic, safety, tolerability, and Hb effect were assessed. Intrasubject dose escalation was not permitted. Treatment failures (Hb <9 g/dL) were rescued with ESA or transfusion.

Results: Among subjects receiving sotatercept (N=30; IV: 0.1 mg/kg [n=7], 0.2 mg/kg [n=8]; SC: 0.13 mg/kg [n=7], 0.26 mg/kg [n=8]), 31 adverse event (AE) occurred in 100%, 67%, 57%, and 57%, respectively. Serious AEs occurred only in the IV 0.1 mg/kg group (29%). AEs were mostly mild/moderate, unrelated to study drug, relatively similar between groups, and generally consistent with subject medical histories. No dose- or route-dependent changes were seen in home blood pressure (BP); no injection site or hypersensitivity reactions were observed. At the end of the 99-day treatment phase, mean change from baseline Hb was -0.5 g/dL (IV 0.1 mg/kg), 0.3 g/dL (IV 0.2 mg/kg), -0.3 g/dL (SC 0.13 mg/kg), and -0.3 g/dL (SC 0.26 mg/kg); 57%, 13%, 43%, and 13% experienced treatment failure requiring rescue, respectively. In the IV 0.2 mg/kg group, 3 subjects discontinued after the first dose.

Conclusions: IV and SC sotatercept demonstrated acceptable safety in ESKD/HD, with no dose- or route-dependent effects on home BP. Enrollment in the highest dose group is ongoing.

Funding: Pharmaceutical Company Support - Study was sponsored by Celgene Corporation.

FR-OR021

The Role of Activin in the CKD-MBD Keith A. Hruska,[1] Toshifumi Sugatani,[1] Olga A. Agapova,[1] Yifu Fang,[1] Hartmut H. Malluche.[2] *[1]Pediatrics, Nephrology, Washington Univ School of Medicine, Saint Louis, MO; [2]Medicine, Nephrology, Univ of Kentucky, Lexington, KY.*

Background: At its inception, the CKD-MBD consists of vascular calcification, an osteodystrophy, decreased aklotho and stimulation of skeletal osteocyte FGF23 secretion. We have shown that inhibition of activin signaling through the activin type 2A receptor (ActRIIA), induced by CKD inhibits vascular calcification. Here, the other components of the CKD-MBD are analyzed.

Methods: CKD with hyperphosphatemia and 60% reduction in GFR (CKD-3) was induced at 14 weeks of age in our *ldlr-/-* high fat fed model of vascular calcification. Some CKD mice were treated with RAP-011 (a type 2 activin receptor, ActRIIA, ligand trap). Skeletal histomorphometry and microCT imaging, renal klotho levels, serum chemistries and FGF23 and PTH levels were measured. Activin klotho and ActRIIA levels were measured by elisa, RT-PCR, westerns and IHC.

Results: Activin levels in the circulation were 10 fold elevated. The *ldlr-/-* high fat fed model harbors a low turnover osteopenic osteodystrophy that was converted by CKD-3 to a high turnover state characterized by PTH levels of 430pg/ml (7 fold elevated), hyperphosphatemia, increased osteoblast numbers,and surfaces, increased osteoclast numbers and eroded surfaces, increased bone formation rates (BFR) but a significant decrease in BFR/osteoblast. CKD-3 decreased renal tubular klotho levels and produced marked (10 fold) elevations in FGF23 levels. Inhibiting activin by an ActRIIA ligand trap surprisingly reduced osteoblast number and surfaces, decreased BFR but increased BFR/osteoblast thereby preserving MAR. RAP-011 decreased osteoclast numbers and eroded surfaces. MicroCT imaging showed that RAP-011 increased cortical bone thickness and cortical bone area compared to CKD-3. RAP-011 treatment did not affect hyperphosphatemia, PTH levels or FGF23 levels. Inhibiting activin signaling increased renal tubular klotho levels.

Conclusions: Activin is a critical factor in the pathogenesis of the CKD-MBD causing aklotho deficiency, vascular and skeletal disease, and surprisingly playing a key role in the osteoblast dysfunction of CKD heretofore attributed solely to PTH and FGF23.

Increase in Trabecular Bone Volume by Inhibition of GSK-3β in Uremic Mice Narihito Tatsumoto,[1,2] Masaki Arioka,[2] Shunsuke Yamada,[1] Masanori Tokumoto,[4] Kazuhiko Tsuruya,[1,3] Takanari Kitazono,[1] Toshiyuki Sasaguri.[2] *[1]Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [2]Dept of Clinical Pharmacology, Faculty of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [3]Dept of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [4]Dept of Medicine, Fukuoka Dental College, Fukuoka, Japan.*

Background: Bone fracture increases the risk of hospitalization and mortality in patients with chronic kidney disease (CKD). Bone volume is closely related to the risk of fracture in CKD. Studies have shown that inhibition of glycogen synthase kinase (GSK)-3β, a critical component of Wnt/β-catenin signaling pathway, increases bone volume through accumulation of β-catenin. However, it remains unknown whether inhibition of GSK-3β increases bone volume in uremia.

Methods: The present *in vivo* study was performed to determine whether inhibition of GSK-3β could increase bone volume in adenine-induced CKD mice. Wild type mice were divided into three groups. One group was fed a control diet (CNT) and the other two groups were fed a diet containing 0.2% adenine with or without lithium chloride (LiCl), a GSK-3 inhibitor; CKD and CKD-LiCl group. GSK-3β heterozygous knockout mice were also fed a diet containing 0.2% adenine (CKD-GSK-3β$^{+/-}$). Bone and blood samples were collected after 6 weeks and trabecular (Tb) and cortical (Ct) bone were analyzed by micro-computed tomography.

Results: CKD mice developed azotemia, hyperphosphatemia, and secondary hyperparathyroidism, followed by a decrease in Ct bone thickness and no change in Tb bone volume after 6 weeks. Treatment with LiCl increased Tb bone volume, accompanied by polyuria and polydipsia. Tb bone volume increased in CKD-GSK-3β$^{+/-}$ mice compared with CNT and CKD mice. There were no significant differences in kidney function, hyperphosphatemia, hyperparathyroidism, and Ct bone thickness among three CKD groups.

Conclusions: Inhibition of GSK-3β increased Tb bone volume in adenine-induced uremic mice.

FR-OR023

Sclerostin Knock-Out Protects from Uremia-Induced Cortical Bone Loss in a Murine Model of Chronic Renal Failure Daniel Cejka,[1] Diego Michael Parada Rodriguez,[1] Stefanie Pichler,[1] Rodrig Marculescu,[5] Ina Kramer,[2] Michaela Kneissel,[2] Thomas Gross,[3] Andreas G. Reisinger,[3] Dieter Pahr,[3] Marie-Claude M. Faugere,[4] Martin Haas,[1] Hartmut H. Malluche.[4] *[1]Div of Nephrology & Dialysis, Dept of Medicine III, Medical Univ Vienna, Vienna, Austria; [2]Musculoskeletal Disease Area, Novartis Insts for BioMedical Research, Basel, Switzerland; [3]Inst of Lightweight Design and Structural Biomechanics, Vienna Univ of Technology, Vienna, Austria; [4]Div of Nephrology, Bone and Mineral Metabolism, Dept of Internal Medicine, Univ of Kentucky, Lexington, KY; [5]Dept of Laboratory Medicine, Medical Univ Vienna, Vienna, Austria.*

Background: Renal osteodystrophy (ROD) affects the majority of patients with advanced chronic kidney disease (CKD) and is characterized by progressive bone loss. This study evaluates the effects of sclerostin-knock-out on bone in a murine model of CKD.

Methods: Severe CKD was surgically induced in sclerostin-knock-out-mice (SOST-KO-CKD) and wild-type (WT-CKD). Mice with normal kidney function serve as controls (SOST-KO-CTRL, WT-CTRL). After 3 months of CKD, blood was drawn and vertebrae and tibia were collected for histomorphometric and µCT analyses.

Results: Cortical thickness (Ct.Th) of the tibia was significantly higher in sost-ko-CKD mice compared to wt-CKD mice ($p<0.001$). WT-CKD mice had lower Ct.Th compared to WT-CTRL ($p<0.05$), whereas no significant differences in Ct.Th were found between SOST-KO-CKD and SOST-KO-CTRL groups. Compared to WT-CKD mice, SOST-KO-CKD animals had higher trabecular number ($p<0.001$) and trabecular thickness ($p<0.001$) and lower trabecular separation ($p<0.001$). Mineral density of trabecular bone was higher ($p<0.001$) in SOST-KO-CKD mice compared to WT-CKD animals. In the lumbar vertebrae, bone volume/tissue volume was higher in SOST-KO-CKD mice compared to the WT-CKD group ($p<0.001$). Osteoid maturation time and mineralization lag time were not influenced by SOST-KO.

Conclusions: Sclerostin knock-out leads to increased bone mass and improved microarchitecture but does not alter osteoid mineralization in a murine model of CKD. Inhibition of sclerostin may be a promising approach to prevent bone loss in CKD.

FR-OR024

Bone Health in Incident Renal Transplant Recipients: A Prospective Bone Biopsy Study Pieter Evenepoel,[1] Geert J. Behets,[2] Liesbeth Viaene,[1] Patrick C. D'Haese.[2] *[1]Immunology and Microbiology, Catholic Univ Leuven, Leuven, Belgium; [2]Pathophysiology, Univ of Antwerp, Antwerp, Belgium.*

Background: Renal transplant recipients are at increased risk of fracture especially in the early post-transplant period. A better knowledge of the pathophysiology of post-transplant bone disease may open perspectives for targeted therapy. More specifically the role of immunosuppressive drugs, persistent hyperparathyroidism and inflammation needs to be elucidated. Bone histomorphometry is the gold standard to assess bone health.

Methods: Patients with paired bone biopsies at time of transplantation and 1 year, enrolled in an ongoing study that aims to unravel the natural history of CKD-MBD after transplantation (NCT01886950), were included in the present interim analysis (n=36, 29 males, age 54 ± 13 yrs). Maintenance immunosuppression consisted of steroids, a calcineurin inhibitor and mycophenolate mofetil. Mean cumulative methylprednisolone dose was 1.7 ± 0.7 g/d. None of the subjects had current or prior exposure to anti-resorptive agents.

Results: Histomorphometric parameters determined at baseline did not (or at best poorly) correlate with parameters determined at 1 year. Static parameters of bone formation (Ob.Pm/T.Pm (%): 0.6 [0.0 -3.7] vs 1.9 [0.0 – 4.0]) and resorption (EPm/B.Pm (%) 2.1 [0.1-4.3] vs 4.7 [3.3 – 8.1]; Oc.Pm/T.Pm (%): 0.0 [0.0 - 0.6] vs 0.9 [0.0 – 1.4]) decreased after transplantation. Inter-individual variation, however, was substantial, and significance was reached for bone resorption and osteoclast perimeter only. Circulating levels of TRAP5b, a biomarker of osteoclast activity, changed accordingly (3.0 [2.0 -4.8] vs 4.7 [3.0- 7.1] U/L, p=0.003). Correlation statistics showed a significant correlation between change of EPm/B.Pm and TRAP5b over time. Trabecular bone loss during the study period was minimal. Cumulative steroid dose, but not PTH level was identified as a significant correlate.

Conclusions: Our data confirm a reduction of bone activity early after transplantation. Additional studies are required to further define underlying pathophysiological mechanisms. Trabecular bone loss in contemporaneous transplantation is minimal, most probably as a consequence of steroid minimization.

FR-OR025

Chronic Kidney Disease Is Associated with Progressive Increase in Arterial Stiffness and Bone Loss Over 1 Year Rathika Krishnasamy,[1,2,3] Nicole M. Isbel,[1,2] David W. Johnson,[1,2] Tony Stanton,[4] David Mudge,[1,2] Scott B. Campbell,[1,2] Sven-Jean Tan,[5] Nigel David Toussaint,[5] Carmel M. Hawley.[1,2] *[1]School of Medicine, The Univ of Queensland, Brisbane, Australia; [2]Dept of Nephrology, Princess Alexandra Hospital, Brisbane, Australia; [3]Dept of Nephrology, Nambour General Hospital, Brisbane, Australia; [4]Cardiovascular Imaging Research Group, The Univ of Queensland, Brisbane, Australia; [5]Dept of Nephrology, The Royal Melbourne Hospital, Melbourne, Australia.*

Background: To assess changes in arterial stiffness, bone structure and markers in stage 4/5 chronic kidney disease (CKD) compared with healthy controls.

Methods: In this prospective, single-centre, observational study, **bone indices** using peripheral quantitative computed tomography (pQCT) [cortical bone mineral density (cBMD), trabecular bone mineral density (tBMD), strength-strain index (SSI), bone mineral content (BMC) and cortical cross-sectional area (cCSA)], **arterial stiffness** [pulse wave velocity (PWV)] and **bone markers** including plasma intact fibroblast growth factor-23 (FGF23) and soluble α-klotho (sKl)were compared between CKD stage 4/5 and controls at baseline and 12 months (12m).

Results: Forty CKD [mean estimated glomerular filtration rate (eGFR):19.5±6.7mL/min/1.73m^2] and 42 controls (eGFR:88.6±12.9mL/min/1.73m^2) completed follow-up. At baseline, CKD subjects had lower cBMD ($p=0.04$), higher aortic PWV ($p=0.047$) and FGF23 ($p=0.001$) compared to controls. Lower baseline cBMD independently correlated with higher PWV ($\beta=-0.51$,$p<0.001$) in the CKD group. At 12m, CKD subjects had a significant decline in cBMD (-0.87%,$p=0.01$), tBMD (-1.70%,$p=0.03$), BMC (-2.60%,$p<0.001$), cCSA (-1.62%,$p=0.01$) and SSI (-3.79%,$p=0.02$) and an increase in PWV by 1.3m/s (16.7%,$p<0.001$). Serum phosphate, calcium, parathyroid hormone and sKl did not significantly change over 12m. FGF23 levels increased [240.6(141.9-1129.8) to 396.8(160.3-997.7),$p=0.001$] and was independently associated with changes in cBMD and PWV. Bone and vascular parameters remained unchanged in controls.

Conclusions: CKD was associated with significant losses of bone structure and greater increases in arterial stiffness and FGF23 levels over 12 months.

FR-OR026

Vascular Calcification Is Mediated by ERK-Dependent Upregulation of Pit1 via Rac1/NADPH/MR Activity Victor Manuel Barrientos,[1] Néstor Abarzúa,[1] Diego Varela,[1] Rodrigo Alzamora, Luis F. Michea.[1,2] *[1]ICBM, Univ de Chile, Chile; [2]Millenium Inst on Immunology and Immunotherapy, Chile.*

Background: Vascular calcification (VC) is a mayor mortality risk factor in patients with chronic kidney disease. During VC, vascular smooth muscle cells (VSMC) of the tunica media transdifferentiate into osteoblast-like cells. High extracellular phosphate (HP) promotes VC through the induction of the sodium-dependent phosphate cotransporter (Pit1) activity, increased NADPH oxidase activity (Nox1) and the expression of osteochondrogenic factors (OCF). Recent studies indicate that antagonists of the mineralocorticoid receptor (MR) ameliorate/prevent experimental VC and arteriosclerosis in mice. The small GTPase Rac1 modulates MR and Nox activity in VSMC. However, the role of Rac1 on vascular calcification remains unknown. We hypothesize that in VSMC, HP activates MR via Rac1 leading to induction of Nox and ERK1/2 activity, promoting VC.

Methods: Effects of HP on VC (Alizarin red staining) and OCF gene induction (RT-qPCR) were evaluated in rat aortic VSMC (A7r5). Inhibitors of Rac1 (NSC23766), MR (spironolactone) and Nox1 (apocynin) were used to determine signaling pathways involved in the activation of ERK caused by HP. Nox activity was determined using the Hyper H_2O_2 Biosensor. A7r5 cells were stimulated with HP, HP+NCS23766 or HP+apocynin to determine the role of Rac1 and MR on HP-induced H_2O_2 production. n=4-5 per group.

Results: HP increased Pit1 mRNA, OCF mRNA (cbfa1 and Sox9) and Nox1 mRNA ($p<0.05$ *vs.* normal phosphate (NP)) and caused mineralization. Aldosterone (100nM) potentiated the effect of HP on mineralization and gene expression ($p<0.05$). Incubation in the presence of spironolactone (10uM) prevented all the effects of aldosterone. Inhibition of Rac1 and NADPH oxidase activity prevented HP-induced H_2O_2 production (2.6% NP; 25% HP; 1.8 % HP+NSC at 20 min of stimuli;$p<0.05$ *vs.* HP). The presence of Rac1 or MR antagonists in culture medium suppressed HP-induced activation of ERK (2.7 times at 10 min;$p<0.05$ *vs*. 0 min).

Conclusions: We conclude that high phosphate-dependent calcification is mediated by ERK-dependent upregulation of Pit1 via Rac1/NADPH/MR activity. Funding: FONDECYT 1130550, IMII P09-016-F.

Inhibition of Wnt Signaling and Matrix Metalloproteinases Attenuates Calcium and Phosphate Induced Calcifications in Vascular Smooth Muscle Cells Uwe Querfeld,[1,2] Veronika Bobb,[2] Christian Freise.[2] *[1]Pediatric Nephrology, Charité, Berlin, Germany; [2]Center for Cardiovascular Research, Charité, Berlin, Germany.*

Background: The trans-differentiation of vascular smooth muscle cells (VSMC) into an osteoblast-like phenotype and matrix remodeling are essential in the pathogenesis of vascular calcifications in patients with chronic kidney disease (CKD). We have previously shown that the matrix metalloproteinases (MMP)-2 and -9 facilitate VSMC calcifications and, vice versa, their inhibition attenuates this process **[1]**. We studied the effects of calcifying conditions, recombinant MMPs and MMP-inhibitors on signal transduction in VSMC.

Methods: Mimicking the disturbed mineral balance during CKD, the trans-differentiation/calcification of murine VSMC was induced by a calcification medium (CM) containing elevated concentrations of calcium and phosphorus (Ca/P). MMP activities were modulated by recombinant MMP-2 or -9 and selective MMP inhibitors. Wnt activation was induced by a recombinant Wnt agonist and assessed in reporter plasmid (pGL4.49[luc2P/TCF-LEF RE/Hygro]) transfected VSMC. MMP-secretions and mRNA expressions were determined by substrate assays and qPCR, respectively.

Results: CM-induced calcifications in VSMC were accompanied by enhanced Wnt-signaling. Even under normal culture conditions, Wnt activation with a Wnt agonist induced VSMC calcifications associated with enhanced mRNA expression and secretion of MMP-2/-9. These Wnt-mediated effects were inhibited by MMP-2/-9 inhibitors. Treatment of VSMC with recombinant MMP-2/-9 induced a time-delayed Wnt-activation after 72h.

Conclusions: Enhanced levels of Ca/P induce Wnt-activation in VSMC, resulting in enhanced production of MMP-2/-9 which further promotes VSMC calcification. These results confirm clinical studies showing upregulations of MMP-2/-9 in experimental uremia [1] and in arteries of patients with CKD [2]. The therapeutic potential of MMP- or Wnt-inhibitors in the prevention of vascular calcification should be further explored in animal models of CKD-associated arteriosclerosis. [1] JASN 25: 2014 (SA-OR062, p.95A; TH-PO555, p.233A; FR-PO833, p.562A) [2] Chung A. et al, Circulation 120, 792-801 (2009).

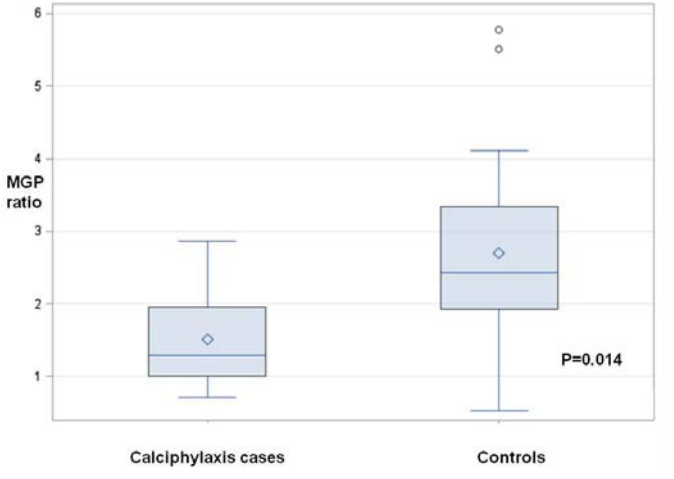
Calciphylaxis Is Characterized by Vitamin K Deficiency and Impaired Matrix Gla Protein Carboxylation Sagar U. Nigwekar,[1] Rajeev Malhotra,[1] Julia Beth Wenger,[1] Sarah Booth,[2] Ravi I. Thadhani.[1] *[1]Massachusetts General Hospital; [2]Tufts Univ.*

Background: Calciphylaxis, a dermal arteriolar calcification disorder linked with high mortality, has unclear pathogenesis. We investigated vitamin K metabolism and its effects on vitamin K dependent carboxylation of calcification inhibitor, Matrix Gla Protein (MGP), in calciphylaxis patients.

Methods: We prospectively recruited 20 ESRD patients with biopsy-confirmed calciphylaxis and obtained plasma samples and clinical information at the time of calciphylaxis diagnosis. Plasma samples and clinical information were also obtained from 20 controls (ESRD patients without calciphylaxis) matched to cases by age, sex, race, and warfarin status. Plasma levels of Proteins Induced by Vitamin K Absence (PIVKA-II) a sensitive measure of vitamin K deficiency, carboxylated MGP (c-MGP), and uncarboxylated MGP (uc-MGP) were measured using ELISA assays. MGP carboxylation status was derived by calculating c-MGP/uc-MGP ratio (MGP ratio). Prevalence of vitamin K deficiency (defined by PIVKA-II level ³2 ng/mL) was compared between cases and controls using Chi-square analysis. MGP ratios were compared between cases and controls using a Mann Whitney U test and multivariable linear regression.

Results: Prevalence of vitamin K deficiency was higher in cases compared to controls (90% vs. 50%, P=0.006) including in patients not on warfarin/vitamin K antagonist therapy (83% vs. 35%, P=0.014). Median MGP ratio was lower in cases compared to controls (1.29 vs. 2.42, p=0.001) including in patients not on warfarin (1.64 vs. 2.98, p <0.001).



In multivariable analyses adjusted for clinical characteristics, vitamin K deficiency was associated with a 48% reduced MGP ratio (P=0.004).

Conclusions: High prevalence of vitamin K deficiency and its potential impact on MGP carboxylation in calciphylaxis call for a therapeutic trial of vitamin K supplementation in calciphylaxis.

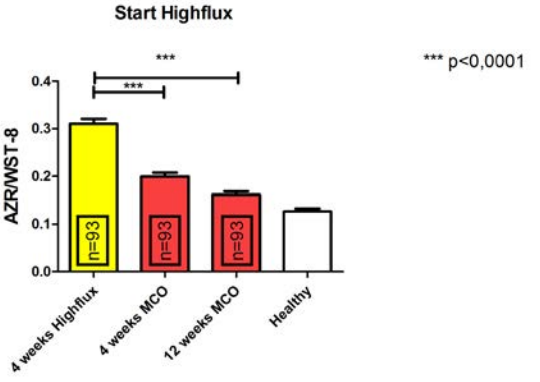
Dialysis with Medium Cut-Off (MCO) Filters Reduces In Vitro Calcification of Human VSMC: Lessons from a Randomized Clinical Trial Daniel Zickler,[1] Markus Storr,[3] Matthias Girndt,[2] Roman Fiedler,[2] Kevin Willy,[1] Ralf Schindler.[1] *[1]Dept of Nephrology and Internal Intensive Care Medicine, Charité Univ Medicine, Berlin; [2]Dept of Internal Medicine II, Martin-Luther-Univ, Halle; [3]Research & Development, Gambro Dialysatoren GmbH, Hechingen.*

Background: Vascular calcification is increased in CKD patients, partly caused by insufficient removal of inflammatory proteins with conventional dialysis filters. We assessed whether dialysis with MCO filters, which allow elimination of middle-sized inflammatory proteins with only limited permeability for albumine, influences vascular calcification in vitro.

Methods: 50 patients were dialysed in a randomized controlled clinical "first-in-man" trial with a MCO and a Highfluxfilter for four weeks in a randomized order. To test for longterm effects the patients were continued on their filter for eight more weeks. After each phase serum samples were drawn. In human VSMC calcification was induced and serum samples were added. After 7-12 days in vitro calcification was assessed via Alizarin red and Alkaline phosphatase assays and normalized to WST-8.

Results: Calcification in VSMC incubated with serum drawn after MCO dialysis was reduced compared to Highflux serum. Serum from patients, who started on a Highflux membrane showed a 35 % reduction (p<0,0001) of alizarin red staining after 4 weeks and a 49% (p<0,0001)reduction after 12 weeks of MCO dialysis. Alkaline phosphatase showed a 23% reduction after 4 weeks and a 32% reduction after 12 weeks MCO. Accordingly, serum from patients, who started on MCO showed an increase of calcification after switch to highflux dialysis.



Conclusions: Dialysis of with MCO filter reduces in vitro vascular calcification. Our results encourage further investigation of the use of MCO filters in chronic dialysis patients with assessment of radiologic signs of vascular calcification and hard clinical end points.

First Experience with a Novel Inhibitor of Vascular Calcification (SNF472) in Healthy Volunteers and ESRD Patients on Hemodialysis Joan Perelló, Carolina Salcedo, Pieter H. Joubert, Ana-Zeralda Canals, Miquel D. Ferrer. *Sanifit, Palma, Spain.*

Background: SNF472, an intravenous (i.v.) formulation of myo-inositol hexaphosphate, is being developed for treating calciphylaxis and for preventing vascular calcification progression in patients with end-stage renal disease on hemodialysis. It selectively inhibits the final common pathway in the etiology of vascular calcification, the formation and growth of hydroxyapatite (HAP) crystals. Non-clinical investigations showed adequate evidence of efficacy and safety to warrant a first study in humans.

Methods: A double-blind, randomized, phase 1 clinical trial was performed in two cohorts of 8 male healthy volunteers (HV) and one cohort of 8 hemodialysis (HD) patients. Single ascending doses of 0.5, 5, 9 and 12.5 mg/kg of SNF472 were administered through 4-hour i.v. infusion to HV into a forearm vein. HD patients received a single i.v. dose of 9 mg/kg through the dialysis tubing before the filter during the 4 hours of dialysis. Safety parameters, including extensive ECG monitoring, were recorded. Blood samples were obtained up to 24h for safety and pharmacokinetics. A PD (pharmacodynamics) assay was used to assess the potential of ex vivo formation of HAP crystals.

Results: SNF472 was well tolerated and no systemic adverse events were observed. Several HV reported irritation at the infusion site. This effect was concentration-dependent (not dose-dependent). In HD patients SNF 472 is diluted >500-fold in the dialysis system before reaching the patient and no local irritation occurred. No effects were seen in safety parameters, including ECG. Ionized calcium was slightly below the lower limit of normal in HV at 12.5 mg/kg. The 5, 9 and 12.5 mg/kg doses produced measurable plasma concentrations above the anticipated EC50 (5µM) and showed a 70-80% reduction in the ex vivo HAP crystal formation PD assay. HD patients had similar SNF472 plasma concentrations (suggesting low SNF472 clearance through the dialysis membrane) and PD effects to HV. Plasma ionized calcium levels were stable.

Conclusions: The data available suggests a favourable benefit/risk ratio of SNF472 and supports further studies in the target population. Supported by RETOS COLABORACIÓN RTC-2014-2460-1.

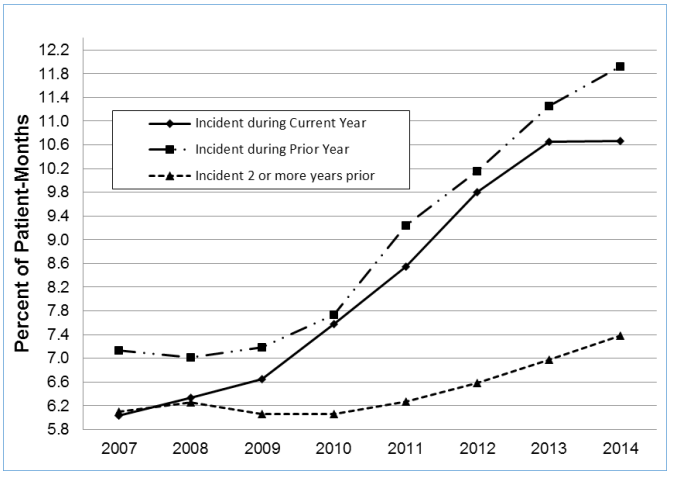
FR-OR031

Use of Peritoneal Dialysis (PD) Before and After the Bundled Prospective Payment System (PPS) Richard Hirth,[1] Tammie A. Nahra,[1] Adam S. Wilk,[1] Marc Turenne,[2] Jonathan H. Segal,[1] John Wheeler,[1] Kathryn Sleeman,[1] Wei Zhang.[1] *[1]UM-KECC, Univ of Michigan, Ann Arbor, MI; [2]Arbor Research Collaborative for Health, Ann Arbor, MI.*

Background: PD rates steadily eroded prior to the PPS. Because the PPS bundles injectable drugs, which are used less in PD relative to hemodialysis (HD) while paying the same rate for PD and HD, the PPS increases the incentive to provide PD. PD rates began to rise in anticipation of the PPS and continued to rise after its implementation. This study extends these early observations to include 4 years under the PPS and examines whether the PD supply shortages of 2014 impacted the growth of PD.

Methods: We used Medicare claims to examine trends in % of patient-months with PD during 2007-2014, for patients incident during the current year, prior year and ³2 years prior. The study period includes 3 pre-PPS years (2007-09), a transition year when the PPS was anticipated but not yet implemented (2010) and the first 4 years of the PPS (2011-14).

Results: PD continued to increase as a % of patient-months through the transition and post-bundle period. Initial increases occurred in the current and prior year cohorts with a trailing increase in the ³2 year cohort, reaching 10.7%, 11.9% and 7.4%, respectively by 2014 (vs. 6.0%, 7.1% and 6.1% in 2007). Growth stalled in the current year cohort during 2014, coincident with PD supply shortages.



Conclusions: PD use continued to increase under the PPS and is now reflected in increases among patients incident ³2 years prior, suggesting that the initial increases among newer patients are translating into longer-term modality tenure. PD fluid shortages are coincident with a stalling of growth among patients incident in 2014. Monitoring modality trends among the 2014 incident cohort will help determine whether those patients eventually started PD after shortages eased or if their rates never catch up.

Funding: Other U.S. Government Support

The Peritoneal Dialysis Outcomes and Practice Patterns Study (PDOPPS): Preliminary Findings from the First Year

Jeffrey Perl,[1] Junhui Zhao,[2] Brian Bieber,[2] Yun Li,[3] Simon J. Davies,[4] David W. Johnson,[5] James A. Sloand,[6] Hideki Kawanishi,[7] Bruce M. Robinson,[2] Francesca Tentori.[2,8] *[1]St. Michael's Hospital, Univ of Toronto, Toronto, ON, Canada; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Univ of Michigan, Ann Arbor, MI; [4]Univ Hospital of North Midlands, Stoke-on-Trent, United Kingdom; [5]Princess Alexandra Hospital, Brisbane, Queensland, Australia; [6]Baxter Healthcare Corporation, Deerfield, IL; [7]Tsuchiya General Hospital, Hiroshima, Japan; [8]Vanderbilt Univ, Nashville, TN.*

Background: The PDOPPS is a prospective cohort study underway in the United States (US), Australia, Canada, Japan, and the United Kingdom, in collaboration with the International Society for Peritoneal Dialysis. PDOPPS aims to understand the impact of clinical practices on patient outcomes, including patient and technique survival. Here, we present results from the first year of data collection.

Methods: 170 randomly selected facilities and 6000 patients will participate in the initial study. A stratified random selection of facilities has yielded national samples of facilities and patients, with 20-45 patients per site. Clinical, demographic, biochemical, and treatment data are collected at 4-month intervals. Follow up is 3-years or until death, kidney transplantation, or 120-days after a change in permanent dialysis modality. Early descriptive data are presented for the three countries.

Results: To date, 99 facilities and 2211 patients have been recruited. Selected patient and treatment characteristics vary widely across countries (Table 1).

Table 1: Selected patient and treatment characteristics in the three initial PDOPPS countries

	US	Canada	Japan
Patient characteristics			
Age, years	57.2	61.6	65.0
Female	45%	39%	35%
Time on PD, years	1.9	2.1	2.1
Diabetes*	29%	35%	31%
Glomerulonepritis*	14%	15%	32%
Coronary heart disease	27%	22%	12%
PD therapy			
# of PD patients per facility	39	75	33
APD	73%	41%	26%
# of overnight exchanges	4.6	5.3	3.6
> 1 daytime exchange	36%	49%	20%
CAPD	27%	59%	74%
# of daytime exchanges	3.9	3.5	3.4
Residual kidney function, peritoneal membrane function, and dialysis adequacy			
Urine volume, L/24hr	0.71	0.92	0.77
D/P creatinine	0.67	0.75	0.66
Total Kt/V	2.32	2.1(1.53)	1.82

As of May 2015; results are shown as mean or %

US: facility N= 56, patient N=507; Canada: facility N=20, patient N=449, Japan: facility N=18, patient N=254

Data collection from Austrilia and the United Kindom is just underway.

* As primary cause of ESRD

Conclusions: PDOPPS is the largest international study of PD patients and outcomes. Early findings demonstrate variability in PD practices (e.g. schedule, adequacy) across countries. PDOPPS will be a valuable resource to identify optimal practices and improve outcomes for patients on PD.

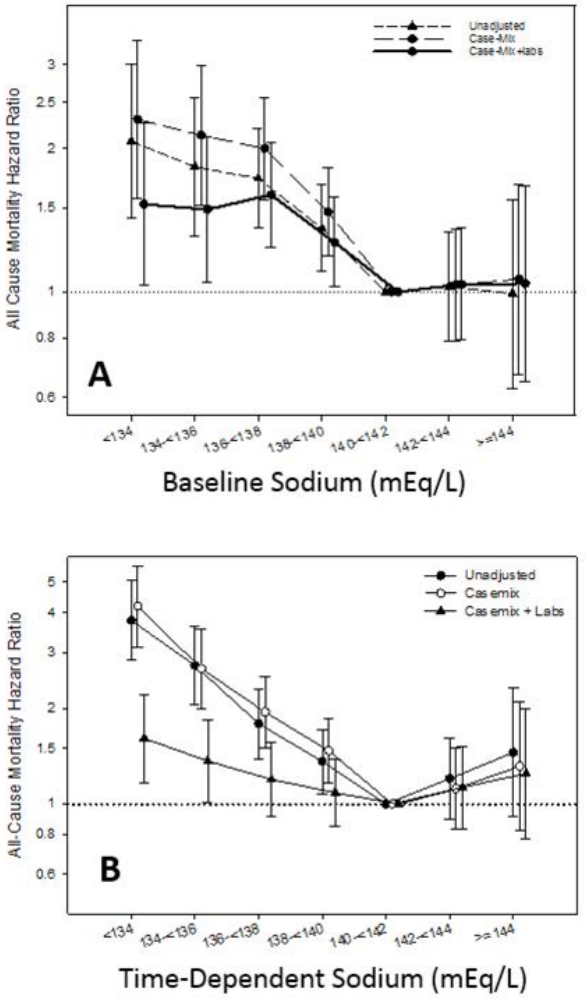
Risk Factors and Sequelae of Hyponatremia in a National Peritoneal Dialysis Cohort

Vanessa A. Ravel,[1] Rajnish Mehrotra,[2] John J. Sim,[3] Kevin T. Harley,[1] Alpesh Amin,[1] Juan Carlos Ayus,[4] Steven M. Brunelli,[5] Elani Streja,[1] Csaba P. Kovesdy,[6] Kamyar Kalantar-Zadeh,[1] Connie Rhee.[1] *[1]UC Irvine; [2]UWashington; [3]Kaiser Perm SC; [4]Renal Consultants Houston; [5]DaVita Clin Research; [6]UTHSC.*

Background: Hyponatremia is common in hemodialysis patients and has been linked with higher mortality risk. In peritoneal dialysis (PD) patients, few studies have examined the association of hyponatremia with mortality which have shown mixed findings. We sought to examine predictors of hyponatremia in a national PD cohort, and hypothesized that lower serum sodium (Na) is associated with higher death risk.

Methods: We examined a 5-year (1/2007-5/2011) cohort of 4687 incident PD patients from a large US dialysis organization with one or more serum Na measures within the 1st 91-days of dialysis. We examined predictors of baseline hyponatremia (Na<140mEq/L) using case-mix+laboratory adjusted logistic regression models. We then examined the association of Na with all-cause mortality. Baseline and time-dependent Na as a proxy of long- and short-term exposure—mortality associations, respectively, were estimated using Cox models with 3 adjustment levels: Unadjusted, case-mix, and case-mix+laboratory adjusted.

Results: Having diabetes; lower residual kidney function, albumin, PTH; and higher glucose, calcium, and ferritin were associated with higher risk of hyponatremia. Baseline Na levels <140mEq/L were associated with higher mortality across all 3 models (ref: Na 140-<142mEq/L). In time-dependent analyses, Na levels <140mEq/L were also associated with incrementally higher death risk in case-mix models. After further adjustment for laboratory covariates, Na—mortality associations persisted for levels <134mEq/L.



Conclusions: In PD patients, lower serum Na levels are associated with higher mortality. Further studies are needed to determine if correction of hyponatremia improves outcomes in this population.

Center-Specific Factors Associated with Peritonitis Risk - A Multi-Center Registry Analysis Annie-Claire Nadeau-Fredette,[1,2,3] David W. Johnson,[1,2] Carmel M. Hawley,[1,2] Elaine M. Pascoe,[1] Yeoung Jee Cho,[1] Philip A. Clayton,[2] Sunil V. Badve,[1] Kamal Sud,[1] Monique Renee Borlace,[1,2] Neil Boudville,[2] Stephen P. McDonald.[2] *[1]Princess Alexandra Hospital, Australia; [2]Australia and New Zealand Dialysis and Transplant Registry; [3]Maisonneuve-Rosemont Hospital, Canada.*

Background: Previous studies have reported significant variation in peritonitis rates across dialysis centers. Limited evidence is available to explain this variability. This study aimed to assess the center-level predictors of peritonitis and their relationship with peritonitis rate variation.

Methods: This registry study included all incident peritoneal dialysis (PD) patients treated in Australia between October 2003 and December 2013. The primary outcome was peritonitis rate, evaluated in a mixed effects negative binomial regression model including patient and center-level characteristics. Peritonitis-free survival was assessed as a secondary outcome in a Cox proportional hazards model.

Results: Overall, 8711 incident PD patients from 51 dialysis centers were included. Center-level predictors of lower peritonitis rates included small center size (HR 0.78, 95% CI 0.69-0.90), high proportion of PD (HR 0.87, 95% CI 0.77-0.99), low performance of peritoneal equilibration test at dialysis start (HR 0.78, 95% CI 0.66-0.93), and low proportion of hospitalisation for peritonitis (HR 0.88, 95% CI 0.75-0.96). In contrast, low proportion of automated PD exposure (HR 1.24, 95% CI 1.10-1.39), large icodextrin exposure (1.26, 95% CI 1.10-1.44) and low (HR 1.25, 95% CI 1.11-1.41) or high (HR 1.14, 95% CI 1.01-1.30) use of antifungal prophylaxis at the time of peritonitis were associated with a higher peritonitis rate. Similar results were obtained for peritonitis-free survival. Accounting for center-level characteristics appreciably decreased peritonitis variability among dialysis centers (p=0.02).

Conclusions: This study identified specific center-level characteristics associated with variation in peritonitis risk. Whether or not these factors are directly related to peritonitis risk or surrogate markers of other characteristics is uncertain and should be validated in further studies.

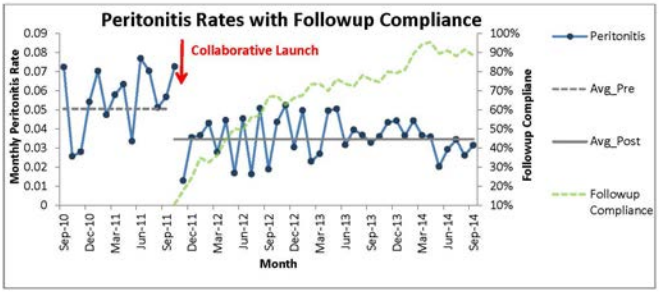
FR-OR035

Successful Reduction in Peritonitis Rates in U.S. Pediatric Dialysis Units: Results of the SCOPE Collaborative Alicia Neu,[1] Troy Richardson,[2] John P. Lawlor,[2] Jayne Stuart,[2] Nancy McAfee,[3] Jason Newland,[4] Bradley Warady.[4] *[1]JHMI; [2]CHA; [3]Seattle Children's; [4]Children's Mercy.*

Background: The Children's Hospital Association's Standardizing Care to Improve Outcomes in Pediatric ESRD (SCOPE) Collaborative seeks to minimize peritonitis in children on chronic peritoneal dialysis (PD) by increasing compliance with standardized PD catheter care practices.

Methods: Peritonitis rates and compliance with care bundles focused on PD catheter insertion, pt/caregiver training and follow-up care were collected monthly. Center-specific monthly peritonitis rates were calculated as (#infections/#pt-mos). Changes in peritonitis rates and compliance were modeled using Generalized Linear Mixed Model techniques assuming a negative binomial distribution with a natural log link function and a binomial distribution with a logit link function, respectively. Models included random effects to accommodate PD center-specific variability.

Results: Data from 24 SCOPE sites that provided peritonitis rates for the 12 mos prior to Collaborative launch were included in the analysis. In the first 36 mos, 751 catheter insertions in 644 pts, 644 training sessions and 7,977 follow up encounters were captured. Compliance with the follow up bundle increased from 11% to 88% (p<0.001) over the 36 mos, but neither insertion (22% to 36%, p=0.064) nor training compliance (75% to 71%, p=0.105) increased significantly. The peritonitis rate decreased significantly (p=0.026) from an average monthly rate of 0.052 (95% CI 0.036, 0.076) pre-launch to 0.035 (95% CI 0.026, 0.047)at 36 mos, figure 1.



Conclusions: Using quality improvement methodology pediatric dialysis units participating in SCOPE significantly increased implementation of standardized follow up care practices and significantly reduced peritonitis rates. Efforts to increase compliance with insertion and training bundles and further reduce infection rates are ongoing.

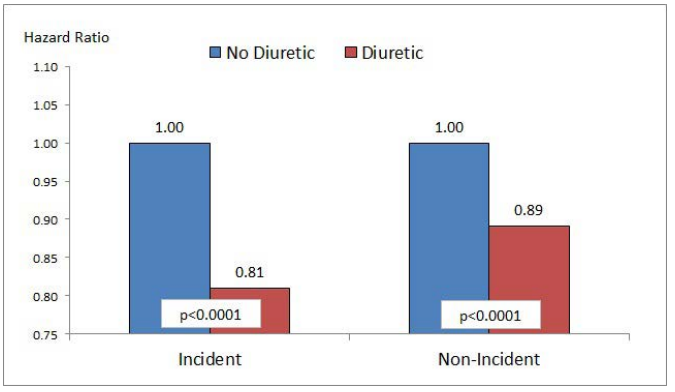
FR-OR036

Diuretic Prescription and Outcomes Among Peritoneal Dialysis Patients in the BRAZPD Study Jennifer L. Bragg-Gresham,[1] Ludimila Guedim de Campos,[2] Thyago Proença de Moraes,[2] Ana Elizabeth Figueiredo,[3] Pasqual Barretti,[4] Rajiv Saran,[1] Roberto Pecoits-Filho.[2] *[1]KECC, Univ of Michigan, Ann Arbor, MI; [2]Pontifícia Univ Católica do Paraná, Curitiba, Brazil; [3]Pontifícia Univ Católica do Rio Grande do Sul (PUCRS), Porto Alegre, Brazil; [4]Univ Estadual do Estado de São Paulo - UNESP, Botucatu, Brazil.*

Background: Diuretics are prescribed to individuals with reduced renal function (RRF), but can continue to play a role in dialysis patients, to manage extracellular fluid volume and hypertension. We assess the prescription (Rx) of diuretics and their association with survival in a representative sample of PD patients.

Methods: We examined diuretic Rx among 9,905 patients from the BRAZPD study, a prospective cohort study launched in Dec 2004. Cox regression was used to estimate associations between baseline diuretic use and mortality, adjusting for age, sex, hypertension, diabetes, Davies score, pre-dialysis care, prior HD, and prior kidney Tx; interaction used to assess Rx by 90-day incident status.

Results: At baseline, 33.9% of patients had diuretic Rx. Patients with Rx were older, had higher BMI, more comorbidities, but longer pre-dialysis care (p<0.0001). A higher proportion of patients with Rx were incident to PD, male, diabetic, hypertensive, taking other anti-hypertensive medications and had received pre-dialysis care; while a smaller proportion of patients with Rx had received a prior Tx or HD (p£0.01). Accounting for these differences, patients with Rx had a lower risk of mortality (HR=0.87, p=0.005). The association was seen among both incident and non-incident patients.



Conclusions: Despite being older and sicker, patients with diuretic Rx had lower mortality. While more striking in incident patients, association was also seen in non-incident patients. If diuretic Rx is a marker of RRF or independently associated with better outcomes remains to be elucidated.

FR-OR037

In-Hospital Mortality Outcome of Cirrhotic Patients with End Stage Renal Disease on Hemodialysis versus Peritoneal Dialysis Mark Abi Nader,[1] Fernando Rodrigo Aguilar,[1] Michael S. Lipkowitz,[1] Parasuram Krishnamoorthy,[2] Ping Li,[1] Serban A. Dragoi,[1] Alex Montero,[1] Wen Shen,[1] Chanigan Nilubol,[1] Judit Gordon.[1] *[1]Nephrology and Hypertension, Georgetown Univ Hospital, Washington, DC; [2]Internal Medicine, Mount Sinai School of Medicine.*

Background: Renal disease is a common complication in cirrhotic patients related to electrolyte and acid-base alterations, inadequate response to diuretic drugs, and hemodynamic instability, often leading to end stage renal disease (ESRD) with need for dialysis. Little is known about the preferred dialysis modality in these patients. We aimed to compare the mortality outcomes between cirrhotic patients on either Hemodialysis (HD) or peritoneal dialysis (PD).

Methods: Nationwide Inpatient Sample database between 2005 and 2012 was queried. Patients with ESRD (ICD9 585.6) and liver cirrhosis (ICD9 571.2; 571.5; 571.6; 572.3; 572.4) were included in the study. Patients having hepatocellular carcinoma were excluded (ICD9 155.0). Both groups were matched, undergoing propensity matching score, for chronic conditions including anemia, diabetes mellitus, hypertension, hepatic encephalopathy, esophageal variceal bleeding, gastrointestinal bleeding (GIB), paracentesis, hepatitis C as well as sex, race, Charlson Comorbidity Index and age. Logistic regression was used for multivariable analysis.

Results: 28,622 cirrhotic patients with incident ESRD were identified. 1.7% of them were on PD. After propensity score matching and multivariable regression analysis, cirrhotic on HD had higher mortality compared to PD patients [4.79% vs 2.70% P = 0.024]. Age>65 and female gender were significant predictors of mortality in both HD and PD groups. Anemia was associated with less mortality rate.

Conclusions: Cirrhotic patients admitted to the hospital for dialysis have higher mortality when started on HD compared to PD.

FR-OR038

AQP1 in Peritoneal Dialysate as Predictive Biomarker of Integrity of the Peritoneal Barrier and Ultrafiltration Efficiency Simone Corciulo,[1] Maria Celeste Nicoletti,[2] Roberto Corciulo,[3] Roberto Russo,[3] Giuseppe Grandaliano,[1] Maria Svelto,[2] Giuseppe Procino,[2] Loreto Gesualdo.[3] *[1]Dept of Emergency and Organ Transplantation, Univ of Foggia, Foggia, Italy; [2]Dept of Biosciences, Biotechnologies and Biopharmaceutics, Univ of Bari, Bari, Italy; [3]Dept of Emergency and Organ Transplantation, Univ of Bari, Bari, Italy.*

Background: The water channel Aquaporin 1 (AQP1) plays a pivotal role in the mechanism of free water ultrafiltration during peritoneal dialysis (PD). Wether or not is AQP1 exclusively expressed in peritoneal capillaries or also in the mesothelial cells (MC) is still debated. It has been hypothesized that decreased expression or function of AQP1 may be responsible for some cases of ultrafiltration failure (UFF). Plasma membrane proteins are released in biological fluids through the exosome pathway to an extent proportional to their abundance at the plasma membrane.

Methods: In this work we investigated the localization of AQP1 in human peritoneum and its presence in exosomes isolated from PD effluent.

Results: Proteomic analysis of peritoneal-derived exosomes showed a significant expression of AQP1. Interestingly, the same samples were devoid of the endothelial marker CD31 but were positive for the mesothelial marker mesothelin, thus suggesting a mesothelial, rather than endothelial origin for these vesicles.

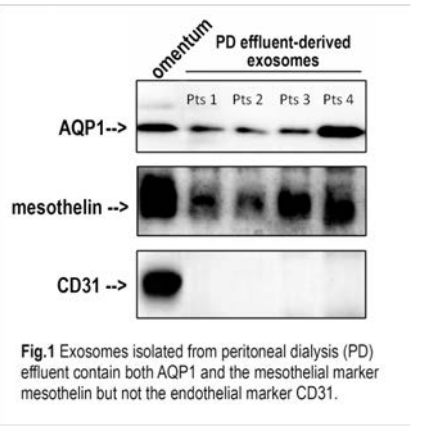


Fig.1 Exosomes isolated from peritoneal dialysis (PD) effluent contain both AQP1 and the mesothelial marker mesothelin but not the endothelial marker CD31.

In human omental biopsies, AQP1 was localized in peritoneal capillaries and at the plasma membrane of MC, where it co-localized with mesothelin.

Conclusions: Our results suggest that AQP1 is expressed in MC and released in the peritoneal cavity through the exosome pathway. This evidence opens the debate on the role of MC in regulating the efficiency of PD and suggests that AQP1 released in the PD effluent may represent a potential non-invasive biomarker of integrity of the peritoneal barrier.

FR-OR039

Vascular Endothelial Cell Damage Is an Important Factor in the Development of Encapsulating Peritoneal Sclerosis Mitsuhiro Tawada,[1] Yasuhiko Ito,[1] Chieko Hamada,[2] Kazuho Honda,[3] Masashi Mizuno,[1] Yasuhiro Suzuki,[1] Fumiko Sakata,[1] Shoichi Maruyama,[1] Yoshifumi Takei,[4] Seiichi Matsuo.[1] *[1]Nephrology, Nagoya Univ, Nagoya, Japan; [2]Nephrology, Juntendo Univ, Tokyo, Japan; [3]Pathology, Tokyo Women's Medical Univ, Tokyo, Japan; [4]Biochemistry, Nagoya Univ, Nagoya, Japan.*

Background: Encapsulating peritoneal sclerosis (EPS) is a rare, but serious and life-threatening complication of peritoneal dialysis (PD); however, the precise pathogenesis remains unclear and predictors have not yet been established. The present study aimed to determine predictors of EPS in peritoneal membrane tissues obtained at catheter removal.

Methods: Eighty-three biopsy samples (10 EPS, 73 non-EPS) were assessed by pathological and immunopathological techniques to identify predictors of EPS. Tissue samples obtained at the time of catheter removal for reasons of peritonitis and a peritonitis episode within the past one month were not included. Furthermore, based on these analyses, the effects of PD solution on human umbilical vein endothelial cells (HUVEC) were studied.

Results: Univariate analysis of the pathological findings associated a thickened peritoneal membrane ($P = 0.045$), new membrane formation scores ($P = 0.006$), decreased ratio of lumen diameter to vessel diameter (L/V ratio, $P < 0.001$), CD31-negative vessels ($P = 0.021$) and fibrin deposition ($P < 0.001$) with the development of EPS. Stepwise Firth's multivariate logistic regression analysis identified glucose exposure scores (odds ratio 2.03, $P = 0.011$) among clinical factors, the L/V ratio (AUC, 0.899; OR, 0.50; $P = 0.002$) and fibrin deposition (OR, 8.50; $P = 0.023$) among the pathological factors as independent predictors of EPS. Multivariate logistic regression analysis of the 10 patients with EPS and 20 controls matched for PD treatment period, diabetes and PD solution (acidic or neutral pH) identified decreased L/V ratio as an independent predictor. In cultured HUVEC, acidic condition and high glucose concentration of PD solution induced necrosis and apoptosis, respectively.

Conclusions: Vascular endothelial cells that become damaged mainly by bioincompatible PD solution might induce vascular leakage leading to EPS, and could serve as a predictor of EPS.

Matrix-Assisted Laser Desorption Ionization-Time of Flight Mass Spectrometry Accelerates Pathogen Identification and May Confer Outcome Benefit in Peritoneal Dialysis-Related Peritonitis Ming-cheng Wang,[1] Wei-hung Lin,[2] Te-hui Kuo.[1] *[1]Div of Nephrology, Dept of Internal Medicine, National Cheng Kung Univ Hospital, Tainan, Taiwan; [2]Dept of Internal Medicine, National Cheng Kung Univ Hospital, Tainan, Taiwan.*

Background: Peritonitis is one of the major complications of peritoneal dialysis (PD) and contributes to technique failure and mortality in PD patients. The aim of this study was to evaluate the effects of matrix-assisted laser desorption ionization-time of flight mass spectrometry (MALDI-TOF MS) on pathogen identification and clinical outcomes in PD-related peritonitis.

Methods: Ninety-eight causative microorganisms of monomicrobial PD-related peritonitis were identified using conventional standard methods, and 57 were identified using MALDI-TOF MS method. The time to pathogen identification using different identification methods was evaluated and compared. The outcome characteristics were time to dialysate effluent white blood cell $<100/mm^3$, length of hospital stay, catheter removal/transfer to hemodialysis, and in-hospital mortality.

Results: MALDI-TOF MS allowed the direct pathogen identification from positive blood cultures accounting for 94.9% of all cases. MALDI-TOF MS method could identify

the causative microorganisms of PD-related peritonitis earlier than the conventional standard method. The average time saved is 64 hours for all pathogens, 52 hours for Gram-positive bacteria, 65 hours for Gram-negative bacteria, 37 hours for Staphylococcus species, 68 hours for Streptococcus species, and 67 hours for E. coli and Klebsiella species. MALDI-TOF MS method group had a shorter length of hospital stay than the conventional standard group (5.2 ± 4.8 days versus 8.2 ± 4.5 days, P = 0.001).

Conclusions: We demonstrate the clinical effects of pathogen identification using MALDI-TOF MS in PD-related peritonitis. Integration of MALDI-TOF MS with blood culture system can promote early pathogen identification and timely pathogen-directed antibiotic therapy, and may confer outcome benefit. We propose that it is time to speed up the pathogen identification in PD-related peritonitis.

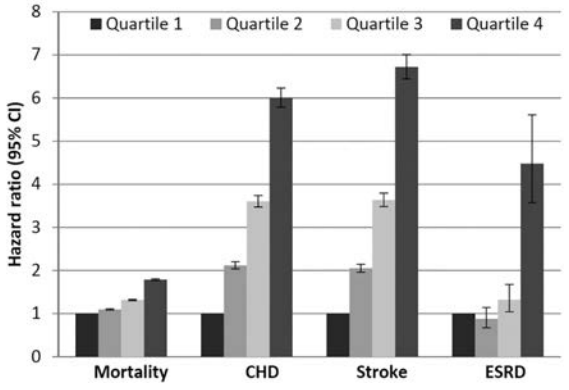
Higher Systolic Blood Pressure Variability Is Associated with Increased Mortality, Coronary Heart Disease, Stroke, and End Stage Renal Disease

Margit K. Mikkelsen,[1] Miklos Zsolt Molnar,[2] Jun Ling Lu,[2] Lenar T. Yessayan,[3] Elvira Gosmanova,[2] Kamyar Kalantar-Zadeh,[4] Csaba P. Kovesdy.[1,2] *[1]VA Medical Center, Memphis, TN; [2]Univ of Tennessee Health Science Center, Memphis, TN; [3]Henry Ford Hospital, Detroit, MI; [4]Univ of California, Irvine, CA.*

Background: Blood pressure does not remain constant, but instead fluctuates dynamically. The implications of this variability in blood pressure are not yet fully understood.

Methods: From among 3,285,684 US veterans with normal eGFR during 2005-2006, we identified 2,865,157 patients who had more than 7 outpatient blood pressure measurements. Systolic blood pressure variability (SBPV) was measured using the standard deviation (SD) of all SBP values (normally distributed) in one individual. Associations of SD quartiles (<10.28, 10.28-12.68, 12.69-15.60, ³15.61 mmHg) with all-cause mortality, coronary heart disease (CHD), stroke, and end stage renal disease (ESRD) was examined using Cox models adjusted for age, gender, race, and baseline eGFR, comorbidities, BMI, SBP, DBP, and antihypertensive medication use.

Results: Higher SBPV was associated with significantly higher risk of all-cause mortality, CHD, stroke, and ESRD. In fully adjusted models SD quartiles 2 through 4 (compared to the first quartile) were associated with mortality hazard ratios of 1.10, 1.32, and 1.79; CHD hazard ratios (95%CI) of 2.12, 3.60, and 6.01; stroke hazard ratios of 2.05, 3.64, and 6.72; and ESRD hazard ratios of 0.88, 1.32, and 4.48.



Conclusions: Higher SBPV is associated with increased risk for mortality, CHD, and stroke independent of confounders. The highest SD quartile was associated with increased risk for ESRD. The effect of interventions that lower SBPV on mortality will need to be examined in clinical trials.

FR-OR042

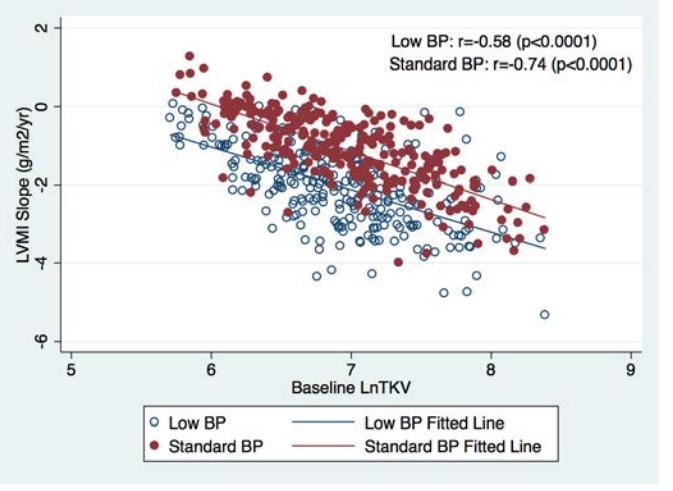
Left Ventricular Mass in Early Autosomal Dominant Polycystic Kidney Disease

Vicente E. Torres,[6] Ronald D. Perrone,[1] Kaleab Z. Abebe,[2] Kyongtae Ty Bae,[2] Peter G. Czarnecki,[3] Robert W. Schrier,[4] Theodore I. Steinman,[5] Susan Spillane,[2] Charity G. Moore.[2] *[1]Tufts; [2]U of Pittsburgh; [3]Brigham and Womens; [4]U of Colorado; [5]BIDMC; [6]Mayo Clinic, for the HALT PKD Investigators.*

Background: Autosomal dominant PKD (ADPKD) associates with hypertension and left ventricular hypertrophy (LVH). HALT PKD study A was designed to assess the effect of intensive BP control and dual renin angiotensin blockade on progression of total kidney volume (TKV) and left ventricular mass (LVM).

Methods: 543 subjects with eGFR >60 ml/min aged 15-50 were randomized to lisinopril (L) and placebo (P) vs L and telmisartan (T) with two levels of BP control: standard (SBP) (120-130/70-80 mmHg) vs low (LBP) (95-110/65-75 mm Hg). Cardiac magnetic resonance measurement of LVM was done at baseline, 24, 48, and 60 months. LVM adjusted for body surface area was expressed as LVM index (LVMI; g/m^2).

Results: The prevalence of LVH at baseline was <1%. LBP reduced LVMI compared to SBP (p<0.001) but there was no effect of dual blockade (p=NS). There was no impact of baseline parameters (eGFR, age, systolic BP, TKV, serum K, urine Na or K, albuminuria, urine aldosterone, sex) on the BP effect on LVMI. Higher baseline TKV and systolic BP had significant associations with more rapid LVMI decline (p<0.0001); a trend of lower baseline eGFR also associated with LVMI decline (p=0.07); females had significantly reduced LVMI decline vs males (p<0.0001) irrespective of BP group.



Conclusions: LVMI decreased significantly after intensive vs standard BP control. Larger TKV, higher systolic BP, male sex, and possibly decreased eGFR were associated with a greater reduction in LVMI, irrespective of the level of BP control. Patient factors associated with a worse kidney outcome predicted improvement in LVMI after a long period of carefully controlled BP. BP reduction in ADPKD shows cardiac benefit and should be a focus of treatment.

Asymmetric and Symmetric Dimethylarginine and Sympathetic Nerve Traffic After Renal Denervation in Patients with Resistant Hypertension: A Longitudinal Study

Carmine Zoccali,[1] Gino Seravalle,[2] Fosca Quarti Trevano,[3] Domenico Spaziani,[4] Filippo Scalise,[5] Carla Auguadro,[5] Patrizia Pizzini,[1] Giovanni Tripepi,[1] Graziella D'arrigo,[1] Giuseppe Mancia,[2] Guido Grassi,[3,6] Francesca Mallamaci.[1] *[1]Clinical Epidemiology and Physiopathology of Renal Diseases and Hypertension, CNR-IFC, Reggio Calabria, Italy; [2]Istituto Auxologico Italiano, Milano, Italy; [3]Clinica Medica, Dipartimento di Scienze della Salute, Univ Milano-Bicocca, Milano, Italy; [4]Unità Operativa di Cardiologia, Ospedale Magenta, Milano, Italy; [5]Cardiologia Interventistica, Policlinico di Monza, Monza, Italy; [6]IRCCS Multimedica, Sesto San Giovanni-Milano, Italy.*

Background: The plasma concentration of the endogenous inhibitor of nitric oxide synthase asymmetric dimethyl arginine (ADMA) associates with sympathetic activity in patients (pts) with chronic kidney disease but the driver of this association is unknown.

Methods: In this longitudinal study (followup:2 weeks-6 months) we performed repeated measurements over time of muscle sympathetic nerve activity (MSNAC), plasma levels of ADMA and symmetric dimethyl arginine (SDMA) and blood pressure (BP) and heart rate (HR) in 14 pts with drug-resistant hypertension who underwent bilateral renal denervation. Stability of ADMA, SDMA, BPs and MSNAC over time (6 months) was assessed in 2 historical control groups of patients maintained on stable anti-hypertensive treatment.

Results: Time integrated changes in MSNAC following renal denervation ranged from -40.6% to +10% (average -15.1%) and these changes were strongly associated with the corresponding changes in plasma ADMA (r= 0.62, P=0.02) and SDMA (r=0.72, P=0.004). Changes in MSNAC went along with simultaneous changes in standardized systolic (r=0.65, P=0.01) and diastolic BP (r=0.61, P=0.02). In the historical control groups, no change in ADMA, SDMA, BPs and MSNAC levels was recorded during a 6-months follow up.

Conclusions: In pts with resistant hypertension changes in sympathetic activity after renal denervation associate with simultaneous changes in plasma levels of ADMA and SDMA. These observations are compatible with the hypothesis that the sympathetic nervous system exerts an important role in modulating circulating levels of ADMA and SDMA in this condition.

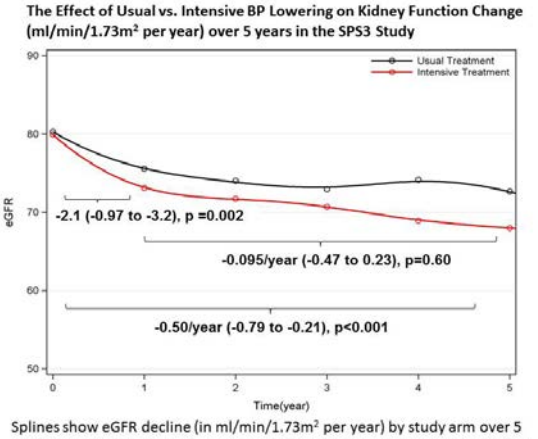
Intensive Blood Pressure Lowering and Kidney Function Decline Among Persons with prior Lacunar Stroke: The SPS3 Randomized Trial

Carmen A. Peralta,[1] Leslie Mcclure,[2] Rebecca Scherzer,[1] Michael Shlipak,[1] Carole White,[3] Oscar Benavente,[5] Pablo E. Pergola.[3] *[1]UCSF; [2]UAB; [3]UTHSC; [4]UCSF; [5]UBC.*

Background: The effect of intensive blood pressure (BP) lowering on kidney function among persons with vascular disease and preserved glomerular filtration rate (eGFR) is not known.

Methods: SPS3 was a multi-center trial to test effectiveness of two BP targets on secondary prevention of stroke. In a post-hoc analysis of 2611 participants randomized to lower SBP (<130 mmHg) vs. higher (130-149 mmHg) with yearly creatinine measures, we evaluated differences in annualized eGFR decline and rapid decline (>30% ml/min/1.73m^2) using linear mixed models and logistic regression, respectively.

Results: Mean age was 63±11; 949(36%) were diabetic, mean eGFR was 80±19,and 410(16%) had eGFR <60 ml/min/1.73m^2 at randomization. At 9 months, achieved SBP was 137±15 mmHg in higher vs. 127±14 mmHg in the lower BP group, and differences persisted throughout follow-up (mean 3.2 years). Relative to higher BP arm, use of ACE/ARB, diuretic and calcium channel blocker were all increased by 20% among persons in the lower BP arm. Compared with higher, lower BP target had faster eGFR decline. Differences were most pronounced during the first year, whereas rates of eGFR decline did not differ between assigned BP groups after year 1.



Splines show eGFR decline (in ml/min/1.73m^2 per year) by study arm over 5 years. The estimates represent *differences* in eGFR decline among persons in higher vs. lower BP arm.

A total of 313(24%) persons in the lower BP group had rapid kidney function decline, compared with 247(19%) in higher (OR 1.4 (95%CI 1.1 to 1.6)). Differences were apparent in the first year (OR 1.4, 1.1-1.8), but were not statistically significant after year 1 (OR 1.0, 0.73-1.4).

Conclusions: In persons with prior lacunar stroke and relatively preserved kidney function, intensive BP lowering was associated with faster renal function decline. Differences were primarily observed during the first year of anti-hypertensive treatment with no evidence of renal protection during follow up.

FR-OR045

Hypertension Does Not Accelerate Age-Related GFR Decline in the General Middle-Aged Population Bjorn Odvar Eriksen,[1] Vidar T. N. Stefansson,[1] Trond G. Jenssen,[1] Ulla Dorte Mathisen,[1] Jørgen Schei,[1] Marit D. Solbu,[1] Tom Wilsgaard,[2] Toralf Melsom.[1] *[1]Meatabolic and Renal Research Group, UiT the Arctic Univ of Norway, Tromsø, Norway; [2]Dept of Community Medicine, UiT the Arctic Univ of Norway, Tromsø, Norway.*

Background: Although hypertension is a risk-factor for ESRD, this complication only develops in a minority of hypertensive patients. Evidence is lacking to support non-malignant hypertension as a sufficient cause of reduced kidney function. This is partly due to the difficulty of assessing normal-range GFR accurately with estimated GFR. In epidemiological studies, estimated GFR has been used almost exclusively because actual measurements of GFR are costly and complicated. We aimed to investigate whether hypertension accelerates GFR decline in the general population using measured rather than estimated GFR.

Methods: We included a representative sample of the general population (age 50 to 62 years) without kidney disease, cardiovascular disease or diabetes at baseline. Baseline GFR was measured by iohexol-clearance in 1594 subjects, and 1299 (81%) had a second measurement in the RENIS Follow-Up Study (RENIS-FU) after a median observation period of 5.6 years. The effect of office blood pressure on the GFR change rate was analyzed.

Results: The mean GFR change rate was -0.95 mL/min/year. The negative sign signifies a decline. In multivariable adjusted linear mixed regression models with random intercept and slope, the increases in the change rate in mL/min/year/10 mmHg (95% confidence intervals) were 0.08 (0.03 to 0.14), 0.18 (0.07 to 0.28), 0.05 (-0.03 to 0.13) and 0.15 (0.07 to 0.24) for increasing systolic, diastolic, pulse pressure and mean arterial blood pressure respectively, indicating that GFR declined more slowly with higher blood pressure within the study time-frame. The regression analyses used time-varying measurements of blood pressure, individual classes of antihypertensive medication and all adjustment variables.

Conclusions: Hypertension is not a direct sufficient cause of accelerated GFR decline in the general middle-aged population. Additional genetic and environmental causal factors are probably necessary for primary hypertension to cause clinically manifest chronic kidney disease.

FR-OR046

Effect of Uric Acid Lowering on Ambulatory Blood Pressure: A Randomized, Double-Blind, Placebo-Controlled Clinical Trial Ciaran Joseph McMullan,[1] Lea Borgi,[1] Gary C. Curhan,[1] Naomi D.L. Fisher,[2] John P. Forman.[1] *[1]Renal Div, Brigham and Women's Hopsital, Boston, MA; [2]Endocrine Div, Brigham and Women's Hospital, Boston, MA.*

Background: Higher levels of uric acid are associated with higher blood pressure (BP) an increased risk of hypertension in many cohort studies, suggesting that uric acid may be a target for prevention of hypertension. However, the effect of lowering serum uric acid on BP is unclear.

Methods: We performed a randomized, double-blind, placebo-controlled trial of normotensive individuals with body mass index (BMI) ³25 and uric acid level ≥ 5.0 mg/dL; subjects were randomized to receive either allopurinol 300/600mg, probenecid 500/1000mg or placebo daily for 8 weeks. Mean 24 hour systolic BP(24hSBP) was measured using 24 hour ambulatory blood pressure monitoring at baseline and 8 weeks.

Results: By the end of the trial, 22, 24 and 26 participants assigned to receive probenecid, allopurinol and placebo, respectively, had adequate 24 hour BP measurements at baseline and 8 weeks. Uric acid levels changed over 8 weeks from means of 5.9, 5.6 and 5.6 mg/dL to 3.5, 2.9 and 5.8 mg/dL in the probenecid, allopurinol and placebo groups, respectively. 24hSBP was not reduced after 8 weeks of uric acid lowering: from 127±10 mmHg to 124±8 mmHg (p-value=0.25) in the probenecid group; 125±9 to 124±10 mmHg (p-value= 0.71) in the allopurinol group; and 121±9 to 122±10 mmHg (p-value=0.61) in the placebo group. Similarly, treatment had no effect on 24 hour diastolic BP.

Conclusions: In contrast to observational studies, this randomized, double-blind, placebo-controlled trial found that uric acid lowering does not improve mean 24 hour BP in normotensive individuals with high uric acid levels, suggesting that uric acid may not be a modifiable target for prevention of hypertension.

Central Role for Altered Arginine Methylation in Salt-Sensitive Hypertension in CKD: A Metabolomic Profiling Study Anna V. Mathew,[1] Adil Jadoon,[1] Jaeman Byun,[1] Robin L. Padilla,[1] Peter Kotanko,[2] Scott L. Hummel,[1] Brenda W. Gillespie,[1] Rajiv Saran,[1] Subramaniam Pennathur.[1] *[1]Univ of Michigan, Ann Arbor; [2]RRI, New York.*

Background: As the nitrogen donor in nitric oxide (NO) synthesis by NO synthase (NOS), arginine and its metabolic products are integrally linked to blood pressure (BP) regulation, however their role in chronic kidney disease (CKD), salt sensitivity and BP response has not been systematically studied. We explored if arginine metabolites alter with sodium restriction and predict favorable blood pressure in response to dietary sodium restriction (DSR).

Methods: Samples from 34 subjects enrolled in the LoSalt trial, a randomized crossover trial of CKD 3-4 patients who underwent DSR (<2g/day) were utilized. Targeted metabolomic analysis of arginine metabolome in pre and post DSR plasma and urine was performed by isotope dilution liquid chromatography mass spectrometry including N^G,N^G dimethylarginine (ADMA), N^G,N'^G dimethylarginine (SDMA), N^Gmonomethyl-L-arginine (NMMA), arginine and citrulline. Salt sensitivity was determined by salutary changes to volume status and BP as measured by bioelectrical impedance spectroscopy (whole-body, segmental and calf) and 24-hour ambulatory blood pressure monitoring (ABPM). Pearson correlation assessed the associations between the metabolites and clinical parameters.

Results: After 4 weeks of DSR, mean urine sodium decreased by 73 ± 71 mmol/24hr and 24-hour systolic BP reduced by 10.8 ± 13.8 mmHg. Higher urine ADMA/ creatinine ratio correlated with lower total body water at baseline (r=-0.57; p<0.01). Changes in urine ADMA/ creatinine ratio (r=-0.46) and urine NOS inhibition index (NII, ADMA+NMMA/SDMA, r=-0.46) negatively correlated with changes in mean arterial ABPM (p<0.05). Urine Total Arginine Methylation Index (TAMI, (ADMA+SDMA+NMMA)/arginine, r=-0.47, p<0.05) negatively correlated with change in extracellular volume.

Conclusions: Our results strongly implicate altered arginine methylation and NOS inhibition with BP response following DSR. Further research should examine whether urinary markers of altered arginine methylation (ADMA, NII and TAMI) can consistently serve as markers of salt sensitivity in both CKD and non-CKD subjects following DSR.

Mutations in *TBX18* Cause Dominant Urinary Tract Malformations via Transcriptional Dysregulation of Ureter Development Asaf Vivante,[1] Marc-Jens Kleppa,[2] Julian Jakob Schulz,[1] Stefan Kohl,[1] Amita Sharma,[3] Jing Chen,[1] Shirlee Shril,[1] Daw-yang Hwang,[1] Anna-Carina Weiss,[2] Elijah O. Kehinde,[4] Erika J. Mancini,[5] Richard P. Lifton,[6,7] Velibor Tasic,[8] Soeren S. Lienkamp,[9] Harald Jüppner,[3] Andreas Kispert,[2] Friedhelm Hildebrandt.[1,7] *[1]Dept of Medicine, Boston Children's Hospital, HMS, Boston, MA, USA; [2]Inst für Molekularbiologie, Med Hochschule Hannover, Germany; [3]Ped Nephrology, MGH, Boston, MA, USA; [4]Div of Urology, Kuwait Univ, Safat, Kuwait; [5]Div of Structural Bio, Univ of Oxford, UK; [6]Dept of Human Genetics, Yale Univ, New Haven, CT, USA; [7]Howard Hughes Medical Inst, Chevy Chase, MD; [8]Univ Children's Hospital, Skopje, Macedonia; [9]Dept of Med, Renal Div Freiburg Med Center, Germany.*

Background: Congenital anomalies of the kidneys and urinary tract (CAKUT) are the leading cause of CKD in children. Identification of monogenic causes of CAKUT permits the first insights into disease mechanisms.

Methods: We performed whole exome sequencing in a large kindred followed by high-throughput sequencing in individuals with CAKUT. Furthermore, we performed a transcriptional reporter assay, protein-protein and protein-DNA interaction studies, as well as *in vivo* studies in *Xenopus laevis*.

Results: We identified a heterozygous truncating mutation (p.G337Vfs*19) of the *T-Box transcription factor 18* gene (*TBX18*) in all 7 affected members of a large kindred. We also detected 2 mutations (p.H524Y and p.K163E) in 3 of 1,295 unrelated families with CAKUT. TBX18 is essential for development of the ureteric mesenchyme and ureteric smooth muscle cells. We found that all 3 TBX18 mutant proteins still dimerize with the wild type protein, but had prolonged half-life, and exhibited reduced transcriptional repression. The mutation p.K163E altered a residue critical for TBX18-DNA interaction, resulting in impaired TBX18-DNA binding. *In vivo* overexpression in *Xenopus laevis* revealed decreased biological activity on pronephric kidney development for p.G337Vfs*19 and p.K163E.

Conclusions: We discovered dominant negative *TBX18* mutations as a novel cause of human CAKUT that act *via* lack of repression of TBX18 transcriptional activity. Our studies implicate ureter smooth muscle cell development in the pathogenesis of human CAKUT.

FR-OR049

ACTN4 Mutations Lead to Increased Contractility of Human Podocytes in Response to Injurious Stimuli and Matrix Stiffening Di Feng,[1] Ramaswamy Krishnan,[2] Gabriel Birrane,[4] Julia M. Steinke,[3] Jiayue Zhang,[1] Martin R. Pollak.[1] *[1]Nephrology, Beth Israel Deaconess Medical Center, Boston, MA; [2]Emergency Medicine, Beth Israel Deaconess Medical Center, Boston, MA; [3]Pediatric Kidney Transplant Program, Helen DeVos Children's Hospital, Grand Rapids, MI; [4]Experimental Medicine, Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Alpha-actinin-4 gene (ACTN4) mutations cause a rare form of familial focal segmental glomerulosclerosis (FSGS) in humans. Individuals with kidney disease-causing ACTN4 mutations tend to have mild to moderate proteinuria, with many developing a progressive decline in kidney function, and eventual end stage kidney disease. All of the disease-causing ACTN4 mutations identified to date are located within the actin-binding domain (ABD) of the encoded protein, increasing its binding affinity to F-actin and leading to abnormal cellular aggregates. The mechanism by which the mutations give rise to FSGS is not well understood.

Methods: We used traction force microscopy to quantify contractile forces exerted by immortalized human podocytes on their underlying substrate. Immunofluorescence staining was used to examine the localization of ACTN4 and actin.

Results: We found that human podocytes transfected with mutant ACTN4 are more contractile in response to the injurious stimulus TGF-beta compared to podocytes transfected with WT ACTN4. We also found that podocytes seeded on a stiff substrate (26 kilopascal) and transfected with mutant ACTN4 are more contractile than podocytes transfected with WT ACTN4. This difference in contractile force between WT and mutant was blunted when podocytes are seeded on a softer substrate (1 kilopascal). Additionally, mutant ACTN4 transfected podocytes show much more prominent actin stress fibers, which are largely absent from WT ACTN4 transfected podocyte.

Conclusions: We demonstrated that mutations in the ACTN4 ABD resulted in increased podocyte contractility in response to injurious circulating stimuli and increased matrix stiffness. These observations raise the hypothesis that reducing the contractility of podocytes by pharmaceutical agents *in vivo* might mitigate podocyte disease due to ACTN4 mutation.

Assessing Two Novel Steroid-Resistant Nephrotic Syndrome Candidate Genes Using the Drosophila Model Sara Gonçalves,[1,2] Noëlle Lachaussée,[1] Christelle Arrondel,[1] Martin Helmstaedter,[3] Oliver Kretz,[3] Olivia Boyer,[1,4] Olivier Gribouval,[1] Christine Bole-feysot,[1] Patrick Nitschke,[1] Marie-Claire Gubler,[1] Tobias B. Huber,[3,5] Geraldine Mollet,[1] Matias Simons,[1,3,6] Corinne Antignac.[1,7] *[1]Inserm U1163 Inst Imagine, Paris Descartes Univ, Paris, France; [2]Renal Div, St. Maria Univ Hosp, Lisbon, Portugal; [3]Renal Div, Univ Hosp Freiburg, Germany; [4]Ped Nephrol, Hosp Necker, Paris, France; [5]BIOSS Albert-Ludwigs Univ, Freiburg, Germany; [6]ZBSA, Freiburg, Germany; [7]Genetics, Hosp Necker, Paris, France.*

Background: Steroid-resistant nephrotic syndrome (SRNS) is a genetically heterogeneous disease. Using exome sequencing we previously identified two homozygous, potentially damaging, missense variants in ADD3 and KAT2B in the affected members of a consanguineous family presenting syndromic SRNS. The first gene encodes adducin, an important regulator of the actin cytoskeleton, and the second the lysine acetyltransferase KAT2B responsible for histone acetylation.

Methods: To address the importance of ADD3 and KAT2B on podocyte function and the impact of the mutations we used the Drosophila model. KD and rescue experiments with the WT and mutated genes were performed using the GAL4:UAS system in Drosophila nephrocytes, the fly counterparts of podocytes. Defects at a molecular and ultrastructural level were assessed using immunostaining and electron microscopy and functional assays were used to assess the filtration/endocytic functions of nephrocytes.

Results: In 3rd instar nephrocytes, adducin KD, but not KAT2B KD, disrupted the actin cytoskeleton, delocalized the slit diaphragm protein Kirre and led to decreased filtration/endocytosis. At the ultrastructural level ADD3 KD led to decreased number of slit diaphragms and foot process effacement. At the adult stage, both adducin and KAT2B KD induced a reduction of nephrocytes. While KAT2B rescue experiments are still pending, the WT but not the mutated form of ADD3 rescued the ADD3 KD phenotypes, namely the actin cytoskeleton defects and Kirre mislocalization.

Conclusions: These findings suggest that ADD3 plays a major role on podocyte morphology and function and that ADD3 mutations maybe causative to some forms of SRNS. However the impact of the KAT2B mutation in the patient phenotype cannot be excluded.

A Novel Mutation in CLCN5 Gene Associated with Silent Clinical Manifestations of Dent Disease and the Histologic Picture of FSGS Milos N. Budisavljevic, Michael G. Janech, Peifeng Deng, Robert Wilson, Thomas Morinelli, John M. Arthur. *Nephrology, MUSC, Charleston, SC.*

Background: It is increasingly recognized that focal segmental (FSGS) and focal global glomerulosclerosis (FGGS) may be seen as a dominant feature in some patients with Dent disease and lead to an erroneous diagnosis of primary FSGS.

Methods: We identified two brothers, 37 and 32 years old, who presented with low grade proteinuria and renal failure. Kidney biopsies of both revealed FSGS and no nephrocalcinosis. Four additional male family members had kidney disease without an established diagnosis.

Results: Pedigree analysis suggested an X-linked mode of inheritance. Extensive evaluation of the medical history from affected individuals revealed no rickets, nephrocalcinosis or nephrolithiasis. We performed whole exome DNA sequencing on 7 family members and identified a variant of the intracellular chloride channel 5 (CLCN5) gene which had not previously been described. The mutation resulted in a substitution of leucine for phenylalanine at position 521 (L521F). We constructed expression vectors (pCMV6-AC-GFP) that encode for wild-type and mutant L521F CLC5, respectively, and transfected HK2 cells. Transfection of HK2 cells with wild-type CLC5 revealed protein localization to both on the cell surface and throughout the cytoplasm. Cells transfected with the mutant construct displayed only intracellular perinuclear localization. CLCN5 encodes the chloride hydrogen exchanger and is important for endocytosis in the proximal tubule. Recent evidence suggested that CLC5 also resides in the podocytes and may play an important role in proper function of the slit diaphragm. Thus, CLCN5 mutations may affect podocyte integrity and lead to FSGS or FGGS. We have identified a novel variant of CLCN5 associated with histologic FSGS. Whether glomerular or tubular expression of the variant is responsible for the kidney disease is not yet clear.

Conclusions: We identified a new mutation in the CLCN5 gene in adult patients who presented with a histologic diagnosis of FSGS but without clinical manifestations of Dent disease. In cell culture, the mutation results in aberrant localization that may underlie pathogenic significance.

Defects of the Nuclear Pore Proteins NUP93, NUP205, or Exportin-5 Link Nephrotic Syndrome to Disrupted SMAD Signaling Daniela A. Braun,[1] Carolin Sadowski,[1] Stefan Kohl,[1] Svjetlana Lovric,[1] Susanne Astrinidis,[2] Shazia Ashraf,[1] Werner Lukas Pabst,[1] Weizhen Tan,[1] Jennifer A. Lawson,[1] Merlin Airik,[1] Richard P. Lifton,[3,4] Heon Yung Gee,[1] Wolfram Antonin,[2] Friedhelm Hildebrandt.[1,4] *[1]Nephrology, Boston Children's Hospital, Boston, MA; [2]Friedrich Miescher Laboratory, Max Planck Society, Tübingen, Germany; [3]Dep. of Genetics, Yale Univ School of Medicine, New Haven, CT; [4]Howard Hughes Medical Inst, Chevy Chase, MD.*

Background: Steroid resistant nephrotic syndrome (SRNS) is a frequent cause of end-stage renal disease in the first decades of life. Identification of single-gene causes of SRNS has furthered the understanding of its pathogenesis. However, additional genes and disease mechanisms remain unknown.

Methods: We combined homozygosity mapping with whole exome sequencing (WES) in 100 individuals with SRNS. To identify additional mutations, we screened our cohort of ~800 individuals with SRNS by microfluidic multiplex PCR (Fluidigm Access Array™) and next generation sequencing. We examined nuclear translocation of SMAD4, utilized a luciferase reporter construct under the control of a SMAD responsive element, and performed co-immunoprecipitation to test the pathogenicity of the identified human disease alleles.

Results: By WES and multiplex PCR, we identified mutations in the genes *NUP93, NUP205*, and *XPO5* (encoding for nucleoporin 93, 205 and exportin-5) in 8 unrelated families with SRNS. All individuals had early onset SRNS with rapid disease progression. We show that all three proteins localize to WT1 positive podocyte precursor cells in developing rat kidney. Human mutations in *NUP93* disrupt the assembly and integrity of the nuclear pore complex (NPC). A human mutation in *NUP205* abrogates the interaction with NUP93 within the NPC. We demonstrate that NUP93 and exportin-5 interact with the transcription factor SMAD4, and that human mutations of *NUP93* abrogate this interaction. Furthermore, human mutations of *NUP93* interfere with SMAD dependent transcription downstream of BMP7.

Conclusions: We identify mutations of *NUP93, NUP205*, or *XPO5* as novel monogenic causes of steroid-resistant nephrotic syndrome in humans, and implicate disrupted SMAD signaling in its pathogenesis.

A Heterozygous Rare Variant in IL-XR Contributes to Autosomal Dominant FSGS in an African American Kindred Gentzon Hall,[1,3,4] Jose A. Gomez,[1] Peter J. Lavin,[5] Eugene C. Kovalik,[1,3] Peter J. Conlon,[6] Rasheed A. Gbadegesin.[2,3,4] *[1]Internal Medicine, Duke Univ; [2]Pediatrics, Duke Univ; [3]Nephrology, Duke Univ; [4]Duke Molecular Physiology Inst, Duke Univ; [5]Trinity College, Ireland; [6]Beaumont Hospital, Ireland.*

Background: FSGS is a disorder characterized by podocyte injury, focal glomerular scarring, nephrotic syndrome and rapid progression to ESKD. Although FSGS disproportionately affects African Americans (AA), there is no report of a causal FSGS gene identified in an AA index kindred. Here we report the discovery of a rare heterozygous missense variant in the interleukin-X receptor (*IL-XR*) as contributory to autosomal dominant (AD) FSGS in a AA kindred from the US.

Methods: We identified an AA kindred with six affected individuals spread over three generations. We performed whole-exome sequencing on three affected members of the family. We confirmed all pathogenic variants by direct sequencing and performed segregation analysis on the family. Complementary molecular genetic analyses were performed in conditionally immortalized human podocytes to evaluate the effects of the segregating variant on JAK/STAT signaling and cell proliferation.

Results: We identified a segregating heterozygous rare variant (K47R) within the ligand binding domain of *IL-XR* in the kindred. The variant was absent from 8,600 Caucasian chromosomes and has a minor allele frequency of 0.003 in the AA population in EVS. The change is conserved in evolution and is considered damaging by *in silico* prediction. We confirmed the expression of IL-XR in kidney and podocytes by RT-PCR, immunohistochemistry, and immunoblot analyses. Because IL-XR is known to signal through the JAK/STAT pathway, we examined the effect of $IL\text{-}XR_{K47R}$ expression on STAT3 activation and proliferation in podocytes. We determined that $IL\text{-}XR_{K47R}$ expression enhanced basal STAT3 activation and induced hyperproliferation.

Conclusions: We report the identification of a heterozygous rare variant in IL-XR as a contributor to AD FSGS in an AA kindred. IL-XR is expressed in the kidney and podocytes and overexpression of $IL\text{-}XR_{K47R}$ significantly enhanced basal STAT3 activation and podocyte proliferation *in vitro*.

FR-OR054

Genetic Investigation and Phenotypic Characterization of Uromodulin Associated Kidney Disease Christine Gast,[1,2] Monica Arenas Hernandez,[3] Anthony Marinaki,[3] Gopalakrishnan Venkat-Raman.[1,2] *[1]Wessex Kidney Centre, Portsmouth Hospitals Trust, Portsmouth, United Kingdom; [2]Genetic and Genomic Medicine, Univ of Southampton, Southampton, United Kingdom; [3]Purine Research Laboratory, St. Thomas' Hospital, London, United Kingdom.*

Background: Uromodulin associated kidney disease (UAKD) is a difficult to diagnose, rare autosomal dominant genetic disorder caused by mutations in the *UMOD* gene. We aimed to determine the frequency and distribution of pathogenic *UMOD* mutations in a familial kidney disease cohort and to investigate any distinguishing clinical features.

Methods: CKD patients with a family history (FHx) of renal disease were ascertained from a large tertiary renal center through a questionnaire study and database search. Patients with a FHx suggesting an unknown genetic diagnosis or UAKD were recruited. DNA was extracted from blood or saliva and sequenced for *UMOD* exons 3-5. Phenotypic characteristics were compared between patients with and without *UMOD* mutations, with significance testing in SPSS.

Results: Of 3,760 patients in CKD stages 3-5, 131 patients with a compatible FHx were identified and recruited. Of these, 30 patients (23%) from 17 families had 11 distinct pathogenic *UMOD* mutations. In 12 patients (9%) from 7 families this was previously unsuspected. UAKD patients had significantly lower protein creatinine ratios (median 28, versus median 222, Mann-Whitney-U p=0.001), less hematuria (c2 p=0.0003), more electrolyte abnormalities (c2 p=0.02) and less severe anaemia (c2 p=0.049) pre renal replacement therapy (RRT). There were no statistically significant differences in uric acid, gout, allopurinol use, hypertension, renal cysts, renal size, and age at presentation or RRT.

Conclusions: UAKD is common amongst familial nephropathy patients, and is poorly predicted by clinical features. Hyperuricaemia or gout, both typical of early UAKD, did not distinguish from prevalent familial nephropathies, but less proteinuria and haematuria did. More electrolyte abnormalities in UAKD could be due to an alteration in tubular water permeability; the reason for less anaemia is unclear. Having demonstrated a high prevalence of UAKD, we advise *UMOD* testing guided by family history regardless of typical phenotype.

FR-OR055

Chaperone Therapy in Stem Cells Derived from Fibroblasts with Missense Mutations in X-Linked Alport Syndrome Dongmao Wang,[1] Sharon D. Ricardo,[2] Judith A. Savige.[1] *[1]Medicine, The Univ of Melbourne (Melbourne Health), Melbourne, VIC, Australia; [2]Anatomy and Developmental Cell Biology, Monash Univ, Clayton, VIC, Australia.*

Background: Forty % of mutations in X-linked Alport syndrome are caused by missense changes, often where Gly is substituted with another amino acid. Chaperone treatment has been useful in other diseases due to missense mutations. The aim of this study was to produce iPS from fibroblasts from a male with X-linked Alport syndrome and determine the effects of the chemical chaperone, 4 phenyl butyric acid.

Methods: Stem cells were made by the Ricardo laboratory from skin fibroblasts from a male with X-linked Alport syndrome due to p.G624D. He had developed renal failure at the age of 54, and had hearing loss, but no lenticonus or central retinopathy. Stem cells were induced to become podocytes, and examined for collagen IV a1 – a6 expression, and for markers of ER stress (ATF6, HSPA5, DDIT3), autophagy (ATG5, BECN1, ATG7) and apoptosis (CASP3, BAD, BCL2) using qRT-PCR (Applied Biosystems 7500). Levels of collagen IV a5 chain were quantitated in an in-house inhibition ELISA. These measurements were repeated after incubation with the chemical chaperone, 10 mM 4-phenyl butyric acid.

Results: The iPS expressed collagen IV a3 and a4 mRNA consistent with a podocyte phenotype. Levels of collagen IV a5 mRNA and protein were not different from those in normal male fibroblasts. However levels of both intra and extracellular collagen IV a5 were reduced suggesting degradation. The Alport iPS had increased transcripts for HSPA5, and apoptosis (CASP3 and BCL2) compared with normal. Incubation with 4 phenyl butyric acid, resulted in a reduction in all markers of autophagy and of CASP3.

Conclusions: iPS derived from Alport fibroblasts represent a model system in which to examine novel treatments. Chemical chaperone therapy has beneficial effects on cells derived from individuals with Alport syndrome due to missense mutations.

Massively Parallel Sequencing (MPS) in Diagnostically Refractory Genetic Renal Disease (GRD) Andrew John Mallett,[1,2,4] Chirag Patel,[2,3,4] Joanna Crawford,[4] Bruce Bennetts,[5] Melissa H. Little,[4,7,8] Helen G. Healy,[1,2] Stephen I. Alexander,[5] Valentine Hyland,[6] Cas Simons.[4] *[1]Kidney Health Service & Conjoint Kidney Research Laboratory, Royal Brisbane and Women's Hospital, Australia; [2]School of Medicine, The Univ of Queensland, Australia; [3]Genetic Health Queensland, RBWH, Australia; [4]Inst for Molecular Bioscience, UQ, Australia; [5]Depts of Molecular Genetics and Nephrology, Children's Hospital at Westmead, NSW, Australia; [6]Molecular Genetics Laboratory, Pathology Queensland, Australia; [7]Murdoch Children's Research Inst, Melbourne, VIC, Australia.*

Background: GRD accounts for 10% of adults and 50% of children with end stage kidney disease. An unknown proportion of cases remain refractory to current clinical genetic tests. Advances in MPS enable attempts to address this in a research setting. We aimed to utilize MPS with pedigree analysis in unresolved cases of GRD.

Methods: Families with clinically diagnosed GRD were recruited in whom clinical genetic testing was either negative or not available. Whole exome sequencing was undertaken and analyzed with custom in house bioinformatics assessment tools accounting for all inheritance patterns. Identified variants of interest were confirmed using Sanger sequencing in clinical laboratories.

Results: 14 families (62 participants) were recruited with a variety of GRD diagnoses and modes of inheritance. A molecular genetic diagnosis has been resolved in 5 families. These include mutations in *RMND1* (compound heterozygous), *IFT140* (compound heterozygous), *HNF4A* (heterozygous), *COL4A5* (hemizygous) and *tRNA(Phe)* (mtDNA) genes. All have been confirmed in a clinical diagnostic laboratory and reported back to the participants with further genetic counseling. Research continues in the remaining 9 families, including application of whole genome sequencing. No reportable incidental genetic findings were identified.

Conclusions: MPS confirmed and clarified a clinical genetic diagnosis in 5/14 families with previously and diagnostically refractory GRD. These results were integrated into clinical practice and demonstrate an emerging role for MPS in the delivery of clinical care. Further studies are required to resolve the remaining families.

FR-OR057

Development and Validation of Targeted Genomic Enrichment and Massively Parallel Sequencing as a Diagnostic Test for Genetic Renal Diseases Christie P. Thomas,[1,3] M. Adela Mansilla,[2] Ramakrishna Sompallae,[2] Sara Mason,[2] Anne E. Kwitek,[2] Colleen Ann Campbell,[2] Richard J. Smith.[1,2] *[1]Internal Medicine, Univ of Iowa, Iowa City, IA; [2]Inst of Human Genetics, Univ of Iowa, Iowa City, IA; [3]Vetarans Affairs Medical Center, Iowa City, IA.*

Background: Many renal diseases have a genetic basis, although definite genetic confirmation of precise etiology is rarely sought, in spite of the value of genetic screening in patients with ESRD both to confirm a diagnosis and to guide the evaluation of living related kidney donors, who may be at increased risk of ESRD.

Methods: To enable comprehensive screening for genetic diseases, we developed a panel that combines targeted genomic enrichment with massively parallel sequencing to simultaneously interrogate 120 genes implicated in 75 renal diseases. To validate this panel, we studied 20 controls and 20 patients with presumed genetic renal disease, four of whom were transplant candidates. We also evaluated six siblings or children who were considering living donation. Samples were sequenced on the Illumina MiSeq®.

Results: On average, we identified 500 variants per sample at a mean depth-of-coverage of 390x. After filtering to remove low quality/common variants, rare/novel variants were annotated using the Human Gene Mutation Database (HGMD®). Pathogenicity of novel variants was predicted in silico using algorithms to score variants based on conservation and function. As a measure of specificity and sensitivity, we Sanger validated 876 variants, confirming all. To optimize relevance of generated data, variants were discussed in the context of clinical data and observed genetic results. We identified causal variants in six of 20 patients (30%) with presumed genetic disease, thus enabling us to counsel these patients and alter their care. We were able to confirm a genetic renal diagnosis in 3 of 4 transplant candidates and offer asymptomatic family members mutation-specific screening to determine if they carried the disease genotype.

Conclusions: This genetic renal disease panel provides a rapid, efficient, unbiased and cost-effective way to diagnose monogenic renal diseases and evaluate living donors at risk for genetic renal disease.

FR-OR058

The B Cell Survival Cytokine BAFF Promotes Murine Lupus Nephritis via Activation of TACI, Not BAFF Receptor Shaun W. Jackson,[1,2] Holly Jacobs,[1] Christopher Thouvenel,[1] Tanvi Arkatkar,[1] Genita Metzler,[1] Nicole Scharping,[1] David Rawlings.[1,2] *[1]Seattle Children's Research Inst, Seattle, WA; [2]Dept of Pediatrics, Univ of Washington, Seattle, WA.*

Background: Transgenic (Tg) over-expression of the B cell survival cytokine BAFF (also known as BLyS) promotes immune-complex glomerulonephritis in mice. Consistent with this, lupus nephritis patients have increased serum BAFF levels and the BAFF-targeted monoclonal Belimumab is an approved SLE therapy. BAFF binds two B cell receptors, BAFF-R and TACI. Since BAFF-R is required for mature B cell survival, this receptor is predicted to explain BAFF-Tg autoimmunity. However, potential important roles for TACI have not been addressed.

Methods: To test the impact of TACI on BAFF-driven autoimmunity, we crossed BAFF-Tg and *Taci-/-* mice. Autoantibodies and urine albumin were measured by ELISA, and B cell phenotyping was performed by FACS.

Results: Despite marked splenic B cell hyperplasia, deletion of TACI abrogated serum anti-nuclear autoantibodies (ANA) in BAFF-Tg mice. In addition, lack of TACI prevented autoantibodies targeting RNA- and DNA-associated self-antigens, including Sm/RNP and dsDNA, across all immunoglobulin isotypes and subtypes, including IgM, IgG, IgA, IgG2b, IgG2c, IgG3. Aged BAFF-Tg mice develop prominent immune-complex glomerulonephritis, characterized by mesangial expansion, glomerular basement membrane thickening and capillary occlusion. Consistent with the lack of serum autoantibodies, *Taci-/-*.BAFF-Tg were completely protected from murine lupus nephritis, as evidenced by lack of albuminuria and restoration of renal histology.

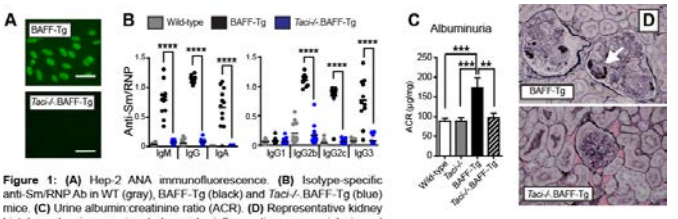

Figure 1: (A) Hep-2 ANA immunofluorescence. **(B)** Isotype-specific anti-Sm/RNP Ab in WT (gray), BAFF-Tg (black) and *Taci-/-*.BAFF-Tg (blue) mice. **(C)** Urine albumin:creatinine ratio (ACR). **(D)** Representative kidney histology showing prominent glomerular inflammation, mesangiolysis and capillary occlusion (arrow) in BAFF-Tg, but not *Taci-/-*.BAFF-Tg mice. **, P<0.01; ***, P<0.001; ****P<0.0001.

Conclusions: We report the novel observation that TACI, not BAFF-R, is the predominant B cell receptor promoting BAFF-mediated murine lupus nephritis. These findings suggest that TACI may be an important therapeutic target in SLE, particularly in patients with high serum BAFF levels.

FR-OR059

B Cell-Intrinsic Interferon Gamma (IFNγ) Signals Promote B Cell Activation and the Development of Lupus Nephritis Shaun W. Jackson,[1,2] Nicole Scharping,[1] Holly Jacobs,[1] Tanvi Arkatkar,[1] David Rawlings.[1,2] *[1]Seattle Children's Research Inst, Seattle, WA; [2]Dept of Pediatrics, Univ of Washington, Seattle, WA.*

Background: The TH1 cytokine interferon gamma (IFNγ) has been implicated in lupus pathogenesis via direct activation of autoreactive T cells. Whether IFN-γ also exerts cell-intrinsic impacts on autoantibody-producing B cells has not been studied. We developed a chimeric lupus model in which Wiskott-Aldrich syndrome protein (WAS)-deficient B cells promote spontaneous humoral autoimmunity (Jackson, et al. *J Immunol* 2014). An important advantage of the WAS chimera model is that dysregulated immune responses are limited to the B cell compartment, allowing genetic manipulation in a B cell-intrinsic fashion. In the current study, we contrast the impact of global, T cell- and B cell-intrinsic deletion of the IFNγ receptor (IFNgR) on development of lupus nephritis.

Methods: We established lupus-prone WAS chimeras in which IFN-γR was deleted on all immune cells (global IFN-γR-null) or specifically on B or T cells. Chimeras were analyzed for autoantibodies, immune activation and immune-complex glomerulonephritis (IC GN) by ELISA, flow cytometry and immunohistochemistry.

Results: Global IFNgR deletion prevented autoantibody (Ab) production and systemic inflammation in WAS chimeras. Strikingly, cell-intrinsic deletion of IFN-γR on either T cells or B cells recapitulated the phenotype of global IFNgR deficiency. Mechanistically, deletion of IFNgR on B cells prevented the formation of spontaneous germinal centers (GCs), required for class-switched Ab formation. Consistent with lack of serum autoantibodies, IC GN was abrogated in B cell IFNgR-null chimeras. Interestingly, B cell-intrinsic deletion of the TH1 transcription factor T-bet prevented pathogenic IgG2c subclass Ab, but did not impact spontaneous GCs or systemic inflammation.

Conclusions: We report a novel T-bet-independent mechanism whereby IFNγ promotes lupus nephritis via direct actions on B cells. This study is the first to directly address the impact of B cell IFN-γ activation in murine lupus, of relevance to both the understanding of disease pathogenesis and to efforts to target IFNγ therapeutically in SLE.

FR-OR060

Mechanisms of Anti-CD20 B Cell Treatment of Experimental Autoimmune MPO-ANCA Glomerulonephritis Poh-Yi Gan,[1] Joshua D. Ooi,[1] A. Richard Kitching,[1,2] Stephen R. Holdsworth.[1,2] *[1]Dept of Medicine, Monash Univ, Clayton, Victoria, Australia; [2]Dept of Nephrology, Monash Health, Clayton, Victoria, Australia.*

Background: Depletion of B cells with anti-CD20 monoclonal antibody (mAb), rituximab, is an effective therapeutic for human MPO-ANCA GN. Its capacity to attenuate established disease suggests that $CD20^+$ B cells are important in maintaining anti-MPO autoimmunity. Whilst B cells are clearly important in maintaining ANCA production, their role in maintaining established nephritogenic anti-MPO CD4 T cell driven autoimmunity is unknown. This study assesses this role and its importance in this disease model.

Methods: Experimental anti-MPO autoimmunity was induced by immunizing C57BL/6 (WT) mice with MPO in Freund's adjuvant and GN triggered using a subnephritogenic dose of anti-GBM globulin. Mouse anti-CD20 mAb (or control mouse anti-IgG2a mAb) was administered to mice with established anti-MPO autoimmunity (day 14) and continued through the development of GN (terminated on day 32).

Results: Administration of anti-CD20 mAb induced profound and continued B cell depletion and protected mice from the development of renal injury, compared to controls (segmental glomerular necrosis: 16±4 vs 44±4%, albuminuria: 221.0±81.6 vs 898.8±330.3mg/24hrs and glomerular $CD4^+$ T cell influx: 0.4±0.07 vs 0.9±0.1, all $P<0.05$). Systemic anti-MPO autoimmunity was also reduced; serum anti-MPO IgG (ANCA) titres (0.21±0.02 vs 0.34±0.07 OD450nm, $P<0.05$) and dermal MPO induced DTH swelling (0.07±0.02 vs 0.2±0.03 Dmm, $P<0.01$). Anti-CD20 mAb treatment decreased MPO specific recall proliferation in draining lymph node cells (104.5±12.7 vs 217.7±55.3 counts per minute, $P<0.05$) with reduced frequency of IFN-γ and IL-17A producing cells (ELISPOT: 22±6 vs 115±27 cells, $P<0.01$ and 6±3 vs 40±18 cells, $P<0.05$, respectively). Furthermore anti-CD20 treatment increased the proportion of proliferating $Foxp3^+$ T regulatory cells (2.9±0.1 vs 1.7±0.1 %, $P<0.001$; 15% of proliferating $Foxp3^+$ T cells in both groups produced IL-10).

Conclusions: In addition to its known capacity to reduce humoral autoimmunity, this study shows that anti-CD20 mAb induced B cell depletion significantly reduces anti-MPO CD4 T cell effectors and enhances T regulatory cells.

Funding: Government Support - Non-U.S.

FR-OR061

Novel Anti-Peroxidasin Antibodies Are Part of the Autoimmune Milieu in Preclinical and Clinical Goodpasture's Disease Abraham Scott Mccall,[1] Gautam B. Bhave,[1] Vadim Pedchenko,[1] Agnes B. Fogo,[3] Dustin J. Little,[2] Thomas P. Baker,[2] Stephen W. Olson,[2] Billy G. Hudson.[1] *[1]Nephrology and Hypertension, Vanderbilt Univ Medical Center, Nashville, TN; [2]Nephrology, Walter Reed Army Medical Center, Bethesda, MD; [3]Pathology, Vanderbilt Univ Medical Center, Nashville, TN.*

Background: Goodpasture's disease (GP) is an autoimmune disorder characterized by autoantibodies directed against the NC1 domains of the a3/α5 chains of collagen IV in the glomerular and alveolar basement membranes. Epidemiologically, anti-MPO positivity often occurs with GP diagnosis. The normally cross-linked collagen IV scaffold forms through the action of the heme peroxidase, peroxidasin, via its HOBr production to from a sulfilimine (S=N) crosslink in the NC1 domain, however loss of the S=N crosslink changes recognition of the NC1 domain by GP antibodies.

Methods: A Vanderbilt GP patient cohort and a retrospective case-control Department of Defense Serum Repository (DoDSR) cohort were tested for recognition of peroxidasin, MPO, a3 and α5(IV) NC1 domains by ELISA with 3:1 age, sex, race, and age of serum matched controls from the DoDSR. Competition binding ELISA was performed to determine antigen specificity and immunofluorescence was performed on GP biopsies for peroxidasin levels. Peroxidasin HOBr production *in vitro* was fluorometrically tested in the presence of purified antibodies.

Results: Anti-peroxidasin autoantibodies are present in GP patient sera 33%(8/24) at diagnosis, and in 66%(4/6) of pre-diagnosis GP patients. Unexpectedly, the anti-peroxidasin specific antibodies cross-react with coated, but not native MPO, accounting for a subset of the currently defined dual-positive patients. We also found significantly elevated focal peroxidasin staining in crescentic glomeruli of GP patients. Importantly, patient IgG containing anti-peroxidasin antibodies significantly inhibited of peroxidasin's HOBr production rate.

Conclusions: Peroxidasin is a novel autoantigen in a subset of GP patients validated in two independent cohorts. Anti-peroxidasin antibodies potentially contribute to disease pathogenesis in GP with possible implications to be explored in other anti-MPO associated disease.

FR-OR062

Autoantibodies against Thrombospondin Type-1 Domain-Containing 7A Induce Membranous Nephropathy in Mice Nicola M. Tomas,[1] Elion Hoxha,[1] Lars Fester,[1] Udo Martin Helmchen,[1] Gerth H. Jens,[3] Friederike Bachmann,[2] Klemens Budde,[2] Friedrich Koch-nolte,[1] Gunther Zahner,[1] Gabriele M. Rune,[1] Gerard J. Lambeau,[4] Catherine Meyer-Schwesinger,[1] Rolf A. Stahl.[1] *[1]Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; [2]Charité- Universitätsmedizin Berlin, Berlin, Germany; [3]Heinrich Braun Klinikum, Zwickau, Germany; [4]Inst de Pharmacologie Moléculaire et Cellulaire, Valbonne, France.*

Background: Membranous nephropathy (MN) is an autoimmune disease and a frequent cause of nephrotic syndrome in adults. Autoantibodies against the podocyte proteins phospholipase A_2 receptor 1 and thrombospondin type-1 domain-containing 7A (THSD7A) have been identified in about 75% of patients with MN. However, it is unclear whether these autoantibodies are causative for the development of MN.

Methods: Sera from two patients with anti-THSD7A autoantibody positive MN and control serum were injected into male BALB/c mice. We then analyzed the morphological and clinical development of MN in these mice.

Results: Mice that received anti-THSD7A positive serum developed subepithelial immune deposits containing human IgG (huIgG), which colocalized with THSD7A, suggesting antigen specificitiy of bound huIgG. Supporting, IgG eluted from frozen kidney sections of these mice was specific for THSD7A in Western blot analysis. All mice that were exposed to human serum were found to have circulating mouse anti-huIgG, but only mice that received anti-THSD7A positive serum had subepithelial deposits containing mouse IgG. Moreover, histological analyses revealed granular subepithelial staining for complement C3, suggesting local activation of the complement system. Electron microscopy demonstrated electron-dense deposits in a strictly subepithelial localization and focal podocyte foot process effacement. Mice injected with anti-THSD7A positive serum developed albuminuria starting day 3, while urinary albumin excretion of mice injected with control serum remained unchanged.

Conclusions: We conclude that anti-THSD7A autoantibodies are pathogenic and can induce MN in mice.

FR-OR063

Epitope Spreading in PLA2R1 Is Associated with Bad Prognosis in Membranous Nephropathy Barbara Seitz-Polski,[1,2,3] Guillaume Dolla,[2] Christine Payre,[2] Sylvia Benzaken,[1] Ghislaine Bernard,[1] Vincent L.M. Esnault,[3] Gerard J. Lambeau.[2] *[1]Immunology, Nice Univ Hospital, Nice, France; [2]Inst de Pharmacologie Moléculaire et Cellulaire, CNRS and Univ of Nice, Valbonne, France; [3]Nephrology, Nice Univ Hospital, Nice, France.*

Background: The phospholipase A2 receptor (PLA2R1) is the major autoantigen in idiopathic membranous nephropathy, with two recently identified epitopes of unknown clinical significance.

Methods: Fifty PLA2R1-positive patients' sera were screened by western blot on a series of PLA2R1 deletion mutants covering the ten extracellular domains. We identified epitopes in the CysR, CTLD1 and CTLD7 domains and confirmed the reactivity against these three domains with soluble forms of each domain using a new ELISA in 69 PLA2R1-positive patients.

Results: Domain-specific ELISAs allowed stratifying 69 PLA2R1-positive patients into three subgroups: 23 CysR, 14 CTLD1 + CysR and 32 CysR + CTLD1 + CTLD7. Median ELISA titers measured using the full-length PLA2R1 antigen were not statistically different between patients' subgroups. The 23 patients with anti-CysR restricted activity were younger ($p=0.008$), had less nephrotic range proteinuria ($p=0.018$) and exhibited more spontaneous remission ($p=0.03$), lower rate of renal failure progression ($p=0.0025$) and less end-stage kidney disease ($p=0.01$) during follow-up. Indeed, 31/69 patients had poor renal prognosis according to KDIGO (urinary protein/creatinine ratio over 4 g/g or eGFR<45 ml/min/1.73m^2 at end of follow-up). High anti-PLA2R1 activity and epitope spreading beyond CysR epitope were independent risk factors of poor renal prognosis in multivariable cox regression analysis. Epitope spreading during follow-up was associated with disease worsening (n=3), whereas reverse spreading from CTLD7 profile back to CysR was associated with favorable outcome (n=1).

Conclusions: We conclude that analysis of the PLA2R1 epitope profile and spreading during follow-up is a powerful tool to monitor disease severity and stratify patients into subgroups with different renal prognosis.

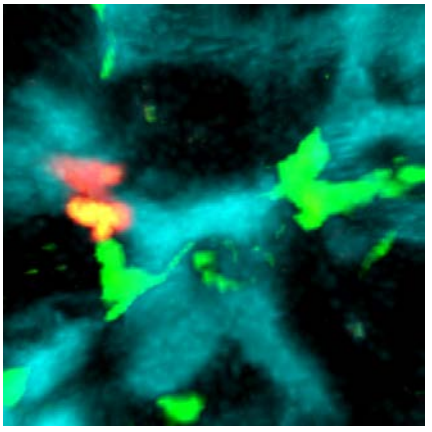
FR-OR064

Intravascular Extensions Allow Renal DC to Capture Bloodborne Antigens and Mediate T Cell Migration into the Kidney Karim Yatim, Martin H. Oberbarnscheidt. *Thomas E. Starzl Transplantation Inst, Univ of Pittsburgh, Pittsburgh, PA.*

Background: We have previously shown that the kidney, a non-barrier, highly vascularized organ possesses an extensive monocyte-derived DC network with around 25% of DC sampling intravascular antigen (Ag) by extending projections into the lumina of cortical postcapillary venules. Here, we hypothesized that renal DC have an active role in immune surveillance via (1) capturing intravascular antigens such as bacteria and immune complexes (IC) and (2) mediate Ag-specific T cell migration into the kidney.

Methods: 2-Photon Intravital Microscopy (2PIM) and flow cytometry was performed on CX3CR1 GFP/+ (DC express GFP) mouse kidneys. Ovalbumin immune complexes (OVA-IC) conjugated to PE-TxRed **or** E.coli expressing Ovalbumin (OVA) and CFP were i.v. injected. For migration experiments, $CD8^+DsRed^+$ OT-I effector T cells were injected i.v.

Results: After systemic administration of fluorescent E. coli we observed (1) DC uptake of bacteria from the intravascular space immediately after injection (2PIM and flow cytometry) and (2) a 41% increase of DCs with intravascular processes after E.coli injection(2PIM). DC also took up i.v. OVA-IC, (2PIM). Furthermore, in the setting of a systemic CFP-OVA E.coli infection, OT-I T cells migrated into the kidney (2PIM and flow) with 2PIM showing stable DC-T cell interactions and DC (green)-mediated T cell (red) migration into the kidney (figure 1) (blood=cyan).



OT-I migration was significantly higher (2-fold) when CFP-OVA E.coli was used as opposed to non-OVA expressing WT E.coli.

Conclusions: We have shown in two different models that renal DC are actively surveilling the blood for Ag. In the case of infection, we demonstrated that DC mediate Ag-specific T cell migration into the kidney. These findings may shed light on the role of DC in infection and the pathogenesis of immune-complex mediated renal diseases.

The C5a Receptor Mediates Anti-Myeloperoxidase Auto-Immunity and Glomerulonephritis

Jonathan Dick, Poh-Yi Gan, Sharon Lee Ford, Maliha A. Alikhan, A. Richard Kitching, Stephen R. Holdsworth. *Centre For Inflammatory Diseases, Monash Univ, Melbourne, Australia.*

Background: C5aR inhibition is currently the subject of a clinical trial for treatment of ANCA associated vasculitis. C5a is known to play an important role in neutrophil behaviour, however whether complement acting through the C5aR influences anti-myeloperoxidase (MPO) autoimmunity itself is unknown.

Methods: MPO autoimmunity was induced by injecting C57BL/6 (WT) or C5aR-/- mice with MPO in Freund's adjuvant. In separate experiments WT mice were injected with $1x10^6$ WT or C5aR-/- MPO-pulsed bone marrow derived dendritic cells (DCs). Anti-MPO glomerulonephritis was triggered by a sub-nephritogenic dose of anti-GBM globulin.

Results: Autoimmunity at 10 days measured by anti-MPO IgG ELISA was significantly reduced in C5aR-/- mice (0.64±0.05 vs 0.20±.0.02)$OD450_{nm}$ p<0.001). This was associated with a lower proportion of splenocytes that were B220+ B cells (58±2 vs 32±2% p<0.001) and a higher serum BAFF(11.4±0.5 vs16.6±1.4 ng/ml p=0.01) compared to WT. T cell immunity to MPO was significantly attenuated in C5aR-/- mice measured by proliferation of recombinant MPO stimulated lymph node culture ([3H]-Thymidine 1302±253 vs 574±123 counts per minute, p=0.01). Th1 response was reduced measured by IFN-γ ELISPOT (55±11 vs 26±6cells p=0.03) and footpad DTH (0.16±0.02 vs 0.04±0.01Dmm p=0.001). There was no difference in Th17 response:IL17A ELISPOT (32±7 vs 31±8 cells). The proportion of CD4+CD25+Foxp3+ T regulatory cells was significantly increased in C5aR-/- mice (11.8±0.2 vs 13.5±0.4% p<0.001). To determine whether C5aR expression on DCs promotes T cell mediated anti-MPO glomerulonephritis, autoimmunity was induced by injection of MPO-pulsed C5aR-/- or WT bone marrow derived DCs into WT mice. Anti-MPO glomerulonephritis was induced 10 days after DC transfer resulting in reduced renal injury (segmental glomerular necrosis 30.9±5% vs 9.9±2%p=0.005) in the group receiving C5aR-/-DCs.

Conclusions: Complement acting through the C5aR plays an important role in modulating both humoral and cellular anti-MPO autoimmunity in mice. This suggests an additional mechanism by which C5aR inhibition in ANCA associated vasculitis may be an effective treatment strategy.

Intestinal T_H17 Cells Drive Renal Tissue Injury in Crescentic Glomerulonephritis

Christian F. Krebs,[1] Jan-Eric Turner,[1] Hans-Joachim Paust,[1] Tobias Koyro,[1] Jan-Hendrik Riedel,[1] Sonja Krohn,[1] Anna Kaffke,[1] Rolf A. Stahl,[1] Samuel Huber,[2] Ulf Panzer.[1] *[1]III. Medizinische Klinik, Univ Hospital Hamburg-Eppendorf, Hamburg, Germany; [2]I. Medizinische Klinik, Univ Hospital Hamburg-Eppendorf, Hamburg, Germany.*

Background: T_H17 immune responses play a critical role in inflammatory disorders and autoimmune diseases. Recent studies indicate that development of T_H17 cell depends on microbial colonization of the gut. However, the impact of gut microbiota induced T_H17 cells for pathogenic T_H17 response in autoimmune diseases, such as crescentic glomerulonephritis (GN), remains unclear.

Methods: To characterize the $CD4^+$ T cell response in the kidney of patients with ANCA-associated GN we established flow cytometry of human renal biopsies. In addition we traced lymphocytes in mice expressing the photoconvertible Kaede protein after induction of experimental glomerulonephritis by using the model of nephrotoxic nephritis (NTN).

Results: Using flow cytometry of renal biopsies we were able to demonstrate the presence of $CD4^+Rorgt^+$ T_H17 cells in the inflamed kidney of patients with ANCA-GN. Interestingly, T_H17 cells in the kidney displayed a gut homing phenotype ($CCR6^+$, $CCR9^+$, $ICOS^+$, IL-7Ralpha$^+$, $CD103^+$), indicating that renal T_H17 cells have been primed in the intestine. Tracing intestinal cells by photoconversion in Kaede mice, we could demonstrate that a significant proportion of the T_H17 cell in the nephritic kidney originated from the small intestine. In line, using germ free mice, we were able to show that renal T_H17 response and consecutive tissue injury in crescentic GN depends on intestinal T_H17 cells. Finally, we demonstrated that treatment of nephritic mice with intestinal microbiota depleting broad-spectrum antibiotics reduced renal T_H17 response and attenuated kidney damage.

Conclusions: These data indicate that pathogenic T_H17 cells in glomerulonephritis, originate from the intestine, migrate into the kidney and induce injury of the renal tissue. This finding might have significant implications for the treatment of renal autoimmune disorders.

FR-OR067

T-Bet Activation in Regulatory T Cells Is Required for General Fitness, Antibody Production and Control of Th1 Responses in Crescentic Glomerulonephritis

Anna Nosko,[1] Malte A. Kluger,[1] Paul Diefenhardt,[1] Simon Melderis,[1] Claudia Wegscheid,[2] Gisa Tiegs,[2] Rolf A. Stahl,[1] Ulf Panzer,[1] Oliver M. Steinmetz.[1] *[1]Nephrology, Hamburg Univ Medical Center; [2]Experimental Immunology, Hamburg Univ Medical Center.*

Background: Mechanisms responsible for down regulation of pathogenic Th1 immunity remain widely unknown. Recently, it was proposed that activation of the Th1 characteristic transcription factor T-bet optimizes $Foxp3^+$ regulatory T cell (Treg) function to counteract Th1 responses.

Methods: Nothing is known about the role of T-bet^+ Treg1 cells in inflammatory disease. We studied their function in the NTN model of acute crescentic glomerulonephritis (GN).

Results: Kidneys of nephritic wild type mice showed increasing percentages of Treg1 cells during the course of NTN, indicating their functional importance. Naïve $Foxp3^{Cre}$x$T\text{-}bet^{fl/fl}$ mice ($Treg1^{-/-}$), lacking Treg1 cells, showed spontaneous skewing towards Th1 immunity. In the absence of Treg1 cells, NTN was aggravated in terms of renal function, histology and inflammatory cell infiltration with selectively elevated renal and systemic Th1 responses. Analyses of Tregs from $Treg1^{-/-}$ mice revealed unaltered systemic numbers, activation, cytokine production and *in vitro* suppressive function. However, expression of the Th1 characteristic trafficking receptor CXCR3 was absent on T-bet deficient Tregs, resulting in significantly reduced renal Treg infiltration. In addition to diminished renal trafficking, overall fitness of Tregs from $Treg1^{-/-}$ mice was greatly impaired. In competitive co-transfer experiments into lymphopenic hosts, T-bet deficient Tregs were outcompeted by wildtype Tregs in terms of proliferation and expression levels of Foxp3. Furthermore, T cell dependent humoral immunity was impaired in $Treg1^{-/-}$ mice, indicating that T-bet activation in Tregs plays a hitherto unrecognized role for antibody production.

Conclusions: Our data indicate the presence of a new subtype of regulatory T cells in crescentic GN. These Treg1 cells are characterized by activation of the transcription factor T-bet, which enhances their overall fitness, directs antibody responses and optimizes their capacity to down-regulate Th1 responses by inducing CXCR3 expression.

FR-OR068

Predicting the Lifetime Risk of End-Stage Renal Disease in Kidney Donor Candidates

Morgan Grams, Yingying Sang, Andrew S. Levey, Kunihiro Matsushita, Shoshana Ballew, Alex R. Chang, Bertram L. Kasiske, Csaba P. Kovesdy, Girish N. Nadkarni, Varda Shalev, Dorry L. Segev, Josef Coresh, Krista L. Lentine, Amit X. Garg. *CKD Prognosis Consortium.*

Background: A tool to comprehensively evaluate the lifetime risk of ESRD in potential living kidney donors could help standardize transplant center acceptance criteria.

Methods: We developed statistical equations to predict the lifetime incidence of ESRD according to a person's baseline demographic and health characteristics before kidney donation. Data sources included prevalence estimates from NHANES, ESRD incidence from USRDS, and ESRD risk associations in low-risk subgroups of 7 general population cohorts (N=4,580,454). Developed equations were applied to the general population (using NHANES) and the recent US donor population (using the OPTN registry) and made available in an online risk calculator (www.transplantmodels.com/lifetime).

Results: For the "base-case" potential donor (eGFR 90 ml/min/1.73 m^2, urine ACR 10 mg/g, systolic blood pressure 120 mmHg, and no adverse health characteristics), the predicted pre-donation lifetime incidence of ESRD varied by age, race, and sex: 2.7%, 1.1%, 0.9%, and 0.6% in 20-year-old black men, black women, white men, and white women, respectively, and 0.6%, 0.3%, 0.3%, and 0.2% in the corresponding 60-year-old candidates. The lifetime incidence of ESRD was higher with additional risk factors, particularly low eGFR or high ACR in young persons (Figure). The predicted lifetime incidence of ESRD before donation was <1% in 88% of recent US donors.

Conclusions: We suggest consideration of pre-donation lifetime ESRD risk in the evaluation and counseling of potential living kidney donors. Our equations estimate a person's lifetime incidence of ESRD in the absence of donation according to multiple demographic and clinical characteristics.

FR-OR069

Post Donation Hypertension and Risk of Death and ESRD Hassan N. Ibrahim, Robert N. Foley, Scott Reule, Danielle M. Berglund, Arthur J. Matas, Aleksandra Kukla, Naim S. Issa, Richard S. Spong. *Univ of Minnesota, Mpls, MN.*

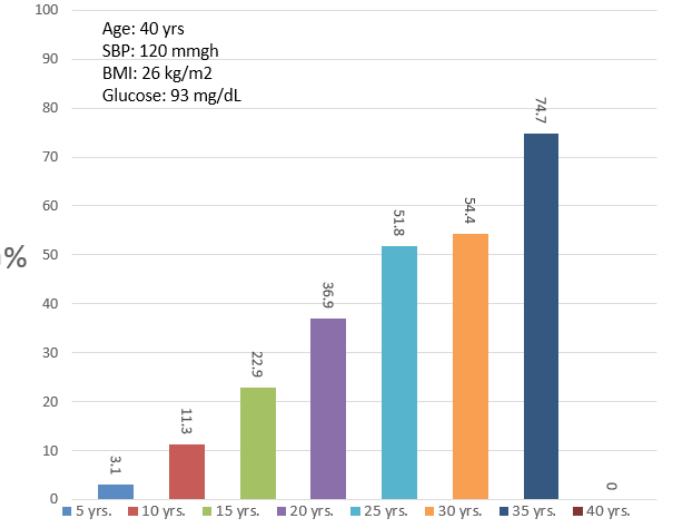
Background: Prevalence of de novo hypertension after kidney donation appears to be similar to that in the general population. Factors associated with it development, however, have not been studied. Goals: 1) ascertain donors' risk of developing HTN, 2) describe the impact of its development on death and renal function and 3) develop a HTN risk prediction model using pre-donation parameters.

Methods: Our donors are followed indefinitely through surveys inquiring about HTN, renal disease and also serial laboratory testing. Risk factors for post donation new onset hypertension were determined using stepwise proportional hazards regression.

Results: HTN status was ascertained in 3638 donors with a mean follow-up of 13±11 years. In total, 972 (27%) developed new onset hypertension. Pre-donation risk factors for development included older age, higher BMI, SBP, and serum glucose at donation (Table 1a). White donors were 40% less likely to develop hypertension, p<0.001 for all. HTN following donation was associated with a nearly 4 fold increased risk of death, proteinuria, and eGFR < 30 ml/min or ESRD (Table 1b). Coefficients from the regression model were then used to create a HTN risk calculator (C-statistic 0.65). A sample output for a 40 year old donor is shown in figure 1.

Variable	Hazard Ratio	p-value
1a) Pre-donation risk factors for HTN		
Age	1.03 (1.03-1.04)	< 0.001
BMI	1.06 (1.04-1.07)	< 0.001
SBP	1.03 (1.02-1.04)	< 0.001
Serum glucose	1.01 (1-1.01)	< 0.001
White race	0.6 (0.45-0.79)	< 0.001
1b) Post donation HTN and hard outcomes		
Death	3.69 (2.88-4.73)	<0.0001
Proteinuria	3.99 (2.62-6.07)	<0.0001
eGFR <30 or RRT	2.48 (1.38-4.46)	0.002

Figure 1. Cumulative risk of HTN for a typical White donor



Conclusions: Hypertension can be reasonably predicted in kidney donors using baseline data. Hypertension is a significant contributor to reduced GFR, ESRD and also death.

FR-OR070

Effect of Changing African American Race to Apolipoprotein L1 *G*enotype on Kidney Donor Risk Index Bruce A. Julian,[1] Robert S. Gaston,[1] Barry I. Freedman,[2] William Mark Brown,[2] Amber M. Reeves-Daniel,[2] Ajay K. Israni,[3,4] David P. Schladt,[3] Stephen O. Pastan,[5] Sumit Mohan,[6] Jasmin Divers.[2] *[1]Univ of Alabama at Birmingham; [2]Wake Forest Univ School of Medicine; [3]Minneapolis Medical Research Foundation; [4]Hennepin County Medical Center, Univ of Minnesota; [5]Emory Univ School of Medicine; [6]Columbia Univ.*

Background: Renal allografts from deceased African Americans (AAs) with 2 renal-risk variants in apolipoprotein L1 gene (*APOL1*) are lost sooner than kidneys from AAs with 0 or 1 variant. For the latter, allograft survival is similar to that for kidneys from European Americans. Kidney Donor Risk Index (KDRI) was developed recently, before *APOL1* effect was described, to quantitatively estimate quality of deceased-donor kidneys; it assigns higher risk for all AA donors. We postulated that replacing AA race with *APOL1* genotype in KDRI improves risk prediction for kidneys from deceased AA donors.

Methods: Using the effect size in retrospective studies, we calculated KDRI wherein only AAs with 2 *APOL1* renal-risk variants received higher KDRI scoring. Weight of *APOL1* risk variants was defined by 10-fold cross validation: 9/10 of available data was used to estimate parameter associated with *APOL1* in Cox proportional hazard regression with other 9 KDRI variables as covariates. Revised KDRI scores were computed and tested on the last subset; predictive ability was measured by c-index. Cross-validation was done 100x for comparison with original KDRI.

Results: Retrospective analyses of 1,149 kidney transplantations from deceased AA donors (979 *APOL1*=0/1; 170 *APOL1*=2 renal-risk variants) showed mean donor age, serum creatinine, and KDRI of 35.4 yr, 1.25 mg/dL, and 1.45. Observed c-index with original KDRI tested with full data was 0.89; distribution of observed *APOL1*-revised KDRI c-indices had minimum 0.55 and maximum 0.98, median 0.87. *APOL1*-revised KDRI c-index was higher than observed KDRI c-index in 44% of cases.

Conclusions: For the 13% of general AA population with 2 *APOL1* risk variants, KDRI did not change. However, for the other 87% of AAs, the revised KDRI improved by deleting AA race as a risk factor and better reflects the quality of these kidneys relative to current system.

FR-OR071

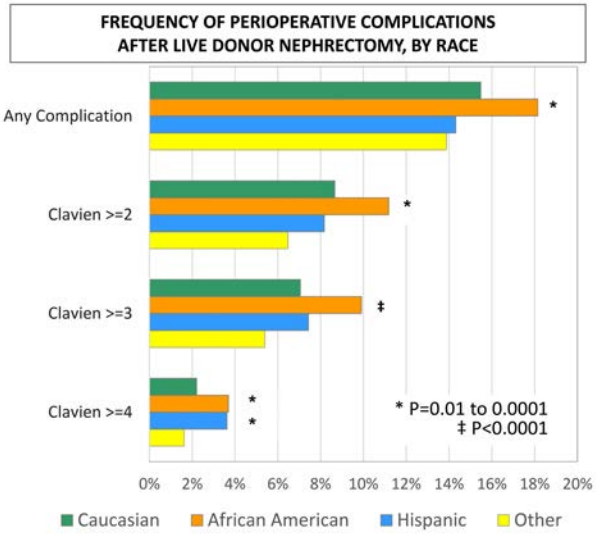
Racial Disparities in Perioperative Complications After Live Kidney Donation Krista L. Lentine,[1] Ngan Lam,[2] David A. Axelrod,[3] Mark Schnitzler,[1] Amit X. Garg,[3] Jesse D. Schold,[4] Daniel C. Brennan,[5] Dorry L. Segev.[6] *[1]Saint Louis Univ; [2]Western Univ; [3]Dartmouth; [4]Cleveland Clinic; [5]Washington Univ; [6]Johns Hopkins.*

Background: The frequency and severity of perioperative complications after contemporary live kidney donation are not well-described.

Methods: We integrated national U.S. donor registry data with administrative records from an academic hospital consortium (98 centers, 2008-2012) to identify predonation comorbidity and perioperative complications captured in diagnostic, procedure and registry sources. Complication severity was graded by Clavien scoring. Correlates (adjusted odds ratio, aOR) of complications were examined with multivariate logistic regression.

Results: Among 14,964 donors, 11.6% were African American (AA) and 72.6% Caucasian; 93.8% of nephrectomies began as laparoscopic, 2.4% as robotic, and 3.7%

as open procedures. Compared with Caucasians, AA donors experienced higher rates of any complication (18.2% vs 15.5%, P=0.005), and those exceeding progressive severity thresholds including Clavien >=4 (3.7% vs 2.2%, P=0.0002) (**Figure**).



After adjustment for demographic, clinical (including comorbidity diagnoses), procedure and center factors, AA race was associated with increased risk of any complication (aOR 1.26, P=0.001), and Clavien >=2 (aOR 1.39, P=0.0002), Clavien >=3 (aOR 1.56, P<0.0001), and Clavien >=4 (aOR 1.56, P=0.004) events. Other significant correlates of Clavien >=4 events included obesity (aOR 1.55), predonation hematologic (aOR 2.78) and psychiatric (aOR 1.45) conditions, and robotic nephrectomy (aOR 2.07), while annual center volume >50 (aOR 0.45) predicted lower risk.

Conclusions: AA race is independently associated with increased frequency and severity of perioperative complications after live donor nephrectomy. Future work should seek to identify underlying mechanisms and approaches to reducing outcome disparities.

Funding: NIDDK Support

FR-OR072

Risk Prediction of End-Stage Renal Disease in Living Kidney Donors

Allan Massie, Dorry L. Segev, Eric Chow. *Johns Hopkins.*

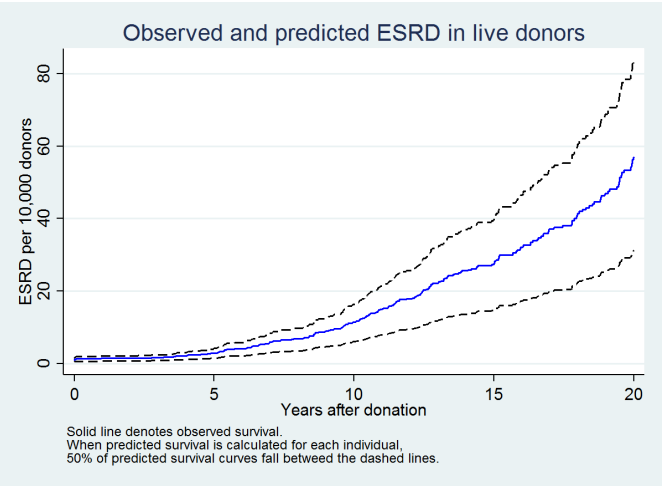
Background: Recent studies have shown increased risk of end-stage renal disease (ESRD) in living kidney donors compared with healthy nondonors. Accurate risk prediction is paramount for informed consent for donation, but individual ESRD risk is unknown.

Methods: Using national donor registry data, we modeled ESRD in 122,773 donors via Cox regression, censoring for mortality. We performed multiple imputation with 50 repetitions to impute body mass index (BMI), unavailable prior to 1999. We used baseline hazard and hazard ratios to calculate individual risk of ESRD at 5, 10, 15, and 20 years post-donation.

Results: Male sex, African-American (AA) race, and higher BMI were associated with greater ESRD risk (all p<0.01, Table 1). Older age was associated with increased risk in non-AA donors (HR per 10y = $_{1.22}$ 1.40 $_{1.60}$, p<0.001), but *decreased* risk in AA donors (HR = $_{0.60}$ 0.76 $_{0.95}$, p=0.02).

Risk factor	HR (*p<0.05; **p<0.01; ***p<0.001)
Male gender	$_{1.51}$ 1.95 $_{2.51}$***
AA race (at age 40)	$_{2.23}$ 3.06 $_{4.21}$***
Age per 10y (non-AA donors)	$_{1.22}$ 1.40 $_{1.60}$***
Age per 10y (AA donors)	$_{0.60}$ 0.76 $_{0.95}$*
BMI per 5 units	$_{1.16}$ 1.48 $_{1.89}$**

Overall cumulative incidence of ESRD at 5, 10, 15, and 20 years was 3.0, 11.6, 27,7, and 56.9 events per 10,000 donors, respectively (Figure 1). Predicted individual 20-year risk ranged from 6.9 per 10,000 (0.07% chance) to 1240.4 per 10,000 (12.4% chance) of ESRD. Median (IQR) individual 20-year risk of ESRD was 49.8 (31.2-83.8) per 10,000 (Figure 1).



A web calculator of individual risk can be found at transplantmodels.com/donesrd

Conclusions: Male gender and higher BMI are associated with greater ESRD risk in kidney donors. Old age is associated with greater ESRD risk among non-AA donors, but younger age is associated with greater risk among AA donors, likely due to donor selection. Greater permissiveness may be warranted for older AA donor candidates; younger AA candidates should be evaluated carefully and counseled about long-term ESRD risk.

FR-OR073

Factors Influencing Decision About Kidney Transplant: A Survey of Dialysis Patients

Fareeha Khalil, Ming Wang, Naman Trivedi, Eric Chang, Nasrollah Ghahramani. *Pennsylvania State Univ College of Medicine, Hershey, PA.*

Background: Kidney transplant (KT) is the treatment of choice for end stage renal disease (ESRD). The decision to pursue KT involves a complex interplay of disease-related, socioeconomic and ethnic factors. We explored factors influencing patients' decision about KT.

Methods: We sent flyers to 1,283 dialysis units. Of 2536 interested participants who fulfilled inclusion criteria, we randomly selected and invited 1400 to complete the questionnaire. Independent variables were demographic factors, distance to dialysis unit, and modes of education about options. In multivariate analysis, we calculated odds ratios (OR) and 95% confidence intervals (CI) for the probability of pursuing KT.

Results: Of 673 participants, 401 had been referred and 201 were listed for KT. Positive predictors of pursuing KT (n=268) included: 'received 3 or more modes of education about KT (OR:3.08;CI:1.62 to 5.87); 'nephrologist discussed the option of KT at least twice in previous year' (OR:2.49;CI:1.43 to 4.32). The 2 most common reasons for not pursuing KT included satisfaction with current treatment (18%) and inadequate finances (14%). Urban residence (OR: 2.64;CI: 1.33 to 5.23) and > 5 years on dialysis (OR: 1.75;CI: 1.09 to 2.81) were associated with likelihood of indicating satisfaction with current treatment as a reason not to pursue KT. Age >60 (OR: 2.18;CI: 1.21 to 3.94) and proximity to dialysis unit (OR: 2.30;CI: 1.27 to 4.17) were associated with higher likelihood of indicating inadequate finances as reason not to pursue KT. Of those pursuing KT, 36% would not consider LDKT, most commonly citing unavailability of potential donor (28%). Positive predictors of pursuing LDKT were: 'nephrologist discussed the option of transplant at least twice in last year'; and married status. Negative predictors of considering LDKT were regular attendance at religious service, age >60, being on dialysis >5 years.

Conclusions: Nephrologist-related factors (delivering diverse education) and patient characterisitcs (age, gender, race, health status perception, marital/socioeconomic status, duration/comfort with dialysis) are important drivers of the decision making process for choice of KT.

FR-OR074

A Propensity-Matched Analysis Comparing Rates of Post-Transplant Diabetes Mellitus (PTDM) in South Asian and Caucasian Renal Transplant Recipients

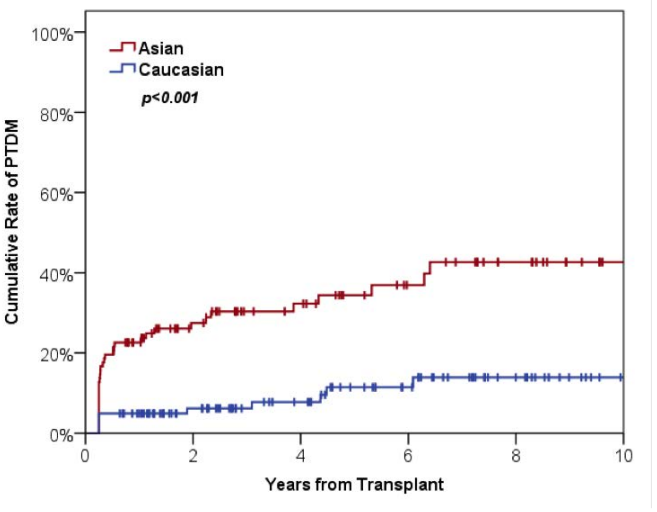
Javeria Peracha, Krishan Parekh, Charles Ferro, Richard Borrows, Adnan Sharif. *Queen Elizabeth Hospital, Birmingham, United Kingdom.*

Background: South Asians have increased risk for type 2 diabetes but the risk of post-transplantation diabetes mellitus (PTDM) is unknown. The aim of this study was to compare PTDM risk in South Asian versus Caucasian kidney allograft recipients in a propensity matched analysis.

Methods: In this retrospective analysis, data was extracted from electronic patient records at a single-centre (2004-2014). 354 Caucasian and 121 South Asians met the inclusion/exclusion criteria for this study. Caucasians were more likely to be older, male and have higher BMI compared to South Asians. Propensity score matching was therefore undertaken to remove their bias effect.

Results: Propensity matching resulted in 102 pairs of kidney allograft recipients. Median follow up was 51 months (range 3-130 months). Both groups had similar baseline

characteristics, although South Asians compared to Caucasians received more deceased-donor kidneys (74% vs. 43% respectively, p<0.001) and were more likely to be CMV positive (77% vs. 43% respectively, p<0.001). Five-year PTDM was higher in South Asians versus Caucasians (34% vs. 11% respectively, hazard ratio 4.3 [95% CI: 2.0–9.4, p<0.001]).



Donor type had significant interaction with ethnicity. While no difference in PTDM was observed in recipients of live kidneys, 5-year PTDM risk was 42% versus 5% for South Asian versus Caucasian deceased kidney recipients respectively (p<0.001). No difference was observed in allograft function, rejection episodes, adverse cardiovascular events or patient/graft survival.

Conclusions: South Asian kidney allograft recipients have increased risk of PTDM, especially in the context of deceased kidney donation. It is important to recognize South Asians as high risk for PTDM to allow targeted screening and management strategies.

FR-OR075

Increased Circulating T-Lymphocytes Expressing HLA-DR in Kidney Transplant Recipients with Microcirculation Inflammation Hee-Yeon Jung,[1] Chan-Duck Kim,[1] Sukyung Lee,[1] Ji-Young Choi,[1] Se-Hee Yoon,[2] Jang-Hee Cho,[1] Sun-Hee Park,[1] Yong-Lim Kim.[1] *[1]Internal Medicine, Kyungpook National Univ School of Medicine, Daegu, Republic of Korea; [2]Internal Medicine, Konyang Univ, Republic of Korea.*

Background: Despite the clinical impact of microcirculation inflammation (MI) and T-lymphocyte on antibody-mediated rejection in kidney transplant recipients (KTRs), the association between MI in allograft biopsy and activity of T-lymphocyte in the peripheral blood is not known. This study aimed to compare the histologic grading of renal allograft according to the Banff score with activity of serum T-lymphocyte subsets and HLA-DR positive monocytes in KTRs.

Methods: A total of 137 indication biopsies from renal allografts were performed from 117 KTRs. Among them, 24 biopsy specimens from KTRs who have data of serum T-lymphocyte subsets and HLA-DR positive monocytes at the time of biopsy were included in this study. The frequencies of serum HLA-DR$^+$, CD4$^+$, CD8$^+$, and CD25$^+$ T cells, and HLA-DR positive monocytes were determined by flow cytometry. The histologic grading of renal allograft was classified according to the sum score of g+ptc (MI), i+t, ci+ct, and cv+ah based on Banff 2013 classification.

Results: The frequencies of CD4$^+$HLA-DR$^+$/T cells, CD8$^+$HLA-DR$^+$/T cells, CD4$^+$HLA-DR$^+$/CD4$^+$ T cells, and CD8$^+$HLA-DR$^+$/CD8$^+$ T cells were significantly increased in KTRs with MI sum score ³1 (n=13) compared to KTRs with MI sum score=0 (n=11) (all P <0.05). Among four subsets, CD4$^+$HLA-DR$^+$/CD4$^+$ T cells were positively correlated with MI sum score (P=0.013). However, no significant differences were observed between two groups categorized based on the sum score of i+t, ci+ct, and cv+ah. Analysis using the receiver-operating-characteristic curve showed that antibody-mediated rejection could be predicted with a sensitivity of 83.3% and a specificity of 58.3% using a cutoff value of 12.25% frequency of CD4$^+$HLA-DR$^+$/CD4$^+$ T cells.

Conclusions: MI was significantly associated with increased frequency of activated T-lymphocyte expressing HLA-DR in KTRs. Further large-scale studies are needed to confirm circulating CD4$^+$HLA-DR$^+$/CD4$^+$ T cells as a useful noninvasive immunologic monitoring tool for prediction of antibody-mediated rejection.

FR-OR076

Monitoring of Calcineurin Inhibitors by NFAT-Regulated Gene Expression in De Novo Renal Allograft Recipients Claudia Sommerer,[1] Martin G. Zeier,[1] Stefan Meuer,[2] Thomas Giese.[2] *[1]Nephrology, Univ Hospital, Heidelberg, Germany; [2]Immunology, Univ Hospital, Heidelberg, Germany.*

Background: Calcineurin inhibitors are critical-dose drugs with a narrow therapeutic range and the optimal monitoring strategies are discussed in terms of safety and efficacy. A new pharmacodynamic monitoring tool – assessing the expression of nuclear factor of activated T cells (NFAT)-regulated genes – has been established to measure directly the functional effect of ciclosporin A (CsA) in an individual patient. Until now, only sparse data on NFAT-regulated gene expression within the early post-transplant period are available.

Methods: Altogether 80 de novo renal transplant patients were enrolled in this prospective observational trial. The immunosuppression consisted of IL-2 receptor antagonist induction, CsA, mycophenolic acid and steroids. The expression of the NFAT-regulated genes (interleukin 2, granulocyte-macrophage colony stimulating-factor, Interferon γ) was determined by qRT-PCR at CsA C0 and C2 at regular follow-up visits within 6 months after transplantation.

Results: The median age of all patients was 47.9±13.7 years (54 male). Residual NFAT-regulated gene expression showed a high interindividual variability. Inversely to reduction of CsA doses expression of NFAT-regulated genes increased from 1.78±1.33% to 8.04±7.36% in month 1 to month 6. Despite of comparable CsA C0 levels NFAT-regulated gene expression was significantly less inhibited in patients with treated biopsy-proven acute rejections(2.9±2.2% vs. 2.0±1.7%, p=0.047). Patients with very low residual expression on NFAT-regulated genes were on increased risk of early infectious episodes. Residual expression of IFNγ and GM-CSF genes correlated most significantly with clinical outcome.

Conclusions: NFAT-regulated gene expression is highly inhibited in the early post-transplant period in renal allograft recipients on CsA treatment. High residual NFAT-regulated gene expression was related to acute rejection episodes but low residual expression with infectious complications. Thus, NFAT monitoring has the potential to support pharmacokinetic monitoring in the early post-transplant period.

Proteomics of Urinary Exosomes to Identify Biomarkers of BK Virus Infection and Acute Rejection Luuk Hilbrands, Mathijs van de Vrie, Jeroen Deegens, Johan Van der vlag. *Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands.*

Background: Acute **c**ellular rejection (ACR) and BK virus associated nephropathy (BKVAN) are frequent causes of graft dysfunction after renal transplantation with similar symptoms but requiring different treatments. We investigated whether patients with an ACR episode or BKVAN could be distinguished based on proteins present in urinary exosomes.

Methods: Urine samples (50 mL) were collected from renal transplant patients with ACR, BKVAN or stable graft function. Urinary exosomes were isolated by ultracentrifugation (110' at 200.000×g). For each group (ACR, BKVAN, controls) we pooled equivalent amounts of exosome proteins of 4 patients (first set) and repeated this with 4 different patients in each group (second set). Subsequently, exosomes were lysed and 40 microgram of protein was resolved by a 4-12% SDS-PAGE. After electrophoresis, gel lanes were cut into 5 pieces according to molecular mass. Proteins were in-gel digested with trypsin, and peptide mixtures were analysed using LC-MS/MS. Proteins were identified using the NCBI database. Partial least squares enhanced discriminant analysis was used to classify the patient groups based on exosomal protein content.

Results: A total of 340 individual proteins was detected in the first set of samples and 385 proteins in the second set, with 204 proteins overlapping between both sets. Our preliminary findings show a number of proteins for which the exosome content differed between ACR and BKVAN. Specific candidate proteins that can serve as urinary biomarkers include acid ceramidase, low density lipoprotein-related protein 2, copine VIII, alpha-1-acid glycoprotein 1 syndecan 4, and lactate dehydrogenase.

Conclusions: In this study we show that profiling of urinary exosomes is a promising tool to identify urinary proteins which allow differentiation between ACR and BKVAN in renal transplant patients.

Identification of Signature Long Non-Coding RNAs in the Development of Diabetic Nephropathy Jianyin Long, Shawn S. Badal, Zengchun Ye, Bernard A. Ayanga, Farhad R. Danesh. *Dept of Emergency Medicine, The Univ of Texas MD Anderson Cancer Center, Houston, TX.*

Background: Long noncoding RNA (lncRNAs) have emerged as potent regulators of multiple cellular processes relevant to cellular homeostasis and differentiation. More recently, lncRNAs have also been implicated in the pathogenesis of a myriad of diseases, including cancer and heart diseases. However, the role of lncRNAs in diabetic nephropathy (DN) is unknown.

Methods: Total RNA-Seq analysis was performed on glomeruli from Type 2 diabetic, db/db mice to explore differentially expressed lncRNAs. Following identification of a candidate lncRNA, Tug1 (Taurine-upregulated gene-1) we employed CRISPR/Cas9 genome editing to deplete Tug1 in cultured podocytes. Tug1 overexpression in podocytes was used for gain of function analysis. To understand the functional role of Tug1 in vivo and because Tug1 is reduced in diabetic podocytes, we generated podocyte-specific, Tug1 transgenic, db/db mice.

Results: RNA-Seq analysis revealed that expression of Tug1, a predicted antioxidant-responsive gene, is significantly reduced in the podocytes of db/db mice. Analysis of in vivo isolated podocytes from db/db mice demonstrated that downregulation of Tug1 over time is correlated with the progression of DN. To interrogate the functional relevance of Tug1, we performed transcriptome analysis on RNA from CRISPR/Cas9 Tug1 depleted podocytes, and found expression of a number of nuclear encoded, mitochondrial genes, including the master mitochondrial regulator, Pgc1α to be significantly decreased. Gain of function experiments revealed Tug1 mediated activation of Pgc1α and associated mitochondrial phenotypes. To assess the therapeutic potential of Tug1 overexpression in vivo, we generated podocyte-specific, Tug1 transgenic mice on the db/db background. Importantly, we observed significant and sustained improvement in ACR and histology up to 24 weeks.

Conclusions: We have found a number of differentially regulated lncRNAs within DN and demonstrated that Tug1 is a mediator of the transcriptional response to high glucose. We demonstrate that Tug1 overexpression in a mouse model of DN exerts a renoprotective phenotype, in part, by rescuing expression of Pgc1α.

Epigenetic Abnormalities Underlie Increased Expression of Nuclear Receptor PXR in Diabetic Kidney Disease Atsushi Watanabe,[1] Takeshi Marumo,[2] Wakako Kawarazaki,[2] Mitsuhiro Nishimoto,[2] Nobuhiro Ayuzawa,[2] Daigoro Hirohama,[2] Kohei Ueda,[2] Hiroo Kumagai,[1] Toshiro Fujita.[2] *[1]Dept of Nephrology and Endocrinology, National Defense Medical College, Tokorozawa, Japan; [2]Div of Clinical Epigenetics, RCAST, Univ of Tokyo, Tokyo, Japan.*

Background: Epigenetic abnormalities have been suggested to mediate the phenomenon of metabolic memory observed in diabetic complications. Because kidney is composed with various cell types, we investigated the epigenetic alterations in a cell type-specific manner and showed that epigenetic changes may induce persistent phenotypic changes of the proximal tubules in the diabetic kidney (JASN 2015 in press). PXR, a xenobiotic nuclear receptor, has recently been shown to play a critical role in metabolic changes in obesity and diabetes. In this study, we investigated the expression of PXR in normal and diabetic kidneys and explored the underlying epigenetic mechanisms and possible function.

Results: Immunohistochemistry and quantitative RT-PCR analysis demonstrated that PXR is selectively expressed in the proximal tubules. Combined bisulfite restriction analysis and bisulfite sequencing revealed that the promoter region of *Pxr* of normal proximal tubules is significantly demethylated as compared to that of non-proximal tubular cells. In diabetic mice, significant increase in *Pxr* mRNA, demethylation of DNA and increased H3K4me3 in the promoter were also observed. Epigenetic changes are likely to play a causative role in PXR induction because DMNT inhibitor and HDAC inhibitor increased mRNA expression of *Pxr* in cultured human proximal tubular cells. To identify specific functions of PXR in proximal tubules, we treated mice with PXR agonist (PCN 100mg/kg once i.p.), and analyzed transcriptome of the kidney by microarray analysis. Significant increase of *Rgc32*, a molecule known to exert fibrotic effects in the kidney, was observed in the PCN-treated kidney.

Conclusions: We revealed that PXR, expressed selectively in the proximal tubules, is increased in the diabetic kidney. Aberrant expression of PXR may be maintained by epigenetic mechanisms and contribute to the progression of diabetic kidney disease through the novel PXR-RGC32 pathway.

Metabolic Control of Chromatin Remodeling by miR-93 in Diabetic Nephropathy Shawn S. Badal,[1] Yin Wang,[1] Jianyin Long,[1] Farhad R. Danesh.[1] *[1]Section of Nephrology, The Univ of Texas MD Anderson Cancer Center, Houston, TX; [2]Molecular and Cellular Biology, Baylor College of Medicine, Houston, TX.*

Background: How podocytes respond to metabolic cues in their environment remains a central question in kidney research. This is relevant in the pathogenesis of diabetic nephropathy (DN), where recent evidence suggests that metabolic events in podocytes may play important roles in regulating chromatin structure. However, the molecular connection linking metabolic states in the cytoplasm to chromatin dynamics remains poorly understood.

Methods: We employed a combined *in vivo* and *in vitro* approach to understand the impact and mechanism of miR-93 overexpression in podocytes within the diabetic millieu. We generated triple transgenic, podocyte-specific, tamoxifen-inducible miR-93 transgenic mice on the Lepr^{db} background (*db/db*). We restored miR-93 expression in kidneys using systemically administered miR-93 mimics. Mechanistically, we employed RNA-Seq and DNase Hypersensitivity-Seq analysis to define novel targets of miR-93 in podocytes.

Results: Diabetic mice with forced expression of Pod-miR-93 exhibited a significant reduction in ACR and total albumin excretion whencompared to non-induced, diabetic controls. Tamoxifen induced mice exhibited a significant reduction in mesangial expansion measured by PAS and podocyte injury measured by Desmin staining, compared to controls. Ultrastructure analysis revealed reduced podocyte effacement, and improved glomerular basement membrane thickness in miR-93 induced mice compared to controls. Restoring miR-93 expression *via miR-93* mimics delivery in diabetic mice rescued the DN phenotype in a similar fashion. RNA-Seq and DNase-Seq analysis revealed a previously unrecognized role for miR-93 as regulator of chromatin dynamics through a novel target in DN, Msk2.

Conclusions: Our data suggest that miR-93 is a critical metabolic/epigenetic switch in the diabetic environment linking the metabolic state to chromatin remodeling through its modulatory effect on Msk2/H3S10 phosphorylation signaling pathway. We propose that low levels of miR-93, via chromatin remodeling, results in global changes to DN-related chromatin signature and transcriptome.

C-Reactive Protein Promotes Renal Fibrosis in Type 2 Diabetes via CD32-Smad3-mTOR Signaling Pathway In Vivo and In Vitro Hui Y. Lan, Yong-ke You, Xiao Ru Huang. *Dept of Medicine & Therapeutics, Li Ka Shing Inst of Health Sciences, and Shenzhen Research Inst, The Chinese Univ of Hong Kong, Hong Kong, China.*

Background: Increasing evidence shows that patients with type-2 diabetic nephropathy (T2DN) is associated with elevated serum levels of C-reactive protein (CRP). In this study, we tested a hypothesis that CRP may promote T2DN by impairing the mTOR pathway via the Smad3-depenent mechanism.

Methods: Human CRPtg-db/db mice and their littermate controls including db/db, db/m and CRPtg-db/m mice were generated by crossing db/m mice with CRPtg mice that overexpress human CRP. Blood fasting glucose, intraperitoneal glucose tolerance test (IPGTT), intraperitoneal insulin tolerance test (IPITT), 24-hour urinary microalbumin levels were measured every 4 weeks in groups of 8 mice over the 36-week period. To study the signaling mechanism, intrarenal TGF-beta/Smad3 and mTOR signaling were also studied in vivo and in vitro in HK-2 tubular epithelial cells.

Results: Compared with littermate db/db mice, CRPtg-db/db mice developed higher levels of blood fasting glucose and enhanced insulin resistance. These was associated with a marked increase in microalbuminuria and the development of more severe renal fibrosis including an increase in collagen I and IV within the diabetic kidney. Enhance renal fibrosis in CRPtg-db/db mice was associated with a maked activation of TGF-beta/Smad3 and mTOR signaling. Further studies in cultured HK-2 TEC revealed that CRP acted through its receptor CD32b to promote high glucose-induced activation of Smad3 via both TGF-beta-dependent and ERK/p38/MAP kinases-crosstalk pathways, which was confirmed by the finding that addition of an neutralizing antibody against CD32 or TGF-beta1 and an inhibitor to ERK or p38 was capable of inhibiting CRP-induced Smad3 signaling. Furthermore, we also found that activated Smad3 then bound directly to mTOR as determined by a ChiP assay and stimulated fibrosis in response to CRP and high glucose, which was blocked by a Smad3 inhibitor (SIS3) and a mTOR inhibitor (rapamycin).

Conclusions: CRP promotes renal fibrosis in T2DN via the CD32b-Smad3-mTOR signaling pathway.

NLRC4 Knockout Ameliorates the Development of Diabetic Nephropathy in Mice Fang Yuan,[1] Yinghong Liu,[1] Ryan Kolb,[2] Fu-You Liu,[1] Weizhou Zhang.[2] *[1]Dept of Nephrology, the Second Xiangya Hospital, Central South Univ, Changsha, China; [2]Dept of Pathology, Univ of Iowa, USA.*

Background: Diabetic nephropathy is a growing health concern with characteristic sterile inflammation. An association of diabetic nephropathy with inflammasome activation has recently been shown, but the pathophysiological relevance of this finding remains unknown.In the current study, we aimed to study the role of NLRC4 inflammasome in the development of diabetic nephropathy in mice.

Methods: The expression of NLRC4 inflammasome and macrophage infiltration in renal tissues of patients with DN were detected by immunohistochemistry. Then,we used NLRC4$^{-/-}$mice to test the hypothesis that diabetic nephropathy is associated with renal NLRC4 inflammasome activation.We used the STZ-induced diabetes model, and followed the mice for up to 8 weeks**.** The mice were randomly divided into 3 groups: the normal control group; the wild-type diabetic group; NLRC4$^{-/-}$ diabetic group.After 8 weeks, serum biochemistry and urine albumin were measured.The kidneys were collected to test the macrophage by flow cytometric analysis and the renal pathologic changes were observed by light microcopy.We also detected the level of IL-1β by ELISA,and NLRC4 inflammasome activation by western blot. NF-κB,JNK signal transduction pathways and inflammatory cytokines in wild-type and NLRC4$^{-/-}$mice were determined by western blot and real-time PCR .

Results: There were significantly increased NLRC4 expression and macrophage infiltration in the renal tubules and interstitium of DN patients compared with that of control patients,and the expression of NLRC4 was positive correlated with glomerular sclerosis. Inflammasome activation(caspase-1 and IL-1β) were detected in wild-type diabetic mice. Conversely, NLRC4 deficient mice were protected against diabetic nephropathy.Furthermore ,inhibition of NLRC4 also suppressed NF-κB,JNK signal transduction pathways and decreased TNF-α,TGF-β and CTGF expression in STZ-diabetic mice.

Conclusions: Our study suggests that inhibition of NLRC4 inflammasome ameliorates the development of diabetic nephropathy in mice.Targeting the inflammasome may be a potential therapeutic approach to diabetic nephropathy.

Mitochondrial Lipid Overload in the Proximal Tubules Leads to Fibrosis Krisztian Stadler, Claudia Kruger. *Oxidative Stress and Disease Lab, Pennington Biomedical Research Center, Baton Rouge, LA.*

Background: While there is ample evidence for defective lipid metabolism in diabetes and insulin sensitive tissues, the role of lipid metabolism in renal disease is underappreciated. Mitochondrial lipid overload – overburdening β oxidation – is an important phenomenon in metabolic flexibility. This metabolic disturbance in the kidney has not been studied.

Proximal tubules almost exclusively use fat as their energy source, therefore it is important to understand what happens when they are overloaded with lipids. Tubular fibrosis seems to be a common pathway where all chronic kidney diseases culminate.

Methods: To test the relationship between mitochondrial lipid overload and tubular damage, we have developed a proximal tubule specific (Ggt CRE) mouse strain lacking carnitine-acetyl transferase - crAT (CrATGgt-/-). CrAT is responsible for the removal of excess fatty acid products from mitochondria. In its absence, incompletely oxidized fatty acids accumulate, pyruvate oxidation is compromised and a reducing environment conducive to superoxide formation created. This can lead to hydroxyl radical production which then will induce lipid peroxidation. By deleting CrAT an ideal system can be created to specifically model lipid radical formation due to metabolic sources.

Results: Knockout mice developed fibrosis, protein casts and tubular injury as they aged when compared to fl/fl controls. This was accompanied with increased TGFβ expression, an increase in serum creatinine levels, increased expression of vimentin, collagen IV, Bax, and caspase-3. Similarly to other mice models of kidney disease, CrATGgt-/- mice displayed phenotypic variations from minor to more severe injury. Kim-1 expression in CrATGgt-/- mice correlated with the severity of fibrosis. Interestingly, mice also developed glomerular injury and FSGS-like lesions, suggesting tubulo-glomerular interactions when tubular mitochondria are overloaded. Challenging mice with high fat diet or uninephrectomy accelerated this phenotype.

Conclusions: Our studies suggest that mitochondrial lipid overload (deletion of CrAT) in the proximal tubules may lead to metabolic/redox disturbances and tubular apoptosis and fibrosis.

FR-OR084

Role of Neuropilin-1 in Glomerular Function and Disease Christina S. Bartlett,[1] Monika Lucyna Wnuk,[2] Vera Eremina,[3] Chengjin Li,[3] Yashpal S. Kanwar,[1] Jeffrey H. Miner,[4] Maria Pia Rastaldi,[5] Susan E. Quaggin.[1] *[1]Feinberg Cardiovascular Research Inst and Div of Nephrology, Northwestern Univ, Chicago, IL; [2]Univ of Bern, Switzerland; [3]Mount Sinai Hospital, Toronto, Canada; [4]Washington Univ, St. Louis, MO; [5]Fondazione IRCCS Ca'Granda Ospedale Maggiore Policlinico, Milano, Italy.*

Background: Neuropilin-1 (NP-1), a co-receptor for a variety of growth factors (e.g. VEGF, PDGF, and TGF-b), is critical for development and patterning of vascular and nervous systems. Mesangial cells strongly express NP-1 yet the physiological relevance of this is unclear. To date, onset of proteinuria in humans following antibody blockade of NP-1 hints at the importance of NP-1 in glomerular function.

Methods: NP-1 expression was assessed by immunofluorescence in biopsy samples from diabetic (DN) and IgA nephropathy (IgAN) patients. To further investigate the in vivo function of NP-1, we analyzed mice with perivascular cell specific deletion of NP-1. Intrinsic cell behaviors affected by NP-1 were examined in primary human mesangial cultures.

Results: DN and IgAN biopsies have notably elevated mesangial expression of NP-1 indicating that NP-1 may have a role in glomerular dysfunction. In mice, deletion of NP-1 in the mesangium restricts glomerular maturation and causes dramatic mesangial expansion, marked GBM thickening and tubular dilatation. NP-1-deficient mutants develop severe proteinuria and succumb to renal insufficiency. In mutant glomeruli lacking NP-1 in the mesangium, VEGFR2 phosphorylation is increased while podocyte ERK signaling is hyperactivated. In vitro, we showed that NP-1 mediates directed migration of mesangial cells towards PDGFB. Inducible gene targeting of NP-1 is currently underway to delineate developmental versus maintenance functions of NP-1 in the glomerulus particularly within the context of DN.

Conclusions: NP-1 expression in the mesangium is needed for glomerular development. NP-1 regulates matrix production and its absence compromises glomerular filtration. Increased expression of NP-1 in DN and IgAN further suggests that glomerular function relies on a finely tuned level of NP-1 signaling. Accordingly, NP-1 may be suitable as target to ameliorate glomerular disease.

Protein S Protects Podocyte from Injury in Early Diabetic Nephropathy Fang Zhong,[1,2] Kim Lee,[1] John C. He.[1] *[1]Dept of Medicine/Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY; [2]Dept of Nephrology, Hang Zhou Hospital of Traditional Chinese Medicine, Zhejiang Chinese Medical Univ, Hang Zhou, Zhejiang, China.*

Background: Elucidating mechanisms that mediate the early stage of diabetic nephrology (DN) may help us identify novel preventive and therapeutic measures for patients with DN. Protein S (PS), a vitamin K-dependent protein, functions mainly as a cofactor for the formation of activated protein C (APC). APC is known to have podo-protective effects in DN. However, the role of PS in DN has not been studied.

Methods: Proteomic analysis was performed in glomeruli isolated from STZ and control rats. The podocytes cell-specific Pros1 homozygous knockout mice (KO) were developed to determine the role of PS in DN. Immortalized human podocytes (HPC) were used for in vitro studies. The expression of TMA receptors and podocyte-specific genes were examined by western blot and RT-PCR. The Protein S expression was examined in human kidney biopsies by immunostaining.

Results: Proteomic analysis of glomeruli revealed higher expression of PS in diabetic glomeruli. Then, we confirmed an increase of PS expression in the glomeruli of diabetic rats by RT-PCR and immunostaining. Interestingly, PS expression also increased in human kidneys with early DN but decreased in those with advanced DN. As a control, plasma concentrations of PS were not significantly different between diabetic and non-diabetic rats or humans. Since the staining of PS was more prominent in podocytes of human diabetic kidney, we determined the role of PS in cultured human podocytes. We found that Knockdown of Pros1 enhanced high glucose-induced apoptosis while overexpression of Pros1 inhibited TNF-α-induced pro-inflammatory gene expression in podocytes likely through activation of tyro3, one of the TMA receptors. To further determine the role of PS in DN, we developed podocyte-specific Pros1 knockout mice (KO) and found that diabetic KO mice (KO-STZ) developed more proteinuria, mesangial expansion, and foot process effacement than diabetic wide-type mice (WT-STZ).

Conclusions: Our data support a protective role of PS against podocyte injury in early DN.

FR-OR086

Deletion of SHP-1 in Podocytes Prevents Diabetic Nephropathy Farah Lizotte, Benoit Denhez, Andréanne Guay, Pedro Miguel Geraldes. *Medecine, Univ of Sherbrooke, Sherbrooke, QC, Canada.*

Background: Both clinical and experimental data suggest that podocyte injury is involved in the onset and progression of diabetic nephropathy (DN) in the patients with type 1 diabetes. Although the mechanisms underlying the development of podocyte loss are not completely understood, insulin and nephrin actions have been shown to play a major role in the podocyte survival and function. We have reported that SHP-1, a protein tyrosine phosphatase, is increased in podocytes of diabetic mice and inhibited insulin and nephrin actions. However, the precise role of SHP-1 in the development of diabetic nephropathy remains to be investigated.

Methods: We have generated a non-diabetic (NDM) and diabetic Akita (DM; *Ins2*$^{+/C96Y}$) conditional podocyte specific SHP-1 knockout (podo-SHP-1KO) mice using the TetON-Cre lox system. Mice received or not doxycycline at 4 weeks of age and renal function (albuminuria and GFR) and pathology were examined at 7 months of age.

Results: Elevated albumin/creatinine ratio and GFR showed in DM mice are prevented by 86% and 100%, respectively in DM mice that lack SHP-1 gene specifically in podocytes. Mesangial cell expansion and glomerular hypertrophy is increased by 1.8 and 4.9 fold in DM mice and reduced by 78% and 72%, respectively in DM podo-SHP-1KO mice. Moreover, the expression of collagen type IV and TGF-ß that is enhanced in DM mice compared to NDM was not increased in DM podo-SHP-1KO mice. Transmission electron microscopy analysis demonstrated podocyte foot process effacement in DM mice that is not observed in DM podo-SHP-1KO mice. Furthermore, inhibition of insulin-induced Akt and ERK phosphorylation showed in DM mice is completely prevented in DM podo-SHP-1KO mice. Similar to insulin, nephrin phosphorylation is restored in DM podo-SHP-1KO mice compared to DM mice.

Conclusions: Our data indicate that the deletion of SHP-1 specifically in podocytes restored insulin and nephrin actions and prevented renal pathology and dysfunction in diabetic mice.

Targeted Proximal Tubule Injury Promotes Progression of Diabetic Kidney Disease in Akita Mice Jae Hyung Chang, Takaharu Ichimura, Venkata Sabbisetti, Joseph V. Bonventre. *Renal Div, Dept of Medicine, Brigham and Women's Hospital, Boston, MA.*

Background: Increasing evidence suggests that the kidney tubulointerstitial injury plays an important primary role in the pathophysiology of diabetes.

Methods: In the present studies, a mouse containing the renal epithelial cell-specific Six2Cre allele was crossed with a mouse transgenic for a Cre-inducible simian diphtheria toxin receptor (DTR). The bigenic mouse was then bred with Akita mice as a genetic model of type 1 diabetes. Targeted tubule injury was induced in these animals (Akita DTR$^{\text{renal epithelial cell}}$ (DTR^{rec})) with injection of diphtheria toxin (DT).

Results: Male Akita mice developed sustained hyperglycemia. A single sublethal dose of DT in Akita DTR^{rec} mice resulted in an acute two-fold rise in urinary albumin excretion and progression of albuminuria over the study period. By 19 weeks after DT injection, Akita DTR^{rec} mice developed an almost five-fold increase in albuminuria, 40% increase in serum creatinine level, almost two-fold increase in blood urea nitrogen (BUN) level, and reduced kidney size when compared with Akita controls. Moderate glomerular mesangial expansion, and increased interstitial fibrosis and tubular atrophy (IFTA) and glomerulosclerosis were observed in Akita DTR^{rec} mice 20 weeks after DT injection. These pathologic changes were accompanied by increased levels of the molecular marker of proximal tubule injury, kidney injury molecule (KIM)-1, in both kidneys and urines of Akita DTR^{rec} animals. Increased proximal tubule DNA damage response (DDR) activation, pro-inflammatory and pro-fibrotic cells infiltration, and peritubular capillary rarefaction were observed in kidneys of DT-treated Akita DTR^{rec} mice.

Conclusions: In diabetes, proximal tubule injury, perhaps from glycotoxins, can drive interstitial inflammation and fibrosis, capillary rarefaction, and secondary glomerular injury leading to progression of diabetic nephropathy. Our findings suggest novel therapeutic targets for the prevention and treatment of diabetic kidney disease.

Wnt11 Signals from the Ureteric Bud Direct Organization of the Nephron Progenitor Niche Determining Nephron Endowment Lori L. O'Brien,[1] Alexander N. Combes,[3] Kieran M. Short,[2] Peter H. Whitney,[1] Odyssé Michos,[1] Ali Ju,[3] Luise A. Cullen-McEwen,[2] John F. Bertram,[2] Melissa H. Little,[3] Andrew P. McMahon.[1] *[1]USC, Los Angeles, CA; [2]Monash Univ, Melbourne, VIC, Australia; [3]Murdoch Childrens Research Inst, Melbourne, VIC, Australia.*

Background: Normal nephron endowment requires a balance of nephron progenitor (NP) self-renewal and differentiation during kidney development. Wnt11, a non-canonical Wnt signal produced by ureteric tip (UT), has been shown to positively regulate the Gdnf-Ret signaling axis and branching morphogenesis. Our current data identifies a new role for Wnt11 in organization of the NP niche.

Results: Six2+ NPs are normally tightly associated with the UT, separating adjacent Foxd1+ interstitial progenitors from the UT. In Wnt11 mutants, inter-niche boundaries become less distinct and Six2+ and Foxd1+ cells intermix. RNA-seq of whole kidneys revealed minimal transcriptional changes within NPs suggesting Wnt11 primarily regulates cell behavior, as expected for a non-canonical Wnt. Single cell analysis of NPs *in vivo* and live imaging of kidney organ cultures shows that NPs normally make extensive membranous contacts with UTs. Long membrane projections extend to the UT from NPs that form layers above the UT. In contrast, NPs in Wnt11 mutants fail to exhibit elongated UT-directed membrane extensions. Wnts signal through Frizzled (Fzd) receptors: Fzd2 and Fzd7 are co-expressed within NPs. *Fzd2-/-;Fzd7-/+*mutants display a similar disorganization of the NPs, suggesting these two receptors likely mediate the non-canonical Wnt11 response. Quantitative analyses of the Wnt11 phenotype revealed a 30% reduction in UTs and 20% reduction in kidney size by E15.5. At birth, UT numbers were further reduced by 40% and mutant kidneys were 38% smaller. Further, NP niches were significantly depleted and prematurely lost. As a consequence, adult nephron number was reduced by 50%.

Conclusions: Taken together, these data highlight the importance of non-canonical Wnt11 signals in maintaining NP behavior, and appropriate stratification and organization of distinct mesenchymal progenitor compartments in the UT niche, a prerequisite for generating a normal nephron complement in the developing mammalian kidney.

Bim Gene Dosage Is Critical in Modulating Nephron Progenitor Survival in the Absence of Dicer Activity During Kidney Development Debora Malta Cerqueira, Andrew J. Bodnar, Yu Leng Phua, Kenneth A. Walker, Jacqueline Ho. *Dept of Pediatrics, Children's Hospital of Pittsburgh, Pittsburgh, PA.*

Background: We have previously demonstrated that conditional depletion of the miRNA-processing enzyme, Dicer, in nephron progenitors results in increased apoptosis and premature depletion of this cell population during kidney development. This is accompanied by increased expression of the pro-apoptotic protein, Bim.

Methods: To determine the functional significance of increased Bim, we generated a mouse model with depletion of both *Dicer* and *Bim* from nephron progenitors in the developing kidney. To this end, *Six2-TGC$^{Tg/+}$*; *Dicer$^{flx/flx}$* mice were crossed with a conditionally floxed *Bim* allele generating the following genotypes: *Six2-TGC$^{+/+}$; Bim$^{flx/+}$*; *Dicer$^{flx/+}$* (control), *Six2-TGC$^{Tg/+}$*; *Dicer$^{flx/flx}$*; *Bim$^{+/+}$* (mutant), *Six2-TGC$^{Tg/+}$*; *Dicer$^{flx/flx}$*; *Bim$^{flx/+}$* (heterozygous rescue) and *Six2-TGC$^{Tg/+}$*; *Dicer$^{flx/flx}$*; *Bim$^{flx/flx}$* (homozygous rescue).

Results: The depletion of *Bim* partially restored the number of nephron progenitors and improved nephron formation in *Dicer*-deficient kidneys. At the molecular level, the expression of the most abundant isoform of Bim (Bim_{EL}) was increased, while the levels of the pro-survival protein Bcl-2 were reduced in mutant compared to control kidneys. In contrast, the loss of *Bim* restored Bcl-2 expression and reduced Bim_{EL} levels in a dose-dependent manner in the homozygous and heterozygous rescue kidneys. Finally, we analyzed the survival and proliferation of nephron progenitors. The loss of *Bim* decreased apoptosis of nephron progenitors in kidneys that were *Dicer*-deficient in the progenitors, with no significant effect on cell proliferation.

Conclusions: Together these data provide evidence for a model in which miRNA-mediated regulation of Bim controls the balance between apoptosis and survival during nephrogenesis, as one potential means of regulating nephron number.

DGCR8-Dependent MicroRNA Biogenesis Is Essential to the Function of Pax8-Positive Epithelial Organs Roman-Ulrich Mueller,[1] Malte P. Bartram,[1] Elena Amendola,[2] Gabriella De vita,[2] Bernhard Schermer,[1] Thomas Benzing.[1] *[1]Dept II of Internal Medicine and Center for Molecular Medicine, Univ Hospital Cologne, Cologne, Germany; [2]Dipartimento di Biologia e Patologia Cellulare e Molecolare, Univ degli Studi di Napoli 'Federico II', Naples, Italy.*

Background: MiRNAs are small regulatory RNA molecules that have been shown to play an important role in physiology, development and disease of many organs. As to most organs our knowledge on the role of miRNAs depends on the use of Dicer-knockout models with this enzyme being a key component of the miRNA biogenesis machinery. However, Dicer has been shown to fulfil a number of other functions beyond the maturation of miRNAs. Furthermore a number of these small RNAs does not depend on Dicer in its maturation. Consequently, the phenotypes observed might well be due to miRNA-independent functions of Dicer. For most organs examined - including renal disease models - we still lack confirmation that the phenotype observed is truly due to miRNA deficiency.

Methods: We examined mice harboring a conditional knockout allele of Dgcr8. Dgcr8 - together with its interaction Partner Drosha - is essential to the nuclear steps of miRNA biogenesis. This mouse line was crossed to a Pax8Cre line to examine and confirm the role of miRNAs in Pax8-positive epithelial organs.

Results: The knockout mice develop a cystic kidney disease and hydronephrosis. End-stage renal disease occurs by the age of 4-8 weeks. On the cellular level this phenotype is accompanied by a strong increase in both cellular proliferation and apoptosis. Furthermore severe hypoplasia of the thyroid gland and consecutive hypothyroidism were observed. The hypoplasia does not appear to depend on a block in differentiation but may rather be due to impaired cell polarization.

Conclusions: This study shows the importance of DGCR8-dependent miRNA biogenesis for both renal and thyroid function and can thus be the basis to future experiments addressing the role of specific miRNA sequences. Nonetheless, some aspects of the phenotype differ from the Dicer knockout model pointing towards miRNA-independent contributions of Dicer and Dgcr8 regarding the pathogenesis of these two organs in our mouse model.

Oxygenation and Von Hippel-Lindau Regulate Nephron Progenitor Differentiation Elina Mukherjee, Jacqueline Ho, Sunder Sims-Lucas. *Univ of Pittsburgh, Pittsburgh, PA.*

Background: During development, oxygenation plays a crucial role in kidney formation. Nephron progenitor (NP) differentiation is highly dependent on appropriate vascularization and subsequently oxygen concentration. Alterations in nephron differentiation lead to kidney malformations. The unperfused NP are hypoxic, which activates the hypoxia inducible factors (HIFs). The HIF genes are potent factors involved in tissue differentiation. Upon oxygenation the Von Hippel-Lindau gene (VHL), degrades the HIFs and allows for tissue differentiation. We previously showed in vitro that oxygenation drives NP differentiation. Thus, we hypothesize that stabilization of HIFs in the NP will cause congenital kidney defects.

Methods: To determine the role of VHL in the NP we utilized VHL floxed mice bred with the *Six2EGFPcre* line, to generate Six2creVHL$^{lox/lox}$ mutant mice. We performed a thorough histological assessment from early kidney development through to post natal ages. We coupled this with immunofluorescence (IF) of the various kidney compartments as well as immunohistochemistry (IHC) and western blot analysis to analyze VHL and HIF expression.

Results: Histology revealed that Six2creVHL$^{lox/lox}$ mutant mice were underdeveloped from E15.5, with fewer differentiated NP derived structures. Postnatal mutant kidneys displayed significant pathology containing fewer nephrons, cystic tubules and proteinaceous casts. The mutant kidneys contained fewer proximal tubules, and remaining tubules were dilated. The mutant animals failed to thrive and were significantly smaller at weaning. IHC staining revealed a down regulation of VHL in the mutants coupled with an up regulation of HIF1a in the NP, which was confirmed via western blot analysis. IF staining of mutant embryonic kidneys showed a delay in NP differentiation with ectopic Six2 remaining highly expressed in NCAM positive epithelialized structures of mutants.

Conclusions: In conclusion, VHL is critical in the NP to regulate the expression of HIFs. Inappropriate up regulation of HIFs causes alterations in NP differentiation, leading to kidney malformations.

Interplay Between the Tbx2 Transcription Factors and Notch Signaling Directs Nephron Segmentation Bridgette Drummond, Yue Li, Amanda N. Marra, Christina N. Cheng, Rebecca A. Wingert. *Biological Sciences, Univ of Notre Dame, Notre Dame, IN.*

Background: Nephron segment patterning remains an enigmatic process. The conservation of nephron segments across vertebrates enables insights through work with animal models, and among these the zebrafish provides a simple system for developmental genetic studies of nephrogenesis. Zebrafish nephrons contain proximal and distal tubule segments, and endocrine cells called the corpuscle of Stannius (CS) also arise from the intermediate mesoderm (IM) and are situated between the distal nephron segments.

Methods: Here, we show that the *T-box 2a/b (tbx2a/b)* orthologs are spatially restricted to the distal IM. *tbx2a* and *tbx2b* single and doubly deficient embryos, as well as *tbx2b^{fby}* mutants, exhibited a modest expansion in the proximal segments accompanied by a reduction in the distal nephron, indicating that these genes have redundant roles in segment patterning.

Results: Abrogation of *tbx2a/b* expression was also associated with significantly expanded CS structures, coincident with increased expression of *sim1a*, a transcription factor that was recently demonstrated to be necessary and sufficient for CS formation. Further, we identified expression of the Notch pathway component *her9* in the developing CS. In exploring the link between *tbx2* genes and Notch, DAPT treatment was found to cause a moderate CS expansion in wildtypes, while DAPT induced further enlarged CS clusters in *tbx2* deficient embryos. Ectopic activation of Notch signaling in *Tg(hsp70::Gal4; UAS::NICD)* led to a reduced CS in wildtypes but not *tbx2* deficient embryos, suggesting the *tbx2* genes function downstream of Notch to inhibit the CS. In addition, ectopic Notch expanded proximal tubule segments at the expense of distal, reducing *tbx2* expression domains and therefore suggesting that Notch promotes proximal segments in part by inhibiting *tbx2* expression.

Conclusions: Taken together, these data suggest a model in which Tbx2a/b are essential for patterning of the distal IM from which the distal nephron segments and CS arise, and thus provide novel insights into the regulatory networks that influence renal ontogeny.

Dot1l Deficiency Leads to Increased Intercalated Cells and Up-Regulation of V-ATPase B1 in Mice Zhou Xiao,[1] Lihe Chen,[2] Qiaoling Zhou,[1] Wenzheng Zhang.[3] *[1]Internal Medicine, Xiangya Hospital, Central South Univ, Changsha, Hunan, China; [2]Graduate School of Biological Sciences, Univ of Texas Health Science Center at Houston, Houston, TX; [3]Internal Medicine, Univ of Texas Medical School at Houston, Houston, TX.*

Background: The collecting duct in the mammalian kidney consists of principal cells (PCs) and intercalated cells (ICs), which regulate electrolyte/fluid and acid/base balance, respectively. The epigenetic regulators of PC and IC differentiation remain obscure. Using Aqp2 and V-ATPase B1B2 to label PCs and ICs, respectively, we previously reported that mice with histone H3 K79 methyltransferase *Dot1l* disrupted in Aqp2-expressing cells ($Dot1l^{AC}$) vs. $Dot1l^{f/f}$ possessed ~20% more ICs and a similar decrease in PCs.

Methods: In this study, we performed multiple double immunofluorescence staining using various PC and IC markers to assess the relative abundance of PC and IC in $Dot1l^{AC}$ and $Dot1l^{f/f}$. Real-time RT-qPCR, luciferase assay, and chromatin immunopreciptation assays were conducted to determine if Dot1l regulates the transcription of *Atp6v1b1* in vivo in mousre kidney and in vitro in IMCD3 cells.

Results: $Dot1l^{AC}$ vs. $Dot1l^{f/f}$ had more IC and less PC, with expanded both a-IC and b-IC populations. These changes were associated with significantly upregulated V-ATPase B1 and B2, but not Aqp2, AE1, and Pendrin. Decreased V-ATPase B1 mRNA expression was coupled with a significant reduction of Dot1l and H3K79 di-methylation bound at the *Atp6v1b1* 5' flanking region. Overexpression of WT Dot1a, but not the methyltransferase-dead mutant Dot1a significantly downregulated a stably-transfected luciferase reporter driven by the *Atp6v1b1* promoter in IMCD3 cells.

Conclusions: Dot1l is a new epigenetic regulator of PC and IC differentiation and *Atp6v1b1* is a new transcriptional target of Dot1l.

DNp63 Progenitor Cells Pattern the Ureteric Bud Stem Cell Niche and Give Rise to β-Intercalated Cells Yuwen Li, Jiao Liu, Altaf-M Khan, Zubaida R. Saifudeen, Samir S. El-Dahr. *Pediatrics, Tulane Univ School of Medicine, New Orleans, LA.*

Background: 1. Ureteric Bud (UB) tip cells constitute a stem/progenitor cell niche with bipotential properties enabling them to self-renew or differentiate, giving rise to all cell types in the collecting duct. Understanding how the UB tip cell commits to the Principal Cell (PC) or Intercalated Cell (IC) fate is essential for the design of strategies to re-build a kidney from stem cells and for hastening epithelial cell regeneration after injury. 2. The N-terminus-truncated p63 isoform, DNp63, is a master transcriptional regulator of epithelial stem cells in skin. 3. Here, we document expression of DNp63 in the UB tip and assess the progenitor cell identity, fate and regenerative potential of DNp63 cells.

Methods: 1. Ret-GFP^{Tg} mice were used to demonstrate expression of DNp63 in Ret tip cells. 2. $DNp63^{GFP/+}$ knockin mice were used to define the spatiotemporal pattern of DNp63. 3. $DNp63^{Cre}$:$Rosa26^{mT/mG\ or\ EYFP}$ mice were used to trace the fate of DNp63 cells from embryonic to adult life. 4. $DNp63^{GFP/GFP}$ mice were used to define the effect of *DNp63* deletion on UB tip cell differentiation. 5. Adult $DNp63^{Cre}$:$Rosa26^{tdTomato}$ were subjected to unilateral ureteral obstruction (UUO) for 7 days to determine the response of fate-restricted DNp63 cells to injury. Cell proliferation was determined by BrdU incorporation.

Results: 1. DNp63 expression is restricted to cell clusters in UB tip until PN day 5 when expression is permanently silenced. 2. *In vivo* lineage analysis identified DNp63 as a marker of UB progenitor cells dedicated to generating H-$ATPase^+$/$Pendrin^+$ cells in cortical nephrons. 3. A fraction of cortical H-$ATPase^+$/$AE1^+$ cells are also DNp63-$lineage^+$, supporting the notion that at least some cortical α-IC are derived from β-IC. 4. $DNp63^{null}$ UB tip cells are maintained. In contrast, progeny of $DNp63^{null}$ collecting duct cells lack H^+-ATPase/carbonic anhydrase II. 5. In response to UUO, DNp63-$lineage^+$ cells proliferate and contribute to collecting duct cells expressing PC and IC markers.

Conclusions: 1. UB tip DNp63 cells are unipotent progenitors of β-ICs. 2. In response to injury, fate-restricted DNp63 lineage cells regenerate damaged collecting ducts.

Critical Role of Talin in Cell-Cell Adhesion and Kidney Development Sijo Mathew,[1,4] Riya Jose Palamuttam,[1] Glenda Mernaugh,[1] Ambra Pozzi,[1,2] Charles R. Sanders,[3,4] Roy Zent.[1,2] *[1]Div of Nephrology and Hypertension, Dept of Medicine, Vanderbilt Univ Medical Center, Nashville, TN; [2]Veteran Affairs Hospital Nashville, Nashville, TN; [3]Dept Biochemistry, Vanderbilt Univ Medical Center, Nashville, TN; [4]Center for Structure Biology, Vanderbilt Univ Medical Center, Nashville, TN.*

Background: Interactions between cells and basement membranes are required for normal kidney development and function. These interactions are primarily mediated by the major cell surface adhesion receptor proteins integrins. Integrins are composed by α and β subunits and have two important functions: ligand binding and regulation of the cytoskeleton. The cytoskeletal protein, talin, is a key regulator of integrin function. Talin has two isoforms talin 1 and 2. Both talins isoforms bind to the membrane proximal NPxY motif of integrin b1 cytoplasmic tail. Talin binding is proposed to promote integrin activation and link integrins to the actin cytoskeleton.

Results: In this study we investigated the role of talin in kidney development by generating mice lacking both isoforms in the developing ureteric bud. These mice die immediately after birth due to renal agenesis. Talin-null collecting ducts cells showed a severe adhesion defect on ECM proteins and were unable to undergo tubule formation in collagen matrigel matrix. In addition they had altered expression of cell-cell adhesion proteins claudin and E-cadherin. To better define the role of talin binding to the integrin b1 cytoplasmic tail in the collecting system development, we generated mice expressing a Y-to-A mutation in the membrane proximal NPxY motif of integrin b1 tail. Surprisingly, these mice only had a moderate developmental phenotype, characterized by a hypoplastic and dysplastic collecting system. Near complete abolition of talin binding with integrin b1 was observed in the mutant when in vitro binding was studied using NMR spectroscopy in isotropic bicelles.

Conclusions: Thus, we conclude that talin is essential for ureteric bud development and that some of its most important effects are likely mediated by integrin-independent processes.

Loss of Frs2α in Peri-Wolffian Duct Stroma Leads to Abnormal Ureteric Bud Induction and Vesicoureteral Reflux Deepti Narla,[1] Kenneth A. Walker,[1] Stacey B. Slagle,[2] Caitlin M. Schaefer,[1] Carlton M. Bates.[1] *[1]Div of Nephrology, Univ of Pittsburgh; [2]Div of Neonatal Medicine, Univ of Pittsburgh School of Medicine, PA.*

Background: Deletion of fibroblast growth factor receptor 2 (Fgfr2) from peri-Wolffian duct stroma (ST) in mice results in aberrant ureteric bud induction, abnormal ureteral insertion into the bladder, and high rates of vesicoureteral reflux (VUR). It is unclear which receptor docking protein(s) is/are responsible for these actions of Fgfr2. Thus, we investigated whether the Fgfr docking protein, fibroblast receptor substrate 2α (Frs2α), had roles in peri-Wolffian duct stroma similar to Fgfr2.

Methods: We conditionally deleted *Frs2*α in per-Wolffian duct stroma with a *Tbx18cre* mouse line ($Frs2a^{ST-/-}$). We assessed embryos for ureteric induction defects and for alterations in candidate downstream targets mediating induction defects. We assessed postnatal mice for VUR with euthanized cystograms and ureter insertions into the bladder via three dimensional (3D) reconstruction.

Results: Embryonic day (E) 11.5 $Frs2\alpha^{ST-/-}$ embryos exhibit nearly random ureteric bud induction sites (several cranially or caudally displaced sites along the Wolffian duct) versus controls; moreover, apoptosis and proliferation rates were unchanged in $Frs2a^{ST-/-}$ Wolffian duct segments between the ureteric bud base and cloaca (common nephric ducts) versus control littermates. E11.5 $Frs2\alpha^{ST-/-}$ embryos had significant decreased Bmp4 mRNA stromal expression, which is known to cause abnormal ureteric bud induction. Postnatal day 1 (P1) and P30 $Frs2a^{ST-/-}$ mice had significantly higher rates (worsening with age) and grades of VUR verses age-matched controls. Refluxing ureters in $Frs2a^{ST-/-}$ mice had improper ureteral insertion locations into the bladder and significantly shortened intravesicular tunnel lengths versus controls.

Conclusions: Deletion of *Frs2*α in peri-Wolffian duct stroma leads to aberrant ureteric induction sites resulting in improper ureteral insertion and shortened intravesicular length and lifelong VUR. Mechanistically, the induction site defects appear secondary to decreased Bmp4 expression in mutant stroma. Finally, it is likely that Frs2α mediates Fgfr2 signaling in peri-Wolffian duct stroma.

HCN3 Positive Urinary Pacemaker Cells Arise from the Neural Crest Norman D. Rosenblum,[1,2,3] Meghan M. Feeney.[1,2] *[1]Dev and Stem Cell Biology, Hosp Sick Children; [2]Dept Lab Medicine and Pathobiology, U Toronto; [3]Div Nephrology, Dept Paediatrics, Hosp Sick Children, Toronto, Canada.*

Background: Coordinated proximal to distal ureteric peristalsis is mediated by HCN3(+) pacemaker cells (PMCs) in the pelvis-kidney junction (PKJ). Perturbations in HCN3 expression and function are associated with congenital hydronephrosis and loss of Hedgehog signaling in in mice. Yet, identification of the specific perturbations in PMC function has been precluded by lack of knowledge of how PMCs develop. The objective of this study is to determine the developmental lineage of HCN3(+) PMCs and identify a molecular signature of these cells during development.

Methods: To determine the lineage of origin of the HCN3(+) PMCs, we genetically labeled five distinct lineages of the urogenital system via Cre-mediated expression of ROSA-tdTomato (tdTom) fluorescent protein and analyzed for co-localization with HCN3, using antibodies, in mouse embryonic kidney tissue. To investigate the molecular signature of the PMCs, HCN3(+) cells were isolated using HCN3 antibodies and fluorescence activated cell sorting (FACS). RNA was prepared from sorted samples and gene expression was analyzed in isolated HCN3(+) PMCs via qRT-PCR and genome-wide RNA sequencing.

Results: TdTom expressed downstream of promoters specific for metanephric or tailbud mesenchyme, ureteric bud or renal stroma failed to co-localize with HCN3-marked PMCs. In contrast, tdTom, expressed downstream of the neural crest (NC) specific Wnt1 promoter, co-localized with HCN3 in the PKJ, demonstrating that HCN3(+) PMCs arise from the NC. HCN3(+) PMCs were FACS isolated from mouse embryonic kidneys with >94% purity and >8,000 HCN3(+) cells were collected per litter. Genetic analysis of HCN3(+) PMCs via qRT-PCR demonstrated enrichment of both Hcn3 and Sox10, a NC marker,

further outlining the NC origin of these cells. Analysis of isolated PMCs, compared to adjacent cells in the PKJ, via RNA sequencing, revealed a 3-7-fold upregulation of genes associated with neuronal function.

Conclusions: We conclude that HCN3(+) urinary PMCs arise from the NC and express genes associated with neuronal function. These results provide a basis to identify molecular mechanisms that control PMC development.

Sox9 Activation Highlights a Cellular Pathway of Renal Repair in the Acutely Injured Mammalian Kidney Sanjeev Kumar,[1] Jing Liu,[1] Paul D. Pang,[1] A. Michaela Krautzberger,[1] Antoine Reginensi,[2] Jill A. Mcmahon,[1] Andreas Schedl,[2] Benjamin D. Humphreys,[3] Andrew P. McMahon.[1] *[1]Dept of Stem Cell Biology and Regenerative Medicine, Univ of Southern California, Los Angeles, CA; [2]Centre de Biochimie, Univ de Nice-Sophia Anitpolis, Nice, France; [3]Renal Div, Brigham and Women's Hospital, Boston.*

Background: Surviving tubular epithelial cells repair the epithelium after acute kidney injury (AKI), but the molecular driver of such a reparative response is not known.

Methods: Mice and injury models: *Sox9$^{IRES\text{-}CreERT2/+}$*, *R26R$^{tdTomato/tdTomato}$*, *Slc34a1$^{CreERT2/+}$*, *TCF/Lef:H2B-GFP* mice, *Sox9$^{fl/fl}$* and *Pax2Cre:Sox8/9* double knock-out mutants mice. AKI was induced via renal ischemia reperfusion injury and unilateral ureteral obstruction. **Lineage tracing:** for induction of CreERT2 protein, mice were injected with low and high-dose tamoxifen pre-and post-ischemic AKI, and during nephrogenesis. **Immunofluorescence, histology, *in situ* hybridization, confocal microscopy, nephron microdissection**. **RNA-sequencing and Fluidigm PCR** based quantification of transcript levels in the kidney.

Results: We identify Sox9 as an acute epithelial stress response that drives epithelial regeneration after injury. Translating ribosome affinity purification of mRNAs from nephron compartment revealed *Sox9* as one of the most upregulated transcription factors early after injury. Sox9+ cells demarcated injured, proliferating proximal tubular epithelial (PTE) cells early after ischemic and obstructive AKI. *Sox9*-descendent cells regenerate a functional PT epithelium and PT-specific pre-injury deletion of *Sox9* impairs renal function recovery and PT repair with increased fibrosis. Four weeks after injury, persistent Sox9 expression demarcates injured PTE cells with unresolved injury-repair responses. During nephrogenesis, *Sox9*-descendent cells give rise to nearly the entire epithelial component of the nephron, including PT, and removal of *Sox9* activity in Sox8/9 conditional mutant mice resulted in striking deficiency of the nephron epithelia.

Conclusions: These findings provide a direct, intrinsic molecular link between regeneration of an injured tubular epithelium and its formation during development.

FR-OR099

AKI Up-Regulates the Transcriptional Activator Etv4 Specifically in Dedifferentiated Proximal Tubule Where It Drives Epithelial Cell Proliferation and Migration Susanne V. Fleig,[1] Fengfeng Xu,[1] Flavia G. Machado,[1] Chia-Chun Wu,[1] Rafael Kramann,[1] Motoko Yanagita,[2] Benjamin D. Humphreys.[1] *[1]Brigham and Women's Hospital, Boston; [2]Kyoto Univ, Japan.*

Background: The transcriptional activator etv4 is required during nephrogenesis but roles in adult kidney are undefined. Proximal tubule repair after AKI occurs by dedifferentiation, but the transcriptional circuitry regulating this process is unknown. We characterized the expression pattern and function of Etv4 in repair after AKI.

Methods: For in vitro studies, we used lentiviral transduction of RPTEC for ETV4 overexpression or inhibition with a dominant-negative Etv4 (DN-Etv4) cDNA. We used an Etv4-nLacZ reporter strain to localize expression, and also generated a novel genetic mouse model for tamoxifen-dependent expression of DN-Etv4 specifically in full proximal tubule (NDRG1-CreERt2;R26-LoxP-DN-Etv4). These mice and cre-negative littermate controls were subject to severe bilateral ischemia/reperfusion surgery.

Results: Cultured RPTEC express Etv4 but DN-Etv4 transduction strongly inhibited proliferation (9.44 ± 3.44% KI67+ cells vs. 57.38 ±6.63% in control, $p<0.001$). By contrast, Etv4 overexpression increased proliferation after starvation (67.14 ±8.93% vs. 34.75 ±18.03% KI67+ cells, $p<0.05$.) In a wound healing assay, Etv4 inhibition reduced migration and increased RPTEC apoptosis while etv4 overexpression increased migration. Etv4-nLacZ reporter mice showed almost no expression in healthy kidney, but after IRI, Etv4 was specifically expressed in dedifferentiated proximal tubule cells (Kim-1+, Ki67+). In moderate or severe IRI timecourse, Etv4 mRNA was strongly upregulated with a 72hr maximum at 30- and 70-fold over baseline. Mice with PT-specific expression of DN-Etv4 showed increased tubular damage at 72h post-IRI compared to controls (Kim1 mRNA 2x, Kim1 protein expression 4x higher, $p<0.01$) with reduced tubular epithelial proliferation (14.2±9% vs. 32.9±2.8% KI67+ tubule cells, $p<0.05$).

Conclusions: Etv4 is specifically induced in dedifferentiated proximal tubule epithelia after AKI. It is a novel positive regulator of epithelial cell proliferation and migration during kidney repair after AKI.

FR-OR100

Tubular Regeneration After Acute Kidney Injury Is Limited and Only Driven by Tubular Progenitors Elena Lazzeri, Anna Julie Peired, Maria Lucia Angelotti, Francesca Becherucci, Duccio Lombardi, Laura Lasagni, Paola Romagnani. *Excellence Centre DENOTHE, Univ of Florence, Italy.*

Background: Traditionally, AKI was considered as reversible because of the high regenerative capacity of the tubule. Despite this, AKI is associated with increased risk to develop CKD, suggesting an incomplete repair of the tubules. In addition, it is debated whether regeneration is mediated by differentiated tubular cells or a population of tubular progenitors.

Methods: We developed inducible transgenic Pax8-rtTA/tetO-cre/ROSA26-Confetti (Pax8/Confetti) mice to track all tubular cells and the PAX2.rtTA;tetO.cre;R26.Confetti mouse model (Pax2/Confetti) to track putative tubular progenitors. Administration of doxycyline at the 5th week of age drove the stochastic expression at single cell level of CFP, GFP, RFP, YFP, allowing to track Pax2+ or Pax8+ cells and their progeny. After 1 week of washout, mice underwent 30 min of unilateral ischemia followed by a 30 day reperfusion period. Inducible PAX8.rtTA;tetO.cre;R26.Fucci2 (Pax8/Fucci2) and PAX2.rtTA;tetO.cre;R26.Fucci2 (Pax2/Fucci2) mouse models were used to study cell-cycle (mCherry in G1cells and mVenus in S/G2/M cells).

Results: Comparison of clonal analysis in confetti mice demonstrated that Pax2+ progenitors is the only population that undergoes clonal expansion after tubular injury, excluding involvement of other tubular cells. However, regeneration was limited, and the majority of lost tubular cells was not replaced. In addition, confocal microscopy and DNA content analysis by flow cytometry in Pax8 and Pax2/Fucci2 mouse models demonstrated that only Pax2+ progenitors complete mitosis, while other tubular cells that entered the cell cycle do not complete cytokinesis and undergo death or growth arrest.

Conclusions: In summary: 1. The tubule displays limited regenerative capacity; 2. Differentiated tubular cells enter the cycle but do not complete mitosis; 3. Only tubular progenitors undergo a complete cell division providing regeneration after injury. Taken together, these results provide an innovative explanation of the mechanisms of tubular repair and a suggestive hypothesis to explain the occurrence of CKD after AKI.

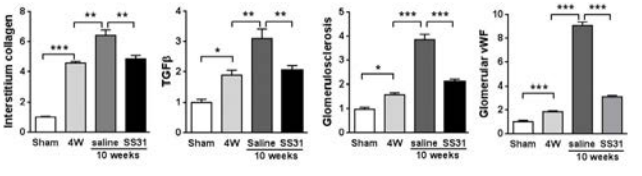
FR-OR101

Mitochondria-Targeting Peptide (SS-31, Bendavia®) Prevents Progression of Chronic Kidney Injury After Acute Ischemia Hazel H. Szeto, Shaoyi Liu, Yi Soong, Surya V. Seshan. *Pharmacology and Pathology, Weill Cornell Medical College, New York, NY.*

Background: It has been estimated that about 15% of patients who survive acute kidney injury (AKI) will advance to chronic kidney disease (CKD) characterized by tubulointerstitial fibrosis and glomerulosclerosis. We recently reported that mitochondria protection by SS-31 during ischemia mitigates microvascular rarefaction, inflammation and fibrosis (Am J Physiol 306:F970-F980, 2014). Here we report that delayed treatment with SS-31 can halt the progression of CKD.

Methods: Sprague-Dawley rats (n=40) were subjected to bilateral renal ischemia for 45 min followed by 4 weeks of reperfusion. Surviving animals (n=27) were then randomized to SS-31 (2 mg/kg/day) or saline by osmotic pump for 6 weeks. Kidneys were harvested for histopathology. Sham animals did not undergo ischemia.

Results: Despite recovery of renal function within 1 week after ischemia, pronounced tubular dilation, interstitial inflammation, glomerulosclerosis, and tubulointerstitial fibrosis was seen at 4 weeks. Further increase in inflammation and fibrosis, accompanied by increase in TGFβ and TNFα, were observed by 10 weeks in saline-treated rats. Pronounced changes were observed in glomeruli, with extensive fibrosis and peri-glomerular infiltration of inflammatory cells. Glomerular endothelial injury is suggested by the large increase in vWF expression. Electron microscopy revealed stressed vacuoles in podocytes and flattened foot processes. Rats that were treated with SS-31 from 4 weeks did not show any progression of glomerular or tubular injury, and prevented the upregulation of TGFβ and TNFα.



Conclusions: These results show that SS-31 can halt the progression of chronic kidney disease even when administered 4 weeks after the acute ischemic injury. SS-31 (Bendavia®) represents a novel paradigm for the treatment of CKD beyond approaches targeted at TGFβ.

Early Activation of Fibroblasts Is Required for Renal Protection and Regeneration After Acute Kidney Injury Dong Zhou,[1] Haiyan Fu,[1] Roderick J. Tan,[2] Youhua Liu.[1] *[1]Dept of Pathology, Univ of Pittsburgh, Pittsburgh, PA; [2]Dept of Medicine, Univ of Pittsburgh, Pittsburgh, PA.*

Background: Acute kidney injury (AKI) is responsible for about 2 million deaths each year worldwide, and its incidence is rising. While the role of vascular, tubular and inflammatory injury in the pathogenesis of AKI is well established, whether interstitial fibroblasts play any role in this process is poorly characterized.

Methods: To address this issue, we established moderate (20 min) and severe (30 min) renal ischemia/reperfusion injury (IRI) models. Sonic hedgehog (Shh) signaling was inhibited by cyclopamine. Conditional knockout mice in which Shh was ablated in tubular epithelial cells were generated and mice were subjected to IRI.

Results: In both moderate and severe IRI, interstitial fibroblasts became activated, as illustrated by vimentin expression, as early as 1 hour after AKI. Fibroblast proliferation as assessed by Ki67 staining was detected in renal interstitium at 4 hours and reached the peak at 12 hours. This early activation of fibroblasts was mediated by Shh signaling, as Shh protein was rapidly induced at 1 hour after IRI and Shh induced fibroblast activation and proliferation in vivo. To investigate the role of tubule-derived Shh in mediating fibroblast activation and injury repair, we generated tubule-specific Shh conditional knockout mice (Ksp-Shh-/-) by mating Shh-floxed mice with Ksp-Cre mice. Mice with ablation of Shh in renal tubules exhibited normal phenotype under physiologic conditions, but displayed an increased level of serum creatinine and morphological injury at 1 day after IRI, compared with controls. This aggravated AKI in Ksp-Shh-/- mice was associated with a decreased vimentin and desmin expression, suggesting a beneficial role of fibroblast activation in this setting. Similarly, pharmacological blockade of Shh signaling by cyclopamine also aggravated serum creatinine and histological damages through inhibiting fibroblasts proliferation.

Conclusions: These studies suggest that fibroblast activation is an early event mediated by Shh signaling and plays an essential role in conferring reno-protection and injury repair in the setting of AKI.

Endothelial Sphingosine 1-Phosphate Receptor 1 (S1P1) Is Necessary for Recovery from Ischemia-Reperfusion Injury (IRI) and Prevention of Fibrosis Heather M. Perry,[1] Amandeep Bajwa,[1] Liping Huang,[1] Hong Ye,[1] Kevin Lynch,[2] Mark D. Okusa.[2] *[1]Medicine, UVA, Charlottesville, VA; [2]Pharmacology, UVA.*

Background: Progression to fibrosis after AKI may result from maladaptive repair processes and can potentiate kidney dysfunction. The endothelium is the keystone of vascular homeostasis and vascular insufficiency after AKI may result in progressive fibrosis. S1P1, a G-protein coupled receptor, is important for endothelial function and we hypothesize that endothelial cell (EC) S1P1 is necessary for recovery from AKI and prevention of fibrosis.

Methods: Tamoxifen inducible, EC specific, S1P1 knockout mice (iTie2CreERT2S1pr1$^{fl/fl}$; S1P1 ECKO) or control (iTie2CreERT2S1pr1$^{wt/wt}$) mice were subject to unilateral IRI or sham operation for 24' and mice were allowed to recover for 3 days. Tamoxifen was then administered i.p. daily for 5d followed by a nephrectomy of the un-operated kidney and mice were euthanized on day 9. Plasma was collected for creatinine (PCr) measurement and kidneys were prepared for histology to assess renal injury, fibrosis by picro-sirius red, detection of aSMA+PDGFRβ+ myofibroblasts by IF, and neutrophils and macrophages by flow cytometry. Total kidney tissue mRNA was measured by RT-qPCR.

Results: S1P1 ECKO mice had higher PCr levels compared to control mice (1.24 vs. 0.38 mg/dL; $p < 0.001$ n = 5-6) on day 9 post IRI. S1P1 ECKO mice had increased tubular atrophy, a higher proportion of fibrotic area in the medulla and cortex (1.57 vs. 0.68 %; $p < 0.05$ n = 4-5), and increased density of interstitial myofibroblasts expressing COL1 and COL3 in IRI kidneys compared to controls. Leukocyte adhesion molecules Pecam-1, Icam1, E-selectin, and Vcam1 expression and the number of neutrophils and Ly6Clo macrophages were increased in IRI kidneys of S1P1 ECKO mice compared to control mice.

Conclusions: During recovery from IRI, S1P1 suppresses endothelial cell activation of leukocyte adhesion molecules and subsequent inflammation to prevent maladaptive repair and tubular atrophy in protection against fibrosis. This data suggests that pharmacological activation of EC S1P1 as a novel therapeutic strategy for preserving EC function during a critical period of recovery after AKI may prevent the progression to fibrosis.

IL-4/13-Mediated Polarization and Proliferation of Renal Macrophages Are Essential for Recovery from Acute Kidney Injury Bing Yao, Yinqiu Wang, Ming-Zhi Zhang, Raymond C. Harris. *Medicine, Vanderbilt Univ, Nashville, TN.*

Background: Cytokines IL-4 and IL-13 play important roles in polarization of macrophages/dendritic cells to an M2 phenotype, which is important in the recovery process following acute kidney injury (AKI). Both IL-4 and IL-13 can activate JAK3/STAT6 signaling.

Methods: Mice with selective DTR expression in proximal tubule ("DTR mice") with or without IL-4 deletion were used for diphtheria toxin-induced AKI via a single DT injection. DTR mice with or without inducible deletion of both IL-4 and IL-13 (DTR:IL-4/13$^{flox/flox}$ mice and DTR: UBC-Cre-ERT2: IL4/IL13$^{flox/flox}$ mice, tamoxifen treatment 2 weeks before experiment) were also used. A selective JAK3 inhibitor, CP-690550, was given via mini-pump at a dose of 15 mg/kg/day.

Results: The effectiveness of CP-690550 was confirmed by decreased p-STAT6 levels 6 days after DT injection. JAK3 inhibition led to more severe kidney injury, delayed recovery from AKI and development of more severe renal fibrosis, in association with increased levels of M1 markers (iNOS and CCL3) and decreased levels of M2 markers (arginase-1 and CD206) in macrophages/dendritic cells. In DTR mice with inducible IL-4/13, both renal IL-4 and IL-13 levels were reduced after tamoxifen injection. Similar to JAK3 inhibition, with IL-4 and IL-13 deletion, macrophages/dendritic cells expressed increased M1 markers and decreased M2 markers. Although IL-4 deletion alone only led to moderately delayed recovery from AKI, deletion of both IL-4 and IL-13 led to more severe kidney injury and delayed recovery, persistent kidney injury (increased KIM-1 expression), and development of more severe renal fibrosis (Sirius red and Masson's trichrome staining and increased expression of α-SMA and collagen I and IV).

Conclusions: These studies demonstrate that both IL-4 and IL-13 are required to effectively polarize macrophages/dendritic cells to an M2 phenotype and to promote recovery from acute kidney injury.

Select ADAM17 Substrates Released from Proximal Tubular Cells Promote Progressive Fibrotic Kidney Disease Eirini Kefalogianni, Muthu lakshmi Muthu, Venkata Sabbisetti, Benjamin D. Humphreys, Joseph V. Bonventre, Andreas Herrlich. *Renal Div, Brigham and Women's Hospital, Boston, MA.*

Background: The metalloprotease ADAM17 activates epidermal-growth-factor (EGF) ligands, tumor-necrosis-factor-alpha (TNFα) and other substrates by ectodomain cleavage of their pro-forms. Sustained EGF receptor (EGFR) activation in tubular cells is linked to injury-induced kidney fibrosis. We showed previously that ADAM17 hypomorph mice and mice with inducible proximal tubular- ADAM17 deletion are strongly protected against ischemia-reperfusion-injury (IRI)-induced fibrosis. We hypothesized that ADAM17's role extends to other fibrotic kidney injuries and that only select ADAM17 substrates mediate its effect by sustaining EGFR activation and by potentiating its pro-fibrotic downstream effects.

Methods: We used ADAM17 hypomorph mice (A17ex/ex) and SLC34a1-Cre-ERt2/ADAM17fl/fl mice (ADAM17 PTC-KO). Mice were subjected to severe bilateral IRI and unilateral ureteral obstruction (UUO). Human AKI and CKD urine samples were tested by ELISA. ADAM17 substrates were studied in primary tubular cells and tubular cell lines *in vitro*.

Results: ADAM17ex/ex and ADAM17 PTC-KO mice are also protected against UUO-induced fibrosis. This effect can be mimicked with a specific ADAM17 inhibitor which blocks its catalytic site (A17 pro-domain). Select EGFR ligands are significantly upregulated by IRI and UUO in mice, and also in urine samples of AKI and CKD patients. These specific EGF ligands have particularly pro-fibrotic and pro-inflammatory effects in primary tubular cells by sustaining EGFR and downstream pathway activation, as compared to other pro-repair EGF ligands. In vivo knockdown of specific pro-fibrotic ADAM17 substrates in tubular cells protects against injury-induced fibrosis. Finally, we detect evidence of activation of ADAM17-dependent pathways in human kidney biopsies of AKI and CKD patients.

Conclusions: Specific proximal tubule released ADAM17 substrates promote sustained pro-fibrotic EGFR activation and progressive kidney disease in mice and possibly humans. Mechanistic differences of molecular action explain why certain EGF ligands are pro-fibrotic and others are pro-repair.

Pericyte Ablation Leads to Acute Kidney Failure Dario R. Lemos,[1] Gabriela Campanholle,[2] Ivan G. Gomez,[1] Jeremy Stuart Duffield.[1] *[1]Molecular Discovery, Biogen; [2]Pfizer.*

Background: Pericytes (PCs) are tissue-resident mesenchymal progenitor cells embedded within the basement membrane of blood vessels. We recently showed that during nephrogenesis pericytes are critical in both vascular and epithelial maturation and patterning. Those data indicate that PCs are important for the maintenance of kidney homeostasis postnatally.

Methods: Diphtheria toxin was delivered *in vivo,* via intraperitoneal injection. Kidneys were collected and preserved for histology. Urine albumin was measured using Albuwell M kit (Exocell Philadelphia, PA). Urine and plasma creatinine levels were measured using creatinine Liquid reagents Assay (DIAZYME, San Diego, CA). Plasma albumin was measured using an Olympus au640 Chemistry Analyzer. Gene expression was measured by Taqman PCR, using pre-made assays (Life Technologies, Palo Alto, CA).

Results: PDGFRβ+ pericytes present in the adult kidney derive from FoxD1+ mesenchymal progenitor cells. Here we created a FoxD1-Cre; Rs26-iDTR mouse to study the effect of pericyte ablation in kidney homeostasis. We observed virtually complete depletion of PDGFRβ+ cells in the kidney, compared to the control group, after two days of daily intraperitoneal diphtheria toxin (DT) delivery without detectable variations in podocyte numbers or glomerular capillary structure. Significant decrease in vascular density, increased vascular cell proliferation and endothelial swelling was detected. This was associated with aberrant vacuolization, lipid accumulation, and injury of the proximal tubules, indicative of epithelial cell dysfunction. These observations were supported by finding elevated levels of plasma creatinine, blood urine nitrogen and albuminuria, markers of organ failure. Mice lacking pericytes progressed to rapid health deterioration and death by three days. Importantly, neither the number of macrophages nor the levels of inflammatory cytokines changed significantly during the treatment, ruling out a role for inflammation-induced damage as the cause for progressive loss of kidney integrity.

Conclusions: Our data show that by supporting homeostasis, pericytes are essential for proper kidney function.

FR-OR107

Preferential Proliferation in Response to Injury by an Interstitial-Derived Collecting Duct Subpopulation Joan Li,[1] Jinjin Guo,[5] Jill A. Mcmahon,[2] Andrew P. McMahon,[2] Melissa H. Little.[1,3,4] *[1]Univ of Queensland, Brisbane, QLD, Australia; [2]Keck School of Medicine of the Univ of Southern California, Los Angeles, CA; [3]Murdoch Childrens Research Inst, Melbourne, VIC, Australia; [4]Univ of Melbourne, Melbourne, VIC, Australia; [5]Univ of Southern California Keck School of Medicine, Los Angeles, CA.*

Background: We have reported the incorporation of Wnt4-expressing interstitial cells into the developing collecting duct (CD) during early postnatal development. These cells, representing a distinct CD subpopulation, may play a specific role in CD repair.

Methods: Time-mated $Wnt4^{GCE/+}$: $R26^{tdTomato/+}$ females received Tamoxifen injection (25mg/kg bw) at E17.5. Male offspring (8-12 wks) were subjected to Unilateral Ureteral Obstruction (UUO) for 3 or 7 days. Mice were euthanized 3 or 7 days after UUO. Kidneys were collected and processed for immunofluorescence studies. Confocal images were analyzed and quantified using Imaris software.

Results: At 7 days after UUO the cortical CDs were severely dilated. This was accompanied by down-regulation and misdistribution of Aqp2 protein as well as up-regulation of Wnt4 expression. Flattening of the CD epithelial cells and up-regulation of aSMA expression suggested epithelial-to-mesenchymal transition (EMT). $Tdtomato^+$ cells within the CD represent a subpopulation derived from the interstitial Wnt4-expressing cells present at E17.5. At 7 days after UUO the percentage of $Tdtomato^+$ cells within the CD increased significantly compared to control (37% vs 14%, p= 0.00001), while pHH3 positivity was significantly higher in these cells at 7 days after UUO compared to control (4.6% vs 0.2%, p=0.03). The number of $Tdtomato^+$ cells within the CD and the proliferation rate were not significantly different at 3 days after UUO compared to control.

Conclusions: In response to UUO damage, CD epithelium underwent EMT accompanied by up-regulation of Wnt4 expression. An interstitial-derived, Wnt4 expressing CD subpopulation showed preferential proliferation capacity compared to ureteric bud-derived CD epithelial cells. These observations support previous work suggesting the presence of possible stem/progenitor cells within this compartment and CD plasticity and imply a distinct repair mechanism from that documented for nephron epithelial cells.

Net Acid Excretion and Progression of CKD: Results from the Chronic Renal Insufficiency Cohort Study Julia J. Scialla,[1] John R. Asplin,[2] Mirela A. Dobre,[3] Alex R. Chang,[4] James P. Lash,[5] Chi-yuan Hsu,[6] Radhakrishna Reddy Kallem,[7] L. Lee Hamm,[8] Harold I. Feldman,[7] Jing Chen,[8] Lawrence J. Appel,[9] Cheryl A. Anderson,[10] Myles S. Wolf.[11] *[1]Duke Univ; [2]Litholink Corp; [3]Case Western Reserve; [4]Geisinger Health System; [5]Univ of Illinois Chicago; [6]Univ of California San Francisco; [7]Univ of Pennsylvania; [8]Tulane Univ; [9]Johns Hopkins Univ; [10]Univ of California San Diego; [11]Northwestern Univ.*

Background: Higher diet-dependent acid load has been associated with faster CKD progression, but not using gold-standard measurements [net acid excretion (NAE)].

Methods: We measured NAE in 24h urines from 1000 CKD participants as urinary ammonia + titratable acidity (calculated from urinary phosphorus, creatinine and pH). Urinary bicarbonate (HCO_3) was negligible. 19 samples with urine pH ≥7.4 were excluded. Urinary biomarkers (UUN and K) were used to calculate net endogenous acid production (NEAP), as previously published. We modeled risk of ESRD or 50% reduction in eGFR (n=290 events) over a median of 5y using Cox models with stratification by diabetes (DM).

Results: Higher NAE associated with greater intake of meat/fish/poultry and calories by questionnaire (each p<0.01) and independently with higher eGFR (p=0.01) and lower serum HCO_3 (p<0.01). Higher NEAP associated with lower fruits and vegetables (p<0.01), but not meat/fish/poultry (p=0.7) or calories (p=0.2). Higher NEAP independently associated with lower HCO_3 (p<0.01) but not eGFR (p=0.8). Unexpectedly, higher NAE associated with lower risk of renal events after adjustment (HR 0.91 per 10mEq higher NAE; p=0.04). The HR associated with NAE differed by DM. NEAP was not associated with higher risk in either group.

Table. Adjusted hazard ratio of ESRD or 50% decline in eGFR in patients with and without diabetes

	Overall (n=918)	No Diabetes (n=461)	Diabetes (n=457)
NAE			
Quartile 1 (<20.5 mEq/d)	1.0	1.0	1.0
Quartile 2 (20.5–30.7 mEq/d)	0.91 (0.66–1.26)	1.24 (0.73, 2.10)	0.80 (0.53, 1.23)
Quartile 3 (30.8–41.9 mEq/d)	0.75 (0.54–1.05)	1.01 (0.57, 1.77)	0.65 (0.43, 0.99)
Quartile 4 (≥42.0 mEq/d)	0.73 (0.49–1.08)	0.99 (0.51, 1.92)	0.61 (0.37, 0.99)
P- trend from continuous model	0.04	0.6	0.01
P-interaction with diabetes		0.02	
NEAP estimated from urine biomarkers			
Quartile 1 (<42.5 mEq/d)	1.0	1.0	1.0
Quartile 2 (42.5–57.7 mEq/d)	1.23 (0.87–1.74)	1.96 (1.04, 3.69)	0.97 (0.63, 1.49)
Quartile 3 (57.8–74.9 mEq/d)	1.09 (0.76–1.55)	1.58 (0.82, 3.05)	0.92 (0.59, 1.43)
Quartile 4 (≥75.0 mEq/d)	1.10 (0.79–1.55)	1.64 (0.87, 3.09)	0.90 (0.60, 1.35)
P- trend from continuous model	0.4	0.08	0.6
P-interaction with diabetes		0.08	

*Adjusted for age, sex, race, diabetes, cardiovascular disease, eGFR, proteinuria, 24 hour urine creatinine, BMI (body mass index)

Conclusions: Higher NAE, but not NEAP, associated with lower risk of renal events in DM. This may be due to changes in renal ammoniagenesis, particularly in diabetic CKD.

FR-OR109

Meat Intake and Risk of End Stage Renal Disease in the Singapore Chinese Health Study Quan Lan J. Lew,[1] Tazeen H. Jafar,[4] Hiromi Wai Ling Koh,[2] Jin Ai Zhen,[3] Khuan yew Chow,[3] Woon-puay Koh.[4] *[1]Singhealth Polyclinics, Singapore; [2]National Univ of Singapore, Singapore; [3]Health Promotion Board, Singapore; [4]Duke NUS Graduate Medical School Singapore, Singapore.*

Background: Although protein restriction is recommended as part of the management for chronic kidney disease, the evidence remains controversial. In addition, few studies have investigated the effects of different sources of protein on kidney disease.

Methods: We used data from the Singapore Chinese Health Study, a prospective cohort with 60, 198 Chinese adults aged 45-74 years at recruitment (1993-1998). Habitual diet information, including frequency and number of servings, was collected via a validated semi-quantitative 165-item food frequency questionnaire. Incident end stage renal disease (ESRD) was identified via record linkage with the nationwide Singapore Renal Registry up to 31 December 2012. Multivariable Cox proportional hazards models were used, with adjustments for total caloric intake, and other lifestyle factors and co-morbidities associated with ESRD.

Results: There were 951 participants with ESRD after a mean of 15.5 years of follow-up. Total protein intake was weakly associated with increased risk of ESRD. Compared to the lowest quartile intake, the adjusted hazard ratio (HR) for those in the upper 3 quartiles combined was 1.23 [95% confidence interval (CI): 0.99-1.53]. Among the different sources of protein, red meat intake was associated with increased risk of ESRD in a dose-dependent manner; the HR (95% CI) for the fourth quartile compared to the lowest quartile was 1.45 (1.19-1.77) (p<0.001 for trend). No statistically significant associations were found with intakes of other protein sources (poultry, fish, eggs, dairy products or legumes). Substituting one daily serving of red meat with the other protein sources significantly reduced the risk of ESRD by 51.9% to 66.3% (all P<0.01).

Conclusions: Red meat intake is associated with an increased risk of ESRD in the general population of Chinese origin. Replacing red meat intake with other sources of protein may reduce ESRD risk.

Funding: Government Support - Non-U.S.

The Course of Acid Retention without Metabolic Acidosi as GFR Declines in CKD: Ten Year Follow Up Nimrit Goraya,[1,2] Jessica Pruszynski,[4] Jan Simoni,[3] Donald E. Wesson.[1,2] *[1]Internal Medicine, Baylor Scott and White Health, Temple, TX; [2]Internal Medicine, Texas A and M, Temple, TX; [3]Surgery, Texas Tech Health Sciences Center, Lubbock, TX; [4]Biostatistics, Baylor Scott and White Health, Temple, TX.*

Background: Patients with CKD 2 (eGFR 60-89 ml/min/1.73 m^2) compared to CKD 1 (eGFR < 90 ml/min/1.73 m^2) due to macroalbuminuric hypertension-associated nephropathy have acid retention despite no metabolic acidosis but the contribution of reduced eGFR to acid retention is unknown.

Methods: We explored the role of reduced GFR in acid retention by re-assessing it after further GFR decline. Acid retention was determined by comparing observed to the expected increase in plasma [HCO_3] in response to retained HCO_3 (dose - urine excretion) eight hours after an oral $NaHCO_3$ bolus (0.5 meq/Kg bw), assuming 50% body weight HCO_3 space of distribution. Specifically, acid retention = [(retained HCO3/0.5 x body weight) – observed increase in plasma [HCO_3]] x (0.5 x body weight). CKD 2 (n=40) and CKD 1 (n=26) patients had blood pressure controlled with regimens including ACE inhibition and followed ten years.

Results: Although eGFR declined in both groups, eGFR was less preserved in CKD 2 (73.5±6.1 to 51.4±4.4 ml/min/1.73 m^2, p < 0.01) than CKD 1 (97.4±7.7 to 84.2±9.1 ml/min/1.73 m^2, p < 0.01). Neither group had or developed metabolic acidosis. Potential renal acid load (PRAL), a measure of dietary acid, was not different between CKD 2 vs. CKD 1 at baseline (60.4±19.4 vs. 62.9±14.5 mmol/day, respectively, p=0.56) or ten years (64.3±17.7 vs. 61.1±12.1 mmol/day, respectively, p=0.54) and ten year vs. baseline PRAL was not different for CKD 2 (p=0.19) or CKD 1 (p=0.76). Acid retention was higher in CKD 2 vs. CKD 1 at baseline (29.8±14.9 vs. 5.3±15.1 mmol, respectively, p < 0.01) and ten years (37.6±9.6 vs. 7.1±16.9 mmol, respectively, p < 0.01). Acid retention was higher at ten years in CKD 2 (p<0.02) but not in CKD 1 (p=0.44).

Conclusions: The data show that GFR reduction exacerbates acid retention in CKD 2 patients with less well preserved eGFR but not in CKD 1 patients whose eGFR was better preserved, supporting the importance of reduced eGFR in mediating the acid retention of CKD.

FR-OR111

Urinary Sodium and Potassium Excretion and Risk of Developing Chronic Kidney Disease Lyanne M. Kieneker,[1] Ron T. Gansevoort,[1] Rudolf A. de Boer,[2] Gerjan Navis,[1] Stephan J.L. Bakker,[1] Michel M. Joosten.[1] *[1]Internal Medicine, Nephrology, UMC Groningen, Netherlands; [2]Cardiology, UMC Groningen, Netherlands.*

Background: It is unclear whether dietary sodium and potassium intake are relevant to the development of chronic kidney disease (CKD) in the general population. Our aim was to examine the associations of urinary sodium and potassium excretion (UNaV and UKV resp.), as estimates of intake, with risk of developing CKD in the general population.

Methods: We studied 5,315 subjects free of CKD at baseline of the Prevention of Renal and Vascular End-Stage Disease (PREVEND) study, a prospective, population-based cohort of Dutch men and women aged 28-75 years. UNaV and UKV were measured in two 24-hour urine specimens at baseline (1997-1998) and midway during follow-up (2001-2003). Incident CKD was defined as de novo development of creatinine+cystatin C-based estimated glomerular filtration rate (eGFR) <60 ml/min/1.73 m^2 and/or albuminuria >30 mg/24h.

Results: Baseline UNaV and UKV were 135 mmol/24h (interquartile range [IQR]: 106-169 mmol/24h) and 70 mmol/24h (IQR: 57-85 mmol/24h), respectively. During a median follow-up of 10.3 years (IQR: 6.2-11.4 years), 872 subjects developed CKD. After multivariable adjustment for important covariables, no association was observed between UNaV and risk of CKD (hazard ratio per 50 mmol/24h decrement [1 standard deviation], 1.03; 95% confidence interval, 0.93-1.13). Each 21 mmol/24h (1 standard deviation) decrement in UKV was significantly associated with a 16% higher risk of developing CKD (multivariable adjusted hazard ratio, 1.16; 95% confidence interval, 1.05-1.29; Figure 1). Sensitivity analyses in which CKD was defined by either eGFR or albuminuria alone, rendered essentially similar results.

Conclusions: Low potassium intake and not high sodium intake was associated with an increased risk of developing CKD in the general population.

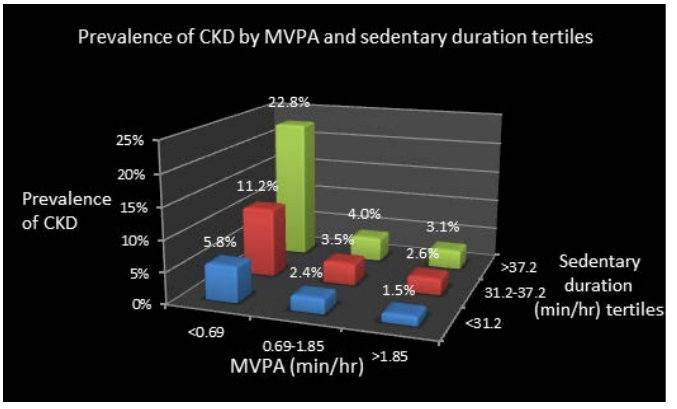
FR-OR112

Sedentary Behavior as a Risk Factor for CKD Dominique Ferranti,[1] Kate Lyden,[3] Xiaorui Chen,[1] Robert E. Boucher,[1] G. Wei,[1] Srini Beddhu.[1,2] *[1]U of Utah; [2]VA SLC; [3]UC Denver.*

Background: Sedentary behavior (engaging in activities in the seated or lying position that barely raise the energy expenditure above resting level) is commonly confused with physical inactivity (lack of moderate/ vigorous physical activity (MVPA)). Sedentary behavior is an important risk factor for DM, HTN and obesity. It is unclear whether sedentary behavior is an independent risk factor for CKD. Therefore, we examined this in 5873 participants in whom intensity and duration of physical activities were measured objectively with an Actigraph accelerometer in the 2003-2006 National Health & Nutrition Examination Survey (NHANES) data.

Methods: Based on the number of counts/min recorded, sedentary (<100/min) and moderate/vigorous (≥ 2020/min) activity durations were defined and normalized to 60 min. Logistic regression models adjusted for age, gender, race, education, smoking, alcohol use, lung disease and mobility limitations were used to examine the associations of sedentary and MVPA durations with the presence of CKD (defined as CKD-EPI eGFR < 60 ml/min/1.73 m^2).

Results: The mean age was 49 ± 13 yrs. 52% were women and 9.5% were black. 7.4% had CKD. The mean sedentary duration was 34.0 ± 5.6 min/hr. MVPA duration was highly skewed with median (25th - 75th percentile) of 1.2 (0.5 – 2.3) min/hr. Prevalence of CKD by sedentary and MVPA durations are summarized in the figure.



Adjusted for MVPA duration, demographics, CAD, CHF, lung disease and mobility limitations, each 5 min/hr ↑ in sedentary duration was associated with ↑ odds of CKD (OR 1.20, 95% CI 1.09 -1.33) in a logistic regression model. This persisted even after adjusting for DM, HTN and obesity (OR 1.18, 95% CI 1.07 -1.31).

Conclusions: These results suggest that sedentary behavior is likely an independent risk factor for CKD and interventions that target sedentary behavior might slow the progression of CKD.

Funding: NIDDK Support

FR-OR113

The Metabolically Healthy Obesity Phenotype and Risk of Incident Kidney Failure Alex R. Chang,[1] Morgan Grams,[2] Amanda Young,[1] Holly J. Kramer,[3] H. Lester Kirchner.[1] *[1]Geisinger Health System; [2]Johns Hopkins Bloomberg School of Public Health; [3]Loyola Univ Medical Center.*

Background: Little data exist on the association between obesity in the absence of metabolic abnormalities (metabolically healthy obesity) and renal outcomes.

Methods: Using data from 86,004 patients in the Geisinger Health System from 2004-2014, we examined the risk of kidney failure (dialysis, transplant, or eGFR < 15 ml/min/1.73m^2) and eGFR decline >= 30% by categories of body mass index (normal 18.5-24.9, overweight 25-29.9, obesity >= 30) and metabolic health (<2 of the following : triglycerides >=150, HDL cholesterol <40 in men, <50 in women, blood pressure >=130/85, and glucose >=100). Cox regression analyses were adjusted for demographics, smoking status, history of cardiovascular disease, and baseline eGFR.

Results: Only 10.6% of patients had normal BMI with 30.0% overweight, and 54.3% obese. Proportions of metabolically healthy individuals in normal, overweight, and obesity groups were 67.9%, 30.0%, and 20.0%, respectively. Over a median follow-up time of 6.0 years, 1,376 patients developed kidney failure and 17,668 developed eGFR decline >= 30%. Compared to metabolically healthy persons of normal BMI, metabolically healthy overweight and obese individuals had similar or lower risk for ESRD (overweight HR 0.75, 95% 0.47-1.19;obese HR 0.77, 95% CI: 0.48-1.25). When examining eGFR decline >= 30% as the outcome, metabolically healthy overweight and obese individuals were at increased risk (overweight HR 1.08, 95% CI: 0.98-1.19; obese HR 1.45, 95% CI: 1.32-1.59). Metabolically unhealthy persons had higher risk for ESRD and eGFR decline >= 30%, with a similar risk regardless of BMI. (Figure) Relationships were similar using a competing risks model accounting for risk of death.

Conclusions: Metabolically healthy obesity is associated with eGFR decline >= 30% but not kidney failure.

FR-OR114

The Metabolomic Signature of Diabetic Kidney Disease Predicts Diabetic Renal Disease Progression Manjula Darshi,[1,2] Loki Natarajan,[2,3] Minya Pu,[2,3] Rintaro Saito,[1,2] Kumar Sharma.[1,2,4] *[1]Center for Renal Translational Medicine, Univ of California, San Diego, La Jolla, CA; [2]Inst of Metabolomic Medicine, Univ of California, San Diego, La Jolla, CA; [3]Moores Cancer Center, Univ of California, San Diego, La Jolla, CA; [4]Veteranls Administration, San Diego Healthcare System, La Jolla, CA.*

Background: We recently published a metabolomic signature of diabetic kidney disease (MSDKD), indicative of mitochondrial dysfunction. Presently we determined the prognostic value for chronic kidney disease progression in diabetic patients from the longitudinal FinnDiane cohort.

Methods: 60 patients with mean 55 years (SD=9.6) age and mean diabetes duration 27 years (SD = 11 years) were analyzed to predict eGFR. Predictors included baseline (BL) metabolites and clinicalvariables, BL eGFR, HbA1c, UACR, and diabetes duration. Principal component weights obtained from the MSDKD were designated as *PCA score1* and *PCA score2*. Linear (for continuous eGFR) and logistic (for dichotomous eGFR: > vs <= 3ml/min/1.73m^2 per year) regression models were examined to determine associations between the PCA scores and eGFR outcomes.

Results: Baseline mean eGFR levels were 86.23 (26.67) mL/min/1.73m^2, HbA1c were 8.3% (SD 1.1), and UACR were 11 (SD 34.1) and follow up was 6.6 (SD 3.5) yrs. eGFR levels at follow up were 81.96 (SD 24.69) mL/min/1.73m^2, and 25% (N=15) declined more than 3 mL/min/1.73m^2 per year. Statistical modeling revealed that, after adjustment for baseline eGFR and follow-up interval, the *PCA Score 2* (mean =0.4, SD=0.64) was a significant predictor of worse (i.e. lower) eGFR (coef.=-12.4, p=0). For dichotomized eGFR (> vs <3 mL/min/1.73m^2 per year decline), the *PCA score2* was the only independent predictor that was selected (odds ratio per SD increase =7.4, 95% CI 1.78-45.73, p=0.01) by the LASSO model. A model to predict follow-up eGFR using clinical variables alone had an AUC of 0.73 (95% CI 0.58-0.88); when *score 2* was included, AUC increased to 0.88 (95% CI 0.79-0.97).

Conclusions: We demonstrate that MSDKD is a strong independent predictor for kidney disease progression in type I and type II diabetes patients, and hence may serve as prognostic biomarker for CKD.

SA-OR001

FMO3 Allelic Variant 158K Affects Trimethylamine Metabolism, Disease Progression, and All-Cause Mortality in Patients with CKD Catherine K. Yeung,[1,2] Cassianne Robinson-Cohen,[1] Richard Newitt,[1] Danny D. Shen,[2] Allan E. Rettie,[3] Bryan R. Kestenbaum,[1] Jonathan Himmelfarb.[1] *[1]Kidney Research Inst, Div. of Nephrology, Univ of Washington, Seattle, WA; [2]Dept of Pharmacy, School of Pharmacy, Univ of Washington, Seattle, WA; [3]Dept of Medicinal Chemistry, School of Pharmacy, Univ of Washington, Seattle, WA.*

Background: Elevated levels of circulating pro-atherogenic uremic toxins are implicated in the development of cardiovascular disease in chronic kidney disease (CKD) patients. Trimethylamine N-oxide (TMAO) is generated from diet and catabolized by intestinal flora to betaine and then to trimethylamine (TMA). TMA is rapidly metabolized by the hepatic enzyme flavin-containing monooxygenase 3 (FMO3) to TMAO, which accumulates in CKD. The FMO3 gene is highly polymorphic; up to 40% of individuals possess a non-synonymous variant.

Methods: We tested the association of FMO3 158K, the most common allelic variant, with plasma TMAO concentration and the TMAO/betaine ratio, CKD progression, and all-cause mortality in 339 participants from the Seattle Kidney Study (SKS), an ongoing clinic-based cohort study of CKD.

Results: Each additional minor allele at the 158K locus was associated with a 0.35 µg/mL higher serum TMAO concentration (1.42, 1.97, 2.10 µg/mL for 0, 1, 2 minor alleles, respectively; p=0.02) and a 0.20 unit higher TMAO/betaine ratio (p=0.05). A greater number of minor alleles at the 158K locus was associated with faster rates of eGFR decline. Participants who had 0, 1 and 2 minor alleles at the 158K locus experienced average eGFR losses of 8%/year, 12%/year, and 14%/year, respectively (p for trend= 0.05). Compared to participants with the homozygous dominant genotype (G/G), heterozygous (G/A) and homozygous recessive (A/A) participants had a 1.94-fold and 2.24-fold higher risk of mortality (p for trend 0.04).

Conclusions: In summary, we demonstrate that common genetic variation within the metabolizing enzyme FMO3 is associated with altered TMA substrate catabolism, CKD progression, and mortality among CKD patients. Further elucidation of these relationships could have implications for personalized recommendations for diet modification in patients with CKD.

SA-OR002

Association Between Mitochondria DNA Copy Number and Incident Chronic Kidney Disease: The Atherosclerosis Risk in Communities (ARIC) Study Adrienne Tin, Morgan Grams, A. Rosenberg, Foram N. Ashar, Josef Coresh, Dan Arking. *John Hopkins Univ, Baltimore, MD.*

Background: Mitochondria play a key role in cellular energy production. Higher mitochondrial DNA copy number (mtDNA-CN) in peripheral blood has been associated with lower risk of diabetes and lower prevalence of microalbuminuria, both risk factors of chronic kidney disease (CKD). It is unknown whether mtDNA-CN is associated with incident CKD.

Methods: We estimated mtDNA-CN from 119 mtDNA single nucleotide polymorphisms (SNPs) genotyped using the Affymetrix 6.0 microarray. Incident CKD was defined as a composite outcome of (a) baseline estimated glomerular filtration rate (eGFR) ≥ 60mL/min/1.73m^2 with a 25% drop to < 60mL/min/1.73m^2, (b) CKD-related hospitalization, or (c) end-stage renal disease (ESRD) based on linkage to the US Renal Data System (USRDS). The association between quartiles of mtDNA-CN and incident CKD was evaluated using Cox regression.

Results: Among 9060 participants, those with higher mtDNA-CN had significantly lower prevalence of coronary heart disease and diabetes, and lower levels of C-reactive protein and white blood cell count. Baseline eGFR did not differ significantly by mtDNA-CN quartiles. Over a median follow-up period of 19 years, 1459 participants developed CKD. Higher mtDNA-CN was associated with lower risk of incident CKD adjusted for age, gender, and race (quartile 4 vs. 1: hazard ratio [HR] 0.76, 95% confidence interval [CI]: 0.66-0.87, p for trend < 0.0001). This association persisted with some attenuation after further adjustment for risk factors of CKD, including prevalent diabetes, hypertension, and coronary heart disease, smoking, high sensitive C-reactive protein and white blood cell count (quartile 4 vs. 1: HR 0.89, 95% CI: 0.76-1.03, p for trend 0.03).

Conclusions: Higher mtDNA-CN is associated with lower risk of incident CKD independent of known risk factors of CKD and inflammation biomarker levels. Further research on modifiable factors influencing mtDNA-CN may lead to insight on the pathogenesis and prevention of CKD.

Urinary EGF Predicts Composite Endpoints in Three Independent Chronic Kidney Disease Cohorts Viji Nair,[1] Li Zhu,[2] Peter X.K. Song,[3] Laura H. Mariani,[1,4] Susan P. Steigerwalt,[6] Jicheng Lv,[2] Jennifer Joyce Hawkins,[1] Hong Zhang,[2] Matthias Kretzler,[1] Wenjun Ju.[1] *[1]Medicine, Univ of Michigan, Ann Arbor, MI; [2]Medicine, Peking Univ First Hospital, PKU Inst of Nephrology, Peking, China; [3]Biostatistics, Univ of Michigan, Ann Arbor, MI; [4]Arbor Research Collaborative for Health, Ann Arbor, MI; [5]St. John Hospital and Medical Center, Detroit, MI.*

Background: The nephrology community is in need of non-invasive biomarkers that can predict CKD progression and identify patients for targeted treatment better than estimated glomerular filtration rate (eGFR) and proteinuria. Our previously identified and validated epidermal growth factor (EGF) as an intrarenal marker for eGFR. The significant correlation of urinary EGF protein (uEGF) with intrarenal EGF mRNA and eGFR suggested that it can be a non-invasive biomarker for kidney function.

Methods: We used Cox proportional hazards models to evaluate the predictive value of uEGF on CKD outcome, defined as a composite of end stage kidney disease or 40% reduction of baseline eGFR, in the Clinical Phenotyping Resource and Biobank Core (C-PROBE), the Nephrotic Syndrome Study Network (NEPTUNE), and the Peking University First Hospital IgA Nephropathy (PKU-IgAN) cohorts with average of follow-up period of 1.8-3.6 years. The goodness of fit and improved prediction ability of markers were assessed by likelihood ratio tests, C-statistics, and Akaike information criterion (AIC).

Results: Lower uEGF was associated with higher risk of reaching composite endpoints: multivariable-adjusted associations of uEGF with the hazard of progression to composite endpoints are 0.27, 0.29 and 0.53 in C-PROBE, NEPTUNE and PKU-IgAN cohort, respectively. Prediction of renal survival by eGFR and albuminuria was significantly improved by addition of uEGF to the model, with an increase of c-statistic from 0.75 to 0.87, 0.74 to 0.80 and 0.71 to 0.75, in these cohorts.

Conclusions: uEGF shows promise as an independent risk predictor of CKD progression. Inclusion of uEGF significantly improved prediction of composite end points by eGFR and proteinuria in diverse populations worldwide with a wide range of CKD.

Normalization of Biomarkers to Urine Creatinine: Impact on CRIC Study Findings Kathleen D. Liu, Dawei Xie, Sushrut S. Waikar, Xiaoming Zhang, Venkata Sabbisetti, Joseph V. Bonventre, Theodore E. Mifflin, Josef Coresh, Robert G. Nelson, Clarissa Jonas Diamantidis, Claudia M. Lora, Francis Perry Wilson, Edgar R. Miller, Jiang He, Jeffrey R. Schelling, Mahboob Rahman, Akinlolu O. Ojo, Paul L. Kimmel, Harold I. Feldman, Vasan S. Ramachandran, Chi-yuan Hsu. *For the NIDDK CKD Biomarkers Consortium.*

Background: There is no standard approach to the reporting of urine biomarkers; some studies normalize to urine creatinine (UCr) concentration and others do not. Whether this influences findings is not well understood.

Methods: Urine kidney injury molecule-1 [KIM-1], neutrophil gelatinase associated lipocalin [NGAL], N-acetyl-beta-D-glucosaminidase [NAG], and liver fatty acid-binding protein [LFABP] were measured in 2466 Chronic Renal Insufficiency Cohort participants. Cox models were used to examine the association between biomarkers and CKD progression, defined as halving of eGFR or incident ESRD. We compared results with and without normalization of biomarkers to UCr.

Results: Baseline mean eGFR was 44±18 mL/min/1.73 m2; median albuminuria was 53 mg/g UCr (6-503). After adjustment for eGFR, albuminuria, as well as socio-demographic and clinical covariates, non-normalized KIM-1 and NAG were independently associated with CKD progression by quintile (Table) and continuous biomarker value analysis [HR per SD 1.16(1.05-1.28) and 1.14(1.04-1.25), respectively] but KIM-1/Cr and NAG/Cr were not. There were no independent associations between NGAL or LFABP and outcomes regardless of normalization.

KIM-1 quintiles (pg/mL)	Adjusted HR	NAG quintiles (mU/mL)	Adjusted HR
≤253	Referent	≤0.8	Referent
>253-522	0.93(0.66-1.31)	>0.8-1.5	1.07(0.72-1.57)
>522-918	1.39(1.01-1.92)	>1.5-2.5	0.93(0.64-1.36)
>918-1675	1.59(1.16-2.18)	>2.5-4.7	1.48(1.02-2.14)
>1675	1.39(1.01-1.93)	>4.7	1.48(1.01-2.15)

Conclusions: Normalization for UCr influences the associations of biomarkers with CKD outcomes. In theory, normalization controls for differences in urine concentration, but more studies are needed to better understand the impact on a variety of clinical outcomes. At minimum, researchers should state their approach *a priori*, measure UCr, and perform sensitivity analyses where the alternate approach is tested.

Proton Pump Inhibitor Use Is Associated with Incident Chronic Kidney Disease Benjamin Lazarus,[1,2] Yuan Chen,[1] Francis Perry Wilson,[3] Josef Coresh,[1] Morgan Grams.[1] *[1]Johns Hopkins Univ, Baltimore, MD; [2]Royal Brisbane and Women's Hospital, Queensland, Australia; [3]Yale Univ School of Medicine, New Haven, CT.*

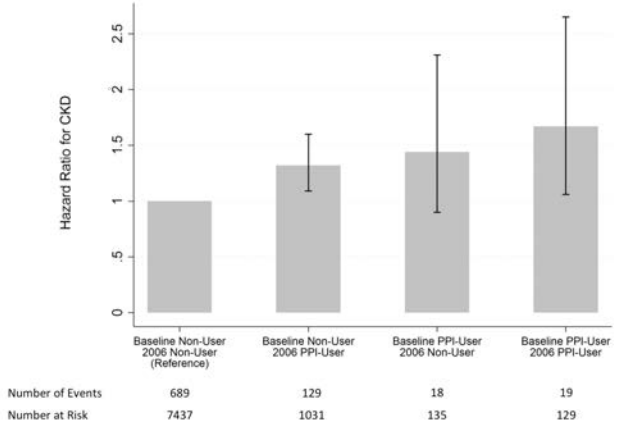
Background: Proton pump inhibitors (PPIs) are one of the most commonly used drugs worldwide, and have been linked to acute kidney injury and interstitial nephritis. We hypothesized that PPI use may also be associated with chronic kidney disease (CKD).

Methods: We followed 10,482 participants in the Atherosclerosis Risk in Communities study with an eGFR of ≥60mL/min/1.73m^2 from a baseline visit (1996-1999) to December 31, 2011. In primary analysis, we evaluated the association between baseline PPI use and incident CKD, using a validated definition of hospitalization and death related diagnostic codes. In sensitivity analysis, we assessed 1) PPI use as a time varying exposure, 2) an alternative outcome of reduced eGFR at follow-up (2011-2013), and 3) the risk of incident CKD in a cohort of respondents in 2006, stratified by PPI use in 2006 and at baseline. We evaluated histamine-2 receptor (H2) antagonist use as a negative control.

Results: Compared to non-users, PPI-users at baseline were more often white, obese, and taking antihypertensive medication. Baseline PPI use was associated with incident CKD in unadjusted (hazard ratio [HR], 1.45, 95% CI, 1.11, 1.90; P=0.006) and fully adjusted analyses (HR, 1.50, 95% CI, 1.14, 1.96; P=0.003). The association persisted when PPI use was modeled as a time-varying variable, and when reduced eGFR was used as the outcome. In the 2006 cohort, participants who reported PPI use at both baseline and 2006 had the highest risk, followed by those who reported use at only one time point, followed by never-users (Figure). There was no significant association between baseline H2-antagonist use and incident CKD (P=0.2).

Conclusions: PPI use is an independent risk factor for CKD. Caution against unnecessary use is warranted.

Figure. Risk of Incident Chronic Kidney Disease (CKD) in a 2006 Cohort of Proton Pump Inhibitor (PPI) Users and Non-Users



SA-OR006

Underuse of Renin Angiotensin System Inhibitors and Other Medications in U.S. Patients with Advanced Chronic Kidney Disease Receiving Nephrologist Care: Results from the International CKDopps Elodie Speyer,[1] Laura H. Mariani,[1] Charlotte Tu,[1] Lindsay Zepel,[1] Celine Lange,[2] Brian Bieber,[1] Christian Combe,[3] Antonio Alberto Lopes,[4] Ziad Massy,[5,8] Roberto Pecoits-Filho,[6] Ronald L. Pisoni,[1] Helmut Reichel,[7] Benedicte Stengel,[8] Bruce M. Robinson.[1] *[1]Arbor Research Collaborative for Health, USA; [2]Biomedicine Agency, France; [3]CHU Bordeaux, Univ de Bordeaux, France; [4]Federal Univ of Bahia, Brazil; [5]Ambroise Pare Univ Hospital, UVSQ, France; [6]Pontificia Univ Catolica do Parana, Brazil; [7]Nephrological Center Villingen Schwenningen, Germany; [8]Inserm UMR1018, France.*

Background: In the US, ~86% of incident ESRD cases are attributable to hypertension or diabetes. Guideline-directed medication use may help to slow CKD progression and lower ESRD incidence. We report early findings on use of key medication classes by CKD stage in the Chronic Kidney Disease Outcomes and Practice Patterns Study (CKDopps).

Methods: CKDopps is a prospective cohort study of patients with eGFR<60 in random national samples of nephrology clinics in Brazil, France, Germany, and the US. Early data from CKDopps (excluding Brazil and Germany for now) were used to characterize medication usage.

Results: 2,621 patients were included from 39 French, and 17 US clinics. The median number of prescriptions ranged from 7-9. Statin use was 52% and aspirin use was 31-48%. RASi (ACEI or ARB) use for CKD Stage 3 and 4 patients was 72 and 77% in France, and 51 and 35% in the US, respectively. Aldosterone blockade use was 3-6. Among diabetics, insulin use was lower in US (32%) than in France (48 and 57% for stage 3 and 4 patients, respectively), as was metformin use which was 30 and 7%, and 10 and 1%. For stage 4 patients, sulfonylurea use was higher in the US (21%) than in France (8%).

Conclusions: These early results show large international differences in medication usage for diabetes and cardiovascular disease amongst CKD patients. Patients in US were much less likely to use RASi, metformin or insulin than in France. Early data from Germany and Brazil will be available by mid 2015. Further investigation should determine the reasons for these practice variations and their impact on CKD progression, survival, and other outcomes.

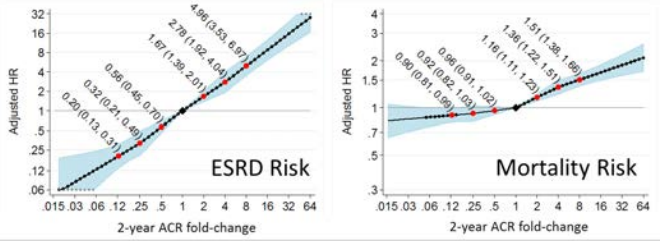
SA-OR007

Albuminuria Changes and Subsequent Risk of End-Stage Renal Disease and Mortality Juan Jesus Carrero,[1] Yingying Sang,[2] Alessandro Gasparini,[1] Abdul Rashid Tony Qureshi,[1] Kunihiro Matsushita,[2] Johan Arnlov,[3] Marie Evans,[1] Peter F. Barany,[2] Bengt Lindholm,[1] Morgan Grams,[2] Shoshana Ballew,[2] Carl Gustaf Elinder,[1] Josef Coresh.[2] *[1]Renal Medicine and Baxter Novum, Karolinska Inst, Sweden; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore; [3]Medical Sciences, Uppsala Univ, Sweden.*

Background: Albuminuria is used to stage chronic kidney disease (CKD). Changes in albuminuria during the course of disease may serve as early indicators of CKD progression and complications beyond eGFR, but the risk implications are not well understood in large clinical studies.

Methods: Observational study from the Stockholm CREAtinine Measurements (SCREAM) project, a laboratory data extraction of all citizens from the region of Stockholm, Sweden, with at least one serum creatinine during 2006-2011; 39802 individuals with repeated albumin to creatinine ratio (ACR) measurements were followed up until 12/31/2012. ESRD risk after baseline (908 events) was related to fold-change in ACR during a baseline window of 1, 2 or 3 years. The secondary outcome was death (3890 events). Adjustment variables included demographics, comorbid history, laboratory assessments and medication, as well as first eGFR and ACR.

Results: The association between ACR changes and ESRD risk was strong and showed a largely linear dose-response relationship (Figure for 2-y baseline period). For example, 8-fold increase in ACR (e.g., from normal of 5 mg/g to microalbuminuria of 40 mg/g) conferred ~5 fold higher risk of ESRD compared to stable ACR. The association was weaker for mortality but significant for ACR increases. The observed risk estimates were similar and consistent at 1-, 2- and 3-y time-window.



Conclusions: Increases in albuminuria were strongly and consistently associated with the risk of ESRD and mortality, suggesting their usefulness as a kidney outcome in clinical studies of CKD progression.

SA-OR008

Prevalence of Chronic Kidney Disease, Diabetes and Hypertension in Rural Tanzania Based of Different Methodologies David W. Ploth,[1] Virginia Fonner,[2] Bruce Horowitz,[3] Philip Zager,[3] Francis Fredrick,[4] Caroline M. West,[2] Michael D. Sweat.[2] *[1]Medicine, MUSC, Charleston, SC; [2]Div of Family Services Research, MUSC, Charleston, SC; [3]Medicine, Univ of New Mexico School of Medicine, Albuquerque, NM; [4]Nephrology, Muhimbili Univ of Health and Allied Sciences, Dar es Salaam, Tanzania, United Republic of.*

Background: Studies were conducted to explore the hypothesis that there are previously underappreciated and interrelated epidemics of chronic kidney disease (CKD), diabetes (DM), and hypertension (HTN) in rural Tanzania.

Methods: We initially assessed prevalence in a probability-based sample of 740 subjects randomly sampled from households in Kisarawe District, TZ. Prevalence of DM was obtained by measuring HbA1c. Blood pressure was measured by AHA guidelines, and kidney function by serum creatinine in blood samples obtained at home interview. Estimation of glomerular filtration rate (eGFR) was computed with the CKD-EPI equation.

Results:

NCD	Diabetes	Pre-Diabetes	CKD Stage 3-5	Pre-HTN	HTN
Criteria	HBA_{1C}>6.5%	HBA_{1C}> 5.9 to < 6.5	eGFR < 60 ml/ min/1.73 M^2	BP 120-130/80-89 mmHg	BP > 140/90
Prevalence	14.7%	30.5%	12.6%	40.0%	17.5%

Following the probability based screening of households, we assessed the same NCD's in individuals who voluntarily presented for healthcare assessment in a community prevention center we established. We measured BP and assessed urine for glycosuria and proteinuria with dipsticks in 685 subjects self-selected from the community. We observed glycosuria in 3.6%, proteinuria in 8.1% and proteinuria and glycosuria in 1.8%. Hypertension was observed in 23.6 % and pre-hypertension in 34.9%. We observed a significant, direct relationship between increasing levels of BP and the prevalence of glycosuria and proteinuria ($p < 0.05$).

Conclusions: In summary we observed unexpectedly high and similar prevalence estimates for CKD, HTN and DM in a probability-based sample in rural Tanzania and from observations in a walk-in community clinic. The higher than expected prevalence of these NCD's will likely contribute to rapidly accelerating rates of cardiovascular morbidity and mortality in these areas. Additional studies are desperately needed to address this problem.

SA-OR009

Race and the Association of Blood Pressure with Clinical Outcomes in U.S. Veterans with Chronic Kidney Disease Csaba P. Kovesdy,[1,2] Miklos Zsolt Molnar,[1] Praveen Kumar Potukuchi,[1] Elvira Gosmanova,[1] Fridtjof Thomas,[1] Jun Ling Lu,[1] L. Ebony Boulware,[3] Keith C. Norris,[4] Kamyar Kalantar-Zadeh.[5] *[1]Univ of Tennessee Health Science Center, Memphis, TN; [2]VA Medical Center, Memphis, TN; [3]Duke Univ School of Medicine, Durham, NC; [4]UCLA, CA; [5]UC, Irvine, CA.*

Background: African American (AA) patients with CKD have poorer BP control, but it is unclear if the association of BP with outcomes is different in AA vs. white patients with CKD.

Methods: We examined the association of baseline SBP with mortality, slopes of eGFR, ESRD, incident coronary heart disease (CHD) and incident stroke in 308,920 US veterans (54,852 AA and 254,068 white) with CKD over a median follow-up of 4.9 years. We used Cox models and logistic regressions with interaction terms to explore race differences in associations of SBP categories (relative to SBP 130-139 mmHg in white patients) with outcomes, adjusted for demographic and socioeconomic characteristics, comorbidities, baseline eGFR, and medications.

Results: Compared to whites, AA patients were younger, less likely to be married, had lower income, more diabetes, but less CVD. Mean baseline SBP (SD) was 133 (17) in AA and 130 (16) mmHg in whites. Elevated SBP was associated with linearly higher risk of all outcomes in both race groups. Race and elevated SBP showed no interaction for the risk of mortality, ESRD, strokes, and CHD. The association of elevated SBP with steeper eGFR slopes was, however, 1.6 fold more pronounced in AA patients.

Adjusted hazard/odds ratios (95%CI)	AA with SBP≥170 vs. white with SBP 130-139 mmHg	White with SBP≥170 vs. white with SBP 130-139 mmHg	P for interaction
All-cause mortality	1.40 (1.27-1.55)	1.44 (1.36-1.54)	0.6
Incident ESRD	10.69 (8.94-12.78)	6.09 (5.07-7.30)	0.6
Steeper slopes of eGFR (<-5 ml/min/1.73m^2/yr)	3.51 (3.13-3.93)	2.20 (2.04-2.38)	0.003
Incident ischemic stroke	1.96 (1.62-2.36)	1.86 (1.62-2.15)	0.7
Incident CHD	1.46 (1.11-1.91)	1.81 (1.48-2.20)	0.8

Conclusions: Hypertension is associated with higher incidence of mortality, vascular events and ESRD in both AA and white patients with CKD. Elevated SBP may affect the progression of CKD more in AA patients.

Funding: NIDDK Support, Veterans Administration Support

SA-OR010

Association of eGFR Decline with Post Dialysis Mortality in Late-Stage CKD Patients Who Transitioned to ESRD Keiichi Sumida,[1] Miklos Zsolt Molnar,[1] Praveen Kumar Potukuchi,[1] Fridtjof Thomas,[1] Jun Ling Lu,[1] Jennie Jing,[2] Vanessa A. Ravel,[2] Melissa Soohoo,[2] Connie Rhee,[2] Elani Streja,[2] Lawrence Agodoa,[3] Kevin C. Abbott,[3] Paul W. Eggers,[3] Kamyar Kalantar-Zadeh,[2] Csaba P. Kovesdy.[1,4] *[1]Univ of Tennessee Health Science Center, Memphis, TN; [2]Univ of California, Irvine, CA; [3]NIH, Bethesda, MD; [4]VA Medical Center, Memphis, TN.*

Background: The rate of eGFR decline is an independent risk factor for mortality in CKD. However,it is not known if pre-dialysis eGFR slopes are associated with outcomes after dialysis initiation.

Methods: We examined the association of pre-dialysis eGFR slopes with all-cause, cardiovascular (CV), and infectious mortality during two years after dialysis start in 19,254 U.S. veterans who transitioned to ESRD between October 1, 2007-September 30, 2011. eGFR slopes were categorized into four groups (<-10, -10-<-5, -5-<0, and 0+ mL/min/1.73m^2/year). Associations were examined in Cox models with adjustment for age, gender, race, comorbidities, and last pre-dialysis eGFR.

Results: Patients were 68.7±11.4 years old, 98% male, 29% black, and 72% diabetic. There were 5,226 all-cause, 2,751 CV, and 613 infectious deaths. Compared to eGFR slope of -5-<0 (42% of the total cohort), the adjusted hazard ratios [95%CI] for those with eGFR slopes of <-10, -10-<-5, and 0+ were 1.26 [1.17-1.35], 1.09 [1.03-1.15], and 1.04 [0.93-1.16], respectively (Table). Similar trends were observed for the associations of eGFR slopes with CV and infectious mortality.

eGFR slopes (mL/min/ 1.73m^2/ year)	Unadjusted HR (95% CI)	P Value	Age, sex, race-Adjusted HR (95% CI)	P Value	Fully Adjusted HR (95% CI)	P Value
<-10	0.67 (0.63-0.72)	<0.001	1.17 (1.09-1.25)	<0.001	1.26 (1.17-1.35)	<0.001
-10 – <-5	0.80 (0.76-0.85)	<0.001	1.03 (0.98-1.10)	0.24	1.09 (1.03-1.15)	0.005
-5 – <0	1.00 (reference)	N/A	1.00 (reference)	N/A	1.00 (reference)	N/A
0+	1.42 (1.29-1.57)	<0.001	1.53 (1.39-1.69)	<0.001	1.04 (0.93-1.16)	0.47

Conclusions: Patients with rapid pre-dialysis eGFR decline have higher mortality risk in the first two years after dialysis start. The rate of eGFR decline in late CKD stages can be an additional predictor of mortality in incident dialysis patients.

Funding: NIDDK Support, Veterans Administration Support

A Randomized Controlled Trial of Rituximab for Severe Idiopathic Membranous Nephropathy (IMN) Pierre M. Ronco,[1,2,8] Karine Dahan,[1] Hanna Debiec,[2,8] Emmanuelle M. Plaisier,[1,2,8] Marine Cachanado,[3] Alexandra Rousseau,[3] Laura Wakselman,[3] Pierre-Antoine Michel,[1] Fabrice Mihout,[1] Bertrand Dussol,[4] Marie Matignon,[5] Christiane I. Mousson,[6] Tabassome Simon.[3,7,8] *[1]Nephrology and Dialysis, AP-HP, Hôpital Tenon, Paris, France; [2]UMR_S 1155, INSERM, Paris, France; [3]Clinical Pharmacology and Unité de Recherche Clinique (URCEST), AP-HP, Hôpital Saint Antoine, Paris, France; [4]Nephrology and Transplantation, AP-HM, Hôpital de la Timone, Marseille, France; [5]Nephrology and Transplantation, AP-HP, Hôpital Henri Mondor, Créteil, France; [6]Nephrology and Transplantation, Centre Hospitalier Univ, Dijon, France; [7]UMR_S1148, INSERM, Paris, France; [8]UPMC, Sorbonne Univs, UPMC Univ Paris 06, Paris, France.*

Background: IMN is a common cause of nephrotic syndrome. Anti-PLA2R antibodies occur in 70% of patients. No randomized controlled trial has evaluated rituximab efficacy and safety.

Methods: Patients with biopsy proven IMN and persistent nephrotic syndrome after 6 months despite Non Immunosuppressive Antiproteinuric Treatment (NIAT) were randomly assigned to 6-month therapy with NIAT and 375 mg/m^2 of rituximab on days 1 and 8, or NIAT alone. At month 6, the primary end point was the rate of remission; the composite end point was defined as reduction of proteinuria > 50% and increase of serum albumin > 30%; secondary end points were proteinuria, serum albumin, serum creatinine, and PLA2R-Ab.

Results: 37 and 38 patients received NIAT with rituximab and NIAT alone. At month 3, rituximab decreased PLA2R-Ab rate and titer (P<0.001), and induced PLA2R-Ab depletion in 56 % of patients (P<0.001). At month 6, 13 (35 %) patients in the NIAT-rituximab group and 8 (21 %) in the NIAT group reached the primary end point (P=0.17); 15 (41 %) patients in the NIAT-rituximab group and 5 (13 %) in the NIAT group reached the composite end point (OR=0.22, 95% CI= [0.07; 0.70]; P=0.007). Serum albumin increased more with rituximab (P=0.029), without difference in proteinuria. Number of SAEs was comparable in both groups.

Conclusions: Rituximab induced immunological and clinical remission defined by a composite end point with a high safety profile (GEMRITUX ClinicalTrials.gov number).

Two-Year Outcomes of Patients with Idiopathic Membranous Nephropathy, Previously Randomized to Either Modified Ponticelli Regimen or to a Combination of Tacrolimus and Steroids Krishan L. Gupta, Raja Ramachandran, Harbir Singh Kohli, Vivekanand Jha. *Nephrology, Postgraduate Insitute of Medical Education and Research, Chandigarh, India.*

Background: The patients with idiopathic membranous nephropathy (IMN followed for 1 year are known to relapse more often with Tacrolimus than with cyclophosphamide either given with oral steroids. The present study aimed at finding the clinical outcome in patients randomized to a combination of Tacrolimus and oral prednisolone (TAC*) or Modified Ponticelli regimen (MPR) (cyclical cyclophosphamide and steroids) at 2 years.

Methods: IMN patients (n=70) with persisting nephrotic syndrome after at least 6 months of ACEIs or ARBs or with complications of nephrotic syndrome were randomized to receive TAC* or MPR. The outcome of the study was remission at the end of 18 and 24 months of initiating therapy. Definition: Complete remission (CR): 24-hour urine protein < 500 mg/day with normal serum albumin (³3.5 gm/dl) and serum creatinine. Partial remission (PR): 24 hour urine protein ≥500 mg/day but <2 gm/day or <50% of baseline with normal serum albumin (³3.5 gm/dl) and serum creatinine.

Results: Of the 70 randomized patients followed for 18 months, 54 had follow-up for 24 months. Intention-to-treat analysis and remission at the end of 12 (n-70), 18 (n-70) and 24 (n-54) months are mentioned in **Table**. At the end of 18 and 24 months response rate with TAC* was lower compared to subjects treated with MPR (p-0.05). The adverse events were comparable in both the groups. PLA2R antibodies titer rose in all patients with relapse of nephrotic range proteinuria.

	12m (TAC*) (n-35)	12m (MPR) (n-35)	18m (TAC*) (n-35)	18m (MPR) (n-35)	24m (TAC*) (n-28)	24m (MPR) (n-26)
Remission	71.4	77.1	62.8	85.7	64.2	88.4
CR	54.2	51.4	54.2	65.7	42.8	69.2
PR	17.2	25.7	8.6	20	21.4	19.2
Resistant	28.6	22.8	37.2	14.3	35.7	11.6

Conclusions: Preliminary analysis suggests that at 2 years post randomization, TAC* is inferior to MPR in maintaining remission of NS (The total follow-up of 70 cases will be presented at ASN).

SA-OR013

Antibody Guided Therapy with Cyclophosphamide and Prednisone in Patients with Idiopathic Membranous Nephropathy Anne-Els van de Logt, Julia M. Hofstra, Jack F. Wetzels. *Nephrology, Radboud Univ Medical Center, Radboud Inst for Health Sciences, Nijmegen, Netherlands.*

Background: The discovery of anti-PLA2R antibodies provides options for individualized therapy in patients with idiopathic membranous nephropathy (iMN). We previously showed that the level of anti-PLA2R antibodies (aPLA2R) after 6-12 months of cyclophosphamide (CP) therapy predicted long-term outcomes (Bech, CJASN 2014). We present the first data of antibody guided therapy.

Methods: CP-therapy (combined with steroids) is started in patients with aPLA2R positive iMN and high risk of progression. aPLA2R are repeatedly monitored (IFT test) at 8, 16, and 24 weeks after start of treatment. If antibodies become negative, CP is stopped and prednisone is tapered. Otherwise, therapy is continued after 24 weeks with MMF and prednisone.

Results: We treated 22 patients (characteristics in table 1). aPLA2R were negative in respectively 15/22 (68%) after 8 weeks, 17/21 (81%) after 16 weeks and 17/20 (85%) patients after 24 weeks of treatment. A partial remission of proteinuria (PCR < 3.0 gram/10 mmol creatinine) was observed in 23 % (5/22), 44 % (8/18) and 67 % (10/15) of patients after 8, 16 and 24 weeks respectively. Thus far, 4 of the 17 patients (24%) developed an immunological relapse after 3.4 (1.6-6.7) months. All 4 patients have persistent or recurrent proteinuria. Thus far, 6 of 22 patients (27%) needed additional treatment; 1 because of renal failure, 3 because of persisting positive aPLA2R at 24 weeks and 2 patients because of an immunological and clinical relapse . At the end of follow-up 14 of the 22 patients (64%) were in clinical remission.

Conclusions: Monitoring of aPLA2R could allow individualized therapy in patients with iMN, thus shortening overall duration of CP therapy. Longer follow-up is needed to establish that the overall relapse rate is acceptable.

Gender (male/female)	16/6
Age (years)	58 (±14)
Serum creatinine (μmol/l)	117 (96-141)
Serum albumin (g/l)	21 (16-23)
Protein-creatinine ratio (g/10 mmol/Cr)	8.7 (5.5-13.3)
Previous immunosuppressive treatment	1/22 (5%)
Follow-up duration (months)	8.0 (4.9-11.3)

Values are expressed as number (percent), means ± SD and median [interquartile ranges].

Is Serum PLA$_2$R Monitoring Clinically Relevant in Idiopathic Membranous Nephropathy? Harbir Singh Kohli, Raja Ramachandran, Vinod Sharma, Vivekanand Jha, Krishan L. Gupta. *Nephrology, PGIMER, Chandigarh, India.*

Background: In this prospective study, we evaluated glomerular staining for PLA$_2$R, serum anti-PLA$_2$R antibodies, and its association with clinical response to therapy.

Methods: Adult IMN on immunosuppressive therapy were enrolled during Sept 2011 to Nov 2014. PLA$_2$R in glomerular deposits was assessed in fresh frozen tissue (Abcam ab80054) by confocal microscopy. Anti- PLA$_2$R was estimated in serum before,6 and 12 months after therapy (ELISA and IIF, EUROIMMUN, Germany). The patients were treated with either alternating monthly cycles of cyclophosphamide and steroids or tacrolimus with steroids. Definitions: complete remission: 24 hr urine protein <0.5gm on 3 occasions with normal serum albumin. Partial remission: urine protein >0.5 gm to 2 gm/day or <50% of baseline with normal serum albumin.

Results: A total of 86 patient, 52 males, 34 females, mean age 42.6 yrs were studied. Sixty three (73.25%) had glomerular PLA$_2$R staining. Sixty (69.76%) showed elevated serum anti- PLA$_2$R by ELISA and 56 (65.11%) by IIF. Fifty-two (60.45%) had both serum and glomerular positivity, 11 (12.79%) had isolated glomerular positivity, 8 (9.3%) had only serum antibodies and 15 (17.44%) had no detectable PLAR in serum or glomeruli. Of 86 who completed 12 months of follow-up, 58 (67%) responded to therapy: 38 (44%) had complete and 20 (23%) partial remission. Of 60 serum PLA$_2$R Ab positive cases, 40(67%) had remission and 20 (33%) were resistant to therapy. Thirty-seven (92.5%) with remission had negative PLA$_2$R Ab at end of therapy and 18 (90%) resistant patients had elevated PLA$_2$R Ab titer (p<0.001). There was parallel reduction in mean PLA$_2$R Ab titre and 24 hr urine protein, 5 cases had clinico-serological discordance; 3 patients showed elevated 12-month anti-PLA$_2$R levels but were in clinical remission - all of them relapsed over the next 2 months. On the other hand, 2 cases who tested negative for anti-PLA$_2$R but continued to have nephrotic syndrome at 12 months, achieved remission by 14 months.

Conclusions: PLA$_2$R antibodies and glomerular deposits are present in over two-thirds of IMN. PLA$_2$R antibodies have an association with clinical response and the immunological recovery may precede clinical recovery.

SA-OR015

An Indirect Immunofluorescence Test (IFT) to Measure Thrombospondin Type-1 Domain-Containing 7A Antibodies (THSD7A-Ab) in Patients with Membranous Nephropathy (MN) Elion Hoxha,[1] Laurence H. Beck,[2] Nicola M. Tomas,[1] Christian Probst,[3] David J. Salant,[2] Rolf A. Stahl.[1] *[1]III. Medizinische Klinik, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; [2]Boston Univ School of Medicine, Boston Univ, Boston, MA; [3]EUROIMMUN AG, Lübeck, Germany.*

Background: THSD7A is a target antigen in MN. Measurement of THSD7A-Ab might be helpful for the diagnosis of MN and when making treatment decisions in these patients.

Methods: In this study we validated an IFT to detect THSD7A-Ab in 2 cohorts of patients with biopsy-proven MN. The presence of THSD7A-Ab was correlated with clinical parameters reflective of disease activity.

Results: Using the western blot (WB) technique, we identified 35 patients positive for THSD7A-Ab, 24 in the Hamburg cohort and 11 in the Boston cohort. 34 out of the 35 cases resulted THSD7A-Ab positive in the IFT analysis. All 35 THSD7A-Ab positive patients were negative for PLA$_2$R-Ab in both analyses. They were 56.5±17.0years old and 14 (40%) were male. Proteinuria was 6.9±4.3g/day, serum creatinine 1.3±0.7mg/dl. In 22 patients the time between serum collection and renal biopsy was less than 6 months and 18 had no immunosuppression prior to serum collection. The control group consisted of 671 patients, 555 with MN (120 of them PLA$_2$R-Ab positive) and 116 with renal diseases other than MN (all of them PLA$_2$R-Ab negative). All these patients were negative for THSD7A-Ab when measured with the IFT. In 30 randomly selected PLA$_2$R-Ab positive patients sera were analyzed and resulted negative for THSD7A-Ab and positive for PLA$_2$R-Ab in IFT and WB analyses.For 4 THSD7A-Ab positive patients follow-up data of at least 12 months could be analyzed. In 1 patient THSD7A-Ab disappeared and he experienced

remission of proteinuria. In 3 patients THSD7A-Ab persisted. 2 of them achieved remission of proteinuria, 1 had a relapse 3 months afterwards. The third patient had no remission of proteinuria during follow-up.

Conclusions: In this cohort of patients with MN the new IFT showed 97% sensitivity and 100% specificity for the detection of THSD7A-Ab compared to WB. A larger cohort of patients and their clinical follow up will be necessary to test its usefulness in patients with MN.

SA-OR016

Melanocortin 1 Receptor (MC1R) Is Dispensable for the Proteinuria Reducing and Glomerular Protective Effect of Melanocortin Therapy Yingjin Qiao,[1] Anna-lena Berg,[2] Yan Ge,[1] Zhangsuo Liu,[1] Rujun Gong.[1] *[1]Brown Medical School; [2]Lund Univ, Sweden.*

Background: Evidence suggests that melanocortin therapy by using ACTH or non-steroidogenic melanocortin peptides attenuates proteinuria and podocyte injury in animal models of glomerular diseases and induces remission of nephrotic syndrome in patients with a variety of proteinuric glomerulopathies, even those resistant to steroids. The underlying mechanism, however, remains elusive. This study aimed to validate the role of MC1R in mediating the beneficial effects of melanocortin therapy in glomerular diseases, as suggested by recent research.

Methods: The recessive yellow MC1R-mutant ($MC1R^{e/e}$) and wild type (WT) mice were injured by lipopolysaccharide (LPS) or adriamycin (ADR) to develop podocytopathy and the effect of NDP-MSH, a non-steroidogenic melanocorin pan agonist, was tested. In patients with steroid-resistant nephrotic syndrome and nonfunctional MC1R mutations, the effect of ACTH therapy was evaluated.

Results: Following LPS or ADR insult, NDP-MSH attenuated proteinuria in WT and $MC1R^{e/e}$ mice to the same extent and ameliorated signs of glomerular injury and podocytopathy, including loss of podocyte markers, *de novo* expression of podocyte damage markers, and podocyte foot process effacement. *In vitro* in primarily cultured podocytes, LPS or ADR elicited apoptosis and podocyte hypermotility, and impaired the filtration barrier function of podocyte monolayers. These injurious effects were mitigated by NDP-MSH to a similar degree in podocytes derived from WT and $MC1R^{e/e}$ mice. Moreover, two patients with congenital red hair and nephrotic syndrome due to idiopathic membranous nephropathy were enrolled and confirmed by gene sequencing to bear nonfunctional MC1R mutations. After failing multiple immunosuppressive regimens, including glucocorticoids, the patients were converted to synthetic ACTH monotherapy for 21 months and 8.5 months respectively (escalation and de-escalation included) and both achieved complete remission of proteinuria, denoting a steroid independent effect.

Conclusions: Melanocortin therapy confers a proteinuria reducing and podoprotective effect in proteinuric glomerulopathies *via* a mechanism independent of MC1R.

Clinical Genetic Testing for the C3 Glomerulopathies and Thrombotic Microangiopathies Using a High-Throughput Panel Fengxiao Bu, Nicolo Ghiringhelli Borsa, Michael Jones, Erika Takanami, Carla Nishimura, Jill Johanna Hauer, Hela Azaiez, Elizabeth Ann Black-Ziegelbein, Nicole Meyer, Diana Kolbe, Yingyue Li, Kathy Frees, Michael J. Schnieders, Christie P. Thomas, Carla M. Nester, Richard J. Smith. *Univ of Iowa, Iowa City, IA.*

Background: C3 glomerulonephritis (C3GN), dense deposit disease (DDD), atypical hemolytic uremic syndrome (aHUS) and thrombotic thrombocytopenic purpura (TTP) are rare diseases with phenotypic similarities and genetic commonalities. Variants in the *CFH*, *CFI*, *CFB*, *C3*, *CFHR5*, *CD46*, *DGKE*, *ADAMTS13*, *THBD* and *PLG* genes, and copy number variation of *CFHR3-CFHR1* contribute to their pathogenesis and inform diagnosis and treatment options. To improve patient care, we developed a comprehensive genetic complement panel (GCP) to screen these genes. Herein we present our one-year experience using this panel in the clinical care of these patients.

Methods: 184 patients (37 with C3G and 147 with TMA) were studied using the GCP panel.

Results: Positive genetic diagnoses were provided in 43% of C3G patients and in 41% of TMA patients.

Disease (n)	*CFH*	*CD46*	*CFI*	*CFB*	*C3*	*CFHR5*	*ADAMTS13*	*THBD*	*DGKE*	*PLG*	Total
TMA (147)	**14**	**9**	**10**	**1**	**8**	**4**	**10**	**2**	**3**	**4**	**65**
aHUS (118)	12(4)*	9(3)	8(2)	1	7(1)	2	6		3(2)	3	51
TTP (6)	1(1)						2	1			4
aHUS/TTP (12)	1		1				2	1		1	6
Other (11)			1		1(1)	2(1)					4
C3G (37)	**6**	**0**	**2**	**3**	**5**	**1**	**1**	**1**	**3**	**1**	**23**
C3GN (30)	5		1	3	3(2)	1	1	1	2	1	18
DDD (5)	1		1		2						4
C3GN/DDD (2)									1		1

17 novel and 71 rare variants (minor allele frequency <1%) were identified, which we classified as pathogenic (11), likely pathogenic (12), or of uncertain significance (65). In C3G patients, the novel/rare variant load was increased in both C3 convertase (*C3* and *CFB*) and complement regulator (*CFH*, *CFI*, *CFHR5*, and *CD46*) genes, consistent with a multifactorial genetic contribution to this disease. In TMA patients, the novel/rare variant load was increased only in complement regulator genes, consistent with an abnormality in regulation of the alternative complement pathway as a driving factor in this disease.

Conclusions: GCP panel provides a comprehensive and efficient genetic screen of complement genes. The observed differences in variant aggregation in patients with C3G and TMA refine our understanding of these diseases.

Amelioration of the Adverse Effects of Prednisolone by Rituximab Treatment in Adults with Steroid-Dependent Minimal-Change Nephrotic Syndrome Yoei Miyabe, Takashi Takei, Yuko Iwabuchi, Takahito Moriyama, Kosaku Nitta. *Tokyo Women's Medical Univ, Japan.*

Background: We previously demonstrated the efficacy of single-dose 6-monthly rituximab infusions in 25 adults with steroid-dependent minimal-change nephrotic syndrome. Herein, we assessed the safety of rituximab treatment and its effect in ameliorating the adverse effects of prednisolone (PRED) in a larger study sample.

Methods: We treated 54 adult patients with four a single-dose 6-monthly infusions of rituximab (375 mg/m^2 BSA per dose). We compared the adverse effects of PRED (osteoporosis, hypertension and diabetes mellitus) between the first rituximab infusion (baseline) and the end of the 24-month observation period. In addition, we examined the adverse effects of rituximab during the same period.

Results: The PRED dose was significantly lower at 24 months than at the baseline. The bone density was significantly higher at 24 months as compared to the baseline value (Z-score: -1.8 vs. -1.1; $p < 0.05$). Blood pressure at 24 months was significantly lower than that at the baseline (120.9/74.4 vs. 111.8/70.3 mmHg; $p < 0.05$). Eight patients with diabetes mellitus showed improved glycemic control at 24 months as compared to that at the baseline. There were no severe adverse effects of rituximab. However, mild infusion reactions occurred in 31 patients (57%). The frequency of the infusion reactions decreased significantly with every successive infusion.

Conclusions: Rituximab treatment was effective and safe in patients with steroid-dependent nephrotic syndrome, allowed reduction of the PRED dose, and ameliorated the adverse effects of PRED. It may be preferentially used in patients at a risk of the adverse effect of PRED.

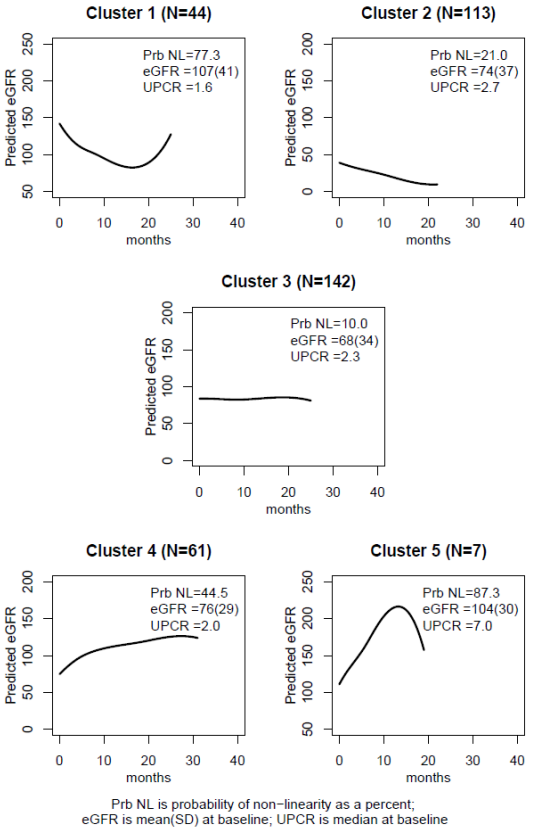
SA-OR019

Determining eGFR Trajectory Clusters in the NEPhrtoic Syndrome STUdy Network (NEPTUNE) Laura H. Mariani,[1,2] Jarcy Zee,[2] Tony Wang,[2] Viji Nair,[1] Wenjun Ju,[1] Jonathan P. Troost,[1] Debbie S. Gipson,[1] Peter X.K. Song,[1] Brenda W. Gillespie.[1] *[1]Univ of Michigan; [2]Arbor Research Collaborative for Health.*

Background: Non-linear changes in eGFR over time are common in nephrotic syndrome. Traditional outcomes (e.g. 50% eGFR decline) may not capture these changes. We identified patient clusters via eGFR longitudinal trajectory and associated clinical characteristics with the groups.

Methods: NEPTUNE is a multi-center, prospective cohort study of children and adults with >500mg/day of proteinuria, enrolled at the time of renal biopsy. eGFR was calculated using the CKD-Epi formula for participants ³18 yo and modified CKiD-Schwartz formula for those <18 yo. 367 patients with ³3 eGFR measurements were included. Each patient's eGFR trajectory was estimated using Bayesian smoothing and a probability of non-linearity was calculated (Li, AJKD, 2012;59(4)). Quadratic regression coefficients from each trajectory were used in a clustering algorithm to identify distinct groups by minimizing within-cluster variance.

Results: Mean follow-up time was 26 mo. 25% (n=92) of the cohort had a trajectory with >50% probability of being non-linear and 10% (n=35) had a non-linearity probability >83%. The clustering algorithm produced five trajectory groups. Baseline mean eGFR ($p<0.001$) and median upcr ($p<0.001$) differed by cluster. Mean age was lowest in clusters 1 and 5 (28 and 25 vs. 39, 39, 31; p=0.002). Race and sex did not vary by cluster. MN composed 13-20% of each cluster whereas FSGS composed 40 and 35% of clusters 2 and 3, respectively (p=0.005).



Conclusions: This unique statistical approach identified clusters which describe individual eGFR trajectories. Non-linear trajectory groups had more young patients, higher eGFR and upcr. Further work is needed to determine whether trajectory clusters represent different underlying disease pathophysiology and to identify cluster predictors at the time of biopsy.

The Role of Calcineurin Inhibitors in Early Treatment of Primary FSGS

Louis-Philippe Laurin,[1] Bethany J. Foster,[4] A. Gasim,[2] Caroline J. Poulton,[3] J. Charles Jennette,[2] Ronald J. Falk,[3] Patrick H. Nachman.[3] *[1]Div of Nephrology, Hôpital Maisonneuve-Rosemont, Montreal, QC, Canada; [2]Dept of Pathology and Laboratory Medicine, Univ of North Carolina at Chapel Hill, Chapel Hill, NC; [3]Div of Nephrology and Hypertension, Univ of North Carolina at Chapel Hill, Chapel Hill, NC; [4]Div of Nephrology, McGill Univ Health Center, Montreal, QC, Canada.*

Background: In primary focal segmental glomerulosclerosis (FSGS), calcineurin inhibitors (CNIs) have primarily been studied in patients deemed resistant to glucocorticoid (GC) therapy. Little data is available about their use early in the treatment of FSGS. We sought to estimate the association between choice of therapy and end-stage kidney disease (ESKD) in idiopathic FSGS.

Methods: An inception cohort of patients with biopsy-proven primary FSGS diagnosed between 1980 and 2012. Time to ESKD between different early therapies was reported with time-dependent Cox regression hazard ratio (HR) with 95% confidence interval (CI).

Results: 458 patients were studied (332 NOS, 64 Tip, 62 Collapsing): age 40.7±20.8 years; 45.6% Black; 48.7% female; follow-up time 92±94 months. 183 patients received no immunosuppression, 173 received GC alone, 90 were treated with CNIs ± GC and 12 received other immunosuppressive agents.

Multivariate determinants of ESKD	HR (95% CI)
Immunosuppression None CNIs and/or GC	 1 0.49 (0.28-0.86)
Age	1.00 (0.99-1.01)
Male sex	1.15 (0.76-1.73)
FSGS variant NOS Tip Collapsing	 1 0.21 (0.09-0.48) 1.71 (0.99-2.95)
Baseline eGFR <30 mL/min/1.73m^2	4.28 (2.81-6.48)
Baseline proteinuria ≥3.5 g/d	1.25 (0.68-2.29)
Baseline serum albumin (per g/dL higher)	0.69 (0.53-0.90)
Baseline hypertension	1.33 (0.81-2.20)

Although not statistically significant, CNIs ± GC were associated with a lower likelihood of ESKD compared to GC alone [HR 0.42 (95% CI 0.15, 1.18)].

Conclusions: The use of CNIs as part of the early immunosuppressive regimen in primary FSGS may be associated with improved outcome, but their superiority over GC alone remains unproven.

SA-OR021

Living Donation Has a Greater Impact on Allograft Survival Than HLA Matching in Pediatric Renal Transplant Recipients

Matko Marlais,[1] Alex J. Hudson,[2] Laura Anne Pankhurst,[2] Susan V. Fuggle,[2] Stephen D. Marks.[3] *[1]Univ College London, United Kingdom; [2]NHS Blood and Transplant, United Kingdom; [3]Great Ormond Street Hospital NHS Foundation Trust, United Kingdom.*

Background: Living donor kidney transplantation accounts for around half of all paediatric (<18 years) renal transplant recipients (PRTR) and results in improved renal allograft survival, although there are no data comparing the effect of HLA-mismatching on outcomes. The UK 2006 Kidney Allocation Scheme prioritises children with good HLA mismatching (Level 1/2: 000 A,B,DR or [0 DR & £1 B]). The aim of this study was to determine the effect of HLA mismatching on deceased and living donor renal allograft outcomes in paediatric recipients.

Methods: Data were obtained from the UK Transplant Registry on all PRTR who received a donation after brain death (DBD) or living donor (LD) kidney-only transplant between 2000 and 2011. HLA A, B and DR mismatch were categorised into four levels and two groups. Data were fully anonymised and ethical principles adhered to.

Results: 1,389 paediatric renal transplant recipients were analysed; 807 (58%) received a DBD donor kidney. Using Cox proportional hazard regression modelling of renal allograft survival, the risk of graft failure is 1.55 times as likely in children who receive a well HLA-matched DBD kidney compared to those that receive a poorly HLA-mismatched LD kidney (p=0.01, 95% CI 1.11-2.18). This analysis accounts for survival improvements across transplant years. In both DBD and LD grafts, there was no difference in renal allograft survival in children who received a good or poorer HLA-mismatched transplant (p=0.16 for DBD graft, p=0.55 for LD graft).

Conclusions: In children, well HLA-matched DBD renal transplants have inferior graft outcomes when compared with poorly HLA-matched LD grafts. It is difficult to justify preferentially waiting for an improved HLA-matched DBD kidney even when a poorer HLA-mismatched LD kidney transplant is available.

Funding: Government Support - Non-U.S.

SA-OR022

UK National Registry Study of Kidney Donation After Circulatory Death for Pediatric Recipients

Matko Marlais,[1] Laura Anne Pankhurst,[2] Alex J. Hudson,[2] Khalid Sharif,[3] Stephen D. Marks.[4] *[1]Univ College London, United Kingdom; [2]NHS Blood and Transplant, United Kingdom; [3]Birmingham Children's Hospital, United Kingdom; [4]Great Ormond Street Hospital, United Kingdom.*

Background: Donation after circulatory death (DCD) is an important source of organs for kidney transplantation and evidence in adults suggests that similar graft outcomes are achieved to donation after brain death (DBD) kidney transplantation. There is very little evidence reporting the use of DCD kidneys in children. The aim of this study was to determine graft outcomes for children in the UK who have received a DCD kidney and compare these to outcomes for all renal transplants.

Methods: Data was collected on all kidney transplants performed for paediatric recipients (age <18 years) in the UK from the NHS Blood and Transplant registry from 2000-2014 and separated into DCD, DBD and living donor kidney transplants. Data obtained included donor and recipient characteristics with 3-year graft survival and overall patient survival. All data were fully anonymised and ethical principles adhered to.

Results: 1773 kidney transplants were performed in children in the UK from 2000-2014. 22 (1.2%) of these were from DCD donors, 955 (53.9%) were from DBD donors and 796 (44.9%) were from living donors. 3-year graft survival was 95.5% in the DCD group, 87.1% in the DBD group and 92.9% in the living donor group. Overall patient survival is 100% in the DBD group, 98.7% in the DBD group and 98.8% in the living donor group.

In the DCD group the median time to asystole was 12.5 minutes and the median standard warm ischaemia time was 13 minutes. In the DCD group there was 1 case of primary non-function and 5 cases of delayed graft function.

Conclusions: This is one of the largest studies reporting outcomes in children who receive DCD kidney transplants. In the post-2000 era children receiving a DCD kidney transplant have good graft survival at 3-year follow up, comparable to those receiving a kidney from a DBD donor or a living donor. This limited evidence encourages the use of selected DCD kidneys in paediatric transplantation as favourable graft outcomes can be achieved, and national DCD allocation algorithms may need to be amended in view of this.

SA-OR023

Longitudinal Change in Neurocognitive Functioning in Pediatric Chronic Kidney Disease Stephen R. Hooper,[1] Matthew Matheson,[2] Rebecca J. Johnson,[2] Arlene C. Gerson,[2] Marc Lande,[2] Susan R. Mendley,[2] S. Shinnar,[2] Debbie S. Gipson,[2] Susan L. Furth,[2] Bradley Warady.[2] *[1]UNC; [2]CKiD Study Group.*

Background: Few longitudinal data exist on the cognitive functioning of children with mild to moderate chronic kidney disease (CKD). We report longitudinal findings for the neurocognitive functioning of participants with mild to moderate CKD from the 48-site CKiD Study, with a particular focus on identifying CKD-related variables predictive of change in cognition over time and progression to renal replacement therapy (RRT).

Methods: The sample comprised 2,009 assessments over a span of approximately 12 years. Measures of IQ, attention, and parent ratings of executive functions were obtained. Joint longitudinal mixed models and time-to-event models with a shared random effect were used to examine the predictive value of CKD-related variables at study entry (glomerular diagnosis, age of CKD onset, iGFR, nephrotic proteinuria, elevated blood pressure, anemia) and over time (duration of disease, iGFR annual percent change) adjusting for baseline covariates (e.g., gender, maternal education), while simultaneously examining the association of neurocognitive decline with RRT.

Results: Median chronological age at study entry was 11.3 yrs; 56% Caucasian; 62% male. 33% had maternal education of a college degree. The median duration of CKD was 7.9 yrs., with 62% of children having disease onset at birth. 21% had a glomerular diagnosis; average iohexol-based GFR was 52.3 ml/min/1.73m^2. After adjusting, lower iGFR and elevated blood pressure at study entry were associated with declining Performance IQ. Lower iGFR and annual percent change in iGFR were associated with worse parent ratings of executive functioning. The shared parameter associating declining neurocognitive abilities with RRT showed Attention Variability to be related to progression to RRT.

Conclusions: Findings suggest that selected disease-related variables should trigger referral for neurocognitive assessment as children with lower iGFR and elevated blood pressure, and those with larger annual iGFR change may be at greatest risk for neurocognitive declines. Attention variability also was significantly associated with CKD disease progression to RRT.

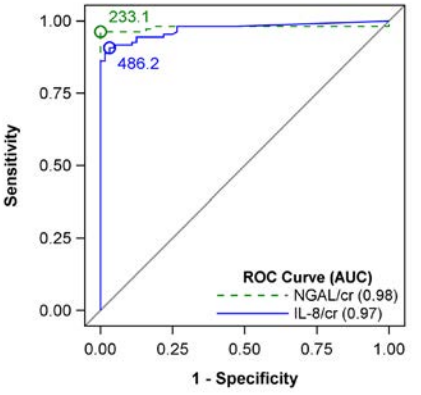
Biomarkers and Urinary Tract Infection in Infants Sindri Valdimarsson, Sverker Hansson, Ulf I. Jodal. *Pediatric Uronephrologic Center, The Queen Silvia Children's Hospital, Sahlgrenska Academy, Univ of Gothenburg, Göteborg, Sweden.*

Background: Urine culture is needed to diagnose infants with urinary tract infection (UTI). Symptoms are nonspecific and urine biomarkers are a possible tool to improve the diagnostic accuracy minimizing the need for investigations and invasive procedures. The aim was to evaluate if urine biomarkers can aid in the diagnosis of UTI.

Methods: This is a prospective study of infants with first UTI. Urine biomarkers were measured in infants with UTI and in a control group of children with fever from other causes. Measured urine biomarkers were Kidney injury molecule 1, Clara cell protein, Retinol binding protein, Neutrophil gelatinase associated lipocalin, high sensitive C-reactive protein, Interleukin-1b, Interleukin-6 and Interleukin-8 (IL-8); all were adjusted for urine creatinine(cr).The area under the ROC curve (AUC) for each biomarker was compared for children with UTI versus children with fever without UTI; the optimal cutoff level for equal weight on sensitivity and specificity was determined.

Results: 108 infants with UTI, 59 boys (mean age 2.7 months) and 49 girls (mean age 4.0 months) and a control group of 64 patients with fever without UTI (23 girls and 41 boys) were included. The biomarkers NGAL/cr and IL-8/cr were superior in differentiating between children with and without UTI. AUC for NGAL/cr was 0.98 and a cutoff value of 233 had 96.3% sensitivity and 100% specificity. AUC for IL-8/cr was 0.97 and a cutoff value of 486 had 91.7 % sensitivity and 95.3% specificity.



Conclusions: This prospective study shows that the urine biomarkers NGAL and IL-8 had high sensitivity and specificity for the diagnosis of UTI in infants. Infants with fever and a low NGAL/cr value were highly unlikely to have a UTI.

Phospholipase A2 Receptor Autoantibodies in Pediatric Membranous Nephropathy Rebecca Kirkwood-Wlison,[1] Maryline Fresquet,[1] Nicholas J. Webb,[2] Paul E. Brenchley,[3] Rachel Lennon.[1,2] *[1]Wellcome Trust Centre for Cell-Matrix Research, Univ of Manchester, United Kingdom; [2]Dept of Paediatric Nephrology, Royal Manchester Children's Hospital, United Kingdom; [3]Manchester Inst of Nephrology and Transplantation, United Kingdom.*

Background: Membranous nephropathy (MN) is the commonest cause of nephrotic syndrome in adults, with most cases being primary, or autoimmune in nature. Understanding of MN advanced with the discovery of phospholipase A2 receptor (PLA2R) as the target autoantigen and with the detection of circulating autoantibodies in the sera of adult patients. In the pediatric population, MN is rare and often presents with persistent, steroid-resistant, proteinuria and is diagnosed by typical histological features on renal biopsy. In this study, we describe the clinical phenotype, renal histological analysis, anti-PLA2R status, and autoantibody binding in 6 children with biopsy-proven PMN treated at the Royal Manchester Children's Hospital over the past 7 years.

Methods: We carried out phenotypic characterisation of patients, determination of anti-PLA2R status by ELISA, anti-PLA2R Ig subclass analysis and histological characterisation of renal biopsies. Anti-PLA2R binding was determined by comparing autoantibody reactivity to recombinant fragments of the PLA2R under denatured and native conditions.

Results: Determination of anti-PLA2R status revealed 50% of children were seropositive. Seropositivity was associated with a severe clinical phenotype with nephrotic syndrome with renal impairment and IgG4 was the predominant subclass. Seronegative patients presented with asymptomatic proteinuria. Autoantibody reactivity patterns to recombinant fragments of the PLA2R, differed with clinical phenotype at presentation.

Conclusions: Here we report, for the first time, a series of 6 children with biopsy-proven MN. We demonstrate a correlation between clinical phenotype and anti-PLA2R status and evaluate autoantibody-PLA2R binding in the paediatric MN population. Our results suggest that minor, or alternative, epitopes exist within the PLA2R which may be responsible for autoantibody binding in paediatric MN.

APOL1-Associated Glomerular Disease in African-American Children in the CKiD and NEPTUNE Cohorts Derek Ng,[1] C. Robertson,[2] C. Gillies,[2] Sophie Limou,[3] Robert Woroniecki,[4] Kimberly J. Reidy,[5] Sangeeta R. Hingorani,[6] Keisha L. Gibson,[7] Christine B. Sethna,[8] Cheryl Ann Winkler,[3] Jeffrey B. Kopp,[9] Susan L. Furth,[10] Bradley Warady,[11] John R. Sedor,[12] Frederick J. Kaskel,[5] M. Sampson.[2] *[1]Johns Hopkins; [2]U of Michigan; [3]NCI; [4]Stony Brook Univ; [5]Montefiore Med. Center; [6]U of Washington; [7]U of North Carolina; [8]Cohen Children's Med Center; [9]NIDDK; [10]Children's Hosp of Philadelphia; [11]Children's Mercy Hosp; [12]Case Western Reserve.*

Background: Little is known about *APOL1* associated nephropathy in children. This study aimed to describe characteristics and longitudinal outcomes in African-American children with glomerular disease, stratified by *APOL1* risk genotype in the Chronic Kidney Disease in Children cohort (CKiD) & the Nephrotic Syndrome Study Network (NEPTUNE).

Methods: Enrollment criteria for CKiD was age 1-16, diagnosis of CKD, & estimated glomerular filtration rate (GFR) of 30-90 mL/min. NEPTUNE subjects were enrolled with suspected primary nephrotic syndrome, proteinuria, >0.5g/day, & clinically indicated biopsy. 56 CKiD subjects with glomerular disease & 48 NEPTUNE pediatric subjects were included here (all African-American). *APOL1* was directly genotyped and subjects were classified as low risk (LR, 0 or 1 risk alleles) or high risk (HR, 2 risk alleles). All analyses were performed under the recessive model; LR vs HR subjects. By *APOL1* genotype, odds of prematurity and eGFR & proteinuria over time were modeled.

Results: All subjects were of similar age (12 to 15 yrs). HR subjects in both cohorts had a lower baseline GFR by about 20 ml/min. The combined cohort demonstrated a significantly increased odds of prematurity in HR subjects (OR: 4.57; 1.4-15.5). NEPTUNE HR subjects had 15% decline in GFR per year, comparable to that seen in all CKiD subjects, independent of genotype. LR NEPTUNE subjects had no eGFR decline (3% per year).

Conclusions: HR genotype was associated with higher odds of prematurity, suggesting an interaction between the *APOL1* HR genotype and prematurity in the development of pediatric glomerular disease and subsequent CKD. NEPTUNE children with the HR genotype had a similar decline in eGFR as CKiD subjects.

Comprehensive Approach to Understand Human Renal Development Based on the Identification of Responsible Genes for CAKUT Akemi Shono, Naoya Morisada, Kandai Nozu, Kazumoto Iijima. *Pediatrics, Kobe Univ Graduate School of Medicine, Kobe, Hyogo, Japan.*

Background: Although regenerative medicine using the pluripotent stem cells holds promise of the treatment for the renal failure, the complexity of the structure composed of diverse cell types makes the difficulty in the establishment of the differentiation protocol into renal nephron. Towards the comprehensive understanding of the molecular network underlying human renal development, this study aims to identify responsible genes for congenital anomalies and the kidney and urinary tract (CAKUT) and reveal the molecular mechanism of pathogenesis.

Methods: Two hundred six CAKUT cases including 115 cases from 105 families of syndromic CAKUT and 91 cases from 82 families of non-syndromic CAKUT together with some indistinguishable cases from CAKUT, were collected in agreement with participants, which was approved by the ethical committee at Kobe University. Genomic DNA samples were analyzed by the next-generation sequencing (Illumina exome and Agilent custom panels) in combination with the conventional Sanger sequencing and/or the DNA microarray subsequent to the phenotype classification based on the clinical manifestation.

Results: Responsible genes in 62 cases from 44 families were identified. The phenotype classification assisted to detect the reported responsible genes including PAX2, EYA1, HNF1B, UMOD, OFD1, SALL1 and CHD7 by Sanger sequencing, and the next-generation sequencing powerfully enabled us to identify responsible/candidate genes including PAX2, UPK3A, RET, FRAS1 and EP300 which were unpredictable from the clinical phenotype. To clarify the molecular mechanisms of candidate genes, further experiments including in vitro and in silico assays would be required.

Conclusions: These results would be significant to understand the network of disease-associated genes and the molecular mechanism underlying the human renal development, and might give us a future perspective for the regenerative medicine.

SA-OR028

A Randomized Study of Cholecalciferol Supplementation in Incident Hemodialysis Patients – Preliminary Evaluation After 2 Years Cristina Jorge,[1,2,5] Patrícia Matias,[1,2,5] Pedro Bravo,[3] Clara Mil-homens,[4] Cecília Silva,[4] Pedro M. Ponce,[4] Carlos M.P.C. Oliveira,[3] Célia Gil,[1,2,5] Manuel A. Ferreira.[1,2,5] *[1]Nephrocare Vila Franca de Xira, Portugal; [2]Dialverca, Portugal; [3]Nephrocare Almada, Portugal; [4]Nephrocare Lumiar, Portugal; [5]NIDAN, Portugal.*

Background: Studies have shown that vitamin D deficiency is associated with cardiovascular (CV) risk factors, morbidity and mortality in uremic patients (pts). Our aim is to prospectively assess the safety and efficacy of vitamin D (cholecalciferol) supplementation in incident HD pts and to compare the clinical results with a control group supplemented with placebo.

Methods: We evaluated 108 (66% M) pts in group A (GA) under VIT D 20 000 U/wk, and 95 (67% M) pts in Group B (GB) on placebo, matched in age, (mean 66 and 65 years), BMI (mean 25,7 and 26,3 kg/m2) respectively, etiology of renal disease and the presence of comorbidities such as HTN, arrhythmia, peripheral vascular disease and cancer. The prevalence of DM (42 vs 57%), ischemic heart disease (18 vs 32%) and cerebrovascular disease (16 vs 27%) was higher in GB. A follow-up of 12 and 24 months (m) was attained respectively in 67 and 18 pts in GA vs 60 and 21 pts in GB.

Results: The basal levels of 25(OH)VitD3 were similar in the two groups (median 11 ng/mL) and significantly increased at 12m in GA (30 vs 11 ng/ml in GB; p<0,001) and at 24m (38 in GA vs 15 ng/ml in GB; p<0,001). Laboratory evolution (Ca, P, PTH, bAP, Hb, CRP or albumin), was similar in both groups. There was difference in the Erythropoiesis Resistance Index (ERI) (mcg/kg/wk/g/dl) at T0 (GA=0,034 > GB=0,023, p=0,03) and at 24M (GA=0,010 < GB=0,022, p=0,01). No differences in the evolution of pulse pressure, left ventricular mass index or vascular calcifications were observed. The leading causes of hospitalization were CV and infectious, similar in both groups. There were 18 (16.7%) deaths in GA and 12 (12.6%) in GB (Log rank=0,752; p=NS, Kaplan-Meier). Treatment with antihypertensive drugs, phosphate binders, active vitamin D, or cinacalcet was similar in both groups.

Conclusions: Cholecalciferol administration at a dose of 20 000 U/week was safe and permitted a significant increase of vitamin D levels and a decrease of ERI in the supplemented group at 24M.

SA-OR029

Levocarnitine Improves Cardiac Function in Hemodialysis Patients with Left Ventricular Hypertrophy Masanori Abe, Noriaki Maruyama, Tetsuya Furukawa, Kazuyoshi Okada. *Nephrology, Hypertension and Endocrinology, Nihon Univ School of Medicine, Tokyo, Japan.*

Background: Levocarnitine deficiency in hemodialysis (HD) patients is common. This may contribute to clinical disorders, including cachexia, erythropoiesis stimulating agent resistant anemia,and glucose intolerance, muscle weakness, and myopathy as well as to intradialytic symptoms such as muscle cramps, hypotension, and cardiac arrhythmia. Although the effect of levocarnitine therapy on uremic anemia has been studied in small trials, its effects on cardiac function remain unclear.

Methods: This prospective, open-label, randomized, parallel, controlled, multi-center trial examined 222 HD patients who were randomly assigned to an oral levocarnitine therapy group (n = 110) or a control (no levocarnitine therapy) group (n = 112). Patients were monitored for 12 months during levocarnitine treatment (administered orally 20 mg/kg/day) or control. The primary endpoint was cardiac function measured by echocardiography. The secondary endpoints were clinical parameters and identification of factors that predict a favorable response to levocarnitine therapy. Echocardiographic parameters were measured at baseline and after 6 and 12 months of therapy.

Results: A total of222 patients were randomly assigned, of whom 148 patients (levocarnitine group, n = 75; control group, n = 73) were analyzed. The ejection fraction values increased from 54.0±5.8% at baseline to 56.0 ± 6.1% after 6 months (p<0.001) to 58.1±5.6% after 12 months (p<0.0001) in the levocarnitine group, while no significant changes in ejection fraction were observed in the control group. Furthermore, left ventricular mass index (LVMI) and N-terminal probrain natriuretic peptide levels were significantly decreased throughout the study in the levocarnitine group. Multivariate analysis revealed that LVMI was an independent predictor of improvement in ejection fraction following levocarnitine therapy. Subgroup analysis revealed that responders to levocarnitine were patients with left ventricular hypertrophy (LVH).

Conclusions: Levocarnitine therapy is useful for hemodialysis patients with LVH; these patients may benefit from such therapy, with amelioration of cardiac function and mitigation of LVMI.

SA-OR030

Predictive Ability of Self-Rated Health and Symptom Burden for Mortality in Hemodialysis Donal J. Sexton,[1] Aoife C. Lowney,[2] Conall M. O'Seaghdha,[3] Sinead Kinsella,[4] Peter J. Conlon.[3] *[1]Medicine, HRB Clinical Research Facility, NUIGalway, Galway, Ireland; [2]Palliative Medicine, Marymount Hospice, Cork, Ireland; [3]Nephrology, Beaumont Hospital, Dublin, Ireland; [4]Renal Medicine, Cork Univ Hospital, Cork, Ireland.*

Background: Little is known about the ability of self-rated health to predict mortality in hemodialysis.

Methods: A prospective cohort study in hemodialysis (N=362). The Euro Quality of Life Questionnaire (EQ5D), the Palliative Care Outcome Scale Renal (POS-S Renal) and the participant self-rated health (EQ visual analogue scale: EQVAS) were used to assess HRQOL, symptom burden and self-rated health. Participants were followed from instrument completion to death or study end.

Results: Over a median (25^{th}-75^{th} centile) of 2.6 (1.41-3.38) years, 32% (N=116) of participants died. With competing risks survival analysis factors most notably associated with mortality adjusted hazard ratio (95%CI) included: higher symptom burden 2.4 (1.3, 4.3) P=0.004 (highest tertile), lower HRQOL 2.6 (1.3, 5.3) P=0.01 (lowest tertile), lower self-rated health 2.7 (1.4, 5.2) P=0.004 (lowest tertile). Answering 'Yes' to the questions: "problems with mobility?" 2 (1.1, 3.3) P=0.01, or "problems with usual activities?" 2.1 (1.4, 3.3), P<0.001. 55% of those aged > 60 years reporting problems with either self care, mobility or daily activities in this study died over a mean (SD) of 2.1 (1.1) years, compared to 18% over 2.5 (1) years in those reporting 'no' to these questions, P<0.001. After age adjustment area under the receiver operating curves (AUC) (95%CI) for mortality were: 0.71 (0.63, 0.80) for symptom burden, 0.76 (0.68, 0.84) for HRQOL and 0.71 (0.62, 0.79) for self-rated health.

Conclusions: Age adjusted participant-rated health and predictive models based on combinations of individual elements from the POS S Renal and EQ5D instruments could possibly aid in mortality discrimination and subsequent advance care planning in hemodialysis.

SA-OR031

Isonatric Dialysis Biofeedback in Hemodiafiltration with Online Regeneration of Ultrafiltrate in Hypertensive Hemodialysis Patients: A Randomized Controlled Study Lucile Mercadal,[1] Frederic Debelle,[2] Christine Fumeron,[3] Lise Mandart,[4] Isabelle Simon,[5] Yahsou Delmas,[6] Sophie Tezenas du montcel.[7] *[1]AP-HP, Paris; [2]RHMS Baudour, Belgium; [3]AURA Paris; [4]CH Vannes; [5]CH Erasme Bruxelles; [6]CHU Bordeaux; [7]Biostatistics, AP-HP, France.*

Background: Biofeedback in hemodiafiltration with online regeneration of ultrafiltrate (HFR) could improve arterial hypertension by using an isonatric mode maintaining a natremia equal between start and end of the dialysis session. We evaluated the impact of Isonatric HFR (HFRiso) on hypertension compared to Conventionnal HFR.

Methods: 47hemodialysis patients having an arterial pressure > 140/90 mmHg were randomized (ratio 2/1) HFR iso versus HFR during 24 dialysis sessions. The course from S1 to S24 of the predialytic systolic (SBP) and diastolic (DBP) blood pressure, the defined

daily dose (DDD) of antihypertensive treatment and of the dry weight were compared by t-test and by mixed model for repeated measurements adjusted for treatment x time interaction. The impact of age, diabetes and cardiovascular co-morbidities on response to treatment was evaluated. Tolerance was evaluated by the number of sessions complicated by symptomatic hypotension.

Results: In the Isonatric HFR group (N=32), the predialysis SBP decreased from S1 to S4 of 9 ± 20 mmHg (-0.12 ± 0.08 mmHg /day) and increased of 5 ± 24mmHg (+0.13 ± 0.05 mmHg /day) in the HFR group (N=15), variation that differed between the 2 groups (DS1-S24, p = 0.035; interaction treatment*time, p=0.012). The DBP (HFRiso -3 ± 14 mmHg vs HFR 5 ± 13 mmHg; p=0.088), the DDD of antihypertensive treatment (HFR iso -0,1 ± 0,9 vs HFR -0,3 ± 1,1, p=0.7) and the dry weight (HFRiso 0,2 ± 1 vs HFR 0,2 ± 1,5kg, p=0.9) did not vary during the study. Age influenced the PAS course independently of the treatment group (interaction age*time, p=0.05). The number of symptomatic hypotension was similar in the 2 groups.

Conclusions: Isonatric HFR improved blood pressure control without increasing dialysis hypotension episodes.

SA-OR032

Relevance of B-Lines on Lung Ultrasound in Volume Overload and Pulmonary Congestion: Clinical and Therapeutic Correlations in Hemodialysis Patients Marc M. Saad, Jeanne Kamal, Wissam Mansour, Boutros Karam, Elias Moussaly, Emad Gobran, Devjani Das, Morton J. Kleiner, Elie El-Charabaty, Suzanne E. El Sayegh. *Internal Medicine/Emergency Dept/ Nephrology, Staten Island Univ Hospital, Staten Island, NY.*

Background: Volume overload in patients on hemodialysis (HD) is an independent risk factor for death from cardiovascular events. The imminent role of B-Lines (BL) on ultrasound (US) in predicting physical performance, morbidity and mortality, raises interest in its utility for assessing volume status in patients on HD.

Methods: ESRD patients on HD at Island Rehab center older than 18 were screened. Those who have lung disease and pregnant women were excluded. Patients achieving their dry weight(DW) had a lung US in a supine position. Residents were trained to visualize BL and recorded scores in real time. Clips were reviewed by blinded certified physicians. Scores were classified as mild (0-14), moderate (15-30) and severe (>30) for pulmonary congestion, as validated by Zoccali et al.

Results: 81 patients on HD were recruited. 58 were males, mean age 59.7 years, hemoglobin 10.6 g/dL. 44 had NYHA Class 1, 24 had class 2, and 13 had class 3. In univariate analysis, NYHA class had significant correlation with BL scores and classes (<0.001), and diastolic dysfunction (0.002). In multivariate analysis, NYHA grade strongly correlates with B-Lines classification (0.01) but not with heart function (0.95). The mean difference between physicians and residents scoring was 3.77 (0.048). However this difference was not significant after classification and scores were in agreement (Kappa = 0.56).

Conclusions: At DW, NYHA grading tightly corresponded to BL classification irrespective of cardiac function. Pulmonary congestion is common among patients on HD; NYHA score is mainly driven by the extravascular water and not by heart dysfunction. These results render fluid overload estimated by BL a better predictor for ESRD patient's performance and a reliable indicator for their volume status assessment. Moreover, moderate lung congestion noted in patients with NYHA class 1 outline the importance of lung US in identifying subtle lung congestion opening a new concept for achieving DW.

SA-OR033

Combined Target Ranges for Blood Pressure and Fluid Overload Ulrich Moissl,[1] Peter Wabel,[1] Paul William Chamney,[1] Bernard J. Canaud,[2] Stefano Stuard.[3] *[1]GRD, Fresenius Medical Care, Bad Homburg, Germany; [2]Medical Board, FMC, Bad Homburg, Germany; [3]NephroCare Coordination, FMC, Bad Homburg, Germany.*

Background: Recent research has revealed areas of increased mortality risk in the combination of systolic blood pressure (BPsys) and fluid overload (FO) (Fig 1a). It was the aim of this retrospective analysis to assess whether classifying patients according to a dedicated flow chart taking into account BP, FO and antihypertensive therapy (AHT) may indicate improved survival compared with a BP target range alone.

Methods: Pre-dialysis FO and BPsys were measured monthly in 31,349 patients from the Fresenius NephroCare Clinic Network. Patients were classified as being on/off target in January 2013 according to the flow chart in Figure 1b, which combines a BPsys target range of 130 to 160mmHg with information about AHT and FO [L] (Target1). FO was measured by bioimpedance spectroscopy. Normohydration was defined as FO normalized by extracellular volume <13% (females) and <15% (males). Target1 was compared with only a BPsys target range of 130 to 160 (Target2). All-cause mortality hazard ratios (HR) were calculated over 2 yrs follow-up time using COX analysis adjusting for 31 different co-morbidities and laboratory parameters.

Results: Unadjusted Kaplan Meier curves revealed a 2yr survival of 82% for patients on Target1, and 75% for being not on Target1 (p<0.0001), Fig 1c. Adjusted HR for patients being on Target1 was 0.74 [95% CI: 0.70 - 0.78]; the adjusted HR for being on Target2 was 0.84 [0.79 – 0.88]. At time of classification 66% of patients were on Target1, while 61% were on Target2.

Conclusions: Combining information on BPsys, AHT and FO indicates survival advantages compared with using only a BP target.

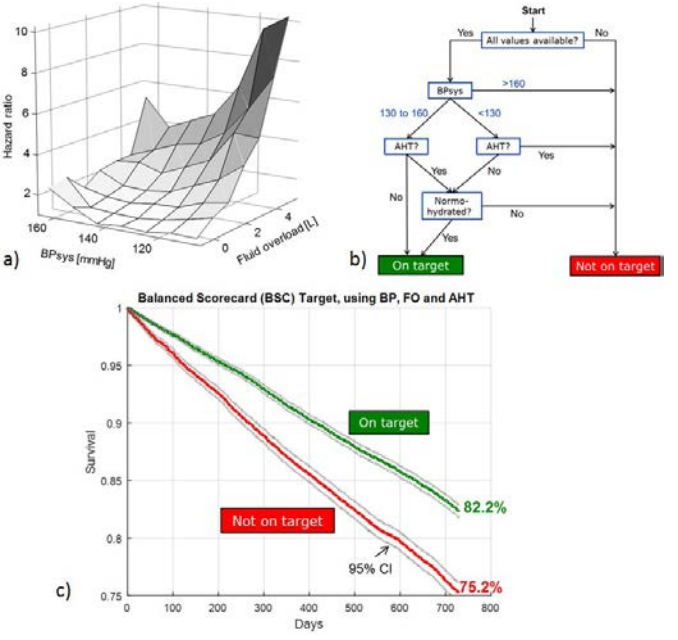

Fig 1. (a) Mortality risk of BPsys and FO. (b) Classification tree based on BPsys, AHT and FO. (c) Kaplan Meier curves for 31,349 patients being on/off target according to classification in Figure 1b.

SA-OR034

Volume Status Assessed by Bioimpedance in Hemodialysis Predicts Mortality Janice P. Lea, Laura Plantinga, Rebecca H. Zhang, Nancy G. Kutner. *Medicine, Emory Univ, Atlanta, GA.*

Background: Mortality rates average over 20% in the End-Stage Renal Disease (ESRD) US population with cardiovascular disease being the leading cause of death. Accurate intravascular volume assessment is critical in the treatment of patients who receive chronic hemodialysis (HD) therapy due to its deleterious effects on the heart and blood pressure (BP). Clinically assessed dry weight and interdialytic weight gain (IDWG) are often used as surrogates of volume status. Bioimpedance has emerged as an effective tool for volume management but is not readily available in clinical practice. Thus we examined the association of volume status determined by bioimpedance with mortality, compared to the association of IDWG and BP with mortality in ESRD patients.

Methods: ACTIVE/ADIPOSE (A Cohort Study to Investigate the Value of Exercise in ESRD/Analyses Designed to Investigate the Paradox of Obesity and Survival) was a multi-center study of prevalent HD patients coordinated by the United States Renal Data System in 2009-2011. The data collection sites were 14 outpatient dialysis clinics in Atlanta and San Francisco. Volume status by bioimpedance defined by calculation of extracellular fluid (ECF): total body water (TBW) ratio. Associations by quartiles of ECF:TBW, IDWG, and BP with 1-year mortality were estimated using Cox proportional hazards regression models.

Results: 660 patients were included in this analysis, with 36 total deaths at 1 year. After adjustments, each increase of 0.01 in ECF:TBW (range, 0.39-0.57) in quartiles was associated with a >30% increased risk of mortality, (HR- 1.32, 95% CI, 1.15-1.52) p<.001. In comparison, quartiles of IDWG (HR- 0.96, 95% CI, 0.78-1.17) and BP (per 10 mmHg, systolic, HR=.99, 95% CI, 0.82-1.19; diastolic (HR=0.90, 95% CI, 0.64-1.25), were not associated with mortality. Further, the associations of ECF:TBW with mortality were independent of BP, IDWG, and BMI.

Conclusions: Volume status by bioimpedance, but not IDWG or BP, was significantly and independently associated with greater mortality in this HD cohort. These findings question the common clinical practice of using IDWG as a surrogate of volume status in the HD population as it may not correlate with clinical outcomes.

SA-OR035

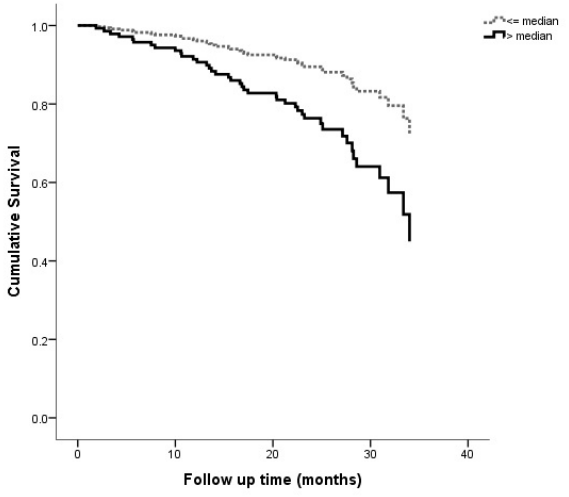
Abnormal Global Longitudinal Strain Is Associated with All-Cause Mortality in Hemodialysis Patients Diana Chiu, Darren Green, Nik Abidin, Philip A. Kalra. *Univ of Manchester, MAHSC, UK.*

Background: Cardiovascular mortality is high in hemodialysis (HD) patients.Early detection of cardiac dysfunction is important.Left ventricular global longitudinal strain (GLS) measures the maximal shortening of myocardial longitudinal length during systole compared to the resting length in diastole.Reduced GLS may reflect abnormal systolic function before loss of ejection fraction (EF) becomes apparent.We aimed to determine the prevalence, clinical correlates and prognostic value of abnormal GLS in stable HD patients.

Methods: Clinical and echocardiographic data were obtained in a prospective study of HD patients at one centre.Survival analysis for GLS was performed using Cox regression adjusted for age, co-morbidities, dialysis chronicity, laboratory data, left ventricular mass index adjusted for height ($LVMIHt^{2.7}$) and Teicholz EF.

Results: The mean age was 62±14years, 69% were male, 39% had diabetes, 29% heart failure, 17% coronary artery disease.The mean GLS was -13.4±3.5%, LV ejection fraction(LVEF) 63.8±12.9% and LVMIHt$^{2.7}$ 53.6±17.2g/m$^{2.7}$. 98% of patients had abnormal GLS (>-20%), compared with 14% with reduced LVEF(<50%) and 55% with LV hypertrophy.Factors associated with an abnormal GLS included LVMIHt$^{2.7}$ (OR 1.06, 95%CI 1.04-1.09, P<0.01), LVEF (OR 0.96, 95%CI 0.94-0.99, P<0.01) and diabetes (OR 2.04, 95%CI 1.08-3.9, p=0.03).Median follow-up was 24 (17-30) months, during which there were 41 deaths (21%).After adjustment for age, diabetes, coronary artery disease, LVEF, LVMIHt$^{2.7}$, 3 month-averaged serum potassium and albumin, a less negative GLS remained an independent predictor of all-cause mortality (HR 1.18 for each 1% worsening change in GLS, 95% CI 1.03-1.35, P=0.02).

Figure 1. Survival in <=median versus >median GLS (median = -13.7%)



Conclusions: Abnormal GLS is highly prevalent amongst HD patients, and appears to be a better marker of all-cause mortality in stable HD patients than the "standard" echocardiographic parameters LVEF and LVMIHt$^{2.7}$.

Trimethylamine-N-Oxide (TMAO) and Cardiovascular Events in Hemodialysis Patients: The Retained Organic Solutes and Clinical Outcomes (ROSCO) Study

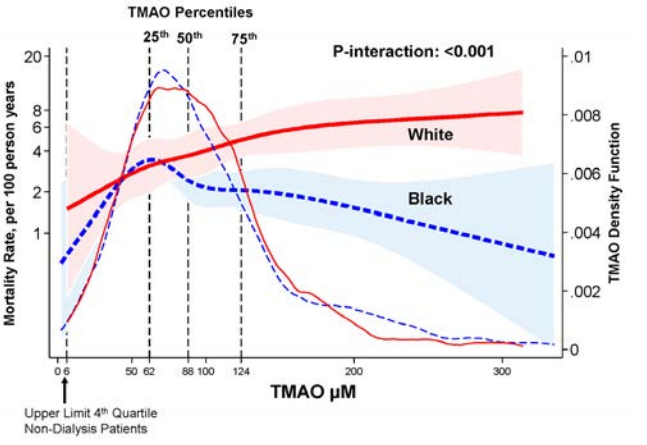
Tariq Shafi,[1] Thomas H. Hostetter,[2] Timothy W. Meyer,[3] Seungyoung Hwang,[1] Michal L. Melamed,[4] Tanushree Banerjee,[2] Josef Coresh,[1] Neil R. Powe.[5] *[1]Johns Hopkins Univ; [2]Univ of California San Francisco; [3]Stanford Univ; [4]Albert Einstein College of Medicine; [5]Case Western Univ.*

Background: Uremic toxins that contribute to cardiovascular (CV) disease and observed higher mortality in whites vs. blacks remain undefined. TMAO, a highly dialyzable metabolite, is associated with accelerated atherosclerosis and CV events in non-dialysis patients but previous studies in dialysis patients have been equivocal.

Methods: We measured TMAO in 1232 patients of the Hemodialysis (HEMO) Trial, 3-6 months after randomization and analyzed its association with CV mortality, sudden cardiac death (SCD) and first CV event, using Cox models adjusted for demographics, clinical characteristics, comorbidities, albumin and residual urea clearance.

Results: Mean age of the patients was 58 years, 34% white and 42% male. Median TMAO level was 88 µM (IQR, 62 to 124) and did not differ by race (p=0.9). The association of TMAO with outcomes differed by race (Figure) and was associated with outcomes only in whites. In whites, each 2-fold increase in TMAO was associated with a 45% higher risk of CV mortality, 70% higher risk of SCD and 15% higher risk of CV events (Table). TMAO levels decreased in the higher Kt/V_{UREA} group but did not have an effect on outcomes (p>0.1).

Fig: Association between TMAO and CV Mortality Rate (Age and Sex Adjusted)



Adjusted HR* (95% CI) of the Association between TMAO and Outcomes

	Events	Overall	White	Black	P-interaction
CV Mortality	220	1.09 (0.96-1.24)	**1.45 (1.24-1.69)**	0.90 (0.77-1.06)	**<0.001**
Sudden Cardiac Death	126	**1.18 (1.02-1.37)**	**1.70 (1.34-2.16)**	0.92 (0.78-1.08)	**<0.001**
First CV Event	644	1.05 (0.97-1.13)	**1.15 (1.01-1.32)**	1.01 (0.92-1.10)	0.09

* Per 2-fold increase

Conclusions: The association between TMAO and CV events differs among white and black hemodialysis patients.

Serum Asymmetric (ADMA) and Symmetric (SDMA) Dimethylarginine and Morbidity and Mortality in Hemodialysis Patients: The Retained Organic Solutes and Clinical Outcomes (ROSCO) Study

Tariq Shafi,[1] Neil R. Powe,[2] Timothy W. Meyer,[3] Seungyoung Hwang,[1] Michal L. Melamed,[4] Tanushree Banerjee,[2] Josef Coresh,[1] Thomas H. Hostetter.[5] *[1]Johns Hopkins Univ; [2]Univ of California, San Francisco; [3]Stanford Univ; [4]Albert Einstein College of Medicine; [5]Case Western Univ.*

Background: ADMA, an endogenous nitric oxide synthase inhibitor, and SDMA, a promoter of oxidative stress, accumulate in dialysis patients and may contribute to uremic toxicity.

Methods: We measured predialysis levels of ADMA and SDMA in 1276 patients of the Hemodialysis (HEMO) Trial, 3-6 months after randomization and analyzed its association with all-cause and cardiovascular (CV) mortality, sudden cardiac death (SCD) and first CV event, using Cox model adjusted for potential confounders (demographics, clinical characteristics, comorbidities, albumin, residual urea clearance).

Results: Mean age of the patients was 58 years, 63% black and 42% male. Median (interquartile range) for ADMA was 0.9 µM (0.8, 1.0) and SDMA was 4.1 µM (3.3, 5.0). In fully adjusted models, ADMA was associated with all outcomes whereas SDMA was only associated with CV mortality (Table). Subgroup analyses did not show significant interactions with race or HEMO interventions.

Fully Adjusted Model for the Association of ADMA and SDMA with Outcomes in the HEMO Study

	Events	IR*	ADMA		SDMA	
			HR** (95% CI)	p	HR** (95% CI)	p

Glomerulus on-a-Chip as a Model to Study the Glomerular Filtration Barrier In Vitro Stefano Da Sacco,[1] Jos Joore,[2] Paul Vulto,[2] Roger E. De Filippo,[1] Laura Perin.[1] *[1]Urology, Children's Hospital Los Angeles, Los Angeles, CA; [2]MIMETAS.*

Background: The glomerular filtration barrier (GFB) has three major components: the podocyte with the "slit diaphragms", the glomerular basement membrane and the fenestrated glomerular endothelial cell (hGEC): each of them is essential for the correct blood filtration. Damage to any of these components often leads to a severe, irreversible GFB disruption with onset of chronic damage requiring drug treatment and eventually dialysis and transplantation. Development of alternative therapeutic approaches is limited by our poor understanding of the complex cell-matrix interactions and cellular cross-talk in vivo and the absence of in vitro GFB models. Therefore, an in vitro system that mimics the complex GFB architecture and that can be used to better study glomerular (patho)-physiology is urgently needed.

Methods: We have generated a population of renal progenitors from human amniotic fluid (hAKPC-P) that can differentiate into podocyte-like cells. Taking advantage of the peculiar characteristics of available microfluidic systems, we have developed an innovative Glomerulus-on-a-Chip system by co-culturing hAKPC-P and hGEC cells in Organoplate™ microfluidic plates. Evaluation of culture conditions, immunostainings and qPCR were performed to characterize the 3D culture.

Results: We have successfully established the conditions for in vitro co-culture of hAKPC-P/hGEC in a microfluidic plate for up to 21 days. Apoptosis and proliferation were assessed by TUNEL and PCNA. Vessel formation by hGEC was confirmed along with expression of endothelial marker VE-Cadherin while hAKPC-P-derived podocytes were positive for nephrin and podocin. De-novo deposition of collagen IV in the 3D microfluidic plates was confirmed by immunostaining.

Conclusions: Our preliminary results suggest the feasibility of Organoplates for co-culture of podocytes and hGEC in a 3D environment that more closely mimics the structure of the GFB. If successful this system might prove useful for the assessment of several aspects of cell-cell and cell-matrix interaction, thus helping to understand podocytes/endothelial crosstalk (or its perturbations) and how this might affects glomerular homeostasis.

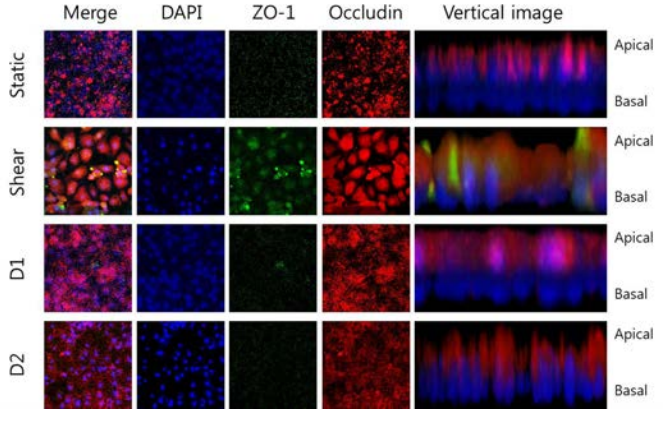
Pharmacokinetic Model for Screening Nephrotoxicity Using Kidney on a Chip Sejoong Kim,[1,2] Sasha Cai Lesher-Perez,[1] Byoung Choul C. Kim,[1] Cameron Yamanishi,[1] Joseph M. Labuz,[1] Shuichi Takayama.[1] *[1]Univ of Michigan College of Engineering, Ann Arbor, MI; [2]Internal Medicine, Seoul National Univ Bundang Hospital, Seongnam, Korea.*

Background: Animal renal clearance is usually higher than human renal clearance, which may underestimate nephrotoxicity. We developed a microfluidic device lined by kidney epithelial cells to mimic in vivo-like microenvironment. We evaluated the nephrotoxicity of two different gentamicin regimens using this kidney on-a-chip and human pharmacokinetic data.

Methods: The microfluidic device had top channels like luminal spaces and bottom channels like interstitial spaces. MDCK cells on the porous membranes between the two channels were exposed with a fluid shear stress (1.0 dyne/cm^2). D1 regimen was 19.2 mM of gentamicin for initial dosage and reduction by half every 2 hours to mimic human renal clearance, and D2 regimen was continuous infusion of gentamicin (3 mM for 24 hours) in the top channels.

Results: After 6-hour shear stress, fluorescences of ZO-1 and occludin were increased and transmembrane permeability was decreased, compared to the static condition. For the next 24 hours, D1 and D2 regimens were applied under shear-stress condition. Although the junctional protein immunoreactivity was decreased in the both regimens, ZO-1 and occludin fluorescences showed higher in the D1 regimen than in the D2 regimen ($P < 0.05$).



D1 regimen sustained the permeability, while D2 leaded to increase in the permeability ($P < 0.05$). In addition, D1 regimen indicated less cytotoxic than D2 (Dead cell 1.43 ± 0.30 % vs. 4.9 ± 0.20%, respectively, $P < 0.05$).

Conclusions: These data suggest that gentamicin may interrupt junctional protein complex and membrane permeability, and that single daily dose alleviate the nephrotoxicity, compared to the continuous infused regimen. Microfluidic devices can be one of novel pharmacokinetic models for evaluating nephrotoxicity.

Computational Prediction and Experimental Analyses of Proteins That Bridge Metabolite Markers of Human Diabetic Nephropathy Rintaro Saito,[1,2,3] Anaïs Rocanin-Arjo,[4] Minya Pu,[1,5] Simone Romoli,[4] Loki Natarajan,[1,5] Wenjun Ju,[6] Matthias Kretzler,[6] Robert G. Nelson,[7] Dana Thomasova,[4] Shrikant R. Mulay,[4] Hans J. Anders,[4] Kumar Sharma.[1,2,3,8] *[1]Inst Metabol Med; [2]Center Renal Transl Med; [3]Dept Med, UCSD, CA; [4]Medizinische Klinik und Poliklinik IV, Klinikum der Univ München, Munich, Germany; [5]Dept Family Med Epidem, UCSD; [6]Dept Internal Med, Nephrology & Dept Comput Med & Bioinfo, Univ of Michigan, MI; [7]NIDDK, AZ; [8]VA Health Systems, SD, CA.*

Background: We have previously shown that thirteen metabolites are shown to be characteristic of human diabetic kidney disease (DKD) and linked to mitochondrial dysfunction. However, novel bioinformatic tools could indicate novel connections among these metabolites to identify new relevant protein targets for human disease.

Methods: We integrated publicly available human protein-protein interaction (PPI) networks with global metabolic networks onto a software (Cytoscape) to enhance the interpretation of metabolomic data. Validation was performed with gene expression data from Nephromine and experimental studies in mice.

Results: We found that all thirteen metabolites can be connected through a single subnetwork of PPIs. We focused on bridge proteins, which were predicted to potentially connect these metabolites through their associated enzymes and found that several proteins had a significant number of connections regulating the original 13 metabolites. These included MDM2 (BH corrected $p < 0.005$, 14 connections) and PEX5 ($p < 0.005$, 9 connections). Of these, MDM2 had the strongest regulation in its gene expression in glomeruli ($p < 0.01$) and tubulointersitium ($p < 0.01$) from two different cohorts of diabetic kidney biopsies. In vivo studies with Nutlin3a, an inhibitor of MDM2 binding site, in both healthy C57B6/JL mice and db/db type 2 diabetic mice resulted in a reduction podocytes, an increase in proteinuria and higher levels of plasma urea levels in healthy and diabetic mice.

Conclusions: Our bioinformatics approach has been demonstrated to make biologically relevant interpretation of dysregulated metabolites, highlighting the significance of MDM2 dysregulation in DKD both in experimental models and in patients with DKD.

Mechanical Properties of Renal Tubules Measured Using Glass Microcantilevers Nicholas J. Ferrell. *Nephrology, Vanderbilt Univ Medical Center, Nashville, TN.*

Background: The mechanical properties of tissues play an important role in maintaining tissue function, and altered biophysical properties affect disease progression. Measuring the mechanical properties of isolated biological structures, including renal tubules can be challenging, especially in tension. We have developed a new method to measure the elastic modulus of renal tubules using glass micropipettes as force measurement cantilevers.

Methods: Cortical tubules were manually dissected from normal mice. Elastic modulus was measured by clamping each tubule between a measurement microcantilever with pre-determined stiffness and a holding micropipette. The holding micropipette was translated using a micromanipulator and images were acquired at fixed displacements. Tubule strain and applied force were determined my measuring the change in the tubule length and deflection of the measurement cantilever. Tubule stress was estimated assuming the resistance to deformation was imparted primarily by the tubular basement membrane. The cross-sectional area of each tubular basement membrane was calculated based on a basement membrane thickness of 0.24 µm. Elastic modulus was calculated from the slope of the stress-strain curve at a given strain.

Results: Stress-strain curves indicated a strain dependent increase in elastic modulus suggesting significant strain stiffening of renal tubules. At low strain (0-15%) elastic modulus was measured at 555±98 kPa. At higher strain (15-30%) elastic modulus was 1113±150 kPa and at even higher stain (30-50%) elastic modulus was 2161±173 kPa. Strain stiffening behavior was observed throughout the range of measurable strain.

Conclusions: These results indicate that renal tubules are highly deformable structures that exhibit increased stiffness as strain increases, a response typical of extracellular matrices such as collagen gels. This method provides a relatively simple means of determining renal tubular biophysical properties and may be a useful tool for evaluating renal tubule mechanical properties in a variety of kidney diseases.

Non-Invasive Measurement of Renal Blood Flow (RBF) in Rat by Magnetic Resonance Images (MRI) Cesar A. Romero,[1] Robert Knight,[2] Oscar A. Carretero.[1] *[1]Hypertension and Vascular Research Div, Henry Ford Hospital; [2]Henry Ford Hospital; [3]Henry Ford Hospital; [4]Henry Ford Hospital.*

Background: Quantitative measurement of RBF provides important information on renal physiology, nephropathies and kidney viability in different animal models. Arterial Spin Labelling–MRI (ASL-MRI) is a non-invasive method to measure blood flow without exogenous contrast media, using arterial water protons labeled by radiofrequency as an endogenous tracer. However, the low signal/noise ratio and the motion artifacts pose a challenge when acquiring RBF in small animals. Our objective is to evaluate the feasibility and reproducibility of the RBF measurement by ASL-MRI under basal conditions and in a high RBF state in rats.

Methods: ASL-MRI images were obtained in seven males Sprague-dawley rats (200-300g) under the inhalatory anesthesia (isofluorane 2%). Rectal temperature probe was used to control the body temperature. After 4 days the MRI studies were repeated in 3 rats (6 kidneys) to evaluate reproducibility, using paired sample T-test and the test-retest reliability (TR) by the equation TR=(1-SDn/Mn)x100 were M and SD are the mean and standard deviation of the RBF in "n" different sessions. RBF was also measured in a set of animals that underwent unilateral nephrectomy 24 hours before and after the surgery. MRI was acquired using a 7 Tesla Varian MRI system with a spin echo imaging sequence using respiratory triggering and navigator correction to reduce motion artifacts. The sequence was averaged 16 times and the total scan time for the entire series of ~20 minutes. In house software was used to analyze the postprocessing imaging.

Results: The mean cortical RBF was 305±59 and 271.8±39 ml/min/100g tissue in right and left kidney, respectively. Re-test analysis showed no differences, with the means of differences 9.4±35ml/min/100g tissue (p=0.58). The TR was 92.4±6%. The RBF before and after the nephrectomy was 270±30 and 456.6±34 ml/min/100g tissue (p=0.004), respectively, showing a relative increase of 69.1%.

Conclusions: ASL-MRI performed with navigator correction and respiratory gating is feasible and reliable non-invasive method to measure RBF in rats.

Intravoxel Incoherent Motion Analysis of Diffusion Weighted Imaging to Measure Glomerular Filtration Fraction – Proof of Concept René van der Bel,[1] Oliver J. Gurney-Champion,[2] Wouter V. Potters,[2] Hein J. Verberne,[3] Liffert Vogt,[1] Erik Stroes,[1] Aart J. Nederveen,[2] C.T.P. (Paul) Krediet.[1] *[1]Internal Medicine, AMC, Univ of Amsterdam, Netherlands; [2]Radiology, AMC, Univ of Amsterdam, Netherlands; [3]Nuclear Medicine, AMC, Univ of Amsterdam, Netherlands.*

Background: Glomerular filtration fraction (FF) can be calculated from the ^{125}I-thalamate clearance (glomerular filtration rate (GFR)) and ^{131}I-hippuran clearance (effective renal plasma flow (ERPF)). This technique is costly and time consuming. Intravoxel Incoherent Motion (IVIM) analysis provides an assessment of diffusion weighted imaging (DWI) for fractions of blood and (pre-)urine within kidney tissue. This could serve as a surrogate for filtration fraction. With this study we a proof of concept for an MRI derived kidney function measurement.

Methods: After a baseline phase, 6 healthy volunteers (age 18-24 yrs) were subjected to continuous Angiotensin II (Ang-II) infusion at 3.0 ng/kg/min. Blood and (pre-)urine fractions and renal blood flow (RBF) were assessed using DWI and phase contrast MRI (Ingenia 3.0T, Philips Healthcare). Fractions were calculated via tri-exponential IVIM model fit to the DWI data (TE 45ms; TR 1344 ms; matrix: 112x68, FOV 336x204 mm^2; voxel size 3.0x3.0x3.0 mm, b-values: 0, 2, 4, 8, 12, 18, 24, 32, 40, 50, 70, 110, 200, 300, 450, 600 s/mm^2; gradient directions: 15). RBF was calculated in the proximal renal artery after manual vessel segmentation. During a second visit, gold standard GFR, ERPF and FF were measured during a similar infusion protocol.

Results: Ang-II decreased both GFR and ERPF (10±7.1%, p=0.016; 24±4.5%, p<0.001), resulting in an increase in FF of 19±3.1% (p<0.001). RBF decreased from 11.1±2.07 to 8.05±1.02 ml/s (by 27%, p=0.001). Renal IVIM imaging showed an increase in the urine fraction of 24.6±14% (p=0.002) and a decrease of the perfusion fraction by 12±21.8% (p=0.096). Renal IVIM measures (pre-)urine fractions and FF were correlated (R=0.44, p=0.033). RBF correlated to the gold standard ERPF (R=0.75, p<0.001).

Conclusions: These data suggest that a combination of IVIM and phase contrast kidney imaging could provide reliable and fast noninvasive FF and ERPF measurement.

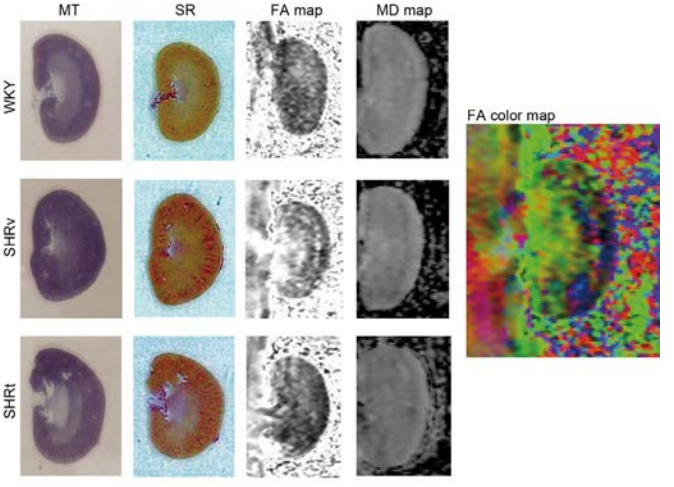
SA-OR044

Visualization of Kidney Fibrosis in Diabetic Nephropathy by DTI MRI Jun-Ya Kaimori,[1] Yoshitaka Isaka,[2] Masaki Hatanaka,[2] Satoko Yamamoto,[2] Hiroshi Shibata,[4] Akira Fujimori,[4] Akihiko Fujikawa,[4] Sosuke Miyoshi,[4] Naotsugu Ichimaru,[1] Toshiki Moriyama,[3] Hiromi Rakugi,[2] Shiro Takahara.[1] *[1]Dept of Advanced Technology of Transplantation, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan; [2]Dept of Geriatrics & Nephrology, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan; [3]Osaka Univ Health Care Center, Osaka Univ, Toyonaka, Osaka, Japan; [4]Drug Discovery Research Inst, Astellas Pharma Inc, Tsukuba, Ibaraki, Japan.*

Background: Renal fibrosis (RF) is a well-known marker for chronic kidney disease (CKD) progression. However, an available examination for evaluation of RF is invasive biopsy. Diffusion MRI was once recognized as a promising option for RF. But now it is controversial and it could not be applied to diabetic nephropathy (DN).

Methods: To seek an optimal imaging method applicable even for fibrosis in DN, we tried series of MR imaging methods,including proton density weighted imaging (PDWI), T1 weighted imaging (T1WI), T2 weighted imaging (T2WI), T2* weighted imaging (T2*WI), diffusion weighted imaging (DWI), and diffusion tensor imaging (DTI).

Results: We identified DTI MRI by spin echo sequence plus a special kidney attachment as the best option for evaluation of UUO fibrosis, compared with normal kidney in the opposite side. To confirm these results, we applied this technique to rat UUO therapeutic model with anti-fibrotic reagent, Fasudil. FA values calculated form DTI MRI showed statistically significant linear correlation with RF area measured by Sirius Red or Masson trichrome staining positive area. Next, by using SHR/NDmcr-cp(cp/cp) rat with or without telumisartan as a RF model of DN, we finally succeeded in visualization and evaluation of fibrosis accumulated in outer stripe of outer medulla region by FA map.



Conclusions: By DTI MRI with spin echo sequence, it may be possible to accurately evaluate RF in CKD including even DN.

Super-Resolution Microscopy Reveals the Formation of a Mat of Contractile Fibers as Part of the Podocyte Foot Process Effacement Phenomenon Hani Suleiman,[1] Jeffrey H. Miner,[3] Andrey S. Shaw.[2] *[1]Pathology and Immunology, Washington Univ in Saint Louis, Saint Louis, MO; [2]Pathology and Immunology, Washington Univ in Saint Louis, Saint Louis, MO; [3]Renal Devision, Washington Univ in Saint Louis, Saint Louis, MO.*

Background: The ~200 nm resolution of traditional microscopes is limited by the wavelength of light. Imaging structures smaller than 200 nm, such as podocyte foot processes and slit diaphragms, has required electron microscopy (EM). New super-resolution imaging techniques can break the diffraction barrier of light, thus allowing us to easily image and resolve the molecular composition of structures in a nanometer range.

Methods: We used an array of antibodies for Stochastic Optical Resolution Microscopy (STORM) to study the spatial distribution of key molecules of the podocyte cytoskeleton and slit diaphragm in healthy and injured glomeruli. We also developed a novel technique that allows us to image podocyte actin cables by EM.

Results: In healthy glomeruli, synaptopodin is localized to the center of each foot process, while nephrin is at the slit diaphragm. As foot processes efface, nephrin redistributes apically away from the base of foot processes. We confirmed this in 3 different injury models. After podocyte injury the positions of synaptopodin and α-actinin-4 clusters did not change, but there was robust recruitment of myosin IIa, normally only in primary processes, to the bases of foot processes. The pattern of myosin IIa staining, in alternating stripes with synaptopodin and α-actinin-4, indicates the formation of contractile actin fibers during effacement. Using our new EM method, we observed a dramatic change in the morphology of actin fibers during effacement.

Conclusions: We demonstrate the utility of super-resolution microscopy to visualize podocyte foot processes. Our data show that in the normal podocyte, contractile actin cables are in primary processes, while only non-contractile actin filaments are in foot processes. After foot process effacement, the contractile cables fall to the bottom of the podocyte and form a sarcomere-like contractile network adjacent to the GBM.

Intravital and Organ Slice Imaging of Podocyte Membrane Dynamics

Sebastian Braehler,[1] Haiyang Yu,[1] Gokul Murali Krishnan,[1] Hani Suleiman,[1] Jeffrey H. Miner,[2] Bernd H. Zinselmeyer,[1] Andrey S. Shaw.[1] *[1]Dept of Pathology and Immunology, Washington Univ School of Medicine, St. Louis, MO; [2]Renal Div, Washington Univ School of Medicine, St. Louis, MO.*

Background: The elaborate network of podocyte foot processes, which is stabilized by the actin cytoskeleton, is one of the key components of the glomerular filtration barrier. The question of whether podocytes change their shape under physiological conditions or in response to injury has been vigorously debated. The Rho-family of small GTPases is at the center of this debate, as these molecular switches control assembly and disassembly of the actin cytoskeleton. Evidence as to whether and how small-GTPases change podocyte shape and dynamics is largely circumstantial, as all studies to date have been conducted *in vitro*.

Methods: Here we use intravital two-photon imaging of fluorescently labeled podocytes to answer these questions. Rosa26-confetti/Podo-Cre mice were used as reference and compared with mice expressing eGFP-labeled, constitutively active Rac1 (eGFP.CA-Rac1) in podocytes. To achieve a higher resolution we also imaged freshly isolated kidney slices in an organ bath.

Results: Podocytes in Rosa26-confetti/Podo-Cre mice showed a stable network of foot processes, with no significant membrane movement. eGFP.CA-Rac1 podocytes lost their characteristic shape and showed increased membrane dynamics and podocyte shedding. Shed podocytes seemed viable, as they were observed migrating in the tubular system. Organ slice imaging resembled the intravital results but yielded a higher temporal-spatial resolution, which validates this approach as a suitable technique to complement intravital imaging. With this approach, we were also able to show that increased membrane dynamics is a feature of injured podocytes in a glomerular disease model.

Conclusions: We show *in vivo* for the first time that Rac1 converts podocytes from a state of immobility to one with greatly increased membrane dynamics and blunted foot processes, which also occurs in a model of glomerular injury. This suggests that foot process effacement is the end result of a highly dynamic state, and that foot process instability could contribute to proteinuria itself.

Intravital Multiphoton Imaging of Podocyte Ca2+ Confirms the Important Role and Mechanism of TRPC6 in Glomerular Pathology

Kengo Kidokoro, Anne Riquier-brison, Janos Peti-Peterdi. *Physiology and Biophysics, and Medicine, Univ of Southern, Los Angeles, CA.*

Background: TRPC6 channels in podocytes are important Ca^{2+} influx pathways involved in the modulation of the actin cytoskeleton and in the actions of angiotensin II (ANG II). TRPC6 overactivity by gain-of-function mutations and high ANGII leads to albuminuria and chronic kidney disease (CKD). However, the regulation of podocyte Ca^{2+} dynamics by TRPC6 and the mechanism of the resulting glomerular dysfunction *in vivo* and in response to injury have been elusive. We aimed to directly and quantitatively visualize and study the dynamic effects of TRPC6 on podocyte and glomerular function during the development of glomerular injury.

Methods: Serial multiphoton microscopy of the intact living kidney of the same wild type (WT), TRPC6 transgenic (TG), and TRPC6 knockout (KO) mice was performed over two weeks of high ANGII treatment (1000 ng/kg/min). All mice expressed the intensely green and calcium sensitive fluorescent protein GCaMP3 only in podocytes. Changes in single cell GCaMP3 fluorescence intensity were measured and served as readout for podocyte $[Ca^{2+}]_i$ changes.

Results: Systolic blood pressure increased from baseline 106±4 to 145±5 mmHg after ANGII treatment for two weeks in weeks in WT mice, and similarly in TRPC6 TG and KO mice. In WT mice, normalized GCaMP3 fluorescence intensity in podocytes ($[Ca^{2+}_i$) increased >2.5-fold, glomerular diameter increased from 64±2 to 76±2 um, and single nephron glomerular filtration rate reduced from 9±1 to 3±1 nl/min, in response to ANGII. Podocyte GCaMP3 fluorescence intensity was increased >2-fold, but reduced by 20%, at baseline in TRPC6 TG and KO mice, respectively. Glomerular functional parameters after ANGII treatment were exacerbated in TRPC6 TG mice, while improved in TRPC6 KO mice. Podocytes with high GCaMP3 fluorescence appeared migrating to the parietal Bowman's capsule after ANGII in WT and TPRC6 TG, but not in TRPC6KO mice.

Conclusions: This study demonstrated *in vivo* direct visual evidence of the critically important pathogenic role of TRPC6 in the development and progression of glomerular disease. Podocyte TRPC6 is a promising therapeutic target for the prevention of CKD.

SA-OR048

Mesangial Filopodial Invasion of Glomerular Capillaries in Alport Syndrome

Dominic E. Cosgrove, Daniel T. Meehan, Brianna M. Dufek, Duane C. Delimont. *Genetics, Boys Town National Research Hospital, Omaha, NE.*

Background: Recent work shows mesangial cell filopodia invade the glomerular capillaries in Alport mice and humans. Filopodia progressively deposit laminin 211 and likely other mesangial matrix proteins in the GBM. Laminin 211 activates focal adhesion kinase in podocytes, which results in up-regulation of metalloproteinases and pro-inflammatory cytokines. These novel observations, which are key to glomerular disease initiation, have been met with some skepticism, which incentivized the current study.

Methods: Three color structured illumination microscopy (SIM, an ultra-high resolution methodology) was used to label mesangial processes, glomerular endothelial cells, and the GBM. A mesangial cell culture bioassay was developed that allows induction of mesangial filopodia. RNAseq analysis of preproteinuric glomeruli identified novel candidates likely involved CDC42 activation in mesangial cells. These candidates were tested in the bioassay.

Results: SIM analysis showed that integrin α8-immunopositive mesangial processes extend, contiguous with the mesangial angles, into the sub-endothelial spaces of the GBM. These processes are exclusive of CD31 immunopositive glomerular endothelium and the laminin α5 immunopositive GBM. Endothelin-1 (ET-1) activates CDC42 in mesangial cells and results in the formation of drebrin-immunopositive actin microspikes (filopodia). Of the six candidate proteins identified that may regulate endothelin A receptor (ET_AR) mediated activation of CDC42, two have been tested by SiRNA knockdown. MAL2 knockdown blocked ET-1 activation of filopodia, while BMP-7 knockdown had no effect. ET_AR knockdown (a positive control) also prevented formation of actin microspikes.

Conclusions: SIM analysis unequivocally proves mesangial filopodial invasion of the glomerular capillaries in Alport mice. The bioassay shows ET-1 mediated activation of CDC42 promotes filopodia formation. RNAseq identified one novel regulator of CDC42 activation, MAL2 which is critical mediator of CDC42 activation. This bioassay can thus be exploited to identify new therapeutic targets with the potential to prevent mesangial filopodial invasion of the glomerular capillaries.

SA-OR049

The DREADD Concept: A Novel In Vivo Tool for Kidney Research Questioning the Role of Ca^{2+} on Actin Dynamics in Podocytes

Sybille Köhler,[1,2] Sebastian Braehler,[4] Julia Binz,[1,2] Matthias Hackl,[1,2] Frank Schweda,[3] Thomas Benzing,[1,2] Bernhard Schermer,[1,2] Paul T. Brinkkoetter.[1,2] *[1]Dept II of Internal Medicine and Center for Molecular Medicine, Univ Hospital Cologne, Germany; [2]Cologne Excellence Cluster on Cellular Stress Responses in Aging-Associated Diseases (CECAD), Univ of Cologne, Germany; [3]Dept of Physiology, Univ of Regensburg, Germany; [4]Dept of Pathology and Immunology, Washington Univ School of Medicine.*

Background: The close homology between the slit diaphragm of the kidney glomerulus and the mechanosensor in C. elegans led to the hypothesis that the slit diaphragm is part of a conserved mechanosensor that is closely linked to an actin-based, contractile cytoskeleton regulated by Ca^{2+}.

Methods: We generated a transgenic mouse line with specific expression of a mutated (Y149C/A239G) G protein-coupled human muscarinic type 3 receptor transgene (hM_3D) in the ROSA26 locus. This receptor is exclusively activated by the synthetic compound clozapine-N-oxide (CNO) and not by the endogenous M_3-ligand acetylcholine. We mated the hM_3D-$STOP^{flox/flox}$-mouse with the podocin:cre mouse to achieve podocyte specific expression. We validated receptor expression and function both, in vitro and in vivo using immunofluorescence stainings, western blotting and live Ca^{2+}-imaging using 2-photon microscopy.

Results: Here, we applied the DREADD (designer receptor exclusively activated by a designer drug, Conklin et al. 1998) concept to further test this hypothesis and to investigate the effects of an intracellular Ca^{2+} increase on the podocyte actin cytoskeleton. Even though we observed a strong Ca^{2+} increase in podocytes after CNO-administration no effects on the actin based cytoskeleton, glomerular perfusion or filtration were observed. Even administration of CNO over a prolonged period (4 wks) did not induce glomerular disease.

Conclusions: In conclusion, increasing Ca^{2+} levels in podocytes alone are not sufficient to induce cytoskeletal rearrangements and to affect glomerular perfusion and filtration. Hence, these results challenge our current view on actin dynamics in podocytes and their role in glomerular perfusion and filtration.

Loss of Epithelial Membrane Protein 2 Aggravates Podocyte Injury via Upregulation of Caveolin-1

Weibin Zhou,[1] Xiaoyang Wan,[1] Zhao-hong Chen,[1,2] Won- Il Choi,[3] Heon Yung Gee,[3] Friedhelm Hildebrandt.[3,4] *[1]Pediatrics and Communicable Diseases, Univ of Michigan, Ann Arbor, MI; [2]Research Inst of Nephrology, Jinling Hospital, Nanjing, China; [3]Boston Children's Hospital, Boston, MA; [4]Howard Hughes Medical Inst.*

Background: Nephrotic syndrome is a chronic kidney disease defined by proteinuria with subsequent hypoalbuminemia, hyperlipidemia and edema, due to impaired renal glomerular filtration barrier function. Glomerular podocytes haven been proposed to play a critical role in the maintenance of glomerular filtration barrier and the pathogenesis of

nephrotic syndrome. We have previously identified mutations in EMP2 (epithelial membrane protein 2) as a novel monogenic cause of this disease. Detrimental mutations in EMP2 have been found in patients with steroid-sensitive and steroid-resistant nephrotic syndrome.

Methods: To understand the pathogenic mechanism underlying EMP2 mutations, we have generated a zebrafish knockout model of emp2 using TALEN and transgenic zebrafish overexpressing caveolin-1 in podocytes. We have also characterized cultured human podocytes with shRNA-mediated EMP2 knockdown.

Results: We found that loss of emp2 in zebrafish up-regulated caveolin-1 (cav1), a major component of caveolae, in embryos and mesonephric glomeruli, and exacerbated podocyte injury. This phenotype could be partially rescued by glucocorticoids. We showed that overexpression of cav1 in zebrafish podocytes was sufficient to induce the same phenotypes seen in emp2 homozygous mutants, which were treatable by glucocorticoids. Consistently, knockdown of EMP2 in cultured human podocytes resulted in an increase of CAV1 and a decrease of podocyte survival in the presence of puromycin aminonucleoside, while glucocorticoid treatment ameliorated these phenotypes.

Conclusions: Taken together, we have established excessive CAV1 as a mediator of the predisposition to podocyte injury due to loss of EMP2, suggesting CAV1 could serve a novel therapeutic target of nephrotic syndrome and podocyte injury.

GLEPP1 Deficiency Defines a Novel Glomerular Disease Eva Koenigshausen,[1] Christian Weigel,[1] Philip Schüppler,[1] Laura Lennartz,[1] Thorsten Wiech,[2] Catherine Meyer-Schwesinger,[2] Roger C. Wiggins,[3] Sophie C. Collinson,[4] Rachel Lennon,[4] Magdalena Woznowski,[1] Ivo Quack,[1] Lars C. Rump,[1] Lorenz Sellin.[1] *[1]Univ Hospital Duesseldorf, Germany; [2]Univ Hospital Hamburg Eppendorf, Germany; [3]Univ of Michigan; [4]Royal Manchester Children's Hospital, United Kingdom.*

Background: Albuminuria is the early clinical marker for glomerular disease. Mutations in GLEPP1 were linked with podocytic diseases in children (MCD/FSGS). GLEPP1 is a receptor tyrosine phosphatase present in the podocyte foot processes. Its precise function is not fully understood.

Methods: GLEPP1 KO and WT mice were examined at 4 and 10 months. Mouse plasma and urine were analyzed for cystatin C, albumin and creatinine. qPCR was performed for collagen IV (col IV) a1-5, laminin (lam) a1, 5 and b1, 2. Western blot (WB) was stained for col IV a1 and lam a1. PAS staining was performed. Cryosections of kidneys were stained for col IV a1 and a2. In EM sections GLEPP1 was labeled with immunogold. GBM defects were imaged by serial block-face scanning EM to generate 3-D models.

Results: GLEPP1 KO mice display a significantly higher urinary ACR and cystatin C compared to WT mice at 10 months. This correlated significantly with focal thickening of the GBM in KO mice, resembling GBM humps in light microscopy and TEM. At the sights of humps, beginning foot process effacement was observed. qPCR revealed significant upregulation of col IV a1, a2 and lam a1, b1 expression while a3 expression was significantly down regulated. WB confirmed qPCR results. Immunofluorescence microscopy of KO glomeruli revealed enhanced expression of col IV a1, a2 in the GBM. The EM 3D models of the GBM confirmed the cone shaped humps and a significant podocyte foot process effacement in KO mice. Two albuminuric patients with similar GBM phenotype and without signs of MCD or FSGS were identified.

Conclusions: GLEPP1 deficiency mediates the formation of GBM humps in mice and potentially in humans. GLEPP1 deficiency mediates GBM composition from a mature to an immature state. This switch can only be seen in aging mice and results functionally in albuminuria and renal disease. GLEPP1 deficiency defines a novel glomerular disease.

SA-OR052

The Role of Podocyte Associated Angiotensin II Type 1a Receptor in Nephrosis Kazunori Inoue, Xuefei Tian, Shuta Ishibe. *Internal Medicine, Yale Univ School of Medicine, New Haven, CT.*

Background: Inhibition of the renin-angiotensin system has demonstrated to reduce both proteinuria and the decline in GFR. This beneficial effect has been postulated to go beyond blood pressure control. Controversies remain on the direct effect of angiotensin II (Ang II) on podocytes. Dynamin plays an important role in angiotensin II receptor type 1a (AT1aR) internalization and we have previously demonstrated that podocyte specific Dynamin 1 and 2 knockout (Dnm KO) mice display severe proteinuria and glomerular sclerosis. Our objective is to determine whether podocyte specific persistant AT1aR signaling in Dnm KO mice results in podocyte injury in–vivo.

Methods: Live cell imaging of fluorescently tagged clathrin and AT1aR in primary podocytes from Wild type (WT) and Dnm KO was performed. WT, Dnm KO, Pod-Cre Agtr1a fl/- Dnm1 fl/fl Dnm2 fl/fl (Pod Agtr1a KO Dnm KO), and Agtr1a -/- Pod-Cre Dnm1 fl/fl Dnm2 fl/fl (Agtr1a KO Dnm KO) mice were generated and characterized to unearth the role of AT1aR in podocytes.

Results: Clathrin mediated AT1aR internalization was observed after Ang II treatment in WT podocytes, but was arrested at the plasma membrane in Dnm KO podocytes. ERK, a downstream target of AT1aR, was continuously activated in Dnm KO podocytes after Ang II stimulation. Compared with Dnm KO mice, both Pod Agtr1a KO Dnm KO, and Agtr1a KO Dnm KO mice showed a decrease in proteinuria (urine albumin creatinine ratio were 3708.7 (ug/mg) (Dnm KO) vs 3089.7 (Pod Agtr1a KO Dnm KO) vs 2166.2 (Agtr1a KO Dnm KO) at 6 weeks old age respectively) and an advantage in survival. Histological examination demonstrated that Pod Agtr1a KO Dnm KO mice showed modest reduction in the progression of glomeruloscrelosis, proteinaceous casts compared with Dnm KO mice. Agtr1a KO Dnm KO mice showed lower mean arterial blood pressure than Dnm KO mice, but there was no difference between the Dnm KO and Pod Agtr1a KO Dnm KO mice.

Conclusions: Our results demonstrate that deletion of Dynamin 1, 2 in podocytes results in sustained AT1aR signaling. Inhibition of AT1aR signaling in podocytes plays a fundamental role in retarding the progression of podocyte injury when compared to total deletion of Agtr1a in Dnm 1, 2 KO podocytes.

SA-OR053

The Spectrum of Nephrotic Syndrome from Minimal Change Disease to FSGS Correlates with Rac1 Activation Richard Robins, Cindy Baldwin, Lamine Aoudjit, Indra R. Gupta, Tomoko Takano. *Nephrology, McGill Univ, Montreal, QC, Canada.*

Background: Within podocytes, cytoskeletal organization is regulated by Rho-family GTPases including Rac1. Clinical and animal studies suggest that Rac1 activation within podocytes contributes to the pathogenesis of nephrotic syndrome (NS). We hypothesize that Rac1 activity is increased in clinical NS and podocyte-specific activation of Rac1 will result in NS in mice.

Methods: Kidney biopsies from patients with minimal change disease (MCD) and idiopathic focal segmental glomerulosclerosis (FSGS) were immunostained for active Rac1. Sera from FSGS patients were used for Rac1 activity assays in cultured podocytes. Mice carrying the tetracycline-inducible constitutively active Rac1 mutant (L61, CA-Rac1, Flag-tagged) were bred with mice with the podocin-driven reverse tetracycline trans-activator to generate double transgenic mice (DTG). Proteinuria was assessed by the albumin/creatinine ratio (ACR). Renal histology was evaluated by light, immunofluorescence (IF) and electron microscopy.

Results: By IF, active Rac1 staining was increased in glomeruli (co-localized with nephrin) in patients with NS. FSGS patient sera activated Rac1 in cultured podocytes. DTG mice had 1 or 2 copies of the *CA-Rac1* transgene; mice with 2 copies had significantly higher proteinuria upon 5 days Dox treatment (high responders), compared with those with 1 copy (low responders). Foot process effacement was more diffuse and pronounced in high responders compared to low responders. When Dox was withdrawn after 5 days, low responders returned to baseline proteinuria after 2 weeks while high responders returned to near baseline levels after 4 weeks. When Dox was withdrawn after 2 weeks in high responders, proteinuria did not resolve. After 1 month, high responders displayed severe glomerulosclerosis.

Conclusions: Active Rac1 staining is increased in patients with NS. FSGS sera promote Rac1 activation in cultured podocytes. In mice, the amount of Rac1 activation within podocytes determines severity of foot process effacement, proteinuria, and degree of reversibility upon Dox withdrawal. The amount of Rac1 activation may be a critical factor determining whether MCD or FSGS arises within the NS spectrum.

Glomerular TNFα Expression Causes Free Cholesterol Mediated Podocyte Apoptosis in DKD and FSGS Christopher E. Pedigo,[1] Farah Leclercq,[1] Mayrin Correa-Medina,[1] Gloria Michelle Ducasa,[1] Judith T. Molina David,[1] Matthias Kretzler,[2] Sebastian Martini,[2] Robert G. Nelson,[3] Alla Mitrofanova,[1,4] Armando Mendez,[5] George William Burke,[4] Sandra M. Merscher,[1] Alessia Fornoni.[1] *[1]Katz Drug Discovery Center, Nephrology, U of Miami; [2]U of Michigan; [3]NIDDK; [4]Surgery, U of Miami; [5]Diabetes Research Inst, U of Miami.*

Background: Tumor Necrosis Factor alpha (TNFα) levels predict the development of Diabetic Kidney Disease (DKD). TNFα inhibition may be efficacious in some patients with Focal Segmental Glomerulosclerosis (FSGS). Podocyte injury is observed in both diseases and glomerular cholesterol accumulation was associated with albuminuria and reduced ATP-Binding Cassette A1 (ABCA1) expression in experimental DKD. We hypothesized that TNFα causes lipid dependent podocyte injury in FSGS and DKD.

Methods: Caspase 3 activity and cholesterol efflux was determined in human podocytes treated with TNFα. Cyclodextrin (CD) was used for cholesterol depletion.

Results: DKD and FSGS sera treated podocytes showed increased TNFα expression. Glomerular TNFα expression correlated with reduced ABCA1 expression in FSGS. Podocytes treated with sera from patients with progressive DKD showed reduced ABCA1 expression compared to non progressive DKD. TNFα treatment increased apoptosis and cholesterol content, reduced ABCA1 mediated cholesterol efflux, esterified cholesterol and Sterol-O-Acyltransferase (SOAT1) activity. ABCA1 overexpression or CD prevented TNFα induced apoptosis. ABCA1 knockdown increased esterified cholesterol content. Treatment of ABCA1 knockdown cells with SOAT inhibitors caused apoptosis that was prevented by CD. TNFα treated mice showed albuminuria and kidney cholesterol accumulation, the former was prevented by CD.

Conclusions: Podocytes treated with FSGS or DKD sera show increased TNFα expression. Increased glomerular TNFα expression correlates with reduced ABCA1 expression in patients with FSGS and reduced ABCA1 expression correlates with DKD progression. TNFα attenuates ABCA1 mediated efflux and reduces cholesterol esterification leading to free cholesterol mediated apoptosis. Our data suggest that targeting the TNFα-ABCA1-cholesterol axis may represent a new strategy to treat DKD or FSGS.

Novel Score to Predict Post-Transplant Outcomes Miklos Zsolt Molnar,[1] Danh V. Nguyen,[2] Vanessa A. Ravel,[2] Elani Streja,[2] Mahesh Krishnan,[3] Yanjun Chen,[2] Csaba P. Kovesdy,[1] Kamyar Kalantar-Zadeh.[2] *[1]Univ of Tennessee Health Science Center, Memphis, TN; [2]Univ of California, Irvine, CA; [3]DaVita Healthcare Partners, VA.*

Background: Several previous studies have developed scoring tools to predict the allograft and patients' survival in kidney transplant patients using information, which was not available at the time of transplantation. We developed a score to predict post-transplant outcomes using pre-transplant information including routine laboratory data available at the time of transplantation.

Methods: Linking the 5-year patient data of a large dialysis organization to the SRTR, we identified 15,125 hemodialysis patients who underwent first kidney transplantation. Prediction models were developed using Cox models for (a)mortality, (b)transplant failure(death censored) and (c)combined death or transplant failure. The cohort was divided into a two-thirds development set and a one-third validation set. We used backward-selection based on Akaike's information criterion to avoid arbitrary and ineffective selection rules based on p-values. We used the bootstrap method to assess model overfitting and calibration using the development dataset. Model predictive discrimination was assessed using the index of concordance, or C statistic, which accounts for censoring in time-to-event(a-c).

Results: Patients were 50±13 years old and included 39% women, 15% African-American and 36% diabetics. For prediction of post-transplant mortality and graft loss 10-10 predictors were used (recipients' age, cause and length of ESRD, hgb, albumin, comorbidities, race and type of insurance as well as donor characteristics such as donor age, diabetes, number of HLA mismatches). The new model showed the overall best C-statistics comparing to the currently used EPTS score.

	Current model	**Model based on EPTS predictors**
	Discrimination C (95%CI)	**Discrimination C (95%CI)**
Combined	0.63 (0.62-0.65)	0.57 (0.56-0.58)
Mortality	0.70 (0.69-0.71)	0.66 (0.65-0.67)
Allograft failure	0.63 (0.62-0.65)	0.59 (0.58-0.61)

Conclusions: The new prediction tool, using exclusively data available prior to the time of transplantation, performs better to predict outcomes than currently used tool such as EPTS.

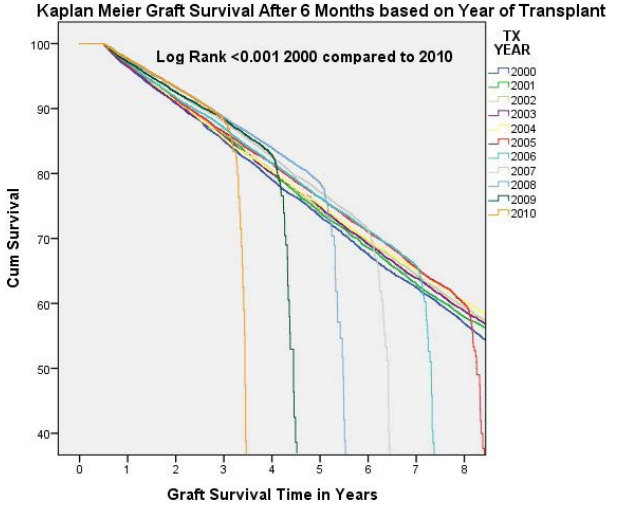
SA-OR056

Long-Term Deceased Donor Kidney Graft Survival Has Improved in the Last Decade Douglas Scott Keith, Gayle M. Vranic, Angie G. Nishio-Lucar. *Medicine, UVA, Charlottesville, VA.*

Background: Long-term graft survival did not improve significantly in the 1990s. We sought to determine if long-term graft survival is improving in the last decade.

Methods: All adults deceased donor renal transplant recipients in the SRTR database between 2000 and 2010 were included in the study. K-M survival analysis was carried out based on year of transplantation in all recipients who had at least 6 months of graft survival. Graft survival, death censored graft survival and death with graft function were analyzed. Cox modeling was carried out to determine if the year of transplant affected the outcomes.

Results: 92,616 deceased donor kidney transplants survived at least six months. The rate of graft failure has improved over the last decade.



This occurred in spite of the decreasing quality of kidneys based on KDPI. The improvement in graft survival was exclusively due to improved death censored graft survival. The rate of death with graft function did not change. This steady improvement in graft survival occurred during a transition in maintenance immunosuppression from cyclosporine based regimens to tacrolimus. Cox analysis confirmed the improvement in graft survival and death censored graft survival but also showed that the rate of death with graft function was decreasing when adjusted for the covariates.

Transplant Year Reference: 2000	H.R of Graft Failure (C.I.)
2001	0.97 (0.93-1.03)
2002	0.94 (0.89-0.98)
2003	0.91 (0.87-0.96)
2004	0.88 (0.84-0.93)
2005	0.85 (0.81-0.89)
2006	0.82 (0.78-0.87)
2007	0.79 (0.75-0.83)
2008	0.71 (0.67-0.75)
2009	0.73 (0.68-0.78)
2010	0.70 (0.65-0.75)
Covariates: Age, Race, Gender, Acute Rejection, DGF, KDPI, HLA mismatch, Dialysis Duration, PRA, and Retransplant	

Conclusions: Long-term graft survival has improved in the last decade in spite of declining donor quality. This improvement was associated with a shift in maintenance immunosuppression to tacrolimus.

SA-OR057

Characteristics Associated with Greater Than 5 Year Kidney Graft Survival Among HIV+ Recipients Laura Panarey, Alden Michael Doyle, Karthik M. Ranganna. *Nephrology and Hypertension, Drexel Univ Hahnemann Hospital, Philadelphia, PA.*

Background: We have previously reported that donor factors have direct influence on the incidence of peri-operative delayed graft function (DGF), decreased time to acute cell-mediated rejection (ACR), and affect graft outcomes.

Methods: Our aim was to identify donor and recipient risk factors associated with > 5 year kidney allograft survival among HIV+ recipients by conducting a retrospective chart analysis of all HIV + transplants performed at our center with at least 5 years of follow up (N=94).

Results: In our HIV + kidney transplant cohort, greater than 5 year allograft survival was significantly associated with modifiable risk factors including: living donor allografts (LRT), minimizing cold ischemia time, and pre-transplant diagnosis of HCV. Non-modifiable demographics not associated with at least 5 year survival included: Age, Sex, BMI, and the history of CAD or DM. Implicated elsewhere; neither ethnicity nor gender mismatch of allograft appeared to significantly affect our HIV + transplant outcomes at 5years. While cellular and humoral rejection are known to affect the HIV + transplant cohort; time to ACR was significantly different, inferior graft survival experienced an earlier first ACR (188 ± 258 days vs. 458 ± 444 days, p = 0.02). Reflected in graft outcomes; inferior graft survival best GFR 50.58 mL/min ± 25 vs. 65.49 mL/min ± 23, p = 0.02.

Conclusions: Our data suggest that optimization of HIV+ kidney transplant outcomes is associated with modifiable factors such as HCV (encouraging data for new treatment); addendum of donor quality (LRT preferable) and avoidance of DGF.

Recipient Factors	**p-Value**	**< 5 year allograft survival**	**> 5 year allograft survival**
Diabetes Mellitus (DM)	P = 0.126	11/73	6/14
Cardiovascular (CAD/PVD/CVA)	P =0.298	14/73	6/14
Hepatitis C Virus (HCV)	P =0.025	35/73	4/20
Protease Inhibitors (HIV treatment)	P>0.05	44/56	12/56
Non-Protease Inhibitor (HIV treatment)	p>0.05	28/38	10/38
Donor Factors	**p-Value**	**< 5 year allograft survival**	**> 5 year allograft survival**
KDRI (kidney donor risk index)	P = 0.044	1.44 ± 0.5	1.18 ± 0.4
Cold Ischemia Time (CIT)	P =0.07	15/72	12/20
Non-Cadaveric Transplant (LRT)	P =0.006	3/73	4/20
DGF	P = 0.013	48/73	11/20

Identifying the Two Specific Types of Antibody-Mediated Rejection and Their Outcomes in Kidney Recipients Olivier Aubert,[1] Alexandre Loupy,[1] Luis G. Hidalgo,[2] Jeff Reeve,[2] Denis Glotz,[1] Christophe M. Legendre,[1] Carmen Lefaucheur,[1] Philip F. Halloran.[2] *[1]INSERM; [2]ATAGC.*

Background: Antibody-mediated rejection (ABMR) can be related to preformed/recurrent anti-HLA DSA or de novo anti-HLA DSA.

Methods: We included 965 kidney biopsies taken from two North American and five European centers and assessed patients with ABMR. We compared patients with preformed/recurrent DSA (Type-1 ABMR) to patients with de novo DSA (Type-2 ABMR). Microarray-based gene expression was assessed in biopsies. Patients with type-1 were managed in two centers with aggressive standardized treatment protocols; type-2 ABMR was managed as standard-of-care.

Results: We identified 278 patients with ABMR: 153 (55%) type-1 and 125 (45%) type-2. The mean time from transplantation to rejection was 10.1±18.8 vs 84.9±71.1 months for the type-1 and 2 ABMR. The mean eGFR at the time of biopsy was lower in type-1 ABMR (38±18) vs type-2 (46±20 mL/min/1.73m^2) (p=0.0012). Kidney biopsies with type-1 ABMR presented with higher microcirculation injury (g+ptc score: 3.3±1.4 vs 2.4±1.5) and less transplant glomerulopathy score (0.5±0.9 vs. 1.6±1.1) (p<0.0001). C4d PTC deposition was similar (32% vs 34%). Using the gene expression assessment, type-1 ABMR exhibited a higher expression of global disturbance transcripts, injury-repair response associated transcripts (IRRATS), endothelial cell associated transcripts (ENDAT), injury-induced transcripts (IRIT3) (p<0.0001) but a lower expression of NK cell transcript burden (NKB) (p=0.0147). Type-1 and Type-2 ABMR exhibited similar high expression of transcripts reflecting γ-IFN response (GRIT1), T cell transcript burden (TCB) and macrophage-associated transcripts (QCMAT). Kidney allograft survival at 4 and 8 years after rejection was superior in type-1 ABMR (72% and 58%) compared to type-2 (51% and 35%) (p<0.0001).

Conclusions: Type-1 and type-2 ABMR present with distinct phenotypes and outcomes. The fact that type-1 ABMR is treated with aggressive defined protocols and has superior outcomes despite lower GFRs and more molecular injury at the time of biopsy suggests that trials of structured aggressive therapy protocols in type 2 ABMR deserve study.

SA-OR059

Serum Dickkopf-1, Renal Allograft Fibrosis and the Risk of Graft Failure After Kidney Transplantation Martin H. De Borst,[1] Charlotte A. Keyzer,[1] Jelmer K. Humalda,[1] Thomas Vanhove,[2] Gerjan Navis,[1] Dirk R. Kuypers,[2] Stephan J.L. Bakker.[1] *[1]Dept of Nephrology, Univ Medical Center Groningen, Netherlands; [2]Dept of Nephrology and Renal Transplantation, Univ Hospitals Leuven, Belgium.*

Background: Renal fibrosis is a final common pathway contributing to graft failure after kidney transplantation (KTx). Aberrant Wnt/β-catenin signaling contributes to progressive renal fibrosis. Dickkopf-related protein 1 (Dkk-1) is a soluble endogenous inhibitor of the Wnt signaling pathway, and is induced in response to tissue injury in animal studies. We investigated whether serum Dkk-1 is associated with renal interstitial fibrosis and graft failure in renal transplant recipients (RTR).

Methods: Serum Dkk-1 was measured by ELISA (R&D) in two cohorts of outpatient RTR. In a cross-sectional cohort we analyzed the relationship between Dkk-1 and prevalent renal fibrosis using logistic regression. In a longitudinal cohort we studied the association with graft failure using Cox regression.

Results: In the cross-sectional cohort (n=225, 60% male, age 54±13 years) serum Dkk-1 was associated with renal fibrosis at two years post-KTx independent of age, sex, proteinuria and eGFR (odds ratio 2.10 [95% CI 1.11-3.95], P=0.02). In the longitudinal cohort (n=700, 57% male, age 53±13 years, 5.4 [1.9-12.0] years after KTx) 45 (6%) patients developed graft failure during 3.1 [2.6-3.8] years of follow-up. Serum Dkk-1 was inversely associated with graft failure (HR 0.45 [95% CI 0.27-0.76], P=0.003 per doubling of Dkk-1), independent of known risk factors for graft failure or Dkk-1 correlates. The association persisted in sensitivity analyses restricted to patients with interstitial fibrosis/tubular atrophy.

Conclusions: We present the first human data connecting serum Dkk-1, an endogenous inhibitor of the pro-fibrotic Wnt/β-catenin signaling, with prevalent renal allograft fibrosis, and with long-term protection against graft failure in RTR. These findings are in line with preclinical studies suggesting that Dkk-1 is induced upon tissue injury and serves as an endogenous anti-fibrotic factor, and position Dkk-1 as a potential target for anti-fibrotic therapy after KTx.

Funding: Pharmaceutical Company Support - The generation of the cohort was made possible by a grant from the Dutch Top Institute Food and Nutrition. M.H.d.B. and C.A.K. are supported by a consortium grant from the Dutch Kidney Foundation (NIGRAM consortium, grant no. CP10.11). This study was funded by a grant from De Cock-Hadders Foundation (grant no. 2015-44).

Longitudinal Assessment of Cardiac Morphology and Function following Kidney Transplantation Clark David Kensinger,[1] Antonio Hernandez,[2] Meagan Fairchild,[4] Guanhua Chen,[3] Loren Lipworth,[4] Talat Alp Ikizler,[4] Kelly A. Birdwell.[4] *[1]Dept of Surgery, Vanderbilt Univ Medical Center; [2]Dept of Anesthesiology, Vanderbilt Univ Medical Center; [3]Dept of Biostatistics, Vanderbilt Univ Medical Center; [4]Dept of Medicine, Vanderbilt Univ Medical Center.*

Background: Despite improvement in traditional cardiovascular (CV) risk factors following renal transplantation, the death rate from CV disease remains high. Our aim was to evaluate the longitudinal change of cardiac morphology and function in a cohort of patients following renal transplantation, as well as to evaluate the association between Fibroblast Growth Factor 23 (FGF-23) concentrations and the evolution of cardiac morphology following transplant.

Methods: We performed a longitudinal prospective cohort study of 145 kidney transplant recipients, measuring left ventricular mass index (LVMI), left atrial volume index (LAVI) and ejection fraction (EF) by echocardiography at months 1 (baseline), 12, and 24 post-transplant. FGF-23 levels were measured at months 1 and 24 post-transplant. A linear mixed effects model was used to assess each outcome adjusting for age, race, gender, time on dialysis, CV disease, mean arterial pressure, glomerular filtration rate, diabetes, and body mass index.

Results: The cohort (mean age 49±13 years) was 74% male and 75% white. LVMI (P=<0.001), LAVI (P=<0.001), and EF (P=0.009) decreased significantly over time following transplant. Results from the multivariate models can be reviewed in Table 1. A one-unit decrease in FGF-23 was significantly associated with a 5.83 grams/meter^2 decrease in LVMI (P=0.04).

Conclusions: LVMI, LAVI and EF improved significantly over 12 and 24 months post-transplant. There was also a significant association between FGF-23 and LVMI following transplant.

Outcome	12 month effect	95% CI	P Value	24 month effect	95% CI	P Value
LVMI	-10.95	-16.34, -5.56	<0.001	-14.77	-22.02, -7.52	<0.001
LAVI	-3.31	-5.13, -1.49	<0.001	-4.95	-7.38, -2.52	<0.001
Ejection fraction	1.5	0.09, 2.91	0.04	2.75	0.87, 4.63	0.005

Tolerance Induction versus Conventional Immunosuppression in HLA-Matched Kidney Transplantation: Comparison at Two Years Post-Transplant John D. Scandling, Stephan Busque, Judith A. Shizuru, Asha Shori, Robert Lowsky, Kent Phillip Jensen, Richard T. Hoppe, Samuel Strober. *Stanford Univ.*

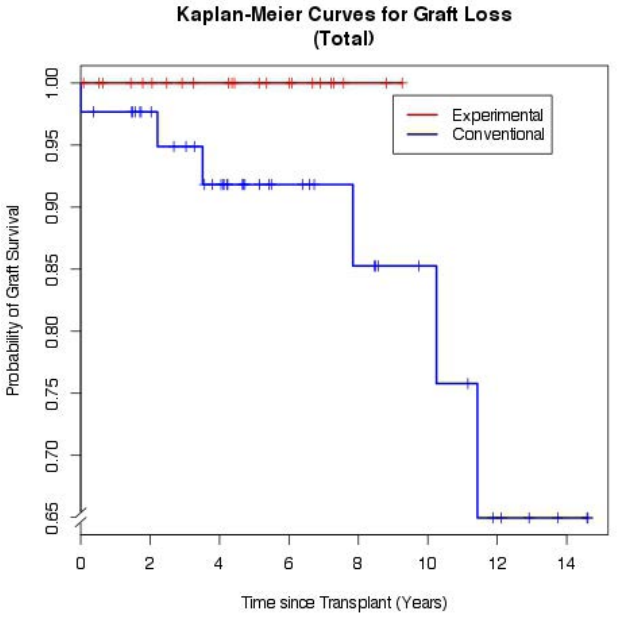
Background: Over 10 years we have studied the safety and efficacy of tolerance induction using hematopoietic cell transplantation in combination with kidney transplantation.

Methods: Twenty-two patients underwent HLA-matched living donor kidney transplantation followed by a conditioning regimen of 10 fractions of total lymphoid irradiation (12 Gy total) and 5 doses of ATG. Infusion of purified donor CD34+ hematopoietic progenitor cells and T cells was on day 11 post-kidney transplant. Fifty-three patients contemporaneously underwent HLA-matched living donor kidney transplantation under conventional immunosuppression.

Results: Seventeen patients developed mixed chimerism of 6 months duration or longer and have now been off immunosuppression from 1 to 7 years. Their outcomes at two years post-transplant are compared to those of the 52 (one graft was lost to thrombosis on day 1) conventionally treated patients.

	Conventionally Treated, 2000-13	Tolerance Induction, 2005-13
Number	52	17
ImmunoRx (mono/dual/triple)	2 / 34 / 16	Off drug 4 to 18 mo (of 24 mo)
Age at transplant (years)	38 +/- 11.2	40 +/- 10.5
Sex (M/F)	26/26	9/8
Cause of ESRD (DM/GN/other)	4 / 17 / 31	1 / 6 / 10
Infection (N of episodes)	8 (1 CMV, 2 v. zoster)	6 (1 CMV, 4 v. zoster)
Cancer	0	1 (breast, at 23 mo)
Acute rejection (N of patients)	3 (5.9%)	0
Creatinine (mg/dL)	1.2 +/- 0.35	1.2 +/- 0.26
Weight gain (kg)	5.2 +/- 7.36	7.4 +/- 8.39
Hypertension	27 (52%)	9 (53%)
Antihypertensive drugs (1/2/3)	15 / 9 / 36	6 / 3 / 0
Hyperlipidemia	20 (39%)	3 (18%)
Post-transplant diabetes mellitus	4 (7.8%)	0

Death-censored graft survival is shown (p=0.10).



Conclusions: Transplantation under this protocol is safe, achieves tolerance eliminating risk of acute rejection, and offers a better metabolic profile and better graft survival with time.

Better Renal Function Preservation with Early Conversion to Everolimus in *De Novo* Renal Transplant Recipients: 24-Month Results from the ELEVATE Study Johan W. De Fijter,[1] Hallvard Holdaas,[1] Patricia M. Lopez,[2] Cesar Escrig,[2] Zailong Wang,[3] Josep M. Cruzado,[1] Markus van der Giet.[1] *[1]For the ELEVATE Study; [2]Novartis, Basel, Switzerland; [3]Novartis Corporation, East Hanover, NJ, USA.*

Background: Long-term exposure to calcineurin inhibitors (CNIs) is one of the key factors contributing to progressive deterioration of renal function and graft loss. We present the 24 month (M) renal outcomes from the ELEVATE study which determined whether early CNI to everolimus (EVR) conversion in renal transplant recipients (RTxRs) provides better preserved renal function compared to continuation of standard CNIs.

Methods: ELEVATE (NCT01114529) was a 24M, multicenter, open-label study, in which *de novo* RTxRs were randomized (RND) at 10–14 weeks post-transplant to convert from CNI to EVR (n=360; C_0 6–10 ng/mL) or continue standard CNI (n=357; C_0 tacrolimus: 5–10 ng/mL, cyclosporine: 100–250 ng/mL); all received enteric-coated mycophenolate sodium + steroids. The primary end point was change in estimated glomerular filtration rate (eGFR; MDRD-4) from RND to M12.

Results: A total of 717 patients were RND; 229 (65%) and 283 (79%) patients completed on study drug in EVR and CNI groups, respectively. The least squares (LS) mean change in eGFR for EVR vs CNI from RND to M12 was 0.25 vs -1.45 (diff: 1.70, p=0.134) and 0.74 vs -1.07 (diff: 1.80, p=0.117) mL/min/1.73 m^2 for intent-to-treat (ITT) and on-treatment (OT) analysis, respectively. Up to M24, mean eGFR was significantly higher at all time-points after RND in EVR vs CNI group for OT analysis. At M24, mean eGFR in EVR vs CNI groups was 62.5 vs 57.4 mL/min/1.73 m^2 (ITT: p=0.006) and 66.1 vs 59 mL/min/1.73 m^2 (OT: p=0.001), respectively. The difference in eGFR at M24 between EVR and CNI groups was 5.1 (ITT) and 7.1 mL/min/1.73 m^2 (OT), respectively, in favor of EVR. Proteinuria (³3 g/day) was reported in three patients in the EVR group and two in the CNI group.

Conclusions: Early conversion to EVR therapy 3M post-transplant vs continued CNI resulted in better preserved renal function up to 2-years of follow-up.

Month 48 Follow-Up Results of the HERAKLES Study: Superior Renal Function After Early Conversion to an Everolimus-Based Calcineurin Inhibitor Free Regimen Klemens Budde,[1] Oliver Witzke,[1] Thomas Rath,[1] Peter Weithofer,[1] Johannes Jacobi,[1] Bruno Vogt,[2] Ingeborg A. Hauser,[1] Rolf A. Stahl,[1] Petra Reinke,[1] Martina Porstner,[3] Martin G. Zeier,[1] Frank Lehner,[1] Wolfgang Arns,[1] Claudia Sommerer.[1] *[1]HERAKLES Study Group, Germany; [2]HERAKLES Study Group, Switzerland; [3]Novartis Pharma, Germany.*

Background: To follow up on renal function (GFR) at month (mo) 48 after kidney transplantation (Tx) in patients (pts) on immunosuppressive regimen with different calcineurin inhibitor (CNI) exposures.

Methods: 802 pts were included in this prospective, open-label, randomized multi-center study. After induction with basiliximab all pts received cyclosporine A (CsA), enteric-coated mycophenolate sodium (EC-MPS) and steroids. 3 mo post Tx 499 pts were randomized 1:1:1 to either a) continue standard (STD) CsA (100-180ng/ml) with EC-MPS (n=166), b) convert to a CNI-free regimen with everolimus (EVR;5-10ng/ml) + EC-MPS (n=171) or c) convert to CNI-reduced regimen CsA (50-75ng/ml) with EVR(3-8ng/ml) (n=162).

Results: GFR (Nankivell, ITT) was similar at randomization 3 mo post Tx and had significantly improved at mo 12 by +5.6mL/min (95%CI:[+2.9;+8.3]; p<0.001) and remained significantly improved by +6.8mL/min in favor of CNI-free regimen at mo 48(p=0.02). 54% of CNI-free, 36% of CNI-reduced and 44% of STD pts had an improvement in GFR at mo 48 (p=0.09 CNI-free vs STD). All 3 groups had similar rejection rate since randomization (13% STD, 16% CNI-free, 16% CNI-reduced) and overall comparable safety profile. Mean trough levels at mo 48 were for CsA 111ng/ml in STD and 86ng/ml in CNI-reduced pts and for EVR 5.5ng/ml in CNI-free and 5.5ng/ml in CNI-reduced pts.

Conclusions: CNI-free as well as reduced CNI in combination with EVR represent both efficacious and safe regimen. CNI-reduced group had higher CsA levels than anticipated. The fact that CNI reduction was not fully accomplished might have prevented GFR differences compared to STD in this randomized treatment group. However, CNI-free regimen was associated with better GFR maintained for 4 years post Tx. The results of this large trial confirm previous reports of improved GFR after CsA withdrawal with EVR in combination with EC-MPS.

SA-OR064

Belatacept pts Had Superior Graft Survival versus CsA pts: Final Results from BENEFIT Flavio Vincenti,[1] J. Grinyo,[2] R. Bray,[3] L. Rostaing,[4] B. Bresnahan,[5] K. Rice,[6] S.M. Steinberg,[7] H. Gebel,[3] M. Polinsky,[8] U. Meier-Kriesche,[8] S. Munier,[8] R. Townsend,[8] C.P. Larsen.[3] *[1]Univ of California, San Francisco; [2]Univ Hospital Bellvitge, Barcelona, Spain; [3]Emory Univ, Atlanta; [4]Univ Hospital and INSERM U563, IFR-BMT, Toulouse, France; [5]Medical College of Wisconsin, Milwaukee; [6]Baylor Univ Medical Center, Dallas; [7]Sharp Memorial Hospital, San Diego; [8]BMS, Lawrenceville.*

Background: At 3 and 5 yrs post-transplant in BENEFIT, renal function was improved in kidney transplant recipients administered belatacept (bela) vs CsA. We report final 7-yr results.

Methods: Pts were randomized to more (MI) or less intensive (LI) bela or CsA regimens. Outcomes were assessed for all randomized, transplanted pts at yr 7. In a prospective analysis, time to death or death-censored graft loss was compared using Cox regression. Presence of DSAs was established centrally (FlowPRA®). Kaplan–Meier estimates for the cumulative rate of de novo (DN) DSAs were derived. Mean calculated GFR (cGFR) was estimated from mos 1–84 using a repeated measures model with an unstructured covariance matrix. Differences in cGFR at each time point were also estimated.

Results: In total, 153/219 of bela MI, 163/226 of bela LI, and 131/221 of CsA pts were evaluable. HRs comparing time to death/graft loss were 0.573 for bela MI vs CsA (*P*=.02)and 0.570 for bela LI vs CsA (*P*=.02)—a 43% risk reduction in death/graft loss for bela (MI or LI) vs CsA. Cumulative event rates of DN DSAs at yr 7 for bela MI, bela LI, and CsA were 1.86, 4.64, and 17.81, respectively. Serious AE rate was similar (71%, bela MI; 69%, bela LI; 76%, CsA). Mean cGFR increased slightly over 7 yrs for both bela regimens but declined for CsA. Differences in mean cGFR at yr 7 were 25.6 mL/min/1.73 m^2 for bela MI vs CsA and 27.3 mL/min/1.73 m^2 for bela LI vs CsA differences favored each bela regimen vs CsA at all time points (*P*<.0001).

Conclusions: In this 7-yr analysis, bela conferred statistically better graft survival and renal function vs CsA, with a reduced incidence of DN DSAs. The bela safety profile was consistent with previous reports.

SA-OR065

Differential Expression of MicroRNA in Urinary Exosomes of Preeclampsia Patients Belinda Bun Jim,[1] Alison P. Sanders,[3] Daniel Flores,[2] Rajeev Rohatgi.[2] *[1]Medicine/Nephrology, Jacobi Medical Center, Bronx, NY; [2]Medicine/Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY; [3]Preventive Medicine, Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Urinary exosomes are low density membrane vesicles originating from the multivesicular bodies of upstream renal epithelial cells. The exosomes contain molecules, such as microRNA (miRNA), which may serve as potential biomarkers for kidney disease, and, in particular, preeclampsia, a systemic disease with renal manifestations that affects 5-8% of pregnant women in the world.

Methods: We recruited 10 preeclamptic pregnant women and 9 healthy pregnant controls; each submitted a 50 mL spot urine sample for exosome isolation. Exosomes were isolated by sequential centrifugation and ultracentrifugation, and the exosomal miRNAs purified using miRNeasy kit (Qiagen).After isolation of miRNA from urinary exosomes, we used the Nanostring nCounter system to assess miRNA expression. Analysis of Variance (ANOVA) was performed to test for differences in exosomal miRNA expression (log2) between cases (n=10) and controls (n=9). Statistical significance was defined at $p<0.05$ and Storey's false discovery rate q-values were calculated.

Results: After adjusting for maternal age and experimental batch, two miRNAs remained statistically significant. miR-544a was upregulated among cases compared to controls, whereas and miR-495 was downregulated. Enrichment analysis of the 624 and 913 highly predicted downstream mRNA targets showed that miR-544a targets were enriched for cardiovascular system diseases including arterial pressure ($p<4.6x10-4$) and vasculogenesis ($p<1.2x10-3$); whereas the targets of miR-495 were associated with renal and urological system development ($p<2.8x10-6$).

Conclusions: We believe that these pilot results demonstrate the potential to identify a biomarker for preeclampsia that may be mechanistically plausible. Larger studies are presently being conducted.

SA-OR066

Functional Testing of Human Epithelial Na+ Channel Missense Variants Identified in the GenSalt Study Evan C. Ray,[1] Jingxin Chen,[1] Tanika Kelly,[2] Jiang He,[2] D.C. Rao,[3] James E. Hixson,[4] Dongfeng Gu,[5] Shaohu Sheng,[1] Thomas R. Kleyman.[1] *[1]Univ of Pittsburgh; [2]Tulane Univ; [3]Washington Univ; [4]Univ of Texas; [5]Peking Union Medical College.*

Background: In Liddle syndrome, epithelial Na^+ channel (ENaC) mutations that result in increased cell-surface expression are associated with early on-set hypertension, underscoring the importance of this channel in modulating blood pressure. Whether genetic variants that result in subtler increases in channel function contribute to salt-sensitive hypertension remains unclear.

Methods: A number of human ENaC variants were identified in 300 Genetic Epidemiology Network of Salt Sensitivity (GenSalt) participants with salt-sensitive hypertension and 300 with salt-independent hypertension. We used the *Xenopus* oocyte expression system to examine the functional properties of missense ENaC variants identified in the GenSalt study.

Results: Among 6 SCNN1A (encoding the ENaC α subunit) variants, 3 (aS115N, aR476W and aV481M) showed significantly greater, and one (αA334T) showed significantly lower ENaC currents than wild type. Among 3 SCNN1B (ENaC β subunit) variants, βD31N showed a significant reduction in ENaC currents; bS635N showed a significant increase in ENaC currents. Both β subunit variants substitute amino acids in intracellular domains. Among 5 SCNN1G (ENaC γ subunit) variants, one (γL438Q) had significantly greater ENaC currents than wild type. Each of the variants located in ENaC's extracellular domain that altered channel activity also altered Na^+ self-inhibition, a process wherein extracellular Na^+ suppresses channel open-probability.

Conclusions: Some missense ENaC variants identified in the GenSalt study alter ENaC function and may influence salt-sensitivity of blood pressure.

SA-OR067

Nephron Specific Deletion of the Prorenin Receptor Modulates Blood Pressure and Urinary Na Excretion Nirupama Ramkumar,[1] Deborah Stuart,[1] Elena V. Mironova,[2] Vladislav V. Bugay,[2] Mykola Mamenko,[3] Shuping No Wang,[1] Oleh Pochynyuk,[3] James D. Stockand,[2] Donald E. Kohan.[1] *[1]Medicine, Univ of Utah; [2]Medicine, Univ of Texas Health Sciences Center - San Antonio; [3]Medicine, Univ of Texas Health Sciences Center - Houston.*

Background: The nephron prorenin receptor (PRR) may modulate blood pressure (BP) and Na balance.

Methods: Since previous models of PRR knockout (KO) mice had early lethality and/or structural defects, we developed an *inducible* nephron-wide PRR KO using the Pax8/LC1 transgenes.

Results: Disruption of nephron PRR at 1 month of age caused no renal histological abnormalities. On a normal Na diet, wild-type (WT) and PRR KO mice had similar BP and Na excretion. However, PRR KO mice had elevated PRC (KO- 377 ± 77 vs WT- 127 ± 19 ng Ang-I/ml/hr) and a 50% decrease in renal ENaC-α protein. Protein levels of NHE3, NKCC2, NCC and ENaC-β/γ were similar between the two groups. Treatment with mouse prorenin (10 nM for 30 min) increased ENaC channel number by 2-fold, but not open probability, in isolated split-open cortical collecting ducts (CCD) from WT mice; this was prevented by PRR inhibition (PRO20) and Akt inhibition (A6730) but unaffected by blockade of AT-1 (losartan), ERK1/2 (U0126) or p38 MAPK (SB203580). Addition of prorenin (10 nM) did not change isolated CCD $[Ca^{2+}]_i$ as assessed by Fura-2 loading (10 min exposure). On a low Na diet, PRR KO mice had increased Na excretion (Day 2: KO - 66 ± 11 vs WT- 42 ± 6 mmol/day; Day 6: KO - 39 ± 4 vs ET- 23 ± 4 mmol/day) however, no differences in BP were observed. PRC remained elevated in PRR KO mice on a low Na diet. PRR KO mice had an attenuated hypertensive response to Angiotensin-II (Ang-II) infusion at 600 ng/Kg/min for 2 weeks (MAP: KO - 117 ± 4 vs WT - 133 ± 4 mm Hg over 2 weeks). Urinary Na excretion was elevated in Ang-II treated PRR KO mice as compared to WT mice (KO-344 ± 14 vs WT-268 ±30 mmol/day).

Conclusions: Taken together, these data indicate that nephron PRR, likely via direct prorenin/renin stimulation of an Akt-dependent pathway, stimulates CCD ENaC activity. Absence of nephron PRR promotes Na wasting and reduces the hypertensive response to Ang-II.

Pendrin Localizes to the Adrenal Medulla and Modulates Catecholamine Release Annie Y. Park,[1] Truyen D Pham,[1] William H. Beierwaltes,[3] Roy L. Sutliff,[1] Jill W. Verlander,[2] Carla L. Ellis,[1] Brandi M. Wynne,[1] Robert S. Hoover,[1] Susan M. Wall,[1] Yoskaly Lazo-Fernandez.[1] *[1]Medicine and Pathology, Emory Univ, Atlanta, GA; [2]Medicine, Univ of Florida, Gainesville, FL; [3]Hypertension and Vascular Research, Henry Ford Hospital, Detroit, MI.*

Background: Pendrin (Slc26a4) is a Cl-/HCO3- exchanger expressed in renal intercalated cells that mediates renal Cl- absorption. Pendrin gene ablation reduces blood pressure and vascular volume. While pendrin gene ablation increases plasma renin concentration, serum aldosterone is not increased, suggesting that pendrin regulates aldosterone production in the adrenal cortex. The purpose of this study was to determine if pendrin is expressed in the rodent adrenal gland and if it modulates adrenal function.

Methods: Pendrin mRNA and protein abundance were explored by PCR, immunoblots and immunohistochemistry. Mean arterial pressure (MAP) was measured by telemetry. Catecholamines were measured by HPLC in plasma samples from mice bearing chronic indwelling jugular catheters.

Results: Pendrin localizes to the rodent adrenal gland in epinephrine- and norepinephrine-producing chromaffin cells of the adrenal medulla rather than in adrenal cortical cells. We examined the effect the pendrin gene ablation on adrenal medullary function by measuring stress-induced catecholamine release. While basal levels of epinephrine (E) and norepinephrine (NE) were similar, E and NE levels were ~25-50% higher pendrin null than in wild type mice after 20 min of immobilization stress. 30 min following relief of stress, NE levels were 50% higher in pendrin null than in wild type mice. MAP rose in both wild type and pendrin null mice following immobilization stress, but MAP in pendrin null mice was 16 mm Hg lower than in wild type mice under basal conditions and 12 mm Hg lower following 20 min of immobilization stress ($P<0.05$). However, 30 min after relief of stress, MAP was the same in both groups (Wild type 121± 1.33 versus 117 ± 3.5 mm Hg, pendrin null mice).

Conclusions: Pendrin is expressed in mouse adrenal medulla where it plays a role in restraining catecholamine release during stress, which probably modulates pendrin-dependent changes in blood pressure.

SA-OR069

Renal-Selective Silencing of Adrenomedullin Gene Causes Hypertension in Mice Xiaoyan Wang, Donghai Zhou, Laureano D. Asico, Hai Lin, John Edward Jones, Pedro A. Jose. *Medicine, Univ of Maryland Medical School, Baltimore, MD.*

Background: Adrenomedullin (ADM) is a potent hypotensive and natriuretic peptide whose gene variants are associated with human essential hypertension. Although the kidney is one of the ADM producing organs, the mechanism by which ADM induces a natriuresis is not clear.

Methods: To determine the role of renal ADM on blood pressure in C57BL6/J mice (3.5 months old, male) fed a 0.6% NaCl diet, we silenced the ADM gene by the renal subcapsular infusion of Adm siRNA (3 mg/day), via osmotic minipump, into the remnant kidney one week after unilateral nephrectomy. Mock siRNA (3 mg/day) was used as control. The mice were placed in metabolic cages for 24 hr urine collection before blood pressure was measured under anesthesia, via the femoral artery on day 7.

Results: Body weight, water/food intake, and serum Na^+, K^+, & Cl^- were similar in the two groups. Systolic blood pressure was elevated in Adm siRNA group (129.3±5.1, mm Hg) relative to Mock group (96.2±1.4n=5/group). The two groups of mice excreted similar amounts of sodium and water but the sodium excretion and blood pressure plot in Adm mice was shifted to the right of Mock mice. Immunofluorescence confocal microscopy in normal mice revealed that ADM was mainly located in the cortex, especially in the apical membrane of renal proximal convoluted tubules (RPCT). ADM colocalized with NHE3 but not with NKCC2 and NCC. ADM also coimmunoprecipitated with NHE3 in whole kidney homogenates. In mouse RPCT cells, Adm siRNA decreased ADM protein to 48 ±4% of Mock group (n=4/group) and doubled the protein abundance of NHE3 (192±21) but did not alter aNKA. In polarized human PPCT cells, human ADM (1 hr, n=5-6/group) inhibited apical sodium transport at 10 nM (84±4 % of vehicle) and 100 nM (81±3%), similar to that achieved with the NHE3 inhibitor EIPA (81±6%, 100 nM).

Conclusions: Our data suggest that a renal-selective silencing of ADM gene increases blood pressure and impairs sodium excretion that is related, in part, to an increase in NHE3 abundance and function in the RPCT.

SA-OR070

Vascular AT1 Angiotensin Receptors Regulate Sodium Transporter Abundance in Kidney Epithelium

Matthew A. Sparks,[1] Susan B. Gurley,[1] Alicia A. McDonough,[2] Thomas M. Coffman.[1] *[1]Duke; [2]USC.*

Background: Vasoconstriction is a signature physiological action of angiotensin II (AngII) acting via AT1 receptors (AT1R).

Methods: In order to define the contribution of AT1R in vascular smooth muscle cells (VSMCs) to BP control, we generated mice with cell-specific deletion of AT1AR from VSMCs (SMKOs) using Cre-loxp technology.

Results: Baseline BP was reduced by ~7 mmHg and responses to AngII-induced hypertension were blunted by in SMKO mice compared to controls (16 vs. 30 mm Hg Δ BP from baseline after 4 wks AngII, P<0.02). Baseline renal blood flow (RBF) was higher, and renal vasoconstriction to AngII was impaired in SMKOs. Moreover, SMKO mice displayed Na+ sensitivity and exaggerated natriuresis during chronic AngII. To investigate the mechanism of the lower baseline BP and the enhanced natriuresis during AngII infusion (1000ng/kg/min for 5 days), we measured a panel of key Na+ transporters in the kidney by immunoblot. Baseline measurements in SMKO vs. controls detected reductions in NKCC2 in both cortex (0.8±0.03 vs. 1±0.03; P=0.0002) and medulla (0.6±0.02 vs. 1±0.05; P<0.0001); medullary NHE3 was similarly reduced (0.6±0.07 vs. 1±0.07; P=0.002). In controls, AngII infusion was associated with reduced cortical and medullary NHE3 and medullary NKCC, consistent with the pressure-natriuresis response, whereas cortical NKCC, NCC and ENaC were all significantly activated. By contrast, in SMKOs, there was no AngII infusion dependent depression in cortical or medullary NHE3, nor medullary NKCC. However, the extent of increase in activated (cleaved) αENaC was significantly less than controls (cortex: 1.46±0.16 vs. 2.58±0.17, P=0.002; medulla: 1.49±0.09 vs. 2.22±0.31, P=0.01). Yet, 24 hr urinary aldosterone excretion was not different between the groups (18.6±2.7 vs. 15.8±4.5 ng/24hrs).

Conclusions: Our studies indicate that the lower baseline BP in SMKO mice is associated with reduced Na^+ transporter abundance along the loop of Henle, and that attenuated hypertension and improved natriuresis during AngII infusion are associated with diminished ENaC activation. We suggest that vascular-epithelial cross-talk modulates renal Na+ handling and thereby contributes to BP control at baseline and during hypertension.

Chronic Inhibition of Renal Outer Medullary Potassium Channel Not Only Prevented but also Reversed Hypertension Development and End Organ Damage in Dahl Salt Sensitive Rats

Xiaoyan Zhou,[1] Wanda Sharif-Rodriguez,[2] Gail M. Forrest,[1] Daphne Szeto,[1] Olga Price,[1] Yonghua Zhu,[1] Andra S. Stevenson,[1] Yuchen Zhou,[1] Sloan Stribling,[1] Maya Dajee,[1] Shawn P. Walsh,[1] Alexander Pasternak,[1] Kathleen A. Sullivan.[1] *[1]Merck & Co., NJ; [2]Regeneron Pharmaceuticals, NY.*

Background: The renal outer medullary potassium (ROMK) channel mediates potassium recycling and facilitates sodium reabsorption through the $Na^+/K^+/2Cl^-$ cotransporter in the loop of Henle and potassium secretion at the cortical collecting duct. Evidence from the phenotype of humans and rodents with functional ROMK deficiency supports the contention that selective ROMK inhibitors (ROMKi) will represent a novel diuretic with potential of therapeutic benefit for hypertension. ROMKi have been recently synthesized by Merck & Co. The present studies were designed to examine effects of ROMKi A on systemic hemodynamic, renal function and structure, and vascular function in Dahl salt-sensitive (SS) rats.

Methods: Four experimental groups: control, high salt diet alone; ROMKi A 3 $mg•kg^{-1}d^{-1}$; ROMKi A 10 $mg•kg^{-1}d^{-1}$; and hydrochlorothiazide (HCTZ) 25 $mg•kg^{-1}d^{-1}$ were included in the prophylactic (from week 1 to week 9 on high salt diet) and therapeutic study (from week 5 to week 9 on high salt diet), respectively. The compounds were administrated in feed. Blood pressure was measured by radiotelemetry. Renal function was assessed in metabolic cage studies. Vascular function was assessed by vascular relaxation assay.

Results: ROMKi A produced sustained blood pressure reduction and improved renal and vascular function and histological alterations induced by a high salt diet. ROMKi A was superior to HCTZ at reducing blood pressure. Furthermore, ROMKi A provided beneficial effects on both lipid profile and bone mineral density.

Conclusions: Chronic ROMK inhibition not only prevented but also reversed hypertension development and end organ damage in Dahl SS rats. Our findings may suggest a great potential of ROMKi as novel antihypertensive agents, particularly in treating salt sensitive hypertension patient population.

SA-OR072

Analysis of Children with Hypercalciuria and Kidney Stones Identified a Mutation in a 5' Upstream Regulatory Element of Claudin-14 That Increases Gene Expression

R. Todd Alexander, Megan E. Ure, Wanling Pan, Emmanuelle Cordat. *Univ of Alberta, Edmonton, AL, Canada.*

Background: Kidney stones are prevalent and painful. The greatest risk factor for kidney stones is hypercalciuria for which the etiology is largely unknown. A recent GWAS study linked hypercalciuria to claudin-14, however it failed to identify the molecular mechanism mediating disease. We recently determined a role for claudin-14 in inducing calcium excretion when plasma calcium levels are elevated. We postulated therefore that children with kidney stones may have a mutation in CLDN14 increasing its expression.

Methods: To assess this hypothesis, we collected DNA from 16 children with idiopathic hypercalciuria and sequenced the target gene, including introns. To assess for a functional effect of the identified SNP we performed dual luciferase assays. We also engineered the identified mutant region in front of the SV40 promoter and the CLDN14 coding sequence and created stable cell lines. *In silico* studies were used to identify potential novel transcritpion factor binding sites introduced by identified SNPs and gel electrophoretic mobility shift assays to asses the binding of a transcription factor to the sequences.

Results: We found an intronic SNP in CLDN14 that occurred with greater frequency in children with hypercalciuria and kidney stones relative to ethnically matched controls (from the 1000 genome project). Dual luciferase assays found the mutant sequence doubled expression while the wild type had no effect (relative to empty vector). Despite similar numbers of the engineered constructs being incorporated into genomic DNA of the stable cell lines, the mutant sequence doubled mRNA and protein expression. *In silico* studies predicted the SNP introduced a novel INSM1 transcription factor binding site. To asses this, we expressed the WT and mutant luciferase constructs in the presence and absence of INSM1 and found a further increase in expression. Finally, gel electrophoretic mobility shift assays confirmed preferential binding of INSM1 to the mutant sequence.

Conclusions: Some children with hypercalciuria and kidney stones have a intronic mutation in CLDN14 that introduces a novel INMS1 binding site.

Funding: Government Support - Non-U.S.

Oxalobacter-Derived Bioactive Factors Reduce Urinary Oxalate Excretion in a Mouse Model of Primary Hyperoxaluria

Hatim A. Hassan,[1] Donna L. Arvans,[1] Yong-chul Jung,[1] Dionysios A. Antonopoulos,[1,3] John R. Asplin,[2] Ignacio Granja,[2] Jason C. Koval,[3] Mark W. Musch,[1] Eugene B. Chang.[1] *[1]Univ of Chicago; [2]Litholink Corporation; [3]Argone National Laboratory.*

Background: Hyperoxaluria is a major risk factor for calcium oxalate kidney stones (COKS) and has no therapy. The probiotic bacterium *Oxalobacter formigenes* (*Of*) plays a critical role in preventing recurrent COKS by metabolizing its host dietary oxalate, leading to reduced intestinal absorption and urinary excretion. *Of* also interacts with colonic epithelium by inducing colonic oxalate secretion, leading to reduced urinary excretion, via an unknown secretagogue. Sustaining *Of* colonization in animals and humans in the absence of high exogenous oxalate remains problematic, underscoring the need for identifying *Of*-derived factors exerting effects similar to live *Of.*

Methods: We previously found that small molecular weight protein(s) and/or peptide(s) in *Of* culture conditioned medium (CM) significantly stimulate oxalate transport (>2-fold) by human intestinal Caco2-BBE cells. To evaluate the CM in vivo effects, CM or OM (control medium) was given rectally as enemas (100 µl twice daily x 23 days) to PH1 mice (a mouse model of primary hyperoxaluria type 1).

Results: The CM significantly reduced urinary oxalate excretion by 32.5% while OM has no effect (µM/mg creatinine: OM = 51.50±3.33; 46.08±2.04; CM = 47.27±3.43; 31.91±4.81; before and after treatment, respectively). To test our hypothesis that the observed reduction in urinary oxalate is due to CM-induced enhanced colonic oxalate secretion, colonic tissues were isolated and mounted in Ussing chambers. While a small net oxalate secretory flux (-1.54) is observed in distal colonic tissues from OM-treated mice, a >10-fold higher net oxalate secretory flux (-16.34) is seen in distal colonic tissues from CM-treated mice(pmol/cm^2/h: OM: J_{MS} (absorptive flux) = 39.99±5.29, J_{SM} (secretory flux) = 41.53±4.59; CM: J_{MS} = 42.62±3.67, J_{SM} = 58.96±3.02), which is due to significantly increased J_{SM}.

Conclusions: We conclude that *Of*-derived bioactive factor(s) retain(s) its/their biological activity in vivo and significantly reduce(s) urinary oxalate excretion in PH1 mice by stimulating distal colonic oxalate secretion.

Hyperoxaluria Requires TNF Receptors to Initiate Crystal Adhesion and Kidney Stone Disease Jonathan Nicodemos Eberhard, Shrikant R. Mulay, Jyaysi Desai, Julian A. Marschner, Santhosh Kumar Vr, Hans J. Anders. *Ludwig Maximillians Univ, Germany.*

Background: Nephro- or urolithiasis involves intratubular mineral hypersaturation as well as lack of crystallization inhibitors to form crystal plugs obstructing renal tubules. Recently, NLRP3 inflammasome-related renal inflammation was added as a pathomechanism of acute oxalosis (Mulay et al, JCI 2013) as well as nephro-/urolithiasis (Knauf et al, KI 2013). As TNF receptor (TNF-R) signaling is a major mediator of inflammation in several chronic kidney diseases (CKD), we speculated that TNF-Rs would also drive the progression of nephrolithiasis-related CKD.

Methods: All *in vivo* experiments were approved by the local government authorities. Immunohistochemistry, WB, RT-PCR and atomic force microscopy (AFM) were used for data analysis.

Results: We observed that kidney immunostaining of humans and mice with hyperoxaluria-related CKD displayed strong tubular positivity for TNF-α, TNF-R1 and TNF-R2, which was absent in healthy kidneys. WB and mRNA expression analyses were consistent in mice kidneys. To test our hypothesis we fed an oxalate-rich diet to wild type (WT) mice or mice deficient for Tnfr1, Tnfr2 or Tnfr1/2. Oxalate feeding induced CaOx nephrolithiasis and progressive CKD in WT mice. Surprisingly, KO mice showed absolutely no intrarenal CaOx crystal deposits, as revealed by computed tomography as well as kidney immunostainings for CaOx, despite comparable hyperoxaluria and urinary calcium concentrations to WT mice. Further, we measured the adhesion forces between tubular epithelial cells and CaOx crystals by atomic force microscopy. We observed that lack of TNFR1/2 impairs CaOx crystal adhesion to the tubular epithelial cell surface. However, in an independent experiment we did not see any direct binding of CaOx crystals to the soluble TNF-R1-IgG fusion protein. Instead, we observed that TNF-R signaling is indeed required for inducing the expression of known crystal adhesion molecules viz. osteopontin, CD44, annexin II on tubular epithelial cells in vitro and in vivo.

Conclusions: We conclude that TNF-Rs are essential mediators of CaOx crystal adhesion at the luminal membrane of renal tubules as a fundamental mechanism of oxalate nephropathy.

SA-OR075

Critical Role of Toll-Like Receptor 4 in Crystal-Induced Inflammation and Renal Failure Venkata Surya Narayana Murty Darisipudi,[1] Christoph Daniel,[2] John R. Asplin,[3] Ignacio Granja,[3] Kerstin U. Amann,[2] Kai-Uwe Eckardt,[1] Peter S. Aronson,[4] Felix Knauf.[1,4] *[1]Dept of Nephrology und Hypertension, Universitätsklinikum Erlangen, Erlangen, Bavaria, Germany; [2]Dept of Nephropathology, Univ Erlangen, Erlangen, Bavaria, Germany; [3]Litholink Corporation, Chicago, IL; [4]Dept of Internal Medicine, Yale Univ School of Medicine, New Haven, CT.*

Background: Crystal-induced inflammation is a serious condition associated with chronic kidney disease. We have recently demonstrated that progressive renal failure in oxalate crystal nephropathy results from NLRP3-mediated inflammation. Since interactions between NLRP3 and Toll-like receptors (TLRs) have been described, we examined the role of TLRs to identify early molecular mechanisms initiating crystal-induced renal failure.

Methods: We evaluated the expression of TLRs in renal sections of mice and humans with crystal-induced renal failure. Age- and gender-matched wild-type and Tlr4-null mice were placed on a high soluble oxalate diet and monitored for progression of renal failure longitudinally by measuring plasma creatinine via retroorbital blood collections, and animals were monitored for mortality. Urine oxalate levels were measured and renal histology examined for crystal deposition, tubular damage and macrophage infiltration using F4/80 staining.

Results: Crystal-induced renal damage was observed to upregulate TLR4 expression in renal tubule epithelial cells and interstitium in mice and humans with oxalate nephropathy. Tlr4-null mice demonstrated reduced crystal deposition, tubular damage and inflammation on renal histology despite identical urinary oxalate excretion as compared to wild-type mice. Moreover, Tlr4-null mice were completely protected from the progressive renal failure that was associated with 100% mortality in wild-type mice.

Conclusions: Taken together, these findings highlight the importance of TLR4 as a critical mediator of crystal-induced inflammation and progressive renal failure. Blocking TLR4 with neutralizing antibodies/inhibitors may represent a therapeutic approach to treat patients suffering from crystal-induced inflammatory kidney disease.

SA-OR076

ALLN-177 Oral Enzyme Therapy Reduces Urinary Oxalate in Patients with Secondary Hyperoxaluria (2^0 HO) and Recurrent Kidney Stones: Results of a Phase 2 Study Gyan Pareek,[1] James E. Lingeman,[2] Zeph Okeke,[3] Linda H. Easter,[4] Danica Grujic,[5] Craig B. Langman,[6] Jennifer Nezzer,[7] Lee Brettman.[5] *[1]Miriam Hospital, Brown Univ; [2]IU Health Methodist; [3]North Shore LIJ; [4]Allena Conslt; [5]Allena; [6]NWU; [7]PRG.*

Background: (2^0HO) can lead to kidney stones (KS) and oxalate nephropathy which can result from excess absorption of dietery oxalate of an unknown cause idiopathic hyperoxaluria (IH), or in patients with enteric hyperoxaluria (EH). Presently there are no pharmacological therapies (Rx) to reduce 2^0HO. ALLN-177 is an orally-administered, oxalate-degrading enzyme Rx that significantly reduced oxalate excretion shown in a previous Phase 1 study. **Objective:** To test the efficacy and safety of ALLN-177 in patients with 2^0HO and a history of recurrent calcium oxalate KS.

Methods: 16 male and female patients with KS within the last 2y (5 EH and 11 IH), were enrolled in a multi-center, open-label, single arm study. Patients continued their regular diets and medical Rx (8/16 subjects had thiazides, K-citrate, or calcium supplements). The study had a 35d screening period, a 3d baseline, a 4d ALLN-177 Rx (7,500 u/meal TID) and a 4d follow up. 8x24h urines were collected. Safety assessments and 24h dietary recalls (DR) were performed. The 1^0 endpoint was the per subject change in mean 24h urinary oxalate (Uox) from baseline to ALLN-177 Rx.

Results: Mean baseline Uox (SD) for all subjects was 77.7 (55.9) mg/d and during 4 days of ALLN-177 Rx, it was reduced 14mg to 63.7 (40.2) mg/d, p=0.0084. Mean daily dietary oxalate, calcium and fluid intakes based on DR were 200, 199, 840 mg and 3.4 L, respectively and did not differ by study period. Mean baseline Uox for EH and IH were 110.5(82.9) vs. 62.7(33.8) mg/d, while the reduction on ALLN-177 Rx was 22.0 (26.6) vs 10.2 (13.3) mg/d, respectively. The CaOx relative urinary supersaturation index was reduced from 11.6 to 8.8, with 95% CI of [-4.9, -0.78]. This difference was driven by oxalate reduction, but not any other urinary parameters. ALLN-177 was well tolerated, and no safety issues were noted.

Conclusions: In this Phase 2 study, ALLN-177 significantly reduced urinary oxalate excretion and supersaturation index.

SA-OR077

Diet-Dependent Net Acid Load, Protein Intake, and Risk of Incident Kidney Stones Pietro Manuel Ferraro,[1,2] Ernest I. Mandel,[2] Gary C. Curhan,[2] Giovanni Gambaro,[1] Eric N. Taylor.[2] *[1]Div of Nephrology, Catholic Univ of the Sacred Heart, Rome, Italy; [2]Channing Div of Network Medicine, Harvard Medical School, Boston.*

Background: Higher dietary acid load and protein intake may increase risk of kidney stones (KS). However, associations between net acid load and stone risk have not been explored in population-based studies, and it is not known whether stone risk varies according to protein type.

Methods: We prospectively examined the association between estimated net endogenous acid production (NEAP), protein intake (vegetable [VP], dairy [DP] and animal non-dairy [AP]) and risk of incident KS in three large ongoing cohorts, the Health Professionals Follow-up Study (n=42,919 men), Nurses' Health Study I (n=60,128 older women), and Nurses' Health Study II (n=90,629 younger women). We used Cox hazards regression models to generate hazard ratios (HRs) adjusted for age, BMI, dietary, lifestyle, and medical factors. We also analyzed multivariable associations between NEAP and 24-h urine composition in >6,000 study participants.

Results: During 3,133,014 person-years of follow-up, there were 6,347 incident KS. There was a significant association between NEAP and KS risk in all cohorts (pooled HR for highest vs lowest quintile 1.41, 95% CI 1.16, 1.72; p-value for trend < 0.001). There was no association between VP intake and risk of KS. There was a significant association between AP intake and risk of KS in HPFS (HR 1.14, 95% CI 0.97, 1.35; p-value for trend = 0.04) and NHS I (HR 1.23, 95% CI 1.01, 1.49; p-value trend = 0.05) but not in NHS II. There was no association between DP and risk except in NHS II, where the HR was 0.83, 95% CI 0.72, 0.95; p-value trend =0.003. After multivariable adjustment, participants in the highest compared with lowest quintile of NEAP had 85 mg/d less urine citrate, 0.18 lower urine pH, 177 mL/d less urine volume, and higher urine supersaturations with respect to calcium oxalate and uric acid (all p-values ≤ 0.001).

Conclusions: In 3 large cohorts, higher NEAP is associated with higher risk of KS, as well as lower urine citrate and pH. In contrast with AP, VP and DP are not associated with higher risk of KS.

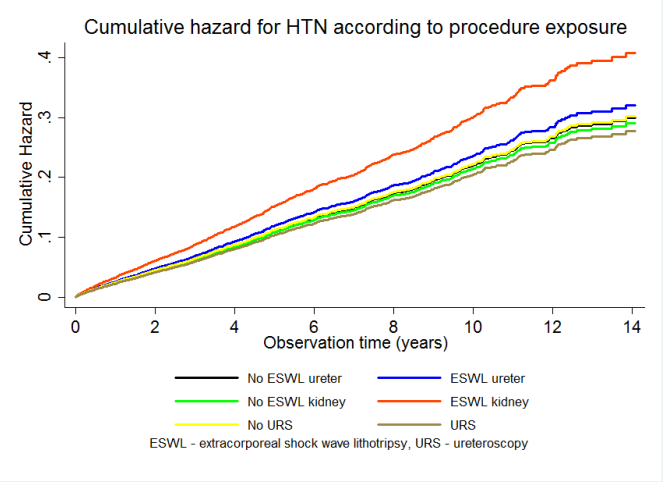
Urologic Interventions for Urolithiasis and Risk of Incident Hypertension and Chronic Kidney Disease: A Population-Based Cohort Study Michelle Denburg,[1,2] Thomas Jemielita,[2] Gregory Edward Tasian,[1,2] Kevin Haynes,[2] Phillip Mucksavage,[2] Justine Shults,[1,2] Lawrence A. Copelovitch.[1,2] *[1]The Children's Hospital of Philadelphia; [2]Perelman School of Medicine, Univ of Pennsylvania.*

Background: We sought to determine if among individuals with urolithiasis, extracorporeal shock wave lithotripsy (ESWL) and ureteroscopy (URS) are associated with a higher risk of incident hypertension (HTN) and/or chronic kidney disease (CKD).

Methods: A population-based retrospective cohort study using The Health Improvement Network comprised 11,570 participants (pts) with incident urolithiasis and 127,464 pts without urolithiasis; pre-existing HTN and CKD were excluded. 1319 and 919 of urolithiasis pts had [3]1 ESWL or URS procedure, respectively. Median year for the start of follow-up was 2006. Cox regression, adjusted for age, gender, diabetes, gout, and calendar time, was used to estimate the hazard ratio (HR) for incident HTN and CKD stage 3-5 in separate analyses.

Results: Over a median of 3.7 and 4.1 years, 1423 (12.3%) and 595 (5.1%) of urolithiasis pts developed HTN and CKD, respectively. Urolithiasis was associated with a HR for HTN of 1.42 (95% CI: 1.35, 1.51; p<0.001) and for CKD of 1.82 (95% CI: 1.67, 1.98; p <0.001). ESWL was associated with an increased risk of HTN with a HR of 1.34

(95% CI: 1.15, 1.57; p <0.001), while URS was not. When further stratified as ESWL to the kidney or ureter, only ESWL to the kidney was independently associated with HTN (HR 1.40, 95% CI: 1.19, 1.66; p <0.001).



Neither ESWL nor URS was associated with incident CKD.

Conclusions: Given that urolithiasis itself was associated with a HR of 1.42 for HTN, an individual who undergoes ESWL to the kidney can be expected to have a HR of 1.96 (95% CI: 1.67, 2.29; p <0.001) compared to an individual without urolithiasis. We recommend judicious use of ESWL if a calculus is asymptomatic or URS is a viable option.

Anti-MicroRNA-21 Oligonucleotides Prevent Renal Fibrosis Progression by Blocking the Auto-Regulatory Loop of miR-21/PDCD4/AP-1 During Myofibroblasts Activation Qi Sun, Junwei Yang. *Center for Kidney Disease, Second Affiliated Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: Renal fibrosis is a final common pathway of chronic kidney injury. During the injury, the resident fibroblasts are stimulated and trans-differentiated into myofibroblasts, which produce a large amount of extracellular matrix (ECM) components and ultimately lead to the loss of kidney function. Sustained activation of myofibroblasts is considered to play a key role in perpetuating renal fibrosis, but the driving force of myofibroblasts activation is only partially understood. Aberrant expression of miRNAs is associated with numerous pathologic processes including renal injury. To date, some investigations have identified specific overexpression of miR-21 in the progression of kidney fibrosis. Nevertheless, the precise role of miR-21 in myofibroblasts activation remains largely unknown.

Methods: To understand the role of miR-21 in the progression of kidney fibrosis, microarray and quantitative real-time PCR analysis were performed to examine the expression level of miR-21 in unilateral ureteral obstruction (UUO)-injured mice. Then, mice were administered with control or antagomir-21 before or during surgery by tail vein injection, to determine whether blocking miR-21 in kidneys affects UUO-induced renal fibrosis.

Results: In this study, we identified miR-21 was instantly up-regulated after TGF-b1 stimulation, and maintained itself at constant high levels by employing a microRNA-21/programmed cell death protein 4/activation protein-1 (miR-21/ PDCD4/ AP-1) auto-regulatory loop during myofibroblasts activation. The persistent up-regulated miR-21 depressed Smad7 and PTEN expression and eventually enhanced TGF-b1/Smad pathway to promote fibrosis progression. More importantly, we found miR-21 sequestration in mouse kidneys attenuated UUO-induced renal fibrosis.

Conclusions: Altogether, these data suggest that miR-21 is a main driving force of myofibroblasts activation and keeps its high expression level by an auto-regulatory loop of miR-21/PDCD4/AP-1. Targeting this aberrantly activated feedback loop may provide new therapeutic strategy in treating fibrotic kidneys.

Silencing of MicroRNA-132 Reduces Renal Fibrosis by Selectively Inhibiting Myofibroblast Proliferation Roel Bijkerk,[1,2] Ruben de Bruin,[1] Coen van Solingen,[1] Janine van Gils,[1] Jacques Duijs,[1] Eric P. van der Veer,[1] Ton J. Rabelink,[1] Benjamin D. Humphreys,[2] Anton Jan Van Zonneveld.[1] *[1]Dept of Nephrology and Einthoven Laboratory for Experimental Vascular Medicine, Leiden Univ Medical Center, Leiden, Netherlands; [2]Renal Div, Brigham & Women's Hospital and Harvard Medical School, Boston.*

Background: Chronic kidney disease is associated with progressive renal fibrosis. Lineage analysis has shown that FoxD1-derivative perivascular cells give rise to the majority of α-SMA positive myofibroblasts during renal fibrosis. We sought to identify pericytic microRNAs that could serve as a target to decrease myofibroblast formation.

Methods: To that end, we induced kidney fibrosis in FoxD1-GC;Z/Red-mice by unilateral ureteral obstruction (UUO) followed by FACS sorting of dsRed-positive FoxD1-derivative cells and profiled for differentially expressed miRNAs.

Results: MiR-132 expression selectively increased 21-fold during pericyte-to-myofibroblast formation whereas miR-132 was only 2.5-fold upregulated in total kidney lysates (both in UUO and ischemia-reperfusion injury). Antagomir-induced miR-132 silencing in the UUO model resulted in 35% decreased collagen deposition and decreased tubular apoptosis. Immunohistochemistry, Western blot and qRT-PCR analyses confirmed a similar decrease in α-SMA positive cells. Pathway analysis of differential gene expression in myofibroblasts identified a rate-limiting role for miR-132 in myofibroblast proliferation that was confirmed by *in vitro* studies with cultured fibroblasts. Indeed, UUO kidneys of antagomir-132 treated mice displayed a significant reduction in proliferating, ki67^{+} myofibroblasts. Interestingly, this reduction in proliferation was selective for the interstitial compartment and did not impair the reparative proliferation of tubular epithelial cells, as evidenced by increased numbers of ki67+ epithelial cells, as well as increased (p-)RB1 and Cyclin-A and decreased RASA1 and p21 levels in total kidney lysates.

Conclusions: Taken together, silencing miR-132 counteracts the progression of renal fibrosis by selectively decreasing myofibroblast proliferation and could potentially serve as a novel antifibrotic therapy.

Characterizing the Molecular Identity of Pathogenic Fibroblasts Using Single Cell RNAseq Yongen Chang,[1] Kai-Hui Sun,[1] Ian Driver,[2] Andrew J. King,[3] Meagan Fricano,[3] Jason Rock,[2] Nilgun Reed,[1] Dean Sheppard.[1] *[1]Dept of Medicine, Univ of California San Francisco, San Francisco, CA; [2]Dept of Anatomy, Univ of California San Francisco, San Francisco, CA; [3]Abbvie Inc., Chicago, IL.*

Background: Fibroblasts are the main effectors of organ fibrosis but their molecular identity is poorly understood. Using Col1a1-GFP mice, we isolated pathogenic fibroblasts from 3 fibrotic organs and performed single cell RNAseq analysis.

Methods: We induced fibrosis in the kidney (unilateral ureteral obstruction), lung (intratracheal bleomycin) and liver (carbon tetrachloride injections). With fluorescence-activated cell sorting, we isolated collagen-expressing GFP positive cells from each organ. Single cell cDNA was obtained via a fluidic system and libraries generated and sequenced. We performed hierarchical clustering (HC) analysis, principal component analysis (PCA) and targeted correlation assays on RNAseq data.

Results: We analyzed 130 kidney cells, 160 lung cells and 177 liver cells. HC and PCA analysis revealed 3 distinct groups of fibroblasts in fibrotic kidney and lung. Group 1 express high levels of collagen 1 and a set of fibroblast-related genes. Group 2 express low levels of collagen 1 and leukocyte markers. Group 3 express intermediate levels of collagen 1 as well as fibroblast-related genes and leukocyte markers. This group may represent circulated fibrocytes. In contrast, collagen-expressing cells in the liver are a mostly homogeneous population that differs substantially in gene expression from those of the lung and kidney. By correlation assays, we found 63 genes that highly correlate with col1a1 in renal, lung and liver fibroblasts. Some of these are known fibroblast-related genes but many are novel.

Conclusions: We characterized the molecular diversity of fibroblasts in 3 fibrotic organs. While pathogenic fibroblasts from the kidney, lung and, less so, liver share a core identity, they also each express a unique set of genes. This study may yield new biomarkers and therapeutic targets for treating fibrosis.

Persistent Activation of Autophagy in Kidney Tubular Cells Promotes Renal Interstitial Fibrosis During Unilateral Ureteral Obstruction Man J. Livingston,[1,2] Zheng Dong.[1,2] *[1]Georgia Regents Univ; [2]Charlie Norwood VA Medical Center, Augusta, GA.*

Background: Renal fibrosis is the final, common pathway of end stage renal disease. Whether and how autophagy contributes to renal fibrosis remains largely unknown.

Methods: Using pharmacological and genetic inhibitory approaches, our study has determined the regulation of renal interstitial fibrosis by autophagy in a mouse model of unilateral ureteral obstruction (UUO) and in TGF-b1-treated proximal tubular cells.

Results: UUO led to renal interstitial fibrosis, which was associated with persistent autophagy in kidney proximal tubules, as indicated by punctuate LC3 staining, LC3-II accumulation, P62 degradation as well as autophagosome formation and maturation. Pharmacological inhibitors of autophagy (chloroquine and 3-methyladenine) partially suppressed interstitial fibrosis during UUO. The inhibitors also suppressed apoptosis in renal tubules. Moreover, knockout of Atg7 specifically from kidney proximal tubules (PT-Atg7 KO) not only blocked autophagy but also attenuated renal fibrosis. Proliferation and activation of fibroblasts, as indicated by the expression of α-SMA and vimentin, was inhibited in these mice, so was the accumulation of extracellular matrix components including fibronectin and collagen fibrils. UUO induced 8.4% interstitial fibrosis in wild-type kidneys after 4 days of obstruction, which was further increased to 13.5% by 1 week and 25% after 2 weeks. The fibrotic lesions were significantly reduced in PT-Atg7 KO kidneys at all three time points, with 4.5% for 4-day, 7.9% for 1-week and 15.2% for 2-week respectively. UUO led to FGF2 expression in wild-type kidneys, which was markedly reduced in PT-Atg7 KO mice. PT-Atg7 KO mice also showed significantly less interstitial macrophage infiltration and tubular apoptosis. In cultured proximal tubular cells, TGF-b1 induced autophagy and the accumulation of fibronectin and, inhibition of autophagy suppressed fibronectin accumulation.

Conclusions: Together, the results suggest that persistent activation of autophagy in kidney proximal tubules promotes renal interstitial fibrosis by regulating tubular cell death, interstitial inflammation, and the production of profibrotic cytokines.

Macrophage Migration Inhibitory Factor Promotes Kidney Fibrosis in ADPKD Xia Zhou,[1,2] Li Chen,[1,2] Dorien J.M. Peters,[3] Mihaela Gadjeva,[4] Xiaogang Li.[1,2] *[1]Internal Medicine; [2]Kidney Inst, Univ of Kansas Medical Center, Kansas City, KS; [3]Leiden Univ Medical Center, Leiden, Netherlands; [4]Harvard Medical School, Boston, MA.*

Background: Macrophage migration inhibitory factor (MIF) is a pleotropic cytokine that functions to induce cell proliferation, inhibit apoptosis and regulate the inflammation. We found that MIF promoted renal cyst growth in different ADPKD mouse models (Chen et al., *JCI*, 2015). Renal cyst progression is accompanied by tubulointerstitial fibrosis which is associated with the renal function decline. However, whether MIF regulates fibrosis in ADPKD remains unknown.

Methods: To understand the role of MIF in regulating renal fibrosis in vivo, we generated *Pkd1*$^{nl/nl}$*:MIF*$^{-/-}$ mice.To explore the pathways mediated by MIF in regulating this process, we treated renal epithelial cells and fibroblasts with MIF or MIF inhibitor, ISO-1.

Results: We found that knockout of *MIF* or inhibition of MIF with ISO-1 not only delayed cyst growth but also decreased renal interstitial fibrosis as examinedby Trichrome Masson staining, and decreased the expression of TGFβ, Col1A1 and Col3A1 mRNA as analyzed by qRT-PCR in postnatal day 28 *Pkd1*$^{nl/nl}$ mice compared with age matched control mice. We further found that knockout of MIF or inhibition of MIF with ISO-1 decreased the phosphorylation and activation of ERK, Akt, S6 and Rb, which were associated with the fibroblast activation and fibrosis development in human diseases, in kidneys of Pkd1 mutant mice whereas fibroblasts treated with MIF induced the phosphorylation of ERK, Akt, S6 and Rb. In addition, MIF treatment induced the expression of 1) TGFβ in mouse IMCD3 cells, 2) COL1A1 and COL3A1 in mouse fibroblasts (NIH3T3), and 3) TGFβ, COL3A1 and fibronectin in rat kidney interstitial fibroblasts (NRF-49F). The expression of TGFβ, COL1A1, COL3A1 and fibronectin induced with or without MIF in the above cells could be inhibited or decreased by the treatment with ISO-1.

Conclusions: MIF activates the renal fibroblasts and promotes renal interstitial fibrosis in ADPKD, which may be mediated by TGFβ, ERK, mTOR and Rb signaling pathways. Targeting MIF may be a viable new therapy for ADPKD.

SA-OR084

HGF/c-met Signaling in Macrophages Attenuates Kidney Fibrosis by Regulating Matrix Remodeling and Turnover Haiyan Fu,[1] Dong Zhou,[1] Liangxiang Xiao,[1] Roderick J. Tan,[2] Youhua Liu.[1] *[1]Dept of Pathology, Univ of Pittsburgh, Pittsburgh, PA; [2]Dept of Medicine, Univ of Pittsburgh, Pittsburgh, PA.*

Background: Kidney fibrosis results from an excessive accumulation and deposition of extracellular matrix (ECM). This is mainly due to an imbalance between matrix synthesis and degradation. While significant progress has been made recently on identifying the matrix-producing cells and elucidating how they are regulated, relatively little is known about the mechanism controlling matrix degradation and turnover.

Methods: We generated hepatocyte growth factor (HGF) receptor c-met conditional knockout mice in which c-met was deleted specifically in myeloid cells including macrophages (Mac-c-met-/-). MIce were then subjected to renal unilateral ischemia/reperfusion injury (UIRI) or unilateral ureteral obstruction (UUO), respectively. Cultured bone-marrow-derived macrophages were also used.

Results: Mice with macrophage-specific ablation of c-met were phenotypically normal. We found that at different time points (3, 7 and 14 days) after UUO, there was no difference in the mRNA levels of major fibrosis-related genes such as α-SMA, collagen I, collagen III and fibronectin in the kidneys between Mac-c-met-/- and control mice, suggesting that HGF signaling in macrophages does not affect matrix synthesis. However, kidney fibrotic lesions as assessed by Masson's-Trichrome staining were more profound in Mac-c-met-/- mice than controls. Comparable results were obtained after analysis of matrix proteins by Western blot. Similarly, in UIRI model, loss of c-met in macrophage significantly aggravated renal lesions at 10 days, with elevated serum creatinine and increased deposition of matrix proteins, whereas renal mRNA expression of major matrix genes was not changed. In vivo, increased deposition of ECM was closely associated with the down-regulation of tissue-type plasminogen activator (tPA) in Mac-c-met-/- kidneys. In vitro, HGF induced tPA, uPA and MMP-12 expression in cultured bone marrow-derived macrophages.

Conclusions: These results suggested that HGF/c-met signaling in macrophages plays a critical role in reducing kidney fibrosis by promoting matrix degradation and turnover.

The Hippo-Salvador Signaling Pathway Regulates Renal Tubulointerstitial Fibrosis Yong kyun Kim,[1] Sun-ah Nam,[2] Wan-Young Kim,[2] Arum Choi,[2] Yumi Kim,[2] Jin Kim.[2] *[1]Dept of Internal Medicine, Medical College, The Catholic Univ of Korea, Seoul, Korea; [2]Dept of Anatomy and Cell Death Disease Research Center, College of Medicine, The Catholic Univ of Korea, Seoul, Korea.*

Background: Renal tubulointerstitial fibrosis (TIF) is the final common pathway of various renal injuries. The mammalian Hippo-Salvador signaling pathway is a highly conserved kinase cascade that regulates contact inhibition, cell proliferation, organ size control, tissue regeneration and tumorinogenesis. The expression pattern and the role of Hippo-Salvador signaling pathway on development of renal TIF remain unknown. Here, we reported that activation of Hippo-Salvador pathway in tubular epithelial cell (TEC) in patients and in mouse model of TIF plays a role in TIF development.

Methods: The expression of Hippo-Salvador pathway including WW45, Mst1/2, Lats1/2, YAP/TAZ were examined . TEC-specific WW45 knockout mice (WW45$^{flox/flox}$;Ksp-Cre^{+}) were generated for in vivo experiments and Hippo-Salvador pathway were knock-downed or overexpressed in HK2 cells. Unilateral ureteral obstruction (UUO) was used for in vivo model and TGF- β treatment was used for in vitro model of renal fibrosis.

Results: Expression of WW45 (a homolog of Drosophilia Salvador and adaptor for the Hippo kinase) and TAZ (transcriptional coactivator with PDZ binding motif, a WW-domain transcriptional regulator) were increased after UUO in mice and in TEC in patients with CKD. In vivo, TEC-specific WW45 deletion enhanced renal TIF after UUO. TEC-specific WW45 deletion enhanced apoptosis and proliferation of TECs after UUO. The expression of TAZ was increased in the kidneys of WW45-deficeint mice after UUO. In Vitro,WW45 deletion induced EMT by TGF-β treatment. WW45 deficiency enhances TGF-β signaling by the interaction of TAZ with Smads.WW45 deficiency also increases activated β-catenin dependent on TAZ.

Conclusions: Our data showed that Hippo-Salvador pathway regulate renal TIF and EMT through TGF-β/Smad and Wnt/β-catenin signaling. Our experiments suggest that Hippo-Salvador pathway is a new mechanism in the pathogenesis of TIF development and indicate that regulation of Hippo signaling pathway may be a therapeutic target to reduce TIF.

SA-OR086

Cytosine Methylation Levels Determine Regeneration versus Fibrosis After Injury Kriti Gaur, Ae Seo Deok Park, Frank S. Chinga, Katalin Susztak. *Renal Electrolyte and Hypertension Div, Univ of Pennsylvania.*

Background: Cytosine methylation is an epigenetic mark that regulates gene expression, whereby increased methylation of promoter regions inhibits gene transcription by interfering with transcription factor binding. We previously showed that human CKD and DKD samples have differences in cytosine methylation levels. We hypothesize that these cytosine methylation differences are functionally important in the pathophysiology of CKD. The ten-eleven translocation (TET) family of proteins, regulate DNA methylation status by oxidizing 5-methylcytosine (mC) to 5-hydroxymethylcytosine (5hmC). In the absence of TET2, there is increased cytosine methylation and decreased hydroxymethylation. Here we examined the functional role of tubular epithelial cell (TEC) methylation levels *in vivo* by deleting TET2 in TECs.

Methods: TET2$^{flox/flox}$ and Cadherin 16 Cre mice were crossed to generate animals with renal tubular epithelial cell deletion of TET2. Kidney injury was induced by administering folic acid intraperitoneally at 6 weeks of age, at a dose of 250mg/kg of body weight and sacrificed 1 or 12 weeks later. Mouse kidneys and primary epithelial cells were analyzed by quantitative RT-PCR, and immunohistochemistry to examine fibrotic changes.

Results: Mice with TEC specific deletion of TET2 appeared histologically normal. We hypothesize that this may be due to the low turnover rate of tubule cells in the kidney. Acute kidney injury and regeneration was induced through administration of folic-acid. Twelve weeks after folate administration control animals almost recovered, while fibrosis appeared more even severe in mice with TEC specific deletion of TET2. These TET2 null mice also had increased expression of collagen, activated myofibroblast and inflammatory markers. We believe that fibrosis developed as a secondary consequence of impaired epithelial cell differentiation, as TET2-deficient TECs remained undifferentiated and yet continued to proliferate.

Conclusions: TET2 is an epigenetic director of renal epithelial repair following injury. Increased TEC cytosine methylation levels interfere with epithelial cell differentiation and directs cells into a profibrotic phenotype.

SA-OR087

Roles of CCN2 and Caspase Activities in Tubular Epithelial Cells Involved in AKI Transition to CKD Takeru Kusano, Tsutomu Inoue, Hirokazu Okada. *Saitama Medical Univ, Iruma-gun, Saitama, Japan.*

Background: In AKI, severely injured tubular epithelial cells (TEC) are destined to be removed by apoptosis while a small part of them survive and transform, which then facilitate interstitial fibrosis (IF).(Nat Med 16;535, 2010) We previously reported that CCN2 and caspase activities in TEC are important for IF in CKD models.(JASN 16;133, 2005, Clin Exp Nephrol (in press)) In this study, we investigate possible linkages between AKI and CKD, focusing especially on roles of CCN2 and caspase activities in TEC.

Methods: CCN2-haploinsufficiency mice (CCN2$^{fx/-}$), mice transgenic for baculovirus pan-caspase inhibitor p35 gene in a nonexpression state (p35), and mice carrying Cre recombinase under the control of proximal tubule-specific g-glutamyltransferase promoter (g-GT.Cre) are used for generation of following mice; g-GT.Cre:p35, p35 is expressed in

TEC; g-GT.Cre:CCN2$^{fx/-}$, CCN2 expression is defected in TEC; g-GT.Cre:p35:CCN2$^{fx/-}$, defective CCN2 with p35 expression in TEC; and CCN2$^{fx/-}$ as the control. We performed 1 hour ischemia and reperfusion injury (IRI) on these 4 groups of mice and evaluated renal fibrosis on day 14.

Results: The mRNA levels of collagen I (ColI),fibronectin EIIIA (FN) and TGF-b1 were significantly lower in g-GT.Cre:CCN2$^{fx/-}$ mice than the control mice (ColI: 7.26±0.62 vs. 63.5±16.7, FN: 1.29±0.18 vs. 9.96±2.83, TGF-b1: 0.83±0.12 vs. 4.35±0.98)($p<0.05$). The fibrosis area% in Masson trichrome stain was significantly narrower in g-GT.Cre:CCN2$^{fx/-}$ mice than the control mice (7.46±1.36% vs. 34.8±3.16%)($p<0.05$). In the comparison between g-GT.Cre:p35CCN2$^{fx/-}$ and g-GT.Cre:CCN2$^{fx/-}$ mice, the fibrosis area% was significantly wider in g-GT.Cre:p35CCN2$^{fx/-}$ mice (16.4±2.12 vs. 7.26±0.62) ($p<0.05$). We also revealed that the number of phosphorylated histone H3-positive TEC were significantly higher in g-GT.Cre:p35CCN2$^{fx/-}$ mice.

Conclusions: In conclusion, CCN2 expressed in TEC promotes IF, a typical feature of CKD, following IRI in the post-AKI kidney. Furthermore, it appears that TEC escaped from caspase activities after IRI exacerbate IF irrespectively of CCN2. Thus, caspase activities and CCN2 in TEC are likely involved in AKI transition to CKD in the opposite direction, at least after IRI.

SA-OR088

Repeated Minor AKI Accelerates Renal Fibrosis and Dysfunction in Klotho Deficit Mice Ken Tsuchiya, Hidekazu Sugiura, Miki Nishida, Kenichi Akiyama, Kosaku Nitta. *Dept of Medicine IV, Tokyo Women's Medical Univ, Shinjuku-ku, Tokyo, Japan.*

Background: It has been recognized that AKI and CKD are not independent disease but integrated syndrome in which there is bidirectional nature of the relationship between them. Especially, frequent occurrence of minor AKI induces acceleration to advancing to the CKD. On the other hand, Klotho protein is one of the key modulator in the preceding the CKD, during which expression of Klotho is markedly suppressed in CKD. Acceleration of renal fibrosis is a basic pathophysiology for progression of CKD, and previously, we showed that the renal interstitial fibrosis was severer in the *kl* (+/-) mice than those in the wild-type mice by ureteral obstruction procedure. So, we hypothesized that kidney with reduced Kltoho expression was more vulnerable to minor or repeated stress during the progression of CKD pathophysiology.

Methods: We explored the effects of repeated minor AKI on the kidney in the rodent model of reduce Klotho expression. Minor AKI was induced by short time clamping of renal artery, once a week for 3 weeks in *kl* (-/+) and wild type mice. Serum creatinine level was measured and the expression levels of fibrosis related marker, such alpha SMA, MCP-1etc., by immunostining and RT-PCR was assessed. Internal expression of Klotho was modified by gene delivery.

Results: Frequent AKI reduced the renal function much more (70% higher in Cr) in *kl* (-/+) mice than wild type mice. Klotho expression quickly diminished after each ischemic maneuver. The expression of fibrotic markers increased (2.2 folds) in the kidney comparing with wild type kidney. The reduction of renal function and tissue damage was attenuated by Klotho gene delivery. Preliminary, gene screening suggested more down regulation of heat shock protein and ATF by AKI accumulation in *kl* (-/+) mouse kidney.

Conclusions: It is likely that reduction of Klotho levels in the kidney, such as in aging or CKD, is a risk factor for accelerating the progression of CKD, resulting in sensitive status to various kinds and frequency of renal damage, and upregulation of the Klotho may attenuate advancing the kidney dysfunction, which is one possible strategies for preventing the final pathway to the ESRD.

SA-OR089

Global Prevalence of Protein-Energy Wasting (PEW) in Kidney Disease: Systematic Review and Meta-Analysis of Contemporary Cohort Studies by the International Society of Renal Nutrition and Metabolism (ISRNM) Juan Jesus Carrero,[1] Csaba P. Kovesdy,[2] Miklos Zsolt Molnar.[2] *[1]Karolinska Inst, Stockholm, Sweden; [2]Univ of Tennessee Health Science Center, Memphis, TN.*

Background: PEW is a common complication in kidney disease, but its prevalence is poorly defined. To increase awareness on the commonness of PEW, we performed a meta-analysis of its global prevalence throughout the kidney disease spectrum.

Methods: We performed a systematic review and meta-analysis of contemporary cohort studies including >50 patients with kidney disease and reporting on PEW prevalence by either subjective global assessment (SGA) or malnutrition-inflammation score (MIS). Searches were restricted to Jan 2000-Nov 2014. Data was reviewed throughout different kidney disease strata (acute kidney injury [AKI], pediatric chronic kidney disease [CKD], non-dialyzed CKD 3-5, dialysis and renal transplant [Tx]). Because PEW may reflect underlying country-specific malnutrition, studies including dialysis patients were analyzed after clustering by their countries' Gross National Income (GNI).

Results: No studies including pediatric patients fulfilled the inclusion criteria for meta-analysis. The PEW meta-prevalence of the rest of kidney disease strata is summarized in the table, along with number of patients and studies. In studies including dialysis patients, PEW prevalence increased considerably across worsening GNI clusters, being consistently higher in peritoneal dialysis (PD) as compared to hemodialysis (HD) patients.

Stratum	Nº of studies	Nº of patients	PEW Prevalence (95% CI)
AKI	4	387	63% (58-67)
non-dialyzed CKD 3-5	12	2682	21% (19-22)
Tx patients	2	1067	30% (28-33)
Dialysis, high-income countries	64	5920 3339 in HD 2581 in PD	35% (34-46) 41% (40-43)
Dialysis, upper middle-income countries	53	8923 5844 in HD 3079 in PD	42% (41-44) 50% (49-52)
Dialysis, low-income countries	8	887 588 in HD 299 in PD	62% (58-66) 74% (69-78)

Conclusions: PEW is common across the entire spectrum of kidney diseases, but it exhibits the highest prevalence among dialysis and AKI patients. Its commonness, together with its well-documented impact on patient outcomes, deserves increased medical attention.

SA-OR090

A Novel Deleterious Role for Dietary Salt-Sugar Interplay in Metabolic Syndrome and Elevated Blood Pressure in Mice Miguel A. Lanaspa, Christina Cicerchi, Ana Andres-hernando, Carlos Alberto Roncal-jimenez, Takuji Ishimoto, Richard J. Johnson. *Univ of Colorado Denver, Aurora, CO.*

Background: High amounts and chronic salt intake are important risk factors for the development and progression of hypertension. Our group has described that also sugars, and in particular fructose, contribute to the pathogenesis of elevated blood pressure thus suggesting a potential interplay between both dietary components in hypertension and metabolic syndrome. Consistently, increased sodium excretion is observed in obese people. Here, we aim to determine whether dietary salt can play a deleterious role in the pathogenesis of other features of metabolic syndrome besides hypertension and if it is related to sugar metabolism.

Methods: Wild type and fructokinase deficient mice –that cannot metabolize sugar and fructose- were exposed to 1% salt in drinking water for 30 weeks and features of metabolic syndrome including elevated blood pressure, fatty liver, insulin resistance, leptin resistance and weight gain were determined.

Results: Exposure of mice to salt induced the hypertonic activation of aldose reductase and the endogenous production of fructose in liver, pancreas and fat. Consistent with increased fructose production and metabolism in these tissues, wild type but not fructokinase deficient mice demonstrated significantly higher fat deposition, fatty liver and blood pressure compared to controls. Furthermore, salt intake in wild type mice induced a significant increase in insulin resistance as determined by oral glucose and insulin tolerance test, hyperleptinemia, hypothalamic leptin resistance, increased food intake and body weight gain compared to fructokinase deficient mice.

Conclusions: Our study indicates that dietary salt can induce multiple features of metabolic syndrome besides high blood pressure. It also suggests interplay between salt and sugar in which salt will induce the endogenous production of fructose . The metabolism of endogenous fructose by fructokinase would be the underlying factor for salt-induced metabolic syndrome in mice. Thus, blockade of fructokinase could be a novel therapeutic approach for the prevention and treatment of hypertension and metabolic syndrome.

Sodium Chloride Promotes Tissue Inflammation via Osmotic Stimuli in Subtotal Nephrectomized Mice Fumiko Sakata,[1] Yasuhiko Ito,[1] Masashi Mizuno,[1] Yasuhiro Suzuki,[1] Takeshi Terabayashi,[1] Takako Tomita,[1] Mitsuhiro Tawada,[1] Shoichi Maruyama,[1] Enyu Imai,[2] Yoshifumi Takei,[1] Seiichi Matsuo.[1] *[1]Nephrology and Biochemistry, Nagoya Univ, Nagoya, Japan; [2]Nephrology, Nakayamadera Imai Clinic, Takarazuka, Japan.*

Background: Chronic inflammation is prevalent in patients with end-stage renal disease, but the precise mechanisms remain unclear. Sodium that is reportedly stored in tissues after high salt intake induces lymphangiogenesis and autoimmune diseases via osmotic stimuli. We studied the effects and mechanisms of high salt loading on tissues and systemic inflammation (with a focus on macrophage infiltration) in sub-total nephrectomized (5/6Nx) mice and in cultured cells.

Methods: Mice underwent 5/6Nx or sham surgery (Sham), and were provided with either tap water (Water) or 1% NaCl (NaCl) for four weeks. Inflammatory changes in peritoneal wall, heart and paraaortic tissues were evaluated by immunohistochemistry, Western blot, ELISA and quantitative PCR. Inhibition studies were performed in vivo and in vitro.

Results: Significantly more macrophages infiltrated the peritoneal wall ($p < 0.001$), heart ($p < 0.05$) and paraaortic tissues ($p < 0.001$) of sub-total nephrectomized mice with salt loading (5/6Nx/NaCl) compared with 5/6Nx/Water. Tissue levels of IL-6, monocyte chemotactic protein-1 (MCP-1) and tonicity-responsive enhancer binding protein (TonEBP) were significantly increased in the peritoneal wall and heart of 5/6Nx/NaCl compared with 5/6Nx/Water. The administration of furosemide or tap water after NaCl for four weeks, indicating reverse NaCl loading, reduced local macrophage infiltration associated with the suppression of MCP-1 ($p < 0.05$) and TonEBP mRNA ($p < 0.01$). A high NaCl concentration

in the culture media of mesothelial cells and cardiomyocytes induced MCP-1 protein, MCP-1 mRNA, serum- and glucocorticoid-inducible kinase 1 (Sgk1), and TonEBP mRNA, all of which were suppressed by TonEBP siRNA and upregulated in 5/6Nx/NaCl. The induction of MCP-1 by high salt did not involve Rac1.

Conclusions: High salt intake enhances macrophage infiltration via the TonEBP-MCP-1 pathway in association with inflammation, oxidative stress and Sgk1 activation during renal failure.

The Relationship of Chronic Kidney Disease Severity with Urine Sodium Excretion Cheryl A. Anderson,[1] Amanda K. Leonberg-Yoo,[2] Joachim H. Ix,[1] Mark J. Sarnak,[2] Lawrence J. Appel.[3] *[1]Univ of California San Diego; [2]Tufts Medical Center; [3]Johns Hopkins Medical Insts.*

Background: In healthy individuals, the gold standard measurement for sodium intake is 24-hour urine excretion. It is unknown whether chronic kidney disease (CKD) severity affects this measurement. We aimed to evaluate whether sodium excretion differs by level of glomerular filtration rate (GFR). We hypothesized that with increased CKD severity, 24-hr urine excretion is reduced, possibly as a result of a greater fraction of sodium being excreted by non-renal pathways (e.g. sweat or lower intestinal absorption) as kidney function declines.

Methods: Baseline data from the African American Study of Kidney Disease and Hypertension (AASK) and the Modification of Diet in Renal Disease (MDRD) Study were used to separately examine the relationship between GFR measured by iothalamate clearance and 24-hour urine sodium excretion. Both studies recruited individuals with reduced GFR. Urine sodium excretion was measured using a single 24-hour urine collection. Linear regression models were adjusted for age, race, sex, and BMI.

Results: In AASK (n=1093) and MDRD (n=814), baseline mean(SD) age was 54.5(10.7) and 51.4 (12.4) years; mean(SD) for GFR (mL/min/1.73m2) was 46.8(14.1) and 33.5(12); and mean(SD) for sodium (g/day) was 3.7(2.0) and 3.5 (1.5); respectively. After adjustment, each SD reduction in GFR was associated with a 0.24 g/day (p=0.002) lower sodium excretion in AASK; and a 0.15 g/day (p=0.001) lower sodium excretion in MDRD.

Conclusions: Our findings challenge the existing paradigm that the amount of sodium excreted in a 24-hour urine collection is roughly equivalent to intake in all persons. Further, the association of reduced urine sodium excretion with advanced CKD may help explain paradoxical risk relationships in studies that did not take into account concurrent kidney function. Controlled balance studies in CKD patients are needed to confirm our findings.

SA-OR093

Lower Risk of ESRD Associated with DASH Diet in Adults with Moderate CKD and Hypertension Tanushree Banerjee,[1] Deidra C. Crews,[2] Meda E. Pavkov,[3] Nilka Rios Burrows,[3] Jennifer L. Bragg-Gresham,[4] Rajiv Saran,[4] Neil R. Powe.[1] *[1]UCSF; [2]JHU; [3]CDC; [4]U Michigan, Ann Arbor.*

Background: Although the Dietary Approaches to Stop Hypertension (DASH) diet, rich in fruits, vegetables, and plant derived protein, has been shown to reduce blood pressure in individuals with normal and mildly impaired kidney function, it is not known whether the DASH diet impacts CKD progression among patients with moderate CKD.

Methods: We determined a baseline diet adherence score (higher score=greater adherence), consistent with DASH diet recommendations, using a 24-hour dietary recall questionnaire in a cohort of 1,110 adults with moderate CKD (eGFR 30-59ml/min/1.73m^2) and hypertension from the National Health and Nutrition Examination Survey III (1988-1994).We related this score to the development of ESRD ascertained over a median of 14.2 years of follow-up via linkage with the Medicare ESRD Registry. We examined the association of baseline level of DASH diet adherence with ESRD after adjusting for demographics, diabetes, eGFR, and albuminuria, while accounting for intervening mortality events using the Fine-Gray competing risks method.

Results: A total of 267 (24.1%) participants developed ESRD. Baseline level of adherence to the DASH diet was greater among older vs younger adults (57.9% vs 42.1%), females vs males (60.4% vs 39.6%), and whites vs blacks (61.4% vs 18.3%); ^{v} $p<0.05$. Compared to quintile 5 (greatest DASH diet adherence score) there was a greater risk of ESRD with lower adherence scores --for quintile 4: Relative Hazard [95% CI] = 1.1[0.8-1.6], for quintile 3: 1.5[0.9-2.8], for quintile 2: 2.7[1.8-3.3] and for quintile 1 (lowest adherence): 1.9[1.4-2.7] (p for trend =0.001). There was effect modification by the DASH score quintiles and diabetes (p-interaction=0.03). The higher risk of ESRD with lower adherence was present among participants with diabetes (2.5[1.4-4.6]) but not among participants with no diabetes (0.7[0.4-1.4]).

Conclusions: Adherence to the DASH diet may lower the risk of progression to ESRD in adults with moderate CKD and hypertension, particularly among persons with diabetes. Our results provide evidence that the DASH diet may be beneficial for adults with moderate CKD.

SA-OR094

Normal Weight with Central Obesity Is Associated with the Highest Risk of Coronary Artery Calcification in Chronic Kidney Disease Patients Mi Jung Lee,[1] Shin-Wook Kang,[1] Curie Ahn,[2] Tae-Hyun Yoo.[1] *[1]Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea; [2]Dept of Internal Medicine, Seoul National Univ, Seoul, Korea.*

Background: In chronic kidney disease (CKD), body mass index (BMI) showed a U-shaped association with cardiovascular (CV) risk. In contrast, central obesity was directly associated with increased CV risk. This bi-directional relationship prompted us to evaluate the CV risk assessed by coronary artery calcification (CAC) based on a combination of BMI and waist-to-hip ratio (WHR) in CKD patients.

Methods: We included 1,217 CKD stage 1 to 5 patients who enrolled in the KoreaN cohort study for Outcome in patients With Chronic Kidney Disease. Patients were divided into 3 groups by BMI (normal, 18.5≤ to <23.0; overweight, £23.0 to <27.5; obese, >27.5 kg/m^2) and were dichotomized by sex-specific median of WHR (0.92 in male; 0.88 in female). CAC was defined as >10 Agatston using a multi-slice computed tomography. Logistic regression analysis was used to assess the independent association of CAC with BMI, WHR, and cross-categorization of BMI and WHR, respectively.

Results: CAC was observed in 500 patients (41.4%). Multivariate logistic regression analysis indicated that BMI was not independently associated with CAC (per 1 kg/m^2 increase, odds ratio [OR]=1.03, 95% confidence interval [CI]=0.98-1.08, P=0.24). However, WHR showed an independent linear association with CAC (per 0.01 increase, OR=1.04, 95% CI=1.02-1.07, P<0.001). Furthermore, when patients were categorized into 6 groups according to combination of BMI and WHR, normal BMI but increased WHR (OR=1.91, 95% CI=1.05-3.48, P=0.03) had the highest risk of CAC compared to others (normal BMI with lower WHR, as reference; overweight with lower WHR, OR=1.46, 95% CI=0.93-2.30, P=0.10; obese with lower WHR, OR=1.51, 95% CI=0.68-3.40, P=0.31; overweight with increased WHR, OR=1.45, 95% CI=0.95-2.22, P=0.06; obese with increased WHR, OR=1.49, 95% CI=0.88-2.53, P=0.14).

Conclusions: In CKD patients, normal weight with central obesity was associated with the highest risk of CAC, suggesting that combining BMI and WHR could be more helpful to stratify CV risk than BMI alone.

MicroRNA-27a Is Decreased in Skeletal Muscle During Atrophy and Is Regulated by Calcineurin/NFAT Signaling: A Regulatory Mechanism for Myostatin Expression Xiaonan H. Wang,[1] Russ Price,[1,2] Jill A. Rahnert,[1] Matthew B. Hudson.[1] *[1]Medicine/Nephrology, Emory Univ, Atlanta, GA; [2]Atlanta VAMC, Atlanta, GA.*

Background: Muscle atrophy occurs in chronic conditions like chronic kidney disease and diabetes. Production of myostatin by muscle plays a central role in the pathogenesis of atrophy during these conditions and research has recently focused on understanding how myostatin (MSTN) is controlled in muscle. MicroRNA-27a (miR-27a) can target MSTN mRNA and decrease MSTN protein in muscle; however, the mechanism(s) that control the level of miR-27a under atrophy-inducing conditions are unknown. The objective of our study was to investigate how miR-27a is regulated during muscle atrophy.

Methods: Diabetes was induced in rats by a single IV injection of 125/mg streptozotocin (STZ). Muscles were harvested 3 days later. Since glucocorticoids mediate many atrophy-inducing effects of diabetes and CKD, some studies were conducted with C2C12 muscle cells incubated with dexamethasone (DEX; 100 nM, 48 h). miR-27a was measured by quantitative RT-PCR using U6 as a control miR.

Results: In hindlimb muscles of STZ rats, miR-27a was decreased 40±3% (mean±SEM), a finding consistent with the reported elevation in MSTN during diabetes. Similarly, treatment of C2C12 myotubes with DEX reduced miR-27a 68±3% within 0.5 h and this suppression was sustained at >51% for at least 48 h. The miR-23a/miR24-2/miR-27a cluster has been reported to be regulated by Calcineurin(CnA)/NFAT signaling and earlier, we found that CnA activity is reduced in skeletal muscle during CKD and STZ and in muscle cells following DEX treatment. Therefore, we investigated the relationship between CnA and miR-27a by measuring miR-27a following alteration in CnA activity. Infection of muscle cells with an adenovirus to overexpress constitutively active CnA increased miR-27a by 35±3%.

Conclusions: These results are consistent with a model in which atrophy-inducing conditions regulate MSTN production in skeletal muscle in part by reducing the level of miR-27a via a mechanism that involves decreased CnA/NFAT signaling. The resulting increase in MSTN will exacerbate muscle loss by accelerating proteolysis.

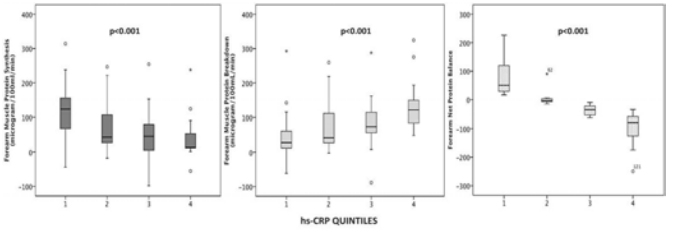
Systemic Inflammation Affects Skeletal Muscle Protein Homeostasis in Maintenance Hemodialysis (MHD) Patients Serpil Muge Deger,[1,2] Adriana Hung,[1,2] Edward D. Siew,[1,2] Cindy Booker,[1,2] Talat Alp Ikizler.[1,2] *[1]Vanderbilt Univ, TN; [2]VA, Nashville, TN.*

Background: Systemic inflammation is closely associated with protein energy wasting (PEW) in MHD. In order to understand its metabolic effects on skeletal muscle metabolism, we examined whole body and skeletal muscle protein turnover in MHD patients with varying degrees of inflammation.

Methods: 129 MHD patients participating in metabolic studies between 1998 and 2011 were included in this analysis. Whole body and forearm skeletal muscle protein turnover was examined using primed infusions of L- (1-(13) C) leucine and L-(ring-(2) H(5)) phenylalanine.

Results: Mean age was 45 ±13 years, 73% were male, 26% were white and 22% had DM. BMI was 28.8 ±7.5 kg/m^2, median (IQR) hs-CRP was 13(0.8, 33.8) mg/dL and HOMA-IR 1.53 (0.74, 2.87). Forearm muscle protein synthesis (FAPS), breakdown (FAPB) and net balance (FANB) were [median (IQR)] 57 (14, 94), 69 (32, 118) and -21 (-58, 22) ug/100ml/min, respectively. Whole body PS, PB and NB were 4.7 (3.8, 5.4), 3.75 (3.2, 4.3) and 0.43 (-0.36, 0.77) mg/kgffm/min, respectively. There was a strong positive correlation between hs-CRP and FAPB (r=0,544 p<0.001) and strong inverse correlation with FAPS (r=-0.525; p<0.001) and FANB (r= -0.957, p<0.001).The FAPB was significantly higher and FAPS and FANB were lower in subjects in the highest quartile of hs-CRP versus all other quartiles (p<0.01 for all).



After adjustment for age, sex, HOMA-IR, and serum HCO3, hs-CRP remained statistically significant predictor of all components of FA protein homeostasis. There were no significant associations between whole-body protein turnover and hs-CRP levels.

Conclusions: Hs-CRP levels independently predict skeletal muscle protein homeostasis in MHD patients. These data suggest that systemic inflammation is an appropriate target for treatment of PEW in MHD patients.

IL-1 Blockade Improves Adiponectin (ADPN) Levels in Patients with CKD Stages 3 and 4

Adriana Hung,[1,2] Kristen L. Nowak,[3] Talat Alp Ikizler,[1,2] Natjalie Salas,[2] Heather Farmer,[3] Rafia I. Chaudhry,[2] Michel Chonchol.[3] *[1]Nashville VA, TN; [2]Vanderbilt Univ, TN; [3]Univ of Colorado Denver, CO.*

Background: Adiponectin (ADPN), an adipose tissue-derived hormone, is known to have insulin sensitizing, anti-inflammatory, and anti-atherogenic properties in the general population. ADPN secretion is suppressed by systemic inflammation, a highly prevalent condition in chronic kidney disease (CKD), and may have cardiovascular health implications in this population. In this study, we evaluated whether short-term administration of a interleukin-1 (IL-1) blocker, improves ADPN levels and insulin sensitivity in patients with CKD stages 3&4.

Methods: This study was a pilot randomized placebo-controlled double-blind trial of administration of IL-1 blockade in patients with CKD stages 3&4. Forty-two patients were randomly assigned (1:1) to receive 160 mg of an IL-1 blocker (rilonacept) or placebo for 12 weeks; 37 completed the trial. The primary outcomes for this analysis were the effect of the intervention on the serum levels of ADPN, leptin, leptin adiponectin ratio (LAR) and HOMA IR. Mixed effect models were used for all analysis.

Results: Mean age was 63±11 years, the median eGFR 37.9 (IQR 29.1, 46.7) ml/min, 76% were males and 24% were African Americans. The values for ADPN, leptin, LAR and HOMA IR at baseline were 17.8±17.42 µg/mL, 27.7±22.8 ng/mL, 2.63±2.76 and 5.6±5.35, respectively. IL-1 blockade resulted in an increase in serum ADPN in the intervention group compared to placebo (p=0.03). Leptin, LAR or HOMA IR levels did not change significantly [table 1].

Table 1. Metabolic indices at baseline and week 12

	IL-1 blockade	Placebo	P-value*
Adiponectin, µ/mL			
baseline	21.1 ± 21.7	13.9 ± 8.1	0.03
Week 12	23.6 ± 24.5	12.7 ± 7.1	
Leptin, ng/mL			
baseline	28.4 ± 23.7	28.3± 23.8	0.8
Week 12	27.2 ± 19.2	26.7 ± 25.6	
LAR			
baseline	2.86 ± 3.2	2.6 ± 2.3	0.3
Week 12	2.02 ± 2.4	3.0 ± 3.1	
HOMA-IR			
baseline	4.73 ± 4.7	6.1 ± 6.5	0.3
Week 12	4.38 ± 3.5	6.9 ± 6.1	

* P-value for test of the difference in change at week 12 between groups

Conclusions: Short-term administration of an IL-1 blocker significantly increased ADPN levels among patients with CKD stages 3&4. The intervention did not impact other insulin sensitivity parameters, including HOMA-IR, leptin and LAR. Results are consistent with those observed in dialysis patients.

Effects of Chronic Intradialytic Resistance Physical Exercises in Nrf2 and NF-κB Expression and Antioxidant Enzymes in Hemodialysis Patients

Denise Mafra, Cinthia Da costa Abreu, Milena Barcza Stockler-Pinto, Ludmila Fmf Cardozo. *Post-Graduate Program in Cardiovascular Sciences, Fluminense Federal Univ (UFF), Niterói, Rio de Janeiro, Brazil.*

Background: Oxidative stress and inflammation are cardiovascular risk factors in patients with chronic kidney disease (CKD) on hemodialysis (HD). Nuclear factor Kappa B (NF-κB) play roles in the coordinated expression of inflammatory genes and Nuclear factor erythroid 2-related factor 2 (Nrf2) increases the transcription of genes encoding enzymes of phase II detoxifying and antioxidant enzymes. Several studies have shown that Nrf2 expression can be modulated by some factors, such physical exercise. The aim of this study was to evaluate the effects of resistance exercise program on the Nrf2 and NF-κB expression and antioxidant enzymes HD in patients.

Methods: This study included 44 patients on regular HD program, 25 patients (14 men, 46.1 ± 16.3 years and 71.2 ± 42.2 months HD) composed the exercise group and 19 patients (7 men, 46.8 ± 12.5 years and 67.4 ± 51,7months HD) the control group. Strength exercise program was performed during HD sessions, 3 times a week (36 exercises sessions). The Nrf2 and NF-κB expressions were analysed by quantitative real time PCR. Superoxide dismutase (SOD)activity and glutathione peroxidase (GPX) levels were measured using ELISA commercial kits.

Results: The Nrf2 mRNA expressionincreased significantly after intervention in exercises group (0.8 ± 0.4 to 1.7 ± 0.8, p<0.01). In both groupsthere were no changes in NF-κB mRNA expression after intervention. The SOD levels reduced in exercise group (from 44.5±3.5U/mL to 28.4±3.3U/ml, p<0.05) and in control group (from 45.1±6.1U/mL to 31.9±4.6U/mL, p<0.05). However,GPX levels increased in exercise group (from 24.7±12.4nmol/mL/min to 53.4±20.04nmol/mL/min, p<0.0001) and in the control group there was tendency to decrease (from 26.0±5,314nmol/mL/mi to 20.6±7,74nmol/mL/min, p=0.06). A negative correlation was found between the differences of NF-κB and GPX plasma levels (before and after 3 months) (R=-0.76, p=0.007).

Conclusions: Chronic intradialytic resistance exercises during 3 months seem to be able to modulate the Nrf2 activation and increase the antioxidant protection in HD patients.

Evaluation of Novel Urine Biomarkers for Diagnosis of Subclinical Acute Tubular Necrosis

Dennis G. Moledina, Isaac E. Hall, Mona D. Doshi, Peter P. Reese, Francis L. Weng, Bernd Schroppel, Heather Thiessen Philbrook, Joseph Ficek, Chirag R. Parikh. *TRIBE-AKI.*

Background: Rise in serum creatinine (SCr) is currently accepted as the "gold-standard" for clinical diagnosis of acute kidney injury (AKI). However, acute tubular necrosis (ATN) may occur without evidence of AKI, a condition known as "sub-clinical AKI." We evaluated the performance of SCr and urinary biomarkers of kidney injury for diagnosis of ATN on kidney biopsy.

Methods: This is a substudy of a multicenter prospective cohort of deceased donors and associated kidney transplants. A diagnosis of ATN was assigned if the kidney biopsy report (read at organ procurement) indicated acute injury in ³25% of tubules. AKI was defined by AKIN criteria based on admission and terminal SCr. Urine biomarkers were measured from stored samples collected at procurement.

Results: Of 581 donors with at least one kidney biopsied, 220(38%) had AKI (Stage 1 or higher). Of the 57 donors with ATN on biopsy, 28 (49%) did not have AKI. SCr had an area under the ROC curve (AUC) for diagnosing ATN of 0.58(95% CI 0.49, 0.67). Sensitivity and specificity for ATN were 51% and 64% using the AKIN stage 1 SCr cut-off; 26% and 83%, respectively, using the AKIN stage 2 cut-off. In the 361(62%) donors without AKI, median NGAL was higher if ATN was noted [79.5(IQR: 22.7-209.5) vs. 30.1(10.2-87.6) ng/mL for those without ATN, P=0.03]. Median L-FABP and YKL-40 were higher (though not significantly) in ATN compared to no ATN [L-FABP 25.6(6.4, 64.0) vs. 10.4(3.4, 41.0) ng/mL, P=0.08; YKL-40 4.3(0.6, 13.6) vs. 1.6(0.5, 5.2) ng/mL, P=0.11]. IL-18, KIM-1 and MCP-1 concentrations were similar regardless of ATN. Adding NGAL to SCr correctly reclassified 26% of donors for ATN events. We noted a trend for lower 6-month recipient estimated glomerular filtration rate (eGFR) [-2.6(95CI -5.4, 0.2) ml/min] for worsening degrees of ATN, but 6-month eGFR was paradoxically better [+3.6(95CI 1.7, 5.4) ml/min] for each higher stage of SCr-defined donor AKI.

Conclusions: SCr lacks sensitivity and specificity for diagnosing ATN. Urinary biomarkers like NGAL, L-FABP and YKL-40 may help distinguish "subclinical AKI," if not improve clinical prediction of biopsy-proven ATN over that of SCr alone.

The Epidemiology and Outcome of Worldwide Acute Kidney Injury in Critically Ill Children: A Prospective Multinational Study

Ahmad Kaddourah,[2] Rajit K. Basu,[2] Stuart Goldstein.[2] *[1]On behalf of the "Assessment of Worldwide Acute Kidney Injury, Renal Angina and Epidemiology in Critically ill Children (AWARE)" investigators; [2]Cincinnati Children's Hospital Medical Center.*

Background: Epidemiologic data for pediatric acute kidney injury (AKI) is limited to retrospective single-center studies. We conducted a prospective observational study of critically ill children to provide an international epidemiological description of pediatric AKI and associated outcomes.

Methods: 32 centers from 5 continents collected data for 3 consecutive months in 2014 from children (aged 3 months to 25 years) admitted to a pediatric intensive care

unit. AKI was defined and classified by serum creatinine and urine output KDIGO criteria within the first 7 days of admission (Stage 2-3 = severe). Outcomes were assessed at 28 days. Children with end-stage kidney disease (ESKD) or kidney transplant in the last 90 days were excluded.

Results: 5,237 children (55% males) were studied. Median age was 64.6 months (IQR 19,149). Day to day ranges of severe AKI prevalence and incidence during the first 7 days were 6.5-10.3% and 1.1–7.0%, respectively. Severe AKI incidence peaked at 7% on day 3 (127/1816). On multivariate analysis, shock on admission (OR 2.4, p=0.007), history of transplantation (OR 4.0, p<0.001) and urinary system comorbidity (OR 2.0, p<0.001) were independent predictors of Day 3 severe AKI. Table 1 depicts the univariate outcome associations with AKI.

	No/ stage 1 AKI n=4142	Severe AKI n=541	p
Mortality (%)	2.6	11.3	<0.001 (all)
Length of stay, mean (SD)	3.9 (6.1)	6.6 (6.9)	
ECMO use (%)	0.39	1.85	
Dialysis (%)	0.31	11.1	
Duration of mechanical ventilation, mean (SD)	5.2 (6.3)	7.7 (7.3)	

Severe AKI independently predicted mortality after adjustment for illness severity (OR 5.1, p<0.001). In a multivariate regression model, a 1-unit change in stage of AKI was associated with 1.28 days increase in illness-severity-adjusted length of stay (p<0.001).

Conclusions: AWARE represents the largest epidemiologic assessment of AKI in critically ill children. We demonstrate AKI is independently associated with multiple deleterious outcomes. Our data will help guide future research to develop accurate and early diagnostic models of AKI.

SA-OR101

Derivation and Validation of Risk Models for Chronic Kidney Disease following Hospitalization with Acute Kidney Injury Matthew T. James,[1] Neesh I. Pannu,[2] Amit X. Garg,[3] Marcello Tonelli,[1] Braden J. Manns,[1] Zhi Tan,[1] Eric Mcarthur,[3] Ron Wald,[4] Pietro Ravani,[1] Robert R. Quinn,[1] Brenda Hemmelgarn.[1] *[1]Univ of Calgary, AB, Canada; [2]Univ of Alberta, AB, Canada; [3]Western Univ, ON, Canada; [4]Univ of Toronto, ON, Canada.*

Background: Some, but not all patients, will develop chronic kidney disease (CKD) after a hospitalization with acute kidney injury (AKI). We developed and validated predictive models for progression of AKI to CKD.

Methods: We studied patients with baseline eGFR>45 mL/min/1.73m^2 who survived >3 months following a hospitalization with AKI. We identified those with a sustained reduction in eGFR<30 mL/min/1.73m^2 for >3 months. Data from 11,437 patients hospitalized with AKI in Alberta, Canada were used to develop the risk models. External validation was performed in a cohort of 9,387 similar patients from Ontario, Canada. Models were derived using logistic regression and evaluated based on discrimination, calibration, integrated discrimination improvement (IDI), and net reclassification improvement (NRI).

Results: Seven variables were associated with a higher risk of progression to CKD: older age, female sex, higher baseline serum creatinine, higher urine albumin, greater AKI severity (KDIGO Stage), lesser recovery of kidney function by the time of discharge, and heart failure. The full model showed good discrimination in the derivation and validation cohorts (c-statistics of 0.85 and 0.82, respectively). A reduced model that included age, sex, baseline serum creatinine, AKI severity, and recovery of kidney function at discharge performed similarly to the full model, but better than a base model that included age, sex, and AKI severity alone (IDI 3.3%; 95%CI 2.3-4.4%, NRI 26.4%;95%CI 18.8-33.9%).

Conclusions: These prediction models can stratify patients for risk of CKD following hospitalization with AKI. The impact of these models for guiding CKD follow-up in the community should be prospectively evaluated.

SA-OR102

Long-Term Outcomes After Rhabdomyolysis Ian J. Stewart,[1] Tarra Ischele Faulk,[1] Jonathan Sosnov,[2] Kevin Chung.[3] *[1]David Grant Medical Center, Travis AFB, CA; [2]San Antonio Military Medical Center, JBSA Fort Sam Houston, TX; [3]US Army Inst of Surgical Research, JBSA Fort Sam Houston, TX.*

Background: There are few data regarding long term outcomes after rhabdomyolysis. We examined the relation of rhabdomyolysis with mortality, renal function and the development of hypertension (HTN) in a US military population injured in combat.

Methods: We queried military databases for US military personnel critically injured in combat between 1 Feb 2002 and 1 Feb 2011. Patients that died within 90 days of injury, had pre-existing HTN or chronic kidney disease, or had missing data were excluded. Demographic variables, creatinine, creatine kinase (CK), mean arterial pressure (MAP), Injury Severity Score (ISS), and burn injury were extracted. Acute kidney injury (AKI) was determined by KDIGO criteria, rhabdomyolysis was defined as a CK>5000 unit/L and MAP was categorized into high (>106mmHg), normal (65-106mmHg) and low (<65mmHg). Outcomes were mortality, eGFR (by CKD-EPI) and a new diagnosis of HTN. Cox proportional hazard regression models were used to test associations.

Results: The analysis included 1962 patients. Patients with rhabdomyolysis (30.3%) were more severely injured as evidenced by higher ISS (median 24 vs 18, p<0.01), more AKI (23.8% vs 12.3% p<0.01), and more patients in the low MAP category (24.0% vs 8.9%, p<0.01). Despite a longer median follow up time for patients with rhabdomyolysis compared to those without (1.3 years vs 1.0 years, respectively), eGFR was higher in rhabdomyolysis patients (118 ± 21 vs 111 ± 20, p<0.001). The follow up period for assessing death and HTN was longer and not significantly different for those with and without rhabdomyolysis (3.7 vs 4.0 years, respectively). While rhabdomyolysis was not associated with long-term mortality, it was associated with HTN (HR 1.32, 95% confidence interval 1.05-1.66, p=0.02) after adjustment.

Conclusions: Rhabdomyolysis was not associated with a decline in eGFR or mortality after a median follow up of approximately 1 and 4 years, respectively. Rhabdomyolysis was independently associated with a new diagnosis of HTN. Long term follow-up of patients with rhabdomyolysis may be needed to understand their true risk.

SA-OR103

Podocyte Injury Is a Potential Contributor to Kidney Damage and Its Irreversibility During Acute Decompensated Heart Failure with Cardiorenal Syndrome Parta Hatamizadeh, Todd Koelling, Mahboob A. Chowdhury, Su Qing Wang, Judith Grossi, Roger C. Wiggins. *Dept of Internal Medicine, Univ of Michigan, Ann Arbor, MI.*

Background: Deterioration of kidney function in association with acute decompensate heart failure (ADHF) is common and may or may not be reversible. Podocytes are vital for glomerular integrity and their injury can lead to glomerular sclerosis and permanent kidney damage. Hemodynamic dysregulations and activation of inflammatory and oxidative pathways are elements of cardiorenal syndrome while both can damage podocytes. We hypothesized that podocyte injury can occur in the context of ADHF.

Methods: We examined urine pellet podocin and nephrin mRNA in 39 ADHF patients during hospitalization and post-discharge as well as 172 adult healthy controls by reverse transcription-polymerase chain reaction. Urine podocin mRNA:creatinine ratio (uPODCr) and urine nephrin mRNA:creatinine ratio (uNephCr) were considered as indices of podocyte stress and podocyte injury, respectively.

Results: Mean age of the patients was 58.9±10.9 years and 31 were male. uPODCr and uNephCr were 5 (P<0.001) and 1.9 (P=0.009) times greater in ADHF patients compared to healthy controls respectively. Post-hospital discharge uPODCr was not different from that of ADHF phase, whether it was measured within a month of discharge or after 3 months of hospital discharge. However, post-hospital discharge uNephCr was not different from ADHF phase when it was measured within a month of discharge; but it was 14 times smaller when it was measured after 3 months of hospital discharge (P=0.03).

Conclusions: In ADHF, podocytes might be under greater stress compared to healthy individuals and may become injured. Podocyte stress level remains markedly elevated several weeks after clinical stabilization of ADHF; but then drops remarkably. Podocyte injury, however, continues to progress even after 3 months of clinical stabilization. Measurement of uPODCr and uNephCr during ADHF may help with risk stratification for permanent kidney damage. Potential interventions to prevent advancement of podocyte stress to podocyte injury in the setting of ADHF, may help prevent permanent kidney injury.

SA-OR104

Micronutrient Loss in Renal Replacement Therapy for Acute Kidney Injury Weng Oh,[1] David S. Gardner,[2] Mark A.J. Devonald.[1] *[1]Renal and Transplant Unit, NUH NHS Trust, Nottingham, United Kingdom; [2]Faculty of Medicine and Science, Univ of Nottingham, Nottingham, United Kingdom.*

Background: Malnutrition is common in acute kidney injury (AKI) patients receiving renal replacement therapy (RRT). No clinical study has quantified and contrasted micronutrient losses between types of RRT that use differing methods to remove solutes (e.g. IHD, by diffusion; SLED-F, by convection; CVVH, by a combination of both).

Methods: Using a prospective, observational design patients (n=24/modality) were consented to the study before their first treatment session. Blood and RRT effluent (dialysate or filtrate) were sampled at baseline (pre-RRT), mid and end-RRT. Amino acids were measured by HPLC, trace elements by ICP-MS and B-vitamins (B1, B3, B6, B9, B12) by LC-MS. Plasma concentrations and dialysate losses (gms) were corrected for dose of RRT (urea reduction ratio or solute removal index, as appropriate). Data were analysed by mixed effect models (Genstat v16).

Results: Patients receiving CVVH had significantly higher plasma amino acids, but not trace elements, at baseline (amino acids: CVVH, 3762 ± 357; IHD, 2039 ± 337; SLED-f, 2505 ± 423 µmol/L; trace elements: IHD, 4156 ± 465; SLED-f 3732 ± 521; CVVH 3982 ± 465 µg/L). At RRT end, plasma amino acids and trace elements had significantly reduced (by 429 ± 223 µmol/L; 600 ± 400 µg/L, respectively). Loss of all trace elements was similar between types of RRT, but SLED-F cleared many (>10) individual amino acids to a greater extent (e.g. lysine loss, -64 ± 23 µmol/L vs. HD) than other types of RRT. Micronutrient loss was largely through effluent but also dialyser adsorption, the latter contributing <1g amino acids. Additional effluent losses were upto 25g with CVVH, 5-6g for IHD and 8-10g for SLED-F (P<.001). Effluent losses of individual trace elements varied significantly, but in all cases were greater for CVVH (e.g. loss of copper, +850 ± 475 µg vs. HD or SLED-F).

Conclusions: RRT results in significant loss of all water-soluble micronutrients. This loss is not equal between type of RRT; SLED-F clears certain amino acids, whereas CVVH clears certain trace elements, highly effectively. This has implications for nutritional management of RRT patients.

SA-OR105

Renal Replacement Therapy Intensity for Acute Kidney Injury and Recovery to Dialysis Independence Ying Wang,[1] Serigne N. Lo,[1] Martin P. Gallagher,[1] Qiang Li,[1] Alan Cass,[1] John A. Myburgh,[1] Robert Faulhaber-Walter,[2] John A. Kellum,[3] Paul M. Palevsky,[3] Claudio Ronco,[4] Patrick Saudan,[5] Ashita J. Tolwani,[6] Rinaldo Bellomo.[1] *[1]George Inst for Global Health; [2]Hanover Medical School; [3]Univ of Pittsburgh School; [4]Bortolo Hospital; [5]Univ Hospital; [6]The Univ of Alabama.*

Background: In acute kidney injury, randomized controlled trials (RCTs) have not found differences in survival with higher intensities of renal replacement therapy (RRT), but trials have not been powered for renal outcomes such as recovery of renal function.

Methods: Through an individual patient data meta-analysis we merged individual patient data from RCTs comparing high with standard intensity RRT. We assessed mortality at 28, 60 & 90 days and renal recovery at 7, 14, 28, 60 & 90 days post randomisation. Renal recovery was assessed two ways; by the proportion of patients RRT dependent and by time to RRT independence at these time points.

Results: Of the eight prospective RCTs assessing different RRT intensities, seven contributed individual patient data (n=3688) to the analysis. Mortality was not different between the high and standard intensity groups across these 7 studies at 28 days (775/1890 and 744/1798 respectively, 41% vs 41.4%, p = 0.24) after randomization, nor at any of the other time points. The proportion of patients RRT dependent at the 14 day point was greater in patients receiving high compared to standard intensity RRT (RR 1.36, 95%CI 1.12-1.65, p = 0.0016), but not at any other time point. Analysis by time to RRT independence suggested that patients receiving higher intensity therapy had less time independent of RRT (Day 28: HR 0.87, 95% CI 0.78 to 0.97, p=0.014, Day 60: HR 0.87, 95%CI 0.78 to 0.97, p=0.012, Day 90: HR 0.84, 95%CI 0.76 to 0.94, P=0.0022). This effect was more pronounced in trials that allowed the use of intermittent hemodialysis (IHD) to deliver higher intensity RRT. The robustness of these effects was confirmed in multiple sensitivity analyses.

Conclusions: Higher intensity RRT does not affect mortality but does appear to delay recipient's recovery to RRT independence. This effect appears to relate to the use of IHD to delivery higher intensity RRT.

Outcomes of In-Hospital Cardiopulmonary Resuscitation (CPR) in Patients with Acute Kidney Injury Fahad Saeed,[1] Jean L. Holley,[2] Sevag Demirjian.[1] *[1]Cleveland Clinic; [2]Univ of Illinois at Urbana-Champaign.*

Background: There is paucity of data on the CPR-related outcomes in patients with AKI. Herein, we have analyzed the impact of AKI on the outcomes of in-hospital CPR.

Methods: We extracted data from the Nationwide Inpatient Sample (NIS, 2005- 2011) including patients with and without AKI who had undergone in-hospital CPR. Baseline characteristics, in-hospital complications and discharge outcomes were compared between the two groups. We determined the effect of AKI on length of hospital stay, discharge destination, and hospital mortality in patients who underwent in-hospital CPR.

Results: 180,970 patients with primary or secondary diagnosis of AKI underwent in-hospital CPR compared to 323,620 patients without AKI. Unadjusted in-hospital mortality rates were higher in the AKI group (78.2 % vs. 71.8% , p=<.0001). After adjusting for age, sex, and potential confounders, patients in the AKI group had higher odds of mortality with odds ratio 1.3, 95 % confidence interval 1.2-1.4, p=<.0001. Survivors in the AKI group were more likely to be discharged to nursing homes; odds ratio 1.4, 95 % confidence interval 1.3-1.5, p=<.0001. Mean length of stay was significantly higher in patients with AKI; 11 ±34 days versus 7 ±26 days, p=<0.0001.

Conclusions: AKI independently increases the odds of in-hospital mortality and nursing home placement after in-hospital CPR.These data may facilitate CPR discussions and decision-making.

SA-OR107

Acute Kidney Injury After Surgical Aortic Valve Replacement and Long-Term Risk of Death and End-Stage Renal Disease Linda C. Ryden,[1] Ulrik Sartipy,[2] Martin Holzmann.[1] *[1]Dept of Internal Medicine, Solna, Karolinska Inst, Stockholm, Sweden; [2]Dept of Molecular Medicine and Surgery, Karolinska Inst, Stockholm, Sweden.*

Background: Acute kidney injury (AKI) is a common complication after cardiac surgery that is associated with adverse outcomes. The incidence of AKI after surgical aortic valve replacement (SAVR) and its association with long-term mortality and end-stage renal disease (ESRD) is not known.The aim of this study was to determine the incidence of AKI and its relationship to mortality and long-term renal outcomes in a large cohort of patients who underwent a first isolated SAVR from 1999 to 2013 in Sweden.

Methods: We included all 9,047 patients from the SWEDEHEART register who underwent primary isolated SAVR between 1999 and 2013 in Sweden. AKI was classified according to the Kidney Disease: Improving Global Outcomes (KDIGO) criteria: stage 1: serum Creatinine (sCr) concentration ≥ 0.3 mg/dL (³26.5 mmol/L) or 1.5- to 1.9-fold increase in sCr; stage 2: 2.0- to 2.9-fold increase in sCr; Stage 3: 3.0-fold increase in postoperative sCr compared to baseline value, or initiation of renal replacement therapy.

Results: In total, 17% of patients developed AKI postoperatively, of whom 13% were AKI stage 1 and 3.7% AKI stages 2–3. During a mean follow-up of 5.6 (standard deviation [SD] 3.7) years, 2,109 patients (23%) died and 29 (0.3%) developed ESRD. After multivariable adjustment, the hazard ratio (HR) with 95% confidence interval (CI) for death in AKI stage 1 was 1.27 (1.12–1.44) and in AKI stages 2–3 was 2.47 (2.03–3.00). The subdistribution HR for ESRD in AKI stage 1 was 4.4 (1.7–12), and in stage 2 to 3 was 5.3 (1.6–18).

Conclusions: AKI is common after a first isolated SAVR and is associated with an increased long-term risk of both death and ESRD, independent of preoperative renal function.

SA-OR108

Incidence and Predictors of Acute Kidney Injury After Total Hip Replacement Kamel A. Gharaibeh, Abdurrahman M. Hamadah, Nelson Leung, Ziad El-Zoghby. *Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: Total hip replacement (THR) is a common procedure that has increased in number with the improvement in life expectancy. Nonsteroidal antiinflammatory drugs (NSAID) are commonly used pre and post THR but their risk of causing acute kidney injury (AKI) in this setting is not well quantified.

Methods: Between 2004 and 2014, 10,327 patients underwent THR. We retrospectively collected demographic and co-morbidities data on those who developed AKI (defined by AKIN criteria) after THR. A control group without AKI was matched by age, gender and year of surgery. Variables associated with AKI were determined by univariate and multivariate logistic regressions.

Results: Mean age was 64.6 ± 13.8 years, 48.6% were male and 114 patients (1.1%) developed AKI (79% stage 1, 18.4% stage 2, 2.6% stage 3). Older age (RR 1.8, per decade, p<0.001) and male gender (RR 1.8, p=0.0016) were associated with AKI. Characteristics of those with and without AKI are shown in table-1. Several variables were associated with AKI (table-1) on univariate analysis but on multivariate analysis only CHF (OR 27.7, p<0.001); HTN (OR 2.8, p<0.001); CKD (OR 2.9, p<0.001) and transfusion (OR 3.5, p<0.001) remained significant. Diabetes (OR 2, p = 0.064); NSAID (OR 0.9, p=0.9); ACEi/ARB (OR 1.5, p=0.23) and diuretics exposure (OR 0.8, p=0.6) were not associated with AKI.

Table-1

Variables	AKI(n=114)	Control(n=114)	P-value
Age±SD	73.4±11.3	73.4±11.5	
Gender (male)	63.2%	63.2 %	
BMI	34.2±11	31.3±7.6	0.02
CKD	49%	21%	<0.001
eGFR(CKD-EPI)	64±1.7	77±1.7	<0.001
CHF	28.1%	0.9%	<0.001
Diabetes	34.2%	16.7%	0.002
HTN	87.7%	64%	<0.001
ACEi/ARB use	67.5%	44.7%	<0.001
Diuretics use	64%	42.1%	<0.001
NSAID use	51.8%	67.5%	0.015
NSAID+ACEi/ ARB+Diuretics	36.8%	28.1%	0.16
Hemglobin (pre-op)	12.8±1.7 (8.7-17.1)	13.5±1.4 (8.4-16.4)	0.0016
Hemoglobin (post-op)	9.9±1.3 (6.5-14.5)	10.6±1.3 (7-13.5)	<0.001
transfusion	61(53.5%)	23(20.2%)	<0.001

Conclusions: The incidence of AKI after THR is low. Several known risk factors were independently associated with AKI after THR; however, ACEi/ARB, diuretics and NSAID exposure were not. A prospective study is needed to confirm these results.

SA-OR109

Discovery and Testing in Rat Models of UT-A1 Urea Transporter Inhibitors Cristina Esteva-Font,[1] Onur Cil,[1] Tao Su,[1] Sujin Lee,[1] Marc O. Anderson,[2] Alan S. Verkman,[1] Puay Wah Phuan.[1] *[1]Medicine and Physiology, Univ of California, San Francisco, San Francisco, CA; [2]Chemistry and Biochemistry, San Francisco State Univ, San Francisco, CA.*

Background: Inhibitors of urea transport function have potential clinical applications as first-in-class salt-sparing diuretics for treatment of edema and hyponatremia (Nat Rev Nephrol 11, 113-123, 2015). Our goal is to develop small-molecule, UT-A1-selective inhibitors and demonstrate their diuretic efficacy in clinically relevant animal models.

Methods: Screening of >250,000 drugs and synthetic small molecules was done using a cell-based fluorescence assay involving osmotic volume response to an urea gradient (Chem Biol 20, 1235-1244, 2013). Pharmacokinetics (PK) was measured in rats by liquid chromatography and mass spectrometry; diuretic efficacy was studied using metabolic cages and in a model of SIADH produced by chronic minipump infusion of dDAVP (5 ng/h) with liquid diet administration.

Results: 22 distinct chemical classes of UT-A1 inhibitors were identified and optimized by structure-activity studies on > 3,000 analogs. Compounds with high UT-A1 vs. UT-B selectivity were identified, some with nanomolar inhibition potency. In addition, analog and natural-product screening identified dimethylthiourea (DMTU) as a non-selective UT

inhibitor. Several classes of compounds gave good PK in rats with predicted therapeutic concentrations in blood and urine. Salt-sparing diuretic action was demonstrated in control, hydrated rats and rats administered dDAVP acutely. Up to a 2.5-fold increase in hourly urine volume and 2-fold reduction in urine osmolality was found. Compounds also prevented hyponatremia in rats chronically treated with dDAVP.

Conclusions: UT-A1 inhibitors show salt-sparing diuretic action in rats, and efficacy in a clinically relevant model of hyponatremia. In contrast to existing diuretics that target renal tubule salt transporters, UT-A1 inhibitors have a novel diuretic mechanism of action involving disruption of urinary concentration by renal countercurrent multiplication.

Pathways for Urea Transport Across the Rat Inner Medullary Thin Limbs of Henle's Loops Kristen K. Evans,[1] William H. Dantzler,[1] Alan S.L. Yu,[2] Thomas L. Pannabecker.[1] *[1]Physiology, The Univ of Arizona, Tucson, AZ; [2]The Kidney Inst, Univ of Kansas, Kansas City, KS.*

Background: Transepithelial solute flows in thin limbs of Henle's loops play critical roles in countercurrent exchange and the urinary concentrating mechanism; our goal is to identify the urea transport pathways in these segments. The rat inner medullary long-loop descending thin limbs (DTLs) consist of water permeable upper and water impermeable lower segments, positioned in the upper and lower 50% of the inner medulla, respectively. Mean transepithelial urea permeabilities of upper DTL are approximately 60 E-5 cm/sec and permeabilities of lower DTL and ascending thin limb (ATL) are approximately 350 to 450 E-5 cm/sec. A urea transporter, UT-A2, has been identified by immunohistochemistry only in a very limited region of the upper DTL, near the outer medullary-inner medullary border and only in the presence of vasopressin.

Methods: Tubules were isolated without enzyme digestion and perfused with concentric glass micropipettes by the method of Burg. The lumen-to-bath transepithelial urea flux was determined and permeabilities were calculated.

Results: Urea transport in isolated perfused upper and lower DTL is not inhibited by peritubular 0.25 mM phloretin and urea transport in lower DTL is not inhibited by 10 mM ouabain and is unaffected by a 125 mM lumen Na^+ and 0 mM bath Na^+ concentration gradient. The urea flux in upper and lower DTLs is almost completely and reversibly inhibited by peritubular 5 mM lanthanum. Activation energy for transepithelial urea permeability measured at 37° and 16° C in isolated perfused lower DTLs and ATLs is approximately 13 kJ/mol, a value that is consistent with channel-like activity.

Conclusions: The data suggest that a substantial fraction of the transepithelial urea flux occurs independently of known facilitated urea transporters such as UT-A1-3, is unlikely to be coupled to Na^+ flux and occurs, in large part, by way of a plasma membrane or paracellular channel-like pathway.

SA-OR111

Comparative Analysis of Vasopressin V1a and V2 Receptors Distribution in the Mammalian Kidney Torsten Giesecke,[1] Taka-aki Koshimizu,[2] Katsumasa Kawahara,[3] Sebastian Bachmann,[1] Kerim Mutig.[1] *[1]Dept of Anatomy, Charité Universitätsmedizin Berlin, Berlin, Germany; [2]Dept of Molecular Pharmacology, Jichi Medical Univ, Shimotsuke-shi, Tochigi-ken, Japan; [3]Dept of Physiology, Kitasato Univ School of Medicine, Kitasato, Japan.*

Background: Vasopressin (AVP) promotes urinary concentration by activating the vasopressin V2 receptor (V2R). Parallel activation of the vasopressin V1a receptor (V1aR) may affect renal acid-base balance and stimulate the renin-angiotensin-aldosterone axis. Analysis of the renal distribution of these receptor subtypes has been difficult owing to the lack of suitable, specific antisera. Here we have extended available data on their distribution and function using subtype-specific antibodies. Subtype-selective agonists were used for functional analysis.

Methods: Antibodies to V1aR- and V2R-specific peptides were generated. Segmental and cellular distribution of the subtypes along mouse and rat nephron were characterized by immunofluorescence and high-resolution immunocytochemistry. Functional studies were performed in AVP-deficient Brattleboro rats using subtype-specific agonists; AO-4-67 was used for V1aR, and desmopressin for V2R activation at short term.

Results: The V2R was localized basolaterally in mouse and rat kidney thick ascending limb (TAL), distal convoluted tubule (DCT), connecting tubule (CNT) and collecting duct (CD) epithelia; macula densa (MD) and intercalated cells were negative. Conversely, application of the anti-V1aR antibody produced basolateral signal exclusively in MD cells and intercalated CNT/CD cells. Staining was controlled using V2R- and V1aR-deficient mouse kidneys, respectively. In line with the localization data, administration of desmopressin in Brattleboro rats induced the activation and trafficking of distal tubular NaCl transporters and of aquaporin 2 in the CNT/CD principal cells, whereas application of AO-4-67 resulted in luminal trafficking of V-ATPase in intercalated cells of CNT/CD.

Conclusions: These data provide morphological support for the distinct epithelial effects of AVP mediated by V2R or V1aR and may improve our understanding of the pathophysiology of nephrogenic diabetes insipidus.

SA-OR112

Role of Nedd4-2 Underlying V2R Activation of ENaC Alan C. Pao,[1,2] Yu Chen,[1] Sheela V. Thomas,[1] Mollie E. Jacobs,[1] Sindhu Chandran,[1] Mariana Labarca,[1] Vivek Bhalla.[1] *[1]Div of Nephrology, Stanford Univ School of Medicine, Stanford, CA; [2]Veterans Affairs Palo Alto Health Care System, Palo Alto, CA.*

Background: Arginine vasopressin (AVP) can increase renal sodium (Na+) reabsorption in the cortical collecting duct (CCD) by stimulating the epithelial Na+ channel (ENaC). One presumed mechanism by which AVP stimulates ENaC is through activation of vasopressin-2 receptor (V2R) and inhibition of the E3 ubiquitin ligase Nedd4-2. Snyder and colleagues first demonstrated that cAMP/PKA signaling reverses Nedd4-2 inhibition of ENaC. However, how V2R signals through Nedd4-2 to regulate ENaC is not fully understood.

Methods: We therefore tested mechanisms by which V2R inhibits Nedd4-2 and increases ENaC cell surface expression in transfected HEK293T kidney cells, an established model for the study of Nedd4-2 function.

Results: We found that V2R, similar to cAMP, relieved Nedd4-2 inhibition of ENaC cell surface expression, but surprisingly V2R did not decrease the interaction between Nedd4-2 and ENaC. Instead, V2R increased expression of Nedd4-2, which in turn increased the pool of Nedd4-2 that interacted with ENaC. The V2R-dependent increase in Nedd4-2 expression was blocked with introduction of mutations that eliminate phosphorylation of Ser-444 of Nedd4-2. While V2R increased Nedd4-2 expression, V2R still relieved Nedd4-2 inhibition of ENaC cell surface expression if Ser-338, Thr-363, and Ser-444 remained intact. If all three residues were disrupted, V2R-mediated stimulation of ENaC was attenuated but not fully prevented, suggesting that V2R signals through additional residues on Nedd4-2 or independent of Nedd4-2.

Conclusions: Our findings provide a molecular basis for how AVP signals through Nedd4-2 to increase ENaC activity and demonstrate how the level of Nedd4-2 expression or interaction with ENaC is not necessarily an accurate surrogate for Nedd4-2 function.

Vasopressin Lowers Renal Epoxyeicosatrienoic Acid Levels by Activating Soluble Epoxide Hydrolase Alexander Paliege,[1] Allein Plain,[2] Markus Bleich,[2] Sebastian Bachmann,[1] Nina Himmerkus.[2] *[1]Anatomy, Charité, Berlin, Germany; [2]Physiology, CAU, Kiel, Germany.*

Background: Activation of the thick ascending limb (TAL) Na(+)-K(+)-2Cl(-) cotransporter (NKCC2) by vasopressin (AVP) is an essential mechanism of volume homeostasis and may also contribute to the development of arterial hypertension and chronic kidney disease. AVP effects in the kidney are counteracted by locally produced eicosanoids including epoxyeicosatrienoic acids (EETs). The effects of AVP on the renal expression of EETs and their metabolizing enzymes have not been determined.

Methods: Adult AVP-deficient Brattleboro rats were treated with the AVP receptor agonist desmopressin (dDAVP, 5ng/h; 3d) via osmotic minipump. Renal EET-levels were measured by mass spectrometry. Regulation of EET-metabolizing enzymes was determined by Affymetrix microarray analysis. Microarray results were confirmed by real-time PCR, immunohistochemistry and Western blot. EET effects on TAL transport activity were studied using the isolated perfused tubule setup.

Results: dDAVP treatment significantly lowered renal EET levels (-56±3% for 5,6-EET, -50±3.4% for 11,12-EET and -60±3.7% for 14,15-EET relative to controls; $p<.05$). Microarray analysis revealed elevated mRNA levels for the principal EET-degrading enzyme soluble epoxide hydrolase (sEH) and unchanged mRNA-levels for the EET-synthesizing epoxygenases. Regulation of sEH was confirmed by real time PCR (+160±37%, $p<.05$) and Western blot (+120±26%; $p<.05$). Immunohistochemistry in control animals demonstrated abundant expression in the macula densa, connecting tubule (CNT), and in the cortical (CCD), outer (OMCD) and inner (IMCD) medullary collecting duct. dDAVP treatment increased protein levels in CNT, CCD, and OMCD with close proximity to TAL profiles. Preincubation of TAL segments with 5,6-EET (1μM; 30 min) significantly reduced furosemide inhibitable short circuit current (-45±5%; $p<.05$) thus confirming inhibitory effects of EETs on NKCC2 transport activity.

Conclusions: We have shown that activation of AVP signaling causes upregulation of renal sEH biosynthesis and enzyme activity. The resulting reduction of EET tissue levels may be instrumental for increased NKCC2 transport activity during AVP-induced antidiuresis.

MicroRNA-132 Regulates Diuresis by Mediating Vasopressin Production Roel Bijkerk,[1,2] Ruben de Bruin,[1] Coen van Solingen,[1] Ton J. Rabelink,[1] Benjamin D. Humphreys,[2] Peter M.T. Deen,[3] Anton Jan Van Zonneveld.[1] *[1]Dept of Nephrology and the Einthoven Laboratory for Experimental Vascular Medicine, Leiden Univ Medical Center, Netherlands; [2]Renal Divison, Brigham & Women's Hospital and Harvard Medical School, Boston; [3]Dept of Physiology, Radboud Univ Nijmegen Medical Centre, Netherlands.*

Background: The collecting duct (CD) principal cells of our kidneys are critical in the maintenance of blood water levels, as binding of vasopressin (AVP) to its V2-receptor and the subsequent translocation of aquaporin-2 (AQP2) water channels to the apical membrane fine-tunes water balance. AVP dependent regulation of water homeostasis can be modulated

by renal prostaglandin E_2 (PGE_2), a metabolite of the cyclooxygenase (Cox) pathway, by inducing the internalization and lysosomal degradation of AQP2. A role for microRNAs (miRNAs) in the regulation of water and electrolyte balance remains virtually unexplored.

Methods: We generated antagomirs to silence miR-132 function. Synthetic AVP (ddAVP) was administered with osmotic minipumps. Mice were housed in metabolic cages and sacrificed 1 day after i.v. or i.c.v. injection of the antagomirs or scrambled controls.

Results: Silencing of miR-132 caused severe weight loss as a result of acute diuresis characterized by increased plasma osmolality and decreased urine osmolality. In addition, urinary PGE2 levels were elevated and hypothalamic AVP mRNA expression and blood AVP levels were decreased, resulting in less translocation of AQP2 in CD cells. We identified Cox2 as a direct target of miR-132, but administration of Cox2-inhibitor Celecoxib did not affect antagomir-132 induced diuresis, suggesting a PGE2 independent pathway. In contrast, infusion of synthetic AVP (ddAVP) reversed antagomir-132 induced diuresis, suggesting an effect on hypothalamic AVP production. Confirming this hypothesis, i.c.v. injection of antagomiR-132 similarly resulted in acute diuresis and decreased AVP production and we found miR-132 to target and increase hypothalamic MeCP2, which is known to block AVP transcription.

Conclusions: Taken together, silencing of miR-132 causes acute diuresis. Our data indicate that this is the result of a MeCP2 mediated decrease in hypothalamic AVP synthesis.

Dephosphorylation at Ser-261 Is a Determinant for the Regulated AQP2 Apical Accumulation Naofumi Yui, Sei Sasaki, Shinichi Uchida. *Nephrology, Tokyo Medical and Dental Univ, Bunkyo-ku, Tokyo, Japan.*

Background: AQP2 apical plasma membrane accumulation is crucial for vasopressin (VP)-regulated urine concentration.It is well known that VP induces post-translational modification on AQP2 phosphorylation at several serine (S) sites in its C-terminus, however, how these complicated phosphorylation and dephosphorylation regulate AQP2 apical accumulation is unknown. Recently, we identified that 1) pS261-AQP2 is continuously targeting to the apical plasma membrane, then internalized into the cytoplasm without any stimulations, 2) pS269-AQP2 is observed intracellularly at 1 min in the initial phase of forskolin (FK) stimulation, 3) S269 phosphorylation preceded S261 dephosphorylation in polarized MDCK cells. Therefore, we hypothesized that dephosphorylation at S261 is crucial for regulated AQP2 apical accumulation at the downstream step during the stimulation.

Methods: To test this hypothesis, we expressed mutated AQP2 and analyzed them in MDCK cells focusing on phosphorylation status at S261 and S269.

Results: In P262L-AQP2, a recessive NDI causing mutant, pS269 was greatly increased with continuous S256 phosphorylation after forskolin (FK) stimulation (20 μM, 10 min) as well as wild-type AQP2 (WT-AQP2), whereas, pS261 was increased after FK treatment contrary to WT-AQP2 (20 μM, 10 min). Surprisingly, pS269-AQP2 was accumulated in the basolateral membrane after FK treatment (20 μM, 10 min). S269A-AQP2, a S269-dephosphorylation mimic, accumulates in the apical membrane after FK treatment (20 μM, 30 min) with a striking reduction of phosphorylation at S261. Interestingly, it took longer time (20 min) to dephophorylate S261 in S269A-AQP2 compared to WT-AQP2 (within 5 min).

Conclusions: These results demonstrated that FK-mediated subcellular translocation of pS269-AQP2 is greatly affected by phosphorylation status at S261 and that FK-mediated AQP2 apical accumulation might be determined by S261 dephosphorylation, which is likely to be facilitated by precedent phosphorylation at S269. Further investigation how VP-mediated S269 phosphorylation catalyzes dephosphorylation at Ser-261 would be important to draw a complete picture of AQP2 translocation mechanism.

ILK Is Important for Recycling of AQP2 and Its Subsequent Entry into the Exocytotic Pathway Fahmy Mamuya,[1] Jose Luis Cano-Peñalver,[2] Dennis Brown,[1] Hua Ann Jenny Lu.[1] *[1]Dept of Medicine, Massachusetts General Hospital, Boston, MA; [2]Inst Reina Sofia de Investigación Renal and Red de Investigación Renal (REDinREN), Inst de Salud Carlos III, Madrid, Spain.*

Background: Within the past decade tremendous efforts have been made to understand the mechanism behind aquaporin-2 (AQP2) water channel trafficking and recycling, in order to open a path towards effective diabetes insipidus therapeutics. A recent study has shown that Integrin Linked Kinase (ILK) conditional-knockdown (cKD-ILK) mice developed polyuria along with decreased expression of AQP2.

Methods: To better understand the role of ILK in this process, we performed in vitro analysis using LLCPK1 cells stably expressing rat AQP2 (W2 cells).

Results: Upon treatment of W2 cells with ILK-SiRNA and the ILK inhibitor, Calbiochem-cpd22, we observed a accumulation of AQP2 in the perinuclear region, without accumulation of AQP2 in the plasma membrane.We next examined the effect of ILK inhibition on endocytosis using a fluid phase marker, FITC-dextran (10 KDa). There was no significant difference in endocytosis of FITC-dextran in W2 cells after ILK inhibition. When we examined the clathrin mediated endocytotic pathway using rhodamine conjugated transferrin, a perinuclear accumulation of rhodamine transferrin was detected in the presence of ILK inhibition, which colocalized with AQP2. To further test whether we could "rescue" AQP2 accumulated in the perinuclear patch, lysine vasopressin (LVP) was added in conjunction with ILK-SiRNA or ILK inhibitor. Interestingly, the canonical LVP induced AQP2 membrane accumulation was prevented. To examine whether these effects were due to an alteration of AQP2 phosphorylation, we performed western blotting of AQP2 phosphorylation, targeting the S256, 261, 269 and 264 sites. Our data did not reveal any significant effects on AQP2 phosphorylation patterns after ILK inhibition.

Conclusions: Therefore, while our data suggest that the ILK signaling pathway modulates AQP2 trafficking, this is not through affecting endocytosis of AQP2 nor modulating the phosphorylation of AQP2. Because ILK inhibition results in the formation of a perinuclear patch in which cellular AQP2 is concentrated we hypothesize that ILK is important for recycling of AQP2 and its subsequent entry into the exocytotic pathway.

GI Regulation of Vesicle Osmotic Swelling Is Required for Nonsecretory Vesicle Fusion: Aquaporin 2 Water Channel as a Paradigm Giovanna Valenti,[1] Maria De santo,[2] Mariangela Centrone,[1] Maria Grazia Mola,[1] Marianna Ranieri,[1] Vincenzo Formoso,[2] Grazia Tamma.[1] *[1]Dept of Biosciences, Biotechnologies and Biopharmaceutics, Univ of Bari, Italy; [2]Dept of Physics, Univ of Calabria, Italy.*

Background: We have previously shown that the heterotrimeric G protein Gai3, associated with AQP2 vesicles, is required for the water channel fusion to the plasma membrane. On the other hand, swelling of secretory vesicles has been implicated in exocytosis. Here we address the question of whether vesicle swelling is also a prerequisite for fusion of nonsecretory vesicles. The role of Gai3 in this process is investigated. AQP2 vesicles are chosen as paradigm of nonsecretory vesicles.

Methods: AQP2 vesicles isolated from rat kidney were analyzed by high resolution dynamic imaging using the atomic force microscope (AFM), allowing analysis of unfixed vesicles in a hydrated environment at nanoscale resolution. In parallel, a rapid fluorescence-based assay of vesicle or cell volume changes in a multiwell format was applied to analyze real time fluorescence kinetic data.

Results: α subunits of PTX-sensitive G proteins, Gai3, was found associated to isolated AQP2 vesicles. Treatment of renal AQP2-transfected MCD4 cells with pertussis toxin (PTX), which inhibits G proteins of the Gi family, inhibited cAMP-triggered increase in osmotic water permeability implicating a critical role of Gai3. Dynamic imaging of isolated AQP2 vesicles by AFM revealed that mastoparan, known to stimulate Gi proteins, caused a significant increase in vesicle swelling. This effect was confirmed by fluorescence-based assay of vesicle volume changes. Of note, mastoparan-induced vesicle swelling was abolished by anti- Gai3 antibodies or by anti-AQP2 antibodies.

Conclusions: Our results demonstrate that Gai3 localized in AQP2 vesicles mediates vesicle swelling regulating rapid water entry though AQP2, a potentially important prerequisite for vesicle fusion to the plasma membrane. We conclude that vesicle swelling is required also for nonsecretory vesicle fusion committed to insert a channel into the plasma membrane and depicts a general mechanism for vesicle fusion.

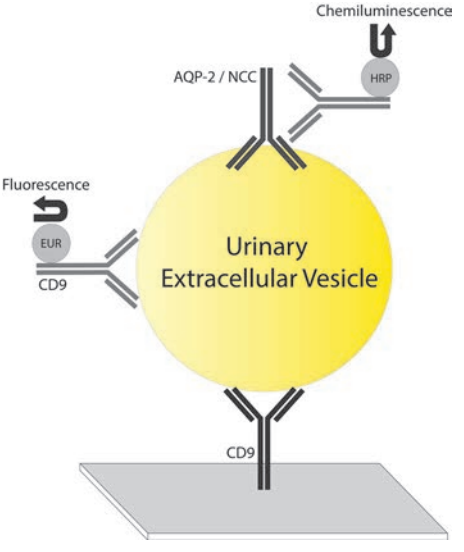
An Enzyme Immunoassay for Urinary Extracellular Vesicles Mahdi Salih,[1] Robert A. Fenton,[2] Robert Zietse,[1] Ewout J. Hoorn.[1] *[1]Internal Medicine, Erasmus MC, Rotterdam, Netherlands; [2]Biomedicine, Aarhus Univ, Denmark.*

Background: Urinary extracellular vesicles (uEVs) are derived from epithelial cells of the kidney and urinary tract. uEVs (also called exosomes) contain disease-related proteins and also transfer information to target cells. As such uEVs offer exciting opportunities for nephrology, but current isolation techniques rely on time-consuming ultracentrifugation hindering high-throughput clinical application.

Methods: To navigate this problem, we designed an enzyme-linked immunosorbent assay (ELISA) that isolates uEVs using a biotinylated CD9 antibody. uEVs are then lysed with a detergent and treated with an antibody targeting the protein of interest. The use of two conjugated antibodies allows quantification of the protein of interest and CD9. We tested the set-up using aquaporin-2 (AQP2) and the sodium chloride cotransporter (NCC).



Results: CD9 but not CD63 coated immunobeads isolated AQP2+ and NCC+ uEVs. Urinary creatinine and CD9 correlated strongly (n=20, r=0.9, P<0.001); thus CD9 can also be used for normalization in spot urines. Our uEV-ELISA sensitively detected AQP2

and NCC (coefficients of variance 5.6 and 3.3%). To verify whether expected effects of vasopressin on AQP2 and NCC were captured by our uEV-ELISA, we performed overnight thirsting followed by water loading in 4 volunteers. After water loading, similar 2-3 fold decreases in AQP2 and NCC were observed using either uEV-ELISA or immunoblotting after isolating uEVs with ultracentrifugation. The results by uEV-ELISA showed good correlations with immunoblot ($r=0.8$ for AQP2, $r=0.6$ for NCC, both $P<0.001$).

Conclusions: We successfully developed an ELISA to capture and quantify uEV-proteins and validated this technique for AQP2 and NCC. Our uEV-ELISA set-up does not require ultracentrifugation or measurement of urinary creatinine and may be used as a platform to examine other uEV proteins of interest in nephrology.

The Long Non-Coding RNA Landscape in Hypoxic and Inflammatory Renal Epithelial Injury Jennie Lin, Xuan Zhang, Chenyi Xue, Sager Jayesh Gosai, Hanrui Zhang, Michael G. Shashaty, Nuala J. Meyer, Alison Grazioli, Katalin Susztak, Mingyao Li, Muredach Reilly. *Medicine, Univ of Pennsylvania, Philadelphia, PA.*

Background: Long non-coding RNAs (lncRNAs) are emerging as key regulators of disease processes. To identify lncRNAs involved in acute renal epithelial injury, we performed whole transcriptome profiling of human proximal tubular epithelial cells (PTECs) in hypoxic and inflammatory conditions.

Methods: Strand-specific RNA-seq (50 million paired-end reads per library) was performed on poly-adenylated RNA fraction of control PTECs and PTECs subjected to 12 hours of hypoxia or cytokine (IL6, TNF-α, and IFN-γ cocktail) stimulation. A transcript was considered differentially expressed (DE) between control and stimulation at > 1.5 fold change with FDR-adjusted $p < 0.05$.

Results: 3,728 mRNAs and 69 lncRNAs were DE between cytokine-stimulated and control PTECs, while 2730 mRNAs and 70 lncRNAs were DE between hypoxic and control cells. Three lncRNAs were prioritized for further study based on abundance. Linc-ATP13A4-8 was specifically upregulated (8.1-fold at 12 hours, FDR $p < 0.001$) in PTEC hypoxia, peaked its expression 15-fold at 24 hours, is located in the nucleus and cytoplasm, and has both synteny and 80.6% conservation of a 206 bp sequence with the mouse genome. Linc-KIAA1737-2 was specifically upregulated after cytokine treatment (4.6-fold at 12 hours, FDR $p < 0.001$), was over 50-fold upregulated at 48 hours, is located primarily in the nucleus with an enhancer region (high H3K4me1/H3K4me3 overlying H3K27ac mark for adult kidney on NIH Epigenomics Roadmap), and is syntenic with mouse with no sequence conservation. Linc-POU5F1-1 increased in expression (2 to 4 fold, FDR $p < 0.001$) in both stimulations, declined in expression after 12 hours, is located in the nucleus with a canonical promoter region shared with protein-coding POU5F1, and is human-specific. All three lncRNAs are expressed in human PTECs from healthy donor nephrectomy kidneys previously micro-dissected and sequenced.

Conclusions: Transcriptome profiling of stimulated renal epithelial cells reveals different lncRNAs that may regulate the cellular response to distinct stressors relevant to acute kidney injury.

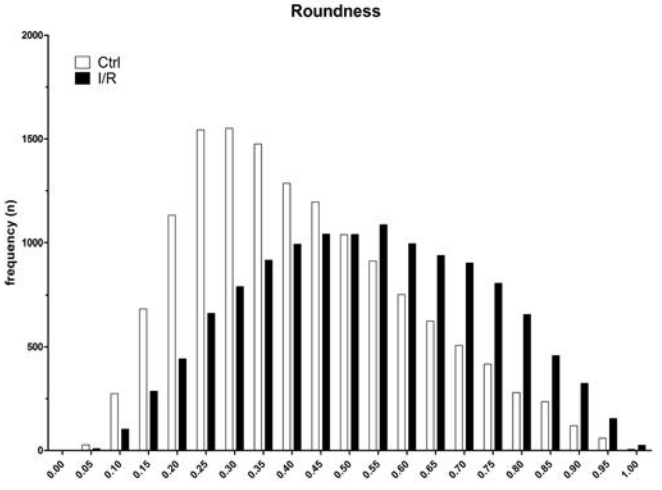
Cortical Consequences of Ischemia-Reperfusion Injury: Computational Studies of the Renal Microvasculature Gunnar Schley,[1] Bernd Klanke,[1] Kai-Uwe Eckardt,[1] Seymour Rosen,[2] Carsten Willam.[1] *[1]Nephrology and Hypertension, Univ of Erlangen-Nuremberg, Erlangen, Germany; [2]Pathology, Beth Israel Deaconess Medical Center, Boston, MA.*

Background: The acute injury of the ischemia-reperfusion (I/R) kidney model affects mainly the outer stripe (OS) of the outer medulla, but its long-term consequence is extensive cortical involvement. We were therefore interested in the long-term effects of such ischemic injury on the cortical capillary network.

Methods: Male C57BL/6 mice (n=11) were subjected to bilateral renal I/R for 25 min and sacrificed 2 weeks later. Untreated mice (n=5) served as controls. Kidney sections were stained for MECA-32 to visualize the renal microvasculature. Vessel geometry was selectively quantified in damaged tissue regions by computer-assisted morphometric analysis.

Results: In the normal subcapsular cortex peritubular capillaries appeared elongated and formed an organized network. Although I/R initially affects the OS, 2 weeks after I/R, marked chronic tubular atrophy occurred in the cortex. Adjacent microvessels' shape remarkably changed: capillaries were significantly smaller (perimeter, diameter decreased) and rounder (circularity and roundness increased, see Figure, aspect ratio decreased) compared to control vessels.



These alterations resulted in an abnormal structural organization. We validated our technique by comparing geometric parameters of vasa recta and the capillary plexus in the inner stripe of the outer medulla in controls kidneys.

Conclusions: Long-term effects of renal I/R involved cortical tubules and microvessels. Semiautomated morphometric analysis of cortical capillaries showed a remarkable shift from organized and elongated towards disorganized, smaller and rounder forms. Thus the late consequences of I/R, a primary medullary insult, are those of profound changes in the cortical microvasculature.

TH-PO003

Glomerular Injury Induces a Calcium Signal in Proximal Tubular Cells – A Mutliphoton *In Vivo* Study Julia Binz, Matthias Hackl, Bernhard Schermer, Thomas Benzing. *Dept II of Internal Medicine and Cologne Center for Molecular Medicine, Univ of Cologne, Cologne, Germany.*

Background: Recently it has been demonstrated that renal tubular cells undergo synchronized necrosis after ischemic injury, implying that the death of a single cell can induce a disastrous chain reaction. An early event in damage signaling is a massive increase in intracellular calcium levels. Therefore we investigated if a localized damage to glomerular cells can influence tubular calcium levels downstream of the damage site.

Methods: 4 weeks old mice expressing the calcium indicator GCaMP3 in proximal tubular cells (Pax8:cre) were anaesthetized, an arterial catheter was placed into the right carotid artery and the left kidney was exteriorized for *in vivo* multiphoton microscopy. Blood vessels were labelled by injection of 70 kDa Texas Red dextrane. Acute glomerular injury was induced by focusing the laser beam on a podocyte to cause a localized injury. The resulting calcium response in tubular cells was recorded with in a time series of the glomerulus and the originating proximal tubulus.

Results: Upon laser induced injury of a podocyte, a strong calcium signal can be observed within seconds in the continuous stretch of proximal tubular cells downstream of the glomerulus. The signal lasts for a few seconds and then the calcium signal returns to baseline. The calcium response in proximal tubular cells is faster than the known calcium wave in podocytes after injury.

Conclusions: Glomerular injury induces a calcium signal in proximal tubular cells *in vivo*, linking glomerular injury to tubular damage signaling. The almost instantaneous calcium increase in tubular cells suggest that the release of podocyte cell content and most probably damage-associated molecular pattern molecules (DAMPs) affects tubular cells, uninjured by the initial damage.

TH-PO004

Inhibition of Oxygen-Sensing Prolylhydroxylases 1 (PHD1) Protects from Acute Kidney Injury Almut Grenz,[1] Raechel Peralta,[2] Uladzimir Shabeka,[1] Sue Murray,[2] Shuling Guo,[2] Gene Hung.[2] *[1]Dept of Anesthesiology, UC Denver, Denver, CO; [2]ISIS Pharmaceuticals, ISIS Pharmaceuticals, Carlsbad, CA.*

Background: Acute kidney injury (AKI) due to ischemia is associated with dramatic increases of morbidity and mortality. Conditions of ischemia with limited oxygen availability inhibit oxygen-sensing prolyl hydroxylases (PHD1-3) with subsequent stabilization of hypoxia-inducible factors (HIFs) resulting in a transcriptionally regulated response towards hypoxia adaptation. *Thus, we hypothesize that a new pharmacological approach to inhibit PHDs on a transcript level via specific antisense treatment before the onset of ischemic injury mediates protection.*

Methods: Mice were studied in two ischemic models of AKI. With a hanging weight system we only compress the renal artery whereby we clamp the whole pedicle by using micro vessel clamps. Renal function was determined by inulin clearance, serum creatinine, BUN, renal NGAL and KIM-1.

Results: Our previous studies in gene-target mice (PHD1-3 KO mice) has shown that renal protection from ischemia was associated with PHD1. To pursue our hypothesis, we first treated wild type mice with PHD1 specific antisense inhibitors (ASO1 and ASO2). We tested the compounds over 2 to 6 week treatment periods in different doses. The optimal treatment length was 2 weeks before renal ischemia (30min ischemia and 24 hours reperfusion by utilizing the hanging weight system) in a dose of 100mg/kg per week. Treatment reduces renal PHD1 RNA by 90% and 60%, respectively and improved the glomerular filtration rate (GFR) by almost 300% in both treatment groups compared to untreated mice following 30min of renal ischemia. In a next step we used the clamp model to induce kidney ischemia. PHD1 specific antisense inhibitor treatment showed comparable kidney protection as in the hanging weight model demonstrated in GFR improvement, serum creatinine and renal tubular injury markers (NGAL, KIM1).

Conclusions: In conclusion, PHD1 oligo treatment before renal ischemia in two different ischemia models shows a tremendous attenuation from renal injury due to ischemia. If translatable from mice to human, these data have important therapeutic implications.

Role of Thioredoxin-Interacting Protein (TXNIP) in Mitochondrial Function of Renal Tubular Cells in Ischemia Reperfusion Injury AKI Model
Natsuki Maeda, Tatsuki Matsumoto, Kazu Hamada-Ode, Yoshiko Shimamura, Koji Ogata, Kosuke Inoue, Yoshinori Taniguchi, Taro Horino, Shimpei Fujimoto, Yoshio Terada. *Kochi Univ, Japan.*

Background: Thioredoxin-interacting protein (TXNIP) has been found to regulate the cellular reduction-oxidation (redox) state by binding to and inhibiting thioredoxin in a redox-dependent fashion. However, little is known about the role of TXNIP in acute kidney injury (AKI) pathogenesis.

Methods: We evaluated the role of TXNIP in renal function in bilateral renal ischemia/reperfusion injury (IRI) model using TXNIP knock-out (KO) and wild type (WT) mice. cultured renal tubular cells (NRK-52E cells) as an in vitro model. To elucidate the functional roles of TXNIP, we evaluated mitochondrial enzymes, morphology, and apoptotic change by transfection of siRNA for TXNIP in cultured renal tubular cells.

Results: TXNIP KO mice had significantly higher SCr (0.78+0.28 versus 0.45 + 0.20 mg/dl) and significantly higher BUN (152.5+32.5 versus 75.3+18.2 mg/dl) at 24h post ischemia compared to WT mice. Immunohistological examination showed severer tubular injury in cortex and outer medulla in TXNIP KO mice compared to WT mice. The number of TUNEL positive tubular cells was increased in in TXNIP KO mice compared to WT mice. The protein expressions of mitochondrial enzymes (ATP5a, UCP2 and complex IV) were decreased in TXNIP KO mice at 24h post ischemia. In vitro experiments, protein and mRNA levels of ATP5a, complex IV, UCP2, PGC-1a were significantly decreased by H_2O_2, and siRNA for TXNIP amplify the reduction of these enzymes in NRK-52E cells.

Conclusions: These data demonstrate that TXNIP protects from IRI induced AKI. TXNIP changes mitochondrial function in oxidative conditions. These results indicate that TXNIP plays a key role in the pathophysiology of AKI.

TWEAK Decreases PGC-1α Expression in Renal Injury and Promotes Mitochondrial Dysfunction in Tubular Cells
Olga Ruiz Andrés, Beatriz SuarezAlvarez-, Cristina Sánchez-Ramos, Maria Monsalve, Maria D. Sanchez-niño, Marta Ruiz-Ortega, Jesus Egido, Alberto Ortiz, Ana Belen Sanz. *Nephrology, Inst de Investigacion Sanitaria - Fundación Jimenez Diaz (IIS-FJD), Madrid, Spain; Dept of Metabolism and Cellular Signalling, Inst de Investigaciones Biomédicas Alberto Sols (CSIC-UAM), Madrid, Spain.*

Background: There is currently no satisfactory therapy for acute kidney injury (AKI). Successful testing of mitochondria-targeted nephroprotective agents suggests a key role of mitochondrial injury in AKI. We hypothesized that an improved understanding of the regulation of factors responsible for mitochondrial biogenesis may provide clues to novel therapeutic approaches to AKI. Thus, we explored the interaction between inflammation and mitochondrial biogenesis regulators.

Methods: Transcriptomics databases from cultured murine tubular epithelial cells and folic acid-induced AKI in mice identified downregulation of PGC-1α and target genes regulated by the inflammatory cytokine TWEAK. Functional studies in vivo ad cell culture studies characterized the TWEAK- PGC-1α relationship.

Results: Transcriptomics identified decreased expression of PGC-1α mRNA and PGC-1α-dependent genes encoding mitochondrial proteins (Ndufs1, Sdha and Tfam) as a shared feature between AKI and TWEAK-stimulated cultured tubular cells. Neutralizing anti-TWEAK antibodies prevented the decrease in kidney PGC-1α and its targets during AKI. TWEAK stimulation decreased kidney PGC-1α expression in healthy mice. TWEAK also decreased the expression of PGC-1α and its targets as well as mitochondrial membrane potential in cultured tubular cells. Adenoviral-mediated PGC-1α overexpression prevented TWEAK-induced downregulation of PGC-1α-dependent genes and the decrease in mitochondrial membrane potential. TWEAK promoted histone H3 deacetylation at the murine PGC-1α promoter. TWEAK-induced downregulation of PGC-1α was prevented by histone deacetylase (HDAC) or NFκB inhibitors.

Conclusions: TWEAK decreases PGC-1α and target gene expression in tubular cells through NFκB activation and histone deacetylation. This information may be used to design therapeutic approaches that preserve mitochondrial function during kidney injury.

Funding: Private Foundation Support, Government Support - Non-U.S.

miR-21 Targets Prolyl Hydroxylase Domain Protein 2 in Renal Ischemia/reperfusion
Xiaoyan Jiao,[1,2,3] Xialian Xu,[1,2,3] Jie Teng,[1,2,3] Yi Fang,[1,2,3] Mingyu Liang,[4] Xiaoqiang Ding.[1,2,3] *[1]Div of Nephrology, Zhongshan Hospital, Fudan Univ, Shanghai, China; [2]Shanghai Inst of Kidney Disease and Dialysis, Shanghai, China; [3]Kidney and Blood Purification Laboratory of Shanghai, Shanghai, China; [4]Dept of Physiology and Center of Systems Molecular Medicine, Medical College of Wisconsin, Milwaukee, WI.*

Background: We previously reported that up-regulation of miR-21 attenuated renal ischemia-reperfusion injury, which was associated with increased hypoxia inducible factor (HIF)-1α expression. HIF-1α is mediated by prolyl hydroxylase domain protein 2 (PHD2) .We hypothesized that miR-21 regulated HIF-1α by targeting PHD2 in the renal ischemic preconditioning (IPC).

Methods: Luciferase reporter assay was performed to examine if miR-21 could target the 3'-untranslated region of PHD2. *In vitro,* hypoxia (1% O_2) for 6h was followed by reoxygenation for 0.5h in HK-2 cell. *In vivo*, bilateral kidneys of mice were clamped for 15min to induce IPC, followed by 35min ischemia 4 days later in the IPC/IR group. The mice for Sham/IR group were subjected to 35min ischemia without IPC. Locked nucleic acid (LNA) modified anti-miR-21 or scrambled anti-miR was transfected into cells or delivered into the mice via tail vein injection less than 1 hour prior to IPC.

Results: miR-21 targeting of PHD2 was confirmed by 3'-untranslated region reporter assay. miR-21 was significantly up-regulated by hypoxia/reoxygenation in HK-2 cell, while PHD2 protein decreased significantly. LNA anti-miR-21 significantly decreased miR-21 levels and increased the abundance of PHD2. In vivo, IPC up-regulated miR-21 expression 24h after the second ischemia. PHD2 expression decreased significantly with up-regulation of HIF-1α protein and VEGF mRNA in the IPC/IR group. miR-21 induced by delayed IPC was effectively inhibited by the LNA anti-miR-21. With down-regulation of miR-21, the protection of delayed IPC was attenuated and PHD2 protein was increased. Furthermore, up-regulation of HIF-1α and VEGF were abolished in the IPC/IR mice after the LNA anti-miR-21 treatment.

Conclusions: miR-21 could protect kidney against IRI via HIF-1α by inhibiting PHD2. The study suggested a new mechanism mediating the effect of miR-21 on HIF-1α and renal IRI.

Funding: Government Support - Non-U.S.

Mir-668 Is Induced via HIF-1 to Prevent Mitochondrial Fragmentation and Protect Kidneys from Ischemia-Reperfusion Injury
Qingqing Wei,[1] Yong Liu,[2] Mingyu Liang,[2] Zheng Dong.[1,3] *[1]Dept of Cellular Biology and Anatomy, Medical College of Georgia, Georgia Regents Univ, Augusta, GA; [2]Dept of Physiology, Center of Systems Molecular Medicine, Medical College of Wisconsin, Milwaukee, WI; [3]Charlie Norwood VA Medical Center, Augusta, GA.*

Background: MicroRNAs are important regulators in various pathophysiological condition including ischemic acute kidney injury(AKI). We identified mir-668 that was significantly up-regulated in ischemic AKI. mir-668 induction was attenuated in kidney proximal tubule-HIF-1-knockout mice, suggesting a role of HIF-1 in the inductive response.

Methods: Analysis of the sequence of the potential promoter region of mir-668 predicted two HIF-1 binding sites. The binding of HIF-1 to one of the sites was verified by Chromatin immunoprecipitation (CHIP) assay, suggesting that HIF-1 may directly regulate mir-668 transcription.

Results: Functionally, inhibition of mir-668 exacerbated kidney injury, supporting a protective role of this microRNA. Consistently, inhibition of mir-668 led to apoptosis in cultured rat proximal tubular cells (RPTC) and overexpress mir-668 reduced ATP-depletion mediated RPTC apoptosis. Interestingly, mir-668 inhibition also induced significant mitochondrial fragmentation, a pathogenic event in renal tubular cell death in ischemic AKI. To further examine the regulation mechanism of mitochondrial morphology by mir-668, we identified a list of potential mir-668 targets by Ago2 immunoprecipitation and RNA deep sequencing.

Conclusions: In summary, mir-668 is up-regulated via HIF-1 during ischemic AKI. Following the induction, mir-668 may play a role in the preservation of mitochondrial dynamics and morphology for the protection of kidney cells and tissues. n also induced significant mitochondrial fragmentation, a pathogenic event in renal tubular cell death in ischemic AKI. To further examine the regulation mechanism of mitochondrial morphology by mir-668, we identified a list of potential mir-668 targets by Ago2 immunoprecipitation and RNA deep sequencing.

Implication of AMPK Activation in Experimental Aristolochic Acid Nephropathy: Use of a Targeted Metabolomic Analysis
Anne-Emilie Decleves,[1] Inès Jadot,[3] Vanessa Colombaro,[3] Kefeng Li,[2] Nathalie Caron,[3] Joelle L. Nortier,[1] Robert K. Naviaux.[2] *[1]Free Univ of Brussels; [2]Univ of California, San Diego; [3]Univ of Namur.*

Background: Experimental aristolochic acid nephropathy (AAN) is a progressive tubulointerstitial injury, characterized by early and transient acute tubular necrosis. In order to better explore the pathogenesis of AAN, a targeted metabolomic analysis was performed in plasma of AA-intoxicated mice. In addition, the effect of AMP-activated Protein Kinase (AMPK) activation with AICAR was also investigated.

Methods: C57BL/6J male mice were randomly subjected to i.p. injection of either sterile saline solution, AA, AA+AICAR, the specific AMPK activator for 4 days. Mice were then euthanized at day 5. Targeted metabolites were detected in plasma using an AB SCIEX QTRAP 5500 triple quadrupole mass spectrometer equipped with a Turbo V electrospray ionization (ESI) source, and Shimadzu LC-20A UHPLC system.

Results: Thirty metabolites were dysregulated in this acute phase of the experimental AAN model. Among them, 23 metabolites were significantly increased in AA-treated mice and 7 were significantly decreased. AICAR treatment ameliorated the change of 15 of these metabolites. Among the observed changes, several metabolic pathways were affected, in particular gut microbiome metabolism, liver and bile acid metabolism, tryptophan metabolism, purine and pyrimidine metabolism and mitochondrial metabolism. Tryptophan-derived metabolites considered as uremic toxin such as xanthurenic acid, kynurenic acid were increased in AA-treated mice and reduced with AICAR.

Conclusions: These metabolomic approach provided novel findings regarding early perturbations occurring in metabolic pathways in AAN. Moreover, our results suggest 1)

a crosstalk between gut microbiome and kidney, especially in relation with tryptophan metabolism and accumulation of uremic toxins; 2) a beneficial role of AMPK in reducing the level of uremic toxins.

Suppressed Renal Mitochondrial Biogenesis After Liver Transplantation in Rats Zhi Zhong,[1] Qinlong Liu,[1,2] Yasodha Krishnasamy,[1] Hasibur Rehman,[1] Peifeng Deng,[1] John J. Lemasters,[1] Rick G. Schnellmann.[1,3] *[1]Medical Univ of South Carloina, Charleston, SC; [2]Darlian Medical Univ, 2nd Affiliated Hospital, Darlian, China; [3]Ralph H. Johnson VA Medical Center, Charleston, SC.*

Background: Suppressed mitochondrial biogenesis (MB) contributes to acute kidney injury (AKI) after renal ischemia-reperfusion and sepsis. AKI occurs frequently after liver transplantation (LT), which substantially increases mortality. This study investigated whether suppressed MB plays a role in AKI after LT.

Methods: Livers were explanted from Lewis rats and implanted after 18 h cold storage. Liver, kidney and blood were collected 18 h after LT or survival was determined at 7 days.

Results: Seven-day survival after LT decreased to 25%. Focal necrosis, apoptosis and leukocyte infiltration occurred in liver grafts, and serum ALT and total bilirubin increased markedly after LT. In the kidney, nuclear DNA-encoded oxidative phosphorylation (OXPHOS) protein ATP synthase-β and mitochondrial DNA (mtDNA)-encoded OXPHOS protein NADH oxidase-3 decreased 44% and 81%, respectively, and their associated mRNAs decreased 72% and 46%, respectively, indicating suppressed OXPHOS protein synthesis. Renal PGC-1α, the master regulator of MB, decreased 57% after LT and mitochondrial transcription factor-A (TFAM), which controls mtDNA replication and transcription, decreased 66%. PGC-1α and TFAM mRNAs also decreased. mtDNA was reduced by 60%. Together, these data indicate marked MB suppression in the kidney after LT. Inhibited MB was associated with 17- and 13-fold increases in NGAL and cleaved caspase-3 in the renal tissue. Mild to moderate histological changes were observed in the kidney, including loss of brush border, vacuolization of tubular cells in the cortex, cast formation and necrosis in some proximal tubular cells. Myeloperoxidase and ED-1 also increased in the kidney after LT, indicating inflammation. Serum creatinine increased >2 fold.

Conclusions: MB is disrupted in the kidneys of recipients of liver grafts after long cold storage, which may contribute to the occurrence of AKI and increased mortality after LT.

TXNIP Is Involved in the Mitochondrial ROS Mediated NLRP3 Inflammasome Activation in Ischemia/Reperfusion Induced AKI Liu Yiran, Wen Yi, Tang Taotao, Bi-Cheng Liu. *Inst of Nephrology, Southeast Univ, Nanjing, Jiangsu Province, China.*

Background: Renal ischemia reperfusion is a leading cause of acute kidney injury (AKI). Previews studies suggest that mitochondrial dysfunction and NLRP3 inflammasome activation are important events of AKI. TXNIP, an endogenous inhibitor of the antioxidant thioredoxin and ROS sensor, may have a role in NLRP3 inflammasome activation. In this study, we explored the relationship between TXNIP on NLRP3 inflammasome activation in ischemia/reperfusion induced AKI.

Methods: Ischemic mice models were built as previewsly reported. MitoTEMPO, a mitochondria-targeted antioxidant, was used to attentuate ROS production. Also, HK-2 cells were cultured for 8h with hypoxia-hypoglycemic plus 2 h normoxia/normal glucose incubation. SiRNA of NLRP3 and TXNIP were applied to interupt the signaling.

Results: In this study, we established an ischemia reperfusion induced-AKI model characterized by tubular necrosis and excessive mROS production.The renal expression of NLRP3 inflammasome, IL-1β and IL-18 were significantly increased in this animal model. However, kidney dysfunction and mitochondrial damage were attenuated obviously in NLRP3$^{-/-}$ mice compared with WT mice with ischemia AKI. In vitro study,oxygen–glucose deprivation injury time dependently increased the expression levels of NLRP3 inflammasome axis and TXNIP. The mitochondrial injury in damaged HK2 cells was suppressed by silence of NLRP3. Furthermore, MitoTEMPO could restore mitochondrial function and dissociate TXNIP from NLRP3 to inhibit NLRP3 inflammasome activation. TXNIP siRNA significantly abrogated the mROS and NLRP3 inflammasome activation.

Conclusions: NLRP3 inflammasome activation induced by excessive ROS production in ischemic AKI is mediated by TXNIP. And the mROS-TXNIP-NLRP3 inflammasome pathway can be a potential target for AKI therapy.

PPAR Activation in Regulatory T Cells Enhances Protection from Kidney Ischemia Reperfusion Injury Gilbert R. Kinsey, Didier Portilla, Liping Huang, Mana Yang, Michael N. Pham, Brian K. Stevens. *Medicine, Univ of Virginia, Charlottesville, VA.*

Background: Regulatory T cells (Tregs) are anti-inflammatory lymphocytes that protect the kidney from multiple types of injury. Our recent studies suggest that Tregs must express the surface receptor programmed death 1 (PD-1) to mediate protection. A metabolic program favoring mitochondrial oxidative phosphorylation (OxPhos) over glycolysis in Tregs is critical for Treg development and function in other models. PD-1 and peroxisome proliferator-activated receptors (PPARs) promote OxPhos in several cell types, but their role in Treg-mediated renal protection is not known.

Methods: Mitochondrial membrane potential (TMRE) and mass (Mitotracker) were assessed using flow cytometry. Tregs isolated from WT or PD-1 KO mice were adoptively transferred to naïve WT recipients 1 hr prior to ischemia reperfusion injury (IRI). WT and PD-1 KO Tregs were exposed to the pan PPAR activator bezafibrate (BEZA) or vehicle (DMSO) overnight, then washed, prior to adoptive transfer in the IRI model.

Results: PD-1 KO Tregs had significantly lower mitochondrial mass and mitochondrial membrane potential (TMRE mean fluorescence intensity: 45±10% of WT Tregs, $p<0.05$). In contrast to WT Tregs, untreated PD-1 KO Tregs offered no protection from kidney IRI in terms of plasma creatinine levels, ATN scores and kidney neutrophil accumulation at 24 hr of reperfusion. Treatment of WT Tregs with bezafibrate overnight significantly enhanced the ability of a sub-optimal number of Tregs to protect the kidney from IRI (24 hr plasma creatinine (mg/dl): Sham 0.4±0.1; IRI + saline 1.8±0.1; IRI+ WT Tregs (DMSO) 1.1±0.3; IRI + WT Tregs (BEZA) 0.6±0.1*, N=7 per group, *P<0.01 vs. DMSO). Bezafibrate treatment endowed PD-1 KO Tregs with modest, but statistically significant, protective ability in the kidney IRI model.

Conclusions: These results demonstrate that PD-1 must be expressed on Tregs in order for them suppress kidney IRI and that PPAR activation *ex vivo* enhances subsequent Treg activity in this model. Our findings suggest that enhanced OxPhos in Tregs promotes their ability to protect the kidney.

Effects of Short Chain Fatty Acids on Inflammatory Process in Acute Kidney Injury Sung Yoon Lim,[1] Young Ju Na,[1] Myung-gyu Kim,[1] So-young Lee,[2] Sang-Kyung Jo,[1] Won-Yong Cho.[1] *[1]Dept of Nephrology, Korea Univ Hospital, Seoul, Korea; [2]Dept of Nephrology, Eulji Univ Hospital, Korea.*

Background: Short chain fatty acids (SCFAs) are the metabolic end products of normal bacterial fermentation of fibers in the large intestine. Emerging evidence suggest the role of gut-kidney crosstalk in regulating inflammatory processes. Purpose of the present study was to elucidate the role of SCFAs in an acute kidney injury (AKI) in which the inflammatory process has a major role.

Methods: Bilateral ischemia reperfusion injury (IRI) was induced in C57BL/6 mice. Sodium acetate were given to mice 30 minutes before ischemia and at the moment of reperfusion. Biochemical values, histological kidney damage and tissue inflammation were assessed. In in vitro analysis, immune cells harvested from mice spleen were stimulated with LPS and the effect of sodium acetate on cytokine production was measured. Effects of SCFAs on T cell proliferation was also determined.

Results: Treatment with SCFAs attenuated IRI and reduced inflammation. Tubular cell apoptosis, determined by TUNEL stain also was decreased by SCFAs. The anti-inflammatory effects of SCFAs persisted until IRI day 14, thereby attenuating renal fibrosis after injury. Significantly lower level of pro-inflammatory cytokines was observed in the supernatant of cells from spleen co-treated with LPS and SCFAs, compared with those treated with LPS alone. Especially, IL-12p70, major inflammatory cytokine of dendritic cells was also reduced, suggesting that SCFAs might modulate the function of dendritic subset. In addition, administration of SCFAs can dose dependently inhibit normal T cell proliferation induced by anti-CD3 Ab stimulation.

Conclusions: Thus, our findings provide evidence that the SCFAs have renoprotective effect in AKI and also that this might be partially mediated by its immune modulatory effect.

TH-PO014

The Renoprotective Effect of Abatacept in Ischemia/Reperfusion Injury in Mice Masaki Saito, Shinya Kaname, Hideki Shimizu, Yoshinori Komagata, Yoshihiro Arimura. *Kyorin Univ School of Medicine, 6-20-2 Shinkawa, Mitaka, Tokyo, Japan.*

Background: Although AKI is still an important complication in hospitalized patients, its prognosis remains poor, thus elucidation of the pathogenic mechanism and its effective treatment is urgently needed. Recently, a role for T cells in the renal ischemia/reperfusion injury (IRI) and also the renoprotective effect of abatacept, an inhibitor for CD28-CD80 T cell costimulatory signals, in the IRI have been reported, while its precise mechanisms are not fully understood. The purpose of this study is to determine the effect and mechanism of abatacept in the IRI model in mice.

Methods: Heminephrectomized mice were divided into three groups; the mice treated with ischemia/reperfusion (22 min) with normal saline or abatacept, and those treated with sham operation without renal ischemia as a control. Renal function (serum urea nitrogen and Cr, urine albumin excretion), pathology including T cell infiltration, expression of mRNA and protein for various parameters in the kidney were evaluated at 1 day after ischemia/reperfusion procedures.

Results: Compared with normal saline-treated mice, renal injury in the abatacept-treated mice were markedly attenuated both functionally and pathologically, with serum parameters improved to almost control levels. In addition, in abatacept-treated mice, apoptosis and expression of KIM-1 and PAI-1 were significantly suppressed as compared with normal saline-treated mice. Although the number of inflammatory cells and expressions of MCP-1 reduced by abatacept, the number of CD3-positive T cells, which was increased after ischemia/reperfusion, was not altered by abatacept.

Conclusions: We here showed that abatacept dramatically ameliorate IRI in mice, suggesting that it might be a new therapeutic option. It may be that abatacept, by blocking CD80-mediated signal in some cells responsible for the pathogenesis, exhibit anti-inflammatory effects, resulting in improvement of IRI, independently of T-cell-mediated acquired immune mechanisms.

Autophagy Is Activated to Protect against Kidney Injury following in Lipopolysaccharide Treatment Shuqin Mei,[1,2] Man J. Livingston,[2] Changlin Mei,[1] Zheng Dong.[2] *[1]Nephrology, Shanghai Changzheng Hospital, Shanghai, China; [2]Cellular Biology and Anatomy, Georgia Regents Univ, Augusta, GA.*

Background: Sepsis, characterized by systemic inflammation, is a major cause of acute kidney injury (AKI) in hospitalized patients, especially in intensive care unit. The pathogenesis of septic AKI is poorly understood. Autophagy is a conserved, cellular catabolic pathway that plays crucial roles in cellular homeostasis including the maintenance of cellular function and viability. The regulation and role of autophagy in septic AKI remains unclear.

Methods: Lipopolysaccharide (LPS), an endotoxin, was injected in C57BL/6 mice to induce endotoxic/septic AKI. Autophagy reporter (*CAG-RFP-EGFP-LC3*) mice were used to monitor the dynamic changes of autophagy following LPS treatment. To determine the pathological role of autophagy, autophagy was inhibited pharmacologically with chloroquine or genetically by using proximal tubule-specific Atg7 (Autophagy gene-7) ablated mice. Blood urea nitrogen (BUN) and serum creatinine were measured to evaluate renal function. HE staining and TUNEL staining were used to detect kidney injury. For in vitro study, cultured proximal tubular cells were treated with LPS in the absence or presence of chloroquine.

Results: LPS induced AKI in mice as indicate by increased in BUN and serum creatinine, and tubular injury, which was accompanied by an increase in LC3II expression. In *CAG-RFP-EGFP-LC3* mice, LPS induced mRFP and EGFP-labeled autophagic puncta in renal tubular cells, further verifying the activation of autophagy. Chloroquine enhanced kidney injury during LPS treatment. For in vitro study, we detected LC3II expression accumulation and P62 degradation after LPS treatment for 12 hours, which was consistent with the mRFP, EGFP-labeled autophagic puncta results showed in proximal tubular cells.

Conclusions: Autophagy is activated in LPS-induced AKI and plays a renoprotective role.

TH-PO016

Vascular Endothelial Growth Factor (VEGF) Contributes to Sepsis-Induced Acute Kidney Injury Arnaldo F. Lopez-Ruiz, Andrea P. Soljancic, Kiran B. Chandrashekar, Luis A. Juncos. *Nephrology, Univ of Mississippi Medical Center, Jackson, MS.*

Background: Sepsis is the most common cause of acute kidney injury (AKI) in the ICU. However, we still have an incomplete understanding of the mechanisms that cause it, and consequently our therapies provide only suboptimal protection at best. Previous studies have shown that VEGF is upregulated in sepsis and plays a role in its associated morbidity and mortality. We recently found that sFlt-1, an endogenous VEGF inhibitor is upregulated in both sepsis and AKI; however not sufficiently to normalize VEGF levels or neutralize its deleterious effects. We tested whether administering additional sFlt-1 protects against AKI and improves the balance between deleterious and protective cytokines and factors.

Methods: We used the cecal ligation and puncture technique (CLP) to induce sepsis. Male Sprague-Dawley rats were randomized into 4 groups: 1) Sham. 2) Sham + sFlt-1, 3) CLP, 4) CLP + sFlt-1. We administered sFlt-1 (12 µg/kg SQ) 6 hs after the CLP or sham procedure. At 24hs the rats were euthanized after collecting blood and kidneys for determination renal function and injury.

Results:

	VEGF pg/ml	Sflt-1 pg/ml	Creat mg/dl	uKIM-1 pg/ml	TNF pg/ml	i-NOS pg/ml	HO-1 ng/ml
SHAM	370± 10	30± 5	0.5± 0.07	135± 5	20± 0.8	1.8± 0.3	0.53± 0.01
CLP	780± 15 *	330± 10 *	2.2± 0.09 *	1900± 50 *	265± 10 *	13± 0.5 *	3.0± 0.1*
CLP+Sflt-1	530± 10 * #	500± 15 * #	1.4± 0.1 * #	1100± 45 * #	130± 6 * #	6± 0.4 * #	7.5± 0.2 * #

Data: Mean ± SEM * p< 0.05 vs Sham #p<0.05 vs CLP

Conclusions: CLP causes AKI within 24hs and is associated with increased intra-renal expression of VEGF, i-NOS, TNF and only a modest increase in renal HO-1. Administering Sflt-1 during sepsis attenuated the severity of AKI and blunted the increase in i-NOS, VEGF and TNFα, while paradoxically causing a large increase in HO-1. Our data demonstrate a protective effect of sFlt-1 in sepsis-induced AKI, suggesting that excessive VEGF is deleterious in this condition, and that sFlt-1 associated induction of HO-1 may play a role in its beneficial actions.

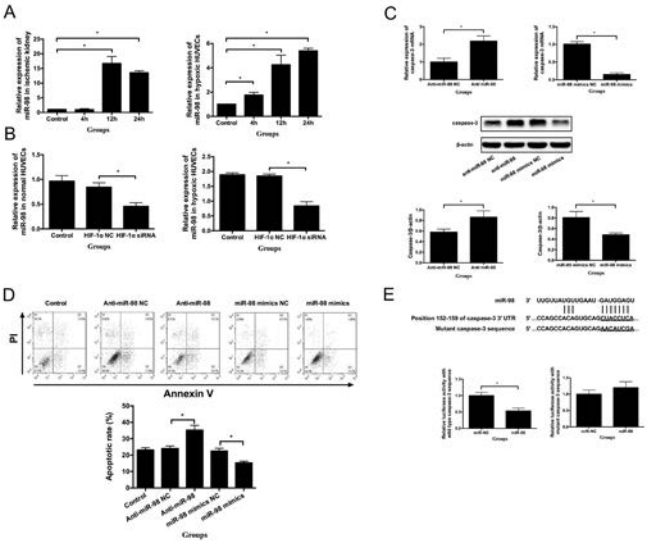
Up-Regulation of miR-98 in the Kidney with Ischemia Reperfusion Injury Protects Endothelial Cells against Apoptosis by Targeting Caspase-3 Guang Yu, Xueli Lai. *Dept of Nephrology, Changhai Hospital, the Second Military Medical Univ, Shanghai, China.*

Background: Endothelial dysfunction is one of the main pathophysiological processes involved in renal ischemia reperfusion injury. In our previous study, we screened the aberrantly expressed miRNAs in the kidney with ischemia reperfusion injury (IRI) by microarray assay, among which miR-98 was predicted to target caspase-3. The present study was performed to whether miR-98 was involved in the regulation of endothelial apoptosis under hypoxia and re-oxygenation (HR) conditions.

Methods: The level of miR-98 in IRI kidney and HR HUVECs was determined by real-time PCR. HUVECs were treated with HIF-1α siRNA to investigate the role of HIF-1α on miR-98 regulation. HUVECs were transfected with miR-98 mimics or antisense oligonucleotides against miR-98 to identify the effect of miR-98 on the expression of caspase-3, as well as the hypoxia-induced apoptosis. Finally, the relationship between miR-98 and caspase-3 was confirmed by dual-luciferase reporter assay.

Results: Both of IRI and HR induced significantly up-regulation of miR-98 in the ischemic kidney and hypoxic HUVECs, respectively (Figure 1A). HIF-1α siRNA remarkably down-regulated the expression of miR-98 in both normal and hypoxic HUVECs (Figure 1B). MiR-98 mimics significantly inhibit caspase-3 expression in HUVECs, while anti-miR-98 significantly up-regulated it (Figure 1C). Furthermore, miR-98 protected HUVECs against apoptosis induced by hypoxia, while anti-miR-98 had the reverse effect (Figure 1D). The dual-luciferase reporter assay showed that miR-98 decreased the luciferase activity when transfected with wild-type caspase-3 sequence, but not mutant sequence at the predicted binding site (Figure 1E).



Conclusions: Renal IRI induces up-regulation of miR-98 potentially dependent on HIF-1α, which protects endothelial cells against apoptosis by targeting caspase-3.

Funding: Government Support - Non-U.S.

TH-PO018

Endothelial Caspase-8 Is a Key Mediator of Sepsis-induced Acute Kidney Injury Bradley K. Hack, Lihua Bao, Chang Xu, Patrick Cunningham. *Section of Nephrology, Univ of Chicago, Chicago, IL.*

Background: Acute kidney injury (AKI) is a frequent complication of gram negative sepsis. Prior work has demonstrated the importance of tumor necrosis factor (TNF) in endotoxin (LPS)-induced AKI. Caspase-8 is a key downstream effector of TNF, leading to apoptosis, and possibly facilitating inflammation. Mice genetically deficient in caspase-8 die *in utero* due to abnormal cardiovascular development.

Methods: To define the importance of caspase-8 activation in the endothelium in sepsis, we generated mice deficient in endothelial cell caspase-8 (EC-Casp8$^{-/-}$), using Cre expressed in the endothelium under inducible control of the VE-cadherin promoter, activated after tamoxifen administration. After one week of tamoxifen followed by a washout period, mice were injected with 0.25 mg/g E. coli LPS i.p. At baseline, EC-Casp8$^{-/-}$ mice showed an absence of caspase-8 staining in endothelium after tamoxifen. Mice were sacrificed at 24 h and blood collected for cytokines, BUN, and creatinine. Kidney tissue was analyzed for light microscopic and immunohistochemistry. A subset of mice underwent renal cortical blood flow measurement by laser Doppler.

Results: As expected, wildtype mice developed significant AKI with elevation of BUN and subtle pathologic injury. In contrast, EC-Casp8$^{-/-}$ mice had significantly less AKI (24 h BUN of 45.3 +± 11.2 v. 114.9 ± 9.9 mg/dl, $p < 0.01$). LPS induced a decrease in renal cortical blood flow that was restored in EC-Casp8$^{-/-}$ mice (24 h renal blood flow of 1472 ± 61 perfusion units (BPU) in saline injected controls, 614 ± 89 BPU in LPS injected wildtype mice, and 1320 ± 159 BPU in LPS injected EC-Casp8$^{-/-}$ mice, $p < 0.01$). EC-Casp8$^{-/-}$ mice

also had reduced evidence of pathologic injury on light microscopy (cortical injury score 0.9 ± 0.20 in LPS injected EC-Casp8$^{-/-}$ mice v. 1.7 ± 0.15 in wildtype, $p < 0.05$), and evidence of less vascular and tubular apoptosis on TUNEL staining.

Conclusions: These findings point to a key role of endothelial caspase-8 in sepsis-induced AKI. Further work will determine the relative role of caspase-8 in affecting renal microvascular perfusion, inflammation, and apoptosis in sepsis-induced AKI.

TH-PO019

Sepsis Reduces Kidney Function in Mice Before Hemodynamic Alterations or Clinical Symptoms Become Apparent Jonathan Street, Yuning George Huang, Peter S.T. Yuen, Robert A. Star. *NIDDK, Bethesda, MD.*

Background: Acute kidney injury (AKI) increases the mortality and morbidity of sepsis. A rise in serum creatinine is used to detect AKI clinically and experimentally, but the slow kinetics prevents early detection of injury. To expand our understanding of the onset of AKI following sepsis we used a novel transcutaneous measurement of the plasma clearance of a fluorescent marker to directly measure GFR in near real-time.

Methods: Sepsis was induced in male CD-1 mice by cecal ligation and puncture (CLP). Blood pressure, heart rate, and activity/locomotion were simultaneously monitored by an implanted telemetry device. FITC-Sinistrin was injected at 0 and 90 min after surgery enabling GFR to be monitored for 5 hours via transcutaneous fluorescence, measured by a miniaturized fluorimeter attached to the mouse back.

Results: Log transformation of FITC-Sinistrin fluorescence decay allowed easy identification of when single pool kinetics applied, permitting calculation of GFR. GFR following CLP was similar to baseline during the first hour. During the second hour GFR fell by 30%, and dropped to 20% of baseline by 5 hours ($p<0.01$). In contrast, mean arterial pressure, and heart rate were stable immediately following CLP, but then began to decrease, and were statistically significantly different from sham 3, and 4 hours later, respectively ($p<0.01$). Activity/locomotion began to decline in the second hour, and was significantly different from sham 4 hours after CLP ($p<0.01$).

Conclusions: Transcutaneous fluorescence measurement of plasma clearance longitudinally enables greater temporal resolution in measured GFR than prior approaches, revealing novel pathophysiology during early AKI. GFR was initially stable after sepsis surgery, then fell rapidly 2 hours later. The fall in GFR preceded hemodynamic alterations and the appearance of clinical symptoms such as reduced activity.

Urinary AIM/CD5 Interacts with Kidney Injury Molecule-1 (KIM-1) and Promotes Recovery from Acute Kidney Injury via Enhancing Intraluminal Debris Clearance Toru Miyazaki, Kento Kitada, Satoko Arai. *Molecular Biomedicine for Pathogenesis, Faculty of Medicine, The Univ of Tokyo, Tokyo, Japan.*

Background: Acute kidney injury (AKI) is associated with prolonged hospitalization and high mortality, and may predispose patients to chronic kidney disease. To date, no effective treatments have been established for AKI. The apoptosis inhibitor of macrophage (AIM; also called CD5L) protein is a circulating protein that associates with IgM pentamers in blood, which protects AIM from renal excretion and maintains high levels of AIM (approximately 5 mg/mL in humans and mice) in blood.

Methods: By *in vivo* studies using AKI mouse models on a wild-type and AIM-deficient background, as well as *in vitro* experiments including phagocytosis assay focusing on the functional relationship between AIM and kidney injury molecule-1 (KIM-1), we here present that AIM is a ligand of KIM-1 and promotes potent clearance of pathogenic dead cell debris by tubular epithelial cells, which is crucial for overall recovery from AKI.

Results: The blood AIM dissociates from IgM upon AKI attack and excreted in urine in AKI patients and mice. The urinary AIM accumulates on intratubular dead cell debris. The accumulated AIM binds to KIM-1 on injured tubular epithelial cells and induces the phagocytic removal of the debris by epithelial cells, facilitating kidney tissue repair. When subjected to ischemia/reperfusion-induced AKI, AIM-deficient mice exhibit abrogated debris clearance and markedly higher mortality due to progressive renal dysfunction than wild-type mice. AIM administration promotes the rapid removal of the debris, thereby ameliorating AKI in both AIM-deficient and wild-type mice.

Conclusions: Our study demonstrates that the AIM/KIM-1 cooperation efficiently promotes recovery from acute kidney injury through rapid clearance of intraluminal debris. These findings could be the basis for novel AKI therapies.

Funding: Government Support - Non-U.S.

Renal Handling of Circulating and Renal Synthesized Hepcidin and Its Protective Effects against Hemoglobin-Mediated Kidney Injury Rachel Van Swelm, Jack F. Wetzels, Vivienne G.M Verweij, Coby M.M. Laarakkers, Jeanne C.L.M. Pertijs, Rosalinde Masereeuw, Dorine W. Swinkels. *Radboudumc, Nijmegen, Netherlands.*

Background: In multiple clinical observational studies it has been demonstrated that increased urinary hepcidin levels are associated with reduced risk of developing acute kidney injury (AKI) due to hemolysis in cardiac surgery patients. This study aimed to get more insight in renal hepcidin handling and its potential protective effects against heme-mediated AKI.

Methods: C57Bl/6 mice were treated with i) a single i.p. dose of 10 µg human hepcidin-25 (hhep25) to study renal handling of systemic hepcidin, ii) a single i.v. dose of 5 mg hemoglobin (Hb) to induce AKI, and iii) Hb combined with hhep25 to evaluate the protective effects of hhep25 on Hb-mediated kidney injury.

Results: Systemic hhep25 was rapidly cleared from plasma and excreted to urine. In addition to hhep25, we also detected the smaller isoforms hhep22 and hhep20 in urine, but not in plasma, showing that hhep25 is degraded in the tubular lumen. Urine hhep25 was 20-fold increased in megalin deficient mice compared to control ($p<0.05$) and immunofluorescence staining showed that hepcidin was present in tubules expressing megalin, but NOT in megalin-deficient tubules, demonstrating that megalin is responsible for hhep25 uptake in the proximal tubules. Administration of hhep25 simultaneously or 4h after Hb injection in wildtype mice significantly attenuated the Hb-induced rise in urinary NGAL and KIM1 levels, and renal IL6 and NGAL mRNA expression. Interestingly, simultaneous administration of Hb and hhep25, but not Hb or hhep25 alone, resulted in an increase in renal Hamp1 mRNA expression (15 fold, $p<0.05$). Administration of hhep25 to Hb-treated mice reduced renal mRNA expression of HO-1, DMT1, H-ferritin and L-ferritin (all $p<0.05$), possibly reflecting the mechanisms by which hepcidin exerts its protective effects.

Conclusions: Systemic hepcidin is filtered to the urine, partly reabsorbed via megalin in the proximal tubules and degraded in the tubular lumen. Moreover, our data suggest that both systemically delivered hepcidin and locally produced hepcidin are involved in renal protection against heme-induced AKI.

TH-PO022

The Lungs in Mice with Acute Kidney Injury Have an Exuberant Inflammatory Response to Endotoxin Hyo-Wook Gil, Chris Altmann, Ana Andres-hernando, Danielle Soranno, Sarah Faubel. *Internal Medicine Renal, Univ of Colorado, Denver, CO.*

Background: Sepsis occurs in 40% of patients after the diagnosis of acute kidney injury (AKI) that may be related to impaired immune function. We sought to determine immune function specifically in the lungs in mice with AKI.

Methods: AKI was induced by bilateral renal pedical clamping. Lung immune function was assessed by intratracheal instillation of either endotoxin (LPS) or Pseudomonas bacteria to induce pneumonia.

Results: Intratracheal LPS was administered 4 hours or 7 days after Sham or AKI. 4 hours after intratracheal LPS, lung inflammation as judged by bronchoalveolar fluid TNF, lung myeloperoxidase (MPO) activity (a marker of lung neutrophils), and lung CXCL1 (a neutrophil chemokine) was greater after AKI+IT LPS versus Sham+IT LPS in both the 4 hour and 7 day group ($P<0.05$ for all endpoints n=4). To determine the role of alveolar macrophages, alveolar macrophages were recovered by bronchoalveolar lavage 4 hours after Sham or AKI, placed in culture, and exposed to endotoxin. Media TNF-α was significantly higher in alveolar macrophages from AKI. Since the response to endotoxin was excessive, we tested the response to pneumonia. AKI or Sham was performed and pneumonia was induced at 2 different time points post procedure: 1) 5 minutes and 2) 7 days. 24 hours after induction of pneumonia, blood cultures were 0 colony forming units (CFU) in Sham and 61 CFU in AKI (n=10); notably, 0% of Sham were bacteremic (n=0 of 10) and 60% of AKI were bacteremic (n=6 of 10) in the 5 minute group; in the 7 day group, blood cultures were higher in AKI and were 31% positive in sham (4 out of 13), and 70% positive in AKI (7 out of 10). Inflammation (as judged by lung MPO activity) was greater in AKI + pneumonia versus Sham + pneumonia in both 5 min and 7 d groups. Lung cultures were similar in Sham and AKI in both time groups indicating similar infection fighting ability between Sham and AKI.

Conclusions: In mice with AKI, the lung immune response to bacteria or gram negative bacteria is characterized by an exuberant inflammatory response which leads to bacteremia during pneumonia .

Inhibition of MEK/ERK by Trametinib Attenuates Sepsis-Induced Systemic Inflammation and Multi-Organ Injury in Mice Joshua Andrew Smith,[1] Philip R. Mayeux,[2] Rick G. Schnellmann.[1] *[1]Drug Discovery and Biomedical Sciences, Medical Univ of South Carolina, Charleston, SC; [2]Pharmacology and Toxicology, Univ of Arkansas for Medical Sciences, Little Rock, AR.*

Background: MEK/ERK signaling is an essential component of the innate immune response in sepsis. We previously demonstrated that a potent and specific inhibitor of MEK1/2, trametinib, prevents endotoxin-induced renal injury in mice. Our goal was to further assess the efficacy of trametinib in a more clinically relevant model of sepsis induced by cecal ligation and puncture (CLP) in mice.

Methods: Male C57BL/6 mice (40 weeks of age) were subjected to CLP, and trametinib (1 mg/kg, i.p.) was administered at 6 h post-CLP. Serum cytokine levels were determined using a Luminex-based multiplex assay. Standard assays were used to measure clinical markers of organ/cellular injury including serum creatinine (SCr), blood urea nitrogen (BUN), alanine aminotransferase (ALT), creatine kinase (CK), and lactate dehydrogenase (LDH) in the serum. Renal microvascular perfusion was evaluated by intravital microscopy. Transcript levels of tubular injury markers and pro-inflammatory cytokines in the renal cortex were determined by qPCR.

Results: Delayed trametinib administration partially attenuated increases in circulating pro-inflammatory cytokines (TNF-α, IL-1β, IL-6, GM-CSF) and development of hypothermia at 18 h post-CLP. In addition, MEK/ERK inhibition restored SCr to baseline levels and reduced other markers of organ/cellular injury (serum ALT, CK, LDH) in CLP animals. In the kidney, trametinib completely reversed the early deficits in peritubular capillary perfusion and decreased mRNA expression of tubular injury markers including KIM-1, NGAL, and HO-1. MEK/ERK blockade also attenuated CLP-mediated up-regulation of cytokines (TNF-α, IL-1β, IL-6) in the renal cortex.

Conclusions: These data reveal that the MEK/ERK inhibitor trametinib attenuates systemic inflammation, AKI, and other organ injury in a clinically relevant model of sepsis, even with delayed administration. Since trametinib is FDA approved, this drug may represent a readily translatable approach to limit organ injury in sepsis.

Chemokine Receptor 5 Blockade Modulates Inflammation and Immunity in Renal Ischemic Reperfusion Injury Kyung Don Yoo,[1] Hajeong Lee,[1] Ran-hui Cha,[2] Jung Pyo Lee,[1] Yon Su Kim,[1] Seung Hee Yang.[3] *[1]Seoul National Univ College of Medicine; [2]National Medical Center; [3]Seoul National Univ Kidney Research Inst.*

Background: The CC chemokine receptor (CCR5) is an important regulator of macrophage trafficking in the kidney in response to inflammation and immunity. Therefore, we investigated a role of CCR5 in the pathogenesis of experimental ischemic reperfusion injury (IRI).

Methods: Bilateral renal artery pedicles clamping for 30 min followed by reperfusion was performed on B6 wild type and CCR5 KO mice. We performed adoptive transfer of LPS treated RAW cells following depletion of macrophage by liposome clodronate (LC) in mice.

Results: CCR5 KO mice showed less aggravated IRI in terms of the apoptosis of tubular epithelial cells and creatinine compare to B6 wild type. CCR5 deficiency decreased mRNA expressions of proinflammatory cytokines but increased mRNA expressions of Th2 cytokines. CXCR3 positivity in CD11b+ cells and iNOS were attenuated in CCR5 KO mice compared to that in B6 wild type mice. On the contrary, the CCR5 KO mice showed increased numbers of Arg1- or CD206-expressing macrophages. LC-treated wild type mice showed severe injury compared to CCR5 KO mice aftertransfer of M1 macrophage. Adoptive transfer of LPS-treated RAW cells, which constitutively express iNOS, reverses the functional protection against IRI only in wild-type, not CCR5 KO mice. When CCR5 was knocked out in macrophages, bone marrow-derived macrophages showed M2 macrophage activation.The migration of Bone marrow-derived macrophage fromwild type mice towardprimary tubular epithelial cell with rCCR5 was increased. Moreover, blockade of CCR5 inhibited migration of macrophages. Renal tissue of patients with delayed graft function frequently contained CCR5 cells, and the number of these cells tended to positively correlate with acute tubular necrosis severity.

Conclusions: These findings show that CCR5 deficiency favors M2 macrophages activation and provide a potential strategy for treating acute kidney injury through blocking CCR5.

TH-PO025

Early Activation of Inflammasome in Acute Kidney Injury After Renal Sympathetic Denervation in Pig Il Young Kim,[1] Min Jung Kim,[1] Joo Hui Kim,[1] Dong Won Lee,[1] Soo Bong Lee,[1] Su Min Park,[2] Jong Man Park,[2] Woo Jin Jung,[2] Harin Rhee,[2] Sang Heon Song,[2] Eun Young Seong,[2] Ihm Soo Kwak.[2] *[1]Internal Medicine, Pusan National Univ Yangsan Hospital, Yangsan, Republic of Korea; [2]Internal Medicine, Pusan National Univ Hospital, Busan, Republic of Korea.*

Background: Renal sympathetic denervation (RDN) is available and implemented as a strategy for the treatment of resistant hypertension. In the aspect of chronic safety, renal function, as assessed by serum creatinine, eGFR(MDRD), and cystatin C was reported to be unchanged from baseline at 6 months. We investigated whether RDN might cause subtle inflammation and subclinical damage in the early phase of acute kidney injury (AKI).

Methods: Female pigs were divided into 6 groups; normal control (group A), Sham-operated control (group B), contrast media control (group C), and renal sympathetic denervation groups subdivided into 3 groups according to the time of sacrifice; immediately (group D), 1 week later (group E), and 2 weeks later (group F) after RDN. We checked IL-1α, 1β, 18, 6, 10, TNF-α, cystatin C, caspase-1, ASC, and NLRP3 as early biomarkers of inflammation and AKI.

Results: There were no significant changes in group B and C compared to group A. Hb, BUN, serum Na, K, Cl, CRP, urine protein/creatinine ratio, and urine albumin/creatinine ratio showed no significant changes between groups. Serum creatinine and cystatin C were increased from 1st week after RDN. Serum LDH was increasedimmediately after RDN, and then decreased at 2nd week.IL-1α, -1β and -18 were increased immediately after RDN, and showed a tendency to be decreased at 2nd week after RDN. IL-6 was increased immediately after RDN, and also increased in contrast media control group. TNF-α was increased from 1st week after RDN. IL-10 was increased immediately after RDN, and decreased at 2nd week. Casapse-1 and ASC expression were increased from 1st week, and decreased at 2nd week after RDN. However NLRP3 expression showed no significant changes between groups.

Conclusions: RDN did not cause clinically significant damages on kidneys. However, RDN can induce the activation of pro-inflammatory cytokines, caspase-1 and then cause transientand self-limited acute kidney injury.

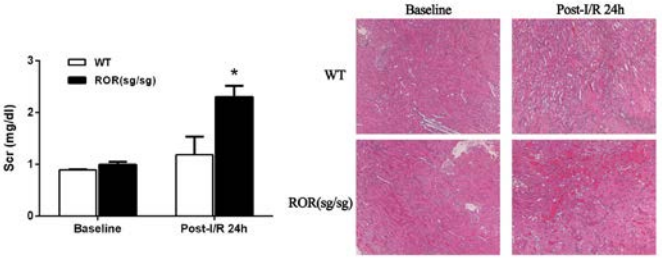
TH-PO026

The Orphan Nuclear Receptor ROR Alpha Exerts a Protective Potential in Acute Kidney Injury via Transcriptional Activation of HIF-1 Jieru Cai,[1] Rende Xu,[2] Xiaofang Yu,[1] Xiaoqiang Ding.[1] *[1]Dept of Nephrology, Zhongshan Hospital, Fudan Univ, Shanghai, China; [2]Dept of Cardiology, Zhongshan Hospital, Fudan Univ, Shanghai, China.*

Background: Emerging evidence indicates that retinoid-related orphan receptor alpha (RORalpha), a member of the ROR subfamily of nuclear receptors, mediates key cellular adaptions to hypoxia and contribute to pathophysiology of many disease states. However, the potential renal functions of RORalpha in response to ischemia/reperfusion (I/R) injury remain unclear. Here, we investigated the renal expression and biological function of RORalpha in acute kidney injury (AKI).

Methods: I/R injury was induced by 35min bilateral clamping of the renal pedicle and 24h reperfusion in wild-type and staggerer (RORalpha(sg/sg)) mice,a natural mutant strain lacking RORalpha expression. Renal injury and RORalpha abundance were analyzed. In addition, human proximal tubular cell line (HK-2) was used to investigate the expression of RORalpha under hypoxia.

Results: RORalpha was detected in both mouse renal endothelial and tubular epithelial cells.Significant up-regulation of RORalpha was found after renal I/R injury. Compared with wild-type, RORalpha(sg/sg) mice displayed significantly increased levels of serum creatinine (2.30±0.21 vs. 1.18±0.35mg/dl, p<0.01), renal tissue damage, and pro-inflammatory cytokine production after ischemic kidney injury.



Further mechanistic studies indicated that RORalpha agonists enhanced transcriptional activity of hypoxia-inducible factor 1alpha (HIF-1alpha) in HK-2 cells, which was abolished by siRNA-mediated silencing of endogenous RORalpha.

Conclusions: These results suggest that RORalpha protects kidney from I/R damage through transcriptional activation of HIF-1 and represents a potential therapeutic target for AKI.

Immunosuppressive Double Negative aβ T Cells Protect Mice from Ischemic Acute Kidney Injury Maria Noel Martina,[1] Sanjeev Noel,[2] Ankit Saxena,[1] Richa S. Majithia,[1] Samatha Bandapalle,[2] Abdel Hamad,[1] Hamid Rabb.[2] *[1]Dept of Pathology; [2]Dept of Medicine, Johns Hopkins Univ, Baltimore, MD.*

Background: TCRaβ+CD4-CD8- double negative (DN) T cells are one of the least understood T cells, partly due to their rarity. We recently found them at high frequency in both murine and human kidney and demonstrated that they secrete large amounts of the anti-inflammatory cytokine IL-10. We tested the hypothesis that DNT cells are immunosuppressive in a mouse model of ischemic AKI and *in vitro*.

Methods: Immunosuppressive functions of kidney DNT cell were assessed by their ability to inhibit CD4 T cell proliferation using a standard T cell suppression assay. DNT cells isolated from the periphery of FasL-deficient *gld* mice (which accumulate large numbers of DN T cells in lymph nodes) were adoptively transferred in to wild type (WT) mice in the presence or absence of anti-IL-10 antibody and assessed their ability to

modulated ischemic AKI. Serum creatinine (SCr) was measured to assess kidney function and histology was studied. DNT cells from human peripheral blood was studied to lay the foundation for translational studies.

Results: Murine kidney DNT cell significantly (p£0.001) inhibited proliferation of CD4 T cells *in vitro*, using $CD4^{+}CD25^{-}$ T cells as controls. Transfer of DNT cells significantly (p£0.01) improved kidney function in WT mice (SCr= 0.5±0.1) following IR-induced AKI compared to WT mice that either received no cells (SCr=1.3±0.4) or conventional T cells (SCr=1.4±0.4). Histological evaluation showed significantly reduced tubular necrosis (p=0.03) in mice that received DNT cells. This protection was lost in mice that received DNT cells with anti-IL-10 Ab (p£0.01). DNT cells were found in normal subjects-n=3 (n=3, 1.6±0.4 %) and higher in renal cell carcinoma patients (n=3, 3.5±0.1%, p£0.001).

Conclusions: Kidney resident DNT cells suppress CD4 T cell proliferation *in vitro* and protect WT mice from IR-induced AKI via IL-10. Furthermore, DNT cells are found in human peripheral blood and increase with kidney cancer. Future studies are warranted to better understand immunosuppressive properties of DNT cells and their clinical significance in AKI and other kidney diseases.

Interleukin-37 Diminishes the Inflammatory Response of Ischemia/Reperfusion-Susceptible Renal Tubular Epithelial Cells Luuk Hilbrands,[1] Wilco P. Pulskens,[1] Sandrine Florquin,[2] Leo Ab Joosten,[3] Janin A. Bublitz,[1] Johan Van der vlag.[1] *[1]Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands; [2]Pathology, Academic Medical Center, Amsterdam, Netherlands; [3]Internal Medicine, Radboud Univ Medical Center, Nijmegen, Netherlands.*

Background: Renal ischemia and subsequent reperfusion (IR) induces excessive local inflammation that results in tubular injury and renal dysfunction. Therapeutic strategies aiming to dampen inflammation might therefore provide new opportunities to diminish renal IR injury. The human cytokine Interleukin (IL)-37 inhibits inflammation via nuclear as well as cell-surface receptors. IL37 is expressed by different cell types, including renal epithelium and circulating monocytes. Cell type-specific effects of IL37 in renal IR remain however unknown.

Methods: Primary tubular epithelial cells (PTECs) and bone marrow-derived macrophages (BMDMs) were isolated from WT and transgenic mice expressing human IL37 (hIL37tg) and cultured. In vitro, cells were pretreated with different concentrations of recombinant human IL37 protein (rhIL37) or vehicle and subsequently stimulated with LPS for 4 or 24hrs. Cytokine release (ELISA) and mRNA expression (quantitative RT-PCR) were determined.

Results: After 24hrs of LPS stimulation, the release of both CXCL1 and IL6 was reduced in hIL37tg PTECs as compared to WT PTECs. This was preceded by diminished CXCL1 and IL6 mRNA levels after 4hrs of LPS stimulation. rhIL37 pretreatment of WT PTECs reduced CXCL1 mRNA, but not IL6 mRNA expression after 4hrs. In hIL37tg BMDMs CXCL1 mRNA levels and protein release were both reduced after 4 and 24hrs of LPS stimulation, as compared to WT BMDMs. IL6 release was only diminished after 24hrs, whereas IL6 mRNA levels did not significantly differ. In contrast, rhIL37 pretreatment of WT BMDMs reduced IL6 mRNA expression after 24hrs of LPS stimulation, but neither affected CXCL1 nor IL6 release.

Conclusions: Our data indicate that both endogenous and exogenous IL37 diminishes inflammatory responses of renal epithelial cells and macrophages, both central players in the pathophysiology of renal IR injury.

TH-PO029

Compensatory Induction of IL-17 Producing NKT Cells in Post Ischemic T Cell Deficient Rats Fed High Salt Diet Purvi Mehrotra, Carlie M. Ivancic, Jason Andrieu Collett, Seth D. Mckinney, David P. Basile. *Dept of Cellular and Intergrative Physiology, Indiana Univ of Medicine, Indianapolis, IN.*

Background: Surviving AKI patients have a higher risk for developing chronic kidney disease (CKD) but the mechanism of AKI to CKD transition is unclear. Previous studies have shown inhibition of T-cell activity by mycophenolate blocked the proteinuria, fibrosis and hypertension in post ischemic rats fed a high dietary salt and that Th17 helper cells are dramatically increased in post ischemic rats on high salt diet. Therefore, we hypothesized that T-cell deficient athymic rats would manifest an attenuated salt sensitive progression of CKD following AKI.

Methods: Athymic rats ($Foxn1^{rnu-/rnu-}$) or heterozygote control euthymic rats ($Foxn1^{rnu-/+}$) were subjected to a model of AKI-to-CKD in which rats are allowed to recover from unilateral I/R (40 min ischemia) for 5 weeks on standard salt diet (0.4% NaCl) and then subjected to contralateral UNX and 4% NaCl diet for 4 additional weeks.

Results: As expected we observed that MMF treatment in control-euthymic rats (day 35-63) lead to significant reduction in renal CD4+ infiltration (35%±4.8, $p^{3}0.05$), Th-17 cells (78%±5.2, $p^{3}0.05$%) and reduced fibrosis by 50% vs vehicle. T cell deficient athymic rats showed an unexpected and similar level of renal fibrosis as compared to euthymic rats and MMF treatment did not have any effect. The increased fibrosis could not be explained by enhanced initial injury in athymic vs euthymic rats, which was similar 24 hours following bilateral I/R, indicating that athymic rats may operate an alternative pro-inflammatory pathway in the absence of T cells. Interestingly, athymic rats showed an increase population of IL-17+ Natural Killer T cells (NKT) (126018±7507) as compared to euthymic rats (63892±12656), which was not sensitive to MMF treatment.

Conclusions: Taken together these data suggest that in the absence of T cells, compensatory NKT cell activity may mediate cytokine production and participate in salt diet induced fibrosis post AKI.

TH-PO030

Chronic Kidney Disease and the Chromogranin A Pathway: From Pathogenic Molecule to Disease Sucheta M. Vaingankar, Saiful A. Mir, Wai W. Cheung, Kuixing Zhang. *Medicine, Univ of California at San Diego.*

Background: The human chromogranin A gene (*CHGA*) variants are associated with autonomic blood pressure regulation and hypertension in the majority population, as well as hypertensive renal disease in African Americans. CHGA proprotein is the master switch for nucleation of catecholamine granules in neuroendocrine tissue. In this study we address the effect of CHGA in acute kidney injury.

Methods: Experimental chronic kidney disease (5/6 th nephrectomized) mouse models were used to study susceptibility of mouse strains (wild type and *Chga -/-*) to kidney injury. Kidney tissues of sham and nephrectomized mice were examined by histology and also profiled for genome-wide expression using NimbleGen microarray. The murine glomerular function was measured by LC-mass spectrometry based assay for creatinine. Array data was analyzed for differentially expressed genes using Bioconductor. The differentially regulated genes were analyzed by GO enrichment analysis using DAVID Bioinformatics Resources. The molecular function and biological process terminologies in the PANTHER database were considered during the GO analysis; the P-value cutoff was set at 0.01. The human study involved twin data set of European ancestry 129 monozygotic and 58 dizygotic twin pairs.

Results: A significantly greater loss of eGFR function was observed in nephrectomized mice expressing CHGA as compared to *Chga* knock out mice. Kidney injury resulted in far greater response of increased plasma CHGA, azotemia, catecholamine and systolic blood pressure in *Chga+/+* mice. Kidney biopsy also showed greater pathology and interstitial fibrosis associated with nephrectomized *Chga+/+* mice. In nephrectomized mice, the differentially up regulated genes in the *Chga+/+* strain include panoply of mitochondrial genes, oxidoreductases and extracellular matrix proteins, wound healing genes and transcription factors. In humans the plasma CHGA concentration has an inverse relationship to plasma creatinine levels.

Conclusions: CHGA expression is inversely correlated to glomerular function and is detrimental to kidney injury outcomes.

TH-PO031

Inhibition of avβ5 Integrin Protects against Renal Ischemia-Reperfusion Injury Amy T. Mccurley,[1] Robert W. Dunstan,[1] Taylor L. Reynolds,[1] Silvia B. Campos-bilderback,[2] Ruben M. Sandoval,[2] Bruce A. Molitoris,[2] Shelia Violette,[1] Michael Crackower.[1] *[1]Biogen, Cambridge, MA; [2]Div of Nephrology, Indiana Univ School of Medicine, Indianapolis, IN.*

Background: Ischemia-reperfusion injury is a leading cause of acute kidney injury (AKI), which is a common clinical complication that lacks effective therapies and can lead to the development and progression of chronic kidney disease. The avβ5 integrin, a receptor for RGD-containing extracellular matrix proteins, has been suggested to be important in acute injury settings including septic shock and acute lung injury. To examine the in vivo function of this receptor in AKI we tested the impact of inhibiting avβ5 in a rat model of renal ischemia reperfusion injury (IRI).

Methods: IRI was induced by removing the right kidney and clamping the renal artery of the left kidney for 30 minutes. Rats were administered avβ5-blocking antibody or an isotype control antibody subcutaneously at various doses and times prior to ischemia.

Results: avβ5 antibody-treatment significantly reduced serum creatinine levels with a single administration 6 hours prior to ischemia. avβ5 inhibition led to significantly reduced renal damage by 3 days after ischemia as assessed by histopathological scoring of fixed kidneys. Antibody blockade of avβ5 also resulted in significantly fewer apoptotic tubular cells, and significant reductions in urinary KIM-1 and serum MCP-1 levels in IRI rats. Global gene expression profiling of kidneys identified several established injury markers that were impacted by avβ5 inhibition including reduced levels of *havcr1* (KIM-1), *lcn2* (NGAL), and *adamts1* transcripts after ischemia. Finally, a single dose of avβ5 antibody 8 hours post-ischemia was shown to significantly reduce serum creatinine levels at 24 hours, suggesting protection from injury with therapeutic dosing is possible.

Conclusions: This study identifies a novel role for avβ5 integrin biology in the pathogenesis of renal ischemia-reperfusion injury. Inhibition of avβ5 integrin with antibody administration may hold therapeutic promise for the treatment of acute kidney injury.

TH-PO032

Blocking avβ6 Integrin Provides Protection in Renal Ischemia-Reperfusion Injury Shelia Violette,[1] Amy T. Mccurley,[1] Paul H. Weinreb,[1] Silvia B. Campos-bilderback,[2] Ruben M. Sandoval,[2] Bradley J. Maroni,[1] Michael Crackower,[1] Bruce A. Molitoris.[2] *[1]Biogen, Cambridge, MA; [2]Indiana Univ School of Medicine, Indianapolis, IN.*

Background: The avβ6 integrin is a key mediator of TGF-β activation and plays an important role in promoting tissue injury and fibrosis. avβ6 is expressed at low levels in normal tissue and upregulated on epithelial cells in disease, providing a target for localized suppression of TGF-β. Function-blocking avβ6 antibodies are protective in models of kidney, lung, and liver fibrosis and a humanized avβ6 antibody (BG00011) is in clinical development in patients with idiopathic pulmonary fibrosis. We evaluated the role of avβ6 in renal ischemia reperfusion injury (IRI), a model in which avβ6 is upregulated in tubular epithelium.

Methods: IRI was induced in rats by removing the right kidney and clamping the renal artery of the left kidney for 30 minutes. A single 3 mg/kg dose of avβ6 antibody (3G9)

or an isotype control was administered 6, 12 or 18 hours pre-ischemia or 4, 8 or 12 hours post-ischemia. Serum creatinine (SCr) was evaluated 24, 48 and 72 hours post-injury and gene expression and histology in kidneys evaluated at 72 hours.

Results: 3G9 treatment significantly reduced SCr levels at all time points evaluated whether administered pre- or post-induction of ischemia. Equivalent effects were detected when 3G9 was administered 6, 12 or 18 hours pre-ischemia and maximal effects observed when administered 4 to 8 hours post-ischemia. 3G9 reduced kidney damage as assessed by histopathological scoring of tubular necrosis, dilation and casts. Gene expression profiling of kidneys identified transcripts impacted by avβ6 inhibition suggesting promotion of repair. This included reduced levels of cell death and necroptosis markers such as GADD45, ATF3, and RIPK3, and an upregulated cell growth signature including cyclins, cyclin-dependent kinases, and epidermal growth factor.

Conclusions: The combined role of avβ6 in regulating IRI and fibrosis highlight the potential for therapeutic intervention with BG00011 in acute kidney injury, a common clinical complication that lacks effective therapies and can lead to the development and progression of chronic kidney disease.

TH-PO033

Suramin Protects from Cisplatin-Induced Acute Kidney Injury Tess Dupre,[1] Mark A. Doll,[1] Parag P. Shah,[1] Michael T. Scherzer,[1] Cierra Sharp,[1] Judit Megyesi,[4] Lavona Casson,[1] Levi J. Beverly,[1] Rick G. Schnellmann,[3] Leah J. Siskind.[1] *[1]Pharmacology/Toxicology, Univ of Louisville, Louisville, KY; [2]Univ of Arkansas for Medical Sciences; [3]Medical Univ of South Carolina.*

Background: Acute kidney injury (AKI) resulting from cisplatin administration remains an obstacle in chemotherapeutic treatments. Suramin, an FDA approved drug for the treatment of trypanosomiasis, has been previously shown to speed recovery from multiple models of AKI and chronic kidney disease and is currently in clinical trails for combination therapy with cisplatin for the treatment of lung cancer.

Methods: In this study we examined the efficacy of the prophylactic use of suramin in a murine model of cisplatin-induced AKI. Nine-week old C57Bl/6 male mice were pre-treated with 10mg/kg suramin via tail vein injection 72h prior to cisplatin administration (20mg/kg, i.p) and sacrificed 72h after cisplatin treatment.

Results: Our data indicate that pre-treatment with suramin protects the kidney from cisplatin injury according to markers of kidney function (BUN, Serum Creatinine), kidney injury (urinary Kim-1, and NGAL). Assessment of renal histology also indicated that suramin pre-treatment significantly protects mice from cisplatin-induced injury. The expression of many pro-inflammatory chemokines and cytokines (TNF-α, IL-1β, IL-6, MCP-1, and CXCL-1) involved in the response of cisplatin-induce AKI were examined via qRT-PCR. Mice pretreated with suramin had significantly reduced expression of all the above inflammatory markers. Western blot analysis indicated that mice pre-treated with suramin were protected from death receptor-mediated apoptosis. We also utilized the same experimental design using 10-month old FVB mice expressing mutant KRAS driven lung tumors. The assessment of both renal and pulmonary histology and markers of kidney function (BUN and Serum Creatinine) indicate that suramin protects mice from cisplatin-induced kidney injury and more importantly does not inhibit cisplatin's anti-tumor efficacy.

Conclusions: Thus, data presented suggest that suramin shows great potential as a renoprotective agent for the treatment and prevention of cisplatin-induced AKI.

TH-PO034

ATIII Attenuates Acute Kidney Injury following Acute Severe Pancreatitis Feng Wang,[1] Zeyuan Lu,[1] Guangyuan Zhang,[1] Jianyong Yin,[1] Niansong Wang,[1] Mingyu Liang.[2] *[1]Nephrology, Shanghai Jiao Tong Univ Affiliated People's Hospital, Shanghai, China; [2]Physiology, Medical College of Wisconsin, Milwaukee, WI.*

Background: Antithrombin III (ATIII) is the major anti-coagulation molecule in vivo and has anti-inflammatory effects. Acute kidney injury (AKI) is the most common organ failure following acute severe pancreatitis (ASP), which often results in death. Herein, we hypothesized that ATIII could protect against AKI following ASP.

Methods: Acute severe pancreatitis was induced in rats by retrograde pancreatic duct infusion of 3.5% sodium taurocholate. Intravenous injection of ATIII (500mg/kg) was carried out 30 min before induction of ASP. Animals were sacrificed 24 hours later. Renal tubular injury and renal function were assessed. Serum amylase, glutamic-pyruvic transaminase (ALT), and serum Ca^{2+} were also measured.

Results: Renal tubular injury scores were increased from 0.5±0.2 in control rats to 4.2±0.5 in the ASP group and to 2.7±0.3 in the ASP+ATIII group 24 hours after ASP induction ($P<0.05$,one-way ANOVA, n=6). Serum creatinine was increased from 23.2±1.6 mmol/L to 92.3±8.6 mmol/L in the ASP group and to 34.8±3.2 mmol/L in the ASP+ATIII group ($P<0.05$, n=6). Blood urea nitrogen was increased from 5.2±0.3 mmol/L to 47.0±1.3 mmol/L in the ASP group and to 30.0±1.9 mmol/L in the ASP+ATIII group ($P<0.05$, n=6). There were no significant differences between ASP group and ASP+ATIII group in serum amylase, ALT, serum Ca^{2+} and pancreatic injury.

Conclusions: ATIII attenuates AKI following ASP.

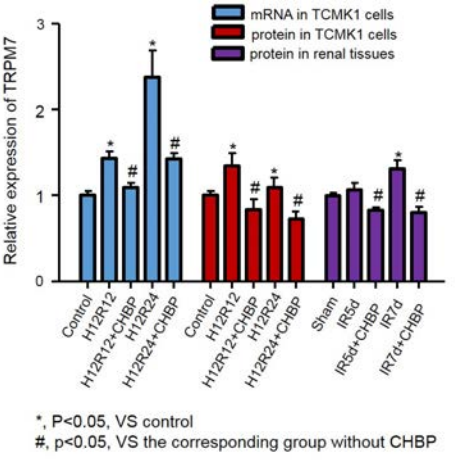
TRPM7 in Renal Ischemia Reperfusion Injury and Renoprotecion of Erythropoietin Derived Cyclic Helix B Peptide Aifen Liu,[1] Jing Wu,[2] Cheng Yang,[3] Yuanyuan Wu,[4] Yufang Zhang,[1] Yaqiu Long,[5] Tongyu Zhu,[3] Yaping Fan,[2] Bin Yang.[1,2,6] *[1]Basic Medical Research Centre, Medical School of Nantong Univ; [2]Nephrology, Affiliated Hospital of Nantong Univ; [3]Urology, Zhongshan Hospital, Fudan Univ; [4]Pathology, Medical School of Nantong Univ; [5]CAS Key Laboratory of Receptor Research, Shanghai Inst of Materia Medica, Chinese Academy of Sciences; [6]Infection, Immunity and Inflammation, Univ of Leicester, Univ Hospitals of Leicester.*

Background: Transient receptor potential melastatin 7 (TRPM7) is multi-function ion channel and kinase. The novel cyclic helix B peptide (CHBP), erythropoietin derivadive, improves renal ischemia reperfusion injury (IRI). Here, the role and mechanism of TRPM7 in IRI and CHBP renoprotection were investigated.

Methods: TRPM7 mRNA and protein, apoptosis, inflammation, renal function and structure were measured in TCMK1 cells and mouse kidneys subjected to 12-h hypoxia (H)/30-min ischemia followed by reoxygenation (R) at different time points. 2-APB (TRPM7 inhibitor) and CHBP were also applied in HR cells and/or IRI kidneys. The correlations between TRPM7 and other injury parameters were analysed.

Results: TRPM7 mRNA and protein were increased in the TCMK1 cells exposed to 12 and 24-h R, while TRPM7 protein was also increased by 42%, 35% and 30% in IRI kidneys at 12 and 24 h, and 7 d. Increased apoptotic cells were reduced 65% by 2-APB in TCMK1 cells post HR, while LDH in supernant and HMGB1 in TCMK1 cells were also increased. Further more, CHBP reduced TRPM7 in HR TCMK1 cells, as well as IRI kidneys.



TRPM7 was significantly correlated with LDH and HMGB1; and serum creatinine, blood urea nitrogen, inflammation, apoptosis and tubulointerstitial damage in these *in vitro* and/or *in vivo* models.

Conclusions: TRPM7 is involved in renal IR-related injuries and CHBP renoprotection, which might be a biomarker for diagnosis and intervention.

Funding: Government Support - Non-U.S.

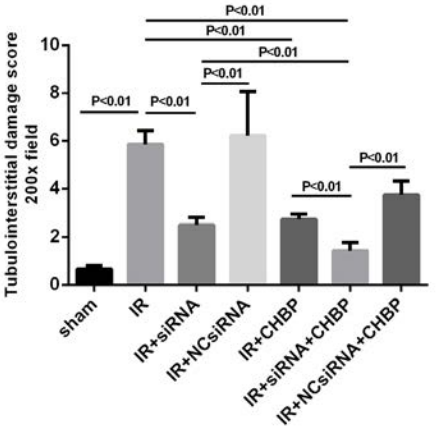
TH-PO036

Caspase-3 siRNA and CHBP Ameliorate Renal Ischemia Reperfusion Injury in Mice Weiwei Chen,[1] Cheng Yang,[4] Yuanyuan Wu,[3] Yufang Zhang,[2] Aifen Liu,[2] Jing Wu,[1] Yaqiu Long,[5] Tongyu Zhu,[4] Yaping Fan,[1] Bin Yang.[1,2,6] *[1]Nephrology, Affiliated Hospital of Nantong Univ; [2]Basic Medical Research Centre, Medical School of Nantong Univ; [3]Pathology, Medical School of Nantong Univ; [4]Urology, Zhongshan Hospital of Fudan Univ; [5]CAS Key Lab of Receptor Research, Shanghai Inst of Materia Medica, Chinese Academy of Sciences; [6]Infection, Immunity and Inflammation, Univ of Leicester, Univ Hospitals of Leicester.*

Background: Ischemia/reperfusion (IR) is a main cause of acute kidney injury (AKI). Up-regulated caspase-3, a key enzyme involved in inflammation and apoptosis, was revealed in renal IR injury and reversed by a novel cyclic helix B peptide (CHBP), derived from erythropoietin. Here, caspase-3 small interfering RNA (C3siRNA) and/or CHBP were applied in a mouse model to further explore underlying mechanisms.

Methods: Bilateral renal occlusion for 30 min was performed in male C57BL/6 mice and followed by 48 h reperfusion. 0.03 mg/kg C3siRNA or its negative control (NC) was injected intravenously 2 h before ischemia. 24 nmol/kg CHBP was injected intraperitoneally post reperfusion. Serum and kidney samples were collected for renal function, histology and molecular biology analyses.

Results: Serum creatinine and tubulointerstitial damage (TID) score were increased by IR injury, but decreased by C3siRNA and/or CHBP (all $P<0.01$). In addition, the expression of 17 kD active caspase-3, active caspase-3+ cells and apoptotic cells were raised by IR injury, but reduced by C3siRNA and/or CHBP ($P<0.01$). More interestingly, there was a significant reduction in TID in the kidneys treated with both C3siRNA and CHBP compared with its sole treatment.



Conclusions: C3siRNA and CHBP ameliorated IR injury, both of which might have certain synergetic effects. CHBP might reduce active caspase-3, subsequently affect apoptosis, and improve renal function and structure.

Resveratrol Ameliorates Contrast-Induced Nephropathy Through Activation of SIRT1-PGC-1α-FoxO1 Signaling in Murine Model

Gang Jee Ko,[1] Yu ah Hong,[2] So yeon Bae,[1] Heui-jung Pyo,[1] Young-Joo Kwon.[1] *[1]Div of Nephrology, Dept of Internal Medicine, Korea Univ School of Medicine, Seoul, Republic of Korea; [2]Div of Nephrology, Dept of Internal Medicine, Catholic Univ College of Medicine, Daejeon St. Mary's Hospital, Daejeon, Republic of Korea.*

Background: Contrast-induced nephropathy (CIN) is a common cause of acute kidney injury among impatient, but the pathogenesis has not been clearly defined. We aimed to investigate whether upregulation of situin 1 (SIRT1)-dependent signaling by resveratrol could attenuate CIN through modulation of renal oxidative stress and tubular apoptosis.

Methods: CIN were established in vivo and vitro model by administration of iohexol in male C57BL/6J mice and rat tubular cells (NRK-52E). Resveratrol (30mg/kg in vivo/ 10 and 50μM in vitro) was treated with iohexol or saline as an activator of SIRT1. SIRT1 expression was reduced by siRNA treatment in vitro study. Tubular cell injury caused by iohexol was examined.

Results: Increase of serum creatinine and tubular injury measured by histologic examinations after iohexol administration was significantly attenuated by resveratrol treatment (creatinine 1.79±0.48 vs 0.72±0.59 mg/dL, $p<0.001$). It resulted in reduction of oxidative stress which were demonstrated by reduced malondialdehyde (MDA) levels and increased Mn superoxide dismutase (SOD). Increased apoptosis in CIN was also reduced by resveratrol treatment examined with caspase 3 expression and TUNEL staining. Attenuation of CIN with resveratrol treatment was accompanied with the increase of SIRT1 expression, activation of PPARγ co-activator 1α (PGC-1α) and dephosphorylation of forkhead box O(FoxO1). Resveratrol treatment also reduced inflammatory cell infiltration induced by iohexol into kidney. On the other hand, SIRT1 inhibition by siRNA treatment accentuated cytotoxicity by iohexol.

Conclusions: Our results suggest that resveratrol attenuates CIN by modulation of renal oxidative stress and apoptosis through the activation of SIRT1-PGC-1α-FoxO1 signaling, and SIRT1 provides a potential therapeutic target to minimize CIN.

Loss of Alpha(E)-Catenin-Fscn2 Signaling Increases Cisplatin-Induced Apoptosis in Aged Kidney

Xinhui Wang, LaNita A. Nichols, Elizabeth A. Borgmann, Alan R. Parrish. *Medical Pharmacology and Physiology, Univ of Missouri School of Medicine, Columbia, MO.*

Background: Aging patients are highly susceptible to acute kidney injury. Previous studies in our laboratory demonstrated a dramatic decrease of α(E)-catenin expression in proximal tubular epithelium in the aged kidney.

Methods: We created stable α(E)-catenin knock-down NRK-52E (C2) cells (NT3 is the non-targeted control) and observed a significant loss of viability in C2 cells as compared with NT3 cells after cisplatin challenge. In this study, we aimed to delineate the pathway by which loss of α(E)-catenin increases cisplatin injury.

Results: Increased caspase-8 and -9 activation, BID cleavage and cytochrome C release were observed in C2 cells after cisplatin treatment. Blocking apoptosis, using caspase-8 or -9 inhibitors, completely abolishes the increased susceptibility of C2 cells. Interestingly, the expression of fascin actin bundling protein 2 (Fscn2) is decreased in α(E)-catenin knock-down cells. Re-expression of Fscn2 in C2 cells attenuates the increased apoptosis following cisplatin challenge. Furthermore, our *in vivo* study showed a significant increase in serum creatinine, KIM-1 and in situ apoptosis levels at 72 hr after a single dose of cisplatin in 24-month-old rats, but not in 4-month-old rats. The expression of Fscn2 was also decreased in aged kidney.

Conclusions: Taken together, these results suggest that loss of α(E)-catenin-Fscn2 signaling increases cisplatin-induced apoptosis in aged kidney.

Adenosine A1 Receptors Alleviate Cisplatin-Mediated Acute Kidney Injury

Yuan Liu, Dongli Tian, Xuemei Li, Limeng Chen. *Dept of Nephrology, Peking Union Medical College Hospital, Beijing, China.*

Background: We have observed the incidence of acute kidney injury (AKI) in 479 lung cancer patients using platinum is 10.39% and AKI is the independent risk factor of in-hospital mortality. The results of previous studies about adenosine A1 receptors (A1ARs) in cisplatin-mediated AKI are controversial. In this study, we aimed to investigate the role of A1ARs in AKI induced by cisplatin and the involvement of mitochondria-mediated cell apoptosis.

Methods: 8- to 10-week-old male C57BL/6J wild type (WT) and $A1AR^{-/-}$ mice were given a single intraperitoneal injection of either vehicle (saline) or cisplatin (25mg/kg, 1mg/ml). Weight, blood pressure and heart rate were monitored. Mice were euthanized 24h/72h after cisplatin. Blood samples were collected to measure serum creatinine and urea. Acute tubular necrosis assessments were done through PAS staining. Western Blot and RT-PCR were used to study the expression change of CD73, A1AR and mitochondria-mediated apoptosis markers.

Results: 1) 72h after cisplatin injection, serum creatinine and urea were substantially elevated (85.9±65.59 vs 8.5±1.16mmol/L, 63.3±33.84 vs 6.7±1.24mmol/L, $p<0.05$) in WT mice which suggested AKI happened. The systolic blood pressure, heart rate and body weight remarkably declined (64±4 mmHg vs 105±2 mmHg , 412±16 bpm vs 721±48 bpm, $p<0.05$) compared with control mice. 2) 24h after cisplatin, the expression of A1AR in WT mice was significantly higher than control mice. Cisplatin also induced the expression of A2bAR and Bax, targets of mitochondria-mediated apoptosis. 3) Compared with WT mice, serum creatinine elevation and tubular injury were more obvious in $A1AR^{-/-}$ mice (25.8±19.28 vs 11.4±0.43mmol/L, $p<0.05$). But contrast to WT mice, A2bAR and Bax expression were not elevated in $A1AR^{-/-}$ mice. The expression of CD73 was up-regulated significantly.

Conclusions: A1AR may be involved in cisplatin-mediated AKI and could alleviate the cisplatin nephrotoxicity. But it doesn't work through mitochondria-mediated apoptosis pathway. A1AR agonists are potential to protect the kidney in cisplatin-mediated AKI.

Testosterone Upregulates Heme-Oxygenase-1 – A Potential Mechanism to Protect against Acute Kidney Injury

Andrea P. Soljancic, Arnaldo F. Lopez-Ruiz, Kiran B. Chandrashekar, Luis A. Juncos. *Medicine-Nephrology, Univ of Mississippi Medical Center, Jackson, MS.*

Background: Sex hormones modulate renal injury during ischemia-reperfusion-induced acute kidney injury (I/R-AKI). We reported that testosterone is reduced during I/R-AKI and that supplementing this hormone ameliorates the renal injury. This protective effect is dependent on the chronicity of therapy and dose (chronic exposure and high doses may exacerbate injury). In this study, we investigated a possible mechanism by which acute administration of low-dose testosterone propionate (A-LD-TP) can protect against I/R-AKI. Because we found that A-LD-TP increased hypoxia inducible factor-1α (HIF-1α), which in turn induces heme oxygenase-1 (HO-1), we hypothesized that the protective effect of A-LD-TP during I/R-AKI is mediated by HIF-1α dependent upregulation of HO-1.

Methods: SD rats were randomized into 4 groups; 1) Sham, 2) I/R-AKI, 3) I/R-AKI+TP, 4) I/R-AKI+A-LD-TP+2-ME. I/R-AKI was induced by 40 min bilateral renal pedicle clamping. A-LD-TP was given 3 h after releasing the clamps, and a HIF-1α antagonist, 2-Methoxystradiol [2-ME] was given 1 day before inducing AKI. Rats were followed for 48hs. Blood, urine and tissue were collected to evaluate renal function, injury, and expression of pro-inflammatory cytokines and the HIF-1α - HO-1 cascade.

Results:

	Creat(mg/dl)	KIM-1(pg/ml)	TNFα(pg/ml)	HIF-1α (pg/ml)	HO-1 (ug/ml)
Sham	0.51±0.06	450±120	30±8	0.45±0.05	0.55±0.1
I/R-AKI	2.4±0.07*	4500±190*	190±15*	5.6±0.3*	5.8±0.3*
I/R-AKI+TP	1.4±0.08#	1700±200#	115±6#	10.6±0.8#	11.7±0.6#
I/R-AKI+TP+2-ME	2.2±0.1	4400±350	175±12	3.95±0.4	6.2±0.4

Conclusions: A-LD-TP supplementation ameliorated I/R-AKI-induced renal dysfunction, inflammation and tubular injury. These beneficial changes were associated with further upregulation of HO-1. Blocking HIF-1α attenuates the cytoprotective effects conferred by A-LD-TP. This data supports the hypothesis that A-LD-TP supplementation activates the renal HIF-1α pathway and its downstream cytoprotective factor (HO-1), which protects against I/R-AKI, thus providing a potential therapeutic target.

Endotoxin Preconditioning Induces an Effective Immune Response That Avoids Collateral Tissue Damage Takashi Hato, Pierre C. Dagher. *Medicine, Indiana Univ, Indianapolis, IN.*

Background: Endotoxin preconditioning is a powerful model of renoprotection against a variety of insults. Harnessing these protective pathways has important therapeutic potential in sepsis. However, the protective molecular pathways remain unknown. Here we examined the metabolic profiles of endotoxin preconditioning.

Methods: Mice were divided into 3 groups: control, endotoxin injury (LPS 5 mg/kg ip) and preconditioning (0.25 mg/kg followed by 5 mg/kg LPS). Renal injury was assessed by serum creatinine and tissue KIM1. Cecal ligation and puncture (CLP) was used to evaluate mortality and bacterial load. Tissues and sera were examined using cytokine assays, 2DIGE proteomics and metabolomics.

Results: Preconditioning improved survival after CLP (75% vs. 25% in non-preconditioned mice). This protection was accompanied by reduced bacterial load in solid organs including kidneys (320 vs. 1,200 cfu/gram tissue). Macrophages harvested from preconditioned mice exhibited robust phagocytic activity. Preconditioning also resulted in renal protection after toxic dose LPS (mean serum creatinine 0.08 mg/dL vs. 0.40 mg/dL in non-preconditioned mice; tissue KIM1 mRNA fold changes 110 vs. 2,960). 2DIGE proteomics analyses revealed upregulation of molecules required for the activation and maintenance of phagocytosis in the preconditioned group. These molecules include clusterin, serum amyloid P-component, neutrophil gelatinase-associated lipocalin, and complement factor B. Despite the activation of these efficient bacterial clearing pathways, serum and tissue proinflammatory cytokine levels were broadly downregulated in preconditioned animals. Tissue metabolomic analysis revealed that preconditioning increased metabolites involved in tissue repair (proline and spermidine), antimicrobial activity (itaconate) and antioxidant pathways (ergothioneine), while uremic toxin levels were reduced (p-cresol sulfate, 3-indoxil sulfate, pseudouridine).

Conclusions: Preconditioning confers tissue protection and increases survival through an organized upregulation of a modified innate immune response characterized by enhanced bacterial clearing and yet lacking the proinflammatory tissue damage frequently observed with ordinary innate immunity.

Myeloid Cell Specific Nrf2 Activation Protects Elderly Mice from Acute Kidney Injury Sanjeev Noel,[1] Samatha Bandapalle,[1] Sekhar P. Reddy,[2] Hamid Rabb.[1] *[1]Dept of Medicine, Johns Hopkins Univ, Baltimore, MD; [2]Dept of Pediatrics, Univ of Illinois, Chicago, IL.*

Background: Transcription factor Nrf2 confers protection against ischemia-reperfusion (IR)-induced acute kidney injury (AKI) in mice by upregulating antioxidant and cytoprotective genes, but the specific cell types where Nrf2 is working is unknown. We recently demonstrated that T cell Nrf2 activity is a major modulator of IR-induced AKI in mice with increased T cell Nrf2 (*J Am Soc Nephrol,* in press). In this study we tested the hypothesis that Nrf2 activation in myeloid cells (neutrophils, macrophages) is protective against IR-induced AKI. We tested our hypothesis in young and elderly mice with genetic deletion of Nrf2 inhibitor, keap1 in myeloid cells (Lysm keap1$^{-/-}$).

Methods: Young (7-8wks) and old (32-48wks) male Lysm keap1$^{-/-}$ and keap1f/f (control) mice underwent 30 minute bilateral kidney ischemia. Serum creatinine (SCr) was measured at 0, 24, 48 and 72h post ischemia. Histological and inflammatory changes in kidney were examined at 72h.

Results: We observed significantly reduced SCr levels in young (0.6±0.1 vs 1.3±0.2, p£0.02, 24h) and elderly (0.4±0.2 vs 1.3±0.3, p£0.02, 48h and 0.2±0.03 vs 0.9±0.2, p£0.02, 72h) Lysm keap1$^{-/-}$ mice as compared to age matched keap1f/f mice. Histological examination of corticomedullary region of kidney tissue revealed a significantly lower necrotic debris (24±8.7 vs 54±3.8, p£0.01), regeneration (22.1±7.0 vs 41.1±4.0, p=0.04) and higher percent of normal tissue (53.8±15.7 vs 5.0±0.6, p£0.01) in elderly Lysm keap1$^{-/-}$ mice. Young Lysm keap1$^{-/-}$ mice did not show any significant difference in kidney histology post AKI compared to young keap1f/f mice. Cytokine analysis showed significantly (p£0.04) higher levels of TGF-β, IL-1β, IL-2, IL-6, IL-10, IL-13, IL-17 and TNF-α in elderly Lysm keap1$^{-/-}$ kidneys. These cytokines were comparable in young Lysm keap1$^{-/-}$ and keap1f/f kidneys post AKI.

Conclusions: These data demonstrate that enhancing Nrf2 activity in myeloid cells can provide protection against IR-induced AKI, which is markedly enhanced in elderly mice. These findings reveal that myeloid cell oxidative stress responses are a mechanism by which elderly are more susceptible to AKI.

Sphingosine-1-Phosphate-3 Deficient Dendritic Cells Modulate Splenic Responses to Ischemia-Reperfusion Injury Amandeep Bajwa,[1] Elvira Kurmaeva,[1] Liping Huang,[1] Joseph C. Gigliotti,[1] Hong Ye,[1] Diane L. Rosin,[2] Peter I. Lobo,[1] Mark D. Okusa.[1] *[1]Medicine-CIIR, UVA, Charlottesville, VA; [2]Pharmacology, UVA, Charlottesville, VA.*

Background: The plasticity of dendritic cells (DCs) permits phenotypic modulation *ex-vivo* by gene expression or pharmacological agents, and these DCs can exert therapeutic immunosuppressive effects *in-vivo* through direct interactions with T-cells by either inducing T regulatory (Treg) cells or causing anergy. Sphingosine 1-phosphate (S1P), a sphingolipid that is the natural ligand for five G-protein coupled receptors (S1P1-5Rs), and S1PR agonists reduced kidney ischemia-reperfusion injury (IRI) in mice. *S1pr3*$^{-/-}$ mice are protected from kidney IRI due to the inability of dendritic cells to mature. We tested the therapeutic advantage of *S1pr3*-deficient bone marrow-derived DC (BMDC) transfers in kidney IRI.

Methods: Renal injury was assessed by plasma creatinine (PCr; mg/dl). *8-wk old C57BL/6 WT and S1pr3*$^{-/-}$ male mice were used for generating highly pure BMDCs from whole BM precursors.

Results: IRI produced a rise in plasma creatinine (PCr) in naïve mice, no cell (NC) and in mice pretreated with WT BMDCs. However, *S1pr3*$^{-/-}$ BMDC-pretreated mice were significantly protected from kidney IRI. *S1pr3*$^{-/-}$ BMDC-pretreated mice had significantly higher numbers of splenic Tregs compared to NC and WT BMDC-pretreated mice. *S1pr3*$^{-/-}$ BMDC-induced protection of the recipient kidney required an intact spleen, B/T cells, and CD11c^{+} DCs, as *S1pr3*$^{-/-}$BMDCs were ineffective in attenuating IRI in splenectomized, *Rag-1*$^{-/-}$ or CD11c^{+} DC-depleted mice. Additionally, *S1pr3*$^{-/-}$ BMDC dependent protection requires CD169^{+}-marginal zone (MZ) macrophage dependent CCL22/macrophage-derived-chemokine (MDC) signaling to increase Treg.

Conclusions: We conclude that genetically induced deficiency or pharmacological blockade of *S1pr3* on allogenic BMDCs could serve as a useful therapeutic approach to prevent IRI-induced acute kidney injury or delayed graft function associated with transplant.

Funding: NIDDK Support

TH-PO044

Spleen Plays a Critical Role in Hepcidin-Mediated Protection against Renal Ischemia-Reperfusion Injury Sundararaman Swaminathan,[1] Yogesh M. Scindia,[1] Mark D. Okusa,[1] Diane L. Rosin,[1,2] Liping Huang,[1] Paromita Dey.[1] *[1]Medicine, Univ of Virginia, Charlottesville, VA; [2]Pharmacology, Univ of Virginia, Charlottesville, VA.*

Background: We showed previously that pretreatment with hepcidin mitigates kidney IRI by acting on hepato-splenic iron compartments. In these studies we observed that changes in the splenic iron content and ferroportin expression far exceeded that in the kidney and liver. We therefore hypothesized that hepcidin-mediated protection is through its iron-retaining effect on the spleen, and that splenocytes are necessary in preventing renal injury following kidney IRI.

Methods: Mice (C57Bl/6, n=6-8) were splenectomized 1 week prior to treatment with saline or 50 mg of hepcidin and 24 hours later were subjected to bilateral renal IRI (26 min). In some experiments, splenocytes (1e6-1e7) from 24 hour saline or hepcidin treated animals were adoptively transferred and the recipient mice were subjected to similar IRI regimen. Outcomes (renal function, injury markers, histopathology and inflammation) were examined after 24 hours of reperfusion.

Results: Splenectomy worsened IR-induced kidney injury (P_{Cr}: IRI; 1.9 Vs Splenectomy+IRI; 2.4, $p < 0.005$). Importantly, hepcidin was not able to rescue splenectomized mice from renal IRI (P_{Cr}: Hepcidin+Splenectomy+IRI; 2.1). Acute tubular necrosis and immune cell infiltration in splenectomized mice treated with or without hepcidin were comparable to untreated mice subjected to IRI. Adoptive transfer of 1e7 splenocytes from hepcidin-treated (but not PBS) mice to naïve mice was sufficient to completely protect kidneys of recipient mice from IRI (P_{Cr}: PBS treated splenocytes; 2.3 Vs Hepcidin-treated splenocytes; 0.25, $p < 0.001$).

Conclusions: Our results demonstrate that protection afforded by hepcidin during episode of renal IRI, is dominantly mediated through its action on the spleen. Moreover,splenocytes of hepcidin-treated mice by themselves are capable of mitigating IRI *in vivo*, supporting our ongoing hypothesis that manipulation of splenic iron metabolism has therapeutic potential for AKI.

TH-PO045

Endothelial Krüppel-Like Factor 4 Mediates the Protective Effect of Statins against Ischemic Acute Kidney Injury Tadashi Yoshida, Maho Yamashita, Matsuhiko Hayashi. *Apheresis and Dialysis Center, Keio Univ School of Medicine, Shinjuku-ku, Tokyo, Japan.*

Background: Endothelial cells participate in the pathophysiology of ischemic acute kidney injury (AKI) by increasing the expression of cell adhesion molecules and by recruiting inflammatory cells. Results of our previous studies showed that endothelial Krüppel-like factor 4 (Klf4) regulated Vcam1 expression and neointimal formation following carotid injury. The aim of the present study was to determine if endothelial Klf4 is involved in ischemic AKI.

Methods: Endothelial *Klf4* conditional knockout (*Klf4* cKO) mice were generated by breeding *Tek-Cre* mice and *Klf4* floxed mice, and their phenotype was analyzed after bilateral renal ischemia.

Results: *Klf4* cKO mice were phenotypically normal before the surgery. However, endothelial *Klf4* deletion exacerbated renal ischemia-reperfusion injury, as indicated by elevated serum levels of urea nitrogen and creatinine and aggravated renal histology. Moreover, *Klf4* cKO mice exhibited the enhanced accumulation of neutrophils and the elevated expression of cell adhesion molecules including Vcam1 and Icam1 in injured kidneys. Interestingly, statins ameliorated renal ischemia-reperfusion injury in control mice, but not in *Klf4* cKO mice, suggesting that the protective effect of statins against ischemic AKI is mediated by endothelial Klf4. Mechanistic analyses in cultured endothelial cells revealed that statins increased *Klf4* expression, and that Klf4 mediated the suppressive effect of statins on tumor necrosis factor-α-induced *Vcam1* expression through reducing the binding of NF-κB to the *Vcam1* promoter.

Conclusions: These results provide evidence that endothelial Klf4 is a mediator of statins and plays a protective role in ischemic AKI by regulating the expression of cell adhesion molecules with concomitant recruitment of neutrophils.

Kidney Endothelial Progenitors Play a Critical Role in Susceptibility to Acute Kidney Injury Katherine V. Maringer, Natasha M. Rogers, Jeffrey S. Isenberg, Sunder Sims-Lucas. *Univ of Pittsburgh, Pittsburgh, PA.*

Background: Acute Kidney Injury (AKI) is characterized by an abrupt decrease in renal function leading to renal failure, and contributing to high percentages of morbidity and mortality. Kidney formation involves the production of nephrons each with a rich vascular supply surrounding it. This complex and high vascularization makes the kidney especially susceptible to ischemic injury. We hypothesize that malformations of the vascular system during kidney development compromise its ability to cope and recover from AKI.

Methods: We generated mice with a conditional deletion of Vegfr2 (floxed) in the Foxd1cre positive renal stroma ($Vegfr2^{ST-/-}$), and evaluated the formation of the vasculature via histology, immunohistochemistry and fluorescent microangiography. Furthermore we performed ischemia reperfusion injury (IRI) on control and mutant mice and determined their ability to recover 1 (injury phase) and 7 days (repair phase) post injury. Lastly, we performed a lineage tracing study where Foxd1cre mice were bred with a TdTomato reporter (permanently labeling all Foxd1 derived cells) and performed IRI and interrogated the percentage of Foxd1 derived endothelial cells that were present in the IRI and contralateral control kidneys.

Results: We determined that the $Vegfr2^{ST-/-}$ mice had dilated microvasculature embryonically and post-nataly. Furthermore, when we stressed the $Vegfr2^{ST-/-}$ animals with IRI they had an increased injury compared to controls (both histologically and inflammatory markers). This increased susceptibility in the mutants continued to be observed 7 days following the injury. Lineage tracing experiments showed the Foxd1 derived endothelial cells are highly plastic during the repair phase of IRI and their deletion in the $Vegfr2^{ST-/-}$ is likely the reason for the increased susceptibility to injury.

Conclusions: From this we determined that Foxd1 derived endothelial cells are highly pertinent to normal formation of the renal vasculature and their risk of AKI. Patients that have an underlying perturbation of the renal microvasculature are likely at higher risk of suffering long term renal damage following AKI.

TH-PO047

Diadenosine Pentaphosphate Reduces Glomerular Filtration Rate Vera Jankowski,[1] Andreas Patzak,[2] Joachim Jankowski.[1] *[1]Inst of Molecular Cardiovascular Research, Univ Hospital RWTH, Aachen, NRW, Germany; [2]Inst of Vegetative Physiology, Charité-Universitätsmedizin, Berlin, Germany.*

Background: Mechanisms and participating substances responsible for the reduction of glomerular filtration (GFR) rate in contrast induced acute kidney injury (CI-AKI) are still matter of debate. Here we hypothesize that diadenosine polyphosphates are released by the action of contrast media and may act on glomerular arterioles thereby reducing GFR.

Methods: Rat tubules were freshly isolated using a modified iron oxide sieve technique and treated with iodixanol (47 mg iodine/ml) at 37°C for 20 min. The supernatant was analyzed regarding the content of ApnA (n=3-5) by using reversed phase chromatography, affinity chromatography and Maldi-MS. Concentration response curves for ApnA (n=3-5, 10^{-12}-10^{-5} mol/l) were measured in isolated perfused glomerular arterioles. The GFR was obtained in conscious mice by inulin clearance.

Results: Treatment of tubules with iodixanol increased the concentration of ApnA (n=3-5) significantly in the supernatant. Ap_nA (n=3-5) reduced afferent arteriolar diameters dose dependent, but did not influence efferent arterioles. Ap_5A acted strongest; its effect weakened with time. Suramin blocked the Ap_5A effect. Further, application of Ap_5A in conscious mice significantly reduced the GFR.

Conclusions: The data indicate that contrast media induced release of Ap_5A act differentially on glomerular arterioles resulting in the reduction of the GFR. This mechanism may add to the reduced GFR in CI-AKI.

TH-PO048

Effect of Anakinra on Inflammasome Markers in Hepatorenal Syndrome Type 1 Sindhura Bobba, Siddhartha S. Ghosh, Todd W. Gehr, Daniel E. Carl. *Dept of Internal Medicine-Div of Nephrology, Virginia Commonwealth Univ Health System, Richmond, VA.*

Background: Hepatorenal syndrome (HRS) type 1 is a life threatening complication of cirrhosis with limited therapeutic options. We hypothesize that Inflammasome plays a major role in HRS type 1 and we investigated this in a mouse model by blocking IL-1β, an end product of inflammasome pathway by Anakinra, so that it could serve as a potential therapeutic agent in patients at risk for HRS type 1.

Methods: C57BL/6 mice received 1mL/kg of carbon tetrachloride (CCl4) biweekly for 12 weeks induce liver cirrhosis. A 6 mg/Kg of Lipopolysaccharide (LPS) was given intraperitoneally to mice to induce acute kidney injury by simulating the inflammatory stressor caused by acute infection. A 30 mg/ kg of Anakinra was given intraperitoneally 3 hours before and 1 hour after LPS to CCl4 and LPS treated mice. Four mouse populations were studied. (1) control mice (2) CCl4 treated mice (3) CCl4 treated mice with LPS (4) CCl4 treated mice with LPS and Anakinra (N=6 per group). Renal function was monitored by measuring urine output, urinary sodium, and serum creatinine measured 10 hrs after administration of Anakinra. The mouse kidneys were then harvested and analyzed by western blot for the presence of inflammasomal markers: IL-1β, caspase 1, and apoptosis- associated speck like protein (ASC) and the therapeutic effect of Anakinra on these inflammatory markers.

Results: Control and CCl4 treated mice showed no change in renal function. The CCl4+LPS treated mice had a significant decrease in urine volume ($p<0.05$) and urinary Na ($p<0.05$) and marked increase in serum creatinine ($p<0.05$) compared to the other 3 mice groups. In CCl4+LPS+Anakinra treated mice IL-1β, caspase 1, and ASC expression significantly decreased ($p<0.05$) compared with CCl4+LPS treated mice.

Conclusions: In the CCl4-induced cirrhotic mouse model, simulating HRS type 1 by administration of LPS, accompanied by an increase in the expression of IL-1β, caspase-1, and ASC in mouse kidney. Anakinra resulted in down regulation of these markers and improvement in renal function. This suggests that agents like Anakinra could be a potential therapeutic option for patients at risk of HRS type 1.

TH-PO049

Matrix Metalloproteinase-7 Protects against Acute Kidney Injury in Mice Haiyan Fu,[1] Dong Zhou,[1] Liangxiang Xiao,[1] Roderick J. Tan,[2] Youhua Liu.[1] *[1]Dept of Pathology, Univ of Pittsburgh, Pittsburgh, PA; [2]Dept of Medicine, Univ of Pittsburgh, Pittsburgh, PA.*

Background: Matrix metalloproteinase-7 (MMP-7), a secreted and zinc-dependent endopeptidase that proteolytically degrades a broad range of extracellular matrix and other substrates, is a direct downstream target of the canonical Wnt/beta-catenin signaling. MMP-7 is specifically induced in the tubular epithelium of the kidneys in a variety of chronic kidney diseases. However, whether MMP-7 plays a role in acute kidney injury (AKI) is still ambiguous.

Methods: MMP-7 expression in the kidneys after AKI was assessed. MMP-7 knockout and wild-type control mice were subjected to renal ischemia/reperfusion injury (IRI) and cisplatin administration, respectively. Cultured proximal tubular epithelial cells (HKC-8) were used an in vitro model.

Results: MMP-7 was markedly induced in renal tubular epithelial cells at 12 hours after IRI. To investigate the role of MMP-7 in AKI, we utilized MMP-7 knockout mice (MMP-7-/-). Mice with global ablation of MMP-7 were phenotypically normal with no appreciable defects in kidney morphology and function. In AKI induced by either IRI or cisplatin, loss of MMP-7 substantially aggravated renal lesions, compared with wild-type controls. MMP-7-/- mice displayed higher mortality rate, elevated serum creatinine, and more severe morphologic injury, which was accompanied by an increased expression of FasL, Caspase 7 and FADD, while little change with Bax. In MMP-7-/- kidneys, more prevalent apoptotic cells were detected in renal tubular epithelial cells after injuries. Moreover, deficiency of MMP-7 also promoted the expression of pro-inflammatory cytokines and chemokines, such as TNF-α, MCP-1 and RANTES, and caused an increased inflammatory cell infiltration as illustrated by immunostaining for $CD3^+$, $CD45^+$ and $F4/80^+$ antigens. In vitro, recombinant MMP-7 protein protected human kidney proximal tubular cells (HKC-8) against apoptosis through inhibiting FasL/Caspase-7/FADD axis.

Conclusions: MMP-7 plays a protective role in the setting of AKI through inhibiting FasL-mediated apoptotic pathway and reducing renal inflammation.

Metformin Protects against Cisplatin-Induced Acute Kidney Injury *via* an AMPK-Dependent Manner Jianzhong Li, Chunsun Dai. *Nanjing Medical Univ.*

Background: Metformin, one of the most common prescriptions for the therapy of type 2 diabetes, is beneficial for early diabetic nephropathy. However, the role and mechanisms for metformin in treating acute kidney injury remain to be established.

Methods: Adult male CD1 mice were injected with cisplatin intraperitoneally to induce AKI. Rat Kidney tubular epithelial cells (NRK-52E) were incubated with cisplatin to induce cell death.

Results: Here, we found that mice exhibited severe kidney injury at day 2 after cisplatin injection. Metformin treatment could markedly ameliorate kidney dysfunction and kidney morphologic abnormality. Cell apoptosis in kidney tissue presented as TUNEL and anti-cleaved caspase 3 staining was much less in metformin-treated mice compared with the diseased control. Anti-Ly6b and anti-F4/80 staining demonstrated that the inflammatory cells infiltration in the kidneys was also diminished in metformin-treated mice. In addition, LC3-II, an autophagy biomarker, was induced at 1h and peaked at 12h in the kidneys after cisplatin injection, whereas autophagy induction as well as p-Ampk abundance were largely enhanced in metformin-treated mice. In cultured NRK-52E cells, cell apoptosis was markedly induced at 12h after cisplatin treatment and metformin could largely attenuate it. Furthermore, cells pretreated with metformin dramatically increased the abundance of phosphorylated Ampk. LC3-II protein level was also significantly induced after metformin treatment. Knocking down Ampk expression with small interfering RNA or using 3-methyladenine to block metformin-induced autophagy could largely diminish the protective effect of metformin on cell apoptosis.

Conclusions: In summary, metformin may protect against cisplatin-induced AKI through promoting tubular cell survival by inducing AMPK activation and tubular cell autophagy.

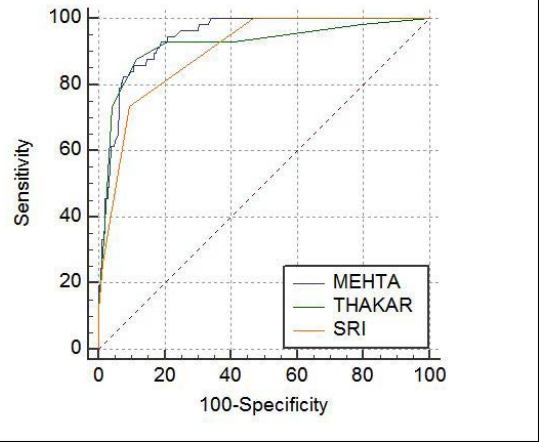
A Comparison of Three Prediction Models for Acute Kidney Injury Requiring Renal Replacement Therapy After Coronary Artery Bypass Graft Surgery Ailene Ramos Buelva-Martin, Aina Bautista-Duque, Oscar D. Naidas. *Dept of Medicine, Section of Nephrology, St. Luke's Medical Center, Quezon City, Metro Manila, Philippines.*

Background: Acute kidney injury (AKI) following cardiac surgery is associated with increased post-operative morbidity and mortality. Scoring systems to predict acute kidney injury requiring renal replacement therapy (RRT) among patients undergoing cardiac surgery have been developed to assess risk pre-operatively and give necessary prophylactic agents and also assist clinicians on the management post-operatively.

Methods: Cross sectional analytic study of 427 patients who underwent coronary artery bypass graft from January 2009-October 2014. The following were excluded: a) on hemodialysis b) with missing data. Primary outcome: acute kidney injury requiring RRT after CABG. Risks were calculated using the three models: Cleveland scoring by Thakar, Simplified Renal Index by Wijeysundera, and the Bedside Tool for Predicting Risk of Postoperative Dialysis by Mehta. The area under the receiver operating curve (AUROC) was determined for each model.

Results: AKI was documented in 25.5% (n=109), 13.3% (n=57) underwent post-operative RRT. Discrimination for the prediction of RRT was good for the three scoring models using AUROCs: Mehta: 0.94 (95% CI, 0.916 to 0.963); Thakar: 0.92 (95% CI, 0.890 to 0.944), and SRI: 0.90 (95% CI, 0.867 to 0.926). Mehta showed the highest predictive value, with significant difference with SRI (P = 0.0053). However, it was not signficantly different with Thakar (p=0.23).



Conclusions: The Bedside Tool for Predicting Risk of Postoperative Dialysis by Mehta showed the highest predictive value but with no significant difference with the predictive value of the Cleveland scoring system. The advantages of the Cleveland scoring over Mehta are the applicability in cardiac surgeries other than CABG and the less number of variables.

TH-PO052

Effect of Off-Pump and On-Pump Coronary Artery Bypass Graft Surgery on Acute Kidney Injury Ailene Ramos Buelva-Martin, Oscar D. Naidas. *Dept of Medicine, Section of Nephrology, St. Luke's Medical Center, Quezon City, Metro Manila, Philippines.*

Background: Acute Kidney Injury (AKI) is one of the serious complications of cardiac surgery. AKI is associated with increased mortality and morbidity. Coronary artery bypass graft (CABG) surgery can be done with a beating-heart (off-pump) or with a cardiopulmonary bypass machine (on-pump). There are conflicting studies regarding reduction of acute kidney injury with the use of the Off-pump CABG vs. On-Pump CABG.

Methods: Adult patients who underwent CABG using Off-pump and the On-pump technique from January 2005 to October 2014 were included in this retrospective cohort study. The following patients were excluded: a)chronic hemodialysis b)baseline eGFR <15ml/min/1.73m2 c)missing data. The outcomes were: AKI defined as absolute increase in the serum creatinine concentration of ³0.3 mg/dL from baseline within 48 hours after CABG and AKI requiring renal replacement therapy. Odds ratio were calculated between the use of Off-pump and On-pump CABG with the respective outcomes.

Results: Postoperative Acute Kidney Injury The incidence of acute kidney injury with off-pump group was lower (4/28 [14.3%]) vs on-pump group (109/427 [25.5%]) with OR 2.05 [95% CI, 0.69 to 6.59]); however, it was not significantly different at p-value 0.19. **Postoperative Acute Kidney Injury with Renal Replacement Therapy** Out of the 109 patients who had acute kidney injury after On-pump CABG, 53 (48.6%) patients underwent hemodialysis. While in the Off-pump CABG group, no one underwent hemodialysis out of the 4 patients who had acute kidney injury postoperatively (OR 8.8 [95% CI 0.5327 to 146.9], P=0.1283). [table1]

Conclusions: There was a lower incidence of AKI and AKI requiring renal replacement therapy in the Off-pump CABG group, however, it was not statistically significant with the On-pump CABG group. There is still insufficient evidence to say that the use of Off-pump CABG technique reduces incidence of AKI. Limitations of this study are: small sample size, confounding variables since this study is a retrospective study, off-pump CABG population may not have been represented accurately. A multi-center study to increase sample size is recommended.

TH-PO053

Renal Dysfunction Detected by an Automatic Alert System: DETECT-H Proyect Pedro J. Labrador, Silvia Gonzalez S, Santiago Polanco Candelario, Elena Davin carrero, Jesús P. Marin, Ines Castellano, Juan R. Gomez-Martino. *Nephrology, San Pedro de Alcantara Hospital, Caceres, Spain.*

Background: The aim was to analyse the prevalence of chronic kidney disease (CKD) and acute kidney injury (AKI), length of stay (LOS) and in-hospital mortality.

Methods: To evaluate renal dysfunction in admissions we developed a fully automated electronic alert system which identifies all adult patients with reduced glomerular filtration rate according to CKD-EPI. Two alert levels were established, <60 and <30 mL/min/1.73m² in patients over 80. Patients admitted to nephrology unit and on dialysis were excluded. Detected patients were retrospectively analysed. CKD and AKI was defined according to KDIGO guidelines. Baseline serum creatinine was the lowest between 0.5-6 months before admission. LOS and in-hospital mortality was recorded.

Results: Between January and June 2014, issued alerts were 1.241 from 11.022 adult admissions (11.3%), from 1.079 patients (13.1% multiple admissions). Median age 77 years (interquartile range (IQR) 70-81), and 53.9% were men. Previous renal function was present in 1.042 patients (84%). Stage 1 9.6%, stage 2 37.7%, stage 3a 25%, stage 3b 17.7%, and stages 4-5 10%. Previous CKD was only registered in 31.9%. AKI was present in 846 admission episodes (69.9% of alerts and 7.7% of overall admissions). AKI stage 1, 2 and 3, respectively was 421 (49.7%), 207 (24.5%) and 218 (25.8%). AKI episode was specified to be suffered in 33.2% patients at discharge. In patients with CKD not AKI 7.5%, in overall AKI patients 45.3%, in AKI 1 30.4%, in AKI 2 47.8% and in AKI 3 71.6%; p<0.001. LOS in overall admissions in the same period was 5.31 days, for overall detected patients median LOS was 8 days (IQR 4-13 days). Median LOS for CKD not AKI, or AKI stage 1, 2 and 3 was 6 (3-10), 8 (5-13), 8 (6-14) and 10 (5-19) days; p<0.001. Mortality for all detected patients was 14.9% (185 patients). In-hospital mortality for CKD not AKI, or AKI stage 1, 2 and 3 was 4.3%, 10.9%, 22.7% and 33.9%. Mortality in patients with AKI stage 3 requiring dialysis was 57.1%, p<0.001.

Conclusions: Electronic alerts could be a useful tool to detect in-hospital renal dysfunction patients to improve CDK and AKI hospital outcomes.

TH-PO054

Identification of a Pediatric Inpatient Cohort at Risk for Developing Acute Kidney Injury Using Machine Learning Methods Michael G. Semanik, Sangeeta R. Hingorani. *Pediatric Nephrology, Seattle Children's Hospital, Seattle, WA.*

Background: Acute kidney injury (AKI) is prevalent amongst pediatric inpatients, and its prevention requires rapid detection of those at risk. A rise in creatinine often comes too late for prevention to be effective. Therefore, this study seeks to apply machine learning methods to routine clinical data in order to identify patients at risk for AKI before creatinine levels rise.

Methods: A cohort of pediatric inpatients with at least one creatinine value was created, then split into AKI and non-AKI groups. AKI was defined using KDIGO creatinine-based criteria. Information on demographics, vital signs, lab values, procedures, and medications were collected for each patient. For the AKI group, only data collected 24 hours before each patient's peak creatinine value were used. Simple logistic regression was used to identify features that predicted the development of AKI, and these features were used to produce two algorithms: a logistic regression-based algorithm and a Bayes Net probability-based algorithm. Both algorithims used 10-fold cross validation to create a training and test set.

Results: 4064 patients were included in the cohort, of whom 370 (9.1%) developed AKI. Sixty features were significantly associated with AKI. The logistic regression algorithim created from these features identified 144/370 AKI patients and 3653/3694 non-AKI patients (giving it a sensitivity of 39% and specificity of 99%). The Bayes Net algorithm's sensitivity was 48% (identifying 176/370 AKI patients) and its specifity was 91% (identifying 3347/3694 non-AKI patients). The ROC areas for the algorithms were 0.84 and 0.81, respectively.

Conclusions: Machine learning methods can be used to identify a cohort of pediatric inpatients that are at increased risk of developing AKI before serum creatinine rises. Identification of this population allows for both additional testing (such as urinary biomarkers) and preventative treatment (such as removal of nephrotoxic drugs). Acute kidney injury predictive algorithms have the potential to improve patient care, and, if correctly implemented, will become more accurate as more data is collected.

TH-PO055

The Jelliffe Method for GFR Estimation with Non Steady State Creatinine Performs Better for Subjects with Higher Weight and Baseline Chronic Kidney Disease Reejis Stephen, Sevag Demirjian, Steve Campbell. *Nephrology, Cleveland Clinic, Cleveland, OH.*

Background: The Jelliffe method is used to estimate the glomerular filtration rate(GFR) when creatinine is in a non-steady state, such as in patients with acute kidney injury (AKI). We explored the agreement between iothalamate-measured renal function (iGFR) and estimated GFR by the Jelliffe method (eGFR) in subjects with AKI after undergoing partial nephrectomy.

Methods: iGFR was measured within a week of partial nephrectomy in subjects who sustained AKI (>0.3 mg/dl rise in serum creatinine from baseline) after partial nephrectomy. iGFR and eGFR based on creatinine drawn at the time of iGFR measurement, were compared using Pearson's correlation (r) in subjects grouped by weight (above and below median weight; 86 Kg) and baseline chronic kidney disease status (CKD; GFR<60ml/min/1.73m^2).

Results: 69 of 90 subjects undergoing partial nephrectomy sustained AKI. Mean age was 61±11 years, and 55 were male. eGFR had a high correlation with iGFR (r=0.75, p<0.001). Correlation of eGFR with iGFR is shown and was significant except in the group with both CKD and lower weight (Table). Subgroup analysis showed that subjects with lower body weight and no CKD had lower correlation (r=0.54) than those with both CKD and the higher weight (r=0.96). The group with no CKD but higher weight had a strength of correlation in between these extremes.

Group; Mean±SD (Kg)	No CKD	CKD
Low Weight; 74 ± 9	0.54 (p 0.003)	0.40 (ns)
High Weight; 105 ± 15	0.79 (p < 0.001)	0.96 (p < 0.001)

Conclusions: GFR estimated by the Jelliffe equation correlates well with measured GFR in the AKI setting. Higher body weight and CKD at baseline are associated with higher creatinine levels, which may account for the better performance of the Jelliffe method in these states.

TH-PO056

Development of a Multicenter Ward-Based Acute Kidney Injury (AKI) Prediction Model Jay L. Koyner, Richa Adhikari, Dana P. Edelson, Matthew M. Churpek. *Dept of Medicine, Univ of Chicago.*

Background: Early identification of those at risk for the development of AKI on the general wards prior to increases in serum creatinine (SCR) would enable preemptive evaluation and intervention to minimize the risk and severity of AKI. We aimed to develop an AKI risk prediction algorithm using electronic health record (EHR) data in non-ICU patients.

Methods: All hospitalized ward patients who had SCr measured in 5 hospitals were included. Patients with a first measured SCr>3.0mg/dl or who developed inpatient AKI outside the general ward were excluded. Using a discrete-time survival model, demographics (age, sex), continuous variables (respiratory rate, pulse, temperature, pulse pressure index, oxygen saturation, systolic and diastolic blood pressure, complete blood count, hepatic panel and blood chemistries) were modeled as restricted cubic splines with 4 knots. The algorithm was derived in 60% of the data and prospectively validated in the remaining 40%. Area under the curve (AUC) was calculated for the prediction of SCr-based KDIGO AKI within 12 or 24 hours. Subgroup analyses were conducted across baseline glomerular filtration rate (eGFR) groups and severity of AKI stage.

Results: Among the 206,192 included patients, 17,522 (8.5%) developed KDIGO AKI on the wards, with 792 progressing to stage 2 and 257 to stage 3 during their hospital stay. The AUC(95%CI) of the model was 0.74(0.74-0.74) for predicting AKI within 24 hours and 0.76(0.76-0.76) for within 12 hours. Accuracy was highest for predicting AKI stage 3 in the next 12 hours (AUC 0.90(0.89-0.92)).

Subgroup	AUC(95%CI)	
	12hr outcome	24hr outcome
Baseline GFR		
GFR ≥90	0.71(0.69-0.70)	0.69(0.68-0.70)
GFR 60-89	0.76(0.75-0.76)	0.74(0.73-0.74)
GFR 30-59	0.75(0.74-0.76)	0.73(0.72-0.73)
AKI Stage		
Stage 1	0.76(0.76-0.76)	0.74(0.74-0.74)
Stage 2	0.77(0.76-0.78)	0.73(0.73-0.74)
Stage 3	0.90(0.89-0.92)	0.87(0.86-0.89)

Conclusions: Readily available EHR data can be used to predict impending AKI on the general wards with good to excellent accuracy across different patient subgroups. Real-time use of this model, prior to changes in SCr, would allow early diagnostic and therapeutic interventions for those at high risk of AKI and may improve cost and outcomes.

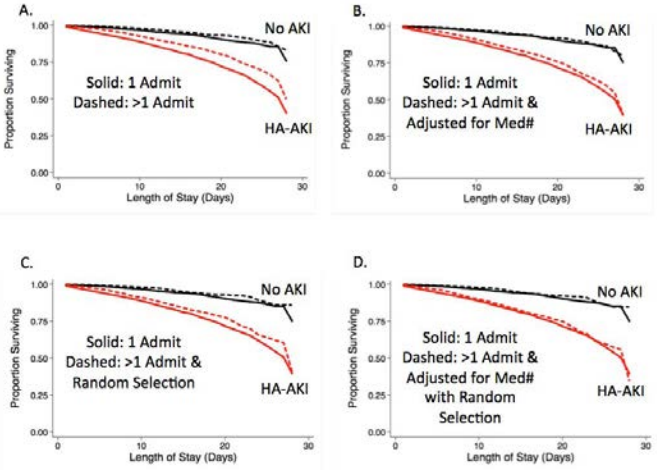
TH-PO057

Survivor Bias: Utilization of Multiple Admissions for Evaluation Risk of Inpatient Mortality Associated with Hospital-Acquired (HA) Acute Kidney Injury (AKI) David G. Warnock, T. Clark Powell, John P. Donnelly. *Univ of Alabama at Birmingham, Birmingham, AL.*

Background: Inpatient deaths censored the cohort at risk, introducing survivor bias favoring those with >1 admission. Analysis of first admissions avoids this bias, but also loses information about those who survive multiple admissions. We evaluated inpatient mortality associated with AKI for adult admissions to UAB Hospital for FY2010-FY2013.

Methods: We used ICD9 codes and all inpatient serum creatinine (sCr) values for 109,456 adult patients with 5,452 inpatient deaths. We excluded patients with patients with <2 sCr values, ESRD, post-renal transplant, eGFR (<5 or >500 ml/min.1.73 m^2), length of stay <1 and >28 days, and patients with community-acquired AKI. Minimum sCr for each admission was used as baseline, and HA-AKI was defined by peak sCr > (0.3 mg/dL + minimal sCr) and date-time for minimal sCr < date_time peak sCr. No-AKI was defined as (peak Scr - minimal sCr) <0.3 mg/dL. Survivor functions included HA-AKI, median age, black race, male gender, Deyo_Charlson comorbidity score, and median admissions for each patient (Med#).

Results: For 40,471 patients with 1 admission, there were 7,594 cases of HA-AKI (19%) with 1,290 deaths (17%), For 14,860 patients with 23,633 admission, there were 6,633 cases of HA-AKI (22%) with 732 deaths (11%). Figure shows survival curves for 1 versus >1 admissions (A); 1 versus >1 admissions adjusted for Med# (B), 1 versus selected >1 random selected admission (C), and 1 versus >1 random selected admission adjusted for Med# (D).



Conclusions: Survivor curves for multiple admissions (dashed lines) fell above the curve for single admissions, demonstrating survivor bias. Combining random selection and adjustment for Med# resolved the survivor bias, permitting inclusion of patients with multiple admissions in risk models for inpatient mortality.

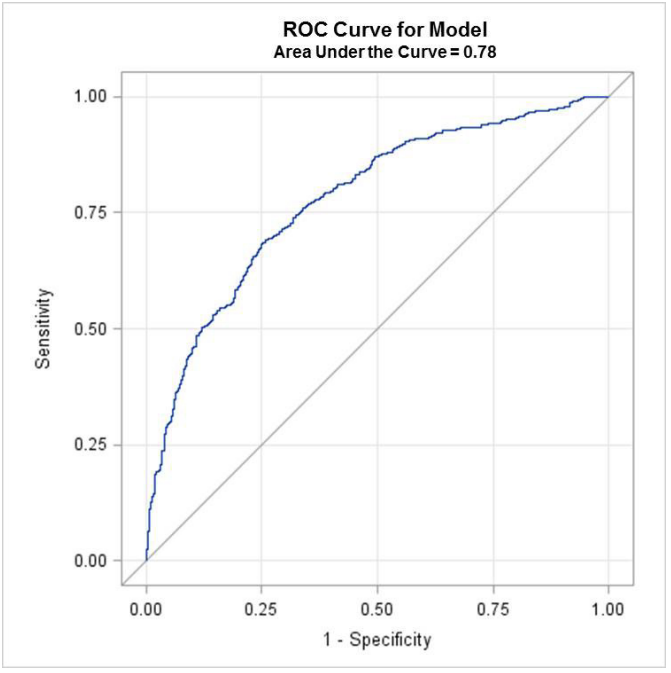
Validation of the Acute Renal Failure Trial Network (ATN) Study Risk Model for Predicting Mortality in Critically Ill Adults with Acute Kidney Injury Ridhmi P. Rajapakse,[1] Christopher M. Keener,[2] Paul M. Palevsky,[1,3] John A. Kellum,[2] Emily Foldes.[2] *[1]Medicine, Univ of Pittsburgh, Pittsburgh, PA; [2]Critical Care Medicine, Univ of Pittsburgh, Pittsburgh, PA; [3]Renal Section, VA Pittsburgh HCS, Pittsburgh, PA.*

Background: Disease specific severity of illness scoring systems have been developed to predict survival of patients with acute kidney injury. Performance of these scoring systems outside of the population in which they have been generated has been poor. We therefore evaluated the performance of the recently developed ATN Study risk model predicting 60 day all-cause mortality in intensive care unit (ICU) patients at initiation of dialysis for acute kidney injury (AKI).

Methods: We evaluated the performance of the ATN Study risk model using the High Density Intensive Care (HiDenIC) Database which contains data on all adult patients admitted to any of the eight ICUs at UPMC between July 2000 and October 2008. Clinical data and physiologic variables were closely matched with the original study model; missing data were imputed by either assuming clinical normality or viewing these data elements following similar rules used to build the original model. Model discrimination was assessed via area under the receiver operating characteristic curve (AUROC). Calibration was assessed using the Hosmer-Lemeshow goodness-of-fit test.

Results: 1747 patients were initiated on renal replacement therapy (RRT) for AKI during this interval; full data for model testing were available for 1300 patients (74%). The AUROC for the model was 0.78 (95% CI: 0.75-0.80) with a Hosmer-Lemeshow goodness-of-fit test p-value of 0.59 (Figure).



Conclusions: The ATN score demonstrated good discrimination and calibration for predicting 60-day all-cause mortality in in ICU patients initiating RRT for AKI in a population separate for the population in which it was developed.

TH-PO059

A Multifaceted Quality Improvement Programme for Tackling Acute Kidney Injury in a Large Teaching Hospital Leonard Ebah, Prasanna Hanumapura subbegowda, Deryn Jennifer Waring, Rachael Challiner, Robert Henney, Alastair J. Hutchison. *Manchester Acute Kidney Injury Strategy, Dept of Renal Medicine, Central Manchester Univ Hospitals, Manchester, United Kingdom.*

Background: Acute kidney injury (AKI) is now widely recognised as a serious health care issue. Up to 25% of hospital patients have been reported to develop it, often with worse outcomes compared to those without AKI. AKI care in hospitals has been shown to be substandard. This study aimed to use quality improvement methodology to improve AKI care and outcomes in a large teaching hospital.

Methods: Several areas of documented poor AKI care were identified and specific improvement activities implemented through sequential Plan-Do-Study-Act (PDSA) cycles. An electronic alert system for AKI was developed, a ten point Priority Care Checklist (AKI PCC) was tested with the aid of specialist nurses and pharmacists whilst targeted education activities were carried out. Impact on key AKI care processes and patient outcomes was studied.

Results: The electronic alert had a sensitivity of 99% for the detection of new cases of AKI. Nine aspects of the PCC saw significant improvements in their attainment: Baseline creatinine 66% to 84%, identification of a cause for AKI 62% to 77%, fluid balance assessment 77% to 92%, appropriate investigations 61% to 77% catheterisation 92% to 99% ultrasound scans 79% to 95% renal or intensive care referrals 80% to 100%, fluid charts 64% to 71% after, and appropriate drugs review 57% to 87%. The intervention led to a significant reduction in variability of delivered AKI care. AKI incidence showed a trend towards reduction; 9.9% of all hospitalisations before any intervention to 7.8% towards the end of the intervention period. AKI related length of stay dropped from 20.2% to 15.5% and AKI deaths also showed a trend towards reduction, from 44 deaths averagely per month to 31 deaths. The number of cases of hospital acquired AKI were down from 107 to 90 per month.

Conclusions: This study demonstrates the success of an AKI care checklist implemented with the aid of a nurse/pharmacist in improving key processes of care and showing an early improvement in key patient outcomes.

TH-PO060

The Quality of Hospital Discharge Communications About AKI Raquel C. Greer,[1] Yang Liu,[1] Deidra C. Crews,[1] Bernard G. Jaar,[1] Hamid Rabb,[1] L. Ebony Boulware.[2] *[1]Johns Hopkins Univ; [2]Duke Univ.*

Background: Post-hospital discharge (DC) care for patients hospitalized with AKI could influence patients' subsequent risks of CKD and related morbidity. High-quality written hospital DC communications (DC summaries to outpatient providers and patient DC instructions) about AKI may help facilitate adequate follow-up and patient self-care.

Methods: We reviewed electronic health records of patients hospitalized with community and hospital-acquired AKI in 2012 at a single hospital in Baltimore MD to characterize the quality of written hospital DC communications about AKI. We assessed patient and system characteristics independently associated with higher quality DC communications (greater number of quality elements out of 10 possible) in a multivariable model.

Results: Among 75 randomly selected hospitalized patients with AKI stratified by KDIGO stage 1 to 3 (n=25 per stage), mean age was 56 years, 48% were African American, 15% had known CKD, median length of stay was 9 days and 65% were discharged from medical (vs. surgical) services. Less than half of DC communications included key elements about AKI.

Presence of 10 Quality Elements about AKI in Discharge Communications (n=75)			
		Presence of Quality Element N (%)	
Type of Quality Element	Quality Elements Possible	Physician Discharge Summary	Patient Discharge Instructions
Mention of AKI occurence	2	33 (44)	10 (14)
Mention of AKI cause	2	32 (43)	1 (1)
Description of AKI course	1	23 (31)	NA
Recommended/scheduled follow-up appointments	2	60 (80)	67 (94)
Recommendations for care specific to AKI	2	11 (15)	6 (8)
Named outpatient provider to receive the discharge summary	1	58 (77)	NA

NA:Not applicable

Communications featured a median of 4 quality elements. Quality elements were greater in communications for patients with more severe AKI (number of additional quality elements (β) [95% CI]: 2.0 [0.6-3.4] for Stage 3 vs. Stage 1) and those discharged from medical (vs. surgical) services (β [95% CI]: 1.2 [0.1-2.3]).

Conclusions: Few hospital DC communications provided information or recommendations for AKI care in sufficient detail to facilitate adequate follow-up. Improvements in this important aspect of care for patients with AKI are urgently needed.

TH-PO061

Prognosis of Contrast Induced Nephropathy After Outpatient Computed Tomography in Chronic Kidney Disease Patients Sehoon Park, Seokwoo Park, Eunjeong Kang, Hajeong Lee, Jung Pyo Lee, Kwon Wook Joo, Yon Su Kim, Dong Ki Kim. *Dept of Internal Medicine, Seoul National Univ Hospital.*

Background: Most studies regarding contrast induced nephropathy (CIN) were done in angiography era but computed tomography (CT) is more common cause of contrast exposure in general populaton. There were few prognosis data concerning CIN after outpatient CT.

Methods: Patients with estimated glomerular filtration rate (eGFR) < 60 mL/min/1.73 m2 underwent outpatient CIN prophylaxis program for contrast CT from 2008 to 2014 in Seoul National University Hospital. Patients received intravenous isotonic saline and oral N-acetylcysteine. Baseline blood sample was done within 2 weeks before CT. Basic data was colleted retrospectively by medical chart review. Prognosis was surveyed from death registry of National Statics Korea and dialysis registry of The Korean Society of Nephrology. CIN was defined by ³0.5mg/dl or ³25% increase of serum creatinine (sCr) from baseline within 48-96 hours after CT. Primary outcome was event of renal replacement therapy (RRT), duration from CT to RRT and survival period after CT. **Results:** 12179 cases of CT were performed with CIN prophylaxis protocol and 2816 cases of CT had baseline eGFR<60 without RRT history and follow up sCr 48-96 hours after CT. 84 (3%) cases of CIN were found and 99 (3.5%) cases went RRT, 551 death reported after CT. Prognosis was analyzed after adjustment with age, sex, baseline eGFR, history of diabetes and hypertension. No relationship between death, RRT incidence, doubling of sCr and CIN was shown. However, we found shorter period from CT to RRT in CIN cases. So we performed analysis with RRT within 6 months as outcome with subgroup devided by eGFR. CIN was risk factor for RRT within 6 months in cases with baseline eGFR<30 (aRR 4.70, 95% CI 1.39-15.90, P=0.013). However, in cases with eGFR³30, start of RRT in acute period was not increased by CIN.

Conclusions: CIN due to CT contrast after appropriate prophylaxis was not related to long term renal prognosis. CIN was a risk factor for start of RRT within 6 months after CT in cases with baseline eGFR<30, but even this relationship was not seen in patients with relatively preserved renal function.

TH-PO062

Outcomes following Intra Arterial Contrast in Chronic Kidney Disease Louise Goodall,[2] Thomas Hugh Douglas Patterson,[2] Jane Elizabeth Cross,[1] William E. James,[1] Venkataraman Manickavasagam.[1] *[1]Nephrology, Lismore Base Hospital, Lismore, NSW, Australia; [2]Medicine, Univ of Western Sydney, Sydney, NSW, Australia.*

Background: Contrast Induced Nephropathy (CIN) is a recognised complication of angiography. Risk factors include chronic kidney disease (CKD), advanced age, diabetes and cardiac insufficiency. Although incidence in the general population is 2-5%, reported

incidence of CIN in CKD is 15-27%. The risk of CIN may have been over-estimated in CKD.We hypothesise that pre-procedure optimisation decreases incidence and improves outcome of CIN. The aim of this study is to determine the incidence and outcome of CIN in CKD patients in our centre.

Methods: Consecutive patients with stage III-V CKD, undergoing peripheral (group 1) or cardiac (group 2) angiography, at a regional Australian hospital between 2005-2015 were included. Pre procedure optimisation included oral N-AcetylCysteine,intravenous hydration with Normal Saline and withholding Metformin and Frusemide. Low osmolality contrast diluted to 1/3 strength (group 1) or half strength (group 2) was used. CIN was defined as serum creatinine rise of >25% from baseline within 72 hours. Primary outcome was incidence of CIN. Secondary outcomes were mortality at 6 months, progression to dialysis and progression of CKD. follow up ranged from 2-73 months.

Results: 537 patients with CKD stage III-V underwent angiography. 222 patients concurrently dialysing were excluded. Median ages were similar in both groups (75years in group 1, 76years in group 2, P=0.25); diabetes was more prevalent in group 1 (70.5% versus 48.4%, P=0.001) and ischaemic heart disease more prevalent in group 2 (60.0% versus 44.3%, P=0.02). Median volume of contrast used was significantly lower for group 1 (35mls, range 2.5-350mls) than group 2 (75mls, range 20-357mls) (P<0.001). The incidence of CIN was 3.7%. Incidence of CIN did not differ between groups (group 1= 4.1%, group 2 = 3.2%, P=0.74). No patient with CIN died within 6 months or progressed to higher CKD stage or dialysis.

Conclusions: Pre procedure optimisation of CKD patients may reduce incidence of CIN. In our study,incidence of CIN in CKD patients was low and did not lead to death or progression of chronic kidney disease.

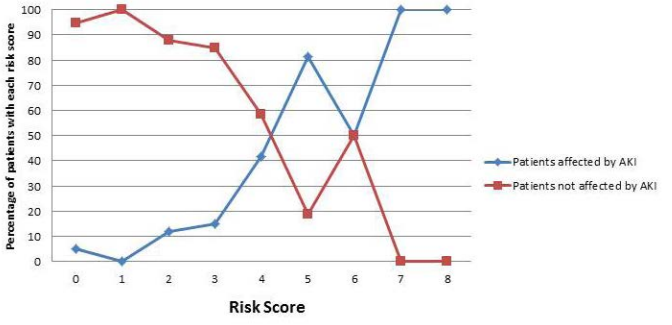
TH-PO063

AKI Risk Scores in Acute Admissions: Selecting the High-Risk or Missing the Vulnerable? Amy Jeanne Riddell, Christopher J. Mulgrew. *Renal Unit, Royal Devon and Exeter Hospital, Exeter, Devon, United Kingdom.*

Background: AKI commonly complicates acute illness. 2014 UK NICE AKI guidelines stress early identification of those at high risk. In patients with many co-morbidities, while risk scores in select groups have been studied, there remains debate as to the effective use of AKI risk scoring in 1^{y} and 2^{y} care populations (currently being investigated by the UK National AKI Programme). If correctly identified, steps could be taken to minimise risk and manage AKI earlier. Alternatively, should we not treat all acutely ill patients as 'at risk'?

Methods: Review of acute admissions to the AMU on 4 weekdays between Mar'14&Mar'15. 158 cases were reviewed and risk scored based on NICE/KDIGO published risk factors. Any AKI, demographic data, specialist nephrology input, length of stay and overall outcomes were recorded.

Results: Of 158 patients, 35 (22%) had AKI during their hospital stay. Most had AKI1 (24/35), vs AKI2 (7/35) and AKI3 (4/35). 28 had AKI on admission vs 7 after admission. Patients with AKI (at any time) had higher median scores (4, (0-9)) than non-AKI (2, (0-7)).



The 7 post-admission AKI cases had a median score of 4 (2-5). Length of stay (LoS) was greater in AKI group (9.2d v 5.8d). AKI was due to sepsis/volume depletion in 68%, alongside other risk factors. There was one death in the AKI group (AKI3).

Conclusions: 2^{y} care AKI risk scoring aims to identify those at high risk to prevent deterioration, but a greater challenge seems to be in 1^{y} care than acute settings. Our data would suggest that while patients developing AKI post-admission may have a range of risk scores on arrival, with high scores correlating with AKI and LoS, the majority with AKI arrive from primary care with high scores. A validated risk score for use in 1^{y} care, aiming to prevent admission, may be more more useful than stratifying all acute hospital admissions - are they not all 'high risk' anyway?

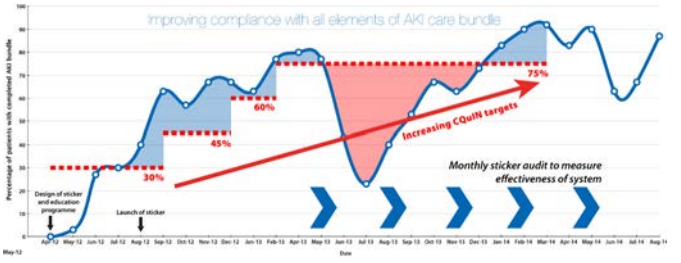
TH-PO064

Acute Kidney Injury Care Bundle Compliance in a Large District General Hospital in UK Preetham Boddana, Shiva Sreenivasan, Israr Baig, Nerys Conway. *Renal Unit, Gloucestershire NHS Foundation Hospitals, Gloucester, Gloucestershire, United Kingdom.*

Background: AKI is a common and harmful condition, which is often treatable and avoidable. The incidence of AKI in patients admitted to a hospital is approximately 3 – 7%. Gloucestershire Hospitals NHS Foundation Trust sees about 500 cases of acute kidney injury (AKI) monthly from a catchment population of 612,000.

Methods: An audit of patients with AKI showed deficiencies in care. We created an AKI care bundle (senior review, medication review, fluid balance, and repeat creatnine within 24 hours) for those patients with AKI, prompted by an AKI sticker for the case notes.

Results: For patients receiving an AKI flag, case notes were audited for appropriate use of the care bundle. We reviewed audit results over a 2-year period to see if the AKI bundles were being used appropriately and if patient care had improved. There has been improvement in AKI care bundle compliance. Figures up to August 2014 show that compliance for AKI care bundle use is 87%.



The compliance since its launch has generally exceeded the Commissioning for Quality and Innovation (CQuIN) targets set in place by the project.

Conclusions: We have shown an improved care in patients with acute kidney injury by using an electronic alert system prompting early management. AKI can easily be identified and managed early and appropriately by frontline staff by frontline staff using an ALERT system. On going study is being taken place in our department to assess if this has reduced patient mortality, morbidity and length of stay in hospital.

TH-PO065

Reducing Post-CABG Acute Kidney Injury by Multipronged Preventive Interventions Wisit Cheungpasitporn, Michael A. Mao, Charat Thongprayoon, Qi Qian. *Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: Acute kidney injury (AKI) post cardiac surgery is frequently a multifactorial event, associated with an increased morbidity and mortality. As AKI has no specific treatment, prevention is critical. This study aims to apply multipronged preventive measures to reduce AKI after coronary artery bypass grafting (CABG).

Methods: Prospective randomized interventional study. Non-dialysis and non-kidney transplant adults (³18 years old) undergoing elective CABG in March 2014-Feburary 2015 were randomized (1:1 ratio) to control and intervention groups. The intervention group was intervened to minimize potential nephrotoxic conditions perioperatively (48 hours prior to the operation to 5 days postoperation). Outcome measures included the incidence and severity of post-CABG AKI using the AKIN criteria, length of hospital stay, discharge disposition and hospital mortality. Data from a similar cohort in March 2013-Feburary 2014 were extracted and compared with the results from the control group to assess the spillover effects.

Results: Post-CABG AKI occurred in 19% (n=33) of the 174 patients in the intervention group; 30% (n=51) of the 172 in the control group, p=0.02, consistent with a 36% AKI risk reduction with the interventions [RR = 0.64 (95% CI: 0.44-0.94)]. Number needed to prevent one AKI was 10. The AKI severity was mostly mild and similar between the two groups; 98% and 94% were in stage 1 AKI in the control and intervention groups, respectively. Compared to non-AKI, AKI patients in both groups had a longer length of hospital stay and higher risk of being discharged to a care facility. No hospital mortality was noted in both groups. The AKI occurrence in the year prior to the study was similar to that in the control group.

Conclusions: Multipronged preventive measures can significantly reduce post-CABG AKI. The implementation of the preventive measures is uncomplicated. This approach can potentially be adopted in most hospital settings. These results should encourage initiatives towards developing AKI prevention protocols.

TH-PO066

Outcomes of Early Initiation of Continuous Renal Replacement Therapy in Elderly Patients with Acute Kidney Injury: A Multicenter Prospective Cohort Study Jae Yoon Park,[1] Dong Ki Kim,[1] Hyung Jung Oh,[2] Kwon Wook Joo,[1] Yun Kyu Oh,[1] Chun Soo Lim,[1] Shin-Wook Kang,[2] Yon Su Kim,[1] Jung Tak Park,[2] Jung Pyo Lee.[1] [1]*Seoul National Univ College of Medicine, Seoul, Korea;* [2]*Yonsei Univ College of Medicine, Seoul, Korea.*

Background: Continuous renal replacement therapy (CRRT) is essential in the management of critically ill patients with acute kidney injury (AKI). However the optimal timing for initiating CRRT remains controversial, especially in elderly patients. Therefore we investigated outcomes of early initiation of CRRT in elderly patients with AKI.

Methods: A total of 616 patients aged equal or over 65 years who started CRRT due to AKI from August 2009 to December 2013 were enrolled prospectively at three centers. They were divided into 2 groups based on the median 6-hours urine output immediately before CRRT was applied.

Results: The mean age of both group was 74.3 years. The median 6-hours urine output was 80 mL. 186 patients (60.0%) were male in early initiation group and 179 patients (60.3%) in late initiation group. The most common cause of AKI was sepsis (45.9% versus 46.0%). Mean arterial pressure was higher in early initiation group (79.8 mmHg versus 76.8 mmHg). Prothrombin time-international normalized ratio, total bilirubin, aspartate aminotransferase and alanine aminotransferase were lower in early initiation group (P<0.05).

Overall cumulative survival and 28-days survival rates were higher in early initiation group (Log-rank $P<0.001$ for both). Furthermore, early CRRT treatment was associated with lower mortality rate after adjustment for age, sex, mean arterial pressure, Charlson comorbidity index, Sequential Organ Failure Assessment score, hemoglobin, serum C-reactive protein, serum albumin level and prothrombin time (hazard ratio, 0.752; 95% confidence interval 0.595-0.951, $P=0.008$).

Conclusions: Early initiation of CRRT was associated with a better prognosis in critically ill elderly patients with AKI.

TH-PO067

Outcomes in Patients with Persistent Dialysis-Dependent AKI Aedan Olaso, Daniel Tseytlin, Hope Kincaid, Sharon E. Maynard. *Lehigh Valley Health Network, Allentown, PA.*

Background: We sought to describe clinical characteristics & outcomes in patients with persistent dialysis-dependent AKI at the time of hospital discharge.

Methods: We performed a retrospective descriptive study of patients requiring dialysis for AKI at the time of hospital discharge in Lehigh Valley Health Network Subacute Dialysis Program between October 2012 & July 2014.

Results: Of 55 patients enrolled in the program, 26(47.3%) recovered renal function & 29(52.7%) developed ESRD. Clinical characteristics of these patients are shown below. The median duration of dialysis in the renal recovery group was 3.5 weeks. Although 75% of patients who recovered renal function did so by 5.1 weeks, 2/26(7.7%) recovered >3 months after dialysis initiation.

Clinical Characteristics	Renal Recovery (n=26)	No renal recovery (n=29)
Age	64	74
Comorbidities - n(%) HTN CHF CAD DM Cerebrovascular ds PVD	 18 (69.2) 5(19.2) 6(23.1) 16 (61) 3 (11.5) 4 (15.4)	 25 (86.2) 10 (34.5) 10 (34.5) 10 (34.5) 1 (3.4) 3 (10.3)
Baseline creatinine (mg/dl)	1.3	2.0
Creatinine on hospital admission (mg/dl)	2.5	3.9
Creatinine on dialysis initiation (mg/dl)	5.2	5.5
Change in creatinine between week 3 & 4 after dialysis initiation	-0.86*	+0.13
Etiology - n (%) ATN Multiple myeloma CIN AIN ANCA CRS Acute renal allograft rejection Other	 15 (57) 0 (0) 2 (7.7) 1 (3.8) 1 (3.8) 3 (11.5) 1 (3.8) 2(7.7)	 7 (24.1) 5 (17.2) 2 (6.9) 1 (3.4) 1 (3.4) 3 (10.3) 2 (6.9) 5 (17.2)

* Among those who recovered renal function but were still dialysis dependent at 4 weeks.

Conclusions: This study indicates that patients who did not recover renal function were older & had higher creatinine levels at each time point than those who recovered renal function. While there was a decrease in serum creatinine from week 3 to week 4 in patients with renal recovery, there was an increase for those who did not recover. More patients who did not recover renal function had HTN, HF & CAD. Additionally, more patients who had ATN recovered renal function, while all patients with multiple myeloma did not. Hypothesis-testing studies are needed to explore whether or not these clinical characteristics may be used to predict which patients are likely to recover renal function and which are not.

TH-PO068

Acute Kidney Injury Episodes Accelerates Rate of Loss of Renal Function in Diabetes Mellitus Charuhas V. Thakar,[1,2] Anthony C. Leonard,[1,3] Karthikeyan Meganathan,[1,3] V. Shane Pankratz.[4] *[1]Internal Medicine, Univ of Cincinnati, Cincinnati, OH; [2]Medicine, Cincinnati VAMC, Cincinnati, OH; [3]Family Medicine, Univ of Cincinnati, Cincinnati, OH; [4]Internal Medicine, Univ of New Mexico, Albuquerque, NM.*

Background: Although acute kidney injury (AKI) is a risk factor for chronic kidney disease (CKD), whether it accelerates the rate of loss of estimated glomerular filtration rate (eGFR) is not known.

Methods: In a de-identified cohort of 3,678 type 2 diabetes patients we studied the impact of AKI on the rate of decline in eGFR. Patients with an entry eGFR of > 30 ml/min and at least two creatinine (Cr) values at least one month apart were followed until their eGFR was < 15 ml/min, death, or the end of the study. Cr measurements spanned over an average of 65 months. Estimated rates of linear eGFR decline were compared between those with and without AKI. We assessed the effect of AKI on the outcome of a rapid decline in eGFR (defined as > 5 ml/min/year) adjusting for demographics, proteinuria, and baseline CKD status (initial eGFR greater or less than 60) in a multivariable logistic model, and expressed this as odds ratios (OR) and 95% confidence limits (95% CI).

Results: Patients' mean (standard deviation) age was 62 (11) years at study entry with an average eGFR of 79.7 (22.5). In 3,055 non-AKI patients the mean eGFR decline was 2.7 vs 4.2 ml/min/yr in the 623 AKI patients ($p < .0001$). For 499 AKI patients with both pre and post-AKI eGFR slopes, the mean decline pre-AKI was 2.7 ml/min/yr versus 6.3 ml/min/yr post-AKI ($p = .03$; paired t-test). In the non-AKI group 23.4% met the rapid decline outcome, compared with 36.0% in AKI group ($p < .0001$); within AKI patients, rapid decline occurred in 37% of patients pre-AKI and 46% post-AKI (paired OR = 1.4; 95% CI, 1.1-1.8, McNemar $p = .008$). AKI was associated with rapid decline (OR 1.8; 95% CI, 1.5-2.2; $p < .0001$), adjusted for age, gender, race, proteinuria, and CKD status.

Conclusions: Compared to no-AKI, diabetic patients with AKI experience an accelerated rate of decline in eGFR; and it occurs at twice the pace in the post- vs pre-AKI periods. Biological and process of care factors may be responsible for this effect.

TH-PO069

Impact of Transient or Persistent Acute Kidney Injury on Chronic Kidney Disease Progression and Mortality After Gastric Surgery for Gastric Cancer Chang Seong Kim, Eun Hui Bae, Seong Kwon Ma, Soo Wan Kim. *Dept of Internal Medicine, Chonnam National Univ Hospital, Gwangju, Republic of Korea.*

Background: Acute kidney injury (AKI) was common after gastric surgery for gastric cancer and associated with adverse outcomes. However, impact of transient or persistent AKI on clinical outcomes after gastric surgery for gastric cancer has not been described. The objective of this study was to determine the incidence, factors, and clinical outcomes associated with transient or persistent AKI after gastric surgery.

Methods: We performed a retrospective study of 4,886 patients with normal renal function who underwent partial or total gastrectomy for gastric cancer between June 2002 and December 2012. Transient AKI was defined as return of serum creatinine to the no-AKI range at discharge after gastric surgery. Our outcomes included occurrence of new-onset chronic kidney disease (CKD), and long-term kidney function and mortality.

Results: AKI occurred in 638 (13.1%) after gastric surgery. Of these, transient AKI was documented in 556 (87.1%). Length of intensive care unit (ICU) and hospital stay, and ICU admission rate (5.8% versus 1.0%) were higher in patients with transient AKI than in those without AKI. Male, use of diuretics and postoperative vasopressor, and lower baseline creatinine were common risk factors for persistent and transient AKI after gastric surgery. After adjusting for confounding factors, patient with transient and persistent AKI had a significantly higher new-onset CKD (odds ratio [OR], 1.62; 95% CI, 1.16–2.26, $P=0.005$; OR, 3.60; 95% CI, 1.77–7.34, $P<0.001$, respectively) and 1-year mortality (OR, 1.75; 95% CI, 1.15–2.66, $P=0.009$; OR, 12.70; 95% CI, 7.57–21.31, $P<0.001$, respectively) compared with no-AKI.

Conclusions: Not only persistent AKI but Transient AKI is associated with increased of hospital complications and a significantly higher risk of CKD progression and long-term mortality than patients without AKI after gastric surgery.

TH-PO070

Use of Non-Tunneled Versus Tunneled Catheters for Renal Replacement Therapy in Acute Kidney Injury Mallika L. Mendu, Sushrut S. Waikar. *Div of Renal Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Background: Treatment of severe acute kidney injury requiring renal replacement therapy (AKI-RRT) requires vascular access, with either temporary, non-tunneled dialysis catheters (NTDC), or tunneled dialysis catheters (TDC). The relative risks and benefits of these two vascular access options have not been well studied.

Methods: We conducted a 1-year prospective cohort study in an academic medical center to compare outcomes between TDC and NTDC for AKI-RRT. We collected information about catheter placement including reasons for type of catheter used, number of insertion attempts, duration of use, and infectious and mechanical complications.

Results: Over one year we collected information on 140 NTDC and 80 TDC placement procedures on 154 patients with AKI-RRT. Compared to NTDCs, TDCs required fewer insertion attempts (1.0 vs. 1.5), had longer median duration of use (58.5 vs. 6.5 days), and had fewer infectious and mechanical complications (6% vs. 25%) (all $p<0.001$). The most common reasons for NTDC over TDC placement were immediate need for use (74%) and suspicion of systemic infection (21%). Tunneled line conversion (22%), infection (11%) and catheter not working (7%) were the most common reasons for NTDC removal. Infection (4%) was the most common reason for TDC removal.

AKI Causes	**NTDC** (N=140, N (%))	**TDC** (N=80, N (%))
Acute Tubular Necrosis	42 (30)	36 (45)
Hypotension	15 (11)	5 (6)
Ischemia	12 (9)	5 (6)
Prerenal	12 (9)	5 (6)
Hospital location		
Intensive care unit	133 (95)	39 (49)
Floor	7 (5)	41 (51)
Mean Insertion Attempts		**p-value**
	1.5	1.0 <0.001
Total Number of Complications (mechanical and infectious)		
	35 (25)	5 (6) <0.001
Median Days Duration of Use (IQR)		
	6.5 (4,10)	58.5 (12, 267) <0.001

Catheter Placement Characteristics

Conclusions: Compared to NTDCs, the placement of TDCs was associated with fewer complications and longer duration of use in patients with AKI-RRT. In appropriate patients, TDCs should be the first choice for vascular access in AKI-RRT.

TH-PO071

Nonapnea Sleep Disorders and the Risk of Acute Kidney Injury: A Population-Based Retrospective Cohort Study Hugo You-Hsien Lin,[1,2,3] Yu-Han Chang,[1] Chi-chih Hung,[1] Shang-Jyh Hwang,[1] Hung-Chun Chen.[1] *[1]Dept of Internal Medicine, Kaohsiung Municipal Ta-Tung Hospital, Kaohsiung, Taiwan; [2]Div of Nephrology, Dept of Internal Medicine, Kaohsiung Medical Univ Hospital, Kaohsiung, Taiwan; [3]Graduate Inst of Medicine, College of Medicine, Kaohsiung Medical Univ, Kaoshiung, Taiwan.*

Background: Nonapnea sleep disorders (NASD) and sleep-related problems, which are high prevalent in patients with kidney diseases,are associated with cardiovascular disease, type 2 diabetes mellitus (DM) and chronic kidney disease (CKD). However, whether NASD is associated with acute kidney injury (AKI) development and prognosishave not been thoroughly investigated. The aim of this study is to determine whether NASD is an independent risk factor of AKI by using the database of National Health Insurance Research Database (NHIRD), which is one of the largest medical databases of the world.

Methods: The retrospective study used an 11-year nationwide database, which random sampled of 1,000,000 individuals covered by the National Health Insurance in Taiwan, to analyze the incidence.The patients with NASD were identified through diagnostic and medication codes. Kaplan-Meier and Cox regression analyses were performed.

Results: From 2000 to 2010, 9,316newly diagnosed NASD cases compared with 27,948 control participants without sleep disorders randomly selected, frequency matched by age, sex, index year from the general population. We demonstrated that the NASD cohort had an adjusted hazard ratio (HR; 95% confidence interval [CI] = 1.16-1.71) of subsequent AKI 1.44-foldhigher than that of the cohort without sleep disorders. Elder age, lower monthly income, hypertension, DM, cerebrovascular disease, CKD status, depression and higher Charlson comorbidity index were significant factors associated with the increased risk of AKI ($p<0.05$). Male and younger (age< 65 year-old) female increased significant risk of AKI development with NASD (HR=2.23; 95% CI = 1.57-3.16, $p<0.001$).

Conclusions: This nationwide population-based cohort study provides evidence that patients with NASD are at higher risk of developing AKI than people without NASD.

TH-PO072

Subarachnoid Hemorrhage Induces Transient Renal Dysfunction Naoki Ikegaya,[1] Kiyoshi Mori,[5] Yasuhiro Yamamura,[4] Mamoru Tomida,[4] Seiya Takehara,[4] Takuya Yoshida,[6] Hiromichi Kumagai,[6] George Seki,[2] Akira Hishida.[2] *[1]Dept of Medicine, Yaizu Cityl Hospital, Yaizu, Japan; [2]Dept of Nephrology, Yaizu City Hospital, Yaizu, Japan; [3]Dept of Neurology, Yaizu City Hospital, Yaizu, Japan; [4]Dept of Neurosurgery, Yaizu City Hospital, Yaizu, Japan; [5]Medical Innovation Center, Kyoto Univ Graduate School of Medicine, Kyoto, Japan; [6]Dept of Clinical Nutrition, Univ of Shizuoka, Shizuoka, Japan.*

Background: Subarachnoid hemorrhage (SAH) is known to induce acute cardiovascular stress as reflected by ECG changes, and renal dysfunction is associated with poor prognosis in SAH. However, the precise effect of SAH on renal function and the possible mechanisms of renal dysfunction in SAH have not been fully understood.

Methods: First, we retrospectively analyzed renal function by serum creatinine (Scr) on day 1, 2, 3, 7, 14, and 28 in 317 patients with stroke including SAH, cerebral infarction (CI) and cerebral hemorrhage (CH). The relationship between renal dysfunction and ECG abnormalities including ST elevation, depression, negative T-wave was evaluated. Next, we prospectively analyzed urinary albumin, NGAL, and L-FABP and serum Cr and NT-proBNP in 22 SAH patients on day 1, 2, and 14.

Results: The retrospective study showed that there was a significant transient increase (+40.7%) in Scr in patients with SAH in the first three days of the acute phase. However, no significant changes in Scr were observed during the course in patients with CI and CH. ECG abnormalities were observed in 57% of patients with SAH. In the prospective study, SAH patients showed increased levels of albuminuria and NT-proBNP on day 0, 1 and 14 and NGAL on day1and 14. Eleven SAH patients with increased levels of NT-proBNP (more than 400 pg/ml) on day 2 showed significantly higher albuminuria (108 ±147 vs.21±11.8 mg/gCr, $p< 0.005$) and urinary NGAL (67.5±101.7 vs. 17.5±15.0 ng/ml, $p< 0.05$) than eleven patients with lower NT-proBNP (less than 400 pg/ml).

Conclusions: Significant renal dysfunction was induced in the acute phase of SAH but not in CI and CH. Renal dysfunction was associated with NT-proBNP elevation, suggesting some interactions between heart, brain and kidneys.

TH-PO073

Acute Kidney Injury Post Nephrectomy in Living Donors? Marilina Antonelou, Andrew Davenport. *Royal Free London NHS Foundation Trust.*

Background: In 2014, the NHS UK introduced an AKI screening algorithm that was integrated into all UK biochemistry laboratories to report cases with AKI with 50% increase in serum creatinine. We aimed to measure the incidence of AKI in healthy living kidney donors post laparoscopic nephrectomy and determine whether this leads to reduction in renal function in the short term.

Methods: Retrospective data collection from 71 living kidney donors presenting between 2006-2011. We calculated serum creatinine (sCr) changes defined as stage 1 AKI as per the KDIGO guidelines (sCr increase by 26.5 umol/L within 48 hours or 1.5-1.9 times baseline increase) and stage 2 AKI (2.0-2.9 times baseline increase).

Results: 54.9% of patients developed AKI: 52.1% AKI stage 1 and 2.8% AKI stage 2. The median age was 53 years (IQR 21-66 years) in the group of patients that developed AKI and 52 years (IQR 27-71 years) in the non-AKI group. 39.7% were males (26.8% with AKI) and 60.6% females (28.2% with AKI) (p 0.07). The AKI group had a lower mean sCr at baseline: 71±22.3 umol/L vs 84±18.0 umol/L (p =0.01). However, there was no difference in the CKDepi at baseline (91.6±18.6 ml/min in the AKI group vs 89±17.3 ml/min, p=0.14) as well as the raw and adjusted for surface area isotopic EDTA-GFR at baseline (101±38.2 ml/min in the AKI group vs 96±22.9 ml/min (p= 0.31) and 89±20.2 ml/min in the AKI group vs 86±16.2 ml/min (p=0.41) respectively). Post nephrectomy there was no difference in absolute renal function (CKDepi in the AKI group 62.8±15.4 ml/min vs 60.2±10.7 ml/min, p=0.06) or change in renal function (33.4±16.5% decrease in CKDepi in the AKI group vs 35.4±14.0%, p=0.25) at 6 months.

Conclusions: Although 54.9% of patients fulfilled the diagnostic criteria for AKI as reported by the laboratory AKI screening algorithm this might not reflect actual kidney injury, and there were no differences in renal function measured after 6 months.

TH-PO074

Fluid Overload and Mortality in Neonatal Intensive Care Unit Patients Requiring Continuous Renal Replacement Therapy Heeyeon Cho,[1] Sang Taek Lee,[1] Hye Won Park.[2] *[1]Dept of Pediatrics, Samsung Medical Center, Sungkyunkwan Univ School of Medicine, Seoul, Korea; [2]Dept of Pediatrics, Seoul National Univ Bundang Hospital, Sungnam, Korea.*

Background: Continuous renal replacement therapy (CRRT) has emerged as a favored modality in the management of the high risk neonates with acute kidney injury (AKI) and with inborn errors of metabolism. Recently, there are some reports that lesser degrees of fluid overload (FO) at CRRT initiation was associated with improved outcomes in children in pediatric intensive care unit (PICU). However, there has been little data that have analyzed the fluid status, risk factors, and outcome of neonates who receiving CRRT. The aim of this study is to evaluate the factors including FO associated with the outcome of neonates with CRRT.

Methods: A retrospective medical record review was performed 34 hemodynamic unstable neonates with AKI who underwent at least 48 hours of CRRT in neonatal intensive care unit (NICU) at Samsung Medical Center between January 2007 and December 2014. We divided into two groups with survivor (N=15) and non-survivor (N=19). Data were collected regarding demographic characteristics, fluid overload, CRRT parameters, and mean circuit time. Fluid overload from NICU admission to CRRT initiation, defined as a percentage equal to {(CRRT initiation weight [kg]–NICU admission weight [kg])/NICU admission weight [kg]}x 100%. CRRT was initiated without anticoagulation, and decided to use the anticoagulation if the initial circuit lifespan was less than 12 hours.

Results: Survivors were more likely to have longer gestational age, fewer days in NICU prior to CRRT, lower percent FO at CRRT initiation, and higher urine output at the end of CRRT. There was no significant difference in mean daily effluent volume between survivors and non-survivors. Adjusted regression analysis revealed that FO at CRRT initiation was associated with mortality, duration of CRRT, and hospitalization period.

Conclusions: Fluid overload might cause mortality, prolonged hospitalization period, and duration of CRRT in neonates. Early initiation of CRRT before severe fluid overload might improve the outcome of neonates requiring CRRT.

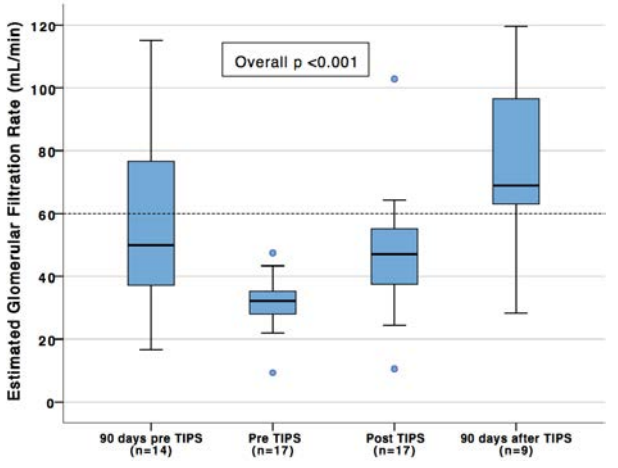
TH-PO075

Survival and Renal Outcomes following Transjugular Intrahepatic Portosystemic Shunt Placement in Hepatorenal Syndrome: A Case Series Guillermo Ortiz,[1] Andrew S. Allegretti,[1] Jie Cui,[1] Julia Beth Wenger,[1] Ishir Bhan,[1] Raymond T. Chung,[2] Ravi I. Thadhani,[1] Zubin Irani. *[1]Nephrology Div, MGH, Boston, MA; [2]Gastrointestinal, MGH, Boston, MA; [3]Radiology, MGH, Boston, MA.*

Background: Few effective treatment options are available for hepatorenal syndrome (HRS). There may be a role for the placement of a transjugular intrahepatic portosystemic shunt (TIPS) in reversing the pathophysiologic changes in HRS.

Methods: We performed a multicenter, retrospective review of patients who underwent TIPS placement concurrent to having HRS from 1995 to 2014 using a centralized clinical data warehouse. Two clinicians adjudicated HRS diagnosis and classified cases as Type 1 (T1-HRS) or Type 2 (T2-HRS) based on review of medical records. Estimated glomerular filtration rate (eGFR), survival, and other parameters were assessed immediately before and after TIPS, and 90 days pre- and post-procedure.

Results: We identified 17 cases. Mean age was 54±12 years, 12 (71%) were male, 7 (41%) had T1-HRS and 10 (59%) had T2-HRS. Median MELD score at time of procedure was 21 (quartile 1, quartile 3: 14, 33). TIPS significantly reduced portal pressure gradient from16 (14, 20) to 7 (5, 8) mmHg (p<0.001). Median eGFR 90 days pre TIPS was 50 (37-77) mL/min; TIPS significantly improved eGFR from 32 (28, 35) pre-TIPS to 47 (38, 55) mL/min post-TIPS (p=0.003) and 69 (63,97) mL/min at 90-days post TIPS (p=0.006).



Ninety-day survival was 53%; 1 subject (6%) received a liver transplant during follow-up.

Conclusions: TIPS improves eGFR in HRS post-procedure and at 90 days follow-up. Further study is needed to identify those who would benefit from the procedure.

TH-PO076

Evolution of the Management of Multiple Myeloma and Impact on Survival and Dialysis Independence Manon Laforet, Noemie Jourde-chiche, Stephane Burtey, Bertrand Gondouin. *Centre de Nephrologie et Transplantation Rénale, Assitance Publique Hopitaux de Marseille, Marseille, France.*

Background: During the past decade, the management of myeloma has evolved. Several studies found an improved disease-free survival since the late 2000s with the advent of new molecules in first line chemotherapy (Bortezomib and / or IMiDs (Revlimid, Thalidomide). Nevertheless, this benefit is mostly seen in patients of less than 65 years old and survival and renal outcomes are not well studied in elder patients. Our study aimed to compare two cohorts of patients according to the period of treatment: before or after 2008 focussing on global and renal outcomes.

Methods: We retrospectively collected clinical and biological data of 135 patients admitted to the University Hospital of Marseille from 1999 to 2014 with a diagnosis of multiple myeloma and acute renal injury (as defined by an increase in serum creatinine above 120 mcmol/L). We separated this cohort based on the year of admission (<or> to 2008, respectively group 1 and group 2). The parameters studied were: overall survival and dialysis independence 2 years after initial chemotherapy.

Results: 88 patients were included in group 1 and 47 in group 2. No differences were seen in terms of baseline characteristics between groups: median age (67.1 vs 70.2), sex ratio, conventional biological parameters. A higher proportion of relapsing patients was found in group 2 (10/47 (22%) in group 2 versus 9/88 (10%) in group 1). A higher proportion of dialysis dependent patients at diagnosis was found in group 2 (26/47, (55.3%) in group 2 versus 36/88 (40%) in group 1). **No difference was seen in terms of overall survival or dialysis independence 2 years after diagnosis of AKI when group 2 was compared to group 1** (OR 1.9 (0.8-4.1) and HR 0.7 (0.4-1.2) respectively).

Conclusions: In our cohort, we did not observe any benefit on overall survival or dialysis independence at 2 years according to the treatment period. Our results are not in accordance with previous papers. Our patients were older with a high proportion of dialysis dependance at diagnosis. More studies are needed to clarify the benefit of the use of novel agents in older patients with severe AKI.

TH-PO077

Effect of Genes Involved in Endogenous Ouabain Synthesis on the Development of AKI After Cardiac Surgery Marco Simonini, Simona Pozzoli, Elena Frati, Elena Bignami, Lorena Citterio, Chiara Lanzani, Nunzia Casamassima, Guido Gatti, Paolo Manunta. *San Raffaele Scientific Inst, Italy.*

Background: Acute kidney Injury (AKI) is an important complication of cardiac surgery. Elevated levels of Endogenous Ouabain (EO), an adrenal stress hormone with haemodynamic and renal effects, have been associated with worse renal outcome after surgery. Polymorphisms in candidate genes related to EO synthesis, as LSS (lanosterol synthase) and HSD3B1 (steroid dehydrogenase), have been described to be involved in determination of EO activity. Aim of this work is to investigate the relationship between these genes and the development of AKI.

Methods: 700 consecutive patients, undergoing cardiac surgery at our Hospital, were genotyped. The primary outcome was AKI according to Acute Kidney Injury Network. Secondary outcomes were length of ICU stay and total in-hospital mortality. Total AKI incidence was 25.1%.

Results: No difference in basal EO plasmatic levels was observed according to LSS or HSD3B1. Patients carrying the derived alleles of the LSS studied polymorphism had a more severe clinical presentation (EuroSCORE: 5.17±4.81 vs 4.88±5.74 vs 3.54±3.49; p=0.05). Likewise, AKI incidence according to LSS polymorphism was greater (34.9% vs 27.5% vs 21%; p=0.029). Even after adjustment for the main covariates (sex, age, eGFR, EF, hypertension, DM, type of surgery and EuroSCORE) results remain significant (AKI logistic regression: Exp(B) 1.97, IC95% 1.05-3.70; p=0.038). Finally, in a higher percentage of the same patients (25.5% vs 17.0% vs 12.6%) i.v. furosemide was used in the immediate post-operative time to maintain adequate diuresis. No other effects of LSS or HSD3B1 were observed.

Conclusions: Patients with at least one derived allele of LSS polymorphism investigation have a greater chance of developing AKI after cardiac surgery, despite on clinical presentation. Moreover, in a higher percent of the same patients, i.v. furosemide was needed to maintain adequate diuresis. These effects appear to be independent on EO plasmatic levels. We believe that these preliminary findings could be interesting for the identification of new cellular mechanisms undergoing the development of post-surgical AKI.

TH-PO078

Obstructive Nephropathy in Ovarian Hyperstimulation Syndrome and Successful Delivery Katherine M. Wang, Syed S. Haqqie, Arif Asif. *Albany Medical Center, Albany, NY.*

Background: Ovarian hyperstimulation syndrome (OHSS) is a well-described iatrogenic complication of exogenous gonadotropin administration preceding *in vitro* fertilization (IVF). Underlying pathophysiology stems from influx of reproductive hormones and inflammatory vasoactive mediators that increase capillary permeability and cause intravascular volume depletion due to large fluid shifts into the interstitial space. Most cases are mild and can be managed on an outpatient basis with close monitoring. We present an intriguing and rare case of severe OHSS with acute renal failure secondary to obstructive nephropathy. Our patient is a nulliparous 38 year old black female stimulated with beta-human chorionic gonadotropin (β-hCG) prior to transfer of fresh embryos resulting in a diamniotic dichorionic twin gestation. She presented to the OB-GYN service with progressive ascites, gaining 17 kg in 1 week, and also acute renal failure due to mechanical obstruction of both ureters from bilaterally enlarged fluid-filled ovaries. Initial ultrasonography estimated the dimension of the left ovary at 22 cm, containing 1.7 L of fluid volume. Her baseline creatinine of 0.8 mg/dL peaked at 5.8 mg/dL prior to placement of bilateral nephrostomy tubes, which led to rapid and effective relief of obstruction and normalization of kidney function within days.At follow-up, patient had spontaneous intrauterine demise of one fetus at 9 weeks; however, she successfully delivered the other fetus preterm at 35 weeks gestational age via C-section. The nephrostomy tubes remained in place for the duration of her pregnancy. This case highlights a rare presentation of a well-known, but potentially life-threatening complication of ovarian induction, which has become an increasingly popular treatment for infertility.

Methods: Cinical couorse of the patient during the entire pregnancy and the outcome.

Results: Successful fetal outcome.

Conclusions: Patient presented with severe obstructive uropathy from very large kidneys from hyperstimulation resulting in acute renal failure and bilateral nephrostomy tube placements. This resulted in release of obstruction, normalization of renal function, and a successful delivery.

TH-PO079

Analysis of the VA/NIH Acute Renal Failure Trial Network Data: Comparison of Outcomes in Nutrition Delivery in Acutely Dialyzed Patients Youngho Kim, V. Shane Pankratz, Eduardo A. Alas, Christos Argyropoulos, Mark L. Unruh. *Div of Nephrology, Univ of New Mexico School of Medicine, Albuquerque, NM.*

Background: The optimal nutrition management for acute kidney injury (AKI) is not well defined and recommendations for nutritional support in acutely ill patients who undergo renal replacement therapy (RRT) are largely based on expert opinion.

Methods: In order to better understand associations between nutrition and outcomes of critically ill patients with AKI requiring RRT, we analyzed data available from the ATN study. Patients were classified by nutritional support provided at the time of enrollment

into the following groups: NPO, Tube feed (TF), Total parenteral nutrition (TPN), and Oral (PO). Two competing outcomes were considered: mortality and continued dialysis dependency among survivors.

Results: Characteristics among groups were similar. ICU predictive scoring systems and disease etiology were strongly associated with mode of nutrition delivery. High ICU predictive score and a surgical primary treating service were associated with a higher percentage of patients treated with TPN. There were significant differences in 60-day outcomes among nutrition groups (p=0.011) [Figure 1]. Notably, PO group had better survival and RRT independency. After adjustment for patient characteristics, the strength of association between mode of nutrition delivery and outcomes weakened and was not statistically significant (p=0.106), although the patterns of association were similar to the unadjusted analyses with TPN having the highest and PO the lowest adjusted risks of death and continued dialysis dependency.

Figure 1: Dialysis dependency and mortality at 60 days

	Unadjusted OR (95% CI)		Adjusted OR (95% CI)	
Baseline Nutrition	Dialysis Dependency	Death	Dialysis Dependency	Death
NPO	1.72 (0.86 – 3.45)	1.89 (1.24 – 2.88)	1.43 (0.69 – 2.97)	1.46 (0.90 – 2.38)
Tube Feed	1.89 (0.89 – 4.03)	2.11 (1.33 – 3.36)	1.47 (0.66 – 3.30)	1.54 (0.90 – 2.63)
TPN	2.87 (1.11 – 7.46)	3.15 (1.68 – 5.92)	2.18 (0.77 – 3.80)	3.14 (1.54 – 6.41)
PO	1.0 (REF)	1.0 (REF)	1.0 (REF)	1.0 (REF)

Conclusions: There was no significant global association between baseline nutrition modalities and 60-day mortality or 60-day dialysis dependence. Further investigation could be performed to prospectively elucidate the benefit of enteral vs. TPN feeding in AKI.

TH-PO080

Pilot Trial of Dietary Restriction for Protection from Acute Kidney Injury in Cardiac Surgery Franziska Grundmann, Torsten Kubacki, Roman-Ulrich Mueller, Maximilian Scherner, Michael Faust, Ingrid Becker, Martin Späth, Marc Johnsen, Thomas Benzing, Volker Rolf Burst. *Univ of Cologne, Cologne, Germany.*

Background: Even small acute changes in kidney function as a result of acute kidney injury (AKI) can result in short-term and long-term complications including chronic kidney disease, end-stage renal disease and death. However, despite an increasing incidence of AKI few preventive and therapeutic options exist. Short-term reduction of calorie intake has been shown to provide effective protection from ischemic AKI in mice.

Methods: In this single-center randomized controlled trial (ClinicalTrials.gov Identifier: NCT01534364) 82 patients with at least one risk factor for postsurgical AKI scheduled for cardiac surgery (CABG, valve replacement) were randomly assigned in a 1:1 ratio into a diet group (DG**:** 60% of calculated energy expenditure for 7 days prior to surgery) or an ad libitum food intake control group (CG). The intention-to-treat population encompassed 76 patients. The primary endpoint was defined as the change in serum creatinine from baseline to 24 hours after surgery, secondary endpoints included incidence of AKI (KDIGO criteria).

Results: Demographic and surgery associated characteristics were similar in both groups (DG 80% male vs. CG 77.5% male; age: DG 72y[63-76] vs. CG 75y[70-77], body weight: DG 84.6kg[72.-91.7] vs. CG 79.1kg[75.0- 72.7], crossclamp time: DG 59min[52-82] vs. CG 59min[44-82]). Average calorie intake in the DG was 1323 kcal and a 3 kg[-4.0 to -2.2] weight loss was observed (no weight change in the CG). With respect to the primary outcome measure there was no difference between the groups. Overall incidence of AKI was similar in both groups with considerably less patients with stage 1 AKI in the DG (n.s.). Length of stay, need for renal replacement therapy and mortality did not differ.

	Diet Group	Control Group
no AKI	21(58.3%)	21(52.5%)
KDIGO 1	7(19.4%)	13(32.5%)
KDIGO 2	6(16.7%)	5(12.5%)
KDIGO 3	2(5.6%)	1(2.5%)

Conclusions: Dietary restriction is safe and feasible in patients awaiting cardiac surgery. Despite its beneficial effect in animal studies restriction of calorie intake did not alter serum creatinine dynamics or AKI incidence after cardiac surgery.

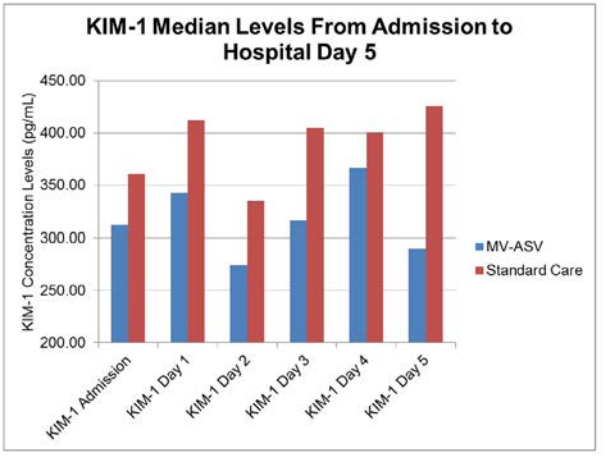
Minute Ventilation-Targeted Adaptive Servo Ventilation Reduces Kidney Injury in Patients with Acute Decompensated Heart Failure Matt Kawahara,[3] Boris Arbit,[1] Elizabeth Lee,[3] Trenton Gluck,[3] Kathleen Sarmiento,[2] Atul Malhotra,[2] Alan S. Maisel.[1] *[1]Div of Cardiovascular Medicine, Univ of California, San Diego, La Jolla, CA; [2]Div of Pulmonary and Critical Care Medicine, Univ of California, San Diego, La Jolla, CA; [3]Cardiac Research, VA San Diego Healthcare System, La Jolla, CA.*

Background: Acute kidney injury (AKI) is a frequent comorbidity in patients admitted for acute decompensated heart failure (ADHF). Minute ventilation targeted adaptive servo ventilation (MV-ASV) relieves apneas, pulmonary congestion, and renal hypoxia. Kidney injury molecule (KIM-1) is a marker of AKI and could be used to detect early injury and the improvement of kidney function. MV-ASV may mitigate AKI in patients admitted of ADHF compared to standard care.

Methods: This is a pilot study in which twenty-one consecutive patients with ADHF were randomized to receive either MV-ASV therapy (S9 VPAP Adapt, ResMed Corp.) with standard care, or standard care alone. MV-ASV therapy was administered for a minimum of six hours per day for up to 5 days, or until discharge. Daily measurements of plasma KIM-1 were obtained with SMC™ technology (Singulex). Daily serum creatinine levels were measured and used to calculate eGFR.

Results: Median baseline KIM-1 levels in the MV-ASV and standard groups were 312pg/mL and 361pg/mL, respectively. In the control group KIM-1 increased 18 % to 426pg/mL while the group with MV-ASV demonstrated a mitigation of kidney injury with a 7% decrease to 290pg/mL. These changes correlated with subsequent changes in serum creatinine and eGFR.



Conclusions: The use of MV-ASV therapy resulted in mitigation of kidney injury typically seen in patients with ADHF during hospitalization.

Early Volume Expansion Improves the Outcome of Shigatoxin-Associated Hemolytic Uremic Syndrome – Data from the North Italian HUS Network Gianluigi Ardissino,[1] Francesca Tel,[1] Ilaria Possenti,[1] Sara Testa,[1] Dario Consonni,[2] Stefania Salardi,[1] Rosaria Colombo,[3] Erminio Torresani.[3] *[1]Center for HUS Prevention, Control and Management, Fondazione IRCCS Ca' Granda, Ospedale Policlinico, Milan, Italy; [2]Unit of Epidemiology, Fondazione IRCCS Ca' Granda, Ospedale Policlinico, Milan, Italy; [3]Unit of Microbiology, Fondazione IRCCS Ca' Granda, Ospedale Policlinico, Milan, Italy.*

Background: Shigatoxin-associated hemolytic uremic syndrome (STEC-HUS) is a severe disease which has no specific treatment and among supportive care, fluid management is concentrated on preventing fluid overload because of oligo/anuric AKI. Hemoconcentration is associated with more severe disease, but it is unknown whether volume expansion (VE) can improve disease outcome. A network of pediatric hospitals has been operating in Northern Italy with the aim of early diagnosis and referral of STEC infections and to investigate the efficacy of VE to minimize disease severity.

Methods: All children with STEC-HUS referred to our centre in 2012-2014 received intravenous saline targeted at inducing a moderate VE (+10% of working weight) on the basis of the hypothesis that prompt restoration of circulating volume can limit thrombi formation and ischemic tissue damage. Their short- and long-term outcomes were compared with those of 38 patients (pts) referred to our centre during the years immediately before the network was established, when their fluid intake was routinely restricted.

Results: The pts undergoing VE showed a mean increase in body weight of 12.5%vs0% in their predecessors and had significantly better short-term outcomes with a reduced rate neurological involvement (7.9%vs23.7%,p 0.059), less need for dialysis (26.3%vs57.9%,p 0.005) or intensive care support (median 8.5,IR 3.5-15.5vs2.0,IR 1-4.5 days,p 0.022), and required fewer days of hospitalisation (median 12.0, IR 7.0-18.0vs9.0,IR 7.0-12.0 days,p 0.025). Long-term outcomes were also significantly better in terms of renal and extra-renal sequels (13.2%vs39.5%,p 0.009).

Conclusions: Pts with STEC-HUS benefit greatly from VE. Early and generous fluid infusions can reduce thrombi formation and ischemic organ damage, and thus have positive effects on both short- and long-term disease outcomes.

TH-PO083

Role of Statins on Contrast-Induced Nephropathy in Patients Undergoing Percutaneous Coronary Intervention Ricardo M. Heguilen, Amelia R. Heguilen, Martin J. Ortemberg, Amador A. Liste. *Nephrology, Hospital Juan A Fernandez, Buenos Aires, Argentina.*

Background: The occurrence of contrast-induced kidney injury (CIAKI) increased and is responsible for ~10% episodes of hospital-acquired AKI. The mechanism of renal dysfunction is incompletely understood; vasoconstriction, hyperosmolarity, free radicals and direct toxicity may play additive roles. Statins reduce O_2 stress, increase renal NO and may prevent AKI. The aim of this retrospective study was to analyse the association between statin and the development of RCIN, defined by an increase in SCr >25 % 48–72 h after the administration of low osmolar contrast agents, in high risk patients (Ps) undergoing percutaneous coronary intervention (PCI).

Methods: Data from 165 consecutive adults with SCr >1.25 mg/dl,undergoing non-emergent PCI during a 24- mo period were assessed. All had received prophylaxis for RCIN (volume expansion + NAC). 31 Pts were removed due to absence of follow up SCr data or lacked information on statin use. Continuous variables are expressed as mean (sd) and categorical variables as frequency. Unpaired t-test, chi2 or Fischer's exact test were used as appropriate. Those variables resulting significantly related to RCIN on univariate analysis, were included in a multivariate logistic regression model. P-values <0.05 were considered significant.

Results: 134 Pts met the admission criteria; 67 were on statins prior PCI. Both groups had similar clinical, and laboratory baseline conditions. 18Pts (13.4%) developed RCIN. There was a lower incidence of RCIN among Pts on statins (4.47%) vs. those not on statins (22.4%) (OR: 0.16; 95% CI: 0.04–0.59; P = 0.004). Multivariate logistic regression revealed that, after adjusting for covariates with significant association with RCIN in the univariate analysis (diabetes, hiponatremia, etc),statins demonstrated to be an independent predictor of decreased risk for RCIN.

	OR	*95% CI*	*p value*
Statin	0.14	0.037 - 0.5653	0.005
DBT	3.67	1.168 - 11.540	0.026
HypoNa	2.45	0.728 - 8.262	0.148

Conclusions: Our data suggest that statin use before PCI reduces the risk of RCIN. Further prospective, well designed, randomized clinical trials in a larger number of individuals are necessary to confirm these findings.

TH-PO084

Statin Use and Survival After Acute Kidney Injury Sandeep Brar, Neesh I. Pannu. *Dept of Medicine, Univ of Alberta, Edmonton, AB, Canada.*

Background: The incidence of acute kidney injury (AKI) in hospitalized patients is rising, and there is a lack of effective therapies for treatment. Recent studies suggest that nephrology follow-up may reduce long term mortality after AKI; however, the processes of care that underlie this finding remain unknown. The objective of this study was to determine if statins which are of known benefit in chronic kidney disease (CKD) are also associated with improved mortality in survivors of AKI with CKD.

Methods: Retrospective cohort study of adults 65 years of age or older, residing in Alberta, who were admitted to hospital between 2002 and 2011, developed AKI during the index hospitalization and progressed to CKD (n= 27,470 mean age 78.7 years, mean post-discharge eGFR 49.6 mL/min/1.73m^2).

Results: Within two years of discharge, only 39.1% of the participants received a statin. Over a subsequent two-year follow up period, the adjusted hazard ratio (HR) (95% confidence interval [95% CI]) for mortality associated with use of a statin was 0.64 (0.59, 0.69). Patients who received a statin also had a lower risk of cardiovascular events (adjusted HR, 0.87; 95% CI, 0.80, 0.94) and all cause re-hospitalization (adjusted HR, 0.81; 95% CI, 0.77, 0.84).

Conclusions: Among AKI survivors with CKD, statin use was associated with decreased mortality, cardiovascular events and re-hospitalization rates.

TH-PO085

Effect of Rosuvastatin on Acute Kidney Injury (AKI) in Sepsis-Associated Acute Respiratory Distress Syndrome (ARDS) Raymond K. Hsu,[1] Jonathon Truwit,[2] Michael Matthay,[1] Joseph Levitt,[3] Boyd Taylor Thompson,[4] Kathleen D. Liu.[1] *[1]UCSF; [2]Medical College of Wisconsin; [3]Stanford; [4]MGH-Harvard.*

Background: While statins may be protective in animal models of sepsis-induced AKI, few human studies have addressed this question.

Methods: We analyzed data from the NHLBI ARDS Network Statins for Acutely Injured Lungs in Sepsis (SAILS), a multicenter randomized controlled trial. 745 patients with sepsis-associated ARDS were randomized to receive rosuvastatin or placebo. Subjects who had AKI at enrollment and subjects with new or worsening AKI were defined by KDIGO creatinine-based AKI criteria. In a secondary analysis, we corrected serum creatinine (SCr) for cumulative fluid balance. The association between statin and AKI was modeled using logistic regression.

Results: 644 subjects did not have ESRD and had available SCr data. Age, sex, race, baseline SCr, and severity of illness were similar in the 2 treatment arms. Among the 511 without AKI at enrollment, AKI incidence was similar in the two groups (38% statin vs 40%, P=0.66). The association remained non-significant after adjustment for demographics and severity of illness, and after correcting SCr for fluid balance. Among 93 subjects with stage 1 AKI at enrollment, the statin arm had a higher incidence of worsening AKI (61% vs 41% placebo, P=0.06). The association was strengthened after adjustment (OR 3.06, P=0.03). However, in the secondary analysis using fluid-corrected SCr, rosuvastatin was not associated with worsening AKI.

Risk of new AKI in patients without AKI at enrollment (n=511)	**OR (Rosuvastatin vs Placebo)**	**P**
Crude	0.92 (0.65-1.32)	0.66
Adjusted	0.99 (0.67-1.44)	0.94
Crude + SCr corrected for fluid balance	0.84 (0.59-1.21)	0.35
Adjusted + SCr corrected for fluid balance	0.91 (0.63-1.34)	0.64
Risk of worsening AKI in patients with stage 1 AKI at enrollment (n=93)		
Crude	2.26 (0.97-5.24)	0.06
Adjusted	3.06 (1.14-8.22)	0.03
Crude + SCr corrected for fluid balance	1.41 (0.61-3.27)	0.42
Adjusted + SCr corrected for fluid balance	1.85 (0.70-4.84)	0.21

Conclusions: Rosuvastatin did not prevent de novo AKI, and may have led to worsening of pre-existing AKI in patients with sepsis-associated ARDS.

Funding: NIDDK Support, Other NIH Support - NHLBI

TH-PO086

Potential Nephroprotective Effects of Carnitine and Phosphodiesterase-5 Inhibitor Therapy in Contrast-Induced Nephropathy Zaher Anis Armaly,[1] Suheil Artul,[2] Adel Rafik Jabbour,[3] Raymond Farah,[4] Amir Abd Elkadir,[1] Bishara Bisharat.[1] *[1]Dept of Nephrology, E.M.M.S. Hospital, Bar Ilan Univ, Nazareth, Israel; [2]Dept of Radiology, E.M.M.S. Hospital, Nazareth, Israel; [3]Dept of Biochemical Laboratory, E.M.M.S. Hospital, Nazareth, Israel; [4]Internal Medicine "B", Ziv Medical Center, Faculty of Medicine, Bar Ilan Univ, Safed, Israel.*

Background: Contrast induced nephropathy (CIN) is connected with , prolonged hospitalization, need for dialysis and increased morbidity and mortality. The current available prophylactic measures are not sufficient to protect against CIN. Therefore, there is unmet need for novel therapeutic agents to prevent the development of CIN. This study examines whether phosphodiesterase type 5 (PDE-5) inhibitor or carnitine exert nephroprotective effects in individuals undergoing imaging that involves radiocontrast media (CM) administration as compared with N- acetyl Cysteine.

Methods: The study included 3 arms of patients with CKD (stage 3-4) as follows:1- Control group (n=14), who were treated with Acetylcysteine of 600 mg twice daily, day before and on the day of CM administration; 2- Carnitine group (n=10), where the patients were infused with 20 mg/kg carnitine over 10 minutes 2 h prior to the CM administration and 24 hours post CT; 3- Phosphodiesterase type 5 inhibitor group (n= 12), where patients were given orally 20 mg tablets of PDE5 inhibitor-Tadalafil 2 h prior to the administration of the CM and in the subsequent day. Urine and blood samples were collected before and at the following time sequence: 2, 6, 12, 24, 48, 120 hours after the contrast administration, for creatinine and NGAL determination.

Results: Administration of CM to CKD patients who were pretreated with Acetyl cysteine caused a significant increase in urinary NGAL, but not of plasma NGAL and SCr. In contrast, pretreatment with carnitine prior to CM prevented the increase in urinary NGAL throughout the follow up period and reduced SCr below basal levels. Similarly, tadalafil administration attenuated the elevation in CM-induced urinary NGAL, but did not affect neither plasma NGAL nor Scr.

Conclusions: These results suggest that carnitine and PDE-5 inhibition may comprise novel nephroprotective approaches aganist CIN.

TH-PO087

Acute Interstitial Nephritis: Case Series, 1998-2015 Xuemei Li. *Nephrology, Peking Union Medical College Hospital, Beijing, China.*

Background: Acute interstitial nephritis (AIN) is an important cause of acute kidney injury. The time and effectiveness of steroids for treatment of AIN is debated.

Methods: Study Design: Case series. **Study population:** 40 cases with acute interstitial nephritis(secondary AIN was excluded) conformed by renal biopsy in PUMC hospital between 1998 and 2015 years were analysed. **Outcomes:** The complete recovery was defined as improvement in serum creatinine level to 124umol/L; partial recovery as a 50% decrease in serum creatinine level from its peak value, but not reaching to 124umol/L; and no recovery as failure to meet criteria for complete or partial recovery or remaining on renal replacement therapy.

Results: The causes were not available in most cases (63%), 15% were identified due to drugs. Infectious causes were 13%. Idiopathic AIN were 10%. 68% patients had no records of baseline serum creatinine levels, which were available for 13 patients only (106±14.7umol/l), and 5(38%) patients had CKD as defined by baseline eGFR <60 mL/min/1.73 m2. 30% patients had hematuria. 33% patients had glycosuria. Some degree of proteinuria (less than 1g/L) was present in 75% of patients. 60% patient had aneamia

(105±14.8). Most of the patients had normal urine output. 5 patients (12.5%) had larger kidney in ultrasound. 33 patients (83%) used steroids treatment.The periods of steroid treatment were 12±4.7months. The time which began to use steroids was 33±15.2days from SCr increased. The doses of steroid were 49±10.1mg/d. The SCr level was 210±83.8umol/l when started steroid treatment. Only 5 patients (13%) added immune inhibits. Of the 40 patients, 48%, 38%, and 10% had complete, partial, and no recovery respectively in discharge. 65% had normal renal function and 30% had CKD by 15±9.7 months. Of the 6 patients who required dialysis or CRRT, no patients were still on dialysis therapy in discharge, all of whom had drug-induced AIN. No patients had ESRD, with no difference by cause of AIN.

Conclusions: The cause of AIN may be different. Steroid treatment may be effective in recovery of kidney function of AIN.

TH-PO088

Causality Assessment in Determining Drug-Induced Renal Injury

Celina D. Cepeda, Linda Awdishu, Etienne Macedo, Ravindra L. Mehta. *Nephrology, Univ of California San Diego, San Diego, CA.*

Background: Drug induced renal injury (DIRI) accounts for 18-27% of cases of acute kidney injury (AKI) and is usually recognized based on the timing and duration of drug exposure.The Naranjo (NJ) and Liverpool (LP) causality assessment tools (CAT) are validated for identifying adverse drug reactions and serious skin reactions, respectively. We hypothesized that inter-rater and inter-tool agreement using the two CAT would not be specific to identify DIRI.

Methods: Thedrug induced renal injury (DIRECT) study is an ongoing prospective multicenter study evaluating genetic determinants of DIRI. Each enrolled case was adjudicated for causality by two independent nephrologists. We analyzed the first consecutive 86 adult (n= 69) and pediatric (n=17) AKI cases. Two nephrologists adjudicated each case and used both CAT to determine likelihood of AKI due to a particular medication(s). We determined inter-rater and inter-tool agreement using percent agreement and kappa scores.

Results: Adjudicators agreed 87.2% (n=75) had DIRI. A single drug was involved in 54.7% (n=47), 2 drugs in 37.2% (n=32), and 3 drugs in 8.1% (n=7) of cases. The inter-rater agreement was better with the NJ vs LP tool (61.6% vs 48.8%) and was significant for adults (p=<0.038) however the inter-tool kappa score was slight (0.181) and was fair (kappa 0.325) for pediatric patients (p=0.006).

Table 1. Percent Agreement and Kappa Values for Drug 1

		Inter-rater		Inter-tool
Categories		**Naranjo**	**Liverpool**	
All Cases	% Agreement Kappa	61.6 0.251 (p=0.01)*	48.8 0.140 (p=0.04)*	50 0.181 (p=0.001)*
DIRI		58.7 0.206 (p=0.052)	52 0.049 (p=0.557)	49.3 0.109 (p=0.074)
No DIRI		81.8 0 (p=1)	27.3 0.064 (p=0.489)	54.5 0.16 (p=0.147)
1 Drug		57.4 0.199 (p=0.126)	57.5 0.250 (p=0.011)*	58.5 0.312 (p<0.001)*
Adult		59.4 0.224 (p=0.038)*	49.3 0.154 (p=0.026)*	47.8 0.142 (p=0.017)*
Pediatric		70.6 0.351 (p=0.116)	47.1 0.131 (p=0.441)	58.8 0.325 (p=0.006)*

*, denotes significant p-value <0.05

Conclusions: For most categories, inter-rater percent agreement and kappa scores were superior using the NJ tool. Neither tool had better than moderate inter-rater agreement. Agreement between the tools was at best fair in determining likelihood of DIRI. Better causality assessment tools need to be developed for DIRI.

TH-PO089

Gadolinium Nephrotoxicity

Kamlesh Reddy Kurre, Ashraf El-Meanawy, Sameer Gupta. *Nephrology, Zablocki VA Medical Center, Milwaukee, WI.*

Background: Gadolinium-based contrast (GBC) agents are widely used as contrast agents for magnetic resonance imaging (MRI) and have generally been considered to be safe. Early on, phase III trials and small studies in low-risk patients suggested a benign renal profile; however, more recent studies raised the possibility of nephrotoxicity. In the US, approximately 34.9 million MRI scans were performed in 2014 and in 45% of these cases a gadolinium chelate was administered. As with iodinated radiocontrast agents, concern for contrast-induced nephropathy existed with gadolinium-contrast as it possessed many similar qualities (hyperosmolar, renal excretion via glomerular filtration). Gadolinium-based contrast agents have recently been reported to induce a usually reversible decrease of glomerular filtration rate in a high-risk population group, especially in patients with altered baseline renal function The lethal dose of gadolinium in animals is increased by 100 folds when gadolinium is in the form of a chelate. This raise a concern that the leaching of free metal from the chelate can pose health risk.

Methods: We present a prospective study involving 122 patients (48 male and 74 female) who had an elective MRI performed. Subjects have been fasting for at least 8 hrs prior to the imaging . We collected a blood sample 1 hr prior to the imaging and followed up with a repeat blood sample collection 48 hrs after completion of the imaging procedure.

Results: These samples were analyzed for serum creatinine and BUN levels . Preliminary data shows that 46.43 % (52 out of 112) of the study subjects exhibited worsening of renal function while 53.57 % (60 out of 112) had normal or slightly improved renal function .

Conclusions: Preliminary data analysis suggests gadolinium induces nephrotoxicity in general population including patients with normal kidney function and with chronic kidney disease . We appreciate the limitation of the study which are mainly the number of subjects and the fasting status of subjects. Since there was no exclusions, patient who are on diuretics and ACEI inhibitors could display a higher base line creatinine which might explain the improvement of renal function post study in some subjects .

TH-PO090

Risk of Pediatric Acute Kidney Injury Is Increased with Vancomycin and Piperacillin-Tazobactam Combination Therapy

Joseph Michael Rusnak,[1] Cristin Kaspar,[1] Timothy E. Bunchman,[1] Nianzhou Xiao,[1] Megan M. Lo,[1] Jeremy S. Stultz.[2] *[1]Pediatric Nephrology, Children's Hospital of Richmond at Virginia Commonwealth Univ, Richmond, VA; [2]Pharmacotherapy and Outcomes Science, Virginia Commonwealth Univ, Richmond, VA.*

Background: Hospitalized pediatric patients at risk for infection are often treated with vancomycin (vanc) and piperacillin-tazobactam (PT). Risk of nephrotoxicity from vanc and other antimicrobials (e.g. aminoglycosides, beta-lactams) is well-described. Recently, an increased risk of acute kidney injury (AKI) resulting from combination therapy of vanc with PT has been reported in the adult literature, but not in the pediatric literature.

Methods: Retrospective single center study of hospitalized pediatric patients £20 years who received vanc, PT, or the combination for 48 hours or more. Data collection included creatinine levels, medication and demographic characteristics. Patients on ECMO or dialysis were excluded.

Results: 164 patients identified, 30 (18.3%) developed AKI (definition: ≥ 50% above baseline creatinine) after beginning treatment with the antimicrobials. Eight patients in the vanc alone and PT alone groups (8%) versus 22 patients in the combination group (34.4%) developed AKI (p<0.0001). The median percent creatinine change from baseline was significant (p=0.03) between the combination and single therapy groups of 104% and 52.3%, respectively.

	AKI	Non-AKI
Total Number (%)	30 (18.3%)	134 (81.7%)
Median Age, years (range)	9.5 (3 months - 20 years)	9 (1 month - 19 years)
Vanc Only	4 (8.2%)	45 (91.2%)
PT Only	4 (7.8%)	47 (92.2%)
Combination Vanc & PT	22 (34.4%)	42 (65.6%)

Conclusions: Results of this study suggest a higher risk of AKI in pediatric patients receiving the combination therapy of vanc and PT compared to single drug therapy with either. Further studies are needed to determine if other confounding factors (e.g. dehydration, medical diagnosis, or additional nephrotoxins) contribute to the risk of AKI with this particular combination, or if there is a safer alternative for broad-spectrum antimicrobial coverage in the pediatric population.

TH-PO091

Associations Between Vancomycin, Other Antibiotics, Acute Kidney Injury and Mortality in Hospitalized Patients

Victoria Gutgarts,[1,2] Christian Suarez,[1,2] Ladan Golestaneh,[1,2] Michal L. Melamed.[1,2] *[1]Nephrology, Montefiore Medical Center, Bronx, NY; [2]Nephrology, Albert Einstein College of Medicine, Bronx, NY.*

Background: Vancomycin is a commonly prescribed antibiotic. Animal and human studies suggest that vancomycin can cause acute kidney injury (AKI). We hypothesized that exposure to vancomycin with other nephrotoxic antibiotics (aminoglycosides) will be associated with AKI compared to vancomycin use with non-nephrotoxic antibiotics in hospitalized patients.

Methods: We performed a retrospective observational study, including patients 18 years or older admitted from 2008 and 2010 at Montefiore Medical Center. All patients had at least two serum creatinine values during their admission and a baseline creatinine within 6 months prior to admission. AKI was defined as a 50% increase in baseline serum creatinine. One year mortality data was from the Social Security Death Index.

Results: Of 46,580 admissions, 2,104 developed AKI (4.7%). 7,889 patients (17%) had exposure to vancomycin, 1,172 patients (2.5%) had exposure to aminoglycosides and vancomycin, 3,700 patients (7.9%) had exposure to fluoroquinolones and vancomycin and 3,994 patients (8.6%) had exposure to cephalosporins and vancomycin. Those developing AKI were more likely female (70% vs 63% p<0.001), had GFR < 60 (37% vs 22% p< 0.001) and vancomycin exposure (31% vs 16% p< 0.001). The AKI risk associated with vancomycin alone was 1.55 (1.37, 1.76), combining vancomycin and gentamicin the risk was 1.95 (1.56, 2.45) while vancomycin with fluoroquinolones was 1.38 (1.17, 1.63) and vancomycin with cephalosporins was 1.37 (1.16, 1.62). The risk of mortality associated

with vancomycin alone was 2.27 (2.06, 2.49), combining vancomycin and gentamicin the risk was 3.87 (3.26, 4.58), combining vancomycin with fluoroquinolones the risk was 3.42 (3.05, 3.84), and combining vancomycin with cephalosporins the risk was 2.62 (2.34, 2.95).

Conclusions: Our data suggests that vancomycin exposure is associated with a high risk of AKI and mortality, especially in combination with aminoglycosides. Further studies should be conducted to evaluate whether aminoglycosides should not be used in combination with vancomycin in order to prevent AKI.

TH-PO092

Adverse Renal Effects of Targeted Anti-Cancer Therapies: A Systematic Review of Data from the FDA Adverse Event Reporting System Kenar D. Jhaveri, Rimda Wanchoo, Daniel W. Ross, Vipulbhai Sakhiya, Steven Fishbane. *Nephrology, Hofstra NSLIJ, NY.*

Background: Novel molecular targeted anti-cancer therapies have shown improvement in patient survival compared to standard chemotherapy. Renal toxicities of novel targeted therapies are limited to case reports.

Methods: We reviewed the FDA Adverse Event Reporting System's (FAERS) quarterly legacy data file (2011-2014). We queried the database for medications listed below. The adverse events queried were: hypokalemia, hypomagnesemia, hyponatremia, hypophosphatemia,proteinuria, renal failure acute. To compare what has been published, we searched PubMed for each medication plus each adverse event.

Results: Total number of adverse events reported were 1,657. Ipilimumab had the highest number of events (341) and these were mostly acute renal failure (126) and hyponatremia (112). In PubMed review all case reports were diagnosis of renal failure. The second highest number of events occurred in cetuximab and most of the events were impaired renal function (128). For all targeted therapies listed below in figure, the most common adverse event was acute renal failure (549). The most common electrolyte abnormality was hypokalemia (367). More males developed renal failure at mean age of 65y as opposed to females with mean age of 61y(<0.01). More females got electrolytes disorders at mean age of 59y compared to males at 61y(<0.01). For all medications, renal adverse events were more common in males mean age 63y compared to females mean age 59y(<0.01). Hypokalemia was more common in females (<0.01) and hyponatremia more common in males (<0.01). Figure below compares all agents searched.

Drug name	Established Toxicity by Literature Review	First, Second Most Common Adverse Event in FAERS
AFATINIB	No reported adverse renal toxicity	Kidney Injury, Hyponatremia
CETUXIMAB	Hypokalemia, Hypomagnesemia	Kidney Injury, Hypokalemia
CRIZOTINIB	Hypophosphatemia,Kidney Injury	Kidney Injury, Hyponatremia
DABRAFENIB	No reported adverse renal toxicity	Kidney Injury, Hyponatremia
ERLOTINIB	Small number of Hypokalemia, Hypophosphatemia	Kidney Injury, Hyponatremia
GEFITINIB	Case report of nephritis, Case report of Proteinuria	Hypokalemia, Hyponatremia
IMATINIB	Hypophosphatemia, Case reports of kidney injury	Kidney Injury, Hyponatremia
IPILIMUMAB	Case reports of nephritis, Case reports of Hyponatremia	Kidney Injury, Hyponatremia
LAPATINIB	Hyponatremia, Hypophosphatemia	Hypokalemia, Kidney Injury
PANITUMUMAB	Hypokalemia, Hypomagnesemia	Hypomagnesemia, Hypokalemia
Pertuzumab	No reported adverse renal toxicity	Kidney Injury, Hypokalemia
REGORAFENIB	Proteinuria, Hypophosphatemia, Renal Failure	Kidney Injury, Hyponatremia
TRAMETINIB	Hypokalemia	Kidney Injury, Hyponatremia
TRASTUZUMAB	Kidney Injury, Hyponatremia	Hypokalemia, Kidney Injury
Trastuzumab Emtansine	No reported adverse renal toxicity	Hyponatremia, Renal Failure
VANDETANIB	Hypophosphatemia	Kidney Injury, Hyponatremia, Hypomagnesemia
VEMURAFENIB	Kidney Injury, Proteinuria	Kidney Injury, Hyponatremia

Conclusions: Our data elucidate previously unknown adverse renal events in targeted therapies. Older males are at higher risk for renal failure and females are at higher risk for electrolytes disorders from certain targeted anti-cancer therapies.

TH-PO093

Vemurafenib and Dabrafenib Related Renal Toxicities Kenar D. Jhaveri, Rimda Wanchoo, Vipulbhai Sakhiya, Steven Fishbane. *Nephrology, Hofstra NSLIJ School of Medicine, NY.*

Background: Vemurafenib and dabrafenib, selective BRAF inhibitors has shown significant improvement in patient survival compared to standard therapy in V600 mutant metastatic melanoma. No cases of AKI have been reported with dabrafenib use. AKI has been recently reported in few case series with vemurafenib use. One case series included a patient who had a kidney biopsy demonstrating acute tubular necrosis as a potential mechanism of renal injury.

Methods: We reviewed the FDA Adverse Event Reporting System's (FAERS) quarterly legacy data file from 3rd quarter of 2011 to 2nd quarter of 2014 for vemurafenib and 2nd quarter of 2013 to 2nd quarter of 2014 for dabrafenib. Vemurafenib and dabrafenib related renal adverse event data were extracted through formation of a query using FAERS assigned unique case identifiers. Search terms utilized were "renal insufficiency, elevated creatinine, renal failure, renal injury, proteinuria, renal impairment, blood creatinine increase, renal failure acute, low phosphorus, hypophosphatemia, hypercreatinemia, hyponatremia, hypokalemia, renal damage".

Results: 132 cases of AKI were reported secondary to vemurafenib to the FAERS in the time frame reviewed. Eighty five patients were men and 47 women (p= 0.01). Average age of the men was 65 years and 59 years for the women (p=0.03). The cases are reported from around the world with France, USA and Germany having most of the cases. Fourteen cases of electrolyte disorders were reported (hypokalemia-6 cases and hyponatremia-8 cases). A total of 13 cases were reported of AKI from dabrafenib to the FAERS in the time frame stated above. Twelve patients were men. Average age of the men were 55 and 75 years for women (p=0.0022). Eight cases of electrolyte disorders were reported (hypokalemia-2 cases and hyponatremia-6 cases).

Conclusions: While the FAERS reporting system is a crude database with scant demographic information, the number of cases reported of AKI is still alarming with the BRAF inhibitors. Vemurafenib appears to be more nephrotoxic than dabrafenib. This renal toxicity seems to be more prominent among male patients with melanoma. Dermatologists, oncologist and nephrologists need to be made aware of this important toxicity.

TH-PO094

Protective Effects of Oral L-Arginine Supplement in Patients with Chronic Kidney Disease After Intravenous Contrast Media Injection: A Randomized Controlled Trial Theerasak Tangwonglert. *Medicine, Phramongkutklao Hospital.*

Background: Contrast-induced acute kidney injury (CI-AKI) is a common complication in hospitalized patients. Nitric oxide-signal transduction plays an important role in prevention of CI-AKI. L-Arginine is an amino acid involved in ammonia detoxification, and is well known as a precursor to nitric oxide, a key component of endothelial-derived relaxing factor.

Methods: A randomized, double blind, placebo controlled trial was done in CKD stage 3-4 patients undergoing computer tomography. Eligible patients were randomly assigned into two groups: arginine 3 g in 6 gelatin capsules orally per day, and placebo 6 capsules as the same manner for 3 days before contrast media injection. Serum cystatin C, creatinine, electrolyte, estimated GFR and urinary nitric oxide were measured at baseline and 48 hours after procedure.

Results: A total of 84 patients were screened. Sixty percent were male with mean age of 74 years. 27 patients in arginine group and 34 patients in placebo group were analyzed. There were no significant differences between the arginine and placebo groups regarding baseline demographic and biochemical characteristics, including baseline GFR (48.8 ± 8.8 mL/min/1.73 m2 versus 48.8 ± 7.5 mL/min/1.73 m2). The incidence of CI-AKI was 3.7% (1 patient) in the arginine group and 23.53% (8 patients) in the placebo (p = 0.036). No serious adverse event was detected in the both groups. There is a trend toward an increase in urinary nitric oxide difference in patients with CI-AKI.

Conclusions: This study indicated that oral L-arginine supplement before intravenous contrast media injection plus the standard hydration regimen can prevent CI-AKI in hospitalized patients with CKD stage 3-4.

TH-PO095

Decline in Estimated Glomerular Filtration Rate After Acute Kidney Injury: A Surrogate Endpoint? Morgan Grams,[1] Yingying Sang,[1] Josef Coresh,[1] Shoshana Ballew,[1] Kunihiro Matsushita,[1] Tom Greene,[2] Andrew S. Levey,[3] Miklos Zsolt Molnar,[4] Zoltan Szabo,[5] Kamyar Kalantar-Zadeh,[6] Csaba P. Kovesdy.[4,7] *[1]JHU; [2]Utah; [3]Tufts; [4]UTHSC; [5]Linköping Univ; [6]UC Irvine; [7]Memphis VA Medical Center.*

Background: Often a transient condition, acute kidney injury (AKI) is not currently accepted as an endpoint for drug registration trials by the US FDA. We sought to determine whether an intermediate-term change in eGFR after AKI has a sufficiently strong relationship with subsequent ESRD to serve as an alternative endpoint in clinical trials of AKI prevention and/or treatment.

Methods: We evaluated 161,185 US veterans who underwent major surgery between 2004-2011. Post-surgical AKI was defined by the KDIGO creatinine criteria;decline in eGFR was calculated from pre-hospitalization value to two time-points post-discharge (60-days, 90-days) and related to ESRD and mortality using Cox proportional hazards regression.

Results: In-hospital mortality varied by AKI status, ranging from 1% for patients without AKI to 35% for those with dialysis-requiring AKI. An eGFR decline of ³30% at 60-days was relatively frequent: 2.5%, 9.7%, 17.2%, and 28.6% in those with no AKI, Stage 1 AKI, Stage 2 AKI, and Stage 3 AKI, respectively. There was a graded relationship between eGFR decline at 60-days and risk of ESRD in persons both with and without AKI (**Figure**). Compared to stable eGFR/no in-hospital AKI, the adjusted hazard ratio (HR) of ESRD associated with a 30% decline at 60-days after AKI was 6.42 (95% CI: 4.8-8.7). Risks for mortality associated with eGFR decline were smaller: the HR for 30% decline 60-days after in-hospital AKI was 1.59 (95% CI: 1.46-1.73). Risk relationships were similar at 90-days.

Conclusions: A 30% decline in eGFR from pre-hospitalization baseline to 60-days or 90-days after an episode of AKI may be an acceptable surrogate endpoint in trials of AKI prevention and/or treatment.

TH-PO096

Creatinine Changes After Contrast: Chloride Poor versus Chloride Rich Solutions Asish Thakkar, Rima Kang, Salem Almaani, Udayan Y. Bhatt. *Nephrology, The Ohio State Univ Wexner Medical Center, Columbus, OH.*

Background: There has been recent emphasis on utilization of chloride poor solutions for the prevention of acute kidney injury (AKI). The purported mechanism is the potential for chloride rich fluids to possibly impair renal blood flow. Similarly, exposure to intravenous radiographic contrast is known to induce renal vasoconstriction. Given these findings, the objective of this project was to examine the effect of chloride rich versus chloride poor intravenous (IV) fluids on the change in serum creatinine occurring after IV contrast administration.

Methods: This project was performed under an IRB-approved Honest Broker Protocol. Retrospective data was obtained from patients receiving IV contrast over a 4 week period. Variables collected included: age, race, gender, type of contrast procedure, baseline creatinine, creatinine at days 1 and 2, and all intravenous medications. Chloride rich solutions (normal saline) and chloride poor solutions (sodium bicarbonate, Plasmalyte, and Lactated Ringers) were identified. Multivariate linear modelling was used to examine the primary endpoint of change in creatinine at day 2 relative to baseline (delta creatinine).

Results:

	Cl Poor(N=22)	**Saline(N=220)**	**p-value**
Age	62.4±11.6	58.7±16.8	NS
Male	6(27.3%)	120(54.5%)	0.021
Caucasian	18(81.8%)	172(78.2%)	NS
Heart Catheterization	2(9.1%)	10(4.5%)	NS
Baseline Creatinine	1.38±0.88	0.94±0.49	0.003
Delta Creatinine	0.09±1.00	-0.06±0.37	NS
Multivariate analysis	**Delta Creatinine Chloride rich verse Cl poor**		**p-value**
Saline	-0.370		0.000

The change in creatinine after IV contrast in the chloride rich group, after adjusting for all variables including baseline creatinine, was 0.37±0.09 lower than in the chloride poor group (p=0.000).

Conclusions: Patients receiving chloride rich IV solutions appeared to have a significantly lower change in serum creatinine after administration of IV contrast compared to patients receiving chloride poor solutions. On this basis, more investigation is needed on chloride poor solutions to fully define the most appropriate utilization.

TH-PO097

Clinical Characteristics in Patients with Alcoholic Ketoacidosis and Acute Kidney Injury Hyeon-Cheol Park, Shinhan Song, Jae seok Kim, Jae Won Yang, Byoung Geun Han, Seung-Ok Choi. *Internal Medicine, Yonsei Wonju College of Medicine, Korea.*

Background: Alcoholic ketoacidosis (AKA) is a serious disorder that has a high mortality. Acute kidney injury (AKI) is a typical complication of AKA, which is known to be associated with increased mortality. This study aimed to investigate clinical characteristics and risk factors for AKI in patients with AKA.

Methods: We retrospectively reviewed records of 357 patients who had been diagnosed with AKA in Wonju Severance Christian Hospital from January 2004 to March 2014. We investigated clinical history and characteristics, laboratory data, progress and mortality. In addition, we estimated Acute Physiology and Chronic Health Evaluation (APACHE) II score and Sequential Organ Failure Assessment (SOFA) score for assessing severity of patients. Lastly, we investigated the risk factors for AKI.

Results: A total of 357 patients were included in the study. Among them, 293 patients (82.1%) were diagnosed with AKI by AKIN (Acute Kidney Injury Network) criteria; stage I (n=80, 22.4%), stage II (n=70, 19.6%), stage III (n=143, 40.1%). Mortality was reported in 84 patients (23.6%), and mean interval from initial visit to mortality was 6.0 ± 10.7 days. As the AKI stage advanced (non-AKI vs. stage I vs. stage II vs. stage III), the mortality rate increased (3.1 vs. 7.5 vs. 25.7 vs. 40.6 %), and APACHE II / SOFA scores were elevated as well (11.1 vs. 13.2 vs. 19.4 vs. 22.5 / 3.6 vs. 4.5 vs. 7.3 vs. 9.5). In addition, clinical history of liver cirrhosis, complications of rhabdomyolysis, pancreatitis, infection, and in hospital cardiac-arrest showed the more occurrence frequencies in the advanced AKI stages. However, alcohol histories including duration of total alcohol intake, last drinking day before the visit, and alcohol amounts to intake were not associated with AKI stages. Lastly, our study demonstrated that independent risk factors for AKI in the patients with AKA included rhabdomyolysis (odds ratio, 7.1, 95% confidence interval, 2.3-22.2) and pancreatitis (3.7, 1.1-11.8).

Conclusions: This study indicates that AKI in the patients with AKA is associated with higher mortality, and the major risk factors for AKI include complications of rhabdomyolysis and pancreatitis.

TH-PO098

Renal Cortical Necrosis following Postpartum Hemorrhage: A Case Series Marie Frimat,[1] Mélanie Decambron,[1] Celine Lebas,[2] Viviane Gnemmi,[3] Benedicte Sautenet,[4] Francois Glowacki,[1] Eric Rondeau,[5] Christian Noel,[1] Francois Provot,[1] Alexandre Hertig.[5] *[1]Nephrology, CHRU Lille, Lille, France; [2]Nephrology, CH Valenciennes, Valenciennes, France; [3]Anatomopathology, CHRU Lille, Lille, France; [4]Nephrology, CHRU Tours, Tours, France; [5]Nephrology, APHP, Tenon Hospital, Paris.*

Background: Pregnancy-related renal cortical necrosis induces severe kidney damage and may thus result in end stage renal disease. Although this obstetrical complication had virtually disappeared in high-income countries, we noted new cases in France during the past few years, all in the aftermath of a postpartum hemorrhage.

Methods: We retrospectively identified 18 patients from 5 French departments of Nephrology who developed renal cortical necrosis following postpartum hemorrhage between 2009 and 2013. Obstetrical and renal features, therapeutic measures, and renal outcome were studied. In order to identify prognostic factors for renal outcome, we stratified the analysis according to the estimated glomerular filtration rate at 6 months postpartum: £15ml/min or dialysis-dependent (Gp1) *versus* > 15ml/min (Gp2).

Results: All patients had a severe postpartum hemorrhage (mean blood loss: 2.6±1.1L). Hemodynamic instability and disseminated intravascular coagulation were reported in 5 and 11 patients, respectively. All had a rapid onset of acute kidney injury and required hemodialysis. Diagnosis of renal cortical necrosis was performed 4 to 33 days following delivery. At 6 months post-partum, 8 patients remained dialysis-dependent and none recovered normal renal function. Retrospectively, the severity of the initial presentation was comparable between the Gp1 (n=9) and Gp2 (n=9) groups. Only the maintenance dose of tranexamic acid treatment was significantly more prolonged in the Gp1 patients (7.1±4.8 hours *versus* 2.9±2.4 hours, *p=0.031*).

Conclusions: The pejorative outcome of pregnancy-related renal cortical necrosis seems darkened by a prolonged use of tranexamic acid. In a setting of gravid endothelium, disseminated intravascular coagulation and concomitant use of fibrinogen, we speculate that the accumulation of this antifibrinolytic drug due to acute kidney injury might facilitate the uncontrolled clotting in renal cortex.

TH-PO099

Intermittent Hemodialysis (IHD) versus Sustained Low Efficiency Dialysis (SLED) for Lithium Toxicity: A Case Series Justine Bunka, Alejandro Quiroga. *Dept of Pediatric Nephrology, Dialysis, and Kidney Transplant, Helen DeVos Children's Hospital, Grand Rapids, MI.*

Background: Severe lithium toxicity is a medical emergency requiring hemodialysis when patients present with toxic levels (above 2.5mmol/L) and/or are symptomatic. This case series describes two pediatric patients who presented with severe lithium toxicity, one who was treated with intermittent hemodialysis (IHD) and the other who was treated with sustained low efficiency hemodialysis (SLED). We report a successful single use of SLED in a pediatric patient with lithium toxicity without the need for further dialysis.

Methods: A 16 year old female with history of depression was admitted to the Pediatric ICU after ingestion of multiple medications as a suicide attempt including lithium carbonate extended release 300 mg tabs. The patient was started on continuous CVVHDF due to hemodynamic instability requiring multiple vasopressor agents. CVVHDF was initiated when the patient's lithium level was 0.62mmol/L and it was continued for 12 hours. Eighteen hours after cessation of CVVHDF, the lithium level rebounded to 2.5mmol/L and conventional intermittent hemodialysis (IHD) was required for 2 consecutive days. After IHD, lithium level decreased to below 1mmol/L when dialysis was discontinued. A 12 year old male with history of bipolar depression on chronic lithium therapy presented to the Pediatric ICU with altered mental status and tremors with a lithium level of 4.0. Sustained low efficiency dialysis (SLED) was done for 8 hours until lithium level was below 1.0. After SLED was discontinued the rebound lithium level peaked at 1.4 and the neurologic symptoms resolved, indicating no further dialysis was needed.

Conclusions: SLED is an effective modality for lithium clearance and may reduce the total duration needed for IHD due to less rebound of lithium level.

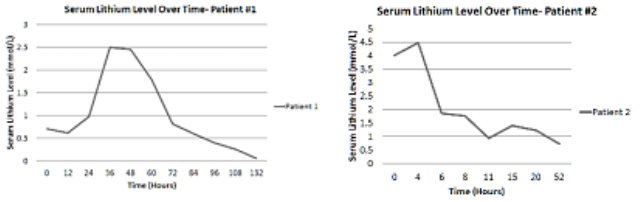

Figure 1. serum lithium levels for Patient #1 and Patient #2
Patient #1 (left) lithium level peaked at 2.5mmol/L which occurred 18 hours after CVVHDF was completed. The remaining levels were taken over the next two days during which the patient received 2 rounds of hemodialysis.
Patient #2 (right) had a Lithium level at presentation of 4.02mmol/L. After 8 hours of SLED the lithium level was 1.0mmol/L. The peak level of the rebound effect was 1.4mmol/L and then the level continued to decrease without any further dialysis.

TH-PO100

Demographic Characteristics of Acute Kidney Injury and Utilization of Continuous Renal Replacement Therapy with Extracorporeal Life Support in Adult Patients Christopher Hebert, Brain Lima, Britton Blough, Avery Smith, Omar Hernandez. *Dept of Internal Medicine, Div of Nephrology, Baylor Scott and White Health Care System, Dallas, TX.*

Background: Extracorporeal life support (ECLS), also known as extracorporeal membrane oxygenation (ECMO) has been used over the last 40 years to help manage patients with severe cardiovascular or respiratory illnesses. Acute kidney injury is a very common complication in this particular patient population as is the need for renal replacement therapy. Much of the success and experience related to extracorporeal therapies has been limited to neonatal and pediatric populations. More recent data suggests that centers who perform a higher volume of ECMO cases have better outcomes. This study presents a demographic assessment of the first 199 cases of ECMO utilization over the last 36 months along with outcomes, specifically related to acute kidney injury.

Methods: We collected data for review of the first 199 cases of patients treated with ECLS at Baylor Scott and White Health Care System since July of 2012. We examined the patient demographics, type of ECLS, indication, location, comorbidities, incidence of acute kidney injury by RIFLE criteria and need for renal replacement therapy. Specific outcome measurements we looked at were overall survival, ability to wean from ECLS or bridge to transplant, withdraw of care, need for long term dialysis, and death.

Results: In our ECMO program, 144 patients were male (72%) and 56 were female (28%). Regarding the types of ECLS, 136 were VA ECMO, 61 were VV ECMO and there were 2 RVADs. The main indications for ECLS were Cardiac in 129 cases, pulmonary in 63 cases, and 8 were ECPR. There were 61 patients who required CRRT. The majority of these were VA ECMO (41 patients) and the rest were VV ECMO (20 patients). A total of 129 patients were weaned from ECLS, 92 of which survived to discharge. Survival was worse in patients with AKI, overall survival on ECMO was 64.5% versus 36% for those on CRRT with AKI.

Conclusions: Our data set is fairly consistent with ELSO registry numbers. AKI appears to impact mortality in similar fashion. We hope to gain insight into more prospective research regarding this unique patient population.

TH-PO101

Performance of Renal Replacement Therapy for Acute Kidney Injury in Adult Patients on Extracorporeal Life Support Christopher Hebert. *Dept of Internal Medicine, Div of Nephrology, Baylor Scott and White Health Care System, Dallas, TX.*

Background: Extracorporeal life support is being used more commonly in adult patients with severe cardiovascular and respiratory illnesses. Acute kidney injury requiring renal replacement therapy is a very common complication in this patient population. Much of the data regarding the technical aspect of these concurrent procedures has been limited to neonatal and pediatric patient populations. We sought to examine the most efficient and effective ways to deliver renal replacement therapy in conjunction with extra corporeal life support.

Methods: Between July 2012 and March 2015, our institution performed 200 cases of extracorporeal life support. Of these cases, 61 required renal replacement therapy. Individual decisions regarding timing of initiation of renal replacement therapy and specific modality were based on physician discretion regarding other patient comorbidities, type of ECMO, and overall goals of care. Data was then collected on isolated cases that faced specific complications with respect to the technical aspect of performing renal replacement therapy. Our institution utilized the NXStage System One dialysis machine, and the Macquet Rotaflow or Cardiohelp ECMO machine.

Results: The most common and effective way to perform continuous renal replacement therapy was to place the arterial line after the pump in the circuit, and return the blood before the oxygenator in the circuit. This minimized the risk of potential thrombosis to the patient and circuit clotting. Machine alarms would have to be interpreted in light of circuit position, and often had to be overridden. These included positive arterial pressures, high venous pressures, arterial blood flow during ECMO "chattering", and high chamber pressures.

Conclusions: Continuous renal replacement therapy can easily be safely and effectively implemented into almost any extracorporeal life support system circuit. There are technical challenges with each type of machine, that can be circumvented through a thorough understanding of each circuit. A good understanding of ECLS and CRRT allows teams to troubleshoot a different set of challenges than traditional CRRT. We hope to evaluate this patient population in a more standardized fashion with respect to interventions and outcomes in future studies.

Prescribed versus Delivered Dose of Continuous Veno-Venous Hemodialysis in a Non-Study Population Aqsa F. Rahman, Majid A. Khan, Akshar N. Patel, Krystal Hunter, Lawrence S. Weisberg, William D. Sirover, Christopher B. McFadden. *Nephrology, Cooper Univ Hospital, Camden, NJ.*

Background: Critically ill patients requiring continuous renal replacement therapy (CRRT) experience high mortality rates. In randomized studies, intensification of CRRT by increasing effluent volumes from 20 to 35 ml/kg/hr did not improve survival. These studies ensured achievement of prescribed dose. We evaluated how often a subject achieves the prescribed dose in a non-study population.

Methods: We conducted a retrospective, observational cross sectional study and examined the electronic medical records (EMR) of subjects receiving CRRT. An automated, real time wireless link from the dialysis machines to EMR, contained data on the CRRT settings and hourly effluent volumes. With this data we calculated percentages of prescribed dosages achieved and compared subjects who did or did not achieve the prescribed dose. Access problems, procedures, electrolyte disturbance or no clear reason documented were investigated as variables in subjects not achieving prescribed doses. Pearson Chi Square or Fisher exact tests were used to compare dichotomous, and Independent T test or Mann Whitney U tests were used to compare continuous variables.

Results: This study represents an analysis of 73 of a planned 90 subjects. We found that 14% subjects achieved 100% of prescribed dose, 53% achieved 80-99% and 33% achieved < 80%. Mean prescribed dose was 25 ml/kg/hr and achieved dose was 20 ml/kh/hr. Access/Filter problems were present in 63.4%, imaging/procedure 12% , electrolyte imbalance 2% and no clear reason documented in 19.2% when goal dose was not achieved. Subjects in whom CVVHD was not interrupted achieved > 96% of prescribed dose which was statistically significant (P<0.001) compared to 76.5% achieved in subjects that had interruptions.

Conclusions: In a non-study population the proportion of patients who do not achieve prescribed CRRT dose is very large. In order to achieve a dose of 20 ml/kg/hr effluent volume the prescribed dose may need to be significantly higher in a non-study population. Timely correction of access/filter problems is another area of focus which may need attention for better dose achievement.

TH-PO103

A Predictive Model for Successful Conversion of Continuous Renal Replacement Therapy to Intermittent Hemodialysis for Acute Kidney Injury in Critical Ill Patients Ji Hyeon Park, Jee Eun Park, Subin Hwang, Hye Ryoun Jang, Wooseong Huh, Dae Joong Kim, Yoon-Goo Kim, Ha Young Oh, Jung eun Lee. *Nephrology, Samsung Medical Center, Seoul, Korea.*

Background: Continuous renal replacement therapy (CRRT) is preferred modality of renal replacement therapy (RRT) in critical ill patients with acute kidney injury (AKI). However, it has several disadvantage such as high cost and risk of continuous anticoagulation. Therefore, initial application of CRRT and subsequent conversion to intermittent hemodialysis (IHD) could be practical. However, there has been no standard criteria for optimal timing of conversion to IHD in pateints receiving CRRT. The aim of this study was to develop a predictive model for successful conversion of CRRT to IHD.

Methods: This case-control study was conducted by retrospective chart review. We identified 513 adult patients who received CRRT at least 24 hours and and then IHD subsequently in ICU between April 2009 and February 2014. Failure in conversion to IHD was defined when CRRT was re-applied within 72 hours after CRRT stop, and 83 out of 513 patients corresponded failure criteria: failure group. Equal number of patients were selected randomly from remaining 430 patients: success group.

Results: Cardiovascular (CV) SOFA score and neurologic (NR) SOFA score at CRRT stop day were only two independent predictors of conversion failure. The risk of failure was discriminated between score 0,1 and score 2-4 for both CV and NR SOFA. CV SOFA score 2-4 was associated with 13 fold increased Odds ratio for failure (95% C.I. 4.6 - 38.3, Ref 0-1) and NR SOFA score 2-4 was associated with 5.4 fold increased Odds ratio for failure (95% C.I. 2.6 - 11.4, Ref 0-1). Final prediction model included CV SOFA and NR SOFA weighting CV SOFA (≥ 2) as 2 points and NR SOFA (≥ 2) as 1 point. Risk score ranged from 0 to 3 points (0; 47%, 1; 29%, 2; 13%, 3; 11%). The performance of this model was acceptable with area under the receiver operating characteristic curve of 0.79 (95% C.I. 0.77–0.86).

Conclusions: The prediction model might provide an objective criteria for conversion to IHD in patients receiving CRRT and contribute to establish cost-effective protocol of RRT for AKI in critical ill patients.

TH-PO104

Mortality Factors in Septic Shock Patients Requiring Continuous Renal Replacement Therapy and Timing Effect Based in Urine Output Xose Luis L. Perez-Fernandez,[1] Florentina E. Sileanu,[2] Joan Sabater Riera,[1] Kathleen D. Liu,[3] John A. Kellum.[2] *[1]Servei de Medicina Intensiva, Hospital Univ de Bellvitge, L'Hospitalet de Llobregat, Barcelona, Spain; [2]Critical Care, Univ Pittsburgh Medical Center, Pittsburgh, PA; [3]Nephrology & Critical Care, Univ California San Francisco Parnassus MC, San Francisco, CA.*

Background: Our primary objective was to identify factors associated with mortality in patients with septic shock and severe acute kidney injury (AKI) in order to design future interventional trials.

Methods: Observational retrospective study conducted in two tertiary care hospitals with more than 100 intensive care unit (ICU) beds each. Data were from 2000-2008 at UPMC (Pittsburgh, USA) and 2006-2012 at HUB (Barcelona, Spain). The final cohort included 938 patients who received CRRT and presented with septic shock. Cox models were used to identify variables associated with 90 day mortality. Timing analyses were performed in patients with severe AKI at ICU admission who were started on RRT within the first 5 days of ICU stay.

Results: Overall 90day mortality was 62.9%. Independent risk factors for death included: age, SOFA score at ICU admission, days from hospital admission to ICU admission, days from ICU admission to CRRT initiation, and medical (vs surgical) admission. Both lower creatinine at CRRT start and lower urine output in the 24 hours before start of CRRT were associated with lower survival. ROC curve analysis identified urine output less than 500 ml in the 24 hours prior to CRRT initiation as the best variable to discriminate between survivors and non-survivors.

Conclusions: In patients with septic shock and advanced AKI (KDIGO stage 3), survival is lower when CRRT is started in the setting of low urine output. However, whether this finding represents differences in severity of illness betweenstudy subjects or is a useful tool to time CRRT initiation needs to be evaluated in a future randomized controlled trial.

Outcomes in Acute Kidney Injury Patients Undergoing Continuous Venovenous Hemodiafiltration and Regional Citrate-Based Anticoagulation: A Comparison Between Individuals with and without Liver Dysfunction Thais OC Santos,[1] Marisa S. Oliveira,[1] Henrique Pinheiro Konigsfeld,[1] Virgilio Gonçalves Pereira,[2] Marcelo Costa Batista,[1,2] Oscar Santos,[1,2] Bento C. Santos,[1,2] Julio M. Monte,[1,2] Marcelino Souza Durao.[1,2] *[1]Univ Federal de São Paulo, Brazil; [2]Hospital Israelita Albert Einstein, Brazil.*

Background: Regional citrate-based anticoagulation (RCA) has been widely used in intensive care unit (ICU) to treat subjects with acute kidney injury (AKI). Patients with liver failure (LF) have citrate metabolism impairment and are likely to experience citrate toxicity.

Methods: A prospective observational study was performed in a private hospital ICU, comparing clinical and laboratory data including citrate (Ci) plasma concentration from patients with and without LF. LF was defined as an International Normalized Ratio (INR) ^{3}2.5. Trisodium-citrate 4% was infused in the dialysis system to keep post-filter ionized calcium between 0.25-0.35mmol/L. Patients with LF had a Ci fixed-set infusion of 17mmol/h (120 ml/h) regardless of the post-filter ionized calcium value.

Results: Two hundred patients were evaluated. LF group patients showed a higher mortality rate (70,5% vs 51,8%, p=0.014). Ci was significantly higher in the LF group (median 3.497vs2.786mg/dL, p£0,03) in all evaluated days.LF group showed higher INR (median 2.68vs1.42, p<0,001), lactate levels (median 34vs16mEq/L, p<0,001) and lower serum bicarbonate (median 15.8vs19.4mEq/L, p<0,001) at baseline, as well as throughout the study period. There was no significant difference regarding systemic ionic calcium levels.LF group patients also underwent more red blood cell transfusions (median 3 vs 1, p<0.001). There were no differences in relation to delivered dose (33ml/kg/h), number of filters used and total dialysis time. Analyzing the relationship between serum levels of citrate and total calcium/ionic calcium ratio (CaT/Cai), we found a weak positive correlation, with the highest correlation coefficient of 0.354.

Conclusions: LF group showed higher mortality.Despite the LF group have presented higher citrate levels, there were no signs of toxicity, especially ionic hypocalcemia. There was a poor correlation between CaT/Cai ratio, a predictor of citrate toxicity, and Ci levels.

Outcomes in a Cohort of Patients with Acute Kidney Injury Submitted to Continuous Venovenous Hemodiafiltration: The Role of Negative Fluid Balance and Early Dialysis Thais O.C. Santos,[1] Marisa S. Oliveira,[1] Henrique Pinheiro Konigsfeld,[1] Marcelo Costa Batista,[1,2] Oscar Santos,[1,2] Bento C. Santos,[1,2] Virgilio Gonçalves Pereira,[2] Julio M. Monte,[1,2] Marcelino Souza Durao.[1,2] *[1]Univ Federal de São Paulo, Sao Paulo, Brazil; [2]Hospital Israelita Albert Einstein, Sao Paulo, Brazil.*

Background: Several factors are associated with adverse outcomes in acute kidney injury (AKI). These include some comorbidities, sepsis, high prognosis scores, positive fluid balance, and delay in beginning dialysis.

Methods: In a prospective and observational study, we evaluated risk factors for death in 183 patients with AKI requiring continuous venovenous hemodiafiltration (CVVHDF).

Results: Sepsis was the main cause of AKI (57%). Overall mortality was 58%. The median cumulative fluid balance (FB) during dialysis was -4127mL among non-survivors and +646mL among the survivors. There were 114 oliguric individuals. Independent risk factors for death in multivariate analysis were chronic obstructive pulmonary disease (COPD) (OR 3.07, 95% CI 1.01 to 9.32, p = 0.047), liver cirrhosis (OR 4.47, 95% CI 1, 77 to 11.3, p = 0.002), hematologic malignancy (OR 6.19, 95% CI 1.83 to 20.93, p=0.003), oliguria (OR 3.01, 95% CI 1.43 -6.32, p=0.004), positive cumulative FB during dialysis (OR 1.13, 95% CI 1.06 to 1.20, p<0.001) and time between ICU admission and beginning of CVVHDF (OR 1.13, 95% CI 1.01 to 1.25, p=0.039). Among survivors, nearly 30% were discharged dependent on dialysis and, among those who were discharged out of dialysis, there was a statistically significant reduction in glomerular filtration rate in relation to admission (81 vs 50mL/min/1,73m^2, p<0,001). The SAPS 3 score at ICU admission showed unsatisfactory performance as a predictor of death in patients with AKI (AUC=0.637, 95%CI, 0.557 to 0.717).

Conclusions: We found an association between positive FB during dialysis, oliguria, late starting dialysis and death in patients with AKI submitted to CVVDHF. Others factors related to death were COPD, hematologic malignancy and liver cirrhosis.

TH-PO107

The Impact of Dialysis-Dependent Acute Kidney Injury on Mortality in Myeloma: Findings from England Hospital Episode Statistics Data Punit Yadav,[1,2] Felicity K. Evison,[1] Jason Sangha,[3] Daniel Ian Ray,[1,2] Adnan Sharif,[1] Jennifer H. Pinney,[1] Mark Trehane Drayson,[1,2] Mark Cook,[1,2] Paul Cockwell.[1,2] *[1]Univ Hospital Birmingham, UK; [2]Univ of Birmingham, UK; [3]St. James Univ Hospital, UK.*

Background: In patients with myeloma, severe acute kidney injury requiring in-hospital dialysis treatment is a life-threatening complication. However the current incidence and mortality risk associated with dialysis is unknown. We aimed to examine the incidence and impact of dialysis on the survival of patients with first diagnosis of myeloma.

Methods: We utilised hospital episode statistics to analyse data from 36,348 patients with a first diagnosis of myeloma in England from April 2006 to March 2014. We examined the incidence and impact of in-hospital dialysis on overall survival, by year of presentation. Cox proportional outcome models were used to adjust for age, gender, area socio-economic deprivation, ethnicity and comorbidity.

Results: We identified 1240 (3.4%) patients who received dialysis treatment within 28 days of a diagnosis of myeloma. In Kaplan-Meier analysis patients who did not receive dialysis had better median overall survival (3.0 years; interquartile range [IQR] 0.7-8.1) than patients who received dialysis [1.4 years; IQR 0.2-4.6]. From 2006/7 to 2010/11 survival improved from 2.6 years [IQR 0.6-7.7] to 3.3 years [IQR 1.0-not reached] for patients who did not receive dialysis and 0.6 [IQR 0.1-2.7] to 1.2 years [IQR 0.4–4.0] for those who received dialysis respectively. Compared to patients who did not receive dialysis, those who received dialysis were more likely to be older, male, and less socio-economically deprived.

Conclusions: Dialysis is a major independent risk factor for increased mortality in patients with myeloma; the overall survival of patients with myeloma requiring dialysis is improving.

TH-PO108

Predictors of Survival in the ICU Patient on Continuous Veno-Venous Hemofiltration (CVVH) Amina Saqib, Jwalant R. Modi, Gautam Kishore Valecha, Abdul H. Siddiqui, Suzanne E. El Sayegh. *Medicine, Staten Island Univ Hospital.*

Background: In the ICU setting, Acute Renal Failure is a part of multiple organ dysfunction syndrome with mortality in these patients ranging from 28%-90%. Continuous Venovenous hemofiltration (CVVH) is most commonly used for renal replacement therapy in ICU's. The objective of this study is to describe demographic characteristics and to establish an association between these characteristics and variables that define the severity of illness and in-hospital mortality outcomes of patients undergoing CVVH.

Methods: Medical records of patients who underwent CVVH from January 2007 to December 2013 in the intensive care at our institution were analyzed. Chi Square test was done for categorical variables. Descriptive analysis was used to identify demographic data.

Results: 233 patients underwent CVVH from January 2007 to December 2013. The overall mortality was 75.22%. 49.3% of patients required ventilatory support. Acute respiratory failure requiring mechanical ventilation was associated with significantly increased mortality, 76.74% vs 40.0 % (p=0.04) in patients who did not require mechanical ventilation. Septic Shock was the most common reason for ICU admission, 71.2% followed by post-operative admissions at 18.8%. The most common indication for CVVH was ATN (63.9%) followed by hyperkalemia (57.0%). However, CVVH for metabolic acidosis was associated with highest mortality at 81.06 % vs. 67.02 % in patients who underwent CVVH for other indications. Poor APACHE II scores were associated with higher mortality. Scores ranging from 0-24 were associated with an overall mortality of 69.9% whereas scores between 25-50 were associated with an overall mortality of 80.53%.

Conclusions: This observational study in patients undergoing CVVH in an ICU setting revealed that patients presenting with worse baseline APACHE II scores had poor in-hospital outcomes. CVVH initiation for metabolic acidosis and use of mechanical ventilation was associated with higher mortality. There are no established guidelines for use of CVVH. This study may aid in delineating the group of patients who may benefit the most from use of CVVH and help us in more judicious use of health care resources. .

TH-PO109

Clinical Effectiveness of Diuretics following Continuous Renal Replacement Therapy Do Hee Kim, Subin Hwang, Jin Hae Kim, Jee Eun Park, Ji Hyeon Park, Jung Eun Lee, Wooseong Huh, Yoon-Goo Kim, Dae Joong Kim, Ha Young Oh, Hye Ryoun Jang. *Div of Nephrology, Dept of Medicine, Samsung Medical Center, Sungkyunkwan Univ School of Medicine, Seoul, Republic of Korea.*

Background: There is no consensus regarding diuretics administration in acute kidney injury (AKI) in patients weaning from continuous renal replacement therapy (CRRT). The effect of diuretics on the clinical course of critically ill patients with AKI was analyzed focusing on urine output and renal recovery following CRRT. In addition, we tried to identify the most optimal administration method of diuretics.

Methods: A total of 1213 adult patients who survived more than 3 days after discontinuing CRRT between September 2009 and December 2014 were included. Changes in renal function and urine output as well as the prescription of diuretics during the 3 days after discontinuation of CRRT were retrospectively analyzed. Patients were categorized depending on re-initiation of RRT within 3 days.

Results: There was no difference in baseline characteristics among all groups. CRRT cessation group had greater urine output after discontinuation of CRRT compared with other groups. Overall, patients who were treated with diuretics (diuretics subgroup) showed greater urine output than patients without diuretics (control subgroup) after cessation of CRRT and there was no difference in the degrees of serum creatinine elevation between control and diuretics subgroups. In CRRT cessation group, continuous infusion of furosemide showed greater urine output compared to other administration methods. However, serum creatinine increased significantly compared to other methods when the infusion was continued for more than 1 day.

Conclusions: Diuretic therapy following CRRT increases urine output significantly without causing significant deterioration of renal function. Compared with other methods using diuretics, continuous infusion of furosemide increases urine output significantly, but also increases serum creatinine further when continued for more than 1 day. Our study suggests that diuretics in patients who had received CRRT may be clinically useful.

TH-PO110

The Prognostic Value of Volume Status Assessment by Bioelectrical Impedance Analysis and Lung Ultrasound on Mortality in Septic Acute Kidney Injury Patients Undergoing Continuous Renal Replacement Therapy Sul A Lee, Shin-Wook Kang, Tae-Hyun Yoo. *Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea.*

Background: Volume overload affects clinical outcome in patients with acute kidney injury (AKI). However, the significance of various methods to evaluate volume status has not been fully evaluated. Therefore, the prognostic value of volume status assessment measured by bioelectrical impedance analysis (BIA) and lung ultrasound (US) on mortality was investigated in septic AKI patients requiring continuous renal replacement therapy (CRRT).

Methods: Septic AKI patients requiring CRRT between April 2014 and February 2015 at Yonsei University Health System were included. Surrogates of volume status were 1) percent of body weight change between CRRT initiation and admission day, 2) over-hydration (OH)/extracellular water (ECW) measured by BIA, and 3) B-lines measured by lung US. Prognostic values of surrogates of volume status for 28-day mortality were evaluated.

Results: Among the 36 enrolled patients, 19 (52.8%) patients died during the follow-up duration. The mean percentage of weight change and OH/ECW measured by BIA was 5.3±20.7 % and 0.3±0.1 L/L. The median number of B-lines counted by lung US was 6 (interquartile range, 4-10). OH/ECW was significantly correlated (r=0.39, P=0.02) with 48-hour fluid balance before CRRT initiation, while the number of B-lines was not. Kaplan-Meier analysis showed that 28-day mortality was higher in patients with the highest OH/ECW tertile compared to patients with lower OH/ECW values (P=0.02). Percent of weight change and the number of B-lines were not significantly associated with 28-day mortality (P=0.44 and P=0.45, respectively). Multivariate Cox proportional hazard regression analysis showed that higher OH/ECW was an independent risk factor for 28-day mortality after adjustment of confounding factors (HR=3.83, 95% CI=1.04-14.03, P=0.04).

Conclusions: Higher OH/ECW measured by BIA was an independent risk factor for 28-day mortality in septic AKI patients undergoing CRRT. Determining fluid status by BIA could be a useful method to stratify mortality risk in this patient group.

TH-PO111

Effect of Fluid Overload on the Outcome Among Acute Kidney Injury Patients Receiving Renal Replacement Therapy After Cardiac Surgery Zhouping Zou,[1,2] Jiarui Xu,[1,2] Wenlv Lv,[1,2] Bo Shen,[1,2] Yi Fang,[1,2] Jianzhou Zou,[1,2] Jie Teng,[1,2] Xiaoqiang Ding.[1,2] *[1]Dept of Nephrology, Zhongshan Hospital, Fudan Univ, Shanghai, China; [2]Shanghai Inst for Kidney and Dialysis, Zhongshan Hospital, Fudan Univ, Shanghai, China.*

Background: We explored the effect of fluid overload in different periods on the outcome among acute kidney injury (AKI) patients receiving renal replacement therapy (RRT) after cardiac surgery in order to guide the fluid manegement strategy.

Methods: Clinical data of patients who developed AKI requiring RRT after cardiac surgery from January 2009 to April 2014 in our hospital were prospectively analyzed. Demographic characteristics were recored. The absolute fluid overload (FO) = fluid in (L) – fluid out (L). Percent fluid overload (%FO)=[(fluid in-fluid out)/admission weight×100]. %FO³10% baseline weight was defined as fluid overload.

Results: A total of 297 patients were enrolled, the hospital mortality was 64.7%(n=192). The %FO at RRT initiation and at the end of RRT in death group was significantly higher than in survival group [5.0 (2.4, 9.3) *vs.* 2.5 (0.2,5.8)%; 8.4(3.6,14.2) *vs.* 3.9(0.4,9.2)%; P<0.05]. Even though the fluid overload before RRT was corrected at the end of RRT, the overall mortality and rate of renal completely recovery was not improved (P>0.05). Compared with patients without fluid overload during the whole ICU stay, patients without fluid overload before RRT but had fluid overload at the end of RRT had significantly higher mortality(P<0.05)and lower renal complete recovery(P<0.05).Among AKI-RRT patients, the incidence of low cardiac output syndrome (LCOS) in death group was significantly higher than in survival group (p<0.001). The hospital mortality in LCOS group was significantly higher than non-LCOS(P<0.001). The %FO at RRT initiation and at the end of RRT in LCOS group was higher than in non-LCOS group [4.7(1.7,7.9) *vs.* 3.1(1.1,5.2), P<0.05; 8.9(4.4,15.3) *vs.* 4.8 (1.4,11.3), P<0.05].

Conclusions: Among patients with AKI-RRT after cardiac surgery, absolute FO and %FO in death group were higher than in survivor group. Fluid overload and LCOS increased the risk of mortality in AKI-RRT patients after cardiac surgery.

TH-PO112

Carnitine Deficiency in Children Receiving Continuous Renal Replacement Therapy Kristen Sgambat, Asha Moudgil. *Children's National, Washington DC.*

Background: Carnitine deficiency is known to occur in chronic hemodialysis, however the effect of continuous renal replacement therapy (CRRT) on carnitine homeostasis has not been studied. The purpose of this study was to investigate carnitine deficiency in critically ill patients with acute kidney injury undergoing CRRT in the pediatric intensive care unit. We hypothesized that patients receiving CRRT are at risk for deficiency due to continuous removal, absent intake, and comorbidities related to critical illness.

Methods: Records of patients with acute kidney injury receiving CRRT at Children's National between 2011 and 2015 were reviewed for total carnitine (TC), free carnitine (FC), Pediatric Logistic Organ Dysfunction-2 (PELOD-2) score indicators, and survival outcome. PELOD-2 score was calculated to measure of severity of illness on a scale from 0 to 33 (maximum severity of illness). The proportion of carnitine deficient patients at baseline, 1, 2, and ≥ 3 weeks on CRRT were compared by Chi square, and relationships with other variables assessed by Pearson's correlation and linear regression.

Results: The study group included 44 CRRT patients, age 8.1± 1.1 years. Severity of illness of the population determined by PELOD-2 score ranged from 2 to 19 (mean 11.2 + 0.43). Of 44 patients, only 14 (31.8%) survived. The prevalence of total and free carnitine deficiency, according to age-and-sex- specific reference values, significantly increased with time on CRRT. At baseline, 26.6% and 40% of patients were TC and FC deficient. Within 1 week, 65.6% (p=0.01) and 71% (p=0.04) were TC and FC deficient, and prevalence of deficiency increased to 80% (p=0.008) and 90% (p=0.01) by 2 weeks; 100% of patients were deficient ³3 weeks (p=0.002 and p=0.01, respectively, vs. baseline). TC and FC negatively correlated with days on CRRT (r=-0.4, p=0.001 and r=-0.37, p=0.003). Lower TC and FC levels significantly associated with higher mortality (β-10.1, p=0.03 and β-8.1, p=0.02 respectively).

Conclusions: Carnitine is significantly and rapidly depleted with longer time on CRRT, and carnitine deficiency is associated with increased mortality. Consequences of deficiency and benefits of supplementation in the pediatric CRRT population should be investigated.

TH-PO113

The Relationship Between Hypophosphatemia and Outcomes During Two Different Intensities of Continuous Renal Replacement Therapy Soo Young Kim,[1] Joung Wook Yang,[1] Ye Na Kim,[1] Ho Sik Shin,[1] Ji-hwan Kim,[2] Yeon Soon Jung,[1] Hark Rim,[1] Bong Geon Chun,[3] Hyun Yul Rhew.[4] *[1]Internal Medicine, Kosin Univ College of Medicine; [2]Internal Medicine, Good GangAn Hospital; [3]Pathology, Kosin Univ College of Medicine; [4]Urology, Kosin Univ College of Medicine.*

Background: To identify risk factors for development of hypophosphatemia in patients treated with two different intensities of continuous renal replacement therapy (CRRT) and to assess the independent association of hypophosphatemia with major clinical outcomes.

Methods: We performed retrospective analysis of data collected from 620 patients. We allocated patients to two different intensities of CRRT (more than or less than 40 mL/kg/hour of effluent generation) and obtained daily measurement of serum phosphate levels.

Results: We obtained total 1800 phosphate measurements in day 0, 1 and 2 and identified 49 patients (8%), 93 patients (15%) and 142 patients (23%) with hypophosphatemia, With lower intensity CRRT, there were 23 episodes of hypophosphatemia/1000 patient days, compared with 83 episodes/1000 patient days with higher intensity CRRT(P < 0.01).

Table 2. Baseline characteristics and outcomes of patients with at least one episode of hypophosphataemia

No. of patients	Serum phosphorus ≥ 2.5 mg/dL (n=432)	Serum phosphorus < 2.5 mg/dL (n=188)	P value

Renal function at initial dialysis			
Urine output, mL/24 hrs	1074 ± 1293	1175 ± 1108	0.515
BUN, mg/dL	43.8 ± 31.7	32.0 ± 26.2	0.003
Serum creatinine, mg/dL	2.9 ± 2.6	2.2 ± 1.9	0.019
Phosphorus level, mg/dL			
Day 1	4.2 ± 2.4	2.8 ± 1.6	0.001
Day 2	5.2 ± 2.0	3.7 ± 1.9	0.001
Day 3	4.3 ± 1.7	1.7 ± 0.5	0.001

On multivariable logistic regression analysis, higher intensity CRRT and hypokalemia were independently associated with an increased odds ratio (OR) for hypophosphatemia. On multivariable models, when analysis was confined to patients alive at 48 hours, hypophosphataemia was not independently associated with clinical outcomes.

Conclusions: Hypophosphatemia is common during CRRT and its incidence increases with greater CRRT intensity. Hypophosphatemia may be not a independent predictor of mortality.

Determinants of Filter Clotting in Acute Kidney Injury (AKI) Cancer Patients in the Intensive Care Unit (ICU) Submitted to Regional Citrate Anticoagulation (RCA) for Continuous Venovenous Hemodialysis (CVVHD)

Veronica T. Costa E Silva, Renato Antunes Caires, Juliana Silva Bezerra, Elerson Costalonga, Ludhmila Abrahão Hajjar, Ana paula Leandro Oliveira, Luciane Oikawa, Cilene Muniz Soares, Luis Yu, Emmanuel A. Burdmann. *Sao Paulo State Cancer Inst, Univ of Sao Paulo School of Medicine, Sao Paulo, Brazil.*

Background: Determinants of filter clotting in AKI cancer ICU pacients submitted to RCA have not been studied.

Methods: We prospectively analyzed all CVVHD performed in AKI adult cancer pcts in the Sao Paulo State Cancer Institute ICU from January 2010 to December 2011. RCA for CVVHD was utilized according to an adapted protocol published by Mehta et al. CVVHD was performed with a Diapact machine (BBraun) with polysulphone hemofilter.

Results: A total of 7,198 hours of CVVHD therapy (250 filters) were performed in 122 AKI pcts. They were 61 ± 16 years-old, 61.5% male, 75.4% on vasopressors and 41.8% on mechanical ventilation. Most (78%) patients had solid cancer, 37.7% with metastatic disease (MD) and 48.4% with previous chemotherapy (CT). Sepsis was the most important AKI etiology factor (71.1%). Hospital mortality was 78.7%. Venous access was temporary triple lumen catheter (11 Fr) in 97% (70% femoral and 27% internal jugular veins). Blood flow was 150 (120 – 150) ml/min and citrate dose was 20.4 (16.3 – 24.5) mmol/hr. Dialysis dose was 28.2 (22.3 – 30.2) ml/Kg/hr and achieved ultrafiltration was 1042 (573 – 1712) ml/24hrs. Median filter patency was 24.8 (11 – 43) hrs and post-filter ionized calcium level was 1.60 (1.40 – 1.80) mg/dL.The independent factors related with clotting on logistic regression model are depicted.

Logistic regression model for clotting during CVVHD

Variable	P	OR (95% CI)
Cancer status: no tumor evidence	0.050	0.44 (0.18 - 0.99)
Genitourinary cancer	0.006	1.83 (1.18 - 2.81)
Platelet count (each 10,000/mm^3)	0.005	1.02 (1.00 - 1.04)
INR	0.005	0.59 (0.41 - 0.85)
Citrate flow (each 10mL/hour)	0.002	0.88 (0.82 - 0.95)

Conclusions: Filter clotting in AKI ICU cancer patients submitted to RCA is related to lower citrate dose, higher INR (international normalized ratio), higher platelet level, genitourinary cancer and uncontrolled cancer disease.

TH-PO115

Pre-Dilution Haemodiafiltration Improves Outcomes in Acute Haemodialysis

Caburn Chamberlain, Preetham Boddana. *Renal Dept, Gloucestershire NHS Foundation Hospitals, Gloucester, Gloucestershire, United Kingdom.*

Background: Haemodialysis is an extracorporeal blood treatment for Renal Failure that requires effective anti-coagulation in order to prevent loss of the blood circuit due to clotting. A haemodialysis blood circuit contains approximately 250ml of blood, equivalent to 1 unit of packed cells. In routine Haemodialysis, this is achieved by the administration of Heparin, or its equivalent, during the treatment, which may be up to four hours duration. In the Acute setting, the administration of Heparin may be contra-indicated for a number of reasons – pre or post surgery, post-stroke, Gastro intestinal bleeds, deranged clotting factors, and so on. Care must then be taken to avoid loss of blood in the dialysis circuit.

Methods: Observational study looking at the effectiveness of traditional anti coagulation strategies such as saline flushes in acute haemodialysis had shown increased frequency of blood circuits lost on dialysis. Over a period of 4 weeks, we used pre-dilution haemodiafiltration instead of conventional post dilution haemodialfiltration. This modality dilutes the blood just before it passes through the dialysis filter. As the majority of the clotting starts as the blood passes along the filter membranes, diluting the blood at this point would theoretically reduce the amount of clotting occurring.

Results: By using this technique, we were able to reduce the number of clotted circuits from 100% down to just 30%, with only 10% leading to loss of the entire blood circuit. There was no significant change in the effectiveness of the treatment, and no significant increase in the cost of the treatment provided.

Conclusions: Over the next few months, we were able to improve on these outcomes still further, by optimizing the variables, and in some cases, adding saline flushes in addition to the pre-dilution HDF. Having used this technique now for some hundreds of treatments, we have reduced the number of blood circuits lost to all but zero. Hence this has become a highly effective technique which has drastically improved patient outcomes, reduced the need for blood transfusions, and saved money without cost implications.

TH-PO116

Nationwide Use of Hemodialysis and Other Extracorporeal Therapies in Poisoned Patients, 2006-2013

Joshua D. King,[1,2] Priyanka Vakkalanka,[1] Diana M. Robinson,[3] Christopher Holstege.[1] *[1]Div of Medical Toxicology, Univ of Virginia, Charlottesville, VA; [2]Div of Nephrology, Univ of Virginia, Charlottesville, VA; [3]Dept of Psychiatry, Univ of Virginia, Charlottesville, VA.*

Background: Nationwide use of extracorporeal therapies (ECT) in poisoned patients has not been characterized since 2005. The purpose of this study was to review the use of hemodialysis (HD), hemoperfusion (HP), and other ECT in poisoned patients throughout the United States from 2006 until 2013.

Methods: The National Poison Data System (NPDS) was queried for all poisoning cases reported to U.S. poison centers between 2006 and 2013 where HD, HP, or other ECT was performed. Data analyzed included demographics and geography, clinical characteristics, exposure chronicity, and reported substances used by patients. The annual prevalence of each therapy per 1,000,000 human exposures was evaluated. The top 30 substances reported among all deaths were characterized among patients receiving HD.

Results: There were 18,252 patients who received ECT, of which 17,900 (98.0%) received HD, 257 received HP, and 214 received some other ECT. The patient population was predominantly 40-59 years of age (45.0%). Poisonings were acute in 56.7% of patients. The prevalence of ECT (per million human exposures) was 865 in 2006 versus 1,140 in 2013. The substances most frequently identified among patients receiving HD included ethylene glycol (n=3,828), lithium (n=3,385), sedatives (n=2,711), salicylates (n=2,352), and opioids (n=1,783). Overall, 9.4% of patients receiving ECT for poisoning died. The three leading substances reported among all deaths included acetaminophen (22.1%), opioids (18.3%), and sedatives (15.3%).

Conclusions: The use of HD in the management of poisoning has continued to increase. While ethylene glycol, lithium, and salicylates remain frequent indications for dialysis, HD seems to be used more often in a supportive role as well given the number of patients treated for opioid and sedative poisoning. We were not able to distinguish the use of intermittent HD versus continuous renal replacement due to database limitations. Hemoperfusion has continued to be rarely used.

TH-PO117

Dialysis Treatment Options for Acute Kidney Injury in the Canadian Intensive Care Unit: A Systematic Review and Cost-Utility Analysis

Danielle Marie Nash,[1,2] Ron Wald,[4] Michel Louis Grignon,[1] Sebastian Przech,[3] Daria O'Reilly.[1] *[1]Clinical Epidemiology and Biostatistics, McMaster Univ, Hamilton, ON, Canada; [2]Kidney, Dialysis and Transplantation Program, Inst for Clinical Evaluative Sciences, ON, Canada; [3]Epidemiology and Biostatistics, Univ of Western Ontario, London, ON, Canada; [4]Medicine, Univ of Toronto, Toronto, ON, Canada.*

Background: Up to 67% of all patients admitted to the intensive care unit (ICU) will develop acute kidney injury (AKI). Treatment for these patients is very expensive. For example, in the United States, the incremental health care costs attributed to AKI are upwards of $10 billion USD per year. In this health economic analysis, we simulate the cost per quality-adjusted life year (QALY) gained comparing three dialysis treatments for patients with AKI in a Canadian ICU setting: continuous renal replacement therapy (CRRT), intermittent hemodialysis (IHD), and sustained low efficiency dialysis (SLED).

Methods: A decision analytic model, with a 1-year time horizon, was developed to compare the incremental cost per QALY gained for the three dialysis modalities. The model used a public payer perspective, with Canadian costs and relevant utility values obtained from targeted searches of the literature. A systematic review of randomized controlled trials was performed to determine the clinical parameters for the model, including the probability of in-hospital death, dialysis dependence and death at one year post-discharge. One-way sensitivity analyses were performed by varying all parameters by +/- 10%.

Results: The incremental cost per QALY gained for SLED compared to IHD was $68,501. Compared to IHD and SLED, CRRT was extendedly dominated (i.e. it is more

cost-effective to provide SLED to some of the eligible patients and IHD to the remaining patients than to provide CRRT). The sensitivity analyses showed that the results are generally robust across a wide-range of parameter values.

Conclusions: Similar to previous economic evaluations, these results suggest that CRRT is not cost-effective compared to IHD. A novel finding is that SLED may be cost-effective depending on the willingness-to-pay threshold.

TH-PO118

Efficacy of Acute Peritoneal Dialysis (PD) Over Sustained Low Efficiency Dialysis (SLED) in Critically Ill ICU Patients with Acute Kidney Injury – A Comparative Study Mitul Bora. *Nephrology, Ayur Sundra Super Speciality Hospital, Guwahati, Assam, India.*

Background: Acute peritoneal dialysis (PD) has largely been replaced by continuous renal replacement therapies (CRRT) and sustained low efficiency dialysis (SLED) in critically ill ICU patient.

Methods: Patient admitted in the ICU with acute kidney injury and multiple organ dysfunction were included in the study irrespective of the etiology of renal failure. Patients were randomly divided in to two group. Group A patients received acute PD and group B patients received SLED. Primary outcomes were correction of uremia, metabolic acidosis, fluid overload, dyselectrolytemia, and mortality. Secondary outcomes were improvement in sensorium, hemodynamic stability, ICU length of stay, cost of treatment and duration of mechanical ventilation.

Results: 116 were enrolled in this study. The mean age was 41.23±11.56 years in group A where it was 45.87± 13.45 years in group B. Average duration of dialysis was 72.80± 67.90 and 19.07 ± 11.08 hours in PD and SLED group respectively. Correction of uremia [Urea 24.78± 10.31 ml/min vs 26.23 ± 9.34 ml/min, creatinine 8.89 ± 3.78 ml/min vs 9.98± 7.09 ml/min, p value <0.001) were similar. Significant acidosis was present in 36 patients in Group A (92%) and in 23 patients (28%) in Group B. SLED had a better correction of acidosis in comparison to PD. Correction of fluid overload was faster in SLED and net ultrafiltration was significantly higher in group B (22.21±21.67 L vs 4.87±5.09 L in group A, P<0.001). No significant differences were seen in correction of hyperkalemia, altered sensorium. PD group had a better hemodynamic stability. Mortality was almost similar in both the groups (81% v 76%). Renal function recovery (21% vs 24%) were also similar. Acute Physiology and Chronic Health Evaluation II score was similar (25.8±5.4 versus 23.9±7.9) and also the duration of ventilatory support (11.9 ±7.3 vs 13.5± 8.7 days). Cost of treatment was much cheaper in the PD group.

Conclusions: Acute PD still remains as a viable alternative to SLED in critically ill patients in low cost setting. Advantages are its low cost, ease of administration, needs less expertisation and its metabolic and clinical outcomes are not inferior to SLED.

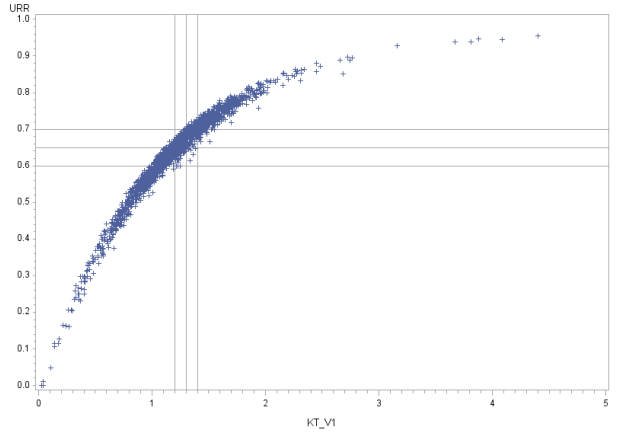
TH-PO119

Measurement of Adequacy of Intermittent Hemodialysis in Acute Kidney Injury: Is There a Simpler Approach? Kelly V. Liang,[1] Jane Hongyuan Zhang,[2] Paul M. Palevsky.[3] *[1]Renal-Electrolyte Div, Univ of Pittsburgh, Pittsburgh, PA; [2]Cooperative Studies Program Coordinating Center, VA Connecticut Healthcare System, West Haven, CT; [3]Renal Section, VA Pittsburgh Healthcare System, Pittsburgh, PA.*

Background: The KDIGO Guideline for Acute Kidney Injury (AKI) recommends a minimum single pool Kt/V_{urea} of 1.3 when intermittent hemodialysis (IHD) is delivered thrice weekly. However, Kt/V in AKI is complicated by uncertainty regarding volume of distribution of urea and non-steady state rates of urea generation. In the Acute Renal Failure Trial Network (ATN) Study, adequacy of IHD was assessed using Kt/V. Using data from the ATN Study, we assessed whether the simpler urea reduction ratio (URR), which does not require assessment of volume status, would provide sufficient correlation with Kt/V to provide a reliable assessment of adequacy of hemodialysis in AKI.

Methods: Using data from IHD in the ATN Study, values of URR were plotted against Kt/V. We determined URR thresholds corresponding to Kt/V values ≥ 1.2, 1.3, and 1.4 and generated receiver operating characteristic (ROC) curves at each level of Kt/V to identify optimal URR thresholds.

Results: There was tight correlation between URR and Kt/V (figure).



The area under the ROC curves were 0.99 for all three Kt/V thresholds. The sensitivity and specificity of $URR^{3}0.67$ for corresponding values of $Kt/V^{3}1.2$ were 0.769 (95% CI 0.745 to 0.793) and 0.999 (95% CI 0.997 to 1.000), and for corresponding values of $Kt/V^{3}1.4$ were 0.998 (95% CI 0.995 to 1.000) and 0.791 (95% CI 0.771 to 0.811), respectively.

Conclusions: A URR $^{3}0.67$ provides a specificity of 0.999 that the corresponding value for Kt/V is $^{3}1.2$ and a sensitivity of 0.998 that the corresponding value of Kt/V is $^{3}1.4$. Therefore, this URR threshold provides a simplified means of assessing adequacy of IHD provided for management of AKI in the acute care setting.

TH-PO120

A Novel Treatment for Edema and Fluid Overload: Transdermal Removal of Interstitial Fluid Leonard Ebah,[1,2,3] Paul E. Brenchley,[1,2,3] Sandip Mitra,[1,2,3] Idalia Dawidowska.[3] *[1]Renal Medicine and Research, Manchester Royal Infirmary, Manchester, United Kingdom; [2]Inst of Cardiovascular Sciences, Univ of Manchester, Manchester, United Kingdom; [3]Renephra Limited, Manchester, United Kingdom.*

Background: Fluid overload is highly prevalent in kidney and heart failure, contributing to worse outcomes. Diuretics are the mainstay of treatment; they sometimes become ineffective requiring intravenous treatment and/or invasive approaches to fluid removal such as dialysis. Transdermal fluid removal from interstitial fluid (ISF), the main fluid reservoir in these overloaded patients presents a potentially attractive elegant solution to fluid removal in these patients.

Methods: Plastic solid microneedle arrays and standard hypodermic needles were tested as methods of accessing epidermal ISF whilst vacuum pressure and superabsorbent wound dressings were investigated as fluid flow enhancers.

Results: 144 interventions were performed, with 71 (49%) resulting in the extraction of at least 1ml of ISF and 36 (25%) at least 5ml. Microneedle access was superior with spontaneous significant flow of ISF in 56% of cases compared to 10% for hypodermic needles (p<0.0001). Vacuum pressure correlated with extracted ISF volume; r=0.42, p=0.03. ISF volume also increased linearly with time (r=0.24, p=0.008) by the equation volume(ml)=5.7t(hrs)-4.5. Of the patient characteristics, edema grade (r=0.46, p=0.003), edema refill time (r=0.28, p=0.01) and serum albumin (r=-0.33, p=0.004) were significantly related to ISF volume extracted. ECFV/TBW was the strongest correlate of ISF volume extraction (r=0.40, p=0.0001). With a Bio-ratio of 0.50 or higher, the OR for extracting 5ml of more was 10.4 [3.4-31]. Microneedle access with suction and a high Bioratio could achieve ISF extraction rates of 2ml/cm2/hr which equates to 800ml over 4 hours using a 10by 10cm skin surface. The microneedle interventions were safe, painless and bloodless.

Conclusions: Microneedle access with vacuum pressure seems promising as a potential safe, minimally invasive transdermal treatment of significant fluid overload. Further evaluation to refine device characteristics and clarify patient stratification may lead to a potential clinical utility of such a device.

TH-PO121

Comprehensive Program to Treat Acute Kidney Injury (AKI) Using Peritoneal Dialysis (PD) in Developing Countries John Callegari,[1,2] Grzegorz Wystrychowski,[3] Nathan W. Levin,[1,2] Ewa Zukowska-szczechowska,[3] Mary Carter.[1,2] *[1]Renal Research Inst, New York, NY; [2]Sustainable Kidney Care Foundation, New York, NY; [3]Dept of Internal Medicine, Diabetology and Nephrology, Medical Univ of Silesia, Zabrze, Poland.*

Background: HD as a therapy for acute kidney injury (AKI) is unavailable in most developing countries due to lack of trained staff, equipment, electricity, water treatment, and funding. However, peritoneal dialysis (PD) can be established in almost any setting as a cheaper modality that requires few resources. A team of pediatric & adult nephrologists with nurses, a functional laboratory, and delivery of PD catheters and supplies. Nephrologists shoudl be trained to place single cuff Tenckhoff catheters.

Methods: In compliance with these prerequisites, AKI PD programs have been started in Benin, Ghana, Tanzania, Cameroon, Ivory Coast, Ethiopia, Uganda and Cambodia with support provided by the Sustainable Kidney Care Foundation (SKCF) and the Saving Young Lives consortium comprised additionally by the International Society of Nephrology (ISN), International Society for Peritoneal Dialysis (ISPD), International Pediatric Nephrology Association (IPNA).

Results: So far, 129 AKI patients were treated with PD in these countries. Aproximately 55% recovered kidney function and were discharged with no need of further dialysis; nearly 20% were diagnosed with end-stage renal disease and referred to hemodialysis where available or given palliative care; 1 in 4 patients died during hospitalization (table 1). Peritonitis rates were 12.3% and were not a factor in outcomes (logistic regression analyses).

	Total Patients	Died		Restored Kidney Function		ESRD		Peritonitis	
Location		N	%	N	%	N	%	N	%
Abidjan, Ivory Coast	11	3	27.3%	5	45.5%	3	27.3%	2	18.2%
Cotonou, Benin	24	5	20.8%	16	66.7%	3	12.5%	3	12.5%
Accra, Ghana	8	2	25.0%	5	62.5%	1	12.5%	1	12.5%
Kumasi, Ghana	61	20	32.8%	30	49.2%	11	18.0%	3	4.9%
Moshi, tanzania	23	4	17.4%	14	60.9%	5	21.7%	7	30.4%
Bahmenda, Cameroon	11	1	9.1%	6	54.5%	4	36.4%	1	9.1%
Totals	138	35	25.4%	76	55.1%	27	19.6%	17	12.3%

Conclusions: PD is a viable treatment modality in low-resource settings and decreases mortality rates in the course of AKI to the levels seen in developed countries. The frequency of PD-related peritonitis is low and does not affect treatment outcomes.

Funding: Private Foundation Support

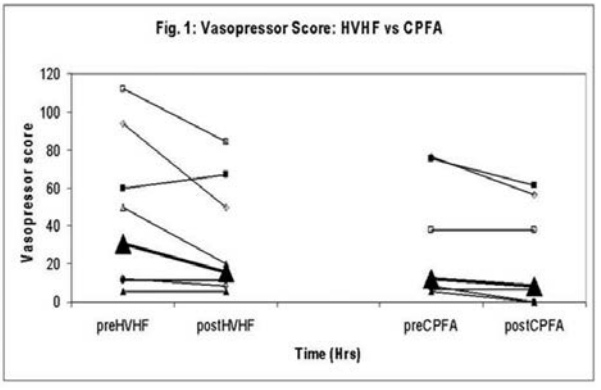
TH-PO122

Pulse High Volume Hemofiltration versus Coupled Plasma Filtration Adsorption in Septic Shock – A Pilot Randomized Study Paolo Lentini,[1] Luca Zanoli,[2] Massimo de Cal,[1] Stefania Rastelli,[2] Andrea Contestabile,[1] Antonio Granata,[3] Roberto Dell'Aquila.[1] *[1]Nephrology, St. Bassiano Hospital, Bassano Del Grappa, Italy; [2]Univ of Catania, Italy; [3]St. Giovanni di Dio, Italy.*

Background: Acute kidney Injury(AKI),a frequent complication in critically ill septic patients is an independent risk factor for increased mortality, particularly when patients require renal replacement therapy(RRT).High Volume Hemofiltration (HVHF) and Coupled Plasma Filtration Adsorption(CPFA)have shown potential improvement in hemodynamics:however, no studies have compared these two methods.Our aim was to compare the hemodynamic effects of HVHF and CPFA in septic shock patients undergoing Continuous Renal Replacement Therapy (CRRT).

Methods: A cross-over study enrolling pts with septic shock undergoing CRRT. Pts were treated with pHVHF+CVVH on Day 1 and CPFA+CVVH on Day 2. HVHF was performed for 8-10 hrs with a replacement fluid rate (Qr) of 85 ml/kg/hr. CPFA was performed for 8-10 hrs using Mediasorb (Bellco®Italy) with a maximum plasma flow rate of 15%. CVVH was performed for the rest of the day with a Qr of 35 ml/kg/hr. Both HVHF and CVVH used polysulfone filters. The primary endpoints were changes in vasopressor requirement (expressed as vasopressor score, VS), in noradrenaline (NA) dose (mg/kg/min), and in mean arterial pressure (MAP) before and after pHVHF and CPFA. These values were compared using nonparametric paired tests.

Results: 8 pts(5M/3F,70.5 yr,SOFA 12.5,SAPS II 69.5).VS and NA dose were significantly decreased after CPFA(p=0.04).These endpoints were not significantly different after pHVHF(p=0.13).When CPFA and pHVHF are compared between each other,the change in VS and NA dose becomes NS (p=0.22).There was no significant change in MAP with either pHVHF or CPFA.



Conclusions: The data provide no evidence for a difference in hemodynamic effects between pHVHF and CPFA in patients with septic shock undergoing CRRT.

TH-PO123

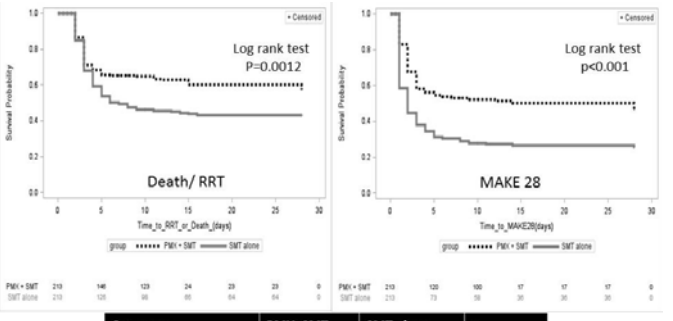
Polymyxin B Hemoperfusion and Renal Outcomes in Septic Shock: A Propensity-Matched Analysis Dinna Cruz,[1] Jing Zhang,[1] Tsukasa Nakamura.[2] *[1]Univ of California San Diego; [2]Shinmatsudo Hospital, Japan.*

Background: Septic acute kidney injury (AKI) is a common ICU complication with high mortality. Only supportive management is available at this time. Hemoperfusion with Polymyxin B fiber column (PMX) reduces blood endotoxin levels & vasopressor requirement, & increases blood pressure. These may improve renal perfusion & decrease renal tubular cell apoptosis. We hypothesized that PMX may improve renal outcomes in sepsis.

Methods: Single center retrospective study of 697 septic shock patients. Patients were treated with PMX (n=337) if they met all criteria: SIRS, documented/suspected infection, vasopressors despite adequate fluid resuscitation, ³1 organ failure, Gram(-) organism &/or elevated endotoxin levels; 360 pts were treated with standard medical therapy (SMT) alone. PMX patients were matched 1:1 with SMT patients, based on a propensity score for the likelihood of receiving PMX. Groups were compared using survival curve analysis & Cox regression for: 1) death or need for RRT at 28-days, and 2) Major Adverse Kidney Events (MAKE28): death, need for RRT, or ³1 point increase in renal SOFA score.

Results: Propensity score matching created a matched cohort of 426 patients. The PMX & SMT groups were well-matched in terms of baseline characteristics, including initial ICU Cr, endotoxin levels, type of organism, & APACHE score. The risk of death/RRT and MAKE28 was significantly lower among PMX patients (Figure). On multivariable analysis, PMX was associated with lower risk for death/RRT (adj HR 0.48, 95%CI 0.36,0.65) and MAKE28 (adj HR 0.48, 95%CI 0.37,0.61). Peak & nadir Cr, ICU & hospital length of stay were also lower in PMX group.

Conclusions: In this retrospective study, PMX, when added to SMT, was associated with better renal outcomes in septic shock. These results warrant further exploration with prospective trials.



Outcomes	PMX+SMT	SMT alone	p
Peak Cr (mg/dl)	2.2 (1.8,3.3)	3.0 (1.2,1.8)	<0.001
Nadir Cr (mg/dl)	1.1 (0.8,1.4)	1.5 (1.2,1.8)	<0.001
Peak minus baseline Cr	0.1 (0,0.4)	0.8 (0.3,1.6)	<0.001
Peak minus nadir Cr	1.0 (0.8,1.6)	1.6 (1.0,2.3)	<0.001
ICU days	6 (4,8)	11 (7,14)	<0.001
Hospital days	21 (14,31)	28 (14,44)	<0.001

TH-PO124

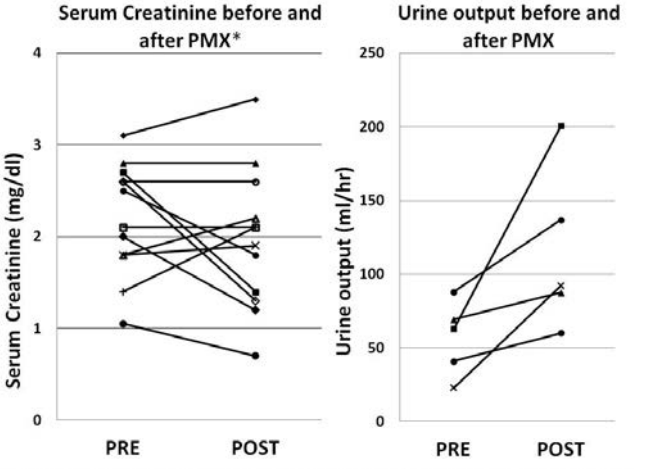
Effect of Polymyxin B Hemoperfusion on Septic AKI: A Systematic Review Dinna Cruz, Deepti Mundkur, Ravindra L. Mehta. *UCSD, San Diego.*

Background: Septic acute kidney injury(AKI) is common in the ICU, and associated with high mortality. Polymyxin B fiber column(PMX) is a medical device that reduces blood endotoxin levels in sepsis. In a prior metaanalysis, PMX hemoperfusion was shown to improve blood pressure and reduce vasopressor requirement, which could help renal perfusion. PMX possibly reduces proapoptotic activity of septic plasma on renal tubular cells. A systematic review was performed to assess renal outcomes when PMX is used in sepsis.

Methods: We searched MEDLINE, PubMed to identify studies on PMX hemoperfusion in sepsis. Full-text articles were screened for renal-related outcomes. The primary endpoint was need for acute RRT after enrollment. Secondary endpoints included development of AKI, change in Cr, BUN, urine output, urine protein and biomarkers after PMX.

Results: A total of 18 studies (n=591 pts) with renal outcomes were identified. In 6 RCTs & 1 non-RCT, patients were treated with either PMX+standard medical therapy(SMT) (n=188) or SMT alone (n=136). In 10 cohort studies 267 pts were treated with PMX+SMT. The following renal outcomes were reported: need for RRT (n=4 studies), serum Cr &/or CrCl (n=10), BUN (n=4), urine output (n=5), urine protein/biomarkers (n=6). One study reported severe AKI (Failure) in 0/8 PMX and 1/8 SMT patients at 72h. Pooled analysis showed a non-significant trend for reduced need for RRT with PMX (OR 0.44, 95%CI 0.19,1.04). Figure 1 shows Cr and urine output before and after PMX. Weighted mean difference for Cr after PMX was not significant but there was an increase in urine output by 45 ml/hr (95%CI 15,74) after PMX.

Conclusions: Based on published studies, PMX has no significant effect on RRT need or Cr in patients with septic shock when added to SMT, although urine output appeared to improve post-PMX. These data provide evidence for scientific equipoise for a randomized clinical trial to address this question.



*2 studies reported summary Cr values separately for survivors and non-survivors

TH-PO125

Four Hour Infusion Piperacillin-Tazobactam in CRRT Patients Is Associated with Improved Target Attainment Compared to 30 Minute Infusion Matthew S. Shotwell,[1] Ed Gould,[2] Phillip Madonia,[2] Ross Marshall Nesbit,[2] Charbel A. Salem,[3] Milen Amde,[3] Olufemi Aduroja,[3] Seth R. Bauer,[4] Michael J. Connor,[3] Joseph J. Groszek,[2] Maria E. Taylor,[5] Peilin Wei,[5] Ashita J. Tolwani,[5] William Henry Fissell.[2] *[1]Biostatistics, Vanderbilt Univ, Nashville, TN; [2]Nephrology and Hypertension, Vanderbilt Univ, Nashville, TN; [3]Nephrology and Hypertension, Cleveland Clinic, Cleveland, OH; [4]Pharmacy, Cleveland Clinic, Cleveland, OH; [5]Nephrology, Univ of Alabama, Birmingham, Birmingham, AL.*

Background: Sepsis is the leading cause of death in acute kidney injury. Dose adjustments to account for kidney failure and continuous renal replacement therapy (CRRT) may result in poor target attainment. Four hour infusion (EI) of beta lactams may result in improved target attainment compared to 30 minute infusion (SI). We conducted a multicenter observational study of piperacillin pharmacokinetics in patients receiving CRRT and compared predicted target attainment in a typical patient receiving EI or SI.

Methods: Piperacillin concentrations were measured in subjects at Cleveland Clinic (3 gm q6h, q8h, or q12h SI; n=29) University of Alabama Birmingham (2 gm q6h or q8h, 3g q6h SI, n=25) and Vanderbilt University (3 gm q8h or q12h, EI; n=14). A two-compartment pharmacokinetic model was fitted simultaneously to all data using nonlinear mixed effects regression in R. Target attainment was quantified as the fraction of the dosing cycle wherein piperacillin concentration was greater than 64 µg/mL. Target attainment for a typical patient was estimated using the population mean (fixed-effect) for each pharmacokinetic parameter.

Results: For EI versus SI in the two most common dosing patterns, 2g q6h and 3g q8h, target attainment was improved by 27% (95% CI: 19, 35) and 23% (95% CI: 18, 28), respectively.

Conclusions: Limits of the study include that it is solely observational, and that subjects in Cleveland and Birmingham were enrolled earlier than subjects in Nashville. These results characterize the typical patient in this population. Additional analysis is warranted to examine the sensitivity of our findings to population pharmacokinetic heterogeneity.

Effects of Complement Factor H and Factor I Deficiency on Anti-MPO Induced Crescentic Glomerulonephritis in Mice Hong Xiao,[1] Peiqi Hu,[1] Cheng Wan,[1] Matthew C. Pickering,[2] Ronald J. Falk,[1] J. Charles Jennette.[1] *[1]Pathology and Laboratory Medicine, Univ of North Carolina, Chapel Hill, NC; [2]Molecular Genetics, Imperial College, London, United Kingdom.*

Background: Complement alternative pathway (AP) activation plays a critical role in the pathogenesis of anti-neutrophil cytoplasmic autoantibodies (ANCA) crescentic glomerulonephritis (CGN). AP is negatively regulated by complement factor H (CFH) and factor I (CFI). Deficiency of either of these regulators results in uncontrolled C3 activation with secondary depletion of C3, factor B and properdin. In this study, we investigate the effects of CFH and CFI deficiency in anti-MPO induced CGN in mice.

Methods: 9-11 wk-old CFH and CFI KO and WT B6 mice were injected with anti-MPO IgG and were sacrificed at day 6 and kidney tissue was obtained for pathologic examination and IF staining with anti-C3 antibodies. Circulating C3 levels were determined by ELISA. In vitro neutrophil function was assayed.

Results: At day 6 of anti-MPO treatment, all CFH-/- mice (n=5) developed much more severe CGN (mean 85% glomeruli with crescents) compared to the WT control mice (n=8, 11% crescents). In contrast, no CGN developed in CHI-/- mice (n=8). Glomerular C3 staining shown strong (score 4+) linear capillary wall staining in CFH-/- mice, whereas CHI-/- mice had weak (1.5+) mesangial staining. On day 0 and day 6 after anti-MPO treatment, the circulating C3 level had no significant differences in WT and CFI-/- mice ($p>0.05$) and substantially reduced in CFH-/- mice ($p<0.001$). *In vitro* neutrophil function assay showed that anti-MPO IgG caused similar activation of neutrophils from CFH-/-, CHI-/- and WT mice.

Conclusions: 1) Absence of the CFH causes more severe anti-MPO induced CGN. This is probably because they have uncontrolled alternative pathway activation and sufficient glomerular capillary wall deposition of complement activation fragments to synergistically attract and amplify anti-MPO activated neutrophils. 2) CHI deficiency protects from anti-MPO CGN. This might be because of no glomerular capillary wall C3 deposits and consumption of circulating AP components, such as factor B and properdin, as a consequence of uncontrolled AP activation.

Can a Bacterial Protein Rescue Disease-Linked Mutations in Complement Factor H? Heather Kerr,[1] Edwin K.S. Wong,[3] Andrew P. Herbert,[2] Anna Richards,[1] David Kavanagh,[3] Paul N. Barlow.[2] *[1]Centre for Inflammation Research, Univ of Edinburgh, Edinburgh, United Kingdom; [2]School of Chemistry, Univ of Edinburgh, Edinburgh, United Kingdom; [3]Inst of Genetic Medicine, Newcastle Univ, Newcastle, United Kingdom.*

Background: Factor H (FH) regulates the complement system. Mutations and polymorphisms in FH are implicated in atypical haemolytic uraemic syndrome and C3 glomerulopathies. Studies using short FH fragments suggested detrimental functional consequences of many disease-linked amino acid substitutions. The protein PspC from *Streptococcus pneumoniae* hijacks host-derived FH in a complement-evasion strategy. Binding of PspCN (N-terminal region of PspC) to wild-type (WT) FH was shown to enhance complement regulation implying that PspCN might restore useful levels of regulatory activity to disease-related variants of FH.

Methods: Overcoming technical hurdles to recombinant full-length FH production, two mutant versions, R53H and S1191A V1197L, were prepared in *Pichia pastoris*. Using surface plasmon resonance (SPR), binding of mutants to C3b, and their C3bBb decay-accelerating activities (DAA), were compared with WT FH. Mutants were also compared to WT FH in erythrocyte DAA and co-factor lysis assays. Measurements were repeated in the presence of PspCN.

Results: R53H decreased FH affinity for C3b and impacted negatively on both assays used to measure DAA as well as the haemolysis-based assay of co-factor activity. The double mutant had WT-like abilities to bind C3b and decay C3b convertase on an SPR chip, but was deficient in cell-based assays, and especially in co-factor activity. PspCN enhanced both C3b binding and DAA on the SPR chip by both mutants and WT. The effects of PspCN on cell-based assays were less clear.

Conclusions: These studies with full-length FH imply that disease-linked substitutions in its C-terminal surface-recognition region (unlike those in the functionally critical N-terminal region) have little effect on SPR-based assays performed on a non-native and hence, in effect, foreign surface. Whether the enhancing effects of PspCN in SPR-based assays can be replicated on host-cell surfaces has therapeutic implications and will be discussed in the light of ongoing measurements.

TH-PO128

Recombinant Complement Factor H in a Model of C3 Glomerulopathy Heather Kerr,[1] Andrew P. Herbert,[2] Talat H. Malik,[3] Anna Richards,[1] Paul N. Barlow,[2] Matthew C. Pickering.[3] *[1]Centre for Inflammation Research, Univ of Edinburgh, Edinburgh, United Kingdom; [2]School of Chemistry, Univ of Edinburgh, Edinburgh, United Kingdom; [3]Centre for Complement and Inflammation Research, Imperial College, London, United Kingdom.*

Background: C3 glomerulopathy (C3G) is an inflammatory renal disorder that is associated with abnormal complement alternative pathway activation. This includes deficiency of complement factor H (FH), the negative regulator of the alternative pathway. FH gene-targeted ($FH^{-/-}$) mice are a model of C3G and spontaneously develop reduced plasma C3 levels and abnormal deposition of C3 within the glomerulus. We tested the efficacy of recombinant murine FH (mrFH) to restore C3 regulation in $FH^{-/-}$ mice.

Methods: MrFH was produced in *Pichia pastoris.* Plasma-purified mFH or hrFH (human) was used as a control. In experiment 1, mice received an injection of mrFH or mFH and were culled at 24 hours. In experiment 2, mice received a daily injection of mrFH or hrFH for 10 days and were culled at 11 days.

Results: A single injection of mrFH resulted in increased plasma FH and C3 levels peaking at 6 hours. In mice receiving mFH, plasma FH and C3 levels remain elevated at 24 hours. Glomerular histology at 24 hours showed a decrease in glomerular C3 staining both for mice receiving mFH and mrFH. In experiment 2, mice receiving daily injections of either mrFH or hrFH exhibited elevated levels of both plasma FH and C3 at 24 hours, but these decreased to baseline within five days. All mice showed reduced C3 glomerular staining at 11 days. Mice receiving hrFH showed strong glomerular IgG staining at 11 days.

Conclusions: Restoration of complement regulation is the goal of treatment for C3G. In our experiments mrFH increased plasma C3 and FH levels and reduced glomerular C3 deposition. The rapid reduction in FH and C3 levels (relative to a slower decline in mice treated with plasma-purified FH) may be due to glycosylation differences between plasma-purified and recombinant protein. Administration of recombinant FH is a rational treatment choice for patients with C3G associated with deficiency or dysfunction of FH. However, the challenges of this approach include plasma half-life, immunogenicity and large scale production.

TH-PO129

Reduced Renal Infiltration of Inflammatory Cells following Selective Endothelial Injury in Mice Deficient for C3, C3aR or C5aR Jan Sradnick, Anika Luedemann, Vladimir T. Todorov, Christian Hugo, Bernd Hohenstein. *Div of Nephrology, Dept of Internal Medicine III, Univ Hospital CGC, Dresden, Germany.*

Background: Complement dysregulation leads to kidney specific diseases such as C3 glomerulopathy and thrombotic microangiopathy. However, data on the specific role of the complement system for local inflammation after endothelial cell injury (ECI) is limited. We here investigated the inflammatory response following site selective renal ECI in mice deficient (-/-) for C3, C3ar or C5ar.

Methods: Renal ECI was induced by intra-arterial injection of Concanavalin(ConA)/ anti-ConA in C3-/- (day (d) 2:n=5; d4: n=4), C3ar-/- (d2:n=5; d4: n=4), C5ar -/- (d2:n=4; d4: n=3) deficient and C57Bl/6 wildt-type (wt) mice (n=5; n=4). Six wt mice served as sham control (ctrl). Kidneys were harvested on day 2 or day 4. Multicolor FACS analysis was used to count macrophages (M), neutrophils (N) and T-cells (T). Cells were stained with the following antibodies: CD11b+ F4/80+ GR1- CD11c- (M), GR1+ CD11b+ (N) and CD4+ CD8+ (T). Histology was used to analyze macrophages (MAC2, F4/80) and the ECI (CD31).

Results: Inflammatory cells were increased in C57Bl/6 mice 2 days after ECI (C57Bl/6: M=1.3%±0.4; N=2.9%±1.0; T=0.8±0.3 vs. sham: M=0.1%±0.04; N=0.15%±0.09; T=0.2%±0.2; $p<0.01$). Compared to C57Bl/6 wt mice a reduced influx of macrophages (C3-/-: 0.3%±0.05; C3ar-/-: 0.4%±0.2; C5ar-/-: 0.5%±0.3) and neutrophils (C3-/-: 0.9%±0.74; C3ar-/-: 0.9%±0.9; C5ar-/-: 0.7%±0.5; ctrl: 0.15%±0.09) was observed in C3, C3ar and C5ar deficient mice ($p<0.01$). CD8+ cells were reduced in C3 -/- mice (C3-/-:0.3%±0.03

d2: wt:0.8%±0.33). Histological analysis using MAC2 and F4/80 support these findings. While histology demonstrated enhanced ECI, no differences in ECI were detected between C3, C3ar and C5ar and wt mice.

Conclusions: The recruitment of inflammatory cells into the kidney after selective ECI depends on the presence and function of C3, C3ar and C5ar. However, C3, C3ar and C5ar deficiency did not modulate the extent of ECI in this disease model.

TH-PO130

Investigating a Pathogenic Role of C5a-C5aR1 Signaling in Diabetic Nephropathy Sih Min Tan,[1,2] Vicki Thallas,[1] Alison Skene,[3] Richard J. MacIsaac,[4,5] David A. Power,[3,4] Mark E. Cooper,[1,2] Elif Ekinci,[3,4] Trent M. Woodruff,[6] Melinda T. Coughlan.[1,2] *[1]Diabetic Complication, Baker IDI Heart & Diabetes Inst, Melbourne, VIC, Australia; [2]Central Clinical School, Monash Univ, Melbourne, VIC, Australia; [3]Endocrine Centre, Austin Health, Melbourne, VIC, Australia; [4]Dept of Medicine, The Univ of Melbourne, VIC, Australia; [5]Dept of Endocrinology & Diabetes, St. Vincent's Hospital, Melbourne, VIC, Australia; [6]School of Biomedical Sciences, Univ of Queensland, Brisbane, Australia.*

Background: Complement 5a is a potent pro-inflammatory effector molecule. Although previous studies indicate a link between activation of the complement pathway and diabetic nephropathy (DN), the role of C5a and its receptor C5aR1 in DN has yet to be determined.

Methods: Complement signaling was characterized in type 1 diabetic (T1D) human, rat and mouse kidneys. C5a-C5aR1 signaling axis was inhibited by using the highly selective and potent C5aR1 antagonist, AcF-[OPdChaWR] (PMX53), in streptozotocin (STZ)-induced diabetic mice (2mg/kg/day, drinking water, 24 weeks, n=6-15 mice/group). C5 and C5aR1 were measured by qRT-PCR and immunohistochemistry. Urinary C5a and albumin were measured by ELISA.

Results: The expression of C5aR1 was increased in renal biopsies from patients with DN compared to healthy donor kidneys (4.2±1.3 vs 15.7±1.8%; p<0.001, n=9-23). C5aR1 expression was upregulated in the renal cortex of STZ-induced diabetic rats (1.0±0.1 vs 1.5±0.2 fold change; p<0.05) and spontaneously diabetic Ins2-Akita mice (1.0±0.1 vs 1.4±0.1 fold change; p=0.05) compared to controls. Urinary C5a was increased in the diabetic rats (181±56 vs 1153±297 ng/24hr; p<0.05) and Ins2-Akita mice (50±9 vs 151±32pg/24hr, p<0.01) after 16 and 26 weeks of diabetes, respectively and was associated with albuminuria (p<0.05). Blockade of C5aR1 signaling with PMX53 attenuated albuminuria in STZ-induced diabetic mice when compared to vehicle-treated diabetic controls (247±30 vs 74±28 µg/24hr; p<0.001).

Conclusions: The C5a-C5aR1 signaling is activated in human and experimental DN. A pilot study using PMX53 indicates that pharmacological blockade of C5aR1 is renoprotective in DN. Further studies are required to validate C5aR as a therapeutic target in DN.

Identification of Glycosaminoglycans That Inhibit Specific Complement Pathways Ditmer Talsma,[1] Romain Vives,[2] Marc Maj Seelen,[1] Coen A. Stegeman,[1] Jacob van den Born.[1] *[1]Nephrology, UMCG, Groningen, Netherlands; [2]Inst. for Struct. Biol., Univ of Grenoble, Grenoble, France.*

Background: Complement has been shown to play a role in renal diseases, such as hemolytic uremic syndrome, C3 glomerulopathy and renal transplantation. It is well known that heparin and other glycosaminoglycans (GAGs) reduce complement activation. However, no studies have yet compared the complement pathway specific inhibitory properties of a library of GAGs. We have tested over 70 different GAGs for their complement inhibiting potential and their specificity for either of the complement pathways.

Methods: 72 GAG-based polysaccharides were tested for their complement inhibiting potential in the Wieslab complement screening assay. To pinpoint the inhibitory effect of GAGs on the lectin pathway (LP), the interference of GAGs on the binding of MBL to mannan and further C4 activation was tested. GAGs were also tested in the Wieslab ficolin 3 screening kit to evaluate their effect on ficolin based LP activation. Direct binding of LP components to heparin was assessed by detecting MBL and MASP 1 & 2 after serum incubation to immobilized heparin-albumin.

Results: Unfractionated regular and partially desulfated heparin exhibit dose-dependent inhibitory potential of all three complement pathways, while small heparin and heparan sulfate (HS)-derived oligosaccharides show specific LP inhibition. These small heparin/HS derivatives do not interfere with the binding of MBL to mannan, but do inhibit the MASP-based activation of C4 and ficolin-3 mediated LP activation. We also find a dose-dependent binding of the MBL/MASP 1&2 complex to immobilized heparin-albumin, but not to albumin.

Conclusions: A large number of heparin(oids)block all three pathways of complement, however small heparin/HS oligosaccharides inhibit the LP of complement specifically, according to our data via the inhibition of the MASP enzymes. Our data also suggest that HS on cell surfaces and in basement membranes might act as a docking platform for the MBL-MASP complex. We speculate that GAG-derived polysaccharides may be useful as MASP specific LP inhibitors.

TH-PO132

Anti-GBM Antibody-Mediated Glomerular Injury Depends on Neutrophil Degranulation Dawn J. Caster,[1,2] Erik Korte,[1] Liliane Hobeika,[1] David W. Powell,[1] Kenneth R. McLeish.[1,2] *[1]Medicine, Univ of Louisville, Louisville, KY; [2]Dept of Veterans Affairs, Louisville, KY.*

Background: Acute proliferative glomerulonephritis (GN) induced by ANCA or by anti-GBM antibodies is neutrophil (PMN) dependent. In vitro studies suggested that endothelial injury induced by ANCA was dependent on PMN granule enzymes, not release of reactive oxygen species. To test the hypothesis that PMN degranulation is responsible for acute GN, degranulation was inhibited in an in vivo model of heterologous anti-GBM disease in mice.

Methods: After collection of urine for baseline protein excretion, two groups of 10 C57BL/6 mice received an intravenous injection of sheep anti-rat GBM (1.5 mg/ 25 g body weight) at time 0. One group also received an intravenous injection of a TAT-fusion protein, TAT-SNAP-23 (0.5 mg/kg body weight) at time 0 and 6 hr later. We showed previously that TAT-SNAP-23 inhibited PMN degranulation in vitro and in vivo. At 24 hr urine was collected for protein excretion, and then mice were sacrificed and kidney tissue prepared for histology. Urine protein was measured as the protein:creatinine (ug/mg). Glomerular proliferation and mesangial expansion were graded on a 0 to 4+ scale.

Results: Baseline urine protein:creatinine did not differ between groups (18 + 3.3 vs 22 + 3.5, untreated vs TAT-SNAP-23 treated). Anti-GBM induced a significant increase in proteinuria, and that increase was significantly inhibited by TAT-SNAP-23 treatment (376 + 108 vs 73 + 15, untreated vs TAT-SNAP-23 treated). By light microscopy there was no difference in proliferation (2.2 + 0.2 vs 2.0 + 0.2) or mesangial expansion 1.2 + 0.3 vs 1.2 + 0.2) between the two groups. By electron microscopy the degree of podocyte foot process effacement was reduced by TAT-SNAP-23 treatment.

Conclusions: We conclude that PMN degranulation plays a critical role in acute glomerular injury induced by anti-GBM antibody deposition. We postulate that proteinuria may result from direct podocyte damage by PMN granule enzymes.

TH-PO133

Shared and End Organ Specific Transcriptional Networks in Skin versus Kidney Biopsies in Systemic Lupus Celine C. Berthier, Jasmine N. Stannard, Emily M. Myers, Lori Lowe, Tamra J. Reed, Sean Eddy, Matthias Kretzler, J. Michelle Kahlenberg. *Univ of Michigan.*

Background: Patients with subacute cutaneous (sCLE) lesions have higher risk of lupus nephritis (LN) compared to those with discoid (DLE) lesions. We hypothesized that renal flares may be triggered via a crosstalk between skin and kidneys. To determine the potential factors contributing to this increased risk, we used systems biology approaches to integrate the regulatory events occurring specifically in sCLE and DLE and compared with those in LN.

Methods: Formalin-fixed paraffin-embedded tissue from 8 normal, 22 DLE and 24 sCLE rash biopsies were analyzed via microarrays. Gene expression profiles from 22 class III + IV LN and 14 healthy microdissected human renal biopsies (ERCB) were compared.

Results: Analyses using Genomatix and Ingenuity softwares highlighted a strong upregulation of IFNg associated pathways unique to DLE, and IL-4 a likely prominent DLE-specific regulator. Type I IFN signaling predominated in sCLE, with unique CD14, CCL-2,-20 chemokine expression. Respectively 415 and 435 genes were regulated in the same direction in the glomeruli of LN patients vs controls and in DLE and sCLE vs normal (q-value <0.01). The 85 genes regulated only in the LN glomeruli and DLE rashes represented a mainly down-regulated network highlighting MEP1B, CDH1 and CD8a as main nodes. Top pathways were epithelial adherens junction signaling. The 105 genes specific to LN glomeruli and sCLE showed a mainly up-regulated network with ITGB2, CD40, SYK, TIMP1 as major nodes. Ingenuity top pathway was crosstalk between dendritic cells and natural killer cells, both of which may play a role in cutaneous and renal lupus pathogenesis.

Conclusions: DLE and sCLE have overlapping and unique transcriptional expression signatures which may guide therapeutic decisions and predict renal involvement. Further analysis of these specific profiles may identify the molecular crosstalk mechanism between skin and kidneys, as well as targets for novel therapy of cutaneous lupus lesions which could help to prevent or delay the renal disease. Our data suggest an inflammatory cell crosstalk between skin and kidneys in sCLE, which may not happen in DLE.

Molecular Determinants of Myeloperoxidase-ANCA Glomerulonephritis: Transcriptomic Analysis Across Three Species Maja Lindenmeyer,[1] Hamad Al nuaimi,[2] Peter W. Hewett,[2] Viji Nair,[3] Caroline O.S. Savage,[2] Matthias Kretzler,[3] Mark Alan Little.[5] *[1]Klinikum Harlaching, Germany; [2]Univ of Birmingham, United Kingdom; [3]Univ of Michigan; [4]UMC Groningen, Netherlands; [5]TCD, Ireland.*

Background: Human myeloperoxidase (MPO)-ANCA vasculitis causes crescentic GN that results in glomerular destruction. This has been modelled in rats (EAV) and mice (MEV), although it tends to resolve spontaneously in these models with little glomerular scarring. To investigate conserved and divergent molecular pathways involved in glomerular injury we analysed the glomerular transcriptome in EAV, MEV and humans with MPO-ANCA vasculitis.

Methods: Glomeruli were microdissected from WKY rats immunised with MPO (EAV) or human albumin (control), from mice receiving anti-MPO (MEV) or BSA (control) antibodies raised in MPO-/- mice (n=5/group), and from patients with MPO-ANCA GN (n=7) and healthy controls (n=18). RNA expression was analysed on Affymetrix arrays. Differential regulation was assessed by ChipInspector and rodent/human orthologs identified using HomoloGene. After restriction of gene lists using co-citation at sentence level, the human network was used to overlap with mouse and rat networks using TALE. In 74 selected genes, regulation was confirmed by rtPCR.

Results: 3512, 1725 and 783 glomerular genes were significantly associated with GN in humans, mice and rats respectively. We observed overlap between human and mouse in 675 (12.9%), human and rat in 134 (3.1%) and across all 3 species in 179 (2.9%) genes. Of these 179 genes, 135 (75.4%) were differentially regulated in the same direction and 44 (24.6%) in opposite directions. We identified 12 canonical pathways (p value <0.001) conserved between human and mouse, and 5 between human and rat.

Conclusions: The transcriptomic profile in MEV was more similar to human disease than EAV. 2.9% of differentially regulated genes were conserved across all 3 species, with a quarter of these regulated in opposite directions between rodent and human. These data provide insights into both shared pathophysiology and mechanisms underpinning the divergent clinical phenotype between rodent and human MPO-ANCA GN.

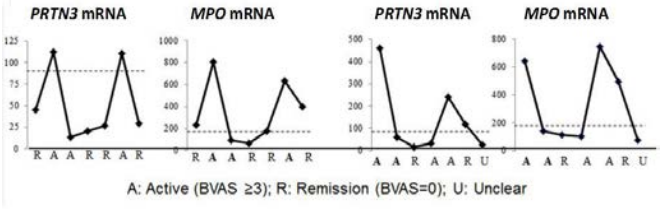
PRTN3 and _MPO_ Expression Correlates with Disease Activity in a Large Inception Cohort with Longitudinal and Serial Measurements Among Patients with ANCA Disease

Jia Jin Yang,[1] JulieAnne G. McGregor,[1] Elizabeth J. Brant,[1] Caroline J. Poulton,[1] Candace Henderson,[1] Britta E. Jones,[2] J. Charles Jennette,[2,1] Dominic J. Ciavatta,[3] Ronald J. Falk,[1,2] William Franklin Pendergraft.[1] *[1]Medicine, UNC-CH; [2]Pathology, UNC-CH; [3]Genectics, UNC-CH, Chapel Hill, NC.*

Background: We demonstrated aberrant up-regulation of autoantigen genes, *PRTN3* and *MPO*, in mature neutrophils and monocytes from patients with ANCA disease (J Am Soc Nephrol 2004, 15:2103-14). Here, we performed a longitudinal and serial analysis of *PRTN3 a*nd *MPO* expression following their disease course.

Methods: A total of 1063 leukocyte samples were collected from 152 ANCA-patients during various stages of disease activity and compared to 152 healthy controls. These patients were followed serially every 3 months over the past 5 years. Q-PCR was used to measure mRNA levels.

Results: *PRTN3* (155±506, p<0.0001) and *MPO* (384±940, p<0.0001) mRNA levels were significantly up-regulated in leukocytes from patients with ANCA disease compared to healthy controls (*PRTN3*:16±34; *MPO*:56±54). *PRTN3* and *MPO* gene transcription correlated closely with disease activity. In the majority of patients with systemic vasculitis, their disease course was characterized by elevated expression in active disease and reduced expression in remission. The duration of increased *PRTN3* and *MPO* expression was variable from several days to several months. Increased *PRTN3* and *MPO* mRNA levels returned to normal in all patients with stable remission.



However, low *PRTN3* and *MPO* mRNA levels were also observed in some active patients, particularly in those with limited organ involvement.

Conclusions: Our longitudinal and serial analysis of *PRTN3* and *MPO* expression in patients with ANCA disease indicates that regulation of *PRTN3* and *MPO* genes strongly tracks with disease activity suggesting that expression of these ANCA autoantigens is involved in disease pathogenesis.

Galactose-Deficient IgA1-Containing Immune Complexes Induce Proliferation of Human Mesangial Cells and Activate PDGF/PDGFR Signaling Pathway

Zhi qiang Huang,[1] Xianwen Zhang,[1,2] Qi Bian,[1,3] Joshua Charles Anderson,[1] Stacy D. Hall,[1] Christopher D. Willey,[1] Bruce A. Julian,[1] Jan Novak.[1] *[1]Univ of Alabama at Birmingham, Birmingham, AL; [2]Medicine, Longhua Hospital, Shanghai Univ of Traditional Chinese Medicine, Shanghai, China; [3]Medicine, Changhai Hospital, Second Military Medical Univ, Shanghai, China.*

Background: Our prior kinomic profiling showed that circulating immune complexes (CIC) and engineered immune complexes (EIC) consisting of galactose-deficient IgA1 (Gd-IgA1) bound by anti-Gd-IgA1 autoantibodies activated multiple tyrosine kinases in cultured human mesangial cells (hMCs) and induced cellular proliferation. Activation of PDGF signaling and an anti-apoptotic processes were two major processes detected. In this study, we assessed the mechanisms involving PDGF/PDGFR and ERK1/2 signaling in hMC stimulated with CIC from sera of patients with IgAN and EIC.

Methods: CIC were isolated from sera of IgAN patients using size-exclusion chromatography. EIC were prepared using Gd-IgA1, anti-Gd-IgA1 recombinant IgG1, and human serum and then isolated using size-exclusion chromatography. hMC proliferation was determined using bromodeoxyuridine (BrdU) uptake. Gene expression of PDGF A, PDGF B, PDGF receptor-α (PDGFR-α) and PDGFR-β was determined using RealTime RT-PCR. Signaling induced by CIC or EIC was assessed by analyzing cell lysates using SDS-PAGE and Western blotting.

Results: Twenty-four hour incubation of hMC with CIC increased cellular proliferation by 30-50%; incubation with EIC increased cellular proliferation by 30-40%. Incubation with CIC and EIC for 15 min and 24 h enhanced phosphorylation of PDGFR-β and ERK1/2. Incubation of hMC with CIC for 24 h enhanced expression of mRNA of PDGF A, PDGF B, and PDGFR-α. Incubation with EIC for 24 h enhanced expression of PDGFR-α and PDGFR-β.

Conclusions: CIC and EIC stimulated proliferation of hMC and activated PDGFR and ERK1/2 signaling. Understanding how CIC and EIC mediate signaling in hMC may lead to future therapeutic approaches for IgAN.

The Pathogenic Role of NLRP3 Inflammasome in IgA Nephropathy and Establishment of a Therapeutic Strategy

Shuk-Man Ka,[1] Yu-Juei Hsu.[2] *[1]School of Medicine, Graduate Inst of Aerospace and Undersea Medicine, National Defense Medical Center, Taipei, Taiwan; [2]Div of Nephrology, Dept of Internal Medicine, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan.*

Background: IgA nephropathy (IgAN) is the most common cause of primary glomerular disorders induced by IgA immune complex. Inflammatory responses have been shown to correlate with the progression of IgAN. NLRP3 inflammasome, a multiprotein complex, positively regulates caspase-1 activity and the maturation and release of IL-1β. NLRP3 inflammasome plays an important role in inflammatory response and controls the pathogenesis of various inflammatory diseases. However, the potential pathogenic role of NLRP3 inflammasome on IgAN is unclear.

Methods: The pathogenic role of NLRP3 inflammasome and molecular mechanisms on IgAN pathogenesis using NLRP3 deficient mice and NLRP3 in kidney were specific knockdown by an ultrasound-mediated microbubble shRNA gene transfer method.

Results: NLRP3 deficient and blockage resulted in attenuation of albuminuria, improved renal function, and blocking of renal progressive lesions, including glomerular proliferation, and periglomerular mononuclear leukocyte infiltration. These findings were associated with (1) inhibiting ROS production and NF-κB activation in the kidney, (2) reducing NLRP3 inflammasome activation in the kidney, (3) inhibiting effect/memory T-cell activation and IL-17 expression, and (4) inhibiting maturation and activation of dendritic cells.

Conclusions: These results indicate that activation NLRP3 inflammasome is involved in the development of IgAN, and a kidney-specific knockdown of NLRP3 may have therapeutic potential for IgAN.

Effects of DPPIV Inhibitor on Renal Function in Mice Model of Adriamycin Induced Nephropathy

Hye Sook Min,[1] Jin Joo Cha,[1] Kitae Kim,[1] Jungyeon Ghee,[1] Jung Eun Kim,[1] Ji Eun Lee,[2] Hyunwook Kim,[2] Jee Young Han,[3] Dae R. Cha,[1] Young Sun Kang.[1] *[1]Internal Medicine, Korea Univ Medical College Ansan Hospital, Republic of Korea; [2]Internal Medicine, Wonkwang Univ Sanbon Hospital, Republic of Korea; [3]Pathology, Inha Univ College of Medicine, Republic of Korea.*

Background: The murine model of adriamycin(ADR) induced nephropathy is characterized by severe proteinuria, development of podocyte injury and glomerulosclerosis. The aim of our study was to investigate the mechanism and preventive effect of fibrosis in glomerular, tubular and interstitial tissue associated with DA1229 treatment in ADR-induced nephropathy.

Methods: 6-week-old balb/c mice were divided into 4 groups as follows: 1) untreated after injection of ADR(control of group 2), 2) immediately treated with DA1229 for 3 weeks after injection of ADR(preventive protocol), 3) untreated after injection of ADR(control of group 4), 4) treated with DA1229 for 2 weeks after 3 weeks from injection of ADR(therapeutic protocol).

Results: Treatment with DA1229 showed preventive effect on weight gain and renal hypertrophy after 5 weeks of injection of ADR. Plasma DPPIV activity was significantly decreased in treatment with DA1229. DPPIV activity in kidney was significantly increased after injection of ADR and was decreased with DA1229. Notably, both preventive and therapeutic protocol significantly decreased proteinuria and albuminuria induced by ADR injection. Urinary excretion of nephrin was significantly decreased and inflammatory and fibrotic molecules in kidney tissue were significantly inhibited with DA1229 treatment. Additionally, infiltration of macrophages and fibrosis in the kidney were attenuated with DA1229 treatment in ADR groups.

Conclusions: Our data suggest that DA1229 might protect renal injury from podocyte injury in ADR-induced nephropathy, via antiinflammatory and antifibrotic effects. DA 1229 might be a potential therapeutic agent in a variety of glomerular disease inducing proteinuria.

Effects of Highly Selective Adenosine 3 Receptor Antagonist on Renal Function in Mice Model of Adriamycin Induced Nephropathy
Hye Sook Min,[1] Jin Joo Cha,[1] Kitae Kim,[1] Jung Eun Kim,[1] Jungyeon Ghee,[1] Ji Eun Lee,[2] Hyunwook Kim,[2] Jee young Han,[3] Sung Jin Kim,[4] Young Sun Kang,[1] Dae R. Cha.[1] *[1]Internal Medicine, Korea Univ Medical College Ansan Hospital, Republic of Korea; [2]Internal Medicine, Wonkwang Univ Medical College Sanbon Hospital, Republic of Korea; [3]Pathology, Inha Univ College of Medicine, Republic of Korea; [4]Internal Medicine, Anyang Sam Hospital.*

Background: Concentration of adenosine in normal kidney increases markedly during renal hypoxia and ischemia. Previous studies have reported that mice lacking renal A3 adenosine receptor(A3AR) show significant protection against acute kidney injury, such as ischemia-reperfusion injury and myoglobinuira-induced injury. Moreover, A3AR antagonist blocked the development and attenuated the progression of renal fibrosis. The aim of this study was to investigate the effects of highly selective adenosine 3 receptor antagonist(LJ1888) treatment in ADR-induced nephropathy.

Methods: We designed three animal groups as following: 1) 6-week-old balb/c mice(control), 2) untreated with LJ1888 after injection of ADR(11mg/kg), 3) treated with LJ1888(10mg/kg) for 2 weeks after 5 weeks of injection of ADR.

Results: Body weight was significantly decreased in both ADR injection groups. ADR injection significantly induced proteinuria and albuminuria, which were notably reduced after treatment of LJ1888. Urine 8-isoprostane and kidney lipid peroxidase level were also decreased with LJ1888. Urinary excretion of nephrin was significantly reduced and kidney nephrin stain showed increased nephrin expressions in the glomeruli of LJ1888 group. Less glomerular injury and macrophage infiltration were observed in LJ1888 treated kidney. Immunoreactions with profibrotic molecule were significantly decreased with LJ1888. Additionally, protein expressions of Nox4, TGF-b1, NF-κB were attenuated with LJ 1888.

Conclusions: These renoprotective effects of LJ1888 on ADR-induced nephropathy may be associated with protective effect on podocyte injury. LJ1888 might be a potential therapeutic agent for glomerulonephropathy inducing proteinuria.

Innate Immunity Is Activated Early in Adriamycin Nephropathy and Is Strongly Associated with Lymphocyte Infiltration
Viviane D. Faustino, Simone CA Arias, Flavia P. Albuquerque, Camilla Fanelli, Victor F. Avila, Lisienny CT Rempel, Orestes Foresto-Neto, Gizely CS Moreira, Claudia R. Sena, Vivian L. Viana, Denise M. Malheiros, Niels OS Camara, Roberto Zatz, Clarice K. Fujihara. *Univ of Sao Paulo, Brazil.*

Background: Protein overload promotes interstitial injury by unclear mechanisms that may involve innate immunity (INIM). Here we investigated the time course of INIM activation in adriamycin nephropathy (AN), and the participation of lymphocytes (LY) in this process.

Methods: AN (5 mg/kg iv) was induced in 30 Munich-Wistar rats. Control rats (C, N=10) received saline only. At 2 (AN_{2wk}), 4 (AN_{4wk}) and 20 (AN_{20wk}) wks, albuminuria (ALB, mg/day), interstitial macrophages (MΦ) and LY (cells/mm^2), α-SMA and collagen (COL). Renal INIM was assessed by gene expression (NLRP3 and IL-6, $2^{-\Delta\Delta Ct}$) and protein content (IL-1β, Casp1, TLR4). Four additional AN rats received mycophenolate mofetil (MMF, 10 mg/Kg/day, vo), and their ALB, LY, α-SMA, COL and renal content of IL-1β, Casp1 and TLR4 were assessed at 30 days.

Results:

	C	AN_{2wk}	AN_{4wk}	AN_{20wk}
ALB	4±2	336±34[a]	356±49[a]	505±34[abc]
MΦ	10±2	213±50[a]	188±29[a]	272±49[abc]
LY	19±5	149±23[a]	188±18[a]	234±22[abc]
%α-SMA	2±1	9±2[a]	12±2[a]	19±3[abc]
%COL	3±1	10±3[a]	13±2[a]	27±2[abc]
IL-1β	0.5±0.1	1.3±0.4	1.8±0.4[a]	4.4±0.9[abc]
NLRP3	1.0±0.1	1.8±0.3[a]	2.4±0.3[a]	2.1±0.2[a]
Casp1	1.0±0.2	1.6±0.3	1.5±0.5	4.0±0.6[abc]
TLR4	1.0±0.2	3.4±0.9[a]	3.4±1.0[a]	8.5±1.4[abc]
IL-6	1.0±0.1	8.1±2.7[a]	8.5±2.3[a]	12.0±1.9[a]

Mean±SE, [a]p<0.05 vs C, [b]p<0.05 vs. AD2wk , [c]p<0.05 vs. AD4wk

Massive ALB promoted early and intense MΦ/LY infiltration and % α-SMA/COL, and activated renal INIM. Ly correlated strongly with INIM parameters. All parameters increased with time. MMF treatment significantly reduced LY (81±12), α-SMA (4±1) and COL (6±1), without changing ALB.

Conclusions: In AN, INIM is activated in concomitance with the early development of renal injury, and relates strongly with lymphocyte infiltration. Both inflammation and INIM activation parallel the progression of renal injury in tis model. FAPESP/CNPq.

TH-PO141

Inhibition of NF-κB Signaling in Podocytes Ameliorates Albuminuria in Adriamycin-induced Nephropathy
Tadashi Yoshida, Maho Yamashita, Matsuhiko Hayashi. *Apheresis and Dialysis Center, Keio Univ School of Medicine, Shinjuku, Tokyo, Japan.*

Background: Inflammation involving the activation of the NF-κB signaling has been shown to contribute to proteinuria in chronic kidney disease. NF-κB is expressed not only in inflammatory cells, such as lymphocytes and macrophages, but also in podocytes. We herein examined the role of NF-κB in podocytes in adriamycin-induced nephropathy.

Methods: Podocyte-specific truncated IκB expressing (Pod-IκBDN) mice, in which the NF-κB signaling was inhibited selectively in podocytes, were generated and analyzed their phenotype following the intravenous injection of adriamycin. Expression of nephrin and podocin was examined by immunostaining.

Results: Pod-IκBDN mice did not exhibit any abnormalities in body weight, blood pressure, and the heart rate before the treatment. Following the administration of adriamycin, albuminuria was observed in both Pod-IκBDN mice and control mice. However, of importance, the amount of albuminuria in Pod-IκBDN mice (373 ± 122 mg/g creatinine) was significantly lower than control mice (992 ±305 mg/g creatinine) 14 days after adriamycin injection. Serum concentrations of urea nitrogen were not different between these mice. Expression of nephrin and podocin in the glomeruli was decreased in adriamycin-treated control mice, but not in Pod-IκBDN mice.

Conclusions: Results suggest that NF-κB in podocytes plays an important role in proteinuric renal disease by regulating the expression of podocyte-specific proteins.

Apoptosis Signal Regulating Kinase 1/p38 Signalling Promotes Renal Inflammation in a Rat Model of Crescentic Glomerulonephritis
Liv A. Amos,[1,2] Yingjie Han,[1,2] John T. Liles,[3] David J. Nikolic-Paterson.[1,2] *[1]Dept of Nephrology, Monash Medical Centre, Clayton, Victoria, Australia; [2]Dept of Medicine, Southern Clinical School, Monash Univ, Clayton, Victoria, Australia; [3]Gilead Sciences Inc, Foster City, CA.*

Background: Apoptosis signal-regulating kinase 1 (ASK1) is required for p38 mitogen-activated protein kinase (MAPK) signalling in tubular cells in response to angiotensin II and oxidative stress, but not to IL-1 or LPS. However, it is not known whether ASK1 is required for p38-dependent glomerular injury. The aim of the study was todetermine whether blockade of apoptosis signal-regulating kinase 1 (ASK1) can suppress renal injury in rapidly progressive glomerulonephritis.

Methods: Accelerated anti-glomerular basement membrane (GBM) disease was induced in groups of 6-8 rats. Treatment with ASK1 inhibitor GS-444217 (30mg/kg/po/bid) or vehicle began 1hr before anti-GBM serum injection and continued until animals were killed on day 1 or 14.

Results: Compared to normal controls, anti-GBM disease showed a 3-fold increase in phosphorylated (activated) p38 in glomeruli on day 1 which was prevented by ASK1 inhibition. In addition, the 20-fold increase in urine protein/creatinine ratio at day 1 was prevented by ASK1 inhibitor treatment. In a separate study, vehicle treated anti-GBM disease exhibited 30±3% (mean±SD) crescents on day 14, which was reduced to 10±2% by ASK1 inhibitor (P<0.001). ASK1 inhibitor treatment reduced proteinuria by 50% compared to the vehicle group (P<0.01), and prevented an increase in serum creatinine (40±9umol/L vs. 27±9umol/L; P<0.05). Glomerular macrophage and T cell infiltration was also reduced by the ASK1 inhibitor (P<0.05), with an associated reduction in macrophage M1/M2 markers (iNOS, CD206). Finally, immunostaining and PCR analysis showed a reduction in renal fibrosis with ASK1 inhibitor treatment.

Conclusions: This study suggests that ASK1 is involved in activating p38 MAPK signalling in glomerular inflammation. In addition, treatment with GS-444217 decreased glomerular inflammation and crescent development. Further studies are required to investigate potential effects of therapeutic intervention in established anti-GBM disease.

Transforming Growth Factor β-Activated Kinase 1(TAK1) Attenuates Experimental Glomerulonephritis
Liv A. Amos,[1,2] Elyce Ozols,[1,2] Yingjie Han,[1,2] David J. Nikolic-Paterson.[1,2] *[1]Nephrology, Monash Medical Centre, Clayton, Victoria, Australia; [2]Medicine, Southern Clinical School, Monash Univ, Clayton, Victoria, Australia.*

Background: Activation of p38/JNK signalling promotes glomerular inflammation. TAK1 is an upstream kinase in the p38/JNK pathway. TAK1 regulates the response to a range of stimuli which promote glomerular inflammation (TNF-a, IL-1 and TLR ligands). Therefore, we investigated whether TAK1 activates p38/JNK signalling in acute glomerular inflammation.

Methods: Global Tak1 gene deletion was induced in Tak1$^{f/f}$ER^{Cre} mice via tamoxifen, while Tak1$^{f/f}$Pod^{Cre} mice have conditional Tak1 deletion in podocytes. Accelerated anti-glomerular basement membrane (GBM) disease was induced in Tak1$^{f/f}$ER^{Cre} and Tak1$^{f/f}$ littermate controls (n=8-11) and killed after 3hr or 24hr. Disease was also induced in Tak1$^{f/f}$Pod^{Cre} and Tak1$^{f/f}$ littermate controls (n=5) and killed at 24hr.

Results: Compared to controls, global deletion of TAK1 had no effect upon the initial inflammatory response at 3hr in terms of neutrophil and macrophage infiltration and platelet deposition. However, at 24hr TAK1 deletion caused exacerbation of glomerular

injury compared to littermate controls in terms of: proteinuria (11.9±5 vs 5.4±0.5 mg/mmol; P=0.03); thrombosis (59±11% vs 8±3% glomeruli; P=0.001); renal function (1.4-fold increase in serum cystatin c; P<0.01); p38 and JNK activation (p-p38+ cells/gcs 20.81±0.45 vs 9.8±0.611; P<0.001; p-c-Jun+ cells/gcs 14.62±1.35 vs 8.171±1.12; P<0.05). The neutrophil infiltrate had largely subsided in control mice at 24hr; however, prominent neutrophil infiltration and platelet deposition was evident in mice with global TAK1 deletion at 24hr (neutrophils/gcs 3.27±0.29 vs 0.42±0.06; P<0.05; platelet clumps/gcs 29.88±3.37 vs 16.69±1.75; P<0.05). This exacerbation of glomerular damage was not due to a direct effect upon podocytes since $Tak1^{f/f}Pod^{Cre}$ mice showed no difference compared to controls in proteinuria, p38/JNK activation or thrombosis at 24hr.

Conclusions: TAK1 is a negative regulator of glomerular p38/JNK signalling and acute renal inflammation, which may operate via limiting neutrophil-mediated glomerular injury.

Funding: Government Support - Non-U.S.

TH-PO144

Absence of Osteopontin Accelerates Oxidative Stress-Induced Fibrosis in Glomerulonephritis Gabriela E. Garcia,[1] Jessica Helen Trostel,[1] Luan D. Truong,[2,3] Richard J. Johnson.[1] *[1]Medicine, Univ of Colorado Denver, Aurora, CO; [2]Pathology, Baylor College of Medicine, Houston, TX; [3]Pathology, The Methodist Hospital, Houston, TX.*

Background: Osteopontin (OPN) is a pro-and anti-inflammatory and profibrotic molecule that simultaneously attenuates oxidative stress in the inflammatory milieu. Evidence suggests that oxidative stress plays a significant role in the progressive fibrosis by upregulating fibrosis related genes. Moreover, elevation of biomarkers of increased oxidative stress has been demonstrated in patients with chronic kidney disease. OPN is highly induced in nephritic kidney and inactivation of macrophages (MΦ) by an $A_{2A}R$ agonist, attenuated OPN expression and protected from progressive kidney injury.

Methods: To further characterize the role of OPN in kidney injury we use OPN-/- mice in anti-glomerular basement membrane glomerulonephritis (anti-GBM GN), an inflammatory and progressive model of kidney disease.

Results: Wild type and OPN-/- mice did not show histological differences in the glomeruli and the tubulointerstitium. However, nephritic kidneys from OPN -/- mice showed severe kidney damage compared with those in WT mice. Fibrinoid necrosis, crescent formation, and tubulointerstitial injury were significantly higher in OPN-/- mice compared to WT mice. In addition, collagen (Col) I, Col III, and Col IV deposition were increased in nephritic kidneys from OPN-/- mice compared with WT mice. MΦ and T cell infiltration in nephritic kidneys was not different between WT mice and OPN-/- mice. Elevated expression of the reactive oxygen species (ROS)-generating enzyme Nox 4 was observed in nephritic kidneys from OPN-/- mice. In contrast, MΦ isolated from WT mice and OPN-/- mice did not show difference in the expression of Nox4. Importantly, the antigen-specific humoral immune response and the glomerular immunoglobulin G deposition were not affected in OPN-/- mice.

Conclusions: These findings suggest that in global OPN -/- mice elevated Nox4 creates a redox imbalance with increased oxidative stress induced-fibrosis. Targeting MΦ OPN could be protective to attenuate inflammation and inflammation-associated fibrosis without affecting the anti-oxidative stress of OPN.

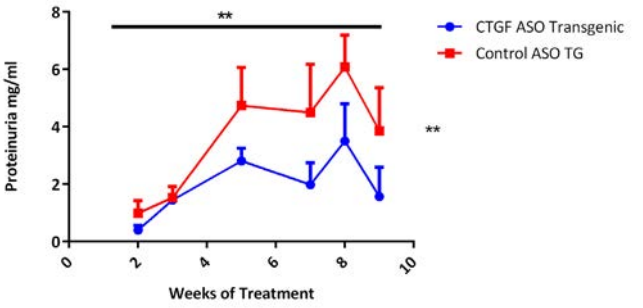
TH-PO145

Investigating Connective Tissue Growth Factor as a Critical Mediator of Cryoglobulinaemia Gayathri K. Rajakaruna,[1] Charles E. Alpers,[2] Alan D. Salama.[1] *[1]UCL Centre for Nephrology, Univ College London, Royal Free Campus, London, United Kingdom; [2]Dept of Pathology, Univ of Washington, Seattle.*

Background: Cryoglobulins are immunoglobulins that precipitate at temperatures below 37 ^{0} C. Cryoglobulinaemic vasculitis (CV) is commonly associated with hepatitis C (HCV) infection and causes a membrano proliferative glomerulonephritis (MPGN) in the kidney. Through a serendipitous finding we have previously established the development of CV in Connective tissue growth factor (CTGF) over expressing transgenic mice. CTGF, a matricellular protein involved in cell proliferation and key regulatory pathways, is elevated in patients with HCV-induced CV. Thymic stromal lymphopoetin (TSLP) transgenic mice also develop CV and have high serum CTGF levels. Higher TSLP levels have been shown in patients with HCV-induced CV. We hypothesized that CTGF overexpression is the key driver for cryoglobulin formation, and represents and potential therapeutic target.

Methods: TSLP Tg animals were used for this pilot study. We investigated whether CTGF anti sense oligonucleotides (ASO) attenuated CV, in comparison to control ASO. 14 TG and 12 WT animals were studied over a 10 week period.

Results: There were no deaths amongst CTGF ASO group whist one control animal died. The incidence of ulcerative ear and neck lesions was 50% lower in the CTGF ASO group compared to the controls.(p=0.0549). The CTGF ASO cohort had lower proteinuria compared to the controls; this was significant between treatment arms and the duration of treatment (p=0.0092 and p=0.0034 respectively).



There was less severe histological injury in the CTGF ASO cohort (mean mesangial expansion score 1.485±SD 0.2824 vs. 2.247± SD 1.116, p=0.0458).

Conclusions: This preliminary pilot study suggests that antagonism of CTGF ASOs may attenuate CV in TSLP Tg animals. Larger studies are required to confirm this observation.

TH-PO146

The Toll-Like Receptor Signaling Pathway Is Activated Before the Development of Renal Injury in the 5/6 Nephrectomy Model Camilla Fanelli, Jessica K. Okuma, Simone CA Arias, Flavia G. Machado, Victor F. Avila, Viviane D. Faustino, Gizely CS Moreira, Orestes Foresto-Neto, Lisienny CT Rempel, Claudia R. Sena, Vivian L. Viana, Hatylas Azevedo, Denise M. Malheiros, Niels OS Camara, Clarice K. Fujihara, Roberto Zatz. *Univ of Sao Paulo.*

Background: Mechanisms of activation of inflammation in Chronic Kidney Disease (CKD) are unclear. We examined the participation of innate immunity in the 5/6 nephrectomy model (Nx) from its beginning to advanced phases.

Methods: Munich-Wistar rats underwent Nx (N=40) or Sham (S, N=10) operation. Tail-cuff pressure (TCP, mmHg), albuminuria (ALB, mg/24h) glomerulosclerosis index (GSI) and cortical interstitium (%INT) were assessed 7, 15, 60 and 120 days after Nx. Gene and protein content of Tlr4, Casp1, Il1b and Nlrp3 were also evaluated. PCR-Array and gene enrichment analysis (GEA) by z-score evaluated gene expression of innate and adaptive immunity components.

Results:

	S	Nx7	Nx15	Nx60	Nx120
TCP	142±1	168±5a	188±5ab	209±3abc	216±4abc
ALB	8±2	44±11a	108±15ab	112±18ab	177±11abcd
GSI	0±0	0±0	0±0	29±8abc	105±17abcd
%INT	0±0	1±0	1±0	4±1abc	5±1abc
Cytokine Cytokine-Receptor Interaction		-2.1a	-2.0a	-2.0a	-2.1a
Hematopoietic Cell Lineage		-1.8a	-0.2a	-1.7a	-1.8a
Type I Diabetes Mellitus				-1.6a	-1.8a
Jak Stat Signaling Pathway					-0.2a
Toll Like Receptor Signaling Pathway		-1.8a	-1.8a	-1.9a	-1.7a
Natural Killer Cell Mediated Cytotoxicity					-1.7a
Fc Epsilon Ri Signaling Pathway					-1.7a
Cell Adhesion Molecules		-1.6a	-1.7a	-1.7a	-1.4

Mean±SE: [a]p<0.05 vs S, [b]p<0.05 vs Nx7, [c]p<0.05 vs Nx15, [d]p<0.05 vs Nx60

In addition, Tlr4, Tlr9, Nlrp3, Lbp2 and Irf7 genes were twice as high in Nx7 vs S. The same was seen for Casp1, Il1b, Tlr2 and Tlr5 after 15d. Tlr4, Casp1 and Il1b protein content increased following gene expression. GEA showed heightening of the Tlr Signaling Pathway (TlrSP) at all times in Nx.

Conclusions: The TlrSP, among other immune-related signaling pathways, is activated in the Nx model since its earliest stages until advanced phases, suggesting that they may contribute to initiate and maintain renal injury in this model.

TH-PO147

TLR2/TLR4-MyD88-NF-κB Pathway Is Involved in Tubulointerstitial Inflammation Caused by Proteinuria Lihong Ding, Dan Liu, Hong Liu, Kun ling Ma, Bi-Cheng Liu. *Inst of Nephrology, Zhong Da Hospital, Southeast Univ, Nanjing, Jiangsu, China.*

Background: Proteinuria, an independent risk factor for progression of chronic kidney diseases (CKD), has been suggested to initiate or aggravate thetubulointerstitial inflammation (TI). While the potential mechanism is still to be clarified. In this study, we hypothesized that activation of the TLR2/TLR4-MyD88-NF-κB pathway might be involved in proteinuria induced TI.

Methods: We established an albumin-overload nephropathy rat model, and the expression of TLR2, TLR4, MyD88, NF-κB as well as TNF-α and IL-6 were detected by immunohistostaining, real-time PCR and Western blot. In vitro, we investigated the impact of albumin stimulation on these parameters in HK-2 cells. Furthermore, siRNA for TLR2, TLR4 and BAY 11-7082, the inhibitor of NF-κB, was applied to study their influence on the expression of TNF-α and IL-6 caused by albumin stimulation.

Results: Rats treated withalbumin-overload induced a significant increase of proteinuria, proteinaceous casts and tubulointerstitial inflammation. The expression of TLR2, TLR4, MyD88 andNF-κB in the proximal tubular cells were significantly increased as well as TNF-α and IL-6 expression. In addition, the expression of TNF-α and IL-6 was significantly correlated with proteinuria. Albumin-overload induced TNF-α and IL-6 expression by TLR2/TLR4-MyD88-NF-κB pathway activation, which could be attenuated by the siRNA for TLR2, TLR4 or NF-κB inhibitor BAY 11-7082 in HK-2 cells.

Conclusions: This study demonstrated that proteinuria might play as an endogenous danger-associated molecular pattern (DAMP) that induced renal TI via the TLR2/TLR4-MyD88-NF-κB pathway.

Funding: Government Support - Non-U.S.

TH-PO148

Targeting Integrin CD11b/CD18 Reduces Inflammation and TLR-Mediated IFN Responses Implicated in Lupus Nephritis Samia Khan,[1] Shehryar J. Khaliqdina,[1] Mohd Hafeez Faridi,[1] David J. Cimbaluk,[1] Mariana Kaplam,[2] Vineet Gupta.[1] *[1]Internal Medicine, Rush Univ Medical Center, Chicago, IL; [2]Systemic Autoimmunity Branch, National Insts of Health (NIH), Bethesda, MD.*

Background: GWAS studies show strong associations between SNPs in the ITGAM locus, which encodes for the α-subunit (CD11b) of the b2 integrin CD11b/CD18 and susceptibility to lupus nephritis. CD11b/CD18 is a leukocytic adhesion receptor that modulates their biological functions and negatively regulates TLR-mediated pro-inflammatory signaling. Insufficient activity of CD11b/CD18 drives disease pathogenesis, hence making it a promising therapeutic target.

Methods: We tested whether activation of CD11b/CD18 with small molecule agonist, leukadherin-1 (LA1), suppresses pro-inflammatory TLR and IFN signaling pathways *in vitro* and *in vivo*. Since stimulation of TLR-induced overproduction of inflammatory cytokines drives lupus nephritis, we also tested whether dampening of these pathways with LA1 treatment reduces kidney injury in lupus prone MLR/lpr mice.

Results: Treatment of macrophages or neutrophils with LA1 and TLR4 agonist LPS or TLR7/8 agonist R848 induced a significant decrease in IL-6, TNFα and MCP-1, as well as type I IFN pathways, as compared to controls. In a murine model of severe sepsis, LA1 treatment significantly prolonged survival and reduced serum IL-6 and IL-1β levels as compared to controls. In a murine model of lupus nephritis (MRL/lpr), renal pathology of kidneys from LA1 treated mice revealed significantly reduced kidney damage as compared to controls. LA1 treatment also reduced proteinurea and IgG levels in the kidney, while protecting glomerular expression of WT1, SYNPO and activated b1 indicating enhanced kidney function. Renal tissue from LA1 treated mice displayed normal foot process width as compared to controls.

Conclusions: LA1-mediated CD11b/CD18 activation suppresses TLR-induced production of pro-inflammatory cytokines and IFN pathways. LA1 treatment also dampens TLR-stimulated overproduction of cytokines *in vivo*, which drives lupus nephritis. These findings indicate a crucial role for CD11b/CD18 in suppressing inflammation and identify LA1 as a promising therapeutic agent for human autoimmune diseases.

TH-PO149

Allopurinol Attenuates Innate Immunity Activation and Renal Injury in the Nx Model, Despite Low Uric Acid Levels Orestes Foresto-Neto, Victor F. Avila, Simone CA Arias, Camilla Fanelli, Lisienny CT Rempel, Denise M. Malheiros, Hugo Abensur, Niels OS Camara, Roberto Zatz, Clarice K. Fujihara. *Univ of Sao Paulo, Brazil.*

Background: Allopurinol **(Allo)** attenuates renal damage in experimental CKD. It is unknown whether this protection is due to inhibition of uric acid (UA) synthesis or to a direct action on oxidative stress and innate immunity (INIM). We studied the effect of Allo in the 5/6 nephrectomy model (Nx) in rats, in which UA degradation by uricase allows its effect on renal injury and INIM to be studied without its confounding action on UA levels.

Methods: Munich-Wistar rats (N=33) underwent Nx or sham operation (**S**, N=16). Nx rats were divided in: **Nx**, untreated; and **Nx+Allo**, given Allo 36 mg/kg/day vo. Tail-cuff pressure (TCP, mmHg), albuminuria (ALB, mg/24h), glomerulosclerosis (GS), urinary NGAL (uNGAL, mg/24h), interstitial collagen 1 (COL) and macrophages (MΦ, cells/mm^2), renal xanthine oxidase activity (rXO, mU/mg), plasma UA (pUA, mg/dL) and renal content of IL-1β (pg/g) and TLR4 (fold increase vs C) were assessed on Day 60.

Results:

	S	Nx	Nx+Allo
TCP	134±2	212±8[a]	191±6[ab]
ALB	3±1	111±15[a]	89±10[a]
% GS	0±0	15±4[a]	10±3[a]
%COL	2±1	9±1[a]	5±1[ab]
uNGAL	29±4	48±5[a]	32±3[b]
MØ	22±2	187±26[a]	130±20[ab]
rXO	70±5	116±7[a]	69±5[b]
pUA	1.3±0.2	2.1±0.2[a]	0.8±0.2[b]
IL-1β	1.5±0.2	4.7±0.6[a]	2.4±0.3[b]
TLR4	1.0±0.1	3.3±0.4[a]	2.3±0.2[ab]

Mean ± SE , [a]p <0.05 vs S; [b]p<0.05 vs Nx

As expected, pUA was only slightly (though significantly) elevated in Nx, remaining far lower than previously seen with uricase inhibition. Allo normalized rXO activity and cancelled the slight increase of pUA observed in Nx. Despite the low pUA, Allo attenuated hypertension and promoted selective tubulointerstitial protection, reducing uNGAL, COL and MΦ. In addition, Allo lowered the renal content of TLR4 and IL-1β, which correlated positively with both TCP and ALB.

Conclusions: In the Nx model, Allo exerts a renoprotective effect even in the context of low UA levels, which is associated, at least in part, with inhibition of innate immunity. FAPESP/CNPq.

TH-PO150

Megalin/Cubulin-Lysosome-Mediated Albumin Reabsorption Is Involved in the Tubular Cell Activation of NLRP3 Inflammasome and Tubulointerstitial Inflammation Dan Liu, Bi-Cheng Liu. *Inst of Nephrology, Zhong Da Hospital, Southeast Univ School of Medicine, Nanjing, Jiangsu, China.*

Background: Albuminuria contributes to the development and progression of chronic kidney disease (CKD) by inducing tubulointerstitial inflammation (TI) and fibrosis. However, the exact mechanisms of TI in response to albuminuria are unresolved. We previously demonstrated that NLRP3 and inflammasomes mediate albumin-induced lesions in tubular cells. Here, we further investigated the role of endocytic receptors and lysosome rupture in NLRP3 inflammasome activation.

Methods: We established an albumin-overload induced rat nephropathy model. The adult male Wistar rats that were uninephrectomized or sham operated under anesthesia 5 days before starting BSA injection. In vitro, tubular epithelial cell line (HK-2) was cultured with or without megalin/cubilin gene siRNA transfection and then stimulated with BSA for different time durations (6h, 12h, 24h, 48h) and concentrations (5, 10, 20,40 mg/ml). Cell lysates and supernatants were collected and determined by western blotting and ELISA. Cathepsin B and Cathepsin D with or without their inhibitors were detected by western blotting and immunofluorescence staining.

Results: The priming and activation signals for inflammasome complex formation were evoked simultaneously by albumin excess in tubular epithelial cells. The former signal was dependent on albumin-triggered NF-κB pathway activation. This process is mediated by the endocytic receptor, megalin and cubilin. However, the silencing of megalin or cubilin inhibited the albumin-induced NLRP3 signal. Notably, subsequent lysosome rupture and the corresponding release of lysosomal hydrolases, especially Cathepsin B, were observed in TECs exposed to albumin. Cathepsin B release and distribution is essential for NLRP3 signal activation, and inhibitors of Cathepsin B suppressed the NLRP3 signal in TECs.

Conclusions: Taken together, our findings suggest that megalin/cubilin and lysosome rupture are involved in albumin-triggered tubular injury and TI.

Targeted Inhibition of Protein Kinase C-a Ameliorates Nephrotoxic Nephritis Nino Kvirkvelia,[1] Maggie McMenamin,[1] Vanessa Iris Gutierrez,[1] Istvan Czikora,[2] Rudolf Lucas,[2] Michael P. Madaio.[1] *[1]Medicine, Georgia Regents Univ, Augusta, GA; [2]Pharmacology and Toxicology, Georgia Regents Univ, Augusta, GA.*

Background: Protein kinase C (PKC) is a ubiquitous phospholipid-dependent enzyme, with multiple isozymes that differ in their structure, biochemical properties, tissue distribution, subcellular localization, and substrate specificity. Since PKC-a expression was shown to be increased in patients with chronic kidney disease and in podocytes in renal biopsies of patients with diabetic nephropathy, we investigated the effect of specific PKC-a inhibition on renal injury in a murine model of acute kidney inflammation.

Methods: Mice were divided into four groups: 1) controls, 2) NTN, 3) NTN + PKC-a inhibitor Ro-32-0432 given i.p. after induction of nephritis on day 2, and 4) NTN group + PKC-a inhibitor conjugated to glomerular specific antibodies (i.e. a well-defined, human mAb (F1.1) directed against a3(IV) collagen) on day 2 to achieve kidney targeted drug delivery.

Results: On day 7, all NTN mice had severe nephritis, as evidenced by increased BUN, proteinuria and histology, whereas mice that received PKC-a inhibitors in either form had minimal evidence of kidney injury. BUN levels were reduced from 99.84±0.33mg/

dL in NTN mice to 32.29±1.70mg/dL in mice receiving free PKC-α inhibitor and to 36.07±4.51mg/dL in mice injected with F1.1 conjugated-PKC-a inhibitor. Serum levels of cytokines, assessed in multiplex analysis (MagPix) further confirmed reduction of inflammation.

Conclusions: These results suggest that PKC-a is an important mediator of antibody-mediated glomerulonephritis, and that glomerular targeted inhibition of this enzyme is feasible. This methodology, has the advantage of diminishing systemic side effects while limiting and/or reversing ongoing damage associated with severe inflammation. This approach has potential therapeutic implications for the treatment of human kidney diseases.

Renal Sympathetic Nerve Activity Controlled by Renal Afferent Sympathoexcitatory or Inhibitory Nerves? Tilmann Ditting,[1] Kristina Rodionova,[1] Sonja Heinlein,[1] Karl F. Hilgers,[1] Christian Ott,[1] Roland E. Schmieder,[1] Martin Hindermann,[1] Kerstin U. Amann,[2] Roland Veelken.[1] *[1]Nephrology & Hypertension, Friedrich Alexander Univ Erlangen, Erlangen, Bavaria, Germany; [2]Pathology, Friedrich Alexander Univ Erlangen, Erlangen, Bavaria, Germany.*

Background: Renal sympathetic nerve activity (RSNA) is important in hypertension, volume disorders or renal disease. It is unclear if increases of RSNA in disease are due to sympathoexcitatory or impaired sympathoinhibitory renal afferent nerves. We present data from nephritic rats suggesting the latter.

Methods: Nephritis due to OX7-antibodies in male Sprague-Dawley-rats. Methohexital anesthetized nephritic rats & controls were instrumented to stimulate renal afferent nerve activity (ARNA) in order to influence RSNA: ipsilateral renal arterial catheter for intrarenal administration (IRA) of the TRPV1 agonist capsaicin to stimulate ARNA (CAP 6.6*10-7M) and induce the release of the tachykinin receptor agonist SP from renal afferents; contralateral stainless steel electrode for RSNA recording; before and after IRA CAP the tachykinin-receptor blocker RP67580 was given. Baseline RSNA & ARNA were assessed. Some nephritic rats were pretreated with tachykinin receptor antagonists to prove increased SP effects.

Results: IRA CAP decreased RSNA from 67.5±12.0 mV*sec to 14.8±4.2 mV*sec ($p<0.05$) over 60 minutes while in nephritis RSNA suppression was abolished. Suppressed RSNA in controls was transiently reversed by the tachykinin inhibitor. Under resting conditions RSNA was higher, ARNA lower in nephritis as compared to controls. Tachykinreceptor antagonism ameliorated damage in renal nephritis suggesting increased SP release from renal afferent nerves despite lack of the tachykinin dependant sympathoinhibition seen in controls.

Conclusions: Our data suggest that a tachykinin dependant reno-sympathetic reflex mechanism exerts sympathoinhibitory effects being impaired under pathophysiological circumstances.

Fan1$^{-/-}$ Mice Develop Karyomegalic Interstitial Nephritis Rannar Airik,[1] Markus Schueler,[1] Merlin Airik,[1] Jonathan Porath,[1] Friedhelm Hildebrandt.[1,2] *[1]Divison of Nephology, Dept of Medicine, Boston Children's Hospital, Boston, MA; [2]Howard Hughes Medical Inst, Chevy Chase, MD.*

Background: Karyomegalic interstitial nephritis (KIN) is a chronic interstitial nephropathy, characterized by tubulointerstitial nephritis and formation of enlarged nuclei in kidneys and other tissues (1). We recently reported that recessive mutations in the gene encoding FANCD2/FANCI-Associated Nuclease 1 (FAN1) cause KIN in humans (2). In order to study the function of Fan1 in kidneys we generated a Fan1 knock-out mouse model.

Methods: Targeted *Fan1*$^{tm1a/+}$ ES cells were obtained from EUCOMM and injected into blastocysts to generate *Fan1*-mice. Abrogation of Fan1 expression in the mutant mice was confirmed by qRT-PCR. Renal histology was studied using hematoxylin/eosin, PAS and Masson's trichrome staining. Tubular damage was induced with intraperitoneal cisplatin injection. Cell culture experiments were performed using mouse embryonic fibroblasts or mesenchymal stem cells isolated from *Fan1*$^{-/-}$ and wild type animals.

Results: *Fan1*$^{-/-}$ mice were born at Mendelian ratio and appeared healthy with no gross abnormality in kidney. Treatment of *Fan1*$^{-/-}$ and wild type mice with 10 or 20 mg/kg cisplatin caused severe tubular injury with cast formation and tubular dilation in *Fan1*$^{-/-}$ animals (n=5), accompanied with dramatic weight loss and lethality. Chronic injection of cisplatin at 2 mg/kg induced karyomegalic interstitial nephritis that lead to renal failure within 5 weeks in *Fan1*$^{-/-}$ animals, but not in wild type mice. Cell culture studies demonstrated decreased survival and reduced colony formation of *Fan1*$^{-/-}$ cells in response to treatment with genotoxic agents.

Conclusions: *Fan1*$^{-/-}$ mice provide a new model to study the pathomechanisms of chronic kidney disease. We demonstrate that *Fan1*$^{-/-}$ mice are highly sensitive to genotoxic insults that lead to kidney failure. Our data indicate that Fan1 is involved in the physiological response of the kidney cells to DNA damage, which has been recently acknowledged to contribute to the pathophysiology of the chronic kidney disease (2, 3).

Down Regulation of Vitamin D Receptor (VDR) Expression Determines Initiation and Progression of HIV-Associated Nephropathy (HIVAN) with Variable Angiotensinogen (Agt) Copies Xiqian Lan, Hongxiu Wen, Anjali Maheshwari, Gauri P. Patil, Ramachandra prasanna Bongu, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY.*

Background: Agt transgenic mice have accelerated renin angiotensin system (RAS). On that account, we hypothesized that mice with enhanced expression of Agt would display accelerated progression of HIVAN. We evaluated the effect of different copies of Agt in the initiation and progression of HIVAN in genetically engineered HIVAN mice (Tg26).

Methods: Control and Tg26 mice with 2 (Tg26/Agt-2) and 4 (Tg26/Agt-4) copies of Agt were evaluated for severity of renal lesions, arteriosclerosis and hypertension at 8 weeks and 16 weeks. Renal cortical sections were stained with sirus red and PAS. RNA was extracted from renal tissues and probed for AT1, AT2, VDR and molecules involved in profibtotic and epithelial mesenchymal transition (EMT) pathways.

Results: Tg26/Agt-4/8wks showed lower blood pressure ($P<0.01$) vs. Tg26/Agt-2/8 wks, while Tg26/Agt-4/16wks displayed higher blood pressure vs. Tg26/Agt-2/16wks. Tg26/Agt-4/8wks displayed attenuated expression of PAI-1 vs. Tg26/Agt-2/8wks; however, Tg26/Agt-4/16wks showed 3-fold greater PAI-1 expression than to Tg26/Agt-2/16wks. Tg26/Agt-2/8wks displayed attenuated expression VDR and enhanced production of Ang II vs. Tg26/Agt-4/8wks, however this pattern reversed at 16 wks. Tg26/Agt-4/8wks displayed attenuated expression of AT1 and AT2 and down regulation of Tert, TGF-β, Snail, and vimentin when compared to Tg26/Agt-2/8wks. However, all these markers were comparable between these groups at 16 wks of age. Tg26/Agt-2/8wks developed renal lesions which were more advanced than Tg26/Agt-4/8wks. Conversely, Tg26/Agt-4/16wks displayed more advanced renal lesions vs. Tg26/Agt-2/16wks.

Conclusions: Tg26/Agt-4 displayed slower progression of HIVAN initially at 8 weeks associated with enhanced renal tissue VDR expression and attenuated expression of AT1, TGB-β, PAI-1, Tert and EMT markers. However, Tg26/Agt-4 at 16 wks displayed accelerated growth due to attenuated VDR expression leading to high blood pressure, upregulation of EMT and profibrotic molecules.

TH-PO155

Egr1 Deficiency Abolishes Inflammatory and Fibrotic Responses of Renal Tubular Cells Li-chun Ho,[1] Junne-Ming Sung,[2] Yau-Sheng Tsai.[1] *[1]Inst of Clinical Medicine, National Cheng Kung Univ, Tainan, Taiwan; [2]Internal Medicine, National Cheng Kung Univ Hospital, Tainan, Taiwan.*

Background: Early growth response-1 (Egr-1) is a transcription factor that has been found to regulate inflammation and fibrosis in non-kidney tissues, but its role in renal failure has not been well established.

Methods: Wild type and Egr1-/- mice were fed with adenine-enriched diet to induce tubulointerstitial nephritis (TIN), and primary tubular epithelial cells (PTECs) were treated with pro-inflammatory and pro-fibrotic cytokines. In addition, human kidney tissues were obtained from diabetic patients with renal failure and from non-diabetic patients without renal failure. The cell-type in which Egr-1 was activated was assessed using immunofluorescence and immunohistochemical stain. The levels of inflammatory and fibrotic markers were analyzed using RT-PCR and Western blotting. Kidney sections were also stained with H&E and Masson's trichrome to assess immune cell infiltration and fibrotic area.

Results: In mouse kidneys with TIN as well as in human kidneys with renal failure, tubular epithelial cell is the primary site for Egr-1 activation and undergoing nuclear translocation. Egr1-/- mice were protected from renal failure, reflected by lower levels of serum urea and creatinine. This is consistent with Egr-1 deficiency-related reductions of immune cell infiltration, NF-κB activity, and expression of cytokines and chemokines in the kidneys. In addition, Egr1-/- mice with TIN had less fibrotic area and attenuated TGFβ signaling than wild-type mice with TIN. Egr-1 deficiency also abolished the ordinary responses of PTECs to TNFα and TGFβ.

Conclusions: Egr-1 activation in the renal tubular cell plays an integrative role for renal inflammation, fibrosis and the subsequent renal failure. Thus, Egr-1 may serve as a therapeutic target for human kidney diseases.

TH-PO156

Angiopoietin-1 Overexpression Attenuates Renal Fibrosis Through Decreasing Inflammation Fan-Chi Chang,[12] Ming-Hsuan Tsai,[2] Yu-hsiang Chou,[2] Shuei-Liong Lin.[23] *[1]Internal Medicine, Taipei Medical Univ Hospital, Taipei, Taiwan; [2]Graduate Inst of Physiology, College of Medicine, National Taiwan Univ, Taipei, Taiwan; [3]Renal Div, Dept of Internal Medicine, National Taiwan Univ Hospital, Taipei, Taiwan.*

Background: Our previous studies have found dysregulated angiogenic growth factors in fibrotic kidney. We thus hypothesized that dysregulated angiopoietin-Tie system is related to microvascular destabilization and inflammation in the injured kidney.

Methods: We use unilateral ureteral obstruction (UUO) and 5 to 6 subtotal nephrectomy (5/6Nx) as animal models of progressive renal fibrosis. Specific overexpression of angiopoietin-1 (Angpt1) is induced with cross-breed between Pax8-rtTA (with C57BL/6 background) and pTRE-hAngpt1 (with ICR genetic background). Under the control of mouse Pax8 promoter, doxycycline administration directs high levels of expression of the reverse tertracycline-dependent transactivator (rtTA) to all proximal, distal tubules and

the entire collecting duct system of both embryonic and adult kidneys. Double transgenic mice inherit both Pax8/rtTA and pTRE-hAngpt1 responder. Littermates that inherited one or no transgenes serve as experimental controls.

Results: In animal model of UUO and 5/6Nx, Angpt1 decreases whereas Angpt2 and Angpt2/Angpt1 ratio increase as renal fibrosis progresses. Cross-breed of pTRE-hAngpt1 (with ICR genetic background) and Pax8-rtTA (with C57BL/6 background) lines is conducted for conditional overexpression. Overexpression of Angpt1 by tubule cells, include all proximal, distal tubules and the entire collecting duct system is induced after doxycycline administration in offspring with two transgenes. Compared to littermate control, transgenic mice with Angpt1 overexpression attenuate interstitial fibrosis in UUO kidney demonstrated by picrosirius red staining. Further analyses demonstrate decrease of inflammatory cell infiltration in UUO kidney of mice with Angpt1 overexpression.

Conclusions: These studies indicate that Angpt1 supplement may provide a novel therapy to attenuate renal fibrosis through reduction of inflammatory cell infiltration in UUO kidney.

TH-PO157

Benidipine Targets Leukocyte Kv1.3-Channels and Slows the Progression of Renal Fibrosis in Rats with Advanced Chronic Renal Failure Itsuro Kazama. *Physiology I, Tohoku Univ Graduate School of Medicine, Sendai, Miyagi, Japan.*

Background: Leukocytes, such as lymphocytes and macrophages, predominantly express delayed rectifier K^+-channels (Kv1.3) in their plasma membranes. In our previous study, the overexpression of these channels in leukocytes was strongly associated with their proliferation in kidneys and the progression of renal fibrosis in the advanced stage chronic renal failure (CRF). Since benidipine, a long-acting 1,4-dihydropyridine Ca^{2+} channel blocker, is also highly potent as a Kv1.3-channel inhibitor, it could exert therapeutic efficacy in advanced CRF.

Methods: Male Sprague-Dawley rats that underwent 5/6 nephrectomy followed by a 14-week recovery period were used as the model of advanced CRF. Benidipine hydrochloride (5mg/kg) was started at 8 weeks after nephrectomy and orally administered daily for 6 weeks. The histopathological features of the kidneys were examined in vehicle-treated and benidipine-treated CRF rat kidneys. Cellular proliferation of leukocytes and the cortical expression of pro-inflammatory cytokines were also examined.

Results: In CRF rat kidneys, Kv1.3-channels began to be overexpressed in leukocytes as early as 8 weeks after nephrectomy. In the cortical interstitium of benidipine-treated CRF rat kidneys, both immunohistochemistry and real-time PCR demonstrated decreased expression of fibrotic markers. Benidipine treatment significantly reduced the number of proliferating leukocytes within the cortical interstitium and decreased the expression of cell cycle markers and pro-inflammatory cytokines.

Conclusions: This study demonstrated for the first time that benidipine slowed the progression of renal fibrosis in rat kidneys with advanced CRF. Kv1.3-channels overexpressed in leukocytes were thought to be the most likely therapeutic targets of benidipine in decreasing the number of proliferating leukocytes and repressing the production of inflammatory cytokines.

Renoprotection by Treatment with CXA10, an Endogenous Nitro-Fatty Acid Cynthia M. Arbeeny,[1] Hong Ling,[1] Mandy M. Smith,[1] Stephen OBrien,[1] Stefan Wawersik,[1] Steven R. Ledbetter,[1] Diane K. Jorkasky.[2] *[1]Genzyme, a Sanofi Company, Framingham, MA; [2]Complexa, Inc., Pittsburgh, PA.*

Background: CXA10 is an electrophilic nitro-fatty acid that modulates anti-oxidant and anti-inflammatory pathways through activation of NRF2 and reduction of NFkB activity. Here, we examine the potential therapeutic benefit of CXA10 in a mouse model of hypertension-induced chronic renal injury that mimics human Focal Segmental Glomerular Sclerosis (FSGS).

Methods: Uninephrectomized male mice (129/sv) were implanted with a DOCA salt pellet (or placebo) at 2 and 5 weeks post-surgery, maintained on 1% NaCl (drinking water), and supplemented with 24% fat diet. Animals (n=8-10/group) were treated for 4 weeks with CXA10 (2.5mg/kg, p.o.); or with enalapril (20mg/kg; in drinking water) as the positive control.

Results: Body weight was slightly decreased and blood pressure was increased with DOCA treatment, and neither parameter was significantly altered by intervention. Kidney- and heart-to-body weight ratios were increased with DOCA and were significantly reduced in the CXA10 but not in the enalapril group, whereas plasma cholesterol levels were reduced in both groups. CXA10 and enalapril significantly reduced albuminuria and nephrinuria but did not significantly improve the reduction in GFR following DOCA. Histologic evaluation revealed that both treatments improved interstitial lesions and fibrosis, whereas only CXA10 reduced glomerular sclerosis and hypertrophy. Molecular markers of glomerular injury and podocyte number were unchanged in all groups, suggesting that structural glomerular injury was modest. Even so, markers of inflammation and fibrosis were elevated in tissue and urine samples in this model. CXA10 reduced urinary MCP-1 as well as mRNA levels encoding MCP-1, osteopontin, collagen III, fibronectin, and PAI-1. Enalapril treatment did not significantly alter this expression profile.

Conclusions: These results provide in vivo evidence that CXA10 is renoprotective in a kidney disease model by affecting anti-inflammatory, anti-oxidant and anti-fibrotic pathways and that the beneficial effects of CXA10 were differentiated from enalapril in this model.

TH-PO159

Selective Knock-Out of Glycogen Synthase Kinase 3-β in Proximal Renal Tubular Epithelial Cells (RTE) Attenuates Inflammation and Tubular Injury After Unilateral Ureteral Obstruction (UUO) Josef Bautista, Eman Mohammad Shaban, Evelyn Tolbert, Rujun Gong, Lance D. Dworkin. *Medicine, Brown Univ, Providence, RI.*

Background: Glycogen synthase kinase 3-beta (GSK-3β) is a ubiquitous serine/threonine protein kinase that regulates a large number of processes in diverse cell types including RTE. Systemic administration of small molecule inhibitors of GSK-3B reduces inflammation and fibrosis and lessens acute and chronic kidney injury. However, the extent to which the beneficial effects of GSK-3β inhibition depend on blocking the enzyme specifically in kidney cells is unknown. We investigated whether gene deletion of GSK3β in RTEs alone would reduce inflammation and progression of CKD.

Methods: The GSK-3β gene was selectively deleted in the renal tubular cells by crossing mice in which exon 2 of the GSK3b gene was "floxed" with mice expressing CRE recombinase under a ɣGT promoter expressed only in adult proximal RTE (KO). Injury was induced by UUO in wild type (WT), KO, and WT mice given low-dose (1 mg/kg) thiadiazolidinone (TDZD), a specific GSK3β inhibitor. After 7 days, kidneys were weighed and examined for tubular and glomerular injury, interstitial edema, and macrophage infiltration. Groups were compared by ANOVA.

Results:

Group	Kidney Wt (gm/100g body wt)	Injured Tubules (%)	Glomerular Injury Score	Interstitial edema score
KO (n=7)	0.74 ± 0.09	35% ± 0.15 *	2.14 ± 0.94	1.47 ± 0.32
WT (n=11)	0.79 ± 0.16	57% ± 0.09	1.54 ± 0.66	1.59 ± 0.35
TDZD (n=11)	0.69 ± 0.12	46% ± 0.12	1.52 ± 0.82	1.77 ± 0.28

*P<0.01 KO vs. WT

Macrophage infiltration assessed by immunohistochemistry also declined by about 40% in KO mice

Conclusions: Selective deletion of GSK-3β in RTE attenuated macrophage infiltration and reduced tubulo-interstitial, but not glomerular injury after UUO. Elimination of GSK-3β signaling in RTE was more effective than systemic, low dose GSK-3β inhibition. Our data suggest that GSK-3β dependent pathways in RTEs play a critical role in promoting interstitial inflammation and tubular injury in CKD.

TIMP-1 Up-Regulates the Expression of MCP-1 Through NF-κB Pathway in Rat Mesangial Cells Xiang-Mei Chen, Xizhao Chen, Qing-gang Li, Guangyan Cai. *Chinese PLA General Hospital, Chinese PLA Inst of Nephrology, State Key Laboratory of Kidney Diseases, National Clinical Research Center for Kidney Diseases.*

Background: In mesangial proliferative glomerulonephritis (MesPGN), tissue inhibitors of metalloproteinases (TIMPs) can regulate transcription factors and cytokines and participate in immune and inflammation reactions in an MMP-independent way.We found that in the anti-Thy-1 nephritis model, TIMP-1 andmonocyte chemotactic protein 1 (MCP-1) were significantly increased at the mesangial dissolved phase and peaked at the mesangial proliferative phase, finally backed to normal at the recovery phase. Our hypothesis is that TIMP-1 can regulate MCP-1 expression through NF-κB in mesangial cells.

Methods: (1) We established the anti-Thy-1 nephritis model. Animals were sacrificed at day 0, 1, 2, 3, 5 and 7, mRNA levels of TIMP-1 and MCP-1 were detected at separate time points by Taqman probe technique. (2) TIMP-1 over-/low-expression rat mesangial cell model were established by GFP-TIMP-1 lentivirus transfection and siRNA interference. (3) The cells of TIMP-1 over-expression were harvested at day 5, 6, 7, and low-expression cells at 48h. Then we detected the mRNA and protein levels of TIMP-1, MMP2, MMP9, NF-κB and MCP-1 by Taqman probe technique and Western blot. (4) TIMP-1 over-expression cells were treated with NF-κB inhibitor BAY 11-7082 (5mmol/L) at 4th day. After 48h-culture, mRNA level were detected.

Results: (1) In rat anti-Thy-1 nephritis, the expression levels of TIMP-1 and MCP-1 was increased gradually and peaked at day 5, then began to decrease. MCP-1 followed the same trend but peaked at day 2. (2)We established the TIMP-1 over-/low-expression model successfully. (3)When TIMP-1 presented over-expression, MMP9, NF-κB and MCP-1 were up-regulated ($P<0.05$); When TIMP-1 presented low-expression, these were down-regulated. ($P<0.001$) The change in expression of MMP2 was not obvious. (4) At 48h after inhibition with NF-κB inhibitor, the expression level of MCP-1 in the TIMP-1 over-expression cells was down-regulated($P<0.01$).

Conclusions: TIMP-1 could participate in the immune and inflammation reactions of MesPGN by up-regulating the expression of MCP-1 through NF-κB in rat mesangial cells.

Calcitriol Protects against Renal Tubular Cell Apoptosis by Promoting M2 Macrophage Polarization in Diabetic Nephropathy Rats Yinfeng Guo, Zhixia Song, Min Zhou, Ying Yang, Xiaoliang Zhang. *Zhong Da Hospital, Southeast Univ, School of Medicine.*

Background: Renal tubular apoptosis is a key event in initiating kidney damage in DN. Heterogeneity of macrophage phenotype and function ultimately determines the outcome of DN. Therefore, we sought to investigate whether calcitriol, known as an important renal-protective drug, is sufficient to protect against tubular cell apoptosis by promoting M2 macrophage in DN rats.

Methods: DN model rats were established by intraperitoneal injection with streptozocin (STZ). The rats were subsequently receiving either calcitriol (0.1mg/kg/d) or vehicle by gavage. Rats were sacrificed at 18w for histological and molecular analysis. In addition, we performed in vitro study using Raw264.7 cells cultured with either high glucose or high glucose followed by 1,25-dihydroxyvitamin D3 medium to assess macrophage phenotype.

Results: Calcitriol significantly improved renal function and ameliorated renal histology in DN rats. The increased tubular cell apoptosis in DN rats was alleviated by calcitriol. Calcitriol up-regulated the expression of anti-apoptotic protein Bcl-2, down-regulated the expression of pro-apoptotic protein such as Bax and caspase-3. Interestingly, calcitriol significantly enhanced M2 macrophage polarization in interstitium with elevated expressions of M2 markers, including CD163, Arg-1 and MR. Moreover, the ratio of CD163/CD68 considered as the proportion of M2 macrophage was about 2.9 fold highly after calcitriol treatment. In vitro, 1,25-dihydroxyvitamin D3 also promote high glucose-induced pro-inflammatory M1 macrophage toward anti-inflammatory M2 polarization.

Conclusions: Calcitriol protects against renal tubular cell apoptosis by promoting M2 macrophage polarization in STZ-induced DN rats.

APOL1 Risk Variants Induce Aberrant THP-1 Monocyte Differentiation and Increased Eicosanoid Production Hewang Lee, Jeffrey B. Kopp. *Kidney Diseases Section, NIDDK, National Insts of Health, Bethesda, MD.*

Background: Apolipoprotein L1 (APOL1) is an innate immune protein and its risk variants are strongly associated with kidney disease. We investigated the effects of APOL1 variants on monocyte differentiation and eicosanoid production in macrophages, as activated tissue macrophages in kidney might contribute to injury.

Methods: THP-1 cells, a human monocytic cell line, were transiently transfected with APOL1-A isoform G0 (ancestral allele) or the renal risk variants G1 and G2 and cultured for 36 hr before RNA was obtained for gene expression studies.

Results: APOL1-transfected THP-1 cells manifested a 6-8 fold increase in CD14 and CD68 gene expression, similar for all three variants, and similar to that seen with phorbol-12-myristate acetate treatment. Furthermore, APOL1 risk variants induced activated monocytes into atypical M1 macrophages with increased RNA encoding M1 markers CD80, TNF, IL1β, and IL6 (all vs EV $p < 0.05$, G1 vs G2 $p > 0.05$), modest increase in M2 markers CD163, CD206, and TGFb1 with G1 transfection (all RNAs vs EV $p < 0.05$) and CD204 and TGFb1 with G2 transfection (both RNAs vs EV $p < 0.05$). Gene expression for eicosanoid generating enzymes was increased as well: cyclo-oxygenase-2, G0, 1.3±0.9 fold over empty vector (EV), G1, 4.1±0.5 and G2, 4.5±0.5 (both G1 and G2 vs G0 $p<0.01$) and thromboxane synthase, G0, 2.1±0.8 fold over EV, G1, 5.2±0.9 and G2, 4.5±0.5 (both G1 and G2 vs G0 $p<0.05$). Thromboxane A2 receptor (TXA2R) gene expression was unchanged with G0, 1.8±0.4 fold over EV ($p>0.05$), and increased with G1, 6.1±1.0, and G2, 4.1±0.5 (G1 vs G0 $p<0.001$, G2 vs G0 $p<0.01$). Higher levels of thromboxane B2, a stable metabolite of thromboxane A2, were present in the supernatant of cultured THP-1 cells transfected with G1 (10.0±1.3 pg/mL/10^5cells, $p<0.05$ vs G0) and G2 (15.1±3.0 pg/mL/10^5cells, $p<0.01$ vs G0) compared to G0 (6.0±1.0 pg/mL/10^5cells), which was similar to EV (6.7±1.0 pg/mL/10^5cells, $p>0.05$ vs EV).

Conclusions: These results demonstrate a novel role of APOL1 variants in the regulation of monocyte differentiation and eicosanoid metabolism, which could modify the immune response and promote inflammatory signaling within the kidney and elsewhere.

Purification and Analysis of Exosomes Derived from Primary Human Proximal Epithelial Cells (PTEC) Helen G. Healy,[1] Xiangju Wang,[2] Andrew J. Kassianos,[2,3] Ray Wilkinson.[1,2,3,4] *[1]Renal Medicine, Royal Brisbane and Women's Hospital, Brisbane, Queensland, Australia; [2]Conjoint Kidney Laboratory, Pathology Queensland, Brisbane, Queensland, Australia; [3]School Biomedical Sciences, Queensland Univ of Technology, Brisbane, Queensland, Australia; [4]Medical School, Univ of Queensland, Brisbane, Queensland, Australia.*

Background: Exosomes are extracellular vesicles secreted by multiple cell types in the body which contain a tissue-type signature courtesy of their incorporated RNA and protein cargo. Exosomes have crucial roles in extracellular communication and are implicated in kidney inflammation and disease progression. Human PTEC play a central role in renal disease yet their exosome expression remains virtually unknown. Here we characterize exosomes from primary human PTEC cultured under normal, hypoxic and inflammatory conditions.

Methods: Exosomes were purified from normal, hypoxic (1% O_2) and inflammatory (IFN-γ/TNF-α treated) PTEC cultures using ultracentrifugation and density gradients and analyzed for morphology (electron microscopy), size/concentration (qNano) and CD9/63/81 expression (Western blot). Protein and microRNA content were analyzed by mass spectroscopy (MS) and sequencing respectively.

Results: Exosomes from all three culture conditions displayed the same size range (50-120nM) and morphology (spherical doughnut shape) with a similar expression of CD9 (high), CD63 (medium) and CD81 (low). However, concentrations of exosomes from both hypoxic and inflammatory conditions increased by more than two fold compared to normal culture conditions. MS analysis demonstrated exosomes from hypoxic cultures contained 134 proteins not expressed in those from normal cultures, whilst inflammatory exosomes contained 152 unique proteins. A number of these proteins have been implicated in development of chronic kidney disease.

Conclusions: Collectively, our data indicate that exosome secretion is increased under "diseased" conditions, and importantly, there is condition specific differential protein expression. Further investigation of exosome protein/microRNA cargo will identify novel targets whose utility in therapies and disease biomarkers warrant analysis.

HIF-2α in Dendritic Cells in Renal Injury Soeren Schwuchow,[1] Joanna Kalucka,[2] Gunnar Schley,[1] Bernd Klanke,[1] Kai-Uwe Eckardt,[1] Alexander Weidemann.[1] *[1]Nephrology and Hypertension, Univ of Erlangen-Nuremberg, Erlangen, Germany; [2]Laboratory of Angiogenesis & Neurovascular Link, Univ of Leuven, Leuven, Belgium.*

Background: Hypoxia-inducible transcription factors, HIF-1α and -2α play key roles in cellular adaptation to hypoxia and have been linked to innate immune responses. In macrophages they are non-redundant and are expressed depending on polarization. However, in other innate immune cells, such as dendritic cells (DCs), the differential role of HIFα isoforms is less clear. DCs are abundant in the kidney and have been implicated in renal (patho)physiology. As shown previously, HIF-1α in DCs affects maturation and T cell stimulation, but whether HIF-2α plays a specific role is elusive. The aim of our study was therefore to elucidate the functional properties of HIF-2α in DCs in vitro and in vivo during renal injury.

Methods: Murine primary DCs (BMDC) were generated from bone marrow of tissue specific conditional knock-out mice (CD11c Cre-HIF-$2a^{lox/lox}$). BMDCs were then stimulated with hypoxia and LPS followed by mRNA, FACS and protein analysis. Bilateral renal ischemia and reperfusion injury (IRI) was used as a model of acute renal injury. To induce chronic kidney injury, mice were subjected to either a 3 week adenine rich diet or to unilateral ureteral obstruction (UUO), followed by the above mentioned analyses.

Results: HIF-2α protein is detected in BMDC after LPS treatment and with hypoxic stimulation. Loss of HIF-2α does not affect expression of maturation markers such as CD86 or MHCII after LPS and the ability of T cell activation. In vivo during acute or chronic renal injury, loss of dendritic HIF-2α does not affect renal function, inflammatory cell responses or the expression of fibrotic or inflammatory markers.

Conclusions: Taken together, our data indicates that loss of HIF-2α in DCs does not affect maturation in vitro and leukocyte infiltration or renal function in models of acute and chronic renal injury in vivo. Thus, in contrast to macrophages, HIFα isoforms in DCs do not seem to play functional opposing roles. This might have important implications for the development of pharmacologic agents targeting HIFα in DCs to modulate immune responses during renal injury.

Fecal Transplantation from Uremic Mice Aggravates Kidney Fibrosis Myung-gyu Kim, Young Ju Na, Sung Yoon Lim, Sang-Kyung Jo, Won-Yong Cho. *Dept of Internal Medicine, Korea Univ Anam Hospital, Seoul, Republic of Korea.*

Background: Emerging evidence showed the important role of kidney-gut crosstalk in diverse pathological processes. Alterations in intestinal barrier or microbiota has been demonstrated in chronic kidney disease (CKD) and thought to be associated with increased cardiovascular risks or progression of CKD. The purpose of this study was to investigate the effect of gut microbiota in the animal model of kidney fibrosis with using fecal transplantation.

Methods: Unilateral ischemia/reperfusion injury (IRI) for 45min was performed in C57/BL6 mice for fibrosis model. Supernatants of centrifuged feces from 5/6 nephrectomized mice (8wks) or age matched control mice were administered 3 times per wk for 3 wks after gut decontamination and degree of fibrosis was compared (CKD feces vs control feces).

Results: Compared to mice with fecal transplantation from control mice, mice who were transplanted with CKD feces showed aggravated fibrosis at 2 wks after unilateral ischemia in the analysis of the Masson's trichrome staining and Western blot for type 4 collagen. Ex vivo analysis of immune cells showed increased number of mature CD80+ CD11c+ cells in mesenteric lymph node whereas percentage of splenic Tregs increased in mice transplanted from uremic mice. Immune cells from these mice showed significantly suppressed cytokine release upon LPS stimulation compared mice with WT feces.

Conclusions: This study showed the possible effect of kidney-gut crosstalk on the progression of CKD and this effect is thought to be partially mediated by immune modulatory effect.

TH-PO166

A Novel Mineralocorticoid Receptor Blocker Protects the Remnant Kidney Better Than Eplerenone as an Add-On to Late Losartan Clarice K. Fujihara,[1] Mark Kowala,[2] Matthew D. Breyer,[2] Claudia R. Sena,[1] Mariliza V. Rodrigues,[1] Simone CA Arias,[1] Camilla Fanelli,[1] Denise M. Malheiros,[1] Jose E. Krieger,[1] Roberto Zatz.[1] *[1]Univ of São Paulo, Brazil; [2]Eli Lilly.*

Background: Aldosterone (Ald) worsens, whereas MR blockers, e.g. eplerenone (E), slow CKD, but cause hyperkalemia, especially with RAS inhibitors, e.g. Losartan (L). LY2180176 (LY) is a novel, nonsteroidal, high-affinity MR blocker (Ki 1.6 nM vs 124 for E). We tested LY as an add-on to L in 5/6 ablation (Nx) rats.

Methods: Male Munich-Wistar rats underwent Nx (N=89) or sham (**S**, N=24) surgery, being divided in (all drugs in mg/kg/d, from Day 60 to 150 post Nx): **Nx**, untreated; **Nx+L**, given L, 50; **Nx+L+E**, L 50 + E 150; **Nx+L+LY**, L 50 + Ly 20. ALB, albuminuria, mg/d; TCP, tail-cuff pressure, mmHg; PR, plasma renin, ng/mL/h; plasma Ald, pg/mL; Serum K^+, mmol/L; GS, Glomerulosclerosis; COL, cortical collagen; interstitial AngII+, cells/mm^2. Genes (italic): RT-PCR (x increase).

Results:

	S	Nx	Nx+L	Nx+L+E	Nx+L+LY

LY normalized TCP and ALB and slowed CKD better then E. LY strongly raised PR and Ald, and restored transporter expression, suggesting volume loss. Despite strong MR blockade, LY did not raise K^+.

Conclusions: LY may become a new asset in the therapy of CKD.

TH-PO167

Role of Innate Immunity in a Model of CKD following Brief Dietary Adenine Overload Gizely CS Moreira, Ricardo P. Mazzonetto, Lisienny CT Rempel, Orestes Foresto-Neto, Camilla Fanelli, Simone CA Arias, Viviane D. Faustino, Claudia R. Sena, Victor F. Avila, Vivian L. Viana, Denise M. Malheiros, Niels OS Camara, Clarice K. Fujihara, Roberto Zatz. *Univ of São Paulo, Brazil.*

Background: Adenine (ADE) excess leads to accumulation of crystals (Crys) at the renal interstitium (INT) through NF-κB activation (AJPRenal:F155,2013). After ADE cessation, INT nephritis progresses even as Crys disappear. Here we verified whether AngII and innate immunity (INIM) are activated in the acute and/or chronic phases of this model.

Methods: Adult male Munich-Wistar rats (n=76) received no treatment (C) or 0.5% ADE in chow for 1 wk, after which Crys/mm^2, tail-cuff pressure (TCP, mmHg), glomerulosclerosis (GS, %), INT collagen (COL, %), INT macrophage (Mϕ) and AngII+ (cells/mm^2), renal IL1β (pg/mg), and renal IL6, NLRP3 ($2^{-\Delta\Delta Ct}$) and TLR4 (WB, fold) were assessed. Measurements were repeated 4 and 24 wk after ADE cessation.

Results:

	1 wk ADE+		4 wk ADE-		24 wk ADE-	
	C	ADE	C	ADE	C	ADE
Crys	-	1.3±0.2^{a}	-	0.6±0.2^{a}	-	0.2±0.1^{ab}
TCP	130±2	157±4^{a}	134±2	141±3^{b}	137±3	150±4^{a}
GS	0±0	0±0	0±0	0±0	0.4±0.2	2.1±1.0^{ab}
COL	5±1	5±1	4±1	9±2	4±1	12±2^{ab}
MΦ	16±2	90±8^{a}	24±6	65±6^{ab}	20±1	64±7^{ab}
AngII+	1±0.3	4±0.6^{a}	1±0.4	4±0.6^{a}	1±1	7±2^{ab}
IL1β	0.9±0.1	6.7±1.1^{a}	1.1±0.3	3.0±0.6^{b}	1.6±0.6	1.4±0.4^{b}
IL6	1.2±0.3	4.9±0.9^{a}	1.2±0.3	1.8±0.3^{b}	1.2±0.3	1.1±0.2^{b}
NLRP3	1.0±0.1	2.0±0.1^{a}	1.0±0.1	1.5±0.1^{ab}	1.0±0.1	1.2±0.1^{b}
TLR4	1.0±0.4	3.6±0.8^{a}	1.0±0.4	1.0±0.1^{b}	1.0±0.2	1.2±0.2^{b}

(Mean ± SE, ^{a}p <0.05 vs C, ^{b}p <0.05 vs 1 wk)

Innate immunity activation was seen at 1 week. However, only Mϕ and AngII+ remained elevated as chronic renal injury settled in, despite disappearance of Crys.

Conclusions: INIM may participate, along with renal AngII production and Mϕ infiltration, in the acute phase of this model. However, INIM seems not to influence the late progression to chronic glomerular and interstitial injury, which may depend on as yet unidentified mechanisms. FAPESP/CNPq.

TH-PO168

Assessing the Role of B7.1 in Diabetic Nephropathy Marcela Herrera,[1] Magnus Soderberg,[2] Johan C. Molne,[3] Beatriz Santamaria pérez,[4] Angela M. Valverde,[4,5] Stephanie C. Heasman,[1] Lutz Jermutus,[1] David J. Baker,[1] Carol Patricia Moreno Quinn.[1] *[1]Cardiovascular & Metabolic Diseases, Medimmune, Cambridge, United Kingdom; [2]AstraZeneca, Molndal, Sweden; [3]Pathology, Sahlgrenska Univ, Gothenburg, Sweden; [4]Inst for Biom Res Alberto Sols, CSIC. UAM, Madrid, Spain; [5]Centro de Investigación Biomédica en Red de Diabetes y Enfermedades Metabólicas Asociadas (ISCIII), Madrid, Spain.*

Background: Upregulation of podocyte B7.1 has been reported in kidney biopsies of Diabetic Nephropathy (DN) patients and in stressed cultured human podocytes. Blocking B7.1 with a CTLA4-Fc fusion (Abatacept) protects the injured podocyte in vitro and improves DN pre-clinically. B7.1 is found in antigen presenting cells and binding of CTLA4-Fc to B7.1 prevents T-cell activation. Since inflammation is an important feature of diabetes, we hypothesized that Abatacept protects the kidneys during DN primarily by blocking T-cell activation.

Results: We investigated B7.1 expression in 42 DN kidney biopsies using immunohistochemistry. B7.1 expression was not detected in podocytes but predominantly localized in a limited number of macrophages, with no differences found between control and DN patients (0.15±0.23 vs. 0.19±0.22cells/mm2). In situ hybridization confirmed these results. In cultured human podocytes, B7.1 was found at relatively low levels when assessed by qPCR, and treatment with high-glucose (30mM for 3, 5, 10 and 14 days) or LPS (20 and 50ug/uL for 24 hrs) did not enhance B7.1 expression. Western blotting analysis confirmed these results. LPS-induced F-actin re-organization was not prevented by Abatacept (10-100ng/mL). We then tested Abatacept in the STZ-induced DN model (high fat-diet-C57Bl6). After 3 weeks of diabetes induction, Abatacept was dosed s.c. at 50mg/kg every 2 days for 12 weeks. At 3 weeks of dosing, urinary albumin:creatinine ratio increased from 3.6±0.8 to 8.3±0.9ug/umoles in the diabetic animals ($p<0.05$) while in the Abatacept group UAC was 4.0±0.6ug/umol ($p<0.05$ vs. DN group). Glucose or HbA1c were unaffected across groups and throughout the study.

Conclusions: B7.1 is a valid target for DN where the mechanism of action is more likely inhibition of T-cell activation rather than podocyte protection.

Systemic Overexpression of Endogenous Secretory RAGE Attenuates Diabetic Kidney Injury Through TLR4 Not TLR2 Signaling Xiaochen Chen,[1] Jin Ma,[1] Elisabeth G.D. Stribos,[1] A. Lianne Messchendorp,[1] Moumita Paul,[1] Eithne Cunningham,[1] Alexandra Sharland,[1] Steven J. Chadban,[1,2] Huiling Wu.[1,2] *[1]Kidney Node Laboratory, Charles Perkins Centre, Univ of Sydney, Australia; [2]Royal Prince Alfred Hospital, Australia.*

Background: Endogenous secretory RAGE (esRAGE) is a soluble decoy receptor that can competitively bind ligands for TLRs/RAGE, including HMGB1. Here we test whether: 1) esRAGE after the induction of diabetes can prevent the development of diabetic nephropathy(DN) in mice with streptozotocin-induced diabetes; 2) the protective effects of esRAGE are attributable to interruption of signaling via the HMGB1 receptors(TLR2, TLR4 and RAGE).

Methods: DN was induced in WT, TLR4$^{-/-}$ and TLR2$^{-/-}$ mice by intraperitoneal injection of streptozotocin. At 2 weeks after STZ injection, mice received an IP injection of $5x10^{11}$ vector genome copies rAAV encoding either esRAGE or HSA, or saline-control. Samples were collected at week 12 post-induction of diabetes.

Results: Diabetic mice that received rAAV-esRAGE, rAAV-HSA or saline developed equivalent degrees of hyperglycaemia. Diabetic WT-mice given rAAV-HSA or saline developed significant albuminuria versus non-diabetic WT-mice(ACR309±213 & 313±215 versus 55±10, $p<0.05$-0.01), whilst rAAV-esRAGE treated-diabetic-mice were protected(118±42, $p<0.05$). WT diabetic-mice developed histological damage including glomerular hypertrophy, podocyte injury, macrophage accumulation and interstitial fibrosis. These changes were significantly attenuated in diabetic mice given rAAV-esRAGE versus rAAV-HSA($p<0.05$-0.01).While both TLR2$^{-/-}$ mice and TLR4$^{-/-}$mice were partially protected against DN, esRAGE treatment provided additional protection to TLR2$^{-/-}$ mice, but not TLR4$^{-/-}$mice. A further study of esRAGE treatment in RAGE$^{-/-}$ mice is underway.

Conclusions: High-level expression of serum esRAGE after the induction of diabetes provided partial protection against the development of DN in STZ-induced diabetic mice, which may operate through the TLR4 pathway.

Calcitriol Inhibits Advanced Glycation End Product (AGE)-Elicited Mesangial Cell Damage by Sequestrated RAGE-NF-κB Signaling Ao Cheng, Yanlin Zhang. *Dept of Nephrology, The First Affiliated Hospital of Xiamen Univ, Xiamen, Fujian, China.*

Background: Actived vitamin D3 (Calcitriol) can effectively slow the progression of chronic kidney disease and its mechanism is not very clear. The advanced glycation products (AGEs) accumulate in the kidney disease through RAGE receptors. The aim of this experiment was to explore the effect and mechanism of Calcitriol on the inflammatory of mesangial cells caused by AGEs, and to further expand the clinical application of actived vitamin D3.

Methods: AGE-HSA was prepared and human glomerular mesangial cells were cultured in vitro. the purpose of the present study was to investigate the efficacy of calcitriol on AGEs-induced inflammatory in human mesangial cell. Pretreatment or not with calcitriol, the human mesangial cell was treatment with various concentrations and time period of AGEs. IL-6 and MCP-1 were measured by real-time PCR and ELISA. The expression of vitamin D receptor (VDR), receptor of advanced glycation end products (RAGE), NF-κB p65 and phosphorylated p65 was measured by Western-blot. NF-κB p65 translation was determined by immunofluorescence. Cellular oxidative stress was measured by reactive oxygen species (ROS) production.

Results: (1) AGE-HSA induces IL-6 and MCP-1 expressing in human mesangial cells, and calcitriol inhibits this effect. (2) Not AGE-HSA but calcitriol induces Vitamin D receptor (VDR) expression in human mesangial cells. And calcitriol inhibits this effect through VDR. (3) AGE-HSA induced Receptor for advanced glycation end products (RAGE) expression, and effects was blocked by calcitriol. (4) Effect of calcitriol on ROS production induced by AGE-HSA in mesangial cells. (5) NF-κB activation in renal mesangial cells was induced by AGE-HSA, and the effect was inhibited by calcitriol.

Conclusions: Calcitriol could attenuate the AGE-induced up-regulation of IL-6 and MCP-1 though VDR by suppressing RAGE expression and subsequent ROS generation and reducing NF-κB activation.

TH-PO171

GLP-1 Receptor Agonist Exendin-4 Ameliorates Renal Injury by Reducing Cholesterol Deposition and Inflammation in Glomerular Endothelial Cell via ABCA1-JAK2/STAT3 Pathway in Diabetic apoE-/- Mice Qinghua Yin, Ping Fu, Fang Liu. *Div of Nephrology, West China Hospital of Sichuan Univ, Chengdu, Sichuan, China.*

Background: Lipid accumulation in glomerular endothelial cells has been found a unique feature, which may contribute to the renal inflammation in diabetic kidney disease. The ATP-Binding Cassette Transporter (ABCA1) is an important transporter responsible for cholesterol efflux. This study was performed to examine the effect of GLP-1R agonist exendin-4 on cholesterol deposition and inflammation in diabetic kidney disease and to explore the possible mechanism.

Methods: The human renal biopsy specimens with diabetic kidney disease were examined by electron microscope to determine lipid droplets. Oil Red O staining and CD31 double staining was also performed. In vivo, the double immunofluorescent staining of CD31 with GLP-1R, ABCA1, p-JAK2 and p-STAT3 was detected in the kidney tissues of exendin-4 treatment diabetic apoE-/- mice. The expression of proinflammatory cytokine (e.g. IL-6, TNF-α), CaMKK, CaMKIV, ABCA1, p-JAK2 and p-STAT3 were examined in the isolation of glomeruli from diabetic apoE-/- mice and exendin-4 treatment diabetic apoE-/- mice and in human renal glomerular endothelial cells (HRGECs) were cultured in high glucose and with cholesterol, exendin-4, STO-609 (CaMKK inhibitor), ABCA1 siRNA and AG 490 (JAK2 Inhibitor).

Results: Extensive lipid accumulation in glomerular endothelial cells of kidney biopsies from DKD patients. Double-labeling of GLP-1R, ABCA1, p-JAK2, pSTAT3 and CD31 was detected in the glomerulus of the renal tissues. Exendin-4 treatment upregulated the expression of CaMKK, CaMKIV, ABCA1, p-JAK2 and p-STAT3 and downregulated IL-6 and TNF-α, as well as ameliorated lipid accumulation compared with diabetic mice. In vitro, exendin-4 decreased the expression of IL-6,TNF-α ,whereas, STO-609(CaMKK inhibitor) , ABCA1 siRNA and AG 490 (JAK2 Inhibitor) all increased IL-6 and TNF-α in HRGECs.

Conclusions: GLP-1R agonist exendin-4 reduced cholesterol deposition and regulated ABCA1 via CaMKK/CaMKIV pathway in glomerular endothelial cells, and then activated ABCA1-JAK2/STAT3 pathway, which may ameliorat renal inflammation in diabetic apoE-/- mice.

Renal Consequences of Coxsackievirus Infection in Non-Obese Diabetic Mice Debra L. Walter,[1,2] Frank L. Schwartz,[3,5] Kelly D. Mccall,[1,3,5] Karen T. Coschigano.[1,4,5] *[1]Molecular & Cellular Biology Program, College of Arts & Sciences; [2]Dept Biological Sciences, College of Arts & Sciences; [3]Dept Specialty Medicine, Heritage College of Osteopathic Medicine; [4]Dept Biomedical Sciences, Heritage College of Osteopathic Medicine; [5]Diabetes Inst, Ohio Univ, Athens, OH.*

Background: Diabetes is the leading cause of end stage renal disease in the United States, however, it is difficult to predict which diabetic patients will go on to develop diabetic nephropathy. Recently, viruses have been found to mediate many autoimmune diseases, such as type 1 diabetes (T1D), that result in kidney damage. While research on viral induction of T1D has been brought into focus, effects of viral infection in the kidneys of T1D patients has remained undefined. Characterizing the consequences of viral infection in the kidney will allow for a better understanding of kidney disease progression in patients with virus-mediated T1D.

Methods: The non-obese diabetic (NOD) mouse is genetically predisposed to develop T1D over time. Disease onset can be accelerated by viral infection, making it a novel model to study virus-mediated kidney damage. In the current study, NOD mice were infected with coxsackievirus at 8-10 weeks of age and euthanized 3, 7, 10 and 14 days and 3, 7, 12 and 17 weeks post infection. Gene expression was measured by real-time PCR.

Results: Coxsackievirus expression in NOD mouse kidneys was upregulated acutely (3 days post infection) along with genes involved in glomerular and tubular damage and the inflammatory response (Lcn2, TLR3, MCP-1, IL-6, TNFα, etc.).

Conclusions: This study characterizes both acute and chronic virus-mediated alterations in the kidneys of NOD mice predisposed to develop T1D. Results will provide information regarding acute and chronic effects of coxsackievirus after a one-time infection, identifying functional changes occurring in the kidney and the immunological responses associated with these changes. These results will provide a better understanding of virus-mediated kidney injury in NOD mice genetically predisposed to develop T1D as a step towards understanding mechanisms of diabetic nephropathy in humans. Renal Protection by Atorvastatin in Sickle Cell Nephropathy Rima S. Zahr,[1] Vanesa Bijol,[2] Kenneth I. Ataga,[3] David Archer.[1] *[1]Pediatrics, Emory SOM, Atlanta, GA; [2]Pathology, Brigham and Womens Hospital, Boston, MA; [3]Hematology, UNC, Chapel Hill, NC.*

Background: Sickle Cell Disease (SCD) affects approximately 100,000 people in the USA. Renal involvement begins early commonly manifested as hyposthenuria with microalbuminuria occurring ~20% of SCD patients <18 years. Current treatment options for sickle cell nephropathy include ACE inhibitors or ARBs to prevent progressive proteinuria. Statins have pleiotropic effects in addition to their lipid lowering properties. Here we investigated the functional effects of Atorvastatin treatment on the development of nephropathy in a murine model of sickle cell disease.

Methods: Cohorts (n=10) of 8-12 week homozygous sickle cell mice were treated with atorvastatin (10mg/kg) or vehicle daily for 8 weeks by oral gavage. We assessed effects of atorvastatin on albuminuria, maximum urine concentrating ability and GFR at baseline and week 8. Urine was collected in metabolic cages for 24hrs and albuminuria quantified by ELISA. GFR was measured by plasma clearance of FITC-Inulin. Mice were water deprived for 12hrs and spot urine for maximum urine concentrating ability. Kidneys were prepared appropriately for light microscopic analysis and glomerular morphometry.

Results: After 8 weeks of daily treatment mice receiving atorvastatin were found to have statistically significant improvement in urine concentrating abilities and improvement in GFR ($p < 0.01$ and $p < 0.001$ respectively). Urine protein excretion was unchanged by treatment with atorvastatin. Under light microscopy there were no gross changes in appearance of glomeruli or glomerular vasculature. In addition we did not find significant statistical changes in glomerular tuft size.

Conclusions: We assessed the pleiotropic effects of statins in SCD. While we did not find differences in urine albumin excretion and glomerular tuft size we found that atorvastatin increased the low baseline GFR and improved urine concentrating abilities in sickle cell mice These complications of are found both in animal and human models. Further studies will examine microscopic examination of podocyte and endothelial structures and look at biomarkers of renal injury.

Endothelin Receptor Antagonism Protects from Sickle Cell Nephropathy Olivia Lenoir, Carole Hénique-Gréciet, Pierre-Louis Tharaux. *Paris Cardiovascular Center - PARCC, INSERM, Paris, France.*

Background: Sickle-cell disease (SCD) is characterized by chronic hemolysis and recurrent episodes of vaso-occlusive events that affect the microcirculation and lead to ischemic tissue injury with multi-organ dysfunction. Sickle cell nephropathy (SCN), a major mortality risk factor in SCD, is characterized by an early increase in glomerular filtration rate with subsequent progressive decline of renal function.Focal and segmental glomerulosclerosis (FSGS) and hypertrophied glomeruli with distended capillaries are the major hallmarks of glomerular lesions. We investigated the effects of chronic mixed ET receptor antagonism in a model of SCD-mediated FSGS.

Methods: We used SAD Hbbsingle/single hemizygous mice on the C57BL/6J background. At 3 months of age SAD mice displayed little evidence of chronic renal damage but significant glomerulomegaly compared to controls. Glomerulomegaly persisted, and was worse, at 6 months of age (average glomerular section area: 2372±207 vs. 1519±180 μm^2, $p<0.001$). In addition, SAD mice had significant glomerulosclerosis. Based on these data we treated SAD mice and controls aged 3 months with the dual ET receptor antagonist bosentan for 9 months in a preventative study, and 6 months old SAD mice for 6 months in a therapeutic study. We assessed blood pressure, kidney structure and function after 6 and 9 months of continuous treatment.

Results: In the preventative study, 6 months of bosentan therapy was associated with ~4-fold less glomerulosclerosis compared to untreated SAD mice (22±8 vs. 86±4%, $p<0.001$). Additionally, there was an 80% reduction in mean glomerular surface area ($p<0.05$). In the therapeutic study, there was a significant reduction in glomerulosclerosis ($p<0.01$) and

glomerulomegaly ($p<0.01$) compared to untreated mice but this was less effective than in the preventative study ($p<0.05$). Furthermore, chronic ET-1 receptor antagonism alleviated the development of tubulointerstital fibrosis in both groups and limited the rise of blood urea nitrogen levels that characterized untreated aged SAD mice.

Conclusions: ET receptor antagonism is a potentially useful preventative or therapeutic approach in SCN. Based on these data clinical trials are warranted.

TH-PO175

Erythropoietin and Its Carboxylated Derivative Protected aganist Chronic Cyclosporine Nephropathy Wenhan Peng, Jianghua Chen. *Kidney Disease Center, The First Affiliated Hospital, College of Medicine, Zhejiang Univ, Hangzhou, Zhejiang, China.*

Background: Erythropoietin (EPO) is known to raise hemoglobin and protect tissues and its carboxylated derivative (CEPO) has no effect on hemoglobin but could induce tissue protection. The aim of this study is to determine the effect of EPO and CEPO on the animal model of chronic cyclosporine nephropathy.

Methods: We evaluated therapeutic effects of EPO and CEPO using a rat model of chronic cyclosporine nephropathy. Rats were randomly divided into five groups: (1) the saline treatment group (control group, n=12); (2) EPO treatment group at low dose (low EPO group, 100U/kg, n=12); (3) CEPO treatment group at low dose (low CEPO group, 100U/kg, n=12); (4) EPO treatment group at high dose (high EPO group, 500U/kg, n=12); (3) CEPO treatment group at high dose (high CEPO group, 500U/kg, n=12).

Results: In control group, the levels of sodium, protein and NAG enzyme of urine, the values of serum creatinine and urea nitrogen, the concentration of MDA and GSH-PX of kidney tissue were significantly increased. Those of EPO and CEPO treatment groups were significantly lower than those of control group. EPO and CEPO could promote to produce new endothelial cells and promote microvascular formation by analysis of CD31 + / CD 34+ cell number of blood and kidney tissue. EPO and CEPO decreased collagen fibers, tubular apoptosis and expression of TGF-b1, Caspase-3 and α-SMA in kidney tissue. The higher doses of EPO and CEPO showed more protection effects. But EPO treatment increased hemoglobin concentration and induced infarction.

Conclusions: EPO and CEPO could effectively antagonize cyclosporine nephrotoxicity through anti-fibrosis,anti-inflammatory cell infiltration, anti-apoptotic, anti-oxidant, promotion new growth of renal tubular epithelial and endothelial cells, and the promotion of release and proliferation of endothelial progenitor cells.

Glucose Promotes Secretion-Dependent Renal Cyst Growth Andre Kraus,[1] Gunnar Schley,[1] Karl Kunzelmann,[2] Rainer Schreiber,[2] Kai-Uwe Eckardt,[1] Bjoern Buchholz.[1] *[1]Dept of Nephrology, Univ Erlangen-Nuernberg, Erlangen, Germany; [2]Dept of Physiology, Univ Regensburg, Regensburg, Germany.*

Background: ADPKD is characterized by continuous cyst growth which is highly based on transepithelial Cl- secretion into the cyst lumen. Since ADPKD is a long-lasting, chronic disease, there is a significant number of patients suffering from both, ADPKD and type 2 diabetes mellitus. Recently, ADPKD patients with type 2 diabetes mellitus were shown to have kidneys with almost double the volume compared to non-diabetic ADPKD patients. Therefore, we wanted to test for the impact of glucose on renal cyst growth.

Methods: We examined the effect of different glucose concentrations ranging from 5.6 mmol/l up to a maximum of 25.0 mmol/l on cyst growth of MDCK cells within a collagen matrix as well as in ex vivo cultured embryonic mouse kidneys treated with forskolin. In addition, we analysed changes in expression of potentially relevant ion channels and transporters at different glucose levels. Furthermore, we performed Ussing chamber experiments with MDCK cells in order to detect alterations of transepithelial Cl- secretion upon changes in glucose concentration.

Results: Cyst expansion highly correlated with the levels of glucose in both cyst models, revealing already significant increase of cyst growth by elevating glucose concentration from 5.6 mmol/l to 11.1 mmol/l. These effects were neither referable to changes in pH or lactate, nor due to osmotic changes demonstrated by the use of equivalent doses of mannitol. However, elevated levels of glucose resulted in significantly increased transcription of the Ca2+-activated Cl- channel Anoctamin (ANO) 1 which we have previously shown is involved in renal cyst growth. In line with these data, CaCCInh-AO1, a specific inhibitor of ANO1, inhibited glucose-dependent cyst expansion in both models. In addition, Ussing chamber experiments revealed a significant increase of Ca2+-dependent Cl- secretion at elevated glucose levels which could be inhibited by the use of CaCCInh-AO1.

Conclusions: Increased glucose levels could augment secretion-dependent cyst growth in ADPKD. Therefore, tight glucose control might be beneficial in ADPKD to reduce cyst growth and preserve renal function.

Kidney Stones Provide a "Third Hit in Autosomal Dominant Polycystic Kidney Disease" Jacob A. Torres,[1] Mina Rezaei,[1] Saeed R. Khan,[2] Thomas Weimbs.[1] *[1]Molecular Celluluar and Developmental Biology, Univ California Santa Barbara, Santa Barbara, CA; [2]Dept of Pathology, Univ of Florida, Gainesville, FL.*

Background: The progression of autosomal-dominant polycystic kidney disease (ADPKD) exhibits high inter- and intrafamilial variability suggesting the possibility that unknown environmental factors may play an important role. Work on mouse models has led to the idea that renal injury is required as a so-called "third-hit trigger" for the initiation of renal cysts. We hypothesized that a much more frequent and prevalent form of renal insult may determine the speed of progression in ADPKD. We report here that chronic or acute hyperoxaluria leads to very rapid dilation of renal tubule diameters in response to CaOx crystal deposition.

Methods: Mice and rats were challenged with intraperitoneally administered oxalate to rapidly produce calcium oxalate crystals or were fed oxalate producing compounds to form oxalate stones inside the kidney. To test the effect of the mTOR pathway, mTOR was inhibited with the administration of rapamycin prior to oxalate administration.

Results: The mTOR and STAT3 signaling pathways are rapidly activated in dilated tubule cells. Fast tubule dilation can be prevented by mTOR inhibition. Once crystals are cleared, mTOR and STAT3 signaling is inhibited and tubule diameters return back to normal. Our results suggest that tubule diameter dilation is an active mechanism employed by the kidney to clear lodged crystals. Both, mTOR and STAT3 have previously been shown to be aberrantly activated in cyst-lining cells in ADPKD and drive cyst growth. We find that challenging pre-conditioned mice lacking primary cilia with oxalate leads to persistent tubule dilation.

Conclusions: These results suggest that cilia are required for reestablishing normal tubule diameters after crystal clearing. Furthermore, these results suggest that renal crystal deposition may be a clinically relevant, environmentally controlled "third-hit trigger" that affects disease progression in ADPKD. This suggests that dietary changes or treatments to reduce renal crystal burden may be effective in slowing ADPKD progression.

Soluble RAGE Alleviates Disease Progression in Autosomal Dominant Polycystic Kidney Disease by Down-Regulation of Cell Proliferation Jong Hoon Park, Eunji Lee, Hyowon Mun, Je Yeong Ko, Do Yeon Kim. *Dept of Biological Science, Sookmyung Women's Univ, Seoul, Republic of Korea.*

Background: Autosomal polycystic kidney disease (ADPKD) is a one of the common genetic renal diseases in which epithelial-lining fluid-filled cysts appear in kidneys. It is accompanied by hyper-activation of cell proliferation, interstitial inflammation and fibrosis around the cyst lining cells, finally reaching end-stage renal disease (ESRD). Previously, we found high expression of ligands stimulating the receptor for advanced glycation endproducts (RAGE) in ADPKD mice. Furthermore, gene silencing of RAGE was revealed to reduce cystogenesis via down-regulation of cell proliferation in vitro, while intravenous administration of anti-RAGE adenovirus in vivo also displayed alleviation of the disease.

Methods: Using either mice primary cells or human ADPKD cell line WT9-12, both sRAGE treatment and over-expression of sRAGE with cloned construct we established herein were tested in vitro. In addition, in vivo test via intraperitoneal injection using ADPKD mice model jck, and confirmed the in vitro results in in vivo systems.

Results: Here, we attempted to identify the role of soluble RAGE (sRAGE) in inhibiting the progression of ADPKD, in vivo. sRAGE is an endogenously expressed form of RAGE which has no membrane-anchoring domain, thereby being able to neutralize the ligands that stimulate RAGE signals. Both over-expression of sRAGE and sRAGE treatment blocked RAGE-mediated cell proliferation in vitro. In addition, sRAGE-injected ADPKD mice showed reduced cysts accompanied by enhanced renal function, inhibition of cell proliferation, inflammation and fibrosis.

Conclusions: These positive therapeutic effects of sRAGE displayed little liver toxicity, suggesting it as a new potential therapeutic target of ADPKD with low side effects.

Metformin Inhibits Cyst Formation in a Zebrafish Model of Polycystic Kidney Disease Ming-Yang Chang. *Kidney Research Center and Dept of Nephrology, Chang Gung Memorial Hospital, Chang Gung Univ College of Medicine, Kueishan, Taoyuan, Taiwan.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by enhanced fluid secretion and abnormal cell proliferation in renal tubular epithelial cells. Recent research has proposed that activation of AMP-activated kinase (AMPK) is a novel treatment strategy for ADPKD. We examined the effects of metformin on the initiation of pronephric cysts in a PKD2 zebrafish model.

Methods: Morpholino-mediated knockdown of pkd2 was performed in wt-1b pronephric-specific GFP-expressing zebrafish embryos to induce visible pronephric cysts for observation. Pkd2 morphants were incubated with metformin (2.5 to 10 mM) in the embryo medium until 48 hours post fertilization.

Results: Metformin significantly reduces the frequency of cyst formation and pronephric tubular cell proliferation in pkd2 morphant embryos. Whole mount in situ hybridization for L-plastin mRNA showed significantly reduced macrophage infiltration

in metformin-treated pkd2 morphants. RT-PCR showed that P2X7, IL-1β and IL-10 mRNA expression were significantly inhibited by metformin. Simultaneously morpholino knockdown of AMPK a1 prevents the rescue effects of metformin on cystogenesis.

Conclusions: We showed that metformin decreases cyst formation through inhibiting cell proliferation and macrophage accumulation in a pkd2 zebrafish model. These results indicate that metformin reduces the earliest cyst formation in polycystic kidney disease, although its effect on progression of disease remained to be investigated.

Cardiac Hypertrophy and Cardiac mTORC1/2 Signaling in Rodent Models of PKD

Kameswaran Ravichandran, Qian Wang, Charles L. Edelstein. *Univ Colorado Denver.*

Background: Cardiac disease is the commonest cause of death in ADPKD patients. Young normotensive ADPKD adults and children have higher LVMI compared to controls. Aim of study was to determine in rodent PKD models: 1) whether there is cardiac hypertrophy and increased mTORC1/2 signaling in the heart 2) the effect of mTOR kinase inhibition on cardiac hypertrophy.

Methods: Heart weight was determined in Pkd1 -/- mice, Pkd2WS25/- (Pkd2 -/- mice) and Han:SPRD (Cy/+) rats. pS6 and p4E-BP1, markers of mTORC1 and pAktSer473, marker of mTORC2, were determined by immunoblot analysis of 3 separate experiments. Pkd2 -/- mice were treated with an mTOR antisense oligonucleotide (ASO) that inhibits mTORC1/2 and PKD from 4-16 wks of age. Cy/+ rats were treated with the mTOR kinase inhibitor, PP242, that inhibits mTORC1/2 and PKD from 3-8 wks of age.

Results: There was increased heart weight in 150 d old Pkd1 -/- mice, 16 wk old Pkd2 -/- mice, 8 wk old normotensive Cy/+ rats and Pkd2+/- mice that are haplo-insufficient for Pkd2 and do not have hypertension. There was increased pS6, p4E-BP1 and pAkt in Pkd1 -/- hearts and increased p4E-BP1 and pAkt in Pkd2 -/- and Pkd2+/- hearts. mTOR ASO resulted in less p4E-BP1 and pAkt and less cardiac hypertrophy in Pkd 2-/- mice. mTOR kinase inhibitor, PP242, resulted in less cardiac hypertrophy in normotensive Cy/+ rats HW/TBW(%) was 0.4 in +/+, 0.52 in Cy/+ ($P<0.05$ vs +/+) and 0.44 in Cy/+PP242 ($P<0.05$ vs. Cy/+).

	++	Pkd1 -/-	++	Pkd2 -/-	Pkd2 -/- ASO	+/+	Pkd2 +/-
HW/TBW (%)	0.46	0.61*	0.52	0.66*	0.56**	0.52	0.69*
p/tS6	+	+++	+	+	+	+	+
p/t 4E-BP1	+	+++	+	++	+	+	++
p/t 4E-BP1	+	++	+	++	+	+	++
*P<0.05 vs +/+	**P<0.05 vs Pkd2-/-	HW=heart weight	p/t= phospho/ total				

Conclusions: There was increased heart weight in normotensive Cy/+ rats and Pkd2+/- mice. There was increased mTORC1 and 2 signaling in Pkd1 -/-, Pkd2 +/- (without PKD) and Pkd2 -/- hearts. mTOR kinase inhibition, that blocks both mTORC1 and 2, resulted in less cardiac hypertrophy. Discovery of an agent e.g. mTOR kinase or 4E-BP1 inhibitor that decreases early cardiac hypertrophy in PKD in addition to decreasing PKD would be a significant finding and would increase the enthusiasm to use these agents in ADPKD patients.

TH-PO181

Polycystic Kidney Disease – A Case of Suppressed Autophagy?

Kameswaran Ravichandran,[1] Charles L. Edelstein.[1] *[1]Univ of Colorado Denver; [2]Univ of Colorado Denver.*

Background: Autophagy is a normal physiological process that involves the degradation of damaged cellular components. Autophagy in general promotes cell survival while apoptosis that promotes cell death. We have reported (Edelstein et al, AJP, 2011) that there are features of autophagy like autophagosomes, mitophagy and autolysosomes in normal tubules and tubular cells lining cysts in Cy/+ rats with PKD and that there is suppression of autophagic flux in cpk mice with PKD.

Methods: 150 day old mice with PKD due to a kidney specific Pkd1 knockout were studied. MDCK cells with a stable knockdown of PC1 was achieved by lentiviral-mediated delivery of a specific SiRNA for PKD1 were studied. MDCK cells that form tubules were used as controls. LC3-II, a marker of autophagic flux and cleaved caspase-3, a marker of apoptosis, were measured by immunoblot analysis of at least 3 separate experiments. Pkd1 -/- mice were treated with bafilomycin-A1 (5 mg/kg//d IP), a lysosomal inhibitor, for 3 days. MDCK cells were treated with bafilomycin 100 nm.

Results: In Pkd1 -/- mouse kidneys there was an increase in LC3 –II compared to wild type. The increase in LC3-II in Pkd1-/- versus wild type kidneys suggests increased autophagosome synthesis or decreased degradation in the lysosome. To investigate these possibilities, Pkd1 -/- mice were treated with bafilomycin-A1. Bafilomycin-A1 had no effect on LC3-II in PKD kidneys of Pkd1 -/- mice. To determine the direct effect of PC-1 knockout on autophagy, PC-1 -/- MDCK cells were studied. In PC-1 -/- cells, there was a decrease in LC3-II compared to control MDCK. In PC1 -/- cells treated with bafilomycin, there was a further suppression of LC3-II, indicating decreased autophagic flux. Increased apoptosis is a feature of PKD kidneys. In the PC-1 -/- cells there was a 2-fold increase in cleaved caspase-3, a marker of apoptosis, associated with the decrease in autophagic flux.

Conclusions: The lack of effect of the lysosomal inhibitor bafilomycin-A1 to increase LC3-II in Pkd1-/- kidneys and in PC-1 -/- cells suggests a defect in autophagy resulting from a block of autophagosome-lysosome fusion and degradation. There was an association between suppressed autophagy and increased apoptosis in PC-1 -/- cells.

Retinoid X Receptor Pathway: A Novel Signaling Cascade Responsible for Cystogenesis in Three Rodent Models of Polycystic Kidney Disease

Daisuke Yoshihara,[1] Masanori Kugita,[1] Harold M. Aukema,[2] Tamio Yamaguchi,[2] Shizuko Nagao.[1] *[1]Education and Research Center of Animal Models for Human Diseases, Fujita Health Univ, Toyoake, Aichi, Japan; [2]Dept of Human Nutritional Sciences, Univ of Manitoba, Winnipeg, MB, Canada.*

Background: Polycystic kidney disease (PKD) is the most common inherited renal disorder and is characterized by innumerable cysts and tubular epithelial cell proliferation. We previously speculated that retinoid X receptor (RXR) may be related to cystogenesis in the Han:SPRD-Cy (*Cy/+*) rat, since VDR/RXR activation, LPS/IL-1-mediated inhibition of RXR function, and LXR/RXR activation were altered in diseased kidneys. RXR is known to induce cellular proliferation and is normally degraded by ubiquitin after binding to its cognate ligand. In human hepatocellular carcinoma, the degradation rate of RXR is abnormally reduced, and treatment with a RXR agonist suppressed its proliferative activity (Adachi, Hepatology 2002). We therefore determined the expression and distribution of renal RXR, and the effect of a RXR agonist in polycystic kidneys.

Methods: Kidneys were obtained from three rodent models: *Cy/+* rats, jck and pcy mice. Expression of RXR was confirmed by western blot analyses. Co-localization of RXR with PCNA, an index for cell proliferation, was detected by standard procedures. In addition, *Cy/+* rats were orally treated with 30mg/kg bexaroten (BEX), a RXR agonist, from 4 to 10 weeks of age.

Results: In all three models, renal RXR levels were increased compared with age-matched rats/mice with normal kidneys. Total RXR was detected in the nuclear extract of cystic kidneys, and increased RXR was co-localized with PCNA in cystic epithelia nuclei. In *Cy/+* rats, BEX treatment significantly decreased RXR expression and kidney weight adjusted to body weight.

Conclusions: RXR was related to aberrant cell proliferation in PKD progression in three different animal models, and a RXR agonist suppressed disease progression in *Cy/+* rats. These findings suggest that RXR signaling may have an important role in cystogenesis and that RXR ligands may have therapeutic potential.

Integrin Linked Kinase Promotes Cyst Growth and Fibrosis in ADPKD

Archana Raman, Gail Reif, Yuqiao Dai, Darren P. Wallace. *Depts of Medicine and Physiology, KU Kidney Inst, Univ of Kansas Medical Center, Kansas City, KS.*

Background: Aberrant expression of extracellular matrix (ECM) molecules and secreted factors contribute to renal cyst growth and fibrosis in ADPKD. Periostin, a matricellular protein involved in tissue development and repair, is overexpressed in kidneys of ADPKD patients and murine models of PKD. Gene knockout of periostin reduced renal cyst growth and interstitial fibrosis, and prolonged the survival of PKD mice. Periostin binds to a_v-integrins (a_vb_3, $a_v\beta_5$) and induces cell proliferation via integrin linked kinase (ILK) activation of Akt/ mTOR, a key signaling pathway involved in PKD. We have determined if knockdown/knockout of ILK prevents periostin-induced proliferation of human ADPKD cells and reduces cyst growth and fibrosis in an ADPKD mouse.

Methods: We knocked down ILK expression in ADPKD cells using lentiviral shRNA. Activation of the Akt/ mTOR pathway was determined by measuring phosphorylation of Akt and S6 kinase (S6K), a downstream target of mTOR. To determine if ILK may be a potential therapeutic target, we knocked out ILK in collecting ducts of *$Pkd1^{flox/flox}$: Pkhd1-Cre* mice, an orthologous model of ADPKD, by breeding these mice with *$ILK^{flox/flox}$* mice. At postnatal day 25, mice were euthanized and kidney weight/body weight (%KW/BW), cystic index, interstitial fibrosis and cell proliferation were measured.

Results: We found that ILK knockdown blocked periostin-induced phosphorylation of Akt and S6K and proliferation of human ADPKD cells. CPD-22, an ILK inhibitor, also blocked the effect of periostin on the Akt/ mTOR pathway and ADPKD cell proliferation. Gene knockout of one ILK allele (*$Pkd1^{flox/flox}$: $ILK^{flox/+}$: Pkhd1-Cre*) or both alleles (*$Pkd1^{flox/flox}$: $ILK^{flox/flox}$: Pkhd1-Cre*) significantly decreased %KW/BW, renal cystic index and cell proliferation. Furthermore, ILK knockdown reduced renal interstitial edema and fibrosis in PKD mice, suggesting that blockade of the ILK signaling pathway may reduce both cyst growth and fibrosis in ADPKD.

Conclusions: Aberrant expression of periostin stimulates ILK activation of signaling pathways that contribute to renal cyst growth and fibrosis, suggesting that ILK may be a therapeutic target for ADPKD.

Periostin Regulates Polycystic Kidney Cell Proliferation and Cyst Formation via CFTR and JAK2/STAT3 Signaling Pathway Sun Ae Han,[1] Hayne C. Park,[2] Hyunsuk Kim,[3] Hyunjin Ryu,[3] Kook-Hwan Oh,[3] Young-Hwan Hwang,[4] Curie Ahn.[3] *[1]Transplanatation Research institute, Seoul National Univ Medical Research Center, Seoul, Korea; [2]Dept of Internal Medicine, Armed Forces Capital Hospital, Sungnam-si, Gyunggi-do, Korea; [3]Dept of Internal Medicine, Seoul National Univ Hospital, Seoul, Korea; [4]Dept of Internal Medicine, Eulji General Hospital, Seoul, Korea.*

Background: Renal cyst formation and fibrosis are the hallmark of autosomal dominant polycystic kidney disease (ADPKD). ADPKD cyst-lining cells have an increased proliferation rate and are surrounded by an abnormal extracellular matrix (ECM). The matricellular protein periostin was shown to be activated in cyst-lining cells in ADPKD and PKD mouse models and may drive renal cyst growth, but the mechanism of periostin-induced cyst formation is still unclear. We examined the effect of periostin expression on cystic fibrosis transmembrane conductance regulator (CFTR) and phosphorylated levels of Janus kinase 2 (JAK2) /signal transducers and activators of transcription 3 (STAT3) signaling pathway.

Methods: Periostin expression was analyzed using immunohistochemistry and western blot analysis in ADPKD cells and normal human kidney (NHK) cells. Cell growth and western blot analysis for related molecular levels were assayed after suppression of periostin by small interfering RNA (siRNA). Finally, a three-dimensional culture was performed to understand how periostin affected cyst formation, in vitro.

Results: The periostin expression was highly increased in ADPKD cells compared to NHK cells. Transfection of ADPKD cells with periostin siRNA decreased cell growth and reduced the expression of CFTR and phosphorylated levels of JAK2/STAT3. In three-dimensional culture, addition of recombinant periostin enhanced cyst formation, whereas periostin depleted cells showed lower level of cystogenesis.

Conclusions: Periostin stimulated cyst formation via CFTR and JAK2/STAT3 signaling pathway in ADPKD.

TH-PO185

The Possible Role of mTORC1 and TCA Cycle in Renal Cyst Formation and Transformation Luca Drusian,[1,2] Monika Pema,[1] Valeria Mannella,[1] Isaline Rowe,[1] Marco Chiaravalli,[1] Musco Giovanna,[1] Alessandra Boletta.[1] *[1]Div Genetics and Cell Biology, San Raffaele Scientific Inst, Milan, MI, Italy; [2]Univ Vita-Salute San Raffaele, San Raffaele Scientific Inst, Milan, MI, Italy.*

Background: We have recently shown that PKD is characterized by an increased use of glycolysis in a process resembling the Warburg effect. This feature of PKD is in part dependent on mTORC1. However, mTORC1 upregulation, increased proliferation and the Warburg effect are hallmarks of cancer. In contrast, ADPKD patients do not have a propensity to increased rates of cancer as compared to the normal population. We aimed at investigating this conundrum.

Methods: We generated a mouse model carrying kidney-specific inactivation of the *Tsc1* gene (*Tsc1*KO), which survives for up to three months and displays cyst formation, followed by cystadenomas and transformation into carcinomas.

Results: This phenotype is fully penetrant and the lesions manifest progressively within a reproducible window of time (P20 to P80). We performed metabolomic profiling both by NMR spectroscopy and by mass spectrometry on these kidneys collected at different time points (P20, P50 and P80). The analysis revealed the presence of major changes at the level of the TCA cycle and a strong accumulation of fumarate, which is completely non-detectable in normal kidneys at any stage. We are currently investigating if these metabolic changes can account for the progressive transformation of cysts into carcinomas. Notably, a preliminary study of metabolic profiling in kidneys derived from mice carrying a kidney-specific inactivation of the *Pkd1* gene, revealed that fumarate does not accumulate in these mutants. We hypothesize that ADPKD kidneys display a mild metabolic change affecting glycolysis, but not the TCA cycle, while cancerous lesions have a more profound metabolic alteration.

Conclusions: These studies will hopefully help identifying metabolic changes specific for PKD and likely good targets for therapy.

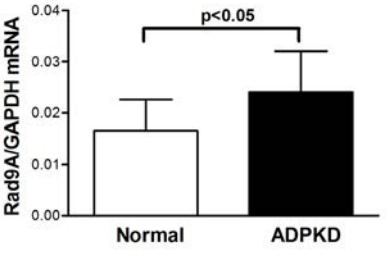
TH-PO186

Aberrant Expression of Rad9 in ADPKD Wei Wang, Michel Chonchol, Berenice Y. Gitomer. *Dept of Medicine, Univ of Colorado, Aurora, CO.*

Background: The pathogenesis of ADPKD is still not fully understood, however, increased proliferation of renal tubular epithelial cells is a key factor in cyst growth. There are similarities between cyst growth in ADPKD and the characteristics of benign tumor. Dysregulated expression of genes involved in cell cycle gene regulation as a result of epigenetic modification by DNA methylation has been associated with oncogenesis. We thus hypothesized that aberrant methylation of cell cycle related genes might be an underlying mechanism in ADPKD.

Methods: Genomic DNA was extracted from normal (HK-2) and ADPKD (WT9-12) tubular epithelial cells using a DNeasy blood and tissue kit (Qiagen). A cell-cycle DNA methylation PCR array (Qiagen) was used to examine gene methylation. RNA was extracted from normal and ADPKD kidneys using RNaqueous-4-PCR kit (Ambion). mRNA levels were examined using real-time RT-PCR.

Results: Among the 22 cell cycle genes examined,Rad9 was significantly different between the control HK-2 and cystic WT 9-12 cells. 62.2% of the gene was methylated in HK-2 cells as compared to only 1.4% in WT 9-12 cells. Rad9 mRNA levels were significantly higher in human ADPKD (0.024±0.008; n=7) kidneys than in normal kidney tissues (0.0166±0.006; n=4).



Conclusions: Aberrant expression of Rad9 occurs in ADPKD kidneys. This is at least partly due to the decreased methylation of the gene. Expression of Rad9 part of the 9-1-1 (Rad9-Hus1-Rad1) complex is increased and has been associated with DNA damage and with tumor growth. Increased susceptibility for genomic DNA damage has been demonstrated in ADPKD which may affect cyst development or growth. While the role of Rad9 in ADPKD merits further study it is intriguing to postulate that Rad9 may play a role in cyst growth.

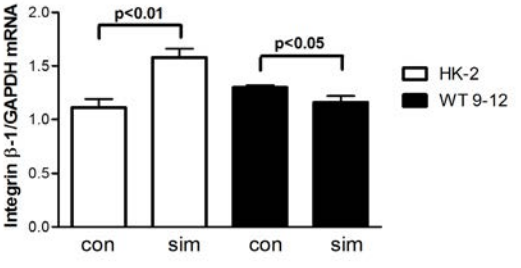
TH-PO187

Effect of Simvastatin on Cell Adhesion in ADPKD Wei Wang, Michel Chonchol, Melissa A. Cadnapaphornchai, Berenice Y. Gitomer. *Dept of Medicine, Univ of Colorado, aurora, CO.*

Background: We have previously shown that statin treatment reduced the rate of cyst growth in children and young adults with autosomal dominant polycystic kidney disease (ADPKD) suggesting that this may be an effective intervention to slow progression of renal disease in ADPKD, however the mechanisms are unclear. Treatment of cultured cystic renal tubular cells with simvastatin significantly reduces cell viability in cystic epithelial cells (WT 9-12) in a time and dose dependent manner but had minimal effect on normal tubular epithelial cultures (HK-2). We hypothesized that loss of viability was associated with reduced cell adhesion due to reduced expression of cell adhesion proteins.

Methods: Cystic tubular epithelia cells and normal renal tubular epithelial cells were treated with 1μM simvastatin for 24 hours and mRNA expression of integrin β-1 and E-cadherin assessed by quantitative PCR.

Results: In normal tubular cells simvastatin significantly increased integrin β-1 expression while a significant decrease in expression was observed in the cystic tubular cells.



In untreated cystic tubular epithelial cells E-cadherin expression was significantly lower compared to normal control cells. Expression of E-cadherin was slightly reduced in the cystic cells after treatment with simvastatin. This cytoxic effect on cystic cells was increased with simvastatin compared to pravastatin.

Conclusions: Simvastatin may have pleiotropic effects on cystic epithelial cells including an effect on cell adhesion. The lack of effect on normal tubular epithelial cells indicates that simvastatin may have specific therapeutic benefits in human ADPKD. Future clinical trials will be necessary to test the benefits of simvastatin on slowing cyst growth.

TH-PO188

Identification of a Renal Pkd1/Pc1 Self-Amplification Mechanism via c-Myc in Polycystic Kidney Disease Marie Trudel, Almira Kurbegovic, Delphine Cotteverte, Jennifer Lake. *Molecular Genetics and Development, Inst de Recherches Cliniques de Montréal, Montréal, QC, Canada.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common monogenic disorder associated mainly with Pkd1 mutations. One of the most extensively studied dominant polycystic kidney disease (PKD) mouse model is the transgenic SBM mice produced by specific targeting of c-Myc expression in the kidneys. All mice reproducibly developed tubular and glomerular cysts leading to renal insufficiency with high similarities to the orthologous Pkd1 dosage-increased and -reduced mouse models.

Methods: The cystogenic mechanisms of SBM and Pkd1 orthologous models were investigated concomitantly by molecular and cellular analyses.

Results: We first determined that Pkd1 dosage-increased and -reduced mouse models lead to stimulation of renal c-Myc expression (5-10-fold) as in ADPKD renal tissues, identifying a key downstream effector and the high relevance of SBM mice. This prompted analysis of SBM mice that showed enhanced protein expression of c-Myc full length and nick-Myc in tubular epithelial cells. C-Myc immunostaining determined intense nuclear sub-localization mainly in cell clusters of cystic tubules. Renal SBM proliferation index was increased 10-fold over non-transgenic controls. Analysis of c-Myc downstream target, the cystogenic hypoxia inducible factor 1 alpha (Hif1α) in SBM kidneys showed intense stimulation as observed in ADPKD, particularly in epithelial cells of cystic tubules and glomeruli. SBM kidneys also displayed a marked activation of β-catenin in renal epithelium that was stimulated as well in both Pc1 dosage-increased and reduced mouse models. Importantly, SBM caused striking upregulation of polycystin-1/Pc1 and Pkd1 ~6-17-fold over endogenous levels in kidneys. SBM and Pkd1 mouse models uncovered a reciprocal cystogenic targeting and an inter-regulatory network of c-Myc and Pc1 in PKD.

Conclusions: Together our data support a regulatory positive Pkd1/Pc1 self-amplification loop via c-Myc that governs ADPKD.

DNMT1 Promotes Renal Cyst Growth in Autosomal Dominant Polycystic Kidney Disease

Xia Zhou,[1,2] Xiaoyan Li,[1,2] Yijian Chen,[1,2] Senta K. Georgia,[3] Xiaogang Li.[1,2] *[1]Internal Medicine; [2]Kidney Inst, Univ of Kansas Medical Center, Kansas City, KS; [3]Children's Hospital Los Angeles, Los Angeles, CA.*

Background: DNA methylation was the first epigenetic modification to be identified. Aberrant expression of DNA methyltransferases (DNMTs) and disruption of DNA methylation patterns are closely associated with human disease. However, the roles and underlying mechanisms of DNMTs in polycystic kidney disease remain unknown. In this study, we investigated the direct involvement of DNMT1 in regulating cystogenesis.

Methods: To understand the role of DNMT1 in cyst growth *in vivo*, we generated *Pkd1* and DNMT1 double conditional knockout *Pkd1*$^{flox/flox}$*:DNMT1*$^{flox/flox}$*:Pkhd1-Cre* mice. To identify the novel DNMT1 target genes involving in cystogenesis, we performed ChIP-seq, MBD-seq and RNA-seq analysis.

Results: We found that knockout of DNMT1 delayed cyst growth characterized by decrease of 1) cyst index; 2) the kidney weight (KW)/body weight (BW) ratios; and 3) the blood urea nitrogen (BUN) levels ($p < 0.01$); as well as the 1) the phosphorylation of ERK, Rb, S6 and STAT3; and 2) the expression of cyclin D1, which were upregulated and contributesd to cyst growth in ADPKD. Further, we identified 8 novel DNMT1 target genes which were found within the intersection of the DNMT1 binding genes identified by ChIP-seq and the CpG islands hypermethylated genes identified by MBD-seq, and were downregulated in cystic renal epithelial cells as analyzed by RNA-seq. The downregulation of these candidate genes were validated by qRT-PCR. One of these genes named Ptprm (protein tyrosine phosphatase receptor type M) is a tumor suppressor gene which regulates the tyrosine phosphorylation of proteins and is hypermethylated in cancers. Inhibition of DNMT1 with 5-azacytidine increased the expression of Ptprm mRNA but decreased the phosphorylation of ERK, Rb, S6 and STAT3 as well as the expression of cyclin D1 as that in *Pkd1* and DNMT1 knockout kidneys.

Conclusions: DNMT1 promotes renal cyst growth in ADPKD through methylation of Ptprm gene to inhibit its expression, leading to increase the phosphorylation and activation of PKD associated pathways.

Triptolide Retarded Disease Progression in Polycystic Kidney Disease Through Reducing Polycystin-2 Over-Expression and Suppressing JAK2/STAT3 Pathway

Ming Wu, Changlin Mei. *Kidney Inst, Dept of Nephrology, Shanghai Changzheng Hospital, Shanghai, China.*

Background: The beneficial effect of triptolide in polycystic kidney disease (PKD) has been shown in several animal models and also in a clinical trial. It is suggested that triptolide inhibits cell proliferation in PKD by activating endoplasmic reticulum bounded calcium channel polycystin-2 (PC2) and thereby enhancing intracellular calcium level. The aim of current study was to prove a new working mechanism of triptolide in PKD that triptolide directly inhibit PC2 mediated mitogenic signaling pathways which is independent of calcium.

Results: Triptolide inhibited ADPKD cell proliferation which was correlated with decreased PC2 protein level and reduced JAK2/STAT3 activation. Over-expression of PC2 restored triptolide suppressed cell proliferation and JAK2/STAT3 activity. Blockage of PC2 by siRNA abolished triptolide mediated inhibition on cell proliferation and JAK2/STAT3 activity. Twelve weeks triptolide treatment reduced BUN and creatinine level by 22% and 25% respectively in cystic Cy/+ Han:SPRD rats. Administration of triptolide decreased the two kidney weight/total body weight ratio and cystic volume density in Cy/+ rats by 18.6% and 12.7% respectively. Western blot analysis showed that tiptolide decreased polycystin-2 protein level and reduced JAK2/STAT3 activation *in vivo*.

Conclusions: Our study revealed a novel triptolide's mechanism of action in PKD. Reducing PC2 over-expressed could be a new strategy for PKD treatment in the future.

Resveratrol Delayed Disease Progression in Polycystic Kidney Disease Through Attenuating P50/p65 Induced Inflammation

Ming Wu, Changlin Mei. *Kidney Inst, Dept of Nephrology, Shanghai Changzheng Hospital, Shanghai, China.*

Background: The natural anti-inflammatory compound resveratrol displayed beneficial effects in a variety of diseases. The current study aimed to study the efficacy of resveratrol in polycystic kidney disease (PKD) and reveal it's underline mechanism.

Results: Five weeks resveratrol treatment reduced BUN and creatinine level by 20% and 24% respectively in cystic Cy/+ Han:SPRD rats. Administration of resveratrol decreased the two kidney weight/total body weight ratio and cystic volume density in Cy/+ rats by 15% and 24% respectively. The proliferation index and the macrophage infiltration index were reduced by 40/% and 43% respectively in resveratrol treated cystic kidneys in comparison to vehicle treated cystic kidneys. Resveratrol reduced protein levels of pro-inflammatory factors such as MCP-1, TNF-α and CFB in Cy/+ kidneys, which was correlated with decreased activity of NF-κB (p50/p65). Resveratrol and NF-κB specific inhibitor QNZ inhibited the expression of MCP-1, TNF-α and CFB and reduced NF-κB activity in ADPKD cells. Moreover NF-κB blockage minimized the reduction but not completely abolish the inhibition of inflammatory factor production by resveratrol treatment.

Conclusions: NF-κB signaling pathway is activated in PKD and partly responsible for PKD inflammation. Targeting inflammation through resveratrol could be a new strategy for PKD treatment in the future.

Increased Hedgehog Signaling in jck Mice and in Human ADPKD

Luciane M. Silva, Bailey A. Allard, Damon T. Jacobs, Gail Reif, Archana Raman, Darren P. Wallace, Pamela Vivian Tran. *Anatomy and Cell Biology, Kidney Inst, Univ of Kansas Medical Center, Kansas City, KS.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is caused by disruption of Polycystin-1 and Polycystin-2, which localize to primary cilia of renal epithelial cells. Activation of the Hedgehog (Hh) pathway relies on primary cilia. Previously, we showed that renal cystic disease in mice caused by deletion of *Thm1*, a ciliary gene and negative regulator of Hh signaling, was attenuated by genetically downregulating the Hh pathway, suggesting a role for enhanced Hh activity in renal cystogenesis. We aim to determine whether a role for dysregulated Hh signaling extends to cystic disease in *jck* mice and in human ADPKD.

Methods: We determined whether Hh activity correlated with disease progression in *jck* mutants. Hh signaling was downregulated in *jck* mice by deleting *Gli2*, the primary transcriptional activator of the Hh pathway, using a ubiquitous, tamoxifen-inducible Cre recombinase. To examine Hh status in human ADPKD, we compared Hh levels in normal human kidney (NHK) and ADPKD tissue and primary cells using Q-PCR, immunohistochemistry and immunofluorescence.

Results: In *jck* mice, expression of Hh target genes, *Gli1*, *Gli3* and *Ptch2,* were elevated at seven weeks of age and increased further at 18 weeks of age. Immunohistochemistry for GLI1 revealed increased expression in renal epithelial and interstitial cells, suggesting both paracrine and autocrine signaling mechanisms. Further, *jck,Gli2* double mutants showed decreased renal cystogenesis compared to single mutant littermates, suggesting a causative role for increased Hh signaling in *jck* cystic disease. In human ADPKD cells and tissues, Hh target gene expression was elevated and GLI1 protein expression was increased in both cystic epithelial cells and interstitial cells. Additionally, even in the absence of a Hh agonist, ADPKD cells showed localization of the Smoothened signal transducer to primary cilia, reflecting increased basal pathway activity.

Conclusions: Increased Hh signaling appears to play a role in renal cystogenesis and could represent a novel therapeutic target for ADPKD.

The Development of a Clinically Relevant Mouse Model for Autosomal Dominant Polycystic Kidney Disease

Wouter N. Leonhard,[1] Hester Happé,[1] Emile De Heer,[2] Dorien J.M. Peters.[1] *[1]Human Genetics; [2]Pathology, Leiden Univ Medical Center, Netherlands.*

Background: To perform pre-clinical studies for Autosomal Dominant Polycystic Kidney Disease (ADPKD), it is desirable that the models have an adult onset of PKD with cysts derived from all tubular segments, but within a time-window that is suitable for therapeutic testing. As described previously, *Pkd1* deletion in neonatal mice leads to rapid PKD and *Pkd1* deletion in adult mice leads to slow PKD. The differences in rate of PKD progression are largely explained by a rather sharp developmental switch that occurs around P13 (Piontek *et. al.* 2007). This suggests that there is limited flexibility in generating models with intermediate phenotypes. Surprisingly, in this study, *Pkd1* inactivation at different ages in tamoxifen inducible *Pkd1* knockout mice led to multiple models for PKD with different characteristics.

Methods: To inactivate *Pkd1*, tamoxifen administration was done on three consecutive days at P10, P16, P18 or P40. Disease progression was monitored by measuring Blood Urea concentration. The cystic burden and segmental origin of the cysts was studied using PAS staining and IHC for segment specific markers.

Results: P10 mice developed PKD within 3 to 4 weeks, with large distal and collecting duct cysts and few proximal tubular cysts. The progression rate in P16 mice was highly variable. By contrast, P18 mice developed end-stage PKD at an age of 14-17 weeks, with

cysts derived from all tubular segments that contributed equally to the phenotype. P40 mice developed end-stage PKD at an age of approximately 22 weeks with predominantly proximal cysts.

Conclusions: Despite a sharp developmental switch at P13 that has been proposed previously (Piontek *et. al.* 2007) it is possible to generate multiple models with different progression rates and different origins of cyst. Notably, *Pkd1* deletion at P18 reproducibly led to adult onset PKD within a time-window that is highly suitable for therapeutic testing. In addition, since cysts were derived from all tubular segments, this model will contribute to finding a clinically relevant therapy for ADPKD patients.

Identification of New Signaling Pathways Related to Polycystic Kidney Disease: From Animal Models to Treatment Olaya Lamas-Gonzalez,[1] Susana Bravo,[1] Ana Belen Sanz,[2] Ana Barcia de la Iglesia,[1] Alberto Ortiz,[2] Terry J. Watnick,[3] Gregory G. Germino,[4] Candido Diaz rodriguez,[1] Miguel A. Garcia-Gonzalez.[1] *[1]Health Research Inst of Santiago de Compostela, Spain; [2]Fundación Jiménez Díaz, Spain; [3]Univ of Maryland School of Medicine; [4]National Inst of Diabetes and Digestive and Kidney Disease National Inst of Health.*

Background: Pathogenesis of Polycystic Kidney Disease (PKD) has been related to a number of different mechanisms that make it very complex and there is no therapy for complete inhibition of cystogenesis, although there are advances in controlling cyst volume and cyst progression.

Methods: Taking advantage of the identified developmental window in PKD using the Pkd1 conditional KO mouse, we have identified the differential proteome of the cystic and non-cystic Pkd1 mutant kidneys. We identify TWEAK as a window dependent modulator of cystogenesis, inhibiting cystic progression in the cystic window, and promoting cystogenesis in the non-cystic window. We perform an exhaustive proteomics analysis of each cyst developmental stage by MALDI-TOF/TOF analysis of peptides and proteins separated either by LC or 2D-PAGE.

Results: We stablish the proteomics fingerprint of each physiopathologic condition and refine new therapeutic targets to a very short list of 12 candidate targets. During cystogenesis, cytoskeleton interactions with the extracellular matrix (focal adhesions) seemed to be altered and, thus their downstream signaling and regulatory pathways. Cell polarity, endocytosis and trafficking of proteins to nucleus are altered as well. Processes such as acyl-CoA, free fatty acid metabolism and their transport are downregulated. Fructose metabolism is also downregulated. We have targeted the identify pathways both inhibiting complete cystogenesis deriving from distal nephron segment, as well as, reducing/delaying global cystic progression.

Conclusions: Here, we first describe the proteome related to the developmental cystic window as well those pathways associated to the cystic progression under inflammatory respond, triggering new possible targeting pathways for both controlling origin and progression of cystogenesis.

TH-PO195

Cytokine Tweak as an Intermediary in Autosomal Dominant Polycystic Kidney Disease (ADPKD) Olaya Lamas-Gonzalez,[1] Ana Belen Sanz,[2] Maria D. Sanchez-Niño,[2] Ana Barcia de la Iglesia,[1] Adrian Cordido-Eijo,[1] Alberto Ortiz,[2] Miguel A. Garcia-Gonzalez.[1] *[1]Health Research Inst of Santiago de Compostela, Spain; [2]Fundación Jiménez Díaz, Spain.*

Background: The pathogenesis of Polycystic Kidney Disease (PKD) remains unclear, but appears to involve altered tubular cell proliferation, cell death, differentiation and polarity as well as inflammatory and pro-fibrotic factors. It has been reported that acute kidney injury (AKI) and inflammation accelerate cystogenesis. TWEAK is a TNF-like cytokine that has a key role in AKI since anti-TWEAK antibodies prevented experimental loss of kidney function and renal inflammation, cell death and proliferation.

Methods: We hypothesize that response to treatment and cyst progression depend on a particular developmental window, so the correct dose and timing of a drug may prevent cystogenesis and make chronic treatment unnecessary. Here, we use a mouse model in which conditional inactivation of the PKD1 gene by Cre-mediated recombination results in cystogenesis at different ages depending on when PKD1 is inactivated.

Results: PKD1 inactivation at day 12 resulted in massive cyst growth by day 30. Under these conditions systemic TWEAK administration for 10 days significatively decreased kidney cystogenesis. By contrast, PKD1 inactivation at day 14 did not result in cyst growth by day 30. Under these conditions systemic TWEAK administration for 10 days significatively promoted kidney cystogenesis. Inflammation background, tissue remodeling and immune response to kidney injure could be playing a key role in the development and progression of ADPKD. Interestingly, liver appeared to present a different developmental pattern than kidney since TWEAK had mild effects in its cystogenesis.

Conclusions: These results demonstrate a developmental impact of PKD1 inactivation and TWEAK in cystogenesis and are pointing out the antagonic effects of the same molecule in different cyst developmental stages. Under the conditions of early PKD1 inactivation of the human condition, TWEAK may protect from cystogenesis if administered early in the disease course. However, detailed time course are needed before human extrapolation given that TWEAK induce cystogenesis in some settings.

TH-PO196

Defects in Epithelial Morphogenesis of Fibrocystin-Deficient Cells Are Associated with Disturbed Cell Adhesion Wolfgang H. Ziegler, Birga Soetje, Lisa P. Marten, Dieter Haffner. *Dept of Pediatric Kidney, Liver and Metabolic Diseases, Hannover Medical School, Hannover, Germany.*

Background: Mutations of the *Pkhd1* gene cause autosomal recessive polycystic kidney disease (ARPKD). *Pkhd1* encodes fibrocystin (FPC), a type I transmembrane protein of largely unknown function, which has been suggested to affect adhesion signaling of cells. Contributions of epithelial cell adhesion and contractility to the disease process of ARPKD remain to be defined. Having established a link between loss of FPC function and epithelial morphogenesis in 3D cell culture, we now aim to determine FPC-mediated parameters of (i) cell contact formation and (ii) the function / orientation of the actin cytoskeletal and microtubular networks.

Methods: We analyze FPC function in Madin-Darby canine renal collecting duct epithelial cells (MDCK) based on *Pkhd1* silencing. Cells are being studied on micro-pattered chips in 3D cell culture conditions, which induce formation of epithelial spheroids. To determine critical differences in cell adhesion parameters, MDCK cells are analyzed in their one and 2(4)-cell stages after seeding on chips using fluorescence microscopy.

Results: Based on defined adhesion conditions, we quantified the impact of FPC-deficiency on size / density of adhesion sites, cell shape characteristics and initiation of an apical surface. In cells deficient for FPC, cell culture conditions supporting correct epithelial morphogenesis induced significantly reduced cell area and number of cell adhesion sites per cell, with differences originating from defects in cytoskeletal organization rather than reduced cell size. Further insight is expected from ongoing analysis of centrosome positioning. Analysis of quantitative parameters in FPC-deficient cells provides a set of cell characteristics that correlate with and are expected to reveal causes of defective epithelial morphogenesis.

Conclusions: FPC silencing in MDCK cells disturbs adhesion signaling and cell-cell interaction resulting in impaired epithelial morphogenesis. Using a cell-based model system, we can address molecular consequences of and analyze rescue strategies for FPC deficiency in collecting duct epithelia.

TH-PO197

Identification of FUBP1 as a PKD2 mRNA 3'UTR Binding Protein That Suppresses Its Translation Wang Zheng, Xing-Zhen Chen. *Dept of Physiology, Univ of Alberta, Edmonton, AB, Canada.*

Background: PKD2, also called polycystin-2, a Ca2+-permeable non-selective cation channel that is mutated in around 15% autosomal dominant polycystic kidney disease (ADPKD). Increasing evidence indicates that the PKD2 protein level is important for embryo development, cell response to ischemic renal injuries, and cyst formation, but there are limited studies so far about how PKD2 protein level is regulated.

Methods: Here, with dual luciferase assays, western blotting, biotin-RNA pull down, gene knockdown in zebrafish, co-immunoprecipitation and GST-pull down, we studied how PKD2 mRNA translation is regulated by its 3' untranslated region (3'UTR).

Results: First, by dual luciferase assays, we identified a fragment in PKD2 3'UTR, named 3FI (3' fragment inhibitory), that negatively regulates luciferease activity. Western blotting with a luciferase antibody confirmed the data obtained from the luciferase assays. By biotin-RNA pull down and mass spectrometry, we identified a 3FI-binding protein, called far upstream element binding protein 1 (FUBP1) that was originally found to promote transcription of oncogene c-Myc. Over-expression and knockdown of FUBP1 decreased and increased the PKD2 protein level, respectively, without altering the mRNA level. More interestingly, tail curvature induced by PKD2 morpholino (MO) knockdown in larval zebrafish was rescued by FUBP1 MO co-injection. Further, by co-IP and GST pull-down, we showed that FUBP1 directly binds with 4EBP1, a translational repressor that binds with eIF4E. Interestingly, 3FI RNA was shown to strengthen this binding.

Conclusions: Therefore, our data indicate that FUBP1 inhibits PKD2 translation through anchoring to PKD2 mRNA 3FI and interacting with 4EBP1.

TH-PO198

Towards Understanding the Structure-Function Relationships of Polycystin-1 Robin L. Maser,[1] Brenda S. Magenheimer,[1] Aaron Matthew Smalter Hall.[2] *[1]Univ of Kansas Med Ctr, Kansas City, KS; [2]Univ of Kansas, Lawrence, KS.*

Background: Appropriate levels of functional polycystin-1 (PC1), product of the PKD1 gene, are the key determinant preventing the development of renal cysts in ADPKD. Recent work revealed the existence of hypomorphic missense mutations of PKD1 and the importance of the proper biogenesis and trafficking of PC1, and suggested that mutation-specific therapies could potentially be designed to correct the biogenesis of mutant PC1. These advances underscore our lack of knowledge regarding PC1 structure and emphasize the importance of understanding PC-1 structure-function relationships. As such, we seek to generate a plausible tertiary structure model of human PC1.

Methods: A combination of comparative protein structure modeling along with validation by biochemical analyses is being used to predict and refine a human PC1 structure model. Our initial goal is to generate a 3D model of the arrangement of the 11 transmembrane (TM) segments and their connecting intra- and extracellular loops. Methodology involves secondary structure prediction and homology modeling between PC1 and known TM domains (using overlapping partitions of PC1 sequence), biophysical parameter-based

prediction of transmembrane domain bundling, and experimental biochemical analyses to validate predicted models. Use of the predicted secondary structure or template-modeled tertiary structure of loops is used to constrain and refine TM segment arrangement.

Results: Initial work has focused on TM segments connected by shorter loops. Thus far, N-linked glycosylation scanning experiments have confirmed the de novo modeling results for TM segments 9 and 11. Glycosylation analyses for TM segment 10 are not entirely consistent with the predicted model, due to an extension of the length of the domain. Such discrepancy may result from the inherent membrane-associating property of this loop region of PC1, as described in earlier published work.

Conclusions: Preliminary, proof-of-concept work has resulted in a coarse model of the last 3 TM segments of PC1. These analyses will provide important knowledge for understanding structure-function relationships of PC1 and for the development of new ADPKD treatments.

A Sorting Nexin 3 Retromer Complex Regulates the Surface Localisation and Activity of Wnt-Activated Polycystin-1 Regulated Polycystin-2 Channels Andrew J. Streets,[1] Shuang Feng,[1] Vasyl Nesin,[2] Leonidas Tsiokas,[2] Albert C. Ong.[1] *[1]Kidney Genetics Group, Academic Nephrology Unit, Univ of Sheffield Medical School, Sheffield, United Kingdom; [2]Dept of Cell Biology, Univ of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Background: Autosomal dominant polycystic kidney disease (ADPKD), is caused by inactivating mutations in *PKD1* (85%) or *PKD2* (15%). The ADPKD proteins, polycystin-1 (PC1) and polycystin-2 (PC2) form a plasma membrane receptor-ion channel complex. PC2 is a member of the transient receptor potential (TRP) superfamily and functions as a non-selective calcium channel. PC2 has been localised to multiple cell compartments in renal epithelial cells including the endoplasmic reticulum, plasma membrane and primary cilia. However the mechanisms controlling the subcellular localization of PC2 are complex and not well understood.

Methods: Y2H, Co-immunoprecipitation and GST pulldown assays were used to identify protein interactions. IF, siRNA knockdown and surface biotinylation was used to monitor protein trafficking and siRNA knockdown and electrophysiology used to monitor PC2 dependent Ca^{2+} channels.

Results: Here, we identify a new isoform of sorting nexin 3 (SNX3-102, isoform 5) as a novel interacting partner of PC2. Compared to the classical SNX3 isoform (SNX3-162, isoform 1), SNX3-102 cannot bind PtdIns(3)P but instead binds directly to the C-terminus of PC2. SNX3-162 binds indirectly to the N-terminus of PC2 via the retromer cargo-specific adaptor protein VPS35. SNX3-102 is expressed mainly in clathrin-coated vesicles whereas SNX3-162 is expressed in early endosomes. Knockdown of SNX3 or VPS35 in LLCPK-1 cells results in increased expression of PC2 and PC1 in the plasma membrane and upregulated Wnt-activated PC2 dependent Ca^{2+} channel activity.

Conclusions: Our results support a sequential model where SNX3-102 regulates PC2 endocytosis by directly binding PC2 and clathrin to cluster PC2 in clathrin-coated vesicles before relaying it to early endosomes where SNX3-162 and VPS35 regulate its sorting and fate. Molecular targeting of endosomal sorting of PC1 and PC2 could lead to new therapeutic approaches in this major human disease.

TH-PO200

Leucine Stimulates the Proliferation of *Pkd1*-Null Renal Epithelial Cells via ERK/MAPK and Mtor Pathway Junya Yamamoto, Saori Nishio, Tasuku Nakagaki, Tatsuya Atsumi. *Dept of Medicine II, Hokkaido Univ Graduate School of Medicine, Sapporo, Japan.*

Background: Mammalian target of rapamycin (mTOR) cascade is one of the important pathways regulating cyst growth in ADPKD and branched-chain amino acids (BCAA) modulate various physiological effects through activating mTOR cascade. We have recently reported that BCAA supplementation accelerates cyst development and disease progression in *Pkd1* conditional knockout mice (*Pkd1*$^{flox/flox}$*: Mx1-Cre* mice).

Methods: To elucidate the effects of BCAA in ADPKD, *Pkd1*$^{-/-}$(PN) and *Pkd1*$^{+/-}$(PH) renal epithelial cell lines were utilized and cultured in a medium with or without leucine. We evaluated cell proliferation by cell count. $3x10^5$ cells were plated on a 10-cm dish, 3 days later the total number of cells was counted. We also performed Ki-67 stains and western blotting of signaling pathway of proliferation.

Results: PN cells treated with leucine significantly increased the rate of proliferation compared to without leucine, but not in PH cells. Ki-67 positive ratio increased only in PN cells treated with leucine. In western blotting analysis, leucine promoted phosphorylation of p70S6 kinase in dose-related manner both in PN cells and PH cells, but leucine activated phosphorylation of ERK only in PN cells. PD98059 (MEK1 inhibitor), U0126 (MEK1 and MEK2 inhibitor) and rapamycin (mTOR inhibitor) attenuated leucine-induced cell proliferation by inhibiting ERK/MAPK pathway and mTOR pathway respectively.

Conclusions: Our findings suggest that leucine accelerates cyst development in ADPKD by promoting cystic epithelial cell proliferation via ERK/MAPK and mTOR pathways.

TH-PO201

Activation of the Polycystin Complex by WNT Ligands Seokho Kim,[1] Hongguang Nie,[1] Vasyl Nesin,[1] Uyen Tran,[2] Patricia Outeda,[3] Chang-Xi Bai,[1] Jacob Keeling,[1] Dipak Maskey,[1] Terry J. Watnick,[3] Oliver Wessely,[2] Leonidas Tsiokas.[1] *[1]Cell Biology, Univ of Oklahoma HSC, Oklahoma City, OK; [2]Cellualr and Molecular Medicine, Cleveland Clinic, Cleveland, OH; [3]Medicine/ Nephrology, Univ of Maryland School of Medicine, Baltimore, MD.*

Background: PKD1 (Polycystin 1) is considered an orphan, atypical G protein coupled receptor complexed with TRPP2 (Polycystin 2 or PKD2), a Ca^{2+}-permeable ion channel. Inactivating mutations in their genes cause autosomal dominant polycystic kidney disease (ADPKD), one of the most common genetic diseases. However, the molecular identity of the extarcellular ligands activating the Polycystin complex is unknown. WNT ligands induce Ca^{2+} signaling on target cells. Here, we tested whether WNTs can bind and activate the Polycystin complex.

Methods: Experimental approaches include electrophysiology, protein-protein-interactions using co-immunoprecipitations, directed cell migration assays, and embryological experiments in Xenopus laevis.

Results: Our data show that secreted WNTs bind to the extracellular domain of PKD1 and induce large whole cell currents and Ca^{2+} influx dependent on TRPP2, but independent of Frizzled (FZD) receptors. Pathogenic *PKD1* or PKD2 mutations that abrogate complex formation, compromise cell surface expression of PKD1, or diminish TRPP2 channel activity suppress activation by a WNT protein. *Pkd2*$^{-/-}$ fibroblasts lack WNT-induced Ca^{2+} currents and are unable to polarize during directed cell migration. In *Xenopus* embryos, PKD1 acts independently of FZD8, but within the same pathway with Disheveled 2 to preserve normal kidney tubulogenesis.

Conclusions: These data define PKD1 as a new class of WNT (co)receptors and implicate defective WNT/Ca^{2+} signaling as one of the causes of ADPKD.

Funding: NIDDK Support

Caffeine Consumption Contributes to Cyst/Kidney Enlargement and Progression of Polycystic Kidney Disease in a *Pkd1*-Deficient Mouse Model Renata Meca,[1] Bruno E. Balbo,[2] Milene Subtil Ormanji,[1] Luiz F. Onuchic,[2] Ita Pfeferman Heilberg.[1] *[1]Nephrology Div, Federal Univ of Sao Paulo, Sao Paulo, SP, Brazil; [2]Nephrology Div, Univ of Sao Paulo, Sao Paulo, SP, Brazil.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common monogenic renal disease, characterized by progressive cyst formation and growth, leading to kidney failure. In cultured cells from ADPKD patients, caffeine increased the levels of cyclic AMP and induced apoptosis and proliferation. We aimed to examine the i*n vivo* effects of Caffeine on cyst growth and progression of renal disease using a murine model orthologous to human ADPKD1.

Methods: *Male and female Pkd1*$^{cond/cond}$Nestin^{cre}(cystic - CysCaf) and P*kd1*$^{cond/cond}$ (NonCystic - NonCysCaf) mice consumed caffeine (3mg/day, in drinking water), from conception to 12 weeks of life. Caffeine was orally administered to the mother until puppy weaning (5 weeks) and thereafter directly supplemented in drinking water.Cistic control animals consumed water (CysCtrl) for the same period.

Results:

	CysCaf	CysCtrl	NonCysCaf
Global Renal Cystic Index(%)	38.5 (15.3-54.3)* n=21	9.4 (2.1-15.2) n=16	NA
Total kidney volume/Body Weight(mm^3/g)	25.5 (22.1-34.4)* n=21	17.4 (15.6-19.5) n=16	NA
sCystatin(pg/ml)	5.95± 1.14* n=13	2.07 0.57 n=4	3.36 0.71 n=4
sUrea(mg/dl)	83.7 21.5*† n=22	48.1 16.6 n=17	64.5 11.4 n=11
Renal Fibrosis Index(%)	0.84 (0.38-1.18)†* n=18	0.37 (0.06-0.47) n=6	0.30 (0.19-0.63) n=13
Cell Proliferation Index - Ki67(%)	5.34 1.66† n=8	2.52 1.34 n=5	0.57 0.23 n=6
* p<0,01 vs CysCtrl,† p<0,05 vs NonCysCaf			
Data are mean±SD or median(interquartile range);NA-not applicable			

Ultrasonographic analysis showed higher global renal cyst index and total kidney volume in the CysCaf group versus CysCtrl. CysCaf group presented higher serum Urea (sUrea) and Cystatin C (sCystatin) and lower maximum urine osmolality (data not shown) when compared to the NonCysCaf and CysCtrl groups. Renal fibrosis was higher in CysCaf than in the other groups and cell proliferation was higher in CysCaf than NonCysCaf kidneys.

Conclusions: Present findings demonstrate that caffeine induced an increase in renal volume and accelerated the progression of polycystic kidney disease in *Pkd1*-deficient mice.

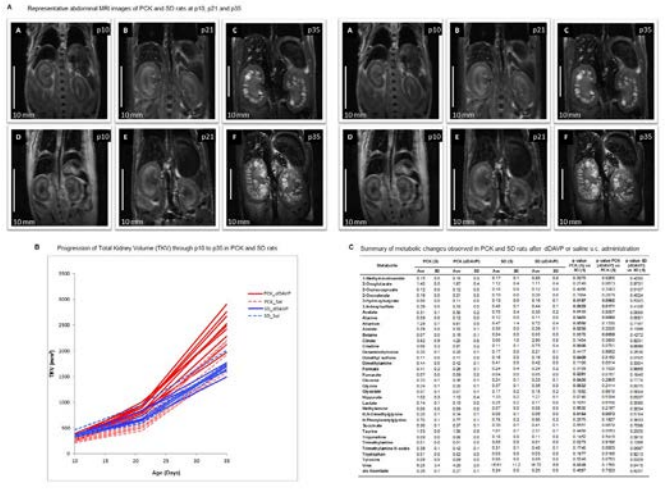
Changes in Urine Metabolites in PCK Rat Induced by dDAVP Administration

Maria V. Irazabal, Ivan Vuckovic, Song Zhang, Fouad T. Chebib, Xiaofang Wang, Hong Ye, Petras P. Dzeja, Slobodan Macura, Vicente E. Torres. *Mayo Clinic.*

Background: V2 receptor agonist 1-deamino-8-D-arginine vasopressin (dDAVP) aggravates the cystic disease of PCK rats by increasing renal cAMP without inducing cystic changes in wild-type rats (WT). We aimed to investigate the urinary metabolic changes in 1) PCK vs WT, and 2) response to dDAVP in PCK and WT rats.

Methods: PCK and WT rats were treated with 20 ng sc of dDAVP b.i.d. from p7 to p21, increasing to 40 ng sc b.i.d. from p22 to p35 inclusive or sc injections of isotonic (0.15 M) saline (S) at identical intervals. Abdominal MRI was performed at p10, p21 and p35 for kidney volume (KV). ^{1}H-NMR-based metabolomics analysis was performed from 24h urine collections at p30. The urine spectra were normalized to creatinine.

Results: Administration of dDAVP significantly aggravated the disease in PCK rats as evidenced by KV at p10, p21 and p35 ($p=0.04$, <0.001 and <0.001), but did not increase significantly KV or generate a cystic phenotype in WT rats (Fig1A-B). BUN levels were not different between groups at p35. Thirty seven urinary metabolites were identified. Thirteen metabolites were significantly different between PCK (S) and WT (S) (Fig1C). dDAVP induced significant changes in 5 metabolites in PCK but only 1 in WT rats. For example, urinary concentration of betaine, an important osmoregulatory compound, was significantly increased in PCK (S) compared to WT (S) and increased even further with dDAVP only in PCK rats.



Conclusions: ^{1}H-NMR-based metabolomics analysis identified 13 significantly different metabolites between PCK(S) and WT(S) rats. dDAVP aggravated the cystic disease and induced significant changes of urinary metabolites in PCK rats. Measurements of kidney tissue and plasma metabolites, in progress, will assist in the interpretation of these findings.

Localized Changes in MicroRNAs Are Critical to the Development of Fibrosis in PKD

Ameya P. Patil, William E. Sweeney, Ellis D. Avner. *Pediatric Nephrology, Dept of Pediatrics, Medical College of Wisconsin, Wauwatosa, WI.*

Background: ADPKD is characterized by proliferation and growth of tubular cysts and development of progressive interstitial fibrosis. These phases are consistently reproduced in the Pkd1$^{(nl/mcw)}$ mouse, an orthologous model of *Pkd1*. In this mouse model, as in human ADPKD, the progression of fibrosis, rather than cyst size, leads to ESRD. MicroRNA's (miRNA's) are small noncoding RNA's that act as potent regulators of gene expression. In ADPKD, the progression of interstitial fibrosis in distinct patterns suggests that crosstalk between cystic epithelia and interstitial cells create a "pro-fibrotic" microenvironment. We hypothesize that changes in miRNA expression are critical to development of fibrosis in ADPKD.

Methods: Laser capture micro-dissection (LCM) of trichrome positive interstitium and, adjacent cystic tubular epithelia were profiled seperately for local miRNA expression with Qiagen miScript 384 HC miRNA PCR arrays at four distinct time points during which fibrosis is initiated and progresses. The miRNA profile was compared to age-matched whole kidney miRNA profiles, correlated with fibrosis pathway arrays, and immunohistochemical analysis.

Results: From PN21 to 28, interstitium and adjacent cystic epithelia demonstrated significant changes in miRNA expression (20 upregulated, 15 downregulated). These changes correlated with: a shift in the site of proliferation; a change in macrophage subtypes and number; significant increase in Tgf-B1,2,& 3, p-Smad2 and col3a1 and significantly decreased BMP7 expression. 9 miRNA's exhibited a variable expression with initiation and then progression of the disease.

Conclusions: 1. Compartmental changes in miRNA expression seen with LCM were not seen in the whole kidney analysis, demonstrating the value of the approach. 2. Pro-fibrotic and ADPKD specific miRNA's(predicted to regulate TGFR1, 2 and 3, collagen 3a1, 4a1, 4a4 and 4a5 and most interestingly EGFR, and STAT3) are significantly altered in peri-cystic interstitium. 3. We speculate that such compartment specific changes in miRNA expression are critical to development of fibrosis in ADPKD and may provide future therapeutic targets to halt the progression of ADPKD.

miR-21 Promotes Cyst Growth in Polycystic Kidney Disease

Ronak Lakhia,[1] Sachin S. Hajarnis,[1] Darren Williams,[1] Karam S. Aboudehen,[2] Matanel Yheskel,[1] Vishal Patel.[1] *[1]Internal Medicine, UT Southwestern, Dallas, TX; [2]Internal Medicine, Univ of Minnesota, Minneapolis, MN.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by the presence of numerous fluid-filled cysts in the kidney. MicroRNAs (miRNAs), short noncoding RNAs that regulate gene expression, have emerged as promising new therapeutic targets for many common diseases. The goal of this study was to identify miRNAs that represent new drug targets for ADPKD.

Methods: Microarrays, Q-PCR, and ISH were performed to determine miR-21 expression in PKD. ChIP and promoter luciferase reporter assays were performed to understand the mechanisms that underlie miR-21 regulation in cystic kidneys. To study the role of miR-21 in ADPKD, miR-21 was inactivated in *Pkhd1*/Cre; *Pkd2*$^{F/F}$ (*Pkd2*-KO) mice, an orthologous mouse model of ADPKD. RNA-Seq was performed to elucidate the differential gene expression pattern between *Pkd2*-KO and *Pkd2*-miR-21$^{-/-}$ KO mouse kidneys.

Results: miR-21 expression was increased in multiple mouse models of PKD, including two orthologous models of PKD. Upregulation of miR-21 was primarily localized to mouse kidney cyst epithelial cells. Increased miR-21 expression was also seen in cysts of human ADPKD tissue samples. cAMP-CREB signaling transactivated the miR-21 promoter in kidney cells. Inactivation of miR-21 in *Pkd2*-KO mice reduced kidney size, cyst number, and prolonged survival. RNA-Seq and subsequent pathway analysis identified cell death as the main biological effect of miR-21 deletion. Accordingly, compared to *Pkd2*-KO mice, *Pkd2*-miR-21$^{-/-}$ KO mice exhibited increased apoptosis of cyst epithelial cells without any change in proliferation. Expression of *Pdcd4*, a pro-apoptotic miR-21 target, was increased in cysts of *Pkd2*-miR-21$^{-/-}$ double knockout mice, indicating that miR-21 inhibits *Pdcd4* in cystic kidneys.

Conclusions: Upregulation of miR-21 is a common feature of mouse and human forms of PKD. Deletion of miR-21 attenuates cyst burden and prolongs survival. miR-21 may promote cyst growth in ADPKD by preventing apoptosis of cyst epithelial cells through direct suppression of *Pdcd4*. Our studies suggest that inhibiting miR-21 may be a useful therapeutic strategy for ADPKD.

Macrophages Programmed by Polycystic Kidney Disease Cyst Cells Produce Soluble CXCR2 Ligands That Promote Cyst Cell Proliferation

Sally M. Salah, Darren P. Wallace, Timothy A. Fields, Katherine Swenson-Fields. *The Kidney Inst, Univ of Kansas Medical Center, Kansas City, KS.*

Background: The presence of renal macrophages in animal models of PKD has been shown to promote disease progression. The mechanisms underlying this phenomenon are incompletely understood but are likely due to reciprocal interactions between infiltrating macrophages and cyst epithelial cells: cyst cells stimulate macrophage differentiation to an M2-like, pro-proliferative phenotype and, in turn, these now "programmed" macrophages secrete unknown factors that promote cyst cell proliferation.

Methods: To identify macrophage-secreted factors that promote disease progression, macrophages were incubated for 48 h with conditioned media from primary human ADPKD cyst cells. These programmed macrophages were either collected and analyzed by RNAseq or were washed extensively and incubated for a further 24 h to allow production of secreted pro-proliferative factors, which were subjected to protein/proteome analysis and antibody array. Similar analyses of resting macrophages were carried out in parallel for comparison.

Results: Co-culture of ADPKD cyst cell conditioned media with macrophages enhances macrophage production of protease-sensitive, pro-proliferative activity. RNAseq and cytokine array analysis revealed up-regulation of multiple candidate pro-proliferative factors in programmed macrophages, including several ligands of the CXCR2 receptor. The addition of a CXCR2 receptor antagonist (SB225002) to ADPKD cells significantly reduced proliferation stimulated by programmed macrophage conditioned media.

Conclusions: Efforts are underway to identify the specific CXCR2 ligands produced by programmed macrophages that are responsible for this pro-proliferative effect. These factors and their signaling pathways could provide new targets for the development of therapies to slow PKD progression.

PKD2-Related Autosomal-Dominant Polycystic Kidney Disease (ADPKD): Mutation Spectrum, Clinical Presentation, and Prognosis
Emilie Cornec-Le Gall,[1,2] Marie-Pierre Audrezet,[1,2] Christophe Charasse,[5] Cecile M. Vigneau,[6] Lise Mandart,[7] Claude Ferec,[1,2] Yannick Le Meur.[1] *[1]CHRU Brest, France; [2]INSERM 1078; [3]CH Saint Malo; [4]CHRU Nantes; [5]CH Saint Brieuc; [6]CHRU Rennes; [7]CH Vannes.*

Background: The milder severity of *PKD2* related ADPKD (~15% of the pedigrees) as compared to *PKD1* is well acknowledged, but population-based studies, enabling to depict the exact burden of the disease, are currently lacking. In this study, we aimed to describe the clinical presentation and the mutation spectrum in a large cohort of *PKD2* patients.

Methods: Genkyst is a cross-sectional cohort which aims to include all consenting ADPKD patients followed in 23 Nephrology centers from the western part of France. Clinical data were collected and a comprehensive molecular analysis of *PKD1* and *PKD2* genes was undertaken.

Results: A total of 70 different *PKD2* mutations were identified in 248 patients from 172 pedigrees (i.e. 20.2% of the mutation-positive pedigrees from Genkyst). A recurrent 28-kb deletion involving exons 10-15 was identified in 45 patients from 23 pedigrees confined in an area of ~3500 km², which represents to our knowledge the first case of founder mutation in ADPKD. Median age at diagnosis in the total cohort was 41.5 yrs. At age 70, cumulative probability of ESRD obtained by Kaplan Meier analysis was 37.4%, whereas probabilities for hypertension, pains related to cysts and gross hematuria were respectively of 93.3%, 46.6% and 23.3%. Although there was no gender influence on renal survival, multiple linear regression demonstrated that men had significantly lower kidney function than women. Disease variability was observed in some patients harbouring the same mutation, suggesting that additional genetic or environmental factors may modulate the disease severity in *PKD2* patients. In line with this hypothesis, familial study led to the identification of PKD1 hypomorphic alleles possibly acting as disease modifiers in 2 *PKD2* pedigrees with marked intra-familial variability.

Conclusions: This large cohort confirms that PKD2 patients typically present with a mild disease and therefore a vast majority of them may not require emerging targeted therapies.

Transcriptome Analysis Identifies A Novel Candidate Therapy for Polycystic Kidney Disease
Robert L. Bacallao,[1,2] Sherry G. Clendenon,[3] James A. Glazier,[3] Rita M.c. De almeida.[4] *[1]Medicine, Indiana Univ School of Medicine, Indianapolis, IN; [2]Medicine, Richard Roudebush VAMC, Indianapolis, IN; [3]Physics, Biocomplexity Inst, Indiana Univ, Bloomington, IN; [4]Physics, Instituo Nacional de Ciencia e Techologic, Univ Federal do Reio Grande do Sul, Porto Alegre, R.S., Brazil.*

Background: ADPKD is a genetic disorder characterized by accumulation of renal cysts culminating in renal failure. A critical need exists ameliorate ADPKD. Transcriptogram analysis is a new method for whole genome gene expression data analysis that more sensitively identifies affected molecular networks and pathways.

Methods: Genes are ordered into a list using a Monte Carlo simulation that minimized distance between associated gene products, such that proximity on the list correlates with co-participation in biological processes. Transcriptogram profiles are then produced by calculating the average transcription level for genes within a moving window. The resulting transcriptogram reveals which pathways are differentially expressed.

Results: Using this approach, gene chip analysis revealed cystic epithelial have significant over expression of cGMP phosphodiesterases, components of inflammasome pathway (IL6, IL1B, NFKB1A, CCL2, BIRC3, TNFAIP3, IL18, PYCARD, MAPK13), and potassium ion transport (KCNJ12, KCNK3, KCNC4, KCNMB4, KCNQ1, KCNS1). Conversely many genes participating in oxidative phosphorylation are expressed at significantly lower levels in cystic epithelia. To test the significance of cGMP phosphodiesterases; human cystic epithelial cells were grown in 3D collagen culture with forskolin plus or minus sildenafil. Strikingly the cGMP phosphodiesterase inhibitor inhibited cyst growth at all doses (4 ug/ml, 2 ug/ml and 1 ug/ml). Average cyst size was decreased compared to controls ($p<1$ E-6 for 4 ug/ml dose, $p<0.01$ for 2 ug/ml dose, and $p<0.01$ for the 1 ug/ml dose). Also frequency analysis of cyst sizes we found that large cysts were absent from sildenafil treated cultures.

Conclusions: Transcriptogram analysis of gene chip data provides a powerful new way to analyze changes in the gene expression profile in ADPKD. Secondly, sildenafil blocks kidney epithelial cyst growth in 3D culture.

Gene Discovery for Autosomal Dominant Polycystic Liver Disease (ADPLD)
Whitney E. Besse,[1] Yiqiang Cai,[1] Ali G. Gharavi,[2] Simone Sanna-Cherchi,[2] Terry J. Watnick,[3] York P. Pei,[4] Vicente E. Torres,[5] Stefan Somlo.[1] *[1]Internal Medicine, Section of Nephrology/Genetics, Yale School of Medicine, New Haven, CT; [2]Div of Nephrology, Columbia Univ Dept of Medicine, NY; [3]Div of Nephrology, Univ of Maryland School of Medicine, Baltimore, MD; [4]Div of Nephrology, Univ Health Network, Toronto, ON, Canada; [5]Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: ADPLD involves identical polycystic liver disease to that seen in ADPKD, but without clinically relevant kidney cysts. While mutations in *PKD1* lead to ADPKD, mutations in genes that indirectly affect Polycystin 1 (PC1) expression or function cause ADPLD. Study of two identified ADPLD genes, *SEC63* and *PRKCSH*, has shown the importance of co/post-translational modifications in the ER for PC1 function, and demonstrated the critical role of PC1 dosage in cyst pathogenesis. We hypothesize that discovery of additional ADPLD genes in patients will identify other functional modulators of PC1.

Methods: We have established a cohort of 161 unrelated individuals and families with ADPLD. Those without known mutations (Discovery Cohort) underwent whole exome sequencing together with linkage analysis where sufficient family material existed. Initial evaluation focused on candidate genes with rare heterozygous loss of function mutations. We established an in vitro bioassay to test a subset of candidates by evaluating PC1 expression and cilia trafficking following knockout of the candidate gene by CRISPR in cell culture.

Results: We found that 65/161 (40%) of ADPLD probands have mutations in *SEC63* (18%) or *PRKCSH* (22%). Initial analysis of exome sequencing of our Discovery Cohort identified three candidate genes that function in ER biogenesis pathways related to the known genes and explain a total of 10 unrelated cases. We have generated cell knockout of one of these new candidate genes and shown a decrease in PC1 expression and as well activation of XBP1s, similar to our earlier findings in *Sec63* knockouts.

Conclusions: ADPLD gene discovery using whole exome sequencing coupled with in vitro assays of PC1 function is an unbiased and achievable approach to identify necessary proteins and pathways for PC1 function, and thus help to better define cyst pathogenesis in ADPLD and ADPKD.

Morpholino and Mutant Studies of Pde3A and Pde1a in Renal Cystogenesis Using Zebrafish
Caroline R. Sussman, Raad B. Chowdhury, Matthew Durant, Peter C. Harris, Vicente E. Torres. *Nephrology & Hypertension, Mayo Clinic, Rochester, MN.*

Background: Numerous studies demonstrate the role of cAMP in cyst development and Polycystic Kidney Disease (PKD) progression. Studies in zebrafish using morpholinos show that Phosphodiesterase (Pde) 1A modulates renal cyst development and associated phenotypes, consistent with its hydrolysis of cAMP.

Methods: MOs were used to assess effects of Pde3A on renal cyst development and associated phenotypes, hydrocephalus and otolith defects. Additionally, we have generated 3 *Pde1a* mutant zebrafish lines using TALENs. Phenotypes were evaluated blinded, and data were analyzed using chi-square on embryos summed within treatments from 3-4 experiments.

Results: Depletion of Pde3A using two splice-blocking MOs increased the incidence of renal cysts at 2 days post-fertilization (dpf). Both MOs targeted exon 12 of *pde3a*, the first exon of the hydrolytic domain, encoding the conserved HD required for hydrolysis. Splice acceptor MO induced cysts with dose dependence at 5 ng (13%) and 10 ng (33%) vs. control MO ($p<0.002$, $n>57$ embryos / treatment). Splice donor MO induced cysts with dose dependence at 1 ng (13%), 2.5 ng (22%), and 5 ng (59%) vs. 5 ng of control MO (0%) ($p<0.003$, $n\geq40$ embryos/treatment). The splice-donor MO also induced hydrocephalus at 2.5 ng (25%) and 5 ng (60%), and otolith defects at 2.5 ng (38%) and 5 ng (79%) vs. 5 ng of control MO (0%) ($p<0.001$, $n\geq60$ embryos/treatment). Injection of 1 ng caused a non-significant trend toward induction of hydrocephalus (3%, $p=0.3$) and otolith defects (8%, $p=0.06$) ($n\geq40$ embryos / treatment). Sequencing of cystic embryos showed altered splicing at the targeted exon. Similar to MOs, *Pde1a* TALENs were generated targeting the exon encoding the conserved HD. We have obtained 3 unique mutant lines which disrupt the HD. In initial studies, $Pde1a^{+/-}$ fish are found at expected frequencies in adult populations, indicating survival equivalent to that of $Pde1a^{+/+}$ fish.

Conclusions: MO studies of Pde3A suggest its involvement in renal cystogenesis and associated phenotypes, similar to previous studies using Pde1A MOs. TALENs effectively induced function-blocking mutations in *Pde1a*, which will allow studies of $Pde1a^{-/-}$ fish.

TH-PO211

Transcriptional Repression of PKD1 by Gene-Body Hypermethylation Induces Renal Cyst Development in ADPKD Yu mi Woo, Yu bin Shin, Jong Hoon Park. *Dept of Life Systems, Sookmyung Women's Univ, Seoul, Republic of Korea.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is a common human genetic disease characterized by the formation of multiple fluid-filled cysts in bilateral kidneys. Although mutations in *polycystic kidney disease 1* (*PKD1*) are predominantly responsible for ADPKD, the focal and sporadic property of individual cystogenesis suggests another molecular mechanism such as epigenetic alterations.

Methods: To determine the epigenomic alterations in ADPKD and their functional relevance, ADPKD and non-ADPKD individuals were analyzed by unbiased methylation profiling genome-wide and compared with their expression data.

Results: Intriguingly, *PKD1* was hypermethylated in gene-body regions, and its expression was downregulated in ADPKD. Hypermethylation of *PKD1* gene-body was associated with recruitment of methyl-CpG-binding domain 2 (MBD2) proteins. Moreover, treatment with DNA methylation inhibitors retarded *in vitro* cyst formation, accompanied with the upregulation of *Pkd1* expression.

Conclusions: These results are consistent with previous studies that knock-down of *PKD1* was sufficient for cystogenesis. Therefore, our results reveal a critical role for hypermethylation of *PKD1* and cystogenesis-related regulatory genes in cyst development, suggesting epigenetic therapy as a potential treatment for ADPKD.

Age- and Sex-Dependent Salt Sensitivity in *Pkhd1*^{pck} Rats Chunhua Jin, Michal Mrug, Bradley K. Yoder, Robert A. Kesterson, Edward W. Inscho, David M. Pollock. *Univ of Alabama at Birmingham, Birmingham, AL.*

Background: Most forms of hypertension are influenced by gender and salt sensitivity. However, interplay of these two factors and their functional consequences in PKD-associated hypertension are incompletely understood. Thus, we tested the hypothesis that age and male sex would pre-dispose animals with PKD to hypertension and risk of renal injury.

Methods: We used *Pkhd1*^{pck} rat model of autosomal recessive PKD to study sex difference in blood pressure in response to high salt (HS) diet. Two month- and eight month-old male and female *Pkhd1*^{pck} rats were surgically implanted with telemetry transmitters and allowed to recover for at least one week before obtaining baseline mean arterial pressure (MAP). Rats were then fed a high salt (HS; 4% NaCl) diet for 3 weeks. At the end of the study, rats were placed in metabolic cages and a 24 hr urine sample was collected before taking a terminal blood sample and kidneys removed.

Results: In the 2-month old *Pkhd1*^{pck} rats, blood pressures were in a normal range and there were no differences between male and female animals. Furthermore, 3 weeks on a high salt diet had no effect on 24 hr MAP. In 8-month old rats, again there were no sex differences between animals on normal rat chow. MAP was progressively increased in both male and female rats after 3 weeks of HS diet treatment. MAP increased from 127±6 to 171±6 mmHg in male and from 112±3 to 127±3 mmHg in female rats, both $p<0.05$. However, the MAP increase was significantly greater in male (Δ44±6 mmHg) versus female (D15±5 mmHg, $p<0.05$) rats. The blood pressure increase in male rats was associated with higher urinary protein excretion compared to female rats (1015±134 vs. 478±45 mg/day, $p<0.05$). These male rats had also higher kidney weight to body weight (bwt) ratio compared to female rats (1.0±0.2 vs. 0.5±0.1 g/100 g bwt, $p<0.05$).

Conclusions: Our studies demonstrate that male *Pkhd1*^{pck} rats with advanced cystic kidney disease are more vulnerable to salt sensitive hypertension and renal injury than age-matched females.

TH-PO213

Sodium Intake versus Disease Progression in Experimental Polycystic Kidney Disease Maatje D.A. van Gastel,[1] Laura R. Harskamp,[1] Debbie Zittema,[1] Dorien J.M. Peters,[2] Ron T. Gansevoort,[1] Esther Meijer.[1] *[1]Nephrology, UMC Groningen; [2]Human Genetics, Leiden UMC.*

Background: Vasopressin, a known determinant of disease severity and progression in ADPKD, increases in response to an increase in plasma osmolarity, of which sodium is the most important osmol. We hypothesized that lowering sodium intake reduces vasopressin concentration and thereby may improve disease progression in ADPKD.

Methods: We used a tamoxifen-inducible kidney epithelium-specific *Pkd1*-deletion mouse model. All mice were treated for 3 weeks with either a low sodium (LS: 0.39 g/kg) or high sodium (HS: 15.2 g/kg) diet, after which physiological effects were studied and mice were sacrificed.

Results: The attached table summarizes the results after the dietary intervention. A higher water intake was seen in *Pkd1*-mice in comparison with healthy controls (HC), in line with the impaired urine concentrating capacity occurring in PKD. For both HC and *Pkd1*-mice water intake was higher in HS groups, in line with the physiological effects of sodium intake. In contrast to our hypothesis, a LS diet did not result in improved disease progression as total kidney weight (TKW), TKW per body weight (TKW/BW), cyst ratio and renal function (creatinine) were similar in all *Pkd1*-mice, regardless of the diet.

	HC LS	HC HS	*Pkd1* LS	*Pkd1* HS
N	15	15	23	25
Weight (g)	16.6 (16.4-18.2)	15.8 (14.2-17.3)	17.2 (14.8-18.0)××	14.6 (13.6-16.0)
TKW (mg)	235 (204-247)**	227 (206-271)**	415 (361-448)×	356 (320-399)
TKW/BW (%)	1.3 (1.3-1.4)**××	1.5 (1.4-1.6)**	2.5 (2.0-2.8)	2.5 (2.1-2.9)
Cyst ratio (%)	5.0 (2.6-7.3)**	6.4 (4.3-9.4)**	27.4 (17.3-30.3)	29.6 (20.8-34.5)
$P_{Creatinine}$ (µmol/L)	7.0 (7.0-9.0)**	6.0 (6.0-8.0)**	11.0 (9.0-13.0)	9.0 (7.0-12.0)
P_{Na+} (mmol/L)	147 (146-148)	146 (145-148)	147 (143-150)	147 (145-149)
Water intake (g)	2.8 (2.6-2.9)*××	3.2 (3.0-3.8)**	3.7 (2.9-4.1)××	4.1 (3.8-5.3)
Na^+ excr (µmol/24h)	161 (89-169)××	556 (372-1210)	45 (39-57)××	488 (276-676)

Variables are given as median (IQR). *p<0.05, **p<0.01: HC vs Pkd1 ×p<0.05, ××p<0.01: LS vs HS, same group.

Conclusions: A low sodium diet results in less water intake, but does not improve disease progression in *Pkd1*-mice.

TH-PO214

Tuba, a CDC42-Specific Guanine Nucleotide Exchange Factor (GEF), Is Necessary for Ciliogenesis and Kidney Development Jeong-in Baek,[1] Soo Young Choi,[1] Xiaofeng Zuo,[1] Joshua H. Lipschutz.[1,2] *[1]Div of Nephrology, Medical Univ of South Carolina, Charleston, SC; [2]Renal Section, Ralph H. Johnson VAMC, Charleston, SC.*

Background: Polycystic kidney disease (PKD) is associated with perturbations in renal primary cilia structure and/or function. The exocyst, a highly conserved eight-protein membrane trafficking complex, is essential for ciliogenesis, and is regulated by Cdc42. Our previous studies showed that Cdc42 deficiency disrupts renal ciliogenesis and causes PKD in zebrafish and mice, and that Tuba is also necessary for ciliogenesis in cultured MDCK cells.

Methods: Tuba knockdown MDCK cells were grown on Transwell filters and in three dimensional (3D) collagen gels, and zebrafish embryos were generated in which *tuba* was knocked down using antisense morpholinos. Ciliary and kidney defects caused by *tuba* deficiency were analyzed at molecular, histological and phenotypic levels.

Results: *Tuba* depletion resulted in an absence of cilia with impaired apical polarization of MDCK cell cysts. In hepatocyte growth factor-induced tubulogenesis, we found that Tuba knockdown significantly inhibited tubule formation. In zebrafish, *tuba* was expressed in ciliated organs, including the brain, eye, neuromast cells, and kidney. *Tuba* morphants phenocopied *cdc42* morphants, with ciliary mutant phenotypes that included: a curly tail, hydrocephalus, and abdominal fluid accumulation. In *tuba* morphant kidneys, pronephric cilia were short and disordered, and glomeruli were disorganized. Moreover, *tuba* morphants showed defects in cardiac laterality, consistent with ciliary dysfunction. Following co-injection of small amounts of *tuba* and *cdc42* morpholinos, that alone had no effect, a severe phenotype was observed, suggesting that *tuba* and *cdc42* act in the same pathway.

Conclusions: Our study showed that Tuba plays a critical role in ciliogenesis and kidney development in MDCK cells and zebrafish. We are generating *tuba* knockout zebrafish and Tuba kidney-specific knockout mice,using CRISPR and the Cre-lox binary mouse system, respectively.These animal models will allow us to better understand the pathogenic mechanisms of PKD, and could lead to novel treatments.

TH-PO215

Kidney-Specific Inactivation of the Exocyst Gene Sec10 in Mice Leads to Primary Cilia Defects and a Cystic Kidney Phenotype Noemi Polgar, Amanda J. Lee, Vanessa H. Lui, Kadee-Kalia Tamashiro, Josephine Andrea Napoli, Ben Fogelgren. *Dept of Anatomy, Biochemistry and Physiology, Univ of Hawaii, Honolulu, HI.*

Background: The primary cilium is a sensory organelle that projects from the apical surface of renal epithelial cells, and has been implicated in the pathogenesis of polycystic kidney disease. The exocyst complex is responsible for guiding the polarized exocytosis of subsets of secretory vesicles. Previous studies in cultured epithelial cells implicated exocyst activity, and particularly its Sec10 subunit, in primary cilia assembly. Our previous inhibition of Sec10 in a zebrafish model resulted in defective ciliary signaling, but no measurable defects in cilia structure.

Methods: To allow *in vivo* studies of the exocyst complex in mammalian kidney development and disease, we have generated a novel transgenic mouse to conditionally knockout the Sec10 gene using the Cre-loxP system. Here, we used the Ksp-Cre mice to specifically delete Sec10 in ureteric bud-derived epithelial tissues, which include distal renal tubules. We analyzed the renal phenotype and primary cilia in the Sec10-mutant kidneys.

Results: Conditional deletion of Sec10 showed a surprising neonatal lethal phenotype of prenatal ureter obstructions, although a small percentage of mice were non-obstructed and survived until at least 3 weeks of age. Histological analysis revealed the 20-day old $Sec10^{FL/FL}$;Ksp-Cre mice had a polycystic kidney phenotype not seen in control littermates. Using immunostaining and confocal microscopy, we visualized primary cilia in renal

tubules of Sec10 mutant and control mice. Sec10-knockout tubules showed a 38.5% average ciliation ratio compared to 84.5% in control kidneys ($p<0.0001$). The primary cilia that were detected in Sec10-knockout tubules were much shorter than those in the control littermates ($p<0.0001$). Furthermore, significantly elevated blood urea nitrogen levels in knockout animals compared to controls suggested impaired kidney function.

Conclusions: Findings from our mouse model provide the first *in vivo* evidence of the exocyst's involvement in mammalian primary cilia assembly and links Sec10 and the exocyst to the pathogenesis of polycystic kidney disease.

Whole Exome Sequencing (WES) Resolves ARPKD-Like and Meckel Syndrome (MKS)-Like Pedigrees Unresolved by Sanger/Ciliopathy Panel Screening Katharina Hopp, Sarah J. Koon, Christina M. Heyer, Vicente E. Torres, Peter C. Harris. *Mayo Clinic.*

Background: ARPKD and MKS have phenotypic and genetic overlap with other ciliopathies, with many unresolved pedigrees after Sanger sequencing of commonly mutated genes (ARPKD: ~10% of severe and ~50% of mild cases; MKS: ~45% of cases).

Methods: We performed WES (Agilent SureSelect, Illumina HiSeq 2000) of 18 Sanger screened, unresolved pedigrees, of which 13 were also assessed by targeted next-generation sequencing (NGS, 258 ciliopathy/cilia genes). Identified variants were filtered/scored based on quality, population frequency, segregation and substitution/gene significance.

Results: Screening for homozygous, compound heterozygous, and *de novo* variants identified disease-alleles in 4 pedigrees. Ped 1, ARPKD diagnosis at 4y, was homozygous for a novel *BBS9* mutation (c.437_438insA), although the proband lacked key Bardet-Biedel Syndrome (BBS) features (retinal dystrophy, obesity, polydactyly, learning disability). The variant was missed by the targeted NGS panel due to preferential WT allele enrichment. Ped 2, two MKS diagnosed fetuses with PKD, polydactyly, hepatic fibrosis, but no CNS abnormalities, inherited two novel *BBS7* variants (c.1405_1406delCA and p.V266E [scored as pathogenic]). Of note, BBS rarely causes embryonic lethality. Ped 3, a 15w MKS-like fetus with occipital encephalocele, sloping forehead and bifid tongue, inherited two *C2CD3* mutations (p.C1114=, caused ex18 skipping, and p.V899M [scored as pathogenic]). This verified findings of the targeted NGS panel and excluded additional genetic disease causes. *C2CD3* is linked to oral-facial-digital syndrome 14 but the fetus lacked key associated features (polydactyly, microcephaly). Ped 4, a 16w MKS fetus with PKD, was initially diagnosed with a single *CC2D2A* variant (c.2182-2A>G). WES identified a second variant (c.3289-1delG) missed by Sanger sequencing.

Conclusions: We show here the value of WES for resolving Sanger/NGS panel unresolved ciliopathy pedigrees, although with low detection rates. In addition, we show BBS genes associated with a broad ciliopathy disease spectrum, reporting for the first time *BBS9* mutations in an ARPKD-like case and *BBS7* mutations in a MKS-like pedigree.

TH-PO217

***IFT81*, Encoding an Intraflagellar Transport Protein, as a Rare Cause of a Ciliopathy Phenotype** Jan Halbritter,[1] Isabelle Perrault,[2] Jonathan Porath,[1] Xavier Gerard,[2] Daniela A. Braun,[1] Heon Yung Gee,[1] Hanan Fathy,[3] Richard P. Lifton,[4] Jean-michel Rozet,[2] Friedhelm Hildebrandt.[1] *[1]Medicine, Boston Children's Hospital, Boston, MA; [2]Imagine Inst, Paris Descartes, Paris, France; [3]Pediatric Nephrology, Univ of Alexandria, Alexandria, Egypt; [4]Genetics, Yale Univ, New Haven, CT.*

Background: Bidirectional intraflagellar transport (IFT) consists of two major protein complexes, IFT-A and IFT-B. In contrast to the IFT-B complex, all components of IFT-A have recently been linked to human ciliopathies when defective. We therefore hypothesized that mutations in additional IFT-B encoding genes can be found in patients with multisystemic ciliopathies.

Methods: We screened 1,628 individuals with reno-ocular ciliopathies by targeted next-generation sequencing, including all IFT-B encoding genes.

Results: Consequently, we identified a homozygous mutation in *IFT81* affecting an obligatory donor splice site in an individual with nephronophthisis and polydactyly. Further, we detected a loss-of-stop mutation with extension of the deduced protein by 10 amino acids in an individual with neuronal ceroid lipofuscinosis-1 (CLN1). This proband presented with retinal dystrophy and brain lesions including cerebellar atrophy, a phenotype to which the *IFT81* variant might contribute. Cultured fibroblasts of this latter affected individual showed a significant decrease in ciliated cell abundance compared to controls and increased expression of the transcription factor GLI2 suggesting deranged sonic hedgehog signaling.

Conclusions: This work describes identification of mutations of *IFT81* in individuals with symptoms consistent with the clinical spectrum of ciliopathies. It might represent the rare case of a core IFT-B complex protein found associated with human disease. Our data further suggest that defects in the IFT-B core are an exceedingly rare finding, probably due to its indispensable role for ciliary assembly in development.

TH-PO218

Loss of Aatf in Murine Tubular Cells Leads to a Nephronophthisis-Like Phenotype Manaswita Jain,[1] Heide Irene Heinen,[1] Heike Goebel,[2] Bernhard Schermer,[1] Thomas Benzing,[1] Katja Hoepker.[1] *[1]Internal Medicine II, Univ Hospital Cologne, Cologne, Germany; [2]Dept of Pathology, Univ Hospital Cologne, Cologne, Germany.*

Background: Genomic integrity is continously being challenged by DNA damage of endogenous or exogenous sources. Aatf is a key regulator of the tumor suppressor p53 in the DNA-damage response signaling cascade. Aatf inhibits the ability of p53 to transactivate pro-apoptotic target genes. The conventional knockout of Aatf in mice is pre-implanationally lethal. A central role of DNA-damage signaling in tubular cells and cystic kidney diseases has been suggested. Here we show that deletion of Aatf in developing distal tubular and collecting duct cells leads to a degenerative, cystic phenotype, much alike juvenile nephronophthisis.

Methods: Conditional knockout mice, histology, phenotypic analysis.

Results: Aatf was knocked out using the Ksp:Cre mouse line in a floxed Aatf genetic background. The homozygous Aatf deletion results in weight loss and kidney failure at the age of 6-10 weeks. The mice show polyuria, polydipsia and have a reduced urine osmolarity. Their kidneys are small, pale and show small cysts predominantly at the cortico-medullary border. Histological examination shows tubular and glomerular cysts and interstitial fibrosis as well as an increased rate of apoptotic cell death.

Conclusions: Alterating the outcome of the p53-driven DNA-damage response in the Ksp:Cre;Aatf knockout leads to clinical and histological signs of juvenile nephronophtisis that links DNA damage response signaling close to cystic kidney disease.

Role for the Primary Cilium in Regulation Interstitial Macrophage Proliferation and Polarization During Kidney Maturation and Injury Cheng 'Jack' Song,[1] Kurt Zimmerman,[1] Michal Mrug,[2] Bradley K. Yoder.[1] *[1]Dept of Cell Developmental and Integrative Biology, Univ of Alabama at Birmingham, Birmingham, AL; [2]Dept of Medicine, Univ of Alabama at Birmingham, Birmingham, AL.*

Background: Induction of cilia loss in juvenile mice results in rapid cyst development while induction of cilia loss in adult mice causes a much slower rate of cyst progression. Rapid cyst formation can be initiated in the adult-induced IFT mutants by ischemic reperfusion (IR) injury suggesting a possible role for inflammation in cyst development. This was recently confirmed by liposome clodronate (LC) mediated depletion of phagocytic macrophages that reduced cyst severity and improved renal function. However, the crosstalk between primary cilia located on epithelial cells and the interstitial macrophages during cyst progression is unknown. Here, we investigate potential connections between primary cilia associated cystogenesis and changes in macrophage populations.

Results: Our preliminary data suggest the presence of a kidney resident macrophage population, likely derived from the yolk sac, which are present in juvenile mice and re-immerge in adult-induced cilia mutants following IR injury. Renal Resident macrophage demonstrates rapid proliferation following IR injury in adult-induced IFT88 mutant mice as early as 3 days following injury and persists for at least day 21. In contrast, resident macrophages from control mice show peak proliferation 3 days following IR injury that then abates at days 7-21.

Conclusions: This work suggests communication between the cilia on epithelial cells and the resident macrophages is important for kidney maturation and repair after injury. Our prediction is that defects in this communication will result in persistent resident macrophage proliferation that contributes to the rate of cyst formation. This work will provide possible targets for therapeutic intervention.

Ciliary Trafficking of Polycystin-1 and Polycystin-2 Is Interdependent Chong Luo, Maoqing Wu, Wassim El-jouni, Jing Zhou. *Harvard Center for Polycystic Kidney Disease Research and Renal Div, Dept of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Background: Mutations in *PKD1* account for over 85% cases of autosomal dominant polycystic kidney disease (ADPKD). About 30% of the *PKD1* mutations are missense mutations which likely produce full-length proteins that are defective in trafficking to the primary cilia. We have recently shown that multiple sequences including a coiled-coil (CC) motif in the C-terminal tail of PC1 regulate full-length PC1 trafficking to primary cilia. PC1 remains to traffic to the primary cilia in cells depleted of PC2. The proteolytic cleavage at the GPS site of PC1 is not required for its ciliary trafficking.

Methods: A set of deletion/mutation constructs in mouse PC1 including those corresponding to ADPKD patient-derived mutations, as well as chimeric constructs with different mPC1 C-terminal motifs were developed. Transient transfection and immonostaining methods were used.

Results: We found that all pathogenic mutations we tested are defective in ciliary trafficking.Ciliary localization of full-length PC1 or its mutants is completely abolished in PC2 knockout cells. However, this defect can be rescued by co-expression of PC2 in a dose dependent manner. Overexpression of PC2 even drives the C-tail-less PC1 mutant to the primary cilia in IMCD-3 cells. This promotion doesn't rely on the previously identified ciliary targeting VxPx motif at the N-terminus of PC2. The ciliary targeting of PC2 is also

regulated by the dose of PC1. Analyses of the C-tail of PC1 also led to the identification of a potential ciliary targeting sequence within the C-terminal tail of PC1 in addition to the previously identified VxPx motif. This sequence is sufficient to drive a chimeric construct to the cilia in IMCD-3 cells and is independent of the presence of PC2.

Conclusions: Ineffective ciliary trafficking of PC1 may represent a pathogenic mechanism of ADPKD. The mechanisms of polycystins trafficking to the primary cilia are complex involving multiple motifs and factors. Ciliary trafficking of full-length PC1 and PC2 are interdependent, they mutually promote each other to traffic to the primary cilia.

Anoctamin 6 Is Localized in the Primary Cilium of Renal Tubular Cells and Is Involved in Apoptosis-Dependent Cyst Lumen Formation

Bjoern Buchholz,[1] Victoria Forschbach,[1] Margarete Goppelt-struebe,[1] Karl Kunzelmann,[2] Rainer Schreiber,[2] Andre Kraus,[1] Kai-Uwe Eckardt.[1] *[1]Dept of Nephrology, Univ Erlangen-Nuernberg, Erlangen, Germany; [2]Dept of Physiology, Univ Regensburg, Regensburg, Germany.*

Background: Anoctamin (ANO) 6 is a member of a novel family of Ca2+-activated Cl- channels. Although ANO6 is the most widely expressed paralogue, only little is known about its subcellular localization. Recently, we could show that ANO6 together with ANO1 is expressed in renal cyst-lining cells. Unlike ANO1, which was involved in cyst expansion, the role of ANO6 remained elusive. Therefore, we analyzed the localization of ANO6 in renal tubular cells and tested for a role in cyst formation.

Methods: We stained polarized MDCK cells for ANO6 in comparison to stably ANO6-deficient cells. In addition, we analyzed human collecting duct (HCD) cells and primary human tubular cells to test for species- and segment-specific expression. We also examined the effect of ANO6 deficiency on MDCK cyst formation and performed Ussing chamber experiments to test for changes in transepithelial Cl- secretion. Additionally, we stained kidney sections comprising healthy and cystic tissues from ADPKD patients for ANO6.

Results: ANO6 was localized in the primary cilium of all tubular cells irrespective of species or tubular origin. In addition, ciliary localization of ANO6 could be detected in human kidneys. ANO6 knockdown resulted in loss of ciliary ANO6 signals but had no effect on ciliogenesis or MDCK cyst growth. In line with these data, ANO6-deficient MDCK cells revealed no alteration in Ca2+-dependent Cl- secretion. However, lumen formation was markedly disturbed in ANO6-deficient cysts which could be referred to an increased number of cells situated within the cyst lumen which normally would get removed by apoptosis. However, ANO6-deficient cells showed a strong reduction of Ca2+-dependent phospholipid scrambling as well as TUNEL- and Caspase3 signals. In addition, apoptotic cyst cells in human ADPKD were characterized by strong co-expression of ANO6.

Conclusions: ANO6 is a ciliary protein and involved in apoptosis-dependent cyst lumen formation.

Regulation of Cilia Function by Protein Palmitoylation

Kasturi Roy, Levente Jozsef, Ethan P. Marin. *Internal Medicine / Nephrology, Yale School of Medicine, New Haven, CT.*

Background: Cilia are microtubule based protrusions of the plasma membrane which serve sensory and signaling functions. Abnormalities in cilia cause diseases known as ciliopathies, which include autosomal dominant polycystic kidney disease and nephronophthsis. Many ciliopathies involve abnormal trafficking of proteins to cilia. Trafficking of proteins may be affected by cysteine palmitoylation, the reversible post-translational attachment of the lipid palmitate to proteins. Since numerous cilia proteins are palmitoylated, here we have explored the role of palmitoylation in cilia function and protein trafficking. As a model, we have used Arl13b, a palmitoylated monomeric G protein that localizes to cilia and that causes a ciliopathy in humans when mutated.

Methods: Mouse inner medullary collecting duct cells (IMCD3) were used as a model system to studie cilia structure and function. A combination of genetic engineering, biochemical, and microscopic approaches were used to determine Arl13b palmitoylation status, localization, and effects on cilia formation.

Results: IMCD3 cells engineered using CRISPR/Cas9 to have mutations disrupting the Arl13b gene did not form cilia unlike the WT parent cells. Preventing palmitoylation of Arl13b by mutagenesis or by chemical inhibitors blocked trafficking to the cilia. Introduction of a myristoylation site restored proper localization of palmitoylation-deficient Arl13b. In order to identify enzymes involved in Arl13b palmitoylation, we characterized localization and activity of all 24 ZDHHC family protein acyl transferases. Five were found to increase Arl13b palmitoylation at least 3-fold. Further, several were found to be expressed in a compartment proximal to the cilia.

Conclusions: These data collectively show that Arl13b is necessary for cilia formation in IMCD3 cells, and that palmitoylation is as a key regulator of Arl13b localization. Further, these studies identify acyl transferase enzymes that may be novel regulators of Arl13b and thus cilia function. Given the large number of palmitoylproteins in cilia, palmitoylation may be a general mechanism regulating localization of cilia proteins and thus controlling cilia function.

Cell Cycle-Dependent Ubiquitylation and Destruction of NDE1 by CDK5-FBW7 Regulates Cilium Biogenesis

Dipak Maskey, Leonidas Tsiokas. *Cell Biology, Univ of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Background: The primary cilium is an antenna-like organelle housing numerous signaling pathways. Loss of primary cilia can have opposing effects on cystogenesis: in general, it induces cystogenesis, but it suppresses cyst formation in mouse models of autosomal dominant polycystic kidney disease (ADPKD). Therefore, inhibiting ciliogenic pathways can be beneficial in treating ADPKD. Cilia are formed when cells exit the cell cycle and disassemble when cells re-enter the cell cycle. We have previously identified NDE1 as a suppressor of ciliogenesis and showed that its expression is markedly reduced when cells exit the cell cycle. However, the mechanisms controlling its downregulation upon cell cycle exit are unknown.

Methods: Methods used in the study included Western blotting and co-immunoprecipitations, sire-directed mutagenesis, ubiquitylation assays, and indirect immunofluorescence.

Results: Focusing on the mechanisms mediating its downregulation, we have now discovered a pathway involving the CDK5 kinase and the FBW7 E3 ubiquitin ligase that controls ciliary formation. Specifically, CDK5, which is active only in quiescent cells, phosphorylates NDE1 at a specific site, which is in turn recognized by the FBW7 E3 ligase and targets NDE1 for degradation through the Skp1, Cullin 1, FBW7 (SCF^{FBW7}) ubiquitin ligase. The destruction of NDE1 by SCF^{FBW7} allows ciliogenesis to proceed normally, cilia to reach their appropriate length and function properly. However, when this pathway is inhibited by depletion of FBW7, CDK5, or chemical inhibition of CDK5, NDE1 levels rise causing a reduction in ciliary length and function.

Conclusions: Our study furthers our knowledge on the mechanisms of ciliary formation and function and helps develop new approaches to treat cystic diseases.

Platelet-Derived PAI-1 Accelerates Podocyte Detachment in FSGS

Namiko Kobayashi,[1,2] Yukina Takahashi,[1] Taiji Matsusaka,[3] Michio Nagata.[1] *[1]Renal Pathology, Univ of Tsukuba, Tsukuba, Japan; [2]Nephrology, Tsuchiura Kyodo General Hospital, Tsuchiura, Japan; [3]Depts of Molecular Life Science and Inst of Medical Science, Tokai Univ School of Medicine, Isehara, Japan.*

Background: Platelet activation has been shown to be involved in glomerular diseases by releasing cytokines and pro-coagulant factors. In FSGS mice, we have previously shown that PAI-1 is upregulated within the glomerular capillary, which accelerates detachment of remnant podocytes through uPAR-mediated b1 integrin endocytosis. Endothelial cells and platelets are the possible producers of intracapillary PAI-1. Although endothelial cells were involved in the early stage in our study, the role of platelet-derived PAI-1 in FSGS is unknown. Here we tested whether platelet-derived PAI-1 is involved in podocyte loss in FSGS mice.

Methods: We used an immunotoxin inducible FSGS model, NEP25 mice. NEP25 mice were injected with immunotoxin (LMB2, 4 ng/g body weight) on day 0 and treated with 2 mg of anti-mouse platelet antibody (Ab group, n=10) or PBS (C group, n=10) on day-1,4,9. Proteinuria, histology, and PAI-1 localization were examined on day 1 and 12. The WT-1-positive cell number was counted on day -1 and 12.

Results: Platelet depletion decreased proteinuria ($P < 0.05$) with the protection of podocyte number on day 12 (3.15 ± 0.21 in Ab group vs. 1.55 ± 0.27 in C group, $P < 0.05$). Glomerular PAI-1 mRNA expression was increased on day 1 in both groups, but it was decreased on day 12 in Ab group (0.14 ± 0.02 in Ab group vs. 1.0 ± 0.23 in C group, $P < 0.05$). Immunostaining showed glomerular PAI-1 was colocalized with CD31 (endothelial cell marker), but not with CD41 (platelets marker) on day 1 in both groups. PAI-1 was colocalized with CD41, and occasionally with synaptopodin, but not with CD31, on day 12 in C group.

Conclusions: In podocyte injury, PAI-1 was initially induced in the endothelial cells and shifted to the platelets later. Since intracapillary PAI-1 has been shown to promote additional podocyte detachment via integrin endocytosis, inhibition of platelets is a plausible strategy to slow progression of FSGS.

TH-PO225

Podocyte Knockdown of Plasminogen Activator Inhibitor-1 (PAI-1) Is Insufficient to Replicate Protective Effect of Systemic PAI-$1^{-/-}$ in Chronic Kidney Disease

Tareq M. Altuhaifi,[1] Jae Won Yang,[1] Taiji Matsusaka,[2] Haichun Yang,[1] Agnes B. Fogo.[1] *[1]Dept of Pathology, Microbiology, and Immunology, Vanderbilt Univ, Nashville, TN; [2]Dept of Molecular Life Science, Tokai Univ School of Medicine, Isehara-shi, Kanagawa, Japan.*

Background: Podocyte injury is a major trigger for glomerulosclerosis. PAI-1 is upregulated in injured podocytes and sclerosing glomeruli. We assessed the role of podocyte vs. systemic PAI-1 in a primary podocyte injury model.

Methods: We generated a podocyte injury model with intact (PAI-$1^{+/+}$/Nep25, n=8) or systemic PAI-1 deficiency (PAI-$1^{-/-}$/Nep25, n=8) by crossing wild type or PAI-$1^{-/-}$ with Nep25 mice, which express human CD25 receptor on podocyte and develop sclerosis after immunotoxin (LMB2) injection. We also generated podocyte PAI-1 knock down mice (PAI-1^{floxed}/Podocin Cre/Nep25, n=7) and its control (PAI-1^{floxed}/Nep25, n=7) by mating PAI-$1^{loxp/loxp}$/teTO-Cre^{+}/Podocin-$rtTA^{+}$ with PAI-$1^{loxp/loxp}$/Nep25 mice. Doxycycline was given from day -7 till day 10. All mice received LMB2 at day 0, and were sacrificed at day10.

Results: Nep25 mice with systemic PAI-1 deficiency had less body weight increase, an index of edema, but similar proteinuria, when compared to those with intact PAI-1, and also had more preserved podocytes, as shown by higher synaptopodin expression and glomerular WT-1$^+$ density (PAI-1$^{-/-}$/Nep25 5.07±0.17 *vs.* PAI-1$^{+/+}$/Nep25 2.59±0.22x10^{-3}/um^2, p<0.05). Total glomerular CD44 positivity, a marker for activated parietal epithelial cells (PEC), was increased in PAI-1$^{-/-}$/Nep25 vs PAI-1$^{-/-}$/Nep25 (5.06±0.35 vs 3.84±0.36/glom, p<0.05). In contrast, Nep25 mice with podocyte specific PAI-1 knockdown had similar edema and proteinuria as its control, and WT1$^+$ density and glomerular CD44 positivity were not different between PAI-1^{floxed}/Podocin Cre/Nep25 and PAI-1^{floxed}/Nep25. However, synaptopodin was higher in mice with podocyte PIA-1 knockdown vs its control (3.82±0.87 vs 1.98±0.23%, p<0.05).

Conclusions: We conclude that podocyte PAI-1 knockdown was insufficient to produce a similar protective effect as seen in systemic PAI-1 knockout in a podocyte-specific kidney injury model. We speculate that this may partially relate to PEC to podocyte transition.

TH-PO226

Reversal of Podocyte Loss in Mice with Membranoproliferative Glomerulonephritis (MPGN) by Imatinib Noppanit Pattanachaiwit, Masayuki Iyoda, Tomasz A. Wietecha, Kelly L. Hudkins, Charles E. Alpers. *Univ of Washington, Seattle, WA.*

Background: Mice transgenic for thymic stromal lymphopoietin (TSLP-Tg) develop cryoglobulinemia and MPGN. Platelet-derived growth factor (PDGF)-D, expressed by podocytes in humans, with its receptor (PDGFR-β) are likely mediators of mesangial expansion in MPGN. Inhibition of PDGFR-β by imatinib, a tyrosine kinase inhibitor, reduces mesangial proliferation in TSLP-Tg mice. The importance of podocyte loss and PDGF-D expression in MPGN are currently unknown. This study sought to identify possible podocyte loss and investigate the effect of imatinib on podocyte density in mice with MPGN.

Methods: Three-week old female mice were assigned to three groups: TSLP-Tg mice treated with imatinib (50 mg/kg) daily by intraperitoneal injection for eight weeks; control TSLP-Tg mice treated with sterile water; and wild type (WT) control mice. Podocytes were identified by immunohistochemical stain (IHC) for p57, and their density morphometrically quantitated. Expression of PDGF-D and PDGFR-β was detected by IHC. Albuminuria was measured from timed urine samples.

Results: Podocyte density in TSLP-Tg mice was significantly less than WT controls (182.67 ± 21.15 vs 278 ± 6.19 podocytes/10^6 μm^3, p = 0.005), and was markedly increased by imatinib (249.17 ± 14.49, p = 0.029). TSLP-Tg mice had significantly increased mesangial (but not podocyte) expression of PDGF-D (248.23 ± 40.75 μm^2) and slightly increased PDGFR-β expression (192.91 ± 17.31) compared to WT controls (124.17 ± 10.46, p = 0.028 and 175.55 ± 6.61, p = 0.388 respectively). The overexpression of PDGF-D was significantly reduced (129.02 ± 10.95, p = 0.025) whereas the expression of PDGFR-β was increased after imatinib treatment (260.51 ± 18.62, p = 0.024). Albuminuria in TSLP-Tg mice was higher than WT controls (16.6 ± 4.66 vs 4.23 ± 0.76 μg/24 h, p = 0.036), and was decreased by imatinib (4.97 ± 1.64, p = 0.049).

Conclusions: This study demonstrates podocyte loss in MPGN. Restoring podocyte number may be a key to reversal of MPGN. Imatinib largely reversed podocyte loss and reduced mesangial injury, PDGF-D overexpression and albuminuria in TSLP-Tg mice. Unlike humans, mesangial cells rather than podocytes express PDGF-D in mice.

Role of Epithelial Membrane Protein 2 in Nephrotic Syndrome Michael D. Donnan, Rizaldy P. Scott, Tuncer Onay, Anna Woo, Susan E. Quaggin. *Feinberg Cardiovascular Research Inst and Div of Nephrology and Hypertension, Northwestern Univ, Chicago, IL.*

Background: Mutations in the human gene EMP2 (Epithelial Membrane Protein 2) have recently been linked to childhood-onset nephrotic syndrome. Its gene product, a tetraspan integral membrane protein, affects various cell behaviors including regulation of cell adhesion, migration, proliferation, apoptosis and tumorigenesis. EMP2 protein modulates the expression of GPI-anchored proteins, caveolin-1, integrin, and the growth factor VEGFA. EMP2 is also necessary for embryo implantation and chlamydial infectivity. We studied the renal expression pattern of EMP2 and generated a conditional Emp2 knockout (KO) mouse as first steps towards understanding its role in glomerular disease.

Methods: We created a floxed *Emp2* (*Emp2*$^{flox/flox}$) mouse containing a LacZ reporter gene controlled by the endogenous *Emp2* promoter. We assessed *Emp2* expression in kidneys using whole-mount β-galactosidase (β-gal) histochemistry. To complement this analysis, we used an antibody against EMP2 to assess its localization by immunofluorescence (IF). Podocyte-specific KO mice (*Emp2*$^{Pod/Pod}$) were generated by breeding Emp2$^{flox/flox}$ mice to the *Nphs1-Cre* driver strain and were assessed for proteinuria.

Results: β-gal staining reveals that *Emp2* is prominently expressed within major vascular bundles and a distinct band of cells within the cortex and renal papillae. Double-label IF using an EMP2 antibody and Lotus lectin suggests that the *Emp2* expression within the renal cortex is in proximal tubules. The EMP2 antibody did not stain the renal papilla or renal vasculature. Whether this disparity is due to cell-specific post-translational modification (e.g. glycosylation) remains to be addressed. However, in both β-gal and IF assays *Emp2* within the glomerulus was not seen. By 3 months of age, *Emp2*$^{Pod/Pod}$ do not have proteinuria.

Conclusions: In contrast to a previous report, we did not observe Emp2 expression in podocytes while *Emp2*$^{Pod/Pod}$ mice do not develop overt kidney disease. Genetic deletion of Emp2 in tubular and endothelial compartments will provide additional insights regarding the etiology of renal dysfunction in patients with EMP2 mutations.

TH-PO228

Discovery of Mesencephalic Astrocyte-Derived Neurotrophic Factor as a Urine Biomarker for Endoplasmic Reticulum Stress-Related Kidney Diseases Yeawon Kim,[1] Heedoo Lee,[1] Scott R. Manson,[2] Jeffrey H. Miner,[1] Fumihiko Urano,[3] Ying Maggie Chen.[1] *[1]Renal Div, Washington Univ, St. Louis, MO; [2]Div of Urology, Washington Univ, St. Louis, MO; [3]Div of Endocrinology, Metabolism and Lipid Research, Washington Univ, St. Louis, MO.*

Background: Accumulating evidence has highlighted the important role of endoplasmic reticulum (ER) stress in the pathogenesis of a variety of kidney diseases. Thus, it is imperative to develop non-invasive biomarkers for detecting ER stress in podocytes or tubular cells in the incipient stage of disease, when clinically a kidney biopsy is not yet indicated. Moreover, restoration of ER homeostasis before irreversible kidney cell injury may hold significant promise as an attractive therapeutic strategy. Here for the first time we discovered mesencephalic astrocyte-derived neurotrophic factor(MANF) as a potential urine biomarker for detecting ER stress in associated kidney diseases.

Methods: We used mouse models of human nephrotic syndrome (NS) caused by podocyte ER stress and of acute kidney injury (AKI) triggered by the ER stressor tunicamycin or ischemia/reperfusion (I/R)-induced tubular ER stress.

Results: In our NS mouse model carrying the C321R laminin β2 (LAMB2) mutation in podocytes, podocyte ER stress was induced. The mutants exhibited MANF induction in podocytes at P24, when proteinuria was minimal, compared with controls. *In vitro*, secretion of MANF by mutant primary podocytes was increased as compared to that by control podocytes. Most importantly, MANF was easily detected in the crude urines of C321R mutants in the incipient stage of disease as compared to the controls. Meanwhile, in tunicamycin or I/R-induced AKI mouse models, urinary MANF excretion concurrent with tubular cell ER stress preceded clinical or histological manifestations of acute tubular injury.

Conclusions: MANF can potentially serve as a urine biomarker to help stratify disease risk and predict disease progression in the ER stress-related kidney diseases. In addition, MANF can help identify subgroups of patients who can be treated with ER stress modulators and monitor treatment response in a highly-targeted manner.

Identification of Differentially Expressed Genes in Rat Puromycin Aminonucleoside (PAN) Nephropathy, a Mimic of MCNS with Next-Generation Sequencing Yoshiyasu Fukusumi, Hiroshi Kawachi. *Dept of Cell Biology, Inst of Nephrology, Niigata Univ Graduate School of Medical and Dental Sciences, Niigata, Japan.*

Background: To explore the novel therapeutic targets of nephrotic syndrome resulted from podocyte dysfunction, we intend to identify the molecules of which gene expression is changed in rat nephrotic models by the Next-Generation Sequencing analysis.

Methods: The profile of gene expression of PAN nephropathy was analyzed by next generation high-throughput RNA sequencing (RNA-Seq) with Solid system 5500. 581 molecules, whose mRNA was clearly altered (more than 5 times increase or less than 20% decreased to normal level), were identified. 20 molecules, which were expected to play a role in maintaining podocyte function, were selected, and the kinetic of the mRNA expression of these molecules were precisely analyzed in several nephrotic models including anti-nephrin antibody (ANA)-induced nephropathy, a proteinuric model caused by the disarrangement of the SD molecules, and in ADR nephropathy, a mimic of FSGS, as well as PAN nephropathy.

Results: In PAN nephropathy, mRNA expression of 153 genes were increased (> 5 times) at 1 h when abnormal proteinuria was not detected yet. mRNA expressions of 121 genes were increased on day 10 when proteinuria peaked. mRNA expressions of 37 genes were increased both time points. 297 genes, whose mRNA expression was lowered to less than 20%, were identified. mRNA expressions of 186 genes were decreased similarly on day 10, and those of 121 genes were decreased at both 1h and day 10. For further analyses Phospholipase A2, group IID (Pla2g2d) and proto cadherin alpha 5 (Pcdha5) were focused. mRNA expression of Pla2g2d was decreased to 11% at 1h and 13 % on day 10 of PAN nephropathy. mRNA expression of Pcdha5 was decreased to 2.7% at 1h and 1.5% on day 10 of PAN nephropathy and 15% on day 5 of ANA nephropathy, whereas the mRNA expression was clearly increased on day 5 of ADR nephropathy.

Conclusions: RNA-Seq is a powerful tool for profiling gene expression and the detection of differentially expressed gene in proteinuric state. It is assumed that the decrease in the mRNA expression of Pla2g2d and Pcdha5 is involved in the development of proteinuria.

Comprehensive Polysome Analysis in Injured Podocytes Masahiro Okabe,[1,2] Yoichi Miyazaki,[2] Takashi Yokoo,[2] Masafumi Fukagawa,[1] Taiji Matsusaka.[1] *[1]Tokai Univ School of Medicine, Isehara, Japan; [2]Jikei Univ School of Medicine, Tokyo, Japan.*

Background: Podocyte injury is the key event for progressive renal failure. It is difficult to isolate the RNA of podocytes from the kidney, which is made up with multiple-type cells.

Methods: To solve this problem, we used Ribotag transgenic mouse line (established by Dr. Amieux PS), in which HA-tag is inserted into the C-terminus of Rpl22, a component of the ribosomal protein, in the presence of Cre recombinase. Ribotag line was mated with nephrin-Cre and NEP25, an immunotoxin-inducible podocyte-selective injury model.

Glomeruli were isolated before or after induction of podocyte injury. Podocyte-specific polysome was yielded by immunoprecipitation with anti-HA antibody and analyzed by Agilent's 8X66K microarray (n=12) and qRT-PCR (n=8).

Results: In a basal condition, microarray analysis revealed 5070 (9.1%) probes were significantly and more than 2-fold enriched in podocytes within the glomerulus, which include most known podocyte genes. qRT-PCR confirmed that Nphs1 and Nphs2 RNAs were concentrated in podocytes (15 and 8.6-fold), while mesangial and endothelial RNAs were diluted. Seven days after immunotoxin injection, 3130 (5.6%)/1938 (3.5%) probes were significantly and more than 2-fold up/down-regulated in podocytes from the basal condition. Nphs1, Podxl, Synpo and Wt1 were decreased (0.37, 0.39, 0.28 and 0.49-fold), and Des, Relb, Gadd45b and Cxcl1 were markedly upregulated (8.1, 6.9, 20 and 160-fold), which were confirmed by qRT-PCR. These changes were significantly correlated with those in Actn4 KO podocytes reported in TRAP study (R=0.520, p<0.001), suggesting that these represent common pathogenic responses. Separately, reviewing 84 published CKD candidate genes identified by GWAS, thirteen, including Vegfa, were found concentrated in normal podocytes whereas Dach1 and Aff3 decreased after podocyte injury (0.42, 0.64-fold) similarly to Vegfa (0.28-fold), suggesting their important functional role in podocytes.

Conclusions: Thus, these comprehensive data provide potentially important insights for understanding podocyte pathophysiology.

TH-PO231

Expression of Mouse uPAR Alternative Isoform 2 Produces a Dimeric Protein and Severe Renal Disease Changli Wei,[1] Brian D. Adair,[2] Jing Li,[1] Liu Shuangxin,[1] Nicholas J. Tardi,[1] Jochen Reiser.[1] *[1]Rush Univ Medical Center; [2]Massachusetts General Hosptial, Harvard Medical School.*

Background: Soluble urokinase receptor (suPAR) has been proposed as a circulating factor in focal segmental glomerulosclerosis (FSGS) by direct activation of podocyte aVb3 integrin. Mouse secretive uPAR isoform 2 (msuPAR) is an alternatively spliced uPAR variant. This study was aimed to evaluate the ability of this isoform to function as a circulating factor.

Methods: For structural study, msuPAR was cloned from podocytes, and expressed in HEK cells with a Flag tag. The recombinant msuPAR protein was purified with Flag beads and analyzed by electron microscopy (EM). For functional study, a transgenic mouse model was created that drives msuPAR expression from adipocytes with consequent release into circulation.

Results: Negative-stain EM and single particle image analysis reveal that msuPAR protein forms a compact, well-defined structure in solution, which is formed by a dimer of two globular domains. The three-dimentional reconstruction shows one of the domains, which provides a good fit for domain 1, connected to the other globular domain in an open conformation, in contrast with the tight closed conformation seen in crystal structures of the intact protein (isoform 1). msuPAR transgenic mice are fertile and they start to develop proteinuria 1 month after birth. With rising serum msuPAR level, progressive proteinuria develops in most animals. By 7 to 8 months old, about 20% of msuPAR transgenic mice developed FSGS-type lesions, while 80% of mice showed mild glomerular damages. Transmission EM analysis showed variant degree of podocyte foot process effacement that correlated to the proteinuria and the light microscopy changes. Analysis of serum level of the inflammatory marker, CRP or IL-6 did not distinguish msuPAR transgenic mice from littermate control. Glomerular b3 integrin activity however was significantly increased in msuPAR transgenic mice.

Conclusions: The mouse secretive isoform uPAR 2 forms a dimeric protein with globular domains. Its expression in transgenic mice results in increased podocyte integrin activation and progressive renal disease with a spectrum from minimal change to FSGS type kidney lesion.

Sildenafil-Dependent Reduction of TRPC6 Expression, Podocyte Injury and Proteinuria Is Mediated via PPARγ Ramon Sonneveld,[1] Joost Hoenderop,[2] Carole Hénique,[3] Jo H.M. Berden,[1] Pierre-Louis Tharaux,[3] Johan Van der vlag,[1] Tom Nijenhuis.[1] *[1]Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands; [2]Physiology, Radboud Univ Medical Center, Nijmegen, Netherlands; [3]Cardiovascular Research Centre, INSERM, Paris, France.*

Background: Increased transient receptor potential channel C6 (TRPC6) activity in the podocyte leads to glomerular injury and proteinuria. Sildenafil (Viagra®) is used to treat erectile dysfunction and pulmonary arterial hypertension where it reduces TRPC6 activity and expression. The nuclear receptor PPARγ is a downstream target of sildenafil via the cGMP-activated protein kinase G (PKG) axis. PPARγ agonists likePioglitazone (Pio) may be antiproteinuric. We hypothesized that sildenafil has renoprotective effects, with PPARγ as central mediator modulating TRPC6 expression and activity in podocytes.

Methods: Using pharmacological compounds in cultured podocytes, rat and mouse models, the role of the PPARγ-PKG in mediating TRPC6 expression/activity was tested.

Results: TRPC6 expression was upregulated in adriamycin-injured podocytes, which was dose-dependently downregulated by sildenafil, the cGMP derivative 8-Br-cGMP or the PPARγ agonist Pio. The PKG blocker KT5823 or the PPARγ antagonist GW9662 enhanced TRPC6 expression. The effects of sildenafil and 8-Br-cGMP were counteracted by inhibition of PKG by KT5823 and PPARγ by GW9662. The effect of Pio was negated only by GW9662. Similar results were shown for TRPC6 promoter activity and calcium influx. Chromatin immunoprecipitation showed binding of PPARγ to the TRPC6 promoter. Healthy rats treated with GW9662 showed proteinuria and upregulation of TRPC6 expression in the podocytes, which was also observed in podocyte-specific PPARγ knock-out mice. Renal injury and increased TRPC6 expression in adriamycin induced nephropathy rats could be prevented by sildenafil and Pio treatment.

Conclusions: Amelioration of podocyte injury by sildenafil involves cGMP- and PKG-dependent binding of PPARγ to the TRPC6 promoter, thereby inhibiting TRPC6 promoter activity, expression and activity. Our data identify sildenafil as a novel antiproteinuric agent, which acts by inhibiting deleterious TRPC6-mediated intracellular podocyte signaling.

TH-PO233

APOL1 Risk Variants Enhance Initiation but Retard the Terminal Part of Autophagy in Podocytes Xiqian Lan,[1] Hongxiu Wen,[1] Ashwani Malhotra,[1] Karl Leon Skorecki,[2] Pravin C. Singhal.[1] *[1]Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY; [2]Medicine, Rambam Health Care Campus, Haifa, Israel.*

Background: Patients with APOL1 Variants carry 10 fold higher chance for the development of HIVAN if not on antiviral therapy. HIV is known to hijack autophagy in the host cells-enhancement of autophagosome formation (the site of viral replication) but inhibits the delivery of autophagosomal cargo (AC) to the lysosomes and thus, prevents viral degradation. Since podocytes are terminally differentiated cells their protein homeostasis is tightly regulated by autophagy. We hypothesized that APOL1 risk variants would also have potential for augmenting the initial phase but would inhibit the terminal phase of autophagy.

Methods: We used human podocytes (HPs) stably expressing APOL1G0, G1, or G2 (Vec/HPs, G0/HPs, G1/HPs, and G2/HPs). Pseudo type HIV or empty vector (control) virus was transduced into Vec/HPs, G0/HPs, G1/HPs and G2/HPs. After 48 h, cells were harvested and assayed for vacuolar density (number of autophagosomes) by staining with acridine orange or monodansylcadaverine (MDC). Protein blots of HPs (Vec, G0, G1, and G2) were probed for mTOR (pathway modulating autophagy), beclin-1 and LC3-II (markers of early steps of autophagy), p62 (marker of degradation of AC) and reprobed for actin. HPs were co-labeled for APOL1 and endosomal/lysomal markers to delineate route of APOL1.

Results: G0/HPs, G1/HPs and G2/HPs displayed greater number of autophagosomes when compared to Vec/HPs. Protein blots of G1/HPs and G2/HPs demonstrated enhanced expression of LC3II and beclin-1 and thus indicating enhancement of initiation of autophagy. Protein blots of G1 and G2/HPs also displayed enhanced expressin of p62, which indicated that AC did not reach to lysosomes. Additionally, G1/HPs and G2/HPs showe attenuated mTOR expression. HIV expression by G1/HPs and G2/HPs further enhanced early markers of autophagy but displayed further attenuation of lack AC at lysosomal compartment. Co-labeling studies of APOL1 revealed decreased presence of APOL1 in lysosomal compartment.

Conclusions: APOL1 risk variants enhance initiation but inhibit terminal phase of autophagy both in control and HIV stimulated states.

TH-PO234

Disparate APOL1 Expression in HIV-Associated Nephropathy Reflects Podocyte Injury Xiqian Lan,[1] Hongxiu Wen,[1] Ashwani Malhotra,[1] Karl Leon Skorecki,[2] Pravin C. Singhal.[1] *[1]Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY; [2]Medicine, Rambam Health Care Campus, Haifa, Israel.*

Background: ApolipoproteinL1 (APOL1) variants G1 and G2 contribute to the higher percent of kidney diseases in African Americans. Renal biopsy specimens in patients of focal segmental glomerulosclerosis (FSGS) and HIV-associated Nephropathy (HIVAN) revealed lower expression of APOL1 by podocytes but higher expression by vascular smooth muscle cells (VSMC). The involved mechanisms for disparate expression of APOL1 by two different cell types in the affected population is not clear. We hypothesized that modulation of APOL1 expression is a marker of ongoing podocyte injury.

Methods: Human odocytes (HPs) and VSMCs were transduced with equal amounts of lentivirus (vector, G0, G1, and G2) and cultured for 48 hours. Subsequently, cells were evaluated for reactive oxygen species (ROS) generation (DCFDA loading and co-labeling with mitotracker green and Red CC1), viability (MTT/Trypan blue assays), apoptosis, and necrosis (morphologic assay by staining with H33342 and propidium iodide). VSMC proliferation was determined by cell counting and labeling for PCNA. In parallel sets of experiments, APOL1 expression in these cells was quantified by Western blotting analysis.

Results: Compared to Vector and G0, HPs expressing G1 and G2 displayed higher rates of ROS generation, enhanced loss of cell viability, greater number of apoptosed and necrosed cells. HPs transduced with G1 and G2 displayed lower expression of APOL1 when compared to G0. VSMCs transduced with G0, G1, and G2 displayed comparable expression of APOL1 expression. VSMCs transduced with either G0 or G1/G2 displayed minimal loss of viability, number of apoptosed or necrosed cells, but they displayed greater number of proliferating cells when compared to Vector transdueced HPs.

Conclusions: APOL1 variants expressing podocytes experience higher degree of oxidative stress but display lower APOL1 expression. On the other hand, VSMCs expressing G1 and G2 experience lesser degree of injury when compared to vector transduced VSMCs.These findings suggest that APOL1 expression by podocytes may be a marker of ongoing stress.

TH-PO235

A Soluble Guanylate Cyclase Activator Is Superior to a Phosphodiesterase Type 5 Inhibitor and a Soluble Guanylate Cyclase Stimulator in Protecting from Diabetic Nephropathy in the ZSF1 Rat Kathleen A. Lincoln, Paul Harrison, Hongxing Chen, Hong Wang, Holly Clifford, Hu Sheng Qian, Diane Wong, Christopher Sarko, Ryan M. Fryer, Jeremy G. Richman, Glenn A. Reinhart, Steven S. Pullen, Carine Boustany. *Cardiometabolic Disease Research, Boehringer-Ingelheim Pharmaceuticals, Ridgefield, CT.*

Background: Therapies which restore cyclic GMP (cGMP) levels within the kidney are hypothesized to slow disease progression. We evaluated the effects of BI703704, a soluble guanylate cyclase (sGC) activator, EX76637; a sGC stimulator, and EX77619; a phosphodiesterase type 5 (PDE5) inhibitor, on the progression of diabetic nephropathy in obese ZSF1 rats.

Methods: Male ZSF1 rats, implanted with telemetry devices, were treated with either BI703704 at 2 mg/kg, EX76637 at 1 or 3 mg/kg , EX77619 at 5 or 15 mg/kg for 10 weeks, during which mean arterial pressure (MAP) and urinary protein excretion (UPE) were determined. At study end, glomerular and renal interstitial lesions were assessed. Alpha smooth muscle actin (α-SMA, a marker of myofibroblast activation) and p-57 (a marker of podocyte health) were determined by immunohistochemistry. Renal cGMP levels were quantified as a measure of target engagement.

Results: By Week 10, similar reductions in MAP were achieved (~8mmHg) across treatment groups vs. vehicle. In parallel, sGC activation resulted in significant reductions in UPE (-31% vs veh), while there was no significant effect of EX76637 (+4% at 1 mg/kg ; -16 % at 3 mg/kg vs veh), or EX77619 (-15% at 5 mg/kg; -9% at 15 mg/kg vs veh). Importantly, BI703704's effects on UPE were accompanied by reductions in the incidence of glomerulosclerosis (-21% vs veh), while neither EX76637 nor EX77619 were effective. In addition, interstitial lesions were modestly reduced by BI703704 (-13 % vs veh) and EX77619 (-18% vs veh). α-SMA was reduced by BI703704 (-27% vs veh) and EX76637 (-8% vs veh), while P57 was significantly increased by BI703704 (+11% vs veh) but not by EX76637 or EX77619. Importantly, target engagement was confirmed for EX77619.

Conclusions: Despite similar effects on MAP, BI703704 was superior to EX76637 or EX77619 in reducing proteinuria and preventing renal damage in kidneys of ZSF1 rats.

Localization of Phosphodiesterase 4 Isoforms in the Renal Cortex Xianzhong Lau, Yuan Zhang, Darren J. Kelly, Robyn G. Langham. *Dept of Medicine (St Vincent's), Univ of Melbourne, Melbourne, Victoria, Australia.*

Background: There are limited therapeutic options for the treatment of chronic kidney disease (CKD). Our recent studies have found that Phosphodiesterase 4 (PDE4) inhibitor roflumilast (RFL) was effective in attenuating renal decline in subtotal nephrectomized (STNx) rats, a model of CKD, indicating that PDE4 inhibition is may be effective in treating CKD. There have been studies on the contribution of cAMP hydrolysis by PDE4 in nephron segments and the mRNA expression distribution of PDE4 isoforms in several cultured renal cells. However, the localization of PDE4 isoforms in the kidney has yet to be explored. Hence, we sought to investigate the distribution of PDE4 isoforms in the renal cortex, as it may also elucidate the renal cell types that RFL targets.

Methods: Sprague-Dawley rats underwent either STNx or sham surgery, further randomized after 2 weeks to receive an oral dose of either RFL (1 mg/kg/day) or vehicle, and sacrificed at 12 weeks. PDE4 isoforms (PDE4A, PDE4B, PDE4C) were localized with immunohistochemistry. Immunofluorescence was used to co-localize PDE4 isoforms with podocytes.

Results: The distribution pattern for each PDE4 isoform was distinct. However, positive staining was mainly localized on the podocytes in the glomerulus (for PDE4A, PDE4B and PDE4C) and distal tubules and in tubulointerstitium (for PDE4A and PDE4C). In the STNx group, positive staining on the podocytes was significantly more intense than the sham group. RFL treatment significantly reduced the elevated expression of PDE4 isoforms in the podocytes.

PDE4 Isoform	Sham	Sham+RFL	STNx	STNx+RFL
PDE4A	3.22±0.49	2.84±0.64	11.38±0.88****	8.44±1.30***†
PDE4B	0.38±0.18	0.50±0.17	8.75±1.50****	5.49±1.21**†
PDE4C	2.17±0.31	2.63±0.25	12.44±1.86****	8.01±0.87**†

Conclusions: PDE4 isoforms are distributed throughout the renal cortex, especially in the podocytes and distal tubules. During CKD, the expression of PDE4 isoforms in the podocytes increases. As the reduction in PDE4 expression with RFL treatment was associated with the attenuation of renal decline, PDE4 inhibition may be especially relevant in preserving podocyte health.

The Glomerular Parietal Epithelial Cell Phenotype Depends on SPARC Levels Shokichi Naito. *Nephrology, Kitasato Univ School of Medical Sciences, Sagamihara, Kanagawa, Japan.*

Background: Parietal epithelial cell (PECs) might play a critical role in a glomerular repair through their progenitor function. Conversely, PECs might paradoxically contribute to the deterioration of glomerular function by augmentation of scarring and crescent formation under certain conditions. The factors governing these PEC functions are not well understood. We have previously shown that SPARC (secreted protein acidic and rich in cysteine) plays a causal role in mediating podocyte detachment and accelerating glomerulosclerosis in experimental crescentic glomerulonephritis. However, the effect of SPARC levels on PECs is unknown.

Methods: Experimental glomerular disease was induced in aged-matched $SPARC^{+/+}$ and $SPARC^{-/-}$ mice by intraperitoneal injection of a sheep anti-rabbit glomerular antibody. Immunostaining methods were then employed on days 0 and 7 of disease.

Results: The number of PEC transition cells, defined as cells co-expressing a PEC marker (PAX2), and podocyte marker (Synaptopodin) was higher in diseased $SPARC^{-/-}$ mice compared with $SPARC^{+/+}$ mice (1.35 ± 0.18 vs. 0.46 ± 0.14, $P < 0.01$ vs. $SPARC^{+/+}$ mice). WT1 staining along Bowman's capsule was higher in diseased $SPARC^{-/-}$ mice (2.57 ± 0.30 vs. 1.37 ± 0.30, $P < 0.01$ vs. $SPARC^{+/+}$ mice). This observation was accompanied by increased PEC proliferation (measured by Ki-67 staining, (4.56 ± 0.46 vs. 2.66 ± 4.99; $P < 0.01$) and an increase in immunostaining for a progenitor marker, neural cell adhesion molecule (1.35 ± 0.05 vs. 1.21 ± 0.05, $P < 0.05$ vs. $SPARC^{+/+}$ mice), in a subpopulation of PECs in diseased $SPRAC^{-/-}$ mice.

Conclusions: PECs have the potential to become glomerular epithelial transition cells. SPARC expression in PECs favors a decrease in the number of PEC transition cells.

Low Dose Hydralazine Augments Losartan Mediated Reversal of Epigenetic Alterations in Diabetic Nephropathy (DN) Himanshu Vashistha,[1] Nirupama Chandel,[2] Xiqian Lan,[2] Anjali Maheshwari,[2] Nairuti H. Shah,[2] Ashwani Malhotra,[2] Leonard G. Meggs,[1] Pravin C. Singhal.[2] *[1]Medicine, Ochsner Health System, New Orleans, LA; [2]Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY.*

Background: Epigenetics has been demonstrated to play a role in the development and progression of DN. Recently, we observed that losartan reverses high glucose-induced podocyte epigenetic alterations. We now hypothesized that low (non-hypertensive) dose hydralazine (HYDZ) will further augment losartan-induced reversal of epigenetic alterations in DN.

Methods: Protein blots of renal tissues/renal cortical sections of 2, 4, and 6 month old control and Akita mice (n=3) were probed for methylation at histone (H)3 lysine (K)4 residue, acetylation at H3 lysine (K)9 residue, SNAIL, vitamin D receptor (VDR), and nephrin. *In vitro* studies, protein blots of control and high glucose (30 mM, HG) treated human podocytes (HPs) were probed for SNAIL, VDR, nephrin, H3K4me3, H3K9ac and actin. Podocyte VDR and nephrin gene methylation status (pyrosequencing)and SNAIL binding at VDR and nephrin promoter (ChIP assay) were determined. Control and Akita mice (n=4) were treated with losartan with/without HYDZ (10 mg/kg/day, 4 weeks) followed by evaluation of proteinuria and renal epigenetic alterations.

Results: Protein blots of renal tissues of Akita mice displayed enhanced expression of SNAIL and H3K4me3 but down regulation of VDR and nephrin. Podocytes in renal cortical sections also displayed similar profile; losartan not only decreased proteinuria but also partially reversed epigenetic alterations and associated SNAIL, VDR and nephrin expressions; HYDZ alone has similar effects on proteinuria and epigenetic markers and further augmented these effects when combined with losartan. HG/HPs displayed enhanced expression of SNAIL and H3K4me3 and attenuated expression of VDR, nephrin, and H3K9ac. Both nephrin and VDR displayed more than 70% cytosine methylation. HG/HP displayed deacetylation of nephrin and degradation via ubiquitation. ChIP assay revealed binding of SNAIL at VDR and nephrin promoter.

Conclusions: Optimal reversal of epigenetic alterations can be used as a therapeutic strategy in DN.

TH-PO239

Klotho Ameliorates Proteinuria by Targeting TRPC6 Channels in Podocytes Jian Xie,[2] Ji-Hee Kim,[1] Kyu-Hee Hwang,[1] Yueh-lin Wu,[2] Noelynn Oliver,[3] Chou-Long Huang,[2] Seung-Kuy Cha.[1] *[1]Wonju College of Medicine, Yonsei Univ, Wonju, Korea; [2]Dept of Medicine, UT Southwestern Medical Center, Dallas, TX; [3]Boehringer Ingelheim Pharmaceuticals Inc., Ridgefield, CT.*

Background: Klotho is a type-1 membrane protein mainly produced in the kidney tubules. The extracellular domain of klotho is secreted into extracellular space. Whether klotho is expressed in podocytes and whether and how it may protect the glomerular filter are unknown.

Methods: TRPC6-mediated Ca2+ influx, cytoskeletal remodeling, and transepithelial albumin flux were studied in cultured mouse podocytes. Klotho expression in cultured podocytes and the kidney was examined by immunostaining, in situ hybridization, and RNA sequencing. Effects of klotho on albuminuria were studied using mouse models with genetically altered expression of TRPC6 and klotho.

Results: Recombinant secreted soluble klotho suppressed ATP-stimulated, TRPC6-mediated Ca2+ influx in cultured mouse podocytes. Cytoprotection by klotho on cultured podocytes is supported by the reduction in ATP-stimulated actin cytoskeletal remodeling

and transepithelial albumin leakage. Overexpression of TRPC6 by gene delivery in mice induced albuminuria, and exogenous administration of soluble klotho ameliorated the albuminuria. Heterozygous klotho-deficient sham-operated mice had no basal albuminuria vs WT sham mice, but het-klotho chronic kidney disease (CKD) mice had aggravated albuminuria compared to that in WT CKD mice with a similar degree of hypertension and reduced clearance function. Klotho is expressed in podocytes of mouse and human kidney. Disrupting the integrity of glomerular filter increased urinary excretion of soluble klotho.

Conclusions: Klotho protects podocytes from injury by suppressing TRPC6-mediated Ca2+ entry. Cytoprotection of podocytes in the native state may be through membranous klotho present on podocyte cell surface or soluble klotho present in Bowman's space. Soluble klotho may be a treatment for proteinuria.

Aminopeptidase A Is Up-Regulated in the Intact Areas of Segmentally Sclerotic Glomeruli in Advanced Focal Segmental Glomerulosclerosis

Juan Carlos Q. Velez, Michael G. Janech, Wayne R. Fitzgibbon. *Div of Nephrology, Medical Univ of South Carolina, Charleston, SC.*

Background: Angiotensin (Ang) II is involved in the pathogenesis of focal segmental glomerulosclerosis (FSGS). We hypothesized that FSGS may be associated with adaptive changes in glomerular expression of Ang-metabolizing peptidases.

Methods: Using fawn-hooded hypertensive (FHH) rats as a model of FSGS, we examined the pattern of glomerular expression of Ang converting enzyme (ACE) and the robust Ang II-cleaving enzyme aminopeptidase A (APA) by Western blot (WB) and immunohistochemistry (IHC).

Results: ACE was absent in glomeruli by both WB and IHC. Overall expression of APA in glomerular extracts was found to gradually decrease over time, with 87% reduction at 60 weeks compared to 6 weeks of age ($p<0.0001$). Glomerular extracts from 30 week-old FHH rats had lower APA expression and lower APA activity compared to age-matched Wistar rats ($p<0.05$). By IHC, 60-week kidneys showed loss of glomerular APA in globally sclerotic glomeruli as well as on the sclerosed area of the segmentally sclerotic glomeruli. On the other hand, the "surviving" intact areas within the segmentally sclerotic glomeruli as well as some normal-appearing glomeruli exhibited a markedly accentuated APA expression. In contrast, the podocyte marker GLEPP1 was not only absent in all sclerotic areas but also attenuated in the intact areas within the segmentally sclerotic glomeruli and in normal-appearing glomeruli, suggesting that APA increases during the late response phase to podocyte injury. To determine whether the APA augmentation corresponded to a feedback response to Ang II, cultured mouse podocytes were incubated with Ang II (100 nM) for 24-72 hours. No change in APA abundance was observed, nor could APA abundance be induced by infusing Ang II in 8-week FHH rats for 4 weeks.

Conclusions: In conclusion, podocyte-localized APA is up-regulated in the "surviving" non-sclerosed segmental areas in glomeruli of FHH rats. However, the mechanism of up-regulation does not appear to be directly mediated by Ang II. Understanding the mechanism of APA up-regulation may provide tools to enhance the actions of a potentially renoprotective peptidase.

Anti-VEGF Treatment by Transfection of the Natural Inhibitor sFlt-1 Increases Albuminuria in Type 1 Diabetic Mice

Pascal Bus, Jan A. Bruijn, Hans J. Baelde. *Dept of Pathology, Leiden Univ Medical Center, Leiden, Zuid-Holland, Netherlands.*

Background: It has been shown that VEGF-A is involved in diabetic nephropathy (DN). In diabetic mice, treatment with anti-VEGF antibodies reduced glomerular hypertrophy. On the other hand, women with pre-eclampsia develop proteinuria due to increased levels of soluble Flt-1 (sFlt-1) – a natural inhibitor of VEGF-A. In this study we investigated the effects of systemic VEGF-A inhibition by sFlt-1 transfection in type 1 diabetic mice.

Methods: Diabetic mice were transfected with an sFlt-1 construct at the onset of diabetes. After five weeks of treatment mice were sacrificed. Collection of urine and blood was performed at baseline, and week 1, 3, and 5. Albuminuria was measured using Rocket Electrophoresis. Kidneys were sectioned and stained for PAS, FA-11 (macrophages) and WT1 (podocytes). Glomerular hypertrophy was measured using Philips Digital Pathology Solutions. One-way ANOVA was performed to measure differences between the groups. Differences with a probability level (P) < 0.05 were considered statistically significant.

Results: Diabetic mice transfected with sFlt-1 had higher albuminuria levels than mice with diabetes alone ($p<0.05$). However, glomerular hypertrophy as well as the number of glomerular macrophages were reduced in the treated group ($p<0.05$). No effect on podocyte numbers was observed.

Conclusions: In contrast to other studies investigating VEGF-A, we reduced VEGF levels with the use of a natural inhibitor. In line with previous findings we showed that sFlt-1 treatment reduced glomerular hypertrophy in diabetic mice. In addition, sFlt-1 treatment resulted in higher albumin levels in diabetic mice. These results show that treatment for reducing VEGF-A levels has to be performed with care since treatment has both beneficial and detrimental effects.

TH-PO242

Apolipoprotein C1 Transgenic Mice Develop Gomerulosclerosis: A Potential Role for Macrophages

Pascal Bus,[1] Rosalie Bor,[1] Jimmy F. P. Berbée,[2] Jan A. Bruijn,[1] Emile De Heer,[1] Hans J. Baelde.[1] *[1]Dept of Pathology, Leiden Univ Medical Center, Leiden, Zuid-Holland, Netherlands; [2]Dept of Medicine, Div of Endocrinology, Leiden Univ Medical Center, Leiden, Zuid-Holland, Netherlands.*

Background: Associations between an *APOC1* polymorphism and the development of diabetic nephropathy (DN) have been identified and confirmed in several meta-analyses. In addition, patients with type 1 and type 2 diabetes have higher serum levels of APOC1 compared to healthy control subjects. APOC1 transgenic (APOC1tg) mice develop albuminuria and glomerulosclerosis at 15 months of age. In this study we investigated the role of macrophages in APOC1 induced glomerulosclerosis in APOC1tg mice.

Methods: APOC1tg and wild-type (WT) mice were sacrificed at various ages. Kidneys were sectioned and stained for APOC1, F4/80 (macrophages), CD11b (M1 macrophages), CD163 (M2 Macrophages) and TNF-alpha. RT-PCR was performed to measure APOC1 mRNA levels. To confirm data from APOC1tg mice, human autopsied kidneys with DN and healthy controls were included, sectioned and stained for APOC1. Correlations were assessed using the Pearson's correlation test.

Results: In APOC1tg mice, the number of glomerular macrophages were already increased at 15 weeks of age, long before the development of glomerular damage, and increased even further in time. A strong linear correlation was found between the number of glomerular macrophages and glomerular damage ($p<0.001$). These macrophages were found to be of the M1 type and expressed high amounts of APOC1 and TNF-alpha. In patients with DN, glomerular APOC1 expression was significantly increased compared to healthy control subjects.

Conclusions: Both our mice and our human autopsied data indicate that APOC1 could play a crucial role in the development of glomerular damage. We hypothesize that APOC1-expression by macrophages causes glomerular damage, potentially by increasing the inflammatory state of these macrophages.

TH-PO243

Decreased Renal α-Klotho Expression Is Associated with Urinary Calcium Excretion in Early Diabetic Nephropathy in db/db Mice

Kyung don Ju, Tsogbadrakh Bodokhsuren Bodokhsuren, Hyo Jin Kim, Seungmi Lee, Miseon Park, Curie Ahn, Kook-Hwan Oh. *Div of Nephrology, Dept of Internal Medicine, Seoul National Univ Hospital, Seoul, Republic of Korea.*

Background: Hypercalciuria is one of the early manifestations of diabetic nephropathy (DN). We surveyed the role of α-Klotho, a protein expressed predominantly in the distal tubules (DTs). α-Klotho is known to up-regulate transient receptor potential vanilloid type 5 (TRPV5) expression, involved in tubular calcium reabsorption.

Methods: We used db/db mice, a type II diabetes mellitus (DM) model. We employed puromycin aminonucleoside (PAN)-induced nephrotic mice and db/m mice for control. PAN mice was induced by injecting 150 mg/kg PAN intraperitoneally for every 2 weeks.

Results: Animals were sacrificed at the age of 15th week. At 15th week, db/db mice and PAN mice developed albuminuria (218 ± 33 mg/day and 68 ± 9 mg/day, respectively), while db/m mice were normoalbuminuric (14 ± 3 mg/day). Urinary calcium excretion (UCa/UCr) significantly increased in db/db mice (0.91 ± 0.09 mg/mg Cr), compared to PAN (0.30 ± 0.02 mg/mg Cr) or db/m mice (0.29 ± 0.03 mg/mg Cr). mRNA and protein expression levels of α-Klotho in the distal tubule were markedly ameliorated. Urinary klotho concentration (UKL/UCr) was significantly decreased in db/db mice (1.45 ± 0.02 fM/mg Cr) compared to PAN (10.77 ± 3.01 fM/mg Cr) or db/m mice (6.39 ± 0.40 fM/mg Cr). By immunohistochemistry and immunofluorescence staining, we also confirmed reductions of renal α-Klotho, FGF receptor type 1 (FGFR1) and TRPV5 expressions in db/db mice.

Conclusions: Thus, renal loss of α-Klotho may affect urinary calcium excretion via inhibition of TRPV5 expression in DTs in early diabetic nephropathy.

TH-PO244

NF-κB System Inhibition Attenuates Renal Injury in Diabetic Nephropathy

Orestes Foresto-Neto, Amanda H. Albino, Simone CA Arias, Lisienny CT Rempel, Gizely CS Moreira, Victor F. Avila, Viviane D. Faustino, Camilla Fanelli, Claudia R. Sena, Vivian L. Viana, Denise M. Malheiros, Niels OS Camara, Clarice K. Fujihara, Roberto Zatz. *Univ of Sao Paulo, Brazil.*

Background: The NF-κB system may be involved in the pathogenesis of diabetic nephropathy (DN). We investigated whether NF-κB inhibition with pyrrolidinedithiocarbamate (PDTC) exerts renoprotection in experimental DN.

Methods: Diabetes was induced in 27 adult male Munich-Wistar rats through streptozotocin injection (65 mg/kg, iv) and maintained moderately hyperglycemic with daily insulin. Rats were divided in untreated (**DM**) and PDTC-treated, 60 mg/kg/day vo (**DM+PDTC**). Untreated nondiabetic rats (**C**, n=12) were also followed. Body weight (BW, g), blood glucose (BG, mg/dL), tail-cuff pressure (TCP, mmHg), urinary albumin/creatinine ratio (Ualb/Ucr), kidney/body weight ratio (KW/BW), % glomerular sclerosis (%GS), interstitial and glomerular macrophage infiltration (intMØ and glomMØ, cells/mm^2) and % glomerular zonula occludens (ZO-1, %) were assessed after 12 months of follow-up.

Results:

	C	DM+V	DM+PDTC
BW	408±9	335±5[a]	335±3[a]
BG	98±2	378±24[a]	386±7[a]
TCP	135±3	134±2	131±2
Ualb/Ucr	1.5±0.2	5.1±1.2[a]	1.3±0.3[b]
KW/BW	0.49±0.01	0.72±0.01[a]	0.64±0.02[ab]
%GS	2.6±0.4	7.9±1.9[a]	2.1±0.7[b]
intMØ	57±6	85±8[a]	45±5[b]
glomMØ	16±3	54±15[a]	33±10[b]
ZO-1	77±1	61±2[a]	75±2[b]

Mean±SE. [a]p<0.05 vs C; [b]p<0.05 vs DM+V.

After 12 mo, untreated DM rats exhibited high Ualb/Ucr, renal hypertrophy, high %GS, intMØ and glomMØ, and loss of %ZO-1, without changes in TCP. Treatment with PDTC attenuated renal hypertrophy and prevented the increase in Ualb/Ucr, %GS, intMØ and glomMØ, and the loss of ZO-1, without interfering with BG or TCP.

Conclusions: PDTC exerts a renoprotective effect on the progress of DN in diabetic rats, suggesting the involvement of the NF-κB system in the pathogenesis of the disease and the possibility that this system becomes a therapeutic target. The beneficial effects of PDTC may also be the result of an antioxidant effect of the drug. FAPESP/CNPq.

TH-PO245

Renin Accelerates Progression of HIVAN-Associated Nephropathy (HIVAN) Through Kidney Cell HIV Gene Expression Partab Rai, Rivka Lederman, Shabirul Haque, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY.*

Background: The activation of renin -angiotensin system has been demonstrated to play an important role for the development and the progression of HIVAN. However, the progression of HIVAN attributed predominantly to Ang II generation by kidney cells. Recently, HIV has been demonstrated to stimulate renin generation by kidney cells *in vitro* studies. We hypothesized that HIV-induced kidney cell renin production might also be enhancing kidney cell HIV gene expression, which may accelerate progression of renal lesions, independent of the effects of Ang II.

Methods: Human podocytes (HPs) were trandudced with either empty vector (EV/HP) or HIV (NL4-3, HIV/HP). To increase endogenous renin production, EV/HPs and HIV/HPs were transfected with siRNA vitamin D receptor (siRNA-VDR/HIV/HPs) or scrambled (Scr-siRNA/HIV/HP) siRNA; protein blots were probed for renin and actin. To evaluate the effect of renin *in vivo*, mRNA expressions of HIV genes from renal tissues of HIVAN (Tg26) mice with high endogenous renin (Tg26 mice either with 2, 3 and 4 copies of angiotensinogen [Agt] or lacking VDR) were quantified by qPCR. To down regulate renal tissue renin expression, Tg26 mice were treated with either vehicle or a VDR agonist (VDA) for 2 weeks and then renal tissues were evaluated for HIV gene expression. Additionally, gene expression and progression of renal lesions were compared in Tg26 mice and Tg26 mice lacking renin.

Results: HIV enhanced renin expression in HPs. Silencing of VDR in HIV/HPs further enhanced expression of Nef, Tat, and Vif. On the other hand, treatment of HIV/HPs with VDA downregulated HIV gene expression. Renal tissues of Tg26-Agt-4 displayed 2-4 fold increase in mRNA expression of gp120, Vpr, Tat, Nef and Vpu vs. Tg26-Agt-2. Similarly, Tg26 mice lacking VDR displayed greater HIV gene expression when compared with Tg26 mice with intact VDR. VDA treatment of Tg26 also down regulated renal tissue expressions of renin as well of HIV genes. Tg26 mice lacking renin, displayed attenuated renal tissue HIV gene expression and slowed progression of renal lesions.

Conclusions: Renin enhances progression of HIVAN through HIV gene expression.

TH-PO246

Podocyte and Tubule Injury Have Different Effects on Renal Handling of Apolipoprotein A-I (ApoA-I) and Its Receptors Jianyong Zhong,[1,2] Haichun Yang,[2] Yohei Tsuchida,[1] Taiji Matsusaka,[3] Agnes B. Fogo,[2] Valentina Kon.[1] *[1]Pediatric Nephrology, Vanderbilt; [2]Pathology, Microbiology and Immunology, Vanderbilt Univ, Nashville, TN; [3]Dept of Molecular Life Science, Tokai Univ School, Isehara-shi, Kanagawa, Japan.*

Background: CKD disrupts HDL composition and function. ApoA-I, the major lipoprotein of HDL, modulates many of its beneficial effects. To determine how injury affects renal handling of ApoA-I, we studied tubule- and podocyte-specific injury models.

Methods: Diphtheria toxin transgenic mice (DT) express human DT receptor in proximal tubular epithelial cells and DT injection causes acute tubule necrosis. Folic acid injury induces crystal formation in distal nephron and distal tubule necrosis. Nphs1-hCD25 transgenic mice (NEP25) express human CD25 in podocytes which can be injured by injection of immunotoxin, LMB2.

Results: Compared to baseline (W0), DT increased urinary KIM-1 and doubled ApoA-I at week 2 (W2 18580±1543 *vs.* W0 10319±2641 ng/mg, p<0.05). Folic acid caused greater increase in Ngal than KIM-1, consistent with distal but not proximal injury with no change in urinary apoA-I or albuminuria. Low dose LMB2 induced edema and albuminuria. Urinary apoA-I increased >10-fold at W2 and remained elevated at W6 (>7-fold) although albuminuria normalized. High dose LMB2 reduced GFR, caused glomerulosclerosis, and increased apoA-I excretion 1400-fold.

In DT, proximal tubule expression of cubilin was reduced and ApoA-I localized to the apical side. By contrast, low-dose LMB2 stimulated cubilin expression without changing ApoA-I localization. Neither injury affected abundance or localization of ApoA-I transporters. High dose LMB2 not only increased cubilin expression but translocated ApoA-I to the cytoplasm of tubular cells and to peritubular capillaries. ABCA1, but not G1 or SRBI, translocated from the apical membrane to cytoplasm of parietal and proximal tubule epithelial cells.

Conclusions: Renal handling of ApoA-I is determined by the glomerular filtration barrier and proximal, but not distal, tubules through mechanisms that involve cubilin and ABCA1. Podocyte injury increases ApoA-I in glomerular filtrate and may be a sensitive marker of injury to the glomerular filtration barrier.

Increased Toxicity of APOL1 Kidney Risk Variants Is Not due to Decreased VAMP8 Binding Patrick D. Dummer,[1] Alison Hickman,[1] Jurgen Heymann,[1] Michael Kruhlak,[2] Katalin Susztak,[3] Cheryl Ann Winkler,[2] Jeffrey B. Kopp.[1] *[1]NIDDK, Bethesda, MD; [2]NCI, Bethesda, MD; [3]Univ of Pennsylvania, Philadelphia, PA.*

Background: Developing effective therapies for APOL1 nephropathies will require insights into the mechanisms of APOL1-associated cell damage. Disease-associated G1 and G2 mutations in the C-terminus of APOL1 increase toxicity through lysosomal membrane permeability (LMP). Vesicle-associated membrane protein (VAMP) 8, a lysosomal soluble NSF attachment protein receptor (SNARE), has been proposed to inhibit APOL1 function by binding the C terminus, with the G1 and G2 mutations decreasing affinity compared to the ancestral G0 variant.

Methods: GFP-LC3 (autophagosome marker), GFP-SNAREs (to monitor vesicle trafficking), and His6-, GFP-, and mCherry-tagged APOL1-A isoform were expressed by transient co-transfection of HeLa and HEK293 cells. Autophagy was assessed by microscopy using GFP-LC3. Endoplasmic reticulum (ER) stress was measured by Western blot for BiP and phospho-PERK. Toxicity was measured by SyTox Blue staining.

Results: APOL1-A G1 and G2 variants increased ER stress and autophagy compared to the ancestral G0 variant. All APOL1 variants traffic to Rab7-, LBPA-, and VAMP8-positive late endosomes and lysosomes. Deletion of the APOL1 C terminus abolished APOL1-induced autophagy and toxicity, but not trafficking to lysosomes. APOL1 bound all R-SNAREs, with greatest affinity for lysosomal VAMP7 and VAMP8. There were no differences in affinity to VAMP8 among the APOL1 variants, and truncation of the APOL1 C terminus did not abolish the interaction. Co-expression of VAMP8 increased APOL1 toxicity. A non-toxic APOL1-A protein lacking the N-terminal signal peptide exhibited the greatest affinity to VAMP8.

Conclusions: APOL1 G1 and G2 toxicity may not be due to decreased VAMP8 affinity, as previously proposed. The APOL1 C terminus is required for toxicity but not for lysosomal trafficking, suggesting the increased toxicity of APOL1 risk variants is not due to altered APOL1 trafficking to lysosomes. Cellular stress pathways beyond LMP, such as autophagy and ER stress, may contribute to the increased toxicity of APOL1 risk variants.

TH-PO248

***N*-Acetylmannosamine Mitigates Neuraminidase-Induced Podocyte Injury in Mice** Marjan Huizing,[1] Obiageri Okafor,[1] Patricia M. Zerfas,[2] Steven Bodine,[1] Matthew F. Starost,[2] A. Rosenberg,[3] William A. Gahl,[1] Jeffrey B. Kopp,[3] May christine V. Malicdan.[1] *[1]Medical Genetics Branch, NHGRI, NIH; [2]Office of Research Services, OD, NIH; [3]Kidney Disease Section, NIDDK, NIH, Bethesda, MD.*

Background: Podocyte injury is present in many glomerular diseases. Current therapies do not achieve sustained remissions and often have adverse events. Recent findings suggest that a subset of patients with glomerular disease may have ongoing desialylation or impaired resialylation of certain renal glycans (glycoproteins and glycolipids), as detected by lectin histochemistry.

Methods: We induced podocyte injury in mice by a single intraperitoneal injection of *Vibrio cholera neuraminidase* (NA), an enzyme that removes a2,6 linked sialic acid end-groups from glycans. The sialic acid precursor *N*-acetylmannosamine (ManNAc) was administered in drinking water at a ~1 g/kg/d dose, either prophylactic (starting 10 days prior to NA and continued for 5 days), or therapeutic (starting 12 hours after NA and continued for 4.5 days).

Results: NA-injected wild type mice developed proteinuria and renal insufficiency in a dose-dependent manner. Podocalyxin and other glomerular glycans were hyposialylated. Histopathology showed acute renal injury predominantly in the cortical region, swollen podocytes, and glomerular mesangial cell hyperplasia and hypertrophy. Ultrastructural studies showed podocyte foot process effacement. Importantly, both prophylactic and therapeutic ManNAc treatments increased renal glycan sialylation and markedly reduced urine albumin/creatinine ratio (ACR) and podocyte injury at Day 5 (N=14 per group).

Neuraminidase	Treatment	ACR Day 0.5	ACR Day 5
-	None	41 ± 26	72 ± 36
+	None	1860 ± 840	485 ± 90
+	Prophylactic ManNAc	2087 ± 1840	85 ± 66*
+	Therapeutic ManNAc	3078 ± 2510	150 ± 72*

* P<0.05 compared to NA with no treatment

Conclusions: ManNAc holds promise to mitigate hyposialylation-related disease mechanisms of glomerular diseases; ManNAc has minimal toxicity and is orally administered. ManNAc is currently tested in a Phase 2 clinical trial for the rare hyposialylation disorder GNE myopathy. We plan a Phase 1 clinical trial of ManNAc in patients with glomerular diseases.

A Mismatch Between Glomerular Volume and Podocyte Mass Is Associated with Albuminuria and Accelerated Podocyte Hypertrophic Injury in Leptin-Deficient Zucker Rats Akihiro Fukuda,[1] Yuji Sato,[1] Takashi Iwakiri,[1] Kazuo Kitamura,[1] Roger C. Wiggins,[2] Shouichi Fujimoto.[1] *[1]First Dept of Internal Medicine, Univ of Miyazaki, Miyazaki, Japan; [2]Nephrology Div, Dept of Internal Medicine, Univ of Michigan, Ann Arbor, MI.*

Background: Glomerular hypertrophy is a well-established component of diabetic nephropathy. We previously reported that failure of podocytes to match glomerular tuft enlargement (in response to growth signaling through the mTORC1 pathway) can trigger proteinuria, glomerulosclerosis and progression to end stage renal disease in dominant negative AA-4E-BP1 Tg rat model. We therefore tested the hypothesis that a mismatch between glomerular volume and podocyte mass causes progression of diabetic nephropathy.

Methods: We used the leptin-deficient Zucker Diabetic Fatty (ZDF-fatty) rat model of type 2 diabetes compared with heterozygous ZDF rats as a control. Glomerular volume and podocyte number per tuft, density (podocyte number per glomerular tuft volume), mass (Glepp1 positive volume) and the urine podocin:aquaporin2 mRNA ratio were measured. Rats were evaluated over a 45 week time-course.

Results: ZDF-fatty rats gained weight much faster than control rats over the first 15 weeks, but did not become hypertensive over the study period. ZDF-fatty rats became diabetic with increased blood glucose and glycosuria by 10 weeks. Albuminuria and urine podocin:aquaporin2 mRNA ratio were also significantly increased by 10 weeks. Sequential kidney biopsies at 15, 30, and 45 weeks revealed that by 15 weeks glomerular volume was already significantly increased above control (1.5-fold, P<0.01) and podocyte density was significantly reduced (P<0.01), although podocyte number per tuft was not detectably decreased. By 45 weeks glomerulosclerosis was present and the Glepp1 peroxidase positive podocyte tuft area was significantly reduced in the ZDF-fatty rats but not in controls.

Conclusions: These data indicate that a mismatch between glomerular volume and podocyte mass (reduced podocyte density) is associated with development of albuminuria and accelerated podocyte hypertrophic stress in this model of type 2 diabetes, compatible with data previously reported in Pima Indians.

TH-PO250

An ER Stress-Regulated Transcript Hosting a MicroRNA Megacluster as Therapeutic Target in the Early Stage of Diabetic Nephropathy Mitsuo Kato, Mei Wang, Zhuo Chen, Supriya Deshpande, Kirti Bhatt, Hyung Jung Oh, Linda L. Lanting, Rama Natarajan. *Beckman Research Inst, City of Hope, Duarte, CA.*

Background: microRNAs (miRNAs) and long non-coding RNAs (lncRNAs) have important roles in the pathogenesis of diabetic nephropathy (DN). We observed that the miR-379 megacluster (MGC, ~40 miRNAs) and its host transcript lncRNA (lncMGC) were upregulated in glomeruli of streptozotocin (STZ)-injected diabetic mice through the ER-stress induced transcription factor, CHOP. Targets of the MGC miRNAs had functions related to DN. We hypothesized that lncMGC may be a therapeutic target in early DN to prevent progression.

Methods: The expression of cluster miRNAs, lncMGC, miRNA targets and profibrotic genes, and early features of DN [glomerular hypertrophy, extracellular matrix (ECM) accumulation] were examined in STZ-injected diabetic CHOP knockout (KO) mice, and also in diabetic mice injected with GapmeRs (LNA–modified antisense oligonucleotides) targeting lncMGC. These parameters were also examined in human mesangial cells (HMC) transfected with GapmeR targeting human lncMGC.

Results: Key miR-379 cluster miRNAs, lncMGC and profibrotic genes were decreased, whereas targets of miR-379 cluster miRNAs were increased in glomeruli of diabetic CHOP KO mice compared to wild type. Glomerular hypertrophy and ECM accumulation were ameliorated in diabetic CHOP KO mice. GapmeR targeting lncMGC decreased lncMGC, cluster miRNAs and profibrotic genes, and also attenuated glomerular hypertrophy and ECM accumulation, but reciprocally upregulated targets of the cluster miRNAs in diabetic mice. GapmeR targeting human lncMGC inhibited lncMGC, miR-379 cluster miRNAs and profibrotic genes, but upregulated cluster miRNA targets in HMC.

Conclusions: These results demonstrate that a unique ER stress-regulated lncRNA and component cluster of miRNAs co-ordinately regulate the expression of several genes involved in glomerular hypertrophy and ECM accumulation associated with early DN. Furthermore, a single oligonucleotide targeting the host lncRNA was effective in preventing these early features of DN, highlighting the GapmeR approach for targeting lncRNAs as a novel therapy for DN.

TH-PO251

No Difference in Cytotoxicity of APOL1-G0 or Risk Variants G1 and G2 John F. O'Toole,[1] Sethu M. Madhavan,[1] Martha Konieczkowski,[1] Yaping Gu,[1] Liping Luo,[1] Zhenzhen Wu,[1] William P. Schilling,[2] Leslie A. Bruggeman,[1] John R. Sedor.[1,2] *[1]Medicine, MetroHealth Medical Center, Cleveland, OH; [2]Physiology and Biophysics, Case Western Reserve Univ, Cleveland, OH.*

Background: The genetic evidence linking variation in the APOL1 gene to kidney disease in ancestral African populations is strong; however, the biological mechanisms that underlie the association remain uncertain. Autophagy and cell death has been observed after the expression of APOL1 and variant dependent cell death has been reported with the transient expression of APOL1. Therefore we sought to examine autophagy and cell death for variant dependent effects in stable expression systems.

Methods: Stable tetracycline inducible HEK293 cells were generated for the expression of APOL1-G0 (reference), the -G1, and -G2 risk variants. Murine podocytes were isolated from transgenic animals expressing human APOL1-G0 or APOL1-G2 under the Nephrin promoter and control animals. Autophagy was monitored with biochemical methods and three assays of cell death were used; a fluorescent assay, an MTT assay and a clonogenic assay.

Results: Three stable HEK293 clones of each genotype were assayed for autophagy and cell death after induction of APOL1 with tetracycline. We noted significant variability in the kinetics of APOL1 induction between clones, which was not dependent upon APOL1 genotype. Stable expression of APOL1-G0, -G1, and –G2, all increased autophagic flux to a similar degree. The stable expression of all APOL1 genotypes (G0, G1 and G2) resulted in cell death in all three assays, without variant dependent differences. Inhibitors of autophagy or autosis did not reduce APOL1-G0, -G1, or -G2 induced cell death and none of the APOL1s activated the apoptosis effector caspase 3. The expression of APOL1 in differentiated mouse podocytes did not induce autophagy or cell death.

Conclusions: Stable expression of APOL1 in cell culture leads to cell death and autophagy induction in a variant independent manner, but the regulated expression of APOL1 in differentiated podocytes does not. The absence of variant dependence of autophagy induction or cell death suggest that alternative mechanisms underlie the genetic association of APOL1 with kidney disease.

TH-PO252

NGAL Regulates TH17 Immunity in ANCA Vasculitis Adrian Schreiber,[1] Erik M. Disteldorf,[2] Ulf Panzer,[2] Ralph Kettritz.[1] *[1]Dept of Nephrology and Intensive Care Medicine, CVK Charité, Berlin, Germany; [2]III. Medizinische Klinik, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

Background: ANCA activate neutrophils and thereby participate in necrotizing crescentic glomerulonephritis (NCGN). NGAL is a marker of intrinsic kidney injury and is expressed by neutrophils and renal tubular cells. Whether or not NGAL is merely a diagnostic marker or participates mechanistically in renal damage is not known. We hypothesized that neutrophil NGAL plays a pathogenic role in ANCA NCGN.

Results: Patients with active ANCA disease demonstrated increased NGAL serum levels by western blot analysis (47.3±13.1OD) compared to patients in remission (19.4±8.1) and healthy controls (2.1±0.4). We then assessed ANCA-activated neutrophils as a potential source for upregulated serum NGAL. By ELISA, both PR3-ANCA and MPO-ANCA stimulated NGAL release from human neutrophils (887±72 and 961±70ng/ml), whereas control IgG induced much lower levels (105±21ng/ml). Mice with anti-MPO-induced NCGN demonstrated upregulated NGAL serum levels by ELISA (data not shown).To assess the role of neutrophil NGAL in vivo, we used a murine model of anti-MPO induced NCGN, where MPO-KO mice were immunized with mMPO and subsequently transplanted with either WT- or NGAL-KO bone marrow (BM). NCGN was significantly aggravated in mice that received NGAL-KO BM (34.8±6.1% crescents in NGAL-KO versus 13.4±2.8% in WT mice). With respect to intrinsic neutrophil function, migration, ROS generation, degranulation and apoptosis were similar in NGAL-KO and WT neutrophils. In addition, humoral immunity did not differ. In contrast, FACS demonstrated increased T cell immunity in NGAL-KO mice: CD4 cells were 28.7±6.1% of renal CD45 cells in NGAL-KO versus 13.9±0.6% in WT mice, TH17 cells were 21.7±7.6% of renal CD4 cells versus 5.7±1.0%, whereas TH1 cells did not differ (14.4±3.8% versus 14.9±1.2% CD4 cells). Furthermore, splenocytes from NGAL-KO BM transplanted mice showed increased IL-17 production. When WT and NGAL-KO mice were immunized with mMPO, we observed an increased percentage of TH1 and TH17 cells in the latter.

Conclusions: Our findings indicate that neutrophil NGAL down-regulates inflammation in ANCA-induced NCGN by inhibiting TH17 immunity.

TH-PO253

***Streptococcus mutans* Strains with Collagen-Binding Protein May Cause IgA-Like Glomerulonephritis in Rats** Taro Misaki,[1] Shuhei Naka,[2] Ryota Nomura,[2] Taisuke Isozaki,[1] Kazuhiko Nakano.[2] *[1]Div of Nephrology, Seirei Hamamatsu General Hospital, Hamamatsu, Shizuoka, Japan; [2]Dept of Pediatric Dentistry, Osaka Univ Graduate School of Dentistry, Suita, Osaka, Japan.*

Background: The precise pathological mechanisms of IgA nephropathy (IgAN) remain unclear. It is known that 10-20% of healthy subjects harbor strains of *Streptococcus mutans*,a known pathogen of dental caries, that possess Cnm, a cell surface collagen-binding protein encoded by the *cnm* gene. Furthermore, it is widely accepted that an association between *S. mutans* with Cnm protein and systemic diseases exists. We previously found that the rate of *cnm*-positive *S. mutans* organisms isolated in saliva specimens was significantly higher in an IgAN group as compared to the controls, and reported those findings atASN Kidney Week 2014 and in *Clinical and Experimental Nephrology* in 2014. The aim of this study was to investigate whether nephritis is induced by Cnm-positive *S. mutans* strains inoculated into the oral cavity of a rat model of dental caries.

Methods: Cnm-positive *S. mutans* strains (JD-17R, JD-52R, JD-74R) were isolated from the oral cavities of 3 IgAN patients. Those along with MT8148, a standard oral isolate, were inoculated into the oral cavities of 2-week-old Sprague-Dawley rats fed a 56% sucrose-containing diet and then we confirmed that the strains were harbored in the oral cavity of each rat 1 week later. From 10 weeks of age, findings of severe dental caries were confirmed in all rats. They were euthanized at 24 weeks of age, then kidney tissues were extirpated and stained with PAS, and immunohistochemistry with the IgA antibody was performed for histopathological analysis.

Results: Dental caries in nearly all of the rats were found extending to the pulp space, which contains nerves and blood vessels. In rats harboring Cnm-positive strains in the oral cavity, mesangial cell proliferation was observed and immunochemical staining of the IgA antibody was seen in the para-mesangial area. However, no abnormal findings were observed in extirpated kidney tissues from rats harboring MT8148 in the oral cavity.

Conclusions: Our results indicate that Cnm-positive *S. mutans* strains harbored in the oral cavity may cause IgA-like glomerulonephritis.

TH-PO254

Prevention of Lupus Nephritis in the BXSB-Yaa Mouse by Metabolic Inhibitors Byron P. Croker,[1,2] Derry C. Roopenian,[3] Laurence Morel.[1] *[1]Pathology, Immunology and Laboratory Medicine, Univ of Florida, Gainesville, FL; [2]Pathology and Laboratory Medicine Service, NF/SG VHS, Gainesville, FL; [3]The Jackson Laboratory, Bar Harbor, ME.*

Background: In a heavily Type II gamma interferon activated model of lupus nephritis (LN) we showed metabolic inhibition by chronic oral combination of 2 deoxyglucose (2DG) and metformin (Met) reversed LN. We now show 2DG + Met prevents LN in the heavily Type I alpha interferon driven BXSB-Yaa LN.

Methods: Mice were treated chronically with test medications in drinking water. At sacrifice blood and tissues were taken for analysis and correlation of renal histopathology with a LN classification modeled on the ISN-RPS classification of LN. For clarity of presentation, % animals with global proliferative glomerulonephritis (Pg) will be given for each treatment group in results. Other animals were classified as normal to mesangiopathic LN (data not shown).

Results: 2DG (Pg 0.0%), 2DG + Met (Pg 0.0%) and rapamycin (Pg 0.0%) all showed marked reduction in LN. Dichloroacetic acid (Pg 20.0%) and Met (single agent, Pg 40.0%) showed moderate but significant reduction of LN compared to disease controls (Pg 76.5%). Untreated C57Bl/6 mice were used as a normal (disease free) control (Pg 0.0%). Target organ preservation is supported by in vivo and in vitro determination of immunologic and metabolic parameters.

Conclusions: This study presents a second model of LN that responds favorably to metabolic inhibition and normalization by existing drugs utilized for other clinical indications.

Funding: Private Foundation Support

TH-PO255

Successful Treatment of a Mesangial Proliferative Glomerulonephritis by Foxd1$^+$ Metanephric Mesenchymal Cells Li Zhang,[1] Meiling Jin,[1,2] Qing-gang Li,[1] Guangyan Cai,[1] Xiang-Mei Chen.[1] *[1]Dept of Nephrology, Chinese PLA General Hospital, Chinese PLA Inst of Nephrology, State Key Laboratory of Kidney Diseases, National Clinical Research Center for Kidney Diseases; [2]Medical College, NanKai Univ.*

Background: This study is aiming to observe the effect of Foxd1$^+$ metanephric mesenchymal cells on MsPGN.

Methods: 1.We use Foxd1$^{cre/GFP}$ transgenic mice and Rosa-DTR^{flox} transgenic mice to screen target embryonic kidney cells, and isolate Foxd1$^+$ metanephric mesenchymal cells by adding diphtheria toxin; 2.We detect Foxd1$^+$ cell proliferation, cell surface markers, and osteogenic adipogenic differentiation potential. 3. 24h after establishment of anti-Thy1 mesangial proliferative glomerulonephritis, Foxd1$^+$ cells were injected vie intravenous, and this group was set as group of treatment. We detect renal pathology and renal function at different time points on control, model and treatment group. 4.Mesangial cells were stimulated by PDGF-BB, we detect the influence of Foxd1$^+$ cells on the proliferation and migration of activated mesangial cells.

Results: 1. The results showed that CD90 positive rate was 0.96.05, CD 44 91.11%, CD106 96.69, CD34 0.53, CD34 0.53%, CD45 0.35%. After the induction, we found that Foxd1$^+$ cells had good osteogenic and adipogenic differentiation capacity. 2.After intravenous injection of Foxd1$^+$ cells could improve the pathological changes in the kidney and could reduce urinary protein significantly. 3.CCK-8 results showed that Foxd1$^+$ cells condition medium could antagonize proliferation of mesangial cells actived by PDGF-BB from 48 hours. Transwell migration assay results showed that Foxd1$^+$ cells could significantly inhibit actived mesangial cell migration.

Conclusions: 1.Foxd1$^+$ metanephric mesenchymal cells could be isolated using transgenic mice, and also are proved that they have the characteristics of stem cells. 2.Foxd1$^+$ metanephric mesenchymal cells could improve the renal pathological changes in anti-Thy1 mesangial proliferative glomerulonephritis, and inhibit the activation of mesangial cells.

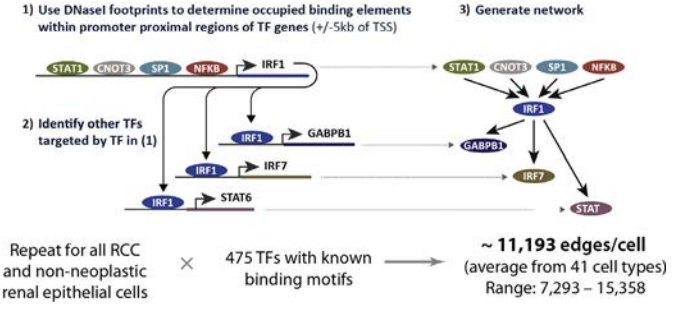
TH-PO256

Beyond HIF1α - Regulatory Genomic Insights into Renal Cell Carcinoma Revealed by DNaseI-seq Shreeram Akilesh. *Pathology, Univ of Washington, Seattle, WA.*

Background: Clear cell renal cell carcinoma (RCC) is the most common sporadic malignancy affecting the kidney. Inactivation of the *VHL* tumor suppressor gene and subsequent stabilization of the HIF1α transcription factor (TF) is very common in RCC. However, it is unclear how HIF1α and the closely related HIF2α (EPAS1) interact with each other and other TFs to produce and maintain the RCC phenotype. Here, we delineate the regulatory genomic landscape of RCC using DNaseI-seq and define the transcriptional regulatory network of RCC.

Methods: Fresh normal human kidney tissue and RCC were disaggregated and cultured to generate primary tubular and renal cell carcinoma cultures. These were subjected to DNaseI-seq and RNASeq according to established protocols. DNaseI hypersensitivity profiling (DNaseI-seq) allows for comprehensive mapping of regulatory DNA at a genomic scale and with single nucleotide resolution. Examination of footprinting depth DNaseI-seq data identifies DNaseI-protected transcription factor (TF) motifs within the promoter of other TFs. Mapping these TF footprints across all TFs with known motifs results in a TF interaction network (*Cell*. 150: 1274-1286).



Results: Even though HIF1α plays an important role in RCC biogenesis, it does not prominently feature in the TF interaction network of RCC. Instead, several other TFs (e.g. FOX, CEBP, SMADs nuclear receptors, etc.) interact to control the regulatory network of RCC with a relatively minor contribution from HIF2α (EPAS1).

Conclusions: While the HIF transcription factors play an important role in RCC oncogenesis, DNaseI-seq reveals that other TFs are responsible for maintaining the RCC phenotype. Systematically testing this regulatory circuitry promises to identify novel pathways to intervene in the growth of this deadly cancer. These techniques/approaches are also being applied to other primary kidney cells such as endothelial cells and podocytes.

TH-PO257

Uneven Reinnervation After Unilateral Renal Denervation: Afferents Dominate Efferents Kristina Rodionova,[1] Franziska Günther,[2] Eric Grouzmann,[5] Michael J.m. Fischer,[2] Sonja Heinlein,[1] Winfried Neuhuber,[3] Christian Ott,[1] Roland E. Schmieder,[1] Kerstin U. Amann,[4] Roland Veelken,[1] Tilmann Ditting.[1] *[1]Nephrology & Hypertension, Friedrich Alexander Univ Erlangen, Erlangen, Bavaria, Germany; [2]Physiolgy 1, Friedrich Alexander Univ Erlangen, Erlangen, Bavaria, Germany; [3]Anatomy 1, Friedrich Alexander Univ Erlangen, Erlangen, Bavaria, Germany; [4]Pathology, Friedrich Alexander Univ Erlangen, Erlangen, Bavaria, Germany; [5]Pharmacologie et Toxicologie, CHUV Lausanne, Lausanne, Switzerland.*

Background: Renal nerve ablation is a beneficial, but controversial treatment for resistant hypertension. We found morphological evidence that intrarenal perivascular afferents reinnervate more thoroughly than efferent sympathetic nerves. We now measured the tissue content of the afferent and efferent neurotransmitters, calcitonine gene relatated peptide (CGRP) and norepinephrine (NE) within 12 weeks after denervation.

Methods: Tissue levels of CGRP and NE from 24 male SD rats (ELISA-test, mass-spectrometry) were measrurd in denervated left (L) and non-denervated right kidneys (R) 1, 4 and 12 weeks after renal denervation±phenol.

Results: CGRP decreased by 72% in denervated (L) kidneys compared to (R) kidneys in week 1 [W1_R: 3.20±0.33 vs. W1_L: 0.97±0.25; p<0.05 (ng/g kidney)]. In week 12 CGRP content in (L) kidneys did not differ from (R) kidneys. We observed a 78% decrease of NA tissue levels [pmol/mg kidney] in week 1 due to surgical denervation [W1_R: 1.09±0.16 vs. W1_L: 0.24±0.06; p<0.05]. In contrast to the CGRP tissue levels there was no complete recovery of NA in week 12. The commonly used addition phenol to the surgical denervation procedure did not influence these results significantly. All data are given as mean±SEM.

Conclusions: We could show that there is a complete reinnervation of CGRP positive perivascular nerves within 12 weeks after renal denervation. However, NA tissue content did not recover completely inspite of complete morphological regrowth of sympathetic nerve fibers. This might potentially result in a net surplus of afferent sympatho-inhibitory influence, adding to the beneficial effect of renal denervation in some cases of resistant hypertension.

Funding: Government Support - Non-U.S.

TH-PO258

An Aristolochic Acid-Induced Nephropathy (AAN) Model for Stable CKD in Mice Hiroshi Kojima, Xuzhen Hu, Yuning George Huang, Ana C. Souza, Jonathan Street, Peter S.T. Yuen, Robert A. Star. *Renal Diagnostics and Therapeutics Unit, NIDDK, NIH, Bethesda, MD.*

Background: ACEi/ARB are standard therapy for progressive CKD but do not slow progression in ~50% of patients. To obtain novel therapies of CKD in humans, better preclinical models are needed. A few mouse models for CKD have been developed, each with strengths and weaknesses. In humans, Aristolochic Acid (AA) causes Balkan nephropathy, with chronic interstitial fibrosis and slow progression to ESRD. However, published AAN mouse models have poorly characterized CKD outcomes.

Methods: CD-1 or C57BL/6 mice were injected i.p. with AA dissolved in DMSO using two regimens: R1: AA I i.p. (3 mg/kg) every 3 d for 6 wk, then 6 wk of disease development; R2: AA i.p. (2.5 mg/kg) every 7 d for 3 wk, then 1 wk of disease development. Spot urine samples and non-invasive GFR by plasma disappearance of FITC-Sinistrin were obtained weekly: serum and kidney were collected at euthanasia. Using aged animals, or addition of salt-loading, uninephrectomy (UNx), or an adenine-rich diet were tested to increase the severity of the model.

Results: CD-1 mice (R1) had severe body weight (BW) loss at 3 wk and was discontinued. Both CD-1 and C57BL/6 (R2) showed moderate loss of BW. All R2 mice survived. Both CD-1 and C56BL/7 mice had elevated BUN, and developed severe tubulointerstitial injury. CD-1 mice showed higher injury score and fibrosis (%) than C57BL/6 mice. There was no elevation of blood pressure in CD-1 (R2). Neither regimen nor strain developed progressive CKD model as urinary albumin transiently peaked then fell, and GFR dropped by 60%, but plateaued within two weeks. Aging, salt-loading, UNx, or an adenine-rich diet did not increase injury or lead to progressive CKD.

Conclusions: AA caused a strain- and regimen-dependent severity of tubulointerstitial injury, with moderate but stable decreases in kidney function (~ human CKD stage 3). AAN may still be a foundation of a progressive CKD model, but additional renal insults might be needed to achieve a progressive CKD model.

The Polymeric Immunoglobulin Receptor Is Expressed in Scattered Cells of Human Kidney and Increase in Expression following Kidney Injury Krzysztof Krawczyk,[1] Helén Nilsson,[1] Jenny C. Nystrom,[2] Martin E. Johansson.[1] *[1]Dept of Translational Medicine, Lund Univ, Malmö, Sweden; [2]Dept of Physiology, Inst of Neuroscience and Physiology, Univ of Gothenburg, Gothenburg, Sweden.*

Background: We have previously shown that the proximal tubules of human kidney contain a scattered cell (SC) population of importance for kidney regeneration, where the markers for SC are identical to those of the pariethal epithelium of Bowmans' capsule. Using gene expression analysis of the SC we found that these may express the Polymeric immunoglobulin receptor (PIGR), a transporter classically attributed to export of secretory IgA and IgM to the mucosal side of the respiratory and gastrointestinal tracts.

Methods: Biopsy material was procured from normal and diseased kidneys. Nephrotic and nephritic diseases were included along with cases of diabetes nephropathy. Immunofluoresence was used for colocalization of PIGR to the SC and immunohistochemistry was performed to assess the distribution of PIGR in the various disease states. Sandwich ELISA was used to measure secretory IgA levels in urine and blood samples from the same disease categories. Primary culture of renal tubular epithelium on permeable supports was used to establish an in-vitro system for functional studies of IgA transcytosis.

Results: Colocalization studies showed that PIGR indeed localizes to the SC of human kidney. Furthermore, the tubular PIGR expression increases as an early response to both acute and chronic renal injury. ELISA measurements of secretory IgA levels in serum and urine samples from patients suffering from various kidney diseases show and increased urinary content of secretory IgA. In vitro, we show that primary renal epithelial cells perform vectorial transport of secretory IgA towards the apical compartment.

Conclusions: The human kidney uses PIGR to export secretory IgA into the tubular luminal contents, a function similar to the established secretion of dimeric IgA onto the mucosal surfaces of the respiratory and gastrointestinal tracts. The levels of urinary secretory IgA increase prominently in response to renal injury.

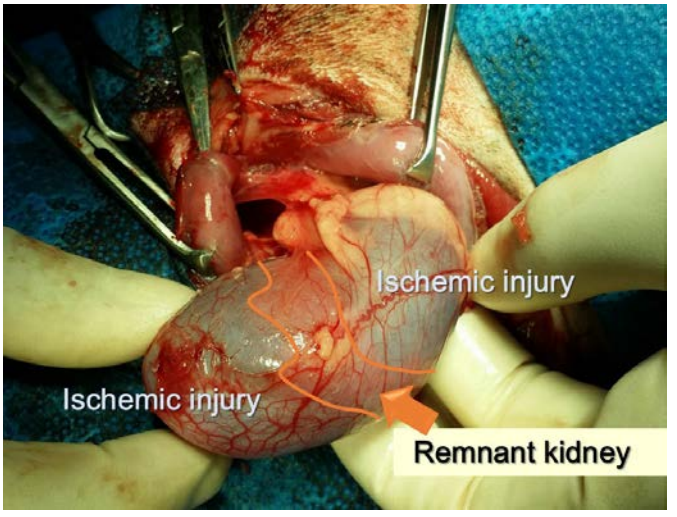
Establishment of Canine Remnant Kidney Model in Beagle Dogs Hajeong Lee,[1] Jun gu Kang,[2] Seung Hee Yang,[2] Dong Ki Kim,[1,2] Kwon Wook Joo,[1,2] Yon Su Kim.[1,2] *[1]Internal Medicine, Seoul National Univ Hospital; [2]Kidney Research Inst, Seoul National Univ College of Medicine.*

Background: The remnant kidney model has been well established in the rodents, whereas it has not been fully understood in higher and bigger animals. Canine remnant kidney model is important for better medical applications. We aimed to establish 1/16 canine remnant kidney model.

Methods: Remnant kidney model was induced in beagle dogs by a two-step subtotal nephrectomy. First, left kidney was exposed by flank incision. Among a total of eight branches of left renal arteries, seven-eighths of left renal arteries were ligated. Ischemia induction was confirmed by visual identification of topical cyanosis.



After 1 week, right kidney was removed and consequently 1/16 remnant kidney model was completed. A total of 20-weeks of subtotal nephrectomy, we sacrificed the animals and their renal histopathologic changes were examined.

Results: During 20 weeks, CKD dogs (n=12) and sham-operated dogs (n=2) were monitored. Blood pressure of CKD dogs had been maintained highly at 2 weeks. In spite of anti-hypertensive medication, 3 CKD dogs died from uremia and hypertension. After surgery, body weights were declined in both CKD and sham-operated dogs in first 2 weeks. Sham-operated dogs had recovered their body weight within 3 weeks, however, CKD dogs had recovered slowly until 3-months after surgery. Blood urea nitrogen, serum creatinine and proteinuria amount were significantly higher than those of sham-operated dogs during overall period. Renal function decline were accentuated during first 3 weeks after subtotal nephrectomy and last 2 weeks before sacrifice. Intra-renal infiltration of inflammatory cells, apoptosis of renal tubular cells, and renal fibrosis were prominent in CKD dog than in sham.

Conclusions: We successfully established 1/16 remnant kidney model by renal artery ligation in beagle dogs.

TH-PO261

Molecular Score of Acute Kidney Injury Identifies Discarded Kidneys That Are Potentially Transplantable Konrad S. Famulski,[1] Silke V. Niederhaus,[2] Jeff Reeve,[1] Jonathan Bromberg,[2] Philip F. Halloran.[1] *[1]Univ of Alberta, Edmonton, AB, Canada; [2]Univ of Marlyland, Baltimore, MD.*

Background: Many kidneys from older deceased donors are discarded due to uncertainty based on conventional features (clinical or histology). We previously showed that the molecular AKI score in implantation biopsies (Bx) predicts future graft function better than histology. Now we hypothesize that AKI scores in kidneys accepted for transplantation will be similar to some discarded kidneys when decision to transplant is based on conventional features.

Methods: Pre-implantation Bx from accepted and discarded kidneys were obtained from brain dead >50 years donors. Decision to discard was based on MAPI scores of wedge Bx in 20/28 discards. Molecular AKI scores and global gene expression were analyzed by microarrays.

Results: The molecular AKI scores in all kidneys were compared by principal component analysis (PCA).

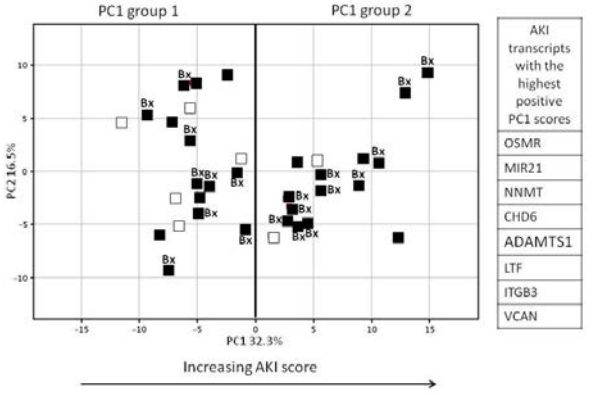


Figure 1. PCA analysis of pre-implantation biopsies from transplanted and discarded kidneys based on the molecular AKI score. □Accepted kidneys, ■Discarded kidneys, Bx – decision to discard was based on the biopsy findings.

PCA defined two sets of kidneys. Group 1 had low AKI scores and included 14 discarded kidneys and 5 accepted kidneys. Thus many discarded kidneys had low AKI scores similarly to accepted kidneys and were potentially transplantable. Group 2 contained 14 discarded kidneys and 2 transplanted kidney, all with high AKI scores. 1852 transcripts associated with PC1 of the AKI scores. Pathway analysis demonstrated that Group 2 kidneys had decreased expression of genes related to oxidative phosphorylation suggestive of activation of MTORC2 pathway, and had increased expression of genes related to antigen presentation driven by IFNG and to response to wounding. Thus Group 2 kidneys with high AKI scores were more stressed than other potentially acceptable kidneys.

Conclusions: Addition of molecular features to the evaluation of biopsies may lead to improved kidney utilization from older donors and offers mechanistic insights into why such kidneys have impaired performance.

TH-PO262

Characterization of Injury in Renal Proximal Tubules During Cold Incubation and Rewarming

Anja H. Bienholz,[1] Gesine Pless-Petig,[2] Andreas Kribben,[1] Ursula Rauen.[2] *[1]Nephrology, Univ Duisburg-Essen, Essen, Germany; [2]Physiological Chemistry, Univ Duisburg-Essen, Essen, Germany.*

Background: Cold incubation and rewarming induce an essential component of preservation injury which is iron-dependent in many cell types. In rat hepatocytes a chloride-dependent component of injury has been described, while chloride-poor solutions accentuated damage in endothelial cells. This work examines the injury induced by cold incubation and rewarming in isolated renal proximal tubules.

Methods: Rat renal proximal tubules were isolated by collagenase digestion and Percoll gradient centrifugation. The vascular storage solution TiProtect® and a chloride-poor modification +/- iron chelators (IC; deferoxamine 0.5mM, LK614 20μM) were used for cold incubation. Incubation of 5ml tubular suspension respectively was performed in closed flasks at 4°C, followed by rewarming in an extracellular buffer (3h at 37°C). LDH release, ATP content and resazurin reduction were measured as indicators of cellular integrity, energy content and metabolic activity.

Results: No differences in LDH release were detected after 24h of cold incubation. After rewarming LDH release was less in solutions with IC (23+6% vs 39+10%; $p<0.05$ chloride-rich and 25+6% vs 50+7%; $p<0.001$ chloride-poor; n=3). After 48, 120 and 168h of cold incubation LDH release was less in solutions with IC. Without IC LDH release showed a tendency to be higher in chloride-poor solutions (53+4% vs 30+7% after 48h of cold incubation; $p<0.001$; n=8). Following rewarming metabolic activity was tendentially better conserved in tubules stored with IC (109+35% vs 47+17%; ns; n=4, chloride-rich). After 48h of cold incubation ATP content was better conserved in chloride-rich than in chloride-poor solutions (51+20% (chlorid-rich, without IC) and 67+12% (with IC) vs 18+6% (chloride-poor, without IC) and 27+6% (with IC); p min. <0.05; n=8). These results were confirmed after 120h of cold incubation.

Conclusions: The results confirm an iron-dependent component of injury in proximal tubules during prolonged cold incubation and rewarming. This data for the first time shows a benefit of chloride-rich solutions for preservation of energy content in renal proximal tubules during cold incubation.

Apoptosis During Extreme Cold Ischemia and Rewarming Involves a Caspase Independent Pathway

Swati Jain, Charles L. Edelstein, Alkesh Jani. *Renal, Univ of Colorado, Aurora, CO.*

Background: Cold ischemia (CS) followed by warm reperfusion (REW) during hibernation is a natural model we have used to understand Delayed graft function (DGF). We have shown that hibernating ground squirrel kidneys and tubular cells (RTEC) survive CS for *several days* in torpor followed by REW in Arousal without RTEC apoptosis. In contrast mouse & human kidneys demonstrate significant tubular apoptosis after CS/REW. We have previously shown that apoptosis during CS/REW in mouse RTECs is mediated in part by a caspase dependent pathway. Here we explore whether a caspase independent pathway of apoptosis is activated during CS/REW. We hypothesized that increased mitochondrial injury during CS/REW in mouse RTECs would result in release of mitochondrial AIF, thus activating caspase independent apoptosis. Furthermore, we hypothesized that squirrel RTECs would be protected from apoptosis and not release AIF during CS/REW.

Methods: Squirrel and mouse RTECs were subjected to cold storage (CS) in UW solution followed by rewarming (REW) in normal media as previously described (Jain, S. Transpl Int, 2015). Apoptosis was quantified by TUNEL assay. AIF was examined in mitochondrial and cytosolic fractions.

Results: Mouse RTECs exposed to CS/REW had significantly increased apoptosis vs. squirrel RTECs. Furthermore, mouse RTECs subjected to CS/REW had significantly increased mitochondrial AIF translocation to the cytosolic fraction vs. squirrel RTECs.

	Squirrel RTECs		Mouse RTECs	
	Cont	CS/REW	Cont	CS/REW
TUNEL +ve cells	0.25±0.2	2.0±0.4	2.7±0.4	26±2.2*
AIF	-	-	-	++++

n = 3; * $p<0.05$ vs squirrel RTECs

Conclusions: The data provide evidence of mitochondrial disruption in mouse RTECs during CS/REW, resulting in caspase independent apoptosis mediated by AIF. One potential reason for the remarkable ability of hibernators to survive prolonged CS/REW far in excess tolerable by nonhibernators is mitochondrial preservation that prevents release of AIF. Understanding caspase independent pathways during CS/REW may lead to improved organ preservation, and novel therapies for DGF.

TH-PO264

Phenotype of Renal Tubular Cell Death During Delayed Graft Function

Swati Jain, Robert J. Plenter, Danica Galesic Ljubanovic, Chelsea M. Ruller, Trevor L. Nydam, Alkesh Jani. *Renal, Univ of Colorado, Aurora, CO.*

Background: Delayed graft function (DGF) independently predicts reduced 5 yr kidney transplant survival. Treatments of DGF are lacking. Cold ischemia (CI) is a significant risk factor for DGF but the mechanism by which CI leads to DGF is unknown. The aim of this study was to determine the effects of CI on donor kidneys alone versus CI followed by warm reperfusion after kidney transplant (CI+Txp). We hypothesized that CI alone would produce a different injury phenotype to CI+Txp.

Methods: Male C57BL6 mice aged 8-12 weeks, were subjected to mouse kidney transplant. Donor kidneys were subjected to 3 hours CI in UW solution, and processed immediately or subjected to syngeneic mouse kidney transplant. Renal function was assessed by serum creatinine (SCr). Renal tubular cell (RTC) apoptosis and necrosis were quantified by an independent nephropathologist. TLR4, RIP3, cleaved BID, Bax, cleaved caspase-8 (CC8) and cleaved caspase-3 (CC3) were examined by immunoblot.

Results: CI+ Txp resulted in a significantly increased SCr (1.9±0.15) vs. transplant without CI (0.3± 0.05). CI alone results in increased RTC apoptosis and CC3 but did not result in necrosis. In contrast, CI +Txp led to; (1) increased CC8, cleaved BID, Bax and CC3, and thus increased RTC apoptosis and also increased programmed necrosis; (2) increased RTC necrosis that was associated with increased RIP3 and TLR4.

	Control	Donor Kidney (CI)	Transplant Kidney (CI+ Txp)
Apoptosis/10hpf	0.6±0.3	10.33±0.8*	13.33±0.3*
ATN Score	0.06±0.03	0.1±0.05	4.83±0.1*
CC3	0.04±0.02	0.37±0.02*	0.21±0.04*†
CC8	ND	ND	0.13±0.06*†
BID	0.1±0.04	0.2± 0.03	0.53±0.01*†
Bax	ND	0.03±0.01	0.33±0.04*†
TLR4	0.5±0.3	ND	0.34±0.01*†
RIP3	ND	ND	0.65±0.2*†

n=3; *$p<0.05$ vs. control, †$p<0.05$ vs. CI; ND=not detected

Conclusions: CI results in RTC apoptosis alone without necrosis. In contrast CI +Txp results in a distinct injury phenotype of RTC apoptosis, and also programmed necrosis that is associated with: (1) increased RIP3 and TLR4; (2) CC8 activation of BID, which may further promote bax activation and thus programmed necrosis. Understanding the phenotype of injury following prolonged CI and kidney transplant may lead to novel therapies for DGF.

Swine Leukocyte Antigens and Orthotopic Kidney Transplantation in Yorkshire Piglets and Yucatan Miniature Swine Todd D. Merchen,[1] Victor Monterroso,[2] Daniel Moralejo,[2] Andrea Saucedo,[2] Daniel Kleven,[3] Chak-Sum Ho,[4] N. Stanley Nahman.[5] *[1]Surgery, Georgia Regents Univ; [2]Laboratory Animal Sciences, Georgia Regents Univ; [3]Pathology, Georgia Regents Univ; [4]Gift of Life Michigan, Ann Arbor, MI; [5]Medicine, Georgia Regents Univ.*

Background: PCR with sequence-specific primers (PCR-SSP) is a rapid and inexpensive approach to low-resolution (Lr) swine leukocyte antigen (SLA) genotyping. PCR-SSP may be used in Yorkshire pigs (Yorks), cheaper than expensive Yucatan miniature swine (YMS), for kidney transplantation (KT). We performed dual exchange allogeneic KT (DEAK) in both Yorks and YMS, and correlated outcome with SLAs.

Methods: Orthotopic DEAK (30 kg sows) was performed in 2 YMS (Pig #9, SLA haplotype Lr-4.5/6.7, blood type A; and Pig #10, SLA Lr-4.5/4.5, A) and 2 Yorks (Pig #7, SLA Lr-6.12/22.15b, non-A; and Pig #8, SLA Lr-4.4/40.12, A). Species couples were operated simultaneously. For YMS Pig #9, the left kidney (LK9) was resected, ex vivo perfused on ice, and stored in an ice bath. LK10 was then removed, perfused and stored while LK9 was transplanted into #10. Then LK10 was transplanted into #9. Both R kidneys were removed. The same procedure was performed in Yorks. No immunosuppression was used; animals were sacrificed (sac) on POD 2-10.

Results: Mean pre-op creatinine (Cr) was 1.05 mg/dl. For YMS, Pig #10 rejected LK9 and died on POD-6 (Cr 19.6). Pig #9 accepted LK10 with Cr 2.4 at sac on POD-9. For Yorks, Pig #7 showed hyperacute rejection (RJX) of LK8 (POD-2, Cr 12.1) and Pig #8 had vascular RJX of LK7 (POD-2, Cr 4.4). All KT organs were well perfused at sac. For YMS, one SLA haplotype mismatch (Lr-6.7) led to RJX of LK9 by Pig #10, whereas complete SLA match in the other direction allowed graft acceptance of LK10 by Pig #9; both animals were blood type A. For Yorks, hyperacute RJX occurred in Pig #7 due to blood type incompatibility. Vascular RJX in Pig #8 resulted from a two class I haplotype-one class II haplotype mismatch.

Conclusions: Orthotopic DEAK and SLA typing with PCR-SSP are equally effective in Yorks and YMS, allowing for predictable patterns of RJX/acceptance. Yorks may offer a reasonable alternative to YMS for the study of experimental KT.

Development of Experimental Model of Renal Thrombotic Microangiopathy in Rat Allogeneic Bone Marrow Transplantation Takafumi Kanemitsu, Go Kanzaki, Yusuke Okabayashi, Michiko Aoki, Kiyotaka Nagahama, Akira Shimizu. *Dept of Analytic Human Pathology, Nippon Medical School, Bunkyo-ku, Tokyo, Japan.*

Background: Renal thrombotic microangiopathy (TMA) after clinical hematopoietic stem cell transplantation (HSCT) is a well-recognized complication that carries a high risk of death. In TMA after HSCT, total body irradiation, use of immunosuppressants for prophylaxis against graft versus host disease (GVHD), viral infection, and GVHD have been proposed as risk factors. However, so far, experimental model of renal TMA after HSCT or bone marrow transplantation (BMT) has not been reported.

Methods: In order to develop the experimental rat model of renal TMA after allogeneic BMT, we performed BMT from Lewis (RT1l) bone marrow cells ($6.0x10^7$ cells) to DA (RT1a) rats after 10G irradiation without immunosuppression. We examined the clinical and pathological characteristics of several organs, including the skin, liver, gut and kidney during 9 months after BMT.

Results: In syngeneic BMT and non-BMT control DA rats, acute or chronic GVHD and renal TMA did not develop by 9 months. In DA rats after Lewis BM cell transplantation without immunosuppression, renal TMA in the kidney developed in 3 out of 6 rats 9 months after BMT with GVHD in the skin, gut, and liver. Renal dysfunction including the increased levels of the serum creatinine (0.33±0.1mg/dL) and urinary protein (0.4±0.1 g/day) developed at 9 months with skin rush, alopecia, decreased body weight, and liver dysfunction (AST: 231 mg/dl; ALT: 112 mg/dl; LDH: 987 mg/dl). Renal pathology showed collapsed and sclerotic glomeruli with endothelial cell injuries in all animals. Renal TMA findings were characterized by the glomeruli with mesangiolysis, duplication of the GBM, and fibrin thrombi formation. Exudative lesions in small arteries were also seen. These renal findings were quite similar findings as renal TMA after HSCT in humans.

Conclusions: In 50% of animals, renal TMA associated with GVHD developed with renal dysfunction after Lewis to DA rat allogeneic BMT. Further studies are needed to assess the mechanism of renal TMA after BMT.

TH-PO268

Beneficial Effect of Exendin-4 on Autophagy Dysfunction During Tacrolimus-Induced Pancreatic Islet Injury Sun Woo Lim, Long Jin, Jian Jin, Chul Woo Yang. *Transplant Research Center & Div of Nephrology, Dept of Internal Medicine, Seoul, St Mary's Hospital, The Catholic Univ of Korea, Seoul, Korea.*

Background: Autophagy is a cellular degradation-recycling system for aggregated proteins and damaged organelles. Previously, we reported that chronic calcineurin inhibitors (CNIs)-induced nephropathy is characterized by excessive autophagosome formation and decreased autophagic degradation rate. We suggested that lysosomal dysfunction may associate in the process of autophagic degradation. In this study, we evaluated the autophagic function in CNI-induced pancreatic beta cell injury, and combined treatment of exendin-4 (Exd), anti-diabetic agent has therapeutic effect by improving CNI-induced lysosomal dysfunction.

Methods: Rats were treated with tacrolimus (TAC, 1.5 mg/kg, s.c.) and Exd, (1 ug/kg, i.p.) for 4 weeks. The effects of Exd on TAC-induced pancreatic beta cell dysfunction were evaluated by IPGTT, serum insulin level, HOMA-IR index, and islet size. Using an INS-1 cells, we examined the effect of Exd on TAC-induced lysosomal dysfunctions such as pH increase, reduced cathepsin B activity and LAMP-2A. Autophagosome formation and autophagic protein aggregates were confirmed by the expression of LC3-II and p62, respectively. Oxidative stress was measured by the concentration of 8-OHdG, MnSOD, catalase, and H_2DCF-DA. The influence on apoptosis was examined by TUNEL assay, Annexin V, and active caspase-3.

Results: Four weeks of TAC treatment increased blood glucose levels and HOMA-IR index, and decreased serum insulin level and islet size. But co treatment with Exd-4 attenuated TAC-induced pancreatic beta cell dysfunction and islet size. Exd treatment improved TAC-induced pH increase, cathepsin B activity, and LAMP-2A expression in INS-1 cells. These were accompanied by restored expression of LC3-II and p62 which is markers for autophagic degradation rate. The markers for oxidative stress and apoptosis were also recovered by cotreatment of Exd.

Conclusions: The results of our in vivo and in vitro studies demonstrate that Exd has an effective antidiabetic agent that exerted antioxidative and antiapoptotic effects via restoring TAC-induced autophagic dysfunction.

Klotho Deficiency Is Associated with Chronic Tacrolimus-Induced Oxidative Injury Sun Woo Lim, Jian Jin, Long Jin, Byung ha Chung, Chul Woo Yang. *Transplant Research Center & Div of Nephrology, Dept of Internal Medicine, Seoul, St Mary's Hospital, The Catholic Univ of Korea, Seoul, Korea.*

Background: We previously demonstrated that experimental animal model of chronic calcineurin inhibitors (CNIs)-induced nephropathy showed down regulated Klotho in renal tissues. We suggested that Klotho deficiency is highly associated with prolonged treatment of CNI-induced oxidative injury and resultant apoptosis and renal dysfunction. To determine whether Klotho deficiency is closely associated with CNI-induced renal injury via oxidative stress, Klotho heterozygote mice were compared with wild type control.

Methods: Mice of wild type (+/+) and Klotho heterozygote (Kl/+) were daily treated TAC (0.25, 0.5 ,1 mg/kg, s.c.) for 4 weeks under the 0.01% sodium diet. The effects of various dose of TAC and Klotho deficiency on renal function, fibrosis, and apoptosis. The expression of Klotho was measured in renal tissue and serum. Oxidative stress was evaluated with measuring 8-OHdG and MnSOD. Using a HK-2 cells, we examined the protective effect of recombinant Klotho under TAC treatment by measuring oxygen consumption rate (OCR), ATP production, amount of ROS, mitochondrial membrane potential (MMP), and apoptosis.

Results: Four weeks of TAC treatment induced renal dyfunction, renal fibrosis, and apoptosis in a dose-dependently in +/+ mice. These changes were aggravated in Kl/+ mice receiving TAC. Reduced Klotho level in urine, serum, and renal tissue was accompanied increased renal injury by TAC treatment. Moreover, 8-OHdG was increased in +/+ mice treated with TAC, and Kl/+ mice showed further increased 8-OHdG. The expression of MnSOD was reversely responded. Based on the in vivo results, in vitro test using HK-2 cells also performed by treatment of recombinant Klotho and/or TAC. Klotho treatment reversed the mitochondrial function such as OCR, ATP production, MMP as well as ROS production and apoptosis.

Conclusions: The results of our in vivo and in vitro studies demonstrate that Klotho has a renoprotective role against TAC-induced renal dysfunction and cellular injury by reducing oxidative stress. These results suggest that Klotho has therapeutic potential in CNI-induced nephrotoxicity.

Discrepant Effect of Metformin on Hyperglycemia in Rats with Tacrolimus- or Sirolimus-Induced Diabetes Mellitus Jian Jin, Long Jin, Ji Hyun Yu, Sun Woo Lim, Byung ha Chung, Chul Woo Yang. *Transplant Research Center & Div of Nephrology, Dept of Internal Medicine, Seoul, St Mary's Hospital, The Catholic Univ of Korea, Seoul, Korea.*

Background: Metformin is the first choice used drug in the treatment of diabetes mellitus. However, the effect of metformin on immunosuppressant-induced hyperglycemia is still controversy. In this study, we aimed to investigate the effects of metformin in tacrolimus-or sirolimus-induced diabetes mellitus.

Methods: Six groups of Sprague-Dawley rats were studied: animals received tacrolimus (1.5 mg/kg) or sirolimus (0.3 mg/kg) and metformin (200 mg/kg) or vehicle for 4 weeks. Body weight, water intake, and urine volume were measured before sacrifice. The effect of metformin on tacrolimus or sirolimus- induced hyperglycemia was evaluated by assessing intraperitoneal glucose tolerance test (IPGTT), islet size, and insulin level. For further analysis, isolated rat islets from normal rats were treated with tacrolimus (30 ng/ml) or sirolimus (90 ng/ml) and metformin (165 ng/ml) for 12hr, then glucose stimulated insulin secretion (GSIS) were performed.

Results: After four weeks, tacrolimus or sirolimus-treated animals showed decreased body weight and increased water intake and urine volume compared with vehicle group. Treatment with tacrolimus or sirolimus caused elevated blood glucose level and reduced serum insulin level. Islet size by measuring insulin-positive area was significantly decreased in tacrolimus or sirolimus-treated group. Combined treatment of metformin did not improved tacrolimus-induced blood glucose level. On the other hand, metformin recovered these value compared with the sirolimus alone. In vitro study of GSIS, combined treatment with metformin and tacrolimus showed a reduction in insulin secretion ability compared with tacrolimus alone. But, sirolimus and metformin-treated group showed higher level of insulin secretion than sirolimus alone.

Conclusions: In this study, we found that metformin confers to the insulin secretion capacity during sirolimus treatment, but not in tacrolimus. Therefore, use of metformin should be considered in transplant recipients receiving tacrolimus.

TH-PO271

Effect of Vitamin D on Th17 Related Immune Responses in Tacrolimus-Based Immune Suppression Byung Ha Chung, Hyunseon Kim, Chul Woo Yang. *Internal Medicine, Seoul St. Mary's Hospital, Seoul, Korea.*

Background: The aim of this study is to investigate the effect of **vitamin D** on Th17 allo-immune responses in tacrolimus (Tac)-based immune suppression.

Methods: First, we investigated the clinical significance of 25-hydroxyvitamin D (25(OH)D) level on the development of acute rejection orserum Th17 associated cytokine levels in kidney transplant recipients (KTRs). Second, we determined the suppressive effect of **1α,25-dihydroxyvitamin D3 (1,25(OH)$_2$D3)**on T cell proliferation upon T-cell specific stimulation or on inflammation of human primary tubular epithelial cells (HPRTEpiC) induced by interleukin-17 (IL-17) or TNF-α. Third, we investigated the pathway of the protective action of 1,25(OH)$_2$D3 on T cell or HPRTEpiC.

Results: In renal transplant recipients under Tac based immunosuppression, 25(OH) D level at KT was significantly associated with the development of acute rejection and the level was inversely correlated with Th17 related cytokines such as IL-17, IL-22, IL-23 and IL-1beta in another KTR patients group. In T cell experiment, Tac suppressed Th1, Th2 and regulatory T cells in a concentration-dependent manner, but did not suppress Th17 cells even at high concentration. In contrast, addition of 1,25(OH)$_2$D3 significantly suppressed Th17 proliferation. Next, IL-17 and TNF-α significantly induced the secretion of IL-6 and IL-8 from HPRTEpiC, however, addition of 1,25(OH)$_2$D3 significantly reduces the secretion of those cytokines.

Conclusions: This study suggests that addition of 1,25(OH)$_2$D3 to Tac is beneficial by suppression of Th17 alloimmune responses and hence it could be proposed as therapeutic strategy to improve allograft outcome.

TH-PO272

Use of D-Lactate for Therapeutic Immunosuppression Ulf H. Beier,[1] Zhonglin Wang,[2] Wayne W. Hancock,[1] Matthew H. Levine.[2] *[1]Children's Hospital of Philadelphia, Philadelphia, PA; [2]Univ of Pennsylvania, Philadelphia, PA.*

Background: Current immunosuppressive therapies are limited by non-specificity and toxicity. Lactic acid is a carboxylic acid present as L- and D- optical isomers. In mammals including humans, lactate is present almost entirely as L-lactate. L-lactate can accumulate in the contexts of ischemia and/or Warburg metabolism, and suppress T cell function.

Methods: We hypothesized that since D-lactate is more slowly eliminated than L-lactate, it may have immune modulatory effects similar to L-lactate that maybe exploited for therapeutic immunosuppression, and tested both optical isomers in vitro and in vivo.

Results: We observed that while both D- and L-lactate (5-40 mM) markedly impaired murine and human CD4 and CD8 T cell proliferation in vitro, D-lactate had stronger effects than L-lactate. Neither D- nor L-lactate affected cell viability and apoptosis (7AAD, annexin V), and IL-2 and IFN-γ cytokine production by CD4 and CD8 T cells were unaffected. However, adding 20 mM D-lactate to CD+CD25-Foxp3- T-effector cells (Teff) under polarizing conditions increased Foxp3+ Treg formation by 46.2 ± 31.5% ($P<0.03$, n=4), whereas the effects of L-lactate were not statistically significant (22.8 ± 22.7%, p=0.09). To test effects of D-lactate in vivo, we adoptively transferred 1×10^6 Teff with or without 1.25×10^5 Tregs into Rag1$^{-/-}$ mice, and treated each group with 90 mmol/kg/d D-lactate or control NaCl for 5 days, and assessed T cell proliferation. D-lactate reduced Teff cell proliferation ($P<0.001$, n=5), and de-novo Foxp3+ Treg formation was increased in D-lactate (21.2 ± 7.4%) vs. NaCl (11.9 ± 3.4%) treated animals ($P<0.01$, n=5).

Conclusions: Together, these results show that sodium D-lactate can impair T cell proliferation and promote Foxp3$^+$ Treg induction. Our data suggest that use of specific, defined metabolites may have important therapeutic value as novel immunosuppressive agents.

Environment and Graft Interaction Impact on Endothelium After Experimental Kidney Transplantation Diana A. Papazova, Nynke R. Oosterhuis, Jaap A. Joles, Marianne C. Verhaar. *Nephrology & Hypertension, Univ Medical Center Utrecht, Netherlands.*

Background: At transplantation (TX) into a CKD recipient, the donor's endothelium is exposed to uremic and oxidative stress that may negatively influence graft function and structure. We hypothesized that in CKD milieu, graft endothelial damage is determined by both donor quality and exposition to uremic and oxidative stress. We also investigated whether healthy environment halts progressive endothelial loss in expanded criteria donor (ECD) graft.

Methods: Male inbred Lewis rats were used as donors and recipients. CKD developed in 24 rats after bilateral ablation of 2/3 of kidney mass. Control rats (n=24) were age-matched. Orthotopic TX was performed: healthy kidney to healthy rat (HD-HR); CKD kidney to healthy rat (CD-HR); healthy kidney to CKD rat (HD-CR); CKD kidney to CKD rat (CD-CR). Right donor kidney served as reference for left kidney (graft) injury at TX. Contralateral kidney of recipient was removed 10-14 days after TX. At wk 6, we evaluated graft function and morphology, and systemic oxidative (TBARS) and vascular damage (aorta calcification).

Results: Graft function (inulin& PAH clearance) at wk 6 after TX confirmed marked impairment after ablation and was not affected by environment (CD-HR vs. CD-CR and HD-CR vs. HD-HR, all NS). TX of healthy vs. CKD graft did not influence oxidative and vascular damage at wk 6 postTX (CD-HR vs. HD-HR and HD-CR vs. CD-CR, both NS). Grafts from healthy donors developed more glomerulosclerosis (GS) and tubulointerstitial injury (TI) and a reduction in glomerular and interstitial endothelium (JG12 stain) compared to reference kidneys after TX in a CKD donor (all $P<0.05$). However, despite similar ischemia-reperfusion, TI and GS did not worsen in ECD grafts and TX of ECD grafts in healthy recipients did preserve glomerular and interstitial endothelium.

Conclusions: TX to CKD environment was less detrimental for ECD graft as shown by preserved endothelium compared to healthy graft, possibly due to preconditioning. In the reverse model, healthy environment halted progression of endothelial damage in ECD grafts. Thus, depending on environment, ECD grafts appear to maintain their structure.

TH-PO274

Heparan Sulfate in the Glycocalyx of Donor Renal Allografts Modulates Transplant Rejection William L. Clapp, Sriram Ambadapadi, Dara N. Wakefield. *Univ of Florida; Univ of Florida; Univ of Florida.*

Background: The molecular mechanisms underlying transplant allograft vasculopathy and chronic rejection are not fully elucidated. Glycosaminoglycans (GAGs) modulate inflammatory cell responses and Heparan sulfate (HS) is the predominant GAG in the endothelial glycocalyx. Binding to GAGs plays an important role in the function of chemokines. The role of donor allograft GAGs in renal transplant rejection is not well defined. In these studies, we investigated the effects of selective HS deficiency and interference with HS-chemokine interaction on renal allograft rejection in the mouse.

Methods: Donor renal allografts from mice with conditional deletion of the N-deacetylase-N-sulfotransferase-1 gene (Ndst1) in endothelial and myeloid/lymphoid precursors leading to HS deficiency were examined. M-T7, a viral-derived secreted glycoprotein was used to block HS-chemokine interaction. Donor renal allografts from C57B1/6 (WT) or Ndst1$^{-/-}$ mice were transplanted into Balb/C mice and then treated with either saline (control) or M-T7.

Results: Compared to the WT, the Ndst1$^{-/-}$ donor renal allografts had significantly reduced scores for lesions induced by rejection including infiltrates, tubulitis, peritubular capillaritis, glomerulitis, vasculitis and mesangial matrix. M-T7 treatment of WT donor renal allografts significantly reduced the histologic markers of rejection. However, the M-T7 mediated decrease in rejection was not observed in the Ndst1$^{-/-}$ donor allografts.

Conclusions: Donor renal allografts, deficient in endothelial glycocalyx HS, reduces renal rejection. Although M-T7 reduces rejection in WT donor renal allografts, M-T7 treatment in Ndst1$^{-/-}$ donor renal allografts is inactive, and negates the reduction of rejection mediated by the Ndst1$^{-/-}$ donors. Donor kidney HS and HS/chemokine interactions may have a major role in reducing allograft rejection.

Identification of Key Meta-Signatures Associated with Acute Rejection Post Kidney Transplant Weijia Zhang,[1] Zhengzi Yi,[1] Karen Lok yee Keung,[1] Li Li,[2] Madhav C. Menon,[1] Barbara T. Murphy.[1] *[1]Renal Div, Medicine, Icahn School of Medicine at Mount Sinai; [2]Dept of Genetics and Genomics, Icahn School of Medicine at Mount Sinai.*

Background: Acute rejection (AR) is a major contributor to chronic allograft dysfunction and graft failure in kidney transplantation. Molecular expression profiling of kidney biopsies has been performed by several independent studies in recent years,but the AR-associated signatures identified from these studies vary.

Methods: Meta-analysis and Bayesian network analysis were performed on 6 kidney biopsy expression datasets to identify key meta-signatures associated with acute rejection and the key drivers were validated in independent expression datasets of kidney transplant and kidney diseases.

Results: Using 733 biopsy samples (239 AR episodes) from 6 expression datasets as discovery cohort, we identified 982 meta genes with differential expression in AR vs noAR patients at FDR<0.05. Gene Ontology enrichment analysis indicated that genes involved in immune response, T/B cell activation and proliferation, antigen processing and presentation,

protein kinase cascade and NFKB signaling pathways were upregulated, while genes involved in metabolism were downregulated.The expression data of metagenes was used to build a meta-coexpression network from which functional submodules were identified. 14 key driver genes were subsequently derived from these network submodules that had differential connectivity in AR compared to noAR patients. The differential modules and key drivers also themselves significantly correlated with HLA antibody and graft survival. Finally, the differential expression of key drivers was validated in independent expression datasets from kidney transplants (N=839) as well as other kidney diseases (IgA and Diabetic nephropathy and Lupusnephritis).

Conclusions: We identified a set of AR-associated key drivers that may play a common and pivotal role for driving the inflammatory responses in acute rejection in kidney transplantation as well as other kidney diseases, which will help the better understanding of molecular mechanism of acute rejection post transplant and therefore improve the early diagnosis/treatment of acute rejection to prevent renal failure.

SNPs of Solute Carrier Family Genes Associated with Acute Renal Allograft Rejection in Korean Population Byeongwoo Kim,[1] Yeong Hoon Kim,[1] Sang ho Lee,[2] Sunwoo Kang.[1] *[1]Dept of Nephrology, Inje Univ, Busan Paik Hospital, Busan, Korea; [2]Dept of Nephrology, College of Medicine, Kyung Hee Univ, Seoul, Korea.*

Background: Solute carrier family has been reported to be associated with various kinds of renal diseases. Thus, we hypothesized that single nucleotide polymorphisms (SNPs) of the solute carrier family genes might have association with acute rejection of kidney transplantation(KT) in Korean population. This study sought to investigate whether polymorphisms of solute carrier family genes are involved in the development of acute renal allograft rejection.

Methods: We firstly selected 349 solute carrier family genes in NCBI gene database and searched the nonsynonymous SNPs on coding region in each genes. Finally we selected 4200 exonic SNPs. The genotypes of these SNPs were performed using AxiomTM genome-wide human assay. SNPStats and SPSS 18.0 were used for the analysis of genetic data. Logistic regression models were performed to determine odds ratio (OR), 95% confidence interval (CI), and P value.

Results: A total of 90 renal allograft recipients transplanted in Pusan Paik hospital. Acute rejection developed in 49 patients among them. Among 4200 SNPs of 349 solute carrier family genes, three SNPs (rs5036 in SLC4A1, rs11643718 in SLC12A3, and rs1047099 in SLCO4A1) only showed significant association with acute rejection ($p<0.05$).

Conclusions: These results suggest that these significant SNPs (rs5036 in SLC4A1, rs11643718 in SLC12A3, and rs1047099 in SLCO4A1) may be associated with the susceptibility to the acute rejection in the KT patients of Korean population.

The Expression and Role of Human Cytomegalovirus-Induced Viral Chemokine Receptor US28 in Smooth Muscle Cells of Renal Allografts Wouter Lollinga,[1] Raymond H. De Wit,[2] Gwenda F. Vasse,[1] Afsar Rahbar,[3] Annelies Riezebos-brilman,[4] Cecilia Söderberg-naucler,[3] Willem Van Son,[1] Johannes S. Sanders,[1] Martine J. Smit,[2] Jacob van den Born.[1] *[1]Nephrology, UMC Groningen, Groningen, Netherlands; [2]Medicinal Chemistry, VU, Amsterdam, Netherlands; [3]Medicine, Karolinska Inst, Stockholm, Sweden; [4]Medical Microbiology, UMC Groningen, Groningen, Netherlands.*

Background: Renal transplantation is the preferred treatment for end-stage renal disease. Human cytomegalovirus (HCMV) infection is associated with decreased renal graft function and survival. HCMV expresses US28, a chemokine receptor that enables HCMV to escape immune surveillance and affect microenvironment in the graft. Our aim was to localize the expression of US28 in renal biopsies and determine its effect on viral dissemination in vitro.

Methods: US28 and immediate early antigen (IEA) expression was semi-quantitatively scored in recipient renal transplant biopsies (n=49) from HCMV-seropositive donors using immunohistochemistry. Expression in glomeruli, endothelium, smooth muscle cells, epithelium and inflammatory infiltrates was analyzed. Primary vascular smooth muscle cells were infected (MOI 0.01) with HCMV WT and US28-deficient HCMV (dUS28) carrying a GFP-tag, to follow viral dissemination in vitro.

Results: IEA was uniformly distributed over the renal compartments. US28 was expressed during active infection and latency. It was expressed in all compartments, but prevalent (Kruskal-Wallis; $P<0.001$) in vascular smooth muscle (42% cells positive) and tubular epithelial cells (30%). It was also expressed in the neointima. Smooth muscle cells were permissive to HCMV and underwent lytic infection in vitro, but dissemination was delayed for US28-deficient HCMV.

Conclusions: In short, HCMV-induced US28 is expressed in smooth muscle cells of renal allografts. US28 expression here suggests a role in vascular disease following viral infection, especially given its presence in the neointima. Absence of US28 decreased HCMV dissemination in smooth muscle cells in vitro, yielding it an interesting target for intervention. The observation that HCMV may interfere with vascular function through the expression of chemokine receptor US28 is an intriguing finding worth further exploring.

Multiple Domains of CTGF Amplify Pericyte Activation to Become Pathological Matrix Producing Cells Shuyu Ren, Bryce Gordon Johnson, Gamze Karaca, Ivan G. Gomez, Jeremy Stuart Duffield. *Research & Development, Biogen, Cambridge, MA.*

Background: Connective tissue growth factor (CTGF), a member of the CCN gene family, is an extracellular matrix (ECM)-associated heparin-binding protein involved in matrix production. CTGF has been shown to contribute to progression of fi bro-proliferative diseases and scarring by modifying of proliferation, migration, and adhesion of fibroblasts. CTGF has also been shown to play a role in ECM remodeling in normal physiological processes including embryogenesis, implantation, and wound healing. However recent new insights into the pathogenesis of fibrosing kidney diseases lead us to re-evaluate CTGF in this context at a cellular level. We therefore generated a mouse model which facilitates tissue specific, conditional over-expression of CTGF using homologous recombination.

Methods: We generated mice conditionally over expressing CTGF in pericytes only. We cloned domains of CTGF and the WNT inhibitor DKK1 and tested their function on primary pericyte cultures.

Results: Overexpression of CTGF in pericytes has no impact on nephrogenesis or adult homeostasis but amplifies fibrogenic and inflammatory responses to kidney disease. CTGF domain IV activates WNT/b-catenin signaling in pericytes, which is inhibited by recombinant DKK-1. CTGF Dom-IV rapidly phosphorylates the co-receptor of WNT/b-catenin signaling - LRP6. DKK-1 blocks CTGF domain IV mediated fibrotic responses in culture including fibrotic gene activation, pericyte morphology changes and migration in JNK MAP kinase dependent, WNT partially dependent pathway. CTGF Dom-I also activates pericyte migration which is also inhibited by DKK-1, JNK inhibition or Wnt ligand secretion.

Conclusions: CTGF over expression restricted to kidney stroma *in vivo* is sufficient to amplify cell activation and myofibroblast transition. Multiple domains of CTGF drive fibrogenic responses in pericytes through WNT and JNK signaling pathways.

Sphingosine Kinase 2 Mediates Kidney Fibrosis Through Epigenetic Change Tsuyoshi Inoue,[1] Amandeep Bajwa,[1] Heather M. Perry,[1] Liping Huang,[1] Hong Ye,[1] Youichiro Wada,[2] Diane L. Rosin,[1] Mark D. Okusa.[1] *[1]Univ of Virginia; [2]The Univ of Tokyo.*

Background: In numerous forms of organ injury, interstitial fibrosis is a final common pathway. Despite recent epidemiological studies, therapies to focus on fibrosis and to delay progressive renal failure are limited. We recently found that sphingosine kinase 2 deficient-mice (SphK2KO) develop less fibrosis after folic acid (FA)- or ischemia-reperfusion-induced kidney injury. Sphingosine 1-phosphate (S1P) is produced by two sphingosine kinase isoforms (SphK1 and SphK2). S1P is involved in diverse functions, but the role of S1P produced by SphK2 is gathering attention as treatments focused on epigenetics have been developed. SphK2 is primarily located in the nucleus, SphK1 is cytoplasmic. S1P produced by SphK2 inhibits histone deacetylase (HDAC) and change in histone acetylation status, which can lead to an altered target gene expression. The aim of this study is to elucidate new mechanisms of kidney fibrosis through epigenetic changes.

Methods: Transcriptome analysis and ChIP-seq of H3K9ac and H3K27ac using primary renal fibroblasts from WT, Sphk1KO and Sphk2KO mice were applied to find new target genes that regulate fibrosis through histone acetylation.

Results: Microarray analysis identified 135 down-regulated (<1/4) genes and 245 up-regulated (>4) genes in Sphk2 KO compared to Sphk1KO mice. ChIP-seq (QuEST) revealed that 258 genes have H3K27ac and 589 genes have H3K9ac only in SphK1KO and not in SphK2KO. The combination of microarray and ChIP-seq analysis yielded 21 candidate genes. To determine the in vivo relevance of gene expression was evaluated using an in vivo fibrosis model (FA model and unilateral IRI). We further applied SphK2 knock down to WT fibroblasts and overexpression to fibroblasts from SphK2KO to determine if the selected genes are regulated by SphK2. Based on these strategies, candidate genes were identified that are regulated by SphK2 through the change of histone acetylation.

Conclusions: The combination of microarray and ChIP-seq of H3K9ac and H3K27ac identified 21 candidate genes. A more detailed investigation is needed, but some genes regulated by SphK2 appear to modulate kidney fibrosis through epigenetic changes.

TH-PO280

MCP-1 Directly Induces Renal Tubulointerstitial Fibrosis Independently of Monocytes/Macrophages Infiltration Meiyan Wu, Hye-Young Kang, Mi Jung Lee, Shin-Wook Kang. *Severance Biomedical Science Inst, Brain Korea 21 PLUS, Yonsei Univ College of Medicine, Seoul, Korea.*

Background: Previous studies have demonstrated the importance of monocyte chemoattractant protein-1 (MCP-1) and its receptor, C-C chemokine receptor 2 (CCR2), in the pathogenesis of tubulointerstitial fibrosis via the recruitment and activation of monocytes/macrophages. However, recent in vitro evidence has suggested that MCP-1 per se may act directly on renal cells via CCR2. Therefore, the results of a number of former studies showing the impacts of MCP-1/CCR2 blockade on renal injury may be partly attributed to a direct inhibitory effect of MCP-1 on renal cells, but this has not been clarified in vivo to date.

Methods: Monocyte/macrophage-deficient mice were induced by either liposome-clodronate or diphtheria toxin. These mice were treated with MCP-1-expressing lentivirus (LV) and/or RS102895, a specific inhibitor of CCR2. NRK-52E cells were treated with

recombinant MCP-1 with or without RS102895, or CCR2 siRNA. The mRNA and protein expression of fibronectin and type I collagen in cultured NRK-52E cells and the whole kidney were evaluated by Western blot and real-time PCR.

Results: Fibronectin and type I collagen expressions were increased in NRK-52E cells exposed to MCP-1, which was then significantly abrogated by co-administration with RS102895 or CCR2 siRNA. LV-MCP-1 transfection in mice (n=6) resulted in significant increases in infiltrated macrophages, fibronectin, and type I collagen mRNA and protein expression in the kidney. However, LV-MCP-1 transfection in monocyte/macrophage-deficient mice (n=6) resulted in increases in fibronectin and type I collagen in spite of an absence of increased macrophage infiltration. This up-regulation of fibronectin and type I collagen protein and mRNA expression in monocyte/macrophage-depleted mice were significantly ameliorated by RS102895 treatment (n=8).

Conclusions: The MCP-1/CCR2 system is directly involved in MCP-1-induced renal fibrosis and blockade of the MCP-1/CCR2 system can be a promising approach to treat various kidney diseases such as diabetic nephropathy, of which MCP-1-induced renal fibrosis is involved in the pathogenesis.

TH-PO281

T-Type Calcium Channel Blocker Attenuates Unilateral Ureteral Obstruction-Induced Renal Interstitial Fibrosis via Activation of the Nrf2 Antioxidant Pathway Soojeong Kim, Eun Sil Koh, Cheol Whee Park, Seok Joon Shin, Sungjin Chung. *Internal Medicine of Nephrology, The Catholic Univ of Korea, Seoul, Republic of Korea.*

Background: Besides the effect on high blood pressure, T-type calcium channel blocker has been reported to exert a renoprotective effect in experimental models with renal fibrosis. However, the exact mechanism of T-type calcium channel blocker on tubulointerstitial fibrosis has not been elucidated. In the present study, we investigated whether the renoprotective effect of T-type calcium channel blocker is associated with modulation of the signaling of oxidative stress-induced renal fibrosis.

Methods: Treatment with a nonhypotensive dose of efonidipine, a T-type calcium channel blocker, or nifedipine, an L-type channel blocker, was initiated one day before unilateral ureteral obstruction (UUO) in C57BL6/J mice, and was continued until 3 and 7 days after UUO. Markers of renal fibrosis, inflammation, apoptosis and oxidative stress were evaluated.

Results: In the obstructed kidneys of UUO mice, treatment with efonidipine significantly attenuated interstitial fibrosis, collagen deposition and inflammation increased by UUO creation compared with treatment with nifedipine. Efonidipine significantly increased the expression of antioxidant enzymes such as HO-1, NQO1, catalase and SOD1. Increased apoptotic cell death and decreased Bcl-2 expression in the obstructed kidneys were also significantly ameliorated by treatment with efonidipine. The expression of the histone acyltransferase p300/CBP-associated factor, which is known as a regulator of inflammatory molecules, was significantly inhibited by efonidipine. These beneficial effects of efonipidine were attributed to the increased nuclear expression of Nrf2 on UUO day 3 and the increased expressions of both total and nuclear Nrf2 with elevated Keap1 on UUO day 7, suggesting that efonidipine would promote activation of Nrf2 differently depending time course after UUO. Nifedipine had little effect on antioxidant enzymes, anti-apoptosis and Nrf2 signaling.

Conclusions: These results suggest that T-type calcium channel blocker exerts beneficial effects in renal interstitial fibrosis by activating Nrf2 and subsequent antioxidant enzymes.

TH-PO282

Fimasartan, the Novel Angiotensin Receptor Antagonist, Protects against Renal Inflammation and Fibrosis in Mice with Unilateral Ureteral Obstruction: A Possible Role of Nrf2 Soojeong Kim, Sungjin Chung, Hye Eun Yoon, Ji hee Lim, Bum soon Choi, Cheol Whee Park, Seok Joon Shin. *Internal Medicine of Nephrology, The Catholic Univ of Korea, Seoul, Republic of Korea.*

Background: A newly developed angiotensin II receptor blocker, fimasartan, has effective blood pressure lowering effect via blocking renin-angiotensin system. Renal interstitial fibrosis is a final pathological process in the progression of chronic kidney disease, which is believed to be due to oxidative injury. Transcription factor nuclear factor-erythroid 2-related factor 2 (Nrf2) is known to regulate cellular oxidative stress and induce antioxidant genes. This study investigated the role of Nrf2 in fimasartan-mediated antioxidant effects in mice with renal fibrosis induced by unilateral ureteral obstruction (UUO).

Methods: Fimasartan was administered intraperitoneally (3mg/kg/day) from the day of UUO surgery in C57BL/6 mice and was continued for 7 days after operation.

Results: UUO-operated mice revealed renal inflammation and fibrosis as evidenced by the degree of fibrosis and inflammatory cell infiltration in histopathological findings, total collagen content in kidney tissues and the expression of fibrotic markers in immunoblot analysis, which were reversed in the obstructed kidneys of fimasartan-treated mice. Fimasartan treatment upregulated renal expression of Nrf2 and its downstream signaling molecules, such as NQO1, HO-1, Nox 1, 2 and 4, GSTm2 and GSTm3 in both protein and mRNA levels. Furthermore, fimasartan increased the expression of antioxidant enzymes including CuSOD, MnSOD and catalase. Significantly less apoptosis in TUNEL staining, decreased pro-apoptotic protein, along with increased anti-apoptotic protein were observed in fimasartan-treated mice.

Conclusions: In conclusion, these results demonstrate that fimasartan has beneficial effects on renal oxidative stress, inflammation and fibrosis, which may be via upregulating of Nrf2 signaling, subsequently the induction of antioxidant pathways.

TH-PO283

The Na/K-ATPase Signaling and Oxidative Stress Contribute to PNx-Mediated Cardiac and Renal Fibrosis in Mice Muhammad A. Chaudhry,[1] Kyle D. Maxwell,[1] Xiaoliang Wang,[2] Yanling Yan,[1] Preeya Tushar Shah,[1] Zi-jian Xie,[2] Jiang Liu,[1] Joseph I. Shapiro.[1] *[1]Pharmacology, Physiology and Toxicology, Marshall Univ JCE School of Medicine, Huntington, WV; [2]Marshall Inst for Interdisciplinary Research, MIIR at Marshall Univ, Huntington, WV.*

Background: We have shown that the Na/K-ATPase signaling regulates cardiac and renal fibrosis both *in vivo* and *in vitro*. We have also demonstrated that increases in oxidative stress activate Na/K-ATPase signaling. Here we report that administration of CoPP (an inducer of heme oxygenase-1, HO-1) and pNaKtide (a Na/K-ATPase signaling antagonist) attenuate 5/6 renal partial nephrectomy (PNx) mediated fibrosis in heart and kidney in C57BL/6 mice.

Methods: The C57BL/6 mice were randomly divided into six experimental groups. (1) Sham surgery (Sham), (2) PNx surgery (PNx), (3) Sham+CoPP, (4) PNx+CoPP, (5) Sham + pNaKtide, and (6) PNx+pNaKtide. CoPP (5mg/KG BW, ip) was given 5 day and one day before surgery as well as every 5 day after PNx surgery. pNaKtide (25mg/KG BW, ip) was given weekly 7days after surgery. All experimental mice were sacrificed 4 weeks after PNx surgery. Expression of collagen-1, HO-1, and protein carbonylation of heart and kidney was determined by western blot.

Results: Comparing with sham, PNx surgery significantly stimulates type 1 collagen expression both in heart and kidney assayed by western blot and histology analyses. Induction of HO-1 by CoPP significantly attenuates PNx-mediated collagen production and protein carbonylation. Administration of pNaKtide, which blocks Na/K-ATPase-mediated c-Src activation, also attenuates PNx-mediated collagen production. Transthoracic Echocardiography analysis demonstrates that treatment with CoPP and pNaKtide restores PNx-induced changes in relatively wall thickness (RWT) and myocardial performance index (MPI).

Conclusions: Attenuating oxidative stress and blocking Na/K-ATPase signaling is capable of restoring PNx-mediated cardiac and renal fibrosis as well as cardiac function.

TH-PO284

Wnt4 Induces Renal Fibrosis by Activating p38 Mitogen-Activated Protein Kinase Pathway Jae Eun Um, Seonghun Kim, Bo Young Nam, Hye-Young Kang, Meiyan Wu, Jimin Park, Tae-Hyun Yoo, Shin-Wook Kang. *Severance Biomedical Science Inst, Brain Korea 21 PLUS, Yonsei Univ College of Medicine, Seoul, Korea.*

Background: Previous studies demonstrated that Wnt signaling pathway plays a key role in the pathogenesis of renal fibrosis and is related to various kidney diseases. However, although Wnt4 is abundantly expressed in renal tubule cells, the roles of these specific Wnt subfamilies in the pathogenesis of renal fibrosis have not been fully explored. Therefore, the effect of Wnt4 on renal tubulointerstitial fibrosis via p38 mitogen-activated protein kinase (MAPK) pathway was examined in unilateral ureteral obstruction (UUO) animals and tumor growth factor-b1 (TGF-b1)-stimulated renal tubular cells.

Methods: In vivo, UUO was performed in C57BL/6 mice (n=12). The kidneys were harvested after 6 days of UUO. Immunohistochemistry was conducted with renal tissues. In vitro, renal proximal tubular cells (NRK-52E) and inner medullary collecting duct cells (IMCD) were each treated with recombinant TGF-b1 with or without Wnt4 siRNA transfection. The effect of recombinant Wnt4 protein treatment was also examined in NRK-52E and IMCD cells. Real-time PCR and Western blot analysis were performed to evaluate Wnt4, fibronectin (FN), collagen type 1 (Col I), α-SMA, phospo-p38 and p38.

Results: Immunohistochemistry revealed a significant up-regulation in kidney Wnt4 expression in UUO mice compared to control mice. The mRNA and protein expression of Wnt4 were significantly higher in recombinant TGF-b1-stimulated NRK-52E and IMCD cells compared to control cells. Protein expression of fibrosis-related proteins such as FN, Col I and α-SMA as well as phospho-p38 MAPK were significantly increased in cells treated with recombinant TGF-b1. Increased fibrosis-related proteins and phosphorylation of p38 MAPK were significantly ameliorated by Wnt4 siRNA transfection in TGF-b1 treated cells. Furthermore, recombinant Wnt4 treatment also led to increase in protein expression of fibrosis-related proteins and phospho-p38 in NRK-52E and IMCD cells.

Conclusions: These findings suggest that Wnt4 may play a role in renal tubulointerstitial fibrosis by activating the p38 MAPK pathway.

TH-PO285

Peroxiredoxin 5 Protects TGF-β Induced Renal Fibrosis by Modulating Stat3 Activation Hoon In Choi,[1] Jung Sun Park,[1] Seong Kwon Ma,[2] Eun Hui Bae,[2] Jong un Lee,[1] Soo Wan Kim.[2] *[1]Dept of Physiology, Chonnam National Univ Medical School, Gwangju, Korea; [2]Dept of Internal Medicine, Chonnam National Univ Medical School, Gwangju, Korea.*

Background: Renal fibrosis is common final pathway of end-stage kidney diseases which is induced by aberrant accumulation of myofibroblasts. This process is triggered by reactive oxygen species (ROS) and proinflammatory cytokines generated by various source of injured kidney cells. Peroxiredoxin 5 (Prdx5) is a thiol-dependent peroxidase that reduces oxidative stress by catalyzing intramolecular disulfide bonds. Along with its antioxidant effects, expression level of Prdx5 also was involved in inflammatory regulation by immune stimuli. However, the physiological effects of Prdx5 in renal fibrosis have not been fully characterized and the underlying mechanisms remain poorly understood.

Methods: As *in vivo* and *in vitro* model of renal fibrosis, Sprague-Dawley rats were subjected to unilateral ureteral obstruction (UUO) for 1 or 7 days. Fibroblast-like rat proximal tubule cells (NRK49F) were treated with transforming growth factor β (TGF-β) for 0, 1, 3, or 5 days. To access the involvement of its peroxidase activity in TGF-β induced renal fibrosis, wild type Prdx5 (WT) and double mutant Prdx5 (DM), converted two active site cysteines at Cys 48 and Cys 152 residue to serine, were transiently expressed in NRK49F cells.

Results: The protein expression of Prdx5 was reduced in UUO kidneys. Upregulation of fibrotic markers, such as fibronectin, vimentin, and alpha-smooth muscle actin (α-SMA), were declined at 5 days in time point of higher Prdx5 expression in TGF-β treated NRK49F cells. The overexpression of wild type Prdx5 by transient transfection in NRK49F cells attenuated the TGF-β induced upregulation of fibronectin and α-SMA. On the other hand, the transient transfection of double mutant Prdx5 did not prevent the activation of fibrotic markers. Overexpression of Prdx5 also suppressed the TGF-β induced upregulation of Stat3 phosphorylation, while phosphorylation of Smad2/3 was unchanged.

Conclusions: Prdx5 protects TGF-β induced renal fibrosis in NRK49F cells by modulating Stat3 activation in a peroxidase activity dependent manner.

TH-PO286

Fucoidanreduces Pressure-Induced Fibrotic Responses in Renal Tubular Cells Through Down-Regulating β-Catenin Tso Hsiao Chen, Cheng-hsien Chen. *Div of Nephrology, Wan Fang Hospital, Taipei Medical Univ, Taipei, Taiwan.*

Background: Fucoidan is a kind of natural fucose-enriched sulfated polysaccharides found mainly in various species of brown algae and brown seaweed. In recent years, many studies show fucoidan reduces hypoxia nephropathy, and also inhibits liver fibrosis. However, the influence of fucoidan on renal fibrosis is not clear yet.

Methods: Rat renal tubular cells (NRK-52E) are applied in this study. We study the influence of low-molecular-weight fucoidan (500 Da) on renal fibrosis in a pressure-stressed cell model. Sixty mmHg of pressure will be applied on NRK-52E cells for different periods to induce EMT. The expression of EMT markers and β-catenin will be monitored by Western blotting.

Results: NRK-52E cells were subjected to 60 mmHg of pressure for the indicated periods. Cellular E-cadherin, TGF-β, CTGF, fibronectin, α-SMA and Snail were detected by Western blotting. We found sixty mmHg of pressure induces EMT markers expression in NRK-52E cells. Fucoidan (0.1 – 1 mg/ml) reduced pressure-induced α-SMA and fibronectin in NRK-52E cells. Fucoidan reduced pressure-induced CD44 and β-catenin, which may be a critical mechanism of anti-fibrosis effect of fucoidan. NRK-52E cells were pretreated with fucoidan for 30 min and then treated with TGF-β for 24 h. We found fucoidan could reduced TGFβ-induced α-SMA and fibronectin in NRK-52E cells.

Conclusions: In summary, fucoidan at adequate doses inhibits pressure-induced fibrotic responses in rat renal tubular cells. The investigation of the protective effect of fucoidan against renal fibrosis may provide a new therapeutic agent for CKD patients.

Indoxyl Sulfate Exacerbates Oxidative Stress and Impairs NF-κB/Nrf2 Levels in RAW Macrophages Denise Mafra,[1] Milena Barcza Stockler-Pinto,[1] Juliana Saldanha,[2] Christophe O. Soulage,[3] Denis Fouque.[4] *[1]Post-Graduate Program in Cardiovascular Sciences, Fluminense Federal Univ (UFF), Niterói, Rio de Janeiro, Brazil; [2]Post-Graduate Program in Medical Sciences, Fluminense Federal Univ (UFF), Niterói, Rio de Janeiro, Brazil; [3]INSA de Lyon, CarMeN, INSERM U1060, Univ de Lyon, Villeurbanne, France; [4]Dept of Nephrology, Centre Hopitalier Lyon Sud, INSERM 1060, CENS, Univ de Lyon, Pierre Bénite, France.*

Background: Indoxyl sulfate (IS), a uremic toxin produced by intestinal bacterias, is accumulated in Chronic Kidney Disease (CKD) patients and exhibits potent inflammatory effects. However, no informed scientific evidence has evaluated the effects of this toxin on nuclear E2-related factor 2 (Nrf2) and nuclear factor-kB (NFkB) expression, which regulate the expression of many detoxifying enzymes and the transcription of pro-inflammatory cytokines genes, respectively, in CKD. Thus the aim of the study was to evaluate the influence of IS in Nrf2, NF-κB and malondialdehyde (MDA) levels in RAW macrophage cells.

Methods: Mouse RAW 264.7 macrophage cells were incubated overnight with IS (250, 500, 1000 or 4000mM) according to the recommendations of the European Uremic Toxin Work Group. Nucleus and cytoplasm were separated using a specific Kit. Quantitative Real-Time PCR analysis and Western Blotting were performed to evaluate the Nrf2 and NF-κB levels. MDA levels were measured by High Performance Liquid Chromatographywith visible detection.

Results: In macrophages culture Nrf2 nuclear translocation and NF-κB protein were not activated by IS, however, NF-κB mRNA expression was stimulated by IS at the concentration of 1000 mM, 4 fold higher than detected in CKD patients i.e.

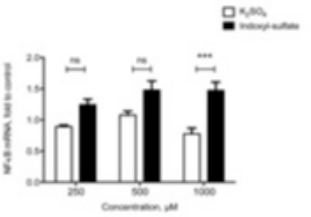

Figure 1. IS up-regulates NF-κB mRNA expression in RAW macrophages

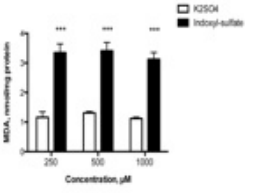

Figure 2. IS exacerbates lipid peroxidation in RAW macrophage

MDA levels were increased by IS in the cells (Figure 2).

Conclusions: IS exacerbates oxidative stress and could activate NF-κB mRNA expression especially for the highest concentrations in RAW macrophages culture.

Association of Intraglomerular Cytokine Environment with Distinctive Infiltrating Myeloid Cell Populations in Lupus Nephritis Sun-sang J. Sung,[1,4] Yan Ge,[1] Chao Dai,[1,4] Hongyang Wang,[1,4] Shu Man Fu,[1] Thu H. Le,[1,4] Jing Yu,[2,4] Rahul Sharma,[1,4] Mark D. Okusa,[1,4] Kline Bolton,[1,4] Young Hahn,[3] Jessica R. Lawler.[1,4] *[1]Medicine, U. of Virginia, Charlottesville, VA; [2]Cell Biology, U. of Virginia, Charlottesville, VA; [3]Microbiology, U. of Virginia, Charlottesville, VA; [4]Center for Immunity, Inflammation, and Regenerative Medicine, U. of Virginia, Charlottesville, VA.*

Background: Glomerular infiltrating myeloid cells are important in mediating intraglomerular tissue damage, cellular dysfunction, and functional obliteration in lupus nephritis.

Methods: A spontaneous chronic lupus model using NZM2328 mice and an anti-GBM-induced GN model were used to assess glomerular cytokine environment and myeloid cell infiltration in SLE by confocal microscopy. Glomeruli were isolated by magnetic bead trapping and single cell suspensions were analyzed by flow cytometry.

Results: In NZM2328 mice with severe proteinuria, increased CD11b+ dendritic cells (DC), CD103+ DC, and MHCII+ and MHCII- macrophages were found infiltrating the kidney interstitium. However, glomerular infiltrating cells in these sick mice consisted mostly of MHC-CD11b+ M2-like macrophages but not MHCII+ cells. Microarray analysis of FACS-purified mesangial cells followed by confocal microscopy analysis of cytokine staining showed that mesangial cells mainly produced IL-6, M-CSF, stem cell factor, KC, and MIP2. Immunofluorescence also showed that endothelial cells produced IP-10 whereas podocytes produced IL-1b. These cytokines likely determine the differences in cellular distribution between the interstitium and glomerulus and mediate GN. Anti-GBM-induced GN showed disproportionately high glomerular infiltration of PMN and Ly6C+ macrophages compared to NZM2328 mice with chronic GN, which suggest significant differences in pathogenesis between the 2 SLE models.

Conclusions: The secretion of selected cytokine and chemokines by glomerular parenchymal cells support a pathway for mediating the infiltration of Ly6C+ monocytes and PMN by CXCR2 and CXCR4 chemokines and the development of monocytes into CD11b+MHC-low macrophages. These infiltrating cells are likely to interact with other cells to cause the pathological conditions in GN.

Mono-Sodium Urate (MSU) Activates PKR and NLRP3 Inflammasome in Human Renal Proximal Tubular Cells (HRPTCs) Shabirul Haque, Nairuti H. Shah, Rabani Bharara, Ramachandra prasanna Bongu, Gauri P. Patil, Amrita Kaur Chawla, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY.*

Background: Protein kinase R (PKR) is triggered by double stranded RNA (ds-RNA) which directly interacts with NLRP3 and activates NLRP3 infalammasomes. Infalammasome is a multiprotein complex consists of caspasse-1, ASC, and NLRPs proteins. Inflammasome activation and maturation augments secretion of proinflammatory cytokines interleukin (IL)-1β and IL-18. High serum uric acid levels have also been reported to promote both acute and chronic tubulointerstitial disease. However, the role of

PKR in MSU mediated tubular cell infalammasome complex has not been investigated. We hypothesized that MSU triggers PKR pathway to activate NLRP3 inflammasomes in tubulointerstitial fibrosis.

Methods: Human renal proximal tubular cells (HRPTCs) were incubated with MSU (100 μg/ml) for either 24 or 48 hours and assayed for pyroptosis by a morphologic assay (through staining with H3342 and propidium iodide). To determine the involved mechanism, protein blots of HRPTCs treated with MSU (100 mg/ml) for 48 hrs were probed for PKR and actin. Total RNA was extracted from HRPTCs treated under similar conditions and cDNAs were amplified with specific primers. To establish causal relationship between caspase-1 activation and pyroptosis, HRPTCs were pulsed with MSU in the presence or absence of caspase-1 inhibitor and then assayed for pyroptosis. To establish a causal relationship between NLRP3 mediated induction of K-efflux and inflammasome formation, HRPTCs were treated with MSU with/without glyburide.

Results: MSU exposure enhanced tubular cell pyroptosis. MSU promoted transcription of NLPR3, caspase-1, and IL-1β. MSU exposure augmented protein expression of PKR, NLRP3, IL-1β and caspase-1. MSU-induced pyroptosis was attenuated by caspase-1 inhibitor. Glyburide treatment showed downregulation of NLRP3, caspase-1 and IL-1β expressions in MSU treated HRPTCs.

Conclusions: MSU activates PKR which leads to NLRP3 inflammasome activation and pyroptosis in HRPTCs.

TH-PO290

Hyperglycemia-Induced NLRP3 Inflammasome Formation Contributes to Podocyte Dedifferentiation via IL-1β and p53 Shabirul Haque, Gauri P. Patil, Amrita Kaur Chawla, Anjali Maheshwari, Ramachandra prasanna Bongu, Rabani Bharara, Rivka Lederman, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY.*

Background: NLRP3 inflammasomes have been reported to play a role in hyperglycemia associated morbidities including diabetic nephropathy. Functionally active inflammasome pathway promotes the maturation of proinflammatory cytokines such as IL-1β and IL-18. We hypothesize that hyperglycemia-induced NLRP3 inflammasome complexes would down regulate p53 pathway through the generation of IL-1β. These interactions would lead to dedifferentiation of podocytes in high glucose milieu.

Methods: Human podocytes (HPs) were incubated in media containing either buffer (C/HP) or high glucose (35 mM, HG/HP) for variable time periods. High glucose (HG) and normal glucose (NG) conditioned media (CM) were collected. Total RNA was extracted from cellular lysates and cDNAs were amplified with specific primers for inflammasome molecular markers (IMMs, NLRP3, ASC, caspase-1, IL-1β, and IL-18). Protein blots of C/HPs and HG/HPs were probed for NLRP3 and reprobed for protein expression of IMMs and actin. To establish a causal relationship between HG and IMMs, HPs were incubated in media with/without HG in the presence or absence of casapse-1 inhibitor/glyburide (K-efflux inhibitor) for 48 hours followed by mRNA and protein analysis for IMMs. Effects of IL-1 β alone and HG-CM were evaluated on podocyte dedifferentiation (loss of podocyte markers- nephrin and syanptopodin by Western blot analysis and immunolabeling).

Results: HG upregulated mRNA and protein expressions of NLRP3, casapse-1, ASC, IL-1β in HPs. Both caspasse-1 inhibitor and glyburide inhibited mRNA and protein expression of IMMs in HG/HPs. HG-CM not only downregulated p53 mRNA transcription but also induced dedifferentiation in HPs in the form of attenuated expression of nephrin and synaptopodin. IL-1β down regulated p53, nephrin and synaptopodin expressions in HPs.

Conclusions: Hyperglycemia induces dedifferentiation of HPs through inflammasome formation and down regulation of p53.

Human Renal Proximal Tubular Epithelial Cells: Effects of Primary Cilia Loss on Epithelial Phenotype and Function Michael Higgins, Tara McMorrow. *School of Biomolecular and Biomedical Science, Conway Inst, Univ College Dublin, Dublin, Ireland.*

Background: The primary cilium is a hair-like microtubule based structure, protruding from nearly all mammalian cells. Originally thought to be a vestigial organelle, it is now well established as a crucial signalling hub. The importance of the primary cilium in cell signalling has become clear with a range of diseases associated with its loss (ciliopathies). Recently there has been increased interest in the link between the primary cilium and the development and progression of cancer, with several cilia associated genes dysregulated in numerous cancers. The primary cilium has been found to be absent in renal cell carcinomas, breast and pancreatic cancers. The aim of this study was to investigate the functional and mechanistic link between cilia and important epithelial characteristics including epithelial marker expression and barrier function. This involved assessing the effects of cilia loss in a human renal proximal tubular epithelial cell line (RPTEC/TERT1).

Methods: Deciliating agents were used to induce loss of the primary cilium. Immunofluorescent labelling of the ciliary marker acetylated α-tubulin was used to detect the primary cilium in the RPTEC/TERT1 cells. Western blotting was used to assess epithelial marker expression and tight junction protein expression. Trans-epithelial electrical resistance (TEER) was measured to assess epithelial barrier function following cilia loss.

Results: Removal of cilia from RPTEC/TERT1 cells by deciliating agents was confirmed by acetylated α-tubulin staining. Deciliation was found to cause alteration of tight junction protein expression, in particular claudin family members. Cilia loss caused an increase in TEER, suggesting a decrease in tight junction permeability and a change in epithelial barrier function following deciliation.

Conclusions: Results suggest an altering of epithelial cell junctions and barrier function following deciliation. Further analysis is being carried out to understand the relationship between the primary cilium and the maintenance of an epithelial phenotype and function.

TH-PO292

Development of a Novel Human Renal Proximal Tubule Epithelial Cell Culture Model That Retains Robust Mitochondrial Respiratory Capacity, and Critical *In Vivo* Renal Functional Attributes Diana Zepeda-Orozco,[1] Kathryn S. Brown,[1] Arpit Sharma,[2] Ian M. Thornell,[3] Eric Taylor.[2] *[1]Pediatrics, Univ of Iowa, Iowa City, IA; [2]Biochemistry, Univ of Iowa, Iowa City, IA; [3]Internal Medicine, Univ of Iowa, Iowa City, IA.*

Background: Renal mitochondrial dysfunction and oxidative stress are implicated in diabetic kidney disease, acute kidney injury, and the progression of chronic kidney disease. The renal proximal tubule is a mitochondria-rich nephron segment that relies on oxidative phosphorylation to carry out its multiple, metabolically demanding absorptive and buffering functions. However, mechanistic investigation of proximal tubule mitochondrial biology with cell culture systems *in vitro* is challenging because available immortal proximal tubule epithelial cells exhibit a transformed, glycolytic metabolism concomitant with loss of key functional parameters.

Methods: In this study, primary human renal proximal tubule epithelial cells (PTECs) were immortalized (iPTEC) by retroviral transduction with hTERT and papilloma virus. To test their utility as a cell culture model of *in vivo* kidney function, we evaluated iPTECs for retention of mitochondrial respiratory capacity and key proximal tubule cell functional attributes.

Results: iPTECs maintained capacity for mitochondrial respiration and oxidative phosphorylation utilizing several substrates including pyruvate and glutamine. Furthermore, iPTECs retained critical proximal tubule functional characteristics, including monolayer formation with expression of E-cadherin, expression of proximal tubule cell transporters, and the ability to perform gluconeogenesis and ammoniagenesis. iPTECs plated on millicell cell culture inserts developed transepithelial potential that was maximal on day 20 and mediated in part by polarized Na/K-ATPase expression in the basolateral membrane.

Conclusions: The development of an immortalized PTEC line with broad retention of *in vivo* functional attributes, including robust oxidative phosphorylation, will enable the study of mitochondria biology in kidney health and disease.

TH-PO293

Pangenomic Analyses of Hypoxia Inducible Factor (HIF) Pathway Activation in Human Primary Renal Tubular Cells Steffen Grampp,[1] Franziska Bertelshofer,[2] Margarete Goppelt-Struebe,[1] Kai-Uwe Eckardt,[1] Johannes Schödel.[1] *[1]Dept of Nephrology and Hypertension, Friedrich-Alexander-Univ Erlangen Nürnberg, Erlangen, Germany; [2]Computer Graphics Group, Friedrich-Alexander-Univ Erlangen Nürnberg, Erlangen, Germany.*

Background: In the kidney, epithelial integrity is crucial for organ function. Ischemic or toxic damage of tubular cells can cause acute kidney injury. Preconditional stabilization of hypoxia inducible factor 1 alpha (HIF-1α) in tubular cells is beneficial in animal models of acute kidney injury. The precise protective mechanisms and the relevance of the HIF system in human kidneys remain unknown. Therefore, the aim of this study was to characterize the hypoxic response and to investigate direct HIF effects in primary human tubular cells.

Methods: Healthy human kidney tissue from patients undergoing tumour nephrectomy was used for tissue studies and isolation of primary tubular cells. HIFs were stabilized using hypoxia (1%) or the hypoxia-mimetic dimethyl oxallylglycine. We used genome-wide analyses of open chromatin (FAIRE-seq) and HIF DNA-binding (ChIP-seq) in freshly isolated primary human tubular cells from several individuals to define conserved regulatory DNA elements and HIF-binding sites.

Results: Immunohistochemistry experiments using human kidney tissue revealed the presence of HIF-1α protein in tubular cells. Co-staining with 11β-hydroxy steroid dehydrogenase localized HIF-1α signals predominantly in the distal convoluted tubule and the collecting duct. Using ChIP-seq we identified over 500 high-stringency HIF-1 binding sites. HIF DNA-binding was strongly enriched in regions of open chromatin and regulatory regions. Patterns of HIF-DNA interactions were conserved across several individuals. Functional clustering of HIF-binding genes showed strong enrichment for protective pathways and included novel binding sites at renoprotective genes such as HO-1 and MUC1.

Conclusions: The importance of the HIF system for cell survival and integrity is well documented for rodent kidneys. We expand analyses of the renal HIF response to human kidneys and identify important mechanisms to potentially preserve tubular function in human kidney disease.

The Na-H Exchanger Regulatory Factor Isoform 1 Is a Critical Determinant of Renal Proximal Tubule Brush Border Composition Rebecca Murray,[1,2] Corey James Ketchem,[1] Amanda R. Sherwood,[1] Michael Merchant,[1] Lauren D. Grant,[1] Barbara Clark,[1,3] Syed J. Khundmiri,[1,2,4] Eleanor D. Lederer.[1,2,4] *[1]Medicine, Univ of Louisville, Louisville, KY; [2]Medical Services, Robley Rex VA Medical Center, Louisville, KY; [3]Biochemistry and Molecular Biology, Univ of Louisville, Louisville, KY; [4]Physiology, Univ of Louisville, Louisville, KY.*

Background: The Na-H Exchanger Regulatory Factor Isoform 1 (NHERF1), a multifunctional scaffolding protein, is required for regulated forward trafficking and brush border membrane (BBM) anchoring of the type IIa sodium phosphate cotransporter, Npt2a. We have shown that OK cells, a model of proximal tubule, lacking NHERF1 (OKH) have decreased BBM expression of Npt2a, SGLT1, ezrin, GGTase and Munc18. OKH cells also show a 50% decrease in total RNA levels and a near absence of Npt2a mRNA. We hypothesize that NHERF1 plays a defining role in BBM protein expression.

Methods: To test this hypothesis, we performed proteomic analysis of BBM proteins from WT and NHERF1 deficient (KO) mice and measured mRNA expression of selected transport proteins from WT and OKH cells.

Results: We identified 148 proteins whose expression was downregulated at least two fold and 78 proteins whose expression was upregulated at least three fold in KO mouse BBM. 14 proteins were absent in KO. Integrity Pathway Analysis demonstrated that 113 of the downregulated proteins were involved in cellular organization, assembly, function, or maintenance, specifically, microvilli and actin cytoskeleton structure (Shroom4, Fascin), protein trafficking (CLIC1 and 4), signaling (taperin, FGFR2), and repair. Immunohistochemistry of KO kidneys and scanning electron microscopy of OKH cells show no obvious defects in cell structure/polarity. The mRNA levels of Npt2a, SGLT1, and NHE3 in OKH were less than 50% of WT but promoter activity of SGLT1 was similar.

Conclusions: We conclude that the presence of NHERF1 defines renal BBM protein expression through post-transcriptional, trafficking, and anchoring mechanisms.

TH-PO295

Tamm-Horsfall Protein (Uromodulin) Regulates IL-23 Expression in S3 Segments by Inhibiting the Rac-1-NOX2 Signaling Pathway of Oxidative Stress Radmila Micanovic, Shehnaz Khan, Frank Witzmann, Tarek M. El-Achkar. *Indiana Univ School of medicine.*

Background: We recently showed that Tamm-Horsfall protein regulates granulopoiesis by inhibiting the expression of IL-23 in S3 segments and the resultant activation of the IL-23/IL-17 axis. The molecular mechanism of this observation is unclear.

Methods: We performed laser micro-dissection (LMD) of S3 segments from THP-/- and THP+/+ kidney sections followed by 2 Dimensional –Differential Gel Electrophoresis (2D-DIGE) to identify pathways that are modulated by THP in vivo. We also used an unbiased, label free proteomics approach to understand the signaling of THP on human proximal HK-2 cells. Additional experimental methodology is described in Results.

Results: Bioinformatics analysis of differentially expressed proteins in S3 segments dissected from THP-/- compared to THP+/+ kidneys revealed that the free radical scavenging network had the highest score of clustering, suggesting that THP regulates redox balance in S3 segments. Using in vivo reporter dyes and by measuring enzymatic markers of oxidative stress (OS), we found increased OS in S3 segments from THP-/-compared to THP+/+ kidneys. Label-free proteomic analysis of HK-2 cells revealed that incubation of these cells with THP inhibited multiple pathways that converge on Rac-1 signaling. Since Rac-1 signaling is essential to the activation of NADPH oxidase (NOX), a major source of reactive oxygen species in cells, we verified that THP-/- mice had increased expression of Rac-1 and Nox-2 but not Nox-4. Treatment of HK-2 cells with THP directly decreased IL-23 expression. In addition, oxidative insult using H2O2, but not LPS, stimulated IL-23 mRNA expression in these cells, suggesting that oxidative stress but not classical endotoxin signaling, is needed for IL-23 induction in epithelial cells.

Conclusions: Taken together, our data support that THP inhibits Rac-1/NOX-2 oxidative stress in S3 segments, which in turn regulates the production of IL-23 and activation of the IL-23/IL-17 axis. These findings significantly enhance our understanding of how THP shapes the function and reactivity of S3 segments, which could have both renal and systemic implications, through the regulation of granulopoiesis.

Abstract Withdrawn

TH-PO297

Hydrophobic Motif Site Phosphorylation of Protein Kinase CbetaII by mTORC2 Regulates High Glucose (HG)-Induced Mesangial Cell Hypertrophy Falguni Das, Nandini Ghosh-choudhury, Meenalakshmi M. Mariappan, Balakuntalam S. Kasinath, Goutam Ghosh-Choudhury. *Univ of Texas Health Science Center at San Antonio, San Antonio, TX.*

Background: Protein kinase C beta II (PKCbII) has been implicated in diabetic nephropathy (DN). Mesangial cell (MC) hypertrophy is a pathologic feature of DN. PKCbII undergoes phosphorylation at the hydrophobic motif site Ser-660 for its activity. We have shown that mTOR complex 1 (C1) regulates MC hypertrophy. How activation of PKCbII by Ser-660 phosphorylation fits into mTOR signaling to control MC hypertrophy is not known.

Methods: Human MCs, immunoblotting, siRNA and shRNA transfections, protein synthesis assays were used.

Results: HG significantly increased phosphorylation of PKCbII at Ser-660 in a PI 3 kinase-dependent manner. siRNAs against PKCbII, dominant negative PKCbII and nonphosphorylatable mutant of PKCbII, PKCbIIS660A, blocked mTORC1 activity due to lack of PRAS40 phosphorylation, resulting in significant inhibition of HG-induced MC protein synthesis and hypertrophy. Also, PKCbIIS660A attenuated phosphorylation of Akt at Ser-473, a putative mTOR complex 2 (C2) site. Specific inhibition of mTORC2 by shRNAs against rictor or Sin1, two exclusive and required components for its activity, suppressed HG-induced phosphorylation of PKCbII Ser-660, PRAS40 and Akt Ser-473, resulting in attenuation of mTORC1 activity leading to inhibition of MC hypertrophy. Constitutively active (CA) Akt or CA mTORC1 reversed shRictor- or shSin1-mediated inhibition of HG-induced MC hypertrophy. Furthermore, CA PKCbII reversed the shRictor- or shSin1-induced inhibition of HG-stimulated Akt Ser-473 phosphorylation and MC hypertrophy. Finally, we show increased phosphorylation of PKCbII Ser660, PRAS40 and Akt Ser-473 in association with activation of mTORC1 in renal cortices of OVE26 mice with type 1 diabetes.

Conclusions: These results provide the first evidence that HG-induced activation of mTORC2 phosphorylates and activates PKCbII to increase the phosphorylation of Akt at Ser-473 to finally activate mTORC1 to induce MC hypertrophy. Thus, we uncover a specific role of mTORC2 for Akt/mTORC1 activation via PKCbII Ser-660 phosphorylation.

Hyaluronan Mediated Motility Receptor Regulates Cell Motility in Glomerular Endothelial Cells in Response to Shear Stress Hesham e hussien Elhegni, Gavin Iain Welsh, Simon C. Satchell. *Academic Renal Unit, Univ of Bristol, Bristol, United Kingdom.*

Background: Laminar shear stress (LSS) is an important determinant of vascular health. The glycocalyx is a carbohydrate-rich layer that covers the endothelial cell surface. Glycocalyx translates shear forces into intracellular signals. Hyaluronan (HA) motility mediated receptor (HMMR) promotes cell motility and invasion through interactions with HA on the cell surface in non-renal cells.

Methods: Human conditionally immortalized glomerular endothelial cells (GEnC) were exposed to LSS (10 dyn/cm2) using an orbital rotator for 0, 24, 48 and 72h. Effects on expression of glycocalyx-related genes were analysed using a custom designed focused Taqman qPCR array. HMMR and CD44 (another hyaluronan receptor) and production of HA itself by radiolabelling were also assessed. Motility assays (scratch assay, 2D chemotaxis and Electric Cell-Substrate Impedance Sensing) were performed on GEnC and siRNA HMMR knockdown GEnC with and without HA fragments. HMMR expression was assessed on freshly isolated and cultured glomeruli.

Results: There was a significant increase in versican expression, peaking at 24h. Thrombomodulin expression significantly increased and reached a plateau within 24h. CD44 expression peaked at 72h of LSS. There was a dramatic decline in HMMR expression by 24h of LSS (10-fold decrease $p<0.0001$) and levels remained suppressed over 72h. Furthermore, HMMR recovered to nearly pre-LSS level after a period without LSS for 24h. LSS increased release of HA into culture medium. What is more, HA fragments increased cell motility where LSS for 24h reduced it. HA fragments did not increase cell motility on siRNA HMMR knockdown GEnC. HMMR expression was increased in isolated glomeruli after 24h in culture.

Conclusions: HMMR is exquisitely shear-sensitive in vivo and ex vivo and acts as a marker for LSS exposure in endothelial cells. Chronic LSS reduces cell motility. Our data suggest this is due to HMMR expression changes and that HMMR is likely to play important roles in glomerular physiology and disease.

TH-PO299

Cell Surface Expression of TRPC6 in Podocytes Depends on Synaptopodin Stability Hao Yu,[1] Andreas D. Kistler,[2] James Otto Meyer,[3] Jochen Reiser.[1] *[1]Internal Medicine, Rush Univ, Chicago, IL; [2]Internal Medicine, Cantonal Hospital Frauenfeld, Frauenfeld, Switzerland; [3]Neuroscience, Univ College London, London, United Kingdom.*

Background: TRPC6 gain-of-function mutations and increased TRPC6 expression in podocytes were found in familial FSGS and acquired glomerular diseases. TRPC6 is expressed in synaptopodin (synpo) rich podocyte yet only a fraction is located on plasma membrane. Modulation of localization and function of TRPC6 harbors potential for treatments.

Methods: Immunogold and co-IP were performed to examine co-localization and interaction of TRPC6 and synpo. Cell surface biotinylation and high throughput analysis were used for quantitative analysis of cell surface levels of TRPC6. Calcium imaging was performed to measure calcium influx mediated by TRPC6. Glomerular isolation, biotinylation and podocyte enrichment were performed to determine podocyte membrane TRPC6 levels in vivo.

Results: Co-localization of TRPC6 and synpo was observed in podocyte foot processes by immunogold double labeling in mouse kidney. Interaction of the two proteins was observed by co-IP in cultured podocytes and mouse glomeruli. TRPC6 levels on cell surface increased in synpo knockdown podocytes and decreased in synpo overexpressing podocytes. Consistent with the changes in expression levels, calcium influx mediated by TRPC6 was enhanced in synpo knockdown podocytes and reduced in synpo overexpressing podocytes. Mechanistically, we found both actin and microtubule cytoskeletons were involved in regulating membrane TRPC6 expression affected by synpo. Membrane TRPC6 expression in podocytes was elevated upon LPS treatment and was restored by cyclosporine A (CsA) in WT mice. Functionally, CsA treatment significantly reduced LPS proteinuria in WT mice (71%) and to a lesser extent in TRPC6-/- mice (45%).

Conclusions: Synaptopodin limits expression of TRPC6 on podocyte plasma membrane. CsA, a drug that stabilizes synpo, is shown to lower podocyte surface TRPC6 levels upon LPS treatment. The partial benefit of CsA in reducing LPS proteinuria in TRPC6-/- mice suggests that CsA protects podocytes partially by lowering cell surface expression of TRPC6 through stabilization of synpo.

APOL1 Risk Variants Enhance Podocyte Oxidative Stress Xiqian Lan, Hongxiu Wen, Ashwani Malhotra, Karl Leon Skorecki, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY.*

Background: APOL1 variants have been implicated for increased prevalence and acceleration in the rate of progression of kidney diseases amongst African Americans. Since oxidative stress has been demonstrated to play a role for loss of podocytes in both experimental animal and human kidney disease models, we hypothesized that APOL1 variants could be inducing podocyte injury through augmentation of oxidative stress.

Methods: Human podocytes (HPs) stably expressing Vector, APOL1G0, APOL1G1, or APOL1G2 were used. Pseudo type HIV or empty vector (control) virus was transduced into Vector/HPs, G0/HPs, G1/HPs, and G2/HPs. After 48 h, cells were loaded with DCFDA and ROS generation was assayed every 10 min for 60 min by a fluorometer. Three sets of experiments were carried out in triplicate. Protein blots of HPs expressing Vector, APOL1G0, APOL1G1 and APL1G2 were probed for molecular markers for oxidative stress and associated down stream signaling (phospho-p53, phospho-Foxo3A, p27, BAD, RIP3, MnSOD, and catalase). To evaluate the status of apoptotic pathway, protein blots of HPs expressing Vector, APOL1G0, APOL1G1, and APOL1G2 were probed for caspase-3 and then reprobed for actin. To determine the role the activation of Ang II type I (AT1R) and II (AT2R), protein blots of HPs expressing APOL1 and variants were probed for AT1R and AT2R.

Results: Both HP/G1 and HP/G2 displayed increased ROS generation when compared to Vec/HPs and G0/HPs. G1/HPs and G2/HPs displayed higher expression of pro-oxidant molecules, including RIP3, P27, BAD, phospho-FOXO3A, phospho-P53; HP/G1 and HP/G2 also enhanced expression of cleaved caspase-3 when compared with vector/HPs and G0/HPs. However, both G1/HPs and G2/HPs displayed lower expression of MnSOD and AT2R. Both G1/HPs and G2/HPs displayed greater ROS generation and enhanced expression of pro-oxidant molecules in HIV milieu when compared to vector/HPs and G0/HPs.

Conclusions: These results indicate that APOL1 risk variants have potential to augment oxidative stress in podocytes and this effect is further exacerbated in HIV milieu.

TH-PO301

The SMAD2/3 Ratio Is Controlled by PLCe in Podocytes Carl J. May,[1] Gavin Iain Welsh,[1] Moin Saleem.[1,2] *[1]Academic Renal Unit, Univ of Bristol, Bristol, United Kingdom; [2]Children's Renal Unit, Bristol Children's Hospital, Bristol, United Kingdom.*

Background: Podocytes are thought to be the target cell in nephrotic syndrome pathogenesis. Mutations in PLCE1: which encodes a lipid signalling enzyme, have been reported in patients with early onset nephrotic syndrome. However, the effects of mutations in PLCE1 in the mature podocyte are not clear.

Methods: A conditionally immortalised human podocyte cell line was established from a patient, with a SNP at nucleotide 321 of PLCE1 that leads to a stop codon. This mutation severely truncates the protein such that no protein expression was detected. This cell line was characterised in order to investigate the deleterious effect of this mutation on podocyte phenotype and function.

Results: The PLCE1 mutant podocytes express lower levels of both epithelial and podocyte markers than wild-type cells. Morphologically they appear more mesenchymal. They demostrate a diminished response to TGF-B1 compared to the wild-type. Interestingly the PLCE1 mutant podocytes show no SMAD2 phosphorylation but a robust SMAD3 phosphorylation. Whereas, the wild-type podocytes which show marked SMAD2 phosphorylation and only low level SMAD3 phosphorylation. It is thought that the SMAD2 pathway is anti-fibrotic while the SMAD3 pathway is pro-fibrotic. The PLCE1 mutant podocytes had equal levels of SMAD2 and SMAD3 while the wild-type podocytes had twice the amount of SMAD2 compared to SMAD3. This biases TGF-B1 signaling along the anti-fibrotic SMAD2 pathway in the wild type. Despite the 1:1 ratio between SMAD2 and SMAD3 the lack of SMAD2 phosphorylation shows that the PLCE1 mutant podocytes are biased towards the pro-fibrotic SMAD3 signaling. Most interestingly, however, PLCE1 knockdown by siRNA in the Wild-type pdoocytes increased the expression of SMAD3 relative to SMAD2. This changes the SMAD bias of the podocyte.

Conclusions: This work suggests that by altering the SMAD2/3 ratio within the podocyte, the PLCE1 mutant enhances the pro-fibrotic response to TGF-B1. This provides a novel therapeutic target to modulate the podocyte's response to TGF-B1 and may prove to be protective against the development of fibrosis.

Dynamin Oligomerization Plays a Catalytic and Structural Role with Regard to Actin Dynamics During Actin-Dependent Clathrin Mediated Endocytosis Changkyu Gu, Sanja Sever. *Nephrology, Massachusetts General Hospital, Charlestown, MA.*

Background: The GTPase dynamin is essential for podocyte structure and function as it plays a role in regulating endocytosis and the actin cytoskeleton. Recently, using a combination of different dynamin mutants and Bis-T-23, we showed that it is possible to directly target actin cytoskeleton dynamics by targeting the dynamin oligomerization cycle in the whole organism. It has been shown that direct dynamin-actin interactions are required for the scission of the clathrin-coated pits in yeast. While actin is critical for endocytosis in yeast cells, data suggest that it plays a cell type specific role in endocytosis in mammalian cell. In this study, we aim to investigate the functional role for dynamin oligomerization in endocytosis.

Methods: Actin polymerization assay was performed to investigate dynamin oligomerization-driven actin polymerization using purified proteins or cytosolic extracts. Electron microscopy was used to explore the effects of dynamin on actin structures. Tfn uptake assay and **Transmission electron microscopy were used to examine endocytosis and Clathrin coated pits profiles respectively.** Total internal reflection fluorescence microscopy was used to monitor clathrin medicated endocytosis.

Results: Here we show, using a combination of diverse dynamin mutants and a small molecule that specifically promotes actin-dependent dynamin oligomerization named Bis-T-23, that dynamin provides a physiological link between gelsolin and Arp2/3 complex driven actin polymerization. Dynaminpromoted Arp2/3 complex driven nucleation by providing free barbed ends via gelsolin displacement in vitro, in cell extracts and in the cell.In addition, dynamin oligomers exhibited a structural role with regard to the actin cytoskeleton by crosslinking microfilaments. This dual role of dynamin oligomerization with regard to the actin cytoskeleton (kinetic and structural) regulated actin dynamics at distinct stages of clathrin-coated vesicle formation, including coated pit formation, constriction and fission.

Conclusions: Dynamin oligomerization plays a catalytic and structural role with regard to actin dynamics during actin-dependent clathrin mediated endocytosis.

Functional Characterization of β-Catenin in Podocyte Damage Michelle Duong, Beina Teng, Hermann G. Haller, Mario Schiffer. *Nephrology, Medical School Hanover.*

Background: β-Catenin plays a crucial role in the Wnt signaling pathway as well as in cell adhesion. In the kidney β-Catenin is critically involved in the development of proteinuria and podocyte damage. Here we investigated if the injury is associated with a certain subcellular localization of β-Catenin and/or is mediated via its binding partner: α-Catenin is an essential binding partner of β-Catenin, which leads to a proper adhesion between cells while the function of β-Catenin as a gene transcription regulator is linked with TCF (T cell-lymphoid factor).

Methods: We used the zebrafish model to express human β-Catenin mutants lacking the ability to bind α-Catenin or TCF. To examine the impact of β-Catenin acting in only one of its subcellular localization, we expressed β-Catenin either in the membrane or in the nucleus. Knockdown of endogenous β-Catenin was conducted by morpholino injection and co-expression of the mutants by injection of mRNA. After that the integrity of the glomerular filtration barrier was analyzed.

Results: Our analysis revealed that β-Catenin tethered to the membrane only seems to be able to partially retain the glomerular filtration barrier, whereas nuclear β-Catenin alone cannot abrogate the impact of the β-Catenin knockdown and leads to loss of high molecular weight proteins from the circulation. Further, zebrafish with β-Catenin missing the function of binding TCF have a normal glomerular filtration function, while the expression of β-Catenin unable to bind to α-Catenin leads to proteinuria.

Conclusions: These results suggest that the cell-cell adhesion function of β-Catenin is of greater importance for the maintenance of the glomerular filtration barrier than its role as a transcription factor.

Vitamin D (VD) Upregulates Nephrin in HIV-Induced Dedifferentiated Podocytes Through Down Regulation of SNAIL Nirupama Chandel, Rivka Lederman, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY.*

Background: HIV infection of kidney cells plays a key role in the development of HIV-associated nephropathy (HIVAN). We recently observed that HIV-induced dedifferentiations of podocytes regulated through SNAIL. We hypothesize that VD has potential to prevent

the Nephrin downregulation through modulation of SNAIL expression. VD may be down regulating SNAIL either through demethylating the signature of active transcritption (H3K4 trimethylatione) at snail promoter or at Nephrine promoter (H3 K27 trimethyllation) or either through reversal of HIV-induced stabilization of SNAIL.

Methods: Renal tissues were harvested from (FVB/N) and HIV-transgenic (Tg26) mice, and VD (EB1089) receiving FVBN and Tg26 mice for two weeks (n=3, 4 wk old). *In vitro* studies, human podocytes (HPs) were transduced with either empty vector (EV) or NL4-3(HIV). EV/HPs and HIV/HPs were treated with EB1089 for 48 hours. Protein blots of renal tissues, EV/HPs and HIV/HPs with/without VD were probed for SNAIL, p62 (marker of endosomal cargo degradation), and histone trimethylation. Immunoprecipitation (IP) studies were carried in cellular lysates of EV/HPs and HIV/HPs with SNAIL antibody. Binding of SNAIL at VDR promoter was evaluated by ChIP assay. Additionally, we evaluated the effect VD on disruption of SNAIL repressor complex at nephrin promoter.

Results: Renal tissues from Tg26 mice (n=3) displayed enhanced SNAIL transcription as well as translation but downregulation of nephrin. VD not only down regulated SNAIL but also uptegulated nephrin expression in renal tissues of Tg26 mice as well as in HIV/HPs. Chip assay revealed enhanced trimethylation at SNAIL promoter and binding of SNAIL at Nephrin promoter in HIV/HPs. VD also enhanced nephrin expression through disruption of SNAIL repressor complex at nephrin promoter in HIV/HPs. HIV/HP displayed decreased levels of p62 which signifies increased HIV induced autophagy in i*n vitro* system.

Conclusions: VD has potential to upregulate nephrin expression in HIV-induced dedifferentiated podocytes through multiple ways including modulation of HIV-induced epigenetic alterations, autophagy, and disruption of SNAIL repressor complexes.

TH-PO305

Krüppel-Like Factor 15 Mediates Glucocorticoid-Induced Podocyte Differentiation Sandeep K. Mallipattu,[1] Lucia Roa,[1] Timothy W. Miller,[1] Jason Ling,[1] Victoria Ly,[1] Monica Patricia Revelo Penafiel,[3] John C. He.[2] *[1]Medicine/Nephrology, Stony Brook Medicine; [2]Medicine/Nephrology, Mount Sinai School of Medicine; [3]Pathology, Univ of Utah.*

Background: Glucocorticoids (GCs) are the initial and often, the primary, treatment for primary glomerulopathies such as MCD and FSGS. The mechanism by which GCs restores podocyte differentiation and improves cell survival is unclear. We previously demonstrated that Krüppel-Like Factor 15 (KLF15), a kidney-enriched zinc-finger transcription factor, was required for podocyte differentiation. Here, we hypothesize that KLF15 mediates GC-induced podocyte differentiation.

Methods: Human podocytes (HP) and primary mouse podocytes (MP) were treated with and without dexamethasone (DEX) (1μM, 10μM) for 3, 6, 12, and 24 hours. Initially, we generated podocyte-specific knockout mice, *Podocin-Cre Klf15$^{flox/flox}$* (*Klf15$^{-/-}$*). Proteinuria was induced in *Klf15$^{-/-}$* and wildtype mice with LPS (10mg/g) and subsequently treated with or without DEX (1mg/kg). HP with stable overexpression of KLF15 (*LentiORF-KLF15*) were generated. Immunostaining for KLF15 was performed on kidney biopsies from patients with healthy donor nephrectomies (n=16), GC-responsive (n=20), and GC-nonresponsive (n=15) FSGS and MCD.

Results: *KLF15* expression was induced in HP and primary MP within 3 hours of DEX treatment. TRANSFAC promoter analysis revealed that KLF15 binding sites occupy genes involved in GC signaling. LPS-treated *Klf15$^{-/-}$* mice exhibited less podocyte recovery (albuminuria, podocyte effacement, nephrin, and synaptopodin expression) after DEX administration as compared to LPS-treated wildtype mice. The pattern of *Tnfα, Il-6, Il-1*β, and *Infγ* were unchanged in the serum and glomerular extracts between both groups of mice treated with DEX. Furthermore, actin stress fiber formation was preserved with G1/S cell cycle arrest in HP with *LentiORF-KLF15* as compared to *LentiORF-RFP* with LPS treatment. Finally, reduced expression of KLF15 in the glomeruli correlated with non-responsiveness to GCs in patients with MCD and FSGS.

Conclusions: These findings suggest that KLF15 is essential for GC-mediated restoration of differentiation markers, ultrastructure, and cell survival in the setting of podocyte injury.

TH-PO306

CXCR4 Plays a Crucial Role in Mediating Oxidative Stress-Induced Podocyte Injury Hongyan Mo,[1] Xue Hong,[1] Lili Zhou,[1] Youhua Liu.[1,2] *[1]Div of Nephrology, Nanfang Hospital, Southern Medical Univ, Guangzhou, Guangdong, China; [2]Dept of Pathology, Univ of Pittsburgh, Pittsburgh, PA.*

Background: Oxidative stress is key mediator to podocyte damage and proteinuria. However, the underlying mechanism remains to be elucidated. In this study, we investigated the potential role of CXCR4, the chemokine receptor for SDF-1α, in mediating oxidative stress-induced podocyte injury.

Methods: In a mouse model of adriamycin nephropathy (ADR), CXCR4 mRNA and protein expression, as well as oxidative stress was examined. AOPPs, advanced oxidation protein products, were utilized to trigger oxidative stress, and their effects on podocyte dysfunction and CXCR4 expression were assessed. AMD3100, a specific inhibitor of CXCR4, was used to block CXCR4 action both in vitro and in vivo.

Results: CXCR4 expression was significantly induced in podocytes as early as 3 days after injection of adriamycin. This was accompanied by an increased upregulation of oxidative stress in podocyte, as detected by MDA assay of kidney homogenate, nitrotyrosin staining in podocyte, and induction of NOX2, a major subunit of NADPH oxidase. Similar results were obtained when we stained for CXCR4 in human kidney biopsies from patients with proteinuric kidney diseases including IgAN, crescent and FSGS. Using immortal podocyte cell line MPC5 and mouse models of podocyte injury induced by ADR or AOPPs, we found that AOPPs induced significant loss of podocyte marker WT1, nephrin and podocalyxin, accompanied by upregulation of mesenchymal marker desmin both in vitro and vivo. Furthermore, AOPPs worsen proteinuria, aggravated glomerulosclerosis and renal fibrotic lesions. Concomitantly, SDF-1α/CXCR4 signaling was remarkably induced in podocytes by AOPPs. Administration of AMD3100, a specific inhibitor of CXCR4, reduced proteinuria, ameliorated podocyte dysfunction and renal fibrotic lesions triggered by AOPPs.

Conclusions: These results suggest that chemokine receptor CXCR4 may play a crucial role in mediating oxidative stress-induced podocyte injury, proteinuria and renal fibrotic lesions.

Funding: Government Support - Non-U.S.

PKCε Is Identified as a Novel Binding Partner of β-Catenin in Podocytes Xuejiao Yu,[1] Beina Teng,[1] Michelle Duong,[1] Mario Schiffer.[1] *[1]Medical School Hannover.*

Background: PKCα, one conventional isoform of PKC, is a binding partner of β-catenin. However, a link between PKCε, a novel isoform, and β-catenin remains unclear. PKCε regulates the cytoskeleton by phosphorylating IQGAP1, a protein involved in the regulation of b-Catenin in the cell-cell adhesion complex. So, we investigated the association between PKCε and β-catenin.

Methods: Staining was performed on murine kidney sections and podocytes to examine the β-catenin expression. Time courses were performed in murine wild type and PKCε-/- podocytes. 7 promising phospho-motifs in β-catenin were selected and site-specific mutations were produced. The interaction between the β-catenin mutants and PKCε were verified by immunoprecipitation. The mutants were overexpressed in murine podocytes using adenovirus. Zebrafish larvae were injected with mutant β-catenin RNA.

Results: During the development of mice β-catenin showed increasing expression level in the glomeruli. However, the upregulation of β-catenin in wild type mice was much higher than those of PKCε-/- mice. While in wild type podocytes,β-catenin showed a translocation from the perinuclear areas to the nuclei during differentiation, the distribution of β-catenin switched the reverse way in PKCε-/- podocytes from the nuclei to the perinuclear areas. During the time course, the expression of active β-catenin was increased and total β-catenin decreased in the wild type podocytes under the stimulation of PMA. However, in the PKCε-/- podocytes, both active β-catenin and total β-catenin displayed decreased expression level. 3 of 7 mutant β-catenin exhibited decreased interaction with PKCε in immunoprecipitation, indicating these phospho-motifs as importantbinding sites. Overexpression of these 3 mutants in wild type podocytes, showed no changes in the time course. These 3 mutant β-catenin were unable to rescue the β-catenin knockdown zebrafish.

Conclusions: It is the first time to indicate that PKCε binds β-catenin directly and they are involved in the process of glomerular disease and podocytes differentiation. 3 phospho-motifs in β-catenin are proved as binding sites for PKCε.

TH-PO308

Reactive Lipids Affect Podocyte Homeostasis Through the Redox Sensitive RhoA-Slit Diaphragm Protein-Akt Axis Krisztian Stadler, Claudia Kruger. *Oxidative Stress and Disease Lab, Pennington Biomedical Research Center, Baton Rouge, LA.*

Background: Podocyte loss is a characteristic early feature of obesity and diabetes related glomerular disease. Despite much attention on reactive lipids in diabetic kidney disease, surprisingly little is really known regarding their biological role in podocytes.

Methods: Here we developed a quantitative lipid radical generating system using the donor AAPH, and conditionally immortalized podocytes to test the effects of reactive lipids on podocyte homeostasis.

Results: Surprisingly, low levels of reactive lipids led to improved motility, dynamic rearrangements of F-actin filaments, increased basal Akt phosphorylation, and increased levels of slit diaphragm proteins nephrin and WT-1. As nephrin directly activates Akt, these observations can be interpreted as beneficial adaptation, adjusting podocyte physiology to an initial stress. Only higher levels of reactive lipids led to motility decline, F-actin aggregates and low levels of pAkt. Since motility and F-actin filaments were affected, we hypothesized that lipid radicals may be sensed through the redox active master regulator protein RhoA, modulating GTP-bound RhoA levels. RhoA has two redox sensitive cysteine residues that may serve as redox switches, resulting in GDP/GTP exchange and modulation of RhoA activity. When tested with a novel G-LISA assay, exposure of podocytes to low levels of reactive lipids indeed rapidly activated RhoA. Next, we have generated constructs to mutate Cys16, Cys20 or both residues on RhoA to ultimately test if RhoA activation is key in the redox sensing mechanism.

Conclusions: In contrast to the traditional view, our results suggest that lipid radicals may act on an adaptive to maladaptive scale to control redox sensitive mechanisms and podocyte physiology. Lipid radicals may affect important signaling elements of podocyte homeostasis in a tightly regulated fashion, through the RhoA-slit diaphragm proteins-Akt axis. Therefore, modulating their levels can be a novel basis for redox-targeted drug development in diabetic complications, such as nephropathy.

The Redox Sensitive Glycogen Synthase Kinase (GSK) 3β Suppresses the Self-Protective Antioxidant Response in Podocytes upon Oxidative Glomerular Injury Changbin Li,[1] Yan Ge,[1] Ai Peng,[2] Rujun Gong.[1] *[1]Nephrology, Brown Medical School, Providence, RI; [2]Dept of Nephrology, Tongji Univ, Shanghai, China.*

Background: GSK3 has been recently implicated in the pathogenesis of kidney diseases, including proteinuric glomerulopathy. However, prior studies were less conclusive because they relied solely on chemical inhibitors of GSK3, which provide poor discrimination between the isoforms of GSK3 apart from potential off target activities. This study aimed to examine the effect of podocyte specific ablation of GSK3β on glomerular pathophysiology.

Methods: GSK3β was selectively knocked out (KO) in mature glomerular podocytes in adult mice by employing the tetracycline-inducible Cre-loxP site specific gene targeting system. KO mice and control littermates were subjected to intraperitoneal protein overload followed by examination of proteinuria and glomerular histology.

Results: In murine kidneys, the β rather than the α isoform of the redox sensitive GSK3 was found to be predominantly expressed in glomeruli and distributed intensely in podocytes. Podocyte specific ablation of GSK3β resulted in a phenotype no different from control littermates with normal kidney function. Electron microscopy demonstrated more glycogen accumulation in podocytes but otherwise normal glomerular ultrastructures in KO mice. Upon oxidative glomerular injury induced by protein overload, KO mice excreted significantly less albuminuria and had much attenuated podocytopathy, characterized by glomerulosclerosis, the loss of podocyte specific marker synaptopodin and by de novo expression of podocyte injury marker desmin, as shown by fluorescent immunohistochemistry staining and by immunoblot analysis of isolated glomeruli. The antiproteinuric and glomerular protective effect observed in KO mice was concomitant with diminished accumulation of reactive oxygen species and attenuated oxidative injuries in glomeruli, which was likely secondary to a reinforced Nrf2 antioxidant response in glomerular podocytes.

Conclusions: Collectively, our data suggests that GSK3β is dispensable for glomerular function and histology under normal circumstances but may serve as a therapeutic target for protecting from oxidative glomerular injuries.

Funding: NIDDK Support, Government Support - Non-U.S.

Vitamin D Receptor (VDR) Inversely Modulates Renin Angiotensin System (RAS) Through MDM2 and p53 in Kidney Cells Hongxiu Wen, Shabirul Haque, Xiqian Lan, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY.*

Background: Vitamin D has been reported to be a negative regulator of renin transcription. However, this concept is not able to provide a logical explanation for activation of the RAS in VDR knockout (KO) mice. We hypothesized that VDR inversely modulates the RAS through modulation of MDM2 and P53 expression. Since MDM2 is a negative regulator of p53 (MDM2 induces transcriptional repression and proteosomal degradation), VDR would also negatively regulate p53 via MDM2. p53 is known to activate the via transcription of angiotensinogen (Agt) and AT1R. On that account we further hypothesize that vitamin D down regulates the RAS through upregulation of VDR/MDM2 and down regulation of p53.

Methods: Protein blots of control and VDRKO mice were probed for MDM2. The same blots were reprobed for p53, angiotensinogen (Agt), renin, AT1R, and actin. RNAs were extracted from renal tissues of control and VDRKO mice. cDNAs were probed with specific primers for MDM2, p53, Agt, and renin. Human podocytes (HP) and tubular cells (HPTC) were silenced for VDR. Protein blots of control and siRNA-VDR/ HP and siRNA/HPTC were probed for MDM2, p53 Agt, and AT1R. To evaluate the role p53, cells were transfected with either p53 plasmid or siRNAp53. To evaluate relationships amongst VDR, MDM2, and p53, protein blots of VDR agonist treated-p53/HP and p53/HPTCs and si-RNAp53/HP and HPTCs were evaluated for MDM2 and p53 expressions.

Results: Renal tissues of VDRKO mice displayed attenuated protein and mRNA expression of MDM2 but enhanced expression of p53, Agt, renin, and AT1R. Both poodcytes and tubular cells lacking VDR also displayed attenuated expression of MDM2 but enhanced expression of p53, Agt, renin, and AT1R. HPs and HPTCs displaying enhanced expression of p53 also displayed down regulation of VDR but activation of RAS; on the other hand, HPs and HPTCs silenced for p53 displayed upregulation of VDR but down regulation of RAS. VDR agonist enhanced expression of VDR and MDM2 but down regulated expression of p53 and the RAS.

Conclusions: VDR determines the status of the RAS through modulation of MDM2 and p53 expression in kidney cells.

TH-PO311

The Role of CD133 Molecule in Renal Papillary Cells and Its Possible Involvement in Wnt Signaling and Cellular Senescence Prevention Elli Papadimitriou, Alessia Brossa, Benedetta Bussolati. *Dept of Molecular Biotechnology and Health Sciences, Univ of Turin, Turin, Italy.*

Background: The nature of cells involved in homeostasis/repair of adult human kidney is unclear. In human tissue, using the AC133 antibody, recognizing a stem cell-specific glycosylation-dependent epitope of prominin (CD133), CD133+ cells with phenotypic and functional progenitor-like properties were detected in all nephron segments as scattered distinct cells with a dedifferentiated phenotype that survive and proliferate after damage. However, the role of the CD133 in the progenitor phenotype and its possible modulation is unknown. In the present study we aim to evaluate the role of the CD133 in the maintenance of cellular stem-like phenotype and its involvement in cellular senescence.

Methods: CD133+ progenitor cells were isolated from the inner medullary of human kidney biopsies. We generated CD133 knock-down (kd) cell lines by infecting them with lentiviruses carrying GFP-shPROM plasmids. Cytotoxicity was evaluated by BrdU uptake or MTT assay. Spheroid formation was evaluated by sphere counting and MTT assay after 48h of hypoxia. The senescence was evaluated by β-galactocydase expression and telomere length measurement by real time PCR. The activity of the Wnt pathway was investigated using a Wnt-reporter luciferase assay.

Results: Preliminary data showed CD133 kd cells downregulated the stem-related gene Oct4A and acquired the differentiation marker AQP1. The activity of Wnt pathway seemed to be reduced in CD133 silenced cells both in basal culture conditions as well as after damage, as shown by a Wnt-reporter assay. Functionally, CD133 kd cells did not modify their response to cisplatin, cyclosporine or hydrogen peroxide, suggesting that CD133 may not be involved in resistance to damage. At variance, in CD133 kd cells the sphere formation was slightly reduced, both in number and size. Interestingly CD133 kd cells showed an increased expression of β-galactocydase, a marker of senescence, compared to CD133+ cells, along with a telomere length shortening.

Conclusions: Our preliminary data suggest that CD133 may be involved in the maintenance of a stem-like phenotype in renal cells along with a delay of senescence.

The Effect of Wnt5a/Ca^{2+} Pathway on High-Glucose Induced Fibrosis of Human Peritoneal Mesothelial Cells Jin Liu, Jianfei Ma, Ye Hu, Linshan Jiao, Yichen Chen. *Nephrology, The First Affiliated Hospital of China Medical Univ, Shenyang, Liaoning, China.*

Background: Fibrosis is the main reason of ultrafiltration failure. Human Peritoneal Mesothelial Cells (HPMC) expresses wnt5a,which induces noncanonical wnt signaling pathway, Increase cytosolic free [Ca^{2+}] ,then dephosphorylation of nuclear factor of activated T-cells 2(NFAT2) translocate to nuclear.The wnt5a/Ca^{2+}/NFAT2 signaling pathway may be activated and necessary for the fibrosis of HPMC.

Methods: HPMC were cultured under normal glucose, high glucose(HG126mM) or BAPTA-AM (calcium chelator,BA for short) /HG for 24h,or BA for 2h,or different concentrations of HG (60 mM, 126 mM, 220 mM) for 24h,or HG126 mM for 0h,6h,12h,24h. Western Blot technique detects Wnt5a expression in cells and NFAT2 expression in nuclears, Nuclear translocation was observed by immunofluorescence microscopy.The Wnt5a mRNA was detected by RT-PCR.The expression of connective tissue growth factor(CTGF) was detected by Elisa.

Results: Western blot shows the expression of Wnt5a elevated in HG groups, which depended on concentration and action time.Wnt5a mRNA elevated in HG group in early stage, and in 48h it decreased.According to the results of Western blot and immunofluorescence in HPMC after HG treatment,NFAT2 translocated from cytoplasm to nucleus,NFAT2 increased in the nuclei by the dependence of action time and concentration of HG.Interestingly, in BA/HG group the expression of NFAT2 decreased in the nucleus,and in BA group there was no statistical significance controlled with normal glucose.The stimulation of HG increased CTGF, which depends on action time and concentration,and after join BA in HPMCS the expression of CTGF reduced.

Conclusions: The noncanonical wnt5a/Ca^{2+}/NFAT2 signaling pathway is activated by high glucose induced fibrosis of Human Peritoneal Mesothelial Cells,and inhibition of this pathway may contributed to the anti-fibrogenesis of HPMC,prolong the period of peritoneal dialysis.

The Serine Protease Hepsin Mediates Urinary Secretion and Polymerisation of Zona Pellucida Domain Protein Uromodulin Martina Brunati,[1] Simone Perucca,[1] Ling Han,[2] Celine Schaeffer,[1] Sara Santambrogio,[1] Eric Olinger,[3] Romain Perrier,[4] Marcel Bokhove,[2] Angela Bachi,[5] Edith Hummler,[4] Olivier Devuyst,[3] Qingyu Wu,[6] Luca Jovine,[2] Luca Rampoldi.[1] *[1]San Raffaele Scientific Inst, Milan, Italy; [2]Karolinska Inst, Stockholm, Sweden; [3]Univ of Zurich, Zurich, Switzerland; [4]Univ of Lausanne, Lausanne, Switzerland; [5]FIRC Inst of Molecular Oncology, Milan, Italy; [6]Lerner Research Inst, Cleveland.*

Background: Uromodulin is the most abundant protein in the urine. Genetic and functional evidence demonstrated that this protein, exclusively produced by renal epithelial cells, plays key roles in kidney function and disease. Uromodulin mainly exerts its function as an extracellular filamentous matrix whose assembly depends on a conserved, specific proteolytic cleavage leading to conformational activation of a Zona Pellucida (ZP) polymerisation domain. In this work we aimed at understanding the nature of such cleavage.

Methods: We used a comprehensive approach, ranging from biochemistry, molecular and cell biology in cells stably expressing uromodulin and in urine and kidney samples of relevant knock-out mice.

Results: Starting from the observation that uromodulin is uniquely cleaved at the urinary site and assembled into polymeric filaments in MDCK cells we demonstrate that physiological cleavage of uromodulin depends on a serine protease, and that this enzyme is likely membrane bound. Differential expression analysis in different cell models identified two candidate enzymes, hepsin and prostasin. Both interact with uromodulin, and could induce its specific cleavage in transfected cells and in vitro. Through gene silencing in

MDCK cells and extensive analysis of urinary uromodulin processing in vivo in hepsin and prostasin knock-out mice, we demonstrate that hepsin is the enzyme responsible for the physiological cleavage releasing urinary uromodulin.

Conclusions: Our findings define a key aspect of the biology of uromodulin that could pave the way for future studies on the regulation of its secretion. Given the similar function of the ZP domain and the high conservation of cleavage site in ZP domain proteins, our results are likely relevant for other members of this protein family.

TH-PO314

The Favorable Effect of AdipoRon on Diabetic Nephropathy through Improvement of Endothelial Dysfunction in *db/db* Mice Yaeni Kim, Ji Hee Lim, Min Young Kim, Hyung Wook Kim, Cheol Whee Park. *Div of Nephrology, Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Seoul, Republic of Korea.*

Background: Adiponectin is one of the numerous adipocyte-derived adipokines that interplays with others to exert the milieu of metabolic syndrome. It binds to adiponectin receptors (AdipoR), AdipoR1 and AdipoR2 and exhibits antidiabetic effects via activation of AMPK and PPAR-α. Orally active synthetic small-molecule AdipoR agonist, AdipoRon binds to both AdipoR and ameliorates obesity-related disease. Therefore, we investigated the possible role of AdipoRon in renal physiology in the view of prevention and development of diabetic nephropathy in diabetic mouse model.

Methods: Male *db/db* mice were fed a diet containing AdipoRon (30 mg/kg/day p.o. for 4 weeks from 17 to 20 weeks of age). Serum, urine and renal tissue were obtained to analyze for changes in metabolic parameters, molecular levels and renal structure.

Results: AdipoRon treatment showed decreased amount of albuminuria with no significant changes in the levels of serum adiponectin, glucose and creatinine and it seems to be weight neutral. Increased expressions of AdipoR1 in the renal cortex and consistent up-regulations of phosphorylated AMPK and PPAR-α level were associated with AdipoRon treatment. AdipoRon treatment showed favorable effects on diabetes-induced GBM thickening, foot process widening and slit diaphragm space narrowing and further decreased glomerular matrix expansions and inflammation.

Conclusions: Increased expressions of renal AdipoR1, not AdipoR2, indicates that renal injury may cause a compensatory up-regulation of relevant receptors in kidneys to mitigate further renal injury. AdipoRon may control oxidative stress in glomerulus through AMPK and PPAR-α activated pathways and further contribute to prevent deterioration of renal function. The protective role of AdipoRon against the development of albuminuria seems to occur through a direct action on podocytes independently of systemic effects of adiponectin. Its reduction of oxidative stress provides protection against albuminuria and podocyte damage thereby ameliorating endothelial dysfunction in diabetic nephropathy.

Diabetes-Induced Impairments in Slit-Robo Signaling Augment Glomerular Angiogenesis Darren A. Yuen,[1] Stephen G. Szeto,[1,2] Mingliang Lu,[1] Lauren Yuk-sum Chan,[1] Krystale A. De freitas,[1] Lisa Robinson,[3] Ahmad Mohammad Omar Sidiqi.[1,2] *[1]St. Michael's Hospital Keenan Research Centre for Biomedical Science, Toronto, ON, Canada; [2]Faculty of Medicine, Univ of Toronto, Toronto, ON, Canada; [3]The Hospital for Sick Children, Toronto, ON, Canada.*

Background: Diabetic nephropathy is characterized by glomerular endothelial cell (GEC) injury. One of the earliest manifestations of this injury is glomerular angiogenesis, a process that classically is thought of as being driven by increased glomerular VEGF production. Slit2 is a regulator of endothelial function, eliciting either pro- or anti-angiogenic effects through its Robo1 and Robo4 receptors, respectively. We have shown previously that glomerular endothelial Robo4 expression is downregulated by high glucose exposure, whereas Robo1 expression is unchanged. **Objectives:** To determine whether high glucose-induced alterations in Robo1 and Robo4 expression regulate VEGF-induced angiogenesis in the diabetic kidney.

Methods: GEC responsiveness to VEGF in angiogenesis assays was examined in both normal glucose (NG) and high glucose (HG) conditions, and following Robo1 knockdown. Using Robo4 knockout (KO) mice, the effect of Robo4 deficiency on diabetic glomerular angiogenesis was also analyzed using fluorescence microangiography (FMA) and PECAM-1 immunohistochemistry.

Results: As compared to GEC grown in NG medium, GEC grown in HG medium expressed lower levels of the anti-angiogenic Robo4 receptor, but not the pro-angiogenic Robo1 receptor, and exhibited greater VEGF responsiveness. Loss of Robo1 eliminated VEGF-induced GEC network formation and migration in both normal and high glucose conditions. In contrast, Robo4 deficiency was associated with enhanced PECAM-1 density and glomerular capillary length in Robo4 KO mice (compared to their WT littermates) after 4 weeks of STZ-induced diabetes.

Conclusions: Our observations suggest that diabetic glomerular angiogenesis is driven not only by enhanced VEGF production, but also by enhanced glomerular endothelial VEGF responsiveness. Our data also suggest that this increased responsiveness is promoted by a shift in glomerular endothelial Slit2-Robo signalling, favouring more pro-angiogenic Robo1, and less anti-angiogenic Robo4 activity.

Funding: Government Support - Non-U.S.

Dynamic Regulation of Endothelial Specific Molecule 1 in Diabetic Mouse Kidney Xiaoyi Zheng,[1] Fariborz Soroush,[2] Sanchita Bhattacharya,[3] Mohammad F. Kiani,[2] Vivek Bhalla.[1] *[1]Div of Nephrology, School of Medicine, Stanford Univ, Stanford, CA; [2]Dept of Mechanical Engineering, College of Engineering, Temple Univ, Philadelphia, PA; [3]Dept of Pediatrics, School of Medicine, UC San Francisco, San Francisco, CA.*

Background: Performing glomerular gene expression profiling in diabetic mouse models with differential susceptibility to nephropathy (DN), we identify endothelial specific molecule 1 (Esm-1), as a novel candidate gene in the development of DN.

Methods: We studied Esm-1 function using a bioinspired microfluidic assay (bMFA) and Esm-1 expression by qPCR and ELISA in diabetic and non-diabetic mice.

Results: Esm-1 is proposed to disrupt LFA-1: ICAM-1 interactions at the leukocyte: endothelial cell interface, and leukocyte infiltration into glomeruli is a known risk factor for DN. In a bMFA, pre-treatment of leukocytes with Esm-1 inhibits rolling and transmigration in a dose-dependent manner. Consistent with the diminution of leukocyte infiltration, 4 weeks after induction of diabetes, Esm-1 mRNA is markedly attenuated in glomeruli from DN-susceptible, DBA/2J, compared to DN-resistant, C57BL/6J, mice (relative fold: 0.085 ± 0.012, $p<0.05$). Secretion of Esm-1 is also lower from glomeruli of DN-susceptible mice (132.6 ± 41.6 vs 226.4 ± 79.3 pg/mL, $p<0.05$). These changes occurred in the background of a dynamic response of kidney Esm-1 to diabetes. Urine Esm-1 excretion increases in diabetic vs. non-diabetic mice (307.7 ± 51.6 vs 102.3 ± 29.7 pg/mg creatinine, $p<0.05$), despite no increase in urine albumin and a ~50% decrease in circulating Esm-1 in diabetic mice. Further *in vitro* studies in cultured glomeruli show that hyperglycemia significantly increases Esm-1 mRNA and protein and suggest that urine Esm-1 reflects increased production by glomeruli.

Conclusions: These results demonstrate that diabetes induces Esm-1 in glomeruli, and this induction is attenuated in DN-susceptible mice. These data suggest that increased production of glomerular Esm-1 would be sufficient to attenuate leukocyte infiltration and consequently, DN. Furthermore, we propose urine Esm-1 as a non-invasive candidate biomarker for resistance to DN.

TH-PO317

Activation of Rho/Rho-Kinase Pathway in Proximal Tubules as a Culprit in Obesity-Related Nephropathy Makiko Naitoh, Hirobumi Tokuyama, Koji Futatsugi, Shu Wakino, Hiroshi Itoh. *Keio Univ, Tokyo, Japan.*

Background: A small GTP-binding protein, Rho, and its effector, Rho-kinase, have several pathological functions. We previously demonstrated that in obesity adipocyte cellular hypertrophy activates Rho/Rho-kinase signaling through mechanical stretch, leading to inflammatory changes(Science signaling, 2011).We have also documented enlarged and vacuolated proximal tubules (PT) in obesity-related kidney damage (Int J Obesity, 2012). We examined whether Rho/Rho-kinase was activated in enlarged PT that were supposed to be under the mechanical stress and contributed to the pathophysiology of obesity-induced kidney damages.

Methods: We created mice that overexpressed dominant negative RhoA genes specifically in PT under the control of promoter of sodium-phosphate co-transporter (PT-DN-RhoA TG). PT-DN-RhoA TG mice (DN) and their wild-type littermates (WT) were fed a high fat (HFD) or low fat diet (LFD) for 12 weeks and compared in phenotypes.

Results: WT on HFD not only developed obesity but also manifested histological changes, including the enlargement in PT as well as in glomeruli, vacuolation of PT, the infiltration of inflammatory cells and the overexpression of stress fibers, which paralleled the increase in urinary albumin and NGAL of tubular injury markers. Enhanced Rho-kinase activity was noted particularly in PT. Inflammatory cytokines were subsequently overexpressed in WT on HFD as compared with those in WT on LFD. In DN, the activation of Rho kinase was attenuated in PT region leading to the decrease in the size, vacuolation and stress fiber formation in PT cell, the decrease in inflammatory cells infiltration and cytokine expressions, and the reduction in albuminuria and PT impairment.

Conclusions: Excess fat intake causes obesity-induced renal injury, which are mediated by an Rho/Rho-kinase activation in PT and inflammatory process. It is surmised that hypertrophic process in PT during obesity formation affects Rho-kinase activation presumably through mechanical stress. This process subsequently induces inflammation and accelerates the histological changes of PT. The intervention of Rho/Rho-kinase may constitute a novel strategy blocking the progression of obesity-induced renal damages.

TH-PO318

SUL121: A Novel Compound Preserving Endothelial Function and Inhibiting Progression of Kidney Damage in Type 2 Diabetes Mellitus in Mice Leo E. Deelman, Sebastiaan Lambooy, Arash Bidadkosh, Hendrik Buikema, Robert H. Henning. *Clinical Pharmacy and Pharmacology, Univ Medical Center Groningen, Univ of Groningen, Groningen, Netherlands.*

Background: Diabetic nephropathy is a common complication of Type 2 Diabetes mellitus (T2DM), a chronic metabolic disorder with increasing incidence worldwide. To stop the progression of diabetic kidney disease, new strategies are urgently needed. Endothelial dysfunction (ED) and reactive oxygen species (ROS) are important targets for novel therapies to stop diabetic nephropathy. To improve ED and inhibit ROS, we recently developed the compound SUL121, a putative hydrogen sulfide (H_2S) inducer and inhibitor of ROS.

Methods: To test the therapeutic effects of SUL121 in diabetic and normal mice, db/db mice and lean control mice were subcutaneously implanted with osmotic mini pumps delivering SUL121 or vehicle from age 10 to 18 weeks. Mice were placed in metabolic cages every two weeks until termination at which time endothelial mediated relaxation in aortic rings was assessed. ROS status and H_2S levels were measured in plasma, and renal expression of H_2S producing enzymes was determined.

Results: While treatment with SUL121 did not alter the glycemic state in db/db, it prevented albuminuria and diabetic kidney damage, as evidenced by an inhibition of the progression of albumin excretion rate, lower albumin creatinine ratio, decreased focal glomerular sclerosis score and normalization of kidney weight. In addition, SUL121 normalized systemic ROS formation, increased renal expression of the H_2S producing enzymes, cystathionine gamma lyase and cystathionine beta synthase (CSE and CBS), and prevented the development of endothelial dysfunction in db/db. SUL121 treatment in lean control mice demonstrated no observable side-effects, indicating that SUL121 is well tolerated.

Conclusions: Thus, SUL121 represents a novel compound inhibiting the progression of experimental diabetic kidney damage via a mechanism that inhibits both oxidative stress and preserves vasorelaxation.

Coagulation Factor Xa and Protease-Activated Receptor 2 as Novel Targets for Treating Diabetic Nephropathy Yuji Oe,[1] Emiko Sato,[1,2] Hiroshi Sato,[1,2] Sadayoshi Ito,[1] Nobuyuki Takahashi.[1,2] *[1]Div of Nephrology, Endocrinology, and Vascular Medicine, Tohoku Univ Graduate School of Medicine, Sendai, Japan; [2]Div of Clinical Pharmacology and Therapeutics, Tohoku Univ Graduate School of Pharmaceutical Sciences, Sendai, Japan.*

Background: Role of hypercoagulability in pathogenesis of diabetic nephropathy (DN) remains elusive. We have recently demonstrated that elevated coagulation factor III (tissue factor) exacerbates DN (J Thromb Haemost 2010, PNAS 2011). Tissue factor activates factor X (FXa), which in turn stimulates protease-activated receptor 2 (PAR2). PAR2 causes inflammation and fibrosis. Accordingly, we hypothesized that activation of FXa- PAR2 signaling exacerbates DN.

Methods: To test this hypothesis, we used diabetic mice with reduced expression of endothelial NO synthase (*Nos3)* as a model of DN. We first tested whether inhibiting FXa ameliorates DN by administering an oral FXa inhibitor Edoxaban (50 mg/kg/day) for 3 months to diabetic mice lacking eNOS ($Ins2^{Akita/+}$; $Nos3^{-/-}$). We next tested whether lack of PAR2 ameliorates DN using diabetic mice lacking PAR2 ($F2rl1^{-/-}$; $Ins2^{Akita/+}$; $Nos3^{+/-}$). Finally, the effects of FXa or PAR2 agonist (SLIGKV) on human endothelial cells (EA. hy926) and conditionally immortalized murine podocytes were evaluated.

Results: Renal expression of FX and PAR2 was up-regulated in DN, together with elevation of FXa activity in the urine. Edoxaban and lack of PAR2 both reduced renal expression of inflammatory and profibrotic genes, and ameliorated diabetic glomerulosclerosis and urinary albumin excretion. FXa or a PAR2 agonist (SLIGKV) increased IL-8 secretion and gene expression of *MCP1* and *PAI1* in human endothelial cells. These treatments also increased *Mcp1* mRNA level in murine podocytes.

Conclusions: We conclude that FXa - PAR2 signaling exacerbates DN possibly through up-regulating inflammatory response. FXa - PAR2 signaling is a promising target for treating or preventing DN.

Herniation of the Mesangium Together with Sprouting of Blood Vessels Out of the Glomerular Entrance Is a frequent Feature of Diabetic Nephropathy Wilhelm Kriz, Jana Loewen. *Anatomy, Univ of Heidelberg, Medical Faculty Mannheim, Mannheim, Germany.*

Background: In contrast to diabetic retinopathy, where neovascularizations have a central pathogenetic impact, in diabetic nephropathy (DN) angio-proliferative processes are generally not considered as a major factor underlying disease progression. The studies by Osterby and Nyberg (J Diab Compl 1987, 1:122) and Min and Yamanaka (Virchows Arch A Pathol Anat 1993, 423:201) have shown neovascularizations in DN but have found little attention.

Methods: Re-evaluation of biopsies of DN (archive: Dep. of Molecular Pathology, German Cancer Research Center, Heidelberg) has revealed that the proliferation of newly formed blood vessels out of the glomerular entrance into the surroundings of the glomerulus is a frequent feature in DN.

Results: In a total of 437 biopsies (so far evaluated) 60.2% contained aberrant vessels at the vascular pole or in periglomerular position. 13% of these cases were associated with diffuse mesangial sclerosis (DMS), 35% with transitional stages from DMS to nodular sclerosis (NS) and 52% with NS. The outgrowth is based on extensive widening of the glomerular entrance accompanied by herniation of the expanded mesangium with displacement of the extraglomerular mesangium and the macula densa. The aberrant vessels spread into glomerular surroundings, preferentially along the outer aspect of Bowman's capsule finally draining into peritubular capillaries. These vessels mostly have the structure of small arterioles. Frequently, almost regularly, accumulations of exudative material are encountered beneath the endothelium or within the layer of smooth muscle cells.

Conclusions: It is suggested that the exposure of mesangial areas to environmental stimuli accounts for the angio-proliferations. As derivatives from glomerular capillaries the aberrant vessels are likely perfused under high pressure accounting for the exudative lesions. The periglomerular matrix and fibrotic envelopes frequently seen in DN (in 69.6% in our material) seem to emerge in response to exudations and possibly other stimuli from the aberrant vessel. The encroachment of these processes along the transition to the tubule likely contributes to the tubulo-interstitial disease.

TH-PO321

Exploiting Angiopoietin-Tie Signaling for Treatment of Diabetic Nephropathy Tomokazu Souma,[1] Isabel Anna Carota,[1] Benjamin R. Thomson,[1] Jing Jin,[1] Susan E. Quaggin.[1] *[1]Div of Nephrology/Hypertension, Feinberg Cardiovascular Research Inst, Feinberg School of Medicine, Northwestern Univ, Chicago, IL; [2]Aerpio Therapeutics, Cincinnati, OH.*

Background: Diabetic nephropathy (DN) is the leading cause of end-stage renal disease in the US, and is characterized by microvascular dysfunction. The Angiopoietin-Tie signaling pathway plays a key role in endothelial health and survival. The endothelial Tie2 receptor tyrosine kinase becomes activated upon binding its endogenous ligand Angiopoietin1 (ANGPT1). This activity elicits a cascade of intracellular signaling events, leading to junctional reinforcement and vasculo-protection. VE-PTP is a Tie2 selective phosphatase, which negatively modulates Tie2 signaling intensity. Here we tested whether augmentation of Tie2 signaling by VE-PTP inhibition protects against DN.

Methods: To test the therapeutic potential of Tie2 activation, we treated $Ins2^{Akita}$ DBA/2J Mice with a VE-PTP inhibitor (AKB-9785, Aerpio) or vehicle control (n=8 in each group). In parallel, cell-based analyses were performed to elucidate ANGPT-Tie signaling events. The role of VE-PTP on the phosphorylation status of Tie2 expressed in HEK293 cells was determined by LC-tandem mass spectrometry (LC-MS/MS).

Results: 17-week treatment of AKB-9785 improved the general status of $Ins2^{Akita}$ mice (body weight change from baseline; vehicle +15%, AKB-9785 +35%, $P<0.01$). Further, AKB-9785 preserved mGFR of $Ins2^{Akita}$ mice (vehicle 560 ml/min, AKB-9785 945 ml/min with 6-week daily treatment, $P<0.067$). LC-MS/MS identified 13 phospho-tyrosine residues in Tie2; all sites were dephosphorylated by VE-PTP co-expression. Treatment with either recombinant Angpt1 or AKB-9785 rapidly induced Tie2 phosphorylation, suggesting Tie2 can be activated in a ligand-independent fashion. Administration of AKB-9785 to Angpt1 KO mice confirmed ligand-independent Tie2 activation occurs *in vivo*.

Conclusions: Our data suggest that the small molecule inhibitor, AKB-9785 is a potent activator of Tie2 phosphorylation, has positive effects in a preclinical rodent model of Type I diabetes and is an attractive therapeutic candidate for DN.

TH-PO322

Berberine Ameliorate High Glucose and Advanced Glycation End Products Induced Glomerular Endothelial Cell Hyperpermeability Nanmei Liu. *Jimin Hospital of Shanghai.*

Background: Glomerular endothelial cells (GEnC) are important part of the glomerular filtration barrier. The dysfunction of glomerular endothelial cells (GEnCs) could be a characteristic of early stage diabetic nephropathy (DN). Accumulating evidence indicate that advanced glycation end products (AGEs) play a pivotal role in the progressive of glomerulosclerosis or thickening of the glomerular basement membrane in DN. Berbine, an extracts from some Chinese plant medicine such as Huanglian Letasiova S(Rhizoma coptidis); Huangbai (cortex phellodendri), Gold Seal (hydrastis canadensis), was reported lower blood sugar and attenuated diabetic nephropathy, but the mechanism still need verified. This study was to investigate the changes of monolayer permeability in GEnCs caused by high concentration glucose and AGEs, and the effects of Berbine.

Methods: GEnCs were cultured in growth medium causing cell proliferation, then seed in a Transwell chamber culture system to form confluent monolayer. The cell was treated with ordinary glucose (5.5mM), or high glucose (25mM), AGE 100mg / mL, berberine (3uM) inspectively. The GENC permeability was evaluated by measuring the diffusion of biotin-conjugated bovine serum albumin (biotin-BSA) across a cell monolayer. The changes of cytoskeleton was obsearved under Confocal laser scanning fluorescence microscopy after double staining of F-actin and G-actin.

Results: The protein leakage rate was increased slightly after treated with high glucose (25mM), but increased significantly in high glucose plus AGE 100mg/mL compared with low glucose control group. High glucose and AGE strongly affected orientation of F-actin fibers, induced rearrangement of F-actin fibers. While berberine intervention can reduce protein leakage rate ($P<0.05$), improved the F-actin cytoskeletal actin disorder significantly.

Conclusions: High glucose and AGE increased permeability of the GEnC monolayer and leads to long-term alterations of F-actin structures. Berberine has a protective effect. The mechanism may be related to inhibit endoplasmic reticulum stress and reduce the cytoskeleton injury.

Arginase Inhibition: A New Treatment for Preventing Progression of Established Diabetic Nephropathy Hanning You,[1] Ting Gao,[1] Timothy K. Cooper,[2] Sidney M. Morris,[3] Alaa S. Awad.[1] *[1]Medicine, Penn State Univ College of Medicine, Hershey, PA; [2]Comparative Medicine, Penn State Univ College of Medicine, Hershey, PA; [3]Microbiology and Molecular Genetics, Univ of Pittsburgh, Pittsburgh, PA.*

Background: Our previous publication showed that inhibition of arginase prevents the development of diabetic nephropathy (DN). However, identification of targets that retard the progression of established DN--which is more clinically relevant--is lacking. Therefore, we tested the hypothesis that arginase inhibition would prevent the progression of established DN. Effects of arginase inhibition were compared to treatment with the ACE inhibitor captopril, a current standard of care in DN.

Methods: Experiments were conducted in *Ins2^{Akita}* mice treated with the arginase inhibitor S-(2-boronoethyl)-L-cysteine (BEC) or captopril starting at 6 wks of age for 12 wks (early treatment) or starting at 12 wks of age for 6 wks (late treatment).

Results: Early and late treatment with BEC resulted in protection from DN as indicated by reduced albuminuria, histological changes, kidney macrophage infiltration, urinary TBARS, and restored nephrin expression, kidney nitrate/nitrite, kidney eNOS phosphorylation, and renal medullary blood flow compared with vehicle-treated *Ins2^{Akita}* mice at 18 wks of age. Interestingly, early treatment with captopril reduced albuminuria, histological changes, and kidney macrophage infiltration without affecting the other parameters, but late treatment with captopril was ineffective.

Conclusions: These findings highlight the importance of arginase inhibition as a new potential therapeutic intervention in both early and late stages of diabetic renal injury.

Transgenic TGF-β1 Receptor Type II (TbRII) Overexpression in Podocytes Promotes STZ Induced Diabetic Nephropathy in Rats Sigrid C. Hoffmann, Stamatia Matina Papagiannarou, Wilhelm Kriz, Tamara Micakovic. *Medical Faculty Mannheim, Univ Heidelberg, Mannheim, Germany.*

Background: Glomerular TGF-β1 is increased early in the course of diabetic nephropathy. The podocytes are sources and targets of TGF-β1. This study addresses the hypothesis that increased TGF-β1 in diabetic rats stimulates the development of diabetic nephropathy via selective signalling in podocytes.

Methods: Transgenic rats carrying the TGRTβRII driven by the podocin promoter were generated. Transgene expression was verified by Northern blotting, in-situ hybridization and Western blotting. Glomerular expression profiling was performed by real time RT-PCR, Western blotting and immunohistochemistry. Podocyte density was determined by counting WT-1 stained podocytes per glomerular area, which was determined morphometrically in 200 glomeruli per rat. At 2 months of age rats received STZ (40mg/kg i.v.) or diluent, respectively. Body weight and kidney function were evaluated by urinary albumin excretion in the 24h-urine and by creatinine clearance at monthly intervals.

Results: TGR expressed the transgenic receptor specifically in podocytes. Glomerular TbRII protein levels were almost twice that of WT. At 5 months of age 40 % of TGR exhibited moderately increased albumin excretion up to 2.2 mg/24hr vs. 0.11 mg/24hr in WT. 3 months after STZ, albumin excretion was significantly increased in 80% of TGR with an average of 4 mg/24hr (max: 7.3) but only slightly elevated in 40% of the WT with in average 0.7mg/24hr (max: 2.2). Expression profiling in isolated glomeruli revealed that in TGR PAI-1 was significantly upregulated and the survival marker blc-2 and podocyte differentiation marker synaptopodin, podocin and nephrin were significantly down-regulated relative to WT. Podocyte number per glomerulus was significantly decreased in diabetic TGR vs. diabetic WT.

Conclusions: Podocyte-selective TbRII-overexpression contributes to the leakage of the glomerular filter in the course of STZ induced diabetic nephropathy which might be mediated by podocyte loss due to podocyte dedifferentiation, downregulation of bcl-2 and PAI-1 upregulation.

Comparison of Glomerular and Podocyte mRNA Profiles in eNOS$^{-/-}$ Diabetic Mice Induced by Streptozotocin Jia Fu,[1,2] Chengguo Wei,[2] Kim Lee,[2] Weijia Zhang,[2] Peter Y. Chuang,[2] Zhihong Liu,[1] John C. He.[2,3] *[1]National Clinical Research Center of Kidney Diseases, Jinling Hospital; Nanjing Univ School of Medicine, Nan Jing, Jiangsu, China; [2]Div of Nephrology, Dept of Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [3]Renal Program, James J Peters VA Medical Center at Bronx, New York, NY.*

Background: Gene expression profiles have never been reported in primary podocytes isolated from the diabetic kidney. Here, we compared mRNA profiles in both isolated glomeruli and sorted podocytes between diabetic and control mice.

Methods: IRG mice carrying a two-color fluorescent reporter gene were first crossed with eNOS$^{-/-}$ mice and then with podocin-rTTA and TetON-Cre mice allowing us to permanently label podocytes. Then, mice were injected with either streptozotocin (STZ-eNOS$^{-/-}$) or vehicle (CL-eNOS$^{-/-}$). STZ-eNOS$^{-/-}$ mice developed typical findings of diabetic nephropathy at 10 weeks after STZ injection. mRNA sequencing was performed in both isolated glomeruli and sorted podocytes from STZ-eNOS$^{-/-}$ and CL-eNOS$^{-/-}$ mice.

Results: Consistent with the previous reports, expression of podocyte-specific markers in the glomeruli were down-regulated in the STZ-eNOS$^{-/-}$ mice compared to CL-eNOS$^{-/-}$ mice. However, these differences disappeared when mRNA levels were corrected for podocyte number/glomerulus. Interestingly, expression of these markers in sorted podocytes did not differ between diabetic and non-diabetic mice. These data suggest that reduced expression of podocyte markers in isolated glomeruli is likely secondary to reduced podocyte number/glomerulus, rather than loss of differentiation markers. Analysis of the differentially expressed genes (DEGs) between diabetic and non-diabetic mice revealed distinct pathways between glomeruli and podocytes. The up-regulated DEGs in isolated glomeruli were involved mostly in the regulation of mitochondrial function and oxidative stress pathway, while the up-regulated DEGs in sorted podocytes were heavily involved in the actin organization.

Conclusions: In conclusion, our data suggest that podocyte-specific gene expression in transcriptome obtained from glomeruli may not represent those of podocytes in diabetic kidney.

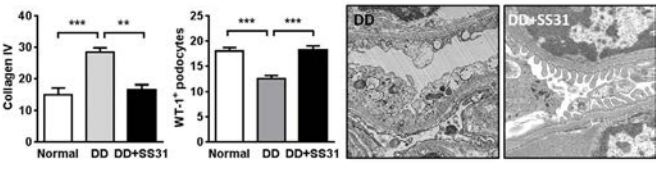
TH-PO326

SS-31, a Mitochondrial Therapeutic, Prevents High Fat Diet-Induced Podocyte Injury Hazel H. Szeto, Shaoyi Liu, Yi Soong, Nazia Alam, Glen T. Prusky, Surya V. Seshan. *Pharmacology, Physiology, Pathology, Weill Cornell Medical College, New York, NY.*

Background: High fat diet (HFD) leads to rapid onset of microalbuminuria and podocyte injury that precedes the onset of insulin resistance and hyperglycemia in mice. It was recently suggested that glomerular injury is triggered by palmitate-induced mitochondrial dysfunction in podocytes (Sun et al., Kidney Int, 2015). We investigated the protective effects of SS-31, a mitochondrial therapeutic, against HFD-induced podocyte injury in mice.

Methods: 4 week-old C57BL/6 mice were fed normal diet (ND) or HFD for 28 weeks. 4 weeks later, HFD mice received streptozotocin (40 mg/kg, qd x 5d). Body weight (BW), blood glucose (BG) and glucose tolerance tests (GTT) were determined after 8 and 24 weeks of HFD. SS-31 (2 mg/kg, sc) or saline was administered to HFD mice daily starting at 8 weeks. Kidneys were harvested at 28 weeks for histopathology.

Results: GTT was abnormal at 8 weeks despite no change in BW or BG. BW and BG were significantly increased at 28 weeks. Histological examination revealed mesangial expansion, thickening of the glomerular basement membrane, elevated collagen-IV, and loss of podocyte markers (podocin and synaptopodin). Electron microscopy revealed extensive vacuolization and swelling in podocytes, with swollen mitochondria, autophagic vacuoles, and loss of foot processes. TGFβ, TNFα and MCP-1 were all significantly increased. Treatment with SS-31 significantly prevented these HFD-induced pathological changes in the glomeruli without affecting BW, BG or GTT.



Conclusions: These results suggest that SS-31 can protect podocytes against HFD-induced mitochondrial toxicity without changing BW, insulin resistance or hyperglycemia. SS-31 (Bendavia™), currently in clinical trials for acute kidney injury, may be useful in the treatment of diabetic nephropathy.

Tristetraprolin Overexpression Ameliorated Inflammation in db/db Mice and Mouse Podocytes Guo Jia, Zhangsuo Liu. *The First Affiliated Hospital of Zhengzhou Univ, Zhengzhou, Henan, China.*

Background: Tristetraprolin(TTP)isawell-characterized,zincfinger-containing, RNA-binding protein.,which plays a role in the regulation of inflammatory factors expression by targeting the 3'untranslated region (3'UTR).We investigated whether TTP modulates inflammation in high glucose induced-podocytes and in db/db mice kidneys.

Methods: Differentiated mouse podocytes were treated by high glucose,and TTP expression and inflammatory factors was measured by quantitative real-time PCR, western blot or ELISA. TTP siRNA or lentiviral vectors containing TTP sequences were transfected into podocytes to down-regulate or up-regulate TTP expression.Db/db mice were used as the diabetic model in the in vivo experiment. At the age of 10 weeks,db/db mice were injected via tail vein with lentiviral vectors containing TTP sequences.At the age of 14 weeks,the lentivirus injection was repeated.Inflammatory factors and podocyte makers were examined in both podocytes and mice kidneys.Urine albumin to creatinine ratio and serum creatinine was also detected.

Results: TTP was down-regulated while IL-6,IL-18,TNF-awere up-regulated in high glucose-induced mouse podocytes.Silencing TTP by siRNA induced inflammatory factors expression.Overexpression of TTP reduced the expression of inflammatory factors in high glucose-induced podocytes.TTP expression was significantly decreased in db/db mice

kidneys compared with db/m mice.Overexpession of TTP by lentivirus injection ameliorated inflammation in db/db mice.Urine albumin to creatinine ratio and urine inflammatory factors was also decreased in db/db mice overexpressing TTP.

Conclusions: TTP is involved in the regulation of inflammation in diabetic conditions. Targeting TTP might be effective in diabetic kidney disease.

CIN85 Deficiency Prevents Nephrin Endocytosis in Podocytes Under Diabetic Conditions Beina Teng, Hermann G. Haller, Mario Schiffer. *Medical School Hannover, Hannover, Germany.*

Background: Podocytes are important for the maintenance of the glomerular filter in the kidney. Podocyte damage is associated with ultrastructural changes and decreased expression of components of the slit diaphragm in many glomerular diseases. Nephrin, a podocyte specific protein is crucial for the intact filtration barrier. Loss of nephrin has been observed in rodent models of experimental diabetes as well as in human diabetic kidney disease. CIN85, a homologue of CD2AP, was identified as a binding partner of nephrin and mediates the nephrin endocytosis via ubiquitination in podocytes.

Methods: Using STZ injection, we induced a type I diabetes in BLC57/N wild type and CIN85Dex2 mice to examine diabetes induced dysregulation of glomerular filtration barrier and alteration of extracellular matrix. We then generated immortalized cell lines of podocytes for the CIN85Dex2 and the CD2AP-/- to examine nephrin endocytosis in both cell types on the molecular level. To inquire the impact of CIN85 and CD2AP on filtration barrier integrity in zebrafish, we examined proteinuria in zebrafish injected with capped mRNAs.

Results: We can demonstrate that the loss of nephrin expression and onset of the proteinuria in diabetic mice correlates with an increased accumulation of ubiquitinated proteins and expression of CIN85 in podocytes. The CIN85Dex2 deficiency leads to preserved nephrin surface expression, reduced proteinuria and Collagen-IV deposition in glomeruli under diabetic conditions. High glucose levels induced an increased CIN85 expression in contrast to a significantly reduced expression of CD2AP and nephrin in both murine and human podocytes. Furthermore, by high glucose stimulation, the CD2AP-/- podocytes, which express more full-length CIN85, showed an increased nephrin endocytosis compared to the CIN85 knockout podocytes. In addition, injection of capped CIN85 mRNA induced a servere edema and proteinuria in zebrafish embryos which could be rescued by co-injection of CD2AP mRNA.

Conclusions: Our findings suggest that CIN85 is involved in the endocytosis of nephrin in podocytes under diabetic conditions promoting the development of glomerulopathy. Therefore CIN85 might be a novel treatment target to preventdiabetic nephropathy.

TH-PO329

Atrasentan Ameliorates Diabetic Nephropathy and Restores Podocyte Number in BTBR*ob/ob* Mice Kelly L. Hudkins, Tomasz A. Wietecha, Floortje Steegh, Kristina M. Sorg, Noppanit Pattanachaiwit, Minseob Eom, Julia K. Shankland, Charles E. Alpers. *Pathology, Univ of Washington, Seattle, WA.*

Background: Leptin deficient BTBR*ob/ob* mice develop type 2 diabetes and DN that closely mimics human DN, including mesangial expansion, podocyte loss, and proteinuria. This study tested the effect of atrasentan (A), an endothelin-1 receptor antagonist, with or without concurrent RAAS inhibition by losartan (L) on DN and whether this can restore podocyte number.

Methods: Cohorts of 18 week old BTBR*ob/ob* mice and BTBR WT littermates were treated via drinking water with A (5 mg/kg/day), A plus L (25 mg/kg/day) or normal water for 6 weeks. Mice were analyzed for body weight, blood glucose, serum creatinine, proteinuria and morphometric measures of numbers of p57 expressing podocytes, collagen IV staining mesangial matrix.

Results: Treatment with A alone had no effect on body weight or blood glucose. Combined treatment with A and L also had no effect on body weight, but significantly decreased blood glucose levels in both BTBR WT (243 + 14.8 vs 160 + 5.6, $p<0.005$) and BTBR*ob/ob* (595 + 5.3 vs 382 + 51.5, $p<0.01$) mice. Treatment with A and combined A and L decreased proteinuria in BTBR*ob/ob* mice, although this did not reach statistical significance due to wide variations within the groups. Serum creatinine was elevated in BTBR*ob/ob* compared to WT mice, and was decreased by treatment with A plus L ($p<0.05$). Mesangial collagen IV was reduced in both the A and A plus L treated mice ($p<0.05$). There were decreased podocytes (p57 expressing cells) in BTBR*ob/ob* (149.7 + 6.7) compared to WT mice (188.7 + 9, $p<0.05$). Podocytes increased in BTBR*ob/ob* mice receiving A (167.0 + 7, ns, $p=0.093$) and were restored to WT numbers in mice receiving A plus L (190.4 + 5.7, $p< 0.001$).

Conclusions: Treatment with A plus L significantly increased podocyte number in diabetic BTBR*ob/ob* mice. A treatment alone increased podocyte number, but to a lesser degree. Podocyte restoration correlated with decreased blood glucose, serum creatinine, and mesangial matrix with A plus L treatment. The benefit of combined A and L treatment in patients with DN may occur in part through a previously unrecognized restoration of podocytes.

TH-PO330

Insulin Signaling in Glomeruli and Podocytes from Insulin Resistant db/db DBA/2J Mice Mette Viberg Østergaard,[1,2] Jesper Worm,[1] Lisbeth N. Fink,[1] Richard Coward.[2] *[1]Global Research, Novo Nordisk A/S, Maaloev, Denmark; [2]Academic Renal Unit, Univ of Bristol, Bristol, United Kingdom.*

Background: Impaired insulin signalling in the podocyte may contribute to the glomerular pathology in systemic insulin resistance and type 2 diabetes (T2D). We hypothesize that insulin signalling in the podocyte is altered early during development of insulin resistance and T2D due to altered insulin receptor (IR), IGF-1 receptor (IGF-1R) or insulin/IGF-1 hybrid receptor (HR) expression levels.

Methods: The development of insulin resistance, T2D, albuminuria, and renal pathology was characterised in db/db DBA/2J mice and wild-type (wt) littermates from 6 weeks of age. Insulin-induced phospho-Akt, phospho-ERK1/2 signalling, and IR, IGF-1R and HR expression levels were investigated in the glomeruli of insulin resistant db/db DBA/2J mice. The PodCre,ROSA$^{mT/mG}$ reporter strain enriched in the DBA/2J background is crossed with the db/db DBA/2J strain to enable isolation of insulin resistant GFP^{+} podocytes by FACS and characterisation of podocyte IR, IGF-1R and HR expression levels.

Results: The body weight was >50% higher in db/db vs. wt mice ($P<0.001$) from 8 weeks. From week 9, db/db males were hyperglycaemic with non-fasting blood glucose ranging from 23.4-30.7 mM (wt range 6.3-7.7 mM; $P<0.05$). Insulin tolerance tests showed development of whole-body insulin resistance by 8 weeks in male and female db/db vs. wt mice ($P<0.05$). The urinary albumin-to-creatinine ratio was elevated in db/db vs. wt mice from 7-12 weeks of ages (range of means 2451-9597 vs. 75-479 µg/mg; $P<0.01$). GFP^{+} podocytes were successfully isolated from glomerular single cell suspensions from PodCre,ROSA$^{mT/mG}$ mice and their purity validated by qPCR analysis of *Nphs2*, *Pecam1*, and *Pdgfrb*. Podocytes are currently being isolated from 9-week-old insulin resistant db/db PodCre,ROSA$^{mT/mG}$ DBA/2J mice to characterise IR, IGF-1R and HR expression levels.

Conclusions: The db/db mouse in the DBA/2J background show early signs of systemic insulin resistance and glomerular disease. Isolating podocytes from this model will allow us to further clarify the roles of IR, IGF-1R and HR in podocytes during the development of insulin resistance and diabetic nephropathy.

PKC-α Triggers EGFR Ubiquitination, Endocytosis and MAPK/ERK Activation in Podocytes with High Glucose Stimulation Hua Su, Yanhong Wei, Chun Zhang. *Nephrology, Huazhong Univ of Science and Technology, Wuhan, Hubei, China.*

Background: PKCα and EGFR are both involved in diabetic kidney disease, however the association between these two proteins during high glucose induced podocyte injury is unclear.

Methods: Diabetes was induced in SD rats by a single intra-peritoneal injection of STZ at a dose of 55 mg/kg body weight in sodium citrate buffer. 14 days later the rats were sacrificed and the cortex of kidney was removed and subjected to plasma membrane isolation and lipid raft fraction. In vitro study human podocyte cell line was employed, and after differentiation it was treated with high glucose or osmotic control for 24 h. The membranous protein expression and endocytosis were assessed by biotinylation and MesNa treatment. Gö6976 and PYR-41 were used as an inhibitor for PKCα and ubiquitin activating E1 enzyme respectively.

Results: By plasma membrane isolation and lipid raft separation we identified that in diabetic rat the abundance of PKCα in membranous fraction and lipid raft domain was elevated, whereas EGFR level was reduced in abovementioned compartments. Consistently, in vitro high glucose treated podocyte the membranous EGFR was downregulated accompanying with the increased membranous PKCα expression which was examined by biotinylation and plasma membrane isolation. Furthermore by immunoprecipitation, biotinylation and MesNa treatment experiments it showed that the ubiquitination and endocytosis of EGFR were enhanced in podocyte under high glucose stimulation which accompanied with MAPK/ERK signaling activation and the injury of podocyte which was proved by the reorganization of F-actin fibers and increased desmin level. However above processes could be ameliorated by either PKCα or ubiquitin activating E1 enzyme inhibitor.

Conclusions: Our observations demonstrate that in high glucose treated podocyte PKCα mediates EGFR ubiquitination, endocytosis from cell plasma membrane and eventually leads to the activation of MAPK/ERK signaling pathway which partially attributes to podocyte injury in diabetic kidney disease.

Activation of Protein Kinase C-β in the Podocyte by Diabetes-Associated Inflammatory Mediators Brad Dieter,[1] Rick L. Meek,[1] Robert J. Anderberg,[1] Sheryl K. Cooney,[1] Katherine R. Tuttle.[1,2] *[1]Providence Health Care, Spokane, WA; [2]School of Medicine, Univ of Washington, Seattle, WA.*

Background: Activation of protein kinase C-beta (PKC-β) is a key signal transduction mediator strongly implicated in development and progression of diabetic kidney disease (DKD). However, the potential role of PKC-b in podocyte mechanisms of DKD has not been previously studied. The aim of this study was to determine whether advanced glycation end-products (AGE) or serum amyloid A (SAA), inflammatory mediators in DKD, activate PKC-β and downstream consequences of inflammation and apoptosis in podocytes.

Methods: Podocytes were exposed to AGE (300 mg/ml) or exogenous SAA (10 mg/ml) for 1 hour. PKC-β activity was measured as the phosphorylated form and by membrane

fraction (Western blot). Immunostaining with imaging by confocal microscopy was used for PKC-β localization. PKC-β was inhibited by LY379196 (100 nm) in podocytes exposed to SAA and AGE for 20 hours. Outcomes included mRNA (qRT-PCR) for pro-inflammatory proteins: C-X-C motif chemokine ligand 5 (CXCL5), C-C motif chemokine ligand 5 (CCL5), monocyte chemoattractant protein-1 (MCP-1), inducible nitric oxide synthase (iNOS), SAA, and TUNEL assay (apoptosis).

Results: AGE and SAA exposure increased PKC-β activation in podocytes as evidenced by increased phosphorylation (1.3-fold, p=0.007 and 1.4-fold, p=0.001, respectively) and increased PKC-β in the membrane fraction (2.1-fold, p<0.001 and 1.6-fold, p=0.002, respectively). Immunostaining for PKC-β revealed greater membrane localization. AGE and SAA exposure also increased podocyte TUNEL staining (2.1-fold, p=0.002 and 3.4-fold, p<0.001, respectively). PKC-β inhibition reduced expression of CXCL5, CCL5, MCP-1, iNOS, SAA, and TUNEL staining.

Conclusions: PKC-β activity is increased in podocytes after exposure to diabetes-related inflammatory mediators. Consequent podocyte inflammatory and apoptotic responses are mediated by the PKC-β pathway.

Podocyte SIRT1 Deficiency Contributes to Albuminuria and Renal Fibrosis in Diabetic Kidney Damage in Mice Yi Guan, Chuanming Hao. *Dept of Nephrology, Huashan Hospital, Shanghai, China.*

Background: SIRT1 has been shown to play an important role in stress response, metabolic disorder and aging process, and is suggested to be involved in the pathogenesis of diabetic kidney damage. The study examines whether and how SIRT1 deficiency is involved in diabetic nephropathy.

Methods: High fat diet plus 5-day-low-dose STZ was used to model type 2 diabetes. The role of SIRT1 in diabetic kidney is examined using SIRT1 heterozygotes (C57BL/J6). Urinary albumin excretion, kidney histology and extracellular matrix protein accumulation were used to assess diabetic kidney damage. Blood pressure was determined by tail-cuff method. Endothelium selective SIRT1 knockout was generated by crossing floxed SIRT1 mice with SCLCreER, and recombination was induced by tamoxifen. Podocyte selective SIRT1 knockout were generated by crossing floxed SIRT1 mice with PodocinCre. Deletion of SIRT1 in endothelium and podocytes was confirmed by immunohistochemistry.

Results: In diabetic kidney, SIRT1 expression was significantly reduced. Urinary albumin excretion of diabetic SIRT1 heterozygote was markedly increased by 4 fold compared with littlemates. Renal histology showed mesangial expansion, Sirius red staining revealed more fibrosis and qPCR indicated higher expression of *PAI-1*, *aSMA*, *Col 18aI*, *Loxl2 gene*, in diabetic SIRT1 knockout than wild type. Losing one allele of SIRT1 did not alter blood pressure in diabetic mice, suggesting that the diabetic kidney damage in the SIRT1 deficient mice is not caused by blood pressure change. To further examine the mechanism by which SIRT1 deficiency increased diabetic damage, endothelium and podocyte SIRT1 was selectively deleted respectively. Following STZ challenge, podocyte SIRT1 deficient mice showed higher albuminuria and developed diabetic kidney damage, compared with wild type. Podocyte SIRT1 deficiency did not alter blood pressure. In contrast, endothelium SIRT1 deletion did not cause significant change in albuminuria and kidney damage in diabetic mice .

Conclusions: SIRT1 deficiency, especially in podocyte is responsible for the development of albuminuria and renal fibrosis. The mechanism by which podocyte SIRT1 protects the kidney from diabetic kidney damage remains to be explored.

β-Arrestins Promote Podocyte Injury in Diabetic Nephropathy Fan Yi. *Pharmacology, Shandong Univ School of Medicine, Jinan, Shandong, China.*

Background: Although autophagy has been implicated in the pathogenesis of diabetic nephropathy (DN), the precise roles and regulatory mechanisms of autophagy are largely unknown. β-arrestins are multifunctional proteins originally identified as negative adaptors of G protein-coupled receptors (GPCRs). Emerging evidence has also indicated that β-arrestins can activate signaling pathways independent of GPCR activation.

Methods: Ten-week-old male β-arrestin-1 and β-arrestin-2 deficient mice (β-arrestin-1$^{-/-}$ and β-arrestin-2$^{-/-}$, 18-20g) were induced by tail-vein injection of streptozotocin (STZ) and were maintained for 12 weeks.

Results: We found that both β-arrestin-1 and β-arrestin-2 were up-regulated in the kidney from streptozotocin-induced diabetic mice, diabetic db/db mice and kidney biopsies from diabetic patients. We further revealed that either β-arrestin-1 or β-arrestin-2 deficiency ameliorated renal injury in diabetic mice. *In vitro*, we observed that podocytes increased both β-arrestin-1 and β-arrestin-2 expressions under hyperglycemia condition, which were associated with suppressing autophagy by negative regulation of ATG12-ATG5 conjugation and the activation of Wnt/β-catenin signaling pathways. Finally, we evaluated the genetic therapeutic efficiency targeting to β-arrestin-1 or β-arrestin-2 in DN showing that *in vivo* gene silencing of β-arrestin-1, β-arrestin-2 or both by intrarenal lentiviral gene delivery ameliorated diabetic renal injury in mice.

Conclusions: This study for the first time demonstrate that β-arrestin-1 and β-arrestin-2 share common mechanisms to mediate podocyte autophagic process (Figure 1), indicating that β-arrestins are critical components of multiple signal transduction pathways that link renal injury to reduced autophagy in DN. Modulation of these pathways may be an innovative therapeutic strategy for treating patients with DN.

Myo-Inositol Oxygenase (MIOX) Contributes to Renal Tubular Injury via Endoplasmic Reticulum (ER) Stress and a Hyaluronic Acid (HA) Production Tatsuya Tominaga,[2] Toshio Doi,[2] Yashpal S. Kanwar.[1] *[1]Pathology, Northwestern Univ, Chicago, IL; [2]Nephrology, Tokushima Univ, Tokushima, Japan.*

Background: MIOX is a renal tubular enzyme which channels myo-inositol into xylulose-pentose pathway. We previously indicated its increased expression in diabetic nephropathy and its transcriptional regulation by high glucose, osmotic agents and oxidant stress. Both ER stress and a macrophage accumulation are contributing factors for progression of the renal tubular injury. In this study, we examined the role of MIOX for the ER stress and chemokine induction.

Methods: MIOX knockout mice were fed with high fat diet (HFD) or treated with tunicamycin (Tm). We crossbred MIOX transgenic mice with PEPCK Cre mice for generating mice with predominant tubular expression of MIOX. HK2 cells were subjected to Tm treatment and transfected with MIOX siRNA. ER stress was gauged by examining the expression of C/EBP homologous protein (CHOP), sXBP1 (transcriptional factor), GRP78 and GRP94 (ER molecular chaperons) in kidney tissues or HK2 cells.

Results: sXBP1, CHOP, GRP78 and GRP94 increased in mice receiving HFD or Tm treatment. These expressions decreased in the MIOX KO mice compared with wild type mice. While, the expressions of GRP78, GADD153 in kidneys increased in MIOX transgenic mice. Also, tubular injury observed following Tm treatment was alleviated in MIOX KO mice and but worsened in MIOX transgenic mice. MIOX expression increased with Tm treatment in a dose-dependent (0.3 - 10 mg/mL) and time-dependent (0.5 - 24 hr) manner in HK2 cells. The sXBP1 and GRP78 expressions also increased following Tm treatment in HK-2 cells. Simultaneously, Tm treatment increased HA synthesis in HK2 cells. The transfection of MIOX siRNA decreased the expression of sXBP1, MCP1, IL6 and hyaluronan synthase 2 (HAS2) under the Tm treatment. Overexpression of MIOX increased sXBP1, CHOP, GRP78 and GRP94, as well as induction of MCP1, IL6 and HAS2.

Conclusions: These findings indicate that MIOX contributes to ER stress and HA synthesis and chemokine induction possibly initiated by macrophage accumulation.

Mitochondrial-Targeted MitoQ Attenuated Renal Tubular Damage in Diabetic Nephropathy by Regulation of Mitochondrial Quality and Modulating Mitophagy Li Xiao,[1] Dang Tang,[1] Jiahui Wang,[1] Xiaoxuan Xu,[1] Yashpal S. Kanwar,[2] Lin Sun,[1] Fuyou Liu.[1] *[1]Dept of Nephrology, 2nd Xiangya Hospital, Central South Univ, Changsha, China; [2]Depts of Pathology and Medicine, Northwestern Univ, Chicago, IL.*

Background: The protection of Mitochondria-targeted ubiquinone (mitoQ) on mitochondrial oxidative damage in various diseases including diabetic kidney disease (DKD) has been reported. However, the mechanism by which Mito Q reverses renal injury in DKD is unclear.

Methods: 15 of renal biopsy samples from patients with DKD were obtained, 20 db/db mice and HK-2 cells, a proximal tubular cells line were used for this study. Patients with MCD and db/m mice used as control. db/db mice were intravenously injection of MitoQ with 5 mg/kg twice/week for 12 weeks. The pathological change of renal tissues was observed by HE, PAS, Mass staining. Mitophagy, mitochondrial fragmentation, mitochondrial ROS production, and mitophagy-related mRNA and protein were detected by EM, mitoSOX staining, immunofluorescence, cofocal, Real-time PCR and western blot.

Results: Compared to MCD patients and db/m mice, defective mitophagy was observed in the kidney tubular of DKD patients and db/db mice, which associated with increased mitochondrial fragmentation, oxidative stress, caspase-3 activity and apoptosis. Furthermore, down-regulated expression of mitophagy-related genes and proteins, such as Pink/parkin, Atg7, NIX and Tom20 were observed, while VDAC is upregulated. These changes above were partially reversed in that of treated with mito Q, and consistent with attenuated tubular damage and urine protein excretion. In vitro study, high glucose (HG) reduced mitophagy with downregulated mitophagy-related proteins as well as LC3 and P62 accumulation. It also increased mitochondrial fragmentation, oxidative stress, caspase-3 activity and apoptosis. However, mito Q abolished these effects. In addition, parkin-siRNA and NIX-siRNA inhibited the benefical effect of mitoQ.

Conclusions: These results indicating that MitoQ could improve mitochondrial quality and attenuate oxidative damage through regulation of mitophagy under DKD condition. MitoQ may be as a potential therapeutic agent for amelioration of DKD.

Evaluation of iNOS Inhibition on Kidney Functions in High-Fat Diet-Induced Obesity Anne-Emilie Decleves,[1,2] Blanche Martin,[2] Vanessa Colombaro,[2] Inès Jadot,[2] Isabelle Habsch,[2] Joelle L. Nortier,[1] Nathalie Caron.[2] *[1]Laboratory of Experimental Nephrology, Faculty of Medicine, Univ Libre de Bruxelles (ULB); [2]Molecular Physiology Research Unit-URPHYM, Univ of Namur (UNamur).*

Background: Central obesity is related to caloric excess promoting deleterious cellular responses in targeted organs. Nitric oxide (NO) has been determined as playing a critical role in the pathogenesis of metabolic diseases. Here, we investigated the implication of iNOS in the development of progressive renal dysfunction leading to obesity-induced kidney disease.

Methods: C57Bl/6 male mice were randomized to a low fat diet (LFD - 10% of total calories from fat) or a high-fat diet (HFD - 60% of total calories from fat) and treated with L-NIL, a specific iNOS inhibitor (0.1 % in drinking water) for 16 weeks.

Results: Mice fed a HFD exhibited a significant increase in body weight, fasting blood glucose, plasma levels of NEFA,triglyceride and insulin. iNOS inhibition with L-NIL prevented these changes in mice fed a HFD. Interestingly, the significant increase in albuminuria and mesangial matrix expansion was not ameliorated with L-NIL while there was a significant amelioration in glucosuria and proteinuria, suggesting that iNOS inhibition is more suitable for tubular function than glomerular function. Moreover, the urinary hydrogen peroxide level, a stable product of ROS production, significantly higher in mice fed a HFD, was reduced with L-NIL. In order to better determine the beneficial effect of L-NIL in the development of obesity, peri-renal white adipose tissue were also investigated. The histological analysis revealed an increasing size of adipocytes in mice fed a HFD. This change was significantly reduced with L-NIL treatment. Inflammation, as attested by macrophage infiltration and enhanced MCP-1 level, was also prevented by L-NIL in the adipose tissue.

Conclusions: These results suggest that inhibition of iNOS leads to beneficial effects in kidney and adipose tissue in mice fed a HFD. This study opens new area of investigations on the involvement of iNOS in obesity-induced organ injury.

The Impact of Diabetes on Total Glomerular Number and Size in Kidney Estimated by Synchrotron Radiation Micro-CT in SPring-8

Yumi Takiyama,[1] Toshihiro Sera,[2] Masanori Nakamura,[3] Ryoichi Bessho,[1] Kentaro Uesugi,[4] Naoto Yagi,[4] Masakazu Haneda.[1] *[1]Dept of Medicine, Asahikawa Medical Univ, Hokkaido, Japan; [2]Dept of Mechanical Engineering, Kyushu Univ, Fukuoaka, Japan; [3]Graduate School of Science and Engineering, Saitama Univ, Saitama, Japan; [4]Research & Utilization Div, Japan Synchrotron Radiation Research Inst, Hyogo, Japan.*

Background: To investigate the impact of diabetes on the number and volume of glomeruli in the whole kidney, we explored CT imaging of male type 2 diabetic db/db mice and of nondiabetic db/m mice at 22 week of age using synchrotron radiation.

Methods: Perfused kidneys with contrast medium were removed and visualized using the synchrotron radiation micro-CT in SPring-8. X-ray image was detected on the fluorescent screen lens coupling sCMOS camera detector with 15.5mm in the pixel size. A segmentation algorithm was conducted to identify and count all glomeruli within the whole kidney, using image analyzing Amira™ software.

Results: Db/m mice had larger kidney volume and more glomerular number in right kidney than left kidney. Intriguingly, diabetes abolished this laterality in db/m mice. Db/db mice had larger glomerular volume than db/m mice. Especially, the cortical glomerular size was remarkably increased. On the other hand, diabetes failed to affect the total glomerular number in kidneys. The mean glomerular volume was strongly correlated with fasting blood glucose, kidney volume, urinary volume and glomerular number in all mice, and urinary volume was a significant independent determinant of the mean glomerular volume, whereas the mean glomerular volume was associated with glomerular number.

Conclusions: Our study, for the first time, showed the impact of diabetes on total glomerular number and glomerular volume of the whole kidney by developing new imaging analyzing system, providing the possibility of glomerular hypertrophy in subjects before diabetes onset.

TH-PO339

NADPH Oxidase-Nox5 Plays a Deleterious Role in Diabetic Nephropathy

Jay Chandra Jha,[1] Stephen P. Gray,[1] Claudine Banal,[1] Harald H. Schmidt,[2] Mark E. Cooper,[1] Rhian Touyz,[3] Chris R. Kennedy,[4] Karin Jandeleit-Dahm.[1] *[1]Diabetes Complications Div, Baker IDI Heart and Diabetes Inst, Melbourne, Australia; [2]Dept of Pharmacology, Maastricht Univ, Maastricht, Netherlands; [3]Inst of Cardiovascular and Medical Sciences, Univ of Glasgow, Glasgow, United Kingdom; [4]Dept of Medicine, Ottawa Hospital Research Inst, Ottawa, Canada.*

Background: Diabetic nephropathy (DN) is the leading cause of end stage renal disease. It has been indicated that recently discovered NADPH oxidase, Nox5 could play a role in DN. Nox5 is present in humans but not in mice or rats. Thus, there is a paucity of information about Nox5 in animal models of DN. We examined the role of Nox5 in a model of human inducible Nox5 transgenic mice expressing Nox5 selectively in either endothelial cells (VEcadNox5$^+$) or vascular smooth muscle cells (SM22Nox5$^+$) in the setting of diabetes.

Methods: VEcadNox5$^+$or SM22Nox5$^+$ mice were rendered diabetic via streptozotocin injections. At week 10 urine samples were collected for the assessment of albuminuria. Animals were culled and kidneys were removed for the assessment of structural damage as well as gene and protein expression of markers of inflammation and fibrosis.

Results: Both VEcadNox5$^+$and SM22Nox5$^+$ mice demonstrated a further increase in albuminuria (ug/24hrs) compared to their respective Nox5 deficient mice in the presence of diabetes (control & diabetic VEcadNox5$^-$: 209±33 & 4139±714; control & diabetic VEcadNox5$^+$: 184±21 & 5888±771; control & diabetic SM22Nox5$^-$: 177±19 & 3036±394; control & diabetic SM22Nox5$^+$: 147±14 & 4273±537). In addition, both diabetic Nox5 transgenic mouse groups appeared to have increased glomerulosclerosis and mesangial area as well as increased gene and protein expression of fibronectin and MCP-1 in the renal cortex when compared to Nox5 negative diabetic mice.

Conclusions: Our findings of an additional increase in albuminuria and glomerulosclerosis as well as increased expression of pro-fibrotic and pro-inflammatory markers in Nox5 transgenic diabetic mice suggest a deleterious effect of Nox5 in the context of diabetic nephropathy and emphasize its role as a target for new renoprotective agents.

TH-PO340

Resveratrol Exhibits Protective Effects on Early-Stage Diabetic Nephropathy by Restoring Mitochondrial Function of Renal Tubular Cells

Hao Ding, Junwei Yang. *Center for Kidney Disease, Second Affiliated Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: Diabetic nephropathy (DN) is a progressive and irreversible renal disease. Mitochondrion plays an important role in the pathogenesis of DN. Resveratrol (RSV), a naturally occurring sirtuin-1 (SIRT1) activator, has been shown to promote mitochondrial function. The aim of the present study is to investigate the renoprotective effects of RSV and delineate its underlying mechanism in early-stage DN.

Methods: Diabetes was induced by streptozotocin (STZ) injection in male CD-1 mice. Two weeks after the onset of DM, the DM mice were further divided into three subgroups concomitantly treated with placebo, RSV 50mg/kg or RSV 100mg/kg for 28 consecutive days. At the end of RSV treatment course, the mice were sacrificed. Primary kidney proximal tubular cells (PTCs) were cultured in high glucose with indicated concentrations of RSV.

Results: In diabetic mice, RSV treatment postponed the progression of DN, as demonstrated by ameliorating the increases of urine albumin excretion, mean artery pressure level, plasma blood glucose level and plasma triglyceride level. Meanwhile, the increases of plasma creatinine level, plasma BUN level, glomerular diameter, mesangial accumulation and renal fibrosis in diabetic mice were also reduced by RSV treatment. Moreover, orally administration of RSV partly restored the distribution and expression of nephrin, WT1 and podocin. We demonstrated that hyperglycemia increased mitochondrial mass and mitochondrial DNA content, upregulated mRNA and protein expression of oxidative phosphorylation enzyme complexes in early-stage DN but led to mitochondrial dysfunction both in vitro and in vivo.RSV acted as a phosphodiesterase 4B inhibitor and SIRT1 activator, attenuated high glucose-induced mitochondrial network fragmentation and impaired oxidative phosphorylation capacity both in vitro and in vivo. Furthermore, it was shown that the protective role of RSV on early-stage DN was probably through AMPK-ACC pathway.

Conclusions: These findings suggested that RSV exhibited a strong ability to inhibit highglucose-induced PTCs damage and may serve as a promising new therapeutic approach for treating early-stage DN.

Possible Implication of Xanthine Oxidase Activation on the Pathogenesis Diabetic Nephropathy

Seiji Itano, Minoru Satoh, Atsushi Uchida, Hiroyuki Kadoya, Hajime Nagasu, Tamaki Sasaki, Naoki Kashihara. *Dept of Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Okayama, Japan.*

Background: Endothelial dysfunction represents a predominant early feature of diabetes and makes diabetic patients prone to renal complications. Recent evidence has indicated possible role of xanthine oxidase (XO) in the pathogenesis of vascular dysfunction associated with diabetes. However, it is not clear whether XO activity is involved in pathogenesis of diabetic nephropathy (DN). We investigated the contribution of XO activation on the progression of mouse DN by selective XO inhibitors, Topiroxostat (Top) and Febuxostat (Feb).

Methods: Male Ins2Akita heterozygote (Akita; 10 weeks old) mice were used. Wild-type (WT) mice were used for control. Akita mice were treated with Top (3mg/kg/day), Feb (1mg/kg/day) or Vehicle (Vehi) for 4weeks. Serum uric acid and urinary albumin excretion (UAE) were measured. Glomerular pathological changes were also examined by light microscope andelectron microscope. Glomerular permeability was assessed using 2 photon microscopy and fluorescent labeling albumin.

Results: Serum uric acid levels showed no significant difference between all groups. Akita+Top or Akita+Feb groups showed significant reduction of UAE in comparison with Akita+Vehi group. Mesangial expansion, glomerular collagen IV deposition, and glomerular endothelial injury (examined by lectin stain and transmission electron microscope) were ameliorated in Akita+Top or Akita+Feb group compared with Akita+Vehi group. Furthermore, glomerular permeability was deteriorated in Akita+Vehi group compared with WT group. These changes were ameliorated with addition of Top or Feb.

Conclusions: XO inhibitors preserved glomerular endothelial function and improved deteriorated glomerular permeability, indicating that XO activation is involved in pathogenesis of DN.

TH-PO342

Effect of Mitochondria-Targeted Ubiquinone Q in Tubular Oxidative Injury of Diabetic Nephropathy Modulate by Mitochondrial ROS/NLRP3/ IL-1β Biological Axis Xiaoxuan Xu,[1] Li Xiao,[2] Chun Hu,[3] Yachun Han,[4] Yashpal S. Kanwar,[5] Fuyou Liu,[6] Lin Sun.[7] *[1]The Second Xiangya Hospital of Central South Univ; [2]The Second Xiangya Hospital of Central South Univ; [3]The Second Xiangya Hospital of Central South Univ; [4]The Second Xiangya Hospital of Central South Univ; [5]Northwestern Univ, Chicago; [6]The Second Xiangya Hospital of Central South Univ; [7]The Second Xiangya Hospital of Central South Univ.*

Background: To understand the underlying mechanism by MitoQ attenuate the progression of DN.

Methods: 18 patients with DN or primary minimal changes disease were enrolle. Renal pathological changes were observed. MitoQ was intraperitoneally injected to the db/db mice twice a week for 12 week(5mg/kg). The injury of kidney and expression of NLRP3,IL-1β, Caspase-1 were tested. HK-2 cells were incubated with D-glucose treated by MitoQ and NLRP3 siRNA. The expression of NLRP3, Caspase-1, IL-1β, FN, Collagen I,Mitochondrial membrane potential(MMP), mt ROS and the mitochondrial translocation of NLRP3 were observed.

Results: The expression of NLRP3, IL-1β, IL-18 increased in kidney of DN patients. which were positively associated with the renal pathological change, oxidative injury in db/db mice. MitoQ ameliorated proteinuria, renal damage, mitochondrial dysfunction, oxidative stress, and apoptosis in the kidney of db/db mice, which was accompanied with decreased NLRP3/IL-1β biological axis related protein and Caspase-1, FN, Col-I. MitoQ also decreased the expression of NLRP3, IL-1β, Caspase-1, FN, Col-I and attenuated mtROS and apoptosis in HK-2 cells. It also recovered MMP and decreased mitochondrial translocation of NLRP3 induced by high glucose. These effect was blocking partially in transfection with lentiviral vectors expressing NLRP3 plasmid , while this effect was abolished by treated with NLRP3 siRNA .

Conclusions: This data indicated that MitoQ ameliorate injury of renal tubular of DN through mtROS/NLRP3/IL-1β axis.

TH-PO343

Inhibition of Enhanced Xanthine Oxidoreductase Activity Prevents the Progression of Diabetic Nephropathy by Attenuating Oxidative Stress Goshi Nagao,[1] Takayo Murase,[1] Ryusuke Sakamoto,[1] Takashi Iwanaga,[2] Naoki Ashizawa,[2] Takashi Nakamura.[1] *[1]Sanwa Kagaku Kenkyusho, Co., Ltd., Japan; [2]Fuji Yakuhin, Co., Ltd., Japan.*

Background: Topiroxostat, a xanthine oxidoreductase (XOR) inhibitor, has been approved as a medicine for hyperuricemia and gout in Japan, and showed a decrease of urinary albumin excretion (UAE) in hyperuricemic stage 3 chronic kidney disease patients in clinical trial. Meanwhile, the induction of oxidative stress and morphological changes known as the representative evidences of diabetic nephropathy (DN) has been reported. We aimed to test the hypothesis that XOR-induced oxidative stress was associated with progression of DN.

Methods: Nine-week-old male diabetic *db/db* mice were fed with diet containing topiroxostat (0.1-10 mg/kg) for 4-8 weeks. The levels of plasma uric acid, UAE concentration for 24 hours, and XOR activity of kidney were determined. PAS staining was performed in paraffin section of renal tissue, and then glomerular tuft area, diameter and cell height of proximal tubules were measured with image analysis software. In addition, immunohistochemical staining for nitrotyrosine was performed.

Results: Treatment with topiroxostat decreased the levels of plasma uric acid and UAE. XOR activity of kidney in *db/db* was significantly elevated compared with that in *db/m*, which was inhibited by treatment with topiroxostat (*db/m*: 47.1±12.6, *db/db*: 87.2±19.7, and 3 mg/kg: 16.6±4.6 pmol/min/mg protein; $P<0.01$, mean±SD). In morphometric analysis, glomerular hypertrophy in *db/db* control was significantly attenuated by treatment with topiroxostat 3 mg/kg (*db/m*: 2952±302, *db/db*: 4028±301, and 3 mg/kg: 3692±270 mm^2; $P<0.05$). The diameter and cell height of proximal tubules in topiroxostat 3 mg/kg group were significantly smaller than those in *db/db* control (*db/m*: 38.6±2.7, 15.9±1.2, *db/db*: 43.8±2.0, 18.5±0.9, and 3 mg/kg: 41.7±1.8; $P<0.01$, 16.8±0.7 mm; $P<0.05$, respectively). As compared to *db/m*, glomerular nitrotyrosine positive area in *db/db* was increased 7.4-fold, which was reduced by 46% by treatment with topiroxostat.

Conclusions: Topiroxostat decreased UAE and attenuated renal morphological changes, at least in part, by inhibition of enhanced XOR-induced oxidative stress in DN.

TH-PO344

Knockout of Matrix Metalloproteinase 2 Attenuates the Progression of Renal Disease in Streptozotocin-Induced Diabetic Dahl Salt Sensitive Rats Takashi Hirata,[1,2] Fan Fan,[1] Naoki Kojima,[2] Teisuke Takahashi,[2] Noriyuki Miyata,[3] Richard J. Roman.[1] *[1]Pharmacology and Toxicology, Univ of Mississippi Medical Center, Jackson, MS; [2]Pharmacology Laboratories, Taisho Pharmaceutical Co., Ltd., Saitama, Japan; [3]Pharmaceutical Business Planning, Taisho Pharmaceutical Co., Ltd., Tokyo, Japan.*

Background: We have found that chronic blockade of MMPs with a broad spectrum inhibitor, XL784, reduced renal injury in type 2 diabetic nephropathy rats. However, the isoforms involved in the development of diabetic nephropathy are unclear.

Methods: The present study examined the role of MMP2 in the development of diabetic nephropathy using a MMP2 knockout (KO) rat in the Dahl salt sensitive (SS) genetic background that we created. Nine week old SS and MMP2 KO rats (n=10) were treated with intravenous injection of streptozotocin (STZ, 50 mg/kg) to induce diabetes and given an insulin implant (2 U/day) to maintain blood glucose around 400 mg/dL. Blood pressure and proteinuria were followed for 12 weeks. Age-matched SS rats (n=5) were studied to serve as a non-diabetic control for the assessment of renal hemodynamics and injury.

Results: Blood glucose and HbA1c levels increased to the same extent in STZ-treated SS (SS-STZ) and MMP2 KO (MMP2 KO-STZ) rats. Systolic blood pressure rose to 195 ± 3 in SS-STZ rats versus 163 ± 3 mmHg in MMP2 KO-STZ rats. Proteinuria increased to 5-fold to 557 ± 33 in SS-STZ rats versus 94 ± 8 mg/day in MMP2 KO-STZ rats. The urinary excretion of MMP2 increased from 45 ± 10 to 2496 ± 365 ng/day in SS-STZ rats but it was absent in MMP2 KO-STZ rats. The kidneys of SS-STZ rats developed more severe glomerulosclerosis, mesangial expansion, and renal fibrosis than MMP2 KO-STZ rats. Glomerular filtration rate (GFR) in SS-STZ rats fell by 33% in comparison to time control SS rats, but GFR only fell by 12% in MMP2 KO-STZ rats.

Conclusions: These data indicate that activation of MMP2 may contribute to the development of diabetes induced renal injury and suggest that a MMP2 selective inhibitor may be useful to prevent the progression of renal disease in diabetic patients.

TH-PO345

Role of DUPS4 in Diabetic Nephropathy Benoit Denhez,[1] Farah Lizotte,[1] Mannix Auger-Messier,[2] Pedro Miguel Geraldes.[1] *[1]Dept of Medicine, Div of Endocrinology, Univ of Sherbrooke, Sherbrooke, QC, Canada; [2]Dept of Medicine, Div of Cardiology, Univ of Sherbrooke, Sherbrooke, QC, Canada.*

Background: Diabetic nephropathy (DN) is the leading cause of end-stage renal disease and is characterized by dedifferentiation and apoptosis of podocytes, which are highly specialized epithelial cells involved in the glomerular filtration process. Podocyte apoptosis is a strong predictor of DN progression. It has been shown that the activation of p38 MAPK induced by hyperglycemia plays an important role in podocytes dysfunction and apoptosis. However, the precise mechanisms leading to the sustained activation of p38 MAPK remain unresolved. DUSP4, a dual specificity phosphatase, is known to bind directly to p38 MAPK and inhibits its activity. Our goal is to evaluate the role of DUSP4 in p38 MAPK activation induced by hyperglycemia, which contributes to podocyte dysfunction and apoptosis in diabetic nephropathy.

Methods: Type 1 diabetic (DM) mice with deletion of DUSP4 (DM-DUSP4KO) was generated and studied during 7 months to evaluate renal function and pathology. Glomerular filtration rate (GFR) and 24h albumin excretion levels were measured in DM mice with or without deletion of DUSP4. Activation of p38 MAPK and expression levels of DUSP4 in podocytes exposed to high glucose (HG) concentrations for 96 hours were evaluated by qPCR and immunoblot.

Results: The mRNA expression of DUSP4 is reduced by 50% in the renal cortex of DM mice. Although elevated GFR in DM mice was similar in DM-DUSP4KO (0,34 vs 0,35 ml/min), albumin excretion was further exacerbated by 3.4 fold in DM-DUSP4KO compared to DM mice. *In vitro*, immunoblot analysis showed that HG level exposure reduced the expression of DUSP4 by 40%, which correlated with an increase of p38 MAPK phosphorylation by 70% in podocytes.

Conclusions: Our results suggest that decrease of DUSP4 expression in podocytes and renal cortex of diabetic mice contributes to podocyte dysfunction in diabetic nephropathy.

Telomerase Deficiency-Dependent Senescence Promotes Diabetic Nephropathy (DN) Progression Huifang Cheng,[1] Xiaofeng Fan,[1] Paisit Paueksakon,[2] Raymond C. Harris.[1] *[1]Medicine, Vanderbilt Univ Medical School, Nashville, TN; [2]Pathology, Microbiology and Immunology, Vanderbilt Univ Medical School, Nashville, TN.*

Background: Diabetes is a common disease in the elderly, and a link with telomere shortening has been reported, although whether it is Diabetes is a common disease in the elderly, and a link with telomere shortening has been reported, although whether it is a cause or a consequence of the disease has not been determined. Both telomerase reverse transcriptase (TerT) and telomerase RNA (TerC) are essential to maintain telomere length.

Methods: To investigate the role of telomerase in DN, we measured telomerase expression in kidneys from mice with streptozotocin (STZ)-induced (type I) and *db/db* (type II) diabetes. We also studied DN in wild type (Wt) and fourth generation (G4) mice with TerC or TerT deletion. *In vitro* studies were performed in primary cultured glomerular endothelial cells (GEnCs).

Results: Renal telomerase expression decreased in both type I and type II diabetic mice, compared with age-matched controls. 26 weeks after STZ injection, TerC and TerT KO mice had more albuminuria than Wt, and EM indicated increased GBM thickness, although mesangial expansion was similar. β-galactosidase, a marker of cell senescence, was mildly elevated in non-diabetic TerC and TerT KO mice. Diabetes accelerated senescence, especially in TerC and TerT KO. In glomeruli, senescence was predominately detected in endothelial cells. GEnCs from TerC deletion mice proliferated much slower than Wt in normal glucose medium (glucose 5.5 mM). After incubation for 96 hours in high glucose (30 mM) medium, GEnCs exhibited cellular senescence, with a marked increase in cells with TerC deletion. There was minimal senescence with incubation with the mannitol osmolality control.

Conclusions: These results indicate that telomerase deficiency promotes DN progression and accelerates glomerular endothelial senescence, implicating a role for the telomere shortening of aging as a predisposing factor for development of DN.

Interaction of the EGF Receptor and the Hippo Pathway in Diabetic Nephropathy Jianchun Chen, Raymond C. Harris. *Medicine, Vanderbilt Univ Medical Center, Nashville, TN.*

Background: Activation of both EGFR and the Hippo signaling pathway can control cell proliferation, apoptosis and differentiation, and their dysregulation can contribute to tumorigenesis. Previous studies have shown that activation of EGFR signaling in renal epithelial cells can exacerbate diabetic kidney injury. YAP is a transcriptional regulator that is regulated by the Hippo signaling pathway, which is a kinase cascade in which Mst1/2 kinases and Sav1 form a complex to phosphorylate and activate LATS1/2, which phosphorylate and inhibit the downstream effector, YAP.

Methods: We induced type I diabetes in proximal tubule EGFR deletion mice ($EGFR^{ptKO}$) and their wild type littermates (WT) by daily low dose streptozotocin injections for 5 consecutive days. A subset of wild type diabetic mice were administrated the EGFR kinase inhibitor, erlotinib. Cell signaling studies were performed in a proximal tubule epithelial-like cell (LLCPKCl4).

Results: STZ injection induced similar levels of hyperglycemia in $EGFR^{ptKO}$ and WT mice. Both total and phosphorylated YAP (at Ser127) increased in diabetic WT mice, primarily in proximal tubule cells, and these increases were inhibited in $EGFR^{ptKO}$ mice or by administration of erlotinib. Further studies demonstrated that EGFR-PI3K-Akt signaling pathway activation mediated YAP gene expression, YAP nuclear translocation and interaction with the TEAD transcription complex, which led to up-regulation of expression of TEAD-dependent genes, CTGF and AREG (amphiregulin). In a renal proximal tubule cell line, either pharmacologic or genetic inhibition of EGFR or Akt blunted YAP expression in response to high glucose treatment. In addition, knocking down YAP expression by specific siRNA inhibited cell proliferation in response to high glucose or exogenous EGF.

Conclusions: This is the first study to demonstrate that the Hippo pathway downstream effector YAP activation is a mediator of EGFR-mediated renal epithelial injury in diabetes.

TH-PO348

Role of Histone Modification in 12-Lipoxygenase Related P21 Gene Regulation Hang Yuan,[1] Nian Liu,[2] Weixia Sun,[1] Fu-zhe Ma,[1] Tao Sun,[1] Mindan Sun,[1] Zhong-gao Xu.[1] *[1]Nephrology, The First Hospital of Jilin Univ, Changchun, Jilin, China; [2]Urology, The First Hospital of Jilin Univ, Changchun, Jilin, China.*

Background: Glomeruli hypertrophy is characteristic pathological changes of diabetic nephropathy, which is associated with p21 protein overexpression under diabetic condition. It has been demonstrated epigenetic histone modifications like acetylation (Ac) and methylation (Me) are involved in gene transcriptional regulation. We have certified 12-Lipoxygenase (12-LO) and its metabolic product 12(S)-HETE can active p21 expression, but the mechanism details are still unclear.

Methods: Mesangial cells (MC) from Rat were used for this study. Chromatin immunoprecipitation assay, QRT-PCR and Luciferase assay were used to detect transcriptional activity, enrichment of H3K Ac as well as Me in the p21 promoter (P) and transcribe (T) regions induced by 12(S)-HETE; transfection was used to overexpression of p300 to see changes of 12(S)-HETE related p21 regulation as well as epigenetic modifications.

Results: 12(S)-HETE enhanced p21 transcriptional activity and mRNA expression; in the promoter regions of P1, P2 and T1 transcribe region, 12(S)-HETE induced significant H3K9Ac as well as H3K4Me1 epigenetic modifications, but no changes were seen in T2 region; on the contrary, 12(S)-HETE treatment prevented H3K9Me3 at p21 promoter obviously, suggest complex Me involved in 12(S)-HETE associated p21 regulation; furthermore, overexpression of p300 obviously enhanced basal as well as 12(S)-HETE associated p21 transcriptional regulation in MC. At same time, 12(S)-HETE treatment also induced histone acetyltransferase p300 occupancy at p21 promoter, reduced demethylase LSD1 nuclear expression and occupancy at p21 promoter.

Conclusions: 12(S)-HETE can induce p300 occupancy at p21 promoter, reduced LSD1 nuclear expression and occupancy at p21 promoter, therefore enhanced H3K9Ac as well as H3K4Me1 at p21 promoter and transcribe regions, decreased H3K9Me3 at p21 promoter, increased p21 expression.

E-Box CpG Hypomethylation of NMN-Producing Enzyme Nampt in Proximal Tubules Enables a Constant Supply of NMN from Tubules to Glomeruli, which Is Disrupted in Diabetic Nephropathy Hirokazu Muraoka, Kazuhiro Hasegawa, Shu Wakino, Hiroshi Itoh. *Keio Univ.*

Background: Nicotinamide mononucleotide (NMN)-producing enzyme nicotinamide phosphoribosyltransferase (Nampt) cooperates with a longevity gene, Sirt1, to exert the stress resistance. We previously reported that high expression levels of **Nampt** lead to NMN production in the proximal tubules (PTs), which contributes to the sufficient supply of NMN to glomeruli (Nat Med 2013). Downregulation of Nampt and NMN in PTs in diabetic nephropathy (DN) leads to glomerular damage. However, the underlying molecular mechanisms by which Nampt is regulated remain unknown. Here, we investigated how Nampt expression is consistently retained at high levels in PTs under normal conditions and decreased in DN.

Methods: Expression levels of Sirt1, TGF-β, and **Nampt** were measured in PTs of mice with DN. A promoter analysis was performed, and luciferase reporter and gel electrophoresis mobility shift assays were used to examine promoter binding. Methylation levels were investigated with methylation-specific PCR and bisulfite sequencing using laser-microdissected PT regions.

Results: Sirt1 expression in mouse PTs was decreased 8 weeks after DN onset. At 24 weeks, TGF-β production increased, which directly lowered Nampt expression in PT. Human renal biopsy samples showed the same patterns seen in mice. CpG islands at -323 to -456 bp in human and at -510 to -28 bp in mice were found to contain four **enhancer (E) boxes** (E1–E4). The basal transcription of Nampt depended on **AhR/ARNT** binding to **E3 and E4**, identifying this as a core promoter. We found that TGF-β activated Dnmt1, leading to the hypermethylation of CpGs in E3 and E4. This hypermethylation blocked AhR/ARNT binding and decreased Nampt expression. The methylation levels of E3 and E4 were significantly higher in DN mice than in non-DN mice.

Conclusions: Although E-boxes are generally enhancer regions, Nampt's E-box is a core promoter with low CpG methylation and is easily bound by AhR/ARNT. This binding results in the regularly high protein expression of **Nampt** providing sufficient NMN under normal conditions. DN-induced PT **TGF-**β production and its concomitant hypermethylation of the E-box disrupt this balance.

TH-PO350

MicroRNA-21 Silencing as Novel Therapeutic Strategy in Diabetic Nephropathy Malte Kölling,[1] Tamás Kaucsár,[2] Celina Schauerte,[1] Joon-Keun Park,[1] Martin Busch,[3] Claudia Bang,[1] Peter Hamar,[2] Hermann G. Haller,[1] Thomas Thum,[1] Johan Lorenzen.[1] *[1]Hanover Medical School, Germany; [2]Semmelweis Univ, Hungary; [3]Jena Univ Hospital, Germany.*

Background: Diabetic nephropathy (DN) is the main cause of end-stage renal disease. We therapeutically inhibited microRNA-21 (miR-21) in mice with DN.

Methods: We used miRNAome analysis, qPCR, in situ PCR, Western Blot, electrophoretic mobility shift assay and bioinformatic algorithms. Furthermore, we fused the 3'UTR of cell division cycle 25a (Cdc25a) and cyclin-dependent kinase 6 (Cdk6) to a Luciferase reporter gene. Luciferase activity was measured after overexpression of miR-21. 28 patients and 20 controls were included. Mesangial cells (MC) and renal fibroblasts were treated with TGF-β. F-Actin staining, Cell Cycle FACS, scratch migration and BrdU incorporation revealed functional changes. In vitro and in streptozotocin-induced diabetic mice, miR-21 was silenced by locked nucleic acid. Immuno-, PAS- and Sirius red stainings were performed.

Results: MiR-21 was among the most up-regulated miRs in kidneys of diabetic mice and was mainly increased in the glomerular and interstitial compartement. In kidney biopsies of patients, miR-21 correlated with the tubulointerstitial injury. Moreover, miR-21 was tightly associated with albuminuria, hypertension and inflammation. Activator Protein-1 regulated miR-21 expression. Cdc25a and Cdk6 were identified as novel targets of miR-21 in MC. MiR-21 mediated repression of Cdc25a and Cdk6 resulted in G1-phase arrest and subsequent MC hypertrophy. In renal fibroblasts, we identified dual specificity phosphatase 8 (Dusp8) as novel target of miR-21, in association with extracellular-signal-regulated kinase signaling activation, increasing renal fibroblast proliferation, migration and extracellular matrix production. MiR-21 silencing in diabetic mice ameliorated various functional parameters including mesangial expansion, tubulointerstitial fibrosis, inflammatory cell infiltration, albuminuria and podocyte loss.

Conclusions: MiR-21 antagonism might thus be a viable therapeutic option in future clinical trials involving patients with DN.

The NMDA Receptor Antagonist MK-801 Reduces Progression of Nephropathy in Two Mouse Models of Type-1 Diabetes Hila Roshanravan, Eunyoung Kim, Stuart E. Dryer. *Biology and Biochemistry, Univ of Houston, Houston, TX.*

Background: Podocytes express ionotropic NMDA receptors that can be activated by endogenous circulating agonists such as L-homocysteic acid and quinolinic acid. Sustained activation of NMDA receptors causes cytotoxicity and oxidative stress in podocytes. Here we examined if the prototypical antagonist MK-801 can reduce nephropathy in mouse type-1 diabetes.

Methods: We examined two mouse models: the Akita mice on a DBA/2J background (with DBA/2J mice as controls), and the low-dose streptozotocin (STZ) protocol in DBA/2J mice. MK-801 or saline were administered by surgically implanting subcutaneous Alzet osmotic minipumps (protocol approved by local IACUC). Nephropathy was monitored by periodic analysis of 24-hr urine samples, and by histology and electron microscopy at the end of the protocol. NMDA subunit expression in renal cortex was examined by immunoblot.

Results: MK-801 treatment was initiated in 7-week Akita mice. Urine albumin secretion is already slightly elevated at that age. Over the next 28 days, albumin excretion increased 3-4 fold in saline-treated mice, but did now show a significant increase in the MK-801 group. At the time of sacrifice there was less foot process effacement in MK-801-treated animals compared to controls. The STZ protocol was carried out at 10 weeks of age, and MK-801 or saline treatment was initiated 15 weeks later. With this model, albuminuria was more severe at the time that drug treatment was initiated. In saline-treated controls albuminuria continued to increase over the next 28 days but did not worsen in the MK-801 group. Foot process effacement, glomerulosclerosis, tubular atrophy and interstitial fibrosis were reduced in MK-801-treated animals. Akita and STZ-treated mice are smaller than their controls. MK-801 did not alleviate this. We observed markedly increased expression of NMDA receptor NR1 and NR2C subunits in renal cortex of Akita and STZ-treated mice compared to controls.

Conclusions: These data support the hypothesis that sustained NMDA receptor expression and/or activation contribute to the progression of diabetic nephropathy, and suggest that targeting these receptors might be a useful therapeutic strategy.

TH-PO352

Role of the N-Type Calcium Channel in a Mouse Model of Diabetic Nephropathy Shoko Ohno,[1] Hideki Yokoi,[1] Kiyoshi Mori,[2] Masato Kasahara,[3] Takashige Kuwabara,[1,4] Moin Saleem,[5] Kazuwa Nakao,[2] Motoko Yanagita,[1] Masashi Mukoyama.[1,4] *[1]Dept of Nephrology, Kyoto Univ Graduate School of Medicine, Kyoto, Japan; [2]Medical Innovation Center, Kyoto Univ Graduate School of Medicine, Kyoto, Japan; [3]Inst for Advancement of Clinical and Translational Science, Kyoto Univ Graduate School of Medicine, Kyoto, Japan; [4]Dept of Nephrology, Graduate School of Medical Sciences, Kumamoto Univ, Kumamoto, Japan; [5]Academic Renal Unit, Univ of Bristol, Bristol Children's Hospital, Bristol, United Kingdom.*

Background: Recent clinical studies have shown that an L-/N-type calcium channel blocker cilnidipine reduces urinary protein in hypertensive patients with proteinuria. In the present study, to explore the functional role of N-type calcium channel ($Ca_v2.2$) in diabetic nephropathy, we investigated renal injury in $Ca_v2.2$-deficient diabetic *db/db* mice.

Methods: We employed mice lacking the N-type calcium channel a1 subunit gene ($Ca_v2.2^{-/-}$) to generate *db/db* (diabetic), $Ca_v2.2^{-/-}$ double mutant mice. Because the genetic background plays an important role in developing diabetic nephropathy, in this study, we backcrossed $Ca_v2.2$ knockout mice on the C57BL/6J background to those on the C57BLKS background.

Results: $Ca_v2.2$ was localized in glomeruli, including podocytes, and vascular walls. Diabetic $Ca_v2.2^{-/-}$ mice showed lower BP than diabetic WT mice by ~20 mmHg, and exhibited ~50% reduction in urinary catecholamines. Compared with diabetic WT mice, both diabetic $Ca_v2.2^{+/-}$ and $Ca_v2.2^{-/-}$ mice revealed a significant reduction (by ~70%) in UAE. The increase in mesangial matrix and downregulation of nephrin in diabetic WT mice were alleviated in diabetic $Ca_v2.2^{-/-}$ mice. There was an improvement in glycemic control in diabetic $Ca_v2.2^{-/-}$ mice but not in diabetic $Ca_v2.2^{+/-}$ mice. Furthermore,*db/db* mice receiving cilnidipine showed a significant reduction in UAE. *In vitro*, depolarization-dependent calcium entry was abolished by ω-conotoxin, a $Ca_v2.2$-specific inhibitor. The reduction of nephrin expression by TGF-β was abolished with ω-conotoxin and cilnidipine in podocytes.

Conclusions: The inhibition of $Ca_v2.2$ exerts renoprotective effects against the progression of diabetic nephropathy.

TH-PO353

D-Carnosine Prevents Diabetic Nephropathy in db/db Mice Giuseppe Pugliese, Carla Iacobini, Stefano Menini. *Dept of Clinical and Molecular Medicine, La Sapienza Univ, Rome, Italy.*

Background: The endogenous dipeptide L-carnosine was shown to act as a quencher of reactive carbonyl precursors of advanced glycation end products (AGEs). However, in humans, it is rapidly inactivated by carnosinase. This study was aimed at evaluating the efficacy of the carnosinase-resistant compound D-carnosine (DC) in preventing diabetic nephropathy in *db/db* mice.

Methods: Adults male *db/db* mice and the corresponding *db/m* controls were treated with a DC derivative (60 mg/kg body weight in the drinking water) or vehicle for 14 weeks. Glomerular sclerosis index (GSI), mean glomerular area (mGA), fractional mesangial area (fMA), and mean glomerular volume (mGV) were assessed morphometrically. Renal expression of inflammatory and disease progression markers were assessed by immunohistochemistry and/or RT-PCR. Serum AGEs and isoprostane-8-epi-PGF_{2a}were measured by ELISA, pentosidine by HPLC and total carbonylated proteins (PCOs) by slot blot immunoassay.

Results: DC treatment induced a significant attenuation of renal disease in *db/db* mice, whereas it did not influence renal structure in *db/m* control mice. Proteinuria (-35%), GSI (-31%), mGA (3.22 ± 0.27 vs. 3.52 ± 0.21 mm^2x10^3), mGV (137.5 ± 10.1 vs. 157.2 ± 13.7 mm^3x10^3), mMA (428.0 ± 82.5 vs. 588.5 ± 48.7 μm^2) and fMA (13.2 ± 1.8 vs. 16.8 ± 1.7%) decreased significantly ($P<0.001$) in DC-treated *db/db* mice, as compared with untreated animals. Glomerular staining for HNE adducts (5.6 ± 2.7 vs. 13.5 ± 2.8 % glom area), fibronectin (11.7 ± 2.6 vs. 19.7 ± 1.8 % glom area) and collagen IV (13.2 ± 3.4 vs. 24.6 ± 3.1 % glom area) were also significantly reduced ($P<0.001$) in DC-treated vs. untreated *db/db* mice. The mRNA levels of F4/80, CXCR3, MCP-1, TNF-α, CHOP, RAGE, galectin-3 and CD36 were also significantly lower in *db/db* mice treated with DC. Finally, serum AGE, pentosidine, PCOs, and isoprostane-8-epi-PGF_{2a}levels were lower in DC-treated vs. untreated *db/db* mice.

Conclusions: DC is effective in reducing carbonyl reactive species and preventing renal injury in *db/db* mice, thus suggesting that carbonyl stress plays a major role in diabetic nephropathy and that DC derivatives might be useful for treatment of this complication.

Funding: Private Foundation Support, Government Support - Non-U.S.

TH-PO354

Effect of an Oral Adsorbent AST-120 on Type 2 Diabetes Rats and Mice Rieko Aoki, Yusuke Yamashita, Sumie Goto, Hiroko Iijima, Fujio Sekine, Shigeaki Miyazaki, Yoshiharu Itoh. *Pharmaceuticals Div, Kureha Corporation, Tokyo, Japan.*

Background: Diabetic nephropathy is a major complication of diabetes and the leading cause of end-stage renal disease. An oral adsorbent AST-120 has been used clinically as a medicine for patients with chronic kidney disease (CKD) to slow down the progression of CKD. However, there is little evidence to support therapeutic efficacy of AST-120 for early stage overt diabetic nephropathy. Our previous study showed that the administration of AST-120 reduced the urinary protein and albumin excretion on SHR/NDmcr-cp (SHR/ND) rats, model rats of metabolic syndrome/ type 2 diabetes. In this study, we aimed to assess the effect of AST-120 on the pathological changes in renal tissues of SHR/ND rats and on other type 2 diabetic model animals, KK-A^y mice.

Methods: Male SHR/ND rats, aged 7 weeks, were administered 8% AST-120 for 12 weeks in their diets. WKY rats were used as a normal. At every 4 weeks, serum and 24-hour urine samples were collected for biomedical studies. The podocyte foot process width (FPW) was measured by Transmission Electron Microscopy as foot process effacement. Pathological changes in renal tissues stained with periodic acid-Schiff (PAS) and Hematoxylin-Eosin (HE) were investigated by light microscopy. Monocyte/macrophage infiltration in renal tissues and tubular injury was investigated by ED-1 staining and kidney injury molecule-1 (KIM-1) staining. Male KK-A^y mice, aged 7 weeks, were administered 8% AST-120 for 8 weeks in their diets. C57BL/6J mice were used as non-diabetic animals. At every 4 weeks, serum and 24-hour urine samples were collected for biomedical studies.

Results: AST-120-administered SHR/ND rats showed significantly lower levels of urinary protein excretion, urinary albumin excretion, and the FPW as compared with SHR/ND rats. The renal histological damage, the number of ED-1 positive cells and KIM-1 positive area were reduced by the administration of AST-120. AST-120-administered KK-A^y mice also showed lower levels of urinary protein and albumin excretion.

Conclusions: These results indicate that the administration of AST-120 at an early stage of diabetic nephropathy has a protective effect on the disease progression.

TH-PO355

Blockade of KCa3.1 Attenuated Diabetic Nephropathy Through Induction of Autophgy Chunling Huang, Xinming Chen, Carol A. Pollock. *Renal Lab, Kolling Inst of Medical Research, Univ of Sydney, Sydney, New South Wales, Australia.*

Background: Autophagy is emerging as an important pathway in many biological processes and diseases including diabetic nephropathy. It was reported that oxidative stress plays a critical role in diabetic nephropathy, and blockade of KCa3.1 ameliorates renal fibrotic responses in diabetic nephropathy through inhibition of the TGF-b1 pathway. The aim of the study is to identify the role of KCa3.1 on dysfunctional tubular autophagy in diabetic nephropathy.

Methods: Human proximal tubular cells (HK2 cells) transfected with scramble siRNA or KCa3.1 siRNA were exposed to TGF-b1 for 48h. The formation of autophagosomes was examined using transmission electron microscopy (TEM). The autophagy marker LC3-II was measured by western blotting and immunofluorescence staining. The activation of oxidative stress was measured by nitrotyrosine using immunofluorescence staining. The signaling pathways of PI3K, Akt and mTOR were assessed with western blotting. In vivo, the expression of LC3-II and nitrotyrosine were examined by imunofluorescence or immunohistochemistry staining in kidneys from diabetic KCa3.1+/+ and KCa3.1-/- mice.

Results: TEM results demonstrated that several autophagic vacuoles appeared in HK2 cells transfected with scramble siRNA exposed to TGF-b1 but decreased autophagic vacuoles were observed in HK2 cells transfected with KCa3.1 siRNA. Western blotting and immunofluorescence staining results showed TGF-b1 significantly increased LC3-II in scramble siRNA-transfected HK2 cells which was reduced in KCa3.1 siRNA transfected-HK2 cells. Blockade of KCa3.1 with transfected siRNA reversed TGF-b1 induced-activation of PI3K, Akt and mTOR signaling pathways. In vivo, diabetic induced upregulation of LC3-II and nitrotyrosine were dramatically attenuated in the kidneys of diabetic KCa3.1-/- mice compared to diabetic KCa3.1+/+ mice.

Conclusions: Blockade of KCa3.1 attenuated diabetic nephropathy through induction of autophgy.

TH-PO356

PBI-4050 Protects against Renal Fibrosis and Improves Pancreatic Function in the Type II Diabetes db/db Mouse Model Lyne Gagnon, Kathy Hince, Lilianne Geerts, François Sarra-Bournet, Alexandra Felton, Liette Gervais, Alexandre Laverdure, William Gagnon, Martin Leduc, Mikaël Tremblay, Marie-Pier Cloutier, John Moran, Frank Cesari, Pierre Laurin, Brigitte Grouix. *ProMetic BioSciences Inc., Laval, QC, Canada.*

Background: PBI-4050, a novel first-in-class orally active compound which is currently in clinical phase Ib/II in metabolic syndrome associated with diabetes, displays antifibrotic activities via a novel mechanism of action. In a double-blind single ascending dose (400 to 2400 mg) in healthy volunteers, PBI-4050 was found to be safe and well tolerated up to 2400 mg without any significant adverse effects (SAEs). Similarly, PBI-4050 was well tolerated in CKD patients with no SAEs observed at 800 mg for 10 consecutive days. In the present study, we examined whether PBI-4050 affected hyperglycemia, insulin resistance and the development of renal fibrosis as well as biomarkers in obese db/db mice.

Methods: db/db mice were uninephrectomized at week 6 and received vehicle (water) or PBI-4050 (100 or 200 mg/kg/day) by daily gastric gavage from 6 to 24 weeks of age.

Results: PBI-4050 treatment ameliorated the fasting hyperglycemia and abnormal glucose tolerance tests seen in vehicle-treated db/db mice. In addition, PBI-4050 led to higher serum insulin, C-peptide and GIP levels which correlates with the improvement of β-cells function observed by immunohistochemistry analysis. Kidney function was also improved by PBI-4050 treatment as shown by significant decrease in hyperfiltration, proteinuria and mesangial expansion lesions. Furthermore, expression of IL-6, Collagen I, MMP2 and Timp1 in kidney were downregulated by PBI-4050 treatment. Moreover, using a mouse cytokines multiplex panel, serum IL-6 and IL-9 levels were significantly reduced in PBI-4050-treated mice.

Conclusions: These studies suggest that PBI-4050 improves hyperglycemia, preserves insulin production and β-cells function and survival, and prevents renal fibrosis in association with regulation of pro-fibrotic and fibrotic biomarkers.

TH-PO357

Kallistatin Protects against Diabetic Nephropathy in *db/db* Mice by Suppressing AGE-RAGE-Induced Oxidative Stress Wai Han Yiu,[1] Dickson WL Wong,[1] Hao-Jia Wu,[1] Ruixi Li,[1] Loretta Y.Y. Chan,[1] Joseph C K Leung,[1] Hui Y. Lan,[2] Kar Neng Lai,[1] Sydney C.W. Tang.[1] *[1]Dept of Medicine, The Univ of Hong Kong, Hong Kong, Hong Kong; [2]Dept of Medicine and Therapeutics, and Li Ka Shing Inst of Health Sciences, The Chinese Univ of Hong Kong, Hong Kong.*

Background: Kallistatin is a serine protease inhibitor that exerts anti-inflammatory, anti-apoptotic and anti-oxidative effects in regulating cellular dysfunction. As oxidative stress plays a critical role in the pathogenesis of diabetic nephropathy, we aim to investigate the effect and mechanisms of kallistatin gene transfer on diabetic renal injury in the *db/db* mouse model of type 2 diabetes.

Methods: Plasmid with kallistatin gene was injected into the kidney of *db/db* mice using ultrasound-mediated microbubble-inducible gene transfer. The therapeutic potential of kallistatin in diabetic kidney was evaluated by histopathology, renal function, oxidative and fibrotic pathways.

Results: Kallistatin expression was induced in tubules of kidney after gene transfer compared with mice treated with empty plasmid. In *db/db* mice, kallistatin overexpression reduced serum creatinine and BUN levels, ameliorated glomerulosclerosis and tubulointerstitial injury and attenuated renal fibrosis by inhibiting TGF-β signaling and the downstream plasminogen activator inhibitor-1 and type IV collagen expression. Furthermore, kallistatin gene transfer significantly attenuated elevated oxidative stress in *db/db* mice as evidenced by suppressed levels of Nox4 and the oxidative marker (8-OHdG and MDA) in diabetic renal tissue. Finally, kallistatin inhibited expression of RAGE in both diabetic kidney and AGE-stimulated cultured proximal tubular epithelial cells, reflecting an anti-oxidative mechanism via AGE/RAGE axis.

Conclusions: Our results suggest a renoprotective role of kallistatin against progression of diabetic nephropathy via anti-oxidative properties. Kallistatin reduced AGE-RAGE-induced Nox4 expression, leading to suppression of oxidative stress and TGF-β-mediated renal fibrosis.

TH-PO358

Kidney pSMAD2 in Type 1 and Type 2 Diabetic Nephropathy Patients and in Mouse Models of Diabetic Nephropathy Lise Thomsen,[1,2] Troels Krarup Hansen,[2] Morten Tonnesen,[1] Emile De Heer,[3] Peter Dijke,[4] Alexander Rosendahl.[1] *[1]Diabetes Complications Biology and Pharmacology, Novo Nordisk A/S, Måløv, Denmark; [2]Dept of Clinical Medicine – Dept of Endocrinology and Internal Medicine, Aarhus Univ Hospital, Aarhus, Dominican Republic; [3]Depts of Pathology, Leiden Univ Medical Center, Netherlands; [4]Depts of Molecular Cell Biology, Leiden Univ Medical Center, Leiden, Netherlands.*

Background: Fibrosis is a hallmark of diabetic nephropathy (DN) leading to chronic kidney disease. However, we lack good animal models resembling kidney pathology of human DN. Renal fibrogenesis has been suggested to be caused by dysregulation of SMAD signalling by members of the TGFβ superfamily. The purpose of this study was to evaluate these events in kidneys from patients and compare to DN mouse models.

Methods: Human (type 1 and type 2 diabetes patient; T1D and T2D) and murine (db/db and streptozotocin (STZ) treated mice) kidneys were stained for pSMAD2. Kidney transcriptional signature of 44 genes including TGFβ/BMP target-genes, BMP modulators, TGFb-superfamily ligands and EMT markers was evaluated in the mouse models.

Results: Nuclear as well as cytoplasmic pSMAD2 expression was increased in tubules of diabetes patients. T1D patients displayed elevated staining in proximal tubuli, whereas T2D patients showed elevated staining in distal tubuli. Increase in SMAD2 activation in distal tubules was also observed in STZ-treated mice, while db/db mice showed noSMAD2 activation. Genetic profiling showed increased expression of BMP antagonists and other genes (CTGF, Gremlin, KCP, USAG1) promoting increased TGFβ activity in both models of DN.

Conclusions: Early experimental DN displays little fibrogenesis, but studying the nuclear pSMAD2 expression suggests that the TGFβ/activin A pathway is upregulated in diabetes patients and mouse DN models. The tubular compartment showed increased pSMAD2 activity in both mouse and man but expression pattern differed between T1D and T2D patients and translated poorly into the mouse models of DN tested in this study. Genetic profiling of murine tissue indicates local blockade of BMP pathways suggesting dampening of the renoprotective BMP7 pathway in both T1D and T2D models.

TH-PO359

Role of Liver X Receptors in Diabetic Nephropathy and Obesity Related Glomerulopathy Michal Herman-Edelstein,[1] Ana Tobar,[1] Talia R. Weinstein,[1] Uzi Gafter,[1] Avry Chagnac,[1] Vivette D. D'Agati,[3] Moshe Levi.[2] *[1]Rabin Medical Center-Felsenstein ,Tel Aviv Univ, Israel; [2]Univ of Colorado; [3]Columbia Univ.*

Background: Our recent human and rodent studies have associated ectopic lipid accumulation and abnormal lipid metabolism in the kidney with diabetic nephropathy (DN) and obesity-related glomerulopathy (ORG). Liver X receptors (LXR) α and β are nuclear receptors that are master regulators of cholesterol metabolism and also inhibit inflammation. Next-generation RNA sequencing data show downregulation of LXR pathways in DN. To obtain insight into the pathophysiology of obesity- induced renal lipotoxicity, we investigated the expression of LXRs and their target genes in human DN and ORG kidney biopsies.

Methods: Renal lipid contents, inflammation ,genes involved in cholesterol and fatty acid metabolism, and LXRs target genes, were studied on amplified mRNA of laser capture microdissection (LCM) isolated glomeruli and tubules from kidney biopsies of patients with established DN (n=16), ORG (N=16), and normal kidneys (n=16).

Results: LXRα and LXRβ mRNA were higher in the glomerular compared to the tubular fraction.LXRα and β mRNA and protein were significantly decreased in DN and ORG kidneys.We found a significant relationship between LXRs mRNA, eGFR ,glomerulosclerosis, and inflammation. Furthermore, we studied the anti inflammatory effect of different LXR agonists including DMHCA, TO-901317and GW3965 against oxLDL and palmitate-induced lipotoxicity in culture podocytes. Our results indicate that all LXR agonists induce cholesterol efflux while DMHCA exhibited limited effect on SREBP1c. Furthermore treatment of diabetic db-db mice with the LXR agonist resulted in significant decreases in albuminuria and expression of the proinflammatory cytokines IL-6 and TNFα in the kidney.

Conclusions: Our results suggest that decreased glomerular and tubular expression of LXRs seems to have a role in DN and ORG. Consequently, decreased activity of LXR and related downstream pathway mediators may contribute to lipotoxicity, inflammation and GFR decline. We suggest that modulation of LXR receptors in the kidney may serve as a novel therapeutic target in DN and ORG.

Dual Activation of FXR and TGR5 by INT-767 Mediates Protection from Diabetic Nephropathy and Retinopathy Xiaoxin Wang,[1] Michal Herman-Edelstein,[2] Jonathan Levi,[3] Uzi Gafter,[2] A. Rosenberg,[3] Jeffrey B. Kopp,[3] Luciano Adorini,[4] Maria B. Grant,[5] Moshe Levi.[1] *[1]Univ of Colorado Denver; [2]Rabin Medical Center; [3]NIDDK; [4]Intercept; [5]Indiana Univ, Indianapolis, IN.*

Background: Bile acids are agonists for the nuclear hormone receptor, farnesoid X receptor (FXR) and the G protein-coupled receptor TGR5. We have found that FXR and TGR5 expression are decreased in human diabetic nephropathy.

Methods: We examined the effect of their combined activation by the dual FXR/TGR5 agonist INT-767 on diabetic nephropathy in DBA/2J mice fed a Western diet and streptozotocin (STZ) induced hyperglycemia.

Results: Diabetic mice developed marked albuminuria, increased glomerular area and mesangial expansion, decreased podocyte (WT-1) density. Diabetic mice also had increased renal triglyceride and cholesterol accumulation, increased NF-κB activity, and increased oxidized protein accumulation. Treatment with 30 mg/kg BW/day INT-767 for 8 weeks normalized albuminuria (ACR), glomerular area and mesangial expansion, podocyte density (WT-1), kidney cholesterol (CHOL), NF-κB transcriptional activity, oxidized proteins, and profibrotic growth factors TGF-β and CTGF and significantly decreased kidney triglycerides (TG). In addition, in the retina INT-767 also reduced the number of acellular capillaries, decreased the inflammatory infiltration into the retina, and corrected the diabetes-associated endothelial progenitor cell dysfunction, restoring cell migration to nondiabetic levels.

	Control	STZ	STZ + INT-767
ACR: mg/g	88±11	603±113*	50±18**
Podocyte Density	42±2	30±2*	38±1**
Kidney TG: µmol/g	7.5±1.3	33.6±2.7*	20.5±2.3**
Kidney CHOL: µg/g	6.6±0.5	9.4±0.7*	6.3±0.7**
NF-κB Activity	1.0±0.1	1.4±0.1*	1.2±0.1**
Oxidized Proteins	0.7±0.1	1.2±0.1*	0.8±0.1**

Conclusions: Our studies therefore indicate that dual activation of FXR and TGR5 protects from diabetic nephropathy and retinopathy by decreasing inflammation, oxidative stress, lipid accumulation, and fibrosis.

High Fat Diet and BCL2-Modifying Factor (Bmf) Overexpression Together Promote Tubular Apoptosis in BMF-Transgenic Mice via Reactive Oxygen Species Generation Anindya Ghosh,[1] Hasna Maachi,[1] Shaaban Abdo,[1] Yixuan Shi,[1] Chao-Sheng Lo,[1] Isabelle Chenier,[1] Janos G. Filep,[2] Julie R. Ingelfinger,[3] Shao-Ling Zhang,[1] John S.D. Chan.[1] *[1]CRCHUM, Univ de Montreal, Montreal, QC, Canada; [2]Research Centre, Maisonneuve-Rosemont Hospital, Montreal, QC, Canada; [3]Pediatric Nephrology Unit, Mass Gen Hosp, Boston, MA.*

Background: We previously reported that the pro-apoptotic gene Bmf is up-regulated in renal proximal tubular cells (RPTCs) of diabetic obese mice (db/db) compared to normal lean mice (db/m+). We investigated whether high-fat diet (HFD) regulates Bmf expression and RPTC apoptosis and studied its underlying molecular mechanism(s) in RPTCs.

Methods: Non-transgenic (non-Tg) mice, catalase-Tg (Cat-Tg) and Bmf-Tg mice overexpressing rat Cat and human Bmf in RPTCs, respectively, were fed normal chow or HFD from 4 to 20 weeks of age. All animals were euthanized at 20 weeks. Blood glucose (BG), systolic blood pressure (SBP) and urinary albumin creatinine ratio (ACR) were monitored bi-weekly. Renal oxidative stress and ROS generation were quantified by dihydroethidium staining and lucigenin assay, respectively. RPTC apoptosis was evaluated by TUNEL assay, immunostaining for active caspase-3 and Bax expression. Pro-apoptotic protein and gene expression were assessed by Western blotting and quantitative-PCR. Rat RPTCs stably transfected with the plasmid pGL4.20 containing rat Bmf gene promoter were also studied.

Results: Non-Tg mice fed HFD had increases in BG, ACR, acetylated p53, renal oxidative stress and pro-apoptotic genes (Bax, Bmf) expression and RPTC apoptosis. Catalase overexpression prevented HFD-induced RPTC apoptosis and pro-apoptotic gene expression in Cat-Tg mice. In contrast, overexpression of Bmf gene in RPTCs with or without HFD aggravated RPTC apoptosis , pro-apoptotic genes expression and ACR. In vitro, high glucose and palmitate attenuated SIRT1 expression, enhanced acetylated p53 expression and stimulated Bmf gene transcription.

Conclusions: We conclude that HFD and Bmf may act in concert to induce ROS-mediated tubular apoptosis, suggesting an important role for Bmf in tubular atrophy in diabetes.

Prevention of Diabetic Nephropathy and Other End Organ Damage by Stem Cell-Based Cure of Type I Diabetes Mellitus in Mice and Rats Christof Westenfelder,[1,2,3] Anna Gooch,[3] Jon D. Ahlstrom,[3] Zhuma Hu,[3] Evan Hurlow,[1,3] Ping Zhang.[3] *[1]Medicine, U of Utah and VAMC, Salt Lake City, UT; [2]Physiology, U of Utah, Salt Lake City, UT; [3]SymbioCellTech, Salt Lake City, UT.*

Background: Endogenous insulin replacement by pancreas or islet transplants is currently the optimal treatment to achieve insulin-independence and end organ protection in patients with T1DM. However, the limited availability of cadaveric pancreas donors, and both the need for permanent antirejection therapy and repeated islet transplants continue to prevent the wide spread use of these therapies. Auto- and allo-immune isolation of transplanted islet cells is currently tested with encapsulation technologies, several of which have failed early. Because β-Cells cannot be adequately expanded ex vivo, Embryonic or induced Pluripotent Stem Cells are evaluated instead. In our present studies, we succeeded to cure T1DM in mice and rats by achieving both adequate culture expansion of islet cells and dual immune isolation by exploiting the robust immune modulating and other trophic activities of Mesenchymal Stem Cells (MSCs).

Methods: Immune isolation of islet cells was accomplished by two methods: either by fusing islet cells and MSCs, creating heterokaryons (β-MSCs), or by generating islet-sized cell clusters (Pseudo islets) composed of islet cells and MSCs. Islet cell expansion was accomplished via reversible epithelial-mesenchymal transition.

Results: Streptozotocin (STZ) diabetic rats and mice and spontaneously diabetic female NOD mice were infused i.p. with either β-MSCs or Pseudo islets. STZ-diabetic NOD/SCID mice were identically treated with canine Pseudo islets. Long-term euglycemia and normal i.p. Glucose Tolerance Tests were obtained in all treated animals. No antibody responses were detected in allogeneic groups, no adverse events were observed and no evidence of diabetic nephropathy or other end organ damage was detected. Retrieval of administered cells resulted in prompt return of hyperglycemia.

Conclusions: We conclude that our pre-clinical data have significant translational utility for clinical T1DM. In further preparation for clinical trials, we are currently conducting a Phase I/II Trial in dogs with T1DM.

High Glucose Modulates Hedgehog Interacting Protein (Hhip) Gene Expression in Diabetic Related Proximal Tubular Cell Damage Shiao-Ying Chang,[1] Xin-Ping Zhao,[1] Min-Chun Liao,[1] Isabelle Chenier,[1] Julie R. Ingelfinger,[2] John S.D. Chan,[1] Shao-Ling Zhang.[1] *[1]CRCHUM, Univ of Montreal, Montreal, QC, Canada; [2]Pediatric Nephrology Unit, Massachusetts General Hospital, Boston, MA.*

Background: Hedgehog Interacting Protein (Hhip) is a putative antagonist of hedgehog (Hh) signaling, since both the full length Hhip and its soluble form (sHhip) bind Hh ligands with nanomolar affinity to attenuate the Hh signaling. We previously reported that high glucose (HG) modulates Hhip gene expression and then, targets TGFb1 signaling in embryonic renal cells, resulting in impaired kidney formation. Given our prior findings we hypothesized that Hhip might be involved in the evolution of kidney damage in diabetic conditions, such as proximal tubular injury during the development of diabetic nephropathy.

Methods: Two diabetic animal models-- the spontaneously diabetic Akita (T1DM) and *db/db* (T2DM) mouse models were used for *in vivo* studies. Renal morphology, immunohistochemistry (IHC), promoter activity analysis and gene expression were assessed by standard methods. Rat immortalized renal proximal tubular cells (IRPTCs) were used *in vitro* studies.

Results: As compared to non-diabetic Akita littermates and lean *db/db* animal (*db/m*), renal Hhip expression/urinary sHhip levels were significantly increased in adult Akita and db/db mice at 20 weeks of age. There was strong Hhip-and TGFb1-IHC expression in diabetic kidneys, mostly localized to glomerular endothelial cells and renal proximal tubular cells. *In vitro,* high glucose significantly stimulated the activity of the plasmid containing mouse Hhip gene promoter in dose-dependent manner. HG stimulated intracellular Hhip and inhibited sHhip level protein expression in time-dependent manner. Hhip siRNA attenuated the stimulatory effect of HG on intracellular Hhip and TGFb1 gene expression in IRPTCs.

Conclusions: Our data suggest that high glucose increases both Hhip and TGFb1 gene expression acting in a paracrine fashion to promote renal tubulointerstitial fibrosis in DN, both *in vivo* and *in vitro.*

Development of Diabetic Nephropathy in Streptozotocin-Treated ID1 Knockout Mice Matthew D. Plotkin. *Univ of Arkansas for Medical Sciences, Little Rock, AR.*

Background: Cell injury induces expression of Id1, a bHLH transcription factor inhibitor that regulates cell cycle and differentiation. Id1 knockout results in increased tissue fibrosis in injury models. Since Id1 may have an important role in maintaining vascular stability during hyperglycemia and oxidative stress associated with diabetes, preliminary studies were done to determine if Id1 knockout would result in kidney pathology in a diabetic nephropathy resistant strain of mice.

Methods: Id1 -/- mice in a B6;129 background and WT littermates were treated with streptozotocin (STZ) 125 mg/kg I.P. for 2 doses to induce type I diabetes (DM). Mice with persistent blood glucose levels > 300 mg/dL (n = 10/genotype) were sacrificed at 3 months. Endothelial and perivascular cells from WT and KO mice were cultured in 2% FBS and used at passages 1 and 2.

Results: In WT B6;129 mice, Id1 levels were increased 15-fold at 3 months in response to STZ induced DM with increased expression detected in glomerular capillary endothelial cells compared with normal mice. WT mice had no pathological changes despite severe hyperglycemia. In contrast, Id1 -/- mice developed mesangial expansion and matrix deposition, focal capillary aneurysms and glomerular arteriolar hypertrophy and increased proteinuria (albumin/cr: 0.61±0.26 mg/mg vs. 0.30±0.14 mg/mg, p = .05). KO mice showed a 5-fold increase in glomerular endothelial and tubular epithelial cell proliferation by Ki67 immunohistochemistry. These changes occurred despite no significant difference in average glucose between WT and KO mice. Comparison of primary co-cultures of WT and KO endothelial and perivascular cells demonstrated 10-fold decreased angiopoietin-1 expression by qPCR and decreased autophagy in response to TGFβ in KO cells. These results correlated with marked p62 accumulation in glomerular arterioles in normal and diabetic KO mice.

Conclusions: Glomerular endothelial Id1 expression is increased with type I DM. KO mice develop diabetic nephropathy suggesting a protective effect of endothelial Id1.

Funding: Veterans Administration Support

TH-PO365

Heterogeneous Nuclear Ribonucleoprotein F Stimulates Sirtuin 1 Expression and Attenuates Renal Proximal Tubular Cell Apoptosis in Mice with Type 2 Diabetes Chao-Sheng Lo,[1] Yixuan Shi,[1] Isabelle Chenier,[1] Janos G. Filep,[2] Julie R. Ingelfinger,[3] Shao-Ling Zhang,[1] John S.D. Chan.[1] *[1]CRCHUM, Univ de Montreal, Montreal, QC, Canada; [2]Research Centre, Maisonneuve-Rosemont Hospital, Montreal, QC, Canada; [3]Pediatric Nephrology Unit, Mass. Gen. Hosp., Boston, MA.*

Background: We hypothesized that overexpression of the transcription factor heterogeneous nuclear ribonucleoprotein F (hnRNP F) can stimulate sirtuin 1 (SIRT1, a NAD+-dependent deacetylase) expression and signaling in renal proximal tubular cells (RPTCs), subsequently attenuating RPTC apoptosis in type 2 diabetic db/db mice.

Methods: We made and studies db/db (BKS strain) transgenic (Tg) mice specifically overexpressing hnRNP F in their RPTCs. Blood glucose (BG), systolic blood pressure (SBP) and albuminuria were monitored bi-weekly in adult male non-diabetic db/m+ littermates, db/db and db/db hnRNP F-Tg mice from 10 to 20 weeks of age. Kidneys were processed for histology and apoptosis studies. Renal oxidative stress and reactive oxygen species (ROS) generation were quantified by dihydroethidium staining and lucigenin assay, respectively. Renal proximal tubular (RPT) gene expression was evaluated by respective real time-qPCR and Western blotting.Rat immortalized RPTCs stably transfected with hnRNP F cDNA or SIRT 1 gene promoter were also studied.

Results: Db/db mice developed higher BG, SBP, renal hypertrophy and albuminuria at week 20 as compared to db/m+ littermates; db/db hnRNP F-Tg mice did not have elevated SBP, renal hypertrophy or albuminuria. ROS generation, apoptosis, acetylated p53, Bax and active caspase-3expression were significantly increased in RPT of db/db mice but not in db/db hnRNP F-Tg mice. In contrast, SIRT 1 and catalase expression were significantly decreased in RPT of db/db mice but not in db/db hnRNP F-Tg mice.

Finally, overexpression of hnRNP F stimulates SIRT1 protein, mRNA and gene promoter activity and reverses high glucose (35 mM D-glucose) and palmitate inhibition of SIRT1 expression in rat RPTCs in vitro.

Conclusions: Overexpression of hnRNP F attenuated RPTC apoptosis in type 2 diabetic mice via up-regulation of SIRT1 gene expression and signaling.

TH-PO366

Lack of CD2AP Disrupts Glucose Transporter 4 Trafficking and Attenuates Glucose Uptake Sanna H. Lehtonen, Surjya Narayan Dash, Zydrune Polianskyte-prause, Vincent Dumont, Tuomas Aleksi Tolvanen. *Dept of Pathology, Univ of Helsinki, Finland.*

Background: Recent data indicate that adapter protein CD2AP is downregulated in diabetic conditions via PI3K/Akt signaling in podocytes. In this study we investigated the role of CD2AP in insulin-dependent glucose transporter 4 (Glut4) trafficking and glucose uptake.

Methods: Glucose uptake was measured using tritium-labeled 2-deoxyglucose. CD2AP-/- and wildtype (WT) podocytes expressing HA-Glut4-GFP were utilized to quantify the amount of Glut4 on the plasma membrane and to study the trafficking of Glut4 by live cell imaging. Protein complexes were analyzed by coimmunoprecipitation and Duolink proximity ligation assay (PLA).

Results: The level of glucose uptake was 32% lower in CD2AP-/- podocytes compared to WT podocytes in the basal state. After insulin stimulation, glucose uptake in WT cells increased 19%, whereas CD2AP-/- podocytes failed to respond. Knockdown of Cd2ap in L6 myoblasts with siRNA lowered glucose uptake by 20% in the basal state and blunted insulin-induced glucose uptake. In line with this, insulin stimulation increased HA-Glut4-GFP on the plasma membrane by 50% in WT podocytes, whereas no difference was observed in cells lacking CD2AP. Live cell imaging revealed dynamic trafficking of HA-Glut4-GFP in response to insulin in WT cells, whereas in CD2AP-/- podocytes HA-Glut4-GFP formed insulin unresponsive clusters in the perinuclear region. Subcellular fractionation indicated that CD2AP is found in intracellular membrane fractions together with Glut4, IRAP and sortilin, constituents of Glut4 storage vesicles (GSVs). Coimmunoprecipitation and PLA assays revealed that CD2AP forms a complex with GGA2, a clathrin adaptor which sorts Glut4 to GSVs. We further found that lack of CD2AP increases the interaction between GGA2 and clathrin. Insulin stimulation further increased GGA2-clathrin interaction and led to perinuclear accumulation of the complex in CD2AP-/- podocytes.

Conclusions: Our results indicate that CD2AP facilitates glucose uptake into podocytes and muscle cells. Interaction of CD2AP with GGA2 suggests a role for CD2AP in sorting of Glut4 to GSVs and insulin-responsive trafficking of Glut4 to the plasma membrane in podocytes.

Tauroursodeoxycholic Acid (TUDCA) Ameliorates Both Tubular and Glomerular Injury in Diabetic Nephropathy, Thus Providing an Added Value to ACE-Inhibition Moh'd Mohanad Ahmad Al-Dabet,[1] Andi Marquardt,[1] Fabian Bock,[1,2] Khurrum Shahzad,[1,3] Madhusudhan Thati,[1] Berend Heinrich Isermann.[1] *[1]Inst of Clinical Chemistry and Pathobiochemistry, Otto-von-Guericke-Univ, Magdeburg, Germany; [2]Dept of Internal Medicine I and Clinical Chemistry, Univ of Heidelberg, Heidelberg, Germany; [3]Univ of Health Sciences, Khayaban-e-Jamia Punjab, Lahore, Pakistan.*

Background: Therapeutic inhibition ofthe Renin-Angiotensin Aldosterone System (RAAS) is firmly established in diabetic nephropathy (dNP). Despite efficient RAAS inhibition dNP frequently progresses to end-stage renal disease, necessitating the need of additional and mechanistically distinct therapeutic approaches. We have recently demonstrated that amelioration of endoplasmic reticulum stress using TUDCA protects mice from dNP (Madhusudhan et. al., Nat Commun 2015). To foster clinical evaluation of TUDCA, which is approved for other medical indications, we determined the efficacy of TUDCA in db/db mice in addition to ACE-inhibition (Enalapril).

Methods: 16 weeks old db/db mice with established albuminuria were randomly assigned to control (PBS), Enalapril (50mg/L, drinking water), TUDCA (150mg/Kg, i.p. daily), or combined Enalapril and TUDCA treatment. Mice were analyzed after 6 weeks of treatment. Albuminuria, glomerular and tubular damage (PAS-staining, electron microscopy, marker proteins), and markers of ER-stress were analyzed.

Results: Both agents (Enalapril and TUDCA) resulted in a significant reduction of UACR, glomerular hypertrophy, and FMA (fractional mesangial area). The combined treatment was more efficient with regard to UACR reduction, but similarly protective against glomerular sclerosis. Unlike Enalapril, TUDCA conveyed additional tubular protection, which was associated with reduced ER-stress (e.g. nuclear ATF6) in the tubular compartment.

Conclusions: A combined therapy of TUDCA and Enalapril is more efficient than Enalapril alone in preventing the progression of dNP in db/db mice. These results should foster translational efforts evaluating TUDCA in patients with dNP.

Funding: Government Support - Non-U.S.

Fatty Acid Binding Protein 3 Might Mediate Diabetic Nephropathy in Mouse Lacking eNOS Gene Shota Ozawa,[1,2] Shuko Ueda,[1] Kiyoshi Mori,[1] Katsuhiko Asanuma,[1] Motoko Yanagita,[1,3] Takahiko Nakagawa.[1] *[1]TMK Project, Medical Innovation Center, Kyoto Univ Graduate School of Medicine, Japan; [2]Pharmacology Research Laboratories II, Mitsubishi Tanabe Pharma Corporation, Japan; [3]Dept of Nephrology, Kyoto Univ Graduate School of Medicine, Japan.*

Background: Insulin deficiency leads to an increase in serum free fatty acid concentration. Diabetic glomerular nodules often contain lipid droplet, suggesting that abnormal fatty acid metabolism might contribute to the development of diabetic glomerular injury. However, its precise mechanism remains unclear. Fatty acid binding proteins (FABPs) are currently considered as key molecules for lipid metabolism.

Methods: Since diabetic eNOS knockout (KO) mouse is considered to be a good model for human diabetic nephropathy, we here investigated whether FABP could mediate glomerular and tubular injury in this model.

Results: First of all, oil red O staining demonstrated that lipid droplets were accumulated in the injured glomeruli in diabetic eNOSKO mice, suggesting that lipid abnormality was involved in the injured process. Microarray assay with isolated glomeruli revealed that among 10 isoforms in FABP family, FABP3 mRNA was most highly expressed in diabetic eNOSKO mice compared to non-diabetic eNOSKO mice. We found that FABP3 protein was predominantly located in the mesangial cells while glomerular injuries were associated with inflammatory processes, such as macrophage infiltration and MCP-1 induction in the diabetic eNOSKO mice. Overexpression of FABP3 resulted in a greater response to palmitate, a satulated FA, to induce MCP-1 in the rat mesangial cells. Furthermore, tubular FABP3 was likely exclusively translocated from cytoplasm to basolateral membrane in proximal tubular epithelial cells under diabetic condition. In turn, the heart, a major organ for FABP3 protein in normal condition, did not show any significant changes in its expression level under diabetic condition in either wild type or eNOSKO mice.

Conclusions: FABP3 likely mediates diabetic glomerular and tubular injury.

Cinacalcet Ameliorates Diabetic Nephropathy Through Intracellular Ca^{++} -CaMKKβ-LKB1-AMPK Activation Ji Hee Lim, Min Young Kim, Yaeni Kim, Eun Nim Kim, Soojeong Kim, Hyung Wook Kim, Cheol Whee Park. *College of Medicine, Dept of Internal Medicine, The Catholic Univ of Korea, Seoul, Republic of Korea.*

Background: In cardiovascular system, the Calcium-sensing receptor(CaSR) simulates the production of NO in the endothelial cells. A decrement in NO bioavailability associated with AMPK inactivation and increased generation of reactive oxygen species are critical to the pathogenesis of diabetic vascular complications. Therefore, we evaluated the renoprotective effect of cinacalcet on glucotoxicity through AMP-protein kinase (AMPK)-eNOS-NO pathway in diabetic nephropathy in *db/db* mice and human glomerular endothelial cells (HGECs).

Methods: Male C57/BLKS *db/db* mice and *db/m* controls at 8 weeks of age were divided to receive either a regular diet chow or a diet containing cinacalcet (10 mg/kg; n=8, respectively). Mice were followed for 12 weeks and were evaluated for renal functions, pathologic phenotypes, and AMPK-eNOS-NO pathway.

Results: Cinacalcet ameliorated albuminuria in *db/db* mice without influencing the changes in blood glucose and Ca^{++} concentrations. The mesangial area expansion and inflammatory cell infiltration in the glomerulus were observed in *db/db* mice, which were all restored by cinacalcet treatment. Cinacalcet increased expression of CaSR, phosphorylation of CaMMKβ and LKB1 and subsequent AMPK activation, which in turn activated PGC-1α and phospho-Ser1177 eNOS-NO. As a result, an increase in the ratio of Bcl-2/Bax in renal cortex and decrease in urinary 8-hydroxy-deoxyguanosin and isoprostane concentrations enhanced the expression of superoxide dismutase; SOD1 and SOD2. In cultured HGECs, cinacalcet decreased oxidative stress and apoptosis by increasing intracellular Ca^{++} and by enhancing phosphorylation of CaMMKβ, LKB1 and AMPK, which were associated with an increase in the phosphorylation of eNOS-NO as well.

Conclusions: In conclusion, the results suggest that cinacalcet improves glucotoxicity through an increase in intracellular Ca^{++} and subsequent activation of the CaMKKβ-LKB1-AMPK signaling in the kidney, especially GECs, and may be a potential therapeutic modality for type 2 diabetic nephropathy.

TH-PO370

Ectopic Expression of TIMP-1 and LTBP-2 in Proximal Tubule-Specific Nampt Conditional Knockout Mice Aggravates Bridging Fibrosis in Diabetic Nephropathy Kazuhiro Hasegawa, Hirokazu Muraoka, Shu Wakino, Hiroshi Itoh. *Keio Univ.*

Background: Nicotinamide phosphoribosyltransferase (Nampt), the rate-limiting enzyme for nicotinamide adenine dinucleotide (NAD) synthesis, and Sirt1, an NAD-dependent histone deacetylase, exert protective effects in various tissues**,** leading to enhanced stress resistance and extended longevity. We previously reported that proximal tubule (PT)-specific Sirt1 transgenic mice are protected against diabetic nephropathy (DN), and that PT-conditional knockout (CKO) aggravates DN (Nat Med 2013). However, the role of Nampt in DN remains unknown. In this study, we established PT-specific conditional **Nampt-deficient mice** to investigate the role of Nampt in DN initiation and progression.

Methods: We generated PT-specific, Nampt-deficient mice by crossing Nampt$^{flox/flox}$ mice with γ-GT-Cre mice. Wild-type (WT) and CKO mice were injected with saline (Sal; control) or streptozotocin (STZ) to induce DN. The phenotypes of four groups of mice, WT+Sal, CKO+Sal, WT+STZ, and CKO+STZ, were analyzed at 8 and 24 weeks after treatment.

Results: At 24 weeks in WT+STZ mice, Nampt expression was reduced in PTs in parallel to renal fibrosis progression. PAM, Masson trichrome, and EVG staining revealed thickening of the **tubular** basement membrane and basement membrane of **Bowman's capsule**. **Peritubular** and **periglomerular fibrosis** in the cortex and **perivascular fibrosis** surrounding interlobular arteries and veins in the medulla were clearly detected in CKO+Sal mice. These fibroses were bridging fibrosis connecting the tubule and glomerulus. DNA microarray, real-time PCR, and immunoelectron microscopic findings clearly showed that expression of tubular tissue inhibitor of metalloproteinase 1 (TIMP-1) and latent transforming growth factor beta binding protein 2 (LTBP-2) was elevated in CKO+Sal ectopically in PTs. Such expression caused basement membrane thickening and fibrosis. All changes were further enhanced in CKO+STZ mice.

Conclusions: Nampt deficiency in PTs induces bridging fibrosis and overproduction of **TIMP-1** and **LTBP-2**. Disruption of Nampt in PTs causes the initiation and progression of DN-induced fibrosis through the novel mechanism of PT-periglomerular-perivascular fibrotic interplay.

TH-PO371

The Presence of the Anti-Fibrotic MicroRNA Crosstalk in the Effect of N-Acetyl-Seryl-Aspartyl-Lysyl-Proline on Kidney Fibrosis in Diabetes

Keizo Kanasaki,[1,2] Swayam Prakash Srivastava,[1] Shi Sen,[1] Daisuke Koya.[1,2] *[1]Diabetology and Endocrinology, Kanazawa Medical Univ, Kahoku, Japan; [2]Div of Anticipatory Molecular Food Science and Technology, Kanazawa Medical Univ, Kahoku, Ishikawa, Japan.*

Background: N-acetyl-seryl-aspartyl-lysyl-proline (AcSDKP) is an endogenous peptide with anti-fibrotic activity. We have shown that restoration of fibroblast growth factor receptor1 (FGFR1) and concomitant induction of microRNA (miR)-let-7s were involved in the anti-fibrotic action of AcSDKP. Endothelial-mesenchymal transtion (EndMT) could be the importnat source of matrix producing mesenchymal cells in fibrotic kidney. Interferon (IFN)γ is potential inhibitor of FGFR1; miR-29 targets IFNγ 3'UTR.

Methods: Streptozotocin-induced diabetic CD-1 mice were used for all animal experiments. Mice were sacrificed at 6 months after the induction of diabetes; either AcSDKP or PBS was given by osmotic mini-pump for 1 month from 5 months after diabetic induction. In vitro experiments were performed using Human Dermal Microvascular Endothelial Cells (HMVEC).

Results: Diabetic CD-1 mice with fibrotic kidneys exhibited suppressed levels of AcSDKP in urine, anti-fibrotic miRs, such as miR-29s and miR-let-7s, as well as the prominent induction of IFNγ and EndMT; these alterations were all reversed by AcSDKP treatment. Transfection studies in HMVEC revealed that miR-29s and miR-let-7s demonstrated crosstalk regulation against the mesenchymal cell activation program. Antagomirs for miR-29 induced IFNγ and suppressed both FGFR1 and miR-let-7s; neutralising antibody for IFNγ restored the levels of both FGFR1 and miR-let-7s.

Conclusions: The present study provides insight into the physiologically relevant anti-fibrotic actions of AcSDKP via anti-fibrotic miRs crosstalk mechanisms. IFNγ is the significant regulator of the miR crosstalk between miR-29s and miR-let-7s. Restoring such anti-fibrotic programs (mediated by AcSDKP) could demonstrate potential utility in combating kidney fibrosis in diabetes.

TH-PO372

Novel Drug-Inducible Megalin Knockout Mice Reveal Marked Increase of Both Total Nephron Glomerular Filtration and Tubular Reabsorption of Albumin in Early Diabetic Nephropathy

Keita P. Mori,[1] Hideki Yokoi,[1] Masato Kasahara,[2] Takashige Kuwabara,[3] Hirotaka Imamaki,[1] Akira Ishii,[1] Kazuwa Nakao,[4] Tomomi Endo,[1] Motoko Yanagita,[1,4] Masashi Mukoyama,[3] Kiyoshi Mori.[4] *[1]Dept of Nephrology, Kyoto Univ Graduate School of Medicine, Kyoto, Japan; [2]Inst for Advancement of Clinical and Translational Science, Kyoto Univ Hospital, Kyoto, Japan; [3]Dept of Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan; [4]Medical Innovation Center, Kyoto Univ Graduate School of Medicine, Kyoto, Japan.*

Background: The early phase of Diabetic nephropathy (DN) is characterized with hyperfiltration (or increased clearance) of creatinine or inulin. On the other hand, recent reports using micropuncture technique or multi-photon microscopy for superficial nephrons indicated that glomerular filtration of albumin is not increased and tubular reabsorption is decreased in rodent models of early DN.

Methods: Tamoxifen (Tam)-inducible megalin knockout mice (iMegKO) were generated by crossbreeding megalin floxed mice (from Professor T. Willnow, Max Delbrück Center) with Ndrg1-CreERT2 mice (from Professor Yanagita), which enable efficient gene disruption in proximal tubules of adult mice. For analysis of DN, iMegKO mice were given low-dose Tam at 8 weeks after streptozotocin (STZ) treatment.

Results: Low or high-dose Tam-treated, non-diabetic iMegKO exhibited 15-fold increase of urinary albumin excretion (UAE), which should represent total nephron glomerular filtration of albumin in normal mice. Megalin protein elimination was almost complete by high dose Tam, but some expression remained in S3 by low dose.By comparing STZ;iMegKO and non-STZ;iMegKO mice, total filtration of albumin was estimated to be elevated by 1.7-fold with STZ. Importantly, total reabsorption of albumin, calculated by subtraction of UAE before Tam from that after Tam, was also elevated by 1.6-fold with STZ. These changes were normalized by insulin treatment.

Conclusions: By use of iMegKO, which allows overall quantitation of albumin handling in the whole kidney including juxtamedullary nephrons, total filtration and total reabsorption of albumin was markedly increased in STZ diabetic mice.

TH-PO373

Erythropoiesis Stimulating Agents Cannot Improves Circulating Endothelial Progenitor Cell Counts in Patients with End-Stage Renal Disease on Maintenance Hemodialysis Because of Erythropoietin Resistance

Hong Joo Lee,[1] Ju-Young Moon,[2] Sang Ho Lee,[2] Chun-Gyoo Ihm,[2] Tae Won Lee,[2] Kyung-hwan Jeong.[2] *[1]Dept of Nephrology, Seoul Red Cross Hospital, Seoul, Republic of Korea; [2]Dept of Nephrology, Kyung Hee Univ School of Medicine, Seoul, Republic of Korea.*

Background: Decreased circulating endothelial progenitor cells (EPCs) associate with occurrence of cardiovascular disease and all cause mortality in end stage renal disease(ESRD) patients on hemodialysis. It is known that erythropoiesis stimulating agents(ESA) connect to vasculoprotective effects such as enhanced nitric oxide production in endothelial cells and mobilization of EPCs. Patients with ESRD on hemodialysis have markedly decreased EPC counts although they are often treated with ESA. We investigated that ESA can improve EPC levels in hamodialysis patients. Or not, we hypothesized that erythropoietin resistance index(ERI) may associate with decreased effect of ESA on EPC.

Methods: We quantified ESA dose and EPCs in blood samples from 86 patients with ESRD on hemodialysis. The ERI was calculated by dividing the weekly erythropoietin dose per kilogram of weight (μg/wk.kg) by the Hb level (g/dL). Participants were divided into 4 groups based on the lowest, median, highest ERI and no use of ESA group.

Results: The number of circulating EPCs at baseline ranged from 1 to 350cells/200ml, with a mean ± SD of 26.0± 48.2 cells/200μL. There was no significant association with ESA dose and EPC counts. However, the EPCs counts of lowest ERI group were significantly higher than the medium, highest EPI and no use of ESA group. There was no different occurrence of cardiovascular events among the groups.

Conclusions: Administration of EPO may not always increase the number of circulating EPCs in ESRD patients on HD. The resistance to erythropoietin may associate with decreased circulation EPC counts.

TH-PO374

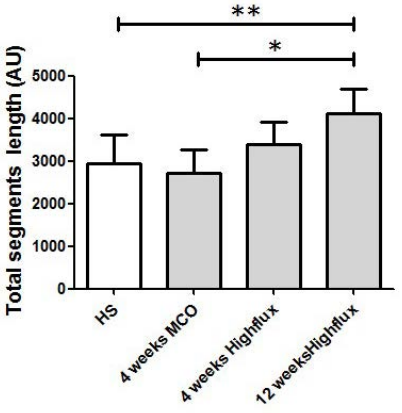
Dialysis with Medium Cut-Off Membranes (MCO) Modulates Endothelial Function In Vitro: Findings from a Randomized Controlled "First in Man" – Trial

Daniel Zickler,[5] Kevin Willy,[5] Ralf Schindler,[5] Matthias Girndt,[1] Roman Fiedler,[1] Markus Storr,[4] Christian Luecht,[5] Duska Dragun,[5] Rusan Catar.[5] *[1]Dept of Internal Medicine II, Martin-Luther-Univ, Halle, Germany; [2]Inst for Epidemiology and Applied Biometry, Eberhard-Karls-Univ Tübingen, Tübingen, Germany; [3]NMI Technology Transfer GmbH, Reutlingen, Germany; [4]Research & Development, Gambro Dialysatoren GmbH, Hechingen, Germany; [5]Dept of Nephrology and Internal Intensive Care Medicine, Charité Univ Medicine, Berlin, Germany; [6]Inst for Chemistry / Food Chemistry, Martin-Luther-Univ, Halle, Germany.*

Background: Cardiovascular mortality in dialysis patients is in part caused by insufficient removal of proinflammatory interleukins. We examined the influence of serum samples from an RCT on markers of EC function. MCO membranes that allow elimination of 45 kd molecules were used for the first time.

Methods: 50 patients were dialyzed with a Highflux and a MCO membrane for 4 or 12 weeks. Serum samples were drawn and tested in an endothelial cell model. Neoangiogenesis was assessed by the measurement of total segments length and KLF2 mRNA, a flow-responsive endothelial transcription factor, was measured. VEGF expression and VEGF protein release was investigated.

Results: Highflux serum enhances neoangiogenesis in EC compared to healthy serum, with MCO filters a reduction was noted. This effect was enhanced after 12 weeks of dialysis (MCO 12 weeks 3206 ±340SEM, $p<0,05$ vs. highflux). The serum drawn from the patients started on MCO showed diametrically opposite results. Antiparallel to neoangiogenesis a significant reduction of KLF2 expression in EC was noted with Highflux serum, while MCO serum showed results comparable with healthy serum. Neither VEGF mRNA nor protein release was significantly altered in EC.



Conclusions: Our findings underline that dialysis with a higher cut-off influences endothelial cell function in vitro.

Pharmacological Inhibition of Prolyl-4-Hydroxylase Improves the Impaired Angiogenic Response to Ischemia in Chronic Kidney Disease

Karl F. Hilgers,[1] Julian Panesar,[1] Nada Cordasic,[1] Johannes Jacobi,[1] Nicolai Burzlaff,[2] Kai-Uwe Eckardt,[1] Carsten Willam,[1] Kerstin U. Amann.[1] *[1]Univ Hospital Erlangen; [2]Univ of Erlangen-Nürnberg, Germany.*

Background: Ischemia-induced angiogenesis is impaired in chronic kidney disease (CKD). Activation of hypoxia-inducible factors has been shown to improve angiogenesis. Here, we investigated whether activation of hypoxia-inducible factors can improve capillary supply in rats with CKD. Inhibition of proly-4-hydroxylase (PHD) was started a few hours after onset of hindlimb ischemia.

Methods: CKD was induced in rats by 5/6 nephrectomy; controls were sham operated. After 8 weeks, ischemia of the right limb was induced by ligation & resection of the femoral artery. Post-conditional activation of hypoxia-inducible factors was induced by 2 intraperitoneal injections of the PHD inhibitor 2-(1-chloro-4-hydroxyisoquinoline-3-carboxamido) acetate (ICA), 12.5 mg/kg, 2 and 6 hours after onset of ischemia. Further animals received placebo injections. Rats were sacrificed 24 h or two weeks after the onset of ischemia. Computer-assisted integration of capillary area normalized for the number of muscle fascicles was performed after double staining for CD31 and laminin of sections of the gastrocnemius muscle.

Results: In control rats, capillary area increased in the ischemic vs. non-ischemic hindlimb by 38±3 % after 2 weeks ($p< 0.01$, N=8). In contrast, there was no significant increase in the ischemic over the opposite limb in CKD (5±4%, N=8, $p>0.1$). ICA increased capillary supply of ischemic limbs of CKD rats by 45±5 % compared to CKD-placebo rats (n=8, $p<0.01$), and by 36±4 % ($p<0.05$) compared to non-ischemic limbs of CKD-ICA animals. After ICA treatment, capillary supply of ischemic limbs was no longer different between CKD and control rats. RT-PCR showed that the ischemia-induced stimulation of VEGF-A was doubled after 24 h by ICA in CKD. The short treatment with ICA did not affect hematocrit levels.

Conclusions: Transient PHD inhibition restores ischemia-induced angiogenesis in CKD rat hindlimb even if applied in a therapeutic approach after onset of ischemia.

Vascular Access Choice in Elderly ESRD Patients

Eunjin Bae, Hajeong Lee, Dong Ki Kim, Kook-Hwan Oh, Yon Su Kim, Kwon Wook Joo. *of Internal Medicine, Seoul National Univ College of Medicine, Seoul National Univ Hospital, Seoul, Republic of Korea.*

Background: The number of elderly ESRD patients is rapidly increasing. Their high prevalence of comorbidity and short life expectancy result in substantial challenges for choice of vascular access. The aim of this study is to suggest optimal choice of vascular access in elderly ESRD patients who require hemodialysis(HD).

Methods: We included outpatients visiting vascular access clinic between january 2008 and March 2014, retrospectively. We divided these patients into 3 groups by age as follows: younger (<65yrs), elderly (65–79yrs) and very elderly (≥80yrs). Various clinical and vascular access associated characteristics were compared among these groups. Cox proportional model was used to analyze the effect of vascular access type on maturation failure, access failure and all-cause mortality.

Results: Among a total of 1,109 patients, 59.1% was men and the mean age was 61±14 years. At the time of HD initiation, 56.4% of patients used central catheters, 38.9% used AVFs and 4.7% used AVGs. Of these, 87.4% (n=973) were chosen AVFs as their permanent vascular access and the proportion of AVF was decreased with age. Compared with AVG, AVF was associated with better survival rate, require less intervention to maintain patency and have lower access failure. Very elderly patients had higher proportion of proximal vascular access and also required more preoperative surveillance and interventions. In total patients, the rate of mortality, access failure, maturation failure was 15.7%, 7.1% and 32%. The mortality benefit with RC AVF was superior to that with both BC AVF and AVG for all age. In elderly group, BC AVF has lowest access failure and highest 1yr patency rate compared with RC AVF or AVG. However, in very elderly group, there was no significant associations between access type and access failure or 2ndary outcomes when adjusted for confounding factors.

Conclusions: We concluded that AVF is the preferred form of vascular access for long term outcome in elderly patients. Nevertheless, BC AVF could be considered by individual characteristics in elderly patients who has complicated radiocephalic site and a short life expectancy.

TH-PO377

Evaluation of Renal Perfusion in CKD Patients Using Arterial Spin Labelling (ASL) Magnetic Resonance Imaging (MRI)

Tsutomu Inoue,[1] Eito Kozawa,[2] Masahiro Ishikawa,[3] Kei Sugiyama,[1] Takeru Kusano,[4] Naoki Kobayashi,[3] Hirokazu Okada.[1] *[1]Nephrology, Saitama Medical Univ, Iruma, Saitama, Japan; [2]Dept of Imaging Diagnosis, Saitama Medical Univ International Medical Center, Hidaka, Saitama, Japan; [3]School of Biomedical Engineering, Faculty of Health and Medical Care, Saitama Medical Univ, Hidaka, Saitama, Japan; [4]Dept of General Internal Medicine, Saitama Medical Univ, Iruma, Saitama, Japan.*

Background: The evaluation of renal blood flow in chronic kidney disease (CKD) is beneficial for the determination of drug efficacy and prognostic expectations of CKD. At present, radionuclide scanning or contrast agents are required for this purpose. In this study, we employed arterial spin labeling (ASL) MRI, which is a non-invasive method of measuring tissue perfusion using magnetized blood as an endogenous contrast agent, for the evaluation of CKD patients.

Methods: A total of consequtive 50 CKD patients (33 males and 17 females, 57.1±16.1 years old) were subjected to MRI, including T1-weighted images, ASL and blood oxygen level-dependent (BOLD)-MRI. MRI was performed using a 3.0-T Imager (Skyra; Siemens, Erlangen, Germany). MATLAB, a technical computing language for data analysis, was used for the production of a perfusion map; while OsiriX, image-processing software for digital imaging and communications in medicine (DICOM), was used for measuring the signal intensity on each map.

Results: The perfusion map showed that the signal intensity of the renal cortex is higher than that of the medulla. Similarly, T2* map obtained by BOLD MRI showed the same tendency. These findings appear to reflect the differences in the volume of blood flow and tissue oxygenation in each area. Mean cortical blood flow was 134.1±43.8 in G4-5 and 180.0±48.6 in G3a/b (ml/min/100g tissue weight, $p<0.05$), with significant differences observed between the two groups.

Conclusions: A reliable, non-invasive and repeatable system for monitoring renal blood flow is currently clinically unavailable. ASL MRI at 3.0 Tesla provides a method of measuring renal perfusion in CKD patients as well as healthy subjects without the need for the administration of exogenous compounds.

In-Vivo Studies of the Microcirculation in Experimental Uremia

Uwe Querfeld,[1,3] Hans-Ulrich Prommer,[2] Johannes Maurer,[2] Karoline Websky,[3] Dorothea Burghardt,[1] Rudi Sampati,[2] Kerstin Sommer,[3] Axel Pries.[2] *[1]Pediatric Nephrology, Charité, Berlin, Germany; [2]Physiology, Charité, Berlin, Germany; [3]Center for Cardiovascular Research, Charite, Berlin, Germany.*

Background: Endothelial dysfunction is a clinical hallmark of cardiovascular disease in patients with CKD. We analyzed morphology and function of the microcirculation in-vivo in mice with experimental uremia.

Methods: In-vivo microscopy of the musculus cremaster capillary bed was performed in BALB/c mice with moderate to severe uremia due to 5/6 nephrectomy or adenine feeding (n=18), and in healthy controls (n=5). Morphological measurements included capillary length, capillary density, and the non-vascularized area. Functional parameters included the arterio-venous difference in oxygen saturation ($av\Delta O_2$) and the change in diameter ($\Delta D/D$) before and after application of acetylcholine, sodium-nitroprusside, papaverine and adenosine.

Results: Capillary length was inversely associated with the degree of experimental uremia, with a reduction of 15% per 100 mg/dL increase of serum urea. Overall, there was a heterogeneous pattern of capillary rarefaction, with areas of normal capillary density and capillary-free areas. The mean non-vascularized area in severely uremic animals (urea > 400 mg/dL) was $19.8x10^3$ mm² ± $50.5x10^3$ mm², and $3.1x10^3$ mm² ±$3.7x10^3$ mm² in controls. The $\Delta D/D$ after pharmacological vasodilatation was 15.4% ± 3.7% in controls, 12.4% ± 4.2% in moderately uremic animals and 7.0% ± 3.5% in severely uremic mice. The $av\Delta O_2$ was 13.1% ± 2.6% in controls, 11.8% ± 3.3% in moderately uremic and 9.8,% ± 2.9% in severely uremic mice, indicating an arteriovenous shunt effect and a diminished oxygen delivery.

Conclusions: These in-vivo studies show a loss of microcirculation in the musculus cremaster of mice with experimental uremia, occurring in a heterogeneous "wipe-out" pattern. Morphological changes (capillary rarefaction) and functional changes ($\Delta D/D$, $av\Delta O_2$) were associated with the degree of experimental uremia. These data suggest that a diseased microcirculation (uremic microangiopathy) contributes to endothelial dysfunction and precedes macrovascular disease in uremia.

TH-PO379

Arterial Biopsies of Children with CKD Show Altered Morphology, Calcium Content and Gene Expression Uwe Querfeld,[1,2] Betti Schaefer,[3] Aysun Bayazit,[4] Ursula Schulz,[2] Kerstin Sommer,[2] Markus J. Kemper,[5] Guido Laube,[6] Francesca Mencarelli,[7] Sandra Habbig,[8] Franz S. Schaefer,[3] Rainer Büscher,[10] Claus Peter Schmitt,[3] Christian Freise.[2] *[1]Pediatric Nephrology, Charité, Berlin, Germany; [2]Center for Cardiovascular Research, Charité, Berlin, Germany; [3]Pediatric Nephrology, Univ of Heidelberg, Heidelberg, Germany; [4]Pediatric Nephrology, Cukurova Univ, Adana, Turkey; [5]Pediatric Nephrology, UKE, Hamburg, Germany; [6]Pediatric Nephrology, Univ of Zurich, Zurich, Switzerland; [7]Pediatric Nephrology, Policlinico S. Ursula Malphigi, Bologna, Italy; [8]Pediatric Nephrology, Univ of Cologne, Cologne, Germany; [9]Pediatric Nephrology, AKH, Wien, Austria; [10]Pediatric Nephrology, Univ of Esssen, Essen, Germany.*

Background: The prospective 4C study investigates cardiovascular comorbidity in children with CKD. We have studied arterial biopsies of 4C-patients and age-matched controls.

Methods: Arterial biopsies were performed at the time of renal transplantation of patients aged 15.4 (8-21) years (n=21). Age-matched healthy control biopsies were obtained from a biobank (Deutsches Herzzentrum Berlin) collecting arterial biopsies from children undergoing elective cardiac surgery. Calcium concentrations were determined by the OCPC method. Intima-media thickness (IMT) was measured manually (Image J software) in H&E stained sections. Gene expressions were analyzed by a Custom RT² Profiler PCR Array. Statistical significances were determined using the Holm-Sidak method, with α=5.000%.

Results: IMT was correlated with the calcium content of biopsies (r=0.41; P<0.05). Marked transcriptomic alterations were detected in the arteries of the CKD patients: Amongst 34 significantly regulated genes (P<0.05-0.0001), SP7 (osterix; ratio 4C/control: 247.5), NOS2 (35.8), RUNX2 (24.8), IL-10 (11.3), TNF (8.3) and TRPV6 (7.7) were upregulated, whereas COL1A2 (0.07), TIMP2 (0.26) and ENPP1 (0.31) were downregulated.

Conclusions: Arterial biospsies from children with stage 5 CKD show an increased calcium content and an upregulation of osteogenic proteins (VSMC and matrix), calcium-transporting proteins, inflammatory cytokines, and downregulation of calcification inhibitors. These findings most likely reflect an early stage of a CKD-specific calcifying arteriopathy.

TH-PO380

Capillary Rarefaction in Omental Biopsies of Children with CKD Uwe Querfeld,[1] Dorothea Burghardt,[1] Betti Schaefer,[2] Maria Bartosova,[2] Hamoud Nasser,[1] Bernd Lahrmann,[3] Joan Nyarangi-Dix,[6] Anja Lingnau,[4] Claus Peter Schmitt.[2] *[1]Pediatric Nephrology, Charité, Berlin, Germany; [2]Pediatric Nephrology, Univ of Heidelberg, Heidelberg, Germany; [3]BioQuant TIGA Center, Univ of Heidelberg, Heidelberg, Germany; [4]Pediatric Urology, Charite, Berlin, Germany; [5]Pediatric Surgery, Charite, Berlin, Germany; [6]Pediatric Urology, Univ of Heidelberg, Heidelberg, Germany.*

Background: Endothelial dysfunction in CKD could be related to a damaged microcirculation. We studied microvascular density in omental biopsies of children with CKD (stage 5) and in healthy age-matched controls.

Methods: Omental tissue was collected from 34 healthy children (0-18 years) undergoing elective abdominal surgery. In a case-control study, we selected 24 age-matched cases with stage 5 CKD from the biobank of the International Peritoneal Dialysis Network with stored omental tissue taken at the time of PD catheter insertion. Biopsies were analyzed by immunohistochemistry for capillary density (CD-31 antibody, Ab), autophagy (LC3A/B (D3U4C) XP® Rabbit mAb), apoptosis (Caspase-3-AK), VEGF-1 (Abcam, Rabbit) and VEGF-R-II expression (VEG Fr-2 (Flk-1). Capillary density was measured by 2 trained observers with a digital microscope (BZ-9000 and Analyzer Software®) and fully automated with Nanozoomer Digital Pathology System and NDP Viewer Software (Hamamatsu Photonics, Japan).

Results: Capillary density was significantly reduced in CKD (median surface area 0.53% vs. 0.95%, p<0.001 in controls). This was confirmed by automatic imaging (0.89% vs. 1.17% p=0.01). Capillary density was inversely associated with age in uremic (r=-0.88, p<0.0001) and healthy children (r=-0.63, p<0.0001). There was an inverse correlation between capillary density and serum BUN (r=-0.53, p£0.05), serum creatinine (r=-0.58, p£0.05), and hemoglobin (r=-0.59, p£0.05). VEGF-1 was reduced by 50% (p<0.05), but VEGF-R-II-was not different (p=0.89). There were no differences in autophagy and apoptosis between groups.

Conclusions: Capillary density was significantly reduced in omental biopsies of children with stage 5 CKD and associated with diminished VEGF signaling. Capillary rarefaction could be an essential part of the cardiovascular pathology induced by CKD.

TH-PO381

CD40 Silencing Reduces NF-KB Activation and the Progression of Atherosclerotic Lesions in the ApoE-/- Murine Model Miguel Hueso,[1] Laura De ramon,[3] Estanislao Navarro,[2] Josep M. Cruzado,[1] J. Grinyo,[1] Joan Torras.[1] *[1]Nephrology, Hospital Bellvitge_IDIBELL; [2]Laboratori d'Oncología Molecular, IDIBELL; [3]Laboratori de Nefrología Experimental, IDIBELL.*

Background: Chronic kidney disease (CKD) and inflammation are risk factors for atherosclerosis. In inflammatory states NF-κB is frequently activated and the CD40/CD40L axis may be a link between inflammation, atherosclerosis and thrombosis. The goal of this work is to study the evolution of atherosclerotic lesions, inflammation and mRNA profiling in an animal model of hypercholesterolemia after CD40 silencing.

Methods: 35 APOE$^{-/-}$ mice of 8 weeks old were sequentially euthanasied (at 8, 10, 14 and 24 weeks of age). We compared a group treated with a siRNA against CD40 with a control group treated with a scrambled siRNA. Atherosclerotic lesions (red-oil, HE), number of macrophages (F4/80) and degree of NFKb activation, in the aorta, were quantified. Furthermore, a mRNA profiling by microarray hybridization was performed.

Results: Silencing CD40 reduced the number (Control-14w:13.7±3%, siRNA-14w:7.7±4%, Control-24w:13.7±7%, siRNA-24w:8.8±5%, p=0.015) and the progression of lesions (Control-10w:0.10±0.09mm^2, siRNA-10w:0.01±0.02mm^2, Control-14w:0.27±0.21mm^2, siRNA-10w:0.18±0.12mm^2, Control-24w:0.68±0.061mm^2, siRNA-24w:0.33±0.16mm^2, p=0.002). SiRNA group displayed lower numbers of infiltrating macrophages (p=0.04) and a lower NF-κB activation than controls (p=0.026). mRNA profiling detected 1996 genes up-regulated and 1285 genes down-regulated associated with the progression of lesions. CD40 silencing showed 190 genes up-regulated and 403 genes down-regulated. The analysis of these genes detected the enrichment of biological processes related with tissular remodelation, macrophage differentiation and apoptosis. CD40 silencing was associated with IFN-gamma production, chronic inflammation, endothelial cell migration and apoptosis.

Conclusions: CD40 and NF-κB were associated with the progression of atherosclerotic lesions in the APOE$^{-/-}$ model.

TH-PO382

Diabetic Cardiomyopathy Is Associated with Loss of Endothelial Glycocalyx in Coronary Microvessels Yan Qiu,[1] Kenton P. Arkill,[2] Gavin Iain Welsh,[1] Andy Salmon,[1] Rebecca R. Foster,[1] Paolo Madeddu,[3] Simon C. Satchell.[1] *[1]Academic Renal Unit; [2]School of Biochemistry; [3]Bristol Heart Inst, Univ of Bristol, United Kingdom.*

Background: Endothelial glycocalyx (Glx) contributes to the microvascular permeability barrier and its dysfunction correlates with diabetic nephropathy. Microalbuminuria represents a major risk factor for cardiovascular disease in diabetes. We hypothesised the albuminuria associated with glomerular endothelial Glx damage in diabetes would be accompanied by coronary microvacscular Glx dysfuction in diabetic cardiomyopathy (DCP).

Methods: CD1 and FVB mice were rendered diabetic with low doses of streptozocin (STZ) i.p. daily for 5 days. Echocardiography was applied to assess DCP by E/A ratio. A group of diabetic CD1 mice were treated with vitamin B_1 analogue Benfotiamine (BFT, 70mg/kg/d) after DCP development.

Results: Microvessels from diabetic CD1 heart had decreased MOA lectin binding at 16 weeks after the development of DCP. Recovered MOA intensity was associated with BFT's beneficial effect on DCP (Ctrl: 17.78±3.48; DCP: 2.53±1.24; DCP+BFT: 30.85±3.80, p<0.05, one-way ANOVA).

FVB mice showed increased albuminuria (7 fold) at six weeks after STZ injection (p<0.001, two-way ANOVA); developed DCP at 7 weeks after STZ injection (p<0.01, two-way ANOVA). Reduced MAL I lectin binding was noted in microvessels from diabetic FVB heart (DCP: 1.64±0.27; ctrl: 2.70±0.27, p<0.05, t test), but not MOA or SNA lectins. Electronic microscopy (EM) of 4%PFA-fixed paraffin-embedded heart sections stained with biotinylated MAL I and streptavidin-conjugated quantum dots indicated MAL I binding molecules localised on endothelial GLx. EM of capillaries from diabetic heart perfusion fixed with alcian blue and glutaraldehyde showed reduced Glx depth (DCP: 14.54±0.79; ctrl: 27.88±5.82 nm, p<0.05, t test).

Conclusions: These evidence suggest Glx damage is associated with DCP development. Recovered heart function with BFT treatment parallels with reversed Glx intensity. Identification of Glx with simpler technique is possible, i.e. specific lectins staining. Thus, correction of disarranged Glx may have therapeutic potential for DCP and other diabetic vascular complications, e.g. diabetic nephropathy.

TH-PO383

Monocyte Subpopulations of Hemodialysis Patients Exhibit Distinct Changes of Cold Shock Y-Box Protein-1 Expression Lara Ewert, Florian Gunnar Scurt, Christos D. Chatzikyrkou, Sabine Brandt, Peter R. Mertens. *Nephrology, Hypertension, Diabetes and Endocrinology, Otto-von-Guericke Univ Magdeburg.*

Background: The cold-shock protein YB-1 is a ubiquitously-expressed RNA/DNA binding protein involved in proliferation, signal transduction, and inflammation. In monocytes YB-1 expression is regulated as part of the cellular differentiation process.

Upon acetylation YB-1 is secreted via a non-classical pathway, influencing inflammatory processes by acting as mitogen and chemokine. In dialysis patients prone to inflammations we investigated monocyte populations and their YB-1 content and degree of acetylation.

Methods: The monocytic phenotypes Mo1/Mo2/Mo3 were differentiated by flow cytometry with the surface marker CD14 and CD16. After permeabilisation and antibody staining intracellular content of acetylated and non-acetylated YB-1 was measured.

Results: In dialysis patients (n=63; 63+/-17 years; m 41; f 22) leukocyte numbers varied markedly (6,500 +/- 2,000/µl) while monocyte fractions were equal among control (n=100; 43+/-11 years, m: 59; f: 41) and patient cohorts. An analysis of the monocytic YB-1 content revealed that non-acetylated YB-1was significantly lower in the dialysis cohort (healthy control: MFI 18000; dialysis cohort: MFI 12000, p<0,001), whereas the amount of acetylated YB-1 was increased in all three monocytic subpopulations in comparison with healthy controls (healthy control: MFI 4850; dialysis cohort: MFI 6700; p<0,001). Amongst the CD14 positive monocytes two distinct subpopulations could be assigned according to their YB-1_{acetyl} content (CD14++YB-1_{acetyl}+;CD14++YB-1_{acetyl}++). In dialysis patients monocytes belonging to the CD14++YB-1_{acetyl} ++ population were significantly more abundant. Notably, challenge with LPS (5 ng/ml for 2h) resulted in a major shift with loss of the CD14++YB-1_{acetyl} ++ population.

Conclusions: Monocyte subpopulations and their YB-1 content are highly regulated and differ significantly between healthy controls and dialysis patients. The cold shock protein YB-1 undergoes acetylation in dialysis patients, which may causally linked to the pro-inflammatory state.

TH-PO384

Epoetin Beta Pegol Improves Endothelial Function in Diabetic Nephropathy Rats Even After Onset of Endothelial Dysfunction Ken-ichi Serizawa, Kenji Yogo, Yoshihito Tashiro, Ryohei Kawasaki, Michinori Hirata, Koichi Endo, Yasushi Shimonaka. *Product Research Dept, Chugai Pharmaceutical Co., Ltd., Japan.*

Background: Endothelial dysfunction is a powerful surrogate marker of cardiovascular events in nephropathy patients, and flow-mediated dilation (FMD) is a useful indicator of endothelial function in clinical settings. Epoetin beta pegol (continuous erythropoietin receptor activator, C.E.R.A.) is a drug for the treatment of renal anemia. In this study, we examined the ameliorating effect of C.E.R.A. on vascular endothelial function as evaluated by FMD in diabetic nephropathy rats.

Methods: Male Spontaneously Diabetic Torii rats (SDT, 22 wks old) were used as type-2 diabetic rats. Male Sprague-Dawley rats (SD) were used as age-matched control. C.E.R.A. (0.6, 1.2 µg/kg) was administered subcutaneously once every 2 wks for 8 wks. At 1 wk after last administration (31 wks old), we assessed endothelial function by FMD in the femoral arteries of anesthetized rats.

Results: Blood glucose level was over 500 mg/dL in SDT rats. FMD was significantly decreased in SDT rats before the start of C.E.R.A. treatment (22 wks old; SD, 16.2 ± 1.3%; SDT, 10.0 ± 1.3%; n = 8), and persisted to 31 wks old (SD, 17.8 ± 1.7%; SDT, 10.4 ± 1.8%; n = 7–8). C.E.R.A. dose-dependently improved FMD in SDT rats (31 wks old; C.E.R.A. 0.6 µg/kg, 17.0 ± 2.0%; C.E.R.A. 1.2 µg/kg, 19.2 ± 2.1%; n = 7–10) without lowering blood glucose. Endothelium-independent vasodilation by nitroglycerin and kidney function were not changed by C.E.R.A. treatment. Because long-term treatment with C.E.R.A. increased hemoglobin (Hb), we also examined the relationship between Hb up-regulation and FMD improvement in a separate experiment. We found FMD was not significantly improved 1 wk after single administration of C.E.R.A. (SD, 15.5 ± 1.6%; SDT, 10.8 ± 0.5%; C.E.R.A. 5 µg/kg, 12.5 ± 2.1%; n = 6–8), whereas Hb levels were comparable with those in long-term C.E.R.A. treatment.

Conclusions: These results demonstrated that C.E.R.A. improved endothelial function as evaluated by FMD in type-2 diabetic rats, even after onset of endothelial dysfunction, and these effects were exerted independently of the increasing shear stress induced by hematopoiesis.

Determinants and Progression of Intimal and Medial Arterial Changes in Children with CKD Frida Dangardt, Devina Bhowruth, Daniela Thurn-Valsassina, Alicja Rapala, Marietta Charakida, Franz S. Schaefer, John Eric- Deanfield, Rukshana Shroff. *Vascular Physiology, UCL, London, United Kingdom.*

Background: I In CKD, both intimal and medial arterial disease occur, and may have different risk factors. A novel imaging technique, very high resolution ultrasound (VHRUS) enables visualization of vessel wall layers separately. We hypothesize that vascular remodeling begins pre-dialysis, progresses on dialysis, and may be reversible after kidney transplantation, and these changes are due to modifiable pathophysiology.

Methods: Intimal (IT) and medial (MT) thickness of the carotid (CA), radial (RA) and dorsal pedal (DPA) arteries were measured by VHRUS (40-50MHz) in 54 children (19 pre-dialysis CKD, 20 on dialysis and 15 post-transplant) at baseline. One year follow up measurements were performed in 24 children (11 pre-dialysis CKD and 15 post-transplant). Conventional ultrasound (CUS) for CA IMT was measured.

Results: Children on dialysis for >1 year had greater CA and DPA MT compared to those on dialysis for <1 year (p = 0.007). In the CKD and dialysis cohort (n=39), higher CA MT at baseline was associated with increased serum phosphate (p<0.001, r=0.42) and PTH levels (p=0.03, r=0.27). No vascular measures were correlated to 25(OH)D, FGF23 or BMI. Renal transplant patients had better GFR and lower serum phosphate and PTH levels, but higher BP, BMI and lipid levels compared to the CKD or dialysis cohort (p<0.01 for all). Transplanted patients had higher CA and RA IT associated with higher lipid levels (p=0.02, r=0.31). At 1-year follow-up transplanted children had a decrease in CA MT (p = 0.01) but not IT. Increased DPA IT in transplanted patients was associated with a higher systolic BP z- score (p = 0.2, r = 0.22). CA IMT by CUS did not reveal any significant changes.

Conclusions: VHRUS assessment of arterial morphology in CKD patients identified potentially modifiable risk factors for intimal and medial vascular disease that were not detected by conventional US. Differential thickening in media and intima in dialysis vs transplant patients suggests vascular remodelling in response to a changing cardiovascular risk factor profile after renal transplantation.

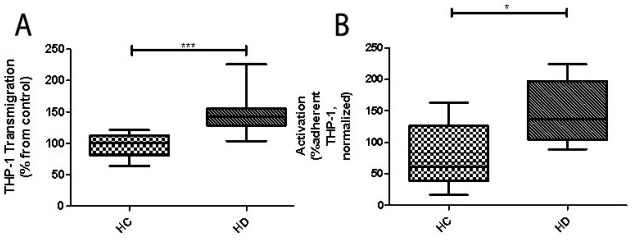
Is Polymorphonuclear Leukocytes' Priming a Prerequisite for Monocyte Activation and Transmigration, Initiating the Atherosclerotic Process? Batya Kristal,[2] Eynav Kliger,[1] Galina Shapiro,[1] Ronit Geron,[2] Shifra Sela.[1] *[1]Eliachar Research Laboratory, Galilee Medical Center, Nahariya, Israel; [2]Nephrology Dept, Galilee Medical Center, Nahariya, Israel.*

Background: Endothelial dysfunction and monocytes transmigration underlie the development of atherosclerosis. Increased counts and priming of peripheral polymorphonuclear leukocytes (PMNLs) are associated with future or ongoing atherosclerosis, however, the role of PMNLs in the accelerated atherosclerotic procces of hemodylasis (HD) patients is still unclear. We hypothesize that atherosclerosis is a circulatory disease, where circulating primed PMNLs activate monocytes and the endothelial layer, at the circulaton. Our aims are to examine endothelial dysfunction, monocytes transmigration, post-transmigration activation and differentiation, induced ex-vivo by primed PMNLs (HD).

Methods: A unique ex-vivo co-cultivation system of 3 cells types was developed, enabling interaction among: primary endothelial cells (HUVEC), in-vivo primed PMNLs and monocytes (THP-1), mimicking the initiation of the atherosclerotic process. The interactions among these cells was examined at the cellular, protein and gene expression levels.

Results: THP-1 transmigration through pre-treated HUVEC with HD PMNLs showed a significant increase in: transmigration



A, post-transmigration activation, B compared to transmigration through HUVEC pre-treated with PMNLs from healthy subjects (HC). THP-1 transmigration correlates with the PMNLs counts and priming state. Pre-treatment with primed PMNLs induced higher MCP-1 expression (2-folds) in HUVEC.

Conclusions: The higher levels of monocytes transmigration, post-transmigration activation and endothelial MCP-1 expression mediated by primed PMNLs suggest a novel mechanism for the initiation of the atherosclerotic process, emphasizing the pivotal role of PMNLs in the initiation of the atherosclerotic process.

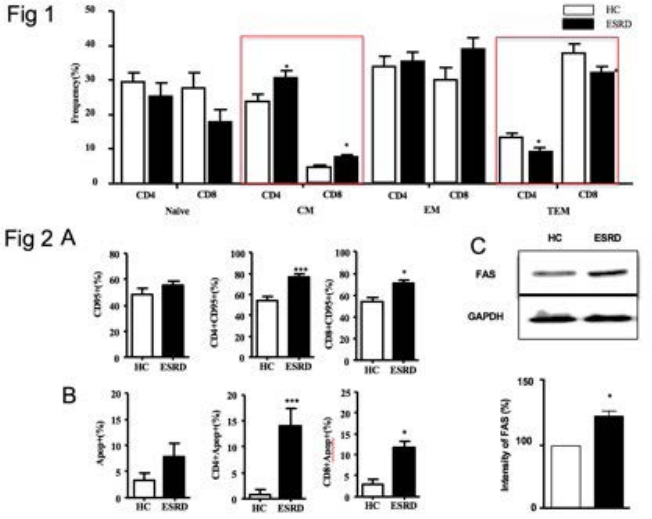
TH-PO387

The Effect of End-Stage Renal Disease (ESRD) on Differentiation of Circulating T Cell Subsets Eun hye Seo,[1] Chae ho Lim,[1] Seunghyun Lee,[2] Young-Il Jo.[1] *[1]Nephrology, Konkuk Univ Medical Center,Konkuk Univ School of Medicine; [2]Dept of Microbiology, Konkuk Univ School of Medicine.*

Background: Progressive loss of renal function is associated with a dysregulation of circulating T cells that may underlie their impaired T-cell immunity. However, it is not known how dysregulation of circulating T cells contribute to the ESRD-related immune deficiency. In this study, we investigated the ESRD-related changes in subsets and differentiation of circulating T cells in ESRD patients.

Methods: Adult ESRD patients on HD and healthy subjects were recruited. Peripheral blood mononuclear cells were collected and staining CD4, CD8, CD45RO, CCR7 and CD95(FAS). The frequency of apoptotic cells was calculated by scoring annexin-V binding cells after back-gating of CD4/CD8 T cells. CD95(FAS) protein levels were confirmed by Western blot analysis and Flow cytometry .

Results: A total of 20 adult ESRD patients on HD (male:female 12:8, DM 65%) and 17 healthy subjects (male:female 6:11) were enrolled. The ESRD patients revealed an increased frequency of CD4+CD25+ Treg and CD14+ cell compared with healthy subjects. However, the frequency of CD4+ and CD8+ T cells decreased in ESRD patients. (Figure. 1-A). Circulating of naïve, central-memory(CM), effector-memory(EM), and terminal effector-memory(TEM) subsets of CD4+ and CD8+ T cells. The CD4+ and CD8+ TEM cell subsets showed a statistically significant decreased in ESRD patients (Figure. 1-B). In ESRD patients, the differentiation of effector memory CD8+ T cells increased (Figure 1), showing a significantly higher percentages of CD4+ TEM (8.7–12.3%, P<0.05) and CD8+ TEM cells (26.8–34.2%, P<0.05). The FAS and apoptosis level showed a statistically significant decreased in ESRD patients (Figure 2).



Conclusions: These results suggested that the T cell dysregulation may play a role in ESRD-related immune deficiency.

TH-PO388

CB1 Cannabinoid Receptor Antagonist Attenuates Cardiac Hypertrophy and Fibrosis in Experimental Chronic Kidney Disease Yu-Juei Hsu, Sung-Sen Yang, Shih-Hua P. Lin. *Div of Nephrology, Dept of Medicine, Tri-Service General Hospital, Taipei, Taiwan.*

Background: Cannabinoid receptor type 1 (CB1R) has been shown to participate in the development of myocardial hypertrophy and fibrosis—two main pathological features of uremic cardiomyopathy. However, it remains unknown whether CB1R is involved in the pathogenesis of uremic cardiomyopathy. Here, we aimed to elucidate the role of CB1R in the development of uremic cardiomyopathy via modulation of Akt signalling.

Methods: The myocardial hypertrophy and fibrosis were evaluated by echocardiography and immunohistochemical staining, respectively, in 5/6 nephrectomy chronic kidney disease (CKD) mice treated with a CB1R antagonist. CB1R and fibrosis marker expression levels were determined by immunoblotting in cardiac tissue obtained from CKD mice and in H9c2 cells exposed to the uremic toxin indoxyl sulfate (IS), with an organic anion transporter 1 inhibitor or a CB1R antagonist or agonist. Akt phosphorylation was also assessed to examine the signaling pathways downstream of CB1R activation in both in vitro and in vivo models of uremic cardiomyopathy.

Results: CKD mice exhibited marked left ventricular hypertrophy and myocardial fibrosis, which were reversed by treatment with the CB1R antagonist. CB1R, collagen I, transforming growth factor (TGF)-β, and α-smooth muscle actin (SMA) expression showed time- and dose-dependent upregulation in H9c2 cells treated with IS. The inhibition of CB1R by either CB1R antagonist or small interfering RNA-mediated knockdown attenuated the expression of collagen I, TGF-β, and α-SMA in IS-treated H9c2 cells, while Akt phosphorylation was enhanced by CB1R agonist and abrogated by CB1R antagonist in these cells.

Conclusions: CB1R blockade attenuates LVH and Akt-mediated cardiac fibrosis in a CKD mouse model. Uremic toxin IS stimulates the expression of CB1R and fibrotic markers and CB1R inhibition exerts anti-fibrotic effects via modulation of Akt signaling in H9c2 myofibroblasts. Therefore, the development of drugs targeting CB1R may have therapeutic potential in the treatment of uremic cardiomyopathy.

TH-PO389

The CD4 T-Cell Response to Cytomegalovirus Targets the Endothelium and Is Linked to Increased Arterial Stiffness in ANCA Associated Vasculitis Dimitrios Chanouzas, Matthew David Morgan, Lovesh Dyall, Jessica Anne Dale, Paul Moss, Lorraine Harper. *Univ of Birmingham, United Kingdom.*

Background: Cytotoxic CD4+CD28- cells have been linked to cardiovascular disease (CVD) but their origin remains unclear. We previously showed that in ANCA associated vasculitis (AAV) these cells are only present in CMV seropositive patients and are independently linked with mortality. CVD is a leading cause of mortality in AAV. Here we have characterised CD4+CD28- cells in AAV and examined their relationship to central pulse pressure (cPP), a marker of arterial stiffness and CVD risk.

Methods: We phenotyped CD4+CD28- cells after overnight stimulation with CMV lysate via flow cytometry and measured cPP using the Vicorder device in 43 CMV+ AAV patients in remission. We stained for CX3CR1, the fractalkine receptor implicated in endothelial damage, and Tbet as Th1 cells are linked to atherogenesis. We used Mann Whitney U for between group comparisons, Spearman rank for correlations and multivariate regression to adjust for confounders.

Results: CD4+CD28- cells expressed Tbet and CX3CR1 and secreted large amounts of IFNγ after CMV lysate stimulation compared to CD4+CD28+ cells (15.7 vs. 0.5%,p<0.001).

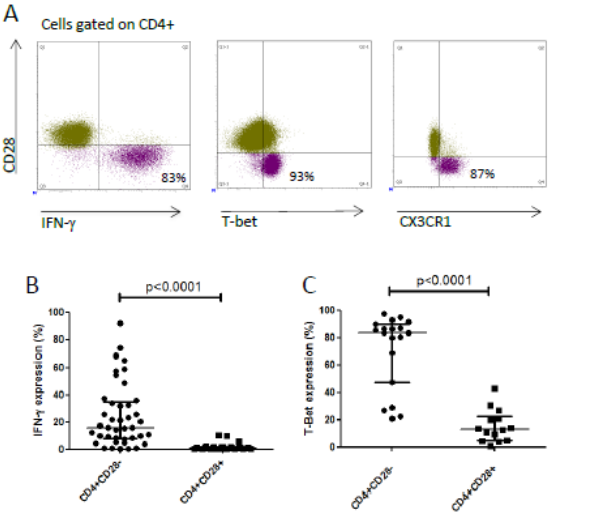


Figure 1 Peripheral blood mononuclear cells were stained after overnight stimulation with CMV lysate and analysed via flow cytometry. (A) Representative staining of IFN-γ, T-bet and CX3CR1 with CD4+CD28- cells shown in purple. (B, C) CD4+CD28- cells secrete significantly more IFN-γ and express significantly more T-bet after CMV lysate stimulation compared to their CD4+CD28+ counterparts.

The CD4+CD28- % correlated with IFNγ secretion after CMV lysate stimulation (r=0.614,p<0.001). The CMV specific CD4+CD28-IFNγ+ percentage as well as absolute count correlated with cPP (r=0.501,p=0.001) and this persisted after controlling for age, gender, mean arterial pressure, urinary ACR and GFR (R square=0.58,B=0.13(95%CI 0.05-0.21),p=0.003).

Conclusions: CD4+CD28- cells in AAV are proinflammatory, Th1, CMV specific cells, able to target the endothelium through expression of CX3CR1 and are independently associated with higher arterial stiffness, a risk factor for CVD. This opens therapeutic possibilities not only in AAV but also in CKD where CD4+CD28- cells are prevalent and linked to CVD.

TH-PO390

A Novel Interacting Molecule with AT1 Receptor, ATRAP, Inhibits Ang II-Induced Proliferative Activity and Oxidative Stress in Vascular Smooth Muscle Cells Koichi Azuma,[1] Kouichi Tamura,[2] Takayasu Taira.[1] *[1]Dept of Medical Science and Cardiorenal Medicine, Zenjinkai Group, Yokohama, Kanagawa, Japan; [2]Dept Medical Science and Cardiorenal Medicine, Yokohama City Univ Graduate School of Medicine, Yokohama, Kanagawa, Japan.*

Background: Ang II influenses the structure and function of vascular smooth muscle cells, and plays an important role in reactive oxygen species production. Superoxide anions are recognized as mediators of intracellular signaling cascades and are known to participate in cardiovascular diseases such as arteriosclerosis and hypertension. Previous studies reported that the production of superoxide is modulated by many factors including Ang II - AT1 receptor signaling. One of the major sources of superoxide in the aorta is NADPH oxidase located in the smooth muscle cells.

Methods: We cloned a novel molecule interacting with carboxy-terminal domain of AT1 receptor, which we named ATRAP (for AT1 receptor-associated protein), using the yeast two-hybrid strategy. In this study, we tested the hypothesis that vascular smooth muscle cells express ATRAP and that ATRAP attenuates Ang II-induced proliferative activity and oxidative stress in vascular smooth muscle cells. We used rat smooth muscle cells and used adenoviral gene transfer for ATRAP overexpression. We used real time PCR,ELISA of TGF-β,p22phox,Rac1,Nox1 and BrdU incorporation assay for cell proliferation.

Results: We identified that the ATRAP mRNA and protein were endogeneously expressed in VSMC, and found a colocalization of ATRAP and AT1 receptor in Ang II-stimulated VSMC. The results of gain-of-function studies by adenoviral gene transfer demonstrated that overexpression of ATRAP significantly inhibited Ang II-mediated increases in c-fos gene transcription, BrdU incorpoaration, and mRNAs expression of NADPH oxidase complex .

Conclusions: These results indicate that ATRAP significantly attenuates Ang II-mediated proliferative activity and oxidative stress in vascular smooth muscle cells, and suggests a novel strategy to inhibit cardiovascular disease such as arteriosclerosis and hypertension.

TH-PO391

Myostatin: A Playmaker in Chronic Kidney Disease and Vascular Damage Daniela Verzola,[1] Giacomo Garibotto,[1] Maria bianca Bertolotto,[2] Samantha Milanesi,[1] Barbara Villaggio,[1] Jan Lindeman,[3] Giorgio Ghigliotti,[5] Claudio Brunelli,[5] Pietro Ameri,[5] Domenico Palombo,[4] Chiara Barisione.[5] *[1]Div Nephrology, Genoa Univ; [2]1st Clinic of Internal Medicine, Univ of Genoa -IRCCS AUO San Martino-IST; [3]Dept Vascular Surgery, LUMC, Leiden, the Netherlands; [4]Unit of Vascular and Endovascular Surgery Univ of Genoa; [5]Research Centre of Cardiovascular Biology Univ of Genoa, Italy.*

Background: Patients with abdominal aortic aneurysms (AAA) have higher prevalence of chronic kidney disease (CKD), that may contribute to arterial deterioration in a mutual detrimental feedback. Myostatin (Mstn), a TGF-β family member with cell-cycle inhibitory effects, is up regulated by CKD, but its role in vascular remodeling is unexplored. We hypothesized that Mstn may play a role in the progression of vascular damage.

Methods: In human AAA(N=8), non aneurysmatic atherosclerotic lesions (NAAL) samples(N=7) and normal abdominal aortas (N=3): Rt-PCR for Mstn and Smoothelin, a protein with contractile function (Smtn), immunostaining for Mstn, Smtn, CD45 and aSMA. In vitro studies: A7R5 vascular smooth muscle cells (VSMC) and human monocytes exposed to normal sera (NS), sera from patients with AAA (AAAS) or Mstn (500 ng/ml) for 48 hours. VSMC: proliferation, rt-PCR for Mstn and Smtn. Human monocytes: rt-PCR for Mstn, α-SMA and MCP-1 dependent chemotaxis.

Results: Mstn mRNA was overexpressed (by 8 folds, $p<0.05$) in AAA. Mstn immunostaining was also higher in AAA and NAAL and associated with downregulated Smtn ($p<0.05$). Mstn colocalized with VSMC (aSMA) and leukocytes (CD45). In A7R5, AAAS upregulated Mstn and downregulated Smtn ($p<0.05$); Mstn exposure decreased Smtn and cell proliferation. In monocytes, AAAS upergulated Mstn and α-SMA and Mstn increased aSMA and chemotaxis ($p<0.01$).

Conclusions: Our data suggest that Mstn is overexpressed in atherosclerotic lesions at sites of leukocyte infiltration and de-differentiated VSMCs. Unrecognized circulating factors in AAA patients enhance Mstn expression in VSMCs and monocytes. In turn, Mstn leads to VSMCs dedifferentiation, blunting their contractile function. In addition, Mstn activates monocytes, contributing to the inflammatory milieu in the aortic wall.

TH-PO392

Carbamylation of Plasma Proteins in Children with Chronic Kidney Disease Christine Pietrement,[1] Anja Christine Sander,[3] Stephane Jaisson,[2] Laetitia Gorisse,[2] Philippe Gillery,[2] Uwe Querfeld, Franz S. Schaefer.[3] *[1]Pediatric Dept, Nephrology Unit, Univ Hospital of Reims, Reims, France; [2]Laboratory of Pediatric Biology and Research, Univ Hospital of Reims, Reims, France; [3]Div of Paediatric Nephrology, Center for Pediatric and Adolescent Medicine, Heidelberg, Germany.*

Background: In adults with ESRD, Hcit concentration predicts increased CV risk and mortality. In adults with CKD and ESRD, CV morbidity and mortality are affected by traditional risk factors which tend to override effects of uremia such as carbamylation due to enhanced post-translational carbamylation of lysine and homocitrullin formation. Such mechanisms may be sensitively studied in children with CKD. Here, we analyzed plasma Hcit levels in a large cohort of children with CKD followed as they progressed to RRT.

Methods: Plasma Hcit concentrations were analysed, by mass spect, in 114 6 to 17 yo children from the 4C (Cardiovascular Comorbidity in Children with CKD) Study cohort with CKD stages 3-5 both cross-sectionally and longitudinally when treatment modality changed to dialysis (n=55) or transplantation (n=59). Factors predicting the change in Hcit were analyzed by multivariate linear modeling.

Results: Hcit concentrations were independent of age but correlated with eGFR ($r=-0.56$, $p<0.0001$) urea ($r=0.61$, $p<0.0001$) and albumin ($r=0.36$, $p=0.0001$) successively increasing from 277±86 mmol/mol Lys in CKD3 to 634±527 in CKD5. Hcit levels declined by an average of 14.6 % after initiation of dialysis, and by 58.1% after transplantation ($p<0.0001$). When adjusting for baseline levels, Hcit concentrations decreased significantly more markedly in patients starting peritoneal dialysis (PD) than in those starting hemodialysis (HD) (-106±226 vs. -52±169 mmol/mol Lys, $p<0.05$).

Conclusions: Hcit is strongly inversely correlated to eGFR and urea. Dialysis only partially compensates for the continued carbamylation process, although continuous PD appears to lower Hcit more efficiently than intermittent HD. After transplantation Hcit concentrations rapidly decrease to the range observed in CKD stage 3. Further studies are underway to analyze the role of protein carbamylation for the early occurrence of intermediate CV endpoints in this pediatric population.

TH-PO393

Effect of Far Infrared Radiation on Platelet Adhesion to Human Umbilical Vein Endothelial Cells Wen-Yi Chen,[1] Daw-yang Hwang,[2] Ke-Li Tsai,[1] Shang-Jyh Hwang.[2,3] *[1]Dept of Physiology, Kaohsiung Medical Univ, Kaohsiung, Taiwan; [2]Divsion of Nephrology, Kaohsiung Medical Univ Hospital, Kaohsiung, Taiwan; [3]Faculty of Renal Care, Kaohsiung Medical Univ, Kaohsiung, Taiwan.*

Background: Far-infrared Radiation (FIR) is an invisible electromagnetic waves with wavelength between 3-1000mm. FIR has multiple effects on the cardiovascular system, including increasing eNOS and heme oxygenase-1 (HO-1) expression in the endothelial cells. FIR improves dialysis fistulas function in hemodialysis patients with impaired endothelial function. Activation of thromboxane A2 receptor (TBXA2R) increses von Willebrand factor (vWF) expression and release, which lead to increased platelet adhesion to endothelial cells and vascular thrombosis. We hypothesis that FIR may reduce TBXA2R expression and decrease platelet adhesion to endothelial cells.

Methods: Cultured HUVECs were treated with or without FIR radiation for 30 minutes. Cells were harvested and total RNA was extracted for RNA-Seq. Total protein expressions of TBXA2R were assessed by western blot. To examine platelet-HUVEC interactions, we labeled platelet with calcein AM and co-culturedcalcein AM-labeled platelet with FIR-treated or controlled HUVECs followed by fluorescence microscopy analysis.

Results: The RNA-Seq results showed increased RNA expression in 665 genes and decreased RNA expression in 1,428 genes. There were 34 pathways of genetic expressions were significant different. Nineteen genes were involved in platelet aggregation (including GNA12, F2RL2, TBXA2R) after FIR radiation. Significant decreases in TBXA2R protein levels were observed after FIR radiation. The platelet binding to HUVEC cells was significantly less in the FIR-treated versus control.

Conclusions: These data suggest that FIR irradiation reduced TBXA2R RNA and protein expressions with decreased platelet adhesion to HUVECs. Our result may provide further mechinisms of FIR in the prevention of thrombus formation.

TH-PO394

Vitamin D Analogs-Induced Ectodomain Shedding of Tumor Necrosis Factor Receptor 1 as an Anti-Inflammatory Action Su-Kil Park, Won Seok Yang. *Div of Nephrology, Univ of Ulsan, Asan Medical Center, Seoul, Republic of Korea.*

Background: 1,25-Dihydroxyvitamin D_3 ($1,25D_3$), causes a disintegrin and metalloprotease 10 (ADAM10)-mediated ectodomain shedding of tumor necrosis factor receptor 1 (TNFR1) in human aortic smooth muscle cells (HASMCs) and thereby decreases responsiveness of the cells to TNF-α. In this study, we examined the potencies of other vitamin D_3 and D_2 analogs to induce ectodomain shedding of TNFR1 in HASMCs.

Methods: TNFR1 was measured by Western blot. Intracellular Ca^{2+} was measured using Fluo-4 AM. ADAM10 was localized by immunofluorescence staining.

Results: 25-Hydroxyvitamin D_3 ($25D_3$) and elocalcitol (an analog of $1,25D_3$) caused ectodomain shedding of TNFR1 at 30 min in a dose-dependent manner, whereas 1,25-dihydroxyvitamin D_2 ($1,25D_2$) and paricalcitol (a derivative of $1,25D_2$) did not. Both $25D_3$ and elocalcitol rapidly induced extracellular Ca^{2+} influx and caused a marked increase in intracellular Ca^{2+}, which was blocked by verapamil, an L-type Ca^{2+} channel inhibitor. In contrast, $1,25D_2$ and paricalcitol caused only small increases in intracellular Ca^{2+}. $25D_3$- and elocalcitol-induced TNFR1 ectodomain sheddings were abolished by verapamil and in Ca^{2+}-free media. Both $25D_3$ and elocalcitol caused the translocation of ADAM10 to the cell surface, which was inhibited by verapamil, while $1,25D_2$ and paricalcitol did not cause ADAM10 translocation. Depletion of ADAM10 by ADAM10-siRNA prevented $25D_3$- and elocalcitol-induced ectodomain shedding of TNFR1. $1,25D_2$ and paricalcitol did not antagonize, but rather increased $1,25D_3$-induced ectodomain shedding of TNFR1.

Conclusions: In summary, both $25D_3$ and elocalcitol caused ADAM10-dependent ectodomain shedding of TNFR1, whereas $1,25D_2$ and paricalcitol did not. This was due to the differences in the potency to induce extracellular Ca^{2+} influx. By causing TNFR1 ectodomain shedding and thereby decreasing responsiveness to TNF-α, vitamin D_3 analogs may regulate inflammatory response of vascular smooth muscle cells.

TH-PO395

Effect of Mycophenolate Mofetil on Cytokine Release and Cholesterol Transport in Different Subsets of Polarized Macrophages Joseph Mattana, Nobuyuki (Bill) Miyawaki, Isaac Teboul, Iryna Voloshyna, Allison B. Reiss. *Medicine, Winthrop-Univ Hospital, Mineola, NY.*

Background: Patients withsystemic lupus erythematosus (SLE) have a 5-9 fold increased incidence of cardiovascular disease (CVD). Lupus nephritis is commonly treated with mycophenolate mofetil (MPA). We examined the effect of MPA on cytokine release and expression of the proteins involved in cholesterol transport in M0, M1 and M2 human macrophages (MΦ).

Methods: THP-1 human monocytes were differentiated to a non-polarized phenotype (M0) (100nM PMA) and then incubated ± MPA (0.5, 1, 5, 10 and 20mg/ml). Supernatants were collected and level of Il-10, IFN-γ and TNF-α were analyzed. M0 were then incubated with 20 ng/ml interferon-γ+100 ng/ml LPS to obtain M1 or 20 ng/ml IL-4 to obtain M2 subsets. M0, M1 and M2 MΦ were incubated ± MPA (0.5, 1, 5mg/ml). Total RNA and protein were isolated. Expression of the major proteins involved in cholesterol transport, ABCA1, CD36 and SRA1, were evaluated by real-time PCR and confirmed with Western blot. Foam cell formation (FCF) was assessed by incubating ±50 mg/ml oxLDL and Oil-red-O staining.

Results: MPA decreased release of IFN-γ and TNF-α at 1mg/ml. At 5mg/ml level of cytokines was as in untreated cells and higher concentrations (10 and 20mg/ml) increased cytokine release up to 1.5 and 1.6 fold. In M0 MΦ MPA increased expression of ABCA1 (reaching 1.83±0.07at 5mg/ml) and decreased expression of CD36 and SR-A1 to 0.75±0.03, 0.6±0.08, respectively ($n=3$, $P<0.05$). FCF was decreased 0.75 times at 1mg/ml but returned to the level of untreated cells at 5mg/ml. In M2 MΦ MPA displayed a significant effect only on SR-A1 decreasing its expression to 0.7±0.04 at 5mg/ml. Effect of MPA on M1 MΦ was contradictory to other subtypes, reducing ABCA1 (0.71±0.04) and augmenting CD36 and SR-A1 expression (2.4±0.1 and 1.9±0.08 at 5mg/ml, respectively). Accordingly, FCF was enhanced 1.5 times at 5mg/ml.

Conclusions: MPA has effects on MΦ cytokine release and cholesterol handling which are dependent on MΦ subtype and concentration. These effects may be important in modifying atherogenesis in patients with SLE and may have relevance in kidney transplantation as well.

Mitochondria Derived Reactive Oxygen Species and Microvascular Dysfunction in Chronic Kidney Disease Danielle L. Kirkman,[1] Meghan G. Ramick,[1] Bryce J. Muth,[1] Raymond R. Townsend,[2] David G. Edwards.[1] *[1]Kinesiology and Applied Physiology, Univ of Delaware; [2]Clinical and Translational Research Center, Univ of Pennsylvania.*

Background: Endothelial dysfunction in chronic kidney disease (CKD) is characterized by reduced nitric oxide bioavailability as a consequence of oxidative stress. Damaged and dysfunctional mitochondria as a result of CKD are likely a large contributor to reactive oxygen species. The aim of this study was to determine if mitochondria derived reactive oxygen species contribute to impairments in nitric oxide mediated microvascular function in CKD.

Methods: Cutaneous vasodilation in response to local heating was assessed in 8 CKD patients (age:67±7 years; eGFR:48±11 ml/kg/1.73m^2) and 8 matched healthy individuals (age:60±6 years; eGFR:91±11 ml/kg/1.73m^2). Participants were instrumented with 2 intradermal microdialysis fibers for the infusion of 1) Ringers solution and 2) mitochondria specific superoxide scavenger mitoTempo. Skin blood flow in response to local heating (42°C) was assessed at the microdialysis sites by laser-Doppler flowmetry. Cutaneous vascular conductance (CVC) was calculated as a percentage of the maximum CVC achieved during sodium nitroprusside infusion at 43°C.

Results: CVC was attenuated in CKD patients compared to healthy controls (86±5 *vs* 95 ±3 %; $p<0.01$). MitoTempo significantly improved CVC in CKD patients (CKD Ringers *vs* CKD MitoTempo: 86±5 *vs* 93±6; $p<0.05$) to levels similar to that of healthy controls (CKD MitoTempo *vs* Healthy Ringers: 93±6 *vs* 95± 3; $p=0.67$).

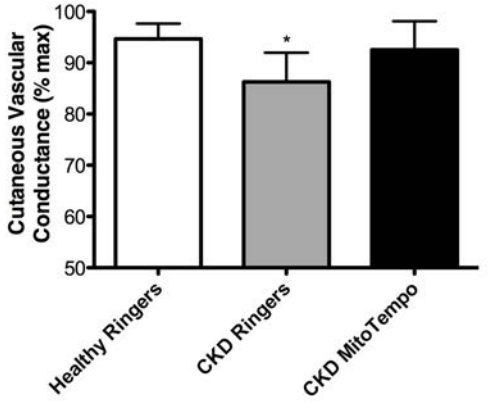

Figure 1. Cutaneous vascular conductance in response to local heating. *p<0.05 *vs* Healthy Ringers and CKD MitoTempo.

Conclusions: MitoTempo improved cutaneous microvascular function in CKD patients suggesting that mitochondria derived reactive oxygen species play a role in microvascular dysfunction in CKD. Improving mitochondria health and reducing mitochondria derived oxidative stress may be a potential therapeutic target for improving endothelial function in CKD.

Indolic Uremic Solutes-Aryl Hydrocarbon Receptor-Tissue Factor: A Novel Uremic Thrombosis Axis and Aryl Hydrocarbon Receptor as an Emerging Antithrombotic Target Moshe Shashar, Laith Al-Rabadi, Mostafa Belghasem, Lawrence Prince-Wright, Jamaica Siwak, Jean M. Francis, Vipul C. Chitalia. *Renal Section, Boston Medical Center, Boston, MA.*

Background: Thrombosis, a highly prevalent complication in CKD patients, remains an area of high unmet clinical need with poorly defined pathogenesis. While recent work has implicated indolic uremic solutes as potent prothrombotic toxins acting through Tissue Factor (TF), a procoagulant protein, it also uncovered Aryl Hydrocarbon Receptor(AHR) as a key mediator of this regulation and a druggable target for thrombosis. Since AHR blockers (AHRBs) inhibited thrombosis in uremic *milieu.* we hypothesized that inhibition of AHR activity destabilizes TF through its ubiquitination.

Methods: Sera from 25 ESRD patients on hemodialysis matched with controls were used. RNA silencing oligos to *carboxy terminus of hsc70-interacting protein* (*CHIP)*, full-length and a truncation of TF and full-length CHIP were expressed in various cell lines. Tissue factor expression and activity were examined using western blotting and a surface procoagulant activity assay, respectively.

Results: Our data showed that TF ubiquitination is inhibited in uremic *milieu*, a process substantially restored by AHRBs. The kinetic profile of this regulation suggested a post-translational mechanism. AHR is known to interact with *CHIP*, a RING-finger E3 ubiquitin ligase, and thus we posited that CHIP regulates TF ubiquitination. Binding and immunofluroesence studies supported an interaction of CHIP and TF in the cytosol. Deletion of the intracelllular domain of TF substantilly abrogated the interaction with CHIP suggesting that CHIP binds at the intracytosolic tail of TF. *CHIP* knock-out and silenced cells showed both significantly elevated TF expression and activity and prolonged TF half-life in uremic *mileu* supporting CHIP's role as an E3 ligase of TF.

Conclusions: Our data suggest CHIP as a candidate E3 ligase of TF and raise a tantalizing possibility of AHRBs regulating TF ubiquitination and thrombosis through CHIP. While supporting a novel post-translational regulation of TF, this work in future will unveil a potential mechanism of action of AHRBs, an emerging class of anti-thrombotics in CKD.

APOL1-B3 G2 Risk Variant Perturbs Cholesterol Homeostasis in THP-1 Macrophages Alex Dinh,[1] Hidefumi Wakashiu,[1] Jurgen Heymann,[1] Alessia Fornoni,[2] Jeffrey B. Kopp.[1] *[1]NIDDK, NIH, Bethesda, MD; [2]Dept of Medicine, Univ of Miami, Miami, FL.*

Background: Apolipoprotein L1 (APOL1) circulates in human plasma bound to high-density lipoprotein (HDL). *APOL1* G1 and G2 variants increase the risk of developing chronic kidney disease. We examined differences in cholesterol homeostasis in THP-1 macrophages stably expressing G0 and G2 variants of the APOL1-B3 (intracellular) isoform.

Methods: THP-1 cells were stably transfected with the G0 or G2 APOL1-B3 variants or an empty vector, and activated with phorbol myristate acetate (PMA) for 3 days. For cholesterol efflux assays, cells were incubated with 1 µCi/mL [3H]-cholesterol for 24 h. Efflux ligands were added to the media for 4 h, after which [3H]-cholesterol in media and cells was quantified. For amphotericin B lysis, cells were exposed to amphotericin B for 5 h. Cell viability was assessed using the CellTiter-Glo luminescent assay. To generate foam cells, THP-1 cells were stimulated with PMA for 2-3 d and incubated with 20 mg/ml oxidized LDL for 18 h. Cells were stained with Oil Red O.

Results: THP-1 macrophages expressing the APOL1-B3 G2 variant exhibited increased survival compared to cells expressing the APOL1-B3 G0 variant at amphotericin B concentrations of 10 mg/ml (93.2%±2.6% vs 79.4%±2.6%), 100 mg/ml (52.4%±0.3% vs 30.8%±0.5%), and 250 mg/ml (11.0%±0.8% vs 8.0%±1.1%), all $p<0.01$. Cells expressing the APOL1-B3 G2 variant had increased cholesterol efflux compared to cells expressing the APOL1-B3 G0 variant (25.2%±3.5% vs 11.6%±5.6%, $p<0.05$). Following incubation with oxidized LDL, APOL1-B3 G2 expressing cells had qualitatively less Oil Red O staining compared to APOL1-B3 G0 expressing cells, indicating a relative decrease in neutral lipid uptake.

Conclusions: Stable expression of the APOL1-B3 G2 risk variant in THP-1 macrophages increased cholesterol efflux and decreased neutral lipid content compared to APOL1 G0 cells, which could lead to cellular cholesterol depletion. This finding may explain the observed protective effect of APOL1 risk variants on cardiovascular mortality in African Americans with type 2 diabetes, a disease characterized by decreased cholesterol efflux and increased propensity to form foam cells.

Indoxyl Sulfate-Induced Endothelial Microparticles Stimulate Vascular SMC Proliferation and Neointimal Hyperplasia Formation Through TGF-β Induction Jung-hwa Ryu, Shina Lee, Dong-Ryeol Ryu, Duk-Hee Kang, Kyu Bok Choi, Seung-Jung Kim. *Internal Medicine, College of Medicine, Ewha Womans Univ, Seoul, Republic of Korea.*

Background: Vascular access stenosis occurs frequently and predominantly as a result of neointimal hyperplasia formation caused by vascular smooth muscle cell(SMC) proliferation. Previous reports showed that endothelial microparticle(EMP) is closely associated with vascular dysfunction and atherosclerosis. In this study, we investigated the effects of EMP on TGF-β signaling and its association with proliferation of vascular SMC and neointimal hyperplasia formation.

Methods: To produce EMPs, HUVECs were stimulated by indoxyl sulfate (IS). IS-induced EMPs were collected by ultracentrifugation of culture media and sorted by flow cytometry. Human aortic SMCs($1.0x10^6$) were treated by EMPs of $2x10^6$ particles Western blot analysis was done for Akt, ERK1/2, p38 MAPK, and Smad3. SMC proliferation was measured by BrdU cell proliferation assay. TGF-β production was measured by PCR and ELISA. Porcine internal jugular veins were cultured *ex vivo* in the presence of EMPs for 12 days, and immunohistochemistry for TGF-β and phospho-specific TGF-β signalings was done.

Results: EMPs stimulated the proliferation of aortic SMCs in a dose-dependent manner. EMPs induced TGF-β secretion from aortic SMCs as well as the phosphorylation of its down-stream signaling molecules including Akt, ERK1/2, p38 MAPK, and Smad3. The proliferation of aortic SMCs and the phosphorylation of the signaling molecules were significantly reduced by anti-TGF-β neutralizing antibody. In *ex vivo* culture of porcine internal jugular veins, neointimal hyperplasia was significantly developed in EMP-treated venous tissues. The expression of TGF-β and the phosphorylated signaling molecules were significantly up-regulated in the area of neointimal hyperplasia.

Conclusions: IS-induced EMPs stimulated the proliferation of vascular SMCs and the production of TGF-β by vascular SMCs, and the proliferation of these cells was mediated by TGF-β. Accordingly, EMPs induced neointimal hyperplasia formation and TGF-β expression in cultured venous tissue. Further investigation is needed to demonstrate the role of EMPs on vascular access stenosis.

TH-PO400

Inflammation, Apoptosis, Fibrosis and Vascular Calcification in a Model of Balloon Injury in Rats with Chronic Kidney Disease Artur P. Mendes. *ISNI, CHLO, Lisboa, Portugal.*

Background: Cardiovascular disease (CVD) is more prevalent and has a worse prognosis in chronic kidney disease (CKD) patients than in the general population and is the leading cause of morbimortality in those patients. Not only traditional risk factors of CVD but also uremia-related ones like inflammation, fibrosis and mineral disorder may contribute to the poor CVD prognosis.

Methods: We developed a model of accelerated vasculopathy in rats with CKD to study the vascular damage in CKD: inflammation, apoptosis, fibrosis and vascular calcification. The animal model consisted of inducing a balloon injury (BI) with angioplasty in the carotid arteries (CA) of 5/6 nephrectomy rats and compare the lesion with non-CKD rats (NR). We used 24 Wistar rats.

Results: We analyzed the normal and injured CA of NR and CKD rats with histology, immunohistochemistry (IH) and RT-PCR, 1 week after the BI. With HE, we saw similar intimal hyperplasia in the CA with BI in both groups. With Masson trichrome and sirius red we observed connective tissue mainly in adventitia layer. With IH for fibronectin we saw abundant expression in hyperplasia areas of the intima of the CA submitted to BI. The expression in the media layer was higher in CKD than NR. In cellular proliferation studies with Mib1 Ab we also appreciated a higher expression of the Ab in the neointima of CKD rats. In IH for activated caspase 3 no expression was noticed in both groups. In the anti-CD68 Ab study we could see macrophages mainly in the adventitia layer of injured CA of the CKD rats than on the NR. We didn't observe tissue calcification with Von Kossa staining in any group. In the RT-PCR studies there were more type 1 collagen and fibronectin in the injured CA than in the non injured CA of the NR, as expected, but also more type 1 collagen and fibronectin in the non injured CA of the CKD rats than in the NR and much more in the injured CA of CKD rats.

Conclusions: In a model of accelerated vasculopathy we have shown a more intense activation of the inflammation and fibrosis pathways in the CKD rats than in NR.

TH-PO401

Post-Transcriptional Guidance of Monocyte to Macrophage Differentiation by the RNA-Binding Protein Quaking Jurrien Prins, Ruben de Bruin, Janine van Gils, Ton J. Rabelink, Anton Jan Van Zonneveld, Eric P. van der Veer. *Nephrology, Leiden Univ Medical Center, Leiden, Zuid-Holland, Netherlands.*

Background: Kidney injury is associated with excessive recruitment and influx of monocytes to sites of tissue damage and their ensuing differentiation into macrophages. This differentiation is associated with a striking increase in protein expression levels of the RNA-binding protein Quaking (QKI). We therefore set out to investigate the role of QKI in monocyte and macrophage function.

Methods: Monocytes expressing an shRNA against QKI were studied for their capacity to adhere, migrate and differentiate into macrophages. RNA-seq and microarray analysis of human monocytes and macrophages, including those of a unique QKI haploinsufficient patient, was performed to identify QKI-mediated splicing events. Identified splice variants of the actin capping protein y-Adducin were validated using a splicing reporter construct and were ectopically expressed in monocytes to study migration using a transwell migration assay. Unilateral ureteral obstruction (UUO) on mice hypomorphic for QKI (QK^v) was performed and analysed.

Results: Specific depletion of QKI protein significantly impaired monocyte adhesion, migration and differentiation into macrophages in vitro. RNA-seq and microarray analysis revealed 571 and 629 splicing events in monocytes and macrophages, respectively. One such event was the inclusion of a cassette exon in y-Adducin, which occurred after depletion of QKI protein, and was found to reduce monocyte migration when ectopically expressed. UUO in hypomorphic QK^v mice revealed a two-fold reduction in macrophage markers (F4/80 and CD115) and decreased interstitial collagen deposition compared to controls.

Conclusions: We show that QKI post-transcriptionally guides monocyte and macrophage function in vitro and in vivo, partially by mediating alternative splicing of pre-mRNA targets of QKI such as y-Adducin. The reduced infiltration of monocytes and ensuing differentiation into macrophages, and deposition of interstitial collagen observed in a UUO model in QK^v mice identifies QKI as a novel target for therapeutic intervention in renal and inflammatory disease.

Induction of Autophagy and Its Role in Endothelial Cell Injury in Response to Carbamylated Low-Density Lipoprotein (cLDL) Chhanda Bose,[1,2] Sudhir V. Shah,[1,2] Oleg K. Karaduta,[1,2] Alexei G. Basnakian,[1,2] Gur P. Kaushal.[1,2] *[1]Dept of Internal Medicine, Div of Nephrology, Univ of Arkansas for Medical Sciences, Little Rock, AR; [2]Medicine Service, Renal Section, Central Arkansas Veterans Healthcare System, Little Rock, AR.*

Background: We and others have demonstrated that plasma levels of carbamylated proteins are elevated in CKD patients and that they are significant predictors of cardiovascular events and all-cause mortality. Autophagy is a highly conserved process of protein and organelle degradation and is involved in regulation of cellular injury. Its induction and role in endothelial cell injury in response to cLDL has not been examined.

Methods: A time course (for up to 24 hours) and concentration dependence of cLDL (0 μM to 500 μM) was performed for autophagy measurements. The effect of cLDL on autophagy was evaluated by increased formation of punctate immunofluorescence staining of GFP-LC3-II from GFPLC3-I following transfection with GFP-LC3 plasmid and conversion of LC3-I to LC3-II as determined by western blot. The effect of inhibition of cLDL-induced autophagy on cell death and DNA fragmentation was determined using 5mM 3-methyladenine (3-MA) and chloroquine. DNA fragmentation will be measured by a TUNEL assay.

Results: Carbamylated LDL treatment of human coronary artery endothelial cells (HCAECs) increased LC3-II punctate dots in a dose- and time-dependent manner. Autophagy induction in response to cLDL was observed by conversion of LC3-I to LC3-II by western blot. The formation of cLDL-induced LC3-II vesicles were markedly inhibited by 3-MA. These studies provide the first evidence that cLDL increases LC3-II protein and autophagosome formation in endothelial cells. The autophagy inhibitor 3-MA suppressed cLDL-induced LDH release, EndoG activation, and DNA fragmentation, suggesting that inhibition of cLDL-induced autophagy provides a cytoprotective role against EndoG activation and cell death in HCAECs.

Conclusions: HCAECs respond to cLDL by induction of autophagy in a dose- and time- dependent manner, and inhibition of cLDL-induced autophagy is cytoprotective against cLDL-induced cell death, DNA fragmentation, and EndoG activation.

Fractalkine Receptor CX3CR1 on Bone Marrow Derived Cells Is Required for Excess Atherosclerotic Inflammation in Renal Impairment Shuwang Ge, Johannes Nordlohne, Barbara Hertel, Hermann G. Haller, Sibylle Von Vietinghoff. *Nephrology and Hypertension, Hannover Medical School, Hannover, Germany.*

Background: Reduced kidney function is an important risk factor of aggravated atherosclerosis. Inflammatory leukocytes are attracted to the lesion and regulate lesion growth and composition. Fractalkine receptor CX3CR1 is highly expressed on peripheral blood leukocytes, but also resident vascular cells such as smooth muscle cells. This study investigated the role of CX3CR1 in atherosclerotic inflammation a mouse model with moderate renal impairment.

Methods: Apolipoprotein E (Apoe-/-) and LDL receptor (LDLr-/-) deficinet mice underwent unilateral nephrectomy or sham surgery and were maintained on high-fat diet. Bone marrow transplantation was conducted after lethal irradiation. Aortic lesion size was quantified macroscopically and histologically in the aortic root and leukocyte infiltration determined by microscopy and flow cytometry.

Results: Apoe-/- mice without CX3CR1 were protected from increased aortic atherosclerotic lesion size and macrophage accumulation in renal impairment. LDLr-/- mice were similarly protected. Renal impairment increased CX3CR1 expression on aortic macrophages. Conversely, in renal impairment, aortic macrophage numbers were significantly decreased in the absence of CX3CR1. In mixed chimeric mice, absence of CX3CR1 on bone marrow cells only sufficed to decrease atherosclerotic macrophage numbers and aortic root lesion size in renal impairment.

Conclusions: CX3CR1 was instrumental in enhanced atherosclerosis in renal impairment. This effect was beyond the CX3CR1 effect observed in normal renal function suggesting that CX3CR1 inhibition should be investigated as a targeted treatment approach in this high-risk group.

TH-PO404

Afferent Arteriolar Endothelial-Dependent Dysfunction Precedes Radiation-Induced Nephropathy and Hypertension John D. Imig,[1] Eric P. Cohen.[1] *[1]Medical College of Wisconsin; [2]Univ of Texas Southwestern.*

Background: Chronic kidney disease (CKD) occurs in 15% of hematopoietic stem cell transplant (HSCT) patients, and has been clearly linked to irradiation at the time of the HSCT. Radiation nephropathy is expressed in rats and in humans as azotemia and hypertension. There is a latent period of 6-8 weeks after irradiation to the development of proteinuria, azotemia, and hypertension in rats. We tested the hypothesis that afferent arteriolar responses to the endothelial-dependent dilator acetylcholine are impaired prior to the development of azotemia and hypertension in rats exposed to total body irradiation (TBI).

Methods: Male WAG/RijCmcr rats were subjected to TBI (11 Gy) and afferent arteriolar responses to acetylcholine using the juxtamedullary nephron technique were determined at one, three, and six weeks.

Results: Systolic blood pressure (117 ± 6 vs. 119 ± 4 mmHg) and BUN (15.6 ± 1.4 vs. 15.8 ± 0.8 mg/dl) were not different between control and TBI groups at 6 weeks. Afferent arteriolar diameters averaged 22.5 ± 0.8 mm (n=30) in controls and 21.7 ± 0.7 mm (n=27) in TBI rats and were not different between control and TBI groups at 1, 3, or 6 weeks. Acetylcholine dilator responses were progressively attenuated from one to six weeks in TBI compared to control rats. During exposure to acetylcholine (0.01, 0.1, 1, and 10 mmol/L), afferent diameter increased by 8 ± 2%, 18 ± 3%, 27 ± 2% and 31 ± 3% in control rats (n=6), and 3 ± 2%, 9 ± 3%, 12 ± 3%, and 16 ± 3% in kidneys of 3 week TBI rats (n=8, $p<0.05$). However, TBI did not change the nitroprusside vasodilator responses at 1, 3, or 6 weeks. Renal microvessels were isolated from control and TBI groups at 3 and 6 weeks for protein expression assessment of endothelial enzymatic pathways Cyp2C, COX, and NOS. We found that epoxygenase Cyp2C protein expression was significantly lower 3 and 6 weeks following TBI compared to control rats.

Conclusions: Taken together, these results indicate that the impaired afferent arteriolar endothelial-dependent acetylcholine responses and decreased epoxygenase enzymes precede the development of proteinuria, azotemia, and hypertension in irradiated rats.

TH-PO405

Elevated Lp-PLA2 Plasma Activity Is an Independent Predictor of Subclinical Atherosclerosis in CKD5-D Patients – No Correlation with Lp-PLA2 mRNA Expression in Isolated Monocyte Subsets Christof Ulrich, Bogusz Trojanowicz, Roman Fiedler, Felix Kohler, Anna-Franziska Wolf, Eric Seibert, Matthias Girndt. *Internal Medicine II, Martin-Luther-Univ Halle-Wittenberg, Germany.*

Background: The continued search for biomarkers indicating future cardiovascular events among patient on renal replacement therapy is well-founded by the extraordinarily high cardiovascular mortality rate in these patients. The combination of inflammatory cells capable of expressing atherogenic molecules within the plaque makes the monocyte-/ Lp-PLA2-axis an interesting subject to study in patients on maintenance dialysis (CKD5-D).

Methods: CKD5-D were stratified upon the presence (A+) or absence (A-) of subclinical atherosclerosis by carotid artery ultrasound. Lp-PLA2 plasma activity was measured by an enzymatic kinetic test and leucocytic Lp-PLA2 mRNA expression by real time PCR. Monocyte subsets were analyzed flow-cytometrically and defined as classical CD14++CD16- (Mo1), intermediate CD14++CD16+ (Mo2) and non-classical CD14+CD16++ (Mo3). mRNA expression analysis of these subsets (N=24) was done after sorting of cells using ARIA II FACS-sorter.

Results: 60 CKD5-D (62.3±15.5 years) patients and 39 healthy control subjects (54.0±8.4 years) were enrolled in a cross-sectional study. Lp-PLA2 mRNA expression in leucocytes and plasma Lp-PLA2 activity were significantly higher in CKD5-D. CKD5-D patients diagnosed with subclinical atherosclerosis (A+) had the most prominent Lp-PLA2 activity values, which even remained significantly different compared to A- after adjustment for age and HbA1c. Among different monocyte subsets Mo1 and Mo2 had the highest Lp-PLA2 mRNA level, but it was Lp-PLA2 mRNA expression on "patrolling" Mo3 cells which was significantly elevated in A+ versus A-.

Conclusions: We conclude that Lp-PLA2 activity is an independent predictor of subclinical atherosclerosis in CKD5-D patients. Among monocyte subsets Mo3 cells appear to have an exceptional position within the setting of atherosclerosis. These vessel patrolling cells may reflect a physiological response to vascular inflammation in CKD5-D patients.

Hypoxanthine, a Uremic Small Solute, Induces Cholesterol Accumulation in Hepatocytes and Incites Atherosclerosis in APO E Deficiency Status Yong-Lim Kim,[1,2] Hye-Myung Ryu,[1] Sukyung Lee,[1] Hee-Yeon Jung,[1] Se-Hee Yoon,[3] Ji-Young Choi,[1] Chan-Duck Kim,[1] Sun-Hee Park,[1] Jang-Hee Cho.[1] *[1]Div of Nephrology and Dept of Internal Medicine, Kyungpook National Univ Hospital, Daegu, Korea; [2]BK21 Plus KNU Biomedical Convergence Program, Dept of Biomedical Science, Kyungpook National Univ, Daegu, Korea; [3]Dept of Internal Medicine, Konyang Univ, Daejeon, Korea.*

Background: Hypoxanthine which originates from purine metabolism is a small free water-soluble uremic toxin. Its biological functions remain unknown. In this study, we investigated the role of hypoxanthine on chronic kidney disease (CKD) and cholesterol synthesis with atherosclerosis development, particularly in apolipoprotein E (APOE)-deficient mice.

Methods: The effect of hypoxanthine on the regulation of cholesterol synthesis and atherosclerosis were evaluated in cultured HepG2 cells and Apoe knockout (KO) mice.

Results: Hypoxanthine had no effect on the renal interstitial fibrosis in CKD mouse. The effect of hypoxanthine on the regulation of cholesterol synthesis and atherosclerosis were evaluated in cultured HepG2 cells and Apoe knockout (KO) mice. In HepG2 cells, hypoxanthine increased intracellular ROS production. Hypoxanthineincreased cholesterol accumulation and decreased APOE and ATP-binding cassette transporter A1 (ABCA1) mRNA and protein expression in HepG2 cells. Furthermore, H_2O_2 also increased cholesterol accumulation and decreased APOE and ABCA1 expression. This effect was partially reversible by pre-treatment with the antioxidant N-acetyl cysteine. Hypoxanthine and APOE knockdown using APOE-siRNA synergistically induced cholesterol accumulation and reduced APOE and ABCA1 expression. Hypoxanthinemarkedly increased serum cholesterol levels and the atherosclerotic plaque area inApoe KO mice.

Conclusions: Hypoxanthine induces cholesterol accumulation in hepatic cells through alterations in enzymes that control lipid transport and induces atherosclerosis in APOE-deficient cells and mice. These effects are partially mediated through ROS produced in response to hypoxanthine.

TH-PO407

Atherosclerosis following Renal Injury Is Ameliorated by Pioglitazone and Losartan via Macrophage Phenotype Suguru Yamamoto,[1,2] Jianyong Zhong,[1,3] Haichun Yang,[3] Yiqin Zuo,[3] Ichiei Narita,[2] Valentina Kon.[1] *[1]Dept of Pediatrics, Vanderbilt Univ Medical Center, Nashville, TN; [2]Div of Clinical Nephrology and Rheumatology, Niigata Univ Graduate School of Medical and Dental Science, Niigata, Japan; [3]Dept of Pathology, Vanderbilt Univ Medical Center, Nashville, TN.*

Background: Chronic kidney disease (CKD) amplifies atherosclerosis which involves renin-angiotensin system (RAS) regulation of macrophages. RAS influences peroxisome proliferator-activated receptor-γ (PPARγ), a modulator of atherogenic functions of macrophages, however, little is known about its effects in CKD related vasculopathy.

Methods: Apolipoprotein E knockout mice were uninephrectomized (UNx) and treated with pioglitazone, losartan, or both (UNx+Pio/Los) for 10 weeks. Extent and characteristics of atherosclerotic lesions and macrophage phenotypes were assessed. Peritoneal macrophages and RAW264.7 cells were used to examine pioglitazone and losartan effects on macrophage phenotype and inflammatory response.

Results: UNx significantly increased atherosclerosis. Pioglitazone and losartan each significantly reduced the atherosclerotic burden by 29.6% and 33.5%, respectively; however the benefit was dramatically augmented by combination treatment (55.7%). Assessment of plaques revealed significantly greater macrophage area in UNx+Pio/Los with more apoptotic cells. The expanded macrophage-rich lesions of UNx+Pio/Los had more alternatively activated, Ym-1 and arginine 1-positive M2 phenotypes. There was no difference in plaque collagen content or calcifications. *In vitro*, pioglitazone alone and together with losartan was more effective than losartan alone in dampening lipopolysaccharide-induced cytokine production, suppressing M1 phenotypic change while enhancing M2 phenotypic change.

Conclusions: Combination of pioglitazone and losartan is more effective in reducing renal injury-induced atherosclerosis than either treatment alone. This benefit reflects mitigation in macrophage cytokine production, enhanced apoptosis, and a shift toward an anti-inflammatory phenotype.

TH-PO408

Differential Activation of Monocyte and Neutrophil Genomics following Fistula Placement Christopher S. Kuppler,[1,2] Lyle L. Moldawer,[2] Scott A. Berceli,[1,2] The HFM Study Group.[3] *[1]Div of Vascular Surgery and Endovascular Therapy, Univ of Florida, Gainesville, FL; [2]Dept of Surgery, Univ of Florida, Gainesville, FL; [3]NIDDK, NIH.*

Background: Systemic inflammation is as an important regulator of flow mediated vascular adaptation. We evaluated the genomic response of circulating leukocytes after fistula (AVF) placement, hypothesizing that this severe flow environment induces unique monocyte (mono) and neutrophil (PMN) expression patterns.

Methods: Blood samples were collected pre-op, 2 weeks, and 6 weeks following AVF creation (n=74). Mono and PMN mRNA was isolated and analyzed for 44,699 genes using the HTA 2.0 microarray. BRB ArrayTools and Ingenity Pathway Analysis was used to identify leukocyte genome changes, relevant ontologies, and upstream regulators.

Results: Compared to pre-op levels, 1,014 mono and 1,594 PMN genes were found to be differentially expressed 2 weeks after AVF placement ($p<0.001$), but returned to baseline by 6 weeks post-op [91 (mono) and 1 (PMN); $p<0.001$]. Mono and PMN showed a divergent, inversely correlated expression pattern (**A**, $p<0.001$), with 892 genes upregulated in mono/downregulated in PMN (Group 1) and 1189 genes upregulated in PMN/downregulated in mono (Group 2). Group 1 genes were mostly associated with intracellular translational control and cell survival; Group 2 genes were associated with the extrinsic stimulation of non-inflammatory systems (**B**). Upstream regulator analysis revealed enhanced interferon signaling in monocytes as the driver of these divergent expression patterns (**C**).

Conclusions: Following AVF creation and exposure to this new flow environment, there is a significant but divergent shift in the genomic profile of leukocytes. We hypothesize that this unique activation pattern has important implications in early AVF adaptation. Integration with the anatomic, physiologic and outcome data sets from the parent HFM study is ongoing.

Identification of Angiotensin Peptides Modulating the Harmful Effects of Ang II Inchronic Renal Failure Joachim Jankowski, Vera Jankowski. *Inst of Molecular Cardiovascular Research, Univ Hospital RWTH, Aachen, NRW, Germany.*

Background: Angiotensin II (Ang II) is essential in the physiology and pathology of vascular regulation. Ang II is the principal vasoactive substance of the renin-angiotensin system (RAS), having a variety of physiological actions. In the past few years, the classical concept of the RAS system has experienced substantial conceptual changes. Angiotensin peptides such as Ang 1-7, Ang III and Ang IV were identified as mediators involved in vascular regulation. Progress of mass-spectrometric techniques affords the opportunity for identification of unknown angiotensin peptides. When screening the molecular mass range of Ang II for novel peptides, we observed two signals which could represent further angiotensin peptides.

Methods: In order to identify novel angiotensin peptides, we isolated these peptides from human plasma. Chromatographic purification and structural analysis by mass-spectrometry revealed Ang II like octapeptides Pro-Glu-Val-Tyr-Ile-His-Pro-Phe and Ala-Arg-Val-Tyr-Ile-His-Pro-Phe,. We named these peptides *Angioprotectin* and *Ala-Angiotensin* (*Ala-Ang*).

Results: *Angioprotectin* antagonises the contractile actions of Ang II. These physiological antagonism of vasoconstrictor actions of Ang II by *Angioprotectin* is mediated by theMas receptor. *Angioprotectin* has a stronger affinity to the Mas receptor than Ang-1-7. Plasma concentrations in healthy human volunteers were about 15 % and in CKD patients up to 50 % of plasma Ang II concentrations. Ang A has the same affinity to the AT_1 receptor as Ang II, but a higher affinity to the AT_2 receptor. Ang A revealed a less vasoconstrictive effect than Ang II in-vitro, which is not modified in the presence of the AT2 receptor antagonist PD 123319, suggesting a lower intrinsic activity at the AT_1 receptor. In healthy subjects, Ang A concentrations are less than 20% of the Ang II concentrations, but the ratio Ang A / Ang II is higher in CKD.

Conclusions: In conclusion, Angioprotectin and Ang A are novel human, vasoconstrictive angiotensin-derived peptides. Due to stronger agonism at the MAS and AT_2 receptor, respectively, and -furthermore- their increased plasma concentration in CKD. Ang A may modulate the harmful effects of Ang II.

TH-PO410

Phosphate (Pi)-Induced Endothelial Microparticles Express Histone H2B which Supports Thrombin Generation Nima Abbasian,[1] Karl Herbert,[2] James O. Burton,[1,3] Nigel J. Brunskill,[1,3] Alan Bevington.[1] *[1]Dept of Infection, Immunity, & Inflammation, Univ of Leicester, Leicester, United Kingdom; [2]Dept of Cardiovascular Sciences, Univ of Leicester, Leicester, United Kingdom; [3]John Walls Renal Unit, Univ Hospitals of Leicester, Leicester, United Kingdom.*

Background: Cardiovascular disease is common in patients with chronic kidney disease. Hyperphosphatemia is a well-known cardiovascular risk factor which we have recently shown can induce the formation of pro-coagulant endothelial microparticles (EMPs) through an elevation of intracellular P_i concentration, and that EMPs express VE-cadherin and superficial phosphatidylserine (PSer) on their surface; however, a comprehensive characterization of the antigenic composition of Pi-induced EMP has been poorly defined.

Methods: EAhy926 endothelial cells were treated with control 1mM vs. high 2.5mM P_i. EMPs were separated from the cultured medium by centrifugation. EMPs were subjected to 'shotgun proteomics' using LC MS/MS analysis. The presence of H2B in EMPs was probed by immunoblotting using anti-H2B antibody. The presence of DNA and RNA in EMPs was determined by Burton DNA Assay and using an Agilent RNA 6000 Pico Kit.

Results: MS analysis demonstrated that high Pi-induced EMPs contain nucleosome components (H2B, H2A, H2A.x, H3.2, and H4), enzymes, proteins involved in vesiculation & signalling, chaperones, and cytoskeleton associated proteins. Immunoblotting using anti-H2B antibody confirmed Pi-induced EMPs are enriched in H2B. DNA and RNA measurements showed EMPs contain both DNA and RNA.

Conclusions: These data for the first time show that Pi-induced EMPs are enriched in H2B, along with DNA, and RNA. H2B promotes activation of the contact pathway and inhibition of fibrinolysis and hence supports coagulation in vivo. In conclusion, Pi-induced EMPs influence thrombosis through expressing PSer, inhibition of fibrinolysis and activation of the contact pathway by expressing H2B. Further studies are needed to confirm the exact mechanistic role of these molecules expressed on Pi-induced EMPs in the pathogenesis of thrombosis in vivo.

Identification of the "*Vasoconstriction Inhibiting Factor*" (*VIF*) – A Potent Endogenous Cofactor of Angiotensin II Acting on the AT2 Receptor Joachim Jankowski, Vera Jankowski. *Inst of Molecular Cardiovascular Research, Univ Hospital RWTH, Aachen.*

Background: The renin-angiotensin-system and especially the angiotensin peptides play a central role in blood pressure regulation. Here, we hypothesize that a yet unknown peptide is involved in the action of Ang-II modulating the vasoregulatory effects as a cofactor.

Methods: The peptide with vasodilatory properties was isolated from adrenal glands chromatographically.The effects of this peptidewere evaluated in-vitro and, in-vivo and the receptor affinity was analysed.

Results: The plasma concentration in humans was quantified in chronic kidney disease patients, heart failure patients and healthy controls. The amino acid sequence of the peptide from bovine adrenal glands was HSSYEDELSEVLEKPNDQAEPKEVTEEVSSKDAAE, which is a degradation product of Chromogranin-A. The sequence of the peptide isolated from human plasma was HSGFEDELSEVLENQSSQAELKEAVEEPSSKDVME. Both peptides diminished significantly the vasoconstrictive effect of Ang-II in-vitro. Therefore, we named the peptide "vasoconstriction inhibiting factor" (VIF). The vasoregulatory effects of VIF are mediated by the AT2-receptor. VIF impairs Ang-II-induced phosphorylation of the p38MAPK-pathway but not of ERK1/2. The vasodilatory effects were confirmed in-vivo. The plasma concentration was significantly increased in renal and hear failure patients.

Conclusions: VIF is a vasoregulatory peptide which modulates the vasoconstrictive effects of Ang-II by acting on the AT2-receptor. It is likely that the increase in VIF may serve as a counter-regulatory effect to defend against hypertension. The identification of this target may help us to understand the pathophysiology of renal and heart failure and may form a basis for the development of new strategies for the prevention and treatment of cardiovascular disease.

A Novel Microfluidic System for Studying Human Microvascular Integrity Graham Marsh, Angela Huang, Jeremy Stuart Duffield. *Research & Development, Biogen, Cambridge, MA.*

Background: The microvasculature of the kidney plays a critical role in kidney physiology, injury, and disease. Proper hemodynamic and biochemical signals are pivotal for sustaining normal functions in kidney microvasculature, which are greatly altered during kidney injury. Traditional 2D cultures *in vitro* fail to reconstruct the microenvironment of the kidney capillary network and cannot accurately examine the microvasculature in injury conditions. To bridge the gap between *in vitro* and *in vivo* models, we developed a novel platform to study kidney microvasculature by building a 3D capillary using a Nortis microfluidic system.

Methods: We seeded primary kidney endothelial cells from a human fetal donor into a 120 mm tube in a collagen matrix. We then flowed media though the device with a controlled shear stress to mimic *in vivo* conditions. The system allows for cells to be grown in co-culture by embedding supporting cells, such as pericytes, in the collagen matrix. In this engineered microenvironment, we are able to deliver growth factors or stimulants in controlled doses to observe changes in microvessel function and morphology. This platform has allowed us to visualize the microvessel with a high resolution by confocal microscopy, to observe cell-cell interactions, study the basement membrane composition, and measure vessel integrity. We evaluated the barrier function of the capillary network by examining vascular leak under normal conditions and in an injury model with TNFα activation.

Conclusions: There was a significant increase in the permeability of the vessels when they are activated with TNFα compared to resting condition, and microvessels co-cultured with pericytes had significantly enhanced microvascular integrity and lowered vascular leak. The microfluidic platform has enormous potential to study the human kidney microvasculature *in vitro* while maintaining the structure and morphology observed *in vivo*.

The Circadian Clock Provides Beneficial Effects against the Endothelial Dysfunction to Promote Atherogenesis by Regulating Plasminogen Activator Inhibitor-1 and Cellular Adhesion Molecules Generation Hideyuki Negoro. *Medicine, Harvard Medical School, Boston.*

Background: The circadian clock is a molecular mechanism that confers 24 hour variations in gene expression and function to regulate number of physiological functions in humans. Disruption of the clock is associated with pathological remodeling in the arterial structure and vascular stiffness. Chronic circadian clock disruption is also associated with dysfunction in endothelial signaling and responses. In this study, we observed if the deletion of Bmal1, a critical component of the circadian clock, can influence plasminogen activator inhibitor-1 (PAI-1) and cellular adhesion molecules, such as monocyte chemotactic protein-1 (MCP-1) and intracellular adhesion molecule-1 (ICAM-1) which play an important part in the progression of vascular diseases.

Methods: Congenic 12- to 16-week-old male, wild-type and Bmal1-KO littermate mice were generated from heterozygote breedings to be used for these studies. We also knocked down Bmal1 to evaluate the protein levels of PAI-1, MCP-1 and ICAM-1 in the knocked down cells.

Results: Endothelial function was reduced in aorta from Bmal1-KO mice. In aorta from Bmal1 KO mice, there was an increase in MCP-1 and ICAM-1 expression in mice with a dysfunctional circadian rhythm. Moreover, Bmal1 KO mice display pre-mature aging to have a dramatic prothrombotic phenotype. This phenotype is linked to changes in the regulation of key risk factors for cardiovascular disease. These include circulating fibrinogen and PAI-1, which are significantly elevated in Bmal1KO mice.We confirmed that PAI-1 levels follow a circadian pattern and this pattern was absent in Bmal1 KOmice.

Conclusions: These findings indicate that circadian clock provides beneficial effects against the endothelial dysfunction to promote atherogenesis by regulating PAI-1and cellular adhesion molecules generation.This study establishes a mechanistic connection between Bmal1 and cardiovascular phenotype.

TNF-Alpha Receptor 1 Is Associated with Mortality in Persons with Coronary Artery Disease Meyeon Park, Daniela Maristany, Eric Vittinghoff, Mary Whooley, Michael Shlipak. *UCSF.*

Background: Inflammation is a possible mechanism to explain the association between atherosclerosis and mortality. Chronic kidney disease is associated with high levels of inflammation. This study evaluated circulating tumor necrosis factor receptor type 1 (TNFR1A), a marker of inflammation, as a risk factor for mortality.

Methods: In the Heart and Soul Study, a cohort with established coronary artery disease (CAD), we measured TNFR1A from baseline serum samples and defined elevated levels of TNFR1A by the highest quartile (Q4, > 3.4 ng/ml). Our outcomes were myocardial infarction, heart failure hospitalizations (HF), and death. We evaluated the associations of high TNFR1A with outcomes using Poisson regression and adjusting for age, race, smoking, hypertension, diabetes, cholesterol, albuminuria, and baseline estimated glomerular filtration rate (eGFR).

Results: Among 981 participants who had TNFR1A measurements at baseline, median TNFR1A was 2.47 ng/ml (1.9-3.4). Median TNFR1A in individuals with eGFR < 60 was 2.9 (3.8–5) and 1.7 (2.1-2.7) in those with eGFR > 60. Median follow-up time was 8.9 years. Higher levels of TNFR1A (Q4 v. Q1-3) were associated with a higher risk of MI in

unadjusted analyses [incident rate ratio (IRR) 2.56 (95% CI 1.73-3.81). This was attenuated by adjustment [IRR 1.59 (0.92-2.72)]. TNFR1A was strongly associated with HF in both unadjusted and adjusted analyses [adjusted IRR 1.79 (1.12-2.86)] as well as with death [adjusted IRR 1.6 (1.22-2.1)].

Conclusions: Levels of TNFR1A are elevated in CKD. TNFR1A is independently associated with HF and mortality. These findings implicate inflammation as a potential contributor to the elevated mortality risk in persons with CAD.

Blood Monocyte Profiles and P2X7 Receptor Expression in Chronic Kidney Disease and End-Stage Renal Disease Serika D. Naicker, Susan Logue, Deirdre Cotter, Matthew D. Griffin. *REMEDI, School of Medicine, National Univ of Ireland, Galway, Ireland.*

Background: Monocytes are innate immune cells with 3 subsets [Classical ($CD14^{++}CD16^{-}$), Intermediate ($CD14^{++}CD16^{+}$) and Non-classical ($CD14^{+}CD16^{++}$)] which have distinct pathogenic roles in chronic inflammation and atherosclerosis. We quantified blood monocyte subsets in a cohort of patients with CKD and ESRD/chronic hemodialysis (cHD) and evaluated their expression of the inflammasome-activating ATP receptor P2X7.

Methods: CKD stage 1-5 was assigned based on MDRD eGFR. PBMCs from healthy adults (CTRL, n=25), patients with CKD stages 1-5 (n=100) or ESRD prior to and after HD (n=32) were analyzed by 8-colour flow cytometry to quantify monocyte subsets and their surface expression of P2X7 receptor. PBMC stimulation cultures were carried out using optimized concentrations of TLR ligands ± ATP.

Results: Total monocyte numbers progressively increased from CTRL through CKD stage 1-5 and ESRD/cHD. Among the subsets, Intermediate monocytes were most highly expanded in CKD in a stage-dependent manner. ESRD patients additionally demonstrated higher numbers of non-classical monocytes which diminished significantly following HD. Surface expression of P2X7 was readily detected on all monocyte subsets in CTRL, CKD Stages 1-5 and ESRD but was most highly expressed by Non-classical monocytes. Compared to CTRL, all stages of CKD were associated with higher monocyte expression of P2X7 but, in ESRD, this was further increased on Non-classical monocytes following HD. High-level interleukin (IL)-1-beta release by monocytes from CRTL and CKD/ESRD patients was observed upon brief exposure to the P2X7 ligand ATP following priming with ligands for TLR4 (highly expressed by Classical monocytes) or TLR7/8 (highly expressed by Non-classical monocytes) indicating active inflammasome response in multiple monocyte subsets.

Conclusions: CKD is associated with a stage-dependent increase in circulating monocytes that is greatest for the Intermediate subset. Non-classical monocytes are also expanded in ESRD and modulated by HD. The P2X7 receptor, which mediates inflammasome activation via extracellular ATP, is expressed by all monocyte subsets in CKD/ESRD but most highly by Non-classicals.

Funding: Government Support - Non-U.S.

TH-PO416

Activation of CXCL16/CXCR6 Pathway by Inflammation Accelerates the Progression of Atherosclerosis in ESRD Patients Zebo Hu,[1] Kun ling Ma,[1] Yang Zhang,[1] Wu Yu,[1] Bi-Cheng Liu.[1] *[1]Inst of Nephrology, Southeast Univ, Nanjing City, Jiang Su Province, China; [2]Inst of Nephrology, Southeast Univ, Nanjing City, Jiang Su Province, China.*

Background: Objective Chronic inflammation plays a crucial role in the progression of atherosclerosis (AS). The current study aimed to observe the effects of inflammation on lipid accumulation in the radial arteries of end-stage renal disease (ESRD) patients with arteriovenostomy and further investigate whether inflammation accelerates the progression of AS via the dysregulation of the CXCL16(CXC chemokine ligand 16, CXCL16)/CXCR6(CXC chemokine receptor 6,CXCR6) pathway.

Methods: Fourty-seven ESRD patients were divided into control group (n=20) and inflamed group (n=27) according to plasma C-reactive protein (CRP) level. Biochemical index and lipid profile of patients were measured. Surgically removed tissues from the radial arteries of patients receiving arteriovenostomy were used in the experiments for preliminary evaluation of AS. Foam cell formation was observed by Hematoxylin-eosin (HE) and Filipin staining. CXCL16/CXCR6 pathway related protein expressions and the expressions of monocyte chmotactic protein 1 (MCP-1), tumor necrosis factor α (TNFα), and CD68 were detected by immunohistochemistry staining and immunofiuorescence staining.

Results: Immunohistochemical staining demonstrated that inflammation increased both protein expressions of MCP-1 and TNF-α in radial arteries of inflamed group accompanied with macrophage infiltration. Further analysis showed that there were significantly increased foam cell formation in continuous cross-sections of radial arteries of inflamed group compared to the controls, which were closely correlated with increased protein expressions of CXCL16, CXCR6, and decreased protein expression of ADAM10.

Conclusions: Inflammation contributed to foam cell formation in the radial arteries of ESRD patients via the activation of the CXCL16/CXCR6 pathway.

TH-PO417

Ablation of Pericytes Induces Capillary Rarefaction and Proximal Tubular Injury Janewit Wongboonsin, Rafael Kramann, Susanne V. Fleig, Flavia G. Machado, Benjamin D. Humphreys. *Renal Div, Brigham and Women´s Hospital, Boston.*

Background: We recently showed that $Gli1^{+}$ cells in the pericyte niche are the predominant source of myofibroblasts in kidney fibrosis. One hypothesis for the mechanism of capillary rarefaction observed in fibrotic kidney disease is that injury induces pericyte detachment from endothelium, leading to capillary dropout and hypoxia. There is no direct evidence supporting this idea, however. In this study we measured pericyte detachment during injury, and asked whether ablation of pericytes in the absence of any other injury destabilizes capillaries and induces tubular injury.

Methods: We performed unilateral ischemia reperfusion injury (IRI) in bigenic Gli1CreER;tdTomato mice and performed fluorescence microangiography (FMA) at 2 weeks after injury to delineate the renal microvasculature and quantify detachment of Gli1+ cells from capillaries. In a second set of experiments we ablated Gli1+ in Gli1CreER, iDTR mice by diphtheria toxin injection, performed FMA and analyzed peritubular capillary changes by automated software-based quantification over a time course of 56 days.

Results: After IRI, Gli1+ cells proliferate and detach from the renal microvasculature. Specific genetic ablation of Gli1+ cells triggers peritubular capillary rarefaction and induces mild focal cortical tubular injury. While peritubular capillary number decreased, peritubular capillary perimeter and area remain unchanged. Injured tubules were characterized by focal Kim1+ expression in cortical areas with decreased FMA+ perfused capillaries. Renal Kim1 and Hif1a mRNA expression increased early after Gli1+ cell ablation. Interestingly, while aSMA and Collagen1a1 mRNA expression decreased early after ablation, confirming the role of Gli1+ cells as myofibroblasts progenitors, we detected increased expression of both fibrotic readouts at 56 days after ablation. Immunostaining for aSMA showed focal cortical areas with myofibroblast expansion and scar formation.

Conclusions: Ablation of Gli1+ pericytes in healthy kidney causes peritubular capillary rarefaction, focal tubular epithelial injury and focal fibrosis in the outer cortex most likely due to hypoxia.

Activation of Tie2 by Deletion of VE-PTP Increases GFR in Mice Isabel Anna Carota,[1,2] Chengjin Li,[3] Vera Eremina,[3] Tuncer Onay,[1] Susan E. Quaggin.[1] *[1]Div. of Nephrology/Hypertension and Feinberg Cardiovascular Research Inst, Northwestern Univ, Chicago; [2]Eli Lilly and Company; [3]Samuel Lunenfeld Research Inst, Mount Sinai Hospital, Toronto, Canada.*

Background: With an increasing number of patients suffering from CKD, there is an urgent need for new therapeutic targets. The Angiopoietin-Tie2 signaling pathway has been implicated in the development of kidney disease. In CKD patients elevated levels of circulating Angpt-2, the antagonist of the tyrosine kinase receptor Tie2, correlate with a decrease in glomerular filtration rate (GFR). Additionally it has been shown that loss of Angpt-1, the Tie2 agonist, leads to enhanced glomerular scarring in diabetic Angpt-1 KO mice. These findings suggest that an imbalance of Tie2 ligands is associated with progression of renal disease. Here we investigate the impact of Tie2 activation on baseline renal function by genetic deletion of its negative regulator the endothelial specific phosphataseVE-PTP in an inducible KO mouse model.

Methods: To study the effect of Tie2 activation following loss of VE-PTP, we generated inducible VE-PTP KO mice. Kidneys were examined histologically and phosphorylation level of Tie2 was quantified by IP from lung lysates followed by Western blot analysis. GFRs were measured using the FITC-Sinistrin clearance method (n=7 KO, 6 contr. at 10 weeks).

Results: Knock-out of VE-PTP enhances Tie2 phosphorylation 2-fold resulting in enhanced Tie2 activity in a ligand-independent manner. Deletion of VE-PTP before embryonic day 13.5 leads to the formation of dilated glomerular capillaries, which are not observed in kidneys of mice when VE-PTP is deleted after E18.5. In contrast, mGFRs of VE-PTP iKO mice (deletion after E18.5) were increased from 298.6±28.0 in controls to 458.1±27.9 ml/min in KO litter mates (p=0.016). Both groups showed no difference in blood pressure, albuminuria or renal histology.

Conclusions: Inhibition of VE-PTP leads to elevated Tie2 phosphorylation suggesting VE-PTP as a potential target to rescue the effects of increased Angpt-2 levels that occur in CKD patients. The increased GFR observed in VE-PTP iKO mice suggest that disrupting VE-PTP–Tie2 interactions may be a strategy to slow progression of CKD.

Circulating VEGF-C Levels Are Associated with Insulin Sensitivity in End Stage Renal Disease Patients Serpil Muge Deger,[1,2] Adriana Hung,[1,2] Edward D. Siew,[1,2] Feng Sha,[1] Charles D. Ellis,[1] Jens Titze,[1] Talat Alp Ikizler.[1,2] *[1]Vanderbilt Univ, Nashville, TN; [2]VA, Nashville, TN.*

Background: Insulin resistance (IR) is a common metabolic derangement in advanced kidney disease. We have previously demonstrated that inflammation is a key mediator of IR in end-stage renal disease (ESRD). Vascular Endothelial Growth Factor C (VEGF-C) is a key regulator of lymphangiogenesis that may contribute to IR. Recent experimental data suggest that the VEGF-C pathway may have important effects on adipose tissue IR by promoting macrophage recruitment. The relationship between VEGF-C and IR in humans

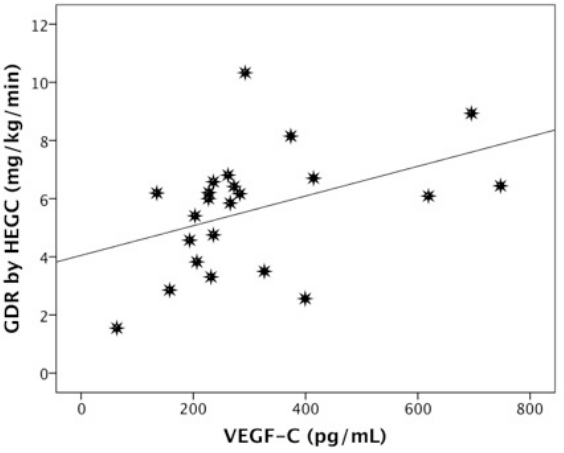
not been well characterized. We aimed to examine the relation between circulating VEGF-C and insulin sensitivity by the gold standard hyperinsulinemic euglycemic clamp (HEGC) in patients on chronic dialysis.

Methods: Fourteen HD and 10 PD patients who participated HEGC were included in this analysis. Serum VEGF-C values were measured by ELISA.

Results: Characteristics of study population are summarized in **(table 1).**

	HD	PD	p
Age (years)	55(38, 60)	48(35, 55)	0.21
Gender(M,%)	93	50	0.03
Race(AA, %)	79	60	0.29
BMI(kg/m^2)	29(26, 33)	30(26, 35)	0.75
Diabetes(%)	21	10	0.43
GDR by HEGC(mg/kg/min)	5.4(3.5, 6.2)	6.4(6, 8.1)	0.07
hs-CRP(mg/L)	4.8(2.5, 11.3_	2.5(1.5, 14)	0.37

Median serum VEGF-C levels were 350 (270, 638) pg/mL in PD and 230 (184, 270) pg/mL in HD patients (p=0.029). The median glucose disposal rate (GDR) derived by HEGC tend to lower in HD compared to PD patients. There was a significant positive correlation between serum VEGF-C and GDR by HEGC (r=0.495, p=0.016).



The association remained significant after adjusted by age, gender, and hs-CRP (p=0.026).

Conclusions: Our data suggest that the lymphangiogenic growth factor VEGF-C may be an important contributor to IR in the chronic uremia and a potential therapeutic target. Further studies are needed to delineate this relation.

Disruption of Angiopoietin-Tie2 Signaling Leads to Cystic Kidney Disease Yael Kenig-Kozlovsky,[1] Rizaldy P. Scott,[1,2] Benjamin R. Thomson,[1,2] Shinji Yamaguchi,[1] Christine Jiang Wu,[1] Stefan Heinen,[2] Susan E. Quaggin.[1,2] *[1]Div of Nephrology-Hypertension and Feinberg Cardiovascular Research Inst, Northwestern Univ, Chicago, IL; [2]Lunenfeld-Tanenbaum Research Inst, Toronto, Canada.*

Background: Angiopoietin ligands Angpt1 and Angpt2 and their cognate receptor Tie2/Tek are essential for development of the heart and systemic blood vasculature. While investigating their function in the shaping of the complex renal vasculature, we uncovered that mid-gestational inactivation of the Angpt1/Angpt2-Tie2 signaling axis remarkably causes cystic kidney disease.

Methods: Using a tetracycline-inducible gene targeting approach we deleted both Angpt1 and Angpt2 or Tie2 at embryonic stage E16.5 in the mouse.

Results: Compound deletion of Angpt1 and Angpt2, or loss of Tie2 led to kidney cyst formation detectable as early as 2 weeks after birth. By 8 weeks of age, enlarged cysts had severely distorted the renal architecture and glomerular filtration rate dropped by ~40%. Surprisingly, mutants did not manifest proteinuria, urine concentrating defects or blood pressure differences relative to control littermates. Cyst formation was predated by a distinctive pattern of renal vascular rarefaction, most notably at the corticomedullary junction. Cysts were lined by flattened mesenchymal-like cells, which expressed vimentin and a-smooth muscle actin but not classic markers for tubular epithelium, blood or lymphatic endothelium.

Conclusions: Recently, we reported that inactivation of angiopoietin-Tie2 signaling impairs the development of lymphatic vasculature and specialized "hybrid" vessels (exhibiting features of both blood and lymphatic vessels) of the eyes resulting in abnormal drainage of aqueous humor, ocular hypertension and glaucoma. Based on these findings, including the renal vascular rarefaction in the absence of Angpt1/Angpt2-Tie2 signaling, we hypothesize that renal cystogenesis may be attributed, in part, to defective vascular and/or lymphatic drainage of interstitial fluid in the kidney. Our study highlights a hitherto unidentified role of angiopoietin-Tie2 signaling in the pathogenesis of renal cysts and suggests this pathway as a potential therapeutic target to alleviate cystic kidney disease.

Funding: Other NIH Support - Grant R01HL124120

TH-PO421

Role of Macrophage in Hyaluronic Acid-Induced Lymphangiogenesis in UUO Model Won Kim, Jong-Hwan Jung, Yujin Jung, Kyung Pyo Kang, Sik Lee, Sung Kwang Park. *Chonbuk National Univ Medical School.*

Background: Hyaluronic acid (HA) is one of important component of extracellular matrix proteoglycan, has many biologic and pathologic effects such as inflammation, angiogenensis, wound healing and tissue remodeling. Renal lymphangiogenesis has been demonstrated in a rat remnant kidney model and in mouse unilateral ureteral obstruction (UUO) model. However, there is few data about role of macrophage in HA-induced lymphangiogenesis in UUO. We investigated the effect of macrophage in HA-induced lymphangiogenesis in UUO.

Methods: RAW 264.7 cells (RAW cell, macrophage cell line) were incubated with TFG b1 and HA production was evaluated by ELISA. LYVE-1-positive lymphatics, HA, vascular endothelial growth factor (VEGF)-C were evaluated by immunofluorescence and ELISA in UUO-induced fibrotic kidney treatment with or without clodronate (macrophage depleting agent).

Results: To evaluate the changes in HA expression in macrophages, RAW cell were treated with TGF-b1. We found that TGF-beta1 (1, 5, and 10 ng/mL) increased hyaluronic acid synthase (HAS)1, HAS2 and HAS3 mRNA expression in the cells. ELISA data demonstrated that treatment of RAW cells with TGF-b1 (10 ng/mL) increased HA production in a time-dependent manner. In UUO model, renal HA level was higher in ureteral obstruction operated kidney than that of sham-operated kidney. Our immunofluorescence finding showed that HA is expressed on interstitial space in UUO kidney. HA accumulation is correlated with the number of LYVE-1-positive lymphatic vessels after ureteral obstruction. HA expression was also costained with F4/80-positive renal macrophages 7 days after ureteral obstruction. Depletion of macrophage with clodronate significantly decreased UUO-induced renal HA expression and UUO-induced increased density of LYVE-1-positive lymphatic endothelial cells. We also found that VEGF-C expression in the kidney was significantly decreased in UUO kidney after treatment with clodronate compared to that after treatment with control buffer.

Conclusions: These results suggest that macrophage has a partial role in HA production and HA-induced renal lymphangiogenesis in UUO model.

TH-PO422

Nfat5/TonEBP Deficiency in B Cells Results in Reduced Antibody Formation, Hypoplastic Cutaneous Lymph Capillary Formation, and Salt-Sensitive Hypertension Jens Titze,[1,2] Ljiljana Rokvic,[1] Patrick Neubert,[1] Kento Kitada,[2] Wolfgang Schuh,[3] Hans-Martin Jack,[3] Friedrich C. Luft.[2,4] *[1]Interdisciplinary Center for Clinical Research, UC Erlangen; [2]Dept of Cin. Pharm., Vanderbilt Univ; [3]Div. of Mol. Immun., UC Erlangen; [4]MDC, Charite Berlin.*

Background: Interstitial Na^+ storage induces pro-inflammatory responses in macrophages (Mϕ), which are mediated by the osmoprotective transcription factor *Nfat5* to promote host defense. However, Mϕ also reduce salt concentration in the subcutaneous barrier by *Nfat5/VEGF-C* driven lymphatic clearance of electrolytes, protecting the organism from excess interstitial Na^+ storage and hypertension. The role of *Nfat5* in B cells is unknown. We hypothesized that *Nfat5* in B cells boosts pro-inflammatory and homeostatic immune responses.

Methods: We fed 6 control (*mb1*^{wt}*Nfat5*$^{flox/flox}$) and 5 *mb1*^{cre}*Nfat5*$^{flox/flox}$ (genetic deletion of *Nfat5* in B cells) mice a high-salt diet (4% NaCl chow/ 0.9% saline; HSD) for 8 weeks and studied their ability to produce antibody after vaccination with trinitrophenyl conjugated to keyhole limpet hemocyanin (TNP-KLH; 100µg i.p.), followed by a boost injection (50 µg) after 6 weeks. We also studied the size of cutaneous lymph capillaries and mean arterial blood pressure (MAP) in these mice fed a HSD.

Results: On HSD, *mb1*^{cre}*Nfat5*$^{flox/flox}$ mice showed a >30% reduction in total IgM / IgG ($p<0.05$), and TNP-KLH-specific IgM / IgG ($p<0.05$) antibody production versus control, indicating reduced pro-inflammatory immune function. Additionally, these mice showed reduced lymph capillary diameters (40±9µm vs. 25±8µm, $p<0.05$), accompanied with increased MAP (117±8mmHg vs. 129±8mmHg, $p<0.05$), indicating reduced homeostatic immune function.

Conclusions: *Nfat5* in B cells is important for specific antibody formation, suggesting that Na^+ storage and B cell osmoprotection is relevant for the T cell/Dendritic Cell (DC)-mediated adoptive immune response in secondary lymphatic organs. We currently study Mϕ, DC, or T-cell driven modulation of the cutaneous lymph capillary network to better understand hypoplastic cutaneous lymph vessel formation, extrarenal lymphatic electrolyte clearance, and the salt-sensitive hypertension in *mb1*^{cre} *Nfat5*$^{flox/flox}$ mice.

Novel Mechanisms for Salt Sensitive Hypertension in Humans: Effects of Salt Loading on Skin Sodium, VEGF-C and Blood Pressure
Viknesh Selvarajah,[1] Kaisa Maki-Petaja,[1] Liliana Domingues Pedro,[2] Sylvaine Fa Bruggraber,[2] Carmel M. McEniery,[1] Ian Wilkinson.[1] *[1]Div of Experimental Medicine and Immunotherapeutics, Univ of Cambridge, Cambridge, United Kingdom; [2]MRC Human Nutrition Research Unit, Fulbourn, Cambridge, United Kingdom.*

Background: Dietary sodium is an important trigger for hypertension. Animal studies show that the skin buffers dietary salt and salt-loading induces lymphangiogenesis mediated by VEGF C from macrophages, helping to maintain BP in response to salt load. The relevance of these mechanisms in humans is unclear.

Methods: We conducted a double-blind randomised crossover trial examining the effects of dietary salt loading on skin sodium, systemic haemodynamics, ambulatory BP and plasma VEGF-C in 48 healthy participants. Participants were placed on a low salt diet (70mmol sodium/day). Dietary compliance was checked using 24hr urine collections. Skin biopsies were taken after placebo and slow-sodium treatment (200mmol daily for 7 days). Skin Na and K concentrations (mg/g tissue) were analysed by ICPOES.Results were expressed as the ratio of Na:K to correct for variability in sample hydration. Plasma VEGF C was analysed by ELISA.

Results: Skin data was available for 47 individuals**.** Mean age was 29.9 ± 8.3 with mean baseline urinary sodium 98.8 ± 55.0 mmol/24 hours. 24hr urine sodium excretion increased from 71.4 ± 43.1 to 225.9 ± 89.0 mmol ($p< 0.001$) with salt loading. Ambulatory MAP showed a non-significant increase from 88 ± 7.0 to 89 ± 7 mmHg ($p=0.10$). Office MAP was unchanged. Skin Na:K increased from 2.91 ± 0.56 to 3.12 ± 0.62 ($p=0.01$). Percentage change in Na:K was negatively correlated with baseline Na:K ($r=-0.40$, $p=0.007$). Changes in ambulatory MAP correlated positively with baseline skin Na:K ($r=0.30$, $p=0.048$). Stroke volume correlated with skin Na:K post placebo ($r =-0.42$,$p=0.002$) and slow sodium ($r = -0.53$, $p<0.0001$) respectively. No significant change was noted in plasma VEGF C.

Conclusions: Skin sodium appears to increases with dietary salt loading and the degree of change correlates with baseline Na:K levels. Ambulatory blood pressure change with dietary salt loading correlates with baseline skin Na:K, supporting a possible role for for the skin as a buffer for dietary sodium.

TH-PO424

Albuminuria Downregulates NKCC2 via Stimulation of COX-2/mPGES-1/PGE2 Cascade in Thick Ascending Limb
Zhanjun Jia,[1,2] Yibo Zhuang,[1] Guixia Ding,[1] Yue Zhang,[1] Songming Huang,[1] Aihua Zhang.[1,2] *[1]Nephrology Dept, Nanjing Children Hospital, Nanjing Medical Univ, Nanjing, China; [2]Nanjing Key Laboratory of Pediatrics.*

Background: Impaired response to loop diuretics is a common phenomenon in nephrotic syndrome patients. However, the pathogenic mechanisms remain elusive. Here we hypothesized that albuminuria itself may act as a key intrarenal factor leading to the dysregulation and dysfunction of NKCC2, as well as the subsequent resistance to loop diuretics.

Methods: C57BL/6 mice were subjected to albumin overload via i.p injection for 12 days. The mouse kidney tissues and renal biopsy specimens from proteinuric patients were analyzed.

Results: After albumin overload, we found an 80% downregulation of Na-K-Cl cotransporter (NKCC2) as determined by Western blotting, qRT-PCR and immunohistochemistry (IHC). Meanwhile, the COX-2 and mPGES-1 were strikingly elevated by 2.1 and 3.5 folds, respectively, as determined via Western blotting and qRT-PCR. By IHC, stimulation of COX-2 and mPGES-1 were localized in the thick ascending limb (TAL, NKCC2 positive tubules). Accordingly, the urinary PGE2 excretion was significantly enhanced by 82% following albumin overload. Interestingly, inhibition of COX-2 via a specific COX-2 inhibitor Celebrex in albumin overloaded mice entirely reversed NKCC2 downregulation in line with normalized urinary PGE2 output. In addition, mice with albumin overload exhibited a remarkable resistance to loop diuretic furosemide (NKCC2 inhibitor), which was completely reversed by COX-2 inhibition. Next, we examined NKCC2 expression in kidney biopsy specimens of proteinuric patients via IHC and found a 50% downregulation of NKCC2 which was negatively correlated with proteinuria severity. Meanwhile, mPGES-1 was strikingly elevated in TAL in parallel with a remarkable increment of urinary PGE2, and both mPGES-1 and urinary PGE2 showed a positive correlation with proteinuria severity.

Conclusions: These novel findings highly suggest that albuminuria plays an important role in mediating the downregulation and dysfunction of NKCC2 via a stimulation of COX-2/mPGES-1/PGE2 cascade in TAL, which could contribute to the impaired response to loop diuretic in proteinuric kidney disease.

The Physiological Roles of Moesin, a Cytoskeletal-Associated Protein, in Renal Salt Reabsorption
Kotoku Kawaguchi, Ryo Hatano, Shinji Asano. *Molecular Physiology, College of Pharmaceutical Sciences, Ritsumeikan Univ, Kusatsu, Shiga, Japan.*

Background: Tubular reabsorption of electrolytes in the kidney is an essential function in regulating fluid balance in the body. In the thick ascending limb of the loop of Henle (TAL), 20-40% Na^+ filtered by the glomeruli are reabsorbed by Na^+-K^+-2Cl^- cotransporter type 2 (NKCC2). In humans, mutations in the gene coding for NKCC2 were identified in patients of Bartter syndrome type I, which is characterized by severe salt losing tubulopathy. Despite of the physiological importance of NKCC2 in NaCl homeostasis, the molecular mechanisms for its membrane trafficking have not been fully elucidated. In 2012, Carmosino *et al*. (*Biol. Cell.* **104**(11): 658-676) reported that moesin, which is a member of ERM (Ezrin-Radixin-Moesin) family, plays an important role in the apical membrane trafficking of NKCC2 by *in vitro* experiments.

Methods: We examined the physiological impact of Moesin in the regulation of renal function *in vivo* by using male moesin-null ($Msn^{-/y}$) mice. Wild-type ($Msn^{+/y}$) and $Msn^{-/y}$ mice were kept in metabolic cages and daily urinary volume and urinary contents of electrolytes were measured. Western blotting and immunostaining were performed to investigate the expressions and localizations of proteins in the medullary tubules.

Results: Fractional excretions of Na^+, K^+ and Cl^- were significantly increased in $Msn^{-/y}$ mice compared to $Msn^{+/y}$ mice. On the other hand, GFR and blood pressure were decreased in $Msn^{-/y}$ mice possibly due to body fluid loss. Immunoblotting for apical surface membrane proteins of medullary tubules did not show a significant difference in NKCC2 expression level between $Msn^{+/y}$ and $Msn^{-/y}$ mice whereas the distribution of NKCC2 in the lipid raft was decreased in $Msn^{-/y}$ mice.

Conclusions: Our results suggest that urinary loss of electrolytes in $Msn^{-/y}$ mice would be due to the disturbed localization of NKCC2 in the apical membrane domain. Since phosphorylated moesin, which represents an active form, is concentrated in lipid raft fractions in $Msn^{+/y}$ mice, moesin might play a pivotal role in the regulation of lipid raft localization of NKCC2 rather than the regulation of membrane trafficking of NKCC2 in TAL.

Paracellular Cation Selectivity in the Thick Ascending Limb of Henle's Loop Increases Under the Control of Vasopressin
Nina Himmerkus,[1] Allein Plain,[1] Rita D. Marques,[2] Jens G. Leipziger,[2] Markus Bleich.[1] *[1]Inst of Physiology, Christian-Albrecht-Univ, Kiel, Kiel, Germany; [2]Dept of Biomedicine, Physiology and Biophysics, Aarhus Univ, Aarhus, Denmark.*

Background: The thick ascending limb of Henle's loop (TAL) has the highest paracellular cation selectivity along the nephron. Trans- and paracellular pathways are strongly interdepended. The transepithelial voltage as driving force for the paracellular reabsorption of cations can be generated either by transcellular transport properties or by paracellular cation diffusion. Arginine vasopressin (AVP) has been shown to stimulate active transcellular NaCl transport and we hypothesize that paracellular permeability properties are co-regulated to support the increase in NaCl reabsorption.

Methods: To measure long term regulation 8-10 week old mice were kept for 4 days on low (antidiuresis, AD, 0.26ml/gBM/d) or high (water diuresis WD, 0.78ml/gBM/d) water intake. Spot urine osmolality was determined as treatment indicator. For acute AVP experiments mice were kept at water ad libitum. mTAL were isolated perfused and transcellular electrophysiological properties (transepithelial resistance R_{te}, voltage V_{te}, equivalent short circuit current I'_{sc}) were assessed as well as paracellular properties (NaCl dilution potential, ion permeabilities P_{Na} and P_{Cl}).

Results: mTAL of AD mice showed a higher active transcellular transport compared to the WD group tubules, represented by a two-fold increase in I'_{sc}. Urine osmolality was positively correlated to I'_{sc}. NaCl dilution potential was increased in the AD group, indicating a higher P_{Na}/P_{Cl}, and a higher P_{Na} compared to WD. P_{Na}/P_{Cl} as a measure of paracellular cation selectivity was also positively correlated to urine osmolality. mTAL from untreated mice were stimulated acutely *ex vivo* for 12 minutes by basolateral application of 10 nM AVP, ($n=6$), in paired experiments. I'_{sc} increased while it decreased in a time control group. At the same time, AVP induced an increase in P_{Na}/P_{Cl} compared to time controls.

Conclusions: Acute application of AVP as well as water restriction increase paracellular cation selectivity and permeablility in mTAL in parallel to the increase of active transcellular NaCl transport.

Adult Nephron-Specific MR-Deficient Mice Develop a Severe Renal Pseudohypoaldosteronism Type 1 Phenotype
Jérémie Canonica,[1,2] Chloe Sergi,[1] Marc P. Maillard,[3] Petra Klusonova,[4] Alex Odermatt,[4] Bernard C. Rossier,[1,2] Simona Frateschi,[1,2] Edith Hummler.[1,2] *[1]Dept of Pharmacology and Toxicology, Univ of Lausanne, Lausanne, Switzerland; [2]National Center of Competence in Research Kidney. CH, Switzerland; [3]Service of Nephrology Dept, Univ Hospital of Lausanne (CHUV), Lausanne, Switzerland; [4]Dept of Pharmaceutical Sciences, Univ of Basel, Basel, Switzerland.*

Background: Aldosterone is the main mineralocorticoid hormone controlling sodium balance, fluid homeostasis and blood pressure by regulating sodium reabsorption in the Aldosterone Sensitive Distal Nephron (ASDN). Germline loss-of-function mutations of the mineralocorticoid receptor (MR) in humans and in mice lead to the "renal" form of type 1 pseudohypoaldosteronism (PHA-1), a case of aldosterone resistance characterized by salt wasting, dehydration, failure to thrive, hyperkalemia and metabolic acidosis.

Methods: To investigate the importance of MR in adult epithelial cells, we generated nephron-specific MR knockout mice ($MR^{Pax8/LC1}$) using a doxycycline inducible system.

Results: Under standard diet, $MR^{Pax8/LC1}$ mice exhibit inability to gain weight and significant weight loss compared to control mice. Interestingly, despite failure to thrive, $MR^{Pax8/LC1}$ mice survive but develop a severe PHA-1 phenotype with higher urinary Na^+ levels, decreased plasma Na^+, hyperkalemia and higher levels of plasma aldosterone. This phenotype further worsens and becomes lethal under a sodium-deficient diet. NCC protein expression and its phosphorylated form are downregulated in the $MR^{Pax8/LC1}$ knockouts, as

well as αENaC protein level, whereas the expression of glucocorticoid receptor (GR) is increased. A diet rich in Na^+ and low in K^+ does not restore plasma aldosterone to control levels, but is sufficient to restore body weight, plasma and urinary electrolytes.

Conclusions: In conclusion, MR expression along the nephron and in the collecting duct system during adulthood is crucial for Na^+ and K^+ homeostasis, and its deletion cannot be compensated neither by sodium transporters including ENaC, nor by GR overexpression, but solely by a high Na^+ and low K^+ rescue diet.

TH-PO428

The Succinate Receptor 1 Is a Physiological Regulator of the Renin-Angiotensin Aldosterone System Peter M.T. Deen,[1] Claudia Carmone,[1] Ana Carolina Ariza,[1] Steef Kurstjens,[1] Olivier Devuyst,[2] Joris Hubertus Robben.[1] *[1]Physiology, Radboud Univ Medical Centre, Nijmegen, Netherlands; [2]Physiology, Univ of Zürich, Zürich, Switzerland.*

Background: It has been shown that oxidative cell stress in diabetes type I (T1DM) induces tubular release of mitochondrial succinate and that subsequent activation of the SUCNR1 in the juxta-glomerular apparatus is needed for renin release and T1DM-induced hypertension. Here, we tested whether the SUCNR1 also has a physiological role in renal water and electrolyte handling.

Methods: Wild-type (wt) and $SUCNR1^{-/-}$ mice 10 weeks old were placed in metabolic cages and 24h clinical parameters were analyzed in order to assess physiologically relevant differences. After sacrifice, kidneys were weighed and collected for further analysis.

Results: Blood and urine analysis of wt and $SUCNR1^{-/-}$ mice showed that loss of SUCNR1 increased sodium and urea excretion, reduced renal renin and plasma angiotensin II (AngII) and aldosterone levels. Immunoblotting revealed a downregulation of the most crucial sodium transporters (NHE3, NCC and ENAC) in $SUCNR1^{-/-}$ mice. Fractional excretion of urea and water were increased in absence of the receptor, coinciding with reduced AQP2 abundance. With an unchanged overall morphology, wet, but not dry, weights of kidneys of $SUCNR1^{-/-}$ mice were significantly increased than of wild-type littermates.

Conclusions: Our data reveal that the SUCNR1 is essential for the physiological maintenance of renin and AngII levels, and proper proximal tubule and collecting duct sodium reabsorption. The increased wet kidney mass is likely due to tubular dilation due to increased tubular pressure because of life-long diuresis. Our data thus indicate that the mammalian SUCNR1 is a physiological regulator of water and volume homeostasis.

Adult Nephron-Specific Beta- and Gamma-ENaC Knockout Mice Develop a Severe Pseudohypoaldosteronism Type 1 (PHA1) Emilie Boscardin,[1] Romain Perrier,[2] Chloe Sergi,[1] Bernard C. Rossier,[1] Edith Hummler.[1] *[1]Dept of Pharmacology and Toxicology, Univ of Lausanne, Lausanne, Switzerland; [2]Inst of Chemistry and Biology of Membranes and Nano-Objects, Univ of Bordeaux, Pessac, France.*

Background: The epithelium sodium channel (ENaC) consists of three subunits (alpha, beta and gamma ENaC) that are expressed at the apical side in tight epithelia in the kidney, and is limiting for sodium reabsorption. Mutations in ENaC subunits is causative for the human pseudohypoaldosteronism type 1 (PHA-1), a salt-losing syndrome. Since mice with ubiquitous and constitutive gene inactivation of beta- and gamma-ENaC die soon after birth, the consequences of a kidney-specific deletion of either beta- or gamma-ENaC cannot studied in adulthood. Therefore, we aimed to unveil the specific role of these ENaC subunits in the adult kidney using an inducible and kidney-specific CreloxP-mediated recombination system.

Methods: We used 4-weeks old doxycycline inducible nephron-specific beta- and gamma-ENaC knockout mice obtained by crossing the double transgenic mouse (PAX8/LC1), which express the reverse tetracycline transactivator under the control of a tetracycline response element (Traykova-Brauch et al., 2008) with the floxed Scnn1b and Scnn1g mice, respectively (Mérillat et al, 2009).

Results: Already following 3-4 days of doxycycline treatment, beta- and gamma-ENaC KO mice develop a severe and lethal PHA-1, characterized by severe body weight loss, severe hyperkalemia (beta-ENaC KO: 11mM, n= 7, Ctl: 5 mM, n= 21, $p<0.001$; gamma-ENaC KO: 11mM, n=6:, Ctl: 5mM; n=7, $p<0.001$), and dehydration. Beta-ENaC KO additionally suffer from severe hyponatremia, while the gamma-ENaC KO present with significant decreased plasma sodium concentration.

Conclusions: Our data demonstrate that the single beta- and gamma-ENaC subunits are crucial for daily maintaining sodium and potassium balance in adulthood.

TH-PO430

New Mechanistic Insights into the Regulation of ENaC by AMPK in Kidney Epithelial Cells Hui Li,[1,2] Kenneth R. Hallows.[1,2] *[1]Medicine, Univ of Pittsburgh School of Medicine, Pittsburgh, PA; [2]Medicine, Univ of Southern California Keck School of Medicine, Los Angeles, CA.*

Background: Renal collecting duct epithelial Na^+ channels (ENaCs) play a key role in total body volume and blood pressure control. The metabolic sensor AMP-activated protein kinase (AMPK) inhibits ENaC currents in kidney and other epithelial cells, but the mechanisms involved are unclear. We hypothesized that AMPK regulation of ENaC could occur via modulation of ENaC degradation, ENaC subunit cleavage status, and/or ENaC protein synthesis.

Methods: Mouse polarized kidney cortical collecting duct ($mpkCCD_{cl4}$) cells were cultured on Transwells for immunoblot analysis and equivalent short-circuit current (I_{sc}) measurements of ENaC following AMPK activity modulation and proteasomal or lysosomal inhibitor treatments. Apical domain biotinylation assays were performed to measure changes in ENaC apical membrane expression, and cycloheximide chase assays were performed to investigate ENaC stability.

Results: AMPK activation decreased cellular ENaC stability in cycloheximide chase assays. ENaC-dependent I_{sc} was inhibited by the AMPK activators AICAR and A769662 (Abbott), and these effects were blocked by the proteasomal inhibitor MG132, but not by the lysosomal inhibitor leupeptin. Western blot analyses revealed that AMPK activation decreased both mature and immature b-ENaC expression as well as cleaved g-ENaC expression, while increasing uncleaved g-ENaC expression. Moreover, treatment of $mpkCCD_{cl4}$ cells with AMPK activators decreased pP70S6K expression, suggesting decreased signaling of the mTOR pathway involved in protein synthesis and cell proliferation. Finally, AMPK activation decreased apical cell surface expression of both mature b- and cleaved g-ENaC, the active forms of ENaC, an effect that was blocked by MG132.

Conclusions: AMPK-dependent regulation of ENaC in $mpkCCD_{cl4}$ cells occurs by: 1) increased targeting of ENaC for proteasomal degradation, thereby decreasing cellular ENaC stability; 2) inhibition of g-ENaC cleavage and g-ENaC surface expression; and 3) inhibition of ENaC protein synthesis along with mTOR pathway inhibition.

TH-PO431

Sodium Retention in Nephrotic Syndrome Occurrs Independly of Proteinuria Alexey Larionov,[1] Geraldine Mollet,[2] Corinne Antignac,[3] Franziska Theilig.[1] *[1]Medicine, Anatomy, Fribourg, Switzerland; [2]Inserm U1163, Paris, France; [3]Inserm U983, Paris, France.*

Background: Patients with nephrotic syndrome often present symptoms of volume retention, such as edema formation or hypertension. The primary dysregulation was localized to the renal cortical collecting duct and involves an inappropriate activation of the epithelial sodium channel, ENaC. Plasma proteases passing the leaky glomerular filter were made responsible; however, clinical observation demonstrated signs of volume retention before the initiation of proteinuria.

Methods: To elucidate the relationship between sodium retention and proteinuria tamoxifen-inducible $podocin^{Cre}$; $Nphs2^{fl/fl}$ were used and metabolic cage experiments for 4 weeks were performed and functional renal parameters were determined. Additionally, morphological and biochemical analysis were performed on kidneys harvested 9 days or 21 days after the beginning of the treatment. **Results:** Compared to $Nphs2^{fl/fl}$, $podocin^{Cre}$; $Nphs2^{fl/fl}$ demonstrated reduced sodium excretion on day 7 (Na^+/creatinine: 246±10 vs. 220±8 µmol/mg) while proteinuria occurred on day 11 (protein/creatinine: 13±1 vs. 6.85±0.8 mg/mg). Blood pressure started to increase on day 10 (BP: 120±12 vs. 74±10 mmHg) and remained high till the end of the experiment. In mice with nephrotic syndrome western blot analysis of kidneys harvested on the day 9 of the experiment demonstrated no change in the full length ENaC subunit abundance and a 3-fold increase in the 30 kDa αENaC cleavage product. Nephrotic kidneys at the day 21 of the experiment demonstrate strongly increased abundance of full length and cleaved forms of α- and γENaC.

Conclusions: Our experiments demonstrate the occurrence of a possibly endogenous protease responsible for cleaving αENaC which may lead to increased sodium retention and hypertension in the early phase of the nephrotic syndrome.

TH-PO432

Altered Renal Electrolyte Handling in Mice with Genetic Knockout of the Insulin-Like-Growth Factor-1 Receptor (IGF1R) from the Collecting Duct Principal Cell Carolyn M. Ecelbarger, Marcus J. Byrd, Patrice Dixon, Lijun Li. *Dept of Medicine, Georgetown Univ, Washington, DC.*

Background: IGF1, produced predominantly in liver, can be increased in the circulation during metabolic syndrome (MetS) due to hyperinsulinemia. In addition to anabolic effects, IGF1 has been shown to activate the epithelial sodium channel (ENaC) in the renal collecting duct (CD); however, the role of the IGF1R in these effects is uncertain, since the insulin receptor can also bind IGF1.

Methods: To address the role of IGF1R in the CD, we produced CD-principal-cell-select knockout (KO) mice, by crossing mice with Cre-recombinase driven by an aquaporin-2 promoter with mice with loxP sites flanking IGF1R gene. Adult KO mice were of normal body weight and had no overt alterations in kidney structure/function. To test the impact of IGF1 infusion on urinary electrolytes, anesthetized male WT and KO mice were infused via the jugular vein with either saline vehicle (V) or a 290 µM solution of IGF1 (I) in saline at a rate of 15 µl/min for 60 minutes (n = 5/genotype/treatment). Urine was collected via a cannulated bladder.

Results: Urine volume was reduced by IGF1 and the reduction was blunted in the KO (µl/60 min): 142 ± 41 (WTV), 45 ± 9 (WTI), 86 ± 9 (KOV), 73 ± 8 (KOI), $p < 0.018$ for treatment. In WT, IGF1 infusion led to a significant 42, 65, and 67% reduction in the concentration of Na+, K+, and Cl-, respectively in urine. Total urine Na+ in the WTI was 20% of WTV. In contrast, the excretion of electrolytes was relatively maintained in KO, i.e., IGF1 led to a 19, 21, and 17% reduction in Na+, K+, and Cl- concentrations, respectively, and means (KOV verus KOI) were not significantly different. The ratio of Na+ to K+ in the urine was also affected by genotype, i.e., increased by 76% in the WT, but reduced

by 9% in the KO (p = 0.023 for interaction). A benzamil test (ENaC antagonist, 1.4 mg/kg·bw, i.p.) revealed 23, 34, and 27% (all significant) reduced total Na+, K+ and Cl- in KO versus WT in 4-hour urine.

Conclusions: These results support a role for IGF1 via the IGF1R to increase Na+ and Cl- reabsorption in the CD, through activation of ENaC. Thus, IGF1 may play a role in sodium retention associated with MetS.

TH-PO433

ENaC Activity in the Cortical Collecting Duct of HKa_1 H,K-ATPase knockout Mice Is Uncoupled from Na Intake James D. Stockand,[1] Elena V. Mironova,[1] Vladislav V. Bugay,[1] I. Jeanette Lynch,[2,3] Michelle L. Gumz,[2,3] Charles S. Wingo.[2,3] *[1]Univ of Texas HSC, San Antonio, TX; [2]NF/SG VHS, Gainesville, FL; [3]Univ of Florida, Gainesville, FL.*

Background: The renal H,K-ATPases are integral membrane proteins of the collecting duct (CD), a segment that mediates Na reabsorption via the mineralocorticoid regulated epithelial Na channel, ENaC. ENaC activity is inversely related to dietary Na intake, a relationship essential to blood pressure (BP) regulation, and its dysfunction contributes to salt-sensitive hypertension. Mineralocorticoids stimulate the activity and expression of renal H,K-ATPases. We hypothesized that HKa_1 H,K-ATPase knockout (KO) would affect ENaC activity.

Methods: Na reabsorption was measured by *in vitro* microperfusion in CCD from KO and control mice fed a 0.2% Na diet. Single channel analysis of ENaC activity in split open CCD by cell-attached patch clamp and measurements of urinary ATP were performed on KO and control mice fed a 0, 0.2, or 2.0% Na diet.

Results: Na reabsorption in the KO was significantly less than in controls and was not significantly inhibited by benzamil. ENaC activity in the KO is uncoupled from Na intake. When fed a 2.0% Na diet ENaC activity is higher in the KO vs. controls; and is lower on a 0% Na diet in KO vs. controls with no difference in activity in the KO on any of the Na diets. Preliminary results suggest that purinergic regulation of ENaC by a local signaling system is abnormal in the KO contributing to inappropriate channel responses to changes in dietary Na. KO mice have lower urinary ATP than controls and show no dietary Na-effect on ATP in contrast to controls where ATP is proportionally related to dietary Na intake. The defect in the KO is likely upstream of the inhibitory purinergic receptor since ENaC in the KO responds normally to exogenous ATP.

Conclusions: These results implicate the HKa_1 H,K-ATPase in the maintenance of Na homeostasis. The lack of response to Na intake implies that renal Na excretion and BP in the KO are expected to be abnormal particularly at extremes in dietary Na intake. Dysfunctional regulation of ENaC and compromised purinergic signaling in the CD are predicted to contribute to the expected BP phenotype.

TH-PO434

High Cholesterol Diet (HCD) Impairs K Secretion in the Rabbit Cortical Collecting Duct (CCD) Rolando Carrisoza-Gaytan, Daniel Flores, Lisa M. Satlin. *Pediatrics, Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: The apical BK channel in the CCD mediates flow-induced K secretion (FIKS). BK channels possess multiple cholesterol recognition/interaction motifs in the α subunit and, in non-renal cells, are inhibited by enhanced cholesterol content in the lipid membrane and hypercholesterolemia. Cholesterol determines membrane fluidity, and changes in membrane cholesterol are expected during postnatal development and in response to HCD. We speculated that HCD, via enhanced incorporation of cholesterol into the plasma membrane (PM), inhibits BK channel-mediated FIKS in the CCD.

Methods: NZW rabbits were randomized after weaning to receive either a standard or a cholesterol enriched diet (HCD; 0.3%) for 4-5 wks, at which time the animals were sacrificed. Kidneys were dissected for (i) isolation of renal cortical membranes for immunoblotting of BKα, ROMK and ENaCβ, and (ii) microperfusion of isolated CCDs to measure net Na absorption (JNa) and net K secretion (JK).

Results: Rabbits fed HCD (n=5) vs. control (n=4) showed lower plasma [Na^+] (130.7+0.7 vs. 137.1+0.7 mM; P<0.001), no difference in plasma [K^+], and greater serum cholesterol (30,491.6+253.6 vs. 1413.2+231.1 mg/mL; P<0.01). Immunoblotting demonstrated a greater abundance of ROMK and ENaC in total membranes and lower abundance of BK and ENaC in cortical PMs of HCD vs. control (n=2 in each group). In 5 HCD CCDs, JNa increased from 14.4+7.9 to 32.3+10.0 pmol/min.mm (P<0.02) in response to an increase in flow rate from 1 to 5 nl/min.mm; this flow-stimulated increase in JNa was less than observed in historical controls (13.2+2.1 to 72.2+10.3; n= 13; P<0.01). In HCD CCDs, JK increased from -4.8+1.6 to -12.4+2.5 pmol/min.mm (P<0.05) in response to a 5-fold increase in flow rate; these transport rates are half those observed in historical controls (-10.4+2.2 to -22.7+5.6; n= 13; P<0.04).

Conclusions: Our results suggest that HCD blunts flow-stimulated but not basal JNa, and inhibits basal JK and FIKS, which may be due to a reduced abundance of ENaC and BK channels in the CCD. Whether enhanced incorporation of cholesterol into the PM of the CCD underlies these changes in transport is currently under investigation.

TH-PO435

Net K Secretion in Thick Ascending Limb of Mice on Low Na High K Diet Bangchen Wang, Donghai Wen, Ryan J. Cornelius, Yang Yuan, Huaqing Li, Jun Wang-France, Steven C. Sansom. *Cellular and Integrative Physiology, Univ of Nebraska Medical Center, Omaha, NE.*

Background: It has been long understood that thick ascending limb (TAL) reabsorbs Na^+, Cl^- and K^+, and high K diet inhibits NaCl reabsorption in TAL. In the present study, however, we found a persistent NaCl reabsorption and a net K secretion in TAL of mice on a low Na high K diet (LNaHK) that is dependent on β4 subunit of large Ca-activated K channels (BK). We hypothesized that K secretion in the TAL was the result of K recycling via BK-α/β4 from the medullary collecting ducts (MCD).

Methods: Wild-type (WT) and mice with a knock-out of BKβ4 (KO) were fed either a control or LNaHK diet for 7-10 days. They received intraperitoneal (IP) injections of vehicle (veh), furosemide (furo), amiloride (ami), or furosemide + amiloride (furoami) and were placed in metabolic cages for 12 hours to collect urine. Urine and plasma [Na] and [K] were measured with flame photometry. Micropuncture was used to measure [K] in the early distal tubule (EDT) of mice before and after IP injection of furo. Fluorescent immunohistochemistry (FIHC) and western blotting were used to determine BK-α and Na-K-Cl cotransporter (NKCC2) expressions.

Results: In WT on a control diet, K clearance was higher in furo-treated mice compared to veh due to increased distal flow. However, in WT on LNaHK, K clearance was significantly lower in furo-treated mice despite increased distal flow, and furoami decreased K clearance more than either drug alone. In KO on LNaHK, K clearance was not different between furo and veh groups. Micropuncture studies showed that furo decreased [K] in EDT of WT on control diet but increased [K] in EDT of WT on LNaHK. In WT on LNaHK, Na clearance was higher and urine osmolality lower in furo-treated mice compared to veh, indicating NKCC2 was still active. NKCC2 expression in medullary TAL was higher in WT on LNaHK compared to control diet. FIHC showed that BK-α was expressed in the apical membranes of MCD of WT on LNaHK, but not KO, which may mediate K recycling in MCD.

Conclusions: These results suggest that there is a furosemide-sensitive BKβ4-dependent net K secretion in the thick ascending limb of mice on LNaHK diet.

TH-PO436

A Decrease in ENaC and ROMK Activity in the Late Distal Convoluted Tubule/Connecting Tubule May Contribute Hyperkalemia in PHAII Mutant WNK4 Knockin Mice WenHui Wang. *Pharmacology, New York Medical College, Valhalla, NY.*

Background: Pseudohypoaldosteronism type II (PHAII) is caused by mutations in with-no-lysine kinase 1 **(WNK1)** and WNK4. Mice harboring PHAII WNK4 mutant by genomic manipulation (**$TgWNK4^{PHAII}$**) developed typical PHAII phenotypes characterized by hypertension and hyperkalemia. While the hypertension is caused by an excessive Na absorption through NCC in the distal convoluted tubule (DCT), hyperkalemia has been attributed to a low Na delivery to the distal nephron. However, the role of ENaC and ROMK in causing hyperkalemia is not explored.

Methods: In the present study, we used the whole-cell patch-clamp technique to examine the ROMK and ENaC activity in the late DCT (DCT2) and early connecting tubule (CNT). The tubule was split open to exposure the apical membrane and was bathed in a solution containing 135 K-gluconate and 10 KCl. The pipette contains a symmetrical K solution.

Results: Western blot confirmed that NCC expression is upregulated in $TgWNK4^{PHAII}$ mice in comparison to the WT and $TgWNK4^{WT}$ mice. The whole cell recording detected amiloride-sensitive Na currents and TPNQ-sensitive K currents (ROMK) in DCT2/CNT. However, both Na currents (40 pA/per cell) and ROMK currents (350 pA per cell) in DCT2/CNT of $TgWNK4^{PHAII}$ mice were significantly smaller than those in WT (Na currents, 260 pA per cell; ROMK 1190 pA per cell) and $TgWNK4^{WT}$ mice (Na currents, 230 pA per cell; ROMK, 960 pA per cell). We also measured the whole cell K currents in the DCT1 which lacks apical ROMK and ENaC channels. In contrast to Na and ROMK currents in the DCT2/CNT, the basolateral K currents in the DCT1 were similar among WT, $TgWNK4^{WT}$ and $TgWNK4^{PHAII}$ mice. This suggests that the upregulation of NCC in $TgWNK4^{PHAII}$ mice did not stimulate the basolateral Kcnj10 channels.

Conclusions: We conclude that ENaC and ROMK channel activity are inhibited in $TgWNK4^{PHAII}$ mice and that $WNK4^{PHAII}$-induced inhibition of ENaC and ROMK may contribute to the suppression of K secretion in the DCT2/CNT in addition to a reduction of Na delivery.

TH-PO437

Gilz Regulates Sodium and Potassium Balance During Dietary Sodium Restriction Priyanka Rashmi, Michael Ng, David Pearce. *Univ of California San Francisco, San Francisco, CA.*

Background: The hormonal regulation of ion transport by the kidney tubules is critical for regulating sodium and potassium balance in blood, extracellular fluid volume and blood pressure. The renin-angiotensin-aldosterone (RAAS) system is the primary regulator of Na^+ reabsorption and K^+ secretion. RAAS regulates multiple transporters implicated in electrolyte homeostasis such as Na^+Cl^- cotransporter (NCC) and epithelial sodium channel (ENaC). While both ENaC and NCC mediate Na^+ reabsorption, they affect K^+ differently:Electrogenic Na^+ reabsorption via ENaC stimulates K^+ excretion, while

electroneutral reabsorption of Na^+via NCC inhibits K^+secretion by competing with ENaC for Na^+ reabsorption. Glucocorticoid induced leucine zipper protein (Gilz) is an aldosterone-regulated gene product reported to cause changes in ion balance but the mechanism has not been explored. In this study we use the Gilz knock out ($Gilz^{-/-}$) mouse generated in our laboratory to show that during sodium deprivation $Gilz^{-/-}$ mice come into sodium balance *more quickly*, than do wild type (WT) and become significantly hyperkalemic. These observations raised the possibility that loss of Gilz results in hyperactivation of an electroneutral Na^+ transporter, which does not stimulate K^+ secretion. Indeed, Gilz knock out mice are more sensitive to thiazide diuretics suggesting increased NCC activity. Consistently, expression of phosphorylated NCC (pT53/58) at the plasma membrane is also higher in the kidneys of Gilz knock out mice than in the WT mice maintained on a sodium deficient diet. In HEK293T cells, overexpression of Gilz isoform 1 (Gilz1) inhibits NCC activation in response to hypotonic low-Cl conditions as assessed by its phosphorylation at T53 and T58. Gilz mediated NCC inhibition is lost in the presence of constitutively active SPAK suggesting that it is at least in part mediated by WNK1/4-SPAK pathway. Indeed, co-expression of Gilz1 inhibits SAPK phosphorylation at S373. Together, our results suggest that during sodium restriction, Gilz1 shifts sodium reabsorption from NCC to ENaC, thus favoring K^+ excretion. This effect may be critical for the maintenance of eukalemia in the face of Na^+ restriction.

Pharmacological Inhibition of the Circadian Regulatory Casein Kinases 1Δ/ε Prevents Aldosterone-Mediated Induction of Na-Cl Cotransporter Activity Michelle L. Gumz,[1,2] Kristen Solocinski,[1,2] Robert S. Hoover,[3,4] Benjamin S. Ko.[5] *[1]Medicine/Nephrology, Univ of Florida, Gainesville, FL; [2]Biochemistry and Molecular Biology, Univ of Florida, Gainesville, FL; [3]Medicine/Nephrology, Emory Univ, Atlanta, GA; [4]Research Service, Atlanta Veteran's Administration Medical Center, Atlanta, GA; [5]Medicine, Univ of Chicago, Chicago, IL.*

Background: The circadian clock protein Per1 transcriptionally regulates the Na-Cl co-transporter NCC and members of the WNK kinase cascade. Per1 must be phosphorylated by casein kinase 1Δ/ε (CK1Δ/ε) in order to enter the nucleus. Previously, we showed that inhibition of CK1Δ/ε decreased Per1 nuclear protein levels and decreased NCC activity under basal conditions in mouse distal convoluted tubule cells (mDCT15).

Methods: mDCT15 cells were treated with a CK1Δ/ε inhibitor prior to either aldosterone (100 nM for 24 hr) or Angiotensin II (AngII) (10^{-11}M for 30 or 120 min) treatment. NCC activity was determined by measuring thiazide-sensitive, Cl-dependent ^{22}Na uptake.

Results: NCC activity was significantly increased following either aldosterone or AngII treatment, consistent with previously published data. In the presence of the CK1Δ/ε inhibitor, however, the aldosterone-dependent increase in NCC activity was prevented. In contrast, the AngII-dependent increase in NCC activity was not affected by CK1Δ/ε treatment.

Conclusions: Inhibition of Per1 nuclear entry via pharmacological blockade of CK1Δ/ε appears to prevent the aldosterone-mediated but not AngII-mediated induction of NCC activity. These results suggest an important role for the circadian clock proteins Per1 and CK1Δ/ε in aldosterone-dependent regulation of NCC with possible implications for the treatment of hypertension.

Disruption of 14-3-3 γ Binding to NCC Altered the Aldosterone-Mediated Regulation of NCC Protein Expression Xiuyan Feng,[1,2] Zhizhi Zhuang,[1] Courtney Marie Caroti,[1,2] Hui Cai.[1,2] *[1]Medicine, Emory Univ School of Medicine, Atlanta, GA; [2]Section of Nephrology, Atlanta Veterans Administration Medical Center, Decatur, GA.*

Background: 14-3-3 γ belongs to a family of multifunction regulatory proteins that mainly bind to phosphorylated Ser/Thr residues in the target proteins. Previous data have shown that 14-3-3 proteins regulate renal ion channel and transporter such as ENaC and UT-A1 by altering their ubiquitinations. We have previously shown that aldosterone increases both total and surface expressions of sodium chloride co-transporter (NCC) via reducing NCC ubiquitination. Thus, we investigated whether 14-3-3 γ is involved in the aldosterone-mediated regulation of NCC.

Methods: Cell culture, transfection, western blot analysis, immunostaining, confocal microscopy, co-immunoprecipitation and C57/B6 mice were used for this study.

Results: Co-immumoprecipitaion (co-IP) in Cos-7 cells showed that 14-3-3 γ is the strongest one binding to NCC among all isoforms of 14-3-3. Immunostaining and confocal microscopy also showed that 14-3-3 γ is localized in distal convoluted tubule in mice. Co-IP experiments in Cos-7 cells showed that wild-type (WT) 14-3-3 γ binds to NCC, whereas 14-3-3 γ K50E mutant almost completely loses its binding to NCC. Western blot analysis showed that WT 14-3-3 γ significantly decreased total NCC expression by 63 % compared to the control group, whereas 14-3-3 γ K50E mutant did not change NCC protein expression. WT 14-3-3 γ increased NCC ubiquitination by 1.5 fold (1.5 ± 0.44 vs 1.00), whereas 14-3-3 γ K50E mutant did not alter NCC ubiquitination compared to the control group. In addition, we implanted aldosterone osmotic mini-pump to WT mice for 14 days and then harvested the kidney tissues. Western blot analysis showed that aldosterone treatment increased total NCC expression by 1.68 folds (1 ± 0.28 vs 1.68 ± 0.15) and decreased the ubiquitinated NCC by 56 %. Co-IP also showed aldosterone decreased the 14-3-3 γ binding to NCC by 57 % without changing total 14-3-3 γ expression.

Conclusions: These results suggested that aldosterone up-regulates NCC expression by disruption of 14-3-3 γ binding to NCC that leads to decreasing NCC ubiquitination.

Calcineurin Inhibitors Upregulate the Thiazide-Sensitive NaCl Cotransporter in Urinary Exosomes of Kidney Transplant Patients Omar Tutakhel,[1] Mathijs van de Vrie,[1] Marco Valdez Flores,[1] Ewout J. Hoorn,[2] Luuk Hilbrands,[1] Joost Hoenderop,[1] René J. Bindels.[1] *[1]Physiology and Nephrology, Radboud Univ Medical Center, Nijmegen; [2]Div of Nephrology & Transplantation, Erasmus Medical Center, Rotterdam, Netherlands.*

Background: Calcineurin inhibitors (CNIs), including cyclosporine A (CsA) and tacrolimus (Tac), are the cornerstone of immunosuppression and superior in preventing acute allograft rejection. This benefit, however, comes at the cost of common adverse effects including hypertension. Recently several studies have shown that CNI-induced hypertension is largely mediated by activation of the thiazide-sensitive NaCl cotransporter (NCC). The aim of the present study was to further substantiate the role of NCC in CNI-induced hypertension by assessing the abundance and activity of NCC in urinary exosomes of CNI-treated patients.

Methods: Kidney transplant patients were enrolled 6 months after transplantation and treated with CsA (n=14), Tac (n=18) or a CNI-free immunosuppressive regimen (n=13). Six healthy subjects were also included. Urinary exosomes were isolated from 10 ml midstream urine samples by ultracentrifugation and normalized by urinary creatinine. The corresponding immunoblots were probed with antibodies specifically recognizing NCC and pNCC-T58. To confirm equal loading of the samples the abundance of the exosomal marker CD9 was determined.

Results: NCC was detected in urinary exosomes by immunoblots as two bands of ~260 and ~130 kDa representing the dimeric and monomeric forms, respectively. Abundance of both NCC and pNCC-T58 in urinary exosomes of CsA and Tac groups was significantly increased in comparison to patients treated with a CNI-free immunosuppressive regimen and healthy subjects. Moreover, both the NCC and pNCC-T58 abundance was 2.5-fold higher in CsA group compared to Tac group. CD9 abundance in urinary exosomes was similar between the various groups.

Conclusions: The present study demonstrates that: *i)* total and phosphorylated NCC abundance is increased in urinary exosomes of CNI-treated kidney transplant patients; *ii)* urinary exosomes can be used as a novel biomarker to assess NCC abundance and activity in CNI-treated kidney transplant patients.

TH-PO441

Generation of Hypertension-Associated *STK39* Polymorphism Knock-in Cell Lines with the CRISPR/Cas9 System Shintaro Mandai, Takayasu Mori, Eisei Sohara, Tatemitsu Rai, Shinichi Uchida. *Dept of Nephrology, Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental Univ, Tokyo, Japan.*

Background: Previous genome-wide association studies identified *STK39*, encoding STE20/SPS1-related proline/alanine-rich kinase (SPAK), as one of a limited number of hypertension susceptibility genes. A recent meta-analysis confirmed the association of *STK39* intronic polymorphism rs3754777 with essential hypertension, among previously reported hypertension-associated *STK39* polymorphisms. However, the physiological function of this polymorphism is yet to be clarified.

Methods: To investigate whether SPAK and the downstream targets are modulated by this polymorphism, we generated *STK39* rs3754777 G > A knock-in human embryonic kidney (HEK293T) cell lines with the clustered regularly interspaced short palindromic repeats (CRISPR/Cas9) system, using a double-nickase (Cas9-D10A), single guide RNAs targeting *STK39* intron 5 around SNP, and a 100-bp donor single-stranded DNA oligonucleotide.

Results: Homozygous (A/A) and heterozygous (G/A) knock-in cell lines were generated. Reverse transcription-polymerase chain reaction (RT-PCR) with sequencing analyses revealed the identical *STK39* transcripts among the wild-type and both knock-in cell lines. Quantitative RT-PCR showed increased *STK39* mRNA expression, and immunoblot analysis revealed increases in total and phosphorylated SPAK with increased phosphorylated Na–K–Cl cotransporter isoform 1 (NKCC1) in both knock-in cell lines. The largest increases in these molecules were observed in the homozygous cell line.

Conclusions: *STK39* intronic polymorphism rs3754777 increases *STK39* transcription, leading to activation of the SPAK-solute carrier family 12 (SLC12A) signaling cascade. Activation of the target cation-chloride cotransporters may be responsible for hypertension susceptibility in individuals with this polymorphism.

TH-PO442

The Major Contribution of WNK4 to the Pathogenesis of Pseudohypoaldosteronism Type II (PHAII) Caused by the KLHL3 Mutation R528H
Koichiro Susa, Eisei Sohara, Daiei Takahashi, Tatemitsu Rai, Shinichi Uchida. *Dept of Nephrology, Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental Univ, Tokyo, Japan.*

Background: Recently, we reported that KLHL3$^{R528H/+}$ knock-in mice, a PHAII model mouse, exhibit the activation of OSR1/SPAK-NCC signaling by the increased protein levels of both WNK1 and WNK4 due to impaired protein degradation by the mutant KLHL3. Previously we have demonstrated that the amount of phosphorylated and total NCC decreased to almost undetectable levels in the WNK4$^{-/-}$ mice, indicating that WNK4 plays the major role in NCC regulation and that other WNKs including WNK1 and WNK3 cannot compensate for the absence of WNK4. In this study, we sought to determine the contribution of WNK4 to the activated OSR1/SPAK-NCC signaling in the KLHL3$^{R528H/+}$ knock-in mice.

Methods: We generated WNK4$^{-/-}$KLHL3$^{R528H/+}$ mice by crossing the WNK4$^{-/-}$ mice with the KLHL3$^{R528H/+}$ mice. In addition, we also generated WNK4$^{-/-}$KLHL3$^{R528H/R528H}$ mice. Thereafter, WNK-OSR1/SPAK-NCC phosphorylation signal cascade was examined in kidneys from these mice.

Results: As previously reported, compensatory increased WNK1 was observed in the WNK4$^{-/-}$ mouse kidney, compared to WNK4$^{+/+}$. Expectedly, both WNK4$^{-/-}$KLHL3$^{R528H/+}$ mice and WNK4$^{-/-}$KLHL3$^{R528H/R528H}$ mice showed further increases in WNK1 in the kidney, due to the KLHL3 mutation. However, although phosphorylated SPAK was increased in the whole kidney to the levels comparable with that in wild-type mouse, total NCC and NCC phosphorylated at S71 were almost completely absent even in WNK4$^{-/-}$KLHL3$^{R528H/R528H}$ mice.

Conclusions: As in the wild-type mice, WNK4 plays the major positive role in the regulation of NCC in the KLHL3$^{R528H/+}$ PHAII model mice.

TH-PO443

Mechanism of Regulation of WNK Kinases
Elizabeth J. Goldsmith. *Biophysics, Univ of Texas Southwestern Med Center Dallas, Dallas, TX.*

Background: WNK1 is a protein kinase on pathway for the regulation of cation-choride cotransporters. We demonstrated that the kinase domain of WNK1 binds chloride ion and inhibits WNK1 autophosphorylation (Piala et al. Sci Signaling 7 ra41 2014). New crystallography improves our understanding of the mechanism of this regulation.

Methods: New crystals of the kinase domain of WNK1 (210-483)/S* (phosphorylated) were obtained using peg-ion screening, that yielded crystals diffracting to 2.1 Å. Data were collected at the APS Beamline 19, and data were processed in HKL2000; the structures was solved by molecular replacement. In addition, the structure of a chloride sensing mutant was solved in an unphosphorylated form of the same construct on diffraction to 2.5 Å.

Results: The structure of the phosphorylated form reveals conformational changes associated with dislodging the chloride from the active site of WNK1, and how a ATP analog, AMP-PNP, binds to the unique WNK1 active site. The structure adopted however, is not in a fully active configuration based on numerous structural cues. The structure of the mutant WNK1/L299F reveals aspects of the contacts of chloride with the protein structure.

Conclusions: The new structural data confirms the chloride regulation of WNK1, and strongly suggests that activation is a multistage process.

TH-PO444

Characterisation of the Cullin-3 Mutation That Causes a Severe Form of Familial Hypertension and Hyperkalaemia
Keith Siew,[1] Frances-Rose Schumacher,[2] Thimo K. Kurz,[2] Kevin O'Shaughnessy.[1] *[1]EMIT, Dept of Medicine, Univ of Cambridge, Cambridge, United Kingdom; [2]MRC PPU, College of Life Sciences, Univ of Dundee, Dundee, United Kingdom.*

Background: Deletion of exon-9 from Cullin-3 (CUL3, residues 403-459: CUL3$^{\Delta 403-459}$) causes pseudohypoaldosteronism type IIE (PHA2E), a severe form of Familial Hyperkalaemia and Hypertension (FHHt). CUL3 bound to KLHL3 ubiquitylates WNK kinases, promoting their ubiquitin-mediated proteasomal degradation. Mutations in both KLHL3 and WNK kinases cause PHA2 by disrupting Cullin-RING-Ligase formation, and since WNKs activate Na-Cl co-transporters (NCC) to promote salt retention, CUL3 regulates blood pressure. The aim of our study was to understand the pathophysiology of CUL3$^{\Delta 403-459}$ mutations which underlies PHA2E severity.

Methods: Blood pressure traces and *in vivo* pressor responses were obtained in CUL3$^{WT/\Delta 403-459}$ and CUL3^{WT} mice by catheterisation of the right carotid artery and jugular vein under anaesthesia (isoflurane). After sacrifice by exsanguination, tissues were harvested for electrolyte and western blot analysis. All data are mean±SEM; student t-test statistical analysis (* P<0.01; ** P<0.001).

Results: CUL3$^{WT/\Delta 403-459}$ compared to CUL3^{WT} have elevated blood pressure [93.9±1.2 vs 81.0±0.7** MAP mmHg], hyperkalaemia [5.1±0.2 vs 4.3±0.1** K^+ mmol/L] and hyperchloraemia [119.4±0.4 vs 115.6±0.6** Cl^- mmol/L] due to renal WNK4 accumulation causing NCC hyperphosphoylation. CUL3$^{WT/\Delta 403-459}$ mice also have stiffened arteries [50.2±1.6 vs 42.6±1.8 Augmentation Index %], increased phenylephrine maximal pressor response [183.9±2.5 vs 164.9±1.4* Systolic E_{Max} mmHg] and a 1.7-fold higher phosphorylation of MYPT1 in aorta suggesting increased vasoconstriction.

Conclusions: We report here a novel knock-in mouse model of CUL3$^{WT/\Delta 403-459}$ that fully recapitulates the human PHA2E phenotype. The PHA2E mutant, CUL3$^{\Delta 403-459}$, is severely compromised in its ability to ubiquitylate WNKs, probably due to altered structural flexibility. Our discovery of a vascular phenotype suggests an explanation for the severity of PHA2E. It will be important to establish if this vascular phenotype exists in PHA2E patients and can be normalised by thiazide treatment.

TH-PO445

Paracellular Na^+ Transport by Claudin-2 Enhances the Efficiency of Oxygen Usage by the Kidney and Protects against Ischemic Injury
Lei Pei,[1] Glenn Solis,[2] Lynn Magenheimer,[1] Mien T.X. Nguyen,[3] Nikhil Kamat,[3] Min Zhuo,[1] Jiahua Li,[1] Timothy A. Fields,[1] William J. Welch,[2] Alicia A. McDonough,[3] Alan S.L. Yu.[1] *[1]Univ Kansas Medical Center; [2]Georgetown Univ; [3]Univ Southern California.*

Background: Claudin-2 is a tight junction protein that mediates paracellular Na reabsorption in the proximal renal tubule (PT). We previously showed that claudin-2 null mice (KO) were able to conserve Na normally by upregulating transcellular Na-K-2Cl transport in the thick ascending limb. Paracellular transport exploits pre-existing electrochemical gradients to drive passive diffusion without consumption of additional ATP. We therefore hypothesized that the shifting of Na transport to transcellular pathways would lead to increased O_2 consumption, intrarenal hypoxia, and increased susceptibility to ischemic injury.

Methods: The ratio between whole kidney Na reabsorption (T_{Na}) and O_2 consumption (QO_2 = RBF X A-VO_2) was determined in KO mice and WT littermates. Intrarenal PO_2 was measured by Clark-type O_2 microelectrode. Mice were subjected to 23 min of bilateral renal ischemia and assessed for injury 48 h after reperfusion.

Results: T_{Na}/Q_{O2} (mol/mol) in KO mice (16.36±1.31) was significantly lower than in WT (10.34 ±1.33), indicating decreased efficiency of O2 utilization. The outer medullas of KO mice kidneys were relatively hypoxic, but after furosemide, KO exhibited a 2.7-fold greater increase in PO2 compared to WT mice. After ischemia-reperfusion injury, BUN (246.98± 12.46 mg/dl KO, 72.19± 21.04 mg/dl WT) and plasma creatinine (0.33±0.16 mg/dl KO, 1.45± 0.08mg/dl WT) were significantly higher in KO compared to WT mice. mRNA of the injury marker, KIM-1, was also higher in KO. KO kidneys exhibited markedly worse tubule injury by histology compared to WT.

Conclusions: Our results indicate that paracellular Na transport in the PT is required for efficient utilization of oxygen in the service of sodium transport. The cost of loss of paracellular transport is medullary hypoxia and increased susceptibility to ischemic injury. Our results suggest that paracellular permeability may have evolved as a general strategy in epithelia to maximize energy efficiency.

The Diuretic and Natriuretic Effect of the GLP-1 Receptor Agonist, Exendin-4, Is Independent of Tubular NHE3
Yiling Fu,[1] Panai Song,[1] Akira Onishi,[1] Falk Bernhard Batz,[1] Manoocher Soleimani,[2] Meinrad Busslinger,[3] Volker Vallon.[1] *[1]Div of Nephrology, UC San Diego & VA San Diego Healthcare System, La Jolla, CA; [2]Dept of Medicine, Univ of Cincinnati, Cincinnati, OH; [3]Research Inst of Molecular Pathology, Vienna, Austria.*

Background: Exendin-4 (EX-4) activates the glucagon-like receptor GLP-1R and is used as an antidiabetic drug, but also induces natriuresis. The natriuretic effect of EX-4 has been associated with phosphorylation and potential inhibition of Na-H-exchanger 3 in proximal tubules, but the quantitative contribution has not been defined.

Methods: Tubule-specific NHE3 knockdown mice were generated (Pax8-Cre/NHE3fl/fl [tubNHE3-/-]) and compared with littermate controls (NHE3fl/fl [WT]). a) EX-4 (10 mg/kg) or vehicle was applied i.p. in a cross-over design together with an oral NaCl load (30 ml/g bw of 0.85% saline) and the urine quantitatively collected over 3 hours in metabolic cages. b) Terminal ^{3}H-inulin clearance studies determined effects of EX4 on GFR, blood pressure (BP), and fractional fluid excretion (FE).

Results: Western blotting revealed non-detectable renal NHE3 in tubNHE3-/-. tubNHE3-/- and WT showed a) similar diuresis and natriuresis during vehicle application (not shown) and EX-4-induced increase in diuresis (50±14 vs 60±17 %) and natriuresis (103±34 vs 100±28 %)(each P<0.01 vs vehicle; n=9-10/group), and b) similar basal values (not shown) as well as EX4-induced changes in GFR (14±6 vs 13±9 %) and blood pressure (-3±3 vs -7±2 %); EX-4 induced similar increase in FE in tNHE3-/- (1.1±0.1 to 3.1±0.8%) and WT (1.1±0.4 to 2.5±0.5%)(each P<0.01 vs basal); n=7-8/group).

Conclusions: The acute EX-4-induced diuresis and natriuresis does not require tubular NHE3 in mice.

Protein Carbonylation of a Single Amino Acid Residue of Na/K-ATPase a1 Subunit Dictates Na/K-ATPase Signaling and Sodium Transport in Renal Proximal Tubular Cells
Yanling Yan,[1] Anna P. Shapiro,[2] Jiang Tian,[2] Deepak K. Malhotra,[2] Zi-jian Xie,[3] Joseph I. Shapiro,[1,2] Jiang Liu.[1,3] *[1]Pharmacology, Marshall Univ JCE School of Medicine, Huntington, WV; [2]MIIR at Marshall Univ, Huntington, WV; [3]Medicine, Univ of Toledo, Toledo, OH.*

Background: We have demonstrated that direct carbonylation modification of the Na/K-ATPase a1 subunit regulates Na/K-ATPase signaling and subsequent transepithelial sodium transport in renal proximal tubules.

Methods: Mutation of Pro224 of rat a1 subunit. Assays for protein carbonylation, c-Src and ERK1/2 activation, Na/K-ATPase activity, NHE3 activity, active transepithelial $^{22}Na^+$ transport, cellular redistribution of ion transporters, etc.

Results: Cardiotonic steroids (CTS, such as ouabain) signaling through Na/K-ATPase, regulate sodium reabsorption in renal proximal tubule (RPT). By direct carbonylation modification of the actuator (A) domain of the Na/K-ATPase a1 subunit, reactive oxygen species (ROS) are required to initiate ouabain-stimulated Na/K-ATPase/c-Src signaling and subsequent regulation of active transepithelial $^{22}Na^+$ transport. A single mutation of Pro224 to Ala in rat a1 subunit was established into a stable cell line, and the mutant cells were compared to the wild-type RPT cells by characterization with Na/K-ATPase a1/b1 expression, [^{3}H] ouabain binding and ouabain-sensitive $^{86}Rb^+$ uptake assays. The mutation of Pro224 to Ala abolishes ouabain-stimulated Na/K-ATPase/c-Src signaling, protein tyrosine phosphorylation, protein carbonylation, redistribution of Na/K-ATPase and sodium/proton exchanger isoform 3 (NHE3), and inhibition of active transepithelial $^{22}Na^+$ transport. However, a mutation of Ala416 to Pro in rat a1 subunit, also characterized as aforementioned, does not affect ouabain-mediated Na/K-ATPase signaling and sodium handling. The data indicates that carbonylation modification of Pro224 in rat a1 subunit dictates ouabain-mediated RPT Na/K-ATPase signal transduction and subsequent sodium transport.

Conclusions: Direct carbonylation of a single amino acid dictates ouabain-mediated Na/K-ATPase signaling and related sodium handling in renal proximal tubules.

TH-PO448

The Mineralocorticoids Receptor Regulates the Expression of Na^+-K^+-ATPase b_3 Subunit in Kidney Collecting Duct Cells Pablo Diaz, Cristian Degregorio, Luis F. Michea, Magdalena Gonzalez. *Univ de Chile, Chile.*

Background: Aldosterone modulates the activity of the Na+-K+-ATPase (NKA) in principal cells (PC) of kidney collecting duct (CD) via activation of the mineralocorticoid receptor (MR). The NKA is a heterodimer with a catalytic α subunit and a regulatory β subunit. a_1, b_1 and b_3 are the only subunit isoforms expressed in the kidney. The β subunit may be determinant of subcellular localization and trafficking of the α-β heterodimers, and also may have a role in the cell-cell adhesion that may be relevant in paracellular permeability. Previous studies addressed the modulation of a_1 and b_1 expression in response to aldosterone. However the role of aldosterone in the regulation of the b_3 subunit has not been analyzed. We tested the hypothesis that the activation of the MR modulates the expression of NKA b_3 subunit in CD.

Methods: C57BL/6 mice underwent adrenalectomy (ADX) or sham surgery (SHAM). The ADX mice received high salt diet or hormone replacement therapy with deoxycorticosterone (ADX+DOCA, 10mg/mL/day). In a second set of experiment mice received spironolactone (Spi, 50 mg/Kg/day) or vehicle (Control) treatment. After 3 days we obtained the kidneys (cortex and medulla) for the analysis of NKA a_1, b_1 and b_3 subunits (mRNA and protein abundance by qRT-PCR and Western blot). Finally, we studied the effect of aldosterone (0.1-100 nM) in primary culture of inner medullary collecting ducts cells (IMCD, 24 hours).

Results: Adrenalectomy increased b_3-subunit mRNA and protein abundance in mouse renal medulla but not in kidney cortex (200% vs control, $P<0.05$ n=4 for mRNA and 65% vs control, $P<0.001$, n=9 for protein). Similarly, Spi treatment increased the abundance of b_3-subunit mRNA and protein in renal medulla only (250% vs control, $P<0.01$, n=8 for mRNA and 100% vs control, $P<0.05$, n=5 for proteins). Both the ADX mice as the Spi-treated mice showed no-significant changes in the abundance of a_1 or b_1 transcripts and proteins. The treatment with Aldosterone decreased b_3 mRNA in IMCD cells (50% vs control,$P<0.01$, n=5).

Conclusions: We conclude that the NKA b_3 subunit expression is downregulated by the activation of the MR.

TH-PO449

Purified Recombinant ApoL1 Forms Anion Channels in Phospholipid Bilayers John C. Edwards. *Internal Medicine, Saint Louis Univ, Saint Louis, MO.*

Background: Variants in the protein ApoL1 confer the increased risk of certain types of chronic kidney disease that is observed in people of African ancestry. ApoL1 has been reported to function as an ion channel but reports vary on the nature of this activity. We sought to characterize ApoL1 channels with anticipation that detailed properties of the channel activity of WT and variant ApoL1 may provide insight into the pathophysiology of ApoL1-associated kidney disease.

Methods: Recombinant ApoL1 was expressed in bacteria with a N-terminal GST tag replacing the signal sequence and separated from the ApoL1 coding region by a thrombin cleavage site, and with a C-terminal V5-6Histidine tag. N-octyl glucoside-solubilzed protein was bound to glutathione agarose. The bound fusion protein was cleaved with thrombin, releasing ApoL1-V5His which was further purified by Ni-affinity. Channel activity was assessed using vesicle-based voltage dependent Cl and K efflux assays employing ion selective electrodes. Single channel properties were investigated using the Tip-Dip lipid bilayer approach with ApoL1 added to the bath solution.

Results: The preparation yields highly purified soluble ApoL1. Introduction of ApoL1 into phospholipid vesicles either by reconstitution via detergent dialysis, or by direct insertion into pre-formed vesicles yields a Cl selective permeability that supports voltage-driven chloride transport. The Cl channel activity requires that the protein interacts with the lipids at low pH (5.0). We do not find potassium-selective permeability when assayed at either pH 5 or 7.5. In tip-dip bilayer, ApoL1 spontaneously inserts at low pH, generating transitions with single channel conductance of about 5 pS, and with a non-rectifying current-voltage relationship. We do not find enhanced channel activity if the bath solution is changed to pH 7.5.

Conclusions: Purified recombinant ApoL1 can insert directly into phospholipid membranes at low pH and function as an anion selective channel. A prominent difference between our preparation and that of others reported to function as a cation channel is that our method avoids denaturation and refolding. Whether the disease associated variants show altered channel properties remains to be determined.

Using ChlopHensor to Measure Intracellular Cl^- in a Transporting Renal Epithelium Aylin R. Rodan,[1] Qifei Sun,[1] Drew Stenesen,[2] Helmut Kramer.[2] *[1]Internal Medicine, UT Southwestern, Dallas, TX; [2]Neuroscience, UT Southwestern.*

Background: *Drosophila melanogaster* eat a K^+-rich diet and secrete a KCl-rich fluid from the main segment of the renal tubule. We have previously shown that ~1/3 of transepithelial K^+ flux through the cation-conducting principal cell is via the basolateral NKCC and is regulated by the WNK-SPAK/OSR1 kinase cascade. This pathway is activated under hypotonic conditions. Cl^- is a key regulator of WNK activity. Here, we measured intracellular Cl^- in the fly tubule using the transgenic Cl^- sensor, ChlopHensor.

Methods: The GAL4-UAS system was used to drive tubule expression of ChlopHensor, a pH- and Cl^--sensitive GFP linked to a pH- and Cl^--insensitive dsRed. Fluorescence after excitation at 488 nm (green), 458 nm (cyan) and 543 nm (red) was quantified using ImageJ. Calibration curves of the green/cyan ratio (to measure pH) and cyan/red ratio (to measure Cl^-) were generated at varying intracellular pH and Cl^- by equilibrating in the presence of 5 mM nigericin, CCCP, valinomycin and 10 mM tributyltinchloride. Fluorescence emission was then measured in the tubule principal cells under varying conditions.

Results: In standard bathing medium (SBM), intracellular Cl^- concentration was 27±2 mM (n=21 cells in 7 tubules), similar to previous measurements made with double-barrelled ion-specific electrodes. In hypotonic medium, Cl^- decreased to 16±1 mM ($p<0.0001$, paired t-test). pH_i was unchanged. In a timecourse experiment, initial Cl^- was 30±4 mM in SBM, then decreased to 20±3, 16±2, and 15±2 mM at 10, 30 and 60 minutes of hypotonic exposure. The decrease in Cl^- in hypotonic conditions was blunted by increasing $[K^+]$ in the hypotonic medium (Δ, 8±1 mM) and increased by decreasing $[K^+]$ and $[Cl^-]$ in the hypotonic medium (Δ, 17±2 mM, $p<0.05$ compared to usual hypotonic and $p<0.001$ compared to high-K^+ hypotonic, one-way ANOVA with Bonferroni correction).

Conclusions: Activation of the WNK-SPAK/OSR1-NKCC pathway in the *Drosophila* renal tubule under hypotonic conditions correlates with decreased intracellular Cl^- concentration. The decrease in Cl^- is accentuated when bath K^+ and Cl^- are lowered, suggesting KCl efflux in hypotonic conditions, perhaps due to regulatory volume decrease mechanisms.

TH-PO451

Potassium-Induced Dephosphorylation of Renal Sodium Chloride Cotransporter Is NOT Dependent on the Anions Naohiro Nomura, Wakana Shoda, Eisei Sohara, Tatemitsu Rai, Shinichi Uchida. *Dept of Nephrology, Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental Univ, Tokyo, Japan.*

Background: Dietary potassium intake is strongly associated with blood pressure and cardiovascular death. High-potassium diets decrease phosphorylation of sodium-chloride cotransporter (NCC) and induce lower blood pressure. In many experimental studies using high-potassium diets, potassium chloride was added to make high-potassium diets. On the other hand, there is a recent report that a high-potassium diet made of potassium citrate increased phosphorylation of NCC. It is also known that chloride itself affects NCC phosphorylation. Thus, the accompanying anion might modulate the NCC phosphorylation response to the high potassium diets, and aldosterone also might be involved in the discrepancy. In this study, we clarified the change of NCC phosphorylation with potassium compounds accompanying different anions, and confirmed the association between potassium intake and NCC phosphorylation with acute oral infusion.

Methods: Adult C57BL/6 mice were fed potassium chloride, potassium gluconate, and potassium citrate with oral gavage. Kidneys were collected after 15 min infusion, because plasma aldosterone level did not show significant difference at this time point. Western blotting was performed with anti-phospho-NCC antibody.

Results: All potassium compound infusion showed significant decrease of NCC phosphorylation. Sodium gluconate and calcium gluconate infusion showed very little and no reduction of NCC phosphorylation respectively.

Conclusions: Rapid potassium infusion decreases phosphorylation of NCC. It is not depend on the anions at least in acute potassium infusion.

Association of Birth History and BMI with APOL1 Risk Alleles in CKiD Rebecca C. Hjorten,[1] Kimberly J. Reidy,[1] Derek Ng,[2] Robert Woroniecki,[3] Susan L. Furth,[4] Bradley Warady,[5] Craig S. Wong,[6] Larry A. Greenbaum,[7] Marva M. Moxey-Mims,[8] Jeffrey B. Kopp,[8] Sophie Limou,[8] Cheryl Ann Winkler,[8] Frederick J. Kaskel.[1] *[1]Pediatrics/ Nephrology, Montefiore, Bronx, NY; [2]Epidemiology, Johns Hopkins, Baltimore, MD; [3]Pediatrics/ Nephrology, Stony Brook Univ, Stony Brook, NY; [4]Pediatrics/Nephrology, Children's Hospital of Pennsylvania, Philadelphia, PA; [5]Pediatric/ Nephrology, Children's Mercy, Kansas City, MO; [6]Pediatrics/ Nephrology, Univ of New Mexico, Albuquerque, NM; [7]Pediatrics/ Nephrology, Emory Univ, Atlanta, GA; [8]NIH, Bethesda, MD.*

Background: In the Chronic Kidney Disease in Children (CKiD), there is a high prevalence of abnormal birth history (BH) and poor growth. African Americans (AA) have increased rates of prematurity. *APOL1* risk alleles are associated with risk of glomerular CKD in AA patients, but the association with BH or growth is unknown.

Methods: Children of AA descent were genotyped for *APOL1* risk alleles (G1, G2). High risk (HR) was defined as 2 risk alleles (G1,G1; G1,G2 or G2,G2) Low risk (LR) was defined as no risk alleles or one G1/G2 allele. Demographics and growth parameters were compared between *APOL1* HR vs. LR groups.

Results: 28/84 AA children with glomerular disease had HR APOL1, 28 had LR APOL1 and 28 did not have APOL1 measured. 26.9% (7/28) with HR APOL1 were premature, versus 3.7% (1/28) in AA LR APOL1 patients and 6.9% (13/191) in non-AA LR APOL1 patients (p=0.010). Also in AA children with HR APOL1, 29.2% (7/28) were small for gestational age, vs. 36% (9/28) in AA LR APOL1 patients and 15.4% (27/191) in non-AA LR APOL1 patients (p=0.011). Overall, 48.1% (13/28) AA children with HR APOL1 had an abnormal BH, versus 35.7% (10/28) in AA LR APOL1 patients and 20.5% (39/191) in non-AA LR APOL1 patients (p=0.007). HR ApoL1 risk alleles were also associated with increased BMI in patients with FSGS (p<0.04).

Conclusions: HR APOL1 in CKiD is significantly associated with an abnormal BH and higher BMI. Further analysis of the interaction of APOL1 genotype with BH and BMI in CKD is warranted.

TH-PO453

Relationships of Serum Growth Hormone, Insulin-Like Growth Factor-1 and IGF-1 Binding Proteins (BPs) in Children with CKD on Growth Hormone Therapy Rose M. Ayoob,[1] John D. Mahan,[1] Larry A. Greenbaum,[2] Amira Al-Uzri,[3] Frederick J. Kaskel,[4] Susan L. Furth,[5] Bradley Warady.[6] *[1]Pediatrics, Nationwide Children's/The Ohio State Univ, Columbus, OH; [2]Pediatrics, Emory Univ, Atlanta, GA; [3]Pediatrics, Oregon Health & Science Univ, Portland, OR; [4]Pediatrics, Albert Einstein COM, New York, NY; [5]Pediatrics, Univ of Pennsylvania, Philadelphia, PA; [6]Pediatrics, Children's Mercy Hospital, Kansas City, MO.*

Background: We evaluated children with chronic kidney disease (CKD) enrolled in the Chronic Kidney Disease in Children (CKiD) study to determine relationships between Growth Hormone (GH), Insulin-Like Growth Factor-1 (IGF-1) and IGF-1 Binding Proteins (BP's), with/without recombinant GH therapy, to assess values that might be useful to guide individual treatment decisions.

Methods: 266 CKiD children: 206 - normal height; 26 - short stature; 34 [18 short, 16 normal height] on recombinant (r) GH therapy were selected for gender, age and GFR matching. Normal height = Height Standard Deviation Score (SDS) > -1.88. GH, IGF-1, and IGFBP-1 were measured by chemiluminometer and ELISA.

Results: Children with CKD on rGH display lower IGF-1/GH than normal height and short CKD children not on rGH therapy.

	IGF-1/GH*	IGF-1/IGF-1 BP 1*
Children Height SDS < -1.88	356.7 [152.3-1017.2]	0.0056 [0.0012, 0.0161]
Children Height SDS > -1.88	811.8 [168.2, 2360.0]	0.0136 [0.0055, 0.0582]
Children on rGH Therapy	138.8 [66.1, 291.0]	0.0098 [0.0017, 0.0308]
p-value (Kruskal Wallis ANOVA)	*0.0002*	*0.02*

* = (median [IQR])

On rGH, IGF-1/IGF-1 BP1 is closer to that in normal height CKD children than in short CKD children. Height SDS correlates with serum IGF-1 in children on rGH better (r = 0.374) than normal height (r = 0.323) and short children (r = 0.048).

Conclusions: IGF-1/IGF-1 BP1 in children on rGH is closer to that in normal height then in short CKD children not on rGH, supporting importance of serum IGF-1 levels achieved in rGH treated children to drive statural growth. Further analyses in samples over time and in paired subjects may provide further insights into effective 'therapeutic targets' for rGH treatment in these children.

TH-PO454

Two-Year Kidney Outcomes of Teen-LABS Participants Edward Nehus,[1] Todd Jenkins,[1] Nianzhou Xiao,[2] Marc P. Michalsky,[3] Anita Courcoulas,[4] Thomas H. Inge,[1] Mark Mitsnefes.[1] *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]Children's Hospital of Richmond at VCU, Richmond, VA; [3]Nationwide Children's Hospital, Columbus, OH; [4]Univ of Pittsburgh Medical Center, Pittsburgh, PA.*

Background: A significant amount of severely obese adolescents undergoing weight loss surgery have evidence of early kidney damage. The objective of this study was to determine if early kidney injury is reversible following weight loss surgery.

Methods: We analyzed data two years following bariatric surgery in the Teen Longitudinal Assessment of Bariatric Surgery (Teen-LABS) cohort, a prospective multicenter study of 242 severely obese adolescents undergoing bariatric surgery. Primary outcomes of albuminuria (urinary albumin to creatinine ratio > 30 mg/g) and cystatin C-estimated GFR (eGFR) were compared to baseline values to determine the effect of bariatric surgery on kidney injury.

Results: At surgery, the mean (± SD) age of the patients was 17 ± 1.6 years, 76% were female, and 72% were white race. Procedures included gastric bypass (67%), sleeve gastrectomy (28%), and adjustable gastric band (5%). Median BMI (IQR) at baseline was 51 (45, 58) kg/m^2, and this decreased to 35 (30, 43) kg/m^2 at two years follow-up. Cystatin C-based eGFR was 108 ± 27 mL/min/1.73m^2 at baseline and by two years post-operatively, eGFR had increased by 10% to 119 ± 27 mL/min/1.73m^2 (p<0.01). Low eGFR (< 90 mL/min/1.73m^2) was observed in 25% at baseline, and this improved to 12% at two years follow-up (p<0.01); 71% with low baseline eGFR experienced normalization of eGFR at follow-up. Alternatively, 7% of subjects with normal baseline eGFR developed incident low eGFR at two years post-op. Albuminuria was observed in 17% at baseline and 12% at two years follow-up (p=0.03). Among those with baseline albuminuria, 69% experienced normalization of albuminuria at follow-up. In contrast, 7% of subjects were observed with incident albuminuria at two years post-op.

Conclusions: Two years following surgery, improvements in kidney function and albuminuria were observed in our cohort. Further study will permit assessment of durability of improvements and longer-term kidney outcomes of severely obese adolescents undergoing bariatric surgery.

Genetic Variation Underlying Uric Acid Clearance in Hispanic Children: The Viva La Familia Study Geetha Chittoor,[1] Sandra L. Laston,[2] Nitesh R. Mehta,[3] Karin Haack,[4] Shelley A. Cole,[4] Anthony Gean Comuzzie,[4] Nancy F. Butte,[3] V. Saroja Voruganti.[1] *[1]Nutrition and Nutrition Research Inst, Univ of North Carolina at Chapel Hill, Kannapolis, NC; [2]South Texas Diabetes and Obesity Inst and Regional Academic Health Center, UTHSC at San Antonio/ Univ of Texas Rio Grande Valley, Brownsville, TX; [3]Pediatrics and USDA/ARS Children's Nutrition Research Center, Baylor College of Medicine, Houston, TX; [4]Genetics, Texas Biomedical Research Inst, San Antonio, TX.*

Background: Variation in renal excretion of uric acid is a key factor in the development of gout, hyperuricemia, and nephropathy. Hyperuricemia (increased serum uric acid concentrations) and hyperuricosuria (increased urinary uric acid concentrations) can lead to uric acid nephrolithiasis. These are two common multifactorial disorders that have been shown to be associated with progression to kidney disease and have a familial inheritance. The genetic determinants of renal handling of uric acid are poorly elucidated.

Methods: We investigated the genetic factors that influence the excretion of uric acid and its related indices in 769 Hispanic children of the Viva La Familia Study. We conducted a genome-wide association analysis for uric acid clearance after accounting for family kinships. All methods were implemented in SOLAR.

Results: All renal uric acid clearance measures were significantly heritable ($p < 2 \times 10^{-6}$). We observed a strong association of uric acid clearance with a single nucleotide polymorphism (SNP) in the zinc finger protein 446 (*ZNF446*) gene on 19q13 [$p < 8 \times 10^{-8}$, rs2033711 (A/G), minor allele frequency (MAF) of 0.30]. The minor allele (G) was associated with increased uric acid clearance. We also found suggestive associations of uric acid clearance with SNPs in *ZNF324, ZNF584*, and *ZNF132* (within 72kb region of 19q13, $p < 1 \times 10^{-6}$, MAFs between 0.28 and 0.31).

Conclusions: Our study indicates, for the first time, the importance of the chromosomal region 19q13 in the regulation of renal clearance of uric acid in Hispanic children.

TH-PO456

Association Between Height and Clinical Outcomes in Children at Time of ESRD Onset Elaine Ku,[1] Richard N. Fine,[2] Chi-yuan Hsu,[1] David V. Glidden,[1] Barbara A. Grimes,[1] Kirsten L. Johansen.[1] *[1]UCSF; [2]Stony Brook Univ.*

Background: Short and tall stature are associated with adverse outcomes in the general adult population. The aim of this study was to examine risk of mortality and transplantation in children with short and tall stature at time of ESRD onset.

Methods: Using data from US Renal Data System, we performed a retrospective analysis of children ages 2-19 who began renal replacement therapy during 1995-2011. We used Cox models adjusted for demographic and socioeconomic factors, calendar year, and cause of ESRD to determine the association between short (<3rd percentile) and tall

(>97th percentile) stature and risk of transplantation and death. In sensitivity analysis, we also evaluated mortality and transplant risk in the subset of children with normal BMI (5th-95th percentile).

Results: Among 13,666 children, 26% of children were short and 3% were tall at time of ESRD onset. During a median follow-up of 7.1 years, 10,354 kidney transplants and 1,795 deaths occurred. Risk of death was higher in children with short and tall stature [table 1], and cause-specific mortality differed by height category. The higher risk of death in children with short stature persisted even when analysis was limited to children with normal BMI. Children with short stature were also less likely to receive a kidney transplant (HR 0.83, 95% CI 0.79-0.87).

Outcome (N=13,666)	**Short Stature** (N=3576)	**Tall Stature** (N=397)
All-cause mortality	**HR* (95% CI)**	**HR* (95% CI)**
Adjusted model (primary analysis)	1.48 (1.33-1.65)	1.30 (1.01-1.67)
Adjusted model among persons with normal BMI (N=9,663)	1.56 (1.36-1.77)	0.98 (0.67-1.44)
Cause-specific mortality		
Adjusted model for cardiac death	1.45 (1.19-1.76)	1.19 (0.76-1.85)
Adjusted model for infectious death	1.77 (1.34-2.33)	1.23 (0.57-2.63)
Adjusted model for malignancy death	0.79 (0.44-1.41)	2.70 (1.11-6.60)

*Reference is children with normal stature

Conclusions: Both extremes of height at ESRD onset were associated with higher risk of all-cause and cause-specific mortality, and short stature was also associated with lower risk of transplantation. Further studies are warranted to determine whether interventions can improve the risk associated with growth failure.

Genital Organ Anomalies in Female Pediatric Patients with End-Stage Renal Disease

Shoichiro Kanda,[1] Naoya Morisada,[2] Yuji Tomii,[1] Keiichi Takizawa,[1] Naoto Kaneko,[1] Tomoo Yabuuchi,[1] Hirotaka Hama,[1] Eiji Nakano,[1] Norimasa Tada,[1] Kiyonobu Ishizuka,[1] Yuko Akioka,[1] Hiroko Chikamoto,[1] Kazumoto Iijima,[2] Motoshi Hattori.[1] *[1]Pediatric Nephrology, Tokyo Women's Medical Univ, Shinjuku-ku, Tokyo, Japan; [2]Pediatrics, Kobe Univ Graduate School of Medicine, Kobe, Hyogo, Japan.*

Background: In the general population, the rate of prevalence of genital organ anomalies in females is 1.3–4.0 per 1000 births. Although female pediatric patients with end-stage renal disease (ESRD) appear to occasionally have genital organ anomalies, the clinical features of them have not been examined.

Methods: We performed a retrospective analysis of female pediatric ESRD patients attending the Department of Pediatric Nephrology, Tokyo Women's Medical University (TWMU) Hospital. The study was in accordance with the ethical guidelines of the Ministry of Health, Labour and Welfare, Japan. The study was also approved by the central ethics board of TWMU and Kobe University.

Results: Eighty-two patients were included in this study. Genital organ anomalies were found in eight (9.7%) patients and consisted of bicornuate uterus in three patients, double uteri with vaginal atresia in two, cicatricial tissue in two, and double uteri in one. Renal phenotypes were congenital anomalies of the kidney and urinary tract in six patients and FSGS in two patients. In seven (87.5%) patients, genital organ anomalies were diagnosed after the start of renal replacement therapy. Two patients complained of acute abdomen associated with their first menstrual period. Genetic and chromosome analyses revealed hypoparatyroidism, deafness, and renal dysplasia syndrome (GATA3, c.1013G>T) in one patient, Turner syndrome in one, Frasier syndrome (46XY, WT1, IVS9+5G>A) in one, and FSGS carrying a mutation of WT1 (c.745C>A) in one.

Conclusions: Our study showed that female pediatric ESRD patients had a frequency of genital organ anomalies of approximately 10%. Additionally, genetic disorders responsible for kidney and genital organ development were detected in four out of eight patients. Therefore, physicians need to be aware of the possibility of genitourinary syndrome and investigate genital organ anomalies in the medical care of female pediatric patients with ESRD.

TH-PO458

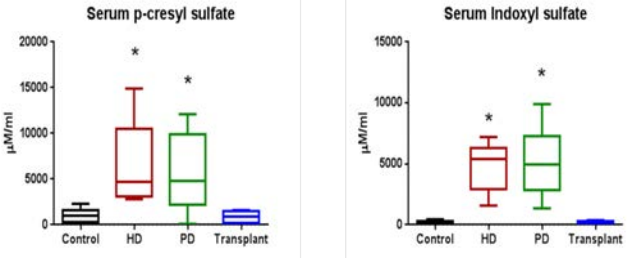
Intestinal Microbiota in Pediatric Patients with End Stage Renal Disease

Janice Crespo-Salgado,[1] Tyrus Stewart,[1] Mike J. Ferris,[1] Mahmoud Kallash,[2] Larry A. Greenbaum,[3] V. Matti Vehaskari,[1] Diego H. Aviles.[1] *[1]Pediatric Nephrology, LSUHSC, New Orleans, LA; [2]Pediatric Nephrology, Women & Children's Hospital of Buffalo, Buffalo, NY; [3]Pediatric Nephrology, Emory Children's Center, Atlanta, GA.*

Background: Cardiovascular mortality is increased in children with end stage renal disease (ESRD). Studies in adult population suggest that uremia increase intestinal permeability and alters the intestinal microbiota. These changes could facilitate the translocation of endotoxin and bacterial metabolites to the systemic circulation leading to inflammation. We hypothesized that children with ESRD have an altered intestinal microbiota that lead to increased bacterially derived uremic toxins, and renal transplantation will reverse those changes.

Methods: Subjects were divided into 4 groups: ESRD on peritoneal dialysis (PD), ESRD on hemodialysis (HD), post kidney transplant and healthy control. PCR and pyrosequencing analysis of 16S rRNA gene was used to assess stool bacterial composition. Serum levels of CRP, D-lactate, p-cresyl sulfate and indoxyl sulfate were detected.

Results: Children with ESRD showed significant decrease in Firmicutes (p=0.006). HD patients showed significant increase in Bacteroidetes (p=0.017) and PD patients showed significant increase in Proteobacteria (p=0.0006). Bacterial diversity was significantly decreased in ESRD and transplant patients. ESRD patients had significantly increased serum levels of p-cresyl sulfate and indoxyl sulfate (p<0.0002).



Conclusions: ESRD in children results in alteration of the intestinal microbiota favoring bacteria able to metabolize and produce more uremic toxins. Renal transplantation does not restore the decreased bacterial diversity, but results in normalization of bacterially derived uremic toxins. These findings may be associated with the increased cardiovascular mortality seen in children with ESRD.

TH-PO459

Cardiorenal Effects of Exposure to Environmental Chemicals in Children

Anglina Kataria,[1] Suzanne M. Vento,[1] Leonardo Trasande,[1] Dov Levine,[1] Debra J. Morrison,[2] Rachel Brody,[2] Kurunthachalam Kannan,[3] Jingchuan Xue,[3] Howard Trachtman.[1] *[1]Pediatrics, NYU Langone Medical Center, New York, NY; [2]Office of Collaborative Sciences, Human Specimen Resource Center, NYU Langone Medical Center, New York, NY; [3]Environmental Health Sciences, School of Public Health, State Univ of New York at Albany, Albany, NY.*

Background: Exposure to short-lived organic chemicals such as bisphenol A and S (BPA/BPS) and phthalates is ubiquitous in the US. Graded exposure to BPA and di-(2-ethylhexyl) phthalate (DEHP), based on urinary excretion, is associated with an increased low-grade albuminuria. Oxidant stress is hypothesized as the mediator underlying these associations. We conducted the following study to assess (1) the mechanism of action of these compounds and (2) the impact of exposure on vascular function in children.

Methods: A cross-sectional study recruiting 10-13 year old children was conducted at Bellevue Medical Center. Demographic information was obtained and height, weight and BP were measured. A first morning and spot urine samples were collected for determination of BPA, BPS, phthalate, 8(OH)-deoxyguanosine, and F2-isprostane excretion (normalized to creatinine excretion). Pulse wave velocity (PWV) was measured non-invasively (SphygmoCor). Multivariate analysis was used to evaluate the relationship between exposures and the laboratory tests.

Results: There were 41 participants, 19 M:22 F, age 12±1 yr. 31 Hispanic, 7 Caucasian, and 3 Other. The mean BMI was 21.7±5.0 and albuminuria 11.4±23.6 mg/g. and 10 (25%) were pre-hypertensive (BP≥90th percentile). The degree of exposure to BPS, total bisphenols, DEHP, and high molecular weight (HMW) phthalates correlated with F2-isoprostane excretion (P<0.05). Multivariate regression also showed each unit of DEHP and HMW phthalate exposure was associated with an increase in PWV of 0.034 m/s (p=0.037) and 0.024 m/s (p=0.041), respectively.

Conclusions: This is the first demonstration of oxidant stress and vascular dysfunction related to environmental chemicals in otherwise healthy children. The link with replacement compounds such as BPS suggests that the consequences of exposure to these chemicals will be a long-term public health problem.

TH-PO460

Safety of Eculizumab in Pediatric Patients with Atypical Hemolytic Uremic Syndrome

Gema Ariceta,[1] Larry A. Greenbaum,[2] Jimmy Wang,[3] John F. Kincaid,[3] Christoph Licht.[4] *[1]Hospital Univ Vall d'Hebron, Barcelona, Spain; [2]Emory Univ, Atlanta, GA; [3]Alexion Pharmaceuticals, Inc, Cheshire, CT; [4]The Hospital for Sick Children, ON, Canada.*

Background: The safety of eculizumab, a terminal complement inhibitor approved for treatment of children and adults with aHUS, was characterized in 4 prospective trials. This post hoc analysis further evaluates its safety in pediatric participants in 3 of the trials.

Methods: Treatment-related adverse events (TRAEs) and serious AEs (SAEs) reported for patients (pts) (<18 y) after 1 year and by end of study (EOS) in studies C08-002, C08-003, and C10-003 were pooled.

Results: Pediatric pts (N=28) received eculizumab for a mean (SD) of 67 (42) weeks. TRAEs occurred in 13 pts (46.4%) after 1 year (**Table**). SAEs are listed in the **Table**. Elevated levels of alanine transaminase and aspartate aminotransferase were noted in some pts before and after receiving eculizumab; levels generally were higher before treatment and normalized over time. By EOS after 433 cumulative months of treatment, there were

no deaths or meningococcal infections; 6 infection-related serious TRAEs occurred in 4 pts: viral upper respiratory tract infection (n=2), influenza, peritonitis (patient was on peritoneal dialysis), respiratory syncytial virus infection, and pyelonephritis (n=1 each).

Conclusions: Eculizumab appears well tolerated in pediatric pts with aHUS. The safety profile of eculizumab in pediatric pts is similar to that in the broader pt population of these studies. Although more infection-related TRAEs were noted, most were mild to moderate in severity, none led to treatment discontinuation, and all pts recovered. Some TRAEs might have been manifestations of underlying aHUS disease.

Medical writing support - Kristen W. Quinn, PhD, of Peloton Advantage, funded by Alexion

Table. Baseline Demographic and Clinical Characteristics and Eculizumab Safety in Pediatric Patients (N=28)

Baseline Demographic and Clinical Characteristics			
Characteristic	Pediatric (<12 y) (n=18)	Adolescent (12–17 y) (n=10)	Total (N=28)
Mean age at baseline, years (SD)	4.3 (3.8)	16.0 (1.5)	8.46 (6.5)
Female, n (%)	9 (50.0)	6 (60.0)	15 (53.6)

Early Renin-Angiotensin System Inhibition in Pediatric Chronic Kidney Disease Patients May Prevent Progression of Renal Failure

Kazuya Matsumura, Midori Awazu. *Dept of Pediatrics, Keio Univ School of Medicine.*

Background: While inhibitors of renin-angiotensin system (RASi) are known to slow CKD progression, the optimal timing of their introduction is not established. Some patients with chronic kidney disease (CKD) have nonprogressive GFR periods (stable or increasing GFR). We compared longitudinal GFR trajectories between patients in whom RASi was initiated during stable periods (early-treated) and those during decline periods (late-treated).

Methods: GFR was estimated by equation for Japanese children and adults. Stable GFR periods were defined as GFR slope = 0 or positive. Fifty-three pediatric CKD patients (stage ^{3}2) were studied (26 males and 27 females, age 3 to 38 years, median 17). Blood pressure (BP) was evaluated as BP index (BP divided by the 95th percentile).

Results: Twenty-seven subjects (11 early-and 16 late-treated) were prescribed with RASi. All of the early-treated subjects showed stable GFR during the follow-up period of 8.5 years (NS vs the late-treated 11.4 years), whereas GFR declined in all the late-treated subjects (P<0.05). Current age and the age at the time of follow up were significantly younger in the early-treated vs the late-treated (12.6 vs 20.6 and 4.1 vs 9.1 years). There was no difference in gender. In the early-treated, 8 of 11 had CAKUT, which was significantly more than the late-treated (4 of 16). The initial GFR tended to be lower in the early-treated than the late-treated (69 vs 92 ml/min/1.73 m^2). There was no difference in BP index (0.88 vs 0.86), but urine protein creatinine ratio was numerically lower in the early-treated (median 0.15 vs 0.27 g/gCr). The reason for the initiation of RASi in the early-treated was hypertension (6), albuminuria (4), or accompanying cardiac disease (3). Of all 53 patients, 26 had stable GFR periods during the course. Ten patients with stable periods were not on RASi because of the absence of hypertension or albuminuria and only one of whom subsequently developed GFR decline, proteinuria, and hypertension requiring RASi.

Conclusions: In pediatric CKD patients, initiation of RASi during periods of stable GFR may prevent CKD progression although the influence of age and underlying disease cannot be ruled out.

TH-PO462

Novel Urinary Biomarkers for Detecting Renal Scar in Children with Febrile Urinary Tract Infection

Takahisa Kimata,[1] Tetsuya Kitao,[1] Sohsaku Yamanouchi,[1] Jiro Kino,[1] Hiroyuki Kurosawa,[2] Yoshiaki Hirayama,[2] Akihiko Saito,[3] Kazunari Kaneko.[1] *[1]Pediatrics, Kansai Medical Univ, Osaka, Japan; [2]Denki Kagaku Kogyo K.K., Tokyo, Japan; [3]Applied Molecular Medicine, Niigata Univ, Niigata, Japan.*

Background: Recurrent febrile urinary tract infections (fUTI) during infancy cause renal scar. Renal scar can be diagnosed through renal scintigraphy while it seems impractical to perform it for all infants with fUTI. Therefore, exploring biomarkers that can identify the patients at high risk of developing renal scar is worthwhile. Urinary excretions of total proteins, beta-2 microglobulins (BMG), and N-acetyl-β-D-glucosaminidase (NAG) have been traditionally used for assessing kidney injury including interstitial damage. In addition, urinary excretions of neutrophil gelatinase-associated lipocalin (NGAL), liver-type fatty acid binding protein (L-FABP), full-length megalin (C-meg) and angiotensinogen (AGT) have recently been reported as sensitive biomarkers for various kidney injuries. This study was undertaken to explore sensitive urinary biomarkers to diagnose renal scar.

Methods: Thirty one infants who underwent renal scintigraphy during the chronic phase after fUTI were enrolled. The following measurements were performed using urine samples; total proteins, BMG, NAG, NGAL, L-FABP, C-meg and AGT. The values were corrected by creatinine and compared between the patients with renal scar (n=20) and these without renal scar (n=10).

Results: Among urinary biomarkers, AGT and C-meg in the group with scar (median value 14.4 mg/gCr and 6.7 pmol/gCr) demonstrated significantly higher levels than those in the group without scar (median value 4.5 mg/gCr and 1.9 pmol/gCr) (P = 0.021 and 0.0046). Among the area under the curves in receiver operating characteristic curve calculated for each urinary biomarker, C-meg yielded the highest value as following: C-meg (0.81)> AGT (0.76) > NAGL (0.60) > protein (0.58) > BMG (0.54) > NAG (0.50) > L-FABP (0.46). When using the point on the curve closest to the (0, 1) point, cut-off in the C-meg (AGT) was 3.06 pmol/gCr (10.4 mg/gCr), the test had 80 % (70 %) sensitivity, 72.7 % (81.8%) specificity.

Conclusions: Urinary C-meg and AGT are useful for renal scar screening.

TH-PO463

Prevalence and Distribution of (Micro)Albuminuria in Toddlers: A Sign of Early Endothelial Dysfunction?

Sophie Van den Belt,[1] Valentina Gracchi,[2] Eva Corpeleijn,[3] Dick de Zeeuw,[1] Hiddo Jan Lambers Heerspink.[1] *[1]Dept Clinical Pharmacy & Pharmacology, UMC Groningen, Netherlands; [2]Dept Paediatric Nephrology, UMC Groningen, Netherlands; [3]Dept Epidemiology, UMC Groningen, Netherlands.*

Background: Microalbuminuria is common in the general population with a prevalence of 7% and is an independent indicator of renal/cardiovascular risk. Whether microalbuminuria is acquired during life (as a result of hypertension/diabetes) or is congenital and already present at birth is unknown. We studied the prevalence of microalbuminuria in toddlers and compared distributions of albuminuria with the general adult population. In addition, we looked for possible associations with antenatal, postnatal and maternal factors explaining albuminuria variations.

Methods: The urinary albumin (U_{AC}) was measured in 1352 children (20-40 months old) from the GECKO Drenthe cohort. Albuminuria distribution was compared with the distribution in 40854 participants of the general adult cohort PREVEND. Difference in prevalence of increased albuminuria (U_{AC}^{3}20 mg/L) was tested with chi-square. Associations between logarithm of U_{AC} and antenatal, postnatal and maternal factors were tested with linear regression analysis.

Results: The median U_{AC} in GECKO was 2.3 mg/L[5-95th percentile: 2.1-25.5] and in PREVEND 6.0 mg/L[2.3-28.6] (P distribution comparison 0.053). Prevalence of U_{AC}^{3}20 mg/L was 6.9% in GECKO and 7.8% in PREVEND(Figure; P=0.195). U_{AC} was lower in boys and not associated with other factors.

Conclusions: The distributions of U_{AC} and the prevalence of microalbuminuria in toddlers and general adult population are comparable. These findings suggest that microalbuminuria is a congenital condition which may predispose those affected at a higher renal/cardiovascular risk later in life.

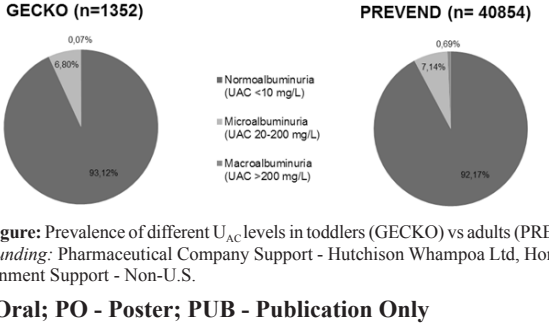

Figure: Prevalence of different U_{AC} levels in toddlers (GECKO) vs adults (PREVEND).

TH-PO464

Validation of a Novel Device to Collect Urine for Albuminuria Assessment in Young Children Sophie Van den Belt,[1] Valentina Gracchi,[2] Dick de Zeeuw,[1] Hiddo Jan Lambers Heerspink.[1] *[1]Dept of Clinical Pharmacy and Pharmacology, UMC Groningen, Netherlands; [2]Dept of Paediatric Nephrology, UMC Groningen, Netherlands.*

Background: Urine collection for albuminuria measurement in babies and toddlers is cumbersome. Taped plastic bags are complicated and may come loose. Old-fashioned cotton wool (pantyliner) or a felt (PeeSpot®) are used as collection devices in a regular disposable diaper. We compared the analytical performance of these two methods.

Methods: The pantyliner and urine collection felt were placed in the diaper; 81 different standard urines with a wide range of albuminuria were applied by hand (in duplicate); incubated for 3 hours at 37°C (simulating the baby), and 72 hours at room temp (simulating transport); extracted by centrifuging. Urinary Albumin Concentration was measured Analytical performance of two methods was tested according National Committee for Clinical Laboratory Standards (NCCLS) guidelines for method comparison, and compared with the standard urine. Performance measures assessed were bias, precision and accuracy.

Results: Median albumin concentration was: standard 66.0 mg/L [IQR 25.0–211.0 mg/L]; pantyliner method 32.0 mg/L [4.7-165.0 mg/L], and PeeSpot method 61.0 mg/L [27.0-216.0 mg/L]. Bias and precision were higher in pantyliner (-34.2% and 32.4 mg/L) than in PeeSpot (3.3% and 5.0 mg/L) and accuracy was lower in pantyliner (48.1%) vs PeeSpot (96.3%). Passing-Bablok regression and Bland-Altman plot showed a systemic underestimation for pantyliner method, but not for PeeSpot method (Figure).

Conclusions: The PeeSpot method is a reliable method for the collection of urine in babies and toddlers albuminuria measurement. This technique should be used in future research into this subject.

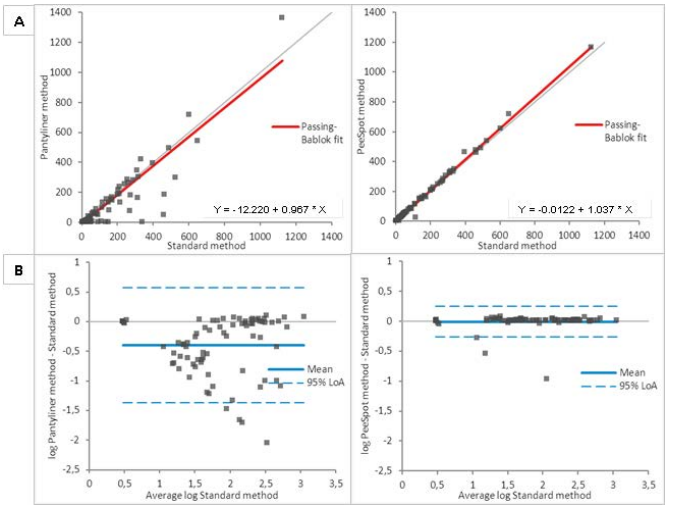

Figure: A; Passing-Bablok regression for pantyliner and PeeSpot. B; Bland-Altman plots for pantyliner and PeeSpot on logarithm of albuminuria. LoA = Limit of Agreement.

A Distinct Urinary Lipid Profile in Patients with FSGS Elif Erkan, Xueheng Zhao, Prasad Devarajan. *Pediatrics, Children's Hospital of Cincinnati.*

Background: Focal segmental glomerulosclerosis (FSGS) accounts for the majority of patients with end-stage renal disease (ESRD) during adolescence. Treatment of FSGS has been a great challenge for pediatric nephrologists due to intertwined molecular pathways underlining its complex pathophysiology. In FSGS patient kidney biopsy sections display increased tubular apoptosis a hallmark for tubular injury. We hypothesize that tubulointerstitial injury caused by the uptake of lipogenic mediators in glomerular filtrate contributes to the progressive nature of FSGS.

Methods: We explored urinary lipid profile of patients with FSGS, minimal change disease (MCD) and healthy controls by High Performance Liquid Chromatography. Normalized data from GC/MS and UPLC/MS analysis including 625 metabolites were thereby used for subsequent statistical analysis. A total of 29 metabolites met the significant threshold of p-value (student two samples t test) less than 0.05 and fold changes between FSGS and MCD urine samples bigger than 2.

Results: We discovered a unique signature characterized by increased concentration of fatty acid (FA) and lysophosphatidylcholines (LPC) and a decrease in urinary concentration of phosphotidylcholine (PC) in patients with FSGS. Patients with FSGS had lower urinary acylcarnitine levels. Patients with FSGS were divided into two groups (four patients in each group) based on their estimated GFR, to normal GFR (105.29 ± 4.11 ml/min/1.73m^2) and low GFR group (69.25 ± 6.49 ml/min/1.73 m^2). Low GFR group had higher urinary FA concentration and lower urinary acylcarnitine concentration ($p<0.05$).

Conclusions: We speculate that these findings indicate increased metabolism of membrane phospholipid PC by phospholipase A2 (PLA2) resulting in higher urinary concentrations of LPC and FA. We propose that decrease in urinary acylcarnitine levels in FSGS implicates an arrest at mitochondrial fatty acid oxidation despite high FA levels. e believe increased by products of PC metabolism further potentiate tubular and podocyte toxicity in FSGS. Validation of urinary lipids as a biomarker in predicting the diagnosis and progression of FSGS in a larger patient population is warranted.

Steroid Dependency in Childhood Steroid-Sensitive Nephrotic Syndrome – Clinical Characterization of a Large Single Center Cohort Anja K. Büscher, Mareen Sadau, Rainer Büscher, Peter F. Hoyer, Stefanie Weber. *Pediatric Nephrology, Univ of Duisburg-Essen, Pediatrics II, Essen, Germany.*

Background: Steroid-sensitive nephrotic syndrome (SSNS) is characterized by preservation of renal function and recurrent disease. Clinical course depends on the number of relapses which is highly variable. A subset of patients presents with relapses during or shortly after steroid therapy (steroid-dependency, SDNS). Mostly, childhood SSNS is of idiopathic origin with minimal change glomerulopathy (MCN) in renal histology. Aim of our study was the characterization of SSNS patients with regard to differences between SDNS and non-SDNS.

Methods: We retrospectively analyzed 100 SSNS patients treated at our hospital. Data collection comprised age at onset, number/trigger of relapses, dose/duration of steroid therapy, time to response, further immunosuppressants, renal function, renal histology, and family history.

Results: 89% of patients experienced relapses (mean 9 (range 0-34)), 55% developed SDNS (after 15 (2-45) months from onset). In 80% of cases trivial infections triggered SSNS relapse. 60% of patients received further immunosuppressants (95% cyclophosphamide, 58% ciclosporinA; sustained disease remission in 24/51%, respectively). Renal biopsy was performed in 70% (93% MCN, SDNS and non-SDNS). SDNS patients were significantly younger at disease onset (4.16ys (SDNS) vs. 5.34ys (non-SDNS), P=0.035; all patients 4.7ys). Mean time to first relapse was significantly shorter in SDNS (6.3months vs. 16.3months non-SDNS; P<0.001; all patients 9.8months). Response to steroids at disease onset was faster in non-SDNS (6.8days vs. 11.7days SDNS; P<0.001). SDNS patients developed secondary steroid resistance in 20% (2% non-SDNS; P<0.01; all patients 12%).

Conclusions: 55% of patients developed SDNS and differed from non-SDNS patients by a younger age at disease onset, a shorter time until first relapse and a slower therapy response. The clinical course in general was influenced by therapy regimen.

Dyslipidemia in Pediatric CKD Patients from KNOW-PedCKD Study Seong heon Kim,[1] Yo Han Ahn,[3] Eujin Park,[3] Kyoung Hee Han,[2] Heeyeon Cho,[4] Joo Hoon Lee,[6] Hee Gyung Kang,[3] Young seo Park,[6] Hae Il Cheong,[3] Curie Ahn,[7] IL-Soo Ha.[3] *[1]Dept of Pediatrics, Pusan National Univ Children's Hospital, Yangsan, Republic of Korea; [2]Dept of Pediatrics, Jeju National Univ School of Medicine, Jeju, Republic of Moldova; [3]Dept of Pediatrics, Seoul National Univ Children's Hospital, Seoul, Republic of Korea; [4]Dept of Pediatrics, Samsung Medical Center, Sungkyunkwan Univ School of Medicine, Seoul, Republic of Korea; [5]Dept of Pediatrics, Yonsei Univ College of Medicine, Severance Children's Hospital, Seoul, Republic of Korea; [6]Dept of Pediatrics, Medical Center, Univ of Ulsan College of Medicine, Seoul, Republic of Korea; [7]Dept of Internal Medicine, Seoul National Univ Hospital, Seoul, Republic of Korea; [8]Dept of Pediatrics, Kyungpook National Univ School of Medicine, Daegu, Republic of Korea.*

Background: Children with chronic kidney disease (CKD) exhibit various co-morbidityes, including dyslipidemia. We investigated the prevalence and characteristics of dyslipidemia in pediatric CKD patients.

Methods: Seven major pediatric nephrology centers of Korea enrolled children younger than 20 years who had CKD. From July 2010 to December 2013, 322 children (M:F 218:104) were enrolled.

Results: Baseline lipid analysis found a high prevalence of dyslpidemia in 49%. Several factors were analyzed including age, gender, CKD stage, primary renal disease, height, weight, BMI, social economic status, hypertension, co-morbidity, z score of height, z score of weight, z score of BMI, gestational age at birth, birth weight, estimated GFR and duration of underlying diseases. Univariate logistic regression analysis demonstrated that several factors including BMI, co-morbidity, Z score of weight and Z score of BMI were associated with dyslipidemia. After multivariate adjustment, social economic status and Z score of BMI were significantly associated with dyslipidemia.

Conclusions: Among children with CKD, dyslipidemia is quite common and is associated with factors such as social economic status and Z score of BMI.

Self-Management/Transition Readiness and Health Services Utilization Among Adolescents/Young Adults with Chronic Conditions in the Pediatric or Adult Settings from Across the USA Maria E. Ferris,[1] Keisha L. Gibson,[1] Hsiao Ling Lai,[2] Susan F. Massengill,[3] John D. Mahan,[4] Randal K. Detwiler,[1] Gerald A. Hladik,[1] Mara Medeiros.[5] *[1]UNC at Chapel Hill, NC; [2]East Carolina Univ, NC; [3]Carolinas Medical Center, NC; [4]The Ohio State Univ, OH; [5]Hospital Infantil de Mexico "Federico Gomez", DF, Mexico.*

Background: The performance in self-management and/or health care transition readiness measurements by adolescents or young adults with chronic conditions (AYA) needs to be correlated to clinical outcomes and health services utilization.

Methods: The 18-question STAR$_x$ Questionnaire is a self-report survey of self-management (adult-focused setting) and/or transition-readiness (pediatric setting) with 6 factors: Medication Management, Provider Communication, Engagement during Appointments, Disease Knowledge, Adult Health Responsibilities, and Resource Utilization. The total raw score ranges from 0-90, with higher scores reflecting more intact skills (Ferris et al., 2015). Data presented is from 321 AYA with chronic health conditions (including chronic kidney disease, transplant, hypertension and lupus), seen in the pediatric- or adult-focused settings at 6 large health systems in the northeast, southeast, and midwest regions of USA, or who attended Victory Junction Camp (from several states in USA). The outcomes/health services utilization measures were adherence (Morisky et al., 1986) and number/length of hospitalizations in the last year.

Results: Higher STARx Questionnaire total score correlated with higher medication adherence ($\beta = .301$, $p = .000$, $R^2 = .070$). Higher STAR$_x$ Medication Management Subscale correlated with higher medication adherence ($\beta = .499$, $p = .000$, $R^2 = .224$). Greater STAR$_x$ Disease Knowledge Subscale correlated with higher medication adherence ($\beta = .216$, $p = .001$, $R^2 = .044$), fewer number of hospitalizations ($\beta = -.453$, $p = .000$, $R^2 = .262$) and inpatient days in the past year ($\beta = -.432$, $p = .000$, $R^2 = .187$).

Conclusions: The strong reliability of the STAR$_x$ Questionnaire in AYA with a variety of conditions treated in either the pediatric or adult-focused clinics, correlates with health outcomes and health services utilization.

TH-PO469

Emotional-Behavioral Functioning of Children Enrolled in the Chronic Kidney Disease in Children (CKiD) Cohort Study Rebecca J. Johnson,[1,2] Matthew Matheson,[2] Arlene C. Gerson,[2] Susan R. Mendley,[2] S. Shinnar,[2] Marc Lande,[2] Amy Kogon,[2] Lyndsay Harshman,[2] Debbie S. Gipson,[2] Bradley Warady,[1,2] Susan L. Furth,[2] Stephen R. Hooper.[2] *[1]Children's Mercy; [2]Chronic Kidney Disease in Children (CKiD) Study Group.*

Background: CKiD is a longitudinal study examining medical, neurocognitive, and psychosocial outcomes for children with mild to moderate CKD ages 1-16 years at study entry. Little is known about how CKD affects emotional-behavioral functioning (EBF), although data from the CKiD study indicate that these children are at increased risk of attention and executive functioning deficits. In one of the largest studies to date, we report EBF of participants at baseline and over time.

Methods: Parents of participants completed the Behavior Assessment System for Children (BASC-2) at baseline and every 2 years. 835 participants had BASC-2 data, including 797 at baseline. Linear mixed models predicted participants' scores on BASC-2 summary measures (Internalizing, Externalizing, Behavioral Symptoms Index, Adaptive Skills) and selected clinical scales (Depression, Attention Problems). Analyses controlled for key demographic (age, sex, ethnicity, maternal education, household income, Full Scale IQ) and medical (GFR, hypertension [HTN], low birth weight, anemia, seizures, proteinuria, glomerular diagnosis, time since CKD onset) covariates.

Results: Children with mild to moderate CKD have EBF scores generally within normal limits at baseline and over time. At baseline, the proportion with scores at least 1 SD above the mean was 24% for internalizing problems and 27% for attention problems, higher than would be expected in a typical sample. In an adjusted linear mixed model, persistent hypertension was related to attention problems ($\beta = 1.81$, 95% CI = 0.40-3.21, $p<.02$).

Conclusions: Children with mild to moderate CKD have parent-reported EBF that is within normal limits, at baseline and over time. However, the proportion with scores more than one SD above the mean is higher than would be expected, suggesting that this population may be at slightly increased risk for internalizing symptoms and attention problems, particularly in the context of HTN, which was associated with increased risk of parent-reported attention problems.

Funding: NIDDK Support, Other NIH Support - National Institute of Neurological Disorders and Stroke (NINDS), National Institute of Child Health and Human Development (NICHD), and the National Heart, Lung, and Blood Institute (NHLBI)

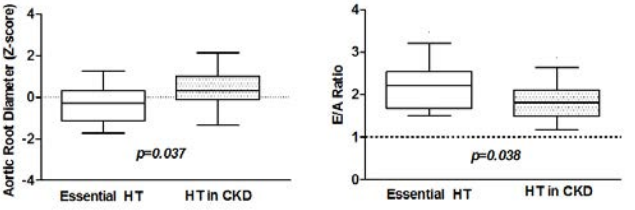
TH-PO470

Echocardiographic Findings in Hypertensive Children with Kidney Disease or Essential Hypertension Gabriel Paris,[1] Wacharee Seeherunvong,[2] Aura Jeannette Arenas morales,[2] Marissa J. Defreitas,[2] Carolyn L. Abitbol,[2] Michael Freundlich,[2] Sethuraman Swaminathan,[1] Gaston E. Zilleruelo.[2] *[1]Pediatric Cardiology, Univ of Miami; [2]Pediatric Nephrology, Univ of Miami, Miami, FL.*

Background: Hypertension (HT) is a major risk factor causing left ventricular hypertrophy (LVH) and diastolic dysfunction. In children with chronic kidney disease (CKD), the cardiovascular morbidity exceeds that of peers without CKD.

Methods: Children with diagnosis of HT underwent echocardiography with concurrent tests of kidney disease were included. LV mass, systolic and diastolic function were reviewed. Diastolic transmitral early (E), late (A), septal E', lateral-mitral E' velocities measured. Calculated E/A<1 and/or E/E' Z-score(Z) >2 defined diastolic dysfunction.

Results: 52 HT children (11±5yr), 29 had CKD (CKD-HT) and 23 essential HT (eHT). No differences in age, gender, body mass index (BMI), %obesity, degree HT between groups. Prevalence LVH (25% & 30%) and LVMI-Z were similar. LVMI-Z was strongly correlated with BMI-Z in both groups (each $r +0.6, p<0.01$) and to a lesser degree with SBP-Z ($r +0.3, p 0.05$). No correlation of LVMI-Z with GFR. Diastolic dysfunction was identified in both eHT and CKD-HT (24% vs. 25%) whereas systolic function was preserved in both groups. Changes of E/A and aortic root diameter were subtle but significantly different between eHT and CKD-HT (see figure). Additionally, a significant decline in E/A (p 0.01) and Septal E/E'-Z (p 0.03) was observed with worsening GFR.



Conclusions: High prevalence of LVH and diastolic dysfunction noted in HT children with or without CKD. Severity of LVH associated with obesity and to a lesser extent to high BP. HT children with CKD had subtle but significantly lower E/A ratio and larger aortic root diameter which could be related to poor renal function.

TH-PO471

Glomerular Capillary Injuries in Thin Basement Membrane Disease Yusuke Kajimoto, Michiko Aoki, Go Kanzaki, Kiyotaka Nagahama, Akira Shimizu. *Analytic Human Pathology, Nippon Medical School, Tokyo, Japan.*

Background: Thin basement membrane disease (TBMD) is diagnosed by diffuse reduction of the thickness of glomerular basement membrane (GBM) in electron microscopy (EM), and characterized clinically by benign familial hematuria. However, some cases progress to end-stage renal disease. In the present study, we performed the clinico-pathological analyses of TBMD, especially focusing on glomerular capillary injuries, including morphological and qualitative alterations of GBM and glomerular capillaries, and correlated with clinical findings.

Methods: In our department, 27 renal biopsy cases of TBMD (1.9%) was identified. We investigated clinical characteristics using clinical records. We also examined pathological characteristics using light and EM, immunostaining for CD34, which can detect glomerular capillaries, immunostaining for α5 (IV) chains of type IV collagen, which is one of the main component of GBM, and low-vacuum scanning electron microscopy (LV-SEM), which allows detailedthree-dimensional observation of GBM surface.

Results: The average age was 37.3±19.5 (5-64) years. 26 cases had hematuria and 21 cases had proteinuria. 17 cases (63.0%) indicated hematuria or proteinuria under 20 years of age. In 6 cases, the eGFR declined in G3a to G4 in clinical CKD stage. In immunofluorescence, α5 (IV) expression was significantly reduced in the GBM with partial enhancement of a2 (IV). In LV-SEM observations, thinning and flattering of GBM was noted with multiple small holes and manufactures in the surface of GBM. In CD34 and PAS staining, narrowed glomerular capillaries increased with accumulation of glomerular extracellular matrix (ECM), associated with glomerular endothelial cell injuries.

Conclusions: In TBMD, narrowing glomerular capillaries developed with increased glomerular ECM, in association with glomerular endothelial injuries. In addition, qualitative (reduced α5 (IV) expression) and ultrastructural alterations of GBM (small holes and manufactures) were noted. These glomerular capillary injuries might be associated with the clinical findings including urinary abnormalities and renal dysfunction.

TH-PO472

Clinical Significance of IgM Disposition in Kidney Biopsy of Paediatric Minimal Change Disease, Single-Centre Case-Control Study Duaa Alromaili, Turki Abdullah Alshareef. *Pediatrics, King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia.*

Background: In many cases of Minimal change nephrotic syndrome, or Minimal change disease (MCD), immunoglobulin M (IgM) is occasionally deposited in the mesangium, and can be seen under the electron microscopy (EM) and immunofluorescence (IF). Based on many studies, the rule of IgM is controversial in minimal change disease MCD which is one of the histopathological types of INS The aim of this study is to explore the clinical significance of mesangial IgM deposits in paediatric MCD cases.

Methods: We reviewed a sample of 313 cases children with MCD who underwent a native kidney biopsy (NKB) at King Faisal Specialist Hospital and Research Centre in Riyadh, Saudi Arabia from 2003 to 2014. The sample is divided furtherly according to the presence of IgM deposits under EM and IF to IgM +IF and IgM-IF, which are labeled as case- control groups respectively. We reviewed the clinical course as per the response to the steroid treatment. Initial adjuvant therapies included: Cyclosporine, Tacrolimus and Cyclophosphamide.

Results: MCD IgM+IF has shown a significant association with the presence of hypertension at the time of diagnosis, where a p-value of 0.03. MCD IgM+IF showed

statistical significance in association of steroid dependence where p-value of 0.04 in the MCD IgM+IF steroid dependence group and p- value of 0.05 in the MCD IgM+IF steroid resistance cases. Chronic kidney disease is not associated statistically with the presence of IgM. In term of treatments, cyclosporine (CSA) has shown a significant association in the development of remission of the MCD IgM+IF with a p value of 0.04 for the subtype.

Conclusions: Our results indicate that IgM+IF may be a marker of the initial disease severity of MCD as it correlates with the outcome of steroid response. Cyclosporine shows a better outcome in achieving the remission in MCD IgM+IF. A prospective study is required to support our conclusion.

TH-PO473

Correlation Between Age-Dependent Expression of Oxidant Handling Genes and Sensitivity to Nicotine Exposure in the Mouse Kidney

Istvan Arany, Samuel Hall, Mehul P. Dixit. *Pediatrics, Univ of Mississippi Medical Center, Jackson, MS.*

Background: Studies have shown that childhood exposure to secondhand smoke may increase adulthood renal risk. Other studies also suggest that children may be more vulnerable to secondhand smoke exposure than adults, which may imply augmented sensitivity to renal oxidative stress. Accordingly, we tested the status of oxidant handling genes and extent of oxidative stress in the kidneys of adolescent mice exposed to active or passive smoking-equivalent nicotine and compared to the kidneys of adult mice.

Methods: 4– and 24-week-old male C57BL/6J mice -that are equivalent to early adolescence and early adulthood, respectively- had ad libitum access to NIC in their drinking water (200 or 5 μg/ml) for 4 weeks that results in either active (>150 μg/ml) or passive (<10 μg/ml) smoking-equivalent cotinine (stable metabolite of NIC) levels in their plasma. Renal oxidative stress (4HNE content), injury (KIM-1 expression) and function (plasma creatinine) were determined. Expression of select pro- and antioxidant genes were determined by Western blotting and microarray.

Results: Active smoking-equivalent NIC exposure resulted in 2.5 fold increase in renal 4HNE content in adolescent mice compared to vehicle, which is significantly higher ($p<0.05$) than in adult mice (1.7 fold). Similarly, renal KIM-1 expression increased 2.2 vs 1.5 fold ($p<0.05$), respectively, while renal function was unchanged. In contrast, passive smoking-equivalent NIC exposure increased renal 4HNE content only in young (1.4x) but not in adult mice. Interestingly, baseline expression of select pro-oxidant genes (p66shc) was higher, while expression of some anti-oxidant genes (Nrf2, MnSOD) was lower in the young kidney compared to the adult kidney. In vitro experiments confirmed that high level of p66shc or low level of Nrf2 or MnSOD exacerbates NIC-mediated ROS production and consequent mitochondrial depolarization-dependent injury in renal proximal tubule cells.

Conclusions: Our results imply that the young kidney exhibits a more pro-oxidant environment than the adult kidney, which may explain their higher sensitivity to chronic NIC exposure-dependent oxidative stress.

TH-PO474

Maternal Nutrient Restriction Aggravates Renal Tubular Necrosis and Interstitial Fibrosis After Unilateral Ureteral Obstruction in Rat Offspring

Mariko Hida,[1] Tokiya Abe,[2] Akinori Hashiguchi,[2] Midori Awazu.[1] *[1]Dept of Pediatrics, Keio Univ School of Medicine, Tokyo, Japan; [2]Dept of Pathology, Keio Univ School of Medicine, Tokyo, Japan.*

Background: Maternal nutrient restriction not only reduces nephron number but may also affect tubules, interstitium, capillary density, endothelial function, and response to oxidant injury. These changes may become apparent only after a secondary injury to the kidney. We examined the response to unilateral ureteral obstruction (UUO) in the kidney of offspring from control and nutrient restricted rats.

Methods: Six-week old offspring from rats given food ad libitum (CON, n=3) and those subjected to 50% food restriction throughout pregnancy (NR, n=6) were subjected to left ureteral obstruction. After 7 days, blood pressure, serum creatinine, urea nitrogen, and urine from the left kidney were examined. Kidneys were stained with Masson trichrome, elastica van Gieson, or CD31. Collagen was quantified by analyzing the color distribution of whole-slide-images after color classification of the pixels. The expression of nitrotyrosine was assessed by immunoblot of kidney lysate.

Results: There was no difference between CON and NR in body weight, blood pressure, serum creatinine, and urine protein or osmolality. Blood urea nitrogen was significantly higher in NR than CON (20.8±0.8 vs 17.5±0.1 mg/dL, $P<0.05$). Macroscopically, pelvic dilation of similar degree was noted in the obstructed kidney of CON and NR. Tubular necrosis, however, was more extensively observed in NR. There was no difference in the collagen area ratio of the contralateral kidney between CON and NR. The collagen area ratio of the obstructed kidney was increased compared with the contralateral kidney, and the increase was significantly greater in NR compared with CON (6.8±3.8% vs 2.6±0.5%, $P<0.05$). There was no difference in immunohisotochemical expression of endothelial marker CD31 between CON and NR. The expression of nitrotyrosine, a marker of oxidative stress, was increased in the obstructed kidney in both CON and NR, and the extent was greater in NR.

Conclusions: NR kidneys are more susceptible to ischemia and fibrosis secondary to UUO, which may be due to increased oxidative stress.

Post-Weaning High-Fat Diet Accelerates Kidney Injury, but Not Hypertension Programmed by Maternal Diabetes

Min-Chun Liao,[1] Yessoufou Aliou,[1] Xin-Ping Zhao,[1] Shiao-Ying Chang,[1] Isabelle Chenier,[1] Julie R. Ingelfinger,[2] Shao-Ling Zhang.[1] *[1]CRCHUM, Univ of Montreal, Montreal, QC, Canada; [2]Pediatric Nephrology Unit, Massachusetts General Hospital, Boston, MA.*

Background: Severe maternal diabetes results in offspring with intrauterine growth restriction (IUGR) phenotype. The long-term outcome of these affected IUGR diabetic offspring who experience overnutrition in early life is incompletely delineated. In the current study, we aimed to establish the underlying mechanisms by which a post-weaning high-fat diet (HFD) accelerates the perinatal programming of kidney injury occurring in the offspring of diabetic mothers.

Methods: Male offspring of non-diabetic and diabetic C57/BL6 dams were fed with standard chow (normal diet, ND) or HFD from 4 to 20 week-old. Biological parameters, renal morphology, and gene expression were assessed. Rat immortalized renal proximal tubular cells (IRPTCs) were used for *in vitro* studies.

Results: As compared to offspring from non-diabetic dams, on ND, the offspring of dams with severe maternal diabetes had IUGR phenotype and developed mild hypertension and evidence of kidney injury in adulthood. Exposing the IUGR offspring to HFD resulted in rapid weight gain, catch-up growth and later, to profound kidney injury with glomerulosclerosis and tubular apoptosis. In adulthood these IUGR animals demonstrated activation of renal TGFb1 and collagen type IV expression, increased oxidative stress and enhanced renal lipid deposition, but not systemic hypertension. HFD or free fatty acid (FFA) in the diet appear to accelerate the process of perinatal programming of kidney injury, associated with increased CD36 and fatty acid binding protein 4 (Fabp4) expression in proximal tubular cells, which may target reactive oxygen species (ROS), NF-κB and TGFb1 signaling.

Conclusions: Early postnatal exposure to overnutrition with a HFD appears to increase the risk of development of kidney injury, but not hypertension, in IUGR offspring of dams with maternal diabetes.

Does Anemia Contribute to Growth Delay in Pediatric CKD? Implications from Adenine Mouse Model of CKD-Related Growth Failure

Oleh M. Akchurin,[1] Adele L. Boskey,[2] Stefano Rivella.[3] *[1]Weill Cornell Medical College; [2]Hospital for Special Surgery; [3]Children's Hospital of Philadelphia.*

Background: Growth delay remains common in children with CKD and it worsens their quality of life. The origin of CKD-related growth failure in children is thought to be muti-factorial but the contribution of anemia remains controversial based on the data from the major clinical studies. Experimental investigations of the role of anemia and iron homeostasis in growth and nutrition in juvenile CKD are lacking.
