Methods: C57Bl6 mice and hepcidin gene (HAMP) knock-out (KO) pups were started on 0.2% adenine diet at weaning (3 weeks) and sacrificed in 8 weeks. Litter-mate controls were fed a regular diet. Weekly measurements of nose to tip of tail length were used for tracking linear growth.

Results: Adenine fed juvenile mice had statistically significant elevation of BUN, serum creatinine and phosphorus at sacrifice. Adenine fed mice had slower rate of weight gain compared with controls and by 3 weeks they stopped gaining and / or started to loose weight. Linear growth was also significantly slower in adenine fed mice. At sacrifice, adenine fed mice had approximately 40% deficit in body weight and 10-15% deficit in body length, as compared with controls (both differences were statistically significant). Bone histology revealed marrow adiposity in adenine fed mice. While wild type adenine fed mice developed anemia, hemoglobin and hematocrit levels remained unchanged in HAMP-KO mice throughout the experiment. However, no differences in linear growth or serum creatinine were observed between wild-type and HAMP-KO adenine-fed mice.

Conclusions: In this study we demonstrated that 0.2% adenine diet reliably induces CKD-related growth failure and anemia in juvenile mice, resembling those seen in children with CKD. Knocking out HAMP rescues the anemia phenotype but does not affect linear growth and renal function decline, thus providing new insights into the interplay between anemia and other CKD complications in children. Our ongoing experiments are directed towards further characterization of the mineral metabolism and erythropoiesis in this model and testing novel therapies that can improve growth in juvenile CKD.

Establishment of Urinary Tract Infections in the Absence of Umbrella Cells and Uroplakin Plaque

Ashley R. Jackson,[1] Birong Li,[2] Kirk M. McHugh,[3] Brian Becknell.[4] *[1]Biomedical Sciences Graduate Program, Ohio State Univ; [2]Center for Clinical and Translational Research, Nationwide Children's Hospital; [3]Div of Anatomy, Ohio State Univ; [4]Nephrology Section, Nationwide Children's Hospital.*

Background: Uropathogenic *Escherichia coli* (UPEC) accounts for 90% of human urinary tract infections (UTI). Urothelial umbrella cells elaborate uroplakin plaques that establish a permeability barrier to urine and pathogens. UPEC attach to Upk1a within uroplakin plaques, invade umbrella cells, and establish intracellular bacterial communities. We genetically ablated plaques and umbrella cells to test their role in UPEC invasion and establishment of experimental UTI.

Methods: Six week old *Upk1b*$^{RFP/RFP}$ and wild type mice were intravesically inoculated with 10^8 cfu UPEC strain UTI89. Upk1a was localized by immunohistochemistry. Bacterial burden and histopathology were analyzed at baseline, 1 and 7 days post infection (dpi). Urothelial permeability was evaluated at baseline using 10,000 dalton FITC-Dextran.

Results: Deletion of Upk1b led to absent urothelial plaques and umbrella cells, as well as reduced expression and apical concentration of Upk1a protein. UPEC established intracellular bacterial communities in wild type but not *Upk1b*$^{RFP/RFP}$ urothelium 1 dpi. *Upk1b*$^{RFP/RFP}$ bladders demonstrated reduced urothelial neutrophil infiltrates 1 dpi. Whereas bacterial recovery from urine, bladder, ureters and kidneys was significantly reduced in *Upk1b*$^{RFP/RFP}$ versus wild type 1 dpi ($p<0.05$, Mann-Whitney), comparable burden was observed 7 dpi. *Upk1b*$^{RFP/RFP}$ but not wild type bladder urothelium was permeable to FITC-dextran.

Conclusions: Upk1b serves an essential role in plaque assembly and terminal differentiation of umbrella cells. Whereas umbrella cells and uroplakin plaques facilitate initial UPEC colonization of the bladder, these structures are dispensable for maintenance of infection. Comparable UPEC recovery from *Upk1b*$^{RFP/RFP}$ urinary tracts 7 dpi supports the existence of alternative UPEC reservoirs, potentially as a consequence of a disrupted urine permeability barrier. Thus, genetic ablation of umbrella cells provides the opportunity to define alternative pathways for UTI pathogenesis.

3D Modeling of the Urinary Tract to Better Understand Urothelial Development and Pathogenesis Leah D. Hunter,[1,2] Claudia F. Mosley,[1,2] Ashley R. Jackson,[2,3] Kirk M. McHugh.[1,2] *[1]Div of Anatomy, Ohio State Univ; [2]Center for Human and Molecular Genetics, Nationwide Children's Hospital; [3]Biomedical Sciences Graduate Program, Ohio State Univ.*

Background: Recent evidence implicates a role for urothelium in the pathogenesis of chronic kidney disease (CKD). To better understand these processes, we plan to three-dimensionally (3D) reconstruct and electronically annotate the expression of urothelial markers during development.

Methods: Embryonic day (E)13.5 (undifferentiated), E14.5 (urothelial differentiation onset) FVB/N mice were 3D reconstructed electronically from 10mm serial sections labeled with urothelial antibodies. Molecular annotations were electronically generated using Stereo Investigator software and quantitated using Neurolucida Explorer.

Results: E13.5 urothelium displayed highly undifferentiated characteristics, lacking keratin (Krt) and uroplakin expression, while E14.5 exhibited significant urothelial identity expressing a wide range of markers. Bladder basal urothelial cells express sporadic Krt5, Krt14 and Ki67. Unexpectedly, Krt5 also localized to intermediate and select superficial cells at E14.5. Shh and p63 uniformly localized to basal and most intermediate urothelial cells. Shh and Ki67 localized to some superficial urothelial cells. Intermediate and superficial bladder urothelial cells expressed uroplakins. Interestingly, uroplakin expression was more prominent in the dorsal urinary tract, while Shh exhibited more ventral patterning, and Krt14 commonly localized to anterior portions of the caudal bladder urothelium. Krt20 was only minimally expressed at E14.5. Overall, E14.5 bladder urothelial cells expressed 13% Krt14, 57% uroplakin, 1% Krt20, 79% p63, 66% Shh, 21% Ki-67, and 34% Krt13, when normalized to E-cadherin.

Conclusions: Molecular annotation and 3D modeling of the entire embryonic urinary tract will provide novel insight into the expression pattern of urothelial-specific proteins temporally and spatially. Future studies will include 3D mapping of these tissues and markers throughout development and disease states. Our work will serve as a vital resource for developing diagnostic and therapeutic measures for CKD.

Cardiac Hypertrophy Causes Elevation in Circulating c-FGF23 Levels in Mice Isao Matsui,[1] Akihiro Shimomura,[2] Yasuo Kusunoki,[1] Daisuke Mori,[1] Sayoko Yonemoto,[2] Masamitsu Senda,[2] Yusuke Sakaguchi,[1] Takayuki Hamano,[2] Yoshitaka Isaka,[1] Hiromi Rakugi.[1] *[1]Geriatric Medicine and Nephrology, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan; [2]Comprehensive Kidney Disease Research, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan.*

Background: Fibroblast growth factor 23 (FGF23) is a bone-derived hormone that regulates phosphate homeostasis. Besides its phosphaturic effect, intact FGF23 induces left ventricular hypertrophy (LVH). However, it remains unclear whether ventricular hypertrophy affects circulating levels of FGF23.

Methods: The activation of the calcineurin/NFAT (nuclear factor of activated T-cells) pathway plays pivotal roles in the pathogenesis of LVH. Using cardiomyocyte-specific calcineurin A transgenic (CnA-TG) mice, we assessed whether ventricular hypertrophy affects circulating levels of FGF23.

Results: CnA-TG mice at age 6 weeks developed ventricular hypertrophy. Heart weight/body weight ratio was 0.0111 ± 0.0014 in CnA-TG mice and 0.0043 ± 0.0003 in wild type (WT) mice. Real time PCR analyses demonstrated that cardiac tissues of CnA-TG mice had higher levels of atrial natriuretic peptide, brain natriuretic peptide, and β myosin heavy chain. Serum C-terminal FGF23 levels of CnA-TG mice was significantly higher than those of WT mice (214.7 ± 68.7 vs. 137.2 ± 19.8 pg/mL, P=0.032), whereas the levels of intact FGF23 were not different between the two groups (CnA-TG mice 27.6 ± 14.4 pg/mL vs. WT mice 24.7± 6.1 pg/mL, P=0.943). All parameters — body weight, food intake, water intake, urine volume, creatinine clearance, serum phosphate/calcium levels, urinary phosphate/calcium excretion, and fractional excretion of phosphate/calcium — were not different between the two groups. Although iron deficiency has been reported to be associated with high circulating c-FGF23, but not i-FGF23 levels, CnA-TG mice had higher transferrin saturation than WT mice (91.5 ± 6.3 vs. 71.7 ± 15.5%, P<0.001).

Conclusions: Cardiac hypertrophy causes elevation in circulating c-FGF23 levels through yet-unknown mechanisms.

Soluble Klotho and Cardiac FGF23 Modulate Left Ventricular Hypertrophy in CKD Patients Maren Leifheit-Nestler,[1] Christian Faul,[2] Dieter Haffner.[1] *[1]Dept of Pediatric Kidney, Liver and Metabolic Diseases, Hannover Medical School, Hannover, Germany; [2]Div of Nephrology and Hypertension, Dept of Medicine, Univ of Miami Miller School of Medicine, Miami, FL.*

Background: Elevated levels of circulating fibroblast growth factor 23 (FGF23) are strongly associated with chronic kidney disease (CKD) mortality, and left ventricular hypertrophy (LVH), a major cause of cardiovascular death in CKD patients. Existence and role of a paracrine cardiac FGF23/Klotho system in the heart, however, remain elusive.

Methods: We conducted a retrospective case-control study in 25 deceased patients with end-stage renal disease, and 25 age and sex-matched healthy controls. At the time of death 18 patients were on dialysis treatment, and 7 patients were transplanted. Myocardial autopsy samples of the left ventricle (LV) were evaluated for endogenous FGF23 expression, FGFR 1-4, Klotho, calcineurin-NFAT signaling mediated LVH, and genes regulating pathological cardiac remodeling by immunohistochemistry and quantitative real-time PCR analysis. The expression of brain natriuretic peptide (*BNP*) served as a marker of LVH.

Results: Here, we find that FGF23 is expressed in human cardiomyocytes, and that myocardial expression of FGF23 in concert with Klotho deficiency strongly correlates with the presence of LVH in CKD patients. Enhanced cardiac *FGF23* expression is associated with chronic phosphate load, up-regulation of *FGFR4* expression, and activation of calcineurin-NFAT signaling, an established inducer of cardiac remodeling and LVH. Most important, these changes are reversed after renal transplantation. Using *in vitro* studies, we observe that cardiomyocytes express and release full-length biologically active FGF23, and that enhanced FGF23 secretion results in cardiomyocyte hypertrophy, which is blocked in the presence of soluble Klotho.

Conclusions: Our results indicate that enhanced levels of FGF23 induce LVH via a paracrine mechanism in settings of Klotho deficiency. In CKD patients, this process is reversed after renal transplantation.

TH-PO481

Role of FGF23 Mediating LVH in a Mouse Model of Klotho Deficiency Maren Leifheit-Nestler,[1] Melis Basaran,[1] Makoto Kuro-o,[2] Ioana Alesutan,[3] Jakob Völkl,[3] Florian C. Lang,[3] Dieter Haffner.[1] *[1]Dept of Pediatric Kidney, Liver and Metabolic Diseases, Hannover Medical School, Hannover, Germany; [2]Center for Molecular Medicine, Jichi Medical Univ, Shimotsuke, Japan; [3]Dept of Physiology, Univ of Tuebingen, Tuebingen, Germany.*

Background: In patients with chronic kidney disease (CKD), high serum concentrations of the phosphaturic hormone fibroblast growth factor 23 (FGF23) result in high mortality rate and left ventricular hypertrophy (LVH). FGF23 signals via FGF receptors (FGFR) in the presence of its cofactor Klotho. Recent studies reveal a Klotho independent pathway of FGF23 in cardiomyocytes to promote cardiac remodeling and LVH. However, Klotho seems to be cardioprotective. The aim of our study was to investigate the role of cardiac FGF23/FGFR signaling in the activation of pathologic cardiac remodeling and LVH in the Klotho knockout (*kl/kl*) mouse.

Methods: Hearts of 8 weeks old *kl/kl* mice and wild-type (WT) mice were excised and weighted. The left ventricle was isolated and stained with wheat germ agglutinin (WGA) to quantify cross-sectional area of individual cardiomyocytes. Furthermore, cardiac tissue was homogenized and analyzed by quantitative real-time PCR for genes involved in pathological cardiac remodeling, and protein lysates were used to determine FGF23-mediated activation of calcineurin-NFAT pathway mediating LVH.

Results: Relative heart weight of *kl/kl* mice was significantly higher compared with WT, and cardiomyocyte cross-sectional area was increased in *kl/kl* mice indicating LVH. Cardiac Fgf23 gene and protein levels were induced significantly in *kl/kl* mice compared with WT. Interestingly, expression of *Fgfr1*, the physiological receptor for FGF23/Klotho signaling, was unaffected in *kl/kl* mice, but *Fgfr-4* was up-regulated significantly. The calcineurin-NFAT protein complex was activated in *kl/kl* mice inducing genes involved in pathological cardiac remodeling and the development of LVH.

Conclusions: Our data suggest that high levels of circulating and cardiac FGF23 contribute to cardiac remodeling and LVH in Klotho deficient mice indicating a direct impact of FGF23 signaling via FGFR4 on cardiovascular disease beyond CKD.

TH-PO482

Cardiac FGF23 in Concert with Klotho Deficiency Affect Myocardial Fibrosis in Dialysis Patients Maren Leifheit-Nestler, Felix Kirchhoff, Dieter Haffner. *Dept of Pediatric Kidney, Liver and Metabolic Diseases, Hannover Medical School, Hannover, Germany.*

Background: Pathologic cardiac remodeling, i.e. left ventricular hypertrophy (LVH) and myocardial fibrosis, is a major cause of cardiovascular (CV) death in patients with chronic kidney disease (CKD). Increased circulating levels of fibroblast growth factor 23 (FGF23) are associated with increased mortality in CKD coinciding with enhanced CV

disease risk factors and LVH. The impact of cardiac FGF23 on myocardial fibrosis in CKD is not known. Here we investigate the association of cardiac FGF23 and its coreceptor Klotho with myocardial fibrosis in autopsy samples of CKD patients on dialysis.

Methods: Myocardial autopsy samples of the left ventricle of 18 deceased CKD patients on dialysis treatment, and age and sex-matched controls were evaluated with human fibrosis *RT² Profiler™ PCR Arrays* including genes responsible for fibrotic remodeling. For histological investigation of cardiac fibrosis, samples were stained with picosirius red and quantified by brightfield and polarized light microscopy. Cardiac FGF23 and soluble Klotho in cardiac tissue were assessed by qPCR and immunohistochemistry, respectively.

Results: The degree of cardiac fibrosis was increased in dialysis patients compared with controls, and correlated positively with duration of ESRD, and dialysis treatment. The expression of cardiac *FGF23* was enhanced in the dialysis group, and associated with fibrosis. The amount of circulating Klotho was reduced in myocardial tissue of our patient cohort, and correlated negatively with cardiac fibrosis. Human fibrosis gene array analyses identified 31 genes regulated significantly in dialysis patients. The TGFβ pathway, with *TGFb1*, *TGFbRs* and *SMAD3*, was up-regulated in patients on dialysis treatment, and *TGFb1* correlated negatively with circulating Klotho. *BMP7* and *SMAD7*, which attenuate fibrotic activity, were down-regulated in our patient cohort. In contrast, the pro-fibrotic target genes *CTGF* and collagen I and III were up-regulated.

Conclusions: Enhanced cardiac *FGF23* expression in concert with Klotho deficiency is strongly associated with fibrotic cardiac remodeling processes in heart tissue of CKD patients on dialysis treatment.

FGF23-Induced LVH Is Reversible in Rodents Ansel P. Amaral,[1,2] Alexander Grabner,[1] Saurav Singh,[1] Karla J. Schramm,[1] Christopher Yanucil,[1] Alexis J. Sloan,[1] Christian Faul.[1] *[1]Medicine, Univ of Miami Miller School of Medicine, Miami, FL; [2]Medicine, Northwestern Univ Feinberg School of Medicine, Chicago, IL.*

Background: Left ventricular hypertrophy (LVH) contributes cardiovascular disease in chronic kidney disease (CKD). Serum levels of fibroblast growth factor (FGF) 23 rise as patients progress to renal failure. We have previously shown that FGF23 can activate FGF receptor (FGFR) 4 and calcineurin/NFAT signaling in cardiac myocytes and induces LVH in rodents. Administration of a pan-FGFR inhibitor in the 5/6 nephrectomy model of CKD immediately after surgery protects rats from developing LVH. Furthermore, LVH in rats 2 weeks after surgery is reversible by pan-FGFR inhibition.

Methods: To further study FGFR4-dependency and reversibility of FGF23-mediated LVH, we elevated serum FGF23 in FGFR4 knockout (-/-) mice and wild type littermates by administration of a high phosphate (2%) diet for 3 months. Furthermore, a group of wild type mice that received a high phosphate diet for 3 months was returned to normal chow for 3 months. LVH was assessed by histology and analysis of cross sectional area of individual myocytes. Serum levels of cleaved FGF23 were determined by ELISA and kidney function by BUN.

Results: Serum levels of phosphate and FGF23 were elevated in mice on high phosphate diet when compared to mice on normal chow. However, only wild type but not FGFR4-/- mice developed LVH after 3 months as evident by significantly increased LV wall thickness and cross sectional myocyte area. When wild type mice were switched from high phosphate to normal chow, the LVH phenotype resolved within 3 months and cardiac parameters were comparable to those of mice that constantly received a normal diet.

Conclusions: FGFR4 is required for the development of LVH in mice with high FGF23. LVH caused by 3 months of FGF23 elevation is reversed when serum FGF23 levels are normalized. We propose that FGF23-induced LVH in CKD is treatable, and that the FGF23/FGFR4 signaling mechanism in the heart provides novel options for pharmacological interventions, including FGFR4 blockade. Progression and reversibility of cardiac injury might depend on the duration of FGF23/FGFR4 activation in the heart.

FGF23/FGFR4 Signaling Mediates LVH in Aging Mice Alexander Grabner,[1] Karla J. Schramm,[1] Saurav Singh,[1] Christopher Yanucil,[1] Alexis J. Sloan,[1] Ansel P. Amaral,[1,2] Christian Faul.[1] *[1]Medicine, Univ of Miami Miller School of Medicine, Miami, FL; [2]Medicine, Northwestern Univ Feinberg School of Medicine, Chicago, IL.*

Background: Serum levels of fibroblast growth factor (FGF) 23 are elevated in patients with chronic kidney disease (CKD) and are independently associated with increased rates of left ventricular hypertrophy (LVH). A recent translational study from our group demonstrated that FGF23 is a causal factor in the pathogenesis of LVH and that FGF receptor (FGFR) 4 mediates the cardiac effects of FGF23. We have shown that constitutive FGFR4 knockout (-/-) mice that were administered a high phosphate diet to elevate circulating FGF23 were protected from LVH. Human studies have shown that serum FGF23 levels increase with age and are associated with LVH in the elderly population. Therefore we wanted to test, if FGF23 is causatively involved in the development of age-related LVH.

Methods: We studied 6 and 18 months old FGFR4-/- mice and wild type littermates. LVH was assessed by H&E staining of cardiac cross sections and quantification of LV wall thickness, as well as analysis of cross sectional area of individual myocytes by WGA-fluorochrome labeling. Serum levels of cleaved FGF23 were determined by ELISA and kidney function by BUN.

Results: Serum FGF23 levels continuously increase in wild type mice with age, whereas kidney function is not altered over time. Compared to 6 months old mice, 18 months old wild type mice develop LVH as evident by significantly increased LV wall thickness and cross sectional myocyte area. Although the increase in serum FGF23 levels in 18 months old FGFR4-/- mice is even higher than in wild type littermates, FGFR4-/- mice do not develop an LVH phenotype.

Conclusions: Aging wild type mice develop elevated serum FGF23 levels as well as LVH. Since aged FGFR4-/- mice are protected from LVH, we postulate that FGF23 mediates age-associated LVH via activation of cardiac FGFR4, similar to the mechanism that we have previously described in animal models of CKD. In our aging model, elevations of serum FGF23 and cardiac effects of FGF23 appear to be independent of reduced kidney function.

TH-PO485

miR-29b and miR-30c in the Regulation of Cardiac Fibrosis by VDRAs Sara Panizo,[1] Manuel Naves,[1] Natalia Carrillo-Lopez,[1] Adriana S. Dusso,[1] Amalia Fernandez-Vazquez,[2] Laura Martinez-Arias,[1] Guillermo Solache-Berrocal,[1] Jorge B. Cannata-Andia,[1] Isabel Rodriguez.[1] *[1]Bone and Mineral Research Unit, IRSIN, REDinREN, Hospital Univ Central de Asturias, Univ de Oviedo, Oviedo, Spain; [2]Centro Medico de Asturias, Oviedo, Spain.*

Background: Cardiac remodeling in chronic kidney disease is associated with increased myocardial fibrosis. miRNAs could have a regulatory role in this process. The aim of the study was to identify the role of some miRNAs in myocardial fibrosis and also their implication in the effect of the vitamin D receptor activation (VDRA) as well as their potencial use as biomarkers.

Methods: Male Wistar rats with chronic renal failure (CRF, by 7/8 nephrectomy) were treated intraperitoneally with equivalent doses of two VDRAs (10 ng calcitriol and 30 ng paricalcitol /kg/day, 5 days per week, during 4 weeks). A placebo group (CRF + vehicle) and a sham group with normal renal function served as controls. Biochemical parameters, cardiac fibrosis (Sirius red staining), miRNAs (miR-29b and miR-30c) levels in heart and serum, and the expression of target genes (collagen I [COL1A1], matrix metalloprotease 2 [MMP2], and connective tissue growth factor [CTGF]) in heart were evaluated.

Results: All VDRAs prevented cardiac fibrosis, achieving statistically significant difference in the paricalcitol treated group. A reduced expression of miR-29b and miR-30c was observed in heart of CRF rats, which was prevented with all VDRAs, observing the better results in paricalcitol group. It is described that miR-29b regulates COL1A1 and MMP2 expression and miR-30c regulates CTGF expression. In the hearts of CRF rats, increases in RNA and protein levels of COL1A1, MMP2 and CTGF were observed, which were prevented with all VDRAs. In serum levels of miR-29b and miR-30c, a significant increase was observed, which was prevented by VDRAs use. In the heart and serum analyses, the more marked effects were observed with paricalcitol.

Conclusions: The VDRAs, particularly paricalcitol, reduced cardiac fibrosis acting on COL1A1, MMP2 and CTGF expression, probably through the regulation of miR-29b and miR-30c. These miRNAs could be useful serum biomarkers for cardiac fibrosis and also potential new therapeutic targets.

TH-PO486

Inhibition of FGFR4 Reduces Changes in Cardiac Contraction Induced by FGF23, but Does Not Rescue Impaired Endothelium-Mediated Vasorelaxation Neerupma Silswal,[1] Chelsea Shapland,[1] Matthew J. Hendrix,[1] Chad D. Touchberry,[2] Alexander Grabner,[3] Christian Faul,[3] Michael J. Wacker.[1] *[1]Univ of Missouri-Kansas City School of Medicine, Kansas City, MO; [2]Health and Sport Sciences, Univ of Memphis, Memphis, TN; [3]Univ of Miami Miller School of Medicine, Miami, FL.*

Background: Fibroblast growth factor 23 (FGF23) is released by bone cells and is an important hormone in bone-kidney crosstalk in the regulation of phosphate. As kidney function declines, plasma FGF23 increases significantly and elevated FGF23 has been correlated with cardiac pathologies. Recently, our laboratory has shown that FGF23 treatment increases intracellular calcium in primary cardiomyocytes, increases contractility of left ventricular muscle strips, and impairs endothelium-mediated relaxation of aortic rings by reducing nitric oxide bioavailability. While FGF receptors (FGFR) 1-4 are expressed in the heart and vasculature, it is currently unknown which FGFR mediates these direct effects of FGF23.

Methods: We tested the effects of FGF23 on adult mouse heart and aortic rings in the presence of an isoform specific FGFR4 blocking antibody (anti-FGFR4; U3 Pharma/Daiichi-Sankyo).

Results: Acute treatment of FGF23 (9000 pg/ml) increased contraction of paced left ventricular muscle strips 1.6 ± 0.1 fold over vehicle ($P<0.01$; n=5). Additionally, FGF23 treatment of paced Landendorff-perfused hearts acutely induced contraction abnormalities typically in the form of mechanical alternans. Both the increase in contractility as well as the alternans were eliminated by pretreatment with anti-FGFR4. Using isometric tension myography, preincubation with FGF23 (9000 pg/ml) caused a 35% inhibition of endothelium-dependent relaxation elicited by acetylcholine in $PGF_{2\alpha}$-precontracted aortic rings (n=3-5; $P<0.05$). However, pretreatment with anti-FGFR4 did not improve relaxation (n=5; $P>0.05$).

Conclusions: FGF23 can directly target cardiomyocytes via FGFR4 to alter cardiac excitation-contraction, but may work through different FGFR isoforms to alter endothelium-mediated relaxation. Our findings have importance for targeting potential mechanisms of arrhythmias and cardiovascular changes directly induced by FGF23.

TH-PO487

Differential Expression and Regulation in Uremia of FGF23 in Bone and Kidney Maria Lerche Mace,[1] Eva Gravesen,[2] Jacob Hofman-Bang,[2] Klaus Olgaard,[2] Ewa Lewin.[1,2] *[1]Nephrology B, Herlev Hospital, Copenhagen, Denmark; [2]Nephrology P, Rigshospitalet, Univ of Copenhagen, Copenhagen, Denmark.*

Background: CKD is associated with increased plasma levels of FGF23 and contribution from extraskeletal sources has been proposed. Our aim was to study the regulation of FGF23 expression in bone and kidney tissues and the potential importance of kidney FGF23 for the increased plasma FGF23 in uremia.

Methods: The remnant kidney model of chronic uremia (8 weeks) in 5/6 nephrectomized rats was used. Groups of uremic and age-matched normal rats (n= 6-9) were treated with a bolus of the FGF receptor (FGFR) inhibitor, PD173074 (PD) 50mg/kg, or calcitriol 200ng or parathyroidectomy (PTX). Intact FGF23 levels in plasma, and FGF23 expression in bone and kidney were studied.

Results: FGF23 was not expressed in the normal kidney, but was induced in injured kidney tissue. FGFR inhibition significantly ($p<0.01$) decreased iFGF23 plasma levels in normal PD rats from 364±22 to 154±18pg/ml, and in uremic PD rats from 1590±229 to 581±84pg/ml, whereas the plasma levels in the vehicle groups remained unchanged, normal 357±26 and uremic 1004±112pg/ml. In parallel, a decrease in FGF23 mRNA in bone tissue was demonstrated in both normal and uremic PD rats, as compared to their vehicle control ($p<0.005$); normal vehicle 1.54±0.23 vs normal PD 0.15±0.02, and uremic vehicle 2.38±0.52 vs uremic PD 0.12±0.2. In contrast, kidney FGF23 mRNA remained unchanged in the uremic PD rats 1.19±0.25 vs vehicle 1.13±0.40 (ns). PTX at time of 5/6 nephrectomy prevented the increase in plasma iFGF23 and bone FGF23 expression in uremia (normal 1.0, uremic 3.01±1.28 and uremic-PTX 0.42±0.09), while it had no influence on induction of kidney FGF23 expression in uremia (uremic 3.87±1.61 vs uremic-PTX 3.06±2.27). Calcitriol further stimulated the increased iFGF23 plasma levels in uremia, whereas it had no impact on kidney FGF23 expression.

Conclusions: FGF23 is induced in the injured kidney. In contrast to bone tissue, the kidney expression of FGF23 in uremia is not regulated by FGFR , PTH or calcitriol signaling. The present results indicate that kidney FGF23 is not contributing to the high plasma levels of iFGF23 in uremia.

MEMO1 Deletion Abolishes Renal Responses to FGF23 Matthias B. Moor,[1] Barbara Haenzi,[2] Nancy Hynes,[3] Olivier Bonny.[1,4] *[1]Dept of Pharmacology & Toxicology, Univ of Lausanne, Lausanne, Switzerland; [2]Wolfson Centre for Age-Related Diseases, King's College London, London, United Kingdom; [3]Friedrich Miescher Inst for Biomedical Research, Basel, Switzerland; [4]Service of Nephrology, Lausanne Univ Hospital, Lausanne, Switzerland.*

Background: Mediator of ErbB2-Driven Cell Motility 1 (Memo) modulates fibroblast growth factor (FGF) signaling in vitro, but its physiological role is unclear. Memo KO mice showed premature aging, insulin hypersensitivity and a deranged mineral metabolism similar to what is observed in FGF23 KO and Klotho mutant mice *(Haenzi B, FASEB J 2014)*. Here, we assessed Memo's role in renal FGF23 effects. We attempted to rescue the Memo KO phenotype, and we established kidney-specific Memo KO mice.

Methods: Exon 2 of *MEMO1* was deleted in the full body of $Memo^{fl/fl}$ mice using a tamoxifen-inducible Cre recombinase to obtain cKO mice. Littermates without Cre served as controls. Twelve Memo cKO and 12 control mice were randomized to receive an intraperitoneal FGF23 or vehicle injection, and kidneys were studied by immunoblotting and qPCR. Memo cKO mice were put on 0.2% or 0.8% phosphate diets, and disease-free survival was assessed. Inducible kidney-specific Memo KO mice were established using the PAX8-LC1 Cre recombinase (*Traykova-Brauch M, Nat.Med 2008*).

Results: Memo cKO mice developed a phenotype of premature aging upon tamoxifen treatment. Reducing dietary phosphate content did not alter disease-free survival. Memo cKO mice lacked renal responses to FGF23. Moreover, the vitamin D inhibitory effect of FGF23 on the 24a-hydroxylase (*CYP24A1*) was absent in cKO mice. Kidney-specific Memo KO mice remained viable and had abolished Memo expression in the kidney but not in other organs upon KO induction. These mice showed renal calcium wasting.

Conclusions: Memo is involved in the mediation of renal FGF23 effects and in renal calcium handling. This explains many similarities that Memo cKO mice share with FGF23 or Klotho KO mice. However, the three mouse models differ in phosphate dependence of the eventually lethal phenotype.

Exploring Bacterial Endotoxin as a Promoter of Fibroblast Growth Factor 23 Production in Chronic Kidney Disease Shiqin Zhang, Jason R. Stubbs. *The Kidney Inst, The Univ of Kansas Medical Center, Kansas City, KS.*

Background: Serum fibroblast growth factor 23 (FGF23) is elevated in chronic kidney disease (CKD) and correlates with circulating concentrations of inflammatory cytokines. Low levels of bacterial endotoxin have been detected in the bloodstream of CKD patients and may promote inflammation in this setting. We hypothesized that endotoxemia may stimulate FGF23 production in CKD.

Methods: We first utilized a mouse osteocyte cell line (IDG-SW3) to explore the direct effects of lipopolysaccharide (LPS) on FGF23 production. Next, we tested the *in vivo* effects of low-dose LPS injection on FGF23 production in both wild-type (WT) mice and mice lacking CD14, a primary LPS receptor. Lastly, we compared the progressive changes in FGF23 production in WT and $CD14^{-/-}$ mice in response to CKD induction by adenine ingestion.

Results: Treatment of IDG-SW3 cells with LPS (1ug/ml) resulted in an 11-fold increase in FGF23 mRNA expression compared to vehicle ($p<0.05$, triplicate experiments). Moreover, intraperitoneal injection of LPS (2mg/kg) in WT mice resulted in a 35-fold increase in calvarial FGF23 gene expression two hours post-treatment ($p<0.001$ compared to vehicle-treated WT mice), which was accompanied by a doubling of serum FGF23 (342.9 ± 124.2 pg/ml vs. 166.5 ± 25.9 pg/ml in vehicle-treated WT mice; $p=0.001$). Identical LPS dosing in $CD14^{-/-}$ mice blunted this response, resulting in only a 10-fold increase in calvarial FGF23 gene expression ($p<0.01$) and no obvious difference in serum FGF23 (188.9 ± 75.8, p=NS) compared to vehicle-treated WT mice (n≥8 per group). Finally, CKD induction in WT mice led to a marked elevation of serum FGF23 (6862.0 ± 4829.1 pg/ml vs. 251.9 ± 133.3 pg/ml in WT mice fed a control diet). The absence of CD14 failed to mitigate FGF23 increments with CKD progression, as $CD14^{-/-}$ mice with CKD exhibited comparable serum FGF23 concentrations to WT mice with CKD (9958.7 ± 5047.6 pg/ml, p=NS; n≥9 per group).

Conclusions: Bacterial endotoxin stimulates FGF23 production by bone by a mechanism that is partially dependent on CD14 signaling; however, the deletion of CD14 in a CKD mouse model fails to attenuate the rise in serum FGF23 that accompanies kidney injury.

Inflammation Affects FGF23 Production in Uremia Maria Encarnacion Rodriguez Ortiz,[1] Juan miguel Diaz-tocados,[2] Juan R. Munoz-Castaneda,[2] Carmen maria Herencia,[2] Julio Manuel Martínez Moreno,[2] Addy Rosa Montes de Oca Gonzalez,[2] Alberto Ortiz,[1] Escolastico Aguilera-tejero,[3] Mariano Rodriguez,[2] Yolanda Almaden peña.[4] *[1]IIS-Fundacion Jimenez Diaz, REDinREN, Madrid, Spain; [2]IMIBIC. Reina Sofia Hospital. Un. of Cordoba, Cordoba, Spain; [3]Dep. Animal Medicine and Surgery, Univ of Cordoba, Cordoba, Spain; [4]Lipid and Atherosclerosis Unit, IMIBIC/Reina Sofia Hospital/Un. of Cordoba. CIBERObn, Cordoba, Spain.*

Background: FGF23 increases since early stages of chronic kidney disease (CKD). In CKD, other factors as inflammation may affect the phosphaturic action of FGF23, and higher FGF23 may be required to control P. We aimed to determine if the production of FGF23 is affected by LPS-induced inflammation in experimental uremia.

Methods: 5/6Nx Wistar rats on diets with 0.2% or 0.4%P received LPS for 15 days. Sham rats also received LPS. Blood, urine, and kidney samples were collected.

Results: Nx rats on a 0.2%P diet had lower FGF23 compared to sham, whereas a 0.4%P diet increased FGF23 levels. LPS-treated groups had more than a 3-fold increase in plasma levels of FGF23 as compared with their respective controls. Fractional excretion of P in sham and Nx rats was not modified by the administration of LPS. No differences in renal Klotho expression were found between sham and rats on a 0.2%P diet. A 50% reduction in Klotho was seen in 5/6Nx rats on the diet containing 0.4%P. The administration of LPS to sham rats reduced Klotho expression by approximately 25%. In 5/6 Nx rats on 0.2% and 0.4%P, LPS reduced Klotho by 70% and 50%, respectively.

	Sham 0.6%P	Sham 0.6%P+ LPS	Nx 0.2%P	Nx 0.2%P+ LPS	Nx 0.4%P	Nx 0.4%P+ LPS
Serum P (mg/dl)	4.86± 0.33	5.45± 0.94	2.41± 0.31[c]	6.40± 1.81	5.74± 0.61	6.44± 0.93
Serum PTH (pg/ml)	22± 0.6	21± 0.5	18± 0.4	29± 6	33± 10	24± 0.6
Serum $1,25(OH)_2D_3$ (pg/ml)	57± 21	37± 7	55± 31	10± 2[a,b]	11.1± 1[a,b]	7± 1[a,b]
Serum FGF23 (pg/ml)	92± 12	245± 73[a]	25± 6[a]	324± 32[a]	142± 19[a]	472± 95[c]
FEP (%)	8.1± 0.6	5.4± 1.4	4.2± 1.7	2.4± 2	16.1± 2.3[a]	14.9± 2.7[a]

Conclusions: The prevention of the increase in FGF23 associated with CKD is not possible in the presence of inflammation.

TH-PO491

Dietary Sodium Bicarbonate Decreases Serum Fibroblast Growth Factor 23 in Normal Rats Nancy S. Krieger, Felix M. Ramos, Min Ho Kim, Kevin K. Frick, David A. Bushinsky. *Medicine, Univ of Rochester School of Medicine, Rochester, NY.*

Background: Patients with CKD have a marked increase in serum fibroblast growth factor 23 (FGF23) which is associated with increased mortality. FGF23 is synthesized in osteoblasts and osteocytes; however, its specific regulators are not clear. During CKD there is a fall in renal net acid excretion leading to metabolic acidosis (MET). We have previously shown that MET directly stimulates FGF23 in mouse bone and in primary osteoblastic cells in vitro, suggesting that an in vivo increase in serum HCO_3 might reduce serum FGF23 levels. In this study we tested the hypothesis that oral $NaHCO_3$ would decrease serum FGF23 levels in normal rats.

Methods: Sprague Dawley rats (250 g) were acclimated to a powdered 1.2% Ca, 0.65% P diet, 13 g/d, for 14d. Rats were either continued on this diet supplemented with 3% NaCl (n=9) or 3% $NaHCO_3$ (n=10) for an additional 8 d. Blood was then obtained by cardiac puncture for measurement of FGF23 by ELISA (intact FGF23, Immutopics) as well as standard metabolic parameters.

Results: Feeding rats $NaHCO_3$ lead to a significant fall in serum FGF23 and an increase in serum HCO_3 compared to feeding NaCl (Table; values are mean±SE; *, p< 0.05; **, p<0.01). Serum PO_4 fell with $NaHCO_3$ as did both serum Cl and K. There were no differences in serum Ca, Na or creatinine with $NaHCO_3$ compared to NaCl fed rats.

Treatment	FGF23 (pg/ml)	HCO_3 (mmol/L)	Ca (mg/dL)	PO_4 (mg/dL)	K (mmol/L)	Cl (mmol/L)
NaCl	391± 27	23.2± 0.68	9.41± 0.09	7.10± 0.21	4.51± 0.26	101.0± 0.67
$NaHCO_3$	255± 15**	27.0± 1.49*	9.59± 0.10	6.16± 0.22**	3.95± 0.07*	98.6± 0.40**

Conclusions: Provision of oral $NaHCO_3$ sufficient to raise serum HCO_3 led to a significant fall in FGF23 in normal rats supporting the hypothesis that pH (or HCO_3) directly regulates FGF23; however, we cannot exclude that a $NaHCO_3$ -induced change in PO_4 contributed to the change in FGF23. If comparable acid-base regulation of FGF23, now demonstrated in vitro and in vivo, is confirmed in humans, it suggests that correction of acidosis in patients with CKD may lower their elevated FGF23 levels.

Metabolic Acidosis Increases Osteoblastic MEPE Expression in Parallel to the Increase in Fibroblast Growth Factor 23 Nancy S. Krieger, Min Ho Kim, David A. Bushinsky. *Medicine, Univ of Rochester School of Medicine, Rochester, NY.*

Background: Serum fibroblast growth factor 23 (FGF23) increases with the severity of chronic kidney disease (CKD), leading to decreased renal tubular phosphate (Pi) reabsorption and serum $1,25(OH)_2D_3$. FGF23 is synthesized in osteoblasts and osteocytes; however, the primary factors regulating its production are not clear. Patients with CKD have decreased renal net acid excretion leading to metabolic acidosis (MET). During MET, acid is buffered by bone with release of mineral calcium and Pi. MET directly stimulates FGF23 in mouse bone and primary osteoblastic cells utilizing the same signaling pathways that lead to MET-induced bone resorption. To further characterize the regulation of FGF23 by MET we utilized primary osteoblasts to study gene expression pathways upstream of FGF23 production, including the major extracellular phosphoglycoprotein, MEPE, and the phosphate-regulating endopeptidase, PHEX.

Methods: Confluent osteoblastic cells isolated from neonatal mouse calvariae were incubated in neutral (NTL, pH=7.50, Pco_2=39 mmHg, [HCO_3^-]=30 mM) or acid (MET, pH=7.20, Pco_2=39 mmHg, [HCO_3^-]=14 mM) medium. Specific RNA gene expression was analyzed by real time PCR with expression normalized to RPL13A and calculated relative to non-incubated cells.

Results: Maximal stimulation of FGF23 was found at 24h (MET=7.26±1.55 vs NTL=3.75± 0.64, p<0.05). MET significantly increased MEPE RNA expression as early as 6h compared to NTL (relative expression: MET=2.23±0.41, vs NTL=1.19±0.16, p<0.05) with a further increase at 24h. There were no significant differences in PHEX expression in response to MET compared to NTL, although there was a progressive decrease in PHEX expression in both groups over 24h.

Conclusions: Thus, MET stimulation of MEPE expression may be an initial step by which MET increases FGF23 production in mouse osteoblasts. By better understanding how MET stimulates FGF23, therapeutic interventions directed toward correction of MET, especially in CKD patients, can be devised to not only prevent bone resorption but also lower FGF23.

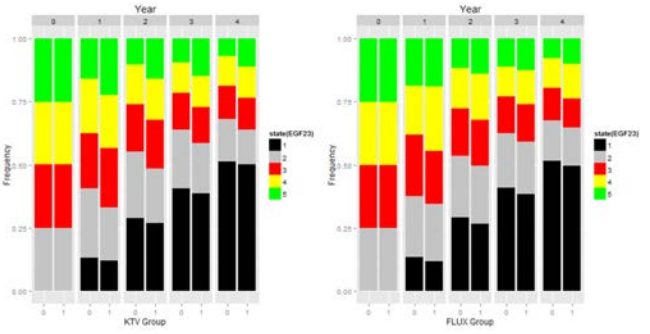
Effect of High-Dose and Flux Hemodialysis on Circulating Markers of Mineral Metabolism in the HEMO Study Anna Jeanette Jovanovich,[1,2] Alfred K. Cheung,[3,4] Tom Greene,[4] Jian Ying,[4] Michel Chonchol.[2] *[1]Denver VA Medical Center; [2]Univ of Colorado Denver; [3]VA Salt Lake City; [4]Univ of Utah.*

Background: There are limited and somewhat contradictory data in the literature on the effects of high versus low dialysis clearance and high versus low flux on circulating markers of mineral metabolism.

Methods: The HEMO Study was a randomized multicenter study of the effects of high-dose versus standard-dose and high-flux versus low-flux hemodialysis. Fibroblast growth factor 23 (iFGF23, pre-specified primary endpoint for these analyses), serum phosphorus, and 25-hydroxivitamin D (25(OH)D) were measured in stored serum samples. We used multi-state analyses to analyze the dose and flux effects on each mineral metabolism marker while accounting for mortality. We estimated the proportions of patients in 5 ordered states (S) for serum phosphorus, 25(OH)D and FGF23: S1= deceased (score=0); S2 = alive in highest quartile (score=1); S2 = alive in 3rd quartile (score =2); S4 = alive in 2nd quartile (score=3); and S5 = alive in lowest quartile (score=4). The average rank was computed over 3 years of follow-up and compared between the randomized groups.

Results: Randomized patients had high rates of coexisting conditions 45% had diabetes, and 80% had a history of cardiac disease. Characteristics of the patients in the two dose groups were similar, as were the characteristics of those in the two flux groups. The state distributions for FGF23 each year by dose (KTV) group and by flux group are shown in Figure 1. FGF23 differed significantly between dose groups (p=0.02) but not between flux groups (p=0.17). No significant differences were observed for serum phosphorus or 25(OH)D.



Conclusions: Over 3 years, high-dose of dialysis appeared to reduce FGF23 compared to standard dialysis dose.

Factors for Persistent Low or High FGF-23 Levels in Maintenance Hemodialysis Patients Sonoo Mizuiri,[1] Yoshiko Nishizawa,[1] Kazuomi Yamashita,[1] Kohji Usui,[2] Shigehiro Doi,[3] Takao Masaki,[3] Kenichiro Shigemoto.[1] *[1]Nephrology, Ichiyoukai Harada Hospital, Hiroshima, Japan; [2]Nephrology, Ichiyokai Ichiyokai Clinic, Hiroshima; [3]Nephrology, Hiroshima Univ, Hiroshima, Japan.*

Background: The aim of this study was to assess the association between serum fibroblast growth factor-23 (FGF-23) and mortality, and to determine the factors for persistent low or high FGF-23 levels, in maintenance HD (MHD) patients.

Methods: We examined serum intact FGF-23, age, dialysis vintage, presence of diabetes, BMI, blood pressure, (Ccr+Curea)/2, Kt/Vurea, hs CRP, b2MG, serum albumin, nPCR, geriatric nutritional risk index (GNRI), serum phosphate, serum calcium, iPTH, active vitamin D dosage, and phosphate binders and/or cinacalcet in 332 MHD patients in September of 2012, 2013 and 2014. Coronary artery calcification score (CACS) was measured in a subgroup (n=173). According to quartile (Q) of FGF-23 in 2012, mortality was assessed by Kaplan-Meyer and adjusted Cox models. Patients with FGF-23 Q1-Q1-Q1 were categorized in Group 1, patients with FGF-23 Q4-Q4-Q4 in Group 3, and the others in Group 2.

Results: Median age and dialysis vintage were 69 years and 66 months, respectively, at baseline. During the 2 years, 71 patients died and 24 patients left our hospital. Baseline FGF-23 levels (pg/ml) were <310 (Q1), 310-1489 (Q2), 1490-5294 (Q3) and >5294 (Q4) (P<0.05), with cumulative survival rates of 65.4%, 78.9%, 85.1% and 80.6%, respectively (P<0.01), and hazard ratios (HRs) for death of 1.0, 0.6, 0.4 and 0.5, respectively, in univariate model. However, there was no significant association between Q of FGF-23 level and mortality in multivariate model. HR for death of CACS was 1.1 (P<0.01), but there were no differences in CACS in patients based on FGF-23 level. Significant associations between Group 1 and diabetes (OR: 3.5), age (OR: 1.1), serum phosphate (OR:0.4) and vitamin D dosage (OR: 0.2), and between Group 3 and serum phosphate (OR: 2.0), iPTH (OR: 1.004) and vitamin D dosage (OR: 1.9), were observed (P<0.05).

Conclusions: FGF-23 in the lowest quartile showed the lowest 2-year cumulative survival rate in MHD patients, and factors for persistent low FGF-23 levels were diabetes, age, serum phosphate and active vitamin D dosage.

TH-PO495

Maintenance of Residual Diuresis and Type of Dialysis Can Influence FGF23 Levels Valentina Corradi,[1,2] Sara Samoni,[2] Francesca K. Martino,[1,2] Elisa Scalzotto,[2] Ilaria Santolin,[3] Elisabetta Galloni,[3] Carla Estremadoyro,[2] Renhua Lu,[2] Carlo Crepaldi,[1,2] Monica Zanella,[1,2] Alessandra Brendolan,[1,2] Claudio Ronco.[1,2] *[1]Nephrology, San Bortolo Hospital, Vicenza, Italy; [2]IRRIV, San Bortolo Hospital, Vicenza, Italy; [3]Neurology, San Bortolo Hospital, Vicenza, Italy.*

Background: Bone mineral disorders are common in patients (pts) with end stage renal disease (ESRD). In particular, hyperphosphatemia can be frequently seen in pts undergoing peritoneal dialysis (PD) and hemodialysis (HD). Recently, several studies investigated the role of fibroblast growth factor 23 (FGF23) in regulation of renal phosphate excretion in ESRD pts. However, patients with residual diuresis (RD) seem to better control serum phosphorus levels than those without RD. The aim of our study was to determine if the dialysis modality and the preservation of RD influence serum levels of FGF23.

Methods: We performed a cross-sectional study in two groups of pts: HD and PD. The variables analyzed were creatinine, urea, calcium, phosphate (Phosp), i parathormone (intact PTH) and cFGF23 (C-term). The urinary output collection refers to one week. All p value were two sides and statistical significance was set at p<0.05. Statistical analysis was performed by SPSS version 20.

Results: A total of 122 pts were enrolled (58HD,64PD).The mean age of HD pts was 64.45±14,25yrs and of PD pts 62,33±13,86 yrs. RD was present in 78 pts (65,46±

12,87yrs) and the median volume was 5600 (3412-9450 ml/week). The median cFGF23 were significantly higher in HD compared to PD pts (2634 [1192-6880] vs 1395 [609-2660] RU/ml; p=0,012) and higher in pts without than in pts with preserved RD (2634 [970-8348] vs 1428 [1042-3047] RU/ml; p=0,030). We found a significant correlation between FGF23 and age, Phosp, dialysis modality and RD. Univariable and multivariable adjusted analysis showed that Phosp, dialysis modality and RD are independent predictors of cFGF23 respectively with OR=0,495 [p<0,001], OR=-0,184 [p=0,040] and OR=-0,189 [p=0,034].

Conclusions: In our study, serum cFGF23 levels were lower in patients with preserved RD and those undergoing PD compared to patients without RD and undergoing HD. The dialysis modality and the preservation of RD are independent predictors of cFGF23 levels.

TH-PO496

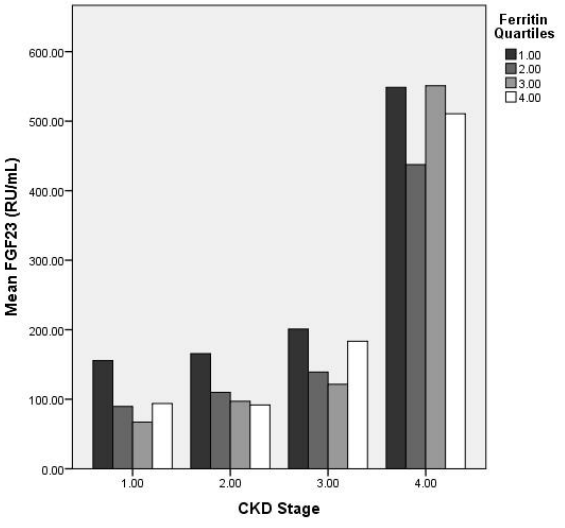
Iron Deficiency Is Associated with Elevated FGF23 Levels in Pediatric CKD

Farah N. Ali,[1] Bradley Warady,[2] Susan L. Furth,[3] Harald Jüppner,[4] Isidro B. Salusky,[5] Anthony A. Portale,[6] Myles S. Wolf.[1] *[1]Northwestern Univ; [2]Children's Mercy Hospital; [3]Children's Hospital of Philadelphia; [4]MGH; [5]UCLA; [6]UCSF.*

Background: FGF23 excess contributes to CV disease and death in CKD. Mechanisms of elevated FGF23 levels in CKD are incompletely understood. Iron deficiency is a novel stimulus of FGF23 production. Given high rates of iron deficiency in CKD, we hypothesize that iron deficiency is related to higher FGF23 levels in pediatric CKD and that iron deficiency induced by proteinuria contributes to higher FGF23 levels in glomerular diseases.

Methods: We measured ferritin, TSAT, C-terminal (c) FGF23, CRP, and urine protein/creatinine (pr/cr) in 551 children in the CKiD Study.

Results: Mean age was 10.2 ± 4.4 yrs; 62% were male; mean eGFR was 53 ± 19 ml/min/1.73m^2; mean TSAT was 26 ± 13%, median ferritin was 46 ng/mL (IQR 27-81); median urine pr/cr was 0.31 mg/mg (IQR 0.10-1.00); median cFGF23 was 114 RU/mL (IQR 80-185). cFGF23 correlated inversely with ferritin (p=0.055) and eGFR (p<0.001) and directly with CRP (p=0.049), proteinuria (p<0.001), and phosphate (p<0.001). Grouping proteinuria into low or high grade (pr/cr >3) revealed no differences in ferritin and TSAT, but TIBC was lower (288 vs 310 µg/dL, p=0.011) and cFGF23 was higher in the high vs low grade groups (362 vs 184, p=0.016). cFGF23 levels were significantly elevated in the lowest ferritin quartile, preferentially in early stages of CKD (Figure).



In multivariate analysis that included proteinuria and CRP, only lower eGFR, glomerular disease, higher phosphate, and lower ferritin were independent predictors of higher cFGF23 levels (p<0.001 for all). The relationship between proteinuria and cFGF23 was mitigated when ferritin was added to the multivariable model.

Conclusions: Iron deficiency is associated with higher cFGF23 levels in pediatric CKD and may contribute to the relationship between proteinuria and higher FGF23.

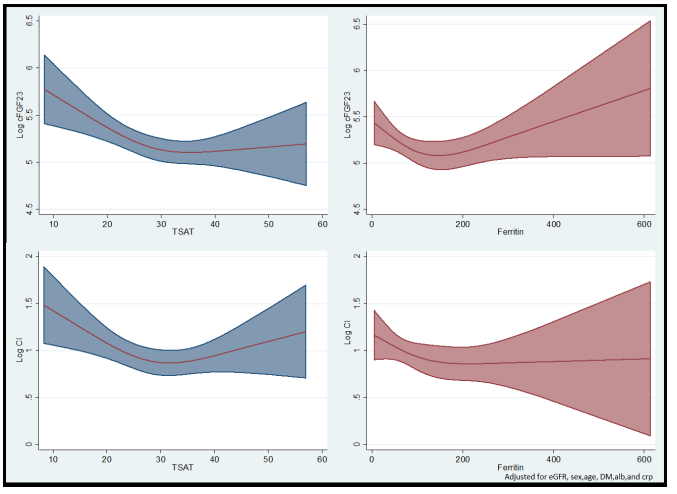
The Ratio of C-Terminal to Intact Fibroblast Growth Factor 23 Was Elevated in Iron Deficient Patients with Chronic Kidney Disease

Sayoko Yonemoto,[1,3] Takayuki Hamano,[2] Naohiko Fujii,[1] Daisuke Mori,[3] Yasuo Kusunoki,[3] Akihiro Shimomura,[2] Isao Matsui,[3] Hiromi Rakugi,[3] Yoshitaka Isaka.[3] *[1]Dept of Internal Medicine, Hyogo Prefectural Nishinomiya Hospital, Nishinomiya, Hyogo, Japan; [2]Dept of Comprehensive Kidney Disease Research, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan; [3]Dept of Geriatric Medicine and Nephrology, Osaka Univ Graduate School of Medicine, Suita, Osaka.*

Background: A recent study showed iron deficiency was associated with elevated fibroblast growth factor 23 levels by c-terminal assay (cFGF23) but not with intact FGF23 (iFGF23) levels in women without chronic kidney disease (CKD). It remains elusive if this holds true also in patients with CKD.In this cross-sectional study, we examined the associations between iron deficiency and FGF23 levels by the two assays in predialysis patients.

Methods: The study population consisted of 100 predialysis outpatients of the nephrology department in a hospital in Japan. We measured plasma cFGF23 (Immutopics) and serum iFGF23 (Kainos). Restricted cubic spine analysis was employed to estimate non-linear relationships between iron markers and ratio of cFGF23 to iFGF23 CI ratio. The CI ratio can be regarded as a FGF23 cleavage marker.

Results: The mean age and eGFR was 70.1±15.0 and 26.9±12.9 ml/min/1.73m^2, and the proportions of female and patients with diabetes mellitus were 30 and 40%, respectively. Only 18 and 6.0% of patients were treated with ESA and oral iron therapy, respectively. The cFGF23 was elevated with the decrease in TSAT and ferritin levels, and the CI ratio was also elevated with the decrease in TSAT and ferritin levels.



Conclusions: In this study, we observed elevation of cFGF23 and CI ratio in iron deficiency patients with CKD. This might be because iron-deficiency stimulates FGF23 transcription and its cleavage simultaneously just as reported in non CKD women.

TH-PO498

Ferric Citrate Hydrate Decreases Circulating FGF23 Levels Independently of Serum Phosphate Levels in Hemodialysis Patients with Iron Deficiency

Akira Iguchi,[1] Noriaki Iino,[3] Ichiei Narita.[2] *[1]Div of Nephrology and Rheumatology, Saiseikai Niigata Daini Hospital, Niigata, Japan; [2]Div of Clinical Nephrology and Rheumatology, Niigata Univ Medical and Dental Hospital, Niigata, Japan; [3]Uonuma Inst of Community Medicine, Niigata Univ Medical and Dental Hospital, Minamiuonuma, Japan.*

Background: Fibroblast growth factor 23 (FGF23) is regulated by dietary phosphate intake and vitamin D receptor activator (VDRA). Iron is another potential modulator for FGF23 metabolism.

Methods: This prospective study enrolled 27 maintenance hemodialysis patients with iron deficiency and hyperphosphatemia who had been treated with sevelamer-HCl. Their phosphate binder was changed to ferric citrate hydrate (FCH), so that their phosphate levels were maintained constant. VDRA, other phosphate binders, and cinacalcet hydrochloride were unchanged. Serum intact-FGF23, C-terminal FGF23, intact parathyroid hormone, 1,25$(OH)_2$D, and other parameters were prospectively monitored for 12 weeks.

Results: Serum levels of phosphate and 1,25$(OH)_2$D were unchanged. Serum ferritin levels increased from 25.6 ± 24.3 ng/mL at baseline to 55.8 ± 33.5 ng/mL at 12 weeks with the administration of FCH. Serum intact-FGF23 and C-terminal FGF23 levels were 2000 (1300.0 – 3471.4) pg/ml and 1608.7 (634.8 – 2308.7) RU/ml at baseline, respectively. At 12 weeks, intact-FGF23 and C-terminal FGF23 significantly decreased to 1771.43 (1142.9 – 2342.9) pg/ml (P = 0.0258) and 1165.2 (626.1 – 1547.8) RU/ml (P = 0.0298), respectively. Serum intact parathyroid hormone levels significantly increased from 96 (65 – 125) pg/ml at baseline to 173 (114 – 283) pg/ml after 12 weeks (P = 0.0006).

Conclusions: Oral administration of FCH decreased both serum intact- and C-terminal FGF23 levels and increased intact parathyroid hormone levels, without any change in phosphate and 1,25$(OH)_2$D. Treatment of iron deficiency with oral FCH may be a useful strategy to reduce serum FGF23 levels independent of phosphate and VDRA.

TH-PO499

Intravenous Iron Leads to Fibroblast Growth Factor 23-Dependent Changes in Calcium-Phosphate Metabolism in Non-Dialysis Patients with Chronic Kidney Disease Stages 3-5

Katarzyna Muras-Szwedziak, Michal P. Nowicki. *Dept of Nephrology, Hypertension and Kidney Transplantation, Medical Univ of Lodz, Lodz, Poland.*

Background: Iron deficiency is a common phenomenon among patients with chronic kidney disease (CKD) treated with erythropoiesis stimulationg agents. Intravenous iron may interfere with calcium-phosphate (Ca-P) metabolism in CKD. Iron infusion may reduce peripheral degradation and clearence of circulating iFGF23 after its secretion by

osteocytes but it is unclear whether it could also modulate FGF23 synthesis. Our research objective was to evaluate the effect of intravenous iron supplementation on the parameters of mineral metabolism in patients with CKD.

Methods: The study included 35 non-dialysis patients with CKD stages 3-5. Each patients received once-daily 100 mg iron solution (Ferric oxide saccharated complex; Vifor, France) for 5 consecutive days. Iron doses were administered in a slow 40-min. intravenous infusion. On day 1 and 3 at baseline and 2 hours after each dose administration, calcium (Ca), phosphorus (P), parathormone (PTH), intact-FGF23 (iFGF23), C-terminal-FGF23 (cFGF23), bonealkaline phosphatase (BAP) were assessed. The measurements were repeated on day 6.

Results: Two hours after the first iron infusion and on day 6 a significant increase in serum iFGF23 was observed (from 257±446.5 to 326.3±529.9 on day 1; p=0.005 and to 451.4±601 on day 6 pg/ml; p<0.05). The concentration of cFGF23 was reduced in parallel only on day 1 (from 654.3±441.3 to 473.6±414 RU/ml; p<0.05). Serum phosphorus concentration decreased significantly on day 1 two hours after iron infusion (from 1.75±0.6 to 1.53±0.35 mmol/l; p=0.005). On following days the changes of cFGF23 and phosphorus concentration were not significant. The serum concentrations of Ca, BAP and PTH were unchangedthroughout the study.

Conclusions: Intravenous iron supplementation may interfere with the mechanisms governing both production and degradation of FGF23 thereby leading to transient hypophosphatemia at the beginning of iron therapy.

TH-PO500

The Increase of Fractional Excretion of Phosphorus Induces FGF23 Resistance due to a Decrease in Renal Klotho Juan R. Munoz-Castaneda,[1] Carmen maria Herencia,[1] Maria Encarnacion Rodriguez Ortiz,[3] Juan miguel Diaz-tocados,[1] Julio Manuel Martínez Moreno,[1] Addy Rosa Montes de Oca Gonzalez,[1] Yolanda Almaden peña,[2] Mariano Rodriguez.[1] *[1]Servicio de Nefrología, Inst Maimónides de Investigación Biomédica de Córdoba (IMIBIC), Hospital Univ Reina Sofia, Córdoba, Spain; [2]Unidad de Lípidos y Aterosclerosis (CIBEROBN), IMIBIC, Hospital Univ Reina Sofia, Córdoba, Spain; [3]Laboratorio de Nefrología, IIS-Fundación Jiménez Díaz, REDinREN, Madrid, España.*

Background: The maintenance of serum phosphate (P) levels is critical in the context of renal diseases to prevent CKD-MBD, the progression of CKD and mortality mainly caused by cardiovascular events. As renal function declines P levels increases instead of the high FGF23. In these conditions an unsolved FGF23 resistance is produced. The mechanisms whereby FGF23 resistance is produced will be evaluated.

Methods: Renal FGFR1 and klotho were analyzed in normal rats receiving continuously infusion of rat recombinant FGF23 and 5/6 Nx rats with high or low levels of P in the diet. An additional group with anti-FGF23 antibody was also used in 5/6 Nx rats unsolved FGF23 resistance is produced.

Results: In normal rats, high levels of FGF23 increased fractional excretion of P (FePi) and renal FGFR1, whereas klotho was decreased. In 5/6Nx with normal FGF23 (0.6%P diet), the FePi was moderately increased and FGFR1 and klotho was decreased. In 5/6Nx rats with high FGF23 levels (1.2%P diet) there was a severe decrease of klotho and an increase of FGFR1. Anti-FGF23 was administered to check whether renal klotho decreases due to high FGF23 or by the increase of FePi. Anti-FGF23 increased serum P decreasing slightly phosphaturia. In addition we checked that in HEK293 cells high P activated the wnt/b-catenin pathway and decreased klotho expression. Dkk1 administration prevented the drop of klotho in presence of high P. Therefore renal FGFR1 levels results FGF23-dependent, whereas the decrease of klotho is induced by the increase in FePi.

Conclusions: High FGF23 levels increase FGFR1, whereas higher phosphaturia decreases klotho expression through the activation of the canonical wnt/b-catenin pathway, which may induce the resistance to FGF23.

Regulation of α-Klotho Expression by Dietary Phosphate During Growth Periods Shiori Fukuda,[1] Hironori Yamamoto,[2] Masashi Masuda,[1] Mari Nakao,[1] Yutaka Taketani.[1] *[1]Dept of Clinical Nutrition and Food Management, Inst of Biomedical Sciences, Tokushima Univ Graduate School, Tokushima, Japan; [2]Dept of Health and Nutrition, Faculty of Human Life, Jin-ai Univ, Echizen City, Fukui, Japan.*

Background: Phosphate is critically important for biological functions, particularly during growth periods. Phosphate deficiency causes bone diseases such as rickets and osteomalacia. On the other hand, excess intake of dietary phosphate increases secretion of fibroblast growth factor 23 (FGF23) and parathyroid hormone (PTH) to maintain plasma phosphate level. FGF23, is a potent phosphaturic factor, binds to α-klotho / FGFR complex in the kidney to promote excretion of phosphate into urine. In addition, excess intake of dietary phosphate also decrease in renal α-klotho expression. Downregulation or lack of α-klotho induces a premature aging-like phenotype such as ectopic calcification and osteoporosis resulted from hyperphosphatemia. However, the effects of high phosphate diet on renal α-klotho expression just after weaning period are still unknown.

Methods: To investigate that, we used C57BL / 6J mice aged 3-4 week old under a rapid growth phase. Mice were fed 0.02, 0.3, 0.6, 0.9, 1.2, 1.5 or 1.8% phosphate diets for 7 days beginning just after weaning at 3 week old.

Results: As a result, elevation of plasma phosphate and FGF23 levels, and decrease in renal α-klotho expression were observed as the content of dietary phosphate increased. In addition, renal calcification was clearly observed in mice fed 1.5 or 1.8% phosphate diets. The renal calcification did not observed when the 8 week-old mice were fed with 1.5 or 1.8% phosphate diet for 7 days. These results suggest that the effects of high phosphate diet during growth periods have a much greater adverse effect on renal α-klotho expression and morphology of the kidney as compared to a similar investigation during maturation periods.

Conclusions: In conclusion, excessive dietary phosphate intake during growth periods such as just after weaning period decreases in renal α-klotho expression relating to premature aging-like lesions.

The Secreted *Klotho* mRNA Transcript Is Continuously Degraded by Nonsense-mediated mRNA Decay and Its Splicing Is Dysregulated After Kidney Damage Rik Mencke, Geert Harms, Jan-luuk Hillebrands. *Pathology and Medical Biology, Univ Medical Center Groningen, Groningen, Netherlands.*

Background: *Klotho* is an anti-aging gene of which two mRNA transcripts have been identified: one corresponds to the full 5-exon coding sequence and the other, alternatively spliced, consists of exons 1-3 and 50 downstream base pairs, forming a stop codon. The latter mRNA is thought to code for a secreted Klotho protein. While soluble Klotho proteins can be detected in blood, urine, and cerebrospinal fluid, a product of this alternative transcript has never been identified. Nonsense-mediated mRNA decay (NMD) research predicts that the premature stop codon induces continuous degradation during translation.

Methods: We first assessed the mRNA transcripts in human kidney and HK-2 cells by RT-PCR and DNA sequencing. We then blocked NMD in HK-2 cells using cycloheximide (CHX) (100 μg/ml) for 2, 4, or 6 h, or using *XRN1* siRNA for mRNA degrading enzyme exoribonuclease 1, to assess possible accumulation of the alternative mRNA by RT-PCR and densitometry. Then, we assessed whether splicing was different in normal human kidneys (N=11) and in chronic rejection transplanted (CRT) kidneys (N=4).

Results: Expression of both *Klotho* mRNA transcripts was confirmed in human kidney and in HK-2 cells by RT-PCR and DNA sequencing. CHX-induced inhibition of translation increased the "secreted" / membrane-bound *Klotho* mRNA ratio from 0.14±0.02 to 0.44±0.06 (p<0.001). Preliminary data show that silencing of *XRN1* has the same effect. Furthermore, already in normal kidneys, there was a marked, reproducible variation in splicing ratios, ranging from 0.03±0.01 to 0.20±0.02. In CRT kidneys, *Klotho* mRNA was expectedly down-regulated and splicing was skewed towards the non-functional alternative splice variant.

Conclusions: The alternative *Klotho* mRNA contains a premature stop codon and is a likely NMD substrate. Soluble Klotho would therefore be cleaved Klotho only. Furthermore, in damaged kidneys, splicing of the *Klotho* gene is dysregulated, which constitutes a new mechanism of Klotho down-regulation.

TH-PO503

Genetic Deletion of NaPi-2c Rescue Phenotype of Klotho Knockout Mice without Improving Severe Hyperphosphatemia Ai Hanazaki, Hiroko Segawa, Kayo Ikuta, Toru Fujii, Ichiro Kaneko, Shihoko Yuki, Shiori Nishiguchi, Kejiro Notsu, Yuji Shiozaki, Sawako Tatsumi, Ken-ichi Miyamoto. *Molecular Nutrition, Inst of Biomedical Sciences, Tokushima Univ Graduate School, Tokushima, Japan.*

Background: SLC34A3/NaPi-2c is one of the renal sodium dependent phosphate (Pi) transporters. Mutation of human NaPi-2c causes hereditary hypophosphatemic rickets with hypercalciuria (HHRH). Thus, NaPi-2c may have an important role on renal Pi reabsorption and bone mineralization in humans. The physiological role of NaPi-2c, however, has not been completely explained yet. NaPi-2c knockout (NaPi-2c-/-) mice showed hypercalciuria, but did not show any Pi abnormality. Recently, Hernand N. et al. reported that kidney specific NaPi-2c conditional knockout mice did not show any abnormality. These results suggested that NaPi-2c has minor role in the Pi homeostasis. To discover the role of NaPi-2c, we examined genetic inactivation of NaPi-2c in klotho knockout (klotho-/-) mice.

Methods: To obtain the klotho and NaPi-2c double knockout (klotho-/-/NaPi-2c-/-, KL2c DKO) mice, kloho+/- mice and Npt2c+/- mice were crossed. Total body weight of each of wild-type, klotho-/-, KL2c DKO and NaPi-2c-/- mice was taken every week. Urine and blood were obtained for biomedical measurements at the several ages of weeks. Tissues were obtained from each mice for histological and calcification analysis.

Results: Genetic disruption of NaPi-2c significantly increased body weight and extended the life span of klorho-/- mice. KL2c DKO mice were viable and larger in size than klotho-/- mice, but smaller than wild-type and NaPi-2c-/- mice. KL2c DKO mice showed slightly decreased plasma Pi levels at early hood, but not adult hood. Plasma FGF23 levels were extremely high in KL2c DKO mice as well as klotho-/- mice.

Conclusions: Our finding demonstrated that NaPi-2c genetic deletion rescued the phenotype of klotho-/- mice without improving severe hyperphosphatemia.

TH-PO504

Klotho/FGF23-Independent and ERα Mediated Direct Downregulation of NaPi-IIa by Estrogen in the Mouse Kidney Proximal Tubule Hassane Amlal, Sulaiman Sheriff, Rose P. Webster. *Internal Medicine, Univ of Cincinnati, Cincinnati, OH.*

Background: Estrogen treatment is associated with renal wasting of inorganic phosphate (Pi) and hypophosphatemia in rats and humans; however the molecular and signaling mechanisms mediating this effect are still not fully understood.

Methods: To determine the roles of estrogen receptor isoforms (ERα and ERβ) and Klotho/FGF23 pathway in these effects, we studied the effects of estrogen on renal Pi handling in the kidneys of mice with null mutations of ERα or ERβ or Klotho and their wild-type (WT) littermates. Accordingly, Females ERα Knockout (KO), ERβ KO and WT mice were placed in metabolic cages and had free access to food and distilled water. After adjustment, mice were injected daily with 17β-estradiol (estrogen) or vehicle for 3 days.

Results: The results indicate that estrogen-treated WT and ERβ KO mice exhibited a significant phosphaturia despite a reduction in food intake. The phosphaturic effect resulted from a significant downregulation of NaPi-IIa and NaPi-IIc protein abundance with no change in their mRNA expression levels. Interestingly, these effects were abolished in ERα KO mice. Further, the results showed that estrogen-treated Klotho KO mice exhibited hypophosphatemia and a significant downregulation of NaPi-IIa with no change in the abundance of NaPi-IIc. *In vitro* studies showed that estrogen treatment (24 hrs) of a cell line (U20S) stably co-expressing both ERα and ERβ caused a significant downregulation of NaPi-IIa protein, when cells are transiently transfected with a plasmid containing ORF-3'UTR but not 5'UTR-ORF of the mouse NaPi-IIa transcript.

Conclusions: In conclusion, estrogen causes phosphaturia in mice despite a reduction in food intake. This effect results from the downregulation of NaPi-IIa and NaPi-IIc protein abundance with no change in their mRNA expression levels. This effect is independent of Klotho/FGF23 pathway and is mediated through the exclusive activation of ERα. A Cis-acting element in the 3'UTR region of mNaPi-IIa mRNA likely plays an important role in the inhibition of its translation by estrogen.

TH-PO505

Effect of Calcitriol on Serum Hepcidin in Individuals with Chronic Kidney Disease Bhupesh Panwar, Orlando M. Gutierrez. *Univ of Alabama.*

Background: Anemia is highly prevalent in CKD. Elevated hepcidin levels are an important mediator of disordered iron metabolism, a key mechanism underlying anemia of CKD. Vitamin D was recently shown to reduce hepcidin levels in healthy individuals. We examined whether treatment with calcitriol reduces serum hepcidin in individuals with CKD.

Methods: 40 participants with stage 3/4 CKD (eGFR 15-60 ml/min) were randomized to placebo or oral calcitriol 0.5mcg daily for 6 weeks. Primary outcome variable was change in hepcidin levels. Secondary outcomes variables included change in iron parameters, calcium and hemoglobin. Samples were drawn at baseline, 3 days, 1 week and 6 weeks after randomization. Repeated measures analysis was used to examine differences in outcome variables over time in the 2 groups.

Results: At baseline, the only differences in the 2 groups were that hemoglobin and creatinine clearance were higher in the placebo vs. calcitriol arm (13.3±1.7 vs 12.2±1.9 mg/dL; and 69.7±26.8 vs 50.9±23.7 ml/min, respectively). Over 6 weeks of follow-up there were no significant differences in serum hepcidin, iron parameters, or hemoglobin between the 2 groups. There was a significant increase in serum calcium at 6 weeks in the calcitriol arm compared to the placebo.

Table 1. Median[IQR] or Mean±SD of outcome variables over a 6 week follow-up.

		Baseline	3 days	1 week	6 weeks
Hepcidin	Calcitriol	72[46,196]	79[39,146]	81[48,151]	91[39,180]
	Placebo	76[46,124]	77[46,121]	73[40,112]	64[39,94]
Ferritin	Calcitriol	140[84,390]	177[91,339]	177[91,339]	177[88,277]
	Placebo	176[73,296]	173[63,238]	173[63,238]	142[57,217]
Transferrin saturation	Calcitriol	25.3±12.5	24.1±7.9	24.9±15.8	23.5±10.5
	Placebo	23.2±8.1	23.6±7.8	22.7±7.6	21.5±5.5
Hemoglobin	Calcitriol	12.3±1.7	12.2±1.7	12.2±1.9	12.1±1.8
	Placebo	13.2±1.6	13.1±1.8	13.2±1.6	13.3±1.7
Calcium	Calcitriol	9.21±0.43	9.28±0.42	9.32±0.48	9.51±0.51*
	Placebo	9.34±0.29	9.39±0.36	9.39±0.36	9.48±0.37

Conclusions: Calcitriol did not reduce serum hepcidin levels among individuals with stage 3/4 CKD. Future studies are needed to assess if nutritional forms of vitamin D affect hepcidin levels in CKD.

TH-PO506

A Double Blind Randomized Trial to Compare the Effect of High-Dose Cholecalciferol versus Placebo on Secondary Hyperparathyroidism in Chronic Kidney Disease Stage 3-4 Per-Anton Westerberg,[1,3] Gunnar Sterner,[2] Osten Ljunggren,[1] Torbjorn Linde.[1] *[1]Medical Sciences, Univ Hospital, Uppsala, Sweden; [2]Nephrology, Skåne Univ Hospital, Malmö, Sweden; [3]Internal Medicine, Ryhov County Hospital, Jönköping, Sweden.*

Background: Suboptimal levels of calcidiol (25D) may accelerate secondary hyperparathyroidism (SHPT) in chronic kidney disease (CKD). The aim of this study is to determine if a substantial increase in 25D has beneficial effects on mineral metabolism, muscle strength or fatigue.

Methods: We conducted a double blind randomized trial (EudraCT 2011-002586-38) of cholecalciferol 8000IU/day versus placebo in 97 adult CKD3-4 patients with mild SHPT and a 25D level below 75 nmol/L. The primary endpoint was the difference in mean change, after 12 weeks, in intact PTH between those treated with cholecalciferol as compared to those recieving placebo. Other endpoints were the proportion of participants having a 30% reduction in PTH, hand grip strength and fatigue, assessed by a questionnaire, and differences in calcium, phosphate, calcitriol and FGF23. The statistical test of treatment effect was based on ANCOVA, with baseline value as covariate.

Results: 95 subjects completed the study. Their median age was 66 years, 64 were males and mean GFR was 32 ml/min/1.73 m^2. Baseline 25D were 57.5±23 and 56.8±22 nmol/L, and PTH 10.9±5 and 13.1±9 pmol/L in the cholecalciferol and placebo groups respectively. 25D increased to 161.6±49 nmol/L and PTH decreased slightly to 10.5±5 pmol/L in the treatment group, while 25D remained stable and PTH increased to 15.2±11 pmol/L in the placebo group. A significant difference in the mean change in PTH between the groups at 12 weeks ($P<0.01$) was recorded. There was no significant difference in the proportion of subjects reaching a 30% decrease in PTH. Additionally, there was no effect on grip strength or fatigue. The calcium level was unchanged in the treatment group, calcitriol increased distinctly from 64.5±43 to 101.5±54 pmol/L, while there were no effects on phosphate or FGF23.

Conclusions: High dose cholecalciferol increases calcitriol and alleviates the development of SHPT in CKD, without causing hypercalcemia or influencing muscle strength or fatigue.

TH-PO507

Comparison Between Paricalcitol and Non-Selective Vitamin D Receptor Activator for Secondary Hyperparathyroidism in Chronic Kidney Disease: A Systematic Review and Meta-Analysis Panpan Cai, Zi Li, Wei Qin, Xiaohong Tang. *Nephrology, West China Hospital Sichuan Univ, Chengdu, Sichuan, China.*

Background: Secondary hyperparathyroidism (SHPT) is a common complication of chronic kidney diseases (CKD). Paricalcitol is a tissue-selective vitamin D receptor activator (VDRA) with the promising effects of lower risks of hypercalcemia, hyperphosphatemia, and even calciphylaxis. We conducted a systematic review and meta-analysis to compare the efficacy and safety of paricalcitol and non-selective VDRA for the management of SHPT in CKD patients.

Methods: We comprehensively searched MEDLINE, Embase, the Cochrane takes Group's Specialized Register and CENTRAL database,collected all randomized controlled trials (RCTs) on comparison paricalcitol and VDRA in adult CKD patients with SHPT. A quality evaluation to every enrolled RCT was conducted. Analysis was performed using the statistical software Review Manager 5.2.

Results: A total of 8 trials involving 674 patients were identified for this review. The quality of included trials was limited. Except for one trial that mentioned two deaths, all other trials did not report all-cause mortality and vascular calcification. Paricalcitol effectively lowered the level of PTH (MD: -11.27, 95% CI: -18.70 to -3.85, P=0.003) but no significant difference was observed in the proportion of patients that achieved the target reduction of PTH between paricalcitol and non-selective VDRA (OR: 2.22, 95% CI: 0.91 to 5.40, P=0.08). No statistical differences were found among patients in terms of serum calcium, episodes of hypercalcemia, serum phosphorus, calcium×phosphorus products and bone metabolism index. The low quality of enrolled studies, lack of hard outcome, and multiple definitions of target PTH reduction composed the limitation of our systematic review.

Conclusions: Current evidence provides some support for the use of this selective VDRA in lowering PTH. No sufficient evidence is available to prove that VDRA can reduce the burden of mineral loading. Further trials are required given the limitation of current research.

TH-PO508

Paricalcitol and Calcitriol Exhibit Differential Effects on Gene Expression in Human Arteries Tzongshi Lu,[1] Li-lun Ho,[2] Thomas F. Hiemstra,[3] Daniel Zehnder,[4] Li-Li Hsiao.[1] *[1]Renal Div, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Chemical Engineering, Massachusetts Inst of Technology, Cambridge, MA; [3]School of Clinical Medicine, Univ of Cambridge, Cambridge, United Kingdom; [4]Univ Hospital Coventry and Warwickshire NHS Trust, Coventry, United Kingdom.*

Background: Vitamin D deficiency is common in patients with CKD, and therapeutic use of vitamin D receptor activators (VDRAs) may improve cardiovascular outcomes. The molecular targets of the VDRAs calcitriol and paricalcitol are incompletely understood.

Methods: We studied gene expression in human arterial explants from healthy individuals and CKD patients after exposure to calcitriol, paricalcitol or vehicle. We selected the leading differentially expressed genes based on log 2 ratio fold changes (Δ). Analysis utilized KEGG and DAVID.

Results: Calcitriol and paricalcitol exhibited differential effects on gene expression. Calcitriol induced expression of Toll-like receptor 4 (TLR4) (Δ 14369) and Nuclear Factor of Activated T-cells (NFAT) (Δ 3851) in healthy arteries. In CKD arteries, Calmodulin-dependent KinaseIIβ (CamKIIβ) (Δ7972) and HIF1β (ARNT) expressions were upregulated (Δ 235). Interestingly, TLR4 is involved in the HIF1 pathway, and NFAT is downstream of CamK in the non-canonical Wnt/calcium pathway. In contrast, paricalcitol significant upregulates Peroxisome Proliferator-Activated Receptor Gamma (PPARγ) (Δ 8461) in healthy arteries and AXIN1 (Δ 1933) in CKD arteries. AXIN1 is also involved in the Wnt signaling pathway.

Conclusions: Our data demonstrate differential effects of calcitriol and paricalcitol on gene expression in human arterial explants. This finding may provide important mechanisms in developing therapeutic strategies for the roles of VDRAs. Further investigation is needed.

TH-PO509

Paricalcitol and FGF23 Effects on the Progression of Cardiac Disease in Pediatric Hemodialysis Wacharee Seeherunvong,[1] Chryso P. Katsoufis,[1] Arpit Kumar Agarwal,[2] Sethuraman Swaminathan,[2] Phillip Ruiz,[3] Gaston E. Zilleruelo,[1] Carolyn L. Abitbol,[1] Michael Freundlich.[1] *[1]Pediatric Nephrology, Univ of Miami; [2]Pediatric Cardiology, Univ of Miami; [3]Pathology, Univ of Miami, Miami, FL.*

Background: FGF23 induces and Paricalcitol (Pc) attenuates left ventricular hypertrophy (LVH) in uremic animals. In adults CKD, Pc has not yet consistently improved LVH. We hypothesized that in young hemodialysis (HD) patients, Pc improves LVH and function despite ↑FGF23 levels.

Methods: Twenty patients (16±4 years) on HD (31±17 months) on Pc >6 months underwent longitudinal biochemical and echocardiography (Echo1 and Echo2) measurements. LV mass index (LVMI) reflects LV structure and shortening fraction (SF) systolic function. To assess LV diastolic function, early (E), late (A) diastolic trans-mitral (m), annular Em, septal Es, tricuspid annular Et velocities were measured with E/A, E/Em and E/Et ratios calculated. Values >2 Z-scores defined diastolic dysfunction. Echo results were reported as height-age adjusted Z-scores. The ratio of the cumulative average weekly Pc dose to the prevalent logFGF23 level (Pc/logF) was used as a reflection of the opposing hormonal effects.

Results: Overall Z-LVMI (1.7±1.3 vs. 2.0±1.8) was unchanged; LVH prevalence ↓ from 55% to 45% (¯Z-LVMI in 35%,p=0.01); SF was normal throughout. Abnormal E, Em and E/Em (in 30-61%) all improved by 25% on Echo2. Z-LVMI correlated with E/Et (r 0.6, p<0.01) suggesting concurrent ↑ LV mass with diastolic dysfunction. Pc dose correlated with Echo2 LVMI & E/Et (both r -0.5, p<0.05), indicating improved LVMI & diastolic dysfunction. LogFGF23 changes correlated positively with the changes of weekly Pc dose (p<0.05) and serum P (p<0.05). Pc/logF ratio (4.0±3.2) correlated with LVMI, wall thickness and E/Et (all r -0.5, p<0.05).

Conclusions: Diastolic dysfunction observed in 2/3 of young HD patients and concurrent LVH improved with Pc despite ↑FGF23 levels. The Pc/logF ratio associated significantly with LV structure and diastolic dysfunction and may reflect the net mechanistic effects of these hormones on myocardial hypertrophy and function. Studies in larger cohorts with higher and longer dose regimens of Pc are warranted.

TH-PO510

A Phase 2A Pharmacokinetic Study of an Oral Vitamin D Compound (2MD) in Patients on Dialysis with Secondary Hyperparathyroidism Daniel W. Coyne,[1] Richa A. Pandey,[1] Hector F. Deluca,[2,3] Julia B. Zella,[2,3] Lori A. Plum,[2,3] Margaret Clagett-Dame.[2,3] *[1]Renal Div, Washington Univ School of Medicine, Saint Louis, MO; [2]Biochemistry, Univ of Wisconsin-Madison, Madison, WI; [3]Deltanoid Pharmaceuticals, Inc., Madison, WI.*

Background: Dialysis patients frequently receive a vitamin D receptor agonist such as the endogenous hormonal form of the vitamin, calcitriol, or an analog (e.g. paricalcitol) for treatment of secondary hyperparathyroidism. Although effective, these drugs can cause hypercalcemia. 2MD is a new vitamin D analogue that suppresses parathyroid hormone (PTH) at doses that do not adversely affect serum calcium and phosphorus.

Methods: We enrolled 11 hemodialysis patients with secondary hyperparathyroidism for a pharmacokinetic (PK) study of oral 2MD. After a 4-week screening period that included a 2-week washout of current pharmaceutical vitamin D therapy, patients received 550ng of 2MD orally after each dialysis treatment for the next 4 weeks. PK studies were performed after the first and final dose.

Results: All eleven patients completed the study. At 4 weeks, the half-life (t1/2) of 2MD was 50.8 ± 25.8h, time to maximum plasma concentration (tmax) was 4.0 ± 2.4h and concentration maximum (Cmax) was 3.44 ± 0.89pg/ml, while the area under the curve (AUC (0-96h)) was 148.0 ± 38.7pg*h/ml. Similar results were observed after a single dose. Mean PTH was suppressed 32% and calcium and phosphorus did not change significantly.

Parameter (unit)[a]	First dose n = 10[b]	Week 4 n = 10
Cmax (pg/ml)	2.50 ± 1.16	3.44 ± 0.89
Tmax (hr)	2.1 ± 1.4	4.0 ± 2.4
AUC (0-t) (pg*hr/ml)	50.7 ± 18.5	148.0 ± 38.7
AUC (0-∞) (pg*hr/ml)	120.8 ± 59.5	204.3 ± 75.7
t1/2 (hr)	55.8 ± 36.8	50.8 ± 25.8

[a] all results are mean ± SD.
[b] One subject was excluded from the PPS because of a major protocol violation.

Conclusions: In hemodialysis patients, 2MD has a much lower Cmax and AUC but a much longer t1/2 than calcitriol and paricalcitol. These characteristics are consistent with its high potency and effectiveness in suppressing PTH without significant perturbations of calcium and phosphorus.

TH-PO511

Effect of a Novel Vitamin D Receptor Analog VS-105 on Chronic Kidney Disease-Mineral Bone Disorder Hideki Fujii, Yuriko Yonekura, Kentaro Nakai, Keiji Kono, Shunsuke Goto, Shinichi Nishi. *Div of Nephrology and Kidney Center, Kobe Univ Graduate School of Medicine, Kobe, Japan.*

Background: VS-105 is a novel vitamin D receptor (VDR) analog to suppress the progression of secondary hyperparathyroidism. Most important clinical problem is hypercalcemia, hyperphosphatemia and vascular calcification. In the present study, we compared the effect of VS-105 on chronic kidney disease-mineral bone disorder (CKD-MBD) to that of paricalcitol (Pari) using CKD model rats.

Methods: We used male Sprague Dawley (SD) rats and CKD was induced by 5/6 nephrectomy at 8 and 9 weeks. At 10 weeks, they were classified into six groups and were administered vehicle (V), low-dose paricalcitol (LP), high-dose paricalcitol (HP), low-dose VS-105 (LV), and high-dose VS-105 (HV) three times a week, except in the sham operation group (C) (the C, V, LP, HP, LV, and HV group). At 20 weeks, the rats were sacrificed and urinary and blood biochemical analyses and calcium contents of the aorta were performed in all the groups.

Results: At 20 weeks, serum calcium levels showed overall comparable results at low doses. However, at higher doses, serum calcium levels were highest in the HP group followed by the HV group. Serum phosphate levels were higher in the Pari treated-group than in the VS-105 treated-group. The urinary excretion of phosphate was greater in the VS-105 treated-group than in the Pari treated-group. Serum parathyroid hormone (PTH) levels were decreased and serum fibroblast growth factor-23 (FGF23) levels were elevated after administering Pari and VS-105; however, despite comparable serum PTH levels, serum FGF23 levels were remarkably elevated in the Pari treated-group compared to the VS-105 treated group. Calcium content of the aorta was higher in the Pari treated-group than in the VS-105 treated-group. The expressions of VDR and Klotho in the kidney were significantly higher in the VS-105 treated-group compared to Pari treated-group.

Conclusions: While serum PTH levels were similar, our data suggested that the effect of VS-105 on CKD-MBD was more favorable compared to paricalcitol. The mechanism appears to be associated with the difference in the expression of VDR and Klotho in the kidney.

TH-PO512

Vitamin D Receptor Modulators Suppress Vascular Remodeling in the Inflammatory State of Subtotally Nephrectomized Rats Masahide Mizobuchi,[1] Keiichi Sumida,[2] Takashi Inoue,[1] Nozomu Hosaka,[1] Hiroaki Ogata,[3] Fumihiko Koiwa,[4] Takanori Shibata.[1] *[1]Dept of Nephrology, Showa Univ School of Medicine, Tokyo, Japan; [2]Nephrology Center, Toranomon Hospital Kajigaya, Kawasaki, Japan; [3]Dept of Internal Medicine, Showa Univ Northern Yokohama Hospital, Yokohama, Japan; [4]Dept of Medicine, Showa Univ Fujigaoka Hospital, Yokohama, Japan.*

Background: Vitamin D receptor (VDR) modulators (VDRMs) have been shown to have pleiotropic effects. In this study we focused on this effect of a novel VDRM, VS-105 on the vasculature in 5/6 nephrectomized rats in which inflammation was induced by lipopolysaccharide (LPS).

Methods: Male SD rats were 5/6 nephrectomized and fed a normal diet. Two weeks after the nephrectomy, an infusion mini pump was implanted through a catheter placed into the right jugular vein; saline was infused for 7 days and LPS was infused for another 4 weeks. During the LPS infusion period, rats were treated (i.p. 3 times/week) with vehicle (propylene glycol; UC), calcitriol (0.015 μg/kg; CAL), or VS-105 (0.9 μg/kg; VS-105). Normal rats on the normal diet served as control (NC).

Results: The UC showed significant increase in serum TNFα levels (pg/ml) compared with NC (36.9 vs 11.0, P<0.05) suggesting the induction of systemic inflammation in

this model. Both VDRMs (CAL: 13.4, P<0.05 vs UC, and VS-105: 6.0, P<0.05 vs UC) significantly suppressed the increase in TNFα. Serum creatinine levels, significantly increased in the UC (P<0.05 vs NC), were not altered by the VDRMs. No statistical significance was observed in serum calcium and phosphorus among all 4 groups. The mRNA expression of PCNA in the aortic tissue was significantly increased in the UC (15.8-fold) compared with the NC (P<0.05), which was significantly suppressed by the VDRMs (CAL: 9.2-fold, P<0.05 vs UC, and VS-105: 5.0-fold, P<0.05 vs UC). A similar observation was made in the Nox4 mRNA levels (7.2-fold in UC, 1.3-fold in CAL, and 1.8-fold in VS-105).

Conclusions: These results demonstrate that VS-105 has a suppressive effect on vascular remodeling in the inflammatory state of 5/6 nephrectomized rats in which oxidative stress is involved, suggesting that VS-105 exhibits anti-inflammatory pleiotropic effects.

TH-PO513

Differential Effects of Ergocalciferol and Cholecalciferol Therapies in Chronic Kidney Disease Cassandra A. Kimber,[1] James B. Wetmore,[2] Jason R. Stubbs.[1] *[1]The Kidney Inst, Univ of Kansas Medical Center, Kansas City, KS; [2]Div of Nephrology, Hennepin County Medical Center, Minneapolis, MN.*

Background: Nutritional vitamin D deficiency is common in patients with chronic kidney disease (CKD) and may contribute to a variety of comorbidities. Prospective studies assessing the comparative efficacy of cholecalciferol and ergocalciferol for correction of 25(OH)D deficiency in CKD patients are lacking.

Methods: We conducted a prospective, randomized, double-blinded trial to assess the relative efficacy of ergocalciferol versus cholecalciferol, 50,000 IU weekly for 12 weeks, to raise serum 25(OH)D levels in vitamin D-insufficient CKD patients (n = 41). Serum 25(OH)D concentrations were assessed at baseline, during therapy (week 6), immediately post-therapy (week 12), and six weeks following discontinuation of therapy (week 18). The primary outcome was the absolute change in 25(OH)D from baseline to 12 weeks. Secondary analyses included change in 25(OH)D from weeks 12 to 18, as well as changes in PTH and $1,25(OH)_2D$ from baseline to 12 weeks.

Results: Mean baseline 25(OH)D concentrations were 20.5 ± 5.5 and 20.9 ± 6.3 ng/mL in the ergocalciferol and cholecalciferol groups, respectively. Cholecalciferol therapy resulted in a greater absolute change in 25(OH)D (45.0 ± 16.5 ng/mL) versus ergocalciferol (30.7 ± 15.4 ng/mL) from baseline to week 12 (p<0.01). However, this superiority of cholecalciferol was transient, as the cholecalciferol group had a more pronounced decline in 25(OH)D (-27.7 ± 19.5 ng/mL) compared to ergocalciferol (-13.2 ± 11.5 ng/mL) following the discontinuation of therapy (week 12 to 18; p<0.01). We observed no significant difference between these two therapies with regard to serum PTH or $1,25(OH)_2D$ changes.

Conclusions: Therapy with cholecalciferol, compared to ergocalciferol, is more effective at raising serum 25(OH)D concentrations in CKD patients while active therapy is ongoing; however, this superiority is offset by a more pronounced decline in 25(OH)D concentrations with cholecalciferol following discontinuation of therapy. We observed no significant difference in serum PTH or $1,25(OH)_2D$ changes between these two therapies.

TH-PO514

Effectiveness of High Dose Ergocalciferol versus Conventional Dose Ergocalciferol on 25-Hydroxyvitamin D Level in Chronic Kidney Disease Patients with Vitamin D Insufficiency Bancha Satirapoj,[1] Siwimon Areepong,[1] Panbubpa Choovichian,[1] Ouppatham Supasyndh.[1] *[1]Medicine, Phramongkutklao Hospital and College of Medicine, Bangkok, Thailand; [2]Phramongkutklao Hospital.*

Background: Patients with chronic kidney disease (CKD) have an exceptionally high rate of 25-hydroxyvitamin D (25OHD) deficiency. Progression of CKD and the all cause mortality link to 25-OHD deficiency. The *KDOQI* guideline, modest supplementation with ergocalciferol to raise serum 25-OHD levels and might improve bone and mineral disorders in CKD. There was limitation of evidence for dosage of ergocalciferol supplement in CKD population.

Methods: This was an open labeled, randomized, controlled study in CKD patients with stage III-IV and serum 25-OHD<30 ng/mL. The patients were randomized into two groups: conventional-group treated with ergocalciferol as recommended by K/DOQI guidelines or high-dose-group treated with double dosage of ergocalciferol from the recommendation. Serum testing including 25-OHD, intact PTH, phosphate, and calcium were performed at baseline and 12th weeks.

Results: Sixty-three patients with average aged 69.23±11.62 years were included. Characteristics of the two groups were similar at baseline. At the end of the 12-week, the mean 25-OHD level significantly increased from 18.98±7.25 to 27.95±10.06 ng/mL in the conventional-group (p<0.001) and increased from 18.15±7.44 to 32.08±9.04 ng/mL in the high-dose-group (p<0.001). There was also a significantly increase 25-OHD levels in high-dose-group compared with conventional-group (13.64±9.87 vs. 8.52±6.77 ng/mL, p= 0.03). Moreover, there was a significantly greater decrease in serum PTH level in the high-dose-group than in the conventional-group(-16.75±26.42 vs. -0.25±26.76 pg/mL, p= 0.03). Serum calcium and phosphate were not significantly different between the groups. There was no adverse effects associated with the treatment.

Conclusions: The studydemonstrated that oral high-dose ergocalciferol had higher efficacy for increasing 25-OHD and decreasing PTH level in patients with CKD than conventional-dose ergocalciferol after 12 weeks of treatment. The high-dose treatment might have potential effects on improved the bone and mineral disorders in patients with CKD.

TH-PO515

A Rapid Liquid Chromatography Tandem Mass Spectrometry (LC-MS/MS) Method for Measurement of 24,25-Dihydroxyvitamin D for the Identification of Patients with *CYP24A1* Mutations Hemamalini Ketha, Ravinder Singh, Rajiv Kumar. *Dept of Laboratory Medicine and Pathology, Dept of Medicine, Mayo Clinic, Rochester, MN.*

Background: Patients with inactivating *CYP24A1* gene mutations exhibit elevated serum $1,25(OH)_2D$ concentrations with resultant hypercalcemia, hypercalciuria and nephrolithiasis. The measurement of serum 25(OH)D to $24,25(OH)_2D$ ratios permits the identification of patients with *CYP24A1* mutations and is clinically valuable in the identification of patients who are candidates for subsequent *CYP24A1* gene sequencing. The objective of our study was to validate a LC-MS/MS assay for $24,25(OH)_2D$ ($-D_3$ and $-D_2$), to establish a range for normal serum 25(OH)D/$24,25(OH)_2D$ ratios and demonstrate the utility of such a ratio in patients with *CYP24A1* mutations.

Methods: We validated a LC-MS/MS assay for serum $24,25(OH)_2D_3$ and $-D_2$. Inter- and intra-assay imprecision, limits of detection (LOD), limits of quantitation (LOQ), analytical measurement range (AMR) and recovery were determined. Interference, carry over, stability and ion suppression studies were performed. The serum 25(OH)D/$24,25(OH)_2D$ reference interval in 91 normal subjects was established and similar measurements were performed in 34 patients with clinically suspected *CYP24A1* mediated hypercalcemia.

Results: The LOD and LOQ were 0.03 ng/mL and 0.1 ng/mL for $24,25(OH)_2D_3$ and 0.1 and 0.5 ng/mL for $24,25(OH)_2D_2$, respectively. Intra- and inter-assay imprecision was 4-15% across the AMR of 0.1-25 ng/mL. No interference was observed with 25(OH)D and $1,25(OH)_2D$. Intra- and inter-assay imprecision was 4-15% across the AMR of 0.1-25 ng/mL. A 25(OH)D/$24,25(OH)_2D$ ratio of 7-35 was observed in normal subjects whereas in patients with *CYP24A1* mutations 25(OH)D/$24,25(OH)_2D$ ratios were significantly increased (99-467; P<0.01). A 25(OH)D/$24,25(OH)_2D$ ratio of ≥99 identifies patients who are candidates for *CYP24A1* genetic testing.

Conclusions: Elevated 25(OH)D/$24,25(OH)_2D$ ratios support the diagnosis of reduced *CYP24A1* activity found in patients with mutations of the *CYP24A1* gene. A 25(OH)D/$24,25(OH)_2D$ ratio of ≥99 in a patient with hypercalcemia of unknown etiology warrants genetic confirmation by sequencing of the *CYP24A1* gene.

TH-PO516

Initiation of AMG 416 After Discontinuation of Cinacalcet Kenneth Liss,[1] Geoffrey A. Block,[2] Glenn Matthew Chertow,[3] Bastian Dehmel,[4] Yan Sun,[4] David M. Spiegel.[4] *[1]Hypertension and Nephrology Association, Eatontown, NJ; [2]Denver Nephrology, Denver, CO; [3]Div of Nephrology, Stanford Univ School of Medicine, Palo Alto, CA; [4]Amgen, Thousand Oaks, CA.*

Background: AMG 416 is a novel intravenous calcimimetic agent that has been shown to significantly decrease parathyroid hormone (PTH) without increasing serum phosphate (P) or the albumin-adjusted serum calcium (cCa) in two 26-week placebo-controlled randomized clinical trials.

Methods: This 4-week, multiple-dose single-arm, open-label safety study was conducted to assess the incidence of hypocalcemia (< 7.5 mg/dL and < 8.3 mg/dL; primary and secondary endpoints respectively) in patients treated with the intravenous calcimimetic AMG 416 after discontinuation of daily oral cinacalcet. Subjects on a stable dose of daily oral cinacalcet (30, 60, or ≥ 90 mg) for a minimum of 4 weeks before and during the 4 weeks of screening were enrolled and underwent a cinacalcet washout period of a minimum of 7 days. Subjects who had a serum cCa ≥ 8.3 mg/dL during the washout period were treated with AMG 416, 5 mg TIW after hemodialysis for 4 weeks followed by a safety observation period for 4 weeks. During the treatment period, the dose of AMG 416 could be restarted at 2.5 mg if a dose hold was required for low serum calcium or low PTH (two consecutive predialysis PTH < 100 pg/mL). Dose increases were not allowed.

Results: 158 subjects were enrolled and 148 completed the washout period and received AMG 416. 140 subjects completed the 4-week treatment period. The per-subject incidence (n, %) of low cCa during the 4 week treatment period was as follows: Prior cinacalcet dose cCa < 7.5 mg/dL cCa < 8.3 mg/dL 30 mg (N=63) 0 (0%) 18 (28.6%) 60 mg (N=47) 1 (2.1%) 4 (8.5%) ≥90 mg (N=35) 0 (0%) 1 (2.9%) No subject had a post-baseline cCa < 7.0 mg/dL and no subject developed symptomatic hypocalcemia. Eight subjects discontinued AMG 416: 4 due to subject request, 2 due to adverse events, 1 loss to follow up, and 1 due to death.

Conclusions: Treatment with AMG 416 at a starting dose of 5 mg can be safely initiated after a 7-day washout of cinacalcet therapy, provided that cCa is ≥ 8.3 mg/dL.

TH-PO517

Treatment with Cinacalcet Increases Plasma Sclerostin Concentration in Hemodialysed Patients with Chronic Kidney Disease and Secondary Hyperparathyroidism Andrzej Wiecek, Piotr Kuczera, Marcin Adamczak. *Dept of Nephrology, Transplantation and Internal Medicine, Medical Univ of Silesia, Katowice, Poland.*

Background: Sclerostin (Scl) is a paracrine acting factor which is expressed in the osteocytes and articular chondrocytes. Results of recent clinical studies suggest that Scl may decrease the osteoblast-related bone formation through the inhibition of the Wnt/b-catenin pathway. The aim of this prospective, single-arm, open-label clinical study was to assess the influence of six-month cinacalcet treatment on plasma Scl concentration in hemodialysed patients with secondary hyperparathyroidism (sHPT).

Methods: In 45 hemodialysed patients with sHPT (PTH>300 pg/ml) plasma Scl as well as serum PTH, calcium and phosphate concentrations were assessed before the first dose of cinacalcet and after 3 and 6 months of treatment. Repeated measures ANOVA with Bonferroni correction was used in the statistical analyses. The results are shown as means and 95% confidence index.

Results: Serum PTH concentration decreased significantly after 3 and 6 month of treatment from 1173 (905-1441) pg/ml to 859 (584-1134) pg/ml and to 700 (432-767) pg/ml; p for trend <0.0001, respectively. Mean serum calcium and phosphate concentrations remained stable during the treatment period. Plasma Scl concentration increased after 3 and 6 months of treatment from 1.39 (1.20-1.58) ng/ml to 1.47 (1.27-1.67) ng/ml and to 1.55 (1.32-1.79) ng/ml; p for trend = 0.04, respectively. There were no significant correlations between the magnitude of the plasma sclerostin increase and the decrease of serum PTH concentration after 3 or 6 months of treatment (r=-0.006;p=0.97 and r=0.004;p=0.98), respectively.

Conclusions: In hemodialysed patients with secondary hyperparathyroidism treatment with cinacalcet increases plasma sclerostin concentration which seems to be independent from the concomitant decrease of parathormone concentration.

The Effect of Cinacalcet Persistence on Risk of All-Cause Mortality and Heart Failure

Diane Reams,[1] Paul Dluzniewski,[3] Abhijit V. Kshirsagar,[2] Brian D. Bradbury,[3] Liron Walsh,[3] M. Alan Brookhart.[1] *[1]UNC Gillings School of Global Public Health, Chapel Hill, NC; [2]UNC Kidney Center, Chapel Hill, NC; [3]Amgen, Inc., Thousand Oaks, CA.*

Background: Cinacalcet (Sensipar®) discontinuation occurs frequently for medical and non-medical reasons, such as parathyroid hormone levels below 150 pg/mL and medication cost. However, the clinical impact of discontinuing calcimimetic therapy is not well studied. We compared the risk of mortality and congestive heart failure (CHF) hospitalization between individuals with persistent cinacalcet use and patients who discontinued therapy for pre-defined non-medical indications.

Methods: Using data from a large dialysis provider merged with data from the USRDS, we identified new users of cinacalcet (2007-2011) from Part D prescription claims. Cinacalcet discontinuation was assessed in 30-day intervals and classified as either for medical or non-medical reasons. CHF hospitalizations were defined as ICD-9 code 428.x in the primary position, with a broader definition used in a sensitivity analysis. Informative censoring was addressed using inverse probability of censoring weighted (IPCW) estimators. The risk differences (RD) and 95% CI's for mortality and CHF hospitalizations were estimated at pre-specified follow-up times by comparing crude and IPCW cumulative risk functions.

Results: We identified 21,827 cinacalcet initiators who contributed 340,622 30-day follow-up intervals. At 12 months, 3,246 initiators (14.9%) had discontinued for medical indications and 12,077 initiators (55.3%) had discontinued for non-medical indications. We observed RDs for all-cause mortality at 12 months and 24 months, RD = -0.03 (95% CI -0.02, -0.03) and -0.04 (95% CI -0.03, -0.05), respectively. For CHF hospitalizations at 12 months and 24 months, RD = -0.00 (95% CI 0.00, -0.00) and -0.00 (95% CI 0.01, -0.01), respectively.

Conclusions: Our results find that approximately 3 extra deaths per 100 persons occur with discontinuation due to non-medical reasons during the first year of treatment. Reduction in risk for CHF hospitalization was evident when a broader definition of hospitalization was used, but no effect was seen with a more specific definition.

TH-PO519

A Bayesian Meta-Analysis of Randomized and Observational Studies on Cinacalcet and Mortality in Secondary Hyperparathyroidism

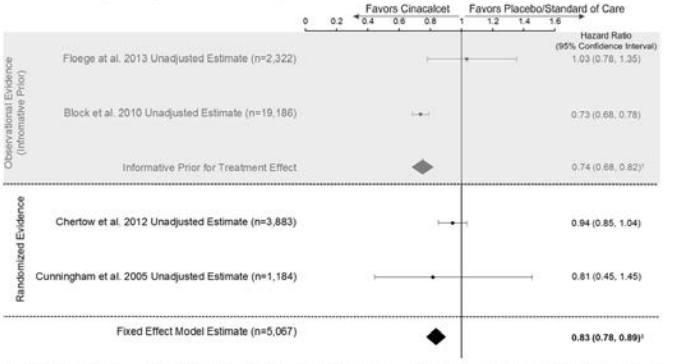
Mark E. Bensink,[1] Greta Lozano-Ortega,[2] Geoffrey A. Block,[3] Glenn Matthew Chertow,[4] Sarah Goring,[2] Heather Bennett,[2] Marie-Louise Trotman,[1] Kerry Cooper,[1] Adrian R. Levy,[5] Vasily Belozeroff.[1] *[1]Amgen Inc., Thousand Oaks, CA; [2]ICON plc, Vancouver, BC, Canada; [3]Denver Nephrology, Denver, CO; [4]Stanford Univ, Palo Alto, CA; [5]Dalhousie Univ, Halifax, NS, Canada.*

Background: Conventional meta-analyses of therapeutic effects focus on randomized controlled trials (RCTs) and exclude valuable information captured in observational studies. We conducted a meta-analysis of the effect of cinacalcet in treating secondary hyperparathyroidism (sHPT) in patients with end stage renal disease (ESRD) using methodology that allows for incorporation of non-RCT evidence.

Methods: We searched MEDLINE, EMBASE, the Cochrane Central Register of Controlled Trials (2000-Februrary 2014) for RCTs and observational studies in which cinacalcet was compared to placebo or standard of care using all-cause mortality as an endpoint. A high Grading of Recommendations Assessment, Development and Evaluation (GRADE) score was used as an entry criterion. We applied a Bayesian approach where evidence from observational studies was used as the informative prior for treatment effect for the meta-analysis of RCTs.

Results: A total of 616 abstracts were identified. High quality studies meeting inclusion criteria included 2 RCTs and 2 observational. There was insufficient data to estimate between-study variance under a random effects model. The fixed effect hazard ratio estimate (95% credible interval) for the effect of cinacalcet on mortality was 0.83 (0.78, 0.89).

Fig. 1 Bayesian Meta-Analysis Evidence and Evidence Synthesis



†Estimate (95% Credible Interval based on the posterior standard deviation from meta-analysis of RCTs with uninformative prior for treatment effect)
‡Estimate (95% Credible Interval)

Conclusions: This Bayesian meta-analysis of high quality studies indicates potential beneficial effects of cinacalcet on mortality in ESRD patients with sHPT.

TH-PO520

WELCOME – Web-Based Evaluation of Clinical Benefit of Cinacalcet in End-Stage Renal Disease in Central and Eastern Europe

Jaroslav Rosenberger,[1] Piotr Mierzicki,[2] Alexander Selyutin,[3] Frantisek Svara,[4] Kinga Jedynasty.[5] *[1]FMC, Kosice, Slovakia (Slovak Republic); [2]SP Wojewodzki Szpital Specjalistyczny, Chelm, Poland; [3]Regional Clinical Hospital Orenburg, Orenburg, Russian Federation; [4]Dept of Medicine, Strahov General Univ Hospital, Prague, Czech Republic; [5]CEE Headoffice, Amgen GmbH, Vienna, Austria.*

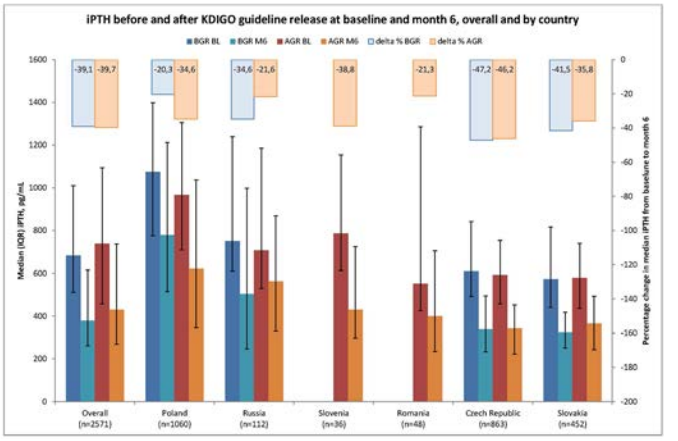
Background: Cinacalcet (MIM) is approved for treatment of secondary hyperparathyroidism (sHPT) in ESRD. Study objective: to describe KDOQI target achievement and treatment patterns before release of KDIGO guidelines (BGR; cut-off 08/2009) and thereafter (AGR).

Methods: Design: multicenter, non-interventional, observational study from CEE. Dialysis patients (pts) starting MIM £1 month prior enrollment (BL) were eligible. Primary endpoint: % achieving PTH £300 pg/mL after 6 months. Secondary endpoints: % at KDOQI target for Ca or P at BL and 6 months; MIM dose; vitamin D sterol (VitD) and phosphate binder (PB) use; adverse drug reactions (ADR). The 2nd interim analysis is reported on 12 cohorts enrolling between 01/2007-12/2012. 4 of 6 countries enrolled pts BGR (Figure).

Results: 2571 pts were enrolled, 2172 (84.5%) completed ³144 days of MIM.

	BGR N=824		AGR N=1747	
	BL	6-mo	BL	6-mo
PTH ≤300 pg/mL (%)	2.8	32.2	1.6	29.1
PTH (pg/mL), median (IQR)	683 (510-1011)	379 (261-615)	739 (547-1094)	430 (269-738)
Ca 8.4-9.5 mg/dL (%)	46.4	58.9	49.5	49.8
P 3.5-5.5 mg/dL (%)	23.7	35.6	32.3	42.5
PB use (%)	82.5	61.7	84.6	61.7
VitD use (%)	59.0	40.5	59.0	43.2

Average median (IQR) MIM dose was 30 (30-42; BGR) and 30 (30-43) mg/day (AGR). Substantial differences in PTH were observed between countries.



110 patients (4.3%) reported ADR (gastrointestinal disorders, n=37; hypocalcemia, n=12); serious ADR: n=2 (cholecystitis, cholelithiasis) in 1 pt. All-cause mortality: 3.1%.

Conclusions: Overall, median PTH was not changed AGR. MIM substantially reduced PTH. Treatment practice varied by country.

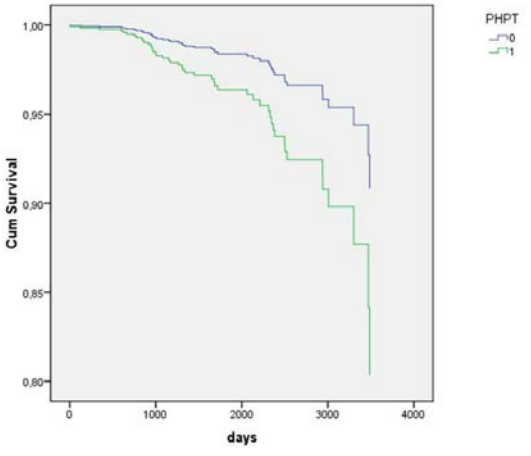
TH-PO521

Persistent Hyperparathyrodism as a Risk Factor for Long Term Graft Dysfunction Maria Julia C. L. N. Araujo, Melani Custodio, Janaina de Almeida Mota Ramalho, William C. Nahas, Rosilene M. Elias, Vanda Jorgetti, Elias David-Neto, Rosa M.A. Moyses. *Nephrology, Univ of Sao Paulo, Sao Paulo, Brazil.*

Background: A successful kidney transplant (KTx) improves most of the mineral disturbances produced by CKD, but some disorders may persist for several years, such as hypercalcemia, elevated PTH and low phosphorus. Previous studies have shown the negative impact of persistent hyperparathyroidism (PHPT) on one year graft function. However, the long term effects of PHPT on renal function are poorly known. Based on that, we aimed to analyze the impact of PHPT on long term graft outcome.

Methods: Retrospective analysis of the isolated adult KTx that ocurred between 01/2005 and 12/2014 at the Hospital das Clinicas - USP. Clinical and laboratory data were collected from the charts. Graft failure was defined as return to dialysis. PHPT was considered when, one-year after Ktx, ionized calcium was > 5,3 mg/dl or PTH >100 pg/ml.

Results: From the total of 1708 Ktx occurred in this period, we analyzed 1102 patients that, one year after KTx had an eGFR>30 ml/min and available data for analysis. Of those, 28% (318) had hypercalcemia and 32% (356) had an elevated PTH. PHPT was present in 47% of the patients. The mean follow up time was 1689 days. Graft failure was observed in 47 patients (33 in PHPT and 14 in non-PHPT group, HR = 1,5; p <0,05). Cox-regression analysis showed that graft failure was dependent on PHPT (β=2.3; 1.3-4.1; p= 0.007) even after adjustment for age at KTx, donor age, donor type, PTX and eGFR at 1 year after KTx, as shown in Figure.



Conclusions: Individuals with PHPT one year after KTx, even those with slightly elevated calcium or PTH, have an increased risk of long term graft failure. Our results call our attention for a better management of CKD-MBD before KTx and during the first year of follow-up.

TH-PO522

Epigenetic Alterations in Secondary Hyperparathyroidism Gonzalo Bedia-Diaz,[1] Agustin F. Fernandez,[2] Jorge B. Cannata-Andia,[1] Adriana S. Dusso,[1] Pablo Roman-Garcia.[1] *[1]Bone and Mineral Research Unit, Hospital Univ Central de Asturias, Univ de Oviedo, RedinRen, Oviedo, Spain; [2]Epigenetics, Hospital Univ Central de Asturias, Oviedo, Spain.*

Background: Secondary hyperparathyroidism (sHPT) is a complication of CKD characterized by a decreased expression not only of genes such as the VDR, CaSR and Klotho, critical to control parathyroid growth and PTH secretion, but also of 80% of the parathyroid genome. Increased parathyroid DNA methylation in sHPT is an epigenetic change that could account for this widespread down-regulation of gene expression. This work examined the contribution of epigenetic alterations to the severity of sHPT.

Methods: To study methylation patterns in the promoter of the VDR, CaSR, Klotho and PTH genes, the methylation-prone areas in the promoter of each gene were identified and amplified using specific biotin-labelled primers. Parathyroid glands were collected from control and severely uremic rats

Serum biochemical parameters of uremic and control rats. Avg +/- SD

	Urea (mg/dL)	Creatinine (mg/dL)	Ca (mg/dL)	P (mg/dL)	PTH (pg/mL)	FGF23 (pg/mL)
Control	111.67±36.10	1.03±0.38	11.93±0.38	7.55±3.96	255.83±518.22	273.69±76.84
sHPT/Uremic	206.50±53.51	2.10±0.39	10.42±1.14	12.38±1.72	1836.83±495.56	3895.50±385.62
pValue	0.01	0.0001	0.02	0.03	0.0002	0.0008

Parathyroid gDNA was extracted and treated with bisulphite to protect methylated cytosines. Specific PCRs were performed, purified and the PCR product, pyro-sequenced.

Results: Only the Klotho promoter was hyper-methylated (147.2% compared to controls-100%) supporting an epigenetic transcription blockage for this gene. In contrast, the VDR and CaSR promoters were robustly hypo-methylated in sHPT (46.7% and 67%, respectively), thus favouring rather than impairing gene transcription. Importantly, the PTH promoter was also significantly hypo-methylated (50.2%). Taken together, these results support an unrecognized contribution of epigenetic modifications to increase the PTH synthesis in sHPT, and to compensate for the marked reductions in VDR and CaSR expression.

Conclusions: Identification of the regulators of these distinct and gene specific epigenetic changes could provide novel targets for therapeutic interventions to improve outcomes in advanced sHPT.

Funding: Government Support - Non-U.S.

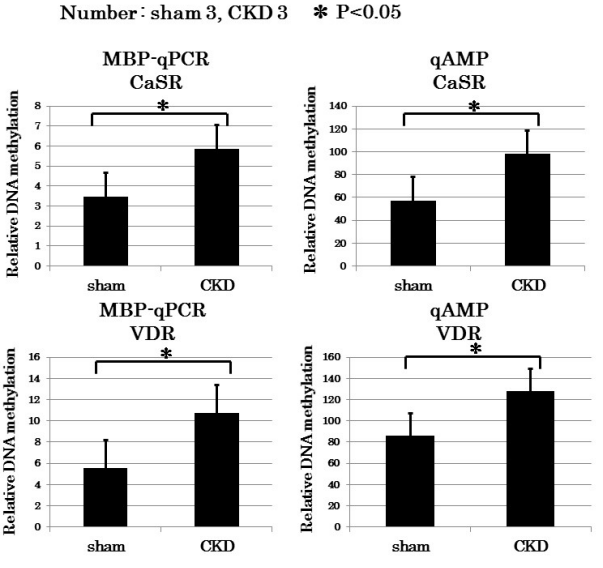
TH-PO523

Chronic Kidney Disease Caused Hypermethylations of CaSR and VDR Genes in Parathyroid Glands Taketo Uchiyama,[1,2] Norifumi Tatsumi,[1] Ichiro Ohkido,[2] Takashi Yokoo,[2] Masataka Okabe.[1] *[1]Dept of Anatomy, The Jikei Univ School of Medicine, Minato-ku, Tokyo, Japan; [2]Div of Nephrology and Hypertension, Dept of Internal Medicine, The Jikei Univ School of Medicine, Minato-ku, Tokyo, Japan.*

Background: The stability of mineral homeostasis is the most important for the health of the organism. Secondary hyperparathyroidism (SHPT), a common disorder in patients with chronic kidney disease (CKD), occurs during early course of progressive renal insufficiency. It is well known that the reduction of calcium sensing receptor (CaSR) and vitamin D receptor (VDR) occur slowly and progressively, however the mechanism is largely unknown. Upstream transcription factors of CaSR and VDR are not clear except Glial cells missing 2 (Gcm2), it has affected the CaSR gene directly and transactivates by Gcm2 response elements in the CaSR promoters. In recent years there are reports about epigenetic studies in the field of various diseases including CKD. However, there are few reports related to mineral homeostasis. Here we investigated altered expressions of CaSR, VDR in CKD rats' parathyroid glands. We then demonstrate that the pathogenomic change of SHPT, the reductions of CaSR and VDR expressions proceed from hypermethylations of CaSR and VDR genes.

Methods: Taqman probe (ABI) were used for quantitative real-time PCR. DNA methylation analysis was performed using a restriction digestion and quantitative PCR (qAMP), a combination of methyl-binding protein (MBP) and quantitative PCR (MBP-qPCR). CKD was induced by two-step 5/6 nephrectomy.

Results: The expression level of Gcm2 was not significant both in CKD rats and controls. We then found hypermethylations of CaSR and VDR in CKD rats.



Conclusions: These results suggest that CaSR reduction was independent to the Gcm2 expressions in CKD rats, and chronic kidney disease caused hypermethylations of CaSR and VDR genes in parathyroid glands.

TH-PO524

Proteomic Comparative Analysis of Parathyroid Oxyphil Cell and Chief Cell Nodules of Uremic Secondary Hyperparathyroidism Patients Shensen Li, Qian Zhang, Minmin Zhang, Jing Chen. *Div of Nephrology, Huashan Hospital, Shanghai Medical College, Fudan Univ, Shanghai, China.*

Background: Secondary hyperparathyroidism (SHPT) is the common abnormality in CKD patients. Hyperplasia of the parathyroid gland (PG) was considered to be an important processes in SHPT pathology. Physiologically, PG mainly composed of chief cells (CC, 95-99%) and oxyphil cells (OC, 1-5%). Our previous study shown that OC in PG were significantly increased in uremic SHPT patients and closely related to oral calcitriol dose

and treatment duration. In order to investigate OC proliferation and vitamin D metabolism, we conducted proteomic analysis to compare differences between PG OC and CC nodules from SHPT patients.

Methods: Two pairs of PG OC and CC nodules were selected to conduct proteomic (liquid chromatography tandem mass spectrometry). The protein expression were quantified and filtered by more than 2-fold between two groups. By using bioinformatics analysis, the protein expression profiles were sorted to several terms (cellular component, molecular function and biological process). Vitamin D metabolism were further analyzed in both cell type groups.

Results: 14691 unique peptides were identified and 2675 proteins were quantified. A total of 174 proteins (6.5%) were more than 2-folds up/down expressed in OC nodules compared to CC nodules (40 increased and 134 decreased in OC nodules). Bioinformatics analysis showed that in cell components, membrane structure including mitochondrial (47.89%) were most significantly differences. In molecular function, protein with binding capacity (38.46%) were the major differences. In biological processes, protein and energy metabolism (33.92%), cell replication and cycle regulatory (10.14%) were significantly differences. Vitamin D transport and metabolic regulation proteins were less expressed in OC than CC nodules, among which, the decreasing of vitamin D binding protein in OC nodules were the most significantly (0.32 times of CC nodules).

Conclusions: Protein, energy metabolism, cell stress and cell cycle regulation are significant differences in the OC from CC nodules. Vitamin D transport and metabolic regulation proteins were less expressed in OC than CC nodules.

Clinical Outcomes in Japanese Chronic Kidney Disease Patients Aged Over 65 Years: A Report from the Gonryo Study Tae Yamamoto,[1] Mariko Miyazaki,[1] Masaaki Nakayama,[2] Gen Yamada,[1] Hiroshi Sato,[1] Sadayoshi Ito.[1] *[1]Tohoku Univ, Sendai, Japan; [2]Fukushima Medical Univ, Fukushima, Japan.*

Background: Japan will become a full-fledged aged society. Aging is a risk factor for progression of chronic kidney disease (CKD) and CKD is common in elderly population. However the information of clinical feature of elder CKD is limited.

Methods: We prospectively followed up 1,750 elder outpatients over 65 years old under the care of nephrologists. Inclusion criteria was the basal age over 65 years, and estimated glomerular filtration rate < 90 mL/min and/or proteinuria. Survival, censored for RRT, was recorded for a follow-up time of 5 years. Patients were divided into 3 age groups, 65-74, 75-85 and over 85 years old, and stratified by CKD stages. The effects on outcomes were evaluated, and assessed in association with body mass index (BMI).

Results: Among 1,750 patients, the median age 74 (min 65- max98) years and males 49.8%, and 118 died and 200 patients started RRT during a median follow-up of 4.60 (qurtile 1.84 – 5.00) years. The ESKD incidence did not differ among age groups. While the risk for survival increased in the higher aged groups (Log-Rank c^2=62.93, P <0.0001), and the incidence rate was higher than that of ESKD in the over 85 years group (164.7 vs. ESKD 126.9 per 1,000 persons per year). When patients were divided by CKD stages, patients with G5 progressed mainly ESKD in all groups, on the other hand, the context of all-cause mortality increased even in G3 and G4 in the higher aged groups compaerd to ESKD. In competing models, the survival risk before developing ESKD associated significantly with high age, smoking, low BMI, low palse pressure and history of cardiovascular disease, but did not with diabetes, renal function, proteinuria and hemoglobin level. A high BMI, which decreased significantly in the higher aged groups (P = 0.043), predicted a better survival in patients over 85 years old, but had no clear effects in patients under 75 years old.

Conclusions: The content of clinical outcomes were different among generations in elder CKD especially in CKD G3-4.In patients over 85 years increased the survival risk before developing ESKD, and the lower BMI associated the higher risk.

TH-PO526

Undocumented Immigrant and Uninsured Status Are Independent Risk Factors for Chronic Kidney Disease Progression Orlando Nicholas Machado,[1] Ilay Rakhman,[1] Jonathan M. Wyrick,[2] Brittany Kalosza,[2] George N. Coritsidis.[1,2] *[1]Div. of Nephrology, Elmhurst Hospital Center, MSSM, Elmhurst, NY; [2]Dept of Surgery, Elmhurst Hospital Center, MSSM, Elmhurst, NY.*

Background: Being uninsured is a risk factor for chronic kidney disease (CKD) progression to end stage renal disease (ESRD). Undocumented immigrants (UI)belong to a vulnerable group in terms of healthcare. Little is known about the association of UI status and CKD progression.

Methods: Records of adult patients admitted to Elmhurst Hospital Center from 2009 to 2014 with CKD stage 4 or 5 as diagnosis or comorbidity were analyzed. ESRD patients were excluded. Covariates analyzed included sex, age, documentation (Social Security Number) and insurance status. Data was analyzed using STATA; Pearson's Chi Squared test was used for bivariate analyses.

Results: Of 703 patients analyzed: 81% had insurance (n=569), 19% were uninsured (n=134), 84% were documented (DOC, n=588), and 16% were UI (n=115). Of the DOC, 89% had insurance (n= 525) vs. 38% (n=44) of UI (p<0.005) and were older than UI (71±15 vs. 59±15, p<0.005). 21% of CKD patients progressed to ESRD (n=151): 20% of DOC compared to 30% of UI (p<0.05). Analyzed by insurance status, 18% of the insured developed ESRD compared to 36% of the uninsured (p<0.0001). On bivariate level, UI was associated with ESRD progression (p<0.05). On multivariate level, documentation status lost significance, but insurance status remains significant for ESRD progression.

Likelihood of Progression to ESRD		
	Model 1 OR(95% CI)	**Model 2 OR(95% CI)**
Documentation Status		
DOC	1.00	1.00
UI	1.18(0.74-1.89)	0.90(0.53-1.53)
Gender		
Male	1.00	1.00
Female	0.82(0.56-1.20)	0.79(0.54-1.16)
Age		
18-59	1.00	1.00
60-79	0.63(0.41-0.94)*	0.70(0.46-1.08)
80-99	0.18(0.10-0.33)**	0.21(0.11-0.39)**
Insurance Status		
Insured		1.00
Uninsured		1.81(1.10-2.10)*
Model 1: Controlling for Documentation Status Gender and Age		
Model 2: Controlling for above and Insurance Status		
**p<0.05, **p<0.0005*		

Conclusions: Documentation and insurance status are associated with ESRD progression. Once controlling for demographic variables, documentation status is no longer significant, but insurance status remains significant for progression.

TH-PO527

The Impact of Medical Comorbidities on Renal Function following Radical or Partial Nephrectomy Michael J. Vacchio, Andrew G. Winer, Emily C. Zabor, A. Ari Hakimi, Paul Russo, Jonathan A. Coleman, Edgar A. Jaimes. *Memorial Sloan-Kettering Cancer Center, New York, NY.*

Background: Increasing utilization of nephron sparing surgery (NSS) for kidney tumors has led to superior renal functional outcomes while maintaining oncologic control. However, the impact of comorbidities on post-nephrectomy renal function is not well understood. Here, we aim to identify patient and disease characteristics which have an adverse impact on renal function following nephrectomy.

Methods: We conducted a retrospective review of data on 440 patients who underwent robotic partial (PN) or radical nephrectomy (RN) for renal tumors by a single surgeon between 2006 and 2014 at our institution. Loess plot was generated to visually assess renal function over time. Univariable and multivariable longitudinal regression analyses incorporated a random intercept and slope to evaluate the association between patient and disease characteristics with renal function following surgery.

Results: Advanced age at surgery, larger tumor size, male sex, history of smoking, hypertension and higher ASA score were significantly associated with lower preoperative estimated glomerular filtration rate (eGFR). On multivariate analysis, independent predictors of reduced renal function following surgery were advanced age, lower preoperative eGFR, and RN. Length of time from surgery was strongly associated with improvement in renal function among all patients.

Table. Multivariable linear mixed effects regression for the association between patient and disease characteristics with eGFR following surgery. Estimates presented are for the fixed effect of the factor of interest.

	Estimate	Std.Error	p-value
Age	-0.389	0.045	0.000
Tumor Size	-0.102	0.186	0.582
Pre-op GFR	0.744	0.030	0.000
HTN	-0.297	1.026	0.773
Radical procedure	-9.590	1.770	0.000
Former smoker	-0.063	1.029	0.951
Current smoker	1.936	1.964	0.325
Months followup	0.120	0.018	0.000

Conclusions: Independent predictorsof post-operative decline in renal function include advanced age, lower pre-operative eGFR and RN. A significant number of subjects had recovery in renal function over time following surgery which continued past the 12 month mark. These findings suggest that patients undergoing nephrectomy can experience long-term improvement in renal function. This improvement is greater among younger patients with higher pre-operative eGFR undergoing PN.

A Longitudinal Analysis of Chronic Kidney Disease and Related Comorbidities Among Human Immunodeficiency Virus (HIV) Patients

Grace Mccomsey,[1] Nicole M. Meyer,[2] Xue Song,[2] Jonathan A. Winston.[3] *[1]Case School of Medicine, Cleveland, OH; [2]Truven Health Analytics, Cambridge, MA; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Patients with HIV infection can present with or develop multiple comorbidities including risk factors for chronic kidney disease (CKD). This study examined CKD and comorbid conditions in HIV patients in the US.

Methods: Adults diagnosed with HIV (ICD-9 code: 042.xx, 795.71, V08) in 2007-2013 were selected from MarketScan Commercial, Medicare, and Medicaid Databases. Patients were continuously enrolled for ≥ 365 days in 2007-2013 and stratified by the presence of CKD based on diagnosis codes. Comorbidities, prevalence (per 1,000 patients), and incidence (per 1,000 patient-years) of CKD in 2007-2013 were assessed.

Results: A total of 31,229 HIV patients (mean age: 42.8; male: 77.9%; mean Deyo-Charlson comorbidity index (CCI): 6.0) were selected from Commercial data, 1,541 (mean age: 71.9; male: 62.7%; CCI: 7.9) from Medicare, and 10,190 (mean age: 42.9; male: 44.1%; CCI: 7.0) from Medicaid. CKD prevalence and incidence were, respectively, 48.6 and 13.1 in Commercial, 242.1 and 61.1 in Medicare, and 114.3 and 28.4 in Medicaid. Prevalence and incidence increased over time. During 2007-2013, end-stage renal disease (ESRD)/dialysis patients accounted for 1.8% of Commercial, 7.7% of Medicare and 4.8% of Medicaid patients. Common CKD risk factors included hypertension (Commercial: 32.5%; Medicare: 77.0%; Medicaid: 55.5%), hyperlipidemia (30.6%, 52.7%, 33.8%), diabetes (11.2%, 36.9%, 25.1%), cardiovascular disease (6.4%, 34.4%, 15.5%), and obesity/overweight (7.0%, 7.5%, 16.9. Annual incremental healthcare costs in 2013 were higher in CKD patients than non-CKD patients (Commercial: $16,406; Medicare: $6,879; Medicaid: $5,663).

Conclusions: We observed an increase in CKD prevalence and incidence over time in HIV-infected person. Because of the potential effects of ART treatment on CKD observed in published data, understanding CKD risk factors of HIV patients will help optimize care of patients, including choice of antiviral regimens and screening and treating of these risk factors.

Association of Short Sleep Duration and Rapid Decline in Renal Function

Ciaran Joseph McMullan, Gary C. Curhan, John P. Forman. *Renal Div, Brigham and Women's Hospital, Boston, MA.*

Background: The kidney, like all other organs in the human body, is influenced by circadian rhythms, allowing renal function to be entrained to the sleep-wake cycle. Coordination of this periodicity in the kidney permits anticipation of the metabolic and physiological demands of the kidney throughout a 24-hour cycle. Unsurprisingly, disruption of the sleep-wake cycle may lead to disruption of renal physiology. Although sleep disruption has been studied extensively in cardiovascular and metabolic disease, its association with chronic kidney disease has not been shown.

Methods: In a prospective cohort study of 4238 participants from the Nurses' Health Study with renal function measured on at least two occasions, we analyzed the association of self-reported sleep duration with decline in renal function over an 11year period.

Results: Individuals who reported shorter sleep duration were more likely to experience a rapid decline in estimated glomerular filtration rate (≥ 25% decline from 1989 to 2000). Compared with sleeping 7-8 hours per night, the adjusted odds ratios for a rapid decline in renal function were 1.65 (95% CI, 1.06-2.55) for ≤5 hours sleep per night, 1.31 (95% CI, 1.06-1.61) for 6 hours sleep per night, and 0.78 (95% CI, 0.48-1.25) for ≥9 hours sleep per night. Similarly, adjusted annualized decline in estimated glomerular filtration rate was 1.2 ml/min/1.73m^2/year, 0.9 ml/min/1.73m^2/year, 0.8 ml/min/1.73m^2/year, and 0.8ml/min/1.73m^2/year for individuals sleeping ≤5 hours per night, 6 hours per night, 7-8 hours per night, and ≥ 9 hours per night, respectively (p-trend = 0.02).

Conclusions: Shorter sleep duration is prospectively and independently associated with faster decline in renal function.

Impairment of Endogenous Nighttime Melatonin Secretion Relates to Intrarenal Renin-Angiotensin System Activation and Renal Damage in Patients with Chronic Kidney Disease

Sayaka Ishigaki,[1] Naro Ohashi,[1] Shinsuke Isobe,[1] Takayuki Tsuji,[1] Akihiko Kato,[2] Hideo Yasuda.[1] *[1]Internal Medicine 1, Hamamatsu Univ School of Medicine, Hamamatsu, Shizuoka, Japan; [2]Blood Purification Unit, Hamamatsu Univ School of Medicine, Hamamatsu, Shizuoka, Japan.*

Background: Activation of the intrarenal renin-angiotensin system (RAS) plays a critical role in the pathophysiology of chronic kidney disease (CKD) and hypertension. Recently, we have demonstrated that the circadian rhythm of intrarenal RAS activation leads to renal damage and hypertension. Melatonin is considered as a major hormone regulating the circadian rhythm and nocturnal melatonin concentrations are reduced in patients with CKD. However, it has not known whether the impairment of endogenous melatonin secretion is related to BP, intrarenal RAS or renal damage in patients with CKD.

Methods: We recruited 53 patients with CKD stage 1-5 and 24-hour ambulatory BP monitoring (ABPM) and urine collection divided into daytime and nighttime were conducted. We investigated the relationship among urinary 6-sulphatoxymelatonin (U-aMT6s), that is the major melatonin metabolite, BP, renal function, urinary angiotensinogen (U-AGT), and urinary protein (U-P) in daytime and nighttime, respectively.

Results: The nighttime U-aMT6s levels were decreased according to the progression of CKD stage and those in CKD stage 5 was significantly decreased compared with those in other CKD stages. The U-aMT6s levels were significantly and negatively correlated with the clinical parameters such as renal function (serum creatinine), systolic BP, U-AGT and U-P in both daytime and nighttime. Multiple regression analyses for U-aMT6s levels were performed using age, sex, serum creatinine and each parameter (systolic BP, U-AGT or U-P) in daytime and nighttime, respectively. U-aMT6s levels tended to correlate with systolic BP (β=0.22, p=0.11), and were significantly associated with U-AGT (β=0.31, p=0.040) and U-P (β=0.26, p=0.041) in nighttime. On the other hand, U- aMT6s had no associations with the clinical parameters in daytime.

Conclusions: Impairment of nighttime melatonin secretion may be associated with nighttime intrarenal RAS activation and renal damage in patients with CKD.

TH-PO531

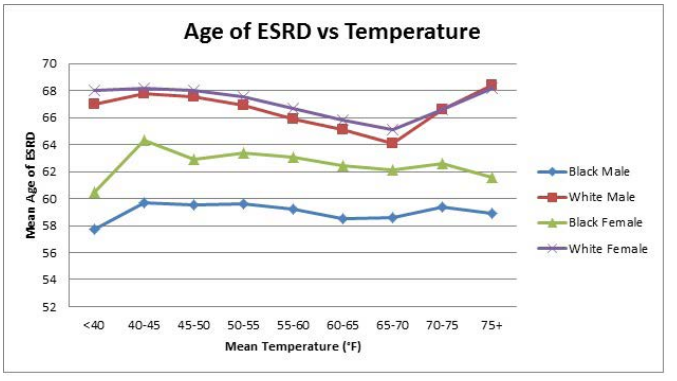
Climate Temperature Affects the Age of Onset of End Stage Renal Disease

Michael E. Bleyer, Marwan M. Abbas, Elizabeth Swain, Kendrah O. Kidd, Anthony J. Bleyer. *Section on Nephrology, Wake Forest School of Medicine, Winston-Salem, NC.*

Background: Increasing global temperatures is a rising concern. We were interested to see if there was a relationship between climate temperature and the age of onset of end-stage kidney disease.

Methods: We obtained demographic data and cause of ESRD on 1,332,402 individuals who had their first occurrence of ESRD between ages 30 and 90 between June 1971 and October 2012 from the United States Renal Data system (USRDS). We obtained the annual mean temperatures from 1990 to 2010 for weather stations throughout the US and linked a participant's zip code to the nearest weather center. We performed multivariate linear regression for white individuals with age of onset of ESRD as the dependent variable, and independent variables being age, gender, mean income for the participant zip code, baseline estimated glomerular filtration rate at the start of dialysis, and mean temperatures according to participant zip code categorically from 40°F to 75°F in 5 degree intervals.

Results: Figure 1 shows the relationship between age of ESRD and temperature with race/gender combinations. Temperature affects white individuals more than African Americans. The U shaped relationship was similar for PKD, IgA nephropathy and Type 2 diabetes. A multivariate model of whites showed the correlation between temperature and age of ESRD persisted after adjustment for other variables (p<0.0001).



Variable	Type III SS	F value	p value
Gender	107334	760	<0.0001
Temperature	118355	838	<0.0001
Year starting dialysis	242949	1721	<0.0001
Median income by zip code	310045	2196	<0.0001
GFR at start of dialysis	1120868	7940	<0.0001

Conclusions: There is a U-shaped relationship between the age of ESRD and mean temperature for a given region in whites, but not in African Americans. This variation persisted after multivariate regression. Global warming could affect the age of onset of ESRD.

TH-PO532

Prognostic Implications of Anemia in Patients with Chronic Kidney Disease Undergoing Elective Percutaneous Coronary Intervention Yuichiro Kitai,[1] Neiko Ozasa,[2] Motoko Yanagita,[1] Takeshi Kimura.[2] *[1]Dept of Nephrology, Kyoto Univ Graduate School of Medicine, Kyoto, Japan; [2]Dept of Cardiovascular Medicine, Kyoto Univ Graduate School of Medicine, Kyoto, Japan.*

Background: Little is known about the prognostic implications of anemia in patients undergoing elective percutaneous coronary intervention (PCI), especially when they have coexisting chronic kidney disease (CKD).

Methods: We identified 2792 patients with CKD who underwent elective PCI from the CREDO-Kyoto registry cohort-2. The primary outcome was 3-year major adverse cardiac events (MACE); composite of all cause death, heart failure hospitalization, and myocardial infarction.

Results: In total, 738 patients (26.4%) had mild anemia (hemoglobin = 11.0–11.9 g/dL for women and 11.0–12.9 g/dL for men), and 740 patients (17.9%) had moderate-to-severe anemia (hemoglobin < 11.0 g/dL both for women and for men). Compared to the no-anemia group, cumulative incidence of MACE was significantly higher in the mild and moderate-to-severe anemia groups (12.2%, 23.5%, and 37.4%, respectively). The adjusted hazard ratios of mild and moderate-to-severe anemia versus no-anemia for MACE were 1.46 (95% confidence interval: 1.13–1.90) and 1.76 (95% confidence interval: 1.33–2.34), respectively. In addition, the risk for MACE showed an accretive increment with exacerbation in either the renal function or anemia (interaction $p < 0.001$).

Conclusions: Even mild anemia was associated with significantly worse 3-year clinical outcomes in CKD patients who underwent elective PCI. Anemia and reduced renal function independently and additively increased the risk for MACE in these patients.

TH-PO533

Pathologic Classification of Diabetic Kidney Disease in Prognosticating Time to End-Stage Renal Disease or Death Askia K. Dunnon,[1] A. Gasim,[2] Fernanda Payan Schober,[1] Yichun Hu,[1] J. Charles Jennette,[2] Amy K. Mottl.[1] *[1]UNC Kidney Center; [2]Dept of Pathology, UNC School of Medicine, Chapel Hill, NC.*

Background: We performed a retrospective, longitudinal study of patients with diabetic kidney disease (DKD) undergoing renal biopsy to ascertain the prognostic value of histopathologic features when combined with clinical information.

Methods: Specimen from clinical native kidney biopsies performed in 1998-2006 containing diabetic glomerulosclerosis in the final diagnoses were analyzed according to the Renal Pathology Society classification system for DKD. Clinical data were extracted from medical records from time of biopsy until the composite outcome of ESRD or death. Multivariate cox proportional-hazards regression was used to estimate hazard ratios (HR) of the composite outcome according to glomerular class or severity of interstitial fibrosis. Covariates included age, gender, diabetes duration, blood pressure, eGFR and urine protein at the time of biopsy.

Results: Baseline characteristics according to glomerular class are displayed below.

Covariates	Class 2a/2b N = 44	Class 3 N = 67	Class 4 N = 19	p-value
Age, yrs	49±18	48±18	56±10	0.1
Female sex, %	43	47	32	0.5
Diabetes duration, yrs	11±6	15±7	13±7	0.07
HbA1c, %	7.7 ±2.4	8.3 ±2.6	6.7 ±1.1	0.2
Systolic blood pressure, mmHg	141±33	151±22	169±30	0.01
Urine protein*, gm/gm median (IQR)	2.8 (1.5-7.0)	5.2 (2.8-8.7)	5.5 (2.4-9.3)	0.2
estimated GFR, ml/min/1.73m^2	23±24	21±18	12±12	0.07
Interstitial fibrosis severity, %: 0/1 2 3	 36 34 30	 12 55 33	 0 16 84	
Time to ESRD or death, months	23 ±23	18 ±26	6 ±7	0.01

The risk for ESRD/death for glomerular classes 2a/b and 3 versus class 4 was HR=0.12 (0.04-0.42) and HR=0.17 (0.06-0.51), respectively. Analysis of interstitial fibrosis (IF) severity 0/1 versus 3 yielded a HR=0.19 (0.06, 0.63). The HR for IF 2 versus 3 was not significant (p=0.09). The only statistically significant clinical covariate in the analyses was eGFR: HR=0.96 (0.93, 0.99) and HR=0.94 (0.91, 0.97), respectively.

Conclusions: Kidney biopsy significantly improves the prognostication of ESRD or death in patients with diabetic glomerulosclerosis.

Funding: Private Foundation Support

TH-PO534

Progression of Chronic Kidney Disease Stage 3 Over 5 Years in a Prospective Primary Care Cohort Study Adam Shardlow,[1,2] Natasha Juliette Mcintyre,[1] Richard J. Fluck,[1] Christopher W. McIntyre,[3] Maarten W. Taal.[1,2] *[1]Renal Medicine, Royal Derby Hospital, Derby, United Kingdom; [2]Faculty of Medicine and Health Sciences, Nottingham Univ, Nottingham, United Kingdom; [3]London Health Sciences Centre, London, ON, Canada.*

Background: CKD stage 3 is commonly diagnosed in primary care. Previous studies indicate that it runs a variable course with only a minority progressing to ESRD. The Renal Risk in Derby study aims to evaluate progression of CKD in a cohort of people with CKD 3 recruited prospectively from primary care in Derbyshire, UK.

Methods: 1741 participants were recruited from local primary care practices. All had eGFR 59-30ml/min on 2 occasions prior to recruitment. At baseline, year 1 and year 5 visits, participants underwent clinical assessment, urine and serum biochemistry. Progression of CKD was defined using KDIGO criteria (25% loss of GFR and an increase in GFR category, or an increase in albuminuria category).

Results: 299 (17.2%) participants died prior to the end of year 5 follow-up. Only 4 participants (0.2%) progressed to ESRD. 1064 participants attended for year 5 visits or submitted blood and urine samples. Mean age was 71 years at baseline. Mean eGFR was 55.3ml/min at baseline and 53.8ml/min at year 5 ($p<0.001$). Progression occurred in 263 participants (24.6%). Binomial logistic regression identified male gender (HR1.55), baseline eGFR (HR0.97), logUACR (HR1.33), diabetes (HR1.57), haemoglobin (HR=0.81) and the change in GFR at year 1 (HR0.95) as independent determinants of progression at 5 years. Progression in eGFR and albuminuria categories occurred largely independently.

	No Albuminuria Progression	Albuminuria Progression
No eGFR Progression	804 (75.6%)	143 (13.5%)
eGFR Progression	86 (8.1%)	30 (2.8%)

Baseline eGFR and change in eGFR at year 1 were independent determinants of eGFR category progression. Albuminuria progression was independently associated with age, male gender, baseline eGFR, logUACR and diabetes.

Conclusions: Our data confirm that the 5-year risk of ESRD is low in CKD 3 but progression occurred in 24.6% of participants. Change in eGFR over 1 year was an independent predictor of progression over 5 years indicating that annual monitoring is beneficial for assessing prognosis.

TH-PO535

Change in Albuminuria and Risk of ESRD in a Large Health System Josef Coresh,[1] Yingying Sang,[1] Morgan Grams,[1] Kunihiro Matsushita,[1] Shoshana Ballew,[1] H. Lester Kirchner,[2] Andrew S. Levey,[3] Lesley Inker,[3] Hiddo Jan Lambers Heerspink,[4] Ron T. Gansevoort,[4] Alex R. Chang.[2] *[1]JHU; [2]Geisinger; [3]Tufts; [4]UMCG.*

Background: Albuminuria is used in chronic kidney disease (CKD) staging but it is uncertain how change in albuminuria is associated with ESRD risk in primary care and other generalizable settings.

Methods: We included Geisinger Health System participants with multiple albuminuria measurements within a 2-year baseline period, using Cox proportional hazards regression to estimate the association of ESRD with log change in albuminuria (per 2-fold rise in albumin to creatinine ratio, ACR). We tested risk for non-linearity and also analyzed 1- and 3-year baseline periods.

Results: 27,121 participants (6.5% of all primary care patients; 75% of diabetics) had at least 2 ACR measurements during baseline. After the 2-year baseline, 296 ESRD events occurred over a median follow-up of 5.2 years. Change in ACR had a geometric mean (25th-75th percentiles) of 1.1 fold rise (1.9 fold decrease - 2.1 fold rise). A two-fold rise in ACR over 2-years was associated with a subsequent HR (95% CI) of ESRD of 1.42 (1.33-1.51) adjusted for initial eGFR, ACR and 7 other risk factors. The HR was generally similar if the 2-fold ACR rise occurred over 1-year (1.48 (1.36-1.61)) or 3-year (1.42 (1.35-1.51)), as well as across the range of baseline ACR (<10, 10-99, 100+) and diabetes status. There was a suggestion toward non-linearity with 8-fold rise showing a stronger association than an 8-fold fall (HR 3.2 vs. 0.4, reference: stable ACR). Limitations: ACR measurement follows clinical care standards and selection criteria. Replication across other settings will be useful.

Conclusions: In primary care, change in ACR is associated with risk of ESRD. The CKD Prognosis Consortium will expand this investigation to multiple settings to inform use of change in ACR as an outcome in clinical practice, research, and regulatory purposes.

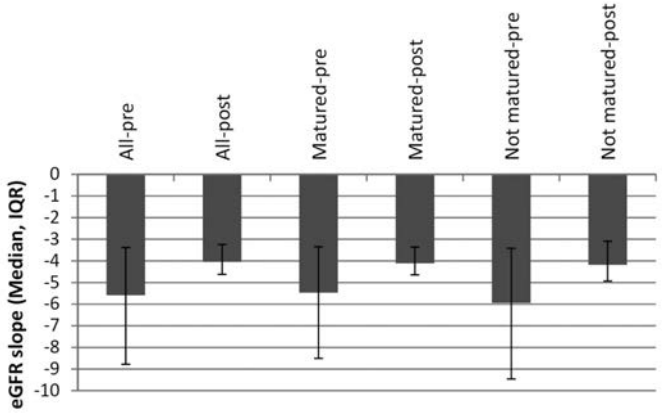
TH-PO536

Association Between Vascular Access Creation and Regression of eGFR Decline in Late-Stage CKD Patients Transitioning to ESRD Keiichi Sumida,[1] Miklos Zsolt Molnar,[1] Praveen Kumar Potukuchi,[1] Fridtjof Thomas,[1] Jun Ling Lu,[1] Jennie Jing,[2] Vanessa A. Ravel,[2] Melissa Soohoo,[2] Connie Rhee,[2] Elani Streja,[2] Lawrence Agodoa,[3] Kevin C. Abbott,[3] Paul W. Eggers,[3] Kamyar Kalantar-Zadeh,[2] Csaba P. Kovesdy.[1,4] *[1]Univ of Tennessee Health Science Center, Memphis, TN; [2]Univ of California, Irvine, CA; [3]NIH, Bethesda, MD; [4]VA Medical Center, Memphis, TN.*

Background: Arterio-venous dialysis access (AVF) creation may be associated with slowing of the decline in eGFR. It is unclear if this is due to physiological benefits of a mature access vs. other confounding factors in late CKD. We hypothesized that the beneficial change in the eGFR would only be seen with a mature AVF.

Methods: From 52,172 U.S. veterans who transitioned to dialysis between 2007-2011, we identified 3,220 who had an AVF created prior to dialysis start, and had at least 3 outpatient eGFR measurements both before the AVF creation and between AVF creation and the initiation of dialysis. We estimated crude and adjusted slopes of eGFR vs. time in multilevel mixed effects models with random intercepts and slopes. Pre- and post-AVF eGFR slopes were compared both overall, and in patients stratified by AVF maturation.

Results: Mean (SD) age was 66.3 (10.8) years, and patients were 98% male, 35% black, and 76% diabetic. Median (IQR) eGFR slope was -5.2 (-8.3 to -3.2) ml/min/1.73m^2/year, and 71% had a mature AVF at dialysis start. Compared with the eGFR slopes before AVF, a significant improvement was observed post-AVF (-5.5 [-8.9 to -3.4] vs. -4.0 [-4.6 to -3.2], P<0.001). This association was present to a similar extent in both patients with matured and un-matured AVF (Figure). Results were unchanged in adjusted models.



Conclusions: Regardless of maturation, the creation of AVF is associated with improved eGFR slopes. Clarifying the mechanism behind this warrants additional studies.

Presence of Periventricular Hyperintensity in Magnetic Resonance Imaging Is a Predictor for Future End Stage Renal Disease in Predialysis CKD Patients Hideaki Shima,[1] Tatsuhiko Mori,[1] Toshihide Naganuma,[2] Mika Sonoda,[3] Tetsuo Shoji,[3] Mikio Okamura,[4] Eiji Ishimura,[3] Masaaki Inaba.[3] *[1]Nephrology, Osaka Medical College, Takatsuki, Osaka, Japan; [2]Urology, Osaka City Univ Hospital, Osaka, Japan; [3]2nd Div of Internal Medicine, Osaka City Univ Hospital, Osaka, Japan; [4]Nephrology, Ohno Memorial Hospital, Osaka, Japan.*

Background: In the general population, periventricular hyperintensity (PVH) evaluated by brain magnetic resonance imaging (MRI), is a predictor of future stroke. CKD is a high risk condition of ESRD as well as cardiovascular disease (CVD). However, no longitudinal studies have been performed to determine the clinical significance of PVH in CKD. In the present study, we investigated the influence of PVH as a predictor of future CVD and ESRD in predialysis CKD.

Methods: This is a prospective cohort study. We examined the effect of the presence of PVH for CVD and renal outcome. CVD and renal outcome are defined as the new onset of stroke, ischemic heart disease, amputation as peripheral arterial disease and the doubling of serum creatinine levels or development of ESRD, respectively. We followed up 404 CKD patients without renal replacement therapy, who underwent brain 1.5T-MRI, for 37 months (median survival time, range: 19-56 months). Cox proportional hazard models were performed to each outcome adjusted by several atherosclerotic factors.

Results: At baseline, PVH were detected in 187 of the 404. During follow-up, 124 cases reached outcomes. In the 22 cases of stroke during follow up, the incidence of stroke was significantly higher in the group with PVH than that of without (p=0.0197, Log rank test). The presence of PVH was significantly associated with the increased risk for the future CVD and renal outcome in an unadjusted model. After adjustment, the power to predict CVD but not renal outcome by PVH was diminished (CVD: 1.44, 95%CI 0.66-3.46, renal outcome: HR 1.70, 95%CI 1.05-2.84).

Conclusions: This is the first report clearly showing that the presence of PVH is a strong predictor for future ESRD in predialysis CKD patients, but not CVD. Presence of PVH was a novel predictor for the progression of CKD. These results show one of the evidence of brain-kidney association.

TH-PO538

Telomerase Activity in Patients with Stage 2-5 Chronic Kidney Disease Mehmet Tugrul Sezer,[1] Veysel Kidir,[1] Ayse Aynali,[2] Atila Altuntas,[1] Salih Inal,[1] Buket Ar?dogan.[2] *[1]Dept of Internal Medicine, Div of Nephrology, Suleyman Demirel Univ, Medical Faculty, Isparta, Turkey; [2]Dept of Medical Microbiology, Suleyman Demirel Univ, Medical Faculty, Isparta, Turkey.*

Background: The relationship between telomerase activity and stages and progression of Chronic Kidney Disease (CKD) is unknown. The aim of this study is to investigate the association between telomerase activity and stages of CKD.

Methods: A total of 120 patients (30 patients from each stages of 2-5) and 30 healthy volunteers applying to the clinic for their routine examinations were enrolled in the study. The individuals from patient and control groups were matched in terms of age and gender. PBMC telomerase activity was measured by *telomeric repeat amplification protocol*.

Results: PBMC telomerase activity was significantly different between the groups ($p < 0.001$). Telomerase activity was found to be lowest in healthy controls (0.15 ± 0.02), and highest in patients with stage 5 CKD (0.23 ± 0.04). Telomerase activity was similar between patients with stage 2, 3, and 4 CKD ($p > 0.05$). There was positive correlation between telomerase activity and CKD stage ($r = 0.412$, $p < 0.001$), serum creatinine ($r = 0.404$, $p < 0.001$), potassium ($r = 0.207$, $p = 0.023$), and intact parathyroid hormone ($r = 0.245$, $p = 0.007$) levels and negative correlation between telomerase activity and estimated glomerular filtration rate (eGFR) ($r = -0.407$, $p < 0.001$), serum sodium ($r = -0.179$, $p = 0.05$), calcium ($r = -0.357$, $p < 0.001$), LDL-cholesterol ($r = -0.218$, $p = 0.017$), hemoglobin ($r = -0.186$, $p = 0.042$), trombocyte ($r = -0.252$, $p = 0.006$), and body mass index (BMI) ($r = -0.240$, $p = 0.008$) values. In linear regression analyses, eGFR and BMI were found to be independent predictors of high telomerase activity in CKD group. (Model 1: $R^2 = 0.151$, for eGFR $\beta = -0.001$, $P < 0.001$. Model 2: $R^2 = 0.195$, for eGFR $\beta = -0.001$, $P = 0.010$; for BMI $\beta = -0.002$, $p = 0.012$).

Conclusions: PBMC telomerase activity is significantly higher in patients with CKD compared to healthy controls. Telomerase activity increases as the CKD stage proceeds, particularly in stage 5. The increase in PBMC telomerase activity is associated with eGFR and BMI.

TH-PO539

Congestive Heart Failure Increases Risk of Long Term Adverse Renal Outcomes Lekha K. George,[1] Santhosh K. Koshy,[1] Miklos Zsolt Molnar,[1] Jun Ling Lu,[1] Kamyar Kalantar-Zadeh,[2] Csaba P. Kovesdy.[1,3] *[1]Univ of Tennessee Health Science Center, Memphis, TN; [2]Univ of California, Irvine, CA; [3]VA Medical Center, Memphis, TN.*

Background: Congestive heart failure (CHF) is associated with poor long term cardiac outcomes and mortality. Reduced cardiac output reduces renal perfusion. It is not known if CHF leads to poor renal outcome including progression to Chronic Kidney Disease (CKD). We hypothesized that a diagnosis of CHF would increase the risk of long-term adverse renal outcome.

Methods: Among 3,570,865 US veterans with eGFR >60ml/min/1.73m^2 during 2005-2006, we identified 156,743 patients with ICD-9 diagnosis of CHF. We examined the association of the presence of CHF with incident CKD, the composite of incident CKD and mortality, and rapid rate of eGFR decline (slopes steeper than -5 ml/min/1.73m^2/year) using Cox proportional hazard analyses and logistic regression, as appropriate. Adjustments were made for age, gender, race, comorbidities, baseline BP, ACEI and statin use, eGFR and cholesterol.

Results: Mean±SD baseline age and eGFR were 68±11 years and 78±14 ml/min/1.73m^2, in CHF patients vs. 59±14 and 84±16 respectively for patient without CHF. CHF patients had higher prevalence of hypertension, diabetes, cardiac, peripheral vascular and chronic lung diseases, stroke, and dementia. Incidence of CKD was 69/1000 patient years (PY) in CHF patients vs. 14.5/1000PY in patients without CHF, and 22% of patients with CHF had rapid decline in eGFR compared to 8.5% in patients without CHF. A diagnosis of CHF was associated with a two-fold higher risk of incident CKD, composite end point of CKD and mortality and rapid eGFR decline.

	Unadjusted	Adjusted
Incident CKD	4.30 (4.26-4.35)	2.12 (2.10-2.14)
Incident CKD and Mortality	2.96 (3.94-3.99)	2.06 (2.05-2.08)
GFR decline >5ml/min/year	2.96 (2.92-3.00)	2.13 (2.10-2.17)

Conclusions: CHF is associated with significantly higher risk of incident CKD, incident CKD and mortality and more rapid GFR decline. Early diagnosis and management of CHF risk factors before it leads to CHF is warranted to reduce the risk of long-term renal complications.

TH-PO540

Left Ventricular Global Longitudinal Strain as Early Detection of Subclinical Myocardial Dysfunction in Chronic Kidney Disease Patients

Secundino Cigarran,[1] Jose Lomban,[3] Ana maria Sanjurjo amado,[1] Diego Coronel,[1] Sheila Casas,[3] Juan Latorre,[1] Mª milagros López hernández,[1] Jesus Calvino.[2] *[1]Nephrology, Hospital Da Costa, Burela, Lugo, Spain; [2]Nephrology, Hospital Lucus Augusti, Lugo, Spain; [3]Cardiology, Hopsital Da Costa, Burela, Lugo, Spain.*

Background: CV mortality is increased in patients with chronic kidney disease (CKD). Little is known regarding the natural longitudinal changes in cardiac structure and function. Global longitudinal strain (GLS) measures myocardial deformation in addition to left ventricular twist.The aim of our cross sectional study is to assess the grade of myocardial dysfunction in CKD stage 1-5ND without previous CV events & normal left ventricular ejection fraction (LVEF).

Methods: 161 pts.38% F,47% DM,Age 67.37±6.8yo,not previous CV events and LVEF >55%.All received ACEI/ARB,CCHB& diuretics.Echocardiogram was performed using Vivid 9 (GE Vigmed Ultrasound Horten, Norway).Parameters derived:GLS, left Atrial volume index (LAVI),E/e´,E/A & LVEF as recommendations of American Society of Echocardiography.Body composition analysis was performed by BIVA and serum biomarkers of inflammation,anaemia,mineral bone disease,renal function (GFR-EPI) and CV risk markers. AGEs mere measured by autofluorescence (AGE´s reader.Diagnostic, Kroningen ND).CKD (%) stage:1 &2 (20%);3(55.5%);4&5 (24.5%).Normal GLS (-20%) LAVI 24 ml/m^2 were considered as published for general population Rev Esp Cardiología 2014;67:651-8.

Results: Mean GLS -15.59 ± 4.4%,LVEF 61.5 ± 4.4%.LAVI 40.6±19.8 ml.GFR showed negative significantly correlation to GLS (r: -228, P<0.016).GLS progress with CKD progression CKD 1&2:-18.1±4.7%,CKD3:-15.96±4.1%;CKD4&5:-13.22± 5.6%(P adjusted 0.008).LAVI:CKD 1&2:49.6±29.8 ml/m^2 CKD3:96.36±42.4ml/m^2,CKD 4&5:83.33± 51 ml/m^2(P adjusted =0.006).16% pts have GLS > 20% and 60% LAVI > 24 ml/m2.GLS correlates negative with cholesterol (r:-191, p= 0.50).No other correlation were met.

Conclusions: GLS&LAVI are two useful parameters to detect early subclinical myocardial damage(myocardial fibrosis & ischemia) in CKD with normal LVEF.We detect abnormal GLS in 16% pts and LAVI in 60% of CKD pts at early stages. Studies of larger CKD populations are required.

Aortic Stiffness and Change in GFR and Albuminuria in Older People

Naya Huang,[1] Lesley Inker,[1] Andrew S. Levey,[1] Meredith C. Foster,[1] Gary F. Mitchell,[2] Lenore J. Launer,[5] Vilmundur Gudnason,[3,4] Runolfur Palsson,[3] Gudny Eiriksdottir.[4] *[1]Deparement of Nephrology, Tufts Medical Center, MA; [2]Cardiovascular Engineering Inc., MA; [3]Univ of Iceland; [4]Icelandic Heart Association, Iceland; [5]National Inst of Aging, MD.*

Background: Higher aortic stiffness (AS) has a direct effect on microvascular structure and function, and may be an underlying mechanism for progression of CKD in older people.

Methods: Our study included community dwelling Icelandic elderly adults. Linear and logistic regression were used to assess the association between AS measures (carotid-femoral pulse wave velocity [CFPWV], carotid pulse pressure [CPP] and augmentation index [AI]) with the change in creatinine-cystatin C based estimated glomerular filtration rate (eGFR) and urine albumin to creatinine ratio (ACR) by two measurements 5 years apart. Rapid eGFR decline was defined as a decrease of ≥ 3 mL/min/1.73 m^2/year.

Results: Of the 629 included, mean age was 75 years at baseline, mean eGFR was 72 mL/min/1.73 m^2 and median ACR was 2.9 mg/g. The table shows associations of AS parameters to change in eGFR. No significant associations were observed between AS parameters and change in ACR.

Table. Associations of AS parameters with change in eGFR

Per SD change	Models	eGFR change (ml/min/1.73m^2/year)	Rapid eGFR Decline Odds Ratio (95% CI)
CFPWV	Model 1	**-0.2 (-0.4, -0.1)**	**1.5 (1.1,1.9)**
	Model 2	**-0.2 (-0.4, -0.1)**	**1.7 (1.3,2.3)**
	Model 3	-0.1 (-0.3, 0.1)	**1.5 (1.1,2.1)**
CPP	Model 1	**-0.3 (-0.4, -0.1)**	**1.4 (1.1,1.8)**
	Model 2	**-0.3 (-0.4, -0.1)**	**1.4 (1.1,1.8)**
	Model 3	-0.1 (-0.3, 0.1)	1.3 (0.9,1.7)
AI	Model 1	-0.1 (-0.2, 0.1)	1.2 (1.0,1.5)
	Model 2	-0.1 (-0.3, 0.1)	1.2 (0.9,1.5)
	Model 3	-0.1 (-0.2, 0.1)	1.2 (0.9,1.5)

CFPWV was negatively inverse transformed. SD, standard deviation; Model 1: unadjusted; Model 2: adjusted by age, sex, heart rate, height and baseline eGFR; Model 3: model 2+mean arterial pressure, high dense lipoprotein, hemoglobin A1c and C-reactive protein. **Bold indicates significance at p < 0.05.**

Conclusions: AS is associated with rapid decline in kidney function in older age beyond traditional cardiovascular risks.

TH-PO542

Central Aortic Blood Pressure in Patients with Chronic Kidney Disease

Rasmus Carlsen,[1] Christian D. Peters,[1] Dinah S. Khatir,[1] Esben Laugesen,[2,3,4] Simon Winther,[5] Niels Henrik Buus.[6] *[1]Dept of Renal Medicine, Aarhus Univ Hospital; [2]Dept of Endocrinology, Aarhus Univ Hospital; [3]Aarhus Univ; [4]Danish Diabetes Academy; [5]Dept of Cardiology, Aarhus Univ Hospital; [6]Dept of Nephrology, Aalborg Univ Hospital.*

Background: Central blood pressure (BP) has been suggested as a better predictor cardiovascular outcome than the brachial BP. However, in patients with chronic kidney disease (CKD) the relationship between aortic BP and brachial BP remains to be elucidated. This study compared invasive measurements of central aortic BP with brachial artery BP and the accuracy of estimated central BP obtained non-invasively by radial artery tonometry.

Methods: 83 with stage 3-5 CKD and 41 patients without signs of renal disease undergoing planned coronary angiography for evaluation of ischemic heart disease were included. BP was sequentially measured at the brachial artery with an oscillometric BP device; in the ascending aorta using an invasive catheter; and by radial artery tonometry using the SphygmoCor device for the estimation of the central BP. Arterial stiffness was assessed by pulse wave velocity (PWV).

Results: The difference between estimated central and invasive systolic BP increased with 3.6(95% CI 1.8;5.3) mmHg per level increase in CKD stage (P<0.001) and 0.1(95% CI 0.05;0.18) mmHg per decrease in eGFR (P=0.001) in unadjusted linear regression. The difference between brachial and invasive systolic BP increased with 3.1(95% CI 1.3;4.8) mmHg per level increase in CKD stage (P<0.001) and 0.1(95% CI 0.03;0.16) mmHg per decrease in eGFR (P=0.003) in unadjusted linear regression. Multivariate adjustment did not change the results. The difference between brachial and invasive systolic BP was significantly associated with PWV (P=0.01).

Conclusions: Our data shows, that central BP increases more than brachial BP with increasing CKD stage. The differences were significantly associated with increased arterial stiffness. As brachial BP is used for calibration of the tonometry based SphygmoCor device, central BP is increasingly underestimated as CKD stage increases. Thus, in advanced kidney disease the utility of non-invasively obtained central BP seems questionable.

TH-PO543

Correlation of Pulse Pressure to Renal Functional Parameters in a Cross Sectional Study of General Population – The Texas Kidney Study

Sharma S. Prabhakar, Katherine Kam. *Medicine, Texas Tech Univ Medical Center, Lubbock, TX.*

Background: Chronic kidney disease (CKD) presents an increasing economic burden. Diabetes and hypertension remain the major risk factors for development and cardiovascular complications the leading cause of mortality among patients with CKD. Pulse pressure has been noted to be an important and independent factor for cardiovascular mortality. Effect of pulse pressure (PP) on renal function in the general population has not been well studied. In this study, we examined the relation of pulse pressure to kidney function in a random, cross-sectional study of unselected population in Texas.

Methods: A cohort of 1606 subjects was recruited from the general population using random digit dialing. Detailed history and physical examination were performed and blood and urine samples were taken for renal function assessment. Estimated glomerular filtration rate (eGFR) was derived using both the 4 variable MDRD formula. Subjects were divided into normal PP group (PP≤45), wide PP group (PP>45) and were further subdivided in different age categories (age <50 and age ≥50) and those with and without systolic hypertension. Correlation of PP to eGFR and logarithmically transformed urine albumin to creatinine ratio ($UACR_{log}$) were analyzed.

Results: A total of 1576 subjects completed the study. There were 976 subjects with normal PP and 603 with wide PP. Among subjects with age ≥50, wide PP was associated with higher $UACR_{log}$ (p<0.001), but not with eGFR (p=0.99). In subjects without systolic hypertension, the group with wide PP compared to normal PP, had a significantly lower eGFR (p<0.0011) and a greater $UACR_{log}$ (p<0.05) . In patients with systolic hypertension, no significant differences in these parameters were seen between the PP groups (p=0.234).

Conclusions: In patients without systolic hypertension, wide PP is a predictor of worse kidney function in terms of eGFR and $UACR_{log}$. This could be attributed to underlying heart disease, severe anemia, thyroid disorders and other factors that lower diastolic blood pressure. Hemodynamic significance of wide pulse pressure on renal functional parameters needs further exploration.

TNFα Receptor Type 2 Is Not Associated with an Accelerated Age-Related GFR Decline in the General Middle-Aged Non-Diabetic Population

Jørgen Schei,[1] Vidar T. N. Stefansson,[1] Bjorn Odvar Eriksen,[1,3] Trond G. Jenssen,[1,4] Marit D. Solbu,[1,3] Tom Wilsgaard,[2] Toralf Melsom.[1,3] *[1]Metabolic and Renal Research Group; [2]Dept of Community Medicine, UiT the Arctic Univ of Norway; [3]Section of Nephrology, Univ Hospital of Northern Norway, Tromsø; [4]Oslo Univ Hospital, Oslo, Norway.*

Background: TNF-α is an inflammatory cytokine that mediates renal injury in animal studies. Soluble TNFα receptor type 2 (sTNFR2) is a reliable marker of TNFα activity and has emerged as an independent predictor for kidney function decline in persons with diabetes. However, few studies have investigated the effect of sTNFR2 on chronic kidney disease (CKD) risk in the general population. Previous studies have mainly used

estimated GFR which is inaccurate in the near normal range of GFR and biased by non-GFR determinants. We investigated whether sTNFR2 is a risk-factor for GFR decline in the general population using measured GFR.

Methods: We measured GFR by iohexol clearance in a cohort of the general population aged 50-62 years without diabetes, kidney- or cardiovascular disease at baseline. Of the 1594 subjects investigated at baseline, 1299 (81%) had a second measurement after a median observation of 5.6 years in the Renal Iohexol-clearance Survey Follow-Up study (RENIS-FU). Baseline sTNFR2 levels were measured by ELISA.

Results: In a linear mixed regression model adjusted for time-dependent variables including sex, weight, height, smoking, use of NSAIDs, HbA1c and albumin-creatinine-ratio, one standard deviation (SD) increase in baseline sTNFR2 was associated with a slower GFR decline of 0.10 ml/min/year (95% CI: -0.01 to 0.19). There was a strong negative association between the baseline values of sTNFR2 and GFR; one SD increase in sTNFR2 was associated with lower GFR (β= -5.63 ml/min, 95% CI: -6.87 to -4.40).

Conclusions: Increased sTNFR2 is not a risk-factor for accelerated decline in GFR in the general middle-aged population. The negative baseline association between sTNFR2 and GFR is probably due to renal clearance of sTNFR2. A longer follow-up time may be necessary to fully evaluate whether sTNFR2 influences age-related GFR decline in the general population.

Abstract Withdrawn

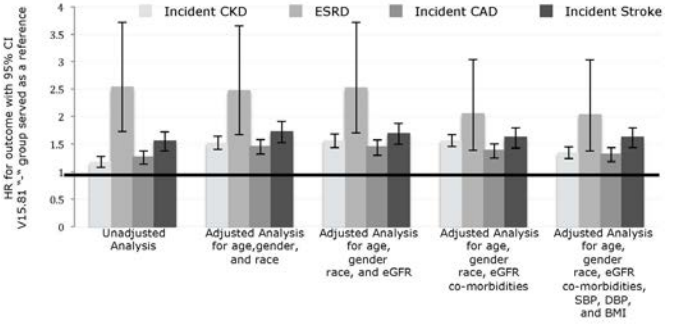
TH-PO546

Diagnosis of Non-Adherence and Renal, and Cardiovascular Outcomes in Newly Treated Hypertensive U.S. Veterans Elvira Gosmanova,[1] Miklos Zsolt Molnar,[1] Ahmed Zeen Alabedeen Alrifai,[1] Jun Ling Lu,[1] Elani Streja,[2] William C. Cushman,[3] Kamyar Kalantar-Zadeh,[2] Csaba P. Kovesdy.[1,3] *[1]Univ of Tennessee, Memphis, TN; [2]Univ of California, Irvine, CA; [3]VA Medical Center, Memphis, TN.*

Background: Adherence is paramount in treating hypertension, yet no gold standard method is available for non-adherence screening delineating high-risk patients. An *ICD-9-CM* non-adherence diagnostic code (V15.81) has been available for many years; however, its utility is poorly studied.

Methods: We examined the association between V15.81 code assigned prior to HTN diagnosis, with renal (incident CKD and ESRD) and cardiovascular (incident coronary heart disease-CHD and stroke) outcomes in 312,489 incident hypertensive individuals identified from a historical prospective cohort. Baseline mean age was 53.8 years, patients were 91% males and 20% African Americans; 10,401 patients had a V15.81 code. We used crude and Cox models adjusted for baseline demographic characteristics, eGFR, BMI, blood pressure, and co-morbidities.

Results: During a median follow up of 7.9 years, event rates were: for incident CKD 7.1 (7.0-7.2)/1000 patient-years, for ESRD 0.15 (0.13-0.16)/1000 PY, for CHD 4.6 (4.5-4.7)/1000 PY, and stroke 4.0 (3.6-4.5)/1000 PY. The presence of a V15.81 code was associated with a higher risk of all renal and cardiovascular outcomes in unadjusted and adjusted analyses including 2 fold higher risk of ESRD and 70% higher stroke risk.



Conclusions: A diagnosis of non-adherence based on the assignment of a V15.81 code prior to the diagnosis and treatment of hypertension was associated with increased adverse renal and CV outcomes in incident hypertensive US veterans.Further research is warranted to examine interventions targeting modifiable patient characteristics linked to non-adherence with the aim to improve outcomes in hypertensive individuals.

Soluble KLOTHO Negatively Correlates with Low-Grade Inflammation in Chronic Kidney Disease Patients Marek Kuzniewski,[1] Beata Kusnierz-cabala,[2] Danuta Fedak,[2] Paulina Dumnicka,[3] Magdalena Barbara Kaziuk.[1] *[1]Dept of Nephrology, Jagiellonian Univ Medical College, Krakow, Poland; [2]Dept of Diagnostics, Chair of Clinical Biochemistry, Jagiellonian Univ Collegium Medicum, Krakow, Poland; [3]Dept of Medical Diagnostics, Jagiellonian Univ Collegium Medicum, Krakow, Poland.*

Background: Circulating soluble KLOTHO (sKLOTHO) is a multifunctional protein, possessing anti-aging properties, recently associated with beneficial modulation of phosphate metabolism, cardiovascular protection and lower oxidative stress. In chronic kidney disease (CKD), sKLOTHO concentrations decrease along with the decrease of kidney function. Our aim was to study the relationship of low-grade inflammation observed in CKD patients with sKLOTHO concentrations.

Methods: The studied group consisted of 90 predialysis CKD patients (13 stage 1, 4 stage 2, 13 stage 3a, 19 stage 3b, 32 stage 4 and 9 stage 5), 52 male and 38 female, age 60+/-17. Serum concentrations of interleukin-6 (IL-6) and C-reactive protein (CRP) were measured to assess inflammation. Soluble KLOTHO concentrations were measured in sera of patients using ELISA method.

Results: Median sKLOTHO concentrations in the whole group of patients were 822 (IQR: 475-1078) pg/ml and was highest in patients with stage 1-2 CKD [1078 (990-1832) vs 704 (469-1034) pg/ml; p=0.002]. Median CRP concentrations were 2.13 (IQR: 0.80-4.97) mg/l. In the whole studied group, log(CRP) and log(IL-6) concentrations negatively correlated with log(sKLOTHO) (R=-0.33; p=0.002 and R=-0.25; p=0.014, respectively). Such correlations were observed throughout CKD stages, even in patients with CKD stage 1-2 (R=-0.66; p=0.005 and R=-0.75; p=0.001). In the whole group, CRP above the median value was associated with significantly lower sKLOTHO [713 (412-1031) vs 979 (574-1823) pg/ml; p=0.042]. In multiple analysis, log(CRP), but not log(IL-6) was a significant predictor of log(sKLOTHO) concentrations (beta=0.22+/-0.10; p=0.045), independently of age and CKD stage.

Conclusions: In CKD patients chronic low-grade inflammation may be one of the factors lowering sKLOTHO concentrations. It is important to carefully diagnose and treat any inflammatory states in those patients, starting at early stages of CKD.

TH-PO548

Inflammasome Activation by Lipopolysaccharide (LPS) and Angiotensin II (Ang II) in CKD Sindhura Bobba, Siddhartha S. Ghosh, Daniel E. Carl, Todd W. Gehr, Richard Krieg. *Nephrology, VCU, Richmond, VA.*

Background: Inflammasome dependent cytokines, such as IL-1β play a role in CKD, but their regulation during renal injury is not clearly elucidated. In this study we analyzed the ontogeny of inflammasome markers during the development of CKD in rats. Earlier studies have shown that changes in gut microbiota releases LPS in the circulation of CKD animals. LPS plays a major role in inflammasome activation. In this study we explored if LPS plays a role to activate inflammasome in CKD.

Methods: CKD was generated in Sprague dawley rats by 5/6 nephrectomy (Nx). Rats were sacrificed at 2, 4, 8 and 12 weeks after Nx (n=5/group). The controls were sham operated rats sacrificed on the 12th week. A group of Nx rats received 10 mg/kg losartan from 4 to 8 weeks. Kidney cytosols were taken to measure inflammasome markers (NFκB, ASC, caspase 1 and 1L-1β) by western blots. Serum LPS was measured by LAL assay. Ang II levels in the kidney were measured by ELISA. Rat mesangial cells were treated with Ang II and LPS to investigate inflammasome activation.

Results: Serum creatinine and urea significantly went up from 2 weeks onwards and glomerulosclerosis was seen from 4 weeks onward. Kidney Ang II concentration increased longitudinally from 2 weeks and plateaued at 8 weeks. Significant increase in caspase 1 and IL-1β were seen only at 8 and 12 weeks, whereas ASC increased from 4 weeks. However, pNFκB was significantly activated from 2 weeks onward. Serum LPS significantly increased from 4 weeks onward. Losartan significantly decreased all the inflammasome markers. Mesangial cells were treated with LPS and/or Ang II to investigate inflammasome activation. 50 ng/ml LPS and 10^{-9}M and 10^{-6}M Ang II did not affect inflammasome activation. When 50 ng/ml LPS and Ang II (10^{-9}M) were combined significant increase in all the inflammasome markers were observed and this was blocked by losartan.

Conclusions: Appearance of LPS at 4 weeks is probably due to increased intestinal permeability associated with CKD. Neither LPS or AngII alone could activate inflammasome. By blocking AT1 receptor we could reduce inflammasome activity. This suggest that Ang II is required for LPS mediated inflammasome activation in CKD.

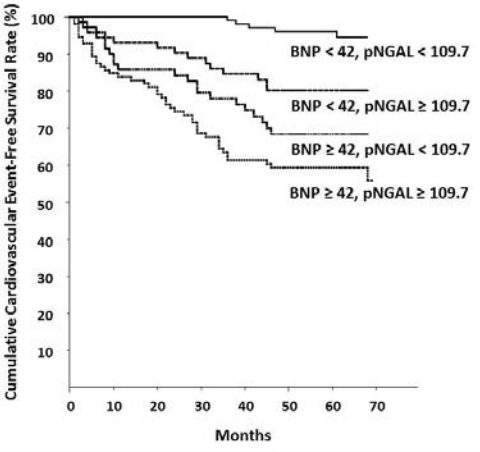
TH-PO549

Plasma Neutrophil Gelatinase-Associated Lipocalin as a Predictor of Cardiovascular Events and All-Cause Mortality in Patients with Chronic Kidney Disease Midori Hasegawa, Kazuo Takahashi, Hiroki Hayashi, Shigehisa Koide, Yukio Yuzawa. *Nephrology, Fujita Health Univ School of Medicine, Aichi, Japan.*

Background: Elevated neutrophil gelatinase-associated lipocalin (NGAL) levels have recently been reported in patients withheart failure, coronary heart disease, or stroke. Here, we aimed to assess the usefulness of plasma NGAL (pNGAL) as a predictor of cardiovascular (CV) events and mortality in patients with chronic kidney disease (CKD).

Methods: In this prospective cohort study, the pNGAL level was measured in 371 ambulatory patients with CKD not on dialysis with an estimated glomerular filtration rate < 60 mL/min/1.73 m^2. CV events were defined as CVdeath, acute coronary syndrome, hospitalization for worsening heart failure, stroke, or aortic dissection.

Results: During a median follow-up period of 58 months, 84 CV events (22.6%) and 32 deaths (8.6%) occurred. On Cox stepwise multivariate analysis of all significant variables ($p < 0.05$) on univariate analysis, pNGAL, B-type natriuretic peptide (BNP), the urinary albumin creatinine ratio, and a history of previous CV diseases were significant predictors of CV events, while pNGAL, BNP, hemoglobin, and age were significant predictors of mortality. Considering both pNGAL and BNP, we stratified patients into four groups, with the median level of each marker as cutoff values (109.7 ng/mL for pNGAL and 42 pg/mL for BNP). Five-year CV event-free survival rates were 94.6%, 80.3%, 68.3%, and 59.4% in the four groups above, respectively ($p < 0.0001$).



Conclusions: Elevated pNGAL could predict future CV events and mortality in patients with CKD, while the combination analysis of pNGAL and BNP was useful in stratifying CV event risk.

Clinical Significance of Urinary Liver-Type Fatty Acid Binding Protein as a Predictor of End Stage Renal Disease and Cardiovascular Disease in Patients with Chronic Kidney Disease

Katsuomi Matsui,[1,2] Atsuko Ikemori,[2] Naohiko Imai,[1,2] Takeshi Sugaya,[2] Takashi Wada,[3] Sayuri Shirai,[1,2] Kenjiro Kimura,[4] Yugo Shibagaki.[2] *[1]Dept of Nephrology and Hypertension, Internal Medicine, St. Marianna Univ School of Medicine Yokohama City Seibu Hospital, Yokohama, Kanagawa, Japan; [2]Dept of Nephrology and Hypertension, Internal Medicine, St. Marianna Univ School of Medicine, Kawasaki, Kanagawa, Japan; [3]Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Kanazawa, Japan; [4]Dept of Internal Medicine, Tokyo Takanawa Hospital, Takanawa, Tokyo, Japan.*

Background: To improve outcomes in patients with chronic kidney disease (CKD), it is important to identify prognostic factors for end-stage renal disease (ESRD) as well as cardiovascular disease (CVD). This study assessed urinary concentrations of albumin, *N*-acetyl-β-D-glucosaminidase (NAG), and liver-type fatty acid-binding protein (L-FABP), as predictors of ESRD and CVD.

Methods: A prospective, observational, multicenter study, comprising 244 Japanese outpatients with CKD who had a follow-up period of at least 3 months. The primary endpoint was the first onset of a nonfatal or fatal CVD event and progression to ESRD, defined as myocardial infarction, stroke, or artery revascularization (coronary, carotid or peripheral), and initiation of dialysis.

Results: During a median follow up of 3.8 years, the primary endpoint occurred in 39 (15.8%) patients. Irrespective of diabetes, high urinary L-FABP correlated with the development of ESRD and CVD. The areas under the receiver operator characteristic curves (AUCs) for predicting the primary endpoint for urinary concentrations of L-FABP, albumin, and NAG were 0.825, 0.797, and 0.722, respectively. Cox regression analyses, which were adjusted for factors knownto influence the primary endpoint, including patient characteristics, and serum and urinary parameters, demonstrated that the primary outcome was associated with high urinary L-FABP and low eGFR ($p = 0.049$, hazard ratio = 1.341 [95% CI, 1.005 -1.790]; and $p < 0.000$, hazard ratio = 0.953 [95% CI, 0.930 - 0.976], respectively).

Conclusions: Urinary L-FABP may be a useful prognostic marker of progression to ESRD and the onset of CVD in patients with CKD.

Elevated Serum Adiponectin Concentrations Might Predict End-Stage Renal Disease in Japanese Patients with Moderate to Severe Chronic Kidney Disease

Hitomi Tanimoto,[1] Hirotake Kasuga,[1] Ryo Takahashi,[1] Keiko Kimura,[1] Chieko Matsubara,[1] Mari Maseki,[1] Yasuhiko Ito.[2] *[1]Dept of Nephrology, Nagoya Kyoritsu Hospital, Nagoya, Japan; [2]Dept Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Japan.*

Background: Adiponectin (ADPN) is an adipocyte-derived, anti-inflammatory, anti-atherogenic, insulin-sensitizing polypeptide. However, elevated serum ADPN levels are associated with high mortality rates and more cardiovascular events in patients with chronic kidney disease. In addition, ADPN reportedly helps to protect renal function, whereas others have found that high ADPN levels predict end-stage renal disease.

Methods: We monitored serum ADPN, Cr and eGFR in 215 outpatients during 2008 and assigned 104 of them with eGFR ≤60 mL/min/1.73 m^2 to groups based on ADPN values ≤ 12.3 (L) or > 12.3 (H) mg/mL. These patients were followed for five years or until they started dialysis.

Results: During the study period, 6 patients in the L group (n=55) and 21 patients in the H group (n=49) started dialysis ($P < 0.0005$). The dialysis-free survival rates at 60 months in groups L and H were 87.4% and 52.2%, respectively ($p < 0.0005$). Cox multivariate analysis identified low ADPN (HR, 0.35; $p < 0.05$), age (HR, 0.9; $p < 0.05$) and eGFR 30 - 60 mL/min/1.73 m^2 (HR, 0.07; $p = 0.00005$) as independent risk factors for end stage kidney disease.

Conclusions: High serum adiponectin levels might predict end stage kidney disease in Japanese patients with moderate-to-severe chronic kidney disease.

TH-PO552

The Association Between Direct Measures of Body Fat, Incident Chronic Kidney Disease and Kidney Function Decline: The Health Aging Body and Composition Study

Magdalena Madero,[1] Ronit Katz,[2] Linda F. Fried,[5] Rachel A. Murphy,[6] Michael Shlipak,[4] Carmen A. Peralta,[4] Joachim H. Ix,[9] Anne B. Newman,[8] Suzanne Satterfield,[7] Kushang V. Patel,[6] Mark J. Sarnak.[3] *[1]National Heart Inst Mexico; [2]Washington U; [3]Tufts; [4]UCSF; [5]VA; [6]NIH; [7]UTHSC; [8]Pittsburgh; [9]UCSD.*

Background: We evaluated and compared the association of CT and anthropometric measures of obesity with kidney outcomes in the Health ABC Study. We hypothesized that CT measures, particularly of visceral fat, would confer the highest risk for kidney outcomes in comparison with other measures.

Methods: CT measures included visceral abdominal fat (VAT) and subcutaneous adipose tissue (SAT), anthropometric measures included waist circumference (WC) and body mass index (BMI). Kidney outcomes included incident CKD (follow-up $eGFR_{cysC}$ less than 60 ml/min/1.73 m^2 in individuals with baseline GFR>60 ml/min/1.73m^2) and kidney function decline (30% decrease in $eGFR_{cysC}$ in follow up at either year 3 or 10). Multivariable logistic regression models were used to evaluate the association with outcomes.

Results: 2489 individuals were included. Mean age was 74±3 y, 49% were male, 39% were black and 15% were diabetic. In continuous models SAT, VAT, BMI and WC were associated with kidney function decline. VAT, BMI and WC were also all associated with incident CKD, but SAT did not reach statistical significance.

	Unadjusted	Adjusted
KF Decline >30%	OR (95% CI)	
VAT (per SD=67)	1.30 (1.17-1.43)	1.19 (1.06-1,33)
SAT (per SD=121)	1.15 (1.04-1.27)	1.18 (1.04-1.34)
BMI (per SD= 4.6)	1.28 (1.15-1.41)	1.20 (1.07-1.34)
WC (per SD= 12.5)	1.32 (1.19-1.46)	1.22 (1.09-1.37)
	Unadjusted	Adjusted
Incident CKD (per SD)	IRR (95% CI)	
VAT	1.36 (1.25-1.47)	1.21 (1.09-1.33)
SAT	1.18 (1.08-1.29)	1.11 (0.99-1.23)
BMI	1.28 (1.18-1.41)	1.15 (1.04-1.27)
WC	1.28 (1.19-1.38)	1.18 (1.06-1.30)

Adjusted for age, gender, race, site, baseline GFR, DM, BP, HTN meds, albuminuria, smoking, LDL and HDL cholesterol, oral estrogen, prevalent CHD and prevalent HF

Similar results were found in categorical analyses using quartiles of the exposure variable

Conclusions: Anthropometric measures of body fat appear to provide as reliable estimates of kidney decline risk as direct measures in elders.

Gender Dependent Association Between Metabolic Syndrome and Arterial Stiffness in Patients with Chronic Kidney Disease: Findings from the Korean Cohort Study for Outcome in Patients with Chronic Kidney Disease (KNOW-CKD) Study Yong Un Kang,[1] Eun Hui Bae,[1] Seong Kwon Ma,[1] Kook-Hwan Oh,[2] Curie Ahn,[2] Soo Wan Kim.[1] *[1]Dept of Internal Medicine, Chonnam National Univ Medical School, Gwangju, Korea; [2]Dept of Internal Medicine, Seoul National Univ Hospital, Seoul, Korea.*

Background: We investigated the relationships of metabolic syndrome (MS) to arterial stiffness in chronic kidney disease (CKD) patients across a wide range of renal function from early CKD to predialysis.

Methods: Risk factors for MS and brachial-ankle pulse wave velocity (baPWV) as measures of arterial stiffness were assessed in 1,256 CKD patients from the KNOW-CKD study. MS was defined by modified National Cholesterol Education Program Adult Treatment Panel III guidelines. Multivariate logistic regressionwas used to test the association between MS and cardiovascular risk factors,measures of Chronic Kidney Disease-Mineral and Bone Disorder (CKD-MBD), and arterial stiffness.

Results: Higher arterial stiffness levels were associated with older age, lower estimate glomerular filtration rate, diabetes, and hypertension. Arterial stiffness was not associated with measures of CKD-MBD including total calcium, intact parathyroid hormone, alkaline phosphatase, and albumin. MS was an important determinant of arterial stiffness in CKD patients after adjustment for demographics, cardiovascular risk factors, and CKD-MBD measures, and medication. Systolic blood pressure (SBP) and fasting plasma glucose were the major determinant of arterial stiffness. In sub-analysis by gender, women had more stronger association between arterial stiffness and MS than men. SBP, waist circumference, and triglyceride were independent determinants of arterial stiffness in women, whereas only SBP predicted arterial stiffness in men.

Conclusions: The presence of MS and its risk factors were associated with increased arterial stiffness and that these relationships were independent of renal function, CKD-MBD measures, and cardiovascular risk factors in CKD patients. Women had more stronger association between arterial stiffness and MS than men and the association between risk factors for MS and arterial stiffness may differ between men and women in CKD patients.

Body Mass Index (BMI) Has a U-Shaped Association with Chronic Kidney Disease (CKD) Progression in Children with Glomerular Diseases Robert H. Mak, Christopher B. Pierce, Nancy MacDonald Rodig, Craig S. Wong, George J. Schwartz, Marva M. Moxey-Mims, Susan L. Furth, Bradley Warady. *Pediatric Nephrology, Univ of California San Diego, La Jolla, CA.*

Background: In adult patients, BMI has a U-shaped association with disease progression in CKD stages II to IV. Data in children have not been reported. We investigated BMI association with disease progression in the Children with CKD (CKiD) Cohort.

Methods: Children with CKD stages II to IV had annual measurements of glomerular filtration rate (GFR), either directly by iohexol clearance or estimated using a CKiD data-derived equation. Stratifying by CKD diagnosis, glomerular (G) and non-glomerular (NG) diseases, GFR decline rate during follow-up was modeled on baseline BMIz-score for height-age and sex using joint shared-parameter models to account for informative censoring associated with renal replacement therapy (RRT). GFR was log-transformed and change was estimated as %/yr.

Results: 866 children with median age 11 [8,15] yrs and median GFR 52 [38,71] ml/min/1.73m^2 at baseline were followed for a median of 4.6 [2.0,6.9] yrs; 131 children initiated RRT or died (n=2) during follow-up. In 276 children with G diagnoses, expected GFR decline rate exhibited a quadratic relationship with baseline BMIz modeled continuously; high and low ends of the baseline BMIz spectrum showed steeper relative declines in GFR rates compared with patients with slightly above average baseline BMIz. Specifically, G children with BMIs <= 25th %tile (10% of G) had expected GFR declines of 13.6%/yr or greater; G children with BMIs between 75th and 90th %tile (20%) had expected GFR declines of 8.5%/yr; G children with BMIs >=98th %tile (15%) had expected GFR declines of 11.3%/yr. Adjusting for sex, age, black race and proteinuria did not change this relationship qualitatively. In contrast, in 590 children with NG diagnoses, BMIz was not associated with expected GFR decline rate, which was 4.5%/yr.

Conclusions: BMIz has a U-shaped associated with disease progression in children with CKD stages II to IV with G but not with NG diagnoses. Weight management in CKD children to avoid extremes in BMIz may improve CKD outcomes and await clinical trials confirmation.

TH-PO555

Combination of Low Body Mass Index and Serum Albumin Level Leads to Chronic Kidney Disease Progression: The Chronic Kidney Disease–Research of Outcomes in Treatment and Epidemiology Study Hiroaki Kikuchi,[1] Eiichiro Kanda,[2] Soichiro Iimori,[1] Shotaro Naito,[1] Sei Sasaki,[1] Eisei Sohara,[1] Tomokazu Okado,[1] Tatemitsu Rai,[1] Shinichi Uchida.[1] *[1]Nephrology, Tokyo Medical and Dental Univ; [2]Nephrology, Tokyo Kyosai Hospital.*

Background: The relationship between nutritional deficiency and chronic kidney disease (CKD) progression is unknown. In the present prospective cohort study, we evaluated the hypothesis that a combination of low body mass index (BMI) and serum albumin level leads to rapid CKD progression.

Methods: The study cohort comprised 728 predialysis patients with CKD (stages 2–5) enrolled from 2010 to 2011. Patients were categorized into 4 groups according to their serum albumin levels and BMI: group 1, low serum albumin level (<4 g/dL) and low BMI (<23.5 kg/m^2); group 2, high serum albumin level (≥4 g/dL) and low BMI; group 3, low serum albumin level and high BMI (³23.5 kg/m^2); and group 4, high serum albumin level and high BMI. The primary outcome was a 30% decline in estimated glomerular filtration rate (eGFR) or start of dialysis within 2 years. The secondary outcome was an annual GFR decline (mL/min/1.73 m^2/year).

Results: Logistic regression analysis adjusted for baseline characteristics (reference, group 4) showed that only group 1 was associated with a high risk of CKD progression; adjusted odds ratio (aOR) 3.07 [95% confidence interval (CI) (1.51, 6.24)]; group 2, aOR 1.81 (95% CI 0.89, 3.70); group3, aOR 1.97 (95% CI 0.96, 4.03). A multivariate general linear regression analysis adjusted for baseline characteristics showed a significant difference in annual eGFR decline between groups 1 and 4 (β =-3.04, $P \leq 0.001$).

Conclusions: This study suggests that combined effects of low body mass index and serum albumin level lead to CKD progression.

TH-PO556

Weight Reduction Has an Additive Effect on the Anti-Albuminuric Effect of Angiotensin II Type I Receptor Blocker in Hypertensive Patients with Chronic Kidney Disease Ho Jun Chin,[1,3] Chun Soo Lim.[2,3] *[1]Internal Medicine, Seoul National Univ Bundang Hospital; [2]Seoul National Univ Boramae Medical Center; [3]Seoul National Univ Hospital, Seoul.*

Background: We searched the additive anti-proteinuric effect of weight reduction in addition to medication of an angiotensin II type I receptor blocker (ARB) for hypertensive chronic kidney disease (CKD) patients with mild overweight.

Methods: This study is a sub-analysis of data from an open-label, case-controlled, randomized clinical trial including 245 hypertensive CKD patients completed the trial (NCT01552954).We were able to calculate the ratios of estimated daily excretion of sodium (eUna), albumin (eUalb), and urea nitrogen (eUUN) in 227 participants during 16 week-trial period with medication of Olmesartan 40 mg a day. The primary outcome of the study was a decrement of eUalb ≥ 25% during 16 weeks. We grouped the participants according to the ratio of weight (WtRatio) during 16 weeks.

Results: The baseline mean values of BMI, GFR, and eUalb were 25.4 ± 3.8 kg/m^2, 67.0 ± 23.9 ml/min/1.73 m^2 and 1.0 ± 0.7 g/day, respectively. The proportion of patients that achieved a decrement of eUalb ≥ 25% during 16 weeks with an ARB medication was 93.0 % (53/57) in group 1 with a decrement of weight ≥ 1.5 %, 83.3 % (25/30) in group 2 with WtRatio between -1.4 % and -0.1%, and 70.6 % (96/136) in group 3 with WtRatio ≥ 0.0 % (p = 0.002). The probability of a decrease in albuminuria was 7.405-fold (95% CI: 2.168-25.293, p=0.001) higher in group 1 compared to group 3, as observed in multiple logistic regression analysis as well. The decrement of eUalb was the highest in group 1 (-59.4 ± 47.1 %) compared to group 2 (-38.4 ± 70.1 %) or group 3 (-26.2 ± 160.4 %) (p=0.005). The additive anti-albuminuric effect of weight change in addition to the medication of an ARB was independent from the change in urinary excretion rate of sodium or urea nitrogen calculated using 24-hour urine collection.

Conclusions: The small change of body weight had an additive anti-albuminuric effect in hypertensive CKD patients with albuminuria using an ARB, independent from the change of sodium or protein intake.

Can Exercise-Induced Proteinuria Predict the Onset of Chronic Kidney Disease? A Systematic Review Naushad Ali Junglee,[1,2] Mahdi M. Jibani,[1,2] Andrew B. Lemmey,[1] Jamie Hugo Macdonald.[1] *[1]Extremes Research Group, School of Sport Health and Exercise Sciences, Bangor Univ, Bangor, Gwynedd, United Kingdom; [2]Renal Unit, Ysbyty Gwynedd, Bangor, Gwynedd, United Kingdom.*

Background: Post-exercise proteinuria (PeP) shares characteristics with proteinuria of chronic kidney disease (CKD) including its cause (increased intraglomerular pressures) and its consequences (albuminuria and reduction in glomerular filtration rate). The aim of this study was to perform a systematic review to determine if PeP could predict the onset or progression of CKD.

Methods: A systematic review of articles published in Ovid Medline(R), Ovid Medline in process, AMED, EMBASE, Pubmed, Cochrane Library and Web of Science between 1946 and 2014 was conducted. Eligible studies included randomized controlled trials

and prospective observational cohorts whose participants had or were at-risk of CKD and performed an exercise test to elicit PeP. Search terms included: exercise, proteinuria, albuminuria, chronic kidney disease and nephropathy. Primary outcomes examined were biomarkers of CKD (e.g. rise in blood creatinine) during a follow-up period of at least three months.

Results: Five studies (n=351) met inclusion criteria. Full meta-analysis was not possible interventions and PeP measurements varied markedly between studies. Therefore, narrative synthesis was performed. When combining results of the primary outcome in four similar studies (n=318), the presence of PeP was highly associated with elevated resting proteinuria at follow-up (c^2 test, $P < 0.0001$) and significant odds ratios (OR) of developing CKD following a positive exercise test vs. not developing CKD were noted for each of these four studies (OR 2.3 to 52). However, interventions induced potential bias with notable differences in type of exercise routines between studies. Also, primary outcomes did not factor confounding variables (e.g. use of angiotensin-receptor antagonists). Finally, findings are only generalisable to a young type I diabetics at risk of CKD.

Conclusions: Despite the limited number of studies in the literature and their shortcomings, PeP shows promise as a predictor for CKD progression. However, there is a need to define the most appropriate exercise test for this purpose.

TH-PO558

Ketoanalogs Supplementation Decreases Dialysis and Mortality Risk in Patients with Advanced Chronic Kidney Disease Che-Hsiung Wu,[1] Vincent Wu.[2] *[1]Taipei Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Taipei, Taiwan; [2]National Taiwan Univ Hospital, Taipei, Taiwan.*

Background: The benefit of alpha-ketoanalogs (KA) supplementation for advanced chronic kidney disease (CKD) patients that followed low-protein diet (LPD) remains undetermined.

Methods: We extracted longitudinal data for all advanced CKD patients in the Taiwan National Health Insurance from January 1, 2000 through December 31, 2010. A total of 1483 patients with advanced CKD treated with LPD, who started KA supplementation, were enrolled in this study. We analyzed the risks of end stage renal disease and all-cause mortality using Cox proportional hazard models with influential drugs as time-dependent variables.

Results: A total of 1113 events of initiating long-term dialysis and 1228 events of composite outcome occurred in patients with advanced CKD after a mean follow-up of 1.57 years. Data analysis using the Cox model suggests KA supplementation is associated with a lower risk for long-term dialysis (table 1) (HR, 0.54 [95% CI 0.47 - 0.62]) and the composite outcome of long-term dialysis or death (HR, 0.49 [95% CI 0.43 - 0.55]) when daily dosage is more than 5.5 tablets. The beneficial effect was consistent in subgroup analysis.

Variables	Hazard Ratio (95% confidence interval)	p value
Diabetes mellitus	1.80 (1.52 - 2.12)	< 0.001
Hypertension	1.25 (1.10 - 1.42)	< 0.001
Age, >60 vs. ≤60 years old	1.29(1.14 - 1.45)	< 0.001
CCI score, >3 versus ≤3	1.26 (1.05 - 1.52)	0.0124
Medicine Hospitalization	8.04 (7.02 - 9.20)	< 0.001
Daily KA dosage (expressed as tablets) larger than 5.5 vs. Unsuitable dose	0.65 (0.43 - 1.00)	0.0492
ACEI use	0.63 (0.49 - 0.81)	< 0.001
ARB use	0.65 (0.56 - 0.76)	< 0.001
KA use	0.54 (0.47 - 0.62)	< 0.001

Conclusions: Among advanced CKD patients that followed LPD, KA supplementation at an appropriate dosage may substantially reduce the risk of initiating long-term dialysis or of developing the composite outcome. KA supplementation represents an additional therapeutic strategy to slow the progression of CKD. The promising results in terms of mortality and commencing chronic dialysis need confirmation with different study designs.

TH-PO559

Serum Fibroblast Growth Factor 21 Is a Significant Predictor for Renal Outcomes in Patients with Chronic Kidney Disease Masashi Kitagawa, Hitoshi Sugiyama, Hiroshi Morinaga, Ayu Akiyama, Toshio Yamanari, Akifumi Onishi, Keiko Tanaka, Yoko Kikumoto, Tatsuyuki Inoue, Jun Wada. *Medicine and Clinical Science, Okayama Univ Graduate School, Okayama, Japan.*

Background: Fibroblast growth factor 21 (FGF21) is a metabolic hormone that plays a significant role in glucose and lipid homeostasis. FGF21 activity depends on its binding to FGF receptors and β-Klotho. Circulating FGF21 levels are independently associated with the renal function. The purpose of this study was to identify the relationship between the serum FGF21 levels and the renal function in patients with chronic kidney disease (CKD) and investigate whether the serum FGF21 levels can predict renal outcomes in patients with CKD.

Methods: We conducted a prospective cohort study. We enrolled 120 CKD patients and measured serum FGF21 levels by a sandwich ELISA. The endpoint was defined as an increase in serum creatinine of 50% or the initiation of renal replacement therapy (median age, 56 years; 62% male; 59% had glomerulonephritis).

Results: At enrollment, the median estimated glomerular filtration rate (eGFR) was 56 (24-73) mL/min/1.73m^2 and median proteinuria was 0.84 (0.31-2.49) g/gCr. The median serum FGF21 levels were 296 (90-560) pg/mL. The natural logarithm FGF21 concentrations negatively correlated with the eGFR (r=-0.4940, p<0.0001) and positively correlated with proteinuria (r=0.2583, p=0.0044). During two years, 29 patients reached the endpoint. The renal survival was significantly lower in patients with serum FGF21 ≥ 296 pg/mL than in those with serum FGF21 < 296 pg/mL (p<0.0001). A Cox regression analysis showed that serum FGF21 ≥ 296 pg/mL was significantly associated with an increased risk for the renal endpoint adjusted for age, gender, body mass index, current smoking, eGFR, proteinuria, pulse pressure, fasting plasma glucose, glycoalbumin, non HDL-cholesterol, phosphate, FGF23 and renin angiotensin system blockade.

Conclusions: The data indicate that the serum FGF21 level is significantly associated with the renal outcomes, suggesting that a higher serum FGF21 level may serve as a novel biomarker for CKD progression.

TH-PO560

Serum Phosphorus Independently Predicts Risk of ESRD in an Urban CKD Clinic Jonathan W. Bazeley, Fei He, Sharon M. Moe, Ali Khalil, Ranjani N. Moorthi. *Indiana Univ.*

Background: Serum phosphorus (PO_4) levels have been positively associated with adverse outcomes in chronic kidney disease (CKD) populations, albeit in cross sectional studies of largely Caucasian cohorts. Given differences in vitamin D and PTH homeostasis in African-Americans (AA) and dietary fluctuation, we tested the hypothesis that PO_4 measured over time (as is done in clinical practice) will be associated with the risk of dialysis initiation in our urban, predominantly AA CKD population.

Methods: A retrospective cohort of 754 adult patients with CKD(eGFR <60ml/min at baseline) visiting the nephrology clinic at a large urban county hospital from 2007-10 were followed until death or May 2012. A Cox proportional hazards model adjusted for demographics, comorbidities, medications, and laboratory values was used to study the association of time varying PO_4 with the end point of time to dialysis initiation (days to event from index date). Death before dialysis was a censoring event(n=100;13.26%).

Results: Of 754 patients, 54% were female, 60% were AA and 57% had diabetes mellitus. The mean age was 58.6 ± 13.6 years (mean ± SD), mean eGFR at the start of follow-up period was 33.4 ± 14.9 ml/min/1.73m^2.The median PO_4 level was (3.9 mg/dl; IQR 3.3-4.3). PO_4 was measured ≥ 2 times in 437 (58%) of patients. During a median follow up of 714 days, 117 (15.5%) patients were initiated on dialysis. When fully evaluated in a multivariable model, the time varying PO_4 remained a significant in predicting time to dialysis initiation (HR 1.44, 95%CI 1.07-1.93).

	Descriptive Statistics	Model 0 (Univariate)		Model 1		Model 2		Model 3 (Full)	
		Hazard Ratio	95% CI*	Hazard Ratio	95% CI*	Hazard Ratio	95% CI*	Hazard Ratio	95% CI*

Hemoglobin (g/dl)[b]	12.2 (11.1-13.4) [b]							0.94	0.76-1.17

* "CI" = Confidence Interval.
[a] Hazard ratios for laboratory values are per 1mg/dL for phosphorus, albumin, bicarbonate, per 1 g/dL for hemoglobin, and per 1ml/min/1.73m^2 for eGFR. Bicarbonate and hemoglobin were baseline measures, while phosphorus, calcium, albumin and MDRD eGFR were time-varying.
[b] Descriptive statistics for laboratory values and eGFR are shown in median ± interquartile range. [c] Hazard ratio for age is per year.
[d] Descriptive statistics for age and BMI are mean +/- standard deviation.
[e] The comparator for African-American is all other races.
[f] "ACE-I or ARB" reflects whether the patient picked up an ACE-inhibitor or ARB from pharmacy during observation period.
[g] ">= 3 anti-HTNives" reflects whether subject picked up 3 or more different categories of anti-hypertensive agents (calcium-channel blockers, beta-blockers, ACE-inhibitors, ARBs, direct renin inhibitors, diuretics, or miscellaneous) from the pharmacy during the observation period.

Conclusions: An increase in serum PO_4 over time was associated with faster progression to dialysis initiation in an AA urban population of CKD patients, even when adjusted for eGFR. The results suggest PO_4 may have independent negative consequences on CKD progression; testing this would require trials that evaluate lowering serum PO_4 on progression to dialysis.

Serum Phosphorus Is Associated with Increased Risk of Kidney Failure Alex R. Chang,[1] H. Lester Kirchner,[1] Amanda Young,[1] Morgan Grams.[2] *[1]Geisinger Health System; [2]Johns Hopkins Bloomberg School of Public Health.*

Background: Limited data exists on the association between serum phosphorus and progression to kidney failure.

Methods: Using data from 28,542 outpatients at Geisinger Health System, we examined the association between serum phosphorus and incident kidney failure (dialysis, transplant, eGFR < 15 ml/min/1.73m^2). Cox regression analyses were adjusted for demographics,

history of cardiovascular disease, eGFR, fasting status, phosphorus-altering medications (estrogen, testosterone, calcium supplements, and other phosphorus-binding medications), time of day (morning, afternoon, evening), and renal risk factors.

Results: Overall, 25% were fasting lab values and 70% were drawn in the morning (8-12am). Elevated serum phosphorus was associated with increased risk of kidney failure. The highest quartile of serum phosphorus (>=3.8 mg/dL) was associated an adjusted hazard ratio of 1.99 (95% CI: 1.65-2.41) compared to the lowest quartile of serum phosphorus. The relationship between serum phosphorus and risk of kidney failure was similar by gender, baseline eGFR, and time of day of measurement. Associations between serum phosphorus and eGFR decline >= 30% were similar.

Conclusions: Elevated serum phosphorus is associated with increased risk of kidney failure. Future studies are needed to determine whether lowering phosphorus levels can delay progression to ESRD.

Serum Calcification Propensity Signifies Myocardial Injury and Myocardial Structural and Functional Abnormalities in Chronic Kidney Disease

Angela Yee Moon Wang,[1] Qizhe Cai,[1,4] Matthias Bachtler,[2] Xiuzhang Lu,[4] Andreas Pasch.[3] *[1]Medicine, Univ of Hong Kong, Queen Mary Hospital, Hong Kong, Hong Kong; [2]Clinical Research, Univ of Bern, Bern, Switzerland; [3]Chemistry, Univ Hospital Bern and Univ of Bern, Bern, Switzerland; [4]Echocardiography, Heart Center, Beijing Chao-Yang Hospital, Capital Medical Univ, Beijing, China.*

Background: A recent novel blood test measuring the maturation time of calciprotein particles or serum calcification propensity (T50) has been shown to predict all-cause mortality in CKD subjects. This study aims to elucidate the mechanisms that explain this association.

Methods: We prospectively recruited 300 stages 3–5 non-dialysis CKD patients (age:60±10yrs, 56%men) & 100 healthy control subjects. Echocardiography with tissue Doppler Imaging & plain cardiac multislice computed tomography were done to evaluate cardiac dimensions, function & coronary artery calcium scores. Their associations with T50 were investigated.

Results: T50 was significantly lower in CKD patients *vs* control subjects (P<0.001). A significant increase in age (P=0.05), serum phosphate (P<0.001), intact parathyroid hormone (P=0.001), C-reactive protein (P=0.031), spot urine protein to creatinine ratio (P=0.001) as well as a decrease in serum albumin (P<0.001) & eGFR (P<0.001) were observed across the three tertiles of decreasing T50 in CKD. Adjusting for age & gender, T50 showed significant inverse associations with left ventricular (LV) mass index (P<0.001), left atrial volume index (P=0.012), early diastolic mitral annular velocity (Em) (P=0.004) & the ratio of early transmitral flow velocity (E) to Em (P=0.001) but not systolic functional parameters. Serum T50 retained significant association with cardiac troponin T (P=0.027) in the model adjusting for age, gender, eGFR & LV mass index. T50 however showed no direct association with baseline coronary artery calcium score.

Conclusions: Low T50 may predict adverse outcomes in CKD via its close associations with myocardial injury, myocardial structural & diastolic functional abnormalities. These data suggest T50 may more be a biomarker reflecting myocardial disease rather than calcification of the coronary arteries.

Loss of AT-1 Receptor Regulation in CKD: Role of β-Arrestin2

Siddhartha S. Ghosh, Sindhura Bobba, Daniel E. Carl, Richard Krieg, Todd W. Gehr. *VCU, Nephrology, Richmond, VA.*

Background: Angiotensin II (A-II) is known to play a major role in renal failure. Studies have proven that A-II down regulates AT-1 receptors via β-arrestin2. In CKD A-II levels increase significantly and mediates it action via ERK signaling. Increased A-II will down-regulate AT-1 receptors in CKD and ERK signaling will decrease. However, regulation of the AT-1 receptor in CKD kidney has not been clearly evaluated. This study was conducted to understand AT-1 receptor regulation in CKD.

Methods: CKD was generated in Sprague dawley rats by 5/6 nephrectomy (Nx). Nx rats were sacrificed at 2, 4, 8 and 12 weeks after Nx (n=5/group). The sham control rats were sacrificed on the 12th week. A group of Nx rats received 10 mg/kg losartan from 4 to 8 weeks. Expression of kidney AT-1 receptor, β-arrestin2, pERK/ERK was measured by western blots. A- II was measured by RIA. Serum from these rats was analyzed for creatinine and urea.

Results: Serum creatinine and urea went up gradually and peaked at 8 weeks. The mean kidney A-II concentration of the control animals was 303±25 fmol/gm. The results shown in the table are expressed as fold change. A-II levels peaked at 8 weeks. AT-1 receptor and ERK signaling went down but was restored by 8weeks. β-arrestin2 expression decreased at 2 weeks and never recovered. Losartan effectively reduced ERK signaling.

	Control	2 weeks	4 weeks	8 weeks	12weeks	Losartan
A-II	1.00± 0.08	1.56+ 0.12*	2.68± 0.25*	3.29± 0.27*	3.31± 0.26*	3.15± 0.38
AT-1	1.00± 0.08	0.13± 0.02*	0.45± 0.05*	0.81± 0.14	0.76± 0.05	0.86+ 0.13
pERK/ERK	1.00± 0.14	0.18± 0.06*	0.53± 0.06*	0.99± 0.12	0.91± 0.19	0.15± 0.05*,†
β- arrestin2	1.00± 0.17	0.25± 0.11*	0.37± 0.08*	0.20± 0.06*	0.33± 0.10*	0.38± 0.20*

*p<0.05 compared to control †p<0.05 compared to 8 weeks

Conclusions: β-arrestin2 is known to internalize AT-1 receptor. Our study shows that normal regulation of AT-1 receptor by A-II is lost as CKD progressed which is likely due to the loss of β arrestin2 . Losartan neither affected AT-1 receptor expression or β-arrestin2 levels but by blocking ERK signaling it could abate A-II mediated deleterious effect on CKD.

TH-PO564

Sphingosine 1-Phosphate Changes in Patients with Chronic Kidney Disease on Hemodialysis and Peritoneal Dialysis

Daria Salata,[1] Malgorzata Marchelek-Mysliwiec,[2] Marta Budkowska,[1] Wojciech Brzoska,[2] Barbara Dolegowska.[1] *[1]Medical Analytics, Pomeranian Medical Univ, Szczecin, Poland; [2]Dept of Nephrology, Transplantology and Internal Medicine, Pomeranian Medical Univ, Szczecin, Poland.*

Background: Sphingosine-1-phosphate is involved in the development and pathogenesis of renal function and physiology of many renal diseases including chronic kidney disease. Changes in concentrations of sphingosine-1-phosphate may affect the renal function and appear to be potential indicators of renal damage and renal graft function. The aim of this study was the evaluation of the biochemical parameters and quantitative analysis of the concentrations of sphingosine-1-phosphate in patients with chronic renal failure undergoing peritoneal dialysis, hemodialysis, or pre-dialysis.

Methods: The study included 120 patients with CKD:, on peritoneal dialysis (n=30) and hemodialyzed (n=30), in predialysis state (n=60). The concentrations of biochemical parameters in serum were determined by colorimetric methods. The concentrations of S1P in the plasma were measured using the RP-HPLC. Obtained results were statistically analysed using STATISTICA PL v.10.1.

Results: The highest average concentration of S1P has been obtained in patients on peritoneal dialysis (83.83 ± 18.99 mg/dL), and the lowest in patients with pre-dialyis therapy (58.06 ± 20.38 mg/dL). The average concentration of S1P in patients before hemodialysis (71.52 ± 19.86 mg / dL) and after treatment (77.83 ±26.48 mg/dL) were similar. Significant differences in concentration of S1P were found between patients with peritoneal dialysis and pre-dialysis patients (p = 0.0002) and between patients after hemodialysis and pre-dialysis (p = 0.003).

Conclusions: Observed higher concentrations of S1P in hemodialysis patients and peritoneal dialysis in comparison to patients treated conservatively. Indicate that activation of cellular lipid sources may be caused by the activation of the coagulation system and increased oxidative stress

Renal Elasticity of Patients with Chronic Kidney Disease Evaluated with Real-Time Ultrasound Elastography

Hugo You-Hsien Lin,[1,2,3] Shang-Jyh Hwang,[1] Hung-Chun Chen,[1] Chi-chih Hung.[1] *[1]Div of Nephrology, Dept of Internal Medicine, Kaohsiung Medical Univ Hospital, Kaohsiung, Taiwan; [2]Dept of Internal Medicine, Kaohsiung Municipal Ta-Tung Hospital, Kaohsiung, Taiwan; [3]Graduate Inst of Medicine, College of Medicine, Kaohsiung Medical Univ, Kaohsiung, Taiwan.*

Background: Ultrasound real-time elastography is a new imaging technique, which provides information about the elasticity of soft tissue. It is widely applied in patients with liver diseases. In patients with chronic kidney disease (CKD), glomerulosclerosis and tubulointerstitial fibrosis could be associated with lower renal parenchymal elasticity. However, little is known about the elasticity of the kidney. We designed a study to evaluate renal elasticity in patients with CKD stage 3-5.

Methods: There were 148 healthy volunteers and 227 patients with CKD in this cohort from Southern Taiwan. Renal sonography was performed on the Hitachi EUB 7500 and HIVISION PREVIUS sonographer with elastrography and the EUP-C715 (1-5MHz) probe.

Results: There were 143 (63.0%) male, 166 (73.1%) diabetes, with a mean estimated glomerular filtration rate (eGFR) of 33.9±15.8 ml/min/1.73 m^2 and a median urinary protein-to-creatinine ratio (UPCR) 502 (122-1491) mg/g in the CKD group. Patients with later CKD stages had lower value of renal elasticity, which means more stiff (p<0.001), and smaller kidney long length (p<0.001). We demonstrated that renal elasticity only correlated with log-transformed UPCR (β = -7.544, P< 0.001). Renal long length correlated with age (β = -0.231, P< 0.001), sex (β = -3.730, P< 0.001), serum albumin level (β = -3.024, P= 0.001), body mass index (β = 0.390, P= 0.009) and eGFR (β = 0.146, P< 0.001). In fully-adjusted logistic regression model, the odds ratio (OR) per 10 unit change of renal

elasticity for rapid renal progression was 0.928 (95% CI, 0.864-0.997; $P = 0.042$). The OR per 1mm change of renal long length for rapid renal progression was 1.022 (95% CI, 0.994-1.050; $P = 0.125$).

Conclusions: Renal elasticity is associated with proteinuria and rapid renal progression in patients with CKD. It may be a useful tool for early detecting renal function change in patients with CKD.

The Availability of Proteinuria/Urinary Beta2-Microglobulin Combination as a Complementary Marker to Predict Early Progress in Chronic Kidney Disease

Chang Hwa Lee, Il hwan Oh, Joon-sung Park. *Internal Medicine, Hanyang Univ College of Medicine, Seoul, Korea.*

Background: Proteinuria as a marker of glomerular damage is of pathogenic importance to the progression of chronic kidney disease (CKD). However, renal tubulointerstitial damage can serve a common pathway of CKD progression. Urinary b_2-microglobulin excretion, a marker of proximal tubular damage, may reflect the presence of tubulointerstitial damage. We hypothesized that the combination of proteinruia and urinary b_2-microglobulin may be useful predictor of renal outcome.

Methods: Proteinuria and urinary b_2-microglobulin excretion were measured in 104 patients with CKD. Based on the value of urine protein-to-creatinine ratio (PCR) or urinary b_2-microglobulin-to-creatinine ratio (UBCR), a total of 104 patients were divided into four groups: group I (n = 39), PCR < 0.5 mg/g and UBCR £300 ug/g: group II (n = 16), PCR < 0.5 mg/g and UBCR> 300 ug/g: group III (n = 24), PCR ³0.5 mg/g and UBCR £300 ug/g: group IV (n =25), PCR ³0.5 mg/g and UBCR> 300 ug/g. Logistic regression analysis was used to compute odds ratio to examine the relationship of proteinuria or increased UBCR with deterioration of renal function (DRF), and Kaplan-Meier analysis was used to compare cumulative renal survivals among the groups.

Results: During a mean follow-up of 71 ± 21 months, renal function deteriorated in 28 of the 104 patients with CKD. Among four groups, there was statistically significant difference in gender ($P < 0.0198$), serum glucose ($P < 0.0147$), serum uric acid ($P < 0.0279$), and eGFR at 12 months ($P < 0.0158$). Logistic regression analysis identified the only combination of proteinuria and high UBCR (OR 7.396; 95% CI, 1.235 to 44.284; $P = 0.028$) as risk factors for DRF. In Kaplan-Meier analyses, group IV had most inferior cumulative renal survival rate and there were statistically significant difference among the groups ($P < 0.008$).

Conclusions: The combination of protein and b_2-microglobulin in urine of CKD may be useful predictors of long-term renal survival. Proteinuria and urinary b_2-microglobulin should not be discretely but simultaneously considered to early detect and delay DRF.

TH-PO567

Renal Hyperfiltration Predicts Increased Urinary Albumin Excretion in the General Non-Diabetic Population

Toralf Melsom,[1,2] Vidar T. N. Stefansson,[1] Jørgen Schei,[1,2] Marit D. Solbu,[1,2] Trond G. Jenssen,[1,4] Tom Wilsgaard,[3] Bjorn Odvar Eriksen.[1,2] *[1]Metabolic and Renal Research Group, UiT the Arctic Univ of Norway; [2]Dep. of Nephrology, Univ Hospital of North Norway; [3]Dep. of Community Medicine, UiT the Arctic Univ of Norway; [4]Dep. of Nephrology, Oslo Univ Hospital, Norway.*

Background: In cohort studies, both low and high estimated glomerular filtration rate (eGFR) have predicted cardiovascular disease (CVD) and death. The increased risk associated with high eGFR has been explained by confounding due to a low serum creatinine in persons with chronic illness. However, abnormally high GFR, renal hyperfiltration, has been hypothesized to cause elevated urinary albumin excretion, a known risk factor for CVD and death. We investigated this hypothesis in the non-diabetic general population using measurements of GFR instead of eGFR.

Methods: In 2007-2009 we measured GFR by iohexol clearance in 1552 persons aged 50-62 years from the general population without diabetes or high albumin-creatinine ratio (ACR) (ACR >3mg/mmol). 1274 (82%) had a follow-up measurement of GFR in 2013-2015. 36 persons with diabetes at follow-up were excluded. Hyperfiltration was defined as an increase in absolute GFR (positive ΔGFR) within the same individual between baseline and follow-up. Since nephron number does not increase with age, this will be a proxy for increased single nephron GFR.

Results: ΔGFR was positively associated with a change in log(ACR) in multiple linear regression. The ratio ACR_{FU} /$ACR_{BASELINE}$ increased 7% (95% CI: 0.4 to 13%) per standard deviation (SD) increase in ΔGFR. The top ΔGFR quartile was associated with a 34% (95% CI: 8 – 68%) increased ACR_{FU} /$ACR_{BASELINE}$ ratio in women, but not in men, $p<0.05$ for the interaction. The odds ratio (95% CI) of high ACR at follow-up was 2.0 (1.3 – 2.9) per SD increase in ΔGFR. We adjusted for baseline CVD risk factors and change in body weight and use of anti-hypertensive medication.

Conclusions: Hyperfiltration predicts high ACR in the general population without diabetes. Although this may represent a link between hyperfiltration and an increased risk of CVD and mortality, it is unknown whether hyperfiltration is associated with these outcomes.

TH-PO568

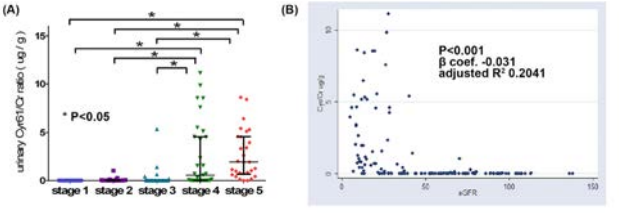
Elevated Urinary Excretion of Cysteine-Rich Protein 61 Is Associated with Rapid Renal Function Decline in Patients with Chronic Kidney Disease

Chun-Fu Lai, Shuei-Liong Lin, Wen-Chih Chiang, Yung-Ming Chen. *Dept of Internal Medicine, National Taiwan Univ Hospital, Taipei City, Taiwan.*

Background: Cysteine-rich protein 61 (Cyr61) has been identified as a proinflammatory factor in animal models of obstructive kidney fibrosis and ischemic kidney injury. We hypothesized that Cyr61 participates to the inflammatory process in injured kidneys and leads to progressive renal failure. The present clinical study aimed to examine urinary Cyr61 excretion in patients with chronic kidney disease (CKD).

Methods: Adult patients with stages 1-5 CKD were recruited from outpatient clinic. Urinary levels of Cyr61 were measured by sandwich enzyme-linked immunosorbent assay. The clinical factors associated with urinary Cyr61 excretion were explored using regression analysis. Rapid renal function decline was defined as estimated glomerular filtration rate (eGFR) decline rate higher than 4 cc/min/year during the follow-up period.

Results: A total of 154 patients were included (n= 29, 31, 34, 31, and 29 in stage 1, 2, 3, 4, 5 CKD, respectively). Their age were 60.9 ± 13.4 years, and there were 57 women (37%). Urinary Cyr61 to creatinine ratio (UCry61CR) was markedly elevated in patients with stage 4 and 5 CKD (Figure 1A). UCry61CR was negatively correlated with eGFR (Figure 1B) and positively correlated with urinary protein to creatinine ratio. Furthermore, eGFR was independently associated with UCry61CR after adjusting age, gender, body weight, body high, and urinary protein to creatinine ratio (β= -0.026, P<0.001). Among patients with stage 3-5 CKD, UCyr61CR was significantly higher in those with rapid renal function decline in the following 3 months (P=0.02).



Conclusions: Urinary Cyr61 excretion increases significantly in patients with advanced CKD. Higher UCyr61CR may be associated with following rapid renal function deterioration.

TH-PO569

Hyperuricemia Can Be a Risk Factor for the Development of Hypertension and CKD – An 8-Year Follow-Up Study

Shinichiro Nishio, Satoru Kuriyama, Naoki Sugano, Takashi Yokoo. *Div of Nephrology and Hypertension, Dept of Internal Medicine, The Jikei Univ School of Medicine.*

Background: Uric acid (UA) levels correlate positively with the prevalence of CKD and/or hypertension, suggesting that UA can be a progression factor. We tested the hypothesis that UA may also have a link to a new incidence of chronic kidney disease (CKD) and hypertension.

Methods: Study design is a cohort study and the predictor is UA levels. Of the 14,360 screened cases, 7,536 participants without CKD were eligible for the analysis of the incidence of CKD. Among these CKD candidates, 6,475 participants were eligible for the analysis of the new development of hypertension. The observation period was 8 years. UA levels were dicided into 4 groups (Group 1:UA<5mg/dL, Group 2:5.0-5.9mg/dL, Group 3:6.0-6.9mg/dL, Group 4:UA≥7mg/dL).

Results: Higher UA levels had a closer association with the new development of CKD at year 8; 1.6% (Group 1), 2.3% (Group 2), 3.1% (Group 3), and 4.9% (Group 4), respectively. Cox proportional hazard analysis showed that the estimates of the CKD development were age, UA levels (Hazard Ratio (HR) 1.372,95% confidence interval (CI) 1.214-1.550), HbA1c and gender, indicating that UA levels can be predictors. The logistic analysis showed that the odds ratio (OR) to estimate CKD incidence in the high UA group (Group 4; OR 3.41, 95% CI, 95%CI 1.99-5.84) was greater than that in the low UA group (Group 1). On the other hand, higher UA levels had a closer association with the new development of hypertension; 6.9% (Group 1), 10.5% (Group 2), 13.0% (Group 3), and 17.0% (Group 4), respectively. Cox proportional hazard analysis showed that the estimates of the hypertension development were BMI, age, HDL-cholesterol, male gender, UA level (HR 1.112, 95% CI, 1.024 to 1.207), and eGFR. The logistic analysis showed that the odds ratio (OR) to estimate hypertension in the high UA group (Group 4; OR 1.33, 95% CI, 1.01 to 1.80) was greater than that in the low UA group (Group 1).

Conclusions: High UA levels are associated with the incidence of CKD and the development of hypertension.

TH-PO570

Associations Between Uric Acid, Adiponectin and Urinary Biomarkers in Persons with and without the Metabolic Syndrome Marit D. Solbu,[1,2] Jon viljar Norvik,[2] Jens Kronborg,[2,3] Bjorn Odvar Eriksen,[1,2] Toralf Melsom,[1,2] Trond G. Jenssen.[2,4] *[1]Section of Nephrology, Univ Hospital of North Norway, Tromsø, Norway; [2]Metabolic and Renal Research Group, UiT the Arctic Univ of North Norway, Tromsø, Norway; [3]Innlandet Hospital Trust, Lillehammer, Norway; [4]Oslo Univ Hospital, Oslo, Norway.*

Background: In the metabolic syndrome (MetS), serum uric acid (UA) is often increased, and adiponectin is low; UA may cause renal damage, whereas adiponectin may be renoprotective. It is not known whether UA and adiponectin interact in development of renal damage. We assessed the cross-sectional association between UA, adiponectin and two urinary biomarkers (albumin creatinine ratio (ACR) and orosomucoid creatinine ratio (oroCR)) in persons with or without the MetS (NCEP-ATPIII definition).

Methods: From the Tromsø Study 2007-08, 7047 persons were included. Three urine specimens were collected and median values of ACR and oroCR used. The associations between UA, adiponectin and the upper vs. three lower quartiles of each biomarker were assessed by logistic regression analysis adjusted for cardiovascular risk factors, medication use and eGFR in persons with and without the MetS.

Results: Mean age was 63.5 (±SD 9.2) years, 57% were women and 27% had the MetS. UA was associated positively with the upper ACR quartile and negatively with the upper oroCR quartile. The association with ACR was stronger in persons with the MetS than in those without (OR 1.18; 95% CI 1.07–1.31; P=0.002 vs. OR 1.08; 95% CI 1.01–1.16; p=0.04 per 1 mg/dL increase in UA.) Adiponectin was positively associated with ACR and oroCR, but only in persons without the MetS (OR 1.08 (95% CI 1.04-1.13); OR 1.07 (95% CI 1.03-1.12), both P<0.001, per µg/mL). There were no interactions between UA and adiponectin in their associations with the urinary biomarkers.

Conclusions: UA and adiponectin did not interact in their associations with biomarkers of renal damage. Contrary to what we expected, adiponectin was positively associated with ACR and oroCR, but only in persons without the MetS. UA was positively associated with ACR only. The findings should be studied longitudinally before firm conclusions could be made.

Funding: Government Support - Non-U.S.

TH-PO571

The Longitudinal Association Between Uric Acid Level and Progression of Chronic Kidney Disease in Chinese Population Ching-Wei Tsai, Shih-yi Lin, Chin-Chi Kuo, Chiu-Ching Huang. *Div of Nephrology and Kidney Inst, China Medical Univ and Hospitals, Taichung, Taiwan.*

Background: Hyperuricemia is commonly observed in patients with chronic kidney disease (CKD). Although increasing evidence supports the association between hyperuricemia and incident CKD, there are conflicting data about the role of hyperuricemia in the progression of CKD. The main aim of current study was to add empirical evidence to the debate on the direction of the relationship among uric acid levels, allopurinol, and CKD progression in Chinese population.

Methods: We conducted a retrospective cohort study in central Taiwan. Patients who had documented hyperuricemia (defined by uric acid greater than 7 mg/dL) and/or receiving uric acid-lowering agents between 2003 and 2005 were included in the study. They were followed till December 31, 2011. Only patients with at least three available renal function profiles were analyzed. CKD progression was evaluated by the change in eGFR using linear mixed models.

Results: Longitudinal analyses showed patients with a baseline uric acid level greater than 7 mg/dl had faster decline in eGFR, comparing to those with uric acid level less than 7 mg/dl. After adjustment for demographics, comorbidities, proteinuria, allopurinol and ACEI/ARB use, three categories of hyperuricemia (uric acid 7-9, 9-11, >11 mg/dl) remained strongly associated with faster decline in eGFR over the follow-up. In multivariate longitudinal analysis, those receiving allopurinol was associated with a significantly faster decline in eGFR than non-allopurinol users during the follow-up.

	beta	p value
uric acid<7 mg/dl	Ref	
uric acid 7-9 mg/dl	-6.7	0.002
uric acid 9-11 mg/dl	-7.2	0.006
uric acid >11 mg/dl	-10.7	0.001
age at exam	-0.6	<0.0011
sex	1.8	0.9
DM	-2.2	0.2
CAD	-0.5	0.8
SBP	-0.03	0.4
Baseline creatinine	-6.4	<0.001
proteinuria	-10.6	<0.001
Allopurinol	-9.6	<0.001

Conclusions: Our study showed higher uric acid level is strongly associated with an accelerated decline in renal function in Chinese population. However, uric acid-lowering therapy with allopurinol was associated with even faster progression of CKD in this study.

TH-PO572

Revisiting Medullary Tophi: A Link Between Uric Acid and Progressive Chronic Kidney Disease? Salem Almaani,[1] Isabelle Ayoub,[1] Sergey V. Brodsky,[2] Tibor Nadasdy,[2] Jason Prosek,[1] Lee A. Hebert,[1] Brad H. Rovin.[1] *[1]Div of Nephrology, The Ohio State Univ, Columbus, OH; [2]Dept of Pathology, The Ohio State Univ, Columbus, OH.*

Background: It is well-established from autopsy studiesthat gouty tophi can form in the kidney, particularly in the renal medulla. Recently hyperuricemia has been identified as a risk factor for progression of chronic kidney disease (CKD). Because each collecting duct serves more than 2000 nephrons, we postulated that obstruction or disruption of collecting ducts by medullary tophi may explain, at least in part, the association between hyperuricemia and progressive CKD. This work was done to determine the prevalence of medullary tophi in CKD patients.

Methods: We queried our nephropathology database over the last ten years for native kidney biopsiesthat had medullary tophi. The presence or absence of CKD and uric acid levelsaround the time of biopsy were determined by chart review.

Results: Predominant medullary tissue was reported in 796 of 7409 total biopsies, and 572 of these were from patients with established CKD. Medullary tophi were seen in36 patients, 35 of whom had CKD, suggesting a minimum prevalence of tophi in CKD and no-CKD of 6.11% and 0.45%, respectively. Medullary tophi occurred with and without hyperuricemia or a history of gout.

ID	Age[1]	Race[2]	Gout	Nephroli-thiasis	Serum Creatinine Concentration/eGFR[4]	Serum Uric Acid Concen-tration[5]
1	42	CAU	Yes	No	2.8/26	9.1

Conclusions: Medullary tophi appear to be far more likely to occur in CKD compared to no-CKD patients. This cross-sectional study cannot determine whether medullary tophi are a cause or consequence of CKD. However, given their strategic location and bulk, it is possible that medullary tophi contribute toprogression of established CKD by causing upstream nephron damage.

TH-PO573

Serum Uric Acid Over 7 mg/dL Is an Independent Risk of Incident End Stage Kidney Disease – A 6-Year Population-Based Cohort Study Ouppatham Supasyndh, Puvanant Wiputhanuphong, Bancha Satirapoj. *Nephrology Div, Dept of Internal Medicine, Phramongkutklao Hospital and College of Medicine, Thailand.*

Background: Uric acid deteriorates kidney function via crystal and non-crystal dependent mechanisms. However epidemiological evidence for the significance of serum uric acid levels on the risk for developing end-stage kidney disease (ESKD) is scarce in a setting of population-based screening especially in Asian population. The purpose of the study was to evaluate the effect of serum uric acid level on incidence of impaired kidney function and ESKD.

Methods: A total of 23,712 individuals from an integrated health care delivery system in the Thai army who participated for health checkups between July 1, 2006, and December 31, 2012 were screened. Only 18,390 participants (14,686 men, 3,704 women) older than 20 years for whom available for body weight, serum uric acid, and creatinine data with estimated glomerular filtration rate (eGFR) over 60 ml/min/1.73m^2 were enrolled in the study. The cumulative incidence of chronic kidney disease (CKD, eGFR<60 mL/min per 1.73 m^2) and ESKD (eGFR<15 mL/min per 1.73 m^2) was calculated according to quartiles of baseline serum uric acid levels and significant high serum uric acid levels (≥7.0 mg/dL).

Results: The mean age of participants was 47.69±6.69 years and body mass index was 24.71 ±3.47 kg/m^2. Fourteen percent (n=2,648) was diabetes and 65.2% (n=11,998) had high blood pressure. Average serum uric acid and eGFR were 6.29 ± 1.55 mg/dL and 87.84 ± 13.27 mL/min per 1.73 m^2, respectively. The incidence of CKD at 6 years follow up was 3.64/1000 person-year. A total of 11 patients (0.06%) of ESKD were observed. Participants with highest serum uric acid quartile (>7.3 mg/dL) had a 3.42-fold increase in adjusted hazard ratio (HR) (95%CI; 2.19 to 5.32), compared to those with the lowest serum uric acid quartile (<5.2 mg/dL). Moreover, serum uric acid ≥ 7 mg/dL were significantly increased risk of ESKD (adjusted HR 5.74 with 95%CI; 1.58 to 20.8, P =0.008). Finally, every 1 mg/dL increasing of serum uric acid, eGFR would decline 2.2 mL/min per 1.73 m^2.

Conclusions: Serum uric acid level is an independent risk of CKD and ESKD in Thai population.

TH-PO574

Proton Pump Inhibitors Are Associated with Increased Risk of Development of Chronic Kidney Disease Pradeep Arora,[1,2] Mojgan Golzy,[3] Anu Gupta,[2] Rajiv Ranjan,[1,2] Randy L. Carter,[3] James W. Lohr.[1,2] *[1]Nephrology, VA Medical Center, Buffalo, NY; [2]Medicine, SUNY, Buffalo, NY; [3]Dept of Biostatistics, UB, Buffalo, NY.*

Background: Proton pump inhibitors (PPI) are one of the common cause of acute interstitial nephritis in the United States. This frequently goes undiagnosed due to its subacute clinical presentation, which may later present as chronic kidney disease (CKD). We investigated the association of PPI use with the development of CKD and death.

Methods: The population included 99,351 patients who were seen in primary care VISN2 clinics from 4/2001 until 4/2008. For evaluation of CKD outcome, 27,835 patients with baseline CKD were excluded. Study data was obtained from Veterans Affairs Health Care Upstate New York (VISN2) network. Data obtained included use of PPI (Yes/No), age, gender, race, retrospective observation time , laboratory data including eGFR, pre-PPI comorbidity variables: vascular disease, chronic obstructive pulmonary disease (COPD), cancer, diabetes, and hypertension. A prospective logistic analysis of case-control data (Prentice and Pyke) was used to investigate the association of treatment (exposure to PPI) with onset of CKD with propensity score in the model.

Results: A total of 24,149/71,516 patients developed CKD. Of those who developed CKD 25.7% were treated with PPI. Patients receiving PPI were more likely to have vascular disease, COPD, cancer and hypertension. Of the total of 99,251 patients analyzed for mortality outcome, 36,290 died. Propensity score analysis showed higher odds for development of CKD (OR 1.29 95% CI 1.24-1.34) and mortality (OR 1.97, 95% CI 1.88-2.06) among patients taking PPIs versus those not on PPIs. Sensitivity analyses showed a significant effect of the interaction of age and PPI use in models with CKD.

variables	contrast	Odds ratio with 95% CI
PPI	Yes vs No	1.29 (1.24-1.35)
Age	1 Year Increase	1.06 (1.05-1.07)
Race	Black vs white	0.92 (0.87-0.98)
Gender	Female vs Male	0.91 (0.84-0.99)
Time	one quater increase	0.9 (0.89-0.91)
Propensity score	0.1 unit increase	0.45 (0.3-0.66

Conclusions: Use of proton pump inhibitors are associated with increased risk of development of CKD.

TH-PO575

Influence of Statin on Iron Utilization and Metabolism in Patients with Chronic Kidney Disease Stage 3-4 Anna Masajtis-zagajewska, Michal P. Nowicki. *Dept of Nephrology, Hypertension and Kidney Transplantation, Medical Univ of Lodz, Lodz, Poland.*

Background: Hepcidin, an acute phase reactant protein is a key regulator of iron homeostasis. Elevated hepcidin levels are expected in the face of decreased glomerular filtration and inflammation. Hepcidin is a potentially modifiable mediator of anemia in patients with chronic kidney disease (CKD). Statins have had potent anti-inflammatory effects in experimental and clinical CKD and may thereby modulate erythropoiesis.

Methods: Thirty-six patients (17 M, 19 F, mean age 58±13 years) with stage 3 and 4 CKD and LDL cholesterol ³100 mg/dl not on statin therapy were studied. In a double blind, crossover study all subjects received in a random order either atorvastatin 20 mg/day or placebo for two 6-month periods with 3-month wash-out. Basic biochemistry, serum inflammatory markers such as hsCRP, IL-6, parameters of iron metabolism including iron, serum hepcidin, *Total Iron Binding Capacity (TIBC)*, Unsaturated *Iron*Binding Capacity (UIBC) and hemojuvelin were measured both before and after each treatment period.

Results: TIBC and UIBC did not change during placebo phase but significantly increased after 6 months statin therapy from 255±43 to 267±45ug/dl (p=0.006) and from 186±48 to 196±50µg/dl (p=0.03), respectively. Serum iron tended to increase from 68.8±19.1µg/dl to 72.4±17.8µg/dl (p=0.08) only during statin treatment. Hemoglobin increased after 6 months statin therapy from 11.6±1.6 to 11.8±1.5g/dl (p=0.001) while after placebo period hemoglobin did not change. Hepcidin levels significantly decreased during statin treatment from 241±337 to 160±210pg/ml (p=0.01), while no effect was found during placebo phase. Hemojuvelin levels did not change after both statin and placebo. IL-6 and hsCRP tended to decrease after 6 months only after statin therapy (from 11.5±11.1 to 11.1±15.2pg/ml; p=0.06 and from 52.2±28.9 to 46.2±28.1mg/dl; p=0.06, respectively. Total and LDL-cholesterol decreased significantly only during statin treatment.

Conclusions: The treatment of CKD patients with statin may reduce inflammation and improve iron utilization through decreased serum hepcidin.

CKD Prevalence and Iron Status: Are They Linked to the Etiology and Ejection Fraction in Chronic Heart Failure Jacek S. Malyszko,[1] Hanna Gajewska,[2] Slawomir Dobrzycki,[2] Jolanta Malyszko.[3] *[1]1st Nephrology, Medical Univ, Poland; [2]Invasive Cardiology, Medical Univ, Poland; [3]2nd Nephrology, Medical Univ, Poland.*

Background: Kidney disease and cardiovascular disease are tightly associated and there is a mounting evidence of inter-organ cross-talk. Anemia and iron deficiency are frequent in CKD. We performed the cross-sectional study on 273 prevalent patients and investigated a) the prevalence of chronic kidney disease in patients with heart failure due to coronary artery disease, cardiomyopathy or valvular disease undergoing percutaneous coronary interventions-PCI; b) iron status (additionally assessed using circulating soluble transferrin receptor-sTfR, hepcidin, hemojuvelin, GDF-15) in these 3 subpopulations in regard to kidney function.

Methods: GFR was estimated by MDRD formula. sTfR, hepcidin, hemojuvelin, GDF-15 were studied using commercially available kits.

Results: Prevalence of CKD (stage 3 or more) was the highest in in valvular disease (34%), the lowest in coronary artery disease (23%). According to the WHO definition, the prevalence of anemia in the studied cohort was 23.1%. We observed a progressive decline in GFR and hemoglobin concentration together with a rise in NYHA class in the whole cohort. Iron deficiency and anemia were the most often found in patients with heart failure due to coronary artery disease, with the highest hepcidin and GDF15 levels, and highest eGFR. Anemic patients had worse kidney function, except valvular disease subgroup relative to non- anemics. In the latter serum hepcidin was the lowest. Iron status in heart failure was related to the etiology of this clinical setting, but not to kidney function. However, when divided into groups with preserved or reduced ejection fraction-EF, CKD, anemia and iron deficiency was more prevalent in patients with worse ejection fraction. Significant correlations were observed between eGFR and age, NYHA class, hepcidin, GDF-15.

Conclusions: The prevalence of anemia and chronic kidney disease is high and depends on the etiology of heart failure and EF in patients undergoing PCI. Hemodynamic changes and subclinical inflammation seems to play a major role in altered iron status and impaired kidney function in heart failure.

Hormone Replacement Therapy in Post-Menopausal Women Is Associated with Better Kidney Function Andrea G. Kattah,[1] Bradley R. Lewis,[2] Stephen T. Turner,[1] Vesna D. Garovic.[1] *[1]Div of Nephrology and Hypertension, Mayo Clinic; [2]Health Sciences Research, Mayo Clinic, Rochester, MN.*

Background: The effect of hormone replacement therapy (HRT) on renal function in post-menopausal women is unclear. Experimental models suggest estrogen has a renoprotective effect, but human studies have had variable results.

Methods: We performed a cross-sectional study on 2217 post-menopausal women who participated in the Family Blood Pressure Program, a mutli-network study aimed at studying the genetics of hypertension. We compared markers of renal function, including urine albumin/creatinine ratio (UACR) and estimated glomerular filtration (eGFR) using the CKD-EPI equation, between women who were using HRT (n=673, median age 60.2) and those who were not (n=1544, median age 62.9). Clinical characteristics, including body mass index (BMI), medical history, medications, family history and blood and urine tests were measured at a single study visit conducted between 2000-2004.

Results: UACR was significantly lower in those on HRT versus those who were not (3.5 vs. 5.2 mg/g Cr, p<0.001), as was the number of women with eGFR < 60 ml/min/1.73 m^2 (7% vs. 10%, p=0.003). We performed linear and logistic regression models using generalized estimating equations for log(UACR), UACR > 25 mg/g Cr and eGFR < 60 ml/min/1.73 m^2 and adjusted for age, race, network, education, smoking, diabetes, hypertension, family history of hypertension, log(BMI), log(HDL), log(LDL) and log(triglycerides). After adjusting for these factors, we found that the use of HRT was still significantly associated with lower log(UACR)(-0.307, p<0.001) and women not on HRT had an odds of 1.6 (95% CI 1.2-2.3) times that of those on HRT of having UACR > 25 mg/g Cr. The association between HRT and eGFR < 60 ml/min/1.73m^2 was no longer significant after adjustment.

Conclusions: The use of HRT in post-menopausal women was associated with lower UACR after adjusting for known risk factors for renal and cardiovascular disease. Strengths of our study include a large sample size and a comprehensive medical history of subjects. Limitations include that subjects were recruited on the basis of hypertension and that we had limited information on the length of time on HRT.

TH-PO578

Tobacco Smoking and Progression of Chronic Kidney Disease: A Role for Reactive Aldehydes? Gabriel Rezonzew,[1] Phillip H. Chumley,[1] Wenguang Feng,[1] Ping Hua,[1] Huma Fatima,[1] Edgar A. Jaimes.[2] *[1]Univ of Alabama at Birmingham; [2]Memorial Sloan Kettering Cancer Center.*

Background: Clinical and experimental evidence supports the role of tobacco smoking as a risk factor in the progression of chronic kidney disease (CKD) of different etiologies. Cigarette smoke (CS) contains numerous compounds that could be responsible for the deleterious effects of tobacco smoking. Among these compounds are included large concentrations of reactive aldehydes such as acrolein that react with thiol groups and active NADPH oxidase as we have previously shown (ATVB'04). In these studies we postulated the hypothesis that acrolein (Acr) accelerates the progression of CKD and that these effects are linked to increased oxidative stress.

Methods: Sprague-Dawley rats (n=6-8) were divided in the following groups: Sham, Sham+Acr (0.5 mg/kg/day via osmotic minipump),5/6Nx and 5/6Nx+Acr. Rats were euthanized after 12 weeks and kidneys saved for glomerular injury score (GIS) and tubular injury score (TIS). Urine was collected every two weeks for proteinuria (Bio-Rad). Urinary isoprostanes and TGF-β were measured by Elisa and adjusted for urinary creatinine.

Results: Sham rats on Acr had a significant increase in proteinuria, urinary excretion of isoprostanes and TGF-β, TIS but not GIS. Rats with 5/6Nx had a significant increase in proteinuria, TIS and GIS and a modest increase in TGF-β. The administration of Acr to 5/6Nx resulted in further increases in proteinuria, isoprostanes and TIS but not GIS. The urinary excretion of TGF-β in these rats was also increased and similar to Sham+Acr.

	Sham	Sham+Acr	5/6Nx	5/6Nx+Acr
Proteinuria (mg/24 hours)	51.1± 9.8	122.4± 10.2*	122.7± 13.6*	420.5± 98.5*,#
Isoprostanes (pg/mg creatinine)	61.4± 10	164.5± 32.4*	51.5± 20	336.5± 126.7*,#
TIS	2.9± 0.6	6.5± 1.2*	8.26± 2.1*	15.1± 2.5*,#
GIS	0	0.1± 0.1	36± 22*	36± 20*
TGF-β (pg/mg creatinine)	5.3± 1.8	50.1± 16.7*	10.7± 4.	51.5± 28.1*,#

* P <0.05 vs Sham, # P<0.05 vs 5/6NX (N=6-8)

Conclusions: These studies suggest that the reactive aldehyde acrolein plays a role as mediator of the deleterious effects of tobacco smoking in the progression of CKD.

Funding: Other NIH Support - National Institute of Environmental Health Sciences

Intermittent Smoking Associates with Chronic Kidney Disease in U.S. Hispanics: The Hispanic Community Health Study/ the Study of Latinos (HCHS/SOL) Nora Franceschini. *Epidemiology, Univ of North Carolina, Chapel Hill, NC.*

Background: Cumulative smoking exposure is associated with chronic kidney disease (CKD). However, the patterns of exposure, such as the effect of intermittent smoking, on CKD risk are unknown. These patterns may be important given the recent increase in alternative smoking exposures such as e-cigarettes.

Methods: Cross-sectional study of 15,664 participants of a population-based cohort of Hispanic/Latinos aged 18-74 years recruited from four U.S. field centers from 2008 to 2011. Data on current, past and never smoking, and smoking pack-years were obtained through a questionnaire. The association between smoking exposure and CKD (estimated glomerular filtration rate <60 ml/min/1.73 m^2 or urine albumin to creatinine ratio ≥ 30 mg/g) was estimated using logistic regression models. We tested the interaction between smoking status and cumulative pack-years at the significance level of 0.05.

Results: Approximately 62% individuals were non-smokers, 17% were past smokers and 22% were current smokers, of which 14% were daily smokers and 8% were intermittent smokers. The adjusted prevalence estimates of CKD were 10% for non-smokers, 11% for past smokers, 8% for daily smokers and 12% for intermittent smokers.There was a significant interaction between smoking status with pack-years of exposure (p=0.0002). In adjusted models accounting for this interaction, there were increased odds of CKD among current daily, intermittent, and past smokers by pack-years compared to never smokers. The association of intermittent smokers with CKD was significant at 10 pack-years of smoking, whereas for daily smokers, it was observed only at 40 pack-years of smoking. Past smokers had a 20% increased odds of CKD compared with non-smokers across pack-years of smoking.

Conclusions: This study demonstrates significant effects of current daily and intermittent smoking on prevalent CKD among Hispanic/Latinos, which was significant at lower pack-years of exposure among intermittent smokers. Our research support efforts to aggressively eliminate smoking exposure through public health interventions and extend these current recommendations to prevention of CKD.

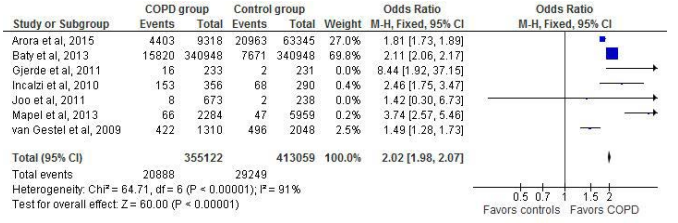
TH-PO580

Incidence of Chronic Kidney Disease in Patients with COPD: Systematic Review and Meta-Analysis Swarna Gouddam,[1] Sameer K. Gunukula,[1] James W. Lohr,[2] Nader Nader,[3] Pradeep Arora.[2] *[1]Medicine, SUNY at Buffalo, Buffalo, NY; [2]Medicine, VAMC, Buffalo, NY; [3]Anesthesiology, VAMC, Buffalo, NY.*

Background: Chronic obstructive pulmonary disease (COPD) is common disease especially in elderly population, and is a important cause of mortality world-wide. Several studies have identified COPD as part of a systemic inflammatory syndrome and reported on the association of comorbidities like lung cancer, osteoporosis, progression of atherosclerosis. However, the relationship between COPD and incidence of chronic kidney disease (CKD) has not been clearly demonstrated in the literature. The focus of our study was to systematically review the medical literature reporting the incidence of renal function disturbances specifically incidence of CKD in patients with COPD.

Methods: We conducted a systematic review using the Cochrane Collaboration Methodology. We searched Medline via Ovid, Pubmed, Embase and ISI web of Science databases from 1950 through 2015. We rated the quality of evidence for each outcome using the Grading of Recommendations Assessment, Development and Evaluation (GRADE) methodology. Meta-analysis was done using Review Manager Version 5.0.20.

Results: Our search resulted in 8 eligible studies. COPD was found to be associated with a significantly increased incidence of CKD (Odds Ratio [OR]=2.10; 95% Confidence Interval [CI] 2.04, 2.16.



Conclusions: COPD patients are at increased risk of developing chronic kidney disease. The exact reasons for the increase in the incidence of CKD are unclear. Clinical research and practice guidelines usually target disease conditions in isolation. Research into COPD and CKD is scant and there is a need for further studies to delve into the pathophysiological mechanisms and clinical implications of incidence of CKD in patients with COPD.

TH-PO581

Effects of Nicotine on the Severity of Diabetic Nephropathy: Role of α7-Nicotine Receptor Mohammed Siddiqui,[1] Wenguang Feng,[1] Gabriel Rezonzew,[1] Lawrence P. Wennogle,[2] Edgar A. Jaimes.[3] *[1]Univ of Alabama at Birmingham; [2]Intra-cellular Therapies; [3]Memorial Sloan Kettering Cancer Center.*

Background: Tobacco smoking plays a major role in progression of chronic kidney disease (CKD) of different etiologies including diabetes mellitus (DM). In previous studies we demonstrated that nicotine is responsible for deleterious effects of smoking in the progression of CKD and pharmacologic blockade of the α7 nicotine receptor subunit (α7-nAchR) reduces the effects of nicotine in a CKD rat model. Whether this receptor also plays a role in the progression of other models of CKD such as diabetic nephropathy is not known.

Methods: DM was induced with streptozotocin (STZ) in eNOS$^{-/-}$ and eNOS$^{-/-}$/α7-nAchR$^{-/-}$ (DKO) mice. A separate group of eNOS$^{-/-}$ mice also received a α7-nAchR blocker (IC200610, 2 mg/kg IP, 5 days a week for 10 weeks). Mice were given nicotine (100mg/ml in drinking water) or tap water for 10 weeks. Blood pressure (BP) was measured by tail-cuff method and urine collected every 2 weeks for albuminuria.

Results: All mice became diabetic after STZ and had no significant differences in weight or blood glucose at sacrifice. All animals were also hypertensive and nicotine had no effect on BP in any of the groups. Diabetic mice receiving nicotine (DN) had higher albumin excretion as compared to diabetic mice on tap water (DT). Diabetic mice on nicotine lacking the α7-nAchR (DN$^{-/-}$) or with pharmacologic blockade (DN+B) had urinary excretions of albumin similar to diabetics on tap water (DT). Neither absence of the α7-nAchR (DT$^{-/-}$) nor pharmacologic blockade (DT+B) had any effect on mice on tap water.

	DN (n=13)	DT (n=10)	DN$^{-/-}$ (n=9)	DT$^{-/-}$) (n=12)	DN+B (n=8)	DT+B (n=7)
Body Weight (gm)	26± 1.0	22± 0.9	25± 1.9	23± 0.5	25± 0.5	26± 1.1
Blood Glucose (mg/dL)	442± 48	542± 17	479± 41	516± 26	441± 43	354± 51
Albuminuria (ng/24 hr)	103± 25*	71± 8	42± 14	46± 7	35± 6	50± 13
Systolic BP (mm Hg)	153± 6	147± 6	153± 5	147± 4	142± 13	150± 11

* p<0.05 vs other groups.

Conclusions: These studies demonstrate that α7-nAchR is a critical mediator of the deleterious effects of nicotine in the severity of diabetic nephropathy.

Funding: Other NIH Support - National Institute of Environmental Health Sciences

TH-PO582

Lithium Nephropathy: A Long-Term Complication of Chronic Lithium Therapy Aleksander Hercegovac. *Nephrology, Maasstad Hospital Rotterdam, Rotterdam, Zuid-Holland, Netherlands.*

Background: Lithium is the treatment of choice for bipolar disorder. Lithium-induced nephropathy is a known complication limiting its use. The aim of this study is to establish the prevalence of renal failure in our population. We sought to quantify the contribution of lithium therapy to the risk of developing renal failure.

Methods: We selected 1751 patients on lithium therapy from the laboratory database of the Delta Center for Mental Health Care, Rotterdam. The database contains measurements of lithium and creatinine concentration over a period from 2000 to 2011. eGFR was calculated using the 4-variable MDRD formula. Renal failure was defined as having GFR<60mL/min on at least 2 measurements 6 weeks apart. A comparison was made between patients with and without renal insufficiency regarding gender, mean lithium concentration in serum, lithium intoxication, duration of therapy, age at initiation of therapy, cardiovascular disease, hypertension and diabetes mellitus.

Results: 305 out of 1751 (17.4%) patients were classified as having renal failure. Occurrence of renal failure was positively correlated with female sex, age at initiation of therapy and duration of lithium therapy (p<0.001). Significant correlation was also observed between renal failure and cardiovascular risk factors. Mean lithium serum concentration was 0.68 mmol/l and did not differ between patients with and without renal failure. In 251 patients follow up data was available for a period of more than 10 years. In these patients history of lithium intoxication did not predict occurrence of renal failure.

Conclusions: Prevalence of renal failure in our cohort is similar to other reports. Longer duration of lithium therapy was found to be associated with an increased risk of renal failure. Contrary to our expectation, lithium intoxication was not correlated with renal failure. Although therapy duration was a significant predictor, one should not forget the importance of cardiovascular risk factors in development of renal failure.

TH-PO583

Study of Organochlorine Pesticides in Patients with Chronic Kidney Disease of Unknown Etiology Om Prakash Kalra,[1] Chetna Gothwaal,[1] Alpana Raizada,[1] Ashok Kumar Tripathi,[2] Sunil Agarwal.[1] *[1]Medicine, UCMS and GTB Hospital, Delhi, India; [2]Biochemistry, UCMS and GTB Hospital, Delhi, India.*

Background: An apparently new form of CKD not attributable to diabetes, hypertension or other known causes, i.e. CKD of unknown etiology (CKDu) has emerged in south Asia, especially Sri Lanka, and Sub-Saharan Africa in the last one decade. CKDu affects younger individuals and is asymptomatic until advanced stages. Organochlorine pesticides (OCPs) are implicated in the etiopathogenesis of CKDu. This study aimed at estimating the serum level of various OCPs (α-HCH, β-HCH, g-HCH, total HCH, Aldrin, Dieldrin, α-endosulfan, β-endosulfan, p,p'-DDT, p,p'-DDE) and total pesticide load (TPL) in patients with CKDu in comparison with patients with CKD of known etiology (CKDk) and to assess their role in etiopathogenesis of CKDu.

Methods: This was a case-control, cross-sectional study conducted in east Delhi. Subjects in the age group 18-60 years of either sex were recruited under 3 groups: Group I: Healthy controls (n=30), Group II: Patients with CKDu (n=30) and Group III: Patients with CKDk (n=30). Detailed history, physical examination, routine investigations and urinary protein excretion estimation were done. Serum OCP levels were estimated by high performance liquid chromatography.

Results: The median serum levels of all OCPs were higher in patients of group II as compared to other study groups and this difference was statistically significant for α-HCH, β-HCH, total HCH, α-endosulfan, p,p'-DDE and TPL. For the same CKD stage, CKDu patients had higher levels of TPL as compared to CKDk patients. Mean blood urea and serum creatinine levels were higher in patients of group II. Significantly greater proportion (66.34%) of CKDu patients had stage V CKD as compared to CKDk patients. CKDu patients had higher urinary protein excretion as compared to CKDk patients though this was statistically insignificant.

Conclusions: Despite some limitations of the study, the presence of higher serum OCPs in individuals with CKDu in comparison to CKDk at corresponding CKD stages suggests their possible role in the etiopathogenesis of CKDu.

Funding: Government Support - Non-U.S.

TH-PO584

Chronic Kidney Disease After Intravenous Colistin Use in Survivors of Severe Infections Alejandro Y. Meraz-Munoz, Juan Carlos Ramirez-Sandoval, Ricardo Correa-Rotter. *Nephrology and Mineral Metabolism, Inst Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico.*

Background: The resurgence of colistin use for multidrug-resistant (MDR) infections has led to an increase of colistin-associated acute kidney injury (AKI). Nevertheless, long-term renal prognosis information is scarce.

Methods: A retrospective cohort study was performed from January 2011 to March 2015. Patients who received colistin for >5 days were included. We excluded cases with CKD, history of kidney transplant, and non-survivors to MDR infection. The primary outcome was the development of CKD after colistin treatment. CKD was defined as eGFR <60mL/1.73m^2 and/or proteinuria during ³3 months.

Results: In all, 132 patients received colistin, of them, 50 (40%) died due to MDR infection. During a median follow-up of 2.1 years (interquartile range [IQR]: 1.2-3.1) in 82 survivors, 28 (35%) progressed to CKD (stage 3: 25, stage 4: 2, and stage 5: 1). Mild AKI occurred in 29 patients during colistin treatment, one patient needed dialysis and 22 progressed to CKD. Independent predictors of colistin-associated progression to CKD in a logistic regression analysis were AKI (odds ratio [OR]: 32.0; 95% confidence interval [CI]: 6.0-87.0), colistin cumulative dose >5 g (OR: 16.0, 95% CI: 2.6-95.0), and age (OR: 1.1, 95% CI: 1.0-1.05).

Conclusions: Patients treated with intravenous colistin had a substantial risk for CKD. Therefore, they should be tightly monitored when cumulative dose is >5 g and AKI is identified.

Table1. Bivariate analyses on factors associated with progression to CKD

Characteristic	Patients without progression to CKD (n=54)	Patients with progression to CKD (n=28)	p value
Age, y (IQR)	38 (25-54)	59 (25-72)	**0.024**
Male gender, n (%)	25 (47)	15 (53)	0.580
Baseline SCr, mg/dL (IQR)	0.6 (0.5-0.7)	0.7 (0.5-0.9)	0.200
SOFA, score (IQR)	4 (2-5)	4 (3-5)	0.420
Colistin dose, mg/kg	4 (4-5)	4 (3-5)	0.290
Diabetes, n (%)	3 (6)	6 (21)	0.058
AKI, n (%)*	7 (13)	22 (78)	**0.001**
Colistin cumulative dose, g (IQR)	3.8 (2.1-4.9)	6 (3.9-8.4)	**0.001**

High-Density Lipoprotein Subfractions and Their Oxidized Subfraction Particles in Patients with Chronic Kidney Disease Hirokazu Honda,[1] Tsutomu Hirano,[2] Masashi Ueda,[3] Shiho Kojima,[3] Shinichi Mashiba,[3] Yasuyuki Hayase,[3] Tetsuo Michihata,[4] Takanori Shibata.[5] *[1]Div of Nephrology, Dept of Medicine, Showa Univ Koto Toyosu Hospital, Tokyo, Japan; [2]Div of Diabetes, Metabolism, and Endocrinology, Dept of Medicine, Showa Univ School of Medicine, Tokyo, Japan; [3]Ikagaku Co. Ltd., Kyoto, Japan; [4]Ebara Clinic, Tokyo, Japan; [5]Div of Nephrology, Dept of Medicine, Showa Univ school of Medicine, Tokyo, Japan.*

Background: Chronic kidney disease (CKD) may lead to reduced concentrations of high-density lipoprotein (HDL) and its subfractions (HDL2 and HDL3), and damage them via inflammation and oxidative stress. The present study aimed to determine the contribution of such changes to cardiovascular disease (CVD) in patients with CKD.

Methods: Levels of total cholesterol, low-density lipoprotein cholesterol, HDL-C, HDL2, HDL3, apolipoproteins, malondialdehyde-modified LDL (MDA-LDL), oxidized (ox) HDL, oxHDL2 and oxHDL3 were measured in blood samples from patients with CKD (stages 2 – 5, n = 86) who were not on dialysis and from patients undergoing hemodialysis (CKD stage 5D, n = 25). The patients were followed up for 28 ± 9 months after baseline examinations and CVD events were recorded.

Results: Levels of HDL3 and ApoA1 in HDL3 fraction decreased according to CKD severity, whereas those of HDL2 and ApoA1 in HDL2 fraction did not differ. Levels of oxHDL were similar across CKD stages. Levels of oxHDL3 and MDA-LDL were decreased, whereas those of oxHDL2 increased according to CKD severity. Multivariate analyses using the Cox proportional hazards model selected high levels of oxHDL and its subfractions, and those adjusted with HDL-C and HDL subfractions or ApoA1 in HDL fractions respectively, compared with HDL-C and HDL subfractions or ApoA1 in HDL fractions alone as independent risk factors for CVD events.

Conclusions: Levels of HDL subfractions and their oxidized subfraction particles differed among patients with CKD. Increasing levels of oxHDL subfractions might cause a high frequency of CVD events in those patients.

TH-PO586

The Relevance of Systolic Blood Pressure to Vascular Disease in Chronic Kidney Disease Patients with and without Vascular Disease: Observations from the Study of Heart and Renal Protection (SHARP) Parminder K. Judge, William G. Herrington. *On behalf of the SHARP Collaborative Group. CTSU, Univ of Oxford.*

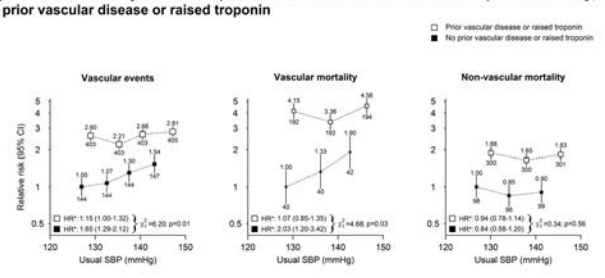
Background: Confounding by prior disease may distort associations between systolic blood pressure (SBP) and disease outcomes in people with chronic kidney disease (CKD), causing uncertainty about the effect of low SBP on vascular risk in advanced CKD. Measurement of troponin may allow confounding by subclinical cardiac disease to be reduced.

Methods: SHARP randomized 9270 people with CKD. Over 5 years, SBP and clinical outcomes were recorded at baseline and at 6 monthly intervals. Cox regression, adjusted for relevant confounders, was used to assess the relevance of usual SBP to vascular outcomes. Analyses were stratified by baseline vascular disease (defined as self-reported vascular disease or troponin-I >0.01 ng/mL).

Results: Overall, there was a "U"-shaped association between usual SBP and vascular risk. Among the 4075 participants without baseline vascular disease, there was a log-linear

association: each 20 mmHg higher usual SBP was associated with an average 65% increase in risk of vascular events (adjusted hazard ratio [HR] 1.65, 95% confidence interval 1.29-2.12) and 2-fold increased risk of vascular death (HR 2.03,1.20-3.42). By contrast, among the 4603 participants with baseline vascular disease, the associations between usual SBP and vascular events (HR 1.15,1.00-1.32; p for heterogeneity=0.01) and vascular death (HR 1.07,0.85-1.35; p for heterogeneity=0.03) were significantly weaker. There was no clear association between usual SBP and non-vascular mortality (HR 0.96,0.82-1.13), irrespective of history of prior vascular disease.

Figure: Relevance of systolic blood pressure to vascular events and cause-specific mortality, by prior vascular disease or raised troponin



SBP=systolic blood pressure. Relative risks adjusted for age, sex, ethnicity, country, education, smoking status, prior diabetes, renal status, body mass index and treatment allocation. *Average HR per 20 mmHg higher usual SBP across range of values studied (i.e. assuming a log-linear relationship).

Conclusions: In CKD, the "U"-shaped relationship between usual SBP and vascular risk appears to be explained by confounding by vascular disease. Trials to assess the effect of lower than currently recommended SBP targets are indicated.

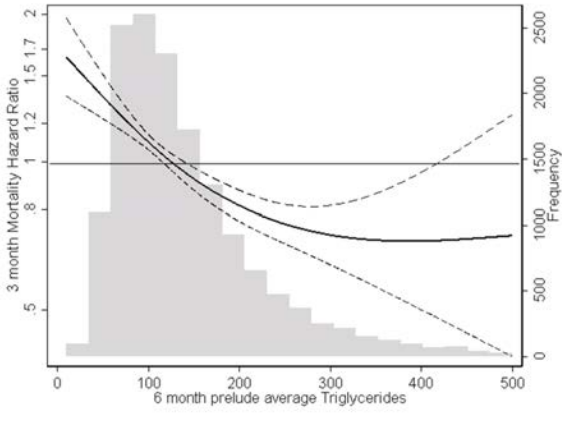
Serum Triglyceride Levels during Progression to ESRD and Early Dialysis Mortality among U.S. Veterans: A Transition of Care in CKD Study Elani Streja,[1] Melissa Soohoo,[1] Connie Rhee,[1] Yoshitsugu Obi,[1] Jennie Jing,[1] Danh V. Nguyen,[1] Moti L. Kashyap,[1,2] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]UTHSC; [3]VA Long Beach.*

Background: High triglyceride (TG) levels are an established cardiovascular risk factor in the general population. In a study of non-dialysis dependent chronic kidney disease, higher TG levels (<200 mg/dL) were associated with higher mortality risk, whereas other data show that patients with low TG levels (<115 mg/dL) have even higher mortality risk. The impact of TG levels in the prelude period immediately preceding transition to dialysis on early post-transition outcomes is not known.

Methods: In a cohort of 52,172 US veterans who transitioned to dialysis between October 2007 and September 2011, we identified 15,345 patients with available TG measurements within the last 6 month prelude period (preceding dialysis transition). We examined the association of TG (averaged over 6 months) as a continuous predictor of early all-cause mortality (within the first 3 months post-transition), using restricted cubic spline analysis and Cox models adjusted for age, sex, race, ethnicity, cause of ESRD, and region of residence.

Results: The mean±SD age was 69±11 years, among whom 27% were African-American, 7% were of Hispanic, and 51% had diabetes listed as their primary cause of ESRD. The 6-month averaged prelude TG showed an inverse linear association with post ESRD mortality risk, in which patients with TG<115mg/dL had a higher risk of mortality and patients with TG³115mg/dL had comparatively better survival.



Conclusions: Among veterans transitioning to dialysis, higher TG levels were associated with lower risk of early post-ESRD mortality. Further studies are needed to investigate underlying mechanisms and to determine how lipid-modulating treatments influence these associations.

Initiation of Statins for Chronic Kidney Disease Patients in the Veterans Affairs Health System Sai Hurrish Dharmarajan,[1] Rajesh Balkrishnan,[4] Kara Zivin,[1] Tanushree Banerjee,[2] Neil R. Powe,[2] Nilka Rios Burrows,[3] Rajiv Saran,[1] Sundar Shrestha.[3] *[1]Univ of Michigan, Ann Arbor, MI; [2]Univ of California, San Francisco, CA; [3]Centers for Disease Control and Prevention, Atlanta, GA; [4]Univ of Virginia, Charlottesville, VA.*

Background: The 2013 Kidney Disease Improving Global Outcomes (KDIGO) guidelines recommend cholesterol-lowering treatment with statins for Chronic Kidney Disease (CKD) patients aged 50 years or older, and those aged 30-49 years with elevated risk of cardiovascular disease (CVD). We investigated the predictors of statin initiation in a cohort of CKD patients in the Veterans Affairs Health System between 2010 and 2012.

Methods: Our sample included patients with at least one outpatient visit with a serum creatinine value in 2010 or 2011. Patients were categorized into five stages of increasing severity based on estimated glomerular filtration rate (eGFR). A cohort of these patients not using statins in the baseline year (2010 or 2011) were identified and followed in the subsequent year (2011 or 2012) to determine statin initiation. A multivariate logistic regression model was used to examine the socio-demographic and comorbidity related predictors of statin initiation.

Results: Our sample included 1,676,215 patients in 2010 and 1,778,655 patients in 2011. Of these, 8.77 % in 2010 and 9.48 % in 2011 initiated statins in the subsequent year. The most significant predictors of statin initiation were diagnosis of CVD in the prior year (adjusted Odds Ratio-aOR: 2.46, 95% CI: 2.43 – 2.49) and diabetes mellitus (aOR: 1.94, CI: 1.92 – 1.95). Using patients with eGFR>90ml/min/1.73m^2 (Stage 1) as reference, CKD Stage 3 patients had a higher odds (aOR: 1.24, CI: 1.23 – 1.26) of statin initiation, in comparison to stage 4 (aOR: 0.87, CI: 0.83 – 0.91) and stage 5 (aOR: 0.33; CI: 0.29 – 0.38) patients.

Conclusions: CVD and diabetes were the most influential predictors of statin initiation in CKD patients in a large cohort of U.S. Veterans. Statin initiation appeared to be lowest in patients with CKD Stage 4 and 5. Future research will consider adherence to statin prescription and its association with CKD progression.

TH-PO589

Association of Urine Kidney Injury Biomarkers with Risk of Cardiovascular Events in CRIC Meyeon Park,[1] Chi-yuan Hsu,[1] Alan S. Go,[2] Dawei Xie,[3] Xiaoming Zhang,[3] Sushrut S. Waikar,[4] Joseph V. Bonventre,[4] Josef Coresh,[5] Robert G. Nelson,[6] Harold I. Feldman,[3] Paul L. Kimmel,[6] Vasan S. Ramachandran,[7] Kathleen D. Liu.[1] *[1]UCSF; [2]Kaiser Permanente; [3]U. of Pennsylvania; [4]Brigham and Women's Hospital; [5]Johns Hopkins Univ; [6]NIH NIDDK; [7]Boston Univ.*

Background: Chronic kidney disease (CKD) is an important risk factor for cardiovascular disease (CVD). We investigated whether kidney injury biomarkers were associated with increased risk of atherosclerotic and non-atherosclerotic CVD events in the Chronic Renal Insufficiency Cohort (CRIC) study.

Methods: Urine kidney injury molecule-1 (KIM-1), neutrophil gelatinase associated lipocalin (NGAL), N-acetyl-beta-D-glucosaminidase (NAG), and liver fatty acid-binding protein (LFABP) were measured in 2466 CRIC subjects in CRIC. Cox proportional hazards models were used to examine the associations between biomarkers indexed to urinary creatinine and heart failure (HF) or a composite of CVD events (myocardial infarction, ischemic stroke, or peripheral artery disease).

Results: Mean age of study subjects was 59.5 (± 10.8) years; 46% were women, 50% had diabetes mellitus, and 34% had history of cardiovascular disease. NGAL/Cr, NAG/Cr and LFABP/Cr were associated with HF and CV events in unadjusted models, but not in multivariable adjusted models (accounting for baseline eGFR, albuminuria, age, sex, race, comorbidities, and medications). Those in the highest two quintiles [Q5 (>2990.3 pg/g) and Q4 (>1830.9 pg/g)] of KIM-1/Cr levels had an increased risk of HF relative to the lowest quintile (Q1, <661.3 pg/g) [Q5 v. Q1 hazard ratio (HR) 1.7 (1.1-2.9); Q4 v. Q1 HR 1.6 (1.0-2.6)]. KIM-1/Cr was not independently associated with HF in the continuous analysis [HR per log SD increase 1.14 (0.98-1.33)]. Higher KIM-1/Cr was independently associated with CVD events in the continuous analysis [HR per log SD increase 1.21 (1.02-1.41)] after adjustment for confounders.

Conclusions: Select urine biomarkers of kidney injury were independently associated with increased risk of HF and CVD events.

TH-PO590

Cystatin C as a Predictor for Mortality in Elderly Patients with Chronic Kidney Disease Sebastjan Bevc,[1] Nina Hojs,[1] Masa Knehtl,[1] Robert Ekart,[2] Radovan Hojs.[1] *[1]Clinic for Internal Medicine, Dept of Nephrology, Univ Clinical Centre Maribor, Slovenia; [2]Clinic for Internal Medicine, Dept of Dialysis, Univ Clinical Centre Maribor, Slovenia.*

Background: The prevalence of chronic kidney disease (CKD) in the elderly is high. Serum cystatin C, an accurate marker of estimation of kidney function have also prognostic utility in CKD patients.The aim of our study was to determine the prediction for mortality of different markers for estimation of kidney function on long-term survival in elderly CKD patients.

Methods: 103 adult Caucasian patients, older than 65 years (56 women, 47 men; mean age 72.5 years; range from 65 to 86 years), were included. In each patient

^{51}CrEDTA clearance, serum creatinine (IDMS traceable method), serum cystatin C (immunonephelometric method) and eGFR using the CKD-EPI creatinine formula were determined on the same day and then followed for 10 years or until patient's death.

Results: The mean ^{51}CrEDTA clearance was 52.2±15.9 ml/min/1.73m^2, mean serum creatinine 142.1±41.9 µmol/l, mean serum cystatin C 1.79±0.6 mg/l, CKD-EPI creatinine formula 39.7±12.9 ml/min/1.73m^2, respectively. In the follow up period of 10 years 60 (61.2%) of our elderly CKD patients (32 men and 28 women) died. Cox regression analysis showed different hazard ratios (HR): for ^{51}CrEDTA clearance HR 0.963 (95% CI 0.592-0.778; P=0.015), serum creatinine HR 1.012 (95% CI 1.007-1.018; P=0.0001), serum cystatin C HR 1.611 (95% CI 1.234-2.105; P=0.0001), CKD-EPI creatinine formula HR 0.957 (95% CI 0.933-0.981; P=0.0001).

Conclusions: Our results indicate that serum cystatin C values at the beginning of follow-up are better in predicting the outcome of elderly CKD patients than other markers for estimation of kidney function.

TH-PO591

The Relationship Between Neutrophil to Lymphocyte Ratio and Cardiovascular Disease in Patients with Chronic Kidney Disease

Dede Sit, Hasan Kayabasi, Emel Gokmen, Zehra Sucuoglu, Serhat Sigirci, Suleyman Yildirim, Bennur Esen, Saadet Pilten guzel. *Bagcilar Training & Research Hospital, Istanbul, Turkey.*

Background: Neutrophil to lymphocyte ratio (NLR) is a new, widely-easily available, inexpensive marker calculated from complete blood count is a new addition to the inflammatory markers. In many studies it has been established that NLR is associated with CVD. In this study we evaluated the relationship between NLR and CVD in patients with predialysis CKD.

Methods: In total 172 predialysis CKD patients who were undergone coronary angiography for CAD where studied. GFR of all patients were calculated using MDRD formula, and according to eGFR, the patients were divided into stage 1-5 CKD via K/DOQI guidelines. The patients were divided into two groups as angiography positive and negative group for coronary artery disease. Demographic, biochemical, hematological parametrs and NLR of pateints were compared.

Results: The mean age of patients was 65.06±10.53 years, 119 were male, and 53 were female. Accorgding to eGFR 16 were stage 1, 75 were stage 2, 46 were stage 3, 17 were stage 4 and 18 were stage 5. There was a statistically significant difference in NLR between twoo groups. In patients with CAD NLR was higher than in patients without CAD (p<0.01). All parameters of patients were detailed in table 1.

Table 1: Comparison of the parameters of patients according to CAD

	CAD		
	No	**Yes**	**p**
Calcium	9,09±0,73	8,6±0,65	0,002
Phosphorus	3,93±1,39	3,79±1,42	0,415
CaxP	35,63±12,37	32,69±12,14	0,195
PTH	156,45±144,7	328,87±476,18	0,238
Albumin	4,05±0,63	3,66±0,5	0,002
CRP	32,26±40,16	42,49±48,58	0,348
Spot Protein/ Creatinin	815,57±1644,7	1501,05±2284,78	0,043
Neutrophil/ Lymphocyte	4,14±4,49	8,46±11,4	0,001

Conclusions: In many studies, NLR is reported as an independent predictor of outcome in coronary artery disease, as well as a predictor of short- and long-term mortality in patients with CVD. We found that NLR is significantly higher among CKD patients with CAD, thus we suggest that it may be used as a new marker to investigate CAD and its results in CKD population.

Change in Skin Autoflourescence Over One Year Predicts Mortality at Five Years in a Prospective Cohort of People with Chronic Kidney Disease Stage 3

Adam Shardlow,[1,2] Natasha Juliette Mcintyre,[1] Richard J. Fluck,[1] Christopher W. McIntyre,[3] Maarten W. Taal.[1,2] *[1]Renal Medicine, Royal Derby Hospital, Derby, United Kingdom; [2]Faculty of Medicine and Health Sciences, Univ of Nottingham, Nottingham, United Kingdom; [3]London Health Sciences Centre, London, ON, Canada.*

Background: Tissue advanced glycation end product (AGE) accumulation is a marker of cumulative metabolic stress assessed by a simple non-invasive measurement of skin autofluoresence (SAF). This has been shown to predict mortality in haemodialysis patients and in earlier CKD in some studies, but the impact of change in SAF over time has not previously been reported. In this study we sought to investigate the associations of SAF and change in SAF over time with mortality in people with CKD stage 3.

Methods: 1741 people with CKD 3 (confirmed by two eGFR values) were recruited from primary care. Participants attended for baseline, year 1 and year 5 study visits and underwent clinical assessment, blood and serum biochemistry. SAF was recorded at each visit. Dates of death were collected from hospital and national records.

Results: At baseline mean eGFR was 53.5 ml/min/1.73m^2, mean age 73 years and mean SAF 2.7 arbitrary units. There was a small decrease in mean SAF after 1 year (-0.1 arbitrary units; p<0.001) but 310 (20.1%) participants evidenced an increase of >10%. 299 (17.2%) participants died prior to the year 5 study visit. Cox proportional hazards showed that both baseline SAF (HR 1.38) and change in SAF (HR 1.53) over the first year were independent determinants of mortality at 5 years in addition to age (HR 1.77), male gender (HR 1.53), baseline eGFR (HR 0.98) and previous cardiovascular disease (HR=1.56). In a sensitivity analysis of participants without diabetes, change in SAF at 1 year remained an independent determinant of mortality (HR 1.5), adjusted for age, gender, baseline eGFR, previous cardiovascular disease and baseline SAF.

Conclusions: Our data show for the first time that an increase in SAF over 1 year is an independent predictor of mortality in CKD stage 3 in addition to baseline SAF. Serial measures of SAF may therefore be useful in predicting risk and monitoring interventions for reducing AGE accumulation.

Fibroblast Growth Factor 21 Plasma Levels and Future Cardiovascular Outcome Among Non-Dialysis Chronic Kidney Disease Patients

Lucie Bauer,[1] Kyrill S. Rogacev,[1] Adam M. Zawada,[1] Sarah Seiler,[1] Insa E. Emrich,[1] Kevin L. Duffin,[2] James R. Voelker,[2] Matthew D. Breyer,[2] Danilo Fliser,[1] Gunnar H. Heine.[1] *[1]Internal Medicine IV - Nephrology and Hypertension, Saarland Univ Medical Center and Saarland Univ Faculty of Medicine, Homburg, Saarland, Germany; [2]Eli Lilly and Company, Indianapolis, IN.*

Background: Patients with chronic kidney disease have substantial metabolic alterations, which comprise insulin resistance, hypertriglyceridemia and low HDL-cholesterolemia. Fibroblast Growth Factor 21 (FGF-21) is a recently discovered hormone which is a central regulator of glucose and lipid metabolism. We examined the effects of chronic kidney disease (CKD) on circulating plasma FGF-21 concentration, and the association of plasma FGF-21 with incident cardiovascular disease.

Methods: We analyzed plasma FGF-21, along with traditional cardiovascular and renal risk factors, in 441 CKD G2 – G4 patients who were recruited into the prospective CARE FOR HOMe cohort. Plasma adiponectin (total and subfractions) were measured in 339 patients. All patients were followed for the occurrence of cardiovascular events; defined either as atherosclerotic (acute myocardial infarction, stroke, amputation above the ankle, any surgical or interventional coronary/cerebrovascular or peripheral-arterial revascularization, or death of any cause) or as cardiac events (admission for heart failure, or death of any cause).

Results: Baseline plasma FGF-21 correlated with higher age (r=0.114), body mass index (r=0.116), waist-hip-ratio (r=0.113), triglycerides (r=0.292) and CRP (r=0.149), as well as with lower eGFR (r=-0.272) and HDL (r=-0.134, all p<0.001), but not with total adiponectin or adiponectin subfractions. In univariate Kaplan-Meier-analyses, higher quartiles of baseline FGF-21 were associated with future atherosclerotic (p=0.001) and cardiac (p<0.001) events. However this association lost statistical significance after adjustment for eGFR.

Conclusions: Our study results demonstrate an increase of plasma FGF-21 levels in CKD patients. Despite its role in glucose and lipid metabolism, plasma FGF-21 does not independently predict adverse cardiovascular outcome among CKD patients.

TH-PO594

Graded Increases in Cardiac Biomarkers Across Advancing CKD Stages

Elizabeth K. Batchelor, Gates Colbert, Nishank Jain, Beverley Adams-Huet, Xilong Li, James Delemos, Susan Hedayati. *UT Southwestern and VA North Texas Medical Centers, Dallas, TX.*

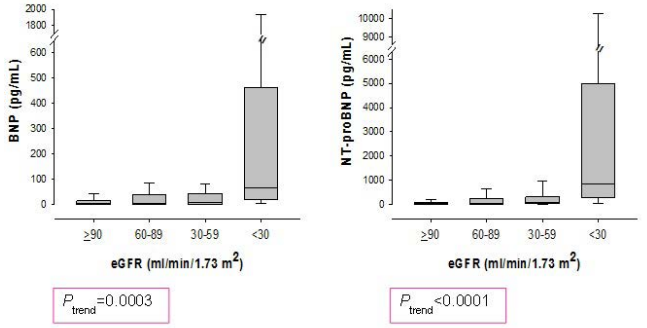
Background: Elevated cardiac troponin T (cTnT) ³10 ng/L is reported in 80% of ESRD patients and associated with poor outcomes. There are less data on whether cardiac biomarkers are elevated in non-dialysis CKD patients.

Methods: We investigated whether cTnT, high sensitivity cTnT (hs-cTnT), brain natriuretic peptide (BNP), and N-terminal-pro-BNP (NT-pro-BNP) levels increase with worsening CKD in 3,298 asymptomatic, multi-ethnic participants of the Dallas Heart Study.

Results: Mean age was 44±10 years. 55% were female, 50% Black, 31% Caucasian, 17% Hispanic, and 2% other races. 288 had CKD, defined as eGFR<60 mL/min/1.73 m^2 or albumin-to-creatinine ratio ³17 mg/g in men or ³25 in women. Of those with CKD, 37% had diabetes mellitus and 66% hypertension vs. 10% and 33% if without CKD, p<0.05. A higher proportion of CKD vs. non-CKD individuals, 8.0 vs. 0.43%, had elevated cTnT ³10 ng/L and hsTnT ³3 ng/L, 58.3 vs. 24.2%, p<0.0001 for both. Mean BNP was 55.5±314.8 in CKD vs. 10.9±32.5 pg/mL in non-CKD, and NT-pro-BNP was 319.7±1225.7 in CKD vs. 53.4±117.5 pg/mL in non–CKD (p<0.0001 for both). There were graded increases in the proportion with elevated troponins as CKD severity increased across stages.

Group	**N (Total=288)**	**cTnT**	**hs-cTnT**
		% ≥10 ng/L	**% ≥3 ng/L**
CKD 1	143	3.5	47.6
CKD 2	76	5.3	61.8
CKD 3	59	15.3	74.6
CKD 4/5	10	50.0	90.0
P		*<0.0001*	*<0.0001*

The same was seen with BNP and NT-pro-BNP levels, with the highest increases in those with eGFR<30.



Conclusions: A higher proportion of CKD vs. non-CKD individuals had elevated cardiac biomarkers, even at early CKD stages. Graded increases in biomarkers were observed across advancing stages. Further research should determine if higher cardiac biomarker cutoffs are warranted to improve diagnostic and prognostic utility in CKD patients.

Circulating Endothelial Cells and Cardiovascular Risk in Chronic Kidney Disease and Hemodialysis Patients

Yasser Ahmed Nienaa,[1] Nahla Mohamed gamal Farahat,[2] Iman Ezzat Elgohary,[1] Marwa Fathy Oraby.[1] *[1]Internal Medicine-Nephrology Unit, Faculty of Medicine, Alexandria, Egypt; [2]Clinical and Chemical Pathology, Faculty of Medicine, Alexandria, Egypt.*

Background: This work was conducted with the aim to study circulating endothelial cells in CKD patients and correlate this with some cardiovascular risk factors.cardiovascular disease remains the leading cause of morbidity and mortality in patients with CKD and may account for 50% of all deaths. Endothelial dysfunction is commonly observed along the CKD spectrum. Endothelial dysfunction is a well-documented early phenomenon in atherosclerosis that precedes structural changes and clinical manifestations. The chronic micro inflammation state present in uremia has been proposed as one of the mechanisms causing endothelial dysfunction. Inflammatory circulating endothelial cells (CECs) are thought to be mature cells that have detached from the intimal mono layer in response to endothelial injury. In humans, elevated levels were reported in various cardiovascular disorders, as a result of mechanical injury, ischemic injury or hypertension.

Methods: This study included 50 subjects classified as follows:Group I 20 patients with CKD not yet on dialysis, group II 20 patients on maintenance hemodialysis and 10 age and sex matched individual used as a control (groupIII). All included individual were subjected to complete blood count, renal function tests, estimation of GFR by MDRD formula, complete lipid profile, high sensitive CRP, ESR and detection of CEC count using flow cytometry.

Results: The study showed increased count of CEC and hs CRP in both CKD groups than the control and it was higher in patients on dialysis than those on conservative treatment. There was a statistically positive correlation between ESR, hs CRP,TG and CECs in the three groups, there was also a statistically negative correlation between estimated GFR and CECs in the three groups.

Conclusions: Measurement of CECs count might offer a mean for recognizing CKD patients at risk of cardiovascular events.

TH-PO596

The Association Between Soluble Klotho and Cardiac Parameters in Chronic Kidney Disease: Korean CKD Patients

Hyo Jin Kim,[1] Kyung don Ju,[1] Tsogbadrakh Bodokhsuren Bodokhsuren,[1] Seungmi Lee,[1] Aram Lee,[1] Shin-Young Ahn,[2] Dong-Wan Chae,[2] Ho Jun Chin,[2] Curie Ahn,[1] Kook-Hwan Oh.[1] *[1]Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea; [2]Internal Medicine, Seoul National Univ Bundang Hospital, Seongnamsi, Gyeonggi-do, Korea.*

Background: Klotho is one of mineral metabolism regulator in chronic kidney disease (CKD). Bone mineral metabolism is important in CKD and it is associated with cardiovascular (CV) complications. We investigated factors determining soluble klotho concentration and the association between klotho and cardiac parameters from Korean CKD patients.

Methods: We analyzed 1,443 CKD patients with soluble klotho at baseline from the prospective KoreaN Cohort Study for Outcome in Patients With Chronic Kidney Disease (KNOW-CKD) study. Left ventricular hypertrophy (LVH) and arterial stiffness were explored as CV parameters. LV mass index (LVMi) was used as a maker of LVH (male > 115 g/m^3, female > 95 g/m^3). Brachial-to-ankle pulse wave velocity (baPWV) was used as a marker of arterial stiffness. Renal outcome (initiation of renal replacement therapy or decline of estimated glomerular filtration rate ≥50% or doubling of creatinine) or composite outcome (renal outcome or death) were analyzed for association soluble klotho level.

Results: Patients were 53.5 ± 12.4 years old and 61.5% were male. In a multivariable linear regression analysis, uric acid and log CRP were positively and hemoglobin was inversely associated with klotho. LVH (OR 0.46; 95% CI, 0.25 to 0.85; P = 0.014) and baPWV (Pearson correlation, -0.099; P = 0.001) were associated with klotho in univariate analysis. However, in multivariable analysis, klotho was not independently associated with LVH and baPWV. 887 (61.5%) patients were investigated for association between klotho and outcomes (23.3+4.7 months follow-up). Analyzed by Cox proportional hazard model, klotho was not associated with renal or composite outcomes.

Conclusions: Soluble klotho was not an independent determining factor for LVH, arterial stiffness, and renal outcomes. Further studies are warranted to elucidate the clinico-pathogenic significance of klotho in Korean CKD patients.

TH-PO597

Elevated C-Reactive Protein, and Albuminuria Increase Mortality Risk in Metabolic Syndrome Patients

Satyesh K. Sinha,[1] Magda Shaheen,[1] Deyu Pan,[1] Keith C. Norris,[2] Susanne B. Nicholas.[2] *[1]Charles R Drew Univ, Los Angeles, CA; [2]David Geffen School of Medicine, UCLA, Los Angeles, CA.*

Background: Metabolic syndrome (MetS) is a serious health condition affecting nearly 25% of adults in the United States and places them at higher risk of cardiovascular disease (CVD), chronic kidney disease, and mortality.Studies have shown that the MetS is associated with albuminuria (urinary albumin excretion [UAE] >30ug/ml). Inflammation has been posited as an important link between the MetS and UAE. However, little is known about the added value of UAE and C-reactive protein (CRP) in predicting mortality in patients with the MetS. Therefore, the study objective was to determine the relationship between mortality and the MetS, after adding both CRP & UAE as additional components.

Methods: We analyzed data from the National Health and Nutrition Examination Surveys 1999-2004 of 5,930 adults aged ³20 years with and without MetS (=>3 components of the MetS according to the definition of National Cholesterol Education Program's Adult Treatment Panel III). We added elevated CRP and UAE as a 6th and 7th criteria, respectively for the MetS. We analyzed data using Cox regression to estimate the hazard ratio (HR) for mortality, controlling for demographics, smoking, and CVD. Data are presented as HR, and 95% confidence interval (CI); p<0.05 was statistically significant.

Results: In the adjusted model, the MetS was not associated with mortality. However, HR for mortality was high with elevated CRP (>0.5 mg/dl; HR=1.84, 95% CI 1.45-2.35, p<0.001) and albuminuria (HR=1.89, 95% CI 1.36-2.63, p<0.001) compared to low CRP (<0.5 mg/dl) and no albuminuria (UAE<30 ug/ml). With addition of elevated CRP to the MetS, HR for mortality was high (HR=1.36, 95% CI 1.05-1.77, p<0.02) vs. low CRP and no MetS. HR for mortality was high when albuminuria was also added to MetS with elevated CRP (HR=1.52, 95% CI 1.12-2.06, p<0.01).

Conclusions: We conclude that elevated CRP and UAE may predict the group at high risk for mortality in MetS patients.

Longitudinal Change in Low-Grade Albuminuria Is a Better Predictor of Cardiovascular Disease Than Change in Serum Uric Acid: The Tromsø Study

Marit D. Solbu,[1,2] Bjorn Odvar Eriksen,[1,2] Toralf Melsom,[1,2] Hilde Merete Storhaug,[2] Jon viljar Norvik,[2] Trond G. Jenssen.[2,3] *[1]Section of Nephrology, Univ Hospital of North Norway, Tromsø, Norway; [2]Metabolic and Renal Research Group, UiT the Arctic Univ of North Norway, Tromsø, Norway; [3]Oslo Univ Hospital, Oslo, Norway.*

Background: Serum uric acid (SUA) and albuminuria are independent risk factors for cardiovascular disease (CVD), but the joint impact of longitudinal changes in SUA and albuminuria on clinical events is unknown. We assessed the associations between change in SUA and urinary albumin-creatinine ratio (ACR) over 7 years and the occurrence of incident myocardial infarction, ischemic stroke and all-cause mortality.

Methods: We included 3931 participants without CVD from the population-based the Tromsø Study; Tromsø 4 (1994/95) and Tromsø 5 (2001/02). SUA change was categorized into four groups according to upper (high) versus the three lower (low) gender specific quartiles of SUA in Tromsø 4 and 5; persistently high, decreasing , increasing, and persistently low SUA. ACR change was categorized the same way. Percentage of change from baseline in SUA and ACR was calculated.

Results: During follow-up (median 9.3 years for CVD; 11.3 years for mortality) there were 379 myocardial infarctions, 223 strokes and 869 deaths. In multivariable analyses increasing ACR predicted mortality (HR 1.65; 95% CI 1.38-1.96). Persistently high ACR predicted myocardial infarction (HR 1.34; 95% CI 1.03-1.75) and stroke (HR 1.79; 95% CI 1.28-2.51). Increasing and persistently high SUA did not predict any endpoint. A ≥50% increase in ACR from baseline predicted myocardial infarction and death, whereas ³15% increase in SUA did not. Change in SUA and ACR did not interact in their association with CVD. Baseline SUA significantly predicted stroke and mortality.

Conclusions: Longitudinally increasing ACR predicted CVD independently from SUA change. Baseline, but not changes in SUA predicted stroke and mortality. This may have implication for the use of change patterns in risk assessment.

TH-PO599

Transient Dipstick-Proteinuria Could Be a Risk of Cardio-Vascular Diseases Kei Nagai,[1] Kunihiro Yamagata,[1] Toshiaki Usui,[1] Koichi Asahi,[2] Kenjiro Kimura,[2] Kunitoshi Iseki,[2] Toshiki Moriyama,[2] Ichiei Narita,[2] Shouichi Fujimoto,[2] Kazuhiko Tsuruya,[2] Tsuneo Konta,[2] Masahide Kondo,[2] Tsuyoshi Watanabe.[2] *[1]Univ of Tsukuba; [2]Steering Committee for 'Design of the Comprehensive Health Care System for CKD Based on the Individual Risk Assessment by Specific Health Checkups.*

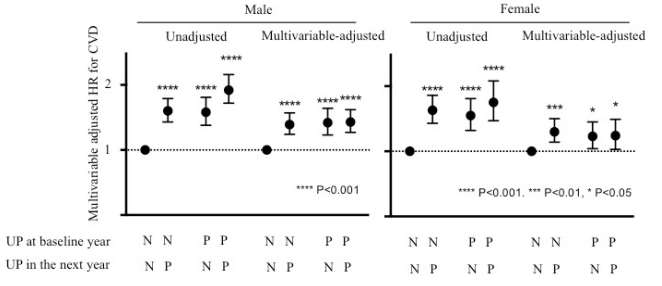
Background: Dipstick-proteinuria is the major method to detect high-risk participants for cardiovascular diseases (CVD). A large part of positive dipstick-proteinuria has gone to negative in the next year, which means transient proteinuria. The aim of this study is to clarify whether transient proteinuria is a risk of CVD comparing to sequentially negative proteinuria with one-year interval measurement.

Methods: By using a population-based 339,172 persons longitudinal cohort receiving annual health checkups sequentially twice or more, we examined presence of dipstick-proteinuria both at baseline year and in the next year. Medical history of CVD was obtained via a self-reported questionnaire. The incidence of CVD event in this study was defined as a negative history at the baseline year and a positive history in the follow-up year. Proteinuria was defined as (+) or more.

Results: Forty-five percent of subjects with positive proteinuria at baseline year in male and 58% of those in female have gone to negative proteinuria in the next year.

	Proteinuria in the next year				Subtotal
At baseline year	Negative		Positive		% per Total
	119,020	95.7%	5,317	4.3%	94.0%
	3,571	45.3%	4,301	54.7%	6.0%
	195,925	97.5%	4,986	2.5%	97.1%
	3,538	58.5%	2,514	41.5%	2.9%

Subjects with proteinuria have higher risk of CVD than those with sequentially negative proteinuria as reference (hazard ratio [HR] and 95% confidential intervals [CI], 1.58 [1.38-1.81] in male and 1.55 [1.32-1.81] in female).



Conclusions: Transient proteinuria could be a risk of the incidence of CVD.

TH-PO600

Urinary Phosphate Excretion Modifies the Association Between Serum Osteoprotegerin and Coronary Calcification in CKD: KNOW-CKD Study Young Youl Hyun,[1] Kyu-Beck Lee,[1] Hyang Kim,[1] Kook-Hwan Oh,[2] Curie Ahn,[2] Dong-Wan Chae,[3] Yong-Soo Kim,[4] Wookyung Chung,[5] Young-Hwan Hwang,[6] Soo Wan Kim,[7] Yeong Hoon Kim.[8] *[1]Sungkyunkwan Univ School of Medicine, Kangbuk Samsung Hospital; [2]Seoul National Univ Hospital; [3]Seoul National Univ Bundang Hospital; [4]The Catholic Univ of Korea, Seoul St. Mary's Hospital; [5]Gachon Univ, Gil Hospital; [6]Eulji General Hospital; [7]Chonnam National Univ Medical School; [8]Inje Univ, Pusan Paik Hospital.*

Background: High serum osteoprotegerin (OPG) is closely related to coronary calcification, but the exact mechanism is not known well. To understand the underlying pathophysiology, we explored whether this association between OPG and coronary calcification is modified by 24-hr urinary phosphate excretion (UPi) in CKD patients.

Methods: This cross-sectional study analyzed 871 participants from the KNOW-CKD cohort who underwent a coronary MDCT, serum OPG measurement and 24-hr urine collection as baseline examinations between 2011~2013. We evaluated the association between serum OPG and coronary artery calcium scores (CACS) in each group with low and high UPi. Effect modification was evaluated by an interaction term and tested by Wald test.

Results: Percentages of participants with CACS > 0 were different between OPG quartiles (23.4%, 41.1%, 52.5% and 78.8% for the lowest to highest quartiles of OPG, P<0.001). In multivariate-adjusted Tobit models, the CACS ratio (95% confidence intervals) comparing the highest quartile of OPG to the lowest quartile was 19.74 (4.14-94.10) in the low UPi group, whereas the ratio was 1.86 (0.48-7.20) in the high UPi group (P for interaction = 0.003). In multivariate logistic model, the odds ratio of highest quartile for CACS > 0 compared with lowest quartile was 6.56 (2.52-17.11) in the low UPi group, whereas the odds ratio was 1.65 (0.68-3.99) in the high UPi group (P for interaction = 0.006).

Conclusions: Serum OPG was associated with coronary calcification only in CKD patients with low UPi, but not in those with high UPi. Further studies are warranted to verify the role of phosphate excretion in OPG-related coronary calcification.

TH-PO601

The Relationship of LV Mass Index and FGF-23/25(OH)D Modulating Phosphaturia Shin-Young Ahn,[1] Ho Jun Chin,[1] Kook-Hwan Oh,[2] Curie Ahn,[2] Dong-Wan Chae.[1] *[1]Internal Medicine, Seoul National Univ Bundang Hospital, Seongnam, Republic of Korea; [2]Internal Medicine, Seoul National Univ Hospital, Seoul, Republic of Korea.*

Background: As renal function declines, level of fibroblast growth factor-23 (FGF-23) rise and 25-hydroxyvitamind D (25(OH)D) decrease. We evaluate the relationship among 25(OH)D and FGF-23 on cardiovascular risk factors such as LV mass index and vascular calcification (VC).

Methods: KNOW-CKD is an on-going, prospective, university hospital based observational cohort study under the sponsorship of Korean Center for Disease Control and Prevention. Cross-sectional analysis of echocardiography data and other clinical data was performed in 1529 participants of KNOW-CKD. The study participants were divided into 4 groups by FGF-23 and 25(OH)D values below and above the median.

Results: Among the 1529 study participants, the mean of age and estimated GFR were 53.6 ± 12.4 years and 50.9 ± 31.7 ml/min/1.73m^2. The median FGF-23 concentration was 17.85 RU/ml (interquartile range [IQR] = 0.42, 31.28), and median level of 25(OH)D was 16.52 ng/ml (interquartile range [IQR] = 13.31, 21.04). The patients who had FGF-23 above the median but 25(OH)D below the median had highest level of serum P, iPTH, mean of pulse wave velocity(PWV), and LV mass index. They also had lowest level of hemoglobin, serum albumin, eGFR, corrected Ca, and bone mineral density of femur neck. After multivariate analysis, the result showed significant correlation between LV mass index and FGF-23/25(OH)D ratio (std β=0.176, p=0.021). Decreasing level of 25(OH) D reduced phosphaturia caused by FGF-23. Finally vascular calcification measured by abdominal aorta calcification showed significant negative relationship with phosphaturia after multivariate analysis (stdβ=-0.095, p=0.031).

Conclusions: We observed the significant association between FGF-23/25(OH)D and LV mass index and FGF-23/25(OH)D and degree of phosphaturia which was correlated with vascular calcification. We suggest that FGF-23/25(OH)D may increase LVMI through modification of phosphaturia and vascular calcification.

TH-PO602

Fractional Excretion of Phosphorus Is Independently Associated with Left Ventricular Hypertrophy in Chronic Kidney Disease Patients Xiaoyan Zhang. *Nephrology, Zhongshan Hospital, Fudan Univ, Shanghai, China.*

Background: Left ventricular hypertrophy (LVH) is an important mechanism of cardiovascular disease in chronic kidney disease (CKD). Elevated Fibroblast growth factor-23 (FGF23) levels are independently associated with LVH. The aim of this study is to investigate whether elevated fractional excretion of phosphorus, as one major action of FGF23, is independently associated with LVH in CKD patients.

Methods: LVH was defined as LVMI (Left ventricular mass index) ≥ 50 g m$^{-2.7}$ in men or ≥ 47 g m$^{-2.7}$ in women. The fractional excretion of phosphorus (FePi [%]) was calculated as [urine phosphorus (mg/dl)/serum phosphorus (mg/dl)]/[serum creatinine (mg/dl)/urine creatinine (mg/dl)]×100.

Results: We measured FePi levels in 1,389 individuals who underwent echocardiography within 3 months. The median FePi level was 13.44%. The mean (± SEM) left ventricular ejection fraction was 67% ± 17%, left ventricular mass indexed to height$^{2.7}$(LVMI) was 42 ± 14 g m$^{-2.7}$, and LVH was present in 24% of participants. The left ventricular ejection fraction was lower in the highest versus the lower quartiles of FePi levels, while the LVMI increased with increasing FePi quartiles. Each ten percent increase in FePi was associated with a 2.406 g m$^{-2.7}$ greater LVMI (95% CI, 2.022–2.789; $P < 0.001$). Each ten percent increase in FePi was associated with a 1.363-fold greater relative risk (RR) of eccentric hypertrophy and concentric hypertrophy (95% CI, 1.275–1.456; $P < 0.001$) compared with normal ventricular geometry. Multivariable analyses that adjusted for age, sex, weight, hypertension, diabetes, GFR, total cholesterol, total triglyceride, hemoglobin, proteinuria, parathyroid hormone (PTH), and serum phosphate demonstrated that elevated FePi was independently associated with increased LVMI (0.745 g m$^{-2.7}$ greater LVMI per ten percent increase in FePi , 95% CI, 0.264–1.226; $P < 0.01$) and conferred greater risk of eccentric and concentric LVH (RR 1.102 per ten percent increase in FePi ; 95% CI, 1.000–1.214; $P < 0.05$).

Conclusions: FePi is independently associated with left ventricular hypertrophy in patients with CKD across a broad range of kidney function.

TH-PO603

Clinical Significance of Vascular Calcification and Retinopathy on Renal and Cardiovascular Outcomes in Patients with Chronic Kidney Disease

Hyeon Seok Hwang, Hye Eun Yoon, Yu ah Hong, Suk young Kim. *Div of Nephrology, Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Korea.*

Background: Vascular calcification and retinopathy is the representative marker of macrovascular and microvascular dysfunction in patients with chronic kidney disease (CKD). While both of them share common pathophysiology, their relationship and combined effects on clinical outcome remained undetermined.

Methods: We included 523 nondialysis-dependent CKD stage 3–5 patients, who had been examined with fundoscopy for diabetic or hypertensive retinopathy. Simple X-ray images of the pelvis and the abdomen were analyzed for the presence of intimal or medial arterial calcifications. The clinical significance of intimal calcification and retinopathy was evaluated in terms of the rate of renal function decline and composite of any cardiovascular event or death.

Results: Intimal calcification was observed in 81 (15.5%) CKD patients, medial calcification in 50 (9.6%) CKD patients, and retinopathy in 258 (49.3%) CKD patients. The presence of retinopathy was independently associated with intimal (odds ratio 1.72, 95% CI 1.03-2.89) and medial calcification (OR 3.41, 95% CI 1.68-6.90). The renal function decline rate was significantly steeper in patients with than in those without intimal calcification (–8.1 ± 9.4 mL/min/1.73 m^2/yr vs. –4.6 ± 10.4 mL/min/1.73 m^2/yr; $P = 0.005$). However, medial calcification was not associated with rapid renal function decline ($P = 0.153$) In multivariate analysis, patients with both intimal calcification and retinopathy were independently associated with a rapid decline in renal function ($\beta = –4.21$; $P < 0.001$). The combined status of retinopathy with intimal or medial calcification independently increased the risk of composite events (hazard ratio 3.34, 95% CI 1.41-4.43 for intimal calcification; hazard ratio 3.19, 95% CI 1.62-6.28 for medial calcification).

Conclusions: Coexistence of intimal calcification and retinopathy were independently associated with CKD progression, and the combined status of retinopathy with intimal or medial calcification was an independent predictor for composite cardiovascular event/death.

TH-PO604

Abdominal Aortic Calcification in Patients with Chronic Kidney Disease

Mieke J. Peeters,[1] Jan A.J.G. van den Brand,[1] Arjan D. Van Zuilen,[2] Marc G. Vervloet,[3] Peter J. Blankestijn,[2] Jack F. Wetzels.[1] *[1]Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands; [2]Nephrology, Univ Medical Center Utrecht, Utrecht, Netherlands; [3]Nephrology, VU Univ Medical Center, Amsterdam, Netherlands.*

Background: Abdominal aortic calcification (AAC) is independently associated with cardiovascular events in dialysis patients and in the general population. However, data in non-dialysis chronic kidney disease (CKD) patients are limited. We studied determinants and prognostic value of AAC in non-dialysis CKD patients.

Methods: We included patients with CKD not receiving renal replacement therapy who participated in the MASTERPLAN study, a randomized controlled trial that started in 2004. In the period 2008-2009 an X-ray to evaluate AAC was performed in a subgroup of patients. We studied AAC using a semi quantitative scoring system by lateral lumbar X-ray. We used baseline and two year data to find determinants of AAC. We used a composite cardiovascular endpoint and propensity score matching to evaluate the prognostic value of AAC.

Results: In 280 patients an X-ray was performed. In 79 patients (28%) the X-ray showed no calcification, in 62 patients (22%) calcification was minor (<4), 139 patients (50%) had moderate or heavy calcification (≥4). Older age, prior cardiovascular disease, higher triglyceride levels, and higher phosphate levels were independent determinants of a calcification score ≥4. AAC score ≥4 was independently associated with cardiovascular events, with a hazard ratio of 5.5 (95% confidence interval 1.2-24.8).

Conclusions: Assessment of AAC can identify patients at higher cardiovascular risk, and may provide important information for personalized treatment. Whether this approach will ultimately translate into better outcomes, remains to be answered.

TH-PO605

Association of Serum Chloride Level with Mortality and Cardiovascular Events in Chronic Kidney Disease: The CKD-ROUTE Study

Shintaro Mandai,[1] Eiichiro Kanda,[2] Soichiro Iimori,[1] Shotaro Naito,[1] Eisei Sohara,[1] Tomokazu Okado,[1] Sei Sasaki,[1] Tatemitsu Rai,[1] Shinichi Uchida.[1] *[1]Dept of Nephrology, Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental Univ, Tokyo, Japan; [2]Dept of Nephrology, Tokyo Kyosai Hospital, Tokyo, Japan.*

Background: Electrolyte abnormalities, particularly dysnatremias, are increasingly recognized as independent predictors of adverse outcomes in individuals with and without renal failure. However, the association of serum chloride level (Cl^-) with mortality or risk of cardiovascular (CV) events in patients with chronic kidney disease (CKD) has yet to be clarified.

Methods: This prospective cohort study included 1134 pre-dialysis CKD G2-G5 patients among the participants of the CKD Research of Outcomes in Treatment and Epidemiology (CKD-ROUTE) study, who newly visited 16 nephrology centers. The primary outcome was a composite of death of any cause and CV events, and the secondary outcome was death of any cause. Data were analyzed with Cox hazards model with adjustment for potential cofounders including serum sodium. Patients were followed up until end-stage renal disease, death, transfer, or the end of 3-year follow-up.

Results: Median Cl^- was 106.0 mEq/L at enrollment [quartile (Q) 1: £103.9, n = 257; Q2: 104.0–105.9, n = 258; Q3: 106.0-108.0, n = 352; Q4: ³108.1, n = 267]. During 33 months' median follow-up, there were 115 CV events, 78 deaths, and 180 composite outcomes. The hazard ratio (HR) for the composite outcome was higher for Q1 than Q3 (unadjusted HR, 1.74; 95% confidence interval (CI), 1.16–2.61; p = 0.007; and adjusted HR, 1.63; 95% CI, 1.05–2.52; p = 0.029). Examined as a continuous variable in a subset of patients whose Cl^- was £106.0, higher Cl^- was associated with lower risk of the composite outcome (unadjusted HR, 0.88; 95% CI, 0.84–0.93; p <0.001; and adjusted HR, 0.94; 95% CI, 0.88–1.00; p = 0.038). The HR for all-cause mortality was also higher for Q1 than Q3 (unadjusted HR, 2.90; 95% CI, 1.56–5.41; p = 0.001; and adjusted HR, 2.56; 95% CI, 1.30–5.05; p = 0.007).

Conclusions: Low Cl^- was associated with greater mortality and risk of CV events in pre-dialysis CKD patients. Low Cl^- may be an additive predictor of adverse outcomes in CKD.

TH-PO606

Association of Urine Potassium with ESRD, Cardiovascular (CVD) Death, and All-Cause Mortality in Chronic Kidney Disease (CKD)

Amanda K. Leonberg-Yoo,[1] Hocine Tighiouart,[2] Andrew S. Levey,[1] Mark J. Sarnak.[1] *[1]Div of Nephrology, Tufts Medical Center, Boston, MA; [2]Research Design Center / Biostatistics Research Center, Tufts CTSI and Inst for Clinical Research and Health Policy Studies, Tufts Medical Center, Boston, MA.*

Background: Low urine potassium excretion is associated with a higher risk of developing hypertension and CVD in the general population. There are few data on the relationship of urine potassium with clinically important outcomes in CKD.

Methods: The association of urine potassium with ESRD (defined as the need for dialysis or transplantation), CVD mortality and all-cause mortality was evaluated in 812 participants enrolled in the MDRD Study. 24-hour urine potassium was measured at the first screening visit (before randomization) and in an average of 22 subsequent visits. Cox-proportional hazards models were adjusted for demographics, CVD risk factors, GFR, proteinuria, randomization assignment, and urine sodium. Interactions were performed with baseline GFR, proteinuria and urine sodium as well as blood pressure randomization.

Results: Mean age at baseline was 52±12 years; 60% were men and 85% were white. Mean 24-hour urine potassium excretion was 61.2±22.7 mEq/day. Median follow up for ESRD and mortality were 6.1(IQR 3.5, 11.7) and 19.2 (10.8, 20.6) years, respectively. Higher urine potassium levels were associated with a lower hazard of CVD mortality and all-cause mortality, but were not associated with ESRD (Table). No significant interactions were noted.

Table: Association of 24-hour urine potassium with clinical outcomes

		First screening visit urine potassium*		Average time-dependent urine potassium*	
	Event N (%)	HR (95% CI)	p-value	HR (95% CI)	p-value
ESRD (per SD ↑)	603 (74)	0.94 (0.86,1.03)	0.17	0.95 (0.84,1.06)	0.36
CVD mortality (per SD ↑)	195 (24)	0.76 (0.63,0.91)	0.003	0.72 (0.58,0.90)	0.004
All-cause mortality (per SD ↑)	430 (53)	0.85 (0.76,0.96)	0.007	0.78 (0.67,0.90)	0.001

*Adjusted for age, sex, race, cause of kidney disease, GFR, urine protein, systolic blood pressure, diabetes, history of CVD, blood pressure and dietary protein randomization group, and urine sodium.

Conclusions: Higher urine potassium is associated with lower risk of CVD mortality and all- cause mortality. It remains to be determined whether higher dietary potassium intake results in improved outcomes in CKD.

Funding: NIDDK Support

TH-PO607

Association Between Serum Bicarbonate and Heart Rate Variability in Hypertensive Adults: The Systolic Blood Pressure Intervention Trial

Kalani L. Raphael,[1] Elsayed Z. Soliman,[2] William C. Cushman,[3] Matthew J. Diamond,[4] Jeff Whittle,[6] Anthony Alexander Killeen,[7] Laura Lovato,[2] Joachim H. Ix,[5] Srini Beddhu.[1] *[1]Univ of Utah; [2]Wake Forest School of Medicine; [3]Memphis VA Medical Center; [4]Georgia Regents Univ; [5]UC San Diego; [6]Clement J Zablocki VA Medical Center; [7]Univ of Minnesota.*

Background: Reduced heart rate variability (HRV), a measure of cardiac autonomic dysfunction, has been associated with lower serum [HCO_3^-] in advanced CKD and ESRD. The purpose of this study is to determine if [HCO_3^-] is associated with HRV in hypertensive adults with more preserved eGFR.

Methods: We examined the cross-sectional association between baseline [HCO_3^-] and HRV in 9,265 participants from the Systolic Blood Pressure Intervention Trial (SPRINT). Three sequential 10-second 12-lead ECGs were used to calculate two time domain measures of HRV (standard deviation of all normal RR intervals [SDNN] and root mean square of the successive differences in normal RR intervals [RMSSD]) from the individual durations between normal RR intervals. Linear regression models (adjusted for demographics, smoking, eGFR, ACR, CVD, and SBP) were performed using [HCO_3^-] as the independent variable and log-transformed SDNN and RMSSD as dependent variables. These models were repeated using [HCO_3^-] as a categorical variable: < 22, 22.0-24.9, 25.0-29.9 (referent), and ≥ 30 mEq/L.

Results: Mean age was 67.9 (9.4) years, 28.4% had CKD, mean eGFR was 71.8 (20.6) ml/min/1.73m^2, mean [HCO_3^-] was 26.3 (2.6) mEq/L, mean SDNN was 21.2 (17.6), and

mean RMSSD was 25.2 (24.6). There was no significant association between [HCO_3^-] and SDNN (beta coefficient -0.01, p=0.94) or RMSSD (beta coefficient 0.04, p=0.71) in adjusted linear regression models. Results were similar in models using [HCO_3^-] as a categorical variable. There was no interaction of these relationships by CKD status (p>0.40 for SDNN and RMSSD).

Conclusions: In this large study of trial participants with normal kidney function to moderate CKD, there was no association between [HCO_3^-] and HRV. The association between lower [HCO_3^-] and reduced HRV may only exist in more advanced CKD.

TH-PO608

Serum Alkaline Phosphatase Negatively Affects Endothelium Dependent Vasodilatation in Naïve Hypertensive Patients Carmine Zoccali,[1] Maria Perticone,[2] Raffaele Maio,[2] Angela Sciacqua,[2] Michele Andreucci,[2] Giovanni Tripepi,[1] Salvatore Corrao,[3] Francesca Mallamaci,[1] Giorgio Sesti,[1] Franco Perticone.[2] *[1]National Research Council-Inst of Clinical Phisiology, Reggio Calabria, Italy; [2]Univ Magna Græcia of Catanzaro, Catanzaro, Italy; [3]Biomedical Dept of Internal Medicine and Subspecialties Univ of Palermo, Palermo, Italy.*

Background: Tissue non-specific Alkaline Phosphatase (Alk-Phos) promotes arterial calcification in experimental models and, independently of other risk factors, high Alk-Phos is a powerful predictor of total and cardiovascular (CV) mortality in the general population and in patients with heart diseases.

Methods: To investigate the relationship between Alk-Phos and atherosclerosis at an early disease stage we tested the association between serum Alk-Phos and the endothelium dependent maximal vasodilatory response to acetycholine in 500 untreated individuals with uncomplicated essential hypertension without liver disease and with Alk-Phos levels well within the normal range of activity of this enzyme.

Results: The maximal response to acetylcholine was inversely related to Alk-Phos (r=-0.55, P<0.001) and this association was unmodified (r=-0.61, P<0.001) in adjusted analyses including demographic and classical risk factors, the BMI, the eGFR, serum phosphate and calcium as well as serum C reactive protein (CRP) and albuminuria. The steepness of the Ach-max/Alk.Phos relationship was substantially attenuated (P<0.001) in patients with serum phosphate above the median value than in those below the median (-5.0% per Alk-Phos Unit vs -10.0% per Alk-Phos Unit) and this interaction remained highly significant (P<0.001) in adjusted analyses.

Conclusions: Our findings offer a novel interpretative clue to explain the association between serum Alk-Phos and phosphate and all cause and CV mortality in previous observational studies in the general population and in patients with heart disease and suggest that the endothelium may be an early target of raised Alk-Phos.

TH-PO609

Alkaline Phosphatase Lowering by Selective BET Inhibition, a Novel Mechanism for MACE Reduction in High Risk CVD, Diabetes and CKD Patients – A Post-Hoc Analysis of Phase 2b Studies with RVX-208 Kamyar Kalantar-Zadeh,[1] Jan O. Johansson,[2] Michael Sweeney,[2] Kenneth E. Lebioda,[2] Ewelina Kulikowski,[2] Christopher Halliday,[2] Norman Cw Wong.[2] *[1]Div of Nephrology and Hypertension, 1Univ of California Irvine School of Medicine, Irvine, CA; [2]Reseerch and Development, Resverlogix Corp, Calgary, AB, Canada.*

Background: RVX-208 development is focused on reducing major adverse cardiovascular events (MACE) in high risk CVD, diabetes and CKD patients. RVX-208 is a first in class select BET inhibitor small molecule that interacts with the second ligand domain found in bromodomain and extra-terminal proteins (BET). It is characterized by reductions in alkaline phosphatase (ALP) and anti-inflammatory effects.

Methods: In the SUSTAIN and ASSURE phase 2b clinical studies, high risk CVD patients were treated with 200 mg b.i.d RVX-208 or placebo for up to 26 weeks duration. Patients with a history of diabetes were analysed as a subgroup.

Results: A significant reduction in MACE in all the RVX-208 treated patients (n=331) compared to placebo (n=168) was observed (p=0.02) as well as in those with diabetes (RVX-208 n=127/placebo n=65) (p<0.01). MACE included death, non-fatal myocardial infarct, and hospital admittance for cardiac reasons. In all patients (n=499), MACE compared to non-MACE patients had higher baseline ALP; 77.0 U/L vs. 72.0 U/L (p<0.05). Similar trends were observed in diabetes patients, 81.0 U/L vs. 75.5 U/L. RVX-208 treatment significantly lowered ALP vs. placebo in all patients (p<0.0001) and especially in those with diabetes (p<0.0001). In addition, in the RVX-208 treated group, patients who did not experience a MACE had greater reductions of ALP compared to those who experienced a MACE (-8.0 U/L vs. +3.0 U/L) (p<0.05).

Conclusions: In phase 2b studies in high risk CVD and diabetes patients treated with RVX-208, a select BET-inhibitor, baseline ALP levels were significantly different between the MACE and non-MACE patients. Furthermore, RVX-208 significantly lowered serum ALP. A prospective phase 3 study currently planned, called BETonMACE, will need to further examine RVX-208's potential in reducing MACE in high risk CVD, diabetes and CKD patients.

TH-PO610

Serum Electrolyte Levels and Risk of Sudden Death in Patients with Moderate CKD Patrick H. Pun, Benjamin A. Goldstein, John Gallis, Sarah H. Timberlake, Midori L. Mccarty, John Paul Middleton, Laura P. Svetkey. *Duke Unversity, Durham, NC.*

Background: Abnormalities in the serum potassium(K), calcium(Ca) and magnesium(Mg) are known to disturb cardiac conduction and are rare causes of sudden death (SD). However, CKD patients are at higher risk for both electrolyte disturbances and SD; the extent to which these processes are related has not been well described. We examined the role of disordered serum electrolyte levels in SD risk among a large cohort of patients with coronary artery disease (CAD) and moderate CKD.

Methods: Retrospective longitudinal cohort study of 38,576 patients undergoing cardiac catheterization at a single institution from 1989 to 2014. Patients with significant CAD were included. Baseline laboratory measures were extracted within 60 days of the time of cardiac catheterization. GFR was estimated using the CKD-EPI equation. The main outcome measures were all-cause death and SD, which was determined by chart review, query of the national death index and information from surviving family members. Cox proportional hazards models were used to determine associations with predictors.

Results: 28% of patients had stage 3-4 CKD (eGFR 15-60). This group had a higher risk of death (HR=2.53, P<0.001), SD (HR 1.80, P<0.001), hyperkalemia (RR=3.5), hypercalcemia (RR=1.7), and hyper- and hypomagnesemia (RR=1.4, RR=1.2) compared to patients without CKD. Elevated K, Ca, and Mg were associated with increased risk of all-cause death among patients with moderate CKD, but not with SD. Hyperkalemia was associated with SD in the absence of CKD.

	No CKD (N=26,992)		CKD 3-4 (N=10,828)	
	HR (95% CI)	P-value	HR (95% CI)	P-value
All Cause Mortality				
Potassium (Normal ref)				
High	1.53 (1.21, 1.94)	<.001	1.17 (1.01, 1.36)	0.042
Low	1.19 (1.06, 1.35)	0.004	1.12 (0.97, 1.29)	0.124
Corrected Calcium (Normal ref)				
High	1.59 (1.29, 1.97)	<.001	1.35 (1.11, 1.64)	0.003
Low	0.91 (0.78, 1.07)	0.253	0.92 (0.77, 1.10)	0.364
Magnesium (Normal ref)				
High	1.18 (1.08, 1.29)	<.001	1.18 (1.08, 1.29)	<.001
Low	1.12 (0.97, 1.29)	0.182	1.09 (0.96, 1.23)	0.182
Sudden Death				
Potassium (Normal ref)				
High	2.48 (1.33, 4.65)	0.004	1.55 (0.89, 2.71)	0.119
Low	1.39 (0.95, 2.04)	0.094	0.97 (0.53, 1.77)	0.917
Corrected Calcium (Normal ref)				
High	0.66 (0.21, 2.06)	0.473	1.60 (0.76, 3.36)	0.214
Low	1.12 (0.65, 1.91)	0.684	1.02 (0.51, 2.05)	0.95
Magnesium (Normal ref)				
High	0.85 (0.60, 1.19)	0.342	1.02 (0.70, 1.50)	0.906
Low	1.24 (0.84, 1.82)	0.273	0.72 (0.40, 1.31)	0.288

Conclusions: Abnormalities in K, Ca and Mg are common among CKD patients and are associated with heightened risk of all-cause death, but are not associated with SD. Targeted management of serum electrolyte abnormalities could reduce overall mortality risk in CKD patients, but other strategies may be needed to protect from sudden death.

TH-PO611

Circulating ACE2 as a Biomarker of Chronic Kidney Disease Progression Lidia Anguiano,[1] Marta Riera,[1] Julio Pascual,[1] Angels Betriu,[2] Jose M. Valdivielso,[2] Clara Barrios,[1] Elvira Fernandez,[2] Maria Jose Soler.[1] *[1]Nephrology, Hospital del Mar-Inst Hospital del Mar d'Investigacions Mèdiques, Barcelona, Spain; [2]Nephrology, Hospital Arnau de Vilanova, Lleida, Spain.*

Background: In a CKD population without previous history of CV disease, ACE2 activity from human EDTA-plasma samples directly correlated with the classical CV risk factors namely older age, diabetes and male gender. Objective: To study circulating ACE2 as a biomarker of renal progression and atheromatous disease(AD) in CKD stages 3-5(CKD3-5) patients.

Methods: Prospective study from 930 CKD3-5 patients without history of CVD. Circulating ACE2 activity was analyzed. We evaluated renal function(serum creatinine, glomerular filtrate MDRD-4), carotid/femoral echography, mortality, renal replacement therapy and AD at baseline and 24 months. ACE2 activity was divided in tertiles(£27.64;27.65-46.34;≥46.35RFU/µL/h). Univariate and multivariate(dependent variable ACE2 natural logarithm) were performed.

Results: Patients with ACE2 in the higher tertile doubled creatinine more frequently(61% higher tertile vs 28% lowest tertile,p=0.013). Patients that showed plaques appearance at 24month had a higher ACE2 activity in comparison to patients without(42.0±2.4 vs 34.2±1.2,p=0.009). Patients that presented plaques at baseline had higher ACE2 than those that have never had (48.2±1.7 vs 34.2±1.2,p<0.001). Femoral plaques: ACE2 increased in patients with baseline plaques(48.9±1.9) or with de novo plaques at 24months(46.6±3.2) respect to patients without plaques(35.9±1.5,p=0.002/p<0.001).

Carotid plaques: ACE2 increased in patients with baseline plaques respect to patients without plaques (49.0±2.1 vs 38.5±1.3, p<0.001). Patients with AD2-3 at 24months showed an ACE2 increase as compared to AD0-1 at 24months(47.6±1.6 vs 35.7±1.6,p<0.001). Multivariate analysis demonstrated circulating ACE2 in CKD3-5 as a predictor of doubling creatinine (β=0.069,p=0.034), de novo appearance of femoral plaques at 24months (β=0.087,p=0.016) and presence of femoral plaques at basal and 24months(β=0.199,p<0.001).

Conclusions: In CKD3-5 patients without history of CVD, circulating ACE2 may become a biomarker of CKD progression and AD appearance at 24months of follow-up.

TH-PO612

Blood Pressure and Risk of Cardiovascular Events at Advanced CKD: The CRIC Study Nisha Bansal,[1] Charles E. McCulloch,[2] Feng Lin,[2] Cassianne Robinson-Cohen,[1] Mahboob Rahman,[3] John W. Kusek,[4] Amanda Hyre Anderson,[5] Raymond R. Townsend,[5] Jackson T. Wright,[6] Alan S. Go,[7] Arnold B. Alper,[8] Radhakrishna Reddy Kallem,[5] Chi-yuan Hsu.[2] *[1]UW; [2]UCSF; [3]UH; [4]UPenn; [5]NIDDK; [6]Case Western; [7]KPNC; [8]Tulane.*

Background: The association of SBP with cardiovascular events (CVD) among patients with advanced CKD is not known and may be an important modifiable risk factor.

Methods: Participants of the Chronic Renal Insufficiency Cohort (CRIC) Study with advanced CKD (defined as eGFR <30 ml/min/1.73 m^2) had SBP measured by standardized methods at yearly in-person visits. We studied the association of SBP with time to physician-adjudicated atherosclerotic CVD (defined as myocardial infarction, stroke, peripheral vascular disease) and heart failure (HF) using Cox models.

Results: Among 1,795 participants with eGFR<30 ml/min/1.73 m^2, mean age was 60±11 years, 46% were women and 46% were African American. Mean eGFR was 26±5 ml/min/1.73 m^2 and mean BP was 131 (±24)/69 (±13) mm Hg. In models adjusted for demographics, clinical site, tobacco use, body mass index, diabetes, urine proteinuria, statin use and number of classes of anti-hypertensive medications, higher SBP was associated with greater risk of incident atherosclerotic disease and HF. Results were similar when participants with prevalent atherosclerotic CVD and HF were excluded.

Association of SBP and risk of atherosclerotic CVD (MI, stroke, PVD) and heart failure (HF) among patients with eGFR<30 ml/min/1.73 m2

	Atherosclerotic CVD N=1,795 Adjusted HR (95% CI)	Atherosclerotic CVD, excluding participants with prevalent atherosclerotic CVD N=1,036 Adjusted HR (95% CI)	HF N= 1,795 Adjusted HR (95% CI)	HF, excluding participants with prevalent HF N= 1,481 Adjusted HR (95% CI)
SBP<120 mm Hg	Ref	Ref	Ref	Ref
SBP 120-140 mm Hg	1.46 (1.05 - 2.02)	1.28 (0.75 - 2.20)	1.21 (0.92 - 1.58)	1.51 (1.08 - 2.12)
SBP >140 mm Hg	2.00 (1.43 - 2.79)	2.28 (1.34 - 3.86)	1.27 (0.96 - 1.68)	1.47 (1.03 - 2.12)

adjusted for demographics, clinical site, tobacco use, body mass index, diabetes, urine proteinuria, statin use and number of classes of anti-hypertensive medications

Conclusions: Among this diverse multi-center cohort of advanced CKD patients, higher SBP was associated with greater risk of atherosclerotic CVD and HF. This is similar to what has been reported in the general population and suggests that treatment guidelines developed for non-CKD populations can be extended to those with eGFR <30 ml/min/1.73 m^2.

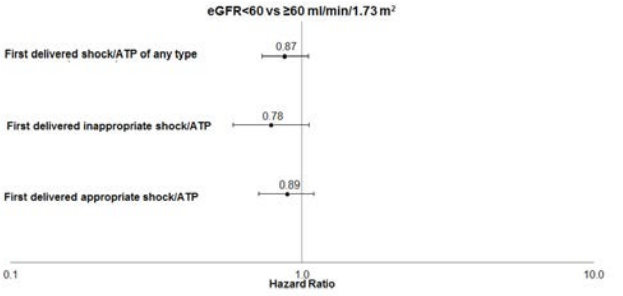
TH-PO613

CKD Does Not Impact Risk and Appropriateness of Device Therapies in Adults with Primary Prevention Implantable Cardioverter Defibrillators Nisha Bansal,[1] Adam Szpiro,[1] Frederick A. Masoudi,[2] Robert Greenlee,[3] Jerry H. Gurwitz,[4] Kristi Reynolds,[5] Grace Hsu Tabada,[6] Sue hee Sung,[6] Ashveena Dighe,[1] Andrea E. Cassidy-Bushrow,[7] Romel J. Garcia-Montilla,[3] Stephen Hammill,[8] Alan Kadish,[9] Param Sharma,[3] Humberto Vidaillet,[3] Alan S. Go.[6] *[1]UW; [2]UC; [3]MCRC; [4]MPCI; [5]KPSC; [6]KPNC; [7]HFH; [8]MC; [9]TC.*

Background: Implantable cardioverter defibrillators (ICD) reduce the risk of sudden cardiac death (SCD). CKD patients are at high-risk for SCD, but whether CKD is associated with greater risk of delivered shocks/anti-tachycardia pacing (ATP) therapies among those with an ICD remains unclear.

Methods: We studied participants in the Cardiovascular Research Network Longitudinal Study of Implantable Cardioverter Defibrillators (CVRN LS-ICD). CKD was defined as eGFR<60 ml/min/1.73 m^2 at the time of ICD implantat. Outcomes included number and type of shock/ATP (inappropriate or appropriate, determined by physician adjudication) within 3 years after implant. We evaluated the associations between kidney function and time to first device therapy, burden of device therapy, and inappropriate vs. appropriate device therapy.

Results: Among 2,161 participants, 49.3% had CKD at the time of ICD implantat. During mean follow-up of 2.3±0.9 years, 9.8% and 18.5% of participants had at least 1 inappropriate and appropriate shock/ATP, respectively. CKD was not associated with time to first shock/ATP of any type.



Adjusted for: age, gender, race, site, NYHA class, ischemic heart disease, hypertension, dyslipidemia, previous myocardial infraction, previous coronary artery bypass surgery, previous percutaneous coronary intervention, atrial fibrillation or flutter, ventricular tachycardia, previous valvular surgery, tobacco use, cerebrovascular disease, diabetes, lung disease, liver disease, systolic blood pressure, body mass index,left ventricular ejection fraction, ICD device type, ACE Inhibitors / Angiotensin II receptor blockers, beta-blockers, and diuretics

CKD was not associated with greater overall burden of shock/ATPs (adjusted relative rate 0.93, 95% CI: 0.74-1.17) or inappropriate vs. appropriate shock/ATP (adjusted relative risk 0.88, 95% CI: 0.68-1.14).

Conclusions: In adults receiving a primary prevention ICD, CKD was not associated with the timing, burden or appropriateness of delivered ICD therapies. Concern for more frequent or inappropriate ICD therapies should not preclude ICD implantation among eligible CKD patients.

Diagnostic and Prognostic Characteristics of Amino-Terminal Pro B-Type Natriuretic Peptide in Patients with Diminished Renal Function: A Systematic Review and Meta-Analysis Jennifer A. Schaub,[1] Steven G. Coca,[2] Dennis G. Moledina,[1] Jeffrey M. Testani,[1] Chirag R. Parikh,[1] Mark Gentry.[1] *[1]Yale Univ School of Medicine, New Haven, CT; [2]Nephrology, Mount Sinai, New York, NY.*

Background: Patients with renal dysfunction have higher plasma Amino-terminal pro B-type Natriuretic Peptide (NT-proBNP), which may complicate interpretation for diagnosis of acute decompensated heart failure (ADHF) or prognosis. We sought to systematically review studies on NT-proBNP testing in patients with and without renal dysfunction.

Methods: We searched MEDLINE, EMBASE and Web of Science through August 2014 and selected studies with sub-group analysis by renal function of the diagnostic or prognostic ability of NT-proBNP.

Results: For diagnosis, nine studies were included with 4,287 patients and 1,325 ADHF events. Patients were mostly divided into sub-groups with and without renal dysfunction by an estimated glomerular filtration rate of 60 ml/min/1.73m^2. In patients with renal dysfunction, the area under the curve (AUC) for NT-proBNP ranged from 0.66 to 0.89 with a median cut-point of 1980 pg/ml while the AUC ranged from 0.72 to 0.95 with a cut-point of 450 pg/ml in patients with preserved renal function. For prognosis, 30 studies with 32,203 patients were included, and mortality in patients with renal dysfunction (25.4%) was twice that of patients with preserved renal function (12.2%). The unadjusted pooled risk ratio (RR) for NT-proBNP and mortality was 3.01 (95% CI, 2.53-3.58) in patients with preserved renal function and was similar in patients with renal dysfunction (3.25 [CI, 2.44-4.32]). There was significant heterogeneity, which was partially explained with meta-regression, if patients with heart failure or coronary artery disease were enrolled.

Conclusions: NT-proBNP retains utility for diagnosis of ADHF in patients with diminished renal function with higher cut-points. Elevated NT-proBNP confers a worse prognosis regardless of renal function.

Changes in Urinary L-FABP as a Biomarker for Cardiovascular Events Atsuko Ikemori,[1,2] Takeshi Sugaya,[1] Katsuomi Matsui,[1] Mikako Hisamichi,[1] Kenjiro Kimura,[3] Yugo Shibagaki.[1] *[1]Dept of Nephrology and Hypertension, Internal Medicine, St. Marianna Univ School of Medicine, Kawasaki, Japan; [2]Dept of Anatomy, St. Marianna Univ School of Medicine, Kawasaki, Japan; [3]Internal Medicine, Tokyo Takanawa Hospital, Tokyo, Japan.*

Background: Contrast medium (CM) induces tubular hypoxia via endothelial damage due to direct cytotoxicity or viscosity. Urinary liver-type fatty acid binding protein (L-FABP) is a tubular biomarker which increases along with tubular hypoxia and may be useful as a detector of systemic circulation injury. The aim of this study wasto evaluate the clinical usefulness of increase in urinary L-FABP levels due to administration of CM as a prognostic biomarker for cardiovascular disease in patients without occurrence of CM-induced nephropathy undergoing cardiac catheterization procedure (CCP).

Methods: Cross-sectional and retrospective longitudinal analyses of the relationship between urinary L-FABP levels and occurrence of cardiovascular events were performed. Urinary L-FABP was measured by ELISA before, and at 6, 12, 24 and 48 h after CCP.

Results: Urinary L-FABP levels were significantly higher at 12h and 24h after CCP compared with before CCP only in the patients with occurrence of cardiovascular events. The difference in urinary L-FABP levels (ΔL-FABP) between before and at 24h after CCP was a risk factor for the occurrence of cardiovascular events.

Conclusions: Measurement of urinary L-FABP before and at 24h after CCP in patients with mild to moderate renal dysfunction may be an important indicator for risk stratification of onset of cardiovascular events in clinical practice.

TH-PO616

Suggested Role of Adiponectin in Reciprocal Relationships Between Pulse Wave Velocity and Bone Mineral Density in CKD Patients Seon Ha Baek,[1] Sung Woo Lee,[1] Shin-Young Ahn,[1] Sejoong Kim,[1] Ho Jun Chin,[1] Ki Young Na,[1] Dong-Wan Chae,[1] Curie Ahn.[2] *[1]Internal Medicine, Seoul National Univ Bundang Hospital, Gyeonggi-do, Republic of Korea; [2]Internal Medicine, Seoul National Univ Hospital, Seoul, Republic of Korea.*

Background: Although adiponectin plays a beneficial role in the regulation of insulin action and atherosclerosis in various populations, the role of adiponectin remains a controversy in patients with chronic kidney disease (CKD).

Methods: A total of 1310 patients (male/female = 794/516) with CKD stage 1 to 5 who enrolled in the KoreaN cohort study for Outcome in patients With Chronic Kidney Disease (KNOW-CKD) from June 2011 to December 2013. We measured serum total adiponectin and examined the association between adiponectin, bone mineral density (BMD) measured by dual energy X-ray absorptiometry, and pulse wave velocity (PWV) calculated by mean value of both brachial-ankle (ba) PWV.

Results: Increasing quintiles of serum adiponectin levels were associated with female gender; lower body mass indices, estimated glomerular filtration rate, triglycerides, BMD and albumin; higher urinary protein creatinine ratios, PWV, phosphorous, intact PTH. T-scores at LS spine (LS), total hip (TH), and femur neck (FN) inversely correlated with ba PWV (LS: r = -0.075, P = 0.010; TH: r = -0.097, P = 0.001; FN: r = -0.111, P <0.001) in male CKD, however, this association was not significant for female CKD (LS: r = 0.019, P = 0.607; TH: r = -0.046, P = 0.223; FN: r = -0.043, P = 0.277). Adiponectin was inversely associated with T-scores at all sites for both male and female CKD patients (LS: r = -0.133, P <0.001; TH: r = -0.135, P <0.001; FN: r = -0.099, P <0.001). Adiponectin was positively associated with ba PWV for male CKD (r = 0.074, P = 0.016), but not for female CKD (r = -0.021, P=0.567).

Conclusions: Adiponectin, BMD, and PWV were associated with each other in male CKD patients. The findings suggested that adiponectin have the role in reciprocal relationships between PWV and BMD in not female but male CKD patients.

TH-PO617

The Association of High-Sensitivity Troponin I and N-Terminal Pro-Brain Natriuretic Peptide with Plasma Galectin-3 in Chronic Kidney Disease Patients Gek Cher Chan,[1] Rui shian Ao,[2] Jialiang Li,[2] Boon Wee Teo.[1,3] *[1]Nephrology, National Univ Hospital, Singapore; [2]Statistics and Applied Probability, National Univ of Singapore, Singapore; [3]Yong Loo Lin School of Medicine, National Univ of Singapore, Singapore.*

Background: Plasma galectin-3 (pG3), a beta-galactoside-binding lectin, regulates inflammation and fibrosis. N-terminal pro-brain natriuretic peptide (NTproBNP), high-sensitivity Troponin I (hsTnI), and pG3 concentrations are elevated in chronic kidney disease (CKD) patients with heart failure. Between hsTnI and NTproBNP, it is unknown which has a better association with pG3. We assessed the relationship of NTproBNP and hsTnI with pG3 in Asian CKD patients and healthy controls.

Methods: We retrieved prospectively collected frozen plasma samples from 163 stable CKD patients and 105 healthy controls. NTproBNP, hsTnI and pG3 were assayed. By univariate analysis, we assessed pG3 for associations with age, gender, ethnicity, systolic (SBP) and diastolic (DBP) blood pressures (mmHg); height, weight, body mass index (BMI, kg/m^2), previously diagnosed CKD, diabetes, hypertension, coronary artery disease, estimated glomerular filtration rate (eGFR, mL/min/1.73m^2); C-reactive protein (CRP), beta-trace protein (BTP), 24-hr urine protein (TUP), serum albumin, uric acid and cystatin C. We created 2 models predicting pG3 using multiple linear regression by backwards elimination to include hsTnI and NTproBNP. Akaike Information Criterion (AIC) was used for comparison. Significance was taken at P<0.05.

Results: Population averages: Age=52.7±15.3 years; BMI=26.9±5.2, eGFR=75 (IQR:36-102); pG3=19.4 (IQR:14.9-29.9)ng/mL, NTproBNP=27 (IQR:11-71) pg/mL, hsTnI=3.1 (IQR:1.6-6.0) ng/L. Age, SBP, DBP, height, BMI, previous disease diagnoses, Ln CRP, Ln BTP, Ln TUP, Ln albumin, Ln uric acid, Ln creatinine, Ln cystatin C, Ln eGFR, Ln hsTnI, Ln NTproBNP were associated with pG3. The best model included Ln hsTnI, diagnosis of CKD, Ln albumin, Ln cystatin C, Ln uric acid, and height. (AIC: 83.3).

Conclusions: NTproBNP and hsTnI are associated with pG3 in CKD patients. The model including hsTnI is a better predictor of pG3.

TH-PO618

ACE/ARB Use in Patients with Severe Kidney Disease and Heart Failure Is Not Associated with Worsening Renal Function, Acute Kidney Injury and Hyperkalaemia Gowrie Balasubramaniam, Sebastian Vandermolen, Sarah Mapplebeck, Michael K. Almond. *Dept of Medicine, Southend Univ Hospital, Southend, Essex, United Kingdom.*

Background: The role of ACE/ARB in patients with severe kidney disease and heart failure needs clarification. This includes patients with preserved systolic function. ACE/ARB use is associated with better cardiac prognosis but there is a risk of worsening renal function, especially in older and frail people.

Methods: We undertook a retrospective analysis of patients who were diagnosed with heart failure in primary care with BNP testing and Echocardiogram. Our centre serves a population of 350,000, details of hospital admissions, drug information and blood results were obtained from our electronic patient records. A BNP>450 and clinical features of heart failure is the criteria used by general practitioners for diagnosis, an eGFR < 30 was used to identify patients with severe kidney disease. We looked at rates of worsening kidney function, AKI and hyperkalaemia.

Results: 159 patients with raised BNP and eGFR <30 were identified on electronic search from 01/12 to 01/14. Mean age was 81.7year (range 41-96), M:F was (79:80). Average follow-up was 17 months. 27 patients with transient rise in serum creatinine (Cr) or on dialysis were excluded. 87 of the remaining 132 patients had echocardiograms; 13 had ejection fraction (EF) <40%, 7 EF had 40-50% and 67 had preserved ejection fraction (>50%). Comparing with EF<50% vs. EF>50%; mortality was 55% (11/20) vs. 10% (7/67), mean BNP was 12,037 vs. 3645, mean Cr was 235 vs. 201 and 1/20 vs. 1/67 reached ESRD, respectively. 84 patients had drug information available.

	On ACE/ARB (n=62)	Not on ACE/ARB (n=22)
Mortality	21%	23%
Episode of AKI	58%	45%
Worsening CKD at follow-up	53%	45%
Mean potassium	4.2	4.7

Conclusions: Impaired EF was associated with worse mortality. ACE/ARB use was not associated with more adverse events with regards to episodes of AKI, worsening egfr and mean potassium. We feel that ACE/ARB treatment for heart failure should be maintained even in the setting of severe renal disease to reduce cardiovascular mortality.

TH-PO619

Protein-Fiber Intake Ratio and Cardiovascular Risk in Older Men with Chronic Kidney Disease Hong Xu,[1] Megan Rossi,[2] Katrina L. Campbell,[2,3] Gloria Lissete Sencion martinez,[1] Johan Arnlov,[4] Tommy Cederholm,[5] Per Sjogren,[5] Bengt Lindholm,[1] Juan Jesus Carrero.[1] *[1]Renal Medicine & Baxter Novum, Karolinska Inst, Stockholm, Sweden; [2]Princess Alexandra Hosp, Brisbane, Australia; [3]Health Sciences & Medicine, Bond Univ, Robina, Australia; [4]Medical Sciences, Uppsala Univ, Uppsala, Sweden; [5]Public Health and Caring Sciences, Uppsala Univ, Uppsala, Sweden.*

Background: The elevated cardiovascular (CVD) risk in chronic kidney disease (CKD) may be partially alleviated through a healthy diet. While protein intake has been linked to CVD events in CKD patients, dietary fiber may be cardioprotective. Nutrients are not consumed in isolation; we hypothesize that CVD incidence associates with dietary patterns aligned with excess of dietary protein relative to fiber.

Methods: Prospective cohort study from Uppsala Longitudinal Study of Adult Men of 390 elderly men aged 70–71 years with manifest CKD (eGFR<60 mL/min/1.73m^2 and albuminuria³20 µg/min) and no clinical history of CVD. Protein and fiber intake and its ratio, were calculated from 7-day dietary records. Cardiovascular structure and function was estimated from echocardiographic examination. Fatal and non-fatal cardiovascular events were registered prospectively during median follow-up of 9.1 (IQR 4.5-10.7) years.

Results: The median of protein-fiber ratio was 4.0 (3.5-4.7); dietary protein was 66.7 (60.7-71.1) and dietary fiber was 16.6 (14.5-19.1) grams/day. Protein-fiber intake ratio, rather than separate components, remained strongly associated to left ventricular cardiovascular structure and diastolic function after multivariable adjustment.During follow-up, 164 first-time CVD events occurred (incidence rate 54.5/1,000 py). Protein-fiber intake ratio was an independent risk factor for CVD incidence [adjusted HR per SD increase (95% confidence interval, CI) 1.29 (1.05, 1.57)]. Although in opposing directions, neither dietary protein [1.10 (0.92, 1.33)] nor dietary fiber [0.83 (0.68, 1.02)] associated with this outcome.

Conclusions: An excess of dietary protein relative to fiber intake associated with cardiovascular structural dysfunction and with incidence of cardiovascular events in a homogeneous population of older men with CKD.

Impact of Percutaneous Transluminal Renal Angioplasty (PTRA) on Long-Term Prognosis in Patients with Severe Atherosclerotic Renal Artery Stenosis (RAS) Yasuhiro Mochida, Takayasu Ohtake, Kunihiro Ishioka, Machiko Oka, Hidekazu Moriya, Sumi Hidaka, Shuzo Kobayashi. *Nephrology, Shonan Kamakura General Hospital, Kamakura, Kanagawa, Japan.*

Background: PTRA for the patients(Pt's) with RAS was concluded to be not superior to medical therapy in terms of preserving renal function, renal events, and cardiovascular events in multicenter randomized trial in ASTRAL and CORAL. However, in these studies, approximately 40% of all Pt's had only mild to moderate RAS (50~70%). Therefore, we studied whether PTRA for the Pt's with more severe RAS would be beneficial or not.

Methods: Eligibility of the study included the Pt's with RAS in stenosis more than 75%, who underwent PTRA in our hospital from September 2004 to December 2007. Mean follow-up period was 81±34 months (median 7 years). We investigated the changes of renal function as primary endpoint, and renal event (doubling of serum creatinine(=Scr) or dialysis initiation) and cardiovascular death as secondary endpoint.

Results: Among 80 RAS patients with PTRA treatment, 74 Pt's were followed by April 2015. There were 24 Pt's with 75-89% (moderate group), 38 Pt's with 90-95% (severe group), and 12 Pt's with more than 95% (more severe group) in stenosis. At the time of PTRA, 92% of all the Pt's had ischemic heart disease . The changes of Scr from baseline to the final hospital visit (mean±SD) were from 1.21±0.59 to 1.47±0.91 mg/dl in moderate, from 1.10±0.34 to 1.89±1.84 mg/dl in severe, and from 1.95±1.14 to 1.76±0.80 mg/dl in more severe group, respectively. During the follow-up period, totally four renal events (5.4%) occurred (1 in moderate , 3 in severe). However, none of the more severe group presented renal event, nor renal function worsening in this group (P=0.002). Fourteen Pt's died (19%), of which cardiac death occurred in 6 Pt's (8.1% among all Pt's) during the follow-up period.

Conclusions: In comparison with 5-year cumulative rate of 22% renal events and 11.4% cardiovascular death in medical group in ASTRAL study, the results in our study clearly demonstrated the effectiveness of PTRA in more severe RAS patients in preserving renal function and protecting from cardiac deaths. PTRA is a useful treatment for the Pt's with more severe RAS .

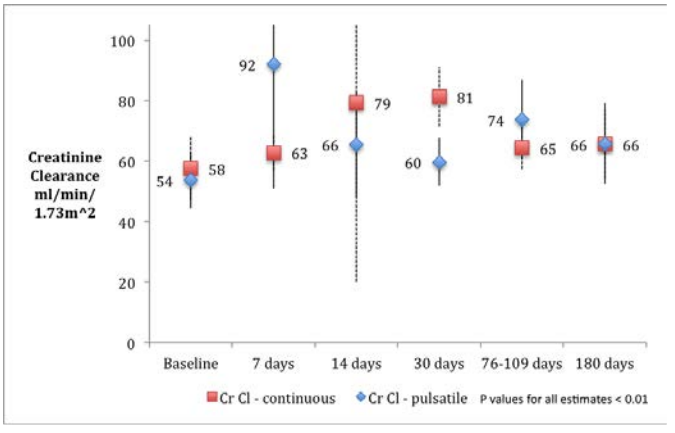
TH-PO621

Changes in Renal Function After LVAD Placement – A Meta-Analysis Reejis Stephen,[1] Chandrashekar Kashyap,[2] Minesh Rajpal,[1] Sankar D. Navaneethan.[1] *[1]Nephrology, Cleveland Clinic, Cleveland; [2]Medicine, MetroHealth Medical Center, Cleveland.*

Background: Renal function after Left Ventricular Assist Device (LVAD) placement predicts survival, irrespective of baseline Creatinine Clearance (CrCl). Continuous flow devices have been reported to have better renal outcomes than pulsatile devices. We compared the change in renal function in recipients of both continuous and pulsatile-flow devices at various time points following LVAD placement.

Methods: We searched MEDLINE for all publications with prospective cohorts and trials of LVAD recipients. Studies documenting renal-function at various time points after LVAD placement were included. CrCl at suitable time points after LVAD placement was pooled using an inverse of variance method and analyzed using random-effects models. Changes in CrCl after continuous and pulsatile flow LVAD placement was compared for cohorts with at least 10 subjects.

Results: 33 studies with 23 cohorts including continuous flow devices (n=1262) and 18 including pulsatile flow (n = 678) were included. Baseline CrCl for continuous and pulsatile-device recipients were similar. Continuous flow LVAD recipients showed higher CrCl at 1 month, compared to baseline and pulsatile-flow device recipients. There was a non-significant trend towards improved renal function after LVAD placement (Figure).



Conclusions: In this pooled analysis, we noted a pattern of an initial improvement in renal function followed by later decline with continuous-flow devices. While CrCl appears to improve after LVAD placement, the long-term effect remains unclear. Further studies focused on renal function and risk factors are needed to better understand the phenomenon in LVAD recipients.

TH-PO622

Impact of Kidney Function on Intima-Media Thickness in Patients with Type 2 Diabetes Yusuke Nakade,[1,3] Tadashi Toyama,[2] Shinji Kitajima,[2] Yasuyuki Shinozaki,[2] Akinori Hara,[2] Miho Shimizu,[2] Yasunori Iwata,[2] Norihiko Sakai,[2] Kengo Furuichi,[2] Takashi Wada.[1,2,3] *[1]Clinical Laboratory, Kanazawa Univ Hospital, Kanazawa, Ishikawa, Japan; [2]Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Ishikawa, Japan; [3]Dept of Laboratory Medicine, Kanazawa Univ Hospital, Kanazawa, Ishikawa, Japan.*

Background: Carotid echo indexes [intima–media thickness (IMT)] are commonly used surrogate markers for cardiovascular disease; However, the impacts of chronic kidney disease (CKD) on changes in IMT are unclear. We examined associations between CKD and IMT in participants with and without type 2 diabetes through longitudinal analysis.

Methods: In total, 424 subjects were enrolled in this study. IMT was measured as per carotid echo indexes. Relationships between IMT and risk factors were analyzed using multiple linear regression analysis, in which we defined IMT as the dependent variable and atherosclerosis-related factors (age, sex, systolic pressure, total cholesterol, body mass index, estimated glomerular filtration rate (eGFR), uric acid, smoking index, number of antihypertensive drugs, statin use, urinary protein levels, past cardiovascular event, glycated hemoglobin, and diabetes duration) as independent variables.

Results: The study population was composed of 70.3 % male subjects. Participants with diabetes accounted for 64.4 % of the total population. The mean follow-up duration was 2.2 ± 1.5 years. Alterations in IMT tended to be associated with systolic blood pressure (+10 mmHg) (β = -0.0084, p = 0.09) and eGFR (+10 mL/min/1.73 m^2) (β = -0.0049, p = 0.06) in all participants. In participants without diabetes, alterations in IMT were associated with eGFR (+10 mL/min/1.73 m^2) (β =-0.0104, p = 0.03) and tended to be associated with systolic blood pressure (+10 mmHg) (β = 0.0094, p = 0.06). No significant relationships were found in participants with diabetes.

Conclusions: Low eGFR was associated with progression of carotid thickness independent of common cardiovascular risk factors in non-diabetic participants.

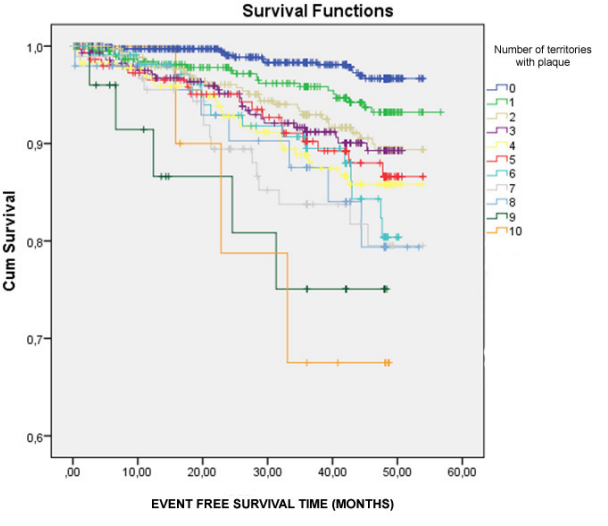
TH-PO623

The Number of Arterial Territories with Atheroma Plaque Predicts Cardiovascular Event-Free Survival in Chronic Kidney Disease. Analysis of the NEFRONA Study after 36 Months of Follow-up Jose M. Valdivielso,[1] Montserrat Martinez-alonso,[3] Marta Gracia,[1] Angels Betriu,[1] David Arroyo,[2] Maria Abajo,[1] Mercedes Salgueira lazo,[4] Jose L. Gorriz,[5] Elvira Fernandez.[2] *[1]Experimental Nephrology, IRBLleida, Lleida, Spain; [2]UDETMA, Arnau de Vilanova Univ Hospital, Lleida, Spain; [3]Statistics Unit, IRBLleida, Lleida, Spain; [4]Unidad Mixta, Hospitales Virgen Macarena y Virgen del Rocio, Sevilla, Spain; [5]Nephrology, Hospital Dr Peset, Valencia, Spain.*

Background: Cardiovascular disease remains the leading cause of morbidity and mortality in patients with chronic kidney disease (CKD).

Methods: The NEFRONA study enrolled 2445 patients in different stages of CKD to assess the value of detection of subclinical atherosclerosis by ultrasound in the prediction of cardiovascular risk. This study shows the data on cardiovascular events (CVE) with a minimum follow-up time of three years, and the COX regression analysis of predicting factors .

Results: There have been 67 fatal and 152 nonfatal CVE and 113 deaths from other causes. The number of missings is 648 (593 renal transplants, 1 non renal transplant and 67 changes of center). The cumulative incidence of CVE is of 8.96% (median follow-up=42.09 months); stage 3: 6.95% (48 months), stage 4-5: 9.29% (42.8 months), stage 5D: 11.34% (23.1 months). Kaplan Meier curves of survival free from CVE show that the survival time is inversely proportional to the number of territories with plaque.



The COX regression analysis shows that the factors significantly predicting event-free survival time are the number of territories with plaque, being on dialysis, smoking, diabetes, high levels of phosphorus, low albumin and 25OH vitamin D as well as having $1,25(OH)_2$ vitamin D below 14 pg/dl.

Conclusions: The severity of arterial atheromatosis estimated by ultrasound predicts the time free from CVE in CKD. Arterial ultrasound is a useful tool to predict cardiovascular risk in CKD patients.

The Effects of Diuretics on the Progression of CKD and Incidence of Cardiovascular Events: Results from the CKD-ROUTE Study – A Prospective Cohort Study of Newly Visiting CKD Patients in Japan

Shotaro Naito, Soichiro Iimori, Eisei Sohara, Tomokazu Okado, Sei Sasaki, Shinichi Uchida, Tatemitsu Rai. *Dept of Nephrology, Tokyo Medical and Dental Univ, Tokyo, Japan.*

Background: Anti-hypertensive agents are requisite for control of blood pressure in CKD patients. Although diuretics seem to be associated with progression of CKD or incidence of cardiovascular (CV) events, this hypothesis has not been adequately elucidated. To evaluate the association of anti-hypertensive agents prescription and outcomes, we analyzed a cohort study of newly visiting pre-dialysis CKD patients in Japan.

Methods: We recruited 937 newly visiting CKD patients followed for the next 3 years. At 6 months visit, use of RAAS inhibitors (RAASi), calcium channel blockers (CCB), and diuretics was assessed, and the association between these medications and outcomes was evaluated. The outcomes were composite kidney endpoint of ESKD or 50% decline of eGFR from baseline, incidence of CV events and CV related death during three years after first visit to nephrologists. We used multivariate Cox proportional hazards regression adjusted by age, sex, albumin, hemoglobin, eGFR, systolic blood pressure, presence of proteinuria and diabetes, and past history of CV events.

Results: At first visit, mean age was 67 years old, 70.2% was male, mean eGFR was 33.7 ml/min/1.73m^2, and mean systolic blood pressure was 139 mmHg. During the follow-up period of 3 years, 114 CV events occurred, 24 patients died of CV events, and 220 patients reached the composite kidney endpoint. In multivariable analysis, risk of CV events and CV related death during the 3-year period was higher in the patients using diuretics at six months visit (adjusted hazard ratio 1.55 [95%CI 1.23-2.33] for CV events, 3.09 [95%CI 1.19-8.02] for CV related death.) The patients taking both diuretics and RAASi had comparable risk of CV events with those taking diuretics only (adjusted HR 1.09 [95%CI 0.54-2.2].) However, none of the three kinds of anti-hypertensive agents had associations with CKD progression.

Conclusions: CKD patients using diuretics were more likely to have CV events and CV related death. RAASi might contribute to reduce the risk of CV events by diuretics.

TH-PO625

Rapid Increase in Aortic Stiffness in Patients on Hemodialysis and Peritoneal Dialysis Compared with Non-Dialysis-Dependent Chronic Kidney Disease Patients: A Longitudinal Study Using MRI-Based Pulse Wave Velocity

Kazuhiko Tsuruya,[1] Hisako Yoshida,[1] Takanari Kitazono.[2] *[1]Dept of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [2]Dept of Medicine and Clinical Sciences, Graduate School of Medical Sciences, Kyushu Univ, Japan.*

Background: Pulse wave velocity (PWV) is a well-established technique for obtaining a measure of arterial stiffness that has the potential to provide information on early atherosclerotic disease. MRI-based PWV measurements have been well validated in comparison with invasive pressure recordings (Grotenhuis et al. J Magn Reson Imaging, 2009). To date, very few studies have reported on MRI-based PWV in patients with chronic kidney disease (CKD), especially in patients with end-stage kidney disease on hemodialysis (HD) and peritoneal dialysis (PD). In the present study, we examined the annual changes in MRI-based PWV from baseline to 2 years and compared them among non-dialysis dependent-CKD (ND), HD, and PD patients.

Methods: A total of 172 CKD patients (ND, n=89; HD, n=47; PD, n=36) were recruited and underwent cardiovascular MRI at baseline and 2 years after. Using cine and phase contrast sequences, the cross-sectional area for distensibility and average blood flow were measured between the ascending and the proximal descending aorta. Annual change in MRI-based PWV was calculated as (MRI-based PWV after 2 years–baseline MRI-based PWV) × 365/interval days between the first and second MRI. Multivariable linear regression was used to evaluate differences in the changes among the 3 patient groups.

Results: The annual changes in MRI-PWV were significantly increased in patients on HD and PD compared with ND patients, even after adjusting various confounding factors including age, sex, and blood pressure (least square means were -0.18, 0.35, and 0.49 in ND, HD, and PD patients, respectively; $p < 0.001$). Meanwhile, there was no difference in the changes between HD and PD patients ($p = 0.736$).

Conclusions: Progression of aortic stiffness is more rapid in patients on HD and PD compared with ND patients independent of age and blood pressure, while comparable between those on HD and PD.

TH-PO626

The Recent ADQI Proposal for a Functional Classification System of Heart Failure in Patients with End-Stage Renal Disease Will Substantially Overdiagnose Cardiac Disease Among Chronic Kidney Disease Patients

Kathrin Untersteller,[1] Francesca Mallamaci,[2] Danilo Fliser,[1] Gerard M. London,[3] Carmine Zoccali,[2] Gunnar H. Heine.[1] *[1]Saarland Univ Medical Center, Homburg, Germany; [2]CNR-Inst of Clinical Physiology, Reggio Calabria, Italy; [3]Manhès Hospital, Fleury-Mérogis, France.*

Background: The Acute Dialysis Quality Initiative (ADQI) XI Workgroup has recently proposed a novel classification for HF stages in advanced CKD, which is based upon a broad spectrum of echocardiographic criteria. We hypothesize that these criteria will substantially overdiagnose HF across the whole spectrum of CKD, as echocardiographic changes are a very frequent finding even among patients with mild to moderate CKD.

Methods: Within the ongoing CARE FOR HOMe study, we echocardiographically examined 317 patients in GFR categories G2 – G4, following American Society of Echocardiography guidelines. According to ADQI criteria, HF is defined by moderate to severe changes in any of the following criteria: valve function, left atrial volume index (LAVI), left ventricular (LV) or right ventricular systolic function, LV mass index, LV diastolic function, LV diameter, or regional LV wall contractility. Patients were followed for a mean of 3.6 ± 1.5 years until the first admission for decompensated HF.

Results: Among the 317 CKD patients, 209 (66%) fulfilled ADQI criteria. HF was detected more often in advanced CKD (G3b/G4: 114/146; 78%) than in milder CKD (G2/G3a: 95/171; 56%). An increased LAVI (158/317; 50%) and diastolic dysfunction (101/317; 32%) were the most frequent findings within the subcategories of echocardiographic changes. Among all 209 patients with ADQI HF, only 24 patients (11%) suffered decompensated HF during follow-up, and event-free four year survival was 89%.

Conclusions: The proposed ADQI criteria will substantially overdiagnose HF among patients with mild to moderate CKD. We suggest defining more conservative echocardiographic criteria for HF prior to introduction of this new classification in daily clinical practice. The validity and reliability of such revised criteria should subsequently be analyzed across the whole spectrum of CKD.

TH-PO627

Prognostic Value of Pulmonary Hypertension in Combination with Heart Valvular Calcification on Cardiovascular Outcome in Maintenance Hemodialysis Patients

Zhilian Li, Zhonglin Feng, Wei Dong, Sijia Li, Wei Shi. *Nephrology, Nephrology Dept of Guangdong General Hospital, Guangdong Academy of Medical Sciences, Guangzhou, Guangdong, China.*

Background: Our previous study had revealed pulmonary hypertension (PH) as a predictor of all-cause mortality, cardiovascular mortality and new onset cardiovascular events in maintenance hemodialysis (MHD) patients. We hypothesize that patients complicated with both PH and heart valvular calcification (HVC) may take higher cardiovascular risk than those suffer from PH or HVC only.

Methods: 304 Chinese MHD patients were enrolled and followed up for 24 months. Each patient underwent Doppler echocardiographic evaluation before entry. A value of Systolic PAP (SPAP) ³35 mmHg was defined as PH. HVC was defined as the presence of bright echoes of >1mm on one or more cusps of the aortic valve, mitral valve or mitral annulus. Patients were divided into 3 groups: No risk group (with neither PH nor HVC, n=140), One Risk Factor Group (with PH or HVC, n=121) and Two Risk Factors Group (with PH and HVC, n=43). The endpoints were all-cause mortality, CV mortality and CV events.

Results: A total of 63 (20.7%) patients died during follow-up from all causes; 18 (12.9%) in Group 1, 29 (24.0%) in Group 2, and 16(37.2) in Group 3. 36 died of CV events (57.1% of the causes of death); 7(5.0%) in Group 1, 16(13.2) in Group 2, and 13 (30.2%) in Group 3. All-cause and CV mortality increased significantly in both Group 2 and 3. 101(33.2%) had new-onset CV during the follow-up period; 29(20.7%) in Group 1, 43(35.5%) in Group 2, and 29 (67.4%) in the non-PH group, which was a significant difference ($p<0.05$).PH in combination with HVC increased risk for all-cause, CV mortality and new onset CV even[HR:4.32(2.01-8.90) versus 1.93(1.03-3.63) for all-mortality, 6.49(2.57-16.39) versus 2.60(1.05-6.44) for CV mortality and 3.51(2.03-6.07) versus 1.40(0.86-2.30) for new onset CV event].

Conclusions: PH in combination with HVC predicts worse outcome than those with either PH or HVC in MHD patients. Echocardiography can easily identify both PH and HVC, and is helpful to stratify risk in this population.

Funding: Government Support - Non-U.S.

TH-PO628

Survival of ESRD Patients Diagnosed with Idiopathic Heart Failure prior to Dialysis

Frances M. Yang,[1] Chen chun Chen,[1] Shuang Li,[4] Adam E. Berman,[2] Lu Y. Huber,[2,3] Matthew J. Diamond,[2,3] Mufaddal F. Kheda,[2] Jusmin Patel,[2] N. Stanley Nahman.[2,3] *[1]Biostatistics, Georgia Regents Univ, Augusta, GA; [2]Medicine, Georgia Regents Univ; [3]Medicine, Norwood VAMC, Augusta, GA; [4]Statistics, UTMB, Galavaston, TX.*

Background: Cardio-renal syndrome type 2 (CRS-2) is defined as chronic abnormalities in heart function leading to kidney injury or dysfunction, and may occur in over 60% of patients admitted for heart failure (HF) (Ronco, Eur Hrt J 31:703, 2010). Idiopathic HF (IHF) may clinically manifest as CRS-2 and progress to ESRD. The prognosis

of patients with pre-dialysis IHF after the institution of dialysis is unknown. We used the USRDS to compare survival between IHF patients diagnosed prior to ESRD (PRE) with patients developing IHF after the institution of dialysis (POST).

Methods: All incident adult ESRD cases from the USRDS from 1967-2012 were queried for a diagnosis of IHF before or after the incident date of dialysis. IHF was defined by the presence of any ICD-9 HF code (428.0 - 428.9), and the absence of other cardiovascular diagnoses. Descriptive statistics and co-morbidities by group were calculated, and survival analysis performed using Cox regression.

Results: 50,052 patients were identified with IHF. 46% and 54% were diagnosed with IHF PRE or POST the incident date of dialysis, respectively. When compared to POST, PRE were older (73% > age 65 vs. 33%), White (61% vs. 59%), diabetic (45% vs. 6%), and female (52% vs. 47%, all $p < 0.001$), and with a hazard ratio (HR) for death of 1.82 (95% CL 1.773-1.861, $p < 0.001$). Diabetes prior to dialysis and age > 44 years also exhibited increased HR for death (1.11 and 1.62, respectively). Non-white race was protective for death in all patients with IHF.

Conclusions: In ESRD, a diagnosis of IHF is common either before or after the incident date of dialysis. PRE is associated with decreased survival, perhaps due to pre-existing heart disease in an older, diabetic population. IHF in POST included younger patients likely with volume overload and an intact ejection fraction; thus with more readily reversible conditions. IHF before and after the incident date of dialysis may be two distinct entities, and suggests unique management strategies for each syndrome may be indicated.

TH-PO629

Association of Sleep Apnea with Mortality in Chronic and End Stage Kidney Disease Patients Manisha Jhamb,[1] Herbert T. Davis,[2] Mark L. Unruh.[2] *[1]Univ of Pittsburgh; [2]Univ of New Mexico.*

Background: Presence of sleep apnea and its severity has been associated with increased mortality in the general population. In the dialysis population, limited evidence suggests an association of nocturnal hypoxemia with mortality. We sought to determine the association of sleep apnea and mortality in patients with advanced chronic kidney disease (CKD) and end-stage kidney disease (ESKD).

Methods: 180 patients (87 CKD stage 4-5, 93 ESKD), underwent 1 night home polysomnography. Sleep apnea severity was measured as number of apneas and hypopneas per hour (apnea-hypopnea index, AHI). Information on patients' demographics, comorbidities and laboratory values was obtained from patient interviews and chart review. Mortality data was obtained from National Death Index. Chi-square and ANOVA were used to test between group differences and Cox proportional hazard model was employed to test association with mortality.

Results: 71% of the patients had sleep apnea (AHI≥5) and 23% had severe sleep apnea (AHI>30). There was no difference in age, race, hypertension, body mass index, smoking status, renal function status (CKD vs ESRD), depression, hemoglobin or albumin levels among patients with no or varying severity of sleep apnea. Males were more likely to have more severe sleep apnea. In both males and females, sleep apnea severity increased with age. Over a mean (SD) follow-up period of 9.0 (3.7) years, there were a total of 31 deaths and 57 patients received kidney transplant. We found no association between sleep apnea severity and all-cause mortality.However, in unadjusted analysis, more percentage of time with SpO2 < 90% was associated with higher mortality [HR 1.03 (1.01-1.06), p <0.001].

	AHI<5	AHI≥ 5 < 15	AHI 15-30	AHI >30	P - value
AHI (events/hour)	2.4 (1.5)	8.7 (2.8)	21.6 (4.2)	57.7 (28.0)	<0.001
Age	47.7 (15.3)	54.4 (15.2)	58.5 (12.5)	56.4 (11.7)	0.09
Sex (male)	26 (50.0%)	21 (46.7%)	34 (81.0%)	32 (78.0%)	<0.001
Race (Black)	14 (26.9%) (	14 (31.1%)	14 (33.3%)	14 (34.1%)	0.97
Diabetes	10 (19.2%)	16 (35.6%)	21 (50.0%)	17 (14.5%)	0.03
Death Rate per 100 person-years (95% CI)	2.15 (0.97-4.78)	4.68 (2.59-8.45)	4.45 (2.31-8.55)	2.24 (0.93-5.38)	-
All-cause mortality, unadjusted HR (95% CI)	1.0	2.48 (0.84-7.37)	2.09 (0.68-6.44)	1.07 (0.30-3.77)	-
All-cause mortality, adjusted HR (95% CI)*	1.0	3.7 (0.9-15.5)	1.7 (0.4 – 7.9)	1.2 (0.3-6.1)	-

*Adjusted for age, sex, diabetes and grp (CKD vs ESRD)

Conclusions: In patients with advanced CKD and ESRD, sleep apnea is common and increases in severity with age. Sleep apnea, as measured by AHI was not associated with all-cause mortality.

TH-PO630

CKD Measures and Segment-Specific Arterial Stiffness: The Atherosclerosis Risk in Communities (ARIC) Study Kunihiro Matsushita,[1] Yuanjie Pang,[1] Yingying Sang,[1] Shoshana Ballew,[1] Hirofumi Tanaka,[2] Gerardo Nmn Heiss,[3] Josef Coresh.[1] *[1]Johns Hopkins Univ; [2]Univ of Texas; [3]Univ of North Carolina.*

Background: Several studies have reported an association of CKD with arterial stiffness but generally focus on either, but not both, of eGFR or albuminuria, assess pulse wave velocity (PWV) at limited segments, or investigate clinical populations.

Methods: We studied 3,687 ARIC participants aged 66-90 (mean 75) years during 2011-13 after excluding those with missing variables and clinical conditions potentially biasing PWVs (e.g., morbid obesity). Four PWV parameters were assessed: carotid-femoral (cf, the indicator of central arterial stiffness), heart- and brachial-ankle (ha and ba, respectively, reflecting both central and peripheral stiffness), and femoral-ankle (fa, the indicator of peripheral stiffness). Multiple logistic regression was used to quantify the associations of eGFR and albuminuria with elevated PWV (highest 25% value) at each segment.

Results: There were 57.9% of women and 23.2% of blacks. After accounting for potential confounders, cfPWV was the only PWV parameter consistently and monotonically associated with both low eGFR and high ACR (Table). haPWV also demonstrated positive association with all high ACR categories. baPWV and faPWV were only significantly associated with high normal ACR (10-29 mg/g). None of haPWV, baPWV, and faPWV was significantly associated with low eGFR.

Conclusions: Both low eGFR and high ACR were independently associated with central arterial stiffness, with more robust results for ACR than for eGFR. In contrast, peripheral arterial stiffness tended to relate to high normal ACR but not necessarily to clinical ACR categories or low eGFR. These results suggest central artery stiffness as a pathophysiologic link in the cardiorenal interaction and potentially unique pathophysiology of elevated ACR within normal range.

Table. Adjusted* odds ratios (95% CIs) for high PWV according to CKD measures.

Impact of Kidney Failure on Management and Outcome of Patients Admitted with Heart Failure Debasish Banerjee, Juan Carlos Kaski, Lisa J. Anderson. *Renal and Transplantation Unit, St. Georges Hospital, United Kingdom.*

Background: Data from epidemiological studies and intervention trials suggest poor prognosis in heart failure patients with kidney disease. However no study has investigated the impact of severe kidney failure on management and outcome of in-hospital heart failure patients.

Methods: We analysed data on clinical, laboratory, management and in-hospital mortality on 990 patients admitted between 01/03/2013 and 17/03/2013.

Results: Severe kidney failure (eGFR<30 ml/min/1.73m²) was present in 19% of patients and moderate kidney failure (eGFR 30-60 ml/min/1.73m²) was present in 43%. Patients with severe kidney failure, compared to the rest were older (79±11vs.75±13 years; $p<0.001$), with lower haemoglobin (10.5±1.9 vs. 12±1.8 g/dL; $p<0.001$), higher potassium (4.8±0.8 vs. 4.2±0.6 mmol/L; $P<0.05$) and higher NT-pro BNP (17915±12911 vs.9240±9577; $p<0.001$). Diuretics use in severe kidney failure patients was less (85% vs. 90%, $p<0.005$); however β blocker use was similar (74% vs. 75%). Furosemide dose was high in severe kidney failure (101±62 vs. 79±43 mg; $p<0.001$) but dose of bumetanide was similar (3.9±2.3 vs. 4.1±1.9 mg, $p=0.5$). In the presence of echocardiographic LV dysfunction severe kidney failure patients were less likely to be on ACEi or ARB (24% vs. 74%; $p<0.001$). 98 patients who died during admission were older (78±10 vs. 76±13 years; $p<0.05$), with lower haemoglobin (11.1±2.2 vs. 11.8±1.9 g/dL, $p<0.01$), higher creatinine (191±123 vs. 135±93 µmol/L; $p<0.001$), higher NT-pro BNP (16536±12727 vs. 10174±10346, $p<0.001$) and higher potassium (4.7±0.9 vs. 4.2±0.6 mmol/L, $p<0.001$). In-hospital mortality was 6% in patients with eGFR>60, 8% with moderate kidney failure and 22% with severe kidney failure. Adjusted for age, haemoglobin, potassium and NT-pro BNP, presence of severe kidney failure was an independent predictor of mortality ($p<0.01$).

Conclusions: Among hospital admissions for heart failure, patients with severe kidney failure had low haemoglobin, high potassium, high BNP; were less often on ACEi/ARB and diuretics; suffered higher in-hospital mortality. Severe kidney failure is common, adversely affects management and outcomes in admitted heart failure patients.

TH-PO632

Pulse Wave Velocity in Children with Chronic Kidney Disease Jonathan D. Savant,[1] Aisha Betoko,[2] Kevin E.C. Meyers,[1,3] Mark Mitsnefes,[2] Joseph T. Flynn,[2] Raymond R. Townsend,[2] Larry A. Greenbaum,[2] Allison Dart,[2] Bradley Warady,[2] Susan L. Furth.[1,2,3] *[1]Dept of Pediatrics, The Children's Hospital of Philadelphia, Philadelphia, PA; [2]Chronic Kidney Disease in Children (CKiD) Study Investigators; [3]Perelman School of Medicine at the Univ of Pennsylvania, Philadelphia, PA.*

Background: Pulse wave velocity (PWV) is a measure of arterial stiffness associated with CV events in the general population and adults with CKD. However, few data exist regarding PWV in children with CKD. We compared observed PWV to normative data in healthy children and examined risk factors associated with elevated PWV in children enrolled in the CKiD cohort study.

Methods: PWV was assessed via carotid/femoral tonometry using the SphygmoCor device (AtCor, Australia). PWV Z-score for height/gender was calculated from and compared to published pediatric norms (Reusz et al., 2010). Multivariate linear regression was used to assess the relationship between PWV and level of proteinuria (UP/C) adjusted for age, gender, race, height, waist circumference, mean arterial pressure (MAP), and GFR.

Results: 249 PWV studies were performed on 90 participants. 63% were male, 20% African American, 49% had glomerular CKD, 9% UP/C >2mg/mg; median age was 16 years, median MAP was 82mmHg, and median GFR was 67 ml/min. Average PWV was 5.1±0.9 m/s, Z-score= -0.01(1.2). As expected, PWV was significantly associated with age and MAP in multivariate analysis (Table 1). Additionally, the point estimate for UP/C was large but non-significant.

Conclusions: In this pediatric cohort with mild kidney dysfunction, arterial stiffness was comparable to that of normal children. Data collection is ongoing to further assess the effects of BP and proteinuria on arterial stiffness in children with CKD.

Table 1. PWV multivariate analysis.

Variable	Estimate ± SE	P-value

The Cardiovascular Comorbidity in Children with Chronic Kidney Disease (4C) Study: Baseline Data of a Multicentre Prospective Observational Study Uwe Querfeld,[1] Anke Doyon,[2] Elke Wuehl,[2] Daniela Thurn-Valsassina,[3] Mieczys?aw P. Litwin,[4] Aysun Bayazit,[5] Ali Duzova,[6] Mahmut Civilibal,[7] Betul Bs Sozeri,[8] Franz S. Schaefer.[2] *[1]Pediatric Nephrology, Charité, Berlin, Germany; [2]Pediatric Nephrology, Univ of Heidelberg, Heidelberg, Germany; [3]Pediatric Nephrology, MHH Hannover, Hannover, Germany; [4]Pediatric Nephrology, Children's Memorial Health Inst, Warsaw, Poland; [5]Pediatric Nephrology, Cukurova Univ, Adana, Turkey; [6]Pediatric Nephrology, Hacettepe Univ, Ankara, Turkey; [7]Pediatric Nephrology, Haseki Hospital, Istanbul, Turkey; [8]Pediatric Nephrology, Ege Univ, Izmir, Turkey; [9]Pediatric Nephrology, Univ Hospital Essen, Essen, Germany.*

Background: The role of CKD-specific factors in the initiation and progression of cardiovascular disease (CVD) are likely to be characterized with increased sensitivity in the pediatric age group. The Cardiovascular Comorbidity in Children with CKD (4C) Study is a multicentre, prospective, observational study in children with CKD aged 6 to 17 years, initial glomerular filtration rate 10-60 ml/min/1.73m² . The prevalence, degree and progression of cardiovascular comorbidity and its association with CKD progression is explored through longitudinal follow-up.

Methods: The morphology and function of the heart and large arteries is monitored by non-invasive methods and compared with aged-matched healthy controls.

Results: A total of 705 patients were enrolled in 55 participating centers from 12 European countries. At baseline examination, 30% of children were hypertensive (ambulatory blood pressure monitoring), 40% had left ventricular hypertrophy (echocardiography), 40% showed an increased initima-media thickness of the carotid artery (cIMT; ultrasound), and 23% an increase in aortic pulse-wave velocity (PWV; oscillometry). By multivariate analysis, systolic blood pressure and serum levels of 25-hydroxyvitamin D, parathyroid hormone, and serum calcium- and phosphorus levels showed significant associations with age-corrected IMT and PWV, respectively.

Conclusions: Children aged 6-17 years with CKD stage 3-5 have significant sublinical CVD. At initial examination, surrogate endpoints of CVD were associated with systolic blood pressure and disturbances of mineral metabolism.

TH-PO634

Impaired Systolic and Diastolic Left Ventricular Function in Children with Chronic Didney Disease: Results from the Cardiovascular Comorbidity in Children with Chronic Kidney Disease (4C) Study Anke Doyon,[1] Pascal Haas,[1] Maria chiara Matteucci,[2] Francesca Mencarelli,[3] Uwe Querfeld,[4] Franz S. Schaefer.[1] *[1]Univ Children's Hospital, Heidelberg, Germany; [2]Ospedale Bambino Gesu, Rome, Italy; [3]Univ Children's Hospital, Bologna, Italy; [4]Charité Children's Hospital, Berlin, Germany.*

Background: Tissue doppler (TD) velocities are sensitive markers of left ventricular function. The aim of this work was to describe TD velocities in a large cohort of children with chronic kidney disease and to assess risk factors for ventricular dysfunction.

Methods: A standardized echocardiographic exam was performed in 128 patients of the 4C Study aged 6 -18 years with eGFR 10-60 ml/min/1.73 m². TD measurements of the left ventricle included early (E') and late (A') diastolic and systolic (S') velocity. Diastolic function was described by E'/A' ratio and left ventricular compliance by early diastolic conventional to tissue doppler (E/E') ratio. Measured values were normalized to z scores using reference data from 325 healthy children.

Results: TD diastolic E' velocity was reduced and A' increased at the mitral and septal anulus, resulting in a reduced E' to A' ratio (z-score -0.14, p<.0001) indicating diastolic dysfunction. Diastolic function (E'/A') was positively correlated with midwall fractional shortening (r=0.23, p<0.01). Reduced diastolic function was independently associated with declining renal function (β=0.006, p=0.005), increased systolic blood pressure (β=-0.04, p=0.045) and pulse wave velocity (β=-0.03, p=0.07). Left ventricular compliance was increased (z-score 0.65, p<.0001), possibly as a result of increased preload. Systolic TD velocities were significantly decreased (z-score -0.24, p=0.001). Reduced systolic velocities in TD imaging were inversely correlated to left ventricular compliance (r=-0.4, p<.0001). The LVMI was not associated to systolic or diastolic TD velocities.

Conclusions: TD evaluation showed alterations of both systolic and diastolic function in children with chronic kidney disease. Renal function and systolic blood pressure are significant predictors for diastolic function. TD velocities are independent of LV mass and provide early information about ventricular dysfunction.

Rapid Early Postnatal Growth Increases Blood Pressure Level in 5-Year-Old Children Born with Low Birthweight Benedicte Stengel,[1] Marion Taine,[2] Marie-Aline Charles,[2] Barbara Heude.[2] *[1]Epidemiology of Renal and Cardiovascular Disease Team, Inserm UMR1018, Villejuif, France; [2]ORCHAD Team, Inserm UMR1153, Villejuif, France.*

Background: Low birth weight (BW) is associated with hypertension and excess ESRD risk in adults, but whether postnatal growth may modify its impact on blood pressure (BP) and albuminuria in children is unknown. We studied the relationship of BW, gestational age (GA), and postnatal growth with BP and albuminuria in 5-year-old children.

Methods: We used data from the EDEN mother-child cohort of 1,119 children followed from birth to age 5. A mean of 17 weights were collected over this period which enabled to predict weights and weight growth velocities at any age. Three standard BP and albumin-to-creatinin ratio were measured at age 5. In order to avoid the reverse paradox phenomenon due to confounding by 5-year corpulence in the analysis of the relationship with BW, we studied BP SD-score preadjusted for age, gender, 5-year BMI and height. BW was also analyzed using age- and gender- specific z-score. We systematically tested interactions between BW categories and weight growth velocities in the relation with BP SD-score at different ages.

Results: Mean BW was 3,285±10 g. At 5 years of age, mean systolic BP was 101.5±0.3 mmHg in boys, and 102.7±0.3 in girls. After adjusting for mothers' pre-pregnancy BMI and hypertension status during pregnancy, the lower the BW z-score the higher the systolic BP SD score (beta=-0.06 ± 0.03, p=0.03), without gender interaction. In children born small for GA, faster weight growth in the first 4 months of life was associated with higher SBP SD-score at 5 years (p for interactions : 0.002 to 0.08 from 1 to 4 months), but not at older ages (p>0.20). Only boys born prematurely had elevated albuminuria level (>1mg/mmol) at age 5 : OR = 2.5[1.2-5.5].

Conclusions: Rapid early postnatal growth associates with higher blood pressure level in 5-year-old children born with low birthweight.They may deserve early monitoring for cardiovascular risk.

Kidney Function and Risk of Subclinical and Clinical Heart Failure in African Americans: The Jackson Heart Study Ronit Katz, Nisha Bansal, Ian H. De Boer, Jonathan Himmelfarb, Maryam Afkarian, Bryan R. Kestenbaum, Bessie A. Young. *Kidney Research Inst, Univ of Washington, Seattle, WA.*

Background: African-Americans (AA) and those with chronic kidney disease (CKD) have high risk for heart failure (HF). We determined in an AA cohort the association of kidney function with left ventricular disease (LVD) and risk of incident HF accounting for baseline LVD.

Methods: We studied Jackson Heart Study participants and calculated eGFR from baseline serum creatinine (CKD-EPI equation) and urine albumin-to-creatinine ratio (ACR) from urine samples. We tested association of eGFR and urine ACR with left ventricular mass (LVM), left ventricular ejection fraction (LVEF) and incident HF.

Results: In 3332 participants, 5% had eGFR<60ml/min/1.73m^2 and 12% had urine ACR>30mg/g. Mean LVM was higher in those with eGFR<60 (175g vs 147g) and urine ACR³30 (169g vs 143g). Mean LVEF was similar across eGFR and ACR levels. The association of eGFR with LVM was significant adjusting for age, sex, education, blood pressure, BMI, smoking, hypertension, statins, diabetes and cardiovascular disease (β-coefficient 13g[95% CI:7,19]), while association with LVEF was not (β-coefficient -0.9%[95% CI:-1.9,0.1]). Urine ACR³30mg/g was associated with higher LVM in adjusted models (β-coefficient 6g[0.7,11]); however, was not associated with LVEF (adjusted β-coefficient -0.4[95%CI:-1.2,0.4]). Rate of HF events was greater in those with CKD (**Table**). Higher urine ACR was strongly linked with incident HF after adjusting for LVM and LVEF (**Table**).

Association of kidney function with risk of incident heart failure among participants in the Jackson Heart Study

	N	#with HF	Rate/year	Model 1* HR (95% CI)	M1* + LVM HR (95% CI)	M1* + LVEF HR (95% CI)
eGFR (per 10 decrease)	3073	84	0.75	1.03 (0.92, 1.14)	0.99 (0.89, 1.10)	1.03 (0.92, 1.15)
eGFR						
≥ 60	2939	71	0.66	1.00 (ref)	1.00 (ref)	1.00 (ref)
<60	134	13	2.51	1.20 (0.61, 2.36)	0.92 (0.45, 1.86)	1.20 (0.61, 2.36)
ACR (per doubling)	3073	84	0.75	1.14 (1.02, 1.28)	1.11 (0.99, 1.24)	1.14 (1.02, 1.27)
ACR						
<30	2745	61	0.60	1.00 (ref)	1.00 (ref)	1.00 (ref)
≥ 30	328	23	2.01	2.09 (1.14, 3.81)	1.93 (1.03, 3.63)	2.09 (1.10, 3.98)

*adjusted for age, sex, systolic blood pressure, diastolic blood pressure, BMI, tobacco use, hypertension medications, lipid lowering medications, history of CHD, history of stroke, history of diabetes, ACR (for eGFR) or eGFR (for ACR)

Conclusions: LVM was higher in AA with lower eGFR and higher ACR. Higher urine ACR was linked with incident HF and not entirely explained by LVD. We show the importance of mild/early kidney dysfunction with risk of HF among AA. More study is needed to characterize the mechanisms by which kidney disease contributes to worse outcomes in HF in this group.

TH-PO637

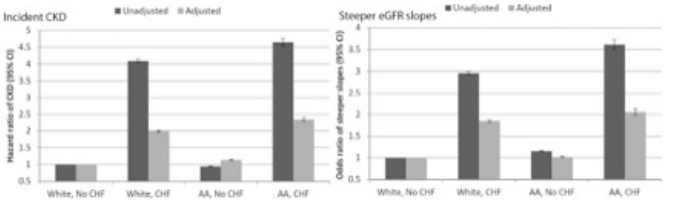
Racial Differences in Risk of Chronic Kidney Disease in Patients with Congestive Heart Failure

Lekha K. George,[1] Santhosh K. Koshy,[1] Miklos Zsolt Molnar,[1] Jun Ling Lu,[1] L. Ebony Boulware,[2] Keith C. Norris,[3] Kamyar Kalantar-Zadeh,[4] Csaba P. Kovesdy.[1,5] *[1]Univ of Tennessee Health Science Center, Memphis, TN; [2]Duke Univ School of Medicine, Durham, NC; [3]UCLA, CA; [4]Univ of California, Irvine, CA; [5]VA Medical Center, Memphis, TN.*

Background: While CKD is more common in African Americans (AA), the prevalence of CV disease is lower in AA patients with CKD. It is unclear if the higher risk of incident CKD associated with AA race is modified by the presence of CHF.

Methods: Among 3,065,749 AA or white US veterans with eGFR>60ml/min/1.73m^2, we identified 143,229 with a diagnosis of CHF (17% AA), and 2,922,520 with no CHF (18% AA). We examined the interaction of race with CHF for the risk of incident CKD and rapid rate of decline in eGFR (slopes <-5 ml/min/1.73m^2/yr) during a median follow up of 7.8 yrs. We examined outcomes in Cox models (for CKD) and logistic regression (for slopes), including interaction terms for race-CHF, and adjusting for baseline age, gender, race, comorbidities, BMI, BP, eGFR and medication use.

Results: Mean±SD baseline age and eGFR were 68±11 yrs and 79±14 ml/min/1.73m^2 for patients with CHF, vs. 59±14 yrs and 84±16 ml/min/1.73m^2 for those without CHF. 327,548 (11%) patients developed incident CKD and 253,081 (9%) experienced rapid eGFR decline. AA race showed a significant interaction with HF for both CKD incidence (p=0.009) and loss of kidney function (p<0.001). Compared to white patients with no CHF, AA patients with CHF experienced a >2-fold higher risk of incident CKD and more rapid eGFR loss after multivariable adjustments (Figure).



Conclusions: The increased risk of renal complications associated with AA vs. white race is higher in patients with CHF compared to those with no CHF. Interventions aimed at improving renal outcomes in AA patients with CHF should be further examined.

TH-PO638

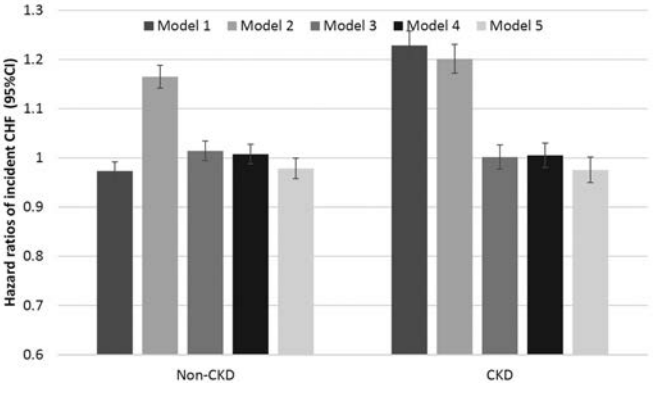
Incidence of Congestive Heart Failure in African-American versus White Patients with and without Chronic Kidney Disease

Csaba P. Kovesdy,[1,2] Miklos Zsolt Molnar,[2] Praveen Kumar Potukuchi,[2] Jun Ling Lu,[2] Kamyar Kalantar-Zadeh.[3] *[1]Memphis VA Medical Center; [2]Univ of Tennessee Health Science Center; [3]Univ of California Irvine.*

Background: African Americans (AA) are at higher risk of cardiovascular disease and its complications, such as congestive heart failure (CHF). CKD is also more common in AA, yet the prevalence of coronary artery disease is lower in AA patients with CKD. It is unclear if the risk of CHF is also lower in AA with CKD, given its more complex pathophysiology in patients with kidney disease.

Methods: Among 2,929,736 AA (N=523,181) or white (N=2,406,555) US veterans with eGFR≥60 ml/min/1.73m^2 and no CHF at baseline, we examined the association of AA race with incident CHF (hospitalization-based ICD9 codes) during a median follow up of 6.7 yrs. We examined outcomes separately in patients who maintained an eGFR≥60 ml/min/1.73m^2 (non-CKD group; N=2,632,034), and those who developed 2 eGFR values <60 with >90 days in-between (CKD group; N=286,597). We used Cox proportional hazards models, without adjustments (Model 1) and with sequential adjustments for baseline demographics and eGFR (Model 2), comorbidities (Model 3), BMI and BP (Model 4), and medications and socioeconomic indicators (Model 5).

Results: 71,137 (event rate: 4.8/1000 patient-years, 95%CI: 4.8-4.9) and 42,067 (26.4/1000PY, 26.2-26.7) patients developed CHF in the non-CKD and CKD groups, respectively. Compared to whites, AA race was associated with similar unadjusted risk of CHF in non-CKD (hazard ratio, 95%CI: 0.97, 0.95-0.99), but with higher unadjusted risk among CKD (1.23, 1.20-1.26). After adjustments, the risk of CHF in AA was minimally lower in both non-CKD and CKD patients (Figure1).



Conclusions: The risk of incident CHF is slightly lower in AA US veterans with and without CKD. These qualitatively different associations compared to the non-veteran population warrant additional studies.

TH-PO639

Continued Underrepresentation of Patients with Kidney Disease in Cardiovascular Trials: An Updated Systematic Review After a Decade

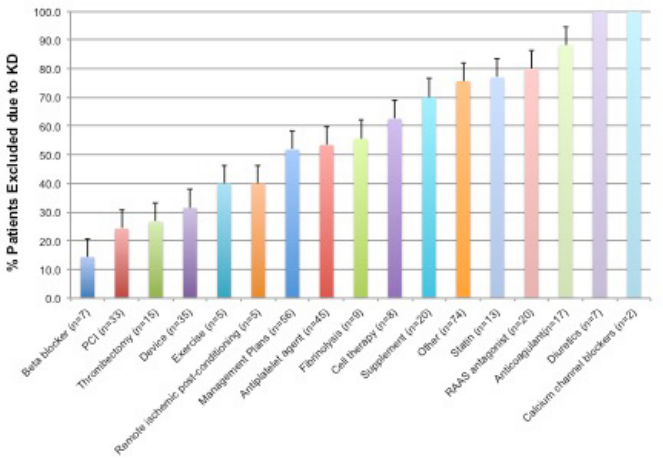
Ioannis Konstantinidis,[1] Aparna Saha,[1] Priti R. Poojary,[1] Priya Simoes,[1] Rabi Yacoub,[1] Chirag R. Parikh,[2] Girish N. Nadkarni,[1] Steven G. Coca.[1] *[1]Mount Sinai Medicine; [2]Yale Univ.*

Background: Cardiovascular disease (CVD) is a major cause of morbidity/mortality in kidney disease (KD). Two systematic reviews showed that KD patients are underrepresented in CVD randomized controlled trials (RCTs) using data from 1985-2005 and 1998-2005. We aimed to update estimates of KD patient representation in major CVD RCTs over the past decade.

Methods: We searched MEDLINE for congestive heart failure/acute coronary syndrome RCTs in major journals between 2006-2014. We excluded RCTs not reporting mortality outcomes, with <100 participants, or were subgroup, follow-up, or post-hoc analyses.

Results: We included 371 trials randomizing 590,040 participants. KD patients were excluded in 212 (57.1%) RCTs and were more likely to be excluded from North American (p=0.02) or industry-funded (p=0.01) trials. They were more likely to be excluded in RCTs of anticoagulants, antiplatelet agents, statins or RAAS antagonists compared to trials of PCI (p£0.01).

Figure 1: Proportion of Trials Excluding Patients with Kidney Disease Based on Intervention Type



Of 212 RCTs excluding KD patients, 111 (52.4%) used serum creatinine, 25 (11.8%) used eGFR cut-offs, 23 (10.8%) used creatinine clearance, 60 (28.3%) excluded if on renal replacement and 36 (17.0%) had non-specific kidney-related exclusions. Only 156 (42.0%) trials reported baseline kidney function and only 84 (22.6%) trials reported the proportion of KD patients in each randomization arm. While 197 (53.1%) reported subgroup analyses of >1 non-renal baseline characteristics, only 60 (16.2%) reported subgroup analyses by renal parameters.

Conclusions: Most CVD RCTs continue to exclude KD patients. They neither adequately report nor analyze outcomes by participants' baseline kidney function.

Funding: NIDDK Support

TH-PO640

Effect of Niacin on Markers of Mineral Metabolism in CKD: The AIM-HIGH Trial

Joachim H. Ix,[1] Ronit Katz,[2] Andrew N. Hoofnagle,[2] Dena E. Rifkin,[1] Andrew Bostom,[3] Jeffrey L. Probstfield,[2] Geoffrey A. Block.[4] *[1]UCSD; [2]U Washington; [3]Brown Univ; [4]Denver Nephrology.*

Background: Niacin blocks intestinal phosphate (P) transport in vitro. Short-term human studies suggest niacin lowers P in CKD patients. Longer-term effects on P, and on other mineral markers are uncertain. Fibroblast growth factor (FGF) 23 is a phosphaturic hormone that induces left ventricular hypertrophy in vitro and higher levels are associated with heart failure and death in CKD patients. Higher serum P may stimulate higher FGF23. We hypothesized that 3-year treatment with niacin would induce lower plasma P (1° aim) and FGF23 (2° aim) in CKD patients.

Methods: AIM-HIGH randomized 3,414 patients with cardiovascular disease (CVD) and dyslipidemia to sustained-release niacin 1500-2000mg vs. placebo (pbo) for prevention of recurrent CVD events (1° endpoint). Both groups were on a background of statin therapy. Exclusions included serum Cr ≥ 2.7mg/dL. The trial was stopped after 3 yrs mean follow-up due to futility. In 352 patients with eGFR<60 ml/min/1.73 m^2, we measured plasma P, calcium (Ca), intact (i) FGF23 (Kainos), intact parathyroid hormone (iPTH), and calcitriol (LC/MS) at baseline, yr 1, and yr 3. Mean levels were compared between arms, and linear mixed models provided summary estimates of the effect of niacin on each.

Results: Demographics, CVD history, and CVD risk factors were well balanced in the pbo (n=174) and niacin (n=178) arms at baseline. Mean eGFR was 47±8 and 45±9 ml/min/1.73 m^2, respectively. At 3 yrs, P was 0.25mg/dL lower in the niacin vs. pbo arm. No significant differences were noted in iFGF23, Ca, iPTH, or calcitriol between arms at 3 yrs.

Baseline (n=339)	31.7±11.2	30.5±11.1	0.315
Year 1 (n=280)	31.0±11.1	30.6±10.2	0.797
Year 3 (n=135)	33.3±12.2	32.1±13.1	0.590
Difference in Slopes (95% CI)	-0.17 (01.33, 0.98)		0.769

Conclusions: Niacin lowers serum P in CKD patients, an effect that extends for 3 yrs. We observed no significant effect of niacin on other mineral measures. Regulation of FGF23 may be more complex than simply reflecting changes in serum P.

TH-PO641

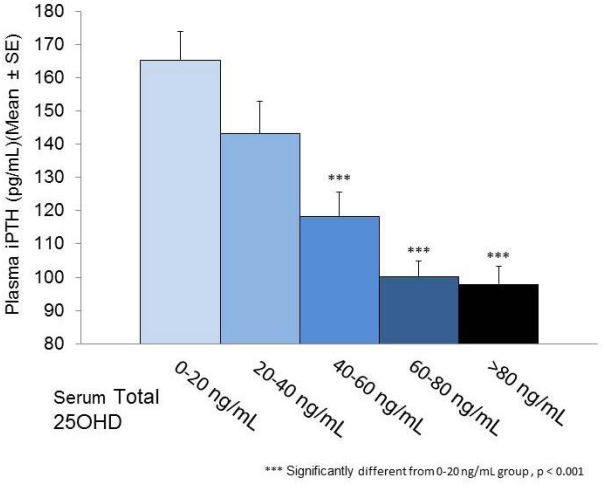
Efficacy and Safety of Modified-Release Calcifediol in Stage 3-4 CKD Patients with Secondary Hyperparathyroidism and Vitamin D Insufficiency

Stuart M. Sprague,[1] Stephen A. Strugnell,[2] Joel Z. Melnick,[2] Jay A. White,[2] Martin P. Petkovich,[3] Charles W. Bishop.[2] *[1]Medicine, NorthShore Univ HealthSystem-Univ of Chicago, Evanston, IL; [2]OPKO Health, Miami, FL; [3]Queens Univ, Kingston, ON, Canada.*

Background: Current approaches to correct vitamin D insufficiency (VDI) in stage 3 or 4 CKD are poorly defined and generally ineffective in controlling secondary hyperparathyroidism (SHPT). The effectiveness of modified-release calcifediol (MRC) at correcting VDI and controlling SHPT was evaluated.

Methods: Two identical, randomized, double-blind, placebo-controlled trials were conducted in patients with SHPT (>85 pg/mL), stage 3 or 4 CKD and VDI (serum 25OHD of 10-29 ng/mL). The trials enrolled a total of 429 subjects from 77 US sites, randomized 2:1 to receive MRC or placebo for 26 weeks. MRC dosing started at 30 mg/d and increased, as needed to lower iPTH, to 60 mg/d after 12 weeks. Subjects were stratified based upon their 25OHD levels (0-20, 20-40, 40-60, 60-80 or > 80 ng/mL) at the end of treatment (EOT). The mean EOT plasma iPTH, serum total 1,25-dihydroxyvitamin D (1,25D), serum Ca and Phos in each group were calculated and compared.

Results: A total of 364 (85%) subjects completed the trials. Serum 1,25D levels progressively increased with increasing 25OHD concentrations, with mean levels 41% higher in the highest quintile compared to the lowest ($p < 0.001$). Conversely, plasma iPTH progressively decreased with increasing 25OHD concentrations, with mean iPTH levels 40% lower in the subjects with the highest- 25OHD concentrations compared to the lowest concentrations (Figure; $p < 0.001$). No changes were observed in serum Ca and Phos concentrations independent of 25OHD concentration.



Conclusions: MRC increased serum total 25OHD levels and total 1,25D, while reducing plasma iPTH, without significantly increasing serum Ca or Phos in CKD patients with SHPT and VDI.

CKD-MBD Indices After 52 Weeks of Sucroferric Oxyhydroxide, an Iron-Based Phosphate Binder, in African American Dialysis Patients

Stuart M. Sprague,[1] Anjay Rastogi,[2] Markus Ketteler,[3] Adrian C. Covic,[4] Jürgen Floege,[5] Viatcheslav Rakov,[6] Llera Armando Samuels.[7] *[1]NorthShore Univ Health System, Chicago; [2]Univ of California; [3]Coburg Clinic and KfH-Dialysis Center, Germany; [4]'Gr.T. Popa' Univ of Medicine and Pharmacy, Romania; [5]RWTH Univ Hospital Aachen, Germany; [6]Vifor Pharma; [7]Temple Univ, Philadelphia.*

Background: A *post hoc* analysis of data from a randomized, open-label, Phase 3 study and its extension investigated the effects of the iron-based phosphate binder sucroferric oxyhydroxide (SFOH; VELPHORO®) vs sevelamer carbonate (SEV; Renvela®) on chronic kidney disease-mineral bone disorder (CKD-MBD) indices in African American dialysis patients.

Methods: Overall, 1059 patients were randomized to SFOH (1.0–3.0 g/day; n=710) or SEV (2.4–14.4 g/day; n=349) for 12 weeks' dose titration then 12 weeks' maintenance. Eligible patients enrolled in a 28-week extension study.

Results: Of the 549 patients who completed the extension study, 100 were African American patients, (n=48, SFOH; n=52, SEV). Serum phosphorus control was maintained over 1 year; both SFOH and SEV were associated with significant decreases in serum phosphorus from baseline to Week 52 (Table), as well as significant reductions in mean

serum fibroblast growth factor-23 (FGF-23). Decreases in mean serum intact parathyroid hormone (iPTH) were seen with both treatments over 52 weeks, but were not significant with SFOH. There were small but statistically significant increases in total calcium levels in both groups over 52 weeks. No significant differences between treatment groups were observed for any of the indices reported here.

Conclusions: SFOH and SEV led to reductions in serum phosphorus, FGF-23 and iPTH over 1-year of treatment in African American dialysis patients. *Post hoc* results so far reflect those from the overall study population.

Table: Serum levels of CKD-MBD indices in African American patients (completers; N=100).

Concomitant IV Iron Use Drives Changes in Iron Indices in African American Dialysis Patients Over 52 Weeks of Sucroferric Oxyhydroxide Treatment

Stuart M. Sprague,[1] Anjay Rastogi,[2] Markus Ketteler,[3] Adrian C. Covic,[4] Jürgen Floege,[5] Viatcheslav Rakov,[6] Llera Armando Samuels.[7] *[1]NorthShore Univ Health System, Chicago; [2]Univ of California; [3]Coburg Clinic and KfH-Dialysis Center, Germany; [4]Gr.T. Popa' Univ of Medicine and Pharmacy, Romania; [5]RWTH Univ Hospital Aachen, Germany; [6]Vifor Pharma; [7]Temple Univ, Philadelphia.*

Background: A *post hoc* analysis of data from a randomized, open-label, Phase 3 study and its extension investigated iron indices after treatment with the iron-based phosphate binder sucroferric oxyhydroxide (VELPHORO®; SFOH) vs sevelamer carbonate (SEV) in African American dialysis patients who received IV iron vs those who did not.

Methods: Overall, 1059 patients were randomized to SFOH (1.0–3.0 g/day; n=710) or SEV (2.4–14.4 g/day; n=349) for 12 weeks' dose titration then 12 weeks' maintenance. Eligible patients enrolled in a 28-week extension study.

Results: Of the 549 patients who completed the extension study, 100 were African American (n=48, SFOH; n=52, SEV). A high proportion of patients in the SFOH and SEV groups received IV iron (95.8 and 92.3%) and erythropoietin-stimulating agents (95.8 and 98.1%) during the 1-year study. Baseline levels of ferritin appeared elevated in both treatment groups with higher levels in the SEV group (Table). Significant increases in ferritin were observed in SFOH 'IV iron' subgroup. Ferritin and TSAT levels increased only in patients receiving IV iron. Hemoglobin was relatively stable over 1 year.

Conclusions: Changes in iron indices in both treatment groups were mainly attributable to concomitant IV iron use. Differences between groups may be due to baseline differences and minimal iron uptake from SFOH, although no signs of iron accumulation were observed over 1 year. *Post hoc* results, in terms of changes in iron indices, reflect those from the overall study population.

Table: Serum levels and changes in iron indices in African American patients by concomitant iron use during the study (completers; N=100).

The Effectiveness and Safety of Cinacalcet: Randomized, Open Label Study in Chronic Hemodialysis Patients with Severe Secondary Hyperparathyroidism

Paweena Susantitaphong,[1] Teerada Susomboon,[2] Wanchana Singhan,[2] Somratai Vadcharavivad,[2] Kearkiat Praditpornsilpa.[1] *[1]Dept of Medicine, Chulalongkorn Univ, Bangkok, Thailand; [2]Dept of Pharmacy Practice, Chulalongkorn Univ, Bangkok, Thailand.*

Background: Secondary hyperparathyroidism (HPT) results in high incidence of cardiovascular disease, bone fracture, and mortality. This study was conducted to demonstrate the efficacy of treatment with cinacalcet compared to control group for controlling plasma parathyroid hormone (iPTH) levels among hemodialysis (HD) subjects with severe secondary HPT.

Methods: 60 adult HD patients with iPTH> 800 pg/mL and serum calcium> 9 mg/dL was randomized 1:1 for treatment (cinacalcet 25-100 mg/day) and control group for 12 weeks follow up. The patients who previously received cinacalcet and parathyroidectomy were excluded. Achievement of>30% reduction of iPTH from baseline was set up as primary end-point.

Results: The mean baseline iPTH of both groups were comparable (1,435±506 pg/mL in control group and 1,535±965 pg/mL in treatment group). Following 12-week treatment in 30 HD patients, the percentage reductions of iPTH was significantly different (-67% in treatment group and -13% in control group, P=0.02). Regarding the ethic issue, we switched the patients in control group to treatment group and follow up as prospective cohort study to further explore the optimal cinacalcet dose on baseline iPTH. The mean cinacalcet dose was 50±23 mg/day. The mean serum calcium and phosphate were significantly decreased from baseline. On contrary, the dialysate calcium was significantly increased from baseline. Subgroup analysis by baseline iPTH on efficacy of cinacalcet showed that higher iPTH level associated with less reduction of iPTH to achieve primary end-point.

Subgroup by baseline PTH level in cinacalcet group	Equal or greater 30% reduction of PTH from baseline at 12-wk follow up
PTH 801-1600 pg/mL	22/26 (85%)
PTH 1601-2400 pg/mL	8/14 (57%)
PTH 2401-3200 pg/mL	1/2 (50%)
PTH >3,200 pg/mL	1/3 (33%)
P-Value (Linear by linear association)	0.018

Conclusions: The high efficacy of cinacalcet was still demonstrated even in case of severe secondary HPT. However, higher iPTH reduced the efficacy outcome of cinacalcet.

TH-PO645

A Double-Blind, Randomized, Placebo-Controlled Trial of Ergocalciferol with/without Calcitriol in Chronic Kidney Disease with Proteinuria

Paweena Susantitaphong, Siriwan Nakwan, Khajohn Tiranathanagul, Pisut Katavetin, Kearkiat Praditpornsilpa, Somchai Eiam-ong. *Dept of Medicine, Chulalongkorn Univ, Bangkok, Thailand.*

Background: These are no available data regarding the role of natural vitamin D with/without active vitamin D on proteinuria and renal function in CKD patients with vitamin D insufficiency/deficiency.This study was conducted to explore the additional effect of both active vitamin D (calcitriol) and natural vitamin D (ergocalciferol) on proteinuria and kidney function in CKD with vitamin D insufficiency/deficiency.

Methods: The first double-blind, randomized placebo-controlled trial was performed to answer this question. Sixty eight patients with eGFR 15-60 mL/min/1.73m^2, UPCR greater than 1 g/g,and vitamin D insufficiency/deficiency were enrolled. Patients were randomly assigned to receive 12-week treatment with oral ergocalciferol plus placebo (n=36) or ergocalciferol plus oral calcitriol (n=32).

Results: The mean baselines UPCR of both groups were comparable (3.6 ± 3.8 g/g in combined group and 3.5±3.0 g/g in ergocalciferol group). Following 12 -week treatment, there were significant reductions in UPCR of both groups from baseline (2.3± 2.1 g/g in combined group and 2.4± 2.0 g/g in ergocalciferol group). The percentage reductions in UPCR of both groups were not significantly different (-25.5% in combined group and -23.7% in ergocalciferol group). These effects were demonstrated in all range of proteinuria, diabetic nephropathy, non-diabetic nephropathy, receiving RAAS blockade and non-receiving RAAS blockade. The mean eGFR and blood pressure did not differ between baseline and 12-week follow up and between both groups. No severe hypercalcemia or serious side effects were noted in both groups.

Conclusions: This is the first RCT which illustrates the lowering proteinuria effect of ergocalciferol in CKD patients with vitamin D deficiency. However, additional calcitriol did not have more effects on proteinuria. Therefore, ergocalciferol should be added for more decreasing proteinuria in CKD patients with proteinuria that cannot tolerate or increase the dosage of RAS blockage due to any side effects.A longer study is required to examine the renal function retardation effects.

TH-PO646

Anemia Correction with Roxadustat Lowers Hepcidin in Chronic Kidney Disease (CKD) Patients Lynda Szczech, Anatole Besarab, Khalil Georges Saikali, Stefan Hemmerich, Lona Poole, Gopal Saha, Kin-Hung Peony Yu, Frank H. Valone, Thomas B. Neff. *FibroGen, San Francisco, CA.*

Background: The hypoxia-inducible factor prolyl hydroxylase inhibitor roxadustat (FG-4592) is being developed for treatment of CKD anemia. Hepcidin regulates iron metabolism and higher levels are associated with greater mortality. This analysis of phase 2 studies was undertaken to explore the consistency of the suppressive effect of roxadustat on hepcidin.

Methods: Among CKD-NDD (017 and 041) & CKD-DD (040 and 053) studies, roxadustat doses, study duration, and comparator (placebo or epoetin) varied. Studies restricted IV iron in general but allowed oral iron. Baseline (BL) hepcidin and change from BL (CFB) are summarized (mean±SD) overall and by BL tertile. Significant differences ($p<0.05$ vs BL) based on within-group comparisons (^).

Results: Mean BL hepcidin in CKD-NDD roxadustat subjects was 292.8±179.8 and 120.3±107.0 ng/mL (studies 017 & 041). Hepcidin fell with roxadustat treatment by 158.4±179.2 & 45.6±87.7. Mean BL hepcidin in CKD-DD roxadustat subjects was 303.9±172.9 & 91.1±90.0 (040 and 053). Hepcidin fell with roxadustat treatment by 26.7±192.0 & 57.4±68.5. For both groups, the greatest declines were in the highest BL tertiles.

Study	Treatment	Hepcidin at BL	CFB during treatment (4 wks, 8 wks for 041)	CFB: highest tertile BL hepcidin	CFB: middle tertile BL hepcidin	CFB: lowest tertile BL hepcidin
017	Roxadustat (N=38)	292.8± 179.8	-158.4± 179.2^	-290.7± 211.2^	-132.3± 67.7	-52.2± 106.5^
	Placebo (N=15)	288.7± 176.3	-29.0 ± 70.6			
041	Roxadustat (N=139)	120.3± 107.0	-45.6 ± 87.7^	-108.3± 120.7^	-22.2± 63.6^	-14.2± 23.1^
040	Roxadustat (N=100)	303.9± 172.9	-26.7± 192.0	-90.3± 247.6	-32.6± 166.7	27.7± 151.8
	Epoetin alfa (N=34)	283.6± 135.2	25.5± 147.9			
053	Roxadustat (N=57)	91.1± 90.0	-57.4± 68.5^	-112.6± 93.1^	-45.2± 26.5^	-16.7± 17.7^

Conclusions: Roxadustat consistently lowered hepcidin in phase 2 studies. The decrement in hepcidin is greatest among those with the highest BL levels. The roxadustat phase 3 trials will include measurements of hepcidin to further define this effect.

Funding: Pharmaceutical Company Support - FibroGen

TH-PO647

Anemia Correction with Roxadustat Increases Soluble Transferrin Receptor (sTfR) in Chronic Kidney Disease (CKD) Patients Lynda Szczech, Anatole Besarab, Khalil Georges Saikali, Stefan Hemmerich, Lona Poole, Kin-Hung Peony Yu, Frank H. Valone, Thomas B. Neff. *FibroGen, San Francisco, CA.*

Background: The hypoxia-inducible factor prolyl hydroxylase inhibitor roxadustat corrected anemia in phase 2 trials without IV iron.This analysis of 4 phase 2 studies explores roxadustat's effect on sTfR levels.

Methods: In phase 2 studies CKD-NDD 017 & 047 and CKD-DD 040 & 048, subjects were randomized to roxadustat at different doses with comparator arms of placebo or epoetin-alfa. Studies restricted IV iron use in general but allowed oral iron. sTfR at baseline (BL) and % change from BL were summarized by treatment.

Results: Among CKD-NDD subjects (n=125), BL sTfR mean±SD was 1.35±0.56 and 3.58±1.69 mg/L (studies 017 & 047 respectively) in roxadustat groups. sTfR rose with roxadustat treatment in both studies by 86.5% and 101.5%. These increases were greater than the placebo arm (15.3% & 2.6%, p=0.0081 & <0.0001 respectively). Among subjects with CKD-DD (n=199), BL sTfR mean±SD was 3.57±1.41 and 3.33±1.47 mg/L (studies 048 & 040 respectively) in the roxadustat group. In 040, the increase in the roxadustat group was greater than in the epoetin arm (31.1% vs -0.7% respectively, p=0.0013). However, in 048, the changes in sTFR were comparable to epoetin arm (32.1 vs 39.9% respectively).

Study Population (N)	Control (N)	Baseline sTfR mg/L Mean (SD)		EOT	% Change from BL Mean (SD)	
		Roxadustat	Control		Roxadustat	Control
017 CKD-NDD (24)	Placebo (10)	1.35 (0.56)	1.37 (0.43)	Day 26-29	86.5 (92.9)	15.3 (42.7)
047 CKD-NDD (61)	Placebo (30)	3.58 (1.69)	3.47 (1.20)	Week 8	101.5 (72.2)	2.6 (17.8)
040 CKD-DD (78)	Epoetin (26)	3.33 (1.47)	3.52 (1.04)	Day 43	31.1 (60.1)	-0.7 (21.3)
048 CKD-DD (73)	Epoetin (22)	3.57 (1.41)	2.92 (1.21)	Week 7	32.1 (54.6)	39.9 (61.8)

Conclusions: Roxadustat consistently increased sTfR in phase 2 studies with oral iron supplementation. Placebo had little effect on sTfr, and epoetin results varied. The consistent increase in sTfR supports sufficient iron delivery for erythropoiesis during the time periods studied. The coordinated erythropoiesis induced by roxadustat is being evaluated in phase 3 trials.

TH-PO648

Anemia Correction with Roxadustat Lowers Cholesterol in Chronic Kidney Disease (CKD) Patients Lynda Szczech, Anatole Besarab, Khalil Georges Saikali, Stefan Hemmerich, Brian K. Roberts, Lona Poole, Kin-Hung Peony Yu, Frank H. Valone, Thomas B. Neff. *FibroGen, San Francisco, CA.*

Background: Hypoxia-inducible factor (HIF) prolyl hydroxylase inhibitor roxadustat is being developed for CKD anemia.The HIF pathway affects cholesterol metabolism & ascension to altitude reduces total cholesterol (TC).This analysis of phase 2 studies explores roxadustat's effect on TC in non-dialysis (NDD) and dialysis (DD) CKD.

Methods: In Phase 2 studies 41&47 in NDD & 40,48&53 in DD, roxadustat dose, study duration and comparator (placebo, epoetin) varied. Studies restricted IV iron but allowed oral iron. Baseline (BL) TC and change from BL (Δ) were summarized overall and by BL tertile. Data are mean±SD.

Results: Among roxadustat NDD subjects (n=206), mean BL TC was 170.9±45.2 and 166.8±39.1 mg/dL (studies 41&47). TC fell with roxadustat by 25.8±29.7 and 33.7±31.8. Among roxadustat DD subjects (n=238), mean BL TC was 171.1±35.1, 174.3±57.3, and 171.0±56.7 (studies 48, 53&40). TC fell with roxadustat treatment by 14.2±36.4, 44.4±45.9 and 36.7±37.0. The greatest declines were among the highest BL tertile in both populations.

Study	Treatment (N)	BL TC	CFB during treatment	CFB in highest tertile of BL TC	CFB in middle tertile of BL TC	CFB in lowest tertile of BL TC
041	Roxa (145)	170.9± 45.2	-25.8± 29.7*	-33.5± 37.1*	-28.7± 26.8*	-15.9± 21.5*
047	Roxa (61)	166.8± 39.1	-33.7± 31.8*	-48.1± 38.1*	-33.8± 14.3*	-16.4± 31.0
	Placebo (30)	182.6± 52.0	+8.0± 30.0			
048	Roxa (74)	171.1± 35.1	-14.2± 36.4*	-21.9± 39.4*	-14.3± 34.5	-7.0± 35.2
	Epoetin alfa (22)	158.4± 28.4	+18.3± 24.3*			
053	Roxa (56)	174.3± 57.3	-44.4± 45.9*	-66.3± 29.2*	-58.0± 36.9*	-11.3± 48.9
040	Roxa (108)	171.0± 56.7	-36.7± 37.0*	-59.3± 48.6*	-35.4± 21.8*	-16.6± 19.8*
	Epoetin alfa (36)	168.9± 40.5	+4.1± 27.4			

*p<0.05 two-sided;within-group comparisons; Δ at wk 9 for 041 and wk 5 for 053.

Conclusions: Roxadustat consistently lowered TC in phase 2 studies.The decrement in TC is greatest among those with highest BL levels. Roxadustat phase 3 trials will include tests to further define this effect and significance.

TH-PO649

AKB-6548 Demonstrates Controlled Hemoglobin (HGB) Response in a Phase 2b Study for the Treatment of Anemia in Patients with Chronic Kidney Disease Not on Dialysis (ND-CKD) Volker H. Haase,[1] Bruce S. Spinowitz,[2] Pablo E. Pergola,[3] Tasha Farmer,[4] Bradley J. Maroni,[4] Charlotte S. Hartman.[4] *[1]Vanderbilt Univ, Nashville, TN; [2]New York Hospital Queens, Flushing, NY; [3]Renal Associates PA and Univ of Texas Health Sciences Center, San Antonio, TX; [4]Akebia Therapeutics, Inc., Cambridge, MA.*

Background: AKB-6548 is a novel, once daily, oral hypoxia-inducible factor prolyl-hydroxylase inhibitor (HIF-PHI) that preferentially stabilizes HIF-2α. Current standard of care for anemia in ND-CKD with recombinant ESAs often results in overshoots and oscillations of HGB levels. It has been suggested that fluctuations in HGB concentrations, rapidly increasing HGB levels, and overshoots of the HGB target are associated with increased risk of cardiovascular events. Presented here are data assessing the control and predictability of HGB response from a Phase 2b study.

Methods: A randomized, double-blind, placebo-controlled study was conducted to assess the HGB response of AKB-6548 over 20 weeks of dosing in ND-CKD subjects with anemia. 210 subjects were randomized 2:1 (138 AKB-6548, 72 placebo) to once daily AKB-6548 (450mg) or placebo. HGB was monitored at each study visit and a protocol-defined dose adjustment algorithm was used to raise and maintain HGB and to minimize excursions ³13 g/dL.

Results: The starting dose of 450 mg once daily was validated by the final average dose of 450 mg/day in the AKB-6548-treated subjects. Only 15 subjects (11%) had a confirmed HGB ³12 g/dL and only 2 subjects (1%) had a confirmed HGB ³13 g/dL. From Weeks 12 to 20, 74% and 81% of all HGB measurements were between 10-12 g/dL and 10-13 g/dL,

respectively. The majority of subjects (120 of 135, 89%) achieved and maintained a stable HGB level with 2 or fewer dose adjustments throughout the 20-week treatment period and 24% (33 of 135) of subjects required no dose adjustment.

Conclusions: AKB-6548 increased and maintained HGB levels in ND-CKD patients in a controlled and predictable manner with minimal dose adjustments. The study provides support that targeting the HIF oxygen sensing pathway is likely to represent a more physiologic and potentially safer approach to treating anemia than currently available therapy.

TH-PO650

Randomized Controlled Trial of Darbepoetin Alfa and Continuous Erythropoietin Receptor Activator Once Every 4 Weeks in Patients with Chronic Kidney Disease at the Pre-Dialysis Stage Tetsuya Furukawa, Kazuyoshi Okada, Ritsukou Tei, Masanori Abe, Noriaki Maruyama. *Div of Nephrology, Hypertension and Endocrinology, Dept of Medicine, Nihon Univ School of Medicine, Tokyo, Japan.*

Background: Subcutaneous injection of Continuous Erythropoietin Receptor Activator (CERA) seems to maintain a stable Hb level than darbepoetin alfa (DA) in CKD patients who are not on dialysisbecause of its longer half-life. We therefore conducted a randomized controlled trial.

Methods: The cohort consisted of 20 CKD patients at the pre-dialysis stage who were receiving a fixed dose of DA with a Hb level >9.5 g/dL and ferritin level >80 ng/mL in the 12 weeks prior to the study. Patients were randomly assigned to receive subcutaneous CERA or DA once every 4 weeks. The study consisted of a 48-week evaluation period. The target Hb range was from 11.0 g/dL to 12.5 g/dL. Primary endpoints were rate of achievement of target Hb and change of eGFR, and the secondary endpoints were change in Hb level after start of the study and change in dose of DA and CERA.

Results: In both groups, the rate of achievement of target Hb level at week 0 was 70%, which rose to 100% in the interval between weeks 4 to 48, with no significant difference between the groups. Despite the absence of a significant difference in Hb level, it was significantly increased from week 24 and from week 8 relative to those at week 0 in the DA continuation group and CERA changeover group, respectively. In addition, the reticulocyte count was significantly increased at weeks 4, 8 and 12 in the CERA changeover group compared with the DA continuation group. The doses of DA and CERA during the evaluation period were not significantly changed. Because the total administered doses of DA and CERA over 48 weeks were 0.998±0.106 mg/kg/4 weeks and 0.956±0.204 mg/kg/4 weeks, the dose conversion ratio was 1.05:1 mg. There was no significant difference in the levels of eGFR and iron state between both groups.

Conclusions: The present study demonstrated that subcutaneous administration of DA and CERA once every 4 weeks to predialysis patients have similar effects on achievement of target Hb levels but longer acting CERA can increase the Hb level earlier than DA.

TH-PO651

QW or Q2W Darbepoetin Alfa in Pediatric Subjects with Chronic Kidney Disease Bradley Warady,[1] John P. Barcia,[2] Nadine M. Benador,[3] Augustina Jankauskiene,[4] Kurt Olson,[5] Ludmila Podracka,[6] Aleksey Shavkin,[7] Poyyapakkam Srivaths,[8] Cynthia Wong,[9] Jeffrey Petersen.[5] *[1]Children's Mercy; [2]UVA Med; [3]UCSD; [4]Vilniaus U; [5]Amgen; [6]UPJS; [7]Children's City; [8]TX Children's; [9]Stanford Med.*

Background: Minimal data are available on the initiation of erythropoiesis stimulating agents (ESA) for the correction of anemia in ESA-naive pediatric patients with CKD. Additionally, the optimal dosing frequency with darbepoetin alfa (DA) in this setting has not been previously evaluated. This study assessed the ability of DA administered either once weekly (QW) or once every 2 weeks (Q2W) to correct anemia in pediatric patients.

Methods: Multicenter, double-blind, randomized study in pediatric subjects (age 1 to 18 years) with CKD and anemia (hemoglobin; Hb < 10.0 g/dL) on or not on dialysis and not treated with an ESA. The primary endpoint was Hb ≥ 10.0 g/dL at any time after the first dose without receiving a RBC transfusion within 90 days prior to initial Hb measurement or after randomization. Subjects were randomized to DA QW or Q2W at an initial dose of 0.45mg/kg or 0.75mg/kg, respectively. For both treatment groups, subsequent DA doses were titrated to achieve Hb 10.0 g/dL to 12.0 g/dL, inclusive over a 25 week period of observation.

Results: 116 subjects were enrolled: 59 were randomized to DA QW and 57 to Q2W. 114 subjects (58 QW; 56 Q2W) were included in the analyses. Mean (SD) Hb for the QW group increased from 8.6 (0.84) g/dL at baseline to 11.3 (1.33) g/dL at week 10 and remained relatively stable (range: 10.9 [1.10] to 11.7 [1.19] g/dL) through week 25. Mean Hb for the Q2W group increased from 8.7 (0.84) g/dL at baseline to 10.9 (1.38) g/dL at week 12 and remained relatively stable between 10.4 (0.97) and 11.1 (1.00) g/dL through end of study. Hb concentrations were corrected to ≥ 10 g/dL in 98% and 84% of pediatric subjects administered DA QW or Q2W, respectively. 4 (7%) QW and 5 (9%) Q2W subjects received RBC transfusions. Safety results were consistent with the known safety profile for DA.

Conclusions: Hb concentrations were corrected to ≥ 10 g/dL in > 80% of pediatric subjects administered DA QW or Q2W. No new safety signals were identified in this pediatric subject population.

Intravenous (IV) Ferric Carboxymaltose (FCM) versus Oral Iron in the Randomized FIND-CKD Trial of Patients with Non-Dialysis Dependent CKD (ND-CKD): A Safety Analysis Simon D. Roger,[1] Andreas H. Bock,[2] Fernando Carrera,[3] Kai-Uwe Eckardt,[4] Carlo A. Gaillard,[5] David B. Van wyck,[6] Bernard Roubert,[7] Maureen Cronin,[7] Iain C. Macdougall.[8] *[1]Renal Research, Gosford, NSW, Australia; [2]Kantonsspital, Aarau, Switzerland; [3]Eurodial, Leiria, Portugal; [4]Uni. of Erlangen-Nuremberg, Erlangen, Germany; [5]Uni. Groningen, Groningen, Netherlands; [6]Davita Healthcare Partners, Denver, CO; [7]Vifor Pharma Ltd, Glattbrugg, Switzerland; [8]King's College Hospital, London, United Kingdom.*

Background: There are safety concerns, including hypersensitivity reactions, iron overload, increased risk of infection, oxidative stress and mortality risk, in patients with CKD receiving IV iron.

Methods: In the 56-week, open-label, multicenter, prospective, randomized FIND-CKD study, 626 anemic patients with ND-CKD and iron deficiency not receiving ESA therapy were randomized (1:1:2) to IV ferric carboxymaltose (FCM), targeting higher (400–600µg/L) or lower (100–200µg/L) ferritin, or oral iron.

Results: In the IV iron arms, two patients had mild hypersensitivity reactions, neither requiring treatment nor hospitalization. Desired target ferritin levels were achieved and transferrin saturation (TSAT) levels were maintained within KDIGO guidelines (mean TSAT 31% in the high ferritin FCM group). The rate of infections was equivalent within all three groups (33.1%, 34.0% and 30.4% in the high ferritin FCM, low ferritin FCM and oral iron groups, respectively), as was the rate of serious infections (3.9%, 3.3%, 3.8%). As a measure of oxidative stress, estimated GFR values were unchanged during the study. Overall, 4.1% of patients died (4.5%, 2.0% and 4.8% in the high ferritin FCM, low ferritin FCM and oral iron groups, respectively). No death was assessed by the investigator as related to study drug. Most frequent causes of death were cardiovascular events and respiratory infections.

Conclusions: Despite this being the longest RCT of oral vs IV iron in ND-CKD patients, the follow-up was still only 12 months and there was no placebo group. Nevertheless, there was no obvious signal of excess harm in patients targeting a higher ferritin range with IV FCM.

TH-PO653

Recruitment for Clinical Trials of Interventions to Prevent ESRD in T2D Patients Adam Smiles,[1] Melissa Major,[1] Masayuki Yamanouchi,[1] Natalia Z. Nowak,[1] Monika A. Niewczas,[1] Jan Skupien,[1] Marcus G. Pezzolesi,[1] Fergus Fleming,[2] James Warram,[1] Matthew D. Breyer,[3] Kevin L. Duffin,[3] Nick Pullen,[4] Andrzej S. Krolewski.[1] *[1]Joslin Diabetes Center, Boston; [2]EKF Diagnostics, London, United Kingdom; [3]Eli Lilly, Indianapolis; [4]Pfizer Global R&D, Cambridge, MA.*

Background: The current dependence of clinical trials of measures to prevent ESRD, on recruitment of patients with T2D and proteinuria is problematic. The eligible pool, shrunken due to ACE inhibitor treatment, largely consists of non-progressors (due to depletion of rapid progressors) whose participation may be less informative.

Methods: In search of alternatives, we recruited T2D patients attending Joslin Clinic from 2003 to 2009 by screening those age 35-69 (and CKD stage 1-3) for onset of albuminuria (ALB), micro or macro, and identified for each a similar patient in the 3x larger pool with normo ALB. 2/3 granted participation consent. Mean baseline eGFR was 95 for Normo and Micro ALB groups and 68 mL/min/1.73 m^2 for Macro-ALB group. Patients were examined at baseline and followed to 2013 to ascertain onset of ESRD or death unrelated to ESRD. Baseline and follow-up blood and urine were assayed for serum creatinine and other characteristics.

Results: After 4-6 year follow-up for 1335 patients (excluding 82 incomplete follow-ups) are summarized according to ALB category:

Outcome	Normo-ALB n=695 [2085]*	Micro-ALB n=484	Macro-ALB n=156	All n=1335 [2725]
ESRD onset	2/0.3% [6]*	7/1.4%	32/21%	41 [45]
Loss>40% eGFR	24/3.5% [72]*	54/11%	49/31%	127 [177]
Death	16/2.3% [48]*	23/4.8%	19/12%	58 [90]
Composite	42/6.0% [126]*	84/17%	100/64%	226 [310]
* expected number if all normo-ALB patients were followed				

Unfavorable outcomes occurred in an estimated 310 of 2725 patients (including all normo ALB patients). Although incidence was highest in Macro-ALB group, 2/3 occurred in Normo and Micro ALB groups and 1/3 occurred in patients with baseline eGFR >90 ml/min/1.73 m^2. Circulating levels of TNFR1 and KIM-1 and urinary levels of MCP-1 and KIM-1 at baseline are associated with risk of these outcomes.

Conclusions: In summary increased clinical trial enrollment of patients with outcomes can be achieved by including patients with normal renal function and Micro or Normo ALB.

***Post Hoc* Analyses of the EPPIC Trials to Assess the Effect of AST-120 in Chronic Kidney Disease Patients**

Gerald Schulman,[1] Tomas Berl,[2] Gerald J. Beck,[3] Giuseppe Remuzzi,[4] Eberhard Ritz,[5] Miho Shimizu,[6] Yuko Shobu,[7] Mami Kikuchi.[7] *[1]Vanderbilt U., Nashville, TN; [2]U. Colorado, Denver, CO; [3]Cleveland Clinic, Cleveland, OH; [4]Mario Negri Inst, Bergamo, Italy; [5]U. Heidelberg, Heidelberg, Germany; [6]Mitsubishi Tanabe Pharma Co, Tokyo, Japan; [7]Kureha Co, Tokyo, Japan.*

Background: The orally administered spherical carbon adsorbent AST-120 is approved in Asian countries for delaying the initiation of dialysis and ameliorating symptoms of uremia in patients with progressive CKD. Two randomized, double-blind, placebo-controlled trials (EPPIC trials) investigated the efficacy and the safety of AST-120 in adults with CKD. The benefit of adding AST-120 was not supported by the results of the primary analysis as reported previously. In order to further assess the efficacy of AST-120, we examined clinical and geographic factors by *post hoc* analyses using pooled populations of 2 trials.

Methods: The primary endpoint was a composite of dialysis initiation, kidney transplantation and serum creatinine doubling. The same statistical methods for the efficacy endpoint analysis were applied for these *post hoc* analyses.

Results: In a multivariable analysis using baseline parameters, positive hematuria and elevated UP/UCr were found to be an independent risk factor for the primary endpoint. In the ITT population with positive hematuria, elevated UP/UCr (³1.0) and ACEI/ARB use, a difference between the AST-120 and the placebo treatment groups was observed in primary endpoint occurrence (HR 0.74, 95% CI 0.56-0.96). In subgroup analysis by country, a higher event rate was observed in the USA population than outside the USA. In the ITT population from the USA with ACEI/ARB use, a difference between the AST-120 and the placebo treatment groups was observed in primary endpoint occurrence (HR 0.74, 95% CI 0.56-0.98).

Conclusions: These results suggest that there may be a beneficial effect of adding AST-120 to standard therapy regimens in high risk populations such as patients with hematuria and elevated UP/UCr and in the patients similar to those enrolled in the USA EPPIC trials. Due to its *post hoc* nature of the analysis, further prospective studies are needed to confirm the results.

TH-PO655

A Phase 2 Study on the Effect of Tenapanor on Albuminuria in Patients with T2DM and CKD

Bergur V. Stefansson,[1] David P. Rosenbaum,[2] Peter J. Greasley,[1] Maria Leonsson Zachrisson,[1] Anna Maria Langkilde.[1] *[1]AstraZeneca R&D, Mölndal, Sweden; [2]Ardelyx Inc., Fremont, CA.*

Background: Patients with type 2 diabetes mellitus (T2DM) and CKD are treated with renin–angiotensin–aldosterone system (RAAS) inhibitors to slow the decline in renal function. The effectiveness of RAAS inhibition is limited by high sodium (Na) intake. Tenapanor (AZD1722), an inhibitor of the Na^+/H^+ exchanger NHE3, reduces absorption of Na and phosphate from the gut. This trial evaluated the effects of tenapanor on albuminuria levels, which may be associated with renal function decline, in patients with T2DM and CKD stage 3 receiving RAAS inhibitors.

Methods: This was a randomized, placebo-controlled, 12-week study (NCT01847092) in patients with urine albumin-to-creatinine ratio (UACR) 200–3500 mg/g. The starting dose of tenapanor hydrochloride was 15 mg bid: there was a 4-week titration period (dose escalation up to 60 mg bid followed by reduction down to 5 mg bid), based on gastrointestinal tolerability, before fixed-dose treatment with 5–60 mg bid for 8 weeks.

Results: Patients were randomized to tenapanor (n=77; mean±SD urinary Na, 182±81 mmol/day; completed, n=51) or placebo (n=77; mean±SD urinary Na, 189±85 mmol/day; completed, n=66). Reductions from baseline to week 12 in UACR were 16% for tenapanor and 11% for placebo (p=0.36). Tenapanor had no observed effect on systolic or diastolic BP or eGFR. Changes (tenapanor vs placebo) in urinary Na were (LS mean±SE) -9.6±9.7 vs -1.5±9.1 mmol/day (p=0.54) and in urinary phosphorus were (mean±SD) -3.8±14 vs 1.7±9.7 mmol/day. Tenapanor treatment resulted in a softer consistency and increased frequency of stool compared with placebo. The tolerability profile of tenapanor was consistent with that seen in other studies, with diarrhea reported more frequently with tenapanor use.

Conclusions: In patients with T2DM and CKD stage 3, the pharmacodynamic effects of tenapanor were confirmed, as shown by softer consistency and increased frequency of stool, and reduced urinary phosphorus excretion following tenapanor treatment. However, these observations did not translate into effects on albuminuria.

Effect of Fluvastatin Treatment on Proteinuria in Diabetic Patients with Chronic Kidney Disease

Jin Joo Cha,[1] Kitae Kim,[1] Hye sook Min,[1] Jungyeon Ghee,[1] Yeo-Joo Kim,[2] Eun-Young Lee,[2] Shin-Wook Kang,[3] Tae-Hyun Yoo,[3] Jung Tak Park,[3] Yaeni Kim,[4] Cheol Whee Park,[4] Ho Jun Chin,[5] Young Sun Kang,[1] Dae R. Cha.[1] *[1]Internal Medicine, Korea Univ, Republic of Korea; [2]Internal Medicine, Soonchunhyang Univ Cheonan Hospital, Republic of Korea; [3]Internal Medicine, Yonsei Univ College of Medicine, Republic of Korea; [4]Internal Medicine, The Catholic Univ of Korea Seoul St. Mary, Republic of Korea; [5]Internal Medicine, Seoul National Univ Bundang Hospital.*

Background: Correction of dyslipidemia with statin has shown to be protective and therapeutic in the progression of cardiovascular events. However its association with progression of kidney disease has not been established. In this study, we investigated the efficacy of fluvastatin (Lescol XR) on the progression of diabetic nephropathy in patients with renal insufficiency.

Methods: A total of 75 diabetic patients with CKD (stage 2 to 4) completed this multicenter, randomized 12 month controlled trial. All patients were treated with 20mg fluvastatin for 6 months. At month 6, patients were randomized to either continue or to discontinue fluvastatin for additional 6months. Primary endpoint was the difference in urinary protein to creatinine ratio between the groups at 12months.

Results: Baseline characteristics showed no differences between the groups in HbA1c, HOMA-IR, diabetes duration and estimated glomerular filtration rate (GFR).Majority of patients (81%) were using RAS blockers. After 6months of fluvastatin treatment, there was no significant decrease in urinary protein excretion or microalbumin excretion. Estimated GFR significantly declined at 6months in both groups and continued to decline after discontinuation of fluvastatin, whereas the change was not significant with fluvastatin treatment. Interestingly, HOMA-IR significantly improved in continuation group. Significant decrease in total and low density cholesterol was observed after 6, 12months in patients treated with fluvastatin.

Conclusions: In conclusion, there was no significant reduction in proteinuria with fluvastatin treatment in diabetic patients with chronic kidney disease. However, our study suggests that there might be a role in statin to slow the progression of kidney disease.

Hyperkalemia in the HALT PKD Trial

Ronald D. Perrone,[1] Kaleab Z. Abebe,[2] Peter G. Czarnecki,[3] Marie C. Hogan,[4] Theodore I. Steinman,[5] Susan Spillane,[2] Charity G. Moore.[2] *[1]Tufts; [2]U Pittsburgh; [3]Brigham and Womens; [4]Mayo Clinic; [5]BIDMC, for the HALT PKD Investigators.*

Background: HALT-PKD was a prospective, randomized trial designed to determine the effects of dual renin-angiotensin system (RAAS) blockade and blood pressure (BP) reduction on ADPKD progression. In view of prior reports of hyperkalemia (HK) with dual RAAS blockade, we describe the frequency and severity of HK in HALT-PKD.

Methods: Study A subjects with eGFR >60 ml/min aged 15-50 were randomized to lisinopril (L) and placebo (P) vs L and telmisartan (T) with two levels of BP control: standard (SBP) (120-130/70-80 mmHg) vs low (LBP) (95-110/65-75 mm Hg). Study B subjects with eGFR 25-60 ml/min aged 18-65 were randomized to L and P vs L and T with SBP only. Serum K was measured every 6 months at study visits, within 1-2 weeks after an increase in L or T dose, and every 3 months when eGFR was less than 30. All elevated serum K values were reviewed on a monthly basis by a quality control committee.

Results: HK was infrequent in Study A; mild, but not moderate or severe HK, was more common in Study B.

Hyperkalemia		STUDY A			:	STUDY B	
(N)	L/T (273)	L/P (285)	SBP (284)	LBP (274)	:	L/T (244)	L/P (242)
Mild >5.5 - 6	7,7 (3%)	5,4 (1%)	8,7 (3%)	4,4 (2%)	:	61,42 (17%)	60,38 (16%)
Moderate >6 - 6.5	5,4 (2%)	1,1 (0.4%)	3,3 (1%)	3,2 (1%)	:	9,9 (4%)	4,4 (12%)
Severe >6.5	1,1 (.4%)	0,0 (0%)	0,0 (0%)	1,1 (.4%)	:	0,0 (0%)	1,1 (0.4%)

events, # participants, (% participants); L/T: lisinopril/telmisartan; L/P: lisinopril/placebo; SBP: standard BP; LBP: low BP. There were no significant differences in HK due to L/T or LBP

Intervention with dietary K reduction, furosemide, or Kayexalate was succesful in reducing serum K in all participants. There was no relationship between HK and serious adverse events (SAEs) and there were no SAEs within 21 days after detection of HK.

Conclusions: HK was infrequent with eGFR>60, despite dual RAAS blockade or intensive BP control. Mild HK was more common with eGFR 25-60, but easily managed. Severe HK was rare. With careful management, dual RAAS blockade and intensive BP control were safe in the HALT PKD trial. Clinical use of dual RAAS blockade or intensive BP control should only be done with close monitoring.

TH-PO658

Chronic Diuretic Therapy Does Not Impair the Effectiveness of Patiromer in Hyperkalemic Patients with CKD Matthew R. Weir,[1] Martha Mayo,[2] Dahlia Garza,[2] Yuri Stasiv,[2] Susan Arthur,[2] Lance Berman,[2] David A. Bushinsky,[3] Daniel J. Wilson,[2] Murray Epstein.[4] *[1]Univ of Maryland; [2]Relypsa, Inc.; [3]Univ of Rochester; [4]Univ of Miami.*

Background: Loop diuretics control volume in advanced CKD and may reduce elevated serum K^+, but can induce intravascular volume depletion or gout and may not be ideal for long-term hyperkalemia (HK) management. Thus, the efficacy of investigational serum K^+ binders in HK pts on chronic diuretics is of interest. We compared patiromer's effects in RAASi-treated CKD pts with HK on diuretics to those not on diuretics in the treatment phase of the 2-part OPAL-HK study.

Methods: Pts (n=243) with baseline (BL) s-K^+ 5.1 to 6.5 mEq/L on RAASi received patiromer (4.2 or 8.4 g BID to start) for 4 wks. For this post hoc analysis, Ds-K^+ from BL to wk 4 was assessed in pts stratified by diuretic use and type. Pts (n=22) receiving aldosterone antagonists were excluded.

Results: Mean (SD) age was 64 (10.5) yr; 58% were male. Mean s-K^+ decreased from BL at wk 4 in all subgroups (**Table**). Reductions in s-K^+ did not differ in pts receiving any diuretic vs those not on diuretics. Patiromer was well tolerated; mild–moderate GI constipation was the most common AE. Hypokalemia (s-K^+<3.5 mEq/L) was infrequent.

Conclusions: The s-K^+-lowering efficacy of patiromer in HK pts was unaffected by concomitant diuretics.

Table: Efficacy, safety, and disease characteristics in pts on patiromer ± diureticsa

Add-On HCTZ Administration to ARB Can Achieve Lower Sodium Balance in CKD Patients Daisuke Fuwa,[1] Michio Fukuda,[1] Toshiyuki Miura,[1] Yoshiaki Ogiyama,[1] Sumiko Abe-Dohmae,[1] Hiroyuki Kobori,[2] Nobuyuki Ohte.[1] *[1]Nagoya City Univ; [2]International Univ of Health and Welfare.*

Background: Recently, we have reported that angiotensin receptor blocker (ARB) can attain lower sodium balance and resultant restoration of nondipper circadian BP rhythm in patients with augmented intrarenal renin angiotensin system (RAS). It has been established that ARB can enhance renal sodium excretion in subjects with sodium deprivation. We tested whether add-on administration of hydrochlorothiazide (HCTZ) can further achieve a lower sodium balance in patients with CKD under ARB treatment.

Methods: CKD patients (n=20) with previous treatment with valsartan (80mg/day) for 2 months or more, office BP >130/80 on at least one occasion were eligible. Filtered tubular sodium load was defined as PNa x GFR. Ambulatory BP and sodium balance were studied before and 8-week administration with HCTZ (12.5mg/day).

Results: Add-on HCTZ to ARB could attain lower sodium balance: tubular sodium load (13200±9300®11800±7800 mmol/day, p=0.04), and tubular sodium reabsorption (13000±9300®11700±7800 mmol/day, p=0.04) were both decreased, while urinary sodium excretion did not change (160±80®161±60 mmol/day, p=0.9). Decrease in tubular sodium load correlated directly with baseline urinary angiotensinogen excretion (uATG) (r2=0.10), and the decrease in night/day SBP ratio (r2=0.16). uATG was significantly decreased (150±10→80±20 mg/gCre, p=0.02).

Conclusions: Add-on administration with HCTZ to ARB can attain the lower sodium balance and resultant restoration of non-dipper BP rhythm with no acceleration of intrarenal RAS.

TH-PO660

Association of Serum Adiponectin Level with Albuminuria in Chronic Kidney Disease Patients Ha yeon Kim,[1] Eun Hui Bae,[1] Seong Kwon Ma,[1] Kook-Hwan Oh,[2] Curie Ahn,[2] Soo Wan Kim.[1] *[1]Internal Medicine, Chonnam National Univ Medical School, Gwangju, Korea; [2]Internal Medicine, Seoul National Univ Hospital, Seoul, Korea.*

Background: Adiponectin, peptide hormone secreted in an adipocytes, has been known to exert anti-diabetic, anti-atherogenic and anti-inflammatory properties. We aimed at determining the relationship between serum adiponectin levels and albuminuria and evaluate determinant factors for serum adiponectin in patients with chronic kidney disease (CKD).

Methods: A total of 1,474 CKD patients were included and divided into three groups according to their albumin-to-creatinine ratio: patients with normoalbuminuria (N = 232), microalbuminuria (N = 459), macroalbuminuria (N = 783). The serum adiponectin was specifically assayed with a commercially available enzyme-linked immunosorbent assay kit.

Results: Serum adiponectin was significantly higher in patients with macroalbuminuria than those without macroabluminuria. (9.7±6.06 mg/ml in patients with normoalbuminuria, 12.4±9.07 mg/ml in patients with microalbuminuria, 14.9±11.09 mg/ml in patients with macroabluminuria). Univariate linear regression analysis showed that the serum adiponectin concentrations correlated with age, albumin-to-creatinine ratio, total cholesterol, low-density lipoprotein cholesterol, high-density lipoprotein cholesterol, whereas negatively correlated with body mass index, estimated glomerular filtration rate, serum albumin and triglyceride. Multiple backward regression analysis revealed that sex, diabetes mellitus, estimated glomerular filtration rate, body mass index, total cholesterol, high-density lipoprotein cholesterol, triglyceride, logarithm of albumin-to-creatinine ratio were independently associated with logarithm of serum adiponectin levels ($r = 0.55$, $p < 0.001$).

Conclusions: The serum adiponectin concentrations are higher in patients with increasing albuminuria and these levels are also associated with renal insufficiency and lipid profiles.

TH-PO661

Effects of Candesartan on Clinical Remission in IgA nephropathy Treated with Steroid Pulse Therapy and Tonsilectomy (CAST IgA Study) – A Randomized Control Study Kentaro Kohagura,[1,2] Hisatomi Arima,[3] Hitoshi Miyasato,[5] Tung-Huei Chang,[6] Hiroyuki Kobori,[4] Kunitoshi Iseki,[7] Yusuke Ohya.[1] *[1]Dialysis Unit, Univ Hospital of the Ryukyus, Nishihara-cho, Okinawa, Japan; [2]Cardiovascular Medicine, Nephrology and Neurology, Univ of the Ryukyus, Nishihara-cho, Okinawa, Japan; [3]Center for Epidemiologic Research in Asia, Shiga Univ of Medical Science, Shiga, Japan; [4]Pharmacology, Kagawa Univ, Kagawa, Japan; [5]Internal Medicine, Okinawa Chubu Hospital, Okinawa, Japan; [6]Internal Medicine, Okinawa Heartlife Hospital, Okinawa, Japan; [7]Clinical Research Center, Tomishiro Central Hospital, Okinawa, Japan.*

Background: Angiotensin receptor blockade (ARB) may have additional benefit on the conventional therapy with steroid pulse and tonsillectomy among Japanese patients with IgA nephropathy.

Methods: Seventy seven patients with IgA nephropathy were randomly assigned to regular regimen consists of steroid pulse followed by oral prednisolone for 6 months and tonsillectomy (control groupor, n=37) regular regimen combined with ARB (candesartan) for 6 months (ARB group, n=40). Among all patients in both groups who did not achieve remission of proteinuria at 12 M, candesartan was initiated and titrated until the 24 M visit. The primary endpoint was the remission of proteinuria (<0.2g/gCr) and hematuria.

Results: Baseline proteinuria (g/gCr, interquartile range) were comparable between the groups (0.90, 0.70-1.20 vs. 0.95, 0.60-1.50, P=0.97). Cumulative remission rate in control group and ARB group at 6, 12 and 24 M were comparable (10.8% vs. 15% [P=0.58], 29.7% vs. 30.0% [P=0.98], 45.9% vs. 42.5% [P=0.76]). The hazard ratio for remission was 1.01 (95% confidence interval, 0.51-1.99; p=0.98). Proteinuria was slightly heavier in control group than ARB group (0.11 vs. 0.21g/gCr, p=0.002) at 6 M, but comparable afterwards (0.20 vs. 0.23 g/gCr at 12 M, 0.12 vs. 0.13 g/gCr at 24 M). Although remission rate of hematuria was comparable until 12M, it was higher in control group than ARB group at 24M (85% vs. 64%, P=0.008).

Conclusions: Early use of ARB regardless of the level of blood pressure combined with steroid pulse and tonsillectomy may not provide benefit for clinical remission among IgA nephropathy.

TH-PO662

Tacrolimus Monotherapy Follows Intravenous Methylprednisolone in Adults with Minimal Change Nephrotic Syndrome: A Prospective, Multi-Centered, Open, Randomized, Controlled Trial Xiayu Li, Jianghua Chen. *Kidney Disease Center, The First Affiliated Hospital, College of Medicine, Zhejiang Univ, Hangzhou, Zhejiang Province, China.*

Background: Adults with minimal change nephritic syndrome (MCNS) show excellent responses to glucocorticoid (GC).However, responding patients may suffer relapses and GC related frequent side effects. Tacrolimus(TAC) may serve as an alternative to GC therapy for adult-onset MCNS with less-frequent side effects.

Methods: This randomized, multicentre, controlled study was undertaken in 8 renal units across the China. 119 adult-onset patients were randomly allocated to receive the conventional GC therapy (GC group) or tacrolimus monotherapy (trough blood level of 4 to 8 ng/mL) follows intravenous methylprednisolone for 10 days (TAC group). The

primary outcome variables was remission. The secondary outcome variables included relapse, time to remission, time to relapse, change of serum creatinine (Scr) and eGFR, and adverse events (AEs).

Results: Remission (either complete or partial remission) was attained by 51 of 53 patients (96.2%) in GC group and 55 of 56 (98.3%) of patients in TAC group (p=0.611).51 of 53 patients (96.2%) in GC group and 52 of 56 patients (92.9%) in TAC group experienced complete remission, respectively (p=0.679). The mean time to remission in GC group (2.7±2.3 weeks) was similar (p=0.548) to TAC group (2.6±2.6 weeks), respectively. Relapse occurred in 25 (49.0%) of GC group versus 25 (45.5%) of TAC group (p=0.847), and 7 patients with GC therapy and 4 patient with TAC therapy suffered frequent relapse. The mean time to relapse in GC group (27.6±16.9 weeks) was similar (p=0.617) to TAC group (25.2±16.9 weeks), respectively. There was no significant difference of SCr and eGFR between two groups during therapy and follow-up periods. Adverse events were more frequent in GC group than in TAC group (128 events versus 81 events), of which 9(7 in GC group and 2 in TAC group) were deemed serious AEs.

Conclusions: The regimen with tacrolimus monotherapy follows short-term intravenous methylprednisolonewas noninferior to conventionalGC treatment in adult-onset MCNS, and could replace steroids as the initial therapy for such patients due to less-frequent side effects.

TH-PO663

Changes in Concentrations of Chemokine Ligands for CCR2 and CCR5 Receptors in Response to Administration of PF-04634817 Karen M. Page, Julie M. Lee, Amira Quazi, Lori Fitz, Weidong Zhang, Steven A. Gilbert, Nick Pullen, Robert Webster, Jeremy D. Gale. *Worldwide Research and Development, Pfizer, Cambridge, MA.*

Background: PF-04634817 is a competitive dual inhibitor of CCR2 and CCR5 receptors. In early clinical studies, administration of this compound to healthy volunteers has been found to elevate circulating levels of the primary CCR2 ligand, CCL2 (MCP-1). The ability of PF-04634817 to reduce albuminuria, compared with placebo, after administration for 12 weeks was tested in a phase 2 study in subjects with diabetic nephropathy and macroalbuminuria. In this study, samples were collected to confirm the previously observed pharmacological effect on CCL2 in this population and to examine the impact on other ligands known to bind to CCR2 or CCR5 receptors.

Methods: CCL2 in serum and urine was measured by ELISA from 226 subjects at Eurofins (The Netherlands) at baseline and during treatment at weeks 4, 8, and 12. CCL5 (RANTES) was measured in plasma and urine as part of a multi-analyte panel at Myriad Rules Based Medicine (Austin, TX) and CCL8 (MCP-2), CCL3 (MIP-1a), and CCL4 (MIP-1b) were measured in plasma using two Luminex assays (Bio-Rad, Berkeley, CA) from 158 subjects at baseline and weeks 8 and 12.

Results: At week 12, serum levels of CCL2 and plasma levels of CCL4 were elevated 9.25 fold ($p < 0.0001$) and 2.11 fold ($p < 0.0001$) respectively following administration of PF-04634817, but not placebo. Elevation of both chemokines was also observed at the earlier time points. Levels of CCL8, CCL5 and CCL3 in circulation and CCL2 and CCL5 in urine did not change in either group.

Conclusions: This study confirms elevation of the CCR2 ligand, CCL2, following treatment with PF-04634817 in diabetic nephropathy subjects. It also identifies the CCR5 ligand, CCL4, as another potential pharmacodynamic marker. The observed lack of apparent change in CCL5 warrants further follow up analysis.

TH-PO664

Circulating Tumor Necrosis Factor Receptor Expression in a Phase 2 Study to Evaluate the Efficacy and Safety of PF-04634817 in Adults with Type 2 Diabetes and Overt Nephropathy Karen M. Page, Lori Fitz, Weidong Zhang, Steven A. Gilbert, George Bashirians, Nick Pullen, Robert Webster, Jeremy D. Gale. *Worldwide Research and Development, Pfizer, Cambridge, MA.*

Background: PF-04634817 is a small molecule dual inhibitor of CCR2 and CCR5, chemokine receptors found on the surface of monocytes and T cells that are involved in the development and progression of diabetic nephropathy (DN). Identifying patients with accelerated renal function decline is an important area of research. Circulating TNFRs have been identified as biomarkers with potential to predict accelerated decline. In the current study, we investigated changes in soluble TNFR-1 and TNFR-2 following 12 weeks of treatment with PF-04634817 or placebo in subjects with DN.

Methods: Soluble TNFR-1 and TNFR-2 were measured from 161 subjects in serum by ELISA at baseline, weeks 8 and 12. Urinary albumin and creatinine concentrations were averaged from 3 consecutive first morning voids immediately prior to each visit. Estimated glomerular filtration rate (eGFR) was measured using the abbreviated (4 variable) Modification of Diet in Renal Disease (MDRD) formula. Study subjects were defined at baseline by a mean UACR of 180.78 ± 160.53 mg/mmol Cr and a mean eGFR of 41.46 ± 12.64 mL/min/1.73 m^2.

Results: Mean concentrations at baseline of soluble TNFR-1 and TNFR-2 were 4.25 ± 1.37 ng/mL and 8.27 ± 2.99 ng/mL respectively. Baseline concentrations were strongly correlated between the receptors ($Corr_s = 0.90$, $p < 0.0001$). Soluble TNFRs were weakly correlated with UACR at baseline ($Corr_s = 0.35$, $p < 0.0001$ and $=0.34$, $p < 0.0001$), in contrast to a stronger inverse correlation with eGFR ($Corr_s = -0.69$, $p < 0.0001$ and $= -0.61$, $p < 0.0001$). The concentration of neither TNFR was changed from baseline following treatment with PF-04634817 and baseline TNFR concentrations were not able to predict changes observed at week 12 in UACR.

Conclusions: At baseline, TNFR-1 and TNFR-2 in subjects with DN were well correlated to each other and more strongly correlated with eGFR than UACR. Our observations do not support either TNFR-1 or TNFR-2 as pharmacodynamic biomarkers or as predictive biomarkers of clinical response as measured by UACR.

TH-PO665

Effects of Intensified Vasodilatory Antihypertensive Treatment on Renal Function, Bloodsupply and Oxygenation in Chronic Kidney Disease Dinah S. Khatir,[1] Michael Pedersen,[2] Per R. Ivarsen,[1] Kent L. Christensen,[3] Bente Jespersen,[1] Niels Henrik Buus.[4] *[1]Renal Medicine, Aarhus Univ Hospital, Aarhus N, Denmark; [2]Comparative Medicine Lab, Aarhus Univ Hospital, Aarhus N, Denmark; [3]Cardiology, Aarhus Univ Hospital, Denmark; [4]Renal Medicine, Aalborg Univ Hospital, Denmark.*

Background: Progression of Chronic kidney disease (CKD) may result from tissue hypoxia induced by small artery structural narrowing, with increased renal vascular resistance (RVR) and impaired blood supply. We investigated whether vasodilating therapy (VT) is superior to non-vasodilating therapy (nonVT) for improvement of RVR, tissue oxygenation, and preservation of kidney function.

Methods: Eighty-two hypertensive grade 3-4 CKD patients (glomerular filtration rate (GFR) 36±15 ml/min/1.73 m^2) were randomised to renin-angiotensin inhibition combined with either VT (amlodipine) or nonVT (beta-blocker metoprolol). At baseline and following 18 months of therapy we determined forearm resistance by venous occlusion plethysmography. Using magnetic resonance imaging (MRI) renal artery blood flow was measured for calculation of RVR, and blood oxygen level dependent (BOLD) MRI was used as a marker of renal oxygenation (R_2*). GFR was measured as ^{51}Cr-EDTA clearance.

Results: The VT and nonVT arms had similar blood pressure levels throughout the study. At follow-up, in the VT group forearm resting resistance had decreased by 7% ($P<0.05$) and RVR by 12% ($P<0.05$), while in the nonVT group forearm resistance increased by 39% ($P<0.01$) while RVR remained unchanged. Cortical and medullary R_2* values were not affected by VT and nonVT. After 18 months GFR decline was similar in the two groups (3.0 vs. 3.3 ml/min/1.73 m^2).

Conclusions: In CKD, long-term VT reduced both peripheral and RVR, but was not associated with improved renal oxygenation and did not influence loss of kidney function compared to nonVT.

TH-PO666

The Epigenetic BET-Inhibitor RVX-208/Apabetalone Shows Favorable Effects on ALP and eGFR in Chronic Kidney Disease (CKD) Patients – A Post-Hoc Analysis of Phase 2 Clinical Trials Kamyar Kalantar-Zadeh,[1] Jan O. Johansson,[2] Michael Sweeney,[2] Kenneth E. Lebioda,[2] Ewelina Kulikowski,[2] Christopher Halliday,[2] Norman Cw Wong.[2] *[1]Div of Nephrology & Hypertension, 1Univ of California Irvine School of Medicine, Irvine, CA; [2]Research and Development, Resverlogix Corporation, Calgary, AB, Canada.*

Background: The epigenetic BET inhibitor RVX-208 is a small molecule with anti-inflammatory and apolipoprotein A-I (apoA-I) enhancing effects. It exerts its' actions by inhibiting bromodomain extra-terminal proteins (BET) thus inhibiting acetylated lysine, present in histones, from binding to the same site. In this process chromatin structure is altered and activity of select genes inhibited. A subpopulation analysis from the double-blind placebo controlled phase 2b program in cardiovascular disease (CVD) identified 81 subjects with CKD based on eGFR < 60 ml/min/1.73m2.

Methods: The effect of selective BET inhibition on key renal parameters in 81 CKD subjects (RVX-208 n=58/Placebo n=23) that were treated with either RVX-208 100mg/day or 150 mg b.i.d or matching placebo for 3 to 6 months were studied. A pooled analysis was performed to assess the changes from baseline for eGFR, ALP and creatinine at 3 and 6 months.

Results: ALP changes for RVX-208 and placebo were -14.2% and -0.34% at 3 months ($p<0.05$ vs. placebo) and -13.9% vs. -6.28% ($p<0.05$ vs. placebo) at 6 months. Following 6 months of RVX-208 treatment, eGFR showed an increase of +3.4% (p=0.04 vs. baseline) in the RVX-208 group compared to a decrease of -5.9% in the placebo group. After 6 months treatment serum creatinine was decreased (-2.82%, $p<0.10$ vs. baseline) compared to increases in the placebo group of +3.0% and +4.85% at 3 and 6 months, respectively. No significant change in eGFR and serum creatinine were observed after 3 months RVX-208 treatment, albeit nominal numbers went in the normalization directions.

Conclusions: Six months treatment with RVX-208, a selective BD2 selective BET-inhibitor significantly lowers serum ALP, and shows trends for eGFR and serum creatinine improvements. A phase 3 study BETonMACE is being planned in which these effects will be assessed in the prospective setting in diabetic CVD patients with or without CKD.

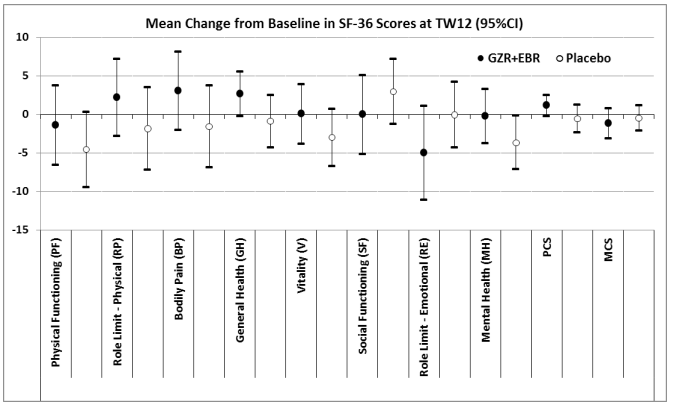
TH-PO667

Impact of Grazoprevir plus Elbasvir on Health-Related Quality of Life in Patients with Hepatitis C Virus Genotype 1 Infection and Chronic Kidney Disease Stages 4 and 5 Jean Marie Arduino,[1] Boshao Zhang,[1] Beth Jackson,[1] David Roth,[2] Annette Bruchfeld,[3] Shazia Khawaja,[1] Elisa Martinez,[1] Chizoba Nwankwo,[1] Chris Mast,[1] Wayne L. Greaves.[1] *[1]Merck & Co., Inc.; [2]Univ of Miami Miller School of Medicine; [3]Karolinska Univ Hospital.*

Background: Health-related quality of life (HRQOL) is diminished in patients with hepatitis C virus (HCV) infection and chronic kidney disease stages 4 and 5 (CKD4/5).A randomized, double-blind, placebo-controlled trial of Grazoprevir 100 mg + Elbasvir 50 mg (GZR+EBR) once daily for 12 weeks was conducted among patients with HCV genotype 1 infection and CKD4/5. GZR+EBR was highly effective, with a sustained viral response rate at follow-up week 12 (FW12) of 99.1%(95% Confidence Interval (CI):95.3%-100.0%). GZR+EBR was well-tolerated, with a safety profile that was comparable to placebo.The aim was to assess whether HCV treatment with GZR+EBR altered the HRQOL profile.

Methods: 224 patients were randomized and received at least one dose of study drug (GZR+EBR:n=111,Placebo:n=113). Patients completed the SF-36v2® Health Survey at baseline, treatment week 12 (TW12), and FW12 (GZR+EBR arm).Mean change from baseline in health domain, mental component summary (MCS) and physical component summary (PCS) scores, with 95% CIs, were estimated.Differences in mean change scores, with 95% CIs, were estimated between treatment groups.

Results: At baseline, mean scores were balanced between treatment groups.At TW12, GZR+EBR had more favorable changes from baseline in PCS and health domain scores (except for SF, RE, MCS) than placebo.



At FW12 for GZR+EBR, GH improved from baseline (mean change score:4.5(95% CI:1.2-7.9)).

Conclusions: Treatment with GZR+EBR had a positive impact on HRQOL as compared to placebo. In addition, changes in HRQOL were substantially more favorable than the large declines in HRQOL historically associated with interferon and ribavirin-containing regimens.

Bortezomib Before, in and After Autologous Hematopoietic Stem Cell Transplantation in Patients with Newly Diagnosed AL Amyloidosis Xiang-hua Huang, Qingwen Wang, Wencui Chen, Dehua Gong, Caihong Zeng, Zhihong Liu. *National Clinical Research Center of Kidney Diseases, Research Inst of Nephrology, Jinling Hospital, Nanjing, Jiangsu, China.*

Background: In previous study, we have demonstrated that the outcome of treating AL amyloidosis with bortezomib with dexamethasone (BD) induction followed by autologous hematopoietic stem cell transplantation (ASCT) was superior to the outcome of the ASCT treatment alone. To further improve the hematologic response rate, we conducted a prospective trial of bortezomib before, in and after ASCT in newly diagnosed AL amyloidosis.

Methods: Newly diagnosed AL amyloidosis patients who met the criteria of ASCT could be included in this trial. Treatment schedule consisted of two cycles of BD induction therapy (bortezomib 1.3mg/m^2 and dexamethasone 40 mg/d on days 1, 4, 8 and 11 followed by 10 days rest), ASCT treatment (the conditioning regimen consisted of melphalan and bortezomib, the dose of bortezomib was 1mg/m^2 in day -6, -3, +1, +4), and four additional 21-day cycles of bortezomib treatment (with a dose of 1.6mg/m2 on day 1 and 8 of the cycle) will be conducted as consolidation therapy after ASCT. The objectives were hematologic response, tolerability and survival.

Results: 18 patients were enrolled in the study. 9 patients had cardiac involvement. The overall hematologic response rate was 94.4% (17/18), including 13 patients (72.2%) with complete response, 4 patients (22.2%) with very good partial response. The organ response rate was 72.2%. The organ response was reached in 13 patients of the 18 patients with renal involvement and 7 of the 9 patients with cardiac involvement. Peripheral neuropathy and infection were the common adverse events during the treatment, and 4 patients have been discontinued bortezomib for neuropathy. No death occurred in this study. After a median follow up of 24 months, the overall survival was 100%, and the estimated progression free survival was 91% at 48 months.

Conclusions: In conclusion, our preliminary data suggest that incorporating bortezomib into induction, conditioning and consolidation with ASCT yielded a high rate of hematologic response with tolerable toxicity. (ClinicalTrial.gov Id: NCT01273844).

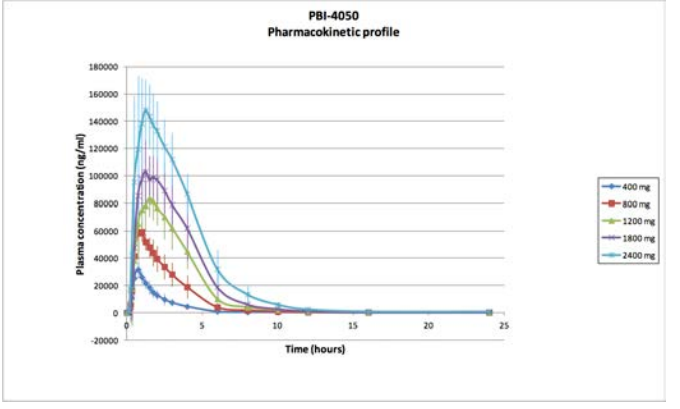
Phase 1 and 1b Studies of PBI-4050, a Novel Anti-fibrotic Agent for Chronic Kidney Disease John E. Moran,[1,2] Lyne Gagnon,[1] Pierre Laurin,[1] Vincent Pichette.[3] *[1]ProMetic Life Sciences, Laval, QC, Canada; [2]Nephrology, Stanford Univ School of Medicine, Palo Alto, CA; [3]Univ de Montréal, Montréal, QC, Canada.*

Background: PBI-4050 is an orally administered new chemical entity with a MW < 300 showing remarkable anti-fibrotic efficacy in multiple pre-clinical models of fibrosis in kidney, liver, lung, and heart. Phase 1 studies in normal volunteers and Phase 1b studies in patients with advanced nephropathy associated with Type 2 diabetes have been successfully completed.

Methods: Single ascending dose (SAD) phase 1 studies were performed in 5 cohorts of healthy volunteers, 6 subjects in each cohort receiving PBI-4050 and 2 receiving identical placebo, at doses of 400 to 2,400 mg po. The 800 mg cohort had studies in both the fasting and fed state. Phase 1b studies were performed in 8 subjects with Stage 3b and 4 nephropathy associated with Type 2 diabetes (eGFR 15-45 mL/min), 2 of whom received placebo; after a single dose of 800 mg po and a washout period, the same patients received 800 mg po daily for 10 days.

Results: In the SAD study all doses were well-tolerated; there were no dose-related adverse events (AE) and no serious AE's. The half-life ($T_{1/2}$) mean was 3.3-5.0 hours, dependent on dose (See Figure). There was a 34% decrease in the area under the curve ($AUC_{0\text{-inf}}$) after a fat meal. Protein binding in plasma was > 99%.



In the patients with CKD the $T_{1/2}$ mean and $AUC_{0\text{-inf}}$ were unchanged and there was no change in plasma protein binding. In the 10 day study there was no significant drug accumulation. One subject experienced diarrhea listed as mild to moderate and possibly related. There were no other significant AE's.

Conclusions: PBI-4050 was found to be safe in normal volunteers and in advanced CKD. The pharmacokinetics and protein binding were unchanged in CKD. Phase 2 studies are underway in patients with CKD associated with Type 2 diabetes.

TH-PO670

Immunogenicity and Safety of Quadrivalent Human Papillomavirus (HPV) Types 6/11/16/18 Recombinant Vaccine in CKD Stage IV-V-VD Kearkiat Praditpornsilpa, Paweena Susantitaphong, Somchai Eiam-ong. *Dept of Medicine, Chulalongkorn Univ, Bangkok, Thailand.*

Background: Up to 70% of sexually active adults will become infected withHPV during their lifetime. HPV infection can result in anogenital cancer and genital warts. Studies have demonstrated the efficacy of HPV-6/11/16/18 vaccination(GARDASIL®) 3 doses at day1, month2, and month6 to lower the occurrence of high-grade cervical intraepithelial neoplasia. HPVvaccination has been integrated in health care in nonCKD. However,immunogenicity and safety of the HPV vaccine have not been proven in CKD. This study investigated the immunogenicity and safety of quadrivalentHPV-6/11/16/18vaccination by the current recommended dose/schedule in CKD stage IV-V-VD.

Methods: This is a prospective, open-label study. CKD stage IV-V-VD patients were enrolled. Vaccine was given as a 0.5mL intramuscular injection at day1,month2,and month6. Each dose contains 20gHPV6L1 virus-like-particle(VLP), 40gHPV11L1VLP, 40gHPV16L1VLP, and 20gHPV18 L1VLP. HPV type-specific Ab response was performed by multiplexed, competitive Luminex immunoassay(cLIA) to neutralizing epitopes on HPV6/11/16/18 at day1 and month7.

Results: Sixty CKD cases(male/female:28/32) received vaccination. Pre-dialysis/ HD/CAPD cases were 2/44/14 cases. Mean age was 25.0±4.7years. Average Cr and eGFR were 10.3±4.5mg/dL and 14.3±12.8mL/min/1.73m^{2}respectively. Five patients underwent kidney transplanation before completing 3 doses of vaccination. At baseline, anti-HPV seropositivity was3.3-8.3% forHPV genotype6/11/16/18.

	Day1		Month7	
HPV genotype	%Seropositivity	MeancLIA (mMu/ml)	%Seropositivity	MeancLIA (mMu/ml)
Anti-HPV6	8.3	49.8	100	928.5
Anti-HPV11	8.3	19.4	100	1,136.1
Anti-HPV16	6.6	69.2	100	6,951.0
Anti-HPV18	3.3	12	100	2,196.3

Patients received 3 doses of vaccine had 100% seropositivity for all genotypes. The average cLIA for genotype6/11//16/18 were 928.4±231.1,1,136±264.6, 6,951.0±1872.3 and2,196.3±761.2mMu/ml respectively. No serious vaccine related adverse events were observed.

Conclusions: Standard dose/schedule of quadrivalent HPV vaccine provided excellent immunogenicity and safety inCKD stageIV-V-VD. HPV vaccination for CKD should be integrated in public health policy.

Minocycline-EDTA: Good Performance for Catheter Patency Maintenance

Marcus Vinicius de Souza Joao Luiz,[1] Cristoforo Scavone,[1] Carmen B. Tzanno-Martins.[2] *[1]Pharmacology, Inst of Biomedical Sciences, Sao Paulo, Brazil; [2]Nephrology, Integrated Centre of Nephrology, Guarulhos, Sao Paulo, Brazil.*

Background: Poor flow (PF) and catheter-related blood stream infections (CRBSI) are highly prevalent among CKD 5D patients with long-term central venous catheters. Heparin (H) catheter lock solutions are commonly used to maintain catheter patency, however PF and CRBSI incidence remains high. The purpose of this study was to evaluate two lock solutions on reduction of PF and CRBSI: one, a lock solution combining of the tetracycline antibiotic minocycline with the anticoagulant/chelation agent EDTA (M-EDTA) versus H; and other, trisodium citrate (C) versus H. M-EDTA and C were also evaluated as to their safety versus H.

Methods: Thirty CKD 5D patients on high-efficiency hemodialysis (blood flow rate = 350 ml/min) at the Integrated Centre of Nephrology (Guarulhos, Brazil) were randomized 1:1:1 to receive M-EDTA, C or H locks for 15 weeks. Lock solutions concentrations were M-EDTA 30 mg/ml/3 mg/ml, C 30% (C) and H 1,000 U/ml and both investigators and patients were blinded to treatment allocation. The primary end-point was a 10% reduction in HD blood flow rates (35ml). The frequency of CRBSI was recorded. Bleeding and lock solution-related adverse events were the primary safety end points. Logistic Regression was performed to evaluate differences in PF rates among the treatments (SPSS version 13.0, IBM, USA).

Results: PF was significantly higher among patients on H (7/10) compared to C (3 /10) and M-EDTA (1/10) locks, according to results of Logistic Regression comparison: H vs C (p=0.082); H vs M-EDTA (p=0.016). Heparin was associated with the highest rate of PF. M and C lock solutions had similar PF rates. Only one CRBSI was identified in a patient on receiving a C lock. No bleeding or adverse events were identified. There was no difference in CRBSI prevention.

Conclusions: M-EDTA and C seem may preserve catheter patency. A larger clinical trial is being conducted in order to confirm these findings and to further evaluate CRBSI rates.

Funding: Government Support - Non-U.S.

TH-PO672

Long-Term Outcomes After Renal Artery Stenting Among Diabetic and Non-Diabetic Patients with Renal Artery Stenosis

Happy Farouk Sadiek, Amol Mittal, Shraddha Narechania, Bassel Akbik, Gaurav Kistangari, Arash Rashidi. *[1]Internal Medicine, Cleveland Clinic-Fairview Hospital, Cleveland, OH; [2]Internal Medicine, Cleveland Clinic-Fairview Hospital, Cleveland, OH; [3]Internal Medicine/Nephrologist, Cleveland Clinic-Fairview Hospital, Cleveland, OH.*

Background: The current study aims to determine if renal-artery stenting affects mortality and/or delays the onset of Renal Replacement Therapy over a 10 year period in diabetic and non-diabetic patients with renal artery stenosis (RAS).

Methods: Using electronic medical records of Cleveland Clinic Health System, 168 patients with a diagnosis of RAS were identified from 01/01/2000 to 12/31/2004. Patients were categorized into two groups - "stented" for those who underwent renal artery stenting and "medical" for those who were treated with medical therapy alone. The primary outcome was time to death. The secondary outcome was a composite end point of death or the need for renal replacement therapy.

Results: Out of 168 patients, 67 were in 'stented' group and 101 in 'medical' therapy group; diabetic patients represented 24% in the stented group and 38% in the medical group. Overall, a higher percentage of deaths were seen in 'stented' group (64% vs. 42%, p 0.02). Multivariable analysis revealed CKD stage=>3 as the only variable significantly associated with death (HR 2.45, 1.32-4.85, p 0.003). In another analysis - bilateral renal artery stenosis, CKD stage =>3 and DM were found to be significantly associated with the occurrence of composite end point of RRT and/or death. On subgroup analysis among diabetics, multivariable analysis revealed mortality benefit among patients who underwent renal artery stenting (HR 0.15, 0.03-0.55, p 0.006) when compared to 'medical' therapy alone; and a trend towards delaying the onset of composite end point (HR 0.28, 0.06-1.11, p 0.07).

Conclusions: Renal-artery stenting in RAS did not confer any benefit in terms of survival or delaying the onset of RRT; however stenting of renal arteries in diabetics showed a survival benefit and may have some benefit in delaying the onset of RRT. Further research is warranted to confirm these findings.

Oral versus Intravenous Hydration to Prevent Contrast Induced Nephropathy

Corinne E.A. Balemans,[1] Yvonne R.P. de Waal,[1] Jan A.J.G. van den Brand,[1] Marc A.G.J. Ten Dam,[2] Louis J.M. Reichert,[3] Jack F. Wetzels.[1] *[1]Nephrology, Radboud Univ Nijmegen Medical Center, Nijmegen, Gelderland, Netherlands; [2]Nephrology, Canisius-Wilhelmina Hospital, Nijmegen, Gelderland, Netherlands; [3]Nephrology, Rijnstate Hospital, Arnhem, Gelderland, Netherlands.*

Background: Contrast Induced Nephropathy (CIN) complicates the use of iodinated contrast media. Guidelines advise identification of high risk patients and intravenous hydration as preventive measure. We conducted a multicenter randomized controlled trial to compare oral (home) hydration versus standard therapy (NCT01654328). The trial was stopped prematurely because of a low recruitment rate.

Methods: Patients with an eGFR<60ml/min/1.73m^2 were stratified for risk of CIN based on eGFR and the presence of risk factors (diabetes, peripheral arterial disease, heart failure, age, anemia, use of diuretics or NSAID's) Exclusion criteria were: overhydration, use of ^{3}2 diuretics, severe heart failure, CKD stage V. High risk patients were randomized. Arm A: sodiumchloride 1g/10kg of body weight/day per os on day -2 and -1 before contrast exposure. Maximum 10g sodiumchloride/day. Arm B: NaCl 0.9% 1000ml in 4 hrs or (in case of heart failure or severe renal failure) 12 hrs before and after contrast administration. We evaluated the incidence of CIN (defined as a rise in serum creatinine ^{3}25% or ≥44umol/L 48-96hrs after contrast) and adverse events.

Results: From Aug 2012 until Nov 2014 there were 1593 radiological procedures in high risk patients. In 1116 the inclusion criteria were met. Only 255 patients gave informed consent. We evaluated 233 procedures (11 missing data, 7 intercurrent hospitalisation, 4 severe nausea and vomiting.) (table 1) provides clinical characteristics and outcome data. Nausea was a frequent complaint during oral hydration. One SAE (overhydration) was related to IV hydration.

	Oral N=154	IV N=79	P
Female	48(31%)	28(35%)	0.56
Age(yrs)	71±9	67±14	0.02
eGFR(ml/min/1.73m^2)	47±16	44±9	0.05
CIN	3(1.9%)	1(1.3%)	1.00
SAE	5	2	1.00

Conclusions: Oral hydration is as effective as intravenous hydration in preventing CIN. Oral hydration obviates the need for hospital admission, and thus reduces costs. Adaptation to the protocol is needed to prevent nausea and vomiting.

TH-PO674

Obstructive Sleep Apnea and Blood Pressure and in Patients with Hypertension and Chronic Kidney Disease, Stage 2

Bodil Gade Hornstrup,[1,2] Jeppe B. Rosenbaek,[1,2] Nikolai Hoffmann-petersen,[1,2] Pia Holland Gjørup,[2] Jost Wessels,[2] Erling B. Pedersen,[1,2] Jesper N. Bech.[1,2] *[1]Univ Clinic of Nephrology and Hypertension, Regional Hospital West Jutland and Aarhus Univ; [2]Dept of Internal Medicine, Regional Hospital West Jutland, Holstebro, Denmark.*

Background: High nocturnal blood pressure (BP) and non-dipping are important prognostic factors in the evaluation of the risk of cardiovascular disease in patients with hypertension (HT). Many patients with chronic kidney disease (CKD) suffer from high nocturnal BP and non-dipping. The mechanism behind this phenomenon is unknown, but might be related to the presence of obstructive sleep apnea (OSA). In general population, OSA is observed in 10-15% of men and 5-8% of women, only symptomatic in 2-4%.

Methods: From a population study in Holstebro County, 238 subjects diagnosed with HT and CKD stage 2 were invited to participate. 70 subjects were included and underwent conventional 24-h ambulatory BP monitoring (ABPM) and applanation tonometry to monitor central BP (HealthSTATS BPro), 24 h urine collection for microalbuminuria, blood samples for creatinine, and cardiorespiratory monitoring to determine apnea hypopnea index (AHI). HT, nocturnal HT, resistant HT and non-dipping were defined according to current guidelines. OSA was diagnosed when AHI > 5.

Results: Of the 70 subjects, 27 (39%) were diagnosed with OSA (average AHI 16,5). The subjects suffering from OSA were more obese, had lower mean oxygen saturation and longer snoring time during sleep. There were no difference between subjects with and subjects without OSA in regard to age, gender, eGFR, u-albumine, number of antihypertensive agents, weekly alcohol intake, Epworth score, and lung function. Subjects with OSA tended to have higher clinic BP, average 24 h BP, nocturnal BP, central BP both 24 h, day and nocturnal. In addition a tendency was measured towards higher frequency of resistant HT and non-dipping in OSA.

Conclusions: The occurrence of OSA in a population with hypertension and CKD stage 2 was larger than expected in general population. In subjects with OSA, there was a tendency towards higher central and brachial BP. It is suggested, that OSA is the cause of high BP in patients with CKD stage 2.

Structured Exercise in Obese Diabetic Patients with Chronic Kidney Disease: A Randomized Controlled Trial (NCT01036490) David J. Leehey,[1,2] Eileen Collins,[1] Holly J. Kramer,[1,2] Cheryl Cooper,[1] Jolene Butler,[1] Conor Mcburney,[1] Christine Jelinek,[1] Susan Oconnell.[1] *[1]Research, Hines VA Hospital, Hines, IL; [2]Medicine, Loyola Univ Medical Center, Maywood, IL.*

Background: Patients with type 2 diabetes, obesity, and chronic kidney disease (CKD) are generally physically inactive and may benefit from an exercise program. However, there have been few randomized controlled trials to determine the benefits of exercise training in this population.

Methods: We hypothesized that exercise training in obese diabetic patients with CKD will improve physical fitness and stabilize renal function. This was a 52-week randomized controlled study. Inclusion criteria were type 2 diabetes, obesity (body mass index > 30 kg/m^2), CKD (stage 2-4), and persistent proteinuria (> 200 mg/day for at least 3 months). Subjects were randomized to a control group consisting of dietary management alone (CON) vs. dietary management plus 12 weeks of exercise training followed by 40 weeks of supervised home exercise (EX).

Results: 46 subjects were enrolled, of whom 36 (n=18 in each group) completed at least the 12-week evaluation. At baseline, mean values (± SD) were as follows: age 70.0 ± 8.0 years, body mass index (BMI) 36.9 ± 4.5 kg/m^2, body fat 41.3 ± 6.6%, glycated hemoglobin (HbA1c) 8.0 ± 1.8%, eGFR 39.9 ± 19.0 mL/min/1.73m^2, and urinary albumin excretion rate (UAE) 1118 ± 1236 mg/24h. Average symptom-limited treadmill time was 7.8 ± 3.8 minutes and peak oxygen consumption (VO_2 peak) was 13.2 ± 3.4 mL/kg/min. Treadmill time was increased from baseline at both 12 weeks and 52 weeks in EX but not in CON ($p < 0.05$). Change from baseline in eGFR was somewhat less in the EX than in the CON group at both 12 weeks (0.2 ± 4.7 vs. -3.4 ± 8.9 mL/min/1.73m^2) and 52 weeks (-2.0 ± 5.8 vs. -3.1 ± 6.0 mL/min/1.73m^2), though this did not reach statistical significance. No changes were seen between the groups in the other parameters.

Conclusions: Obese diabetic subjects with CKD have markedly impaired physical fitness. A structured exercise program improved exercise capacity but did not affect renal function.

TH-PO676

Strength Training Intervention in Patients with Advanced Chronic Kidney Disease: A 20 Week Pilot Study Jordana B. Cohen,[1] Erica D. Palmer,[1] Angela M. Sheridan,[1] Brenden David Connor,[1] Mary B. Leonard,[2] Kathryn H. Schmitz,[1] Francis Perry Wilson.[3] *[1]Univ of Pennsylvania, Philadelphia, PA; [2]Stanford Univ, Stanford, CA; [3]Yale Univ, New Haven, CT.*

Background: Although chronic kidney disease (CKD) is highly associated with sarcopenia and poor functional status, the feasibility and impact of longitudinal strength training in subjects with advanced CKD is not well understood.

Methods: Patients took part in a predominantly home-based 20 week program with 60 minutes of resistance training three times per week. We measured dual-energy X-ray absorptiometry (DXA) assessment of appendicular lean mass (ALM), bio-electrical impedance analysis (BIA) of fat free mass (FFM), 1 repetition-maximum (1RM) assessment of maximum quadriceps strength, short-physical performance battery (SPPB) assessment of functional status, 24-hr urine creatinine collection (UCr), and Kidney Disease and Quality of Life Short Form (KDQOL-SF) in individuals >=45 and <80 years of age with baseline eGFR >=15 and <=45 mL/min/1.73m^2. We used paired t-testing and Wilcoxon sign-rank to assess for changes in within-subject measurements before and after the intervention period as well as change-on-change analyses.

Results: 22 subjects completed the training program. The median age was 71 years, 63% were male, median eGFR was 27.9 mL/min/1.73m^2, and median BMI was 29.2 kg/m^2. There was a significant improvement in 1RM (mean difference 15.9 kg +/- 6.5, p=0.03), but no significant change was appreciated in ALM (p=0.99), FFM (p=0.99), SPPB score (p=0.67), 24-hr urine creatinine (p=0.22), eGFR (p=0.26) or KDQOL-SF score (p=0.78). There was a significant decrease in AST (p=0.01), ALT (p=0.01), and total bilirubin (p<0.01). There was also a significant association between within-subject improvement in 1RM and improvement in FFM (p=0.02).

Conclusions: In this small study of patients with advanced CKD, we successfully developed a predominantly participant-driven strength training program. The significant improvement in 1RM indicates that patients were adherent with the protocol, however larger studies are needed to assess for the effect of strength training on anthropomorphic measures, serologic measures, and quality of life.

TH-PO677

Effect of a Medication Management Intervention on Acute Care Utilization After Hospitalization in CKD Katherine R. Tuttle,[1,2,3] Radica Z. Alicic,[1,3] Robert Short,[1,2] Joshua J. Neumiller,[2] Kenn B. Daratha,[2,3] Brian J. Gates,[2] Cynthia F. Corbett.[2] *[1]Providence Health Care; [2]Washington State Univ; [3]Univ of Washington.*

Background: People with chronic kidney disease (CKD) are hospitalized often and incur high risk of readmission.The study objective was to test the effect of a medication management intervention during the hospital-to-home transition on subsequent acute care utilization.

Methods: A single-center, randomized, controlled clinical trial of an intervention to improve medication information transfer (MIT) was conducted by pharmacists in participants' homes within the first week of hospital discharge and compared to usual care. Hospitalized participants with CKD stages 3-5 (not treated by dialysis or transplant) were enrolled. The primary outcome was a composite of hospital readmissions and visits to emergency departments or urgent care centers within 90 days of discharge.

Results: Enrollee (n=182) characteristics included: age 69±11 (mean±SD) years; women 48%; diabetes 56%; hypertension 83%; eGFR (CKD-EPI creatinine) 41±14 ml/min/1.73m^2; albuminuria 43 (4,521; median, IQ range) mg/g creatinine. The 3 top categories of primary diagnoses for hospitalization were cardiovascular disease (30 %), infection (19 %), and kidney disease (14 %). Enrollees lost before the baseline visit (n=41, mainly due to severe illness) were not included as active study participants. In intent-to-treat analysis (n=141), the primary outcome occurred in 32/72 (44 %) of the MIT group and 28/69 (41 %) of those in usual care (Kaplan Meier, log-rank p=0.72). At 90 days post-discharge, achievement of guideline-based CKD goals did not differ significantly between MIT and usual care groups: blood pressure <140/90/<130/80 mm Hg in those without/with albuminuria, respectively (43 % vs 50 %); hemoglobin A1c <7.5 % in diabetic participants (69 % vs 76 %); hemoglobin >11 g/dl (81 % vs 83 %); and phosphorous <5 mg/dl (97 % vs 96 %).

Conclusions: A medication management intervention conducted during the hospital-to-home transition did not reduce subsequent acute care utilization for hospitalized people with CKD. This high-risk population may require more comprehensive interventions to improve outcomes after hospitalization.

Impact of Decision Making Tools Use at the Time of Modality Choice and PD Take on in a Multicentre-Multinational Setting Belen Marron,[1] Janusz Ostrowski,[2] Delia Timofte,[3] Marietta Torok,[4] Jose C. Divino-Filho.[1] *[1]Diaverum Home Therapies. Medical Office, Diaverum, Munich, Germany; [2]Wloclawek Diaverum Clinic, Diaverum, Wloclawek, Poland; [3]Sema Diaverum Clinic, Diaverum, Bucharest, Romania.*

Background: Different factors have been attributed to low PD take on such as late referral, unplanned start, physician bias towards PD, large HD availability and lack of patient´s choice. Some references apply for 50% of PD if a good modality information is provided. Objectives: To analyze the impact of a structured modality information program with the use of decision making tools (DMTs) on type of modality choice and start.

Methods: Observational, prospective, multicentre and multinational experience. All patients under ESRD 4-5 and/or after an unplanned dialysis start if non-informed before were recruited to undergo a DMT process for RRT choice. Process included: personal values evaluation, RRTs information with different tools, deliberation and patient´s modality election.

Results: 444 patients, mean age 61,5 y. from 31 clinics in Poland, Hungary and Romania underwent a DMTs evaluation between August-December 2014.Staff considered PD as contraindicated in 45% of Polish patients, 32% in RO and 24% in HU. Reasons behind were mix causes and "other" than abdominal or mental. Home orientation was stated for 30% (PL), 40% (RO) and 54% (HU). Written information was largely used for 71 to 97% of patients; DVD in 9-21% and in centre HD/PD touring visits in 31-75%. PD as elected modality varied among countries: 10% (RO), 21% (PL) and 35% (HU). For patients who started dialysis (n= 163), PD was used in 10% (RO), 14% (PL) and 36% (HU).

Conclusions: Use of DMTs at the time of RRT modality choice is encouraging and complies with patient´s empowerment. An increase in PD take-on has been observed in our institution after DMTs use. However, when compared with other references, our patient´s PD election is still low and factors behind this fact needs to be elucidated with a larger recruitment pool (in process).

TH-PO679

Thrombotic Microangiopathy And Complement Factor C4d Predict Poor Prognosis in IgA Nephropathy and Henoch-Schönlein Purpura Nephritis Jamie S. Chua,[1] Malu Zandbergen,[1] Johan W. De Fijter,[2] Ron Wolterbeek,[3] Jan A. Bruijn,[1] Ingeborg M. Bajema.[1] *[1]Pathology, LUMC, Leiden, Netherlands; [2]Nephrology, LUMC, Leiden, Netherlands; [3]Medical Statistics, LUMC, Leiden, Netherlands.*

Background: Thrombotic microangiopathy (TMA) was previously reported to be clinically relevant and underdiagnosed in IgA nephropathy (IgAN). Complement factor C4d is a common denominator of TMA. Aim: to validate the prevalence of TMA and to determine the clinical significance of TMA and C4d in IgAN and Henoch-Schönlein Purpura Nephritis (HSN).

Methods: We included 129 native renal biopsies from 2003-2013; IgAN in 82% and HSN in 18%. Biopsies were classified according to Oxford MEST-scores, scored for vascular lesions including TMA, arterial intimal sclerosis and arteriolar hyalinosis, and immunostained for C4d. Retrospectively collected clinical data included hypertension and renal function. Three groups were distinguished: absence of both TMA and C4d; presence of both TMA and C4d; and presence of either TMA or C4d. Changes in eGFR over time were compared using a linear mixed model. Renal survival was analyzed with Cox regression. Prognostic values of C4d, TMA and hypertension for renal survival were analyzed with multivariable Cox regression.

Results: The prevalence of TMA in this cohort was 20% (n=26). TMA was mainly chronic (65%; 17/26) and was localized in arterioles (81% of TMA cases), glomeruli (15%) or both (4%). TMA was associated with interstitial fibrosis and tubular atrophy, arterial intimal sclerosis, hyalinosis and hypertension (p-values<0.05). TMA was strongly associated with the presence of C4d deposits (p<0.001). Linear Mixed Model analysis: patients with hypertension and both C4d and TMA had significantly lower eGFR (mean decrease 24 and 40 ml/min/1.73m^2 respectively). Patients with both TMA and C4d had significantly worse renal survival than the two groups without both C4d and TMA (HR 6.33 and 3.38 resp.) corrected for hypertension (HR 4.52 and 3.30 resp.).

Conclusions: The prevalence of TMA in IgAN and HSN is substantial (20%) but lower than previously reported. TMA was mainly chronic, arteriolar and associated with C4d, hypertension and chronic lesions. TMA and C4d mark poor renal function and poor renal survival in IgAN and HSN.

TH-PO680

Glomerular Complement Factor C4d Marks Glomerular Basement Membrane Duplications: C4d Beyond Antibody Induced Injury

Jamie S. Chua,[1,2] A. Gasim,[2] Ron Wolterbeek,[1] Harsharan Kaur Singh,[2] Volker Nickeleit.[2] *[1]LUMC, Leiden, Netherlands; [2]UNC, Chapel Hill, NC.*

Background: C4d deposits along peritubular capillaries (ptc) mark antibody mediated rejection (ABMR) in renal allografts. The diagnostic significance of linear C4d deposits along glomerular basement membranes (GBM-C4d), which can occur as isolated event, is poorly understood. **Hypothesis**: GBM-C4d, especially when isolated, is not a sign of ABMR but rather a marker of structural GBM changes and duplications in native kidneys and renal transplants.

Methods: We analyzed 319 renal allograft biopsies from 219 patients. GBM remodeling was analyzed by light (Banff cg-score) and by electron microscopy. Linear C4d staining by immunohistochemistry (IHC) and immunofluorescence (IF) was scored along the GBM and ptcs. Controls: native kidneys with minimal change disease (n=10) and chronic thrombotic microangiopathy with GBM duplications (n=26).

Results: Transplants: GBM duplications/transplant glomerulopathy (TG) occurred in 52/319 biopsies (16%). By IF, 49/52 (94%) TG cases had GBM-C4d; 36/49 (73%) had isolated GBM-C4d lacking ptc-C4d deposits. By IHC, 74% of TG cases had GBM-C4d; 60% of which as isolated event. GBM-C4d staining intensity correlated with Banff cg-scores (IF: rs=0.453, p<0.01; IHC: rs=0.478, p<0.01). 80% of cases (24/30) with GBM duplications present only by electron microscopy revealed GBM-C4d. Association GBM-C4d with TG/GBM duplications: p<0.001. Statistical significance between GBM-C4d staining and structural GBM duplications remained after omitting cases with presumed or definitive ABMR (DSA-positivity, C4d positivity in ptcs,transplant glomerulitis). Multivariate logistic regression: GBM duplication/TG was an independent predictor of GBM-C4d positivity. **Native kidneys**: GBM-C4d occurred in 24/26 (92%) cases with thrombotic microangiopathy and GBM duplications; no staining was seen in minimal change disease.

Conclusions: The diagnostic significance of linear C4d deposits along ptc versus GBM differs. C4d along ptc marks ABMR while linear GBM-C4d is associated with structural GBM duplications in native and transplanted kidneys, independent of the etiology or antibody induced injury. In transplants GBM-C4d serves as marker for TG.

TH-PO681

Predicting Outcome in Patients with Anti-GBM Glomerulonephritis Using the Histopathological Classification for ANCA-Associated Vasculitis: Preliminary Results

Emma Elisabeth Van Daalen,[1] J. Charles Jennette,[2] Jan A. Bruijn,[1] Ingeborg M. Bajema.[1] *[1]Pathology, Leiden Univ Medical Center, Leiden, Netherlands; [2]Pathology and Laboratory Medicine, Univ of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: The renal biopsy in anti-glomerular basement membrane glomerulonephritis (anti-GBM GN) is characterized by crescent formation. No histopathological classification has been implemented for the disease. We have applied the histopathological classification for ANCA-associated vasculitis (AAV) to see whether this classification can distinguish patients regarding renal outcome.

Methods: We analyzed biopsies of 20 patients, diagnosed with anti-GBM GN between 1984 and 2014 at a university hospital in the Netherlands. We classified these biopsies according to the histopathological classification for AAV: sclerotic (≥50% sclerotic glomeruli), focal (≥50% normal glomeruli), crescentic (≥50% cellular crescents) or mixed (no dominant lesion) class. We collected data on serology, renal function and end-stage renal disease (ESRD) during 5-year follow-up.

Results: Fourteen biopsies (70%) were categorized as crescentic, three (15%) as focal, two (10%) as mixed and one (5%) as sclerotic. Mean age was 47.4 years (SD: 17.1, range: 17.0-74.9) and differed between classes (P=0.039), with the focal class having the youngest patients with a mean age of 25.4 years. Estimated glomerular filtration rate (eGFR) at time of biopsy differed between classes (P<0.001), focal class having a mean of 80.2 ml/min/1.73m^2, crescentic 6.9 and mixed 8.7 (no available data for sclerotic class). Mean eGFR at 1 year was 107.6 in the focal, 10.1 in the crescentic, and 21.8 in the mixed class (P<0.001).The occurrence of ESRD differed between groups (P=0.016), with no occurrence in the focal group .

Conclusions: These preliminary results show that the histopathological classification for AAV is useful for anti-GBM GN, predicting outcome in terms of eGFR at time of biopsy and at 1 year after biopsy. The focal group had more favorable outcomes regarding renal function and development of ESRD.

TH-PO682

The Role of C4d Immunohistochemistry to Highlight Immune Complex Deposition in IgA Nephropathy

Umer Sheikh,[1] Hong Qu,[2] Alton Brad Farris,[1] Thomas E. Rogers,[1] Carla L. Ellis.[1] *[1]Pathology, Emory Univ Hospital and School of Medicine, Atlanta, GA; [2]Pathology, St. John Hospital and Medical Center, Detroit, MI.*

Background: IgA glomerulonephropathy (IgAN) is one of the most common immune complex associated nephropathies worldwide. It may develop de novo or recur in an allograft. Recently, C4d immunohistochemistry has been show to highlight immune complex deposits in a variety of glomerular diseases. Limited conclusive data is available regarding the utility of C4d immunohistochemistry to highlight mesangial deposits in IgAN despite some authors claim to the contrary. The presence of this finding would be beneficial in cases where immunofluorescence studies are unavailable. Our study seeks to determine the ability of C4d immunohistochemistry to highlight mesangial, IgA dominant immune complex deposition.

Methods: A retrospective study from two institutions is performed. 24 cases (19 native and 5 allografts) from one and 36 native cases from the other of IgAN diagnosed between the years of 2005 and 2012 were selected (n=60). All cases were confirmed IgAN by immunofluorescence and electron microscopy. Paraffin-embedded tissue sections from all biopsies were then stained for C4d immunohistochemistry by each respective institutional protocol. Cases from each institution were reviewed by the respective senior author for the presence, intensity and location of glomerular staining by the C4d antibody.

Results: All native and allograft cases of IgAN from both institutions showed complete absence of mesangial C4d immunoreactivity with some non-specific tubular epithelial staining in some cases and some low intensity, segmental capillary wall staining in others. Control tissue reacted appropriately.

Conclusions: Our results suggest that at least in our small cohort spanning two academic medical centers, the utility of C4d immunohistochemistry to support a diagnosis of IgAN in the native or allograft population is limited despite recent evidence of C4d deposition in immune complex associated disease. Although complement deposition with C3 is typically seen in IgAN, C4d deposits are not identified, suggesting the lack of this specific complement factor in IgAN.

TH-PO683

DNA Methylation as a Biomarker of Disease Status in Patients with ANCA-Associated Vasculitis

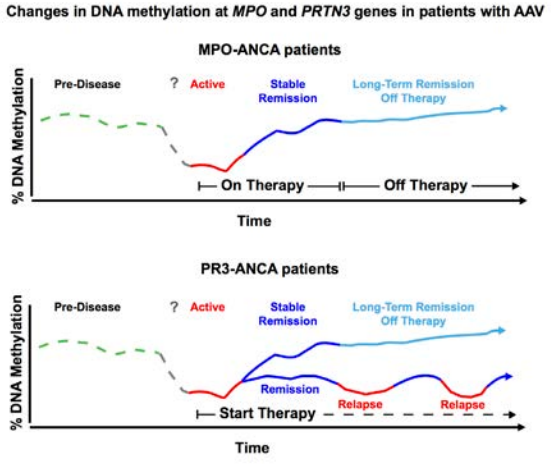
Britta E. Jones, Jia Jin Yang, Akhil Muthigi, Susan L. Hogan, Joshua Starmer, Candace Henderson, Elizabeth J. Brant, JulieAnne G. McGregor, William Franklin Pendergraft, Ronald J. Falk, Dominic J. Ciavatta. *Univ of North Carolina at Chapel Hill-Kidney Center.*

Background: ANCA-associated vasculitis (AAV) is associated with environmental exposures and age, both of which are linked to changes in DNA methylation. We tested whether DNA methylation changes in patients compared to healthy controls and if DNA methylation may be used as a biomarker of disease status.

Methods: AAV patients (67) were followed longitudinally through disease activity and remission (143 leukocyte samples), including 21 patients in long-term remission off therapy and 32 healthy individuals. DNA methylation was measured using mass spectrometry and bisulfite sequencing at myeloperoxidase (*MPO*) and proteinase 3 (*PRTN3)*. Expression was measured for *MPO*, *PRTN3* and DNA methyltransferase 1 (*DNMT1*).

Results: Patients with active AAV were hypomethylated compared to healthy individuals. Within paired active and remitting patients, MPO-ANCA and half of PR3-ANCA patients showed increased DNA methylation. In PR3-ANCA patients with increased methylation in remission, DNA methylation correlated with expression of *MPO* and *PRTN3,* and stable remission. *DNMT1* expression in leukocytes from active and remitting patients was 0.6 fold and 0.8 fold, respectively, of healthy individuals. At *MPO* and *PRTN3* there is a positive correlation between DNA methylation and *DNMT1* expression.

Conclusions: AAV patients are characterized by dynamic changes in DNA methylation; differences in methylation during disease remission suggest these fates have an epigenetic basis.



MPO-ANCA patients restore DNA methylation in remission, while chronically relapsing PR3-ANCA patients may benefit from therapies that increase DNA methylation. These data suggest that DNA methylation in leukocytes may function as a biomarker of disease status in AAV.

TH-PO684

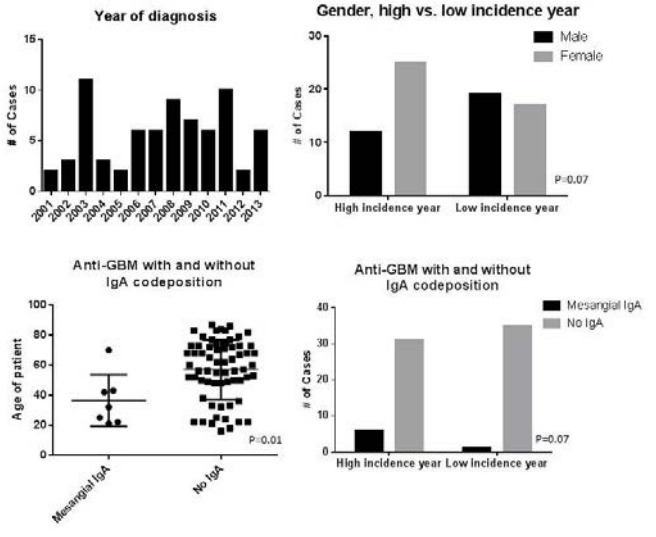
Epidemiologic Features of Anti-Glomerular Basement Membrane Disease

Nicole K. Andeen,[1] Anthony Chang,[2] Shreeram Akilesh.[1] *[1]Pathology, Univ of Washington; [2]Pathology, Univ of Chicago.*

Background: Anti-glomerular basement membrane (anti-GBM) disease is a rapidly progressive glomerulonephritis mediated by autoantibodies to the noncollagenous domain of the alpha-3 chain of type IV collagen. Previous reports demonstrated an association with a seasonal or environmental exposures in some cases (PMID: 4604010, 3256901). We sought to understand epidemiologic factors associated with anti-GBM disease.

Methods: Reports from consecutive cases of anti-GBM diagnosed at the University of Washington were retrospectively reviewed, with specific attention to epidemiologic parameters. Statistical analysis was performed on Graphpad Prism using Fisher's exact and Mann-Whitney tests.

Results: Seventy three (M=31; F=42) cases of anti-GBM disease were identified, with a median age of 56 years. Overall, 2 to 11 cases were seen per year (median = 6); a high incidence year was defined as > median number of cases. 60% of cases were diagnosed in winter or spring (95% CI: 48-72%), and 40% in summer or fall (95% CI 28 – 52%). The M:F ratio was 1:2 in high incidence years, but nearly 1:1 with a male predominance in low incidence years (p=0.07). Of variables studied, concurrent deposition of IgA in the mesangium was associated with younger age at diagnosis (p=0.01); 6 of 7 of these were seen in a high-incidence year (p=0.07). No associations among ANCA-positivity vs. respiratory symptoms, age, sex, and/or season of presentation were identified.



Conclusions: There were quantitative and qualitative differences in epidemiologic parameters in anti-GBM disease. Unlike low incidence years, cases diagnosed in high incidence years showed a trend for increased likelihood of concurrent mesangial IgA deposition, and male gender. The findings suggest potential differences in the environmental and/or gender-based triggers in the development of anti-GBM.

TH-PO685

The Lumped System Utilized in the Japanese Histological Grade Classification of IgA Nephropathy May Produce a Score with a Broader Applicability Compared to the Split System of Oxford Classification

Kensuke Joh,[1] Akinori Hashiguchi,[2] Akira Shimizu,[3] Ritsuko Katafuchi,[4] Tetsuya Kawamura.[5] *[1]Dept of Pathology, Tohoku Graduate School of Medicine, Sendai-City, Miyagi-ken, Japan; [2]Dept of Pathology, Keio Univ School of Medicine, Tokyo, Japan; [3]Dept of Pathology, Nihon Medical School, Tokyo, Japan; [4]Div of Internal Medicine, Fukuoka Higashi Medical Center, Fukuoka, Japan; [5]Div of Kidney and Hypertension, Jikei Univ School of Medicine, Tokyo, Japan.*

Background: Japanese Histological Grade Classification (JHGC; HG1-HG4) (J Nephrol, 2013) and Oxford classification (Oxford) were compared with a focus on their ability to predict renal functional decline (RFD) and proteinuric remission (PUR).

Methods: 411 Japanese with IgAN (male 49%) were collected from 32 centres in Japan. The patients, whose median age was 36.2 years old, were prospectively followed for a median of 36 months. The average amount of initial proteinuria (PU) was 0.8 g/day. Mean eGFR was 77.9±29.6 ml/min/1.73m^2 and median rate of decline in eGFR was -0.7 ml/min/1.73m^2.

Results: 24 % and 55% of patients received steroid and RAS blockade, respectively. The ICC among 5 observers on M, E, S, T, and HG scores were fair or good. In multivariate Cox analysis, hazard ratio (HR) of MEST in Oxford for 1.5 time's increase of serum creatinine (sCr) was not significant, whereas HG3 and HG4 in JHGC were significant (HR of 13 and 42, respectively) even after adjustment by steroid, RAS blockade, initial PU, initial eGFR, and initial MAP ($p<0.05$). When comparing HG, M, E, S and T, HG score was the only independent predictor in isolation or in comparison to varied combinations of MEST parameters. The HR for PUR (an endpoint of proteinuria as 0.3 g/day) was not significant in Oxford, whereas HG3, initial MAP and steroid were independent predictors with HR as 0.4, 0.9, and 1.7, respectively ($p<0.05$).

Conclusions: HG score was more effective than Oxford in predicting both RFD and PUR in the Japanese cohort consisting of earlier stage of IgAN. The inherent flexibility in a lumped approach (JHGC) as opposed to a split system (Oxford) may make the HG score more robust when being applied to diverse cohorts allowing a wider application of scoring.

TH-PO686

Prospective Cross-Sectional and Longitudinal Observational Study of Urinary Podocyte Markers and Urinary Megalin in Kidney Disease of ANCA-Associated Vasculitis

Hiroshi Kajiyama,[1] Keiju Hiromura,[2] Daisuke Ikuma,[1] Junya Suwa,[2] Hidekazu Ikeuchi,[2] Hiroyuki Kurosawa,[3] Yoshiaki Hirayama,[3] Masanori Hara,[4] Akihiko Saito,[5] Yoshihisa Nojima,[2] Toshihide Mimura.[1] *[1]Dept of Rheumatology and Applied Immunology, Saitama Medical Univ, Iruma, Saitama, Japan; [2]Dept of Medicine and Clinical Science, Gunma Univ Graduate School of Medicine, Maebashi, Gunma, Japan; [3]Diagnositcs Research Dept, Denki Kagaku Kogyo K.K., Machida, Tokyo, Japan; [4]Dept of Pediatrics, Yoshida Hospital, Tsubame, Niigata, Japan; [5]Dept of Applied Molecular Medicine, Niigata Univ Graduate School of Medicine and Dental Sciences, Niigata, Japan.*

Background: The purpose of this study is to clarify the significance of urinary podocyte markers (urinary podocyte number (U-Pod/Cr) and urine podocalyxin (PCX) (U-PCX/Cr)) and urinary megalin (A-Meg/Cr, megalin's extracellular domain; C-Meg/Cr, full-length of megalin) in ANCA-associated vasculitis (AAV).

Methods: AAV patients (30 cases) were recruited from August 2009 to April 2014. Presence of proteinuria and/or reduced eGFR or histological renal diagnosis was defined as kidney disease (KD)(+). U-Pod/Cr, U-PCX/Cr, A-Meg/Cr and C-meg/Cr were measured around the treatment start (M0), and at 1 (M1), 3 (M3), 6 (M6) and 12 months (M12) after treatment.

Results: At M0, urinary protein creatinine ratio (U-PCR) was significantly higher, and eGFR was significantly lower in KD(+). CRP was not different between KD(+) and KD(-) at M0. U-Pod/Cr was significantly higher in KD(+), and U-PCX/Cr, A-Meg/Cr and C-Meg/Cr were not different at M0, although there was a trend of high C-Meg/Cr in KD(+), compared with KD(-). After treatment in KD(+), CRP (from M1 on), U-PCR, urinary-NAG (U-NAG)/Cr (from M3 on) significantly improved. U-Pod/Cr and C-Meg/Cr (from M6 on) were significantly improved after treatment in KD(+), and U-PCX/Cr and A-Meg/Cr were not significantly changed. Only the correlation of C-Meg/Cr with U-NAG/Cr (p=0.028, Spearman r:0.46, 95%CI 0.04-0.74) was significant between laboratory data and urinary markers measured at M0.

Conclusions: U-Pod/Cr and C-Meg/Cr are elevated in AAV kidney disease and improve after treatment. U-Pod/Cr and C-Meg/Cr may reflect podocyte and proximal tubular injuries, respectively, in AAV.

TH-PO687

Clinical and Histological Determinants of Renal Outcome in Lupus Nephritis Emilie Rijnink,[1] Suzanne Wilhelmus,[1] Mathilde M.M. Almekinders,[1] Ron Wolterbeek,[2] Jan A. Bruijn,[1] Ingeborg M. Bajema.[1] *[1]Pathology, Leiden Univ Medical Center; [2]Statistics, Leiden Univ Medical Center.*

Background: The ISN/RPS 2003 histopathological classification of lupus nephritis (LN) is based on lesions historically thought to be relevant for prognosis, but for some lesions the evidence base is lacking. Without preconceptions, we tested a wide range of histologic and clinical features to objectively identify prognostic indicators of renal outcome in patients with LN.

Methods: 42 histological and 7 clinical parameters were determined as candidate predictors of renal outcome. A cohort of patients was identified from the pathology archives of our center, diagnosed with any class of LN between 1990-2011. Renal biopsies were rescored for 42 histologic parameters. eGFR and proteinuria were recorded at time of renal biopsy, as well as during 1, 5, and 10 years of follow-up. For preliminary analyses, variables were tested using univariate mixed models, in which $p<0.05$ for fixed effects was considered statistically significant.

Results: Interim analysis was performed on 29 patients, of whom none developed end-stage renal disease. Significant associations with eGFR were found for age ($p=0.03$) and eGFR ($p<0.001$) at time of renal biopsy, percentage of normal glomeruli ($p<0.01$), percentages of glomeruli with mesangial hypercellularity ($p=0.05$), endocapillary hypercellularity ($p=0.03$), endothelial swelling ($p=0.03$), endocapillary mononuclear cells ($p=0.01$), wire loops ($p=0.02$), and cellular crescents ($p<0.05$), as well as the presence of an interstitial infiltrate ($p=0.04$). Significant associations with proteinuria were found for eGFR at time of biopsy ($p=0.02$), percentage of glomeruli with mesangial global sclerosis ($p=0.02$), presence of cellular and fibrocellular crescents ($p=0.01$), as well as the presence of an interstitial infiltrate ($p<0.01$) and tubular atrophy ($p=0.02$).

Conclusions: Besides histological parameters characteristic of the previously established classes of LN, also interstitial and clinical parameters may have prognostic significance. These and other features will be studied in an extended dataset in multivariate analyses of which the outcome may be relevant for future modifications of the LN classification.

TH-PO688

Specificity of Full House Immunofluorescence for Systemic Lupus Erythematosus Emilie Rijnink,[1] Yoe Kie Onno Teng,[2] Tineke Kraaij,[2] Jan A. Bruijn,[1] Ingeborg M. Bajema.[1] *[1]Pathology, Leiden Univ Medical Center, Netherlands; [2]Nephrology, Leiden Univ Medical Center, Netherlands.*

Background: The finding of full house immunofluorescence (IF) in combination with various histological lesions in renal biopsies of patients without overt systemic lupus erythematosus (SLE) poses a diagnostic challenge. We studied the clinical course of these patients as compared to patients who did have SLE at the time of biopsy.

Methods: Patients with full house IF on renal biopsy between 1968-2014 were identified from the pathology archives at our center. Clinical records were reviewed for the presence of ACR or SLICC criteria for the classification of SLE at the time of renal biopsy and during follow-up.

Results: 149 patients with full house IF on renal biopsy were identified. At time of biopsy, 112 had SLE according to >4 ACR criteria (SLE_{ACR}), 7 according to SLICC criteria (SLE_{SLICC}), and 30 did not fulfill criteria for SLE. Of the latter 30, one was classified as SLE_{SLICC} during follow-up. Survival without end-stage renal disease regardless of immunosuppressive therapy was better in the group of patients with $SLE_{ACR/SLICC}$ than in those without SLE ($p<0.01$). No difference was noted between patients with SLE_{SLICC} or SLE_{ACR} ($p=0.16$). Compared to patients with $SLE_{ACR/SLICC}$, patients without SLE were significantly more often male, had significantly higher serum creatinine, CH50, and C3, and had significantly less frequent anti-ENA, anti-SS-A, anti-RNP70, and anti-C1q. All SLE criteria were significantly more frequent in patients classified as $SLE_{ACR/SLICC}$, except for chronic cutaneous lupus, and oral/nasal ulcers.

Conclusions: This study demonstrates that the presence of full house IF in renal biopsies as a marker of biopsy-confirmed LN, has limited specificity for SLE. This contrasts with the SLICC classification, where biopsy-confirmed LN was seen as a highly specific feature of SLE. Our results show that patients with full house IF without SLE are clinically distinct from SLE patients. Consequently, for clinical and study purposes, a separate classification for these patients is warranted.

TH-PO689

Novel Urinary Tubular Biomarkers for Diagnosis and Predictive Active Lupus Nephritis Bancha Satirapoj, Panbubpa Choovichian, Ouppatham Supasyndh, Kulachon Leelasiri. *Medicine, Phramongkutklao Hospital and College of Medicine, Bangkok, Thailand.*

Background: Tubulointerstitial damage is important in the prediction and progression of lupus nephritis (LN). *Novel urinary tubular biomarkers included neutrophil gelatinase-associated lipocalin (NGAL), kidney injury molecule-1 (KIM-1) and periostin have been reported to increase in progressive kidney injury*. Therefore, these urinary biomarkers may relate and predict renal activity in systemic lupus erythematosus (SLE) patients.

Methods: We performed a diagnostic and prospective study in SLE patients with biopsy-proven active LN and with inactive LN. All patients were collected urine for *NGAL, KIM-1 and periostin measurement* by ELISA. After standard treatment in active LN patients, urinary biomarkers were repeated.

Results: A total of 67 patients with SLE including 35 patients with active LN and 32 patients without active LN were included. Urinary levels of KIM-1 was higher in active LN compared to inactive LN (median 2.17 (IQR; 0.92, 5.18) vs.0.29 (IQR; 0.13, 1.11) μg/g creatinine, *P<0.001*), while no significant difference was found in urinary NGAL and periostin levels. Urinary KIM-1, NGAL and periostin correlated positively with proteinuria, and only KIM-1 and NGAL correlated negatively with renal function. On ROC analysis, urinary KIM-1 (AUC; 0.80, 95%CI 0.69-0.92) outperformed conventional biomarkers (serum creatinine, urine protein, serum complements and anti-dsDNA antibody) in differentiating active LN from non-LN group. On follow-up after treatment in active LN patients (n = 19), there was no significant difference in all urinary tubular biomarkers between response and nonresponse LN patients.

Conclusions: Levels of urinary KIM-1, but not of urinary NGAL and periostin may be potentially useful markers of LN activity and urine KIM-1 is better performance than conventional markers of active LN. However, these novel tubular biomarkers are not predictive for a clinical response to treatment of active LN.

TH-PO690

Revisiting of Anti-Phospholipase A2 Receptor Antibodies and Its Antigen as Specific Biomarkers in Membranous Nephropathy Li Lin, Jing Xu, Xiaoxia Pan, Wen Zhang, Weiming Wang, Jingyuan Xie, Nan Chen. *Dept of Nephrology, Rui Jin Hospital, Shanghai Jiao Tong Univ, School of Medicine, Shanghai, China.*

Background: M-type phospholipase A2 receptor (PLA2R) as antigen in idiopathic membranous nephropathy (IMN) is a success model of fast-speed translational medicine. The objective of this study was to assess the prevalence and clinical value of serum antoantibodies against the M-type phospholipase A2 receptor (anti-PLA2R) in Chinese MN patients.

Methods: In this prospective study, 195 patients with MN including 37 MN patients with coexisting diseasesand 70 patients with other glomerular diseases were enrolled. Anti-PLA2R antibodies in serum were assessed by direct immunofluorescence assay (IFA). The staining of PLA2R in glomeruli was evaluated by standard immunofluorescence microscopy.

Results: Anti-PLA2R was only found in MN patients. PLA2R-related MN rate in MN was 87.23%, the positive rate of the serum anti-PLA2R and glomeruli PLA2R were 68.09% and 83.21%, respectively. PLA2R-unrelated MN patients had more coexisting diseases compared with PLA2R -related MN patients (61.11%vs 21.13%, $p=0.01$),but in MN patients with coexisting diseases, the rate of PLA_2R-related MN is 72.97%, thus we regard that PLA_2R in glomeruli or anti- PLA_2R in circulation is not suitable for discrimination of IMN and SMN. In 54 MN patients who have received treatment the positive rate for Anti-PLA2R was 8.33%, 31.58% and 69.57% in Complete remission (CR), Partial remission (PR), and disease active patients, respectively ($p=0.001$). More Anti-PLA2R positive patients at the start of the study developed nephrotic-range proteinuria(70.31%)compared to Anti-PLA2R negative PLA-related MN (53.85%) ($p=0.004$), but there was no statistical difference in remission rate during follow-up ($p=0.406$).

Conclusions: We confirm that anti-PLA2R antibody measured by IFA is specific detected in serum of MN patients but it is controversy as used in the differential diagnosis of IMN and as a biomarker to predict outcome of disease. the absence of predictive value may be due to the fact that you have not looked at quantitative data (would need ELISA or quantitative expression of IF data).

TH-PO691

Endoplasmic Reticulum Stress Marker Glucose-Regulated Protein 78 Instead of Calcineurin Expression within Kidney Is Predictive of Poor Response to Cyclosporine Treatment in Idiopathic Membranous Nephropathy Wei Zhang, Yu-bing Wen, Baobao Wang, Liangyan Zhang, Weifeng Lin, Jianling Tao, Limeng Chen, Hang Li, Mingxi Li, Xuewang Li, Xuemei Li. *Div of Nephrology, Peking Union Medical College Hospital, Peking Union Medical College & Chinese Academy of Medical Sciences, Beijing, China.*

Background: Cyclosporine (CsA) is effective to achieve 60-70% remission rate in treatment of idiopathic membranous nephropathy (IMN). Little is known if Endoplasmic Reticulum stress marker glucose-regulated protein 78(GRP78) within kidney before CsA treatment could predict post treatment outcome.

Methods: Seventy-six adult biopsy-confirmed IMN patients treated by CsA for at least six months from Peking Union Medical College Hospital from 1996 to 2014 were retrospectively reviewed. They were grouped into non-remission (NR) (n=12), partial remission (PR) (n=12), or complete remission(CR) (n=52) at the end of six month treatment of CsA with an initial CsA dosage (2.8±0.7 Mg/Kg/d). GRP78 in kidney and Calcineurin (CAL) expression in the kidney and serum were assayed by immunohistochemistry and ELISA, and their expressions were correlated with clinical outcome.

Results: Serum CAL and kidney CAL expression in IMN patients are significantly increased compared to healthy controls, although there is no difference in either serum or kidney CAL among NR, PR or CR groups. There is a negative correlation between serum CAL activity and renal CAL expression ($p=0.034$). However, glomerular GRP78 expression in NR group is significantly higher than CR group (Bonferroni correction $p<0.0083$). There is a positive correlation between kidney CAL expression and GRP 78 expression ($p<0.05$).

Conclusions: ER stress marker GRP78 expression in glomerular section of kidney instead of serum or kidney CAL expression could be an additional marker, which negatively predicts the clinical response to CsA treatment in IMN patients. New drugs targeting to alleviate ER stress in IMN could be developed to treat those non-responders to CsA. (Supported by National Natural Science Foundation of China 81170665 to Dr. Jianling Tao).

TH-PO692

Selected Reaction Monitoring for Quantification of Angiotensin-II Signature Proteins in Urine Ana Konvalinka,[1] Andrei Drabovich,[2] Xuewen Song,[1] York P. Pei,[1] James W. Scholey,[1] Eleftherios P. Diamandis.[2] *[1]Medicine, Div. of Nephrology, Toronto General Hospital, Toronto, ON, Canada; [2]Laboratory Medicine and Pathobiology, Lunenfeld Research Inst, Toronto, ON, Canada.*

Background: Angiotensin-II (AngII) mediates polycystic kidney disease progression. However, there are no specific markers of kidney AngII activity. We previously defined 83 AngII-regulated proteins *in vitro*, which reflected kidney AngII activity *in vivo*. We aim to quantify these proteins in urine using a mass spectrometry technique called selected reaction monitoring (SRM), and establish their role as markers of kidney AngII activity in patients with ADPKD.

Methods: We demonstrated that 47 of 83 AngII-regulated genes were differentially expressed in cystic vs normal kidney tissue. We then selected 18 AngII-regulated proteins upregulated in cystic tissue and/or present in urine. We developed SRM assays for 37 peptides corresponding to 18 AngII-regulated proteins. To assess reproducibility and recovery, we spiked in bovine serum albumin (BSA), and the corresponding heavy-labeled peptides. We determined an optimal method for detection of AngII-regulated peptides. Heavy peptides corresponding to 13 identified AngII-regulated peptides were purchased and spiked into urine. Ultimately, 20ug of total protein/sample was concentrated and analyzed on triple-quadrupole mass spectrometer. We quantified AngII-regulated peptides in urine samples of 9 ADPKD and 2 healthy subjects.

Results: Technical replicate CVs were <6% for BSA peptides, and recovery was ~100%. Calibration curves demonstrated linearity (R^2>0.99) and CVs<20% in the concentration range of 7/13 peptides in normal and ADPKD urines. Deamidated peptides accounted for 1-40% of total concentration. Peptides were quantified in all urine samples. Peptides corresponding to proteins TSP1, BST1, and LAMB2 had the highest excretion rate in urine of the only ADPKD patient with impaired GFR.

Conclusions: We have developed a protocol for SRM quantification of AngII-regulated proteins in urine. Seven AngII-regulated peptides were quantified in urine samples. Future studies will examine if urine excretion rate of AngII signature proteins is associated with cyst size and GFR in larger cohorts of ADPKD patients.

TH-PO693

Establishment of Proteomic Profiles of Normal Glomeruli Using Laser Microdissection and Mass Spectrometry Ying Sun,[1] Mingxi Li,[1] Yubing Wen,[1] Wei Sun,[2] Jian Sun,[3] Xuemei Li.[1] *[1]Dept of Nephrology, Peking Union Medical College Hospital, Beijing, China; [2]Dept of Core Instrument Facility, Inst of Basic Medical Sciences, Inst of Basic Medical Sciences, Chinese Academy of Medical Sciences, Peking Union Medical College, Beijing, China; [3]Dept of Pathology, Peking Union Medical College Hospital, Beijing, China.*

Background: Laser microdissection combined with mass spectrometry (LMD/MS) has become an powerful tool in proteomics study. There is little data of normal glomeruli proteomic profiles which are fundamental in the study of differential proteomics of kidney diseases. Our study aimed on establishing proteomic profiles of normal glomeruli from formalin-fixed paraffin-embedded (FFPE) specimen through LMD/MS.

Methods: Normal kidney cortices were obtained from four patients underwent nephrectomy due to renal carcinoma. 10-mm FFPE sections were prepared for laser microdissection, 4-6 glomeruli were cut out each case and collected for digestion. Peptides were quantified using Thermo Scientific LTQ Orbitrap Velos mass spectrometer. MASCOT software was used for identification of proteins, with tandem mass spectrometry data searching against UniProt. Scaffold 4 software was used to integrate results, taking proteins with credibility of ≥95% and identified peptides number > 1 into statistics.

Results: 67 proteins were identified in normal glomeruli from four cases with LMD/MS analysis. High abundance glomerular structural proteins and blood-related proteins are shown below.

MS/MS View	Accession Number	Molecular Weight
Alpha-actinin-4	O43707	105 kDa
Zinc-alpha-2-glycoprotein	P25311	34 kDa
Na(+)/H(+) exchange regulatory cofactor	Q15599	37 kDa
Uromodulin	P07911	70 kDa
Synaptonemalcomplex protein 2	Q5T4T6	94 kDa
Basement membrane-specific proteoglycan	P98160	469 kDa
Osteopontin	P10451	35 kDa
Peroxiredoxin-2	P32119	22 kDa
Lamininsubunit alpha-5	O15230	400 kDa
Tubulinbeta chain	P07437	50 kDa

Conclusions: This study obtained proteomic profile of normal glomerular from FFPE samples, which can provide comparison data for differential proteomic study of glomerular diseases. Further study is needed to analyse the function and location of glomeruli proteins identified with LMD/MS.

Funding: Government Support - Non-U.S.

TH-PO694

Systemic Lupus Erythematosus/ANCA-Associated Vasculitis Overlap Syndrome in Patients with Biopsy-Proven Glomerulonephritis Noemie Jourde-chiche,[1] Pierre-André Jarrot,[2] Laurent Chiche,[3] Laurent Daniel,[4] Bertrand Gondouin,[1] Bertrand Dussol,[1] Stephane Burtey.[1] *[1]Nephrology, Aix-Marseille Univ, Marseille, France; [2]Internal Medicine, Aix-Marseille Univ, Marseille, France; [3]Internal Medicine, Hopital Europeen, Marseille, France; [4]Pathology, Aix-Marseille Univ, Marseille, France.*

Background: SLE and AAV are distinct auto-immune diseases with possible renal involvement. Some patients fulfil both SLE and AAV classification criteria, defining the SLE/AAV overlap syndrome. We aimed: 1) to report clinical, biological and pathological characteristics of patients with SLE/AAV overlap syndrome and a biopsy-proven glomerulonephritis (GN), 2) to evaluate the incidence of overlapping auto-antibodies and of the overlap syndrome in a cohort of patients with lupus nephritis (LN) or crecentic GN (CGN).

Methods: A nationwide survey was conducted to identify cases of SLE/AAV overlap syndrome. Data were collected from SLE and AAV French research groups. Inclusion criteria were diagnosis of both SLE and AAV and biopsy-proven GN between 1995 and 2014. An independent cohort of LN and CGN was used to study the prevalence of overlapping antibodies and/or overlap syndrome. Additional cases were identified through a systematic literature review.

Results: The national survey identified 8 cases of SLE/AAV overlap syndrome. All patients were female, median age was 40 years. AAV preceded (n=3), followed (n=3) or occurred concomitantly (n=2) to SLE. Six patients had rapidly progressive GN, and 3 had alveolar hemorrhage. All patients had antinuclear antibodies (ANA), 7 had p-ANCA anti-myeloperoxidase (MPO) antibodies. Renal biopsy showed LN or CGN. Remission was obtained in 6 patients. Literature review identified 31 additional cases with similar profile. Cohort analysis revealed ANCA positivity in 24% of LN, ANA positivity in 55% of CGN, with no correlation with pathological findings, and a prevalence of 2/110 (1.8%) for SLE/AAV overlap syndrome.

Conclusions: In patients with GN, SLE/AAV overlap syndrome may occur but its prevalence seems low. Most patients have an aggressive renal presentation, with usually both ANA and anti-MPO antibodies. Further studies are needed to assess shared pathogenesis and therapeutic options.

TH-PO695

The Effect of Chronic Kidney Disease on Plasma Cell-Free DNA Levels and Apoptosis Alessandra Brocca, Grazia Maria Virzì, Sabrina Milan manani, Massimo de Cal, Claudio Ronco. *S Bortolo Hospital, Vicenza, Italy.*

Background: Cell-free plasma DNA (cfDNA) is composed of circulating extracellular DNA fragment that originates from necrotic and apoptotic cells reflecting inflammation. cfDNA has been found in many conditions, in which apoptosis or necrosis was involved suggesting that such events are the main source for its presence. CfDNA quantification is a possible method to determine cell damage in vivo. Caspase-3 is an effector caspase, it is responsible for progression to apoptosis. We focused on plasma cfDNA and Caspase-3 detection in patients with different stages of Chronic Kidney Disease (CKD), as index of inflammation, apoptosis and tissue damage in this population.

Methods: We enrolled 25 CKD patients who came to our center for routine visit and we divided them according to CKD stage (1-5). In addition, 8 healthy volunteers (CTR) were enrolled as control group. cfDNA was extracted from plasma and quantified by Real Time PCR for the β-globin gene. Quantitative plasma level of Caspase-3 was performed by ELISA.

Results: Quantitative analysis of plasma cfDNA and Caspase-3 showed significantly higher levels in CKD patients compared with CTR (both $p<0.05$). Furthermore, cfDNA and Caspase-3 levels were significantly different comparing CKD stages (both $p<0.05$). A significant positive correlation was observed between cfDNA and Caspase-3 levels (Sperman's rho=0.66 $p<0.001$) and Caspase-3 levels were significantly different between CKD stages ($p=0.002$). Positive correlations were observed between urea/cfDNA (Sperman's rho=0.57 $p=0.01$) and urea/Caspase-3 (Sperman's rho=0.53 both $p=0.02$).

Conclusions: In conclusion, our data suggest that cfDNA is increased in the plasma of CKD patients and cell apoptosis is one of the potential source of cfDNA. Plasma levels of cfDNA could be a potential biomarker of cytotoxicity due to uremic status of CKD patients. cfDNA can be considered as a direct marker of cell apoptosis which plays a pivotal role in the pathophysiology of CKD. Its levels increase in case of CKD progression AKI and are correlated to urea and cytotoxicity. Plasma levels of cfDNA could be a potential biomarker of cytotoxicity due to uremic status and progression of CKD in these patients.

TH-PO696

Correlation of the Quantification Methods of Proteinuriain Glomerular Disease Patients Gabriela Miranda Mu?oz, Carmen Vozmediano Poyatos, Maria Dolores Sanchez de la Nieta Garcia, Francisco Rivera Hernandez, Isabel Ferreras Garcia. *Nephrology, Ciudad Real Univ General Hospital, Ciudad Real, Ciudad Real, Spain.*

Background: This study evaluate the correlation between the measurements of 24-hour proteinuria(P24H) versus protein/creatinine ratio(P/C*r*) from patients with glomerular disease(GD) diagnosed histologically in Nephrology's Service in HGUCR. Assess whether

this correlation varies with the GD, age, sex, blood pressure control(BP), body mass index(BMI), glomerular filtration rate(GFR) by MDRD, proteinuria degrees mg/24h(PD), urine output(UO) and ACEi/ARBs treatment.

Methods: Observational cross-sectional study of renal biopsies performed 2010-2014. Spearman´s coefficient and multiple linear regression was used to identify the correlation of the two proteinuria determinations.

Results: 148 biopsies collected; 96 were GD. Mean age 54±18 years; 66% male; BMI 27.71±5.75. The GD was: glomerulonephritis(GN) IgA 21%, membranous(MGN)19%, vasculitis17%, focal segmental(FSGS)13%, minimal change(MCGN)10%, lupus10%, and others10%. The GFR was categorized >60 mL/min 37.5%; 30-60mL/min 22.9% and <30mL/min 39% and PD was categorized <300mg 8.3%; 300-3500mg 47.9%; >3500mg 43.8%. The BP was controlled in 60.4%. Median P24H 3.01g/24h(1.18-4.79) and P/C*r* 2.72(1.16-5.0). P24H and P/C*r* showed significant correlations(r=0.71;*P*<0.001). An 1g increase in ratio P/C*r* resulted in an increased in P24H of 0.7g/24h(95% CI 0.59-0.87;*P*<0.001). There was no correlation seen in subgroup analysis of UO<1liter/day and vasculitis(r=0.39;P=0.13). The correlation was higher in women than men(r=0.81*vs* r=0.64), if aged ≤65 than >65(r=0.85*vs* r=0.50), in controlled BP(r=0.79*vs* r=0.57), in GFR>60 ml/min(r=0.90) and in PD <300 mg(r=0.71). In group of ACEi/ARBs(r=0.75*vs* r=0.66) and in BMI group(r=0.83 r=0.59 r=0.76). IgAGN(r=0.67), MGN(r=0.77), FSGS(r=0.78), MCGN(r=0.93) and lupus(r=0.90).

Conclusions: Excellent correlation was observed P/C*r* and P24H. The P/C*r* is useful in IgAGN, MGN, FSGS, MCGN and lupus, regardless of sex, age, BP, ACEi/ARBs and BMI. The correlation was greater with higher GFR and with lower PD. Perform proteinuria determinations in 24-hour urine in patients with UO<1liter/day and vasculitis.

TH-PO697

Renal Functional Reserve and Electron Microscopy in the Evaluation of Subclinical Lupus Nephritis Renato V. Almeida. *Nephrology, Federal Univ of Paraná, Curitiba, Brazil.*

Background: The aim of this research was to study the renal functional reserve (RFR) and electron microscopy (EM) in patients with subclinical lupus nephritis, and to evaluate the changes in the urinary excretion of albumin, retinol-binding protein and electrolytes induced by amino-acids (AAs) infusion; and their relationship with the renal morphology data.

Methods: In 25 lupus patients (SLE group) and in 15 controls, on the 24-hour urine collection and on urine specimens taken after both an oral water load and an AAs infusion, glomerular filtration rate (GFR: creatinine clearance - ml/min/1.73m^2),microalbuminuria (uALB) and sodium excretion ($FENa^+/Na_u$) were evaluated. The urinary retinol-binding protein (RBP) was evaluated only in the SLE group which was also divided in subgroups according to the classification of lupus nephritis (ISN/RPS 2003). Biopsies were also analized in order to characterize the renal ultrastructural abnormalities (EM).

Results: Both in the SLE group and controls there was a significant increase in GFR, uALB, $FeNa^+$ and Na_u after the AAs infusion. The SLE group showed significantly higher stimulated GFR than controls; and higher basal and stimulated values for uALB (ug/min) and uALB (um/mg creatinine), respectively, Urinary RBP showed no basal value above 0.4 ug/ml and after stimulation it resulted significantly decreased. When we compared these data to the renal biopsy findings, we found that class II patients showed higher basal GFR than class I patients. Ultrastructural abnormalities in EM were present in 40% of the cases.

Conclusions: The results suggest that in patients with subclinical lupus nephritis, AAs infusion elicits an increase in GFR which indicates the presence of RFR. Although RFR was not a parameter of disease severity in the SLE group, the presence of higher mean-values for uALB - both basal and stimulated - suggests altered glomerular permselectivity in these patients. Higher basal GFR in class II patients might suggest that compensatory hyperfiltration precedes the decline of renal reserve in patients with more severe forms of lupus nephritis. Electron microscopy findings showed low sensivity to predict the severity of disease.

Funding: Government Support - Non-U.S.

TH-PO698

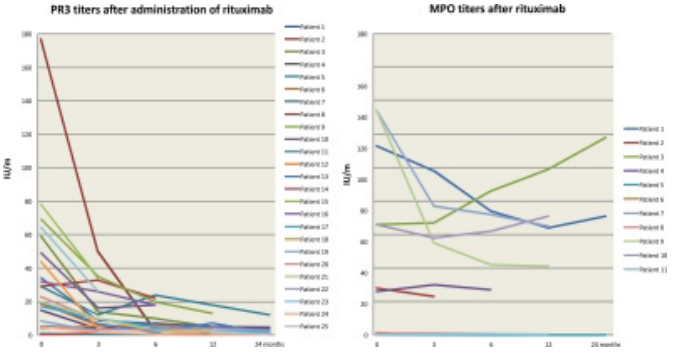
Course of PR3 Titers versus MPO Titers in ANCA Vasculitis Patients After Rituximab Therapy Vega Goedecke, Marcus Hiss, Hermann G. Haller, Annette D. Wagner. *Dept of Nephrology and Hypertension, Medical School Hannover, Hannover, Germany.*

Background: Rituximab has been proven to be an effective therapeutical agent in moderate to severe cases of ANCA vasculitis. B cell depletion plays a major role in suppressing inflammatory processes mediated by granulocytes in ANCA vasculitis. PR3 antibodies are specific for cANCA vasculitis, whereas MPO antibodies are detectable in pANCA vasculitis.

Methods: We compared the time course of anti-PR3 titers in 25 cANCA patients with the course of anti-MPO titers in 11 pANCA patients receiving rituximab induction therapy. We compared anti-PR3 and anti-MPO titers before initiation of rituximab therapy and approximately 3 months, 6 months, 12 months and 24 months after starting therapy. The mean age of both groups was comparable (51,6 in cANCA patients vs. 58,1 years in pANCA patients). The female to male gender ratio was 13/12 in cANCA patients and 6/5 in pANCA patients.

Results: Our results show that rituximab therapy significantly lowers anti-PR3 titers in cANCA vasulitis patients after 3, 6, 12 and 24 months. In contrast, anti-MPO titers are not lowered significantly in pANCA vasculitis patients after rituximab therapy.

	female/ male	age	average titer before treatment	average titer after 3 months	average titer after 6 months	average titer after 12 months	average titer after 24 months
cANCA patients	13/12	51,6	anti-PR3 32,4 IU/ml	anti-PR3 15,7 IU/ ml	anti-PR3 9,2 IU/ml	anti-PR3 5,1 IU/ml	anti-PR3 3,1 IU/ml
pANCA patients	5/6	58,1	anti-MPO 51,8 IU/ml	anti-MPO 37,3 IU/ ml	anti-MPO 40,1 IU/ ml	anti-MPO 45,5 IU/ ml	anti-MPO 63,1 IU/ ml



Conclusions: Clinical experience shows that anti-MPO titers correlate less well with clinical disease activity than anti-PR3 titers. Detailed further analysis of our data will show whether MPO titers correlate with long term clinical patient outcome and FACS analysis data will elucidate involved cell types in pANCA vasculitis.

TH-PO699

Comparison of Urinary Microvesicle Isolation Methods for miRNA Profiling in Nephrotic Syndrome Ilse M. Rood,[1] Thomas Laufer,[2] Thomas Brefort,[2] Hannah Schroers,[2] Johan Van der vlag,[1] Jack F. Wetzels,[1] Jeroen Deegens.[1] *[1]Nephrology, RadboudUMC, Nijmegen, Netherlands; [2]Comprehensive Biomarker Center GmbH, Heidelberg, Germany.*

Background: Urinary microvesicles (uMV) are a promising source for biomarker discovery, including miRNAs (small noncoding single stranded RNAs, which regulate gene expression). UMV can be isolated by different techniques. In healthy subjects, an exosome precipitation protocol yielded the highest quantities of miRNA in uMV. The optimal isolation method of uMV for miRNA profiling in proteinuria is unknown.

Methods: Urine samples were collected from 1 normal control (NC) and 4 patients with nephrotic syndrome (NS1-4). UMV were isolated by 6 different protocols: exoquick(B), Qiagen's exoRNeasy(C), exoquick after additional 17.000g centrifugation step (D), Qiagen's exoRNeasy after additional 17.000g centrifugation step (E), ultracentrifugation (UC) (F), UC followed by size exclusion chromatography(G). The miRNA-profiles were compared with the profile of raw urine (A) to correct for contamination. We determined the expression profiles of all miRBase release v20 human miRNAs using CBC's custom Agilent SurePrintG3 Human miRNA (8x60K) microarrays.

Results: Results are shown in the table. miRNA-analysis was unsuccessful in 5/35 samples (method B/D/G) due to insufficient amount of RNA. Method C and E resulted in highest amount of total miRNAs and in highest percentage miRNAs that were not detected in A. In method F, despite lower amount of total miRNAs, 9-56 additional miRNAs that were not present in A/C/E, were detected.

	Method (# of miRNAs / % not present in A / # of miRNAs in C not present in A/E/F, in E compared to A/C/F and in F compared to A/C/E)						
Sample	**A**	**B**	**C**	**D**	**E**	**F**	**G**
NC	271	294/34	614/56/53	284/35	554/51/0	312/34/51	156/21
NS1	179	-	477/63/7	134*	480/63/4	324/51/56	214/37
NS2	188	181/25	434/57/7	229/29	441/58/27	305/41/35	-
NS3	130*	-	420	217	341	367	243
NS4	154	208/39	346/58/30	-	400/62/74	236/42/9	-

*analysis is ongoing

Conclusions: Method C, E and F are the most consistent methods. Method C and E had the highest yield of miRNAs that were not detected in raw urine. Method F may be of additional value to detect miRNAs not present in A/C/E.

TH-PO700

Gross Hematuria of Glomerular Origin in Adults Sami Safadi,[1] Samih H. Nasr.[2] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Anatomic Pathology, Mayo Clinic, Rochester, MN.*

Background: Gross hematuria is a relatively uncommon presentation of glomerulonephritis. Glomerular gross hematuria (GGH) is more frequent in children than adults. IgA nephropathy and Alport syndrome are the most common causes of GGH in children. The clinicopathologic characteristics of GGH in adults have not been systematically evaluated. We investigated the etiology and clinicopathologic characteristics of GGH in a large single-center cohort of adults.

Methods: Adult patients (³18) with native kidney biopsy were identified from the pathology database. The electronic medical record (EMR) was searched for the symptom of gross hematuria in these patients. The EMR was then examined manually to select patients with GGH. Patients with a urological cause of hematuria were excluded. Univariate logistic regression was used to test association between age, gender, and diagnosis.

Results: Between 1993 and 2015, 101 patients with GGH were identified. 51% were male and 88% were white. Median age at biopsy was 52 yrs. (18-89). The clinicopathologic causes of GGH were heterogeneous as shown in table 1. The most common causes were: IgA nephropathy/HSP nephritis (IgA/HSP) (36%), thin basement membrane disease (TBMD) (14%), pauci-immune crescentic GN (PICGN) (13%), and monoclonal protein related glomerular disease (amyloidosis, MIDD, PGNMID) (13%). Younger adults were more likely to have IgA/HSP (OR 3.2, p<0.01), and less likely to have PICGN (OR 0.05, p<0.01). Male patients were more likely to be older on presentation (dif 8 years, p<0.05). Female patients were slightly more likely to have loin pain hematuria syndrome (LPHS) and TBMD. Only 30% of patients with IgA/HSP with GGH had crescents on biopsy.

Conclusions: This is the first study to analyze GGH in adults. We show that causes of GGH in adults are very heterogeneous, but most cases are due to IgA/HSP or TBMD disease in younger adults, and PICGN in older adults.

IgM Staining in Immunofluorescence Is a Risk Factor for Relapsing in Focal Segmental Glomerulosclerosis Daiane Silva, Gisele Vajgel Fernandes, Luis H.B.C. Sette, Renata Silva, Denise Maria do nascimento Costa, Maria Alina G.M. Cavalcante, Lucila Maria Valente. *Nephrology, Univ Federal de Pernambuco, Recife, Pernambuco, Brazil.*

Background: Glomerular IgM and C3 deposits are frequently found in idiopathic focal segmental glomerulosclerosis (iFSGS). Some experimental studies have suggested that IgM deposits may play a role in activation of the complement system in the glomeruli. However, the clinical meaning of the IgM deposits is unclear in iFSGS patients. In this study we analyzed outcomes regarding the presence of IgM deposits in biopsies of iFSGS patients.

Methods: We collected data from single center retrospective cohort of patients with histologic diagnosis of iFSGS between 2002-2014 that had a minimum follow-up period of 6 mo. Secondary FSGS, collapsing glomerulopathy (CG), childhood onset of iFSGS and patients with baseline Scr>3.0mg/dL where excluded. Relapsing was defined as new onset of nephrotic proteinuria after remission.

Results: We reviewed data from 96 patients, however 38 were excluded: secondary FSGS (14), CG (20) and patients with baseline Scr>3.0mg/dL (2), leaving 58 patients to analysis. The mean age was 31.3±14.3y, 58.6% were female and 46.5% were self-identified as white. Labs showed: mean Scr 1.2±0.6mg/dL; proteinuria 8.1±4.95 g/d; Salb 1.9±0.9 mg/dL; GFR (MDRD) 81 ±41ml/min. The median follow up period was 34.5 mo. Interstitial fibrosis was moderate to severe in 26%, IgM and C3 deposits were present in 31% and in 12% of the biopsies, respectively. ACEI/ARB was used in 81%, prednisone in 96.6% and cyclosporine in 46.6% of the cases. Complete or partial remission was achieved in 79.3% of the patients during follow-up. Relapsing was seen in 17 of 41 cases (41.5%). IgM staining in the glomeruli was the only significant risk factor for relapsing in the multivariate analysis (OR 6.1 [CI 1.02-36.4]; P=0.047). Nevertheless, C3 deposits showed some association but lost strength in the multivariate analysis (OR 8.3 [CI 0.79-87.7] P=0.077).

Conclusions: In a single center retrospective cohort we found that IgM staining in immunofluorescence was a risk factor for relapsing in idiopathic FSGS.

TH-PO702

Targeted Metabolomics Reveals Reduction in TCA Cycle Metabolites in Non-Diabetic Hypertensive Chronic Kidney Disease Stein I. Hallan,[1] Maryam Afkarian,[2] Leila R. Zelnick,[2] Bryan R. Kestenbaum,[2] Shoba Sharma,[3] Rintaro Saito,[1] Kumar Sharma,[1] Ian H. De Boer.[2] *[1]Center for Renal Translational Medicine, UCSD, San Diego, CA; [2]Kidney Research Inst and Div of Nephrology, Univ of Washington, Seattle, WA; [3]Clinical Metabolomics Inc, La Jolla, CA.*

Background: Interesting metabolic disturbances have recently been described in DKD using metabolomic analysis. Non-diabetic hypertensive CKD is common and needs to be better characterized.

Methods: Using a targeted quantitative panel of 66 organic acids, we compared plasma concentrations and urine excretion/24h in 22 adults with stage 3-4 non-diabetic hypertensive CKD to those of 10 healthy controls.

Results: After correcting for multiple testing, urinary excretion of 27 metabolites and plasma concentration of 33 metabolites differed significantly (range -68% to +113%). All 27 altered urine metabolites was reduced in CKD, while 27 of 33 altered plasma metabolites were higher in CKD. Pathway analysis based on significantly altered metabolites identified seven metabolic pathways significantly altered in CKD, most strikingly the TCA cycle (6 of 20 measured metabolites significantly different, q<0.001).

	Pathway	FDR	Impact
1	TCA-cycle	0.0000	0.25
2	Phenylalanine metabolism	0.0000	0.14
3	Glyoxylate & dicarboxylate-metabolism	0.0001	0.10
4	Propanoate metabolism	0.0015	0.03
5	Butanoate metabolism	0.0023	0.11
6	Tyrosine metabolism	0.0051	0.11
7	Ketone bodies metabolism	0.0284	0.70
8	Alanine, aspartate, & glutamate-metabolism	0.0358	0.00
9	Fatty acid biosynthesis	0.2310	0.00
10	Valine, leucine, & isoleucine degradation	0.7820	0.00

Urinary excretion of citrate, cis-aconitate, isocitrate, oxoglutarate and succinate was reduced 40-68%. Based on data from Nephromine, expression of genes for four TCA cycle enzymes was reduced in human kidney tissues with nephrosclerosis. One transcription factor (TFAP2C) regulating TCA genes was also significantly reduced in nephrosclerosis.

Conclusions: In conclusion, in non-diabetic CKD, targeted metabolomics identified differences in the urinary excretion and plasma concentrations of small molecules that are consistent with both reduced renal excretion and impaired metabolism. Reductions in TCA cycle metabolites and gene expression were also identified and suggested suppressed mitochondrial function in CKD.

The Application of Laser Microdissection and Liquid Chromatography – Mass Spectrometry in the Diagnosis of Renal Amyloidosis Michiko Aoki, Dedong Kang, Yusuke Kajimoto, Takafumi Kanemitsu, Kiyotaka Nagahama, Akira Shimizu. *Analytic Human Pathology, Nippon Medical School, Tokyo, Japan.*

Background: In our department, renal amyloidosis of kidney biopsies have been diagnosed by congo-red stain, immunofluorescence (IF) for immunoglobulin light (L) and heavy (H) chains, and immunostaining for amyloid A, transthyretin, and b2-microglobulin. Recently, it has been reported that liquid chromatography tandem mass spectrometry (LCMS/MS) is helpful for detection of the amyloid precursor proteins.

Methods: We retrospectively investigated 30 cases of renal amyloidosis, 11 cases (36.7%) of AA and 19 cases (63.3%) of AL amyloidosis, from a series of renal biopsies in our department from 1999 to 2014. We examined the component proteins in deposited amyloid in formalin fixed paraffin embedded tissues using laser microdissection of glomeruli and LCMS/MS. These results were compared with the results of serum immunofixation electrophoresis (IEP) and findings of IF.

Results: We retrospectively investigated 30 cases of renal amyloidosis, 11 cases (36.7%) of AA and 19 cases (63.3%) of AL amyloidosis, from a series of renal biopsies in our department from 1999 to 2014. We examined the component proteins in deposited amyloid in formalin fixed paraffin embedded tissues using laser microdissection of glomeruli and LCMS/MS. These results were compared with the results of serum immunofixation electrophoresis (IEP) and findings of IF.

Conclusions: LCMS/MS could detect the component proteins in amyloid depositions in all cases, even in the cases that had less than 5% area of amyloid deposition in glomeruli. Furthermore, among AL amyloidosis, which was diagnosed previously, we found 2 cases of AH amyloidosis and 2 cases of AHL amyloidosis. LCMS/MS is very helpful for diagnosis of amyloidosis, especially AHL and AH amyloidosis.

TH-PO704

THSD7A Staining of Membranous Glomerulopathy in Clinical Practice Reveals Cases with Dual Autoantibody Positivity Christopher Patrick Larsen,[1] Larry N. Cossey,[1] Laurence H. Beck.[2] *[1]Nephropath, Little Rock, AR; [2]Boston Univ Medical Center, Boston, MA.*

Background: The majority of primary membranous glomerulopathy (MG) cases are due to antibodies directed against the podocyte phospholipase A2 receptor (PLA2R) antigen. Recently, thrombospondin type-1 domain containing 7A (THSD7A) was described as a second antigenic target leading to MG. We sought to validate an immunohistochemical stain for the diagnosis of THSD7A-associated MG on renal biopsy material.

Methods: Immunohistochemical staining for THSD7A (Sigma) and PLA2R (Sigma) was performed in all cases of non-SLE associated MG diagnosed in our laboratory between December 2014 and April 2015. This included a total of 258 cases. Both stains were performed on formalin fixed paraffin embedded tissue. PLA2R was performed by immunofluorescence while THSD7A was performed by immunoperoxidase. Serologic testing for PLA2R (ELISA, WB) and THSD7A (WB) antibodies was performed in a subset of cases to determine the specificity of positive THSD7A staining for the diagnosis of THSD7A MG.

Results: MG stained positive for THSD7A-only in 7 (2.7%) cases, PLA2R-only in 141 (54.7%) cases, and showed dual positivity for THSD7A and PLA2R in 2 (0.8%) cases. Staining was negative for both in 108 (41.8%) cases. Serologic testing was performed for antibodies to PLA2R and THSD7A in 9 cases with both serum and biopsy material available and the results are shown in Table 1.

Biopsy result	Serum Anti-PLA2R +	Serum Anti-THSD7A +
MG with PLA2R only (n=3)	3/3	0/3
MG with THSD7A only (n=2)	0/2	2/2
MG with dual PLA2R and THSD7A (n=2)	2/2	2/2
MG negative for PLA2R and THSD7A (n=1)	0/1	0/1
Non-membranous glomerulopathy (n=1)	0/1	0/1

Conclusions: Based on these findings we believe it is possible to specifically diagnose THSD7A-associated MG based on renal biopsy staining. Additionally, we confirm that only a minority (3.5%) of MG cases reflect THSD7A-associated disease. Interestingly, 2 (22%) THSD7A-positive cases showed dual positivity for PLA2R and THSD7A with serologic studies showing evidence of antibodies to both THSD7A and PLA2R antigens in these patients. These cases demonstrate the importance of using a panel based approach to subtyping MG.

TH-PO705

Clinical Characteristics Associate Differently with Single Nephron GFR Than Total GFR in Normal Adults Aleksandar Denic,[1] Lilach O. Lerman,[1] John C. Lieske,[1] Mariam P. Alexander,[2] Harini A. Chakkera,[3] Emilio D. Poggio,[4] Richard J. Glassock,[5] Andrew D. Rule.[1] *[1]Div of Nephrology, Mayo Clinic, MN; [2]Dept of Pathology, Mayo Clinic, MN; [3]Div of Nephrology, Mayo Clinic, AZ; [4]Dept of Nephrology, Cleveland Clinic, OH; [5]Dept of Medicine, Geffen School of Medicine, CA.*

Background: Total GFR (GFR) is the product of mean single nephron GFR (snGFR) and the number of nephrons. Thus, associations with GFR may be attributable to associations with snGFR, nephron number, or both.

Methods: We identified 1,520 living kidney donors at Mayo Clinic and Cleveland Clinic with pre-donation contrast-enhanced CT scans and iothalamate clearance (GFR), and with kidney biopsies at the time of donation. snGFR was estimated from GFR divided by nephron number (CT bilateral cortical volume x biopsy non-sclerotic glomerular density). GFR, snGFR, and nephron number were associated with clinical and biopsy characteristics (age and sex-adjusted).

Results: Donors were 58% women, mean±SD age of 43±12 y, GFR of 103±20ml/min/1.73m^2, nephron number of 872,280±390,668 per kidney, and snGFR of 0.073±0.042 ml/min/1.73m^2. There was a strong decline in nephron number and modest rise in snGFR with age such that the net effect was an age-dependent decline in GFR.

*p<0.05; **p<0.001; NS p>0.05	Total GFR =		snGFR ×		Nephron number	
Characteristics	% diff.	p value	% diff.	p value	% diff.	p value
Age, per y	-0.6	**	0.3	*	-1	**
Female sex	1.5	NS	10.9	**	-8.5	**
Family history of ESRD	1.6	NS	12.3	**	-10	**
Glomerular volume, per SD	0.6	NS	26	**	-20.3	**
Tubular area, per SD	0.8	NS	14	**	-11.4	**
Glomerulosclerosis >5%	0.4	NS	14	**	-12	**
Intimal thickening >50%	2.7	NS	13	**	-7.7	**

Female gender, family history or ESRD, larger glomerular volume, larger tubular area, glomerulosclerosis, and intimal thickening all associated with fewer nephrons and higher snGFR, with the net effect that none associated with GFR.

Conclusions: Among normal adults, the age-dependent fall in GFR underrepresents the loss of nephrons because of a concurrent increase in snGFR. Total GFR did not associate with many risk factors because of the counterbalancing association of these risk factor with both lower nephron number and increased (likely compensatory) snGFR.

Funding: NIDDK Support

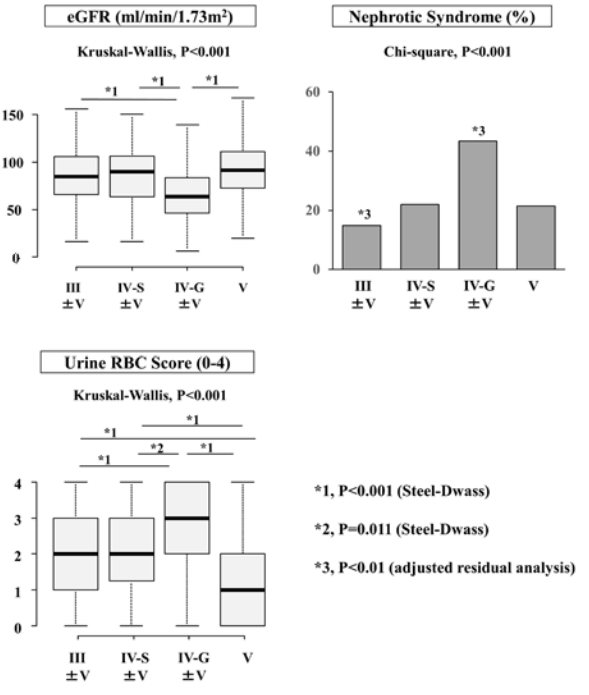
TH-PO706

Clinical and Histological Features of Lupus Nephritis in Japan: An Analysis of the Japan Renal Biopsy Registry (J-RBR) Keiju Hiromura,[1] Ken Kayakabe,[1] Hidekazu Ikeuchi,[1] Hitoshi Sugiyama,[2] Michio Nagata,[3] Hiroshi Sato,[4] Hitoshi Yokoyama,[5] Yoshihisa Nojima.[1] *[1]Dept of Medicine and Clinical Science, Gunma Univ, Maebashi, Japan; [2]Dept of Medicine and Clinical Science, Okayama Univ, Okayama, Japan; [3]Kidney and Vascular Pathology, Faculty of Medicine, Univ of Tsukuba, Tsukuba, Japan; [4]Clinical Pharmacology and Therapeutics, Graduate School of Pharmaceutical Sciences, Tohoku Univ, Sendai, Japan; [5]Div of Nephrology, Kanazawa Medical Univ, Uchinada, Japan.*

Background: A cross-sectional study was conducted to examine clinical and histological features of lupus nephritis (LN) in Japan.

Methods: Using the database of J-RBR, a nationwide prospective registry conducted by Japanese Society of Nephrology, we examined 372 LN patients whose ISN/RPS Class was available, out of total 18,463 registered patients who received renal biopsy between 2007 and 2012.

Results: Median age was 37 years old (IQR 27-48); 9.4% of patients were less than 20 years old and 81.2% of patients were female. The frequency of each ISN/RPS Class was as follows; I, 1.3%; II, 7.5%; III±V, 25.3%; IV-S±V, 13.4%; IV-G±V, 30.4%; V 21.2%; VI, 0.8%. Among Class III to V, patients with IV-G±V had lower eGFR, higher urine RBC score and higher incidence of nephrotic syndrome (Figure). In addition, the frequency of mixed proliferative and membranous type (III/IV+V) and chronic lesion (A/C or C) was significantly higher at the second or later biopsy compared to the first biopsy (mixed type, 21.5% vs 43.9%, p=0.003; chronic lesion 51.1% vs 82.1%, P=0.002).



Conclusions: In Japan, patients with IV-G±V LN were significantly associated with decreased renal function and nephrotic syndrome. In addition, the frequency of mixed proliferative and membranous type and chronic lesions was higher at the repeat biopsy, suggesting that these histological features reflect progression of the disease or refractory nature to treatment.

MicroRNA Signatures in Renal Disease: A Meta-Analysis of Tissue and Urine Datasets Christos Argyropoulos, Mark L. Unruh, V. Shane Pankratz. *Internal Medicine, Univ of New Mexico, Albuquerque, NM.*

Background: MicroRNA (miRNA) are negative regulators of gene translation and an emerging biomarker in a wide variety of diseases. Little is known about the ability of miRNA to classify patients with renal pathology.

Methods: We undertook a meta-analysis of normalized miRNA profiles from clinical samples in Gene Expression Omnibus. miRNAs in miRBasev20 were scored for kidney relevance according to their experimentally or computationally ability to bind to proteins in the kidney proteome (http://www.proteinatlas.org). Elastic Net (EN) regression was then used to select short miRNA signatures according to their ability to classify diseased from healthy samples using 10-fold cross-validation.

Results: Using our systems biology approach we identified 739 miRNAs as potential kidney biomarkers out of 1689 candidates. A total of 8 studies with 178 samples were identified. Of those, 2 studies in patients were lupus (N=30) were excluded due to the incompatibility of the normalization strategy with the other samples. miRNAs profiles from 31 urine samples and 117 biopsy samples were available for analyses.

Dataset	Platform	Source	Normal	Abnormal
GSE53771	Microarray (μA)	Renal Bx (Bx)	28	8 (Transplant, TxP AKI)
GSE30282	μA	Bx	10	30 (TxP Cell Rejection). 11 (TxP AB Rejection), 14 (DGF)
GSE28283	μA	Bx: Cortex	3	5 (Hypertension, HTN)
GSE28344	μA	Bx: Medulla	3	5 (HTN)
GSE48318	qPCR	Urine exosomes	2 (Normoalbumin-uria, NA)	2 (Microalbuminuria, MA)
doi: 10.1371/ journal. pone.0054662	qPCR	Whole urine	10 NA	17 (MA within 2 years)

The median (IQR) AUC for individual miRNAs to classify diseased samples was 0.59(0.46-068) for unselected miRNAs but increased to 0.64(0.54-0.69) in the preselected ones. A short signature of 19 miRNAs achieved a superior classification performance for renal pathology (cross-validated AUC 0.96).

Conclusions: This is the first study to date examining the performance of a panel of miRNAs in classifying patients with kidney disease. A panel of miRNAs may classify patients with native and allograft renal disease aiding the interpretation of elevated creatinine in clinical practice.

TH-PO708

Study into the Effect of Aquaporin-2 on the Efficcacy and Predicted Effect of Tolvaptan in Patients of Nephrotic Syndrome Eiichi Sato,[1] Tsukasa Nakamura,[2] Mayuko Amaha,[2] Mayumi Nomura,[2] Daisuke Matsumura,[2] Akiko Fujii,[1] Yuko Ono,[1] Yoshihiko Ueda.[1] *[1]Dept of Pathology, Dokkyo Medical Univ, Koshigaya Hospital, Koshigaya, Saitama prefecture, Japan; [2]Div of Nephrology, Dept of Internal Medicine, Shinmatsudo Central General Hospital, Matsudo, Chiba Prefecture, Japan.*

Background: A retrospective investigation was conducted into the efficacy and adverse drug reactions of tolvaptan in the treatment of diabetic nephropathy and MCNS (Minimal Change Nephrotic Syndrome) with heart failure.

Methods: The subjects of this study were 56 patients with chronic kidney disease (due to diabetic nephropathy) and MCNS with heart failure who over the last 2 years and who were treated with tolvaptan. We defined effective cases as those showing a 2-fold increase in urinary volume compared to pre-administration levels or a clear improvement in edema or heart failure symptoms.Immunohistochemistry was also used to examine aquaporin-2 expression in the epithelial cells of the collecting duct (the site of tolvaptan action) based on renal biopsy findings. A score of (-) is assigned when the collecting duct shows no staining; a score of (+) is assigned when less than 50% is stained; a score of (++) is assigned when at least 50% of the biopsy specimens is stained.

Results: Of the 56 cases, 49 were tolvaptan responders. No problematic side effects were observed. Comparison of tolvaptan responders and non-responders indicated that serum Cre levels were significantly lower in responders. We conducted immunostaining for aquaporin 2 in the collecting duct. In diabetic cases. findings were positive for the responder but negative for the non-responder. In MCNS cases findings were positive for the responder but weak positive for the non-responder.

Conclusions: Diabetic nephropathy and nephrotic syndrome responders exhibited aquaporin 2 expression in collecting duct epithelial cells. No expression or weak positive expression was observed in diabetic nephropathy and in MCNS non-responders.

TH-PO709

Subclinical Anti-Smith and Anti-Ribonucleoprotein Antibodies Precede Proliferative Lupus Nephritis Diagnosis Stephen W. Olson,[1] Lisa K. Prince,[1] Dustin J. Little,[1] Kevin C. Abbott.[3] *[1]Nephrology, Walter Reed National Military Medical Center, Bethesda, MD; [2]Nephrology, Naval Medical Center San Diego, San Diego, CA; [3]NIDDK, National Inst of Health (NIH), Bethesda, MD.*

Background: Lupus Nephritis (LN) manifests in approximately 50% of Systemic Lupus Erythematosus cases. Anti-Smith (SM) and Anti-Ribonucleoprotein (RNP) antibodies are associated with proliferative lupus nephritis (PLN) at diagnosis. We hypothesized that prediagnostic anti-SM and anti-RNP antibodies were more common in PLN than SLE without LN.

Methods: This case-control Department of Defense Serum Repository study compared 3 longitudinal prediagnostic quantitative anti-SM and anti-RNP antibody levels in 23 patients with biopsy-proven PLN from the Walter Reed National Military Medical Center with 21 age, sex, race, and age of serum matched SLE without LN disease controls. Immunoassays were performed at Quest Diagnostics.

Results: More PLN patients had an anti-SM antibody level ≥4 AI than matched disease controls at any time (52% vs. 5%; p<0.001) and <2 years (47% vs. 6%, p=0.01) before diagnosis, but not >2years before diagnosis (22% vs. 0%, p=0.11). More PLN patients had an anti-RNP antibody ≥4 AI than matched disease controls at any time (57% vs. 14%, p=0.005), < 2years (53% vs. 19%, p=0.04), and >2 years (39% vs. 0%, p=0.008) prior to diagnosis. Only an anti-SM antibody absolute rise over time of >4 AI prior to diagnosis was specific for PLN (30% vs. 0%; p=0.02). But, anti-RNP antibody more often preceded anti-SM antibody when there was a clear antecedent antibody (89% vs. 11%, p=0.003).

Conclusions: In a large subgroup of PLN patients, anti-RNP antibodies were consistently elevated prior to anti-SM antibodies, but not rising, years prior to diagnosis. Anti-SM antibodies predominantly elevate in the last two years prior to PLN diagnosis which supports a possible direct contribution to PLN pathogenicity. Our data suggests that SLE patients with baseline RNP antibody along with a rising anti-SM antibody levels may benefit from increased surveillance for early signs of PLN. A more prompt biopsy diagnosis would allow for proactive therapeutic intervention to preserve maximal renal function.

The Relationship Between Phospholipase A2 Receptor Autoantibody and Idiopathic Membranous Nephropathy Weifeng Lin,[1,2,3] Hang Li,[1,2,3] Xuemei Li,[1,2,3] Yan Qin,[1,2,3] Ying Su,[1,2,3] Yang Yu,[1,2,3] Yin Guan,[1,2,3] Yubing Wen,[1,2,3] Xuewang Li.[1,2,3] *[1]Dept of Nephrology, Peking Union Medical College Hospital; [2]Peking Union Medical College; [3]Chinese Academy of Medical Sciences.*

Background: The value of PLA2R autoantibody is still controversial in diagnosis, activity monitoring and prognosis estimation in idiopathic membranous nephropathy (IMN). The test method is non-uniform.

Methods: A total of 233 patients with biopsy-proven IMN at Peking Union Medical College Hospital from 2012 January to 2014 March were enrolled. A control group was set up. The serum antibody titer collected at the time of renal biopsy was measured by quantitative ELISA. 14 IMN patients with detectable antibody at biopsy were followed up to retest antibody 6 months later. Besides, the diagnostic accuracy between ELISA and immunofluorescence (IF) method for IMN was compared. The consistency and difference in antibody detection between two methods were also performed.

Results: The total sensitivity of antibody was 60.0% in IMN. However, it increased to 71.3% if patients didn't receive immuno-suppression therapy before testing. The antibody specificity was 100.0%. Hypoalbuminemia became severe (P<0.05) and the proportion of nephrotic arrange proteinuria rose gradually (P<0.05) as antibody levels increased. The antibody changes were consistent with clinical outcomes. The antibody AUC-ROC for IMN diagnosis was 0.800 by ELISA. There was no significant difference in AUC-ROC between ELISA and IF in IMN diagnosis (P>0.05). The kappa value of antibody detection consistency between ELISA and IF was 0.941±0.033. The positive rate of antibody detection wasn't significantly different between ELISA and IF (P<0.05).

Conclusions: PLA2R autoantibody has high sensitivity, notable specificity and good diagnostic accuracy for IMN. The antibody positive rate is affected by immunosuppression therapy and disease activity. The antibody could reflect disease activity and predict outcomes. Moreover, There is no significant difference in diagnostic accuracy and antibody detection difference between ELISA and IF. The antibody detection consistency is good between ELISA and IF.

TH-PO711

Factors Related to the Glomerular Volume in Different Cortical Zones of the Human Kidney Yusuke Okabayashi, Go Kanzaki, Nobuo Tsuboi, Kotaro Haruhara, Kentaro Koike, Yoichi Miyazaki, Tetsuya Kawamura, Makoto Ogura, Takashi Yokoo. *Div of Nephrology and Hypertension, The Jikei Univ School of Medicine, Tokyo, Japan.*

Background: Recent studies have shown that glomerular enlargement is a surrogate marker of low nephron number in primary hypertension and in people with lower birth weight. To date, however, information is limited regarding the diversity in the distribution of glomerular size within the same kidney of relatively healthy human adults.

Methods: A total of 89 autopsy kidneys without apparent renal diseases were analyzed to measure the glomerular volume (GV) in different parts of the renal cortex. The mean GV was calculated from the measured each glomerular area. Relationships between the GV and the other clinicopathological features were investigated.

Results: The GV showed wide variations between the individuals and showed maximal 7-fold and 4-fold variations in superficial and juxtamedullary cortex, respectively. The GV showed close inverse correlations with the glomerular density in each cortical area. Multivariate analysis revealed that independent factors associated with the mean GV were low glomerular density in the superficial cortex, and hypertension in the juxtamedullary cortex.

	Superficial cortex				Juxtamedullary cortex			
	Univariate		Multiivariate		Univariate		Multiivariate	
Variables	r-value	p-value	t-value	p-value	r-value	p-value	t-value	p-value
BSA (m^2)	0.217	0.092	1.526	0.133	0.024	0.854	-	-
Weight of left kidney (g)	0.166	0.202	-	-	0.087	0.505	-	-
eGFR (ml/min)	-0.143	0.273	-	-	-0.101	0.438	-	-
Hypertension	0.181	0.163	0.307	0.760	0.340	0.007	2.437	0.018
Interstitial fibrosis/tubular atrophy (%)	0.034	0.794	-	-	0.021	0.875	-	-
Global glomerulosclerosis (%)	0.424	0.001	1.934	0.058	0.104	0.426	-	-
Glomerular density (/mm^2)	-0.463	<0.001	-2.480	0.016	-0.172	0.186	-0.493	0.624

As a whole, compared to the GV in the superficial cortex ($2.7\pm1.0 \times 10^6 mm^3$), the averaged GV in the juxtamedullary cortex ($3.1\pm0.8 \times 10^6 mm^3$) was significantly larger. Of note, in 27 cases (30%), the mean GV in the superficial cortex was larger than that of the juxtamedullary cortex. Such individuals with glomerular enlargement in the superficial cortex were characterized by a low glomerular density and/or large body size.

Conclusions: In each individual kidney, there are considerable variations in the distribution of the GV. Nephron number/body size and hypertension underlie the enlargement of glomeruli in superficial and juxtamedullary cortex, respectively.

TH-PO712

Highly Sensitive Method for Quantification of Iohexol Vera Jankowski, Joachim Jankowski. *Inst of Molecular Cardiovascular Research, Univ Hospital RWTH, Aachen, Germany.*

Background: Iohexol is used for accurate determination of the GFR in CKD patients. However, high iohexol amounts might lead to adverse effects in organism. In order to minimize the iohexol dosage required for the GFR determination in humans,the development of a sensitive quantification method is essential.Therefore, the objective of our preclinical study was to establish and validate a simple and robust LC-ESI-MRM method for iohexol quantification.

Methods: In order to test whether a significantly decreased amount of iohexol is sufficient for reliable quantification, a LC-ESI-MRM mass-spectrometric approach was assessed. We analyzed the kinetic of iohexol in rats after application of different amounts of iohexol (15 mg-150 µg/rat). Blood sampling was conducted at four time points. Iohexol and the internal standard (iothalamic acid) were separated from serum proteins using centrifugal filtration device with a cut-off of 3 kDa. The chromatographic separation was achieved on an analytical Zorbax SB C18 column. The detection and quantification were performed by ESI-MRM operating in a positive ion mode. Furthermore, the effect of iohexol on early regulated gene expression in thyroid and renal cortex was tested to determine a threshold of physiological active iohexol concentrations.

Results: A linear correlation of the iohexol amount and mass-signal (MS) intensity was found in the range of 50 pg-40 ng ($r^2 = 0.998$). The lowest limit of quantification (LLOQ) was 50 pg. The intra- and inter-day accuracies were between 91.2 % and 98.7 %. The intra- and inter-day precisions were between 2.7 % and 9.2 %. The recovery rate of iohexol was determined in the range of 100.8 % ± 10.9 %. The gene expressions test revealed that iohexol dosages exceeding 0.5 mg/kg induce a group of genes in thyroidal tissue that comprises transcription factors and genes of cellular stress response.

Conclusions: This mass-spectrometric based method has been proved to be sensitive, selective and suitable for the quantification of iohexol in serum. Due to high sensitivity of this novel method the iohexol application dose as well as the sampling time in the clinical routine could be reduced in the future in order to further minimize side effects in humans.

TH-PO713

Proliferative Lupus Nephritis: Are Three Years Enough for Histological Remission? Marcelo Alejandro De Rosa, Federico Fuentes, Gabriel Pedro Alvarez, Graciela Elena De Rosa, Jorge E. Toblli. *Univ of Buenos Aires, Argentina.*

Background: The duration of the treatment in Proliferative Lupus Nephritis (PNL) has not been determined. Almost 30 percent of patients will relapse during or after treatment, in the first 5 years. Furthermore, the factors associated to renal relapses remain unclear. Hence, a prospective histological control study (re-biopsy) performed before the end of the third year of treatment in patients with complete renal remission for a year may contribute to a better understanding on the relapses in PNL.

Methods: A total of 24 patients with PLN were included in this pilot study. All patients presented focal or diffuse PLN in the first renal biopsy, and received induction with cyclophosphamide and corticosteroids by six months. The maintenance therapy was based on mycophenolic acid and low doses of corticosteroids for at least 2 years and 6 months. On those patients who presented total remission during a year (proteinuria £0.5g/24h, inactive urinary sediment, and stable creatinine), a second renal biopsy was performed before reduction of treatment. Renal biopsies were classified according to ISN/RPS 2003.

Results: After a media of a 34 (30-42) months of treatment and in complete remission for a year, 70,8% of patients had mesangial or proliferative lupus activity.

Table 1

Baseline results			
N: 24	mean	median	range
Age (years)	35.5	31	21-64
Gender (M/F)	5/19		
Time of treatment (months)	34	34.2	30-42
Proteinuria g/day	0.2	0.2	0.05-0.43
Creatinine (mg/dl)	0.7	0.73	0.6-1.04
2nd.Biopsy			
Histological class	n 24	IF: IgG, C1q	
Class I	3	-	
Class II	5	+	
Class III (A, A-C)	11	+	
Class III (C)	3	-	
Class IV (A, A-C)	-		
Class IV (C)	1	-	
Class III/V	1	+	

Activity index mean	2 (1-3)		
Chronicity index mean	3 (2-4)		
Histological activity	17	+	70.8 %
No Histological activity	7	-	29.2 %
Total	24		100 %

Conclusions: This study showed that after a satisfactory treatment, most patients with PLN, still presented mesangial or focal proliferative changes with positive IF for IgG and C1q in their second renal biopsy. While data in the present study suggest silent lupus activity, the association of these histological findings with potential relapses in PNL invites to an open discussion.

TH-PO714

The Clinical and Renal Pathological Features and Presence of Anti-PLA2R Antibody in 9 Patients with Both Membranous Nephropathy and IgA Nephropathy Xin Zhang, Weifeng Lin, Jianing Li, Yubing Wen, Jianfang Cai, Hang Li, Xuemei Li, Xuewang Li. *Nephrology Dept, Peking Union Medical College Hosptial, Beijing, China.*

Background: Both membranous nephropathy (MN) and IgA nephropathy (IgAN) rank top among the primary glomerulonephropathy but they rarely coexist in the same patient. Whether they are accidentally concurrent remains controversial. Here we reported the clinical and pathological features of 9 cases with concomitant biopsy-proved MN and IgAN.

Methods: The 9 patients were admitted to our hospital for renal biopsy between 2009 and 2014, none having apparent secondary causes of renal diseases. 36 age-, sex-, and biopsy-year- matched controls with isolated IgAN or isolated primary MN, respectively, were randomly selected. Clinical features were compared across these groups. Anti-PLA2R antibody was assayed with ELISA test by using the -80°preserved serum samples in 9 cases and 36 controls with isolated MN.

Results: The clinical and pathological features of cases and controls were summarized in table 1. Table 1 the clinical and pathological features among patients with combined IgAN and MN, isolated primary MN, and isolated IgAN.

Group	Combined IgAN and MN	Isolated primary MN	Isolated IgAN
Cases	9	36	36
Male	6	27	26
Age, yrs	40.2±8.4	40.9±7.6	38.6±9.8
24h-Upr, g/24h	5.9±3.7	6.7±5.5	1.6±1.9*
Serum creatinine, mmol/L	74.4±20.2	75.4±17.6	116.5±110.9*
Serum albumin, g/L	29.1±6.9	27.4±7.2	38.8±8.4*
Mesangial proliferation	None	None	All
Lee's grading of IgAN Grade I Grade II Grade III Grade IV	 3 0 6 0	N/A	 0 0 11 25
MN Classification Grade I Grade II Grade III or IV	 3 6 0	 5 29 2	N/A

* $p<0.05$ vs concomitant group. A positive anti-PLA2R was detected in 2 patients among the cases and 18 patients among the isolated MN controls. The presence of anti-PLA2R antibody did not differ significantly between the two groups ($p>0.05$),neither did the grading of MN ($p>0.05$). However, the pathological lesions in the 9 cases was less severe as compared with the controls with isolated IgAN ($p<0.05$).

Conclusions: The clinical features and presence of anti-PLA2R of patients with combined MN and IgAN are more likely to mimic isolated primary MN.

TH-PO715

MiRNA Profiling in Urine Exosomes Indicates Renal Tubulointerstitial Fibrosis in CKD Patients Yang Zhou, Junwei Yang. *Center for Kidney Disease, Second Affiliated Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: Renal fibrosis is an inevitable outcome of chronic kidney disease (CKD). It was reported that various microRNAs regulated the progression of tubulointerstitial fibrosis. However, whether fibrosis-related miRNAs are excreted in urine exosomes, as well as the changes of miRNA profiles in urine exosomes of CKD patients were unknown.

Methods: Morning urine specimens were collected from 10 healthy donor and 16 CKD patients, whose renal biopsy showed mild to moderate tubulointerstitial fibrosis. Urine exosomes were isolated from 2ml samples using urinary exosome isolation kit and observed by transmission electron microscopy. Quantification of miRNA levels in urine exosomes were determined using stem-loop qRT-PCR followed by real-time PCR. CD63 levels in exosomes were analysis by western blot.

Results: Urinary exosomes appeared as clusters of vesicles of 30-200nm in diameter under electron microscope, surrounded by a double-layer membrane. CD63, a major exosome marker associated with membranes of cellular vesicles, in exosomes isolated from same volume of urine indicated that the excretion of exosomes varied among different people. Moreover, the markedly increased CD63 levels in CKD patients suggested that the excretion rate of exosomes was probably upregulated in CKD patients with renal interstitial fibrosis. Most of preciously reported fibrosis-related miRNAs, including miR-21, miR-29 family, miR-30e, miR-192 and miR-200 family were detectable in urine exosomes. However, their contents varied significantly from fmol/L to nmol/L. Furthermore, miRNA levels in urine exosomes were not associated with their levels in kidney. MiR-21 and miR-29c levels in urine exosomes were markedly increased and decreased as their upregulation and downregulation in kidney, respectively. MiR-29b, miR-30e and miR-200b levels in urine exosomes were markedly increased despite their downregulation in kidney. Although miR-192 level in urine exosomes was as large as ~10^{-4}mmol/L, its excretion was not significantly changed in CKD patients as compared with healthy control.

Conclusions: Profiling of miRNA in urine exosomes might indicate renal tubulointerstitial fibrosis in CKD patients.

Glucosuria in Normoglycemic Non-Diabetic Kidney Disease: Not Necessarily due to an Isolated Proximal Tubule Defect Abdurrahman M. Hamadah, Kamel A. Gharaibeh, Samih H. Nasr, Nelson Leung. *Nephrology and Hypertension, Mayo Clinic, MN.*

Background: In the absence of hyperglycemia, glucosuria has been classically attributed to either a global dysfunction of the proximal tubule known as the Fanconi syndrome, or familiar renal glucosuria which includes inherited defects in the genes that encode the glucose handling kidney transporters. We have investigated the clinical observation that glucosuria is common in other kidney disease entities.

Methods: We analyzed the data for adult patients with native kidney biopsy between January 2014 and January 2015 at our institution that had concurrent urinalysis. We identified the patients who had glucosuria on urinalysis, in the absence of concurrent hyperglycemia (serum glucose > 180 mg/dL) or diagnosis of diabetes mellitus.

Results: 186 adult patients with native kidney biopsy with concurrent urinalysis were identified. Sixty six patients (35%) had evidence of glucosuria on urinalysis. Twenty two (33 %) of these patients had either hyperglycemia (serum glucose > 180 mg/dL) or diabetes and were excluded from the analysis. The remaining sub-group of 44 (67 %) patients had a median age of 58 (19-81 years), 43 % were women, and 81 % were Caucasian. Median urinary glucose was 40 mg/dL (range 16-236). Concurrent serum glucose for this group showed a median of 101 mg/dL (range 54-149), with 66 % of patients having glucose less than 110 mg/dL. In this subgroup, biopsy findings included 32 (73 %) patients with glomerular disease (most commonly glomerular microangiopathy and pauci-immune crescentic glomerulonephritis), 10 (22 %) tubulointerstitial disease (most commonly acute tubular necrosis), and 2 (4%) arteriosclerosis as the predominant features on biopsy. No evidence of proximal tubulopathy was found amongst this group.

Conclusions: Glucosuria in the absence of hyperglycemia and diabetes, although classically associated with isolated proximal tubule dysfunction, is common in other kidney diseases and is a frequent occurrence in glomerular disease, which likely reflects a degree of secondary tubular injury. Future delineation of the pathophysiology of this observation may improve the understanding of tubular function in glomerular disease.

TH-PO717

Severe Renal Interstitial Fibrosis Can Be a Predictor of Renal Function in Patients with Lupus Nephritis, Especially in Cases With the International Society of Nephrology/Renal Pathology Society Class IV Daisuke Honda, Kisara Onda-Tsueshita, Isao Ohsawa, Hiroyuki Inoshita, Satoshi Horikoshi, Yasuhiko Tomino. *Div of Nephrology, Dept of Internal Medicine, Juntendo Univ Faculty of Medicine, Tokyo, Japan.*

Background: The ISN/RPS classification of lupus nephritis (LN) pays little attention to the interstitial injuries. We explored the association between irreversible interstitial fibrosis and renal function in patients with LN, especially class IV cases that have not been thoroughly examined in this aspect.

Methods: Forty-three patients of LN were enrolled in this study. All patients were classified using the ISN/RPS classification and were divided into 4 grades according to interstitial fibrosis extent (no, 0%; mild, 1-25%; moderate, 26-50%: and severe, more than 50% fibrosis of the interstitial area, n = 8, 16, 11 and 8, respectively). All 8 patients with severe fibrosis were classified in class IV. Blood and urine analysis was evaluated at the time of renal biopsy and last follow-up period. We compared the data according to both categorizations in all patients, and in only class IV cases (n = 23).

Results: In each class categorized with the ISN/RPS classification, renal function showed no significant difference. When all patients were classified according to interstitial fibrosis severity, their renal function at the time of renal biopsy showed no significant difference. However, renal function with severe fibrosis at the last follow-up period was significantly worse than those in the other fibrosis grades (sUN, $p < 0.01$; sCre, $p < 0.05$; and eGFR, $p < 0.05$). Moreover, when we examined only class IV patients, renal function in patients with severe fibrosis at the last follow-up period was significantly worse than that in patients with non-severe fibrosis (sUN, $p < 0.01$; sCre, $p < 0.05$; and eGFR, $p < 0.01$). On the other hand, the serological activities of systemic lupus erythematosus (SLE) significantly improved under all categorizations.

Conclusions: We conclude that severe renal interstitial fibrosis can be a predictor of renal function in patients with LN, independent of glomerular lesions and the serological activities of SLE, especially in cases with ISN/RPS class IV.

TH-PO718

Correlating Biophysical Structure Characteristics with Diagnosis and Phenotypic Severity in Complement-Mediated Renal Disease Jill Johanna Hauer, Fengxiao Bu, Nicolo Ghiringhelli Borsa, Michael Jones, Erika Takanami, Elizabeth Ann Black-Ziegelbein, Diana Kolbe, Yingyue Li, Carla Nishimura, Kathy Frees, Hela Azaiez, Christie P. Thomas, Carla M. Nester, Michael J. Schnieders, Richard J. Smith. *Univ of Iowa, Iowa City, IA.*

Background: Rare genetic variations in the *C3, CFH,* and *CFB* genes may lead to dysregulation of the alternative pathway of the human complement system, altering the innate immune response associated with complement activation. The phenotypic consequence includes the thrombotic microangiopathies (TMA) and C3 glomerulopathies (C3G).

Methods: In this study, we compared variants identified in TMA patients to variants identified in C3G patients. Each variant was analyzed in a pipeline that included structural optimization of the wild type and mutant proteins based on molecular mechanics calculations. Initially, the wild type protein structure was optimized using the polarizable AMOEBA force field and dead-end elimination techniques. Each variant was then individually introduced to the wild type structure, which was then re-optimized. Both wild type and variant models were analyzed in molecular dynamics simulations and differences between wild type and variant free energies were calculated.

Results: Overall, for each variant we were able to obtain both: 1) qualitative data describing location and interactions; and 2) quantitative changes to protein conformation and stability relative to the wild type baseline. From these data, we were able to create a spectrum of free energy changes correlating to disease severity and enhance our interpretation of rare and novel variants, as well as identify biophysical characteristics specific to TMA and C3G.

Conclusions: These methods allow us to understand the biophysical consequences of every variant, predict the phenotypic severity of novel variants, and ultimately inform patient diagnosis.

TH-PO719

Urinary EGF Is Associated with Interstitial Fibrosis and Tubular Atrophy in Proteinuric Patients Wenjun Ju,[1] Viji Nair,[1] Michelle R. Smith,[1] S.M. Bagnasco,[2] L. Barisoni,[3] Matthias Kretzler.[1] *[1]Medicine, Univ of Michigan, Ann Arbor, MI; [2]Pathology, The Johns Hopkins School of Medicine, Baltimore, MD; [3]Pathology, Univ of Miami, Miami, FL.*

Background: Interstitial fibrosis (IF) and tubular atrophy (TA) are key morphologic determinants of progression and strong predictors for renal outcome. However, their broader clinical application is limited by the invasiveness of the kidney biopsy procedure. Non-invasive biomarkers predictive of IF/TA have not been reported. Our transcriptome–driven approach identified EGF as a predictor of kidney function, and urinary EGF (uEGF) improved prediction of renal outcome by glomerular filtration rate (GFR) and albuminuria. EGF's expression is limited to tubule epithelium and its role in epithelial cell regeneration suggested that the improved predictive value by uEGF may due to its potential association with chronic tubulointerstitial damage (c-TID).Here we aim to investigate the correlation between uEGF and TID, reflected by the % of cortex affected by IF/TA, and whether uEGF can predict c-TID in adult patients of the NEPTUNE cohort.

Methods: Whole slide images of glass slides stained with Silver, Trichrome and PAS from 102 cases stored in the NEPTUNE digital pathology repository were assessed for % of cortex involved by IF/TA by 5 pathologists. The % of cortex involved by IF/TA was determined in each individual stain and averaged in an overall % value. We derived EGF mRNA levels in the tubulointerstitium using genome-wide expression data and measured uEGF using fully validated ELISA assay. uEGF was normalized by urine creatinine level. A regression model was utilized to predict c-TID using uEGF level.

Results: Both tubulointerstitial EGF mRNA and uEGF correlated significantly ($p<0.0001$) with IF/TA.

spearman rank correlation	EGF mRNA	uEGF
IF	-0.55	-0.75
TA	-0.53	-0.74

The correlations remain significant after adjusted for eGFR and proteinuria. uEGF predicted patients' c-TID (%IF/TA) using a regression model in 102 adult NEPTUNE patients ($r=0.77/0.74$, $p < 2.2e-16$, predicted versus observed IF/TA).

Conclusions: uEGF shows promise as a non-invasive biomarker predictive of the biopsy dependent-IF/TA score in proteinuric patients.

Funding: NIDDK Support

Considerations in the Use of Urine Protein: Creatinine Ratio (uPCR) and g/24h for Measuring Proteinuria in Nephrotic Patients in a Clinical Study

Christine Barrett,[1] Gengqian Cai,[2] Caroline O.S. Savage.[1] *[1]GlaxoSmithKline plc, United Kingdom; [2]GlaxoSmithKline plc.*

Background: uPCR on spot urine samples is used as an alternative to measurement of g protein/day from 24h urine collections, due to its ease of use and the correlation between the two. Most studies on correlation have concentrated on patients with subnephrotic levels of proteinuria. In a clinical study (*BEL116472)* to evaluate the mechanism of action of belimumab in idiopathic membranous nephropathy (IMN), uPCR and g protein/24h were assessed, correlation determined and variability in uPCR evaluated.

Methods: Samples from 14 patients with IMN and nephrotic proteinuria (>4g/10mmol uPCR at screening) were tested. On 2 occasions during screening, spot morning samples were tested for uPCR. At key timepoints, consecutive 24h urine collections, or a spot morning sample and post dose 24h collection were used to test uPCR, g protein/24h and g creatinine/24h.

Results: Median uPCR 8.31 mg/10mmol (range 3.21-12.20) or 11.70 g/24h (range 3.99-20.40) at baseline was found in 11 M and 3 F aged 24 to 70y . High correlation (0.88–0.99) was observed between uPCR and g protein/24h within all groups with high, medium or low creatinine excretion. Different slopes were seen in each group: low- 0.93; medium– 1.34; high- 1.77. In individual samples, the ratio of g protein/24h to uPCR ranged from 0.66 to 2.97. In addition, with screening and prior to dosing data, a big range of within subject coefficient of variation for uPCR was observed: 8.5%-57.7%. Analysis of 6 mth history of proteinuria in the absence of immunosuppression prior to screening showed great variability and no specific pattern of worsening or improvement. Values for g protein/24h also varied considerably in consecutive samples.

Conclusions: uPCR values in patients with nephrotic syndrome are heavily influenced by creatinine excretion. This should be considered when setting eligibility criteria in clinical studies, or if basing dosing on levels of protein excretion. Variability in proteinuria in longitudinal samples from patients with nephrotic levels of proteinuria means that caution should be applied to values from single samples within clinical studies, whether using uPCR or g/24h.

Increasing Incidence of Class V Membranous Lupus Nephritis: A Single Institution Biopsy Experience

Parker C. Wilson, Alison G. Obstler, Michael Kashgarian. *Dept of Pathology, Yale Univ School of Medicine, New Haven, CT.*

Background: Lupus nephritis (LN) contributes significantly to morbidity and mortality in patients with systemic lupus erythematosus (SLE) and is categorized into classes based on the pattern of glomerular injury seen on kidney biopsy. We assessed the proportion of patients presenting with class V or III/IV+V since the advent of systemic immunotherapy for SLE.

Methods: The distribution of patients by LN class at initial presentation was assessed at 5-year intervals from 1998-2013 at our institution. 131 consecutively diagnosed cases of biopsy-proven LN and 54 repeat biopsies were classified using ISN/RPS criteria. Patient information was collected from the medical record. Chi-square test for trend was used to compare the incidence of class V or III/IV+V at 5-year intervals.

Results: The frequency of class V increased from 1998 to 2013 [p = 0.03: 1998 = 9.7%, 2003 = 16.6%, 2008 = 13.0%, 2013 = 29.7%] and was associated with a decreasing incidence of class III/IV [p = 0.0003: 1998 = 78.0%, 2003 = 73.3%, 2008 = 69.5%, 2013 = 37.8%]. Among the 54 patients with a repeat biopsy, 25 individuals who presented with class III/IV underwent a class switch to class V or III/IV+V. These findings showed a tendency for increased use of mycophenolate mofetil at the end of follow-up. Age, gender, race, and BMI were not statistically different over time.

Characteristics (*=Baseline, #=Follow-up)	1998	2003	2008	2013
* Patients (#female)	41 (32)	30 (24)	23 (22)	37 (25)
* with Class V	4	5	3	11
* with Class III/IV+V	1	0	1	7
* with Class III/IV	32	22	16	14
* Mean Age at First Biopsy	31.3	32.5	35.3	35.3
* Non-Hispanic White	17 (65%)	12 (63%)	12 (75%)	14 (58%)
* BMI	29.1	30.3	31.2	29.0
# Mycophenolate Mofetil Use at End of Follow-up (2012-2015)	28.5%	29.4%	66.6%	42.8%

Conclusions: The incidence of class V lupus nephritis increased in the interval 1998-2013. These findings were associated with a decreasing incidence of class III/IV and a tendency for these patients to switch to class V or III/IV+V on repeat biopsy. These changes occurred during a period of increased use of systemic immunotherapy, which may have altered the manifestation of lupus nephritis to a more indolent course.

TH-PO722

Serum Autoantibodies in Membranous Nephropathy Patients with Negative Anti-PLA2R Antibody

Jianing Li, Hang Li, Jianfang Cai, Weifeng Lin, Yubing Wen, Xin Zhang, Xuewang Li. *Div of Nephrology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Beijing, China.*

Background: Anti-PLA2R antibodies are negative in up to 30% patients with idiopathic membranous nephropathy (iMN). Autoantibodies against Thrombospondin Type-1 Domain-containing 7A (THSD7A), α-Enolase(αENO) or SOD_2 have also been reported in iMN patients. We evaluated the clinical significance of these autoantibodies in iMN patients with negative serum anti-PLA2R-antibody.

Methods: In this prospective study, we consecutively recruited 97 iMN patients with negative anti-PLA2R antibody, 31 iMN patients with positive anti-PLA2R antibody, 17 patients with secondary membranous nephropathy (sMN), 28 patients with primary glomerular diseases other than MN, and 40 healthy controls. ELISA kits were used to assay serum autoantibodies against THSD7A, SOD_2 and αENO.

Results: A positive anti-THSD7A antibody was detected in 3 of 97 iMN patients with negative serum anti-PLA2R antibody, 1 of 31 iMN patients with positive serum anti-PLA2R antibody, but none of patients with sMN or other glomerular diseases or healthy controls. For titers of anti-SOD_2 antibody, there was no statistical difference among anti-PLA2R antibody-negative iMN, anti-PLA2R antibody-positive iMN, sMN and other glomerular diseases.Result is the same for anti-αENO antibody. IMN patients with negative serum and absent of anti-PLA2R, anti-THSD7A , anti-SOD_2, and anti-αENO antibodies had lighter proteinuria, higher eGFR, and higher serum albumin(all $P<0.05$) at baseline and shorter duration for remission($P<0.05$) as compared with iMN patients with at least one positive above-mentioned antibodies.

Conclusions: In the present study, we found anti-THSD7A may have diagnostic significance for iMN, whereas iMN patients absent of anti-THSD7A , anti-SOD_2, and anti-αENO antibodies may be associated with milder clinical manifestation and better response to treatment as compared with those with positive anti-THSD7A , anti-SOD_2, or anti-αENO antibodies.

TH-PO723

Interstitial Fibrosis Score by Whole Slide Imaging (WSI) Is a Predictor of Outcome in Proteinuric Renal Glomerulopathies

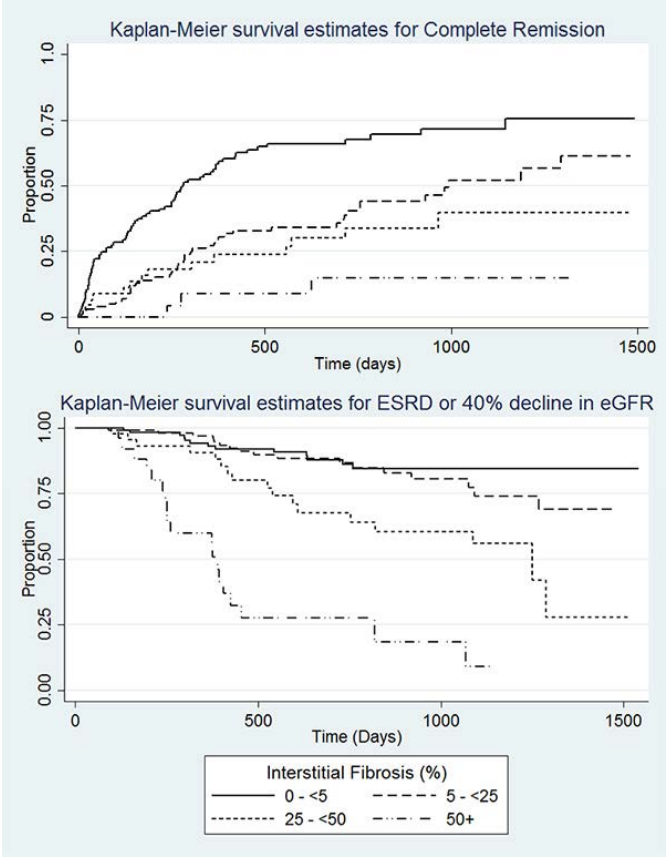
Laura H. Mariani,[1] Sebastian Martini,[1] L. Barisoni,[2] Pietro A. Canetta,[3] Jonathan P. Troost,[1] Jeffrey B. Hodgin,[1] Matthew Palmer,[5] A. Rosenberg,[7] Kevin V. Lemley,[6] Chien Hui-Ping,[4] Gerald B. Appel,[3] Howard Trachtman,[8] Stephen M. Hewitt,[7] Matthias Kretzler,[1] S.M. Bagnasco.[4] *[1]Univ of Michigan; [2]Univ of Miami; [3]Columbia Univ; [4]Johns Hopkins Univ; [5]Univ of Pennsylvania; [6]Children's Hosp, Los Angeles; [7]NIH; [8]NYU.*

Background: Interstitial fibrosis(IF), tubular atrophy(TA), and interstitial inflammation(II) are determinants of progression of renal disease. Standardized assessment could add value to current classification of glomerulopathies.

Methods: NEPTUNE is a multi-center, prospective study of children and adults with >500mg/day of proteinuria and clinically indicated renal biopsy. We studied 310 patients with minimal change disease (MCD n=88), focal segmental glomerulosclerosis (FSGS n=125), membranous nephropathy (MN n=58) and IgA nephropathy (IgAN n=39). IF, TA and II were quantified as % of interstitial space, on digitized whole slide biopsy images (WSI) by 2-5 pathologists (r>0.8 inter-reader agreement). Multivariable cox proportional hazards models were fit to assess hazard of complete remission (CR) and composite of reaching ESRD or 40% drop in eGFR.

Results: IF was highly correlated with TA ($r^2=0.98$, $P<0.001$) and II ($r^2=0.66$, $P<0.001$). Median(IQR) for IF was 7(2, 22) and varied by diagnosis [MN 7(4, 13), MCD 1(0, 3), FSGS 17(5, 39), IgA 21(11, 35), $P<0.001$]. 57% of the cohort had no II. Median II was highest in IgAN ($P<0.001$). IF was strongly correlated with baseline eGFR ($r=-0.71$, $P<0.001$) and

UPCR (r=0.18, P=0.002). Adjusting for age, race, diagnosis, baseline eGFR and UPCR, each 10% increase in IF score had HR of 0.81 (95%CI 0.67, 0.96, P=0.018) for CR and 1.55 (95%CI 1.3, 1.9, P<0.001) for ESRD/40% eGFR drop.



Conclusions: IF has predictive value in assessing risk of progression and remission across different types of proteinuric glomerulopathy.

Study of Relapse Patients with Steroid-Dependent Minimal Change Nephrotic Syndrome following Rituximab Treatment

Yuko Iwabuchi, Takashi Takei, Yoei Miyabe, Takahito Moriyama, Kosaku Nitta. *Dept of Medicine, Kidney center, Tokyo Women's Medical Univ, Tokyo, Japan.*

Background: In recent years, several clinical trials have shown the efficacy of rituximab (RTX) in patients with steroid-dependent minimal-change nephrotic syndrome (MCNS). We previously reported the efficacy and safety of a single dose of RTX infusions during 24-months at an interval of 6 months for patients with steroid-dependent MCNS in adults (Medicine 93: e300, 2014). But there are few reports about the relapse, and we also had some patients with relapse after RTX treatment. Therefore, the objective of this study was to evaluate the case that relapsed in patients with RTX.

Methods: We conducted a prospective cohort study with a historical control to evaluate the effect of single-dose infusions of RTX at 375 mg/m^2 BSA per dose at intervals of 6 months during 24-months followed by continuous RTX treatment as a maintenance therapy. 40 patients had RTX treatment, and 11 cases had a relapse during 24-months followed.

Results: In 11 cases with relapses, the patients with CD19 recovery (CD19>10/μL) at the time of the relapse were six, and mean CD19 at relapse was 56.4/μL, and the mean time to relapse from the RTX infusion was 178 days. On the other hand, three patients had relapse with CD19<10/μL, and mean CD19 at the time of the relapse was 2.63/μL, and the mean time to relapse from the RTX infusion was 77 days. Two patients were not measured CD19 revel at the time of relapse, and the time to relapses from the RTX infusion were 128 days and 146 days each.

Conclusions: The cause of relapse after RTX treatment seemed to be the result of the recovery of CD19. However, we experienced two cases that relapsed without recovery of CD19, so we report it with clinical course.

TH-PO725

Long-Term Outcome in Glomerulonephritis with Organized Microtubular Monoclonal Deposits (Immunotactoid Glomerulonephritis): A Case Series of 25 Patients

Léa Dufour,[1] Vincent Javaugue,[1] Guy Touchard,[1] Frank Bridoux.[1] *[1]Nephrology, Hospital, Poitiers, France; [2]Anatomopathology, Hospital, Poitiers, France; [3]Hematology, hospital Saint Louis, Paris, France.*

Background: Glomerulonephritis (GN) with organized microtubular monoclonal deposits (GOMMID), also referred to immunotactoid glomerulopathy, is a rare entity distinct from fibrillary GN and type 1 cryglobulinemic GN. Treatment and outcome in GOMMID remain poorly described.

Methods: Twenty-five adults (17 men, median age: 61 years) from 21 nephrology departments were retrospectively studied. Inclusion criteria were: Congo Red-negative, monotypic IgG glomerular deposits, with microtubular organization (10-60 nm in external diameter) by electron microscopy (EM), without pathological criteria for cryoglobulinemic GN.

Results: Renal manifestations included: constant proteinuria (median: 6.0 g/d), nephrotic syndrome (72%), microscopic hematuria (79%), hypertension (79%), median serum creatinine: 130 μmol/l. Biopsy proven extrarenal manifestations in 2 cases (mononeuritis, nodular hypodermitis). Eighteen patients had a serum and/or urinal monoclonal component, 12 had a lymphoproliferative disorder (chronic lymphocytic leukemia [CLL] n=9; lymphocytic B cell lymphoma n=3). Kidney biopsy showed atypical membranous GN (n=14) or membranoproliferative GN (n=11), with IgG deposits: IgG1 (n=8/15), IgG2 (n=5/15), IgG3 (n=2/15), mostly kappa (n=15/25). By EM, microtubule mean diameter was 15.6 nm. Intracytoplasmic lymphocyte microtubular inclusions were observed in n=4/11 (CLL n=3, lymphocytic B cell lymphoma n=1). Twenty-one patients received chemotherapy based on alkylating agent (n=17) and/or Rituximab (n=6). Renal response occurred in 15 cases (71%), associated with hematological response in 9 evaluable cases. Eleven patients received a second line of chemotherapy. After a median follow-up of 45 months, 17 patients had a persistent renal response, 5 had reached end-stage renal disease and 5 had died.

Conclusions: GOMMID should be suspected in patients with glomerular disease in the context of CLL or lymphocytic B cell lymphoma. Early chemotherapy, adapted to the underlying B-cell clone, is associated with a favorable renal outcome in 68% of patients.

TH-PO726

PLA2R-Related Membranous Nephropathy in a Patient with Mannan-Binding Lectin Deficiency

Stéphane Bally,[1] Hanna Debiec,[2] Chantal Dumestre-Perard,[3] Frédérique Dijoud,[4] John Rendu,[5] Pierre M. Ronco,[2] Denise Ponard.[3] *[1]Nephrology and Dialysis, CHU Chambéry, Chambéry, France; [2]UMR_S1155, INSERM, Paris, France; [3]Immunology Laboratory, CHU Grenoble, Grenoble, France; [4]Pathology Center, Hôpitaux de Lyon, Lyon, France; [5]Biochemistry and Molecular Genetics laboratory, CHU Grenoble, Grenoble, France.*

Background: About 75% of patients with primary membranous nephropathy (MN) have autoantibodies against phospholipase A2 receptor (PLA2R), predominantly of IgG4 subclass. C3 and C5b-9 occur in glomerular immune deposits, implicating complement activation as a putative effector mechanism. It was also shown that purified anti-PLA2R IgG4 could activate the mannose binding lectin (MBL) pathway, but the respective role of the three pathways of complement activation remains elusive. Here we report the case of a patient with PLA2R related MN and MBL deficiency who developed MN.

Methods: Kidney biopsy specimens were evaluated for staining for PLA2R, IgG subclasses, and various complement components, including C3, C1q, C4d, factor B, properdin and C5b-9. MBL concentration was assayed by ELISA and its activity was measured from C4 cleavage. Polymorphisms in exon 1 and in the promoter region for *MBL2* were detected by direct sequencing.

Results: Kidney biopsy showed MN with intense staining for PLA2R, IgG4, C3, factor B, properdin and C5b-9 and weak staining for C1q, IgG1 and C4d within the subepithelial deposits. Exploration of the lectin pathway revealed a severe MBL quantitative and functional deficiency (concentration 12 μg/l, normal range 30-3000 μg/l; and activity < 10% normal range 35-135%). Genotyping revealed a 57 (A/C) heterozygous polymorphism in codon 57 of exon 1 associated with homozygous and heterozygous variation at -550 (L/L) and -221 (X/Y) respectively in the promoter region, suggesting that the patient harbours the LXA/LYC haplotypes linked to MBL deficiency.

Conclusions: Due to MBL deficiency, binding of anti-PLA2R antibodies to PLA2R could not activate complement by lectin pathway. This is a first case of MN where complement was mainly activated by the antibody independent alternative pathway which does not exclude a direct role for the auto-antibody on receptor function with alteration of podocyte biology.

Alternatively Activated CD163$^+$ Macrophages Are a Common Feature in Progressive Interstitial Fibrosis Yohei Ikezumi,[1] Takeshi Yamada,[1] Hiroya Hasegawa,[1] David J. Nikolic-Paterson,[2] Akihiko Saitoh.[1] *[1]Dept of Pediatrics, Niigata Univ Medical and Dental Hospital, Niigata, Japan; [2]Monash Univ Dept of Medicine, Monash Medical Centre, Clayton, Victoria, Australia.*

Background: Recent studies have shown a disease-specific macrophage (MQ) phenotype in pathologies such as tumor metastasis, arteriosclerosis and diabetes. However, a kidney disease-specific MQ phenotype has not been described. This study examined whether alternatively activated CD68$^+$CD163$^+$ MQ are associated with interstitial fibrosis irrespective of the nature of the underlying disease.

Methods: Biopsies taken from children with IgA nephropathy (IgAN; n=81), purpura nephritis (HSPN; n=23), lupus nephritis (LN; n=16), minimal change nephrotic syndrome (MCNS) treated with cyclosporine (CyA) for >2 years (n=15), and chronic allograft injury (CAI; n=13, 28 biopsies) were immunostained for collagen I, pan macrophages (CD68) and CD163. Biopsies of thin basement membrane disease (n=9) or MCNS without CyA treatment (n=12) were used as controls. In vitro studies used monocyte-derived MQ from healthy human volunteers.

Results: Significant interstitial fibrosis and accumulation of CD68$^+$ MQ was evident in all progressive disease groups. Most interstitial CD68$^+$ MQ co-expressed CD163 (89-99%). By contrast, CD163 expression by glomerular CD68$^+$ MQ varied from 20-93% across the progressive disease groups, indicating much greater heterogeneity of M1/M2 phenotypes in this compartment. Interstitial CD163$^+$M2-type MQ correlated with the degree of interstitial fibrosis in each type of progressive renal disease (all $p<0.01$), with proteinuria in IgAN ($p<0.001$), HSPN, and LN ($p<0.01$), and with kidney function in CAI ($p<0.001$). In addition, CD163$^+$ MQ co-localized in fibrotic lesions with excess type I collagen deposition. In vitro studies showed that dexamethasone (Dex) up-regulated CD163 expression by MQ, and that Dex plus oxidized LDL increased MQ production of pro-fibrotic factors (FGF-1, FGF-2, TGF-b1, CTGF).

Conclusions: Our study identifies CD163$^+$ M2-type MQ as the main MQ population associated with interstitial fibrosis across a range of progressive forms of kidney disease, suggesting a functional role for this MQ subset in renal fibrosis.

Increased Urinary Angiotensinogen Is Associated with Crescent Formation in Initial Stage of Henöch Schönlein Purpura Nephritis Yanjie Huang, Xiaoqing Yang. *Dept of Pediatrics, The First Affiliated Hospital of Henan Univ of Traditional Chinese Medicine, Zhengzhou, Henan, China.*

Background: To investigate the relative factors of increased urinary angiotensinogen (uAGT) in children with Henöch Schönlein Purpura Nephritis (HSPN).

Methods: The severity of histopathological changes in HSPN is classified by the International Study of Kidney Disease in Children (ISKDC) into six categories: grade I-VI. 85 inpatient children with HSPN were underwent renal biopsy in our hospital from 2014 June to 2015 march, and their histopathological changes included grade II (mesangial proliferation, n=21) and grade III ((a) focal or (b) diffuse mesangial proliferation or sclerosis with <50% crescents, n=64). The grade III was again divided into IIIa (n=39) and IIIb (n=25) groups, III£25% crescent (n=52) and III>25% crescent (n=12) groups. Morning urine and serum of HSPN patients were collected on the day before renal biopsy. The levels of AGT and collagen type IV (CL-IV) in urinary and serum were detected using ELISA method. The urinary microalbuminuria and IgG levels were measured using immunoturbidimetric method. All indexes mentioned above were corrected with urine creatinine ratio.

Results: The serum AGT and CL-IV concentration had no significant difference among different groups. The uAGT levels were higher in grade III (30.13±13.69ug/gCr) than gradeII group (12.09±4.87ug/gCr), and also higher in grade III>25% crescent (57.69±23.31ug/gCr) than grade III£25% crescent group (28.26±12.02ug/gCr). The uAGT level had no significant difference between grade IIIa and IIIb group. The uAGT concentration was positively correlated with uCL-IV (r=0.505) and uIgG (r=0.512) respectively.

Conclusions: The increased uAGT level in initial stage of HSPN was related with the crescent formation. The enhanced uCL-IV suggested the glomerular basement membrane (GBM) may be cleavaged while the crescent formation. On the other hand, the increased uIgG concentration also showed the severe injury of GBM. Therefore, the combined detection of uAGT, uCL-IV and uIgG may contribute to judge the severity of pathological injury of HSPN.

TH-PO729

Ultrasound Microscopy Through a Fine Fiber for Renal Tissues Takane Ito, Takahiro Kanai, Jun Odaka, Takanori Yamagata. *Pediatrics, Jichi Medical Univ, Shimotsuke, Tochigi, Japan.*

Background: Renal pathology is a fundamental examination in observations of renal tissue conditions by light microscopy (LM), aiding in precise diagnoses. However, we cannot avoid a bleeding risk in renal biopsies. Additionally, we cannot sometimes make precise diagnoses in cases that the obtained renal tissue includes few glomeruli. Ultrasound (US) microscopy has been already developed, which enables histopathological observations by using the high frequency US. However, it has not been used clinically. We have been developing US microscopy through a fine quartz fiber (1mm in diameter). Our aim is to observe renal tissues in vivo using this method. As a result of this, we could perform safe and precise renal biopsy. For this purpose, we examined that the US microscopy through the fine fiber could obtain equivalent images of renal tissues with LM ex vivo.

Methods: We made the renal tissue slide specimens of patients with glomerulonephritis. Specifically, we made the unstained US microscopic slide specimens and the Periodic Acid-Schiff staining LM slide specimens from the paraffin blocks of renal biopsy tissues. Furthermore, we obtained their images of the US microscopy and LM.

Results: We could make discrimination between glomeruli and renal tubules by the US microscopy. In addition, mesangial cell proliferation and increased matrix, and fibrocellular crescent were detected by the US microscopy, which was enough to evaluate the conditions and lead to diagnoses.

Conclusions: We succeeded in obtaining the images of renal tissues using the US microscopy through a fine quartz fiber ex vivo. Furthermore these images were similar to them of LM. This preliminary study provides a first step toward clinical application of US pathological observation in renal diseases. These high-resolution images through a fine fiber could not only make live images of renal tissues possible, but prevent removing renal tissues which few glomeruli include in. This enables safe and precise renal biopsy, and we can thereby make precise diagnoses of renal diseases. This study provides an important contribution to future diagnoses and treatments of renal diseases, and further studies are warranted.

TH-PO730

Serum Levels of Antiglycan IgG Autoantibodies in Patients with IgA Nephropathy Predict the Oxford Classification Scores S and T Nicolas Maillard,[1] Hitoshi Suzuki,[2] Blandine Laurent,[1] Bruce A. Julian,[2] Christopher R. Mariat,[1] Jan Novak,[2] Francois C. Berthoux.[1] *[1]Nephrology, Dialysis, Transplantation, CHU Saint Etienne, Saint Etienne, France; [2]Dept of Microbiology, Univ of Alabama at Birmingham, Birmingham.*

Background: IgA nephropathy (IgAN) is driven by mesangial deposition of immune complexes consisting of galactose-deficient IgA1 (Gd-IgA1) and IgG antiglycan autoantibodies, leading to glomerular injury and chronic kidney disease. As serum levels of Gd-IgA1 and IgG autoantibodies have prognostic significance, we evaluated in this study the relationship between these markers and renal histology according to the Oxford classification.

Methods: Ninety-seven biopsy-proven IgAN patients were selected from our to equally represent the absolute renal risk scores from 0 to 3. Gd-IgA1 and IgG autoantibody levels were assessed in the serum samples obtained at the time of diagnosis using ELISA. Oxford classification and global optical scores (GOS) were compiled based on the evaluation of stored kidney tissue sections. A logistic regression analysis and c statistics were performed.

Results: Eighty-six patients were included in the Oxford analysis (biopsies from 11 patients did not have sufficient tissue) and GOS was calculated. IgG autoantibody levels predicted a T score of 1 or 2, using a logistic regression model (estimate 1.04, p=0.01), and an S score of 1 (estimate 1.10, p=0.006), but did not predict a positive M or E score. GOS was predicted by IgG autoantibody levels (linear regression, $p<0.001$). The ROC curve analysis revealed an areas under curve of 0.68 [0.55-0.81] and 0.68 [0.57-0.80] predicting positive T and S scores from IgG autoantibody levels. Gd-IgA1 levels were not associated with any histological pattern.

Conclusions: IgG autoantibody levels correlated with GOS and predicted positive S and T scores according to Oxford classification in IgAN.

TH-PO731

Comparison of Native and Transplant Percutaneous Renal Biopsy: Safety and Diagnostic Yield William Luke Whittier, Samuel N. Saltzberg, Stephen M. Korbet. *Nephrology, Rush Univ, Chicago, IL.*

Background: No prospective studies exist which directly compare the safety and adequacy of the percutaneous native (NRB) and transplant (TRB) renal biopsy. We report a large single-center prospective series comparing the success and complication rate of NRB and TRB over a twenty year period.

Methods: From 01/1995 to 04/2015, 1,705 adult pts underwent NRB (N= 767) or TRB (N=938) by a Nephrology attending or fellow. Data were collected prospectively in all biopsies. Real-time U/S guidance and automated needles were used for all biopsies. NRB was performed with either a 14 or 16 gauge needle while TRB was with a 16 gauge needle. All NRB pts were observed in the hospital for at least 24 hours and TRB pts for at least 3 hours. Complications were defined by the need for an intervention (i.e. transfusion, surgery or embolization), readmission, or death.

Results: At the time of biopsy, NRB pts were younger (47±17 vs. 50±14 years, $p<0.0001$) and more often female (62 vs. 48%, $p<0.0001$) compared to TRB. TRB pts had higher blood pressure (systolic BP: 140±22 vs. 133±18 mmHg, $p<0.0001$), higher serum creatinine (3.1±1.8 vs. 2.3±2.2 mg/dl, $p<0.0001$), increased aPTT (28±4.3 vs. 27±5 seconds, $p<0.0001$) as well as lower Hgb (11.2±1.8 vs. 11.7±2.1 g/dl, $p<0.0001$) compared to NRB. A fellow performed the biopsy in 91% of NRB compared to 63% of TRB ($p<0.0001$). Adequate tissue for diagnosis was obtained in 99% of NRB and TRB (p=0.71). Total number of glomeruli on light and immunofluorescent microscopy was 33±17 for TRB and 31±13 for NRB (p=0.11). The only factor predictive of a complication in the TRB was pre-TRB Hgb (no complication, 11.2±1.7 vs. complication, 10.1±1.7 g/dl, $p<0.0001$). Compared to TRB pts, NRB pts had a greater drop in Hgb post-PRB (0.97±1.1 vs. 0.73±1.3 g/dl, $p<0.0001$), had more complications (6.5 vs. 3.9%, p=0.02) and/or transfusions (5.2 vs. 3.3%, p=0.045). There was 1 death in each group attributed to the biopsy.

Conclusions: The NRB and TRB remain successful and safe procedures. There are more complications with NRB compared to TRB despite TRB pts having more risk factors. Differences in technique, operator (fellow or attending), or needle size may explain this variability.

TH-PO732

Serum Immunoglobulin E Level Is Associated with Renal Progression in Immunoglobulin A Nephropathy Shin yeong Lee, Jin sug Kim, Sang ho Lee, Se yun Kim, Yu ho Lee, Kyung-hwan Jeong, Tae won Lee, Ji hoon Lee, Yang gyun Kim, Ju-Young Moon, Chun-Gyoo Ihm. *Dept of Nephrology, Kyung Hee Univ Medical Center, Seoul, Korea.*

Background: Previous studies reported that serum Immunoglobulin E(IgE) levels are elevated in Immunoglobulin A nephropathy(IgAN) and suggested IgE levels as a prognostic indicator in IgAN. The aim of this study is to explore the association between plasma IgE level of IgAN patients and renal outcome.

Methods: This study is an observational study of IgAN patients undergoing kidney biopsy between 1995 and 2012. We collected the data of patient's demographics and serum IgE levels from routine laboratory examination. We retrospectively analyzed the correlation between serum IgE level and clinical parameters and pathologic findings. We defined renal progression if patient meets the following criteria; 1) negative value of delta estimated glomerular filtration rate(eGFR)(ml/min/1.73m2/months) and 2) a rise in serum creatinine(SCr) an absolute level ³1.3 mg/dl(male) or 1.2mg/dl(female).

Results: A total of 117 patients were included. The mean level of initial eGFR and serum IgE were 84.79±37ml/min/1.73m2 and 304±607IU/mL. The distribution in glomerular grades using the H. S. Lee grading was as follows; grade 1, 28 patients(23.9%); grade II, 62 patients(53%); grade III, 19 patients(16.2%); grade IV, 6 patients; grade V, 1 patient. Of the 117 patients, twenty-two (22%) had renal progression. Serum IgE level was significantly high in renal progression group compared to nonprogressive group. (590±1247 vs. 238±290, p=0.014). Gender(76% vs 50%, P=0.011) and history of gross hematuria (9% vs 29%, p=0.024) were significant difference between high and low IgE group. But no significant differences were seen for delta SCr,delta eGFR, delta proteinuria and pathologic findings. Linear regression analysis showed that male gender(β=0.308 ,p =0.028), initial proteinuria(β=0.617 ,p=0.008) and delta proteinuria (β=0.404, p =0.028) were significant associated with IgE levels.

Conclusions: These results suggested that serum IgE level is probably associated with renal progression in IgAN patients. Further studies are needed to elucidate immunopathogenesis of the increased IgE level in IgAN.

TH-PO733

Podometric Changes in Perinatal Kidneys (127 to 471 Day Post-Conception) Masao Kikuchi, Larysa T. Wickman, Su Qing Wang, Mahboob A. Chowdhury, Roger C. Wiggins, Raja Rabah. *Div of Nephrology, Dept of Internal Medicine, Univ of Michigan, Ann Arbor, MI.*

Background: We recently reported that glomerular volume increases and podocyte density decreases with age from 4 to 89 years in man. However the changes that occur before and immediately after 38 weeks gestation are not well defined.

Methods: Podometric parameters (including glomerular volume, podocyte number, density and cell size) were estimated from archival tissue sections with recently developed technology (Venkatareddy et al. JASN 2014 and Yang et al. JASN 2015) using autopsied kidney samples from newborn and infants without kidney disease as a proximate cause of death (n=25, age 0-240 day-old). Because premature kidneys were included, post-conceptional age (range 127-471 day-old) was used instead of postnatal age.

Results: The younger post-conceptional age was, the greater the proportion of immature glomeruli present (R^2=0.63, P<0.001). Compared to mature glomeruli, immature glomeruli were smaller (1.4×10^5 vs 4.9×10^5 μm³, P<0.001) and podocytes were smaller (140 vs 320 μm³, P<0.001) and fewer per glomerular tuft (300 vs 520, P<0.001), and present at higher podocyte density (2,700 vs 1,400 /10^6 μm³, P<0.001). In mature glomeruli podocyte density decreased linearly with age (R^2=0.54, P<0.001) due to a rapid increase in glomerular volume (+210% per year, R^2=0.48, P<0.001). Podocyte number per glomerular tuft did not change with age (R^2=0.008, P=0.68). Mean podocyte cell volume increased with age (+140% per year, R^2=0.39, P<0.002). Glomerular volume correlated with kidney-to-body weight ratio (R^2=0.49, P<0.001).

Conclusions: Prior to and after term there is a very rapid decrease in podocyte density (increase in glomerular volume and podocyte size without a change in podocyte number or proportion of the glomerulus that constitutes podocytes). These large perinatal adaptations could play a role in triggering glomerular syndromes prevalent early in life.

TH-PO734

Novel Monoclonal Antibody KM55 Specifically Detected Glomerular Galactose-Deficient IgA1 in Patients with IgA Nephropathy Hitoshi Suzuki,[1] Junichi Yasutake,[1,2] Yuki Tanbo,[1,2] Yusuke Suzuki.[1] *[1]Nephrology, Juntendo Univ Faculty of Medicine, Tokyo, Japan; [2]Nephrology Research Labs, Kyowa Hakko Kirin Co., Ltd., Tokyo, Japan.*

Background: Galactose-deficient IgA1 (Gd-IgA1) has been proposed as an important effecter molecule in patients with IgA nephropathy (IgAN). Our previous study revealed that Gd-IgA1-specific monoclonal antibody KM55 could be a new tool for detecting circulatory Gd-IgA1 in patients with IgAN, which enabled us to study molecular roles of Gd-IgA1. In this study, we further examined pathophysiological significance of Gd-IgA1 in glomerular deposits of patients with IgA nephropathy by immunohistochemical analysis with KM55.

Methods: Immunostaining of Gd-IgA1 and immunoglobulins (IgA and IgG) was performed with KM55 and anti-immunoglobulin polyclonal antibodies in paraffin embedded sections of renal biopsy specimens from patients with IgAN (n=16), and other renal diseases (n=19); such as lupus nephritis and membranous nephritis. Area of glomerular deposits of Gd-IgA1 and immunoglobulins were semi-quantitated by spectral imaging using Nuance software.

Results: Glomerular Gd-IgA1 was specifically detected in all patients with IgAN, but not in those with other renal diseases. Gd-IgA1 could not be detected even in patients with lupus nephritis whose glomerular IgA were positive. In patients with IgAN, immunofluorescence with KM55 revealed diffuse and global glomerular staining of Gd-IgA1. Moreover, double staining of Gd-IgA1 and IgA showed that Gd-IgA1 was localized predominantly in the mesangial region; however the localization of IgA was similar to that of Gd-IgA1 but was more broadly observed.

Conclusions: This is the first observation to clearly reveal that Gd-IgA1 could be specifically deposited in glomeruli of IgAN, strongly suggesting the pathophysiological function of Gd-IgA1 in patients with IgAN. Further studies are necessary to clarify the underlying mechanisms of Gd-IgA1 deposition and induction of renal injuries in IgAN. Novel monoclonal antibody KM55 against galactose-deficient IgA1 could be a powerful tool to detect nephritogenic IgA in patients with IgAN.

Serum Levels of Galactose-Deficient IgA1 in Patients with IgA Nephropathy Correlate with Serum Levels of IgG Autoantibodies William J. Placzek,[1] Yuko Makita,[4] Matthew B. Renfrow,[1] Bruce A. Julian,[3] Yusuke Suzuki,[4] Jan Novak,[2] Hitoshi Suzuki.[4] *[1]Biochemistry and Molecular Genetics, The Univ of Alabama at Birmingham, Birmingham, AL; [2]Microbiology, The Univ of Alabama at Birmingham, Birmingham, AL; [3]Medicine, The Univ of Alabama at Birmingham, Birmingham, AL; [4]Internal Medicine, Juntendo Univ, Tokyo, Japan.*

Background: IgA nephropathy (IgAN) is an autoimmune disease in which IgA1 with some *O*-glycans deficient in galactose (Gd-IgA1) is recognized by anti-glycan IgG and/or IgA autoantibodies to form pathogenic immune complexes. Some of these immune complexes deposit in the kidney and induce glomerular injury. In this study, we assessed possible associations between serum levels of Gd-IgA1 and IgA, and Gd-IgA1 and IgG or IgA autoantibodies.

Methods: Serum samples from 135 patients with biopsy-proven IgAN, 79 patients with other renal diseases, and 106 healthy controls at Juntendo University, Tokyo, Japan, were analyzed for levels of total IgA and IgG, Gd-IgA1, and Gd-IgA1-specific IgA and IgG autoantibodies and the data assessed for possible associations.

Results: Patients with IgAN had higher total IgA compared to healthy controls and exhibited a significantly stronger correlation between total IgA and Gd-IgA1 levels (r=0.639 *vs.* r=0.901, p<0.0001). Gd-IgA1 levels strongly correlated with levels of Gd-IgA1-specific IgG autoantibodies in patients with IgAN (r=0.4909, p<0.0001), but not in healthy controls or disease controls. Levels of Gd-IgA1 did not correlate with the levels of IgA autoantibodies in any of the three groups. Furthermore, among IgAN patients with levels of Gd-IgA1-specific IgG higher than the mean + 2 SD level of healthy controls, only 37% also had an elevated level of Gd-IgA1-specific IgA autoantibody.

Conclusions: Our data revealed a new association between the key autoantigen, Gd-IgA1, and IgG autoantibodies in patients with IgAN, further supporting their key role in the pathogenesis of IgAN.

Cryoglobulinemic Glomerulonephritis: A Single-Center Experience Insara Jaffer Sathick,[1] Tyler V. Klobucher,[2] Nelson Leung,[1,3] Samih H. Nasr.[4] *[1]Div of Nephrology, Mayo Clinic, Rochester, MN; [2]Mayo Medical School, Rochester, MN; [3]Div of Hematology, Mayo Clinic, Rochester, MN; [4]Div of Anatomic Pathology, Mayo Clinic, Rochester, MN.*

Background: Cryoglobulinemic glomerulonephritis(CryoGN) is a recognized form of glomerulonephritis. However,the clinical characteristics are not well-established due to lack of large studies with biopsy and serological confirmation. We present our experience with 42 cases of serologically and biopsy-proven CryoGN.

Methods: We conducted a retrospective search for patients with cryoglobulinemia and kidney biopsy and identified patients with CryoGN.

Results: From 2000 to 2014, we identified 569 patients with cryoglobulinemia. Of the 71 patients who underwent kidney biopsy for kidney dysfunction,42(59%) had CryoGN, the remaining had other pathology, including interstitial nephritis, lupus nephritis, fibrillary GN and amyloidosis. Median age of CryoGN patients was 59 yrs;male/female ratio, 23:19. Median eGFR by MDRD equation was 41ml/min/1.73m2 at onset. 88% had nephritic syndrome and rest had nephrotic syndrome. 74% had Type II, 19%- Type I and 7%-Type III cryoglobulinemia. Hypocomplementemia was present in 83%. 76% had skin involvement, 16% had joint symptoms, 14% had neuropathy and 1% had pulmonary involvement. 4 patients required dialysis. Etiology of cryoglobulinemia was a hematological disorder in 40%(of which 88% lymphoproliferative and 12% MGRS) and hepatitis C in 26% patients.

Etiology of Cryo GN(% total)	Type I(19%)	Type II(74%)	Type III(7%)
Hematological (40%)	23	71	6
Hepatitis C (26%)	9	82	9
Connective Tissue Disease (17%)	14	72	14
Idiopathic (17%)	34	66	

80% patients received immunosuppression for treatment, 54% receiving Rituximab. Median duration of follow up was 18 months. Median overall survival was 36.4 months. At 6 months, median eGFR improved to 48ml/min1.73m2.

Conclusions: Though CryoGN is the most common pathology in cryoglobulinemia, a wide array of other lesions is seen**.** Most patients with CryoGN have skin lesions while other systemic features of cryoglobulinemia are rare. In this study hematological disorders were the commonest etiology for CryoGN followed by hepatitis C infection.

The Clinicopathological Impact of Medullary Ray Injury on Early Stage Renal Allografts Takahito Niikura,[1] Akimitsu Kobayashi,[1] Yasuyuki Nakada,[1] Izumi Yamamoto,[1] Yudo Tanno,[1] Ichiro Ohkido,[1] Masayoshi Okumi,[2] Hideki Ishida,[2] Kazunari Tanabe,[2] Hiroyasu Yamamoto,[1] Takashi Yokoo.[1] *[1]Nephrology and Hypertension, The Jikei Univ School of Medicine, Tokyo, Japan; [2]Urology, Tokyo Women's Medical Univ, Tokyo, Japan.*

Background: Interstitial fibrosis and tubular atrophy (IF/TA) constitute an important cause of renal graft loss.Previously, we examined medullary ray injury (MRI) inducing IF/TA via non-immunological mechanisms, classifying the etiology of MRI into calcineurin inhibitor (CNI) toxicity (32.8%), vesicoureteral reflux (50%), and urinary tract infection (8.6%) (Pathol Int. 2010;60:744–9). However, we did not examine the influence of the etiology on the long-term renal allograft prognosis, since the timing of the biopsies differed among the cases. Herein, we focused on MRI observed in protocol biopsies within 3 months, examining the influence on the renal allograft prognosis.

Methods: Retrospectively, we divided 53 protocol biopsies within 3 months into two groups with (n=34) and without (n=19) MRI. The MRI+ cases with isometric vacuolization and aah in the Banff classification were classified as CNI toxicity (MRI+CNI); the cases with Tamm-Horsfall protein casts in the interstitium and thyroid-like appearance were classified as urinary tract system abnormalities (MRI+UT); and the remaining cases as others. We compared the annual change in serum creatinine (sCr) levels over 3 years and the extent of fibrosis (ct+ci) at the 1-year biopsies. Cases with rejection were excluded.

Results: The sCr levels declined in both groups, but were significantly higher in the MRI+ group than the MRI– group at 3 years (p=0.024). Examining three MRI+ subgroups, only MRI+UT had significantly high sCr levels compared to the MRI– group (p=0.019). The observation of IF/TA in the base-line and 1-year biopsies in the MRI+ group indicated the significant development of IF/TA.

Conclusions: Cases developing MRI within 3 months after kidney transplantation were significantly more likely to develop IF/TA at the 1-year biopsies. These cases had higher sCr levels at 3 years. In the cases with MRI in the base-line biopsies, interventions might preserve kidney graft function over the long-term.

TH-PO738

Diagnostic Gene Signature from Urinary Extracellular Vesicles Can Be Used as Biomarker for Non-Invasive Diagnosis of Clear Cell Renal Cell Carcinoma Giuseppe De Palma,[1] Fabio Sallustio,[1,2] Vanessa Galleggiante,[3] Monica Rutigliano,[3] M. Battaglia,[3] Francesco Paolo Schena.[1] *[1]C.A.R.S.O. Consortium, Univ of Bari, Valenzano, BA, Italy; [2]Dept of Science, Biological and Environmental Sciences and Technologies, Univ of Salento, Lecce, LE, Italy; [3]Urology, Andrology and Kidney Transplantation Unit, Dept of Emergency and Organ Transplantation, Univ of Bari, Bari, BA, Italy.*

Background: Clear cell renal cell carcinoma (ccRCC) is one of the most common malignancies and due to its intimate association with urine, it appears well suited for studies to identify non-invasive biomarker in this material. The extracellular vesicles (EV) can be isolated in urine. They transport proteins and nucleic acids that reflect the physiopathological status of renal cells. The purpose of this study has been to analyze the transcripts in the urinary EV from ccRCC patients and to specific transcripts for preventive diagnosis of ccRCC.

Methods: We enrolled 12 patients with a diagnosis of ccRCC undergoing unilateral nephrectomy. We collected pre-intervention urine. A group of healthy volunteers (n = 11) with negative urine analysis was used as control. The EV were isolated from the urine by differential centrifugation. Total RNA was extracted, quantified and qualitatively evaluated. Illumina HumanHT-12 v4 BeadChip was used for microarray analyses. Then, the dysregulated genes were validated by qRT-PCR in independent cohorts of 12 patients and 10 controls.

Results: We identified four genes (GSTA1, CEBPA, PCBD1, RCC2) differentially modulated in ccRCC patients and we investigated whether the functions of these genes could be related to ccRCC through the pathways analysis. The qRT-PCR validated a number of potential diagnostic biomarkers that could be used to distinguish ccRCC patients at an early stage from healthy individuals. Some potential biomarkers were already present in pathways involved in the pathogenesis of cancer as glutathione or arsenate mediated detoxification instead other biomarkers were new.

Conclusions: Using this approach, we have identified a signature of four transcripts that could be used as biomarkers for non-invasive diagnosis of ccRCC.

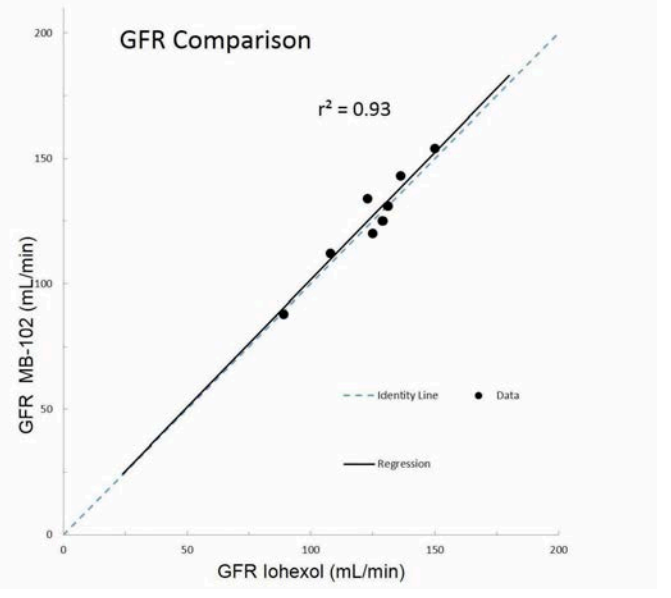
TH-PO739

Initial Clinical Trial Results of a Real-Time Point-of-Care Glomerular Filtration Rate Measurement Utilizing a Novel Fluorescent Tracer Agent Richard B. Dorshow,[1] Martin Debreczeny,[1] Jeffrey C. Fink,[3] Thomas C. Dowling.[2] *[1]MediBeacon, LLC, St. Louis, MO; [2]College of Pharmacy, Ferris State Univ, Grand Rapids, MI; [3]Dept of Medicine, Univ of Maryland Medical System, Baltimore, MD.*

Background: A first-in-human clinical study with MB-102, a fluorescent tracer agent engineered to have photophysical and clearance properties for use as a real-time point-of-care measure of glomerular filtration rate (GFR) is reported. The clearance of this agent can be monitored noninvasively by transdermal fluorescence.

Methods: Blood samples were taken over a period of 12 hours post simultaneous administration of MB-102 and iohexol to assess pharmacokinetic parameters including clearance on 32 subjects recruited to have normal renal function. Urine samples were collected concurrently to assess percent injected dose recovered in the urine. A prototype noninvasive fluorescence detection device was employed to simultaneously measure the transdermal fluorescence from MB-102 to assess correlation with the plasma pharmacokinetics.

Results: The plasma pharmacokinetics displayed the expected 2 compartment model of a vascular-tissue equilibrium phase followed by renal excretion only. The GFR measured from the MB-102 plasma pharmacokinetics matched the GFR measured from iohexol.



The % injected dose of MB-102 appearing in the urine (99+/-7%) matched that of iohexol. The MB-102 time-dependence of the transdermal fluorescence monitored by the prototype device matched that of the plasma (r^2~0.98). No significant adverse events were reported.

Conclusions: MB-102 was shown to be a GFR tracer agent in humans from the plasma pharmacokinetic match and the % injected dose in urine match to iohexol. The transdermal fluorescence pharmacokinetics mirrored that of the plasma pharmacokinetics thus demonstrating that the validity of this noninvasive GFR measurement.

Analysis of Exogenous Near Infrared Fluorescent Markers for the Transcutaneous Measurement of Glomerular Filtration Rate Jiaguo Huang,[1] Stefanie Weinfurter,[1] Johannes Pill,[2] Norbert Gretz,[1] Rossana Perciaccante,[3] Federica Rodeghiero,[3] Lepoldo Della ciana.[3] *[1]Medical Faculty Mannheim, Univ of Heidelberg, Mannheim, Germany; [2]Mannheim Pharma & Diagnostics GmbH, Mannheim, Germany; [3]Cyanagen S.r.l., Bologna, Italy.*

Background: Recently, we developed approaches for the transcutaneous measurement of GFR in lab animals. Using fluorescent markers allows GFR assessment without blood and/or urine sampling. Therefore, there is considerable interest in the development of exogenous fluorescent markers for real-time and accurate measurement of GFR via transcutaneous fluorescent methods using new dye conjugates.

Methods: A near infrared (NIR) cyanine was synthesized by a five-step synthetic procedure. This dye was used to label (2-hydroxypropyl)-β cyclodextrin. The chemical structure was fully confirmed by ^{1}H-NMR, ^{13}C-NMR, and HRMS spectra. Optical properties were characterized by UV-2450 spectrophotometer and fluorescence spectrometer. The percent plasma protein binding (PPB) was determined by equilibrium dialysis of fluorescent marker solutions incubated with rat plasma using a two-chamber dialysis set-up. Elimination half-life was determined in combination with a miniaturized new electronic device for

the transcutaneous fluorescence detection in freely moving rats. Recovery rate in urine was measured in conscious rats after intravenous injection using metabolic cages. Mean ± S.D are given.

Results: The NIR marker was synthesized in a high yield. It exhibits good water solubility with concentrations reaching more than 200 mg/mL with a molecular weight range from roughly 1200 up to 2700 D. In addition it shows a low plasma PPB, i.e. 3.7 %, which is clearly lower than that of iothalamate (9.5 %). The excitation and emission are 705 nm and 790 nm respectively providing low background and high tissue penetration for in vivo application. The noninvasive real-time monitoring of clearance resulted in a half-life of 33.4 ± 4.6 min and 34.9 ± 6.8 min without and with probenecid treatment, respectively. A high urinary recovery of the marker with 99 ± 7.3% of the dose given was observed within 24 h.

Conclusions: We identified the marker with a high potential as exogenous fluorescent tracer for GFR measurement. A patent has been filed.

Phospholipase A2 Receptor Antibodies in Membranous Nephropathy: Biopsy, Serum and Urine Findings Aikaterini K. Nikolopoulou, Theresa H. Page, Gurjeet Bhangal, Janet Lee, Paul Brookes, Tom Cairns, Liz Lightstone, Megan Griffith, H. Terence Cook, Charles D. Pusey. *Renal and Transplant Centre, Imperial College London, London, United Kingdom.*

Background: The major target antigen in Membranous Nephropathy (MN) is the phospholipase A2 receptor (PLA2R); its exact role is not yet fully understood. In this retrospective study we examined the presence of PLA2R in biopsy tissue, PLA2R antibodies in serum and urine of patients with MN, and aimed to identify associated clinical variables.

Methods: 120 MN patients were identified from 2008 - 2014: 74 with idiopathic MN (iMN); 12 secondary MN; 9 recurrent MN post transplantation; 25 class V lupus MN (LMN). 27 controls with other GN were also used. Immunofluorescence (IF) for PLA2R was performed on paraffin embedded biopsies and ELISA (EUROIMMUN) for the detection of PLA2R antibodies in serum and urine.

Results: In the iMN group 35/74 (47%) biopsies stained positive, 30 (40%) negative and 9(12%) borderline. Circulating PLA2R antibodies were detected in sera from 30/74(40%) patients within 6 months from biopsy, all of whom had positive or borderline staining on biopsy. In the secondary MN group 5/12 stained positive; 1 had a detectable PLA2R antibody. In the transplant cohort 3/9 stained positive; 1 had a positive serum. Of 25 class V LMN, 3 stained positive and 1 had a positive serum antibody. There was no correlation between staining or the level of PLA2R antibody with proteinuria or creatinine at the time of biopsy. Urine from 5 iMN patients with active disease was positive for PLA2R antibodies; 26 healthy controls and 6 iMN patients in remission tested negative.

Conclusions: Our data suggest that IF for PLA2R in biopsy tissue is more sensitive than serum testing for the presence of PLA2R antibodies. This cross sectional study did not demonstrate a correlation between PLA2R staining or antibody levels and proteinuria at the time of biopsy; however a longitudinal study to assess the variations of PLA2R Ab levels with clinical outcomes is in progress. The presence of PLA2R antibodies in urine of patients with active disease is interesting although further studies are required to determine whether this is due to nonspecific proteinuria.

TH-PO742

Belimumab in Idiopathic Membranous Nephropathy: An Interim Analysis of Exploratory Biomarkers Including Anti-PLA2R Autoantibodies Christine Barrett,[1] Shaun Flint,[1] Robert Brian Henderson,[1] Tim Sebastian Schmidt,[1] Sophie I. Gisbert,[1] Gengqian Cai,[2] Caroline O.S. Savage.[1] *[1]GlaxoSmithKline plc, United Kingdom; [2]GlaxoSmithKline plc.*

Background: Belimumab, a B-lymphocyte stimulator (BLyS)-specific inhibitor has been shown to reduce anti-phospholipase A2 receptor (PLA2R) autoantibodies and proteinuria in a mechanistic study (BEL116472) in idiopathic (primary) membranous nephropathy (IMN). Here we report an interim analysis of individual patient responses and analysis of exploratory pharmacodynamic (PD) biomarkers.

Methods: 14 anti-PLA2R autoantibody positive IMN patients with nephrotic range proteinuria received 10mg/kg iv belimumab every 4 wks (or 2 wks if >10g/24h) for up to 100 wks. 11 of these completed at least 28 wks treatment, with 3 withdrawals before wk 16. Assessment of proteinuria, anti-PLA2R antibody levels, belimumab kinetics, BLyS levels and B cell immunophenotypes was performed.

Results: There was a significant reduction in anti-PLA2R antibodies by wk 12 (-46%, p=0.025) and in uPCR by wk 36 (-38%, p=0.022). 9 of 11 subjects showed a reduction of >50% in anti-PLA2R levels at the primary endpoint (wk 28). 6 of 11 achieved at least partial remission of proteinuria and negative or borderline anti-PLA2R levels by last follow-up to date (44-104 wks). Lack of remission was linked to a smaller fall in anti-PLA2R levels, or anti-PLA2R at wk 28 >100 RU/ml, or a shorter follow-up (≤ 36 wks). Week 2 belimumab trough levels showed strong negative correlation with baseline uPCR (r_s=-0.94 p<0.0001). The correlation of baseline BLyS level with proteinuria response was weak. Exploratory belimumab PD effects included a reduction in naive B cells and expanded memory B cells.

Conclusions: This mechanistic trial of belimumab in IMN has enabled a novel analysis of PD and PK endpoints, confirming but also extending the PD effects previously reported in studies of SLE. Further analysis of anti-PLA2R antibody kinetics as a predictor of remission may also be informative.

Funding: Pharmaceutical Company Support - GlaxoSmithKline plc

TH-PO743

Diagnostic Performance of M-Type Phospholipase A2 Receptors Autoantibodies (Anti-PLA2R) for the Differentiation of Idiopathic Membranous Nephropathy (iMN) without Mesangial Immunocomplexes in Kidney Biopsy Hugo Enrique Chavez,[1] Juan Carlos Ramirez-Sandoval,[1] Magdalena Madero,[2] Ricardo Correa-Rotter,[1] Jose Antonio Nino-Cruz.[1] *[1]Nephrology and Mineral Metabolism, Inst Nacional de Ciencias Medicas y Nutrición Salvador Zubiran, Distrito Federal, Mexico; [2]Nephrology, Inst Nacional de Cardiología Ignacio Chávez, Distrito Federal, Mexico.*

Background: The presence of mesangial immunocomplexes in membranous nephropathy without an apparent cause constitutes a controversial element and has been considered a potential indicator of an unidentified secondary cause. The value of anti-PLA2R for diagnosis of iMN and for this specific purpose has not been assessed. **Objective**: Assess the diagnostic performance of anti-PLA2R to differentiate iMN (without mesangial deposits) and MN with presence of mesangial deposits as well as from other glomerulonephritis (GM).

Methods: We prospectively enrolled 108 cases with biopsy proven GM: 40 iMN, 33 systemic lupus erythematous (23 with proteinuria >1 g/day), and other. In 27 MN, we found proteinuria>1 g/day, of which 21 had typical granular deposition along the basement membrane (iMN cases); the 6 other had mesangial deposits without a diagnosed secondary cause of MN. Serum anti-PLA2R was assessed by ELISA (euroimmun, Germany).

Results: 21/108 patients had anti-PLA2R >9 RU/mL, all of them had iMN. Among patients with MN and proteinuria>1g/day, 19/27 had anti-PLA2R>9 RU/mL. The area under the ROC curve (AU-ROC) of anti-PLA2R was 0.87 (95% , CI: 78-0.96) when cases of MN and proteinuria>1 g/day were compared vs. other cases. At a cutoff of 9 RU/mL, sensitivity and specificity were 70% and 99% respectively. When we predefined cases of iMN and presence of mesangial deposits as probably not idiopathic, the AU-ROC was 0.95 (95%. CI: 0.87-1.00). In this analysis, at the cutoff of 9 RU/mL, the sensitivity and specificity were 91% and 99% respectively. All clinically diagnosed MN that had mesangial immunocomplex deposition were negative for Anti-PLA2R.

Conclusions: Anti-PLA2R levels had an excellent diagnostic performance to detect iMN. Anti-PLA2R >9 RU/mL may be sufficient to diagnose iMN precluding the need of a renal biopsy.

TH-PO744

Declining Renal Function in Idiopathic Membranous Nephropathy: A Report from Two Tertiary London Renal Units Sanjana Gupta,[1] Kieran Mccafferty,[2] Horia Stanescu,[1] Stephen H. Powis,[1] Alan D. Salama,[1] John Connolly,[1] Stephen B. Walsh,[1] Robert Kleta,[1] Muhammad M. Yaqoob,[2] Neil Ashman.[2] *[1]UCL Centre for Nephrology; [2]Royal London Hospital.*

Background: Idiopathic Membranous Nephropathy (iMN) is a major cause of nephrotic syndrome in adults. Renal function may deteriorate (progressor) or be preserved (non-progressor patients).

Methods: We performed a retrospective analysis of patients with biopsy proven iMN between 2000-2015.

Results: We identified 188 patients with biopsy proven iMN.

Median age	58 (44-71)
Male %	68
Ethnicity (White / Black / Asian / Unknown) %	48 / 17 / 24 / 11
Diagnosis Serum creatinine (sCr) (µmol/L)	86.5 (64 – 111)
Diagnosis Serum albumin (sAlb) (mmol/L)	25 ± 7
Diagnosis urine protein creatinine ratio (PCR)	900 (485 – 1255)
Spontaneous remission %	34
Renal replacement therapy %	34
Deceased %	12

20% of patients were progressors (increase in sCr >50%, no RRT). There was no statistical difference between sCr (101 ± 6 vs 92 ± 9 µmol/L, ns), sAlb (25.2 ± 1.3 vs 26.2 ± 0.8 mmol/L, ns) or PCR (893 ± 87 vs 895 ± 94, ns) at diagnosis between progressors and non-progressors, respectively. Progressors were more likely to be Asian (36% vs 21%, p=0.058) and non-progressors black (32% vs 20%, p=0.058). Of the 37 patients that spontaneously remitted, 5% relapsed. 65% of patients were treated with immunosuppressives. 60% received prednisolone, the most used first line agent was cyclophosphamide 35%, then anti-proliferatives 34% and calcineurin inhibitors (CNI) 23%. There was a significant difference between treatment between progressors and non-progressors; progressors were treated with CNI (38% vs 15%, p=0.04). Rituximab was used 3 times. The complication rate from immunosuppression was 25%. The most common was diabetes from steroid therapy at 10%. Infection occurred in 2% and drug specific complications in 7%. Thromboembolism rate from nephrosis was low at 14%.

Conclusions: At diagnosis there was no significant difference in sCr, sAlb or PCR between progressors and non-progressors. Progressor patients with iMN may benefit from immunosuppression, but this is associated with risks. It is important to identify progressor patients; there is an unmet need for a biomarker to do this.

TH-PO745

End-Stage Renal Disease from Membranous Nephropathy in the United States, 1995 to 2010 Robert N. Foley,[1] Scott Reule,[1] Donal J. Sexton.[2] *[1]Div of Nephrology, Univ of Minnesota; [2]Div of Medicine, National Univ of Ireland, Galway.*

Background: While management has evolved substantially, it is unknown whether the burden of end-stage renal disease from membranous nephropathy (end-stage membranous nephropathy, ESMN) has declined.

Methods: Here retrospective United States Renal Data System data were used to enumerate incidence trends and outcomes of ESMN in the US between 1995 and 2010 (n = 7035, overall rate 1.9 per million per year).

Results: When adjustment was made for demographic shifts, adjusted incidence ratios (AIR, compared to 1995-1996) rose to 1.15 in 1997-1998 and remained stable between 1.09 and 1.14 in subsequent biennia. Other associations of ESMN included older age (AIR 4.08 for age 40-64 (Vs. < 20 yrs.), 9.55 for 64-79, and 8.09 for ≥ 80) male sex (AIR 2.20) and Black/African American race (AIR 3.15 Vs. White). Incidence trends differed by age group: AIR fell for age 40-64 (0.84 in 2009-2010 [Vs. 1995-1996]) and rose for age ≥ 80 (AIR 2.63). ESMN patients were more likely than matched controls to be listed for transplant (9.8 vs. 7.5 per 100 person years [PHPY]) and to receive a transplant (7.4 vs. 4.6 PHPY) and less likely to die (9.8 Vs. 15.9 PHPY). Among patients with ESMN, African American patients were as likely as whites to be listed for transplant (adjusted hazards ratio [AHR] 1.05), less likely to receive a transplant (AHR 0.61) and less likely to die prematurely (AHR 0.85).

Conclusions: While ESMN has not declined meaningfully in the last two decades, trends differ by age and racial disparities in outcomes on renal replacement therapy are apparent.

TH-PO746

42 Cases of Primary Sjögren Syndrome with Membranous Nephropathy: Clinicopathologic Features and Ectopic Germinal Center Formation Mengyu Zhou, Yubing Wen, Jing Wang, Xiaoxiao Shi, Yang Yu, Hang Li, Mingxi Li, Xuemei Li, Xuewang Lee, Limeng Chen. *Dept of Nephrology, Peking Union Medical College Hospital, Beijing, China.*

Background: To study the clinicopathologic features of primary Sjögren Syndrome (pSS) with membranous nephropathy (MN) from a single hospital center. Pathogenesis including the formation of ectopic germinal center (EGC) was explored.

Methods: From 1990 to 2014 in Peking Union Medical College Hospital, all pSS patients who underwent renal biopsy with a diagnosis of MN were reviewed. CD21 immunohistochemistry study was used to characterize EGC formation.

Results: Among 154 pSS patients with a renal biopsy, 94 (61%) were diagnosed with glomerulonephritis, including 42 (45%) cases of MN. The majority were female (76.2%) with an age of 52.3±15.0 years. At the time of renal biopsy, the patients presented with microscopic hematuria (80.9%), proteinuria (4.57±3.11g/24h), hypoalbuminemia (26.5±7.3 g/L) with normal eGFR (92.8±26.3 ml/min). Hypergammaglobulinemia and hypocomplementemia were present in 26.8% and 20.5% patients respectively. Pathologically, 17 (40.5%) cases had atypical MN, featured by mesangial electron-dense deposit or C1q staining. On immunofluorescent study, C3 was positive in 43.9% cases and C1q positive in 34.1%. IgG subtype staining showed positivity of IgG4 (95%), IgG1 (55%), IgG3 (50%) but not IgG2. Most patients showed clinical improvement on prednisone (1mg/kg/d) and/or immunosuppressant (cyclophosphamide or cyclosporine), while 2 patients had progression of CKD with persistent or recurrent proteinuria. CD21 staining on 36 available biopsy samples revealed the presence of EGC in 11 (31.4%) cases, and EGCs were notably abutting or surrounding the glomeruli in 7 cases. Grading of interstitial lymphocyte infiltration revealed the percentage of G0 (absent), G1 (scattered), G2 (focal) and G3 (EGC formation) to be 5.7%, 34.3%, 28.6% and 31.4%, respectively, which was negatively correlated with eGFR (p=0.008) and positively correlated with glomerulosclerosis index (p=0.001).

Conclusions: MN is the most common type of glomerulonephritis among pSS patients. Interstitial lymphocyte infiltration and EGC formation may be pathologically related to glomerular damage.

TH-PO747

In Primary Membranous Nephropathy, Relapse After Partial Remission Is Predicted by Serum Albumin Level Taewoo Lee,[1] Vimal K. Derebail,[1] Daniel C. Cattran,[2] Ronald J. Falk,[1] Heather N. Reich,[2] Patrick H. Nachman.[1] *[1]UNC Kidney Center, Chapel Hill, NC; [2]Toronto General Hospital, Toronto, ON, Canada.*

Background: In primary membranous nephropathy (MN), partial remission (PR), defined as 50%reduction of proteinuria+attaining<3.5g/day with stable GFR, is associated with decreased risk of ESKD, compared to No remission. However, PR is associated with greater risk of relapse (46%,median 8 months) compared to complete remission (proteinuria<0.3g/day) (23%,median 25 months). Relapses are associated with increased risk of ESKD. We investigated risk factors of relapse among patients who achieve PR by 18 months, thus simulating the setting of a clinical trial.

Methods: From the Glomerular Disease Collaborative Network cohort, we identified 135 patients who had a minimum of 24 months of follow up from biopsy. Patients who reached a PR at 18 months were included for the analysis. Patients with a relapse (proteinuria >3.5g /day) were compared to those with no relapse. Risk factors for relapse were explored by logistic regression analysis. A threshold of serum albumin (salb) associated with risk of relapse was evaluated using a receiver operator curve (ROC).

Results: Among 86 patients who met inclusion criteria, 30(35%) relapsed over a median follow up of 33months. Patients with relapse were similar to those with no relapse with respect to baseline demographics, proteinuria, salb, eGFR and immunosuppressive treatment. Relapsers had significantly lower salb level at 18 months compared to non relapsers (3.47±0.68 vs 3.89±0.46 respectively; P=0.002). C-statistics from the ROC for salb as a predictor of relapse was 0.75. 22% of patients with salb>3.5 g/dl at 18 month relapsed (median time to relapse 174 months; 0.7/100 patient-month), compared to 72% of patients with salb£3.5 g/dl (median time 42months; 2.4/100 patient-month).

Conclusions: Attaining a PR and a salb> 3.5 g/dl at 18 months after biopsy is associated with a low risk of relapse. We suggest that a definition of PR should include attaining a salb> 3.5 g/dl in addition to the target decrease and level of proteinuria. This definition should be evaluated as a possible surrogate endpoint for clinical trials in MN.

TH-PO748

Clinical Significance and Risk Factor of Relapse in Proteinuria in Primary Membranous Nephropathy Taewoo Lee,[1] Vimal K. Derebail,[1] Caroline J. Poulton,[1] Ronald J. Falk,[1] Daniel C. Cattran,[2] Heather N. Reich,[2] Patrick H. Nachman.[1] *[1]UNC Kidney Center, NC; [2]Toronto General Hospital, ON, Canada.*

Background: Achieving complete remission (CR) of proteinuria (<0.3 g/day) in primary membranous nephropathy (MN), is associated with excellent long-term renal outcome. Patients achieving partial remission (PR), defined as >50% reduction in proteinuria to <3.5 g/day with stable renal function, also show favorable prognosis compared to patients with no-remission (NR). Relapse in proteinuria is associated with a higher risk of ESKD. We investigated the risk factors of relapse in patients who have achieved a PR at any point.

Methods: To identify variables associated with relapse we studied 466 patients with primary MN registered in the Glomerular Disease Collaborative Network. 293 patients with at least 12 months of follow up were included. Time-to-event analysis from the time of PR to relapse was performed to evaluate risk factors for development of relapse. We incorporated various changes of remission status (PR, CR, and NR) during follow-up as time-dependent variable along with baseline patient characteristics.

Results: Of 293 patients, 213(83%) achieved PR and 80 (17%) had NR. Among patients with PR, 95 patients (45%) reached CR, and 118 (55%) remained in PR until the last follow-up or relapse. A total of 63 relapses were observed (48 from PR and 15 from CR). By univariate analysis, older age, male sex, higher baseline proteinuria, PR (vs CR) and lower serum albumin (sAlb) at PR were significantly associated with increased risk of relapse. Higher sAlb at PR was associated with a lower risk of relapse (HR, 0.49 [95% CI, 0.289-0.831]) adjusted for age, sex, proteinuria at baseline, and immunosuppressive therapy. 34% of patients with sAlb £3.5g/dl at PR had a relapse (median time to relapse 7.4 months) compared to 20% relapsers among patients with sAlb >3.5g/dl (median time 21.8 months; P<0.001).

Conclusions: A serum albumin level > 3.5 g/dl when patient achieve first PR is associated with a low subsequent risk of relapse. We suggest that incorporating a normalized serum albumin level into the definition of PR would improve its predictive value of subsequent outcome.

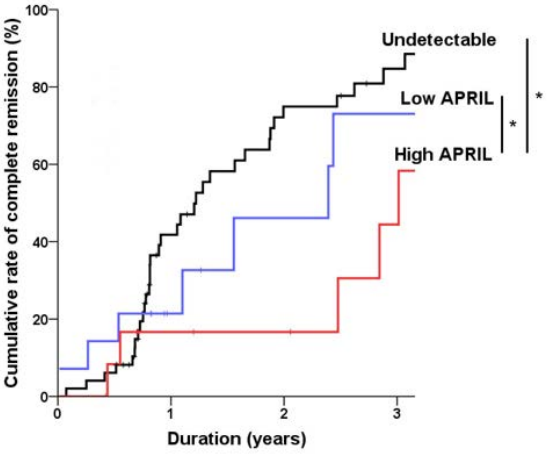
TH-PO749

Clinical Implication of BAFF and APRIL in Membranous Nephropathy Seung Seok Han, Eunjin Bae, Kwon Wook Joo, Yon Su Kim, Dong Ki Kim. *Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea.*

Background: BAFF and APRIL have a role in B cell development. Additionally, these are related with several autoimmune diseases. However, the clinical implication of BAFF and APRIL remains unresolved in patients with membranous nephropathy (MN).

Methods: 84 patients with primary MN were recruited, and their plasma BAFF and APRIL levels at the time of diagnosis were compared with the data on patients with secondary MN (n=13) and healthy individuals (n=111). The time to complete remission was used as primary outcomes and the hazard ratios (HRs) by plasma BAFF and APRIL levels were calculated after adjustment of multiple variables.

Results: The plasma BAFF levels in primary MN (0.94 ± 0.26 ng/mL) were significantly higher than those of healthy individuals (0.54 ± 0.16 ng/mL) and lower than of secondary MN (1.59 ± 1.09 ng/mL). For the APRIL, a substantial number of primary MN patients (n=51) had undetectable plasma level. The APRIL levels of primary MN (0.73 ± 2.50 ng/mL) were similar to the levels of healthy individuals (0.54 ± 0.16 ng/mL), but lower than those of secondary MN (8.07 ± 25.68 ng/mL). The BAFF levels were positively associated with the auto-PLA_2 antibody titers, but the APRIL levels were not. The cumulative rates of complete remission were significantly different between APRIL groups (undetectable, low level, and high level) (Figure 1), in contrast to the similar remission rates between the BAFF tertile groups. Patients with high plasma APRIL attained the complete remission lower than patients with undetectable level: adjusted HR, 0.29 (0.089–0.921); P=0.036.



Conclusions: The present study first demonstrates the plasma levels of BAFF and APRIL and their predictability for outcome in patients with membranous nephropathy.

TH-PO750

The Clinical and Prognostic Significance of Segmental Glomerulosclerosis Among Patients with Idiopathic Membranous Nephropathy Hala M. KFoury, Sufia Husain, Abdulkareem Alsuwaida, Mohammed A. Al-Ghonaim, Saad S. Alobaili, Tariq Aljohani, Tameem Ashry, Jamal S. Al Wakeel. *College of Medicine, King Saud Univ, Riyadh, Saudi Arabia.*

Background: Idiopathic membranous nephropathy (iMN) is a main cause of nephrotic syndrome in adults. In this study, we attempt to examine the relationship between segmental glomerular sclerosis in iMN and progression towards chronic kidney disease.

Methods: The study included 89 patients with iMN, followed over sixteen years, to evaluate the prognostic significance of glomerular segmental sclerosis in terms of renal survival. In the two groups (one with and one without segmental sclerosis), we analyze the various factors that are prognostic in iMN (eg. serum creatinine, proteinuria, etc.) and the histologic parameters.

Results: Segmental glomerulosclerosis was noted in 41 (46.1%) of 89 cases with iMN, representing cases from 57 (64.0%) males and 32 (36.0%) females. The prevalence of interstitial fibrosis and tubular atrophy did not contrast substantially between the two respective groups (3.38 ± 7.8 versus 1.22 ± 3.3, p=0.137). Only IgM positivity among the sclerosis group, compared to the non-sclerosis group was statistically significant (48.8% versus 25.0%, p=0.02). The median serum creatinine was significantly different among the two groups of 101 µmol/l in cases with sclerosis vs. 92 µmol/l among cases without sclerosis, p =0.059. The baseline proteinuria recorded was 2.2 gm and 2.9 gm per day in the two respective groups, p value=0.9. At last follow up, the median serum creatinine was similar among the two groups (median 90 µmol/l and 81 µmol/l, respectively).

Conclusions: Our study revealed that segmental glomerulosclerosis was not associated with the severity of interstitial fibrosis. Although baseline serum creatinine was higher in patients with glomerulosclerosis at the time of biopsy, there was no impact on longterm outcome of the patients. Further studies are needed to outline the therapeutic regimen in iMN with segmental glomerulosclerosis.

TH-PO751

Clinical Features and Outcomes of Membranous Nephropathy with Crescents Jia Wang,[1] Ping Zhu,[2] Zhao Cui,[1] Minghui Zhao.[1] *[1]Renal Div, Dept of Medicine, Peking Univ First Hospital, Beijing, Beijing, China; [2]Renal Div, Dept of Medicine, The First College of Clinical Medical Science, China Three Gorges Univ, Yichang, Hubei, China.*

Background: Cases of membranous nephropathy with crescents have been reported, in the absence of lupus, HBV-associated glomerulonephritis, anti-glomerular basement membrane nephritis, or antineutrophil cytoplasmic antibody. Disease presentation and outcomes of these patients are unclear.

Methods: All patients with biopsy-proven MN, diagnosed from 2008 to 2014 and followed up, were enrolled retrospectively. Patients with ANCA, anti-GBM antibodies, lupus, malignance or HBV infection were excluded. Clinical features and outcomes were compared between patients with crescentic MN and non-crescentic MN.

Results: In 401 consecutive patients with primary MN, 28 (6.9%) patients having crescent formation. All patients presented with proteinuria (6.5±4.8 g/24 h) and hematuria. 21.4% of patients had declined eGFR (<60ml/min/1.73m^2) on biopsy. Glomeruli showed on average 4.9% (range, 2.2-16.7%) involvement by crescents. Tubular atrophy was more common in these patients (96.3% vs. 78.6%, P=0.031). 12 (42.9%) patients received immunosuppressive therapy, similar to those with non-crescentic MN (41.33%). Fewer patients achieved remission in those with crescentic MN (67.9% vs. 86.7%. P=0.029). Crescent formation was a risk factor for no remission of treatments (RR=3.079, P=0.033). Higher percentage of crescents in glomeruli was also susceptible for no remission (RR=1.166, P=0.038). During follow-up, more patients with crescentic MN presented with eGFR decline (10.7% vs. 1.3%, P=0.031). Crescent formation was a risk factor for worse renal outcome (RR=10.24, P=0.046).

Conclusions: MN patients with crescent formation showed inferior response to treatments and worse renal outcome during follow-up, although the baseline clinical characters were similar on biopsy. The crescent was a risk factor for poor prognosis of MN patients.

TH-PO752

Prevalence of Cancer in Membranous Nephropathy Patients Yasuyuki Nagasawa, Sayuri Kawada, Mana Yahiro, Yuki Morikami, Tomoko Kimura, Kiyoko Yamamoto, Aritoshi Kida, Masayoshi Nanami, Yukiko Hasuike, Takahiro Kuragano, Takeshi Nakanishi. *Dept of Internal Medicine, Div of Kidney and Dialysis, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan.*

Background: Membranous Nephropathy is one of major primary glomerulonephritis. This disease was known to have high prevalence of cancer. Recent meta-analysis reported that estimated prevalence of cancer in membranous nephropathy patients was 10%[95%CI, 6.1-14.6] (Leeaphorn-N et al, Am J nephrol,2014). The aim of this study is to reveal the prevalence of cancer with image investigation information.

Methods: This study is retrospective cohort study. Among 720 cases who receive renal biopsy from 2000 to 2012 in Hyogo College of Medicine University Hospital, 73 membranous nephropathy patients were enrolled sequentially in this study. Exclusion Criteria is secondary membranous nephropathy induced by collagen diseases, such as Lupus nephritis. Information about cancer and image scanning was collected from medical records.

Results: Mean age was 60.2±15.2 years old. Male was 49% and Female was 51%. Patients with smoking was 55% (Current 24%, Past 31%), and alcohol Drinking was 48%. Chest Xp and fecal occult blood examination were done for all patients. Gastroscope was done for 20 cases (27%), abdominal CT was done for 33 cases (45%), and chest CT was done for 31 cases (42%) according to the risk factors. At renal biopsy, 6 patients had past history of cancers; larynx, uterine body, renal, epipharynx, and colon cancers (2 cases). 3 patients were diagnosed as cancer around renal biopsy; thyroid, gastric, and colon cancers. 7 patients were suffering from cancers after renal biopsy; lung renal, cervical cancer, breast, tongue, and colon cancers. The prevalence of all cancers (both at renal biopsy and after diagnosis of membranous nephropathy) was 20.8%. Prevalence of cancer in membranous patients seemed to be higher than Caucasian membranous cohort. The previous review reported that only 20% cancers were found at renal biopsy, although our result suggested 46% cancers were diagnosed at renal biopsy, probably because of high prevalence of advanced imaging check-up of cancers.

Conclusions: The prevalence of cancer in membranous patients was 20.8%.

TH-PO753

Efficacy of Low-Dose Prednisone Treatment Combined with Mizoribine on Idiopathic Membranous Nephropathy and Nephrotic Syndrome Yoshihiro Matsumoto, Yasushi Shimada, Youichi Nojima, Kimitoshi Shiratori. *Nephrology and Dialysis, Shizuoka City Hospital, Shizuoka, Japan.*

Background: Idiopathic membranous nephropathy (IMN) patients with persistent high-grade proteinuria are at the highest risk for developing end-stage renal failure. We previously reported the effects of treatment with mizoribine followed by low-dose prednisone in 4 IMN patients. The purpose of the present study was to further assess the effects of this combined treatment in a larger study group.

Methods: Twenty-two patients with IMN and nephrotic-range proteinuria received combined treatment. Mizoribine was initiated at a dose of 150 mg/day, and 1–3 months later, 20 mg/day prednisone was added to mizoribine regimen. The dosage of prednisone and/or mizoribine was tapered according to the urinary protein-to-creatinine ratio (P/C). We evaluated patient responses for up to 36 months after initiation of combination therapy.

Results: Before treatment, patient urinary P/C ranged from 2.8 to 15.9 g/g. Although these values did not decrease during mizoribine monotherapy, all patients showed P/C decreases over the course of combination therapy. At 12, 24, and 36 months after combination therapy, 55% (12/22), 70% (14/20), and 79% (11/14) of patients attained complete remission, respectively. The 21 patients of 22 (95%) attained partial or complete remission at 12 months after combination therapy. Side effects including fracture were observed in 4 patients.

Conclusions: The addition of prednisone after mizoribine monotherapy can be beneficial for most of all IMN patients with nephrotic syndrome. The risks associated with immunotherapy can be decreased by initially prescribing mizoribine alone, which might act as a base for establishing therapy, followed by low-dose prednisone treatment.

TH-PO754

Response to Immunosuppressive Therapy in PLA_2R-Associated IMN and Non-PLA2R-Associated IMN Jia Wang, Qionghong Xie, Chuanming Hao. *Div of Nephrology, Huashan Hospital, Shanghai, China.*

Background: According to the renal PLA2R immunohistochemistry, iMN could be categorized into PLA2R-associated and non-PLA2R-associated iMN. We conducted a retrospective, multicenter cohort study of 99 patients to compare the effect of immunosuppressive therapy on PLA_2R-associated and non-PLA_2R-associated iMN patients.

Methods: 99 biopsy-proven iMN patients were collected from Huashan hosipital and Peolple's hosipital of Wuxi in past 5 years. The iMN with positive PLA2R immunohistochemistry in kidney biopsies were designated as PLA2R associated MN. 79 of the 99 iMN patients were PLA_2R-associated iMN and 13 were non-PLA_2R-associated iMN. 49 patients were treated with prednisone plus CTX, and fifty with prednisone plus CNIs. 95% of the patients were on ACEI/ARB. The patients were followed for 15 months.

Results: The baseline characteristics between the PLA2R-associated and non-PLA2R-associated iMN was demonstrated in Table 1 (left part). In patients with non-PLA_2R-associated MN, the remission rate at 3-month was significantly higher than that in PLA_2R- associated group (table 1 right part). Relapses were observed in 8 patients of PLA_2R-associated group and none of non-PLA_2R-associated group.

	PLA2R (+) (n=78)	PLA2R (-) (n=13)	P		PLA2R (+) (n=78)	PLA2R (-) (n=13)	P
CTX%	47.4% (37/78)	61.5% (8/13)	0.346	3 month-remission	44.9%	76.9%	0.032
gender (M:F)	52:26	5:8	0.102	3 months-CR	2.6%	30.8%	0.003
age	53.81± 14.64	53.54± 17.52	0.953	6 month-remission	64.1%	76.9%	0.557
urine protein (g/24h)	5.51 (4.02, 7.72)	5.23 (2.34, 12.51)	0.829	6 months-CR	11.5%	46.2%	0.007
albumin (g/L)	19.45± 5.05	21.58± 9.07	0.423	9 month-remission	77.3%	91.7%	0.455
creatinine (μmmol/L)	78 (61.65, 93.75)	68.6 (60, 132.5)	0.875	9 months-CR	24.2%	50.0%	0.140
cholesterol (mmol/L)	7.86± 2.69	6.93± 1.88	0.238	12month-remission	79.7%	100%	0.197
triglyceride (mmol/L)	2.1 (1.77, 3.21)	1.82 (1.57, 2.98)	0.434	12month-CR	27.1%	50%	0.222

Conclusions: The non-PLA_2R- associated IMN responded quicker to the immunosuppressive therapy compared with PLA_2R-associated IMN, and relapses were more frequent in PLA_2R-associated IMN. Non-PLA_2R- associated IMN may have a better response to immunosuppressive therapy.

Funding: Government Support - Non-U.S.

TH-PO755

Prevalence of Enhanced Granular Expression of Thrombospondin Type-1 Domain-Containing 7A in Glomeruli in Japanese Patients with Idiopathic Membranous Nephropathy Takamasa Iwakura,[1] Naro Ohashi,[1] Akihiko Kato,[2] Hideo Yasuda.[1] *[1]Internal Medicine 1, Hamamatsu Univ School of Medicine, Hamamatsu, Shizuoka, Japan; [2]Blood Purification Unit, Hamamatsu Univ School of Medicine, Hamamatsu, Shizuoka, Japan.*

Background: Membranous nephropathy (MN) is a leading cause of nephrotic syndrome in adults. Autoantibodies against M-type phospholipase A2 receptor (PLA2R) and thrombospondin type-1 domain-containing 7A (THSD7A) were reported as the primary causes of MN. Although PLA2R is a major pathogenic factor for idiopathic MN, the prevalence of MN patients seropositive for PLA2R in Japan is lower than in other countries. In this study, we conducted immunohistochemical analysis of the presence of THSD7A and PLA2R in renal specimens of MN patients to estimate the prevalence of THSD7A/PLA2R-related idiopathic MN in Japan.

Methods: All patients with the histologic diagnosis of MN in adults made in our institution between 1995 and 2015 were included in this study. Immunohistochemical analysis for THSD7A and PLA2R were performed to these patients, and samples showing enhanced granular staining along capillaries of glomeruli were recognized as histologically positive for THSD7A and/or PLA2R. We collected the clinical information and laboratory data at the time of biopsy in order to classify MN patients into primary and secondary, and in order to compare characteristics of patients with enhanced expression of THSD7A and that of PLA2R.

Results: Enhanced granular expression of THSD7A and PLA2R was detected in 9.1% and 52.7%, respectively, of the patients with idiopathic MN. Although none of patients with secondary MN displayed enhanced granular expression of THSD7A, 5.4% of them had enhanced granular expression of PLA2R.

Conclusions: The prevalence of enhanced granular expression of THSD7A in glomeruli in Japanese patients with idiopathic MN was higher than the prevalence of MN patients seropositive for THSD7A in USA and Europe. This higher prevalence of THSD7A-related MN is likely associated with the lower prevalence of PLA2R-related MN in Japan.

TH-PO756

PLA2R Autoantibodies and Glomerular PLA2R Deposit in Membranous Nephropathy: How to Evaluate the Roles They Played? Huazhang Qin, Wei-bo Le, Ming-chao Zhang, Caihong Zeng, Hao Chen, Qiang Ren, Da cheng Chen, Ke Zuo, Feng Xu, Zhihong Liu. *National Clinical Research Center of Kidney Diseases, Research Inst of Nephrology, Jinling Hospital, Nanjing, Jiangsu, China.*

Background: Higher Glomerular PLA2R-Antigen deposit (GAg) rates compared with the serum Phospholipase A2 receptor-Antibody (SAb) positive rates were reported. However, the exact roles played by this two biomarkers remained unknown.

Methods: A total of 572 patients diagnosed IMN were included. Both SAb and GAg were detected . Fifty-two IMN patients received repeat renal biopsy were also included.

Results: In the 572 patients, 401 (70.1%) were SAb positive (SAb+) while 171 (29.9%) were SAb negative (SAb-). In SAb+ patients, the glomerular PLA2R-Antigen deposition (GAg+) was observed in 99.1% (397/401). Interestingly, the GAg+ was observed in 68.4% (117/171) SAb- patients. Patients with SAb manifested more severe proteinuria (3.9 g/24h vs 2.8 g/24h, P<0.001) and lower eGFR (104 ml/min.1.73m2 vs 110 ml/min.1.73m2, P=0.002) than patients without SAb. Further comparison between patients with SAb+/GAg+ and SAb-/GAg+ showed a similar profile (more severe clinical manifestation in patients with SAb). Patients with SAb+/GAg+ also showed lower chance of proteinuria remission and higher chance of renal function decline in the follow up when compared to patients with SAb-/GAg+. Changes of SAb and GAg were observed in patients with repeat renal biopsy, in 11 patients the SAb+ turned into SAb-, among them 1 patients failed to achieve remission, 7 patients achieved remission and 4 remitted during the interval but relapsed at the time of repeat biopsy. While the GAg+ turned into GAg- in only 3 patients, all achieved remission at the repeat biopsy. The proportion of GAg disappearance was lower than SAb (P=0.016).

Conclusions: The GAg deposit can be detected in a large proportion of SAb negative patients, which can be explained by the lag of GAg disappearance in the follow up. The SAb was more tightly correlated to disease activity ,treatment response and prognosis than the GAg. We recommend adopting GAg deposit detection as a supplement to SAb in IMN diagnosing and keeping on monitoring SAb in the follow up.

TH-PO757

Phospholipase A2 Receptor Autoantibody in Membranous Nephropathy Complicated with HIV Infection Weifeng Lin,[1,2] Xin Zhang,[1] Jianing Li,[1] Hang Li,[1] Jianfang Cai,[1] Xuemei Li,[1] Yubing Wen,[1] Xuewang Li.[1] *[1]Dept of Nephrology, Peking Union Medical College Hospital; [2]Peking Union Medical College.*

Background: When membranous nephropathy (MN) complicated with HIV-infection, it's difficult to discriminate the relationship between them. MN is idiopathic or secondly to HIV-infection? The therapy should cover MN, HIV or both? Although PLA2R autoantibody is a potential biomarker for the differential diagnosis of idiopathic and secondly MN, its role in MN complicated with HIV-infection is unknown.

Methods: 6 patients with biopsy-proven MN complicated with HIV-infection admitted to Peking Union Medical College Hospital from 2011 January to 2015 March were recruited in this study. 5 HIV-infection patients without nephropathy were selected as control group. Serum PLA2R autoantibody in all patients were detected by ELISA method. The serum samples of MN group were collected at renal biopsy. The medical records were retrospectively reviewed.

Results: The antibody was found in most patients with MN complicated with HIV-infection (5/6). However, the antibody in HIV-infection without nephropathy were all negative (5/5). The basic line of clinical data in 6 MN complicated with HIV-infection patients were as follows: all males, 24h-UP (12.62±6.65)g/d, serum albumin (19.16±5.49) g/L, and serum creatinine (81.7±30.17)mmol/L. Table1 shows antibody test results, treatments and renal outcomes in 6 MN patients. Table1 6 patients with MN complicated with HIV-infection.

Patient	NO.1[a]	NO.2	NO.3	NO.4	NO.5	NO.6
Nephrotic Syndrome	(+)	(+)	(+)	(+)	(+)	(+)
PLA2R antibody	(-)	(+)	(+)	(+)	(+)	(+)
Treatment	HAART[b] ACEI[c] GCS[d]	HAART ACEI GCS+ CsA[e]	HAART ACEI GCS+ CTX[f]	HAART ACEI	ACEI	HAART ACEI
Renal outcome	PR[g]	CR[h]	CR	PR	PR	SR[i]

[a] also had HBV infection. [b]highly active antiretroviral therapy. [c] angiotensin converting enzyme inhibitors. [d] glucocorticoids. [e] Cyclosporine A. [f] cyclophosphamide. [g] partial remission. [h] complete remission. [i] spontaneous remission before HAART and ACEI therapy.

Conclusions: MN complicated with HIV-infection seems to be two independent diseases if PLA2R autoantibody is positive. First line immunosuppressive therapy is likely necessary for MN complicated with HIV-infection if antibody is positive.

TH-PO758

Comparison of Outcomes Between Individuals with Pure and Mixed Lupus Nephritis: A Retrospective Study Nosayaba Enofe,[1] Anju A. Oommen,[1] Jason Cobb,[1] Jose E. Navarrete,[1] Demilade Adedinsewo,[2] Oluwatobiloba A. Osikoya,[3] Helene B. Fevrier,[4] Alton Brad Farris,[5] Laura Plantinga,[1] Titilayo O. Ilori.[1] *[1]Dept of Nephrology, Emory Univ School of Medicine, Atlanta, GA; [2]Morehouse School of Medicine, Atlanta, GA; [3]Lee Univ, Cleveland, TN; [4]Dept of Epidemiology, Rollins School of Public Health, Emory Univ, Atlanta, GA; [5]Dept of Pathology and Laboratory Medicine, Emory Univ School of Medicine, Atlanta, GA.*

Background: Lupus nephritis (LN) is divided into six classes (ISN/RPS Class I to VI) but can occur as a mixture of two classes. Pure proliferative LN (PPLN) comprises Class III or Class IV only while mixed proliferative and membranous LN (MPLN) comprises combinations of Class III & V or Class IV & V. Our aims were to compare individuals with biopsy-proven PPLN vs. MPLN in terms of clinical presentation and outcomes of complete or partial remission at 2 years and end-stage renal disease (ESRD)] and clinical predictors of outcomes.

Methods: A retrospective review of all adult (>18) LN patients (n=278; PPLN (n=60) and MPLN (n=96)) identified from a native renal biopsy registry at a hospital network performed January 2000-December 2011. We assessed associations of LN category (MPLN vs. PPLN) with: time to remission (define as ≥ 25% improvement in eGFR if baseline abnormal and urine protein creatinine ratio <0.5) and ESRD (defined using ICD-9 diagnosis code - 585.6 or the onset of chronic renal dialysis) using multivariable Cox proportional hazards analysis.

Results: The population was predominantly female (84.0%) and African American (71.8%), with a mean age of 33.4. Over follow-up (median, 1.5 years), using the PPLN group as the reference group, we did not find any associations between MPLN and time to remission (HR=0.13, 95% CI = 0.01-1.36) or ESRD (HR=0.30, 95% CI = 0.07-1.26). Baseline eGFR was significantly associated with time to remission (HR = 0.90, 95% CI = 0.84 - 0.98).

Conclusions: We found no significant differences in remission or progression to ESRD between patients with PPLN and MPLN. We, however, demonstrated that higher baseline eGFR at presentation were important factors in achieving remission in individuals with LN.

TH-PO759

Pure Class V Lupus Nephritis: Towards a Better Understanding of Lupus Membranous Nephropathy Compared to Its Proliferative Counterparts Fernanda Payan Schober, Keisha L. Gibson, Taewoo Lee, Caroline J. Poulton, Mary Anne Dooley, William Franklin Pendergraft. *UNC Kidney Center, UNC Chapel Hill, Chapel Hill, NC.*

Background: Class V lupus nephritis, also known as lupus membranous nephropathy, accounts for approximately 10-20% of patients with lupus nephritis. There is not a consensus on the best treatment for isolated class V lupus nephritis, so providers often turn to the proliferative lupus nephritis and idiopathic membranous nephropathy (IMN) literature to extrapolate treatment approaches and outcomes. Here we compare clinical data between patients with lupus membranous, proliferative lupus nephritis and IMN.

Methods: Clinical and treatment data for lupus membranous patients were extracted from electronic medical records starting at the time of diagnosis until date of chart review.

Results: Patients with lupus membranous resembled the lupus nephritis population more than the IMN population as they were more likely to be African American women in the fourth decade of life. At presentation, lupus membranous patients had preserved kidney function but significant proteinuria, much like patients with IMN. Almost all of these patients (94%) received immunosuppression. At mean follow up of 7.1 years, the mean serum creatinine remained 1.1 mg/dl, but proteinuria improved to a mean of 1.6 gram/day.

	Lupus Membranous (n=41)	Lupus Nephritis (n=601)	Idiopathic Membranous (n=558)
Female:Male (%)	37:4 (90:10)	510:90 (85:15)	216:342 (39:61)
Age (mean)	34 ± 16	34 ± 16	53± 15
Ethnicity (%) Caucasian African American Asian American Indian Other Unknown	 3 (7) 35 (85) 1 (2) 1 (2) 1 (2) 0 (0)	 200 (33) 297 (49) 8 (1) 9 (1) 25 (4) 62 (10)	 412 (74) 92 (16) 1 (0.1) 1 (0.1) 12 (2) 38 (7)
Serum Creatinine (mg/dl)	1.1 ± 0.6	1.56 ± 2.3	1.4 ± 1.3
Serum Albumin (mg/dl)	3.2 ± 4	1.5 ±1.8	2.6 ±0.8
Proteinuria (gm)	8.4 ± 13	4.3 ± 26	8.2±16

Conclusions: Patients with lupus membranous make up a substantial portion of patients with lupus nephritis. They present with significantly more proteinuria than patients with proliferative lupus nephritis, but have less kidney impairment. There's a clear need for more prospective multi-center randomized controlled studies to determine the most effective treatment in this population.

Necrotizing Glomerular Lesions Portend a Worse Prognosis for Patients with Lupus Nephritis Fernanda Payan Schober,[1] Keisha L. Gibson,[1] Mary Anne Dooley,[1] Elizabeth R. Blyth,[1] Caroline J. Poulton,[1] Harsharan Kaur Singh,[2] Volker Nickeleit,[2] William Franklin Pendergraft.[1] *[1]UNC Kidney Center, UNC Chapel Hill, Chapel Hill, NC; [2]UNC Pathology, UNC Chapel Hill, Chapel Hill, NC.*

Background: Necrotizing glomerular lesions on kidney biopsy are uncommonly found in patients with lupus nephritis (LN) and are similar in appearance to those lesions found in patients with ANCA glomerulonephritis. The presence of these lesions portends a worse prognosis and has been reported previously to be more common in patients of African descent†. Here we describe the clinical and histologic features of 48 patients with lupus nephritis and necrotizing glomerular lesions on native kidney biopsy.

Methods: Patients with lupus nephritis who had necrotizing and crescentic lesions were identified from the UNC Division of Nephropathology database. Clinical, histologic, treatment, and long-term outcome data were obtained from the electronic medical record.

Results: Demographic and histologic data are shown in the following table. Most notably, these patients were predominantly African American women with class IV lupus nephritis high overall disease activity.

	Tuft Necrosis (n=48)
Female Male	41 (87%) 7 (14%)
Ethnicity Caucasian African American Hispanic Asian American Indian	 11 (23%) 32 (67%) 3 (6%) 1 (1%) 1 (1%)
Age	34 + 12
Serum creatinine (mg/dl)	1.64 +1.3
Proteinuria (gm)	3.71 + 3.1
LN Histologic class II III IV V Mixed	 2 (5%) 4 (5%) 24 (56%) 3 (7%) 10 (23%)
Activity Index	10.9 +3.6
Chronicity Index	3.5 + 2.8
£SLEDAI	11.1 + 9.6

Conclusions: This cohort represents one of the largest of its kind in the literature to date. Necrotizing lesions are more characteristic of pauci-immune ANCA vasculitis, but have been described in patients with lupus nephritis as well. This rare variant is an understudied glomerular disease that portends a poor prognosis with an increased risk of progression to ESKD. There is a need for prospective multi-center treatment studies to determine durable therapeutic avenues. †Korbett, et al.Severe lupus nephritis:Racial differences in presentation and outcome. *JASN.*18:244-254.2007.

Membranous Lupus Nephritis: Immunoglobulin Deposits and Clinical Correlations Eduardo J. D. de Sa Carneiro Filho, Alcino Gama, Leonardo Abreu Testagrossa, Denise M. Malheiros, Luis Yu, Cristiane B. Dias, Lectícia Jorge, Viktoria Woronik. *Nephrology Div, Univ of São Paulo, São Paulo, Brazil.*

Background: Lupus nephritis histological hallmark, mostly in proliferative classes, is a "full house" (FH) pattern of immunoglobulin deposition and complement. However, Haas showed that membranous lupus nephritis (MLN) depicted this pattern only in 65% of the patients. The importance of FH deposition in MLN disease is still a matter of debate. It remains to be determined association between immunoglobulin deposition with clinical disease aggressiveness or transformation into proliferative forms.

Methods: All MLN patients submitted to kidney biopsies from July 1999 to August 2007 were included and biopsy tissue was studied by light microscopy and immunofluorescence. Patients were classified according to immunoglobulin glomerular capillary wall deposition in rich (rIF), with two or more deposited immunoglobulins, and poor (pIF) with a single and exclusive IgG deposition. Clinical and laboratorial data were collected at baseline, after one year and at the end of follow-up. Treatment was decided based on literature protocols.

Results: We included 15 patients in pIF group and 46 in rIF. At baseline, groups were similar regarding age, complement level, ANA, anti-DNA and proteinuria. Interestingly pIF was significantly associated with a lower eGFR at baseline that persisted after one year follow-up. At the end, the pIF showed a not significant tendency to lower eGFR.

	rIF	pIF	p
N	46	15	
Age	33±10	34±12	
MDRD Baseline	96±34	78±40	0.04
MDRD after 1 year	103±32	76±40	0.01
MDRD Final	80±39	63±33	ns
PTN Baseline (g/day)	4.6±3.6	4.4±5.7	ns
PTN Final (g/day)	1.2±1.8	2.1±3.8	ns
C3 (mg/dL)	85±32	96±52	ns
Hematuria Baseline	39%	46%	ns
ACLIgG Baseline	54%	71%	ns
ACLIgM Baseline	45%	64%	ns
Mesangial Hypercellularity	76%	53%	ns
Immunosuppression			
Pred	22%	50%	ns
Double	78%	50%	ns

Conclusions: We found 25% of MLN patients with only one deposited immunoglobulin. The poor IF group compared to rich IF showed lower MDRD at baseline and even after one year. Studies are needed to elucidate the role of different patterns of deposits in the pathogenesis of MLN.

TH-PO762

Segmental versus Global Subclasses of Proliferative Lupus Nephritis: Clinical Correlations Eduardo J. D. de Sa Carneiro Filho, Alcino Gama, Mariana Pin de Andrade, Beatriz Holanda, Leonardo Abreu Testagrossa, Denise M. Malheiros, Luis Yu, Cristiane B. Dias, Lectícia Jorge, Viktoria Woronik. *Nephrology Div, Univ of São Paulo, São Paulo, Brazil.*

Background: The International Society of Nephrologists and Renal Pathology Society classification of lupus nephritis proposes a subclassification of proliferative forms into segmental (S) and global (G). Data comparing renal outcomes between these two subclasses is controversial and pathogenesis also seems to differ (Bariéty J, 2005). We aimed to compare histopathology with clinical correlations.

Methods: Seventy-one biopsy-proven patients with proliferative (classes III or IV) lupus nephritis data were retrospectively analyzed. Twenty-nine of them were classified as global and 42 as segmental. All procedures were performed in one single center between 2004 and 2014.

Results: All patients received induction therapy with steroids plus either intravenous cyclophosphamide monthly pulses or daily oral mycophenolate mofetil. Although there was no difference in age, eGFR and hemoglobin levels at baseline (see *table*), after a median follow-up of 3.6 years the global subgroup had worse renal outcome (final eGFR 59.6 ± 37.6 vs 78.9 ± 28.4, p 0.02). During follow-up, there was also a tendency for faster eGFR recovery rate in segmental subgroup after treatment (5.2 vs 1.8 ml/min/year, p 0.2). Interestingly, the prevalence of males in global subgroup was significantly higher (20% vs 4%, p 0.03).

	Global	Segmental	p
N	29	42	
Baseline features			
%Male	20%	4%	0.03
Age (y)	31.8±12	31.5±9	ns
Hb (mg/dL)	10.9±1.4	11±1.1	ns
MDRD Baseline (ml/min/1.73m^2)	55.2±26	63.9±27	ns
Follow-up features			
Follow-up (y)	3.63	3.62	ns
MDRD Final (ml/min/1.73m^2)	59.6±37.6	78.9±28.4	0.02
MDRD Delta per year	+1.8±2.3	+5.2±2.9	0.2

Conclusions: In global compared to focal proliferative lupus nephritis patients: male sex prevailed and renal function decreased on 3.6 years follow-up in spite of similar MDRD on baseline. Prospective studies are necessary to determine if histological pattern is relevant to guide the clinician's therapy choice.

TH-PO763

Renal Pathological Classification in Lupus Nephritis: What Else We Can Tell? Yang Jing, Dandan Liang, Haitao Zhang, Zheng-zhao Liu, Wei-bo Le, Minlin Zhou, Weixin Hu, Caihong Zeng, Zhihong Liu. *National Clinical Research Center of Kidney Diseases, Research Inst of Nephrology, Jinling Hospital, Nanjing, Jiangsu, China.*

Background: To observe the discrepancy between class III and class III+V, between class IV and class IV+V, and between subclass IV-S and IV-G on clinicopathological features and renal outcomes and explore the pathological lesions associated with poor renal outcomes in patients with different classes.

Methods: The records of all adult patients with biopsy-proven proliferative lupus nephritis followed for at least 1 year were reviewed. All patients were pathologically classified according to the 2003 ISN/RPS classification of lupus nephritis and each pathological lesion was semiquantatively scored.

Results: Patients with class III+V (class IV+V) presented with more severe proteinuria and chronic pathological lesions and milder acute pathological lesions than patients with class III (class IV); patients with subclass IV-G presented with more severe hypertension, proteinuria and hypocomplementemia, lower ANCA positivity rate, more severe glomerular cell proliferation and hyaline deposit, and milder fibrinoid necrosis and crescent than patients with subclass IV-S. The renal outcomes between patients with class III and class III+V, between class IV and class IV+V, and between subclass IV-S and subclass IV-G were not different respectively. Global glomerulosclerosis, cellular crescent, fibrous crescent, glomerular cell proliferation, tubular acute injury, interstitial inflammation and TMA were predictors for ESRD.

Conclusions: LN patients with proliferative lesions combined with membranous lesions presented with both clinicopathological characteristics of the two types of lesions, but their renal outcomes were not different from patients with pure proliferative lesions. Patients with subclass IV-S and subclass IV-G LN had their own clinicopathological characteristics respectively, but the division of class IV into the two subclasses was not meaningful for predicting renal outcomes. In addition to glomerular lesions, tubulointerstitial and vascular lesions were also predictors for poor renal outcomes.

TH-PO764

Ability of Spot Urine Protein/Creatinine Ratio (Spot PCR) to Correctly Identify the Proteinuria Endpoints of Complete Remission (CR), Partial Remission (PR), and Treatment Failure (TF) as Determined by 24 Hour Urine PCR (24 PCR): Experience of the Abatacept and Cyclophosphamide Combination Efficacy and Safety Study (ACCESS) Ganesh B. Shidham,[1] Daniel J. Birmingham,[2] Brad H. Rovin,[3] Lee A. Hebert.[4] *[1]Div of Nephrology, OSUWMC, Columbus, OH; [2]Div of Nephrology, OSUWMC, Columbus, OH; [3]Div of Nephrology, OSUWMC, Columbus, OH; [4]Div of Nephrology, OSUWMC, Columbus, OH.*

Background: Spot PCR is an inherently highly variable estimate of 24 hour proteinuria magnitude, compared to 24 PCR (Ann Rheum Dis, 73, 475, 2014). So, it is likely that using spot PCR rather than 24 PCR to guide management increases the risk of management error. The present work is the first to rigorously test this hypothesis. ACCESS is a prospective randomized phase 2 trial of Abatacept or placebo added to the Euro-Lupus regimen of cyclophosphamide and prednisone followed by azathioprine and low dose prednisone. A unique feature of ACCESS was concurrent testing for spot PCR (monthly) and 24 PCR (each three months). ACCESS proteinuria endpoints were CR, PR, and TF assessed at 6 months and 12 months of follow-up (Arth Rheum 66, 3096, 2014).

Methods: Evaluable data (spot PCR measured within one month of the 24 PCR) was present at six months in 100 patients, and at twelve months in 54 of the 100 patients. Spot PCR was deemed correct if it was concordant with the 24 PCR determination of whether CR, PR, or TF was present, and deemed incorrect if discordant with the 24 PCR determinations of whether CR, PR, or TF was present.

Results: At 6 month follow up, spot and 24 PCR were concordant in 36 CR, 25 PR, 10 TF, and discordant in 10 CR, 11PR, and 8 TF. At 12 month follow up, spot and 24 PCR were concordant in 36 CR, 11 PR, and 2 TF, and discordant in 4 CR, 2 PR, 0 TF. Totals: Concordant 120, Discordant 35. $P < 0.001$ (null hypothesis that concordance is 95% is rejected).

Conclusions: The error rate of spot PCR in identifying ACCESS proteinuria endpoints (defined by 24 PCR) was 23%. Proteinuria endpoints in LN trials are broad targets and mainly involve low level proteinuria. This minimizes the impact of spot PCR variability.

Induction Treatments for Proliferative Lupus Nephritis: A Network Meta-Analysis Suetonia Palmer,[1] David J. Tunnicliffe,[2] Allison Tong,[2] Dimitris Mavridis,[3] Jonathan C. Craig,[2] Marcello Tonelli,[4] David W. Johnson,[5] Giovanni F.M. Strippoli.[2,6] *[1]Univ of Otago Christchurch; [2]Univ of Sydney; [3]Univ of Ioannina; [4]Univ of Calgary; [5]Univ of Queensland; [6]Univ of Bari.*

Background: Intravenous cyclophosphamide has been standard care for inducing remission among patients with proliferative lupus nephritis (class III and IV). More recently, several agents have been trialed, however, given the numerous treatment options and head-to-head trials, there is uncertainty about the comparative effectiveness of all available treatment options.

Methods: Immunosuppressive treatments to induce remission of kidney disease among patients with proliferative lupus nephritis were all compared using network meta-analysis of parallel-group randomized controlled trials. Outcomes were complete disease remission, treatment failure, all-cause mortality, end-stage kidney disease, major infection, alopecia, ovarian failure and malignancy. Effect sizes for treatments were calculated using random-effects network meta-analysis and compared to intravenous cyclophosphamide (referent). Trials were critically appraised using Cochrane risk of bias.

Results: 47 studies involving 3510 patients were eligible. Mycophenolate mofetil was superior to intravenous cyclophosphamide for inducing disease remission (network odds ratio 1.60, 95% CI 1.07-2.41), and resulted in lower risks of treatment failure (0.48, 0.26-0.87), and alopecia (0.22, 0.13-0.39). Mycophenolate mofetil had uncertain risks of death (OR 1.14, 0.49-2.65), major infection (1.30, 0.88-1.92) and ovarian failure (0.48, 0.11-2.08) versus intravenous cyclophosphamide. Comparative effects of other treatments including azathioprine and calcineurin inhibitors alone or in combination were uncertain. Information for end-stage kidney disease and malignancy endpoints for all treatments was sparse. Treatment effects were generally consistent within networks. Methodological reporting in trials was frequently unclear.

Conclusions: Mycophenolate mofetil is more effective than intravenous cyclophosphamide for induction treatment of proliferative lupus nephritis.

TH-PO766

A Systematic Review on Tacrolimus Treatment in Lupus Nephritis Tineke Kraaij,[1] Edwin Bredewold,[1] Tom Huizinga,[2] Ton J. Rabelink,[1] Yoe Kie Onno Teng.[1] *[1]Nephrology, LUMC, Leiden, Netherlands; [2]Rheumatology, LUMC, Leiden, Netherlands.*

Background: Recently, 2 large randomized controlled trials (RCTs) have been published on the efficacy of tacrolimus (TAC) in Asian LN patients. Both trials used different treatment regimens and efficacy was not consistent between the trials. Therefore, the role of TAC in the treatment of LN remains unclear. Thus, we performed a systematic review on TAC treatment for LN.

Methods: We searched multiple databases for all human studies investigating TAC treatment in LN. Then studies were selected on clinical relevance and results were analysed on renal response and adverse events.

Results: We found 26 clinical studies from which data were extracted from all controlled studies: 6 RCTs and 3 case-control studies involving a total of 888 patients. As induction treatment, TAC with steroids resulted in 82% responders of which 56% complete responders (CR). Induction with steroids, mycophenolate (MMF) and TAC resulted in 85% responders, of which 46% CR. Data from 1 RCT performed with TAC in combination with steroids as maintenance treatment, resulted in 100% responders of which 56% CR. Generally, control patients receiving induction treatment with cyclophosphamide achieved 66% response of which 29% CR. Those receiving induction treatment with MMF achieved 76% response of which 53% CR. Overall infections were observed in 26% of TAC treated patients compared to 26% of control patients treated with cyclophosphamide and 29% in MMF treated control patients. A rise in serum creatinine was observed in 5% of all TAC treated patients compared to 2% in the cyclophosphamide control group and 0% in the MMF control group.

Conclusions: This systematic review suggests that TAC-based treatments can achieve comparable renal responses in LN as conventional regimens. Currently, limitations of the available studies are the heterogeneity of TAC-based regimens, lack of studies in non-Asian LN patients and lack of long-term safety data. Altogether, these data warrant further RCTs on TAC-based regimens for LN. At this time, TAC can only be advised as consideration in difficult LN patients, such as therapy-refractory patients (especially if severe proteinuria is present) and in preparation or during pregnancy.

TH-PO767

Predicting Chronic Kidney Disease (CKD) in Lupus Nephritis (LN) Ana Malvar,[1] Valeria Gabriela Alberton,[1] Bruno Jorge Lococo,[1] Haikady Nagaraja,[2] Brad H. Rovin.[3] *[1]Hospital Fernandez, Buenos Aires, Argentina; [2]Ohio State Univ, Columbus, OH; [3]Ohio State Univ Wexner Medical Center and the CKD Biomarker Consortium.*

Background: Early identification of LN patients likely to develop CKD may permit therapy to be adjusted and CKD to be avoided. Clinical and histologic parameters measured after completing induction therapy were associated with long-term kidney outcomes in a cohort of LN patients to define predictors of new CKD.

Methods: Patients (n=69) with biopsy-proven class III/IV LN were induced with steroids and MMF (53%) or cyclophosphamide (44%) for 6 months, had repeat kidney biopsy (biopsy 2, 6.6±0.7 months), and were put on maintenance therapy. Long-term (median 73 months) follow-up was available on 87% of the cohort. Multivariate linear regression was used to develop a predictive model for future serum creatinine (SCr) based on clinical and histologic variables obtained after induction.

Results: No difference was seen in CKD at last follow-up among patients who did or did not achieve a complete clinical renal response after induction (19% vs 18.4%, respectively). Among patients with complete histologic renal remission after induction, 36% had a final SCr of 1.3-2.9 mg/dl. There was no relationship between the NIH activity index at biopsy 2 and long-term kidney function. However, the median NIH chronicity index (CI) at biopsy 2 of patients who developed CKD was 6 (range 2-8) compared to 4 (range 0-7) in patients who did not develop CKD ($p<0.02$). Regression analysis showed a significant linear correlation between CI ≥ 4 at biopsy 2 and log(SCr) at long-term follow-up ($R^2=0.36$, $p < 0.0001$). In multivariate analysis CI and SCr at biopsy 2 were independent predictors of long-term SCr ($R^2=0.48$, $p < 0.0001$). For a given level of SCr at biopsy 2, a 1 unit increase of CI in the range of 4-8 corresponded to a 20% increase in last SCr.

Conclusions: Neither clinical nor histologic remission after induction predicts long-term renal function in LN. However, the combination of SCr and chronic damage on kidney biopsy after induction accounts for 48% of the long-term variability of renal function in those patients who reach a threshold level (CI=4) of chronic kidney damage.

Funding: NIDDK Support

TH-PO768

Clinical and Histologic Remission in Class IVG and IVS Lupus Nephritis (LN) After Induction Therapy Ana Malvar,[1] Bruno Jorge Lococo,[1] Valeria Gabriela Alberton,[1] Diego Morales,[1] Brad H. Rovin.[2] *[1]Hospital Fernandez, Buenos Aires, Argentina; [2]Ohio State Univ Wexner Medical Center, Columbus, OH.*

Background: The ISN/RPS classification of LN distinguishes class IV with predominantly segmental lesions (IVS) from class IV with global (IVG) lesions. It has been suggested that IVS may have a lower remission rate than IVG, possibly because it is more like a vasculitis than IVG. However several studies found no significant difference in long-term kidney survival between these subclasses. We examined differences in histologic and clinical remissions between IVG and IVS in our LN cohort with serial kidney biopsies.

Methods: SLE patients (n=43) were biopsied at first presentation of kidney involvement (Bx1) and again at 6 months after completing induction therapy (Bx2). Class IVG and S patients were treated identically with steroids plus MMF or cyclophosphamide. NIH activity (AI) and chronicity (CI) indices, proteinuria and serum creatinine (SCr) were compared. Complete clinical response (CCR) was defined as normal SCr and proteinuria < 500 mg/d. Complete histologic remission was defined as an AI=0 at Bx2.

Results: Clinical outcomes and histologic data are shown in the Table. All patients were ANCA negative. Final SCr and proteinuria were determined after a mean follow-up of 54±7 months. Only 4 patients were lost to long-term follow-up.

Bx1	CRR Bx2	Final SCr ≤1 (mg/dl)	Final Proteinuria (g/d)	AI Bx1	AI Bx2	CI Bx1	CI Bx2
IVG (n=33)	39%	87%	0.32± 0.24	10.3± 2.9	3.7± 2.8	3.5± 1.9	4.9± 1.9
IVS (n=10)	80%	89%	0.26± 0.19	8.5± 2.2	0.1± 0.3	2.6± 1.8	4.4± 0.7
P (IVG vs IVS)	0.034	1.00	0.43	>0.05	<0.05	>0.05	>0.05

Conclusions: Class IVS LN has an excellent early clinical and histologic response to standard-of-care LN induction therapy. Class IVG takes longer to respond, but over time there are no differences in long-term renal outcomes between Class IVG and IVS LN as assessed by SCr and proteinuria. This suggests that these subclasses may be treated similarly. These results also raise the possibility that class IVS patients who have complete clinical and histologic remission after induction may do well with an abbreviated course of maintenance therapy.

TH-PO769

Complete Remission Rate and Outcome in Severe Lupus Nephritis: The Impact of Baseline Serum Creatinine Stephen M. Korbet, William Luke Whittier, Edmund J. Lewis. *Rush Univ Medical Center, Chicago, IL.*

Background: A complete remission (CR) in severe lupus nephritis (SLN) is associated with a favorable long-term outcome. Numerous factors including level of serum creatinine (SCr) at baseline have been shown to impact on CR rate and outcome. We assess the impact of baseline SCr on CR rate and outcome in SLN.

Methods: We evaluated the 86 adult patients in the prospective, controlled trial of plasmapheresis in SLN and compared them based on SCr level at baseline (£1.0, 1.01-1.5, 1.51-2.0, 2.01-3.0 and >3.0 mg/dl; n= 22, 23, 16, 12, 13 respectively). The CR rate (defined by a serum creatinine (SCr) of ≤ 1.4 mg/dL and UPro of £0.33 g/day) and long-term outcomes (stable renal function, dialysis and death) were compared. Pts were followed for 121±64 mo.

Results: Baseline clinical features (age, gender, race and UPro) were similar among the groups. All pts had ISN/RPS class IV lesions and while the activity index was similar among the groups, the chronicity index (2 vs 3 vs 3 vs 5 vs 5, respectively, P 0.007) was significantly higher with increasing levels of SCr. At follow-up, CR rates (86% vs 52% vs 19% vs 25% vs 0, respectively, P <0.0001) were significantly higher and occurred in a shorter period of time (6 vs 12 vs 23 vs 18 mo, respectively, P 0.33) in pts with lower levels of SCr. Pts with a baseline SCr of £1.0 mg/dl were >16 times as likely (odds ratio, 16.2; 95% confidence interval, 4.2-61.5) to attain a CR and >6 times as likely (odds ratio, 6.1; 95% confidence interval, 1.9-18.6) to have stable renal function at last follow-up compared to pts with a SCr >1.0 mg/dl. The 15-yr renal survival (76% vs 57% vs 48% vs 25% vs 10%, respectively, P <0.0001) and patient survival without ESRD (76% vs 40% vs 42% vs 25% vs 8%, respectively, P <0.0001) was greatest in the patients with a SCr of £1.0 mg/dl at baseline.

Conclusions: The CR rate and outcome in SLN are significantly affected by baseline serum creatinine. The CR rate is highest and long-term prognosis most favorable in pts with a baseline SCr £1.0 mg/dl; the group with the least amount of chronic disease on biopsy. This emphasizes the importance of early diagnosis and treatment in pts with SLN.

TH-PO770

Urine Adiponectin Isoforms and Kidney Lesions in Lupus Nephritis (LN) Xiaolan Zhang,[1] Divya Indrakanti,[1] Anthony Alvarado,[1] Sergey V. Brodsky,[1] Hermine Brunner,[2] Brad H. Rovin.[1,3] *[1]Ohio State Univ Wexner Medical Center, Columbus, OH; [2]Cincinnati Children's Hospital, Cincinnati, OH; [3]CKD Biomarker Consortium.*

Background: Human adiponectin isoforms exert different effects on inflammation. Urine adiponectin is increased at LN flare, but the relationship between adiponectin isoforms and kidney lesions in LN has not been studied.

Methods: Urine and plasma total and high molecular weight (HMW) adiponectin isoforms were measured by specific ELISAs in samples from 39 normal controls and 97 biopsy-diagnosed LN patients. Urine adiponectin levels were normalized and log-transformed, and then examined for associations with histologic lesions on kidney biopsy by ANOVA, nonparametric Wilcoxon ranked-sum testing and multiple linear regression analysis.

Results: The HMW to total adiponectin ratio was increased in plasma (p=0.022) and urine (p=0.0004) of LN patients compared to controls. Total and HMW adiponectin levels were highly correlated within the plasma (R^2=0.91, $p < 0.0001$) and urine (R^2=0.64, $p < 0.0001$) in LN, but between plasma and urine only HMW adiponectin showed a correlation, and this was minor (R^2=0.21, $p< 0.037$). Urine adiponectin levels increased with the severity of ISN/PRS class. The highest total and HMW urine adiponectin levels were found in patients who had combined class III or IV + V LN. Using urine HMW adiponectin levels to differentiate between control and LN patients, and between single and combined LN classes, receiver-operating characteristic analysis showed areas under the curve of 0.96 and 0.85, respectively. Urine HMW adiponectin was significantly increased when glomerular proliferation, cellular crescents or interstitial inflammation were present on the biopsy, and HMW adiponectin correlated with the biopsy activity index (R^2=0.31, $p < 0.0001$), but not chronicity index. Using HMW adiponectin plus urine hemopexin plus serum creatinine, an equation to predict biopsy activity index was constructed with a R^2=0.46.

Conclusions: Urine adiponectin isoforms increase with the severity of active kidney lesions in LN. The increase in urine adiponectin is not simply a reflection of changes in systemic adiponectin, and may be due to intra-renal processing.

Funding: NIDDK Support

TH-PO771

Significance of Serum Cystatin C as a Biomarker for Clinical Practice in Patients with Lupus Nephritis Hua Zhou, Di Lu, Hairong Tang, Lizhi Li, Huimeng Qi, Lining Wang. *Nephrology Dept, 1st Hospital of China Medical Univ, Shenyang, China.*

Background: Serum Cystatin C (sCysC) as a novel biomarker of renal function has been studied in many primary glomerular diseases. However, sCysC was barely reported in lupus nephritis (LN). We aim to compare the changes of sCysC and traditional biomarkers in LN patients.

Methods: 106 patients with LN proven by renal biopsy were studied. sCysC, serum creatinine (sCr), BUN, 24 hr total urinary protein (uTP), serum albumin (sAlb), systemic lupus erythematosus disease activity index (SLEDAI), C3, C4, IgG, ANA, DsDNA, C-reaction protein (CRP), and ESR were examined before and 1, 3, 6, 12, 24 months after treatment with steroid and immunosuppressants. estimated glomerular filtration rate (eGFR) was calculated by EPI-sCysC, EPI-sCr, and EPI-sCysC + sCr. The strength of correlation was compared between sCysC and sCr with uTP, sAlb, SLEDAI, and CRP before and after treatment.

Results: sCysC and eGFR (EPI-sCysC+sCr) showed stronger correlation with uTP, sAlb, SLEDAI, and CRP before the treatment (table). During treatment, a similar trend was seen in sCysC and eGFR (EPI-sCysC). sCysC also showed a better statistical p value than SCr/BUN in response to treatment with steroid plus either all kinds of immunosuppressants or cyclophosphamide.

Index	sCysC	sCr	BUN	eGFR (EPI-sCysC)	eGFR (EPI-sCr)	eGFR (EPI-sCysC+ Scr)
uTP r (p value)	**0.25** (p= 0.03)	0.16 (p= 0.097)	0.24 (p= 0.012)	-0.23 (p= 0.06)	-0.11 (p= 0.29)	**-0.31** (p= 0.014)
sAlb r (p value)	**-0.44** (p< 0.0001)	-0.28 (p= 0.004)	-0.29 (p= 0.0012)	0.40 (p= 0.0008)	0.17 (p= 0.08)	**0.47** (p< 0.0001)
SLEDAI score r (p value)	**0.41** (p= 0.0004)	0.29 (p= 0.003)	0.36 (p= 0.0001)	-0.42 (p= 0.0004)	-0.14 (p= 0.16)	**-0.45** (P= 0.0001)
CRP r (p value)	**0.28** (p= 0.02)	0.25 (p= 0.012)	0.10 (p= 0.31)	-0.25 (p=0 .046)	-0.14 (p= 0.19)	**-0.26** P= 0.036

Conclusions: sCysC and eGFR based on sCysC might be useful early biomarkers to diagnose LN and better to monitor the treatment of LN. sCysC will likely help in clinical decision making for early intervention and the timing of reducing key treatments. Prospective study is needed to investigate the effect of early treatment based on sCysC increase (sCr normal) in large cohort of LN patients.

Funding: Government Support - Non-U.S.

TH-PO772

Neutrophil Modular Blood Transcriptional Signature Is Associated with Lupus Nephritis and Its Severity in SLE Noemie Jourde-chiche,[1] Bertrand Gondouin,[1] Stephane Burtey,[1] Laurent Daniel,[2] Bertrand Dussol,[1] Laurent Chiche.[3] *[1]Nephrology, Aix-Marseille Univ, Marseille, France; [2]Pathology, Aix-Marseille Univ, Marseille, France; [3]Internal Medicine, Hopital Europeen, Marseille, France.*

Background: Lupus nephritis (LN) is a severe complication of SLE. . The aim of this study was to assess the link between blood transcriptional signatures and LN, comparatively with other pathological conditions associated with renal injury.

Methods: 102 patients were included: 62 SLE patients, 40 controls with various conditions (10 with crescentic GN due to ANCA-associated vasculitis (AAV), 15 with severe bacterial sepsis, 15 with non-proliferative glomerular diseases), and their matched healthy controls. SLE samples were split in those at the time of: a biopsy-proven active LN (group 1, n=24); an extra-renal flare (group 2, n=11); a clinically quiescent visit (group 3, n=34). Microarray data were generated using Illumina beadchips and analyzed using modular repertoire analyses.

Results: Modular repertoire analysis in SLE patients revealed, in addition to the activation of IFN-related modules, a strong upregulation of M5.15, a module of 24 transcripts annotated "neutrophil". There was no correlation between M5.15 and SLEDAI, anti-dsDNA level or IFN modules activity. M5.15 was strongly associated with active LN (p=0.009), but not with non-renal manifestations. The neutrophil modular signature was present in 67%, 18% and 47% of patients from group 1, 2 and 3 respectively. In group 2 and 3, its presence was associated with a past history of LN or the occurrence of LN during the follow-up. M5.15 was correlated with acute renal failure (p=0.03) and serum albumin (p=0.01). In group 1, the median value of M5.15 was higher in patients with proliferative than non proliferative LN (66.7 vs 18.8 %, p=0.04). AAV and sepsis patients shared the neutrophil signature observed in SLE, but displayed no IFN signature, while those with non-proliferative GN had none of these signatures.

Conclusions: Modular repertoire analysisdemonstrates that neutrophil signature is correlated with occurrence and severity of LN in SLE. This result could allow the design of new biomarkers in LN.

TH-PO773

Anticoagulation and Longterm Outcomes in Patients with Renal Artery Stenosis and Antiphospholipid Syndrome Alina L. Casian, Shirish Sangle, Sotiria Manoustathopoulou, David D'Cruz. *Lupus Unit, Guy's Hospital, London, United Kingdom.*

Background: Our previous data showed renal artery stenosis (RAS) is more prevalent in antiphospholipid syndrome(APS)(26%) compared to the general hypertensive population(8%),and anticoagulation with INR>=3 was associated with initial reduction of chronic kidney disease(CKD) and hypertension.

Methods: We identified 37 patients with RAS and APS fulfilling Sapporo criteria: anticardiolipin IgG/IgM titer>40 units or >99th percentile (or +lupus anticoagulant) on >=2 occasions >=6 weeks apart AND vascular thrombosis(or pregnancy morbidity). RAS was diagnosed by magnetic resonance angiography(MRA).

Results: 15 patients had APS alone and 22 APS associated with autoimmune conditions (13 lupus, 5 ANCA vasculitis, 4 mixed). Median age at RAS diagnosis was 48 years, 31/37(83.8%) were female and median follow-up was 10.4 years. 25/37(67.6%) had previous thrombosis. 7/37(18.9%) had bilateral RAS, 3 artery occlusion. 6/37(16.2%) had coeliac stenosis. Recanalization of RAS occurred after hydroxychloroquine in 3/37 and 9/37(24.3%) underwent angioplasty+/-stenting. MRA was repeated in 11/37(29.7%) after 2 years. 23/37(62.2%) were anticoagulated, with 9/37(24.3%) on antiplatelet therapy. 13/37(35.1%) received hydroxychloroquine, 10/22(45.5%) immunosuppressives and 18/37(48.6%) antihypertensives. 9/37(24.3%) died after a median of 10 years since RAS diagnosis. 21/37(56.8%) developed CKD: 6 endstage renal failure(ESRD) and 15 with median eGFR 39 mls/min.

Patient Group	CKD	ESRD	Death
Anticoagulation(23)	15/23	4/23	5/23
No anticoagulation(14)	6/14	2/14	4/14
p value	0.3	1.0	0.7
APS(15)	7/15	3/15	1/15
APS+autoimmune disease(22)	14/22	3/22	5/22
p	0.3	0.7	0.4
Medical therapy(28)	13/28	3/28	7/28
Angioplasty (9)	8/9	3/9	2/9
p	0.05	0.14	1

Conclusions: The majority of patients with RAS and APS were female, developed CKD and did not benefit from angioplasty. Anticoagulation was not associated with longterm reduction of ESRD or death, suggesting a non-thrombotic pathogenic process underlying

RAS, e.g.intimal hyperplasia. Treatment of associated vascular risk factors and autoimmune disease is paramount. Anticardiolipin antibodies and renal MRA are useful for screening hypertensive lupus patients.

TH-PO774

A Prospective Study to Investigate Mycophenolic Acid Pharmacokinetics and Its Clinical Correlations in Lupus Nephritis Patients Desmond Y.H. Yap,[1] Chun-Hay Tam,[2] Sunny Sze ho Wong,[2] Maggie Kam Man Ma,[1] Susan Yung,[1] Daniel Tak Mao Chan.[1] *[1]Medicine, The Univ of Hong Kong, Hong Kong, Hong Kong; [2]Medicine and Geriatrics, United Christian Hospital, Hong Kong, Hong Kong.*

Background: The dosing regimen of mycophenolate mofetil (MMF) in the treatment of lupus nephritis (LN) is adopted from the kidney transplant experience. The role of therapeutic drug monitoring of mycophenolic acid (MPA) level in managing LN remains undefined.

Methods: We prospectively studied LN patients on maintenance treatment with prednisolone and MMF. Blood MPA level at 1, 2, 4, 8, 10 and 12 hours (i.e. C1, C2, C4, C8, C10 and C12) after MMF administration was measured with an enzymatic assay upon recruitment and repeated at 6-month intervals for 24 months, and at occurrence of clinically significant events, to investigate their clinical correlations.

Results: 51 patients were included, with prednisolone and MMF dose of 6.2±1.8mg/d and 1284±493mg/d respectively at baseline. C1, C2 and C12 MPA levels were 9.9±8.7mg/L, 8.6±6.2mg/L, 1.9±1.4mg/L during disease remission. C1, C2 and C12 MPA levels correlated with $AUC_{0\text{-}12}$ (r= 0.52, 0.85 and 0.77; p=0.004, <0.001 and <0.001 respectively). C12 correlated inversely with hemoglobin, white cell and platelet counts (r= -0.359, -0.226, -0.20; p=0.001, 0.010 and 0.024 respectively). There was no association between C12 and anti-dsDNA, serum creatinine or 24-hr urine protein excretion (p=0.53, 0.07 and 0.37 respectively). C1 and C2 showed no association with clinical or serological parameters. Clinically significant events included infection in 2 patients, gastrointestinal upset in 3 patients, and renal flare in 5 patients. C12 MPA level at the time of these events were 1.7±1.6mg/L, 2.6±1.7mg/L and 1.5±0.9mg/L respectively.

Conclusions: C12 MPA level showed good correlation with drug exposure, and may be associated with renal flare and haematological side-effects but not infection.

TH-PO775

Long-Term Prospective Study of Tacrolimus-Based Treatment in Lupus Nephritis Patients Kazunori Karasawa, Keiko Uchida, Yukari Asamiya, Takahito Moriyama, Mitsuyo Itabashi, Takashi Takei, Kosaku Nitta. *Dept Medicine, Kidney Center, Tokyo Women's Medical Univ, 8-1 Kawada-cho, Shinjyuku-ku, Tokyo, Japan.*

Background: This study aimed to examine whether long-term maintenance treatment with tacrolimus for patients with lupus nephritis (LN) is effective and safe.

Methods: A total of 27 adult patients with LN after induction therapy were enrolled. Tacrolimus was initiated at a dose of 3 mg/day. Patients treated with other immunosuppressive agents were also switched to tacrolimus. Prednisolone doses were tapered throughout the period according to individual disease activity. Prospective data on renal response, lupus nephritis disease activity index (LNDAI) including hematuria, proteinuria, C3 and anti-ds DNA antibody (score range: 0-10), and prednisolone dose, were collected.

Results: Four patients discontinued tacrolimus treatment due to its ineffectiveness, complications including acute myeloblastic leukemia, or their personal intention to become pregnant or discontinue medication. A total of 23 patients (mean age 52.6 ± 11.8 years and mean duration of LN 15.6 ± 8.7 years) were treated with tacrolimus throughout a 5-year period and their data were analyzed. The mean urinary protein/creatinine ratio significantly decreased from a baseline of 1.12 ± 1.47 to 0.33 ± 0.78 at 1 year (p = 0.005) and 0.40 ± 1.54 at 5 years (p = 0.016), while mean eGFR levels were unchanged throughout the 5 years of tacrolimus treatment. The mean LNDAI was significantly decreased from a baseline of 3.54 ± 2.53 to 1.96 ± 1.40 at 1 year (p = 0.021) and 2.08 ± 1.44 at 5 years (p = 0.022). Similarly, the mean prednisolone dose significantly decreased from a baseline of 0.35 ± 0.21 mg/kg/day to 0.22 ± 0.15 mg/kg/day at 1 year (p = 0.022) and 0.17 ± 0.09 mg/kg/day at 5 years (p = 0.001). The mean blood concentration of tacrolimus was 4.0 ± 2.3 ng/ml. Only one patient experienced a disease flare, and there were no deaths during the study period.

Conclusions: Our results suggest that tacrolimus can be potentially effective for the treatment of LN; moreover, the current dosage appeared to be generally well-tolerated for long-term maintenance treatment in patients with LN.

TH-PO776

Comparison of Kidney Function and Mortality of Mexican Children versus Adults with Lupus Nephritis Luis Gerardo Gonzalez-Correa, Enrique Rojas-Campos, Benjamin Gomez-Navarro, Alfonso M. Cueto-Manzano, Petra Martínez. *Unidad de Investigación Médica en Enfermedades Renales, Inst Mexicano del Seguro Social, Guadalajara, Jalisco, Mexico.*

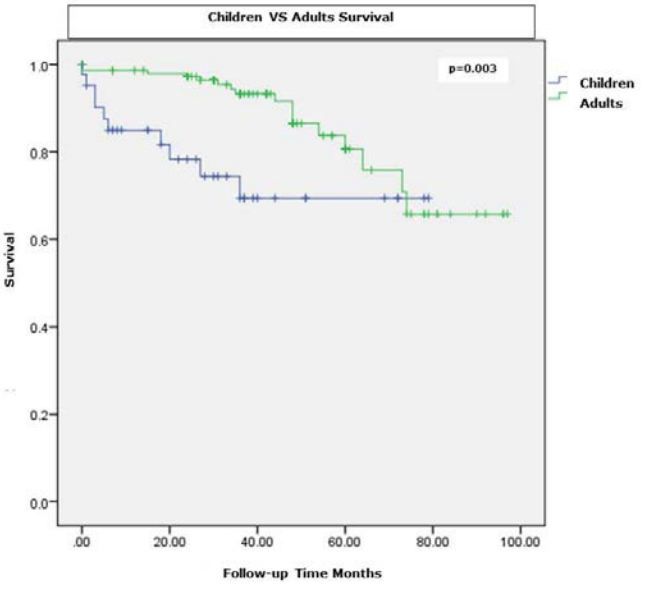
Background: Childhood-onset lupus nephritis (CLN; onset before 16 years of age) has been associated with a more aggressive disease course as compared to adulthood-onset lupus nephritis (ALN). Kidney factors such as LN Class and Activity and Chronicity Indexes are related to renal prognosis. No information is available in our setting. **Aim:** To compare kidney function and mortality of CLN vs ALN.

Methods: Retrospective cohort study. Medical records of patients with LN biopsy proven performed Jan/2005 – Dec/2012 were reviewed. Clinical, kidney function and sociodemographical variables were recorded. Kidney biopsy findings, LN class, Activity and Chronicity Indexes, and patient status (alive▫deceased) were also analyzed.

Results: There were 53 patients with CLN and 188 with ALN, with a follow–up of 24±23 vs 43±22 months, and age 12±2 vs 32±11 years, respectively.Main results are shown in the table.

Variable	CLN		ALN	
	Baseline	Final	Baseline	Final
Proteinuria g/day	2.0 (1.0-5.0)	0.5 (0.2-1.4)	2.1 (0.6-4.3)	0.5 (0.2-1.5)
CrCl (ml/min/1.73m^2)	85±42	98±45	80±29	76 ±34*
Activity Index	10±4	4±3	8±3	7±4
Chronicity Index	2±1	5±2	3±2*	4±2
LN Class		Loss of Kidney function		Loss of Kidney function
	N (%)	N (%)	N (%)	N (%)
Class II	12 (23)	1 (8)	23 (12)	1 (4)
Class III	12 (23)	1 (8)	42 (22)	5 (12)
Class IV	22 (41)	8 (36)	54 (29)	10 (18)
Class V	4 (7)	0	48 (25)	1 (2)
Mixed Class	3 (6)	0	21 (12)	5 (24)
Death	10 (19%)		14 (7%)*	
Death Sepsis	30%		36%	

*p<0.05 vs CLN



Conclusions: Patients with CLN had higher mortality and those with ALN had lower CrCl at the end of follow-up. Children died mainly due to infectious causes which might be related to the immunosuppression used because of the high prevalence of class IV LN.

TH-PO777

Determining Long-Term Outcomes in Lupus Nephritis Through Molecular Analysis of Serial Kidney Biopsies Samir Parikh,[1] Ana Malvar,[2] Huijuan Song,[1] Jianying Zhang,[1] Lianbo Yu,[1] Brad H. Rovin.[1] *[1]Div of Nephrology, The Ohio State Univ Wexner Medical Center, Columbus, OH; [2]Nephrology, Hospital Fernandez, Buenos Aires, Argentina.*

Background: Most patients with proliferative lupus nephritis (LN) achieve a partial remission (PR) after induction therapy. With time some patients will attain complete remission (CR) while others will not improve. We tested whether gene expression in serial kidney biopsies could identify markers of long-term kidney outcome in patients who achieved a PR after induction.

Methods: The expression of 511 immune response genes was evaluated for 9 pairs of proliferative LN biopsies. A kidney biopsy was done at flare (bx1) and after induction therapy was completed (bx2). All patients achieved a clinical PR prior to bx2. At 3 year follow-up 4 patients were in CR and 5 patients did not improve or worsened (NR). Gene

expression profiles were compared at bx1 and at bx2 between these CR and NR patients. Transcripts were considered differentially expressed only if they met both criteria of at least a 1.5-fold change (FC) and p-value < 0.01.

Results: At flare, 2 transcripts were differentially expressed between CR and NR. IL-28a, a type 3 interferon gene was decreased 2.6-fold (p=0.006) and mannose-binding lectin serine peptidase 1 (MASP1), a member of the complement lectin-pathway, was decreased 1.8-fold (p=0.009) in CR versus NR. From bx1 to bx2, 8 genes were differentially expressed in the CR group. Expression of adhesion molecule VCAM1 and macrophage regulator CEBPB was decreased while expression of TGF-β activator SMAD3, inhibitor of TLR signaling, TOLLIP, and inhibitor of NF-κB signaling, TRAF4 was increased. In NR, from bx1 to bx2, 9 genes were differentially expressed. Expression of the type 3 interferon, IL28b and the TNF-receptor TNFRSF13b (TACI) was decreased while expression of complement C2 and CFB and the TNF cytokine TNFSF8 was increased.

Conclusions: Molecular characterization of kidney biopsies at LN flare along with the change in expression after treatment identifies differentially-expressed genes among patients who eventually have or do not have a CR. Some of these genes may be candidate biomarkers of long-term renal outcomes in LN.

TH-PO778

Evaluation of Healthcare Resource Utilization and Costs by Immunosuppressant Pattern of Use in Lupus Nephritis Shih-Yin Chen, Ning Wu, Jie Ting, Fei Shih. *Biogen.*

Background: US-based treatment guidelines recommend 6 months of immunosuppressant (IS) therapy before continuing or switching regimen for class III/IV lupus nephritis (LN) patients. Literature suggested that management of LN is costly, but published data on how costs and healthcare resource utilization (HRU) may vary by IS pattern of use are limited.

Methods: We identified LN patients initiating cyclophosphamide (CYC) or mycophenolate mofetil (MMF) in 2010-2013 from a US commercial/Medicaid claims database. All-cause costs and HRU during the year post-IS initiation were examined. Comparison was made between the following four groups based on their IS utilization during the first 6 months and 7-12 months post-IS initiation: 1) patients who used the same IS continuously for at least 7 or up to 12 months (reference group), 2) patients who switched/added-on IS after 6 months, 3) patients who switched/added-on IS within 6 months, and 4) patients who discontinued IS within 6 months.

Results: Final sample included 1,567 LN patients (mean age=37 years; 86% female) initiating CYC (16.1%) or MMF (83.9%). Patients who remained on the same IS throughout had significantly lower costs and HRU compared to other three groups.

	Overall (N=1,567)	Patient groups			
		Remained on the same treatment (reference group; N=833)	Switched/ added-on after 6 months (N=223)	Switched/ added-on before 6 months (N=206)	Discontinued before 6 months (N=305)
Annual per patient costs (mean)					
Total	$37,636	$25,261	$44,308*	$59,437*	$51,832*
Inpatient	$13,564	$6,407	$17,085*	$23,442*	$23,867*
Emergency room	$1,771	$1,407	$2,238*	$1,998*	$2,272*
Outpatient	$16,543	$11,567	$17,942*	$28,080*	$21,319*
Pharmacy	$5,757	$5,880	$7,043*	$5,916	$4,374*
HRU (%)					
Hospitalizations	26%	19%	35%*	39%*	30%*

*Significantly different from reference group at P <0.05

Conclusions: In LN patients, those who required additional IS or discontinued before 6 months incurred more than twice the annual total costs compared to those who continued the same IS through 7-12 months. Identifying safe and efficacious therapies early for LN patients may have economic implications. Future study supplemented with clinical markers to understand the economic impact of achieving early renal response is warranted.

TH-PO779

Retrospective Analysis of 65 Pregnancies in Patients with Lupus Nephritis in France Jean-charles Puthet,[1] Noemie Jourde-chiche,[2] Dominique Chauveau,[3] Eric Daugas,[4] Laurent Juillard.[1] *[1]Hôpital Edouard Herriot - Hospices Civils de Lyon, France; [2]Hôpital La Conception - CHU Marseille, France; [3]Hôpital Rangueil - CHU Toulouse, France; [4]Hôpital Bichat - APHP , on behalf of the French Cooperative Group on Lupus Nephritis, France.*

Background: Lupus nephritis (LN) mostly affects women of childbearing age. Despite the improvement in care over the last decades, pregnant women with LN are still at high-risk of maternal and foetal complications.

Methods: The aim of this study is to outline retrospectively the care and pregnancy prognosis carried out after 24 weeks of gestation between 2004 and 2014, in patients with LN diagnosed before or during pregnancy.

Results: Data was collected from 65 pregnancies in 44 patients across nine French hospitals centres. LN was revealed by pregnancy in five cases. A preparation phase preceded the pregnancy in 90% of the cases, and complete remission from the disease was obtained for more than 24 months in 74% of them. Corticosteroids and hydroxychloroquinine were generally continued (68% and 73% respectively). Azathioprine and aspirin were administered in 37% and 65% of pregnancies. Maternal complications occurred in 40% of pregnancies, mainly preeclampsia (18%) and LN flares (20%). The risk factors associated with LN flares during these pregnancies were: the presence of positive anti-native DNA antibodies (p <0.0001), low C4 (p = 0.004), the absence of complete remission of LN at conception (p < 0.001), or inactivity of LN inferior to 12 months (p = 0.003). Preeclampsia occurred more frequently with the degradation of kidney function or an increase in proteinuria at conception (p = 0.011 and p = 0.001). The perinatal death rate was calculated at 6.8%. We observed 25% premature births and 15% intrauterine growth retardation (IUGR).

Conclusions: We found encouraging results. The incidence of maternal and foetal complications during pregnancy was reduced compared to previous European studies including lupus patients. Risk factors of major maternal complications are best characterized.

TH-PO780

Nephrotic Syndrome and Pregnancy Iris C. De Castro,[1] J. Ashley Jefferson,[1] Thomas R. Easterling.[2] *[1]Div of Nephrology, Dept of Medicine, Univ of Washington School of Medicine; [2]Dept of Obstetrics and Gynecology, Univ of Washington School of Medicine, Seattle, WA.*

Background: In the absence of hypertension or renal insufficiency, some consider the perinatal outcomes in pregnant women with nephrotic syndrome to be good. However, the diagnosis and management of both maternal and fetal well-being is challenging.

Methods: We describe the presentation, management, and maternal and fetal outcomes of 31 pregnancies in 24 women with biopsy proven nephrotic syndrome during pregnancy. We include hemodynamic data from UltraCOM cardiac output measurements. All patients had nephrotic-range proteinuria (>3.5g/24hr and or >3.5g/g on spot urine protein: creatinine ratio) during pregnancy, a kidney biopsy diagnosis, and serum creatinine <1.5mg/dL at presentation.

Results: There were 24 subjects (9 primiparas) with 31 pregnancies and 32 offspring. Mean age was 27.6 years (range 16- 39 years) and mean gestational age at presentation was 18.7 weeks (range 5- 40 weeks). Labs revealed a mean creatinine 0.85mg/dL (range 0.4- 1.4mg/dL), mean serum albumin 1.97g/dL (range <1- 3.2g/dL), and mean proteinuria 8.96g/24h (range 3.6- 32g). UltraCOM data was available for 18 pregnancies. Mean cardiac output at presentation was markedly elevated at 8.38L/min. 14 of 31 pregnancies were known to have kidney disease before pregnancy. Nephrotic syndrome was newly diagnosed in 16 patients. Biopsy was performed during pregnancy in 10 subjects (median age of gestation 20.5 weeks (range 2-27 weeks)) changing management in 70%. 6 were biopsied postpartum. Biopsy diagnoses were FSGS(11), IgAN(3), lupus nephritis(3), membranous nephropathy(3), and 1 case each of Fibrillary GN, MPGN, C3GN, and minimal change disease. Maternal complications included preeclampsia(10/31), acute kidney injury(3/31) and cellulitis(3/31). Mean age of gestation at delivery was 35.4 weeks (range 25-40 weeks). 17 delivered via caesarean section. Fetal complications included birth weight <2,500g(18), IUGR(3), and 10 were admitted to NICU.

Conclusions: Pregnant women with nephrotic syndrome are at high risk for developing maternal and fetal complications despite the absence of significant hypertension or renal insufficiency.

TH-PO781

The Relationship Between Serum Cholinesterase, Number of Organ Involvement and Fibrotic Markers in Japanese Patients with IgG4-Related Disease Hirofumi Nishikawa, Yoshinori Taniguchi, Tatsuki Matsumoto, Kazu Hamada-Ode, Yoshiko Shimamura, Koji Ogata, Kosuke Inoue, Taro Horino, Shimpei Fujimoto, Yoshio Terada. *Kochi Univ, Japan.*

Background: To evaluate the relationship between cholinesterase, number of organ involvement and serum fibrotic markers in Japanese patients with IgG4-related disease (IgG4-RD) including kidney involvement.

Methods: The clinical symptoms, laboratory, pathological and FDG-PET/CT findings of Japanese patients with IgG4-RD (n=20) were assessed. Several laboratory data of IgG4-RD with multiple organs' involvements (IRDMOI) (n=10), IgG4-RD with limited organ's involvement (IRDLOI) (n=10), ANCA-associated vasculitis (AAV) (n=10) and Sjögren Syndrome (SjS) (n=10) were comparatively examined. Furthermore, we studied the relationship between the numbers of organ involvement (NOI) and several fibrotic markers (ELF score and serum Dkk-1) in IgG4-RD group.

Results: Serum cholinesterase (ChE) levels were significantly lower in IRDMOI group than IRDLOI, AAV and SjS groups. All cases did not show hepatic dysfunction in laboratory examinations. Serum albumin and IgG levels were significantly lower and CRP levels were significantly higher in AAV group, compared with IgG4-RD and SjS group. There were no significant differences in these levels between IRDMOI and SjS. In total IgG4-RD cases, ChE levels inversely correlated with NOI and fibrotic score, and fibrotic score positively correlated with NOI. Finally, Dkk-1, one of Wnt inhibitors, levels in IRDMOI were significantly lower than IRDLOI and healthy subjects (p<0.05).

Conclusions: The ELF score and serum Dkk-1 level might be a clinically useful indicators of active fibrosis and the extent of disease in Japanese patients with IgG4-RD. Notably, serum ChE levels could predict these phenomena.

TH-PO782

Crescentic IgA Nephropathy – A Prospective Study Krishan L. Gupta,[1] Prabhakar Doddi,[1] Ritambhra Nada,[2] Raja Ramachandran.[1] *[1]Nephrology, PGIMER, Chandigarh, India; [2]Pathology, PGIMER, Chandigarh, India.*

Background: Crescentic IgA nephropathy (cIgAN) carries a very poor prognosis and the initial creatinine at presentation predicts long-term outcome. The present prospective study was carried out to evaluate the clinico-pathological correlation and outcome of cIgAN.

Methods: Patients ³12 yrs with Crescentic IgAN were included in the study. Patients with infection with evidence of systemic disease like HSP, SLE, hepatitis B surface antigen, anti hepatitis C antibody and HIV-I/II were excluded from the study. Patients were followed prospectively monthly for a period of 12 months or till end stage renal (ESRD) or death. Primary objective of the study was to evaluate percentage of patients achieving remission/ ESRD and the secondary outcome to see for histological correlation with clinical outcome.

Results: A total of 60 cases of crescentic IgAN were enrolled in the study. The mean age of the patients was 28.91±10.14 (12-60) years. The study included 46 (76.67%) males and 14 (23.33%) females. The mean 24 hour-urine protein (UP), serum creatinine and serum albumin were 2.22±1.33 gm, 6.37±4.13 mg/dl and 3.39±0.78 gm/dl respectively. Active sediments were present in 44 (74.57%) patients at presentation. The clinical presentation was RPRF in 34 (56.66%) cases, nephrotic syndrome in 04 (6.66%) and CKD in 20 (33.33%) and 2 (3.33%) cases presented with only subnephrotic proteinuria. Seventeen (28.33%) patients received combination of pulse cyclophosphamide and steroids, 29 (48.33%) received only steroids and 14 (23.34%) cases with tubular atrophy and interstitial fibrosis >70% were not treated with any immunosuppressive. At the end of 12 months 03 (5%) achieved CR, 08 (13.33%) had PR progressive CKD in 09 (15%) and 02 (3.33%) had persistent NS. Thirty-eight (63.33%) cases progressed to ESRD by the end of 12 months. Serum creatinine at presentation and IFTA> 50% and presence of fibrous crescent on biopsy was risk factor for ESRD.

Conclusions: Crescentic IgAN carries a very poor prognosis, with majority of the cases progressing to ESRD by 12 months. Serum creatinine at presentation and presence of diffuse IFTA and fibrous crescents on biopsy predicts development of ESRD.

TH-PO783

Comprehensive Microbiome Analysis of Tonsillar Crypts in IgA Nephropathy Hirofumi Watanabe, Shin Goto, Masafumi Tsuchida, Ichiei Narita. *Div of Clinical Nephrology and Rheumatology, Niigata Univ Graduate School of Medical and Dental Sciences, Niigata, Japan.*

Background: IgA nephropathy (IgAN) is the most prevalent primary chronic glomerular disease, in which the mucosal immune response, especially elicited in the tonsils or intestine, has been estimated to be involved with the development of the disease. To explore the relationship between IgAN and bacterial flora in the tonsils, we conducted a comprehensive microbiome analysis.

Methods: We enrolled 21 IgAN patients, 14 recurrent tonsillitis (RT) patients without urine abnormalities and 20 children with tonsillar hyperplasia (TH) who had been performed with tonsillectomy. Genomic DNA from tonsillar crypts of each patient was extracted, and V4 regions of the 16S ribosomal RNA (rRNA) gene were amplified and analyzed using a high-throughput multiplexed sequencing approach. Differences of the genus composition among three groups were statistically analyzed by PERMANOVA, and visualized by principal component analysis (PCA).

Results: In 16S rRNA analysis, substantial diversity of bacterial compositions was detected in each sample. *Prevotella*, *Fusobacterium*, *Sphingomonas*, and *Treponema* were dominated in IgAN. The proportion of the *Haemophilus* spp., *Porphyromonas* spp., and *Treponema* spp. of IgAN was different from that of TH. However, there was no bacterial genus that differs significantly in the frequency of between IgAN and RT. The PCA did not separate IgAN from RT, although it was discriminated from TH. In addition, we compared the bacterial composition between IgAN patients with higher and lower serum IgA levels; however, no difference in composition of microbiome between the two groups was observed.

Conclusions: Similar pattern of bacteria are present in tonsillar crypts of both IgAN and RT, suggesting that the host responsiveness to these bacteria is important in the development of IgAN.

TH-PO784

Urinary N-Acetyl-β-D-Glucosaminidase Level Is Associated with Tubulointerstitial Fibrosis and Therapeutic Response in Immunoglobulin A Nephropathy Yosuke Yamada, Makoto Harada, Akinori Yamaguchi, Koji Hashimoto, Makoto Higuchi, Yuji Kamijo. *Dept of Nephrology, Shinshu Univ School of Medicine, Matsumoto, Nagano, Japan.*

Background: Therapeutic response in Immunoglobulin A nephropathy (IgAN) patients has been shown to be affected by the severity of chronic renal lesion, such as tubulointerstitial fibrosis. Urinary N-acetyl-β-d-glucosaminidase (U-NAG) is a known biomarker of tubulointerstitial injury. The present study aimed to clarify if U-NAG level was associated with the severity of tubulointerstitial fibrosis and whether it could predict the effectiveness of combined steroid pulse and tonsillectomy therapy (ST), which is the primary treatment for IgAN in Japan.

Methods: Among the 81 IgAN patients who were diagnosed by kidney biopsy and treated with ST between March 2005 and April 2015 at Shinshu University Hospital, the U-NAG data of 77 patients were investigated for relationships between clinical and histological data. To search for associations between U-NAG level and clinical remission (CR) rate, we examined 39 of the above 77 patients who were observed for 3 years following ST. CR was defined as proteinuria of less than 0.3 g/gCre and urinary erythrocytes of less than 5 /high-power field.

Results: Multiple linear regression analysis adjusted by age and estimated glomerular filtration rate (eGFR) indicated that U-NAG level was significantly associated with tubulointerstitial fibrosis score ($p<0.001$) and the percentage of global sclerotic glomeruli ($p=0.008$). Multiple logistic regression analysis adjusted by age, sex and eGFR indicated that the CR rate 3 years after ST was significantly associated with tubulointerstitial fibrosis score (Odds Ratio [OR] 0.092, 95% Confidence Interval [CI] 0.009-0.914, p=0.042) and U-NAG level (OR 0.713, 95%CI 0.530-0.958, p=0.025).

Conclusions: U-NAG is a potentially useful biomarker of the severity of renal tubulointerstitial fibrosis and global glomerular sclerosis percentage in IgAN. U-NAG measurement may also aid in the prediction of therapeutic response to ST in IgAN.

TH-PO785

Beneficial Effect of Immunosuppressive Therapy for IgA Nephropathy with Moderately Impaired Renal Function Kyung sun Park,[1] Jongha Park,[2] Jong Soo Lee,[2] Hyun Chul Chung.[2] *[1]Div of Nephrology, Dept of Internal Medicine, Dongkang Medical Center, Ulsan, Korea; [2]Div of Nephrology, Dept of Internal Medicine, Ulsan Univ Hospital, Ulsan, Korea.*

Background: A variety of treatment has been attempt to slow progression of IgA nephropathy (IgAN) such as renin-angiotensin system inhibitors and adding corticosteroid for patients with impaired renal function. We compared clinical outcomes of IgAN patients who were treated with vs. without immunosuppressive therapy (IST), and explored identified risk factors associated with progression of renal dysfunction.

Methods: Patients who were diagnosed as IgAN between 2001 and 2014 were screened. Among them, patients who had initial estimated glomerular filtration rate (eGFR) of 30-60 mL/min/1.73 m^2 and had followed up for at least 12 months were included in this analysis.

Results: A total of 92 patients were analyzed. 39 patients received IST (Group 1) and 53 did not (Group 2). Median follow-up (59 vs. 77 months) and mean age (46.6 vs. 47.4 years) were not different. In Group 1, mean arterial pressure (MAP, 99 vs. 93 mmHg, P=0.019), serum creatinine (1.66 vs. 1.45 mg/dL, P=0.003), and median amount of proteinuria (2033 vs. 1115 mg/day, P<0.001) were significantly higher, but mean eGFR (43.7 vs. 50.1 mL/min/1.73 m^2, P<0.001) and serum albumin (3.5 vs. 4.0 g/dL, P=0.009) were lower than Group 2 at baseline. Three patient of Group 1 and 7 of Group 2 progressed to end-stage renal disease (ESRD). ESRD-free survival was comparable between two groups (P=0.639). For 1 year, the change of mean eGFR was significantly different between 2 groups (3.8 of Group 1 vs. -1.3 mL/min/1.73 m^2 of Group 2, P=0.027).

	Group 1 (n=39)	Group 2 (n=53)	P
Mean eGFR;ml/min/1.73m^2			
.baseline	43.7	50.1	
.at 1 year	47.5†	48.8*	
.change	3.8	-1.3	0.027

†P=0.069, *P=0.179 compared to baseline

In multivariate linear regression, age at diagnosis (standardized beta, 0.212; P=0.041), MAP (standardized beta, -0.227; P=0.027), baseline eGFR (standardized beta, 0.566; P<0.001) and IST (standardized beta, 0.273; P=0.013) were independent predictors of last-visit eGFR.

Conclusions: IST may have a beneficial effect for slowing progression of IgAN with moderately impaired renal function.

TH-PO786

Longitudinal Study of a Kindred with Familial IgA Nephropathy Reveals Stable Serum Levels of Galactose-Deficient IgA1 Hiroyuki Ueda,[1,2] Yoshimi Ueda,[1,2] Zina Moldoveanu,[1] Stacy D. Hall,[1] Karen Hart,[1] Krzysztof Kiryluk,[3] Ali G. Gharavi,[3] Dana Rizk,[1] Bruce A. Julian,[1] Jan Novak.[1] *[1]Univ of Alabama at Birmingham, Birmingham, AL; [2]The Jikei Univ School of Medicine, Tokyo, Japan; [3]Columbia Univ College of Physicians and Surgeons, New York, NY.*

Background: Patients with IgA nephropathy (IgAN) have elevated levels of circulatory galactose-deficient IgA1 (Gd-IgA1). Familial form of IgAN has been reported among people of all ancestries. Serum Gd-IgA1 levels are heritable in patients with familial and sporadic IgAN. Moreover, 50% of first-degree relatives of patients with familial IgAN have high serum Gd-IgA1 levels (≥95th percentile of healthy controls) without clinical signs of IgAN. This study is a longitudinal follow-up of a large kindred with familial IgAN.

Methods: Pedigree includes 4 men with biopsy-proven IgAN. Members recruited in 2005 and 2014 included 2 IgAN patients, 13 relatives, and 7 genetically unrelated individuals (marry-ins). Blood samples were drawn to determine for total IgA and Gd-IgA1 levels. Gd-IgA1 was measured using lectin ELISA and expressed relative to a standard Gd-IgA1 in U/100 ng of serum IgA. Spot urine sample was obtained for urinalysis and protein/creatinine ratio. Abnormal urinalysis was defined by hematuria (³2+ blood) and/or protein/creatinine ratio ³0.5 g/g.

Results: Mean (± SD) ages of IgAN patients, blood relatives, and marry-ins were 48 (±3), 43 (±16), 61 (±12) yr in 2014. Two patients had multiple kidney transplantations. Except for the 2 IgAN patients, no individual had an abnormal urinalysis. Serum Gd-IgA1 levels for marry-ins were similar to other healthy controls. Serum Gd-IgA1 levels were higher in blood relatives and IgAN patients than in marry-ins at each sampling time ($P = 0.03$). Serum Gd-IgA1 levels demonstrated longitudinal stability in most individuals (Intraclass correlation coefficient = 0.812; 95% CI 0.604-0.917).

Conclusions: Serum Gd-IgA1 levels in 22 individuals in this multiplex IgAN pedigree were stable over a 9-year period. No blood relative developed IgAN or exhibited a urinary abnormality during the 9-year follow-up.

TH-PO787

Childhood IgA Nephropathy with Nephrotic Syndrome (NS-IgAN) at Onset Yuko Shima,[1] Koichi Nakanishi,[1] Taketsugu Hama,[1] Masashi Sato,[1] Hiroko Togawa,[1] Hironobu Mukaiyama,[1] Hiroshi Kaito,[2] Kandai Nozu,[2] Ryojiro Tanaka,[3] Kazumoto Iijima,[2] Norishige Yoshikawa.[4] *[1]Pediatrics, Wakayama Medical Univ, Wakayama, Japan; [2]Pediatrics, Kobe Univ, Kobe, Japan; [3]Pediatric Nephrology, Hyogo Childrens' Hospital, Kobe, Japan; [4]National Center for Child Health and Development, Tokyo, Japan.*

Background: Clinical characteristics and long term outcomes of childhood NS-IgAN are not fully clarified.

Methods: We retrospectively analyzed 426 consecutive biopsy-proven samples of childhood IgAN from July 1976 to June 2013. There were 30 cases with NS-IgAN (7.0%) at onset. We compared clinical and pathological findings between NS- and other IgAN.

Results: Clinical findings showed significant differences (NS vs non-NS) in males (77 vs 53%, p=.008), gross hematuria (77 vs 51%, p=.006), and duration from onset to renal biopsy (1.5 vs 8.4 months, p<.001). Pathological findings had significant differences in mean mesangial hypercellularity score (M, 1.5 vs 0.8, p<.0001), median endocapillary hypercellularity (E, 27.3 vs 3.9%, p<.0001), and median crescents (C, 15.2 vs 3.6%, p=.0006). Logistic analyses showed a significant relation between M, an acute lesion, and NS-IgAN. Although Kaplan–Meier analysis showed significantly lower renal survival rate in cases with NS-IgAN than other cases (p=.02), the 10-year renal survival rate of NS-IgAN was 92.7% (95%CI=75.0–98.2). The prognostic factors for renal survival were proteinuria disappearance, M, E, tubular atrophy/interstitial fibrosis (T) and C, but not presence of NS at onset. Combination therapy including PSL and immunosuppressants was given to 20/30 NS-IgAN patients, and 21 showed disappearance of proteinuria. Three cases (9.7%) developed chronic renal failure (eGFR<60) during the observation period (6.2±3.2 years). All three cases received combination therapy and showed heavy proteinuria after 2 years of treatment. The factor T, a chronic lesion unmodifiable by treatment, was identified in patients refractory to treatment.

Conclusions: Renal outcome of childhood NS-IgAN was good. Modifiable acute lesions are the dominant pathological findings in childhood NS-IgAN.

TH-PO788

Predictive Factors of Spontaneous Remission in Patients with Immunoglobulin A Nephropathy Tae-Hyun Yoo,[1] Kyoung Sook Park,[1] Tae ik Chang,[2] Shin-Wook Kang.[1] *[1]Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea; [2]Dept of Internal Medicine, NHIC Ilsan Hospital, Gyeonggi-do, Korea.*

Background: Although immunoglobulin A nephropathy (IgAN) is commonly considered as a lifelong disease, incidences of spontaneous remission (SR) have been occasionally reported. We investigate the incidence as well as the clinical predictors of SR in IgAN.

Methods: Medical records of biopsy-proven IgAN in Severance hospital from 2006 to 2014 were reviewed. SR was defined as complete remission reached without any immunosuppressive therapy. Two different SR criteria were used to classify the patients into SR or non-SR (NR) group. A criteria proposed in previous reports was chosen as criteria I [urine red blood cell (RBC) count<5/HPF and random urine protein-to-creatinine ratio (UPCR)<0.3 g/g]. Criteria II was defined to better represent a normal renal function state [urine RBC<3/HPF, UPCR<0.2 g/g, and estimated glomerular filtration rate (eGFR)>60 mL/min/1.73m^2]. Cox proportional hazard analysis was performed to identify independent predictors of SR.

Results: A total of 488 patients were investigated. The mean age was 36.9±12.2 years and 43.2% were male. Mean eGFR at the time of renal biopsy was 87.2±30.0 mL/min/1.73m^2. SR occurred in 95 patients (19.5%) by criteria I and in 61 patients (12.5%) by criteria II. According to the classification based on criteria II, SR group showed lower levels of UPCR (0.64±1.05 vs.1.44±1.52 g/g, P<0.001) and higher serum albumin concentrations (4.4±0.5 vs. 4.1±0.5 g/dL, P<0.001) compared with NR group. In multivariate Cox hazard models for prediction of SR, the levels of UPCR [per 1 g/g increase, criteria I, hazard ratio (HR)=0.58, 95% confidence interval (CI)=0.41-0.83, P=0.003; criteria II, HR=0.63, 95% CI=0.40-0.99, P=0.047] was an independent predictor of SR after adjustment for age, sex, diabetes, mean arterial pressure, eGFR, serum albumin concentrations, Haas subclass, and the use of renin-angiotensin-aldosterone system blockers.

Conclusions: The incidence of SR in IgAN was substantially frequent. UPCR levels may be an independent predictor of SR in patients with IgAN.

TH-PO789

Comparison of the Effect of Oral Steroid and Tonsillectomy Combined with Steroid Pulse Therapy for IgA Nephropathy Yoshie Hoshino, Takahito Moriyama, Mitsuyo Itabashi, Takashi Takei, Ken Tsuchiya, Kosaku Nitta. *Dept of Medicine, Kidney Center, Tokyo Women's Medical Univ, Tokyo, Japan.*

Background: Recently, in Japan, IgA nephropathy (IgAN) has been often treated by tonsillectomy combined with steroid pulse therapy (TSP) instead of traditional oral steroid therapy (oPSL). However, there are few reports described about the comparison of them.

Methods: We identified the 68 IgAN patients who were diagnosed in our institution between 1991 and 2013, and met the following criteria: (1) age³16 years old; (2) proteinuria >1 g/day; (3) estimated glomerular filtration rate (eGFR) ³30 ml/min/1.73m2; (4) treated by TSP or oPSL with our standard protocol; (5) follow-up period >1 year; (6) interval from renal biopsy to initiation of therapy £3 years; (7) not combined with other renal disease. We compared the clinical findings at the time of renal biopsy, histological findings, renal function and urinary findings during the follow-up period between both groups. We defined complete remission (CR) as proteinuria <0.3 g/g•creatinine and urinary red blood cells <5 counts/HF.

Results: After adjusting clinical findings by propensity score, each 20 patients were selected in both groups. Almost of all clinical and histological findings at baseline between both groups did not differ (TSP vs. oPSL group; eGFR: 77.5 vs. 75.7 ml/min/1.73m2 and proteinuria: 1.9 vs. 2.2 g/day). The CR rate was increased significant earlier (mean duration: 17.7±3.4 vs. 43.9±10.8 month, p<0.001) and higher (at 3 years: 61 % vs. 5 %, p<0.001) in TSP than oPSL group by Kaplan-Meier analysis. Renal function was decreased from baseline in both groups, however the ratio of patients with renal dysfunction (25% decreasing from baseline eGFR) was significantly lower in TSP than oPSL group during 3 years (at 3 years: 7 vs. 50 %, p<0.001). TSP (HR 4.00, 95%CI 1.03-21.06, p=0.04, higher eGFR (HR 2.43, 95%CI 1.10-5.80, p=0.03), lower triglyceride (HR 1.44, 95%CI 1.05-2.10, p=0.02) were the contributive factors to CR in multivariate analysis.

Conclusions: TSP therapy is useful for reaching CR and protecting renal function rather than oPSL therapy for IgAN with moderate to severe proteinuria.

TH-PO790

Evaluation of KDIGO Clinical Practice Guidelines for IgA Nephropathy by Japanese Multicenter Large Cohort Study Kyoko Watanabe,[1] Kentaro Koike,[2] Akihiro Shimizu,[2] Nobuo Tsuboi,[2] Keita Hirano,[1] Makoto Ogura,[2] Sayuri Shirai,[3] Yoshinari Yasuda,[4] Takashi Yasuda,[5] Shoichi Maruyama,[4] Tetsuya Kawamura,[2] Seiichi Matsuo,[4] Takashi Yokoo.[2] *[1]Ashikaga Red Cross Hospital, Ashikaga, Tochigi, Japan; [2]Div of Nephrology and Hypertension, The Jikei Univ School of Medicine, Minato-Ku, Tokyo; [3]Div of Hypertension and Nephrology, St. Mariana Univ, Kanagawa, Japan; [4]Nephrology, Nagoya Univ, Nagoya, Japan; [5]Nephrology, Kichijooji Asahi Hospital, Musashino-shi, Tokyo, Japan.*

Background: Current KDIGO clinical practice guidelines for IgA nephropathy (IgAN) neither advocate tonsillectomy nor steroid therapy for patients with eGFR<50ml/min. However,IgAN patients referred to nephrologists often have reduced eGFR at the time of referral.Therefore,we evaluated the KDIGO guidelines to assess,and further develop their clinical significance for treatment of IgAN with reduced eGFR by a large multicenter cohort study in Japan.

Methods: Of 1,174 patients registered for the multicenter cohort study led by the Progressive Kidney Disease Study Group funded by Japan Ministry of Health,Labor,and Welfare in 2012,cases with eGFR<50ml/min at the time of biopsy were selected.Primary outcome was defined as 1.5 times increase in creatinine concentration from baseline.

Results: Enrolled 201 patients showed 36.8 ml/min as mean eGFR and 1.15 g/day as median level of proteinuria. During the median follow up of 4 years,70 patients (34.8%) reached primary outcome. Like KDIGO recommendations,multivariate analysis adjusted with eGFR, proteinuria,and blood pressure at baseline revealed that steroid therapy alone did not significantly improve renal prognosis compared with no steroid therapy (hazard ratio [HR] 0.74; 95% confidence interval [CI] 0.43 to 1.25). By contrast,combining steroid therapy with tonsillectomy demonstrated significantly improved renal survival compared to no steroid therapy (HR 0.25; 95%CI 0.06 to 0.71).

Conclusions: In keeping with KDIGO recommendations, our results did not suggest improvement in renal prognosis by steroid therapy alone for IgAN with eGFR <50ml/min.However,they indicated that combining steroid therapy with tonsillectomy could be associated with a significantly better renal outcome.

TH-PO791

The Effect of Renin-Angiotensin System Blockade on the Incidence of End-Stage Renal Disease in IgA Nephropathy Shigeru Tanaka,[1] Toshiharu Ninomiya,[1,5] Ritsuko Katafuchi,[2] Kosuke Masutani,[1] Masaharu Nagata,[1] Akihiro Tsuchimoto,[1] Hideki N. Hirakata,[3] Kazuhiko Tsuruya,[1,4] Takanari Kitazono.[1,5] *[1]Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [2]Kidney Unit, National Fukuoka-Higashi Medical Center, Fukuoka, Japan; [3]Nephrology and Dialysis Center, Japanese Red Cross Fukuoka Hospital, Fukuoka, Japan; [4]Dept of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [5]Div of Research Management, Center for Cohort Studies, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.*

Background: The impact of renin-angiotensin system blockade (RASB) on the incidence of end-stage renal disease (ESRD) remains unclear in IgA nephropathy (IgAN). This study assessed associations between RASB treatment and the incidence of ESRD in IgAN using propensity score approaches.

Methods: We retrospectively analyzed 1267 patients with IgAN biopsied between 1979 and 2010. Propensity scores were calculated using logistic regression. Associations between RASB and ESRD were examined using a Cox regression model adjusted by inverse probability of treatment weighted, regression, stratification and matching.

Results: During follow-up (median 5.1 years), 130 patients developed ESRD. With Cox regression adjusted by inverse probability of treatment weighted, RASB use was significantly associated with a lower risk of ESRD (hazard ratio, 0.57; 95% confidence interval, 0.41–0.79). Significant associations were observed for other propensity score-based

approaches. In stratified analysis, a beneficial association between RASB and ESRD was observed in patients ³35 years, with hypertension, reduced estimated glomerular filtration rate (<60 mL/min/1.73 m^2), mesangial proliferation and segmental glomerulosclerosis (*P* for interaction <0.05), and tended to be greater in patients with proteinuria (³1.0 g/24 h), extracapillary proliferation, and receiving methylprednisolone pulse therapy (*P* for interaction <0.10).

Conclusions: Treatment with RASB was associated with a lower incidence of ESRD in the real-world practice of IgAN.

TH-PO792

Long-Term Outcome in 56 Patients with Assumed Benign IgA Nephropathy

Thomas Knoop, Bjorn Egil Vikse, Einar Svarstad, Sabine Leh, Rune Bjoerneklett. *Renal Research Group, Dept of Clinical Medicine, Univ of Bergen, Bergen, Norway.*

Background: Patients with IgA nephropathy (IgAN) presenting with mild to moderate proteinuria and estimated glomerular filtration rate (eGFR) ≥ 60 mL/min/1.73m² are assumed to have excellent renal prognosis. There is however limited data on very long-term outcome (>15 years) in such patients.

Methods: Patients with biopsy proven IgAN were retrieved from the Norwegian Kidney Biopsy Registry when fulfilling the following criteria; biopsy taken at Haukeland University Hospital 1988-1999, eGFR ≥ 60 mL/min/1.73m² and proteinuria < 1 gram/24 hours at presentation. Patients were invited for a medical examination and the following data were recorded: responsible physician during follow-up period (none/primary physician/ nephrologist), antihypertensive treatment (any/ angiotensin converting enzyme inhibitor (ACE-I)/angiotensin receptor blocker ARB)), blood pressure (BP), eGFR, urinary albumin creatinine ratio (UACR) (0-2.5 mg/mmol creatinine (negative) / 2.5–30 (microalbuminuria) / 30-100 (manifest albuminuria) />100 mg/mmol creatinine) and hematuria.

Results: We report data for 56 patients with a median follow-up time of 22 years after diagnosis. Nine patients (16 %) had no medical follow-up, thirty-five patients (63 %) were followed by a primary physician on a regular basis, and twelve patients (21 %) were followed by a nephrologist. Thirteen patients (23 %) had eGFR < 60ml/min/1.73m2 (eight with eGFR 30-45 and five with eGFR 45-60). Fifteen patients (27 %) had microalbuminuria, six patients (11 %) had manifest albuminuria and three patients (5 %) had UACR > 100 mg/mmol creatinine. Twenty-three patients (41 %) were treated with an ACE-I/ARB. Fifteen patients (27 %) had hypertension (BP >140/90 mmHg), nine of these had antihypertensive treatment and six were untreated. Nineteen patients (34%) had hematuria. Ten patients (18 %) had no medication, normal BP, eGFR ≥60 ml/min/1.73m2 and normoalbuminuria. Of notice, several patients with no medical follow-up had microalbuminuria, hypertension and/or decreased eGFR < 60ml/min/1.73m2.

Conclusions: Prognosis in patients with assumed benign IgAN is not always favorable and adequate medical follow-up is needed.

Funding: Government Support - Non-U.S.

TH-PO793

J-Curve Effects of Uric Acid on the Progression of IgA Nephropathy

Yuta Matsukuma,[1] Shigeru Tanaka,[1] Kosuke Masutani,[1] Akihiro Tsuchimoto,[1] Ritsuko Katafuchi,[2] Hideki N. Hirakata,[3] Kazuhiko Tsuruya,[1,4] Takanari Kitazono.[1] *[1]Dept of Medicine and Clinical Science, Kyushu Univ, Fukuoka, Japan; [2]National Fukuoka Higashi Medical Center, Fukuoka, Japan; [3]Japanese Red Cross Fukuoka Hospital, Fukuoka, Japan; [4]Dept of Integrated Therapy for Chronic Kidney Disease, Kyushu Univ, Fukuoka, Japan.*

Background: Recently, low uric acid (UA) as well as high UA has been emerged as a risk factor for cardiovascular disease (CVD).However the impact of low UA on the outcome of IgA nephropathy(IgA–N) remains unknown.

Methods: We retrospectively investigated 1226 patients with IgA-N diagnosed between 1978 and 2010. Patients were divided into three groups by tertile of UA: low (T1), middle (T2), and high (T3) tertiles (<6.1, 6.1–7.1, and >7.1 mg/dL in men and <4.4, 4.4–5.4, and >5.4 mg/dL in women, respectively). The risk factors of developing end stage kidney disease (ESKD) were assessed using a Cox proportional hazards model.

Results: After an average of 5.2 years of follow–up, 145 patients (11.8%) developed ESKD. High UA was an independent risk factor for ESKD after adjusting for potential confounding factors, hazard ratio (HR) for men, 1.27; 95% confidence interval [CI], 1.07 to 1.49, and HR for women, 1.41; 95% CI, 1.11 to 1.78, for every 1-mg/dL increase in UA), respectively. We also found that the HR showed a J-shaped trend with tertile of UA in both men (HR for T1, 1.24; 95% CI, 0.56 to 2.67, T2 [reference], HR for T3, 1.78; 95% CI, 1.03 to 3.21) and women (HR for T1, 2.64; 95% CI, 1.08 to 6.67, T2 [reference], HR for T3, 2.16; 95% CI, 1.06 to 4.86). Notably, low UA in women was significantly associated with the progression to ESKD.

Conclusions: UA showed a J–shaped trend with the progression of IgA–N. Not only high UA but also low UA is a risk factor for ESKD, and the trend was more clearly observed in women.

TH-PO794

Remission of Urinary Protein at 2 Years After Diagnosis with Normal Renal Function and Remission of Urinary Protein at 1 Year After Diagnosis with Decreased Renal Function as an Accurate Prognostic Marker in IgA Nephropathy

Takayuki Fujii,[1] Junichi Hoshino,[2] Joichi Usui,[3] Satoshi Suzuki,[1] Yoshifumi Ubara,[2] Kunihiro Yamagata.[3] *[1]Seirei Sakura Citizen Hospital, Sakura, Japan; [2]Toranomon Hospital, Tokyo, Japan; [3]Univ of Tsukuba, Tsukuba, Japan.*

Background: Level of proteinuria (UP) has a strong association with poor renal prognosis in IgA nephropathy. Recent studies reported that the level of UP, especially, remission of UP (CR) defined as less than 0.3 g/d, during the follow-up was a more accurate prognostic factor than at diagnosis. In this multicenter study, we evaluated which post-diagnosis measurement point achieving CR strongly associated with the renal prognosis.

Methods: 1,077 patients diagnosed with IgA nephropathy between March 1981 and December 2013, and could be followed-up for at least 3 years or reached end-stage kidney disease (ESKD) were enrolled. We performed a retrospective cohort study among 2 divided groups: 638 with eGFR≥60 mL/min/1.73m² (A) and 439 with eGFR<60 mL/min/1.73m² (B). The endpoint of this study was a 50% decrease in eGFR or ESKD. The annual daily UP level until 3 years after diagnosis was categorized into 2 grades: <0.3 g/d and ³0.3 g/d and its association with the renal prognosis was investigated. The hazard ratio of the endpoint adjusted with clinical and pathological findings and treatment was examined.

Results: Regarding CR as a reference, UP³0.3 g/d was not a significant poor prognostic factor at diagnosis, but at 1 year, especially at 2 years, it became a significant factor in group A. On the other hand, in group B, UP³0.3 g/d was already shown to be a significant factor at diagnosis and the strongest factor at 1 year.

	eGFR≥60 ml/min/m²		eGFR<60 ml/min/m²

after 1 year	reference	4.91(2.03-14.64)	reference	16.54(6.76-54.82)
after 2 years	reference	10.84(3.68-48.33)	reference	4.91(2.62-10.11)

Conclusions: CR within 2years after diagnosis with normal renal function and CR within 1year after diagnosis with decreased renal were the most accurate predictors for a favorable outcome in IgA nephropathy.

TH-PO795

Copeptin, a Surrogate Marker for AVP, Is Associated with Disease Severity and Progression in IgA Nephropathy Patients

Debbie Zittema,[1] Jan A.J.G. van den Brand,[2] Jack F. Wetzels,[2] Ron T. Gansevoort.[1] *[1]Nephrology, Univ Medical Center Groningen, Groningen, Netherlands; [2]Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands.*

Background: The disease course of IgA Nephropathy (IgAN) is difficult to predict. Copeptin, a surrogate marker for AVP, has been described to cause kidney damage in various renal diseases. We investigated therefore the associations of copeptin with disease severity and progression in IgAN.

Methods: Included were 60 biopsy proven IgAN patients from the Radboud UMC Nijmegen, of whom urine and blood samples were available. Urinary excretion of a1M, b2M, KIM-1 and NGAL and plasma copeptin was measured at baseline. Survival analyses was performed for the composite outcome death, end stage renal disease (ESRD), doubling of serum creatinine, start of immunosuppressive therapy and the individual components.

Results: In IgAN patients (male: 72%, age: 42±13 year, eGFR: 48±21 mL/min/1.73m², copeptin: 9.4 (5.5-18.1) pmol/L) copeptin was associated at baseline with proteinuria (St. β=0.34, p=0.05), a1M (St. β=0.41, p=0.003) and b2M (St. β=0.38, p=0.005), adjusted for age, sex and eGFR, and with NGAL when adjusted for age and sex (St. β=0.34, p=0.01). During a follow-up of 7±3 years, copeptin (divided in tertiles) was positively associated with the composite outcome (p=0.03) and with start of immunosuppressive therapy (p=0.04) using a log rank test. When patients who started immunosuppressive therapy during follow up (n=14) were excluded, copeptin (as continuous variable) was furthermore associated with the incidence of ESRD (p=0.01, HR=1.09; i.e. a 9% increase in risk of ESRD per 1 pmol/L increase in copeptin), doubling of serum creatinine (p=0.004, HR= 1.07) and the composite outcome (p=0.003, HR= 1.07) in Cox regression models, adjusting for proteinuria and sex. After additional adjustment for eGFR, which is debatable as eGFR decline could be part of the causal pathway between copeptin and outcomes, the survival analyses lost significance.

Conclusions: Copeptin is a promising disease severity marker in IgAN with additive predictive value for future kidney function loss over proteinuria, but not over eGFR, the strongest predictor of disease progression in this study.

TH-PO796

Clinical Outcomes of Nephrotic Syndrome in IgA Nephropathy Eu gene Jeong,[1] Su mi Lee,[1] Young ki Son,[1] Dongyeol Lee,[2] Hansae Kim,[2] Sung Hyun Son.[3] *[1]Dept of Internal Medicine, Dong-A Univ Hospital, Busan, Republic of Korea; [2]Dept of Internal Medicine, Bong Seng Memorial Hospital, Busan, Republic of Korea; [3]Dept of Internal Medicine, BHS Han Seo Hospital, Busan, Republic of Korea.*

Background: Uncommonly, IgA nephropathy can be complicated by nephrotic syndrome. In such cases, although, corticosteroid therapy should be recommended, the response to steroid treatment has been variable, and spontaneous remission without steroid treatment can occur in some cases. Here, we report our experience of clinical outcomes of nephrotic syndrome in patients with IgA nephropathy.

Methods: Thirty-three patients with biopsy-proven IgA nephropathy with nephrotic syndrome were enrolled between March 1990 and March 2009 in Dong-A university hospital. We retrospectively analyzed the data, including demographic, clinical, and laboratory records.

Results: The mean follow-up duration were 62 ± 45 months (10-204) in 33 patients. Complete remission occurred in 10 patients with steroid therapy and 2 patients without steroid therapy. Partial remission occurred in 7 patients with steroid therapy and 8 patients without steroid therapy. There were 6 patients with progressive deterioration of kidney function during follow-up periods.

Conclusions: Of IgA nephropathy patients with nephrotic syndrome, 36% of patients have complete remission, 45% of patients have partial remission. Steroid treatment may effectively reduce proteinuria. However, spontaneous remission occurs in some cases. Large-scale studies may be necessary in the future.

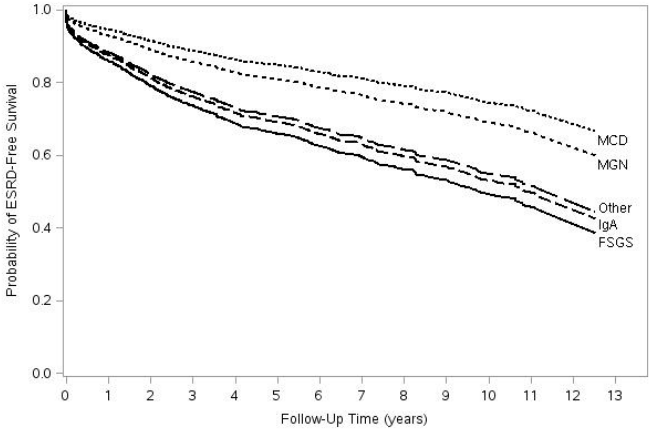
TH-PO797

Comparative Outcomes in Primary Glomerulonephritis Among a Large Diverse United States Population John J. Sim,[1] Michael Batech,[2] Teresa N. Harrison,[2] Taurino N. Avelar,[1] Aviv Hever.[1] *[1]Nephrology and Hypertension, Kaiser Permanente Los Angeles Med Ctr, Los Angeles, CA; [2]Research and Evaluations, Kaiser Permanente Southern California, Pasadena, CA.*

Background: Glomerulonephritis (GN) remains an important cause of end stage renal disease (ESRD) in the United States and the world. Within a large diverse population of an integrated health system, we sought to evaluate rates of primary GN and then compare ESRD and mortality outcomes within different GN's.

Methods: Retrospective longitudinal cohort study in the period 1/1/2000 through 12/31/2013 among patients within Kaiser Permanente Southern California. Patients who had biopsy proven primary GN were characterized and followed until they reached the outcome of ESRD or mortality. ESRD was defined as receiving dialysis or renal transplant.

Results: 2,849 patients were identified with biopsy proven GN. The mean age of the cohort was 47 yrs with 48% females, 37% Hispanics, 30% whites, 17% blacks, and 12% Asians. Focal segmental glomerulosclerosis (FSGS) was the most common GN among all race/ethnic groups (36% overall) followed by membranous GN (MGN) (12%), minimal change disease (MCD)(11%), IgA nephropathy (IgAN) (10%), and others (31%). The mean follow up was 3.8 yrs. ESRD occurred in 26% (704 required dialysis and 38 had a renal transplant). Mortality occurred in 18%. ESRD occurred among 35% of FSGS, 19% among IgAN, 12% among MGN, 10% among MCD, and 29% among other GN's.



Conclusions: Among a large racially/ethnically diverse United States population, FSGS was the most prevalent GN and was associated with the highest rate of progression to ESRD among all race/ethnic groups. This diverse cohort may give insight into characterizing and risk stratifying different GN's which may pave the way for more optimal management strategies.

TH-PO798

A Specific Transcriptomic Profile Characterizes Peripheral Blood Mononuclear Cells (PBMCs) from Uremic Patients (pts) Treated with On Line Hemodiafiltration (OL-HDF) Compared to Those Treated with Bicarbonate Dialysis (BHD) Simona Simone,[1] Annarita Chieti,[1] Matteo Accetturo,[1] Roberto Corciulo,[1] F. Rascio,[2] Paola Pontrelli,[1] Giovanni Stallone,[2] Loreto Gesualdo,[1] Giuseppe Grandaliano,[2] Giovanni B. Pertosa.[1] *[1]Dept of Emergency and Organ Transplantation, Univ of Bari, Italy; [2]Dept of Medical and Surgical Sciences, Univ of Foggia, Italy.*

Background: Recent studies suggest that OL-HDF can reduce the progression of dialysis-related cardiovascular diseases, but the molecular mechanisms underlying this improvement are not yet known. The aim of our study was to identify, through a high-throughput approach, differences in gene expression profiles of PBMCs from pts undergoing OL-HDF compared to BHD.

Methods: The transcriptomic profile was evaluated in PBMCs isolated from 10 pts regularly dialyzed with OL-HDF (convective volume³22 L) and 10 pts treated with BHD using microarray analysis (Agilent Technologies). The results were evaluated by statistical (unpaired t test) and functional pathway analysis (Ingenuity Pathway Analysis).

Results: We observed that 868 genes were differentially expressed in the comparison between OL-HDF and BHD (fold change>1.5). Thirty-seven functional gene networks were identified and atherosclerosis signaling was the top canonical pathway associated with BHD ($p=2.45x10^{-4}$). Among the downregulated genes in OL-HDF there were PDGF (FC -2.13) and Clusterin (FC -2.14), involved in vascular injury and Monoamine Oxidase A (MAO-A, FC=-2.43), an important source of oxidative stress and a major contributing factor to the development of ventricular hypertrophy and hearth failure. Interestingly, Apolipoprotein E (Apo-E) gene, an anti-oxidant/inflammatory protein, was upregulated (FC=+1.7) by OL-HDF. qPCR, performed in an independent testing-group [15 BHD, 15 OL-HDF] confirmed that PDGF, Clusterin and MAO-A were down-expressed in OL-HDF ($p=0.01$), whereas APO-E resulted higher expressed ($p<0.01$).

Conclusions: The OL-HDF can contribute to cardiovascular risk reduction through the modulation of pathways involved in the progression of atherosclerotic disease. This observation could open new perspectives in the prevention of cardiovascular risk in dialysis pts.

TH-PO799

Twice-Weekly versus Thrice-Weekly Hemodialysis in Patients with or without Residual Kidney Function Hyeon Seok Hwang,[1] Suk young Kim,[1] Su Hyun Kim,[2] Yong-Lim Kim,[3] Yon Su Kim,[4] Shin-Wook Kang,[5] Chul Woo Yang.[1] *[1]College of Medicine, The Catholic Univ of Korea, Korea; [2]Chung-Ang Univ College of Medicine, Korea; [3]Kyungpook National Univ School of Medicine, Korea; [4]Dept of Internal Medicine, Seoul National Univ College of Medicine, Korea; [5]Yonsei Univ College of Medicine, Korea.*

Background: Residual kidney function (RKF) accounts for large solute removal and significantly contributes to survival benefits in hemodialysis (HD) patients. However, there are no reliable outcome data suggesting that the frequency of HD might be safely reduced in patients with substantial RKF.

Methods: A total of 685 patients receiving more than 3 months HD therapy were included from the CRC registry for ESRD. The presence of RKF was defined as more than 100 ml/day of urine volume, and patients were classified into twice-weekly HD with RKF (n = 113), thrice-weekly HD with RKF (n = 137) and thrice-weekly HD without RKF (n = 435).

Results: The baseline RKF was significantly higher in twice-weekly HD patients with RKF than in thrice-weekly HD patients with RKF, and it remained higher at 12 months follow-up. The sum of weekly renal Kt/V and delivered-standard Kt/V per week was similar pattern between twice-weekly and thrice-weekly HD patients with RKF. The thrice-weekly HD patients with RKF showed significantly higher survival rate than twice-weekly HD patients with RKF or thrice-weekly HD patients without RKF ($P = 0.002$). In multivariable analyses, compared with thrice-weekly HD patients without RKF, thrice-weekly HD patients with RKF were associated with lower risk for all-cause mortality (HR 0.11; 95% CI 0.02-0.53). However, twice-weekly HD treatment with RKF did not reduce the risk of mortality (HR 0.65; 95% CI 0.22-1.87). For hospitalization of cardiovascular events, thrice-weekly HD therapy with RKF was independently associated with lower risk, (HR 0.40; 95% CI 0.16-0.98), but twice-weekly HD patients with RKF were not associated (HR 0.80; 95% CI 0.38-1.71).

Conclusions: Twice-weekly HD patients with RKF have similar outcome compared to thrice-weekly HD patients without RKF. However, thrice-weekly HD patients with RKF were more advantageous for mortality and CVE than those without RKF.

TH-PO800

Comparison of Outcomes Between Incremental and Abrupt Initiation of Hemodialysis: A Propensity-Matched Analysis of a Prospective Cohort Study in Korea Ji In Park,[1,2] Yong-Lim Kim,[2,3] Shin-Wook Kang,[2,4] Chul Woo Yang,[2,5] Yon Su Kim,[2,6] Jung Pyo Lee.[2,7] *[1]Kangwon National Univ; [2]Clinical Research Center of End Stage Renal Disease in Korea; [3]Kyungpook National Univ; [4]Yonsei Univ; [5]The Catholic Univ of Korea; [6]Seoul National Univ; [7]Seoul National Univ Boramae Medical Center.*

Background: When patients are diagnosed as end-stage renal disease (ESRD) and initiate hemodialysis (HD), thrice-weekly HD is a very common format. Recent report suggested possible benefit from beginning HD therapy less than three times weekly and incremental increase of dialysis dose, but there are not sufficient data. We compared outcomes of thrice-weekly and incremental HD.

Methods: A total of 1273 patients who were diagnosed as having ESRD and initiated hemodialysis from 2008 to 2014 were prospectively enrolled. The patients were classified into the abrupt initiation group (3 sessions/week) or the incremental initiation group (1-2 sessions/week). We compared HRQOL evaluated by KDQOL-SF and Beck's depression inventory (BDI) score at 3 months and 12 months after HD, and residual renal function by daily urine volume at 12 months after HD and all-cause mortality between the groups.

Results: Before propensity score matching, the abrupt group tends to be younger and showed smaller daily urine volume, higher modified Charlson comorbidity index (mCCI), and higher serum blood urea nitrogen and creatinine level compared to incremental group. A total of 432 patients (288 for abrupt and 144 for incremental group) were selected by propensity score matching. HRQOL tends to be better in incremental group for every domain of KDQOL-SF and BDI, but none of them showed significant difference at 3 months. At 12 months after HD, only cognitive functioning domain was better in incremental group. Daily urine volume at 12 months after HD was similar in two groups. All-cause mortality was comparable between two groups before and after propensity score matching.

Conclusions: Incremental initiation of HD showed comparable results with abrupt group regarding HRQOL, residual renal function and all-cause mortality. Incremental HD might be considered as another format of initiating HD for selected ESRD patients.

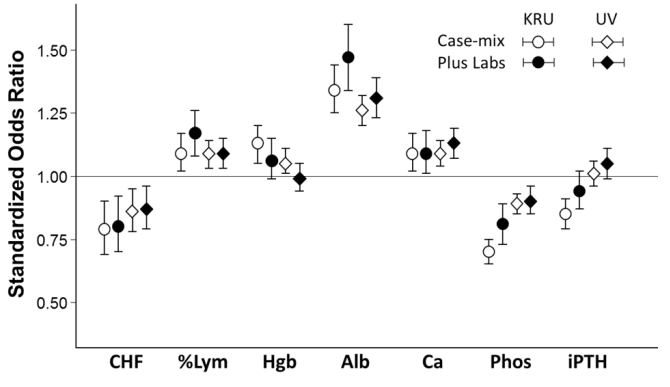
TH-PO801

Predictors of Substantial Residual Kidney Function in the First Year of Hemodialysis Treatment Yoshitsugu Obi,[1] Elani Streja,[1] Connie Rhee,[1] Anna Mathew,[2] Joline L.T. Chen,[1] Wei Ling Lau,[1] Steven M. Brunelli,[3] Csaba P. Kovesdy,[4] Rajnish Mehrotra,[5] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]Hofstra North Shore-LIJ Health System; [3]DaVita Clin Research; [4]UTHSC; [5]UW.*

Background: Residual kidney function (RKF) plays a critical role in dialysis adequacy, quality of life, and survival in hemodialysis (HD) patients. Therefore, identifying predictors related to preservation of RKF may contribute to improving patient management and developing novel strategy for preserving RKF.

Methods: In a longitudinal cohort of 18,091 patients who initiated conventional HD over four years (1/2007-12/2010),we examined the association of baseline characteristics during the first 3 months of their dialysis treatment with RKF [renal urea clearance (KRU) and urinary volume (UV)] after one year. We employed multivariate logistic regression analyses using ³3 mL/min/1.73m² of KRU or ≥600 mL/day of UV as outcomes with 2-level adjustments for case-mix variables and laboratory measurements in addition to baseline RKF values.

Results: Patients were 62±14 years old, 37% female, 29% non-Hispanic Black, and 67% diabetic. Median KRU and UV were 2.95 (IQR, 1.63-4.64) mL/min/1.73m² and 800 (IQR, 500-1,300) mL/day, respectively. High %lymphocyte, higher serum concentrations of albumin and calcium, and lower serum concentrations of creatinine and phosphorus were consistently associated with better preserved RKF indices irrespective of models. A history of congestive heart failure was an independent predictor for loss of RKF.



Conclusions: Better nutritional and CKD-MBD indices were associated with preserved RKF while a history of congestive heart failure were associated with loss of RKF at 1 year of hemodialysis initiation in this large national cohort. Additional studies to preserve RKF in dialysis patients are warranted.

TH-PO802

Clinical Determinants of Ultrafiltration Rates in Hemodialysis Adam K. Horeish, Jeffrey M. Rimmer. *Univ of VT Med Ctr, Bulington, VT.*

Background: High rates of ultrafiltration (UFR) are associated with adverse events. Approaches to reduce UFR other than fluid restriction alone are needed.

Methods: We examined characteristics associated with ultrafiltration rates (UFR) in patients dialyzed at UVMMC. Ultrafiltration rates (volume removed/pre-dialysis weight/treatment time) are followed electronically. Charts of 233 patients treated in October 2015 were examined with IRB approval. Patient characteristics and laboratory values were determined for 177 patients receiving three treatments during each of 4 consecutive weeks. These include average weight (PWt), treatment duration (RxT),and inter-dialytic weight gain (WtG); age, gender, dialysis vintage, sequence (TThS vs MWF), treating unit, diabetes, heart failure, prescribed diuretics, difference between serum and dialysate sodium (DifNa), percent urea reduction (PRU), absolute urea reduction, serum potassium, albumin, hemoglobin and pre and post dialysis blood pressure. The relation of weight, weight gain and treatment length were examined with descriptive statistics. Other potential explanatory variables were explored with multivariable regression models using both average UFR and average UFR for first weekly treatment as dependent variables.

Results: The range and median for PWt, RxT, and WtG respectively are 41.6 to 226, 81 Kg, 3 to 5.5, 4 hrs; and 0.63 to 8.38, 2.69 kg. When the values of PWt, RxT and WtG are below the median, 48.4%, 44.8% and 19.1% of patients respectively have a UFR > 10 ml/kg/hr and 15.6%, 23.9% and 48.9% if above the median. Variables significantly associated with UFR by regression are enumerated in table 1.

	1st UFR		AVG UFR	
R Square	0.321		0.317	
	BETA	P	BETA	P
Age	-0.042	0.007	-.045	0.002
Vintage	0.014	0.025	NA	NA
PreBP	0.022	0.037	0.020	0.042
DifNa	0.327	0.000	0.300	0.000
PRU	0.154	0.000	0.136	0.000
Sequence	-1.452	0.000	-1.525	0.000
Unit 5	1.258	0.030	1.525	0.005
Potassium	0.502	0.000	0.596	0.000
On Lasix	-0.765	0.117	-0.844	0.054

Variables not listed did not reach significance.

Conclusions: The large effect of low PWt requires long RxT to avoid high UFR with moderate WtG. Other prescribed variables that could be used to modify UFR include TThS vs MWF schedule, DifNa and possibly diuretic use.

TH-PO803

Study on Hemodialysis (HD) Time and Prognosis in Maintenance HD Patients: The Q-Cohort Study Kiichiro Fujisaki,[1] Shigeru Tanaka,[1] Masatomo Taniguchi,[1] Kazuhiko Tsuruya,[1] Hideki N. Hirakata,[2] Takanari Kitazono.[1] *[1]Dept of Medicine and Clinical Science, Kyushu Univ, Fukuoka, Japan; [2]Div of Nephrology, Japanese Red Cross Fukuoka Hospital, Fukuoka, Japan.*

Background: HD time has been recognized as an important factor of dialysis adequacy. However, there have been few reports on studying the associations between HD time and prognosis in maintenance HD patients. We present some findings from a prospective cohort study, the Q-cohort Study, which was set up to explore the risk factors for mortality in Japanese HD patients. In the present study, we examined the associations between HD time and mortality in Japanese HD patients.

Methods: A prospective multicenter cohort study (Q-Cohort Study) was conducted between December 2006 and December 2010. A total of 3,459 Japanese HD patients were prospectively followed for 4 years. We examined the association of HD time and prognosis using a Cox proportional hazards model. Propensity scores were calculated using logistic regression.

Results: During follow-up period, 566 patients died from any causes. Patients with HD of 5 hours or more (n = 2,144) showed significantly lower mortality risk for all cause death at hazard ratio = 0.82 (95% confidence interval: 0.68 to 0.99) compared with those with HD of less than 5 hours (n = 1,315) after adjusting for confounding risk factors. This association remained significant using a propensity score-based approach. We stratified the analysis by patient age in 10-year increments, this finding remained significant only in patients with older than 80 years.

Conclusions: Our results suggest that HD time of 5 hours or more improves all-cause mortality especially in older HD patients.

TH-PO804

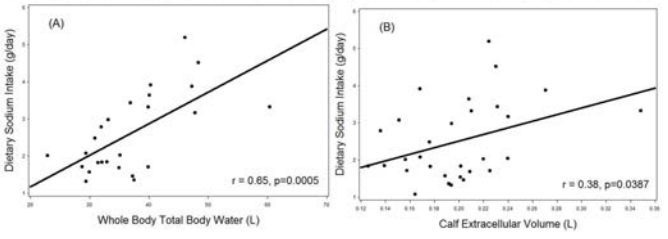
Salt Taste Sensitivity, Sodium Intake, and Fluid Status in Hemodialysis
Panduranga S. Rao,[1] Robin L. Padilla,[1] Linton Cuff,[1] Tanu P. Verma,[1] Debra Peterman,[1] Michael Heung,[1] Scott L. Hummel,[1] Peter Kotanko,[2] Brenda W. Gillespie,[1] Rajiv Saran.[1] *[1]Univ of MI; [2]Renal Research Inst.*

Background: Dietary Sodium intake (SI) contributes to volume status and blood pressure (BP) control in hemodialysis (HD) patients. Salt taste sensitivity (STS) may drive sodium intake, and has not been systematically studied in HD. We sought to assess the relationship between STS, SI, fluid status (as determined by bioelectrical impedance spectroscopy (BIS)) and pre-dialysis BP in HD patients.

Methods: As part of an ongoing randomized trial involving a low sodium diet, adults receiving outpatient HD were assessed for STS using commercial taste strips impregnated with 0-1.6% sodium chloride (NaCl); mean SI was estimated from 3-day food diary. Total Body Water (TBW) and Extracellular Volume (ECV) were estimated using whole-body and segmental (calf-resistivity) BIS, respectively.

Results: Baseline data on 33 enrolled patients (16 male, 17 black, 13 white, mean age 52 ±15yr) were analyzed. Mean monthly pre-HD systolic BP was 151 ± 16 mmHg. Mean SI was 2.5 g/day (range: 1.1-5.2). Mean estimated SI was 0.8 g/day higher in patients without STS compared to those with STS £1.6% NaCl (p=0.06). Higher SI correlated with higher calf ECV (r=0.38, p=0.04), whole body-BIS TBW (r=0.65, p=0.0005) and ECV (r=0.34, p=0.09). Mean Calf ECV was significantly lower in those with STS *vs* those without STS at 1.6% (0.19 *vs* 0.23 L; p=0.04). There was no correlation between SI and pre-dialysis BP (in-center routine or standardized).

Correlation of Dietary Sodium Intake with (A) Total Body Water and (B) Calf ECV BIS



Conclusions: Salt taste sensitivity and measures of hydration status by bioelectrical impedance spectroscopy are correlated with sodium intake in hemodialysis. These findings suggest that patients with low salt taste sensitivity may be particularly at risk for fluid excess. Future research should examine mechanisms of Salt taste sensitivity and its role in management of hemodialysis patients.

TH-PO805

Arrhythmic Risk in Patients with Type II Diabetes on Hemodialysis: Preliminary Results from the Monitoring in Dialysis (MiD) Clinical Study
Prabir Roy-Chaudhury,[1] Don E. Williamson,[2] James A. Tumlin,[3] David M. Charytan,[4] Kowdle chandrasekhar Prakash,[5] Vijay K. Kher.[6] *[1]Univ of Cincinnati; [2]Nephrology Associates; [3]Univ of Tennessee; [4]Brigham and Womens Hospital, Boston; [5]Apollo Hospitals-Chennai; [6]Medanta-Medicity.*

Background: 40% of the overall ESRD population has diabetes and these patients are considered to be at increased risk of cardiac events. The goal of this analysis was to describe the pattern of both clinically significant events and documented arrhythmias in a subset of patients with Type II diabetes from the Monitoring in Dialysis (MiD) study.

Methods: The MiD study is a prospective, multi-center, observational study designed to characterize the type and frequency of documented and adjudicated arrhythmias in hemodialysis patients during a 6-month period, using an implanted continuous cardiac monitoring device (Medtronic Reveal XT or Reveal LINQ). All documented arrhythmias and clinically significant arrhythmias (CSA) defined as bradycardia ≤40 bpm for ≥6 sec, asystole ³3 sec, sustained ventricular tachycardia ³130 bpm for ³30 sec and symptomatic arrhythmias during this period were then correlated temporally to the dialysis cycle (first, second or third dialysis session of the week; during or after hemodialysis; how long after hemodialysis).

Results: Type II Diabetes was present in 39/66 (59%) of the MiD patients. The mean age was 62 (36-76) years, 72% male, mean years on HD 2.8 (1-15), 36% with a history of cardiac arrhythmias with a mean follow-up of 8.6 months (range 0.6-13.9). Arrhythmic risk in the Type II diabetic patients was similar to the previously reported data on the entire study population, with the highest incidence of documented arrhythmias occurring in the 12 hour period starting with each dialysis session (particularly in the 8 hours after the end of the session). The incidence then decreased, followed by a gradual rise during the rest of the interdialytic period. Interestingly, the incidence of CSA in the 12 hour period starting with the first dialysis session of the week was much greater than in the overall study population.

Conclusions: The increase in the incidence of CSA in diabetic ESRD patients suggests that these patients could be a target population for the use of the Reveal implant.

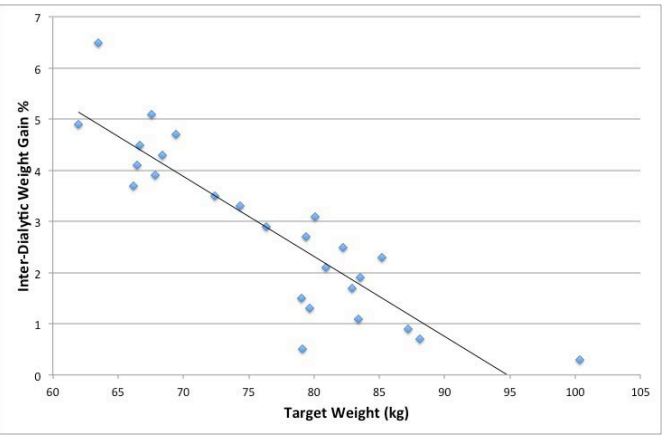
TH-PO806

Individualising Fluid Restriction Based on Target Weight Can Prevent a High Ultrafiltration Rate
Emily See, John W. MacD. Agar. *Nephrology, Univ Hospital, Geelong, VIC, Australia.*

Background: Fluid restriction (FR) in haemodialysis patients has traditionally been advised by residual urine output and an arbitrarily defined oral intake, commonly 750ml/day. Surprisingly, little attention has been paid to individualising FR according to target post-dialysis weight (TW), despite the logical argument that smaller patients require less fluid. Excessive inter-dialytic weight gain (IDWG), when calculated as a percentage of TW (IDWG%), results in a high ultrafiltration rate (UFR) if session length (t) is constant [UFR(ml/kg/hr) = IDWG(ml) ÷ TW(kg) ÷ t(hr)]. Since a high UFR has been linked to a poor clinical outcome, these patients must be identified and targeted. We aim to determine if a high IDWG% can be predicted from TW and then be used to individualise FR.

Methods: Data were prospectively collected from 14,112 sessions in 139 patients undergoing in-centre thrice-weekly haemodialysis between Jan-Dec 2014. Mean age was 68.9yr, 56% were male. Mean TW and IDWG% were calculated every 6 weeks. Results were divided into IDWG% cohorts, within each of which an average TW was calculated.

Results: Mean IDWG% was 2.30% (range 0.1-6.4). IDWG% was inversely proportional to TW (r^2=0.78).



From this data, we devised a formula that calculates an individualised FR based on the desired UFR (dUFR), the session duration (t), TW, and interval days between sessions (n). As [IDWG = FR x n]; and [IDWG = dUFR x t x TW]; therefore [FR (ml) = dUFR x t x TW ÷ n + residual urine output].

Conclusions: Patients with low TW are most at risk of high IDWG% and, consequently, a high UFR. A high UFR leads to rapid intravascular volume contraction which triggers post-dialytic thirst and reinforces the inevitable cycle of further high IDWG%. As TW provides a readily accessible clinical end-point that predicts at-risk patients, we propose that FR be individualised according to TW to enable patients to remain below the desired UFR.

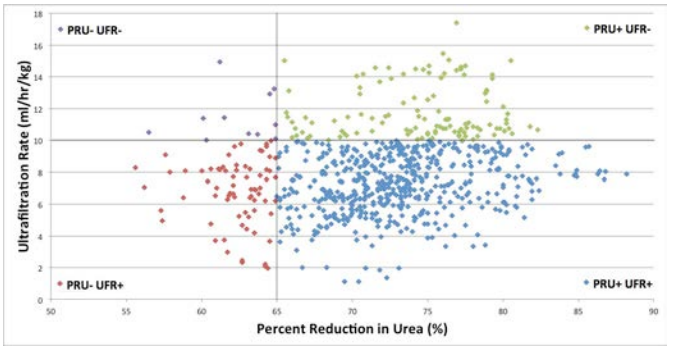
TH-PO807

Ultrafiltration Rate Should Be Independently Targeted as a Marker of Haemodialysis Adequacy
Emily See, John W. MacD. Agar. *Dept of Nephrology, Univ Hospital, Geelong, VIC, Australia.*

Background: For 30 years, solute clearance has been the key determinant of dialysis adequacy. This emphasis has marginalised the critical contribution of safe rates of fluid removal to "adequate" dialysis. Ultrafiltration rate (UFR) has been proposed as an easily measurable marker of volume management (Agar 2015 HDI) and several studies have demonstrated a correlation between high UFR and poor clinical outcomes. Despite this association, UFR is not routinely targeted and the proportion of patients who meet percentage reduction in urea (PRU) but not UFR targets is unclear. While a "safe" UFR_{MAX} is yet to be conclusively defined, current literature supports an escalating clinical risk beyond a UFR of 10ml/hr/kg and an absolute risk above 13ml/hr/kg.

Methods: Data were prospectively collected from patients undergoing in-centre thrice-weekly conventional haemodialysis over a 12-month study period (Jan-Dec 2014). PRU and mean UFR were calculated every 6 weeks. UFR <10ml/hr/kg was defined as "volume-adequate" and PRU >65% was considered "solute-adequate".

Results: 720 episodes were collected from 115 patients. The mean age was 68.9yr and 56% were male. 73% of episodes met both adequacy targets (PRU+UFR+). 10% met the UFR but not the PRU target (PRU-UFR+). 16% met the PRU but not the UFR target (PRU+UFR-). 1% met neither (PRU-UFR-). In patients who met the PRU target 18% did not meet the UFR target.



Conclusions: Adequacy of solute removal does not equate to adequacy of volume removal. When a solute marker is used as the sole determinant of dialysis adequacy, a significant number of patients undergo "volume-inadequate" dialysis. These patients were more likely to be female and have a lower post-dialysis weight. Given the potentially substantial clinical implications, we propose that UFR be independently targeted allowing composite solute and volume markers to together define truly "adequate" dialysis.

TH-PO808

Fluid Management with Technology-Assisted Probing Peter B. De Oreo,[1] Mary kay Deck,[2] Anne M. Brumfield.[2] *[1]Medical Affairs, Centers for Dialysis Care 1, Shaker Heights, OH; [2]Systems, Intelomed 2, Wexford, PA; [3]Clinical Services, Intelomed 2, Wexford, PA.*

Background: Intradialytic hypotension (IDH) is associated with mortality. Rapid fluid removal is associated with cardiovascular (CV) morbidity and mortality. Decreased pulse pressure during HD is associated with improved outcomes. A focused intervention approach assisted by monitoring technology was used to assess fluid management as defined by 1) achievement of post weight within 1 kg around dry weight, 2) avoidance of IDH [SBP<90], 3) decrease in pulse pressure (PP) from pre-post dialysis.

Methods: 24 patients (16 controls, 8 intervention) were included. Control data: 18 treatments (txs) with same staff, room, time interval. Intervention data: 36 baseline txs prior to protocol along with 18 txs during active monitoring and guided probing. The protocol required setting goal to .2 KG < dry weight OR < .2 KG last post weight with small goal changes early in treatment, set of defined actions based on CV physiologic monitoring via CVInsight™ (CVI) [Intelomed, Wexford, PA] and relative plasma volume (RPV) via Crit-Line III® [Fresenius, Kaysville, UT]. Interventions were employed based on monitoring data, with a goal to increase UF tolerance without increasing IDH events. BP was measured every 15 minutes.

Results: Intervention patients demonstrated significant improvement in all three fluid management parameters during the protocol compared to preceding txs.

	PW<DW–1 KG*	PW<DW+1 KG*	SBP < 90[t]	Pre PP[t]	Pst PP[t]	UFR[t]	PW/DW[t]
Baseline	.09 ±.02	.24±.02	.07± 01	71±1.3	68±1.2	5.73±.19	.01 ±.001
Protocol	.34±.04	.15±.04	.01±.02	66±1.6	63±1.6	7.74±.32	.028±.001

* p <.0001, [t] p<.05

Intervention patients also demonstrated significant improvement in IDH compared to Control patients that dialyzed without guided probing.

Conclusions: A focused effort to improve fluid management through technology guided probing supported by CVI measures of cardiovascular stress and RPV, was successfully executed by chair-side staff. Optimizing fluid removal goals while simultaneously avoiding IDH events illustrates the benefit of patient monitorin.

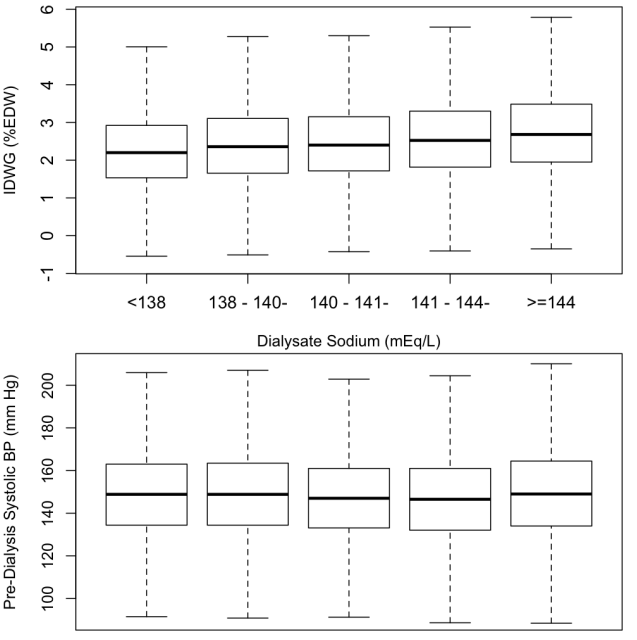
TH-PO809

Increased Mortality Associated with Higher Dialysate Sodium Concentrations Is Not due Solely to Higher Interdialytic Weight Gains and Blood Pressure Ambreen Gul,[1] Ronald Schrader,[1] Susan Paine,[1] Philip Zager.[1,2] *[1]DCI, Albuquerque, NM; [2]UNM, Albuquerque, NM.*

Background: There is ongoing controversy regarding the optimal DNa. Many investigators have urged the use of DNa of 134 to 138 mEq/L, to limit interdialytic weight gain (IDWG) and improve control of hypertension. In contrast, others have cautioned that low DNa may be associated with increased hospitalization and mortality.

Methods: We conducted a retrospective observational study of 26,000 chronic hemodialysis (HD) patients treated in facilities operated by Dialysis Clinic Inc. from 2009-2013 to assess the relationships of DNa to IDWG and predialysis systolic BP (SBP) and their effect on mortality. We fit a time-varying Cox proportional hazards regression model for mortality, which included all incident and prevalent patients. There were over 630,000 patient-months of follow-up. Multiple data values for each patient were aggregated by month. Predictor variables in addition to DNa included demographics, monthly lab values, and session-level data including IDWG and pre- and post-dialysis BP. Individual clinic effects were fit as random effects. Time-varying predictors were lagged by 2 months.

Results: Higher DNa concentrations were associated with only modest increases in IDWG and predialysis SBP [figure]. Moreover, neither predialysis SBP ≥ 150 mm Hg or IDWG < 4.2% of estimated dry weight were associated with increased mortality. Nevertheless, higher DNA concentrations were associated with increased mortality (HR [95%CI] = 1.09 [1.02, 1.16]) for DNa > 140 mEq/l (Referent DNa =140 mEq/L) after adjusting for all other variables including IDWG and BP.



Conclusions: Although reducing DNa to < 140 mEq/L may have only a modest impact on IDWG and predialysis SBP it has the potential to significantly decrease mortality.

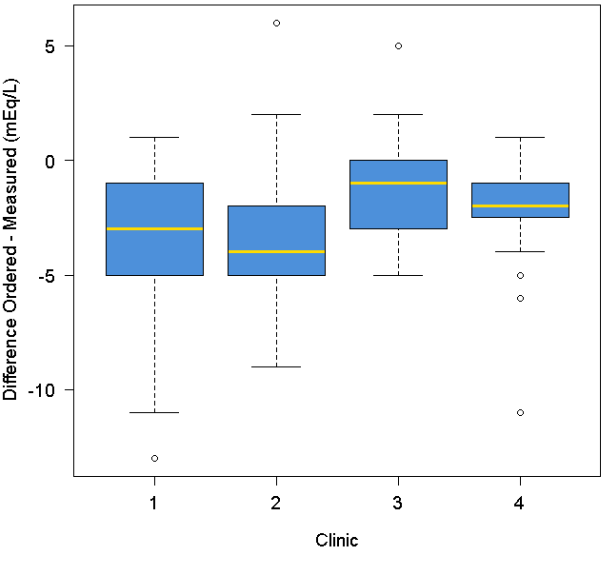
TH-PO810

Comparison of Ordered versus Measured Dialysate Sodium Concentrations Ambreen Gul,[1] Dana Miskulin,[3] Leonard A. Arbeit,[4] Sriram Narsipur,[5] Susan Paine,[1] Ronald Schrader,[1] Philip Zager.[1,2] *[1]DCI, Albuquerque, NM; [2]UNM, Albuquerque, NM; [3]Tufts, Boston, MA; [4]SUNY, Stony Brook, NY; [5]SUNY, Syracuse, NY.*

Background: There is controversy regarding the optimal dialysate sodium concentration (DNa). Many investigators have urged the use of DNa of 134 to 138 mEq/L, while others have cautioned that low DNa may be associated with increased hospitalization and mortality. Unfortunately, throughout this debate, little attention has been paid to how closely delivered DNa matches ordered DNa.

Methods: We studied 333 hemodialysis (HD) patients at 4 DCI facilities. We sampled dialysate from the arterial dialyzer port prior to the start of HD for measurement of DNa. Units 1 and 2 used Fresenius 2008 K and 2008 K[2] machines and Fresenius Granuflo® Dry Acid and NaturaLyte®, mixed onsite from dry concentrates. Units 3 and 4 used Gambro Phoenix machines and pre-mixed acid concentrates obtained from Rockwell and bicarbonate cartridges from Baxter or Gambro. The online clearance feature was off.

Results: Measured DNa was usually higher than ordered DNa. The magnitude of difference varied by clinic (p <.0001).



Least squares mean differences (95% CI) were larger at Clinics 1 [-3.27 (-4.02, -2.53) mEq/L] and 2 [-3.77 (-4.49, -3.05) mEq/L] vs. with Clinics 3 [-1.44 (-2.10, -0.78) mEq/L] and 4 [-1.78 (-2.47, -1.10) mEq/L]. The percentages of measured DNa concentrations within ± 2 mEq/L of the ordered DNa at Clinics 1, 2, 3 and 4 were 47, 25, 71 and 77%, respectively.

Conclusions: Measured DNa concentrations were often significantly higher than ordered DNa in facilities using Fresenius machines and dialysate concentrates mixed onsite. Routine measurement of DNa should be incorporated into facilities' QAPI programs. Future studies looking at clinical outcomes associated with differences in prescribed DNa, should include measurements of delivered DNa concentrations .

Successful Use of Bivalirudin Protocol to Prevent Extracorporeal Thrombosis in Hemodialysis Patients with Heparin Induced Thrombocytopenia

Abdullah Hamad, Fadwa S. Al-Ali, Hoda Tolba, Rania Abdelaziz Ibrahim, Mohamed Elsayed. *Nephrology, Fahd Bin Jasim Kidney Center, Hamad General Hospital, Doha, Qatar.*

Background: Heparin Induced Thrombocytopenia (HIT) has been reported in hemodialysis (HD) patients with a variable prevalence of 1-13%. There have been few reports using Lepirudine, Argatroban and Danaparoid in the management of extracorporeal thrombosis (ECT) during dialysis in these patients as heparin is contraindicated. We are reporting use of Bivalirudin to prevent ECT.

Methods: Our Study was done in Fahad Bin Jassim Kidney Center in Doha, Qatar (a large outpatient HD clinic of 300 patients). All patients diagnosed with HIT were included. HIT was diagnosed by ELISA method.

Results: 8 patients had confirmed positive HIT AB, 2 were receiving warfarin for atrial fibrillation with no ECTevents and were excluded. One patient had a negative repeat test for HIT AB with no ECT events so he was excluded too. 5 patients with HIT AB and recurrent ECT events during dialysis were included. 3 patients had fistula and 2 had permanent catheter. A protocol was developed to start and adjust Bivalirudin based on **activated partial thromboplastin time** (aPTT) value. Table 1 summerize patients dosing and adjustment on protocol.

Bivalirudin Infusion Protocol for HIT in Hemodialysis Patients

1.Initial Infusion Rate 0.02 mg/Kg/hr.
2.Baseline aPTT should be checked and then 2 hours after infusion initiated
3.aPTT should be checked 2 hours after infusion every session until a PTT in therapeutic range with no further clotting then once per week.
4.Risk for bleeding versus thrombosis must be evaluated to determine safe and effective dose:
In high risk of bleeding, adjust aPTT to 1.5 – 2.5 X normal,
In high risk of clotting or active HITTS, adjust aPTT to 2.0 – 2.5 X normal

aPTT Ratio	Dose Adjustment
< 1.2	Increase dose by 20% and repeat aPTT after 2 hrs.
1.2 - 1.4	Increase dose by 10% and repeat aPTT after 2 hrs.
1.5 – 2.5	No dose change and monitor aPTT as protocol
2.6 – 3.5	Decrease dose by 10% and repeat aPTT after 2 hrs.
3.6 – 4.4	Decrease dose by 20% and repeat aPTT after 2 hrs.
> 4.5	Hold therapy until aPTT ratio < 3.5 then restart at a reduced dose and repeat aPTT after 2 hrs.

Patient	Dialysis access type	Duration on Bivalirudin	Starting dose	Final dose	Adjustment of dose
1	fistula	5 months	1.8 mg/hour	3.4 mg/hour	6 times
2	fistula	4 months	1.6 mg/hour	2.1 mg/hour	2 times
3	permcath	2 months	2 mg/hour	4 mg/hour	4 times
4	fistula	4 months	1.5 mg/hour	1.8 mg/hour	1 time
5	permcath	8 months	1.7 mg/hour	3 mg/hour	3 times

Conclusions: We are reporting a successful use of Bivalirudin protocol to prevent ECT in HD patients with HIT. It provided a simple dosing initiation with easy adjustment based on weight, aPTT and ECT events. The protocol provided excellent safety where no bleeding complications occured in these patients thoughout the study.

TH-PO812

(1®3)-β-Glucans and Endotoxins in Hemodialysis

Jonathan P. Wong,[1] Yonglong Zhang,[2] Enric Vilar,[1] Malcolm A. Finkelman,[2] Ken Farrington.[1] *[1]Lister Renal Unit, United Kingdom; [2]Associates of Cape Cod.*

Background: Endotoxemia is widely reported in dialysis patients and proposed to be related to systemic inflammation. Endotoxins are detected using the Limulus Amoebocyte Lysate (LAL) assay. However, the LAL assay is prone to interference and can be activated by (1®3)-β-glucans (BG), a component of fungal cell wall, through an alternative LAL enzymatic pathway leading to falsely high endotoxin signals. High endotoxin content reported in dialysis patients may be due, to an unknown extent, to BG-based activation of LAL.

Methods: Predialysis blood samples were collected from 10 hemodialysis (HD) patients with systemic inflammation and 10 HD patients without inflammation and tested for endotoxin using the kinetic turbidimetric LAL assay (KTA2, Charles Rivers). Endotoxin measurements were performed with and without a BG blocking buffer. The buffer prevents the activation of the LAL assay by BG, to ensure that LAL activation is endotoxin-specific. The same samples were also assayed for BG content using an FDA-cleared BG detection assay (Fungitell®, Associates of Cape Cod). Differences in endotoxin and BG content were compared between inflamed and non-inflamed patients. Differences in endotoxin content in samples assayed with and without a BG blocking buffer were compared.

Results: Blood endotoxin was higher in patients with systemic inflammation although this did not reach statistical significance (0.027 vs 0.013 EU/ml, p=0.579). Endotoxemia was detected in 55% of patients. On repeat measurement with a BG blocking buffer, no patients had detectable endotoxemia. Both inflamed and non-inflamed patients were found to have similarly significant elevated blood BG (60 vs 81.3 pg/ml, p=0.29). There was no significant correlation between levels of BG and endotoxin (r=0.435, p=0.055). No endotoxin and very low concentration of BG (3pg/ml) was detected in saline washout from the blood compartment of the dialyser.

Conclusions: Elevated blood endotoxin reported in HD patients may be due to BG interference. This suggests that endotoxin measurements should be carried out with BG blocking buffers. The source and clinical significance of elevated BG levels in HD patients is unknown and requires investigation.

The Correlation of BNP and hANP in Hemodialysis Patients and Their Prediction Ability of Life Prognosis

Koji Takemura, Fumitaka Fujino, Yoshihiro Miyauchi, Takashi Watanabe. *Nephrology, Asahi General Hospital, Asahi, Chiba, Japan.*

Background: B-type natriuretic peptide (BNP) and human atrial natriuretic peptide (hANP) have been reported to be useful for assessment of the volume status, cardiovascular risk, or life prognosis in hemodialysis patients. However, correlation or superiority of the two parameters are not clear. The aims of this study were to assess whether BNP and hANP have correlation, and whether they are predictive.

Methods: Two hundred and twenty-eight hemodialysis patients at one hospital were assessed in March 2012. BNP and hANP were measured at the end of hemodialysis. And we observed the patients' survival until May 2015.

Results: This study analyzed 228 patients. Results showed that BNP and hANP had strong correlation in patients without chronic heart failure (EF>40%): R^2=0.70 in those with atrial fibrillation (Af), R^2=0.57 without Af. 69 deaths occurred in about 3 years; in univariate analysis, BNP and hANP were significant predicting factors (p=0.004 and p=0.013 for each) and in multivariate analysis, age and hANP were significant predicting factors in multivariate analysis (p=0.019 and 0.011).

Conclusions: BNP and hANP had strong correlation in hemodialysis patients without chronic heart failure. They also predicted life progonosis, and especially hANP had independent prediction ability. In hemodialysis paients, BNP and hANP are useful for assessment of life prognosis in spite of various known or unknown confounding factors.

TH-PO814

Intracranial Fluid Shifts During Hemodialysis Measured Using VIPS (Volumetric Integral Phase-Shift Spectroscopy) Is Influenced by Osmolarity, Sodium and Less So by Urea Nitrogen

Chethan P. Venkatasubba rao,[1] Sreedhar A. Mandayam,[2] Eric Bershad,[1] Eusebia Calvillo,[1] Jose Ignacio Suarez.[1] *[1]Neurology, Baylor College of Medicine, Houston, TX; [2]Nephrology, Baylor College of Medicine, Houston, TX.*

Background: End Stage Renal Disease (ESRD) patients undergoing hemodialysis(HD) experience a drop in serum osmolarity. This may result in cerebral edema. Cerebral edema has been measured by invasive monitors or imaging studies. We used Volumetric Integral Phase-shift Spectrocopy(VIPS), a non-invasive technology that detects fluid-induced phase shifts in low-energy radio waves transmitted through the brain.

Methods: The protocol was approved by the IRB of Baylor college of Medicine. ESRD on HD subjects without intracranial illnesses were enrolled. VIPS monitoring was performed pre, intra and post HD. Measured and calculated serum osmolarity(osm) and mini mental state examination was performed pre and post HD.

Results: 19 patients (12 males) were enrolled. Median age was 50 years. 1 patient withdrew. Of the 31 HD runs, 21 complete data sets were analyzed. There was a mean increase of 10.6% in the total Intracranial fluid(ICF) value from baseline corresponding to an average of 7 mOsm reduction. The ICF change measured by VIPS correlated with osm changes (r=0.31), best with change in Sodium change [Post HD – pre HD](r= 0.51), less so with the BUN change (r=0.14) and least with glucose (r=0.01). Subjects with sodium < 135 at baseline had a tendency to develop lower ICF change (3% n=5) as compared to eunatremic subjects (12%, n=16, p=0.22).

Conclusions: VIPS provides real-time non-invasive monitoring of intracranial fluid shifts. Subjects develop serum osmolar reductions during HD, which can potentially be a model for studying cerebral edema. Sodium shifts had a higher correlation to ICF change in our study. Further research to confirm our findings are warranted.

TH-PO815

Online Hemodiafiltration Using Citrasate® Dialysis Solution – An Alternative to Systemic Anticoagulation? Pavlina Richtrova, Lukas Kielberger, Jan Mares, Tomas Reischig. *1st Medical Dept, Charles Univ Medical School and Teaching Hospital, Plzen, Czech Republic.*

Background: Citrasate® is a dialysis solution using citrate (contrary to more common acetate) as the acidifying buffer compound. According to recently published data, its application could decrease or even obviate the need for systemic anticoagulation in hemodialysis (HD) patients. Particularly so during online hemodiafiltration (HDF) as in this setting predilution should provide yet higher in-dialyzer citrate concentrations resembling regional citrate anticoagulation (RCA).

Methods: In a prospective, randomized, cross-over study, 10 long-term HD patients were examined during 4h HDF procedure using Citrasate® (0.8 mmol/l citrate) in a predilution setting without additional systemic anticoagulation. Standard HDF procedure using acetate-buffered solution together with fractionated heparin was applied as a control. Along the session, blood and dialysate were sampled to enable analysis of thrombogenicity, acid base balance, calcium metabolism, and dialysis efficacy. Data are given as means±SD, statistical significance was calculated by ANOVA.

Results: No HDF session was terminated prematurely though the semiquantitative dialyzer clotting score showed increased clotting under citrate solution (p=0.001). At the same time, procedure efficacy assessed by spKt/V, as well as serum calcium, bicarbonate and pH did not differ significantly. While in controls the thrombin-antithrombin (TAT) levels remained unchanged, during citrate-buffered HDF a steady increase of TAT was demonstrated: from 3.6±2.36 and 5.6±3.85 µg/l at 0h to 7.8±7.65 and 38.9±23.25 µg/l at 4h for acetate and citrate respectively (p<0.001).

Conclusions: From a clinical standpoint, HDF using Citrasate® excluding heparin may serve as a viable alternative to RCA where systemic anticoagulation is to be avoided. No issues were detected in terms of safety, tolerability, and dialyzer performance. Even then, increased laboratory markers of thrombogenicity suggest inferiority of such approach precluding its use for regular HD.

TH-PO816

Hypertension in Hemodialysis Patients: Dialysis Techniques and Hormonal Regulation Guido Gatti, Chiara Lanzani, Marco Simonini, Simona Pozzoli, Stefano Tentori, Elena Brioni, Lorena Citterio, Elisabetta Messaggio, Simona Delli carpini, Nunzia Casamassima, Teresa Arcidiacono, Maria Teresa Sciarrone Alibrandi, Rita Quartagno, Marco Melandri, Giorgio Slaviero, Donatella Spotti, Paolo Manunta. *Nephrology, Dialysis and Hypertension, IRCCS San Raffaele Scientific Inst, Milan, Italy.*

Background: Hypertension in hemodialysis patients has a prevalence of 50-80% and is associated to increased cardiovascular mortality. Endogenous ouabain (EO), a digitalis-like cardiotonic steroid produced by adrenal glands, in hemodialysis patients is associated to left ventricular mass, volume and eccentric hypertrophy remodeling. N-terminal pro B-type natriuretic peptide (NT-proBNP) is associated with heart failure and fluid overload. Hemodiafiltration (HDF) improves cardiovascular survival than bicarbonate hemodialysis (HD). The aim is to explore the relationship between BP values, hormonal regulation (EO and NT-proBNP) and hemodialysis techniques.

Methods: We enrolled 93 chronic hemodialysis patients; we performed ABPM of 24 hours, blood and effluent dialysis fluid analysis. 42 patients were treated with HDF, 51 with HD.

Results: NT-proBNP is directly associated with SBP of 24h and indirectly with EF of left ventricle; it is removed by HDF by convective clearance (decrease of 57%), as medium molecular weight compounds, and not by HD (increase of 21%). EO is directly associated with interdialytic weight gain and interventricular septum; it decreases with dialysis session independently of dialysis technique (decrease of 20%). Patients with cardiopathy have higher EO plasma levels than patients without cardiopathy. Beta-2 microglobulin is directly associated with NT-proBNP and SBP of 24h.

Conclusions: These data show that NT-proBNP is an index of hypertension and heart failure, while EO is linked to fluid overload and left ventricular hypertrophy. NT-proBNP is removed by convection, while EO decreases with dialysis independently of dialysis technique (may ultrafiltration determine the decrease?). Convective clearance, expressed indirectly by beta-2 microglobulin, may influence BP control through the modulation of NT-proBNP.

TH-PO817

NT-proBNP Is a Useful Biomarker to Identify Cardiac Dysfunction in Japanese Hemodialysis Patients Minako Shimizu,[1] Ayumu Nakashima,[2] Shigehiro Doi,[3] Takao Masaki.[4] *[1]Dept of Nephrology, Hiroshima Univ Hospital, Hiroshima, Japan; [2]Dept of Nephrology, Hiroshima Univ Hospital, Hiroshima, Japan; [3]Dept of Nephrology, Hiroshima Univ Hospital, Hiroshima, Japan; [4]Dept of Nephrology, Hiroshima Univ Hospital, Hiroshima, Japan.*

Background: Serum N-terminal pro-brain natriuretic peptide (NT-proBNP) is a well-established diagnostic biomarker of heart failure in populations without kidney dysfunction. However, the clinical significance of NT-proBNP in hemodialysis (HD) patients remains unclear.

Methods: We enrolled 1428 HD patients from 14dialysis centers in Hiroshima, Japan and performed cross-sectional analysis. Blood samples for measurement of serum NT-proBNP were collected at pre- and post-HD sessions. Among all participants, ultrasonic cardiography (UCG) was performed in 395 patients (27.7%). We evaluated whether serum NT-proBNP levels were associated with left ventricular hypertrophy (LVH) on the electrocardiogram (ECG), and LVH and ejection fraction (EF) on UCG. We also used multiple regression analysis to investigate the clinical factors that correlated with the reduction ratio of NT-proBNP levels due to HD.

Results: The mean pre- and post-HD NT-proBNP levels were 8789 ± 15311 and 5257 ± 8939 pg/mL, respectively. Multivariate regression analysis revealed that the post-HD NT-pro-BNP was significantly correlated with LVH on ECG as well as EF and LVH on UCG ($P < 0.001$). When both pre- and post-HD NT-proBNP were evaluated in the same patients, the odds ratios (ORs) for LVH on ECG, and LVH and EF on UCG were lower at pre- than post-HD (ORs: 1.36, 2.16, 3.47 versus 1.19, 1.54, 2.37,respectively). However, the sensitivity and specificity of pre- and post-HD NT-proBNP to predict LVH and EF were similar. In multiple linear regression analysis, the reduction ratio (%) of NT-proBNP due to HD was correlated with Kt/V ($P < 0.001$), membrane area ($P < 0.001$), membrane type ($P < 0.001$), modality ($P < 0.001$), % body weight gain ($P < 0.001$), treatment time ($P < 0.001$) and ultrafiltration rate ($P = 0.003$).

Conclusions: NT-proBNP is a useful biomarker to identify LVH and LV dysfunction in HD patients. Blood samples should be taken post-HD despite the NT-proBNP reduction due to HD.

TH-PO818

Similar Complement Activation by Heparin-Coated Dialyzer Compared with Heparin-Free Dialysis Using Predilution Susan J. Logtenberg,[1,2] Casper F.M. Franssen,[1] Marc Maj Seelen.[1] *[1]Nephrology, Univ Medical Center, Groningen, Netherlands; [2]Internal Medicine, Diakonessenhuis, Utrecht, Netherlands.*

Background: Heparin-coated dialyzers have been shown to be an effective method for heparin-free hemodialysis and are increasingly used. Conflicting reports on complement activation by heparin have been published, however. Complement activation could therefore be potential harmful for patients that are scheduled for transplantation shortly after hemodialysis (HD). We investigated the difference in complement activation between heparin-coated dialyzers and heparin-free HD using conventional filters with predilution.

Methods: We measured C3 and C3d levels in 16 (5 F) consecutive patients that were treated with either a heparin coated filter (n=8 (Evodial®)) or a conventional filter (n=5 cellulose triacetate, n=3 polyamide) with predilution 1-2l/h. C3 and C3d were measured before and at the end of a single HD treatment session. C3d to C3 ratios were calculated.

Results: Mean age was 58±16 years. The figure shows C3d/C3 ratios before and after HD for individual cases in the different filter groups. Mean C3d/C3 ratios increased during HD with all types of dialyzers. Mean C3d/C3 ratio in the heparin-coated dialyzer group increased from 9.7±7.6 before HD to 12.4±7.8 after HD (p=0.001). Mean C3d/C3 ratio in the conventional filter group increased from 8.0±2.1 to 11.8±5.4 (p=0.03). C3d/C3 ratio increased during HD with both the polyamide (from 7.5±1.8 to 10.0±1.2; p=0.09) and the cellulose triacetate dialyzer (from 8.3±2.4 to 12.9±6.9; p=0.02). There was no significant difference in the change of C3d/C3 ratio between the heparin coated filter group and the conventional filter group (2.7±1.4 vs. 3.7±3.7, respectively (p=0.5)).

Conclusions: Heparin-coated dialyzers induce similar complement activation during HD when compared to conventional dialyzers.

TH-PO819

A Heparin-Grafted Membrane plus Citrate Containing Dialysate versus Regional Citrate Anticoagulation: Results of the CiTED Study Christoph Metalidis, Ruben Poesen, Annelore De winter, Dirk R. Kuypers, Pieter Evenepoel, Bjorn Meijers. *Nephrology, Univ Hospitals Leuven, Belgium.*

Background: Heparin is the mainstay anticoagulant during dialysis. Alternative anticoagulant strategies include regional citrate anticoagulation (RCA), heparin-grafted dialyzers or saline flushes. Of these, RCA is the most efficacious, although technical complexity and labor intensiveness preclude widespread use. Heparin-grafted membranes are easy to use, but dialyzer patency is inferior to RCA. Whether combination of citrate-containing dialysate plus heparin-grafted membranes is non-inferior to RCA is unknown.

Methods: The CiTrate plus EVodial in Dialysis (CiTED) study is a prospective, open-label randomized cross-over study comparing citrate-containing dialysate plus heparin-grafted membranes vs. RCA. In the study arm, we scheduled 750 dialysis sessions using combination of a heparin-grafted AN69ST dialyzer (Evodial 180®, BAXTER) and 1 mmol/L citrate-containing dialysate (Selectbag Citrate®, BAXTER). In the control arm, 750 sessions of RCA were scheduled using Polyflux 170 (BAXTER) dialyzers and calcium-containing dialysate. In all sessions, scheduled treatment duration was 4 hours.

No systemic heparin was used. Primary endpoint was non-inferiority for clotting events of the combination of a heparin-grafted membrane plus citrate-containing dialysate vs. RCA, with a prespecified non-inferiority margin of 10%.

Results: We included 25 patients, receiving 1285 study dialysis sessions in total, 636 in the study arm and 649 in the control arm. Both anticoagulation strategies were safe. Overall, clotting rates were low: 37/636 (5.82%) in the study arm and 42/649 (6.47%) in the control arm. The primary endpoint of non-inferiority was met (P < 0.0001). In secondary analysis, using Cox proportional hazard analysis, time to clotting did not differ between study arms (P 0.62).

Conclusions: Combination of a heparin-grafted dialyzer with citrate-containing dialysate is non-inferior to conventional RCA. The procedure is easy to perform without additional pumps or calcium measurements. Combination of a heparin-grafted dialyzer and citrate-containing dialysate is a valid alternative to RCA in patients requiring heparin-free dialysis.

TH-PO820

Effect of L-Carnitine on Markers of Mineral Bone Disease in the CARNIDIAL trial Lucile Mercadal,[1] Michel Chonchol,[2] Messaoud Ouziala,[4] Christine Fumeron,[5] Aude Servais,[6] Sophie Tezenas du montcel.[9] *[1]Nephrology, AP-HP, Pitié-Salpêtrière, Paris, France; [2]Nephrology, Univ of Colorado, Denver; [3]CMC Pantin, Aubervilliers; [4]AURA Paris; [5]Nephrology, AP-HP, Necker; [8]Statistics, AP-HP, Pitié-Salpêtrière, Paris.*

Background: Previous studies suggested that L-carnitine in hemodialysis patients decreases intact parathyroid hormone levels (iPTH). We studied the effects of L-carnitine on markers of mineral bone disease (MBD), including fibroblast growth factor (FGF23) in a randomized, double-blind trial.

Methods: We evaluated the effects of 1 g of intravenous L-carnitine after each dialysis session for 1 year when compared to placebo in a randomized and double-blind trial. C-terminal FGF23 (cFGF23) were measured at baseline, every 3 months and end of study in 91 chronic hemodialysis patients. Serum calcium, phosphate and iPTH were available at similar time points. The effect of L-carnitine on serum calcium, phosphate, iPTH and plasma cFGF23 was studied by mixed linear models for repeated measurements in intent-to-treat. We also examined the relation of cFGF23 with intravenous (IV) iron and EPO dose.

Results: Serum calcium and phosphate increased more in the L-carnitine than in the placebo group (calcium: β of L-carnitine x time 0.005 ± 0.002 mmol/L.month, p=0.03; phosphate: β of L-carnitine x time 0.02 ± 0.006 mmol/l.month, p=0.001). In both groups, serum iPTH was stable over time and plasma cFGF-23 increased (β log FGF23 0.05 ± 0.01 rHu/mL.month, p<0.0001). In multivariable analyses on 166 measurements, cFGF23 was positively correlated with serum calcium (β 1.5 ± 0.6, p=0.01), serum phosphate (β 1.2 ± 0.2, p<0.0001) and negatively correlated with EPO dose (β -0.41± 0.17, p=0.02). No association was observed between cFGF23 and IV iron administration (p=0.13), serum ferritin (p=0.7) and iron saturation (p=0.7).

Conclusions: L carnitine treatment slightly increased serum calcium and phosphate without an effect on iPTH or cFGF23. FGF23 was inversely correlated with ESA dose but not with IV iron dose.

Clinicopathological Characteristics of Lanthanum Deposition in the Gastrointestinal Tract of Dialysis Patients Shigeo Hara,[1,2] Akira Fujimori,[3] Shinichi Nishi.[4] *[1]Dept of Diagnostic Pathology, Kobe Univ Graduate School of Medicine, Kobe, Hyogo, Japan; [2]Div of Pathology, Ako City Hospital, Ako, Hyogo, Japan; [3]Div of Nephrology, Konan Hospital, Kobe, Hyogo, Japan; [4]Dept of Nephrology, Kobe Univ Graduate School of Medicine, Kobe, Hyogo, Japan.*

Background: Lanthanum carbonate (LC) is a phosphate binder for dialysis patients with hyperphosphatemia. Recent studies have reported gastric lanthanum deposition in patients treated with LC (Haratake J et al. Am J Surg Pathol 2015; Makino M et al. Pathol Int 2015); however, clinicopathological features of LC deposition have not been fully evaluated. The present study was conducted to elucidate the clinicopathological characteristics of LC deposition in the gastrointestinal (GI) tract.

Methods: Pathological specimens of the GI tract (n = 60) obtained from the patients (n = 28) being administered LC were retrospectively reviewed. Prevalence, distribution, and duration from initiation of administration of LC to the detection of lanthanum deposition were evaluated.

Results: Among 28 patients (male:female = 17:11; mean age, 68.5 years), LC deposition was observed in 11 (39.3%). Pathological specimens were obtained from the pharynx (n = 1), esophagus (n = 5), stomach (n = 40), duodenum (n = 1), colon (n = 12), and appendix (n = 1). LC deposition was confined to the stomach (n = 16) and the duodenum (n = 1). The duration from the initiation of administration to the first histological detection of LC ranged from 0.35 to 5.39 years (mean, 1.91±0.45 years). In 4 patients, follow-up biopsy revealed no improvement in the gastric LC deposition.

Conclusions: Lanthanum deposition occurs in approximately 40% of dialysis patients and is mostly confined to the stomach. Its deposition can be seen histologically within a couple of months from the commencement of LC administration.

TH-PO822

Comparative Effectiveness of Oral and Injectable Vitamin D Receptor Activator on Infectious Mortality in Hemodialysis Patients: The Q Cohort Study Shigeru Tanaka,[1] Toshiharu Ninomiya,[2,5] Masatomo Taniguchi,[2] Masanori Tokumoto,[1] Hideki N. Hirakata,[3] Hiroaki Ooboshi,[1] Kazuhiko Tsuruya,[2,3] Takanari Kitazono.[2,5] *[1]Div of Internal Medicine, Fukuoka Dental College, Fukuoka, Japan; [2]Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [3]Div of Nephrology and Dialysis Center, Japanese Red Cross Fukuoka Hospital, Fukuoka, Japan; [4]Dept of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [5]Div of Research Management, Center for Cohort Studies, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.*

Background: Vitamin D receptor activator (VDRA) has recently been reported to be associated with better survival after infection in hemodialysis patients. The optimal administration route of VDRA to prevent infection death remains unclear. The aim of this study is to investigate the comparative effectiveness of VDRA between oral route and injectable form on infectious mortality in hemodialysis patients registered in a prospective cohort study.

Methods: A total of 3,278 subjects were divided into 3 groups by the administration type of VDRA: oral group (n=1,835), injectable group (n=459) and non-user (n=984). Impacts of VDRA on infectious mortality were examined using a Cox regression model adjusted with propensity score-based approaches.

Results: During follow-up (median 3.9 years), 534 patients died and 115 patients developed infection death. The use of injectable VDRA was associated with a significant lower infectious mortality compared to non-user, while oral VDRA did not significantly reduce the risk of infection mortality compared to non-user (hazard ratio [HR] for injectable VDRA, 0.40; 95% confidence interval [CI], 0.18–0.91, and HR for oral VDRA, 0.78; 95% CI, 0.53–1.15, respectively). Direct comparison between oral and injectable VDRA revealed that the injectable group was also significantly associated with better survival than oral group (HR, 0.33, 95% CI, 0.13–0.83).

Conclusions: Treatment with injectable VDRA has a more favorable impact on the infectious mortality compared to oral VDRA in the real-world practice of hemodialysis patients.

TH-PO823

Aldosterone Levels in Patients on Hemodialysis/Relationship with the Metabolic Syndrome Mar?a Jose Fernandez Reyes,[1] Manuel M. Heras,[1] Maria Gonzalez,[2] Olaia Rodriguez fraga,[2] Ramiro Callejas,[1] Alvaro Molina,[1] Vanesa Lopes-martin,[1] Maria astrid Rodriguez gomez,[1] Leonardo Calle.[1] *[1]Nephrology, Hospital General Segovia, Segovia, Spain; [2]Biochemistry, Hospital Univ La Paz, Madrid, Spain.*

Background: Recently it has been shown that serum aldosterone (SA) levels are correlated with several components of the metabolic syndrome (MSyn). OBJETIVE: to establish SA levels on hemodialysis (HD) patients and its possible association with insulin resistence (homeostasis model assessment of insulin resistance HOMA-IR), excess body fat and/or serum adypocitokines levels.

Methods: 44 stable patients on HD, not taking ACE inhibitors/angiotensin receptor blockers. Mean age: 72.5±12.5years; 52.3% men; 34.1% diabetics. Mean time on HD:43.2±49 months. 28 patients were anuric. All measurements were done prior to the midweek HD session.

Results: SA levels were above the normal range (1.17-23.6 ng/dl) in 63.6% of patients . Plasma Renin Activity (PRA) was above the normal range (0.23-3.32 ng/mL/hour) in 27.3% of patients . SA median: 31.15 (p25: 5.6; p75: 411 ng/dl); PRA median: 1.14 (p25: 0.04; p75: 20,9 ng/mL/hora). There were not statistically significant difference (Student´s-t) in SA levels between anuric and non-anuric; male and female; presence and absence of myocardiopathy or diabetes. There were no statistically significant correlations (Spearman) of SA levels or PRA with urine volume; residual renal function; dose or length of time on HD; age; or Charlson Comorbidity Index. SA levels were positively correlated (Spearman) with ARP (r= 0.72; p< 0.0001); body fat mass in kg/m2 (r=0.32; p=0.045); serum leptin levels (r=0.30; p= 0.05); HOMA-IR (r= 0.36; p=0.017) and negatively with serum adiponectin levels (r=- 0.31; p=0.041). Multivariate logitic regression analysis showed that SA levels above its median level were independently associated to PRA and HOMA-IR.

Variables Independientes	Odds ratio	95% CI	Valor de p
HOMA-IR	1,236	1,025-1,452	0.01
Plasma renina Actividad	2,664	1,136-6,248	0,024

Conclusions: SA levels are elevated in a high percentage of HD patients and such elevation is associated with PRA and several components of MSyn (insulin resistance; body fat mass; and serum levels of adypocitokines).

TH-PO824

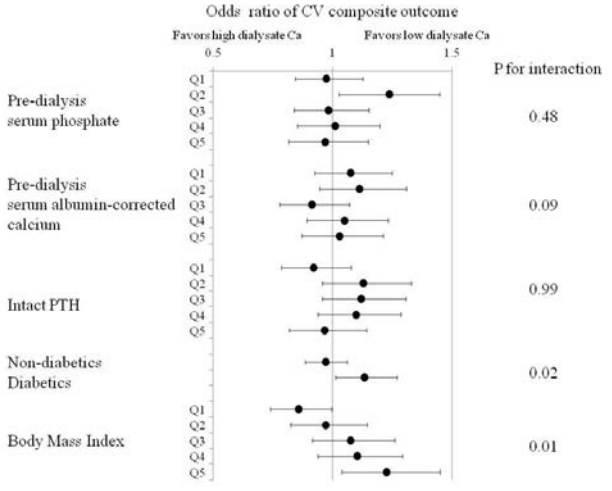
Dialysate Calcium Concentration Was Significantly Associated with Cardiovascular Diseases in Diabetics and Patients with High Body Mass Index among Hemodialysis Patients

Miho Tagawa,[1] Takayuki Hamano,[2] Shinichi Sueta,[3] Seiji Hashimoto,[2] Satoshi Ogata.[2] *[1]Nara Medical Univ, Nara, Japan; [2]Patient Registration Committee of Renal Data Registry, Japanese Society for Dialysis Therapy, Tokyo, Japan; [3]Kyoto Univ, Kyoto, Japan.*

Background: Previous studies showed that higher dialysate calcium (Ca) concentration was positively associated with cardiovascular (CV) diseases. Which patient characteristics modify this association has not been studied.

Methods: This was a longitudinal study based on the Japan Renal Data Registry (JRDR) from 2008 to 2009. Predictor variables were dialysate Ca concentration (³3.0 mEq/L vs 2.5 mEq/L). Primary outcome was CV composite event (either myocardial infarction, stroke, amputation, or CV death). Statistical analyses were performed using multivariable logistic regression model, adjusted for potential confounders.

Results: Among 300,660 patients on JRDR database, data for 38,697 patients were available for analyses after excluding patients with missing data. Serum albumin corrected Ca was significantly higher (9.27±0.77 vs 9.18±0.79 mg/dL) and intact parathyroid hormone (iPTH) was significantly lower (135[65-236] vs 164 [85-274] pg/ml) among high dialysate Ca users compared with low dialysate Ca users. The odds ratio of CV composite outcome among high dialysate Ca users was higher among diabetics and patients with higher body mass index (BMI) (p for interaction 0.02 and 0.01, respectively).



Additional adjustment for pre-dialysis serum albumin corrected Ca and iPTH did not change the effect size of high dialysate Ca among diabetics and patients with high BMI.

Conclusions: Diabetes and BMI, but not serum phosphate, Ca, or iPTH were effect modifiers for the association of high dialysate Ca and CV composite outcome. High dialysate Ca was significantly associated with CV composite outcome among diabetics and patients with high BMI.

TH-PO825

Association of Serum and Dialysate Electrolytes with Arrhythmic Risk in Incident Hemodialysis

Jacqueline Watt,[1] Esther D. Kim,[2] Larisa Tereshchenko,[3] Stephen M. Sozio,[3] Bernard G. Jaar,[3] Lucy A. Meoni,[3] Michelle M. Estrella,[3] Rulan S. Parekh.[2,3] *[1]McMaster Univ; [2]Univ of Toronto; [3]Johns Hopkins Univ.*

Background: Arrhythmias and sudden cardiac death (SCD) may occur during or shortly after receiving dialysis treatment. The extent to which serum and dialysate concentrations of potassium (K) and calcium (Ca) are associated with the risk of arrhythmias in incident hemodialysis is unclear.

Methods: In 402 patients from the Predictors of Arrhythmic and Cardiovascular Risk in End Stage Renal Disease (PACE) study, we analyzed the association of serum (ionized Ca[iCa], K, magnesium [Mg]) and dialysate (dCa and dK) electrolyte concentrations with prolonged QTc interval (Bazett's formula) and heart rate variability (HRV). Outcomes were measured by a 5-minute signal-averaged ECG. Prolonged QTc was defined as >460ms in women and >440ms in men. Baseline associations were examined using linear and logistic regression, and repeated measures were analyzed using mixed-effects models.

Results: At baseline, 86.3% had QTc prolongation, of whom 68.5% had persistent QTc prolongation at the follow-up visit. In the baseline analysis, higher iCa was associated with a shorter QTc interval and lower odds of having QTc prolongation, independent of demographic and cardiovascular risk factors, CRP, and pH.

Adjusted Associations	Baseline	Repeated Measures
	β or OR (95% CI)	β or OR (95% CI)
QTc Interval	-10.6(-17.7, -3.6)*	-10.6(-17.5, -3.7)*
Heart Rate Variability	2.9(0.6, 5.1)*	2.9(0.7, 5.1)*
QTc Prolongation	0.1(0.0, 8.1)	

*p<0.05

Higher iCa was also associated with higher HRV. The association of iCa with QTc interval and HRV remained significant in the repeated measures analysis. Associations with serum K, Mg, dCa, and dK were not significant at baseline or over follow-up. Serum-to-dialysate Ca gradient, but not K gradient was associated with higher HRV at baseline and over follow-up (β=0.3(0.0, 0.6) and 0.3(0.0, 0.6) respectively).

Conclusions: Serum iCa, but not K and Mg, is consistently inversely associated with QTc prolongation and the serum to dialysate gradient is also associated with HRV. This suggests that the absolute serum level as well as the lower dCa concentration increases arrhythmic risk.

TH-PO826

Phosphorus Kinetics During Hemodialysis: Further Validation of a Pseudo-One Compartment Model

J. Ken Leypoldt,[1] Baris U. Agar,[2] Alfred K. Cheung,[3] Angelito A. Bernardo.[1] *[1]Medical Products (Renal), Baxter Healthcare Corporation, Deerfield, IL; [2]Medical Products (R&D), Baxter Healthcare Corporation, Round Lake, IL; [3]Nephrology, Univ of Utah, Salt Lake City, UT.*

Background: A pseudo-one compartment model has been proposed to describe phosphorus kinetics during hemodialysis (HD) and postdialysis rebound. This model suggests that phosphorus mobilization from tissues is proportional to the difference between the predialysis serum (C_{pre}) and instantaneous serum concentration. The current study evaluated the ability of a pseudo-one compartment model to describe the kinetics of phosphorus during two short HD treatments on the same day separated by a 1-hr inter-treatment period without dialysis. The latter is the postdialysis rebound period for the first treatment.

Methods: Serum was collected frequently during both HD treatments and the inter-treatment period to assess phosphorus kinetics in 21 chronic HD patients. Phosphorus mobilization clearance (K_M) and predialysis central distribution volume (V_{pre}) were estimated for each patient during the first HD treatment and the inter-treatment period. Assuming those kinetic parameters remained constant for each patient, phosphorus concentrations during the second HD treatment were used to estimate the driving force concentration (C_{df}) for phosphorus mobilization during that treatment.

Results: Treatment times (117±14 vs. 117±14 min), dialyzer phosphorus clearance (151±25 vs. 140±32 mL/min) and net fluid removal (1.44±0.74 vs. 1.47±0.76 L) were similar during both HD treatments. Phosphorus concentration at the start of the second HD treatment (3.3±0.9 mg/dL) was lower (P<0.001) than at the start of the first or C_{pre} (5.4±1.9 mg/dL). K_M and V_{pre} were 98±44 mL/min and 11.0±4.2 L, respectively. Calculated C_{df} was 4.9±2.0 mg/dL, not significantly different from C_{pre} (P=0.12). C_{df} and C_{pre} were correlated (R=0.72, P<0.001).

Conclusions: The results from this study demonstrate that the driving force concentration for phosphorus mobilization during HD is constant and equal to that predialysis, consistent with a fundamental assumption of the pseudo-one compartment model.

TH-PO827

Association of Sleep Apnea and Sleep Quality with Left Ventricular Mass in Hypertensive Hemodialysis Patients in the Blood Pressure in Dialysis–SLEEP study

Manisha Jhamb,[1] Cynthia A. Kendrick,[2] Dana Miskulin,[3] Lavinia A. Negrea,[4] David W. Ploth,[5] Jennifer J. Gassman,[2] Mark L. Unruh,[6] Philip Zager.[6,7] *[1]Univ of Pittsburgh; [2]Cleveland Clinic; [3]Tufts; [4]Case Western; [5]MUSC; [6]UNM; [7]DCI.*

Background: Sleep apnea (SA), short and fragmented sleep may contribute to cardiovascular disease in hemodialysis (HD) patients. However, the relationship of sleep quality with left ventricular mass (LVM) is not well described.

Methods: Chronic HD patients joined an ancillary study during the baseline period of the Blood Pressure in Dialysis (BID) trial. SA was monitored for 1 night with a portable home monitor (ApneaLink with oximetry) and measured as Apnea Hypopnea Index (AHI). Sleep-wake behavior was assessed by actigraphy over a 5-day period. LVM was measured by MRI.

Results: We studied 42 patients. SA was present in 84% and was moderately severe (AHI >15) in 48%. 61% of patients slept <6 hrs/night and 89% had poor sleep efficiency. Patients with AHI£15 had longer dialysis vintage , lower hemoglobin, and lower Kt/V than those with AHI>15. BMI, systolic BP, diastolic BP, heart rate, number of antihypertensive medications, inter-dialytic weight gain, history of myocardial ischemia, and MRI characteristics did not differ between the two groups. LVM index was inversely correlated with sleep duration and efficiency (Pearson's r= -0.35, $p \leq 0.04$ for both, AHI (r= -0.01) and hypoxemic index (r= -0.04).

	No-mild SA (n=22)	Mod-Severe SA (n=20)
	Mean ± SD	Mean ± SD
LV Mass (g)	154 ± 50.0	153 ± 57.4
LV Mass Index (g/m²)	78.2 ± 23.8	76.8 ±30.4
LV End Diastolic Volume (ml)	195 ± 52.6	200 ± 69.1
LV End Systolic Volume (ml)	89.6 ± 29.2	102 ± 51.7
RV End Diastolic Volume (ml)	154 ± 45.2	156 ± 60.1
RV End Systolic Volume (ml)	76.4 ± 26.1	82.2 ± 37.3
LV Ejection Fraction (%)	53.3 ± 12.4	50.8 ± 11.1
Inferior Vena Cava diameter (mm)	21.4 ± 8.2	23.3 ± 7.5

Conclusions: SA and poor sleep quality were common among hypertensive HD patients. Short sleep duration and poor sleep efficiency, but not the severity of SA, were associated with higher LVM indices.

TH-PO828

Role of Nicotinic Acid as Phosphate Lowering Agent in End Stage Renal Disease Patients on Maintenance Hemodialysis

Khalid Tahir,[1] Hafiz I. Ahmad,[1] Syed Rizwan Bokhari,[1] Syed A. Khalid,[1] Arif Asif.[2] *[1]Dept of Nephrology, Allama Iqbal Medical College/ Jinnah Hospital, Lahore, Pakistan; [2]Div of Nephrology and Hypertension, Albany Medical College, Albany, NY.*

Background: Hyperphosphatemia is associated with higher risk of mortality and morbidity in End Stage Renal Disease (ESRD) patients. Use of Nicotinic Acid as phosphorus lowering agent has been studied in many countries but available data is sparse and limited. We conducted a study to determine the mean decrease in serum Phosphorous level with Nicotinic acid use in our dialysis patients.

Methods: Nicotinic acid, in a dose of 250 mg twice a day with food for 4 weeks, was given to 45 ESRD patients with serum Phosphorous level more than 5.5 mg/dl. Serum phosphorus level was measured at the start and then at the end of study. Data was analyzed for decrease in serum phosphorus level with Nicotinic acid use.

Results: Mean age of 45 patients was 44.6 ± 13.9 years and 57.8% were male. Serum Phosphorus level before treatment was 5.6 - 10.8 mg/dl (mean 6.91 ± 1.33) and after treatment for one month it was 2.60 - 8.70 mg/dl (mean 5.82 ± 1.40). Mean decrease in phosphorus level with Nicotinic acid after one month of treatment was 1.08 ± 1.16 mg/dl (p value < 0.001).

Conclusions: Nicotinic acid is an effective and cheaper phosphate lowering agent in dialysis patients. Further larger and Randomized Controlled Trials are needed to establish the role of this cheaper phosphate lowering agent.

TH-PO829

Cerebral and Cognitive Effects of Short- and Long-Term Hemodialysis – A Pilot Study

Xiufeng Li,[1] Yelena Slinin,[2] Gregory J. Metzger,[1] Lynn E. Eberly,[1] Donald R. Dengel,[1] David Tupper,[3] Anne M. Murray.[3] *[1]Univ of Minnesota, MN; [2]Veterans Affairs Medical Center, MN; [3]Hennepin County Medical Center, MN.*

Background: The short- (≤6 months) and long-term (³12 months) effects of conventional hemodialysis (HD) on brain structure, cerebral blood flow and cognitive function are not well understood.

Methods: We conducted a small longitudinal pilot study to investigate the effects of HD initiation on brain MRI and cognitive function in 4 HD patients by obtaining pre- and post- initiation brain MRIs and cognitive testing. The MRIs were obtained at 3-6 months before HD initiation (baseline), and at ~6 and ~12 months after HD initiation. The Modified Mini-Mental State Examination (3MSE) was performed within one month of the baseline and 12 month MRI examinations. MR diffusion tensor imaging (DTI) measured white matter (WM) fractional anisotropy (FA)(connectivity), and pseudo-continuous arterial spin labeling (PCASL) imaging was used to evaluate grey matter (GM) cerebral blood flow (CBF). A two-tailed paired t -test was used to compare pre- and post- initiation results. Patients provided written informed consent to participate in the IRB- approved protocol.

Results: Progressive and significant declines in frontal and temporal WM FA (Fig. 1), prefrontal CBF (Fig. 2), and cognitive function (Fig. 3, left) were found following HD initiation (Table 1 for p values). The decline in frontal WM FA on MRI was correlated with the 3MSE decline (R= 0.42)(Fig. 3, right).

Table 1. P values from the comparisons between the baseline and follow-up sessions.

		6 months	12 months
FA	Frontal	0.031	0.025
	Temporal	0.048	0.044
CBF	Prefrontal	0.038	0.048
	Anterior Hippocampus	0.042	0.013

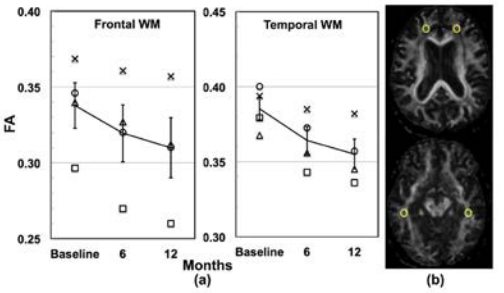

Figure 1. Results from longitudinal DTI studies performed about 3 to 6 months before (baseline), 6 and 12 months after hemodialysis initiation (N=4): (a) regional fractional anisotropy (FA) measurements overs time in frontal (left) and temporal (right) white matter (WM), and (b) bilateral regions of interests used for FA measurements overlaid on FA maps. Error bars represent standard errors.

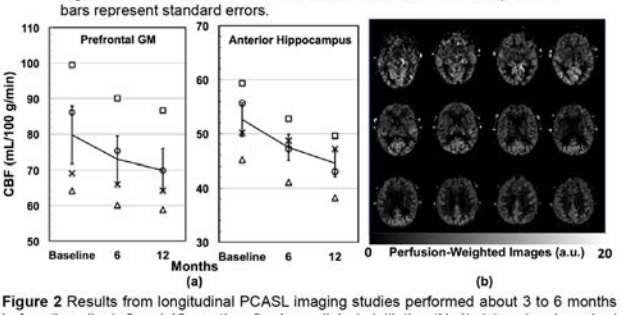

Figure 2 Results from longitudinal PCASL imaging studies performed about 3 to 6 months before (baseline), 6 and 12 months after hemodialysis initiation (N=4): (a) regional cerebral blood flow (CBF) measurements across time in prefrontal grey matter (GM) (left) and the anterior portion of the hippocampus (right), and (b) one subject's perfusion-weighted images covering middle part of the brain from the study before hemodialysis initiation. Error bars represent standard errors.

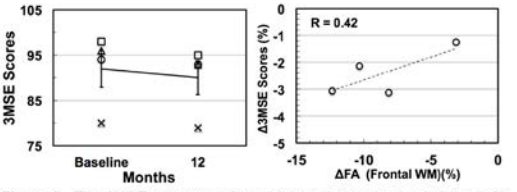

Figure 3. The 3MSE test scores from the baseline and annual visits (left), and the scatter plot for relative percent changes of 3MSE test scores and fractional anisotropy (FA) measurements in frontal WM (right) (N=4). Error bars represent standard errors.

Conclusions: Our results suggest that HD may adversely alter cerebral vascular function and progressively induce cerebral structural abnormalities and associated cognitive decline.

Funding: NIDDK Support

TH-PO830

Patient and Dialysate Temperature Characteristics in Incident Hemodialysis Patients: Results from a Large U.S. Population

Xiaoling Ye,[1] Len A. Usvyat,[2] Yue Jiao,[2] Peter Kotanko,[1,3] Franklin W. Maddux.[2] *[1]Renal Research Inst, New York, NY; [2]Fresenius Medical Care North America, Waltham, MA; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: In chronic hemodialysis (HD) patients the use of dialysate at a temperature below the patient's core temperature ("cool" dialysate) has been associated with improved outcomes in observational and prospective randomized studies [Odudu et al., CJASN 2015; Eldehni et al., JASN 2015; Selby, Sem. Dial 2008]. Little is known about temperature profiles in large US populations.

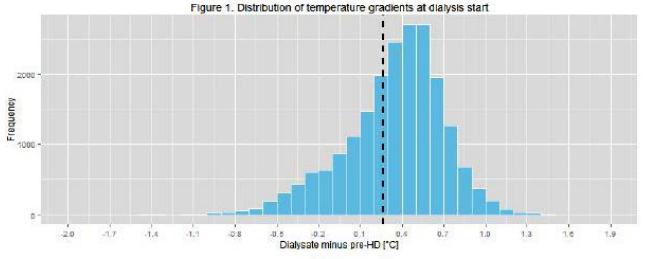
Methods: We include a subset of incident HD patients who were treated in Fresenius Medical Care North America facilities from 1/2010 to 12/2014 and who survived the first year of HD. Pre- and post-HD body temperatures were measured with thermometers. The dialysate temperature was measured by the HD machine. The dialysate-to-patient temperature gradient was computed as dialysate temperature minus patient temperature.

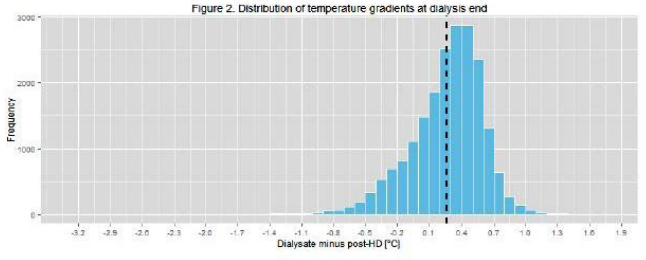
Results: We studied 20,360 incident HD patients (age 62.5 (SD 14.5) years; 57.6 % males; 68.1% White, 29.2 Black, 2.7% others). The vast majority (83.8 %) had a dialysate temperature above body temperature at the start; and at the end (80.6%) of HD.

Table 1. Patient and dialysate temperatures

Temperatures [C°]	Mean (SD)	Range	95% CI
Pre-HD body	36.37 (0.23)	35.13 to 37.40	36.36 to 36.37
Post-HD body	36.45 (0.21)	35.21 to 39.04	36.44 to 36.45
Post-HD minus pre-HD body	0.08 (0.16)*	-1.00 to 2.97	0.07 to 0.08
Dialysate (actually delivered)	36.71 (0.31)	35.00 to 37.57	36.71to 36.72
Dialysate minus pre-HD	0.34 (0.36) *	-1.86 to 1.79	0.34 to 0.35
Dialysate minus post-HD	0.26 (0.33) *	-3.16 to 1.70	0.26 to 0.27

* different from zero (P<0.0001)





The prescribed dialysate temperature was 36.87±0.31 °C. We observed a small yet significant rise in body temperature during HD.

Conclusions: Delivered dialysate temperature exceeds the body temperature in majority of patients. This may provide potential opportunities for dialysate temperature reduction to improve intradialytic stability and outcomes.

Funding: Pharmaceutical Company Support - Fresenius Medical Care North America

TH-PO831

Effect of a Single Hemodialysis Session on Visual Evoked Potentials

Savas Sipahi,[1] Ahmed Bilal Genç,[1] Yalcin Solak.[1] *[1]Nephrology, Sakarya Univ Research and Training Hospital, Sakarya, Turkey; [2]Neurology, Sakarya Univ Research and Training Hospital, Sakarya, Turkey.*

Background: Some studies have shown that visual evoked potentials (VEPs) may be a marker of dysfunction in visual pathways in uremic subjects. However, data are scarce regarding effect of hemodialysis procedure on VEPs. We aimed to compare VEPs of hemodialysis patients with healthy volunteers and in particular to assess the impact of a single hemodialysis session on VEPs.

Methods: Thirty hemodialysis patients were included in the study. We also recruited 30 age and gender matched control subjects. Patients with diabetes mellitus, cataracts, glaucoma, and stroke were excluded . Demographic characteristics, midweek predialysis and postdialysis laboratory values, amount of ultrafiltration at that dialysis session were recorded. Patients underwent VEP measurement through which P100 latency values were determined just before hemodialysis session and 24 after hemodialysis session. We assessed the changes in P100 values with single hemodialysis session. We also investigated effect of ultrafiltration on VEPs in maintenance hemodialysis patients.

Results: There was no difference between the groups in terms of age and gender (mean age 49 ± 12 and 48 ±11 years, respectively). Median duration of hemodialysis was 78 months (range 12-192). At baseline there was no difference with respect to P100 values between the groups (100.6 ± 8.8 vs 99 ± 5.8, p=0.4, for hemodialysis and controls respectively). Both right and left eye VEPs showed a significant decrease measured 24 hours after dialysis session compared with baseline values (right VEP; 100.6 ± 8.8 predialysis and 97 ± 8.7 postdialysis, p<0.001, left VEP; 101.9 ± 9.2 predialysis and 97.3 ± 8.1, p<0.001). There was no correlation between baseline predialysis P100 values and age, serum urea, hemoglobin, and dialysis vintage. Amount of ultrafiltration was not significantly correlated with postdialysis P100 latency values.

Conclusions: Our results did not show a significant difference in P100 latency values between hemodialysis patients and healthy controls. A single hemodialysis session significantly shortened P100 latency values compared with baseline values.

TH-PO832

^{23}NaMRI Detects Bound versus Soluble Tissue Sodium Content in Hemodialysis Patients

Anke Dahlmann,[1] Carolin Maier,[1] Christoph Kopp,[1] Peter Linz,[2] Daniela Amslinger,[2] Matthias Hammon,[3] Kai-Uwe Eckardt,[1] Friedrich C. Luft,[5] Jens Titze.[4] *[1]Nephrology and Hypertension, Univ Hospital Erlangen, Germany; [2]Junior Research Group II, Interdisciplinary Center for Clinical Research, Erlangen, Germany; [3]Radiology, Univ Hospital Erlangen, Germany; [4]Clinical Pharmacology, Vanderbilt Univ, Nashville; [5]Experimental and Clinical Research Center, MDC, Berlin, Germany.*

Background: Tissue sodium content is elevated in patients with end-stage renal disease and can be corrected by hemodialysis treatment. Until now no data are available concerning the extent of water free sodium storage in muscle and skin tissue in humans. ^{23}Na magnetic resonance technique (MRI) can offer options to distinguish *non-invasively* between soluble and bound (water free) tissue sodium content.

Methods: We used ^{23}Na magnetic resonance spectroscopy and imaging at 3Tesla (T) to quantify Na^+ content in skeletal muscle and skin of the lower leg. Analysis of specific MRI echo times (2ms vs. 4ms during sodium signal decay) allowed determination of bound vs. total and soluble sodium content. 39 hemodialysis patients were measured before and after regular dialysis treatment with ^{23}Na MRI.

Results: Initial bound sodium content of M. triceps surae in dialysis patients was 1.58±0.78 mmol/l, which represents 7.5±4.1% of total detectable sodium signal in this tissue. While parts of soluble sodium content were removed during dialysis treatment, its bound fraction was unaffected by HD (1.63±0.54 mmol/l). Therefore the ratio of bound to total sodium significantly increased up to 10.0±4.1% (p<0.05) post dialysis. Initial bound sodium content in skin was 2.19±1.19 mmol/l, which represents 9.4±4.2% of total sodium signal in this tissue. This value was significantly higher compared to muscle tissue. During hemodialysis its content decreased significantly to 1.63±0.89 mmol/l (p<0.05). Due to the simultaneous reduction of soluble skin sodium, the ratio of bound to total sodium was unchanged by hemodialysis (9.3±5.0%).

Conclusions: Reduction of tissue sodium content by hemodialysis treatment differs in skin and muscle tissue: While bound sodium content in muscle was unaffected by hemodialysis, bound sodium content in skin tissue could be mobilized by HD.

TH-PO833

Blood Pressure in Hemodialysis Patients: Which Measurement Is More Reliable?

Jose Mora-Macia, Francesc J. Moreso, Jose Ignacio Merello, Rosa Ramos. *Hemodialysis, Fresenius Medical Care, Spain.*

Background: The reliability of blood pressure (BP) measurements during the hemodialysis (HD) is controversial. The aim of this study was to evaluate which interval of intradialytic BP has less Bias in comparison with home BP monitoring (HBPM).

Methods: A cross-sectional study was done with interdialytic HBPM as reference standard and interdialytic BP measurement as test. Index BP recordings tested were predialysis (pre-HD), postdialysis (post-HD) and intradialysis (intra-HD). Dialysis unit BP recordings were averaged over 1 week: 2 pre-HD, 2 post-HD and 7 intra-HD (every 30 min); and HBPM over 1 week (the same days): 3 morning and 3 evening readings. BP measurements during dialysis were measured by dialysis nurses using the validated oscillometric BP monitor OMRON M3 (HEM 7051 E, Omron Healthcare), and the same device was used for the patient at home. Patients were instructed to bring the device to the dialysis. Patients with symptomatic hypotension during dialysis were excluded. To measure Bias, average HBPM was subtracted from each of these three index BP intradialytic recordings. Bias was defined as the mean difference in BP (pre-HD, intra-HD, post-HD) compared with HBPM.

Results: 192 patients, mean age 63.8±14.8 y.o. (70% male), of 11 HD clinics of Fresenius Medical Care of Spain were included, 33% diabetic. All patients were on th ree times weekly HD. The mean time on HD was 46±57 months.

	HBPM	Pre-HD	Intra-HD	Post-HD
SBP	135±21.4 (80,194)	143.0±21.6 (92,225)*	130.7±20.9 (83,204)*	136.1±23.2 (84,207)¥
DBP	69.3±11.2 (44,97)	71.1±11.1 (46,117)*	68.4±10.4 (49,105)**	70.2±10.4 (48,98)¥
Bias SBP	reference	-7.97±12.1 (-48,+22)&	4.35±13.16 (-37,+44)&	-1.08±15.95 (-52,+42)&
Bias DBP	reference	-2.08±6.18 (-35,+16)&	0.90±6.67 (-23,+21)&	-0.92±7.44 (-25,+21)&

Data are expressed as mean±SD (range). * p<0.001 vs HBPM. ** p=0.062 vs HBPM. ¥ NS vs HBPM. & p<0.0001 ANOVA between HD

Conclusions: BP at the end of the HD, in not hypotensive symptomatic patients, not differ from HBPM and have less Bias that predialysis or intradialysis BP measurements. So, the postdialysis BP measurements are the most reliable BP readings.

TH-PO834

End-Dialysis Overweight and Chronic Inflammation: A Dangerous Association – A 36-Month Prospective Observational Study Ezio Movilli. *U.O. of Nephrology, Spedali Civili and Section of Nephrology Univ of Brescia, Brescia, Italy.*

Background: Attaining dry body weight is paramount in dialysis practice, but this goal is not always reached. We hypothesized that the amount of end-dialysis overweight (edOW), could be associated to increased chronic inflammation and mortality. Aim of the study: to evaluate the effect of edOW on serum C-reattive protein(hsCRP) concentrations and on survival in a cohort of 182 prevalent HD patients (pts) followed for 36 months.

Methods: In 182 pts (117 men, age 65±12 years, vintage 48 months; range 6-336), edOW was present in 98/182 (54%) pts. Mean value was 0.4±0.2 Kg (range: 0.1-1.4). In the 98 pts with edOW (Group 1) and in the other 84 (Group 2) we evaluated: Ultrafiltration rate(UFR), hsCRPdry body weight (dBW), Kt/V, protein catabolic rate (PCRn), interdialytic weight gain (IDWG), mean arterial pressure (MAP). Unpaired Student's t test was employed to compare groups, linear regression analysis to test correlations, log-rank test and Kaplan-Meier curves to evaluate survival.

Results: Mean UFR was 11.7±2.8 ml/Kg/hour, dBW 64±12 Kg, hsCRP 6.6 (0.2-36) mg/L, Kt/V 1.27±0.09, PCRn 1.06±0.10 g/Kg/day, IDWG 2.8±0.4 Kg, MAP 97±6.5 mmHg. edOW and hsCRP were directly and significantly correlated (r= 0.67; p<0.0001). Comparison between pts with (Group 1) and without (Group 2) edOW showed significant differences in: UFR (12.7±2.6 vs 10.9±2.6 ml/Kg/hour; p< 0.0001), hsCRP (13.0±8.1 vs 5.2±5.3 mg/L; p< 0.0001), and PCRn (1.03±0.09 vs 1.08±0.10 g/Kg/day; p<0.004). 98 pts (54%) died during follow-up for cardiovascular complications in 69% of cases. Survival curves showed significantly greater mortality in Group 1 vs Group 2 in relation to the amount of edOW, and hsCRP (p<0.0001).

Conclusions: : edOW and chronic inflammation are directly correlated in HD pts, and both are associated to a greater long-term risk of mortality.

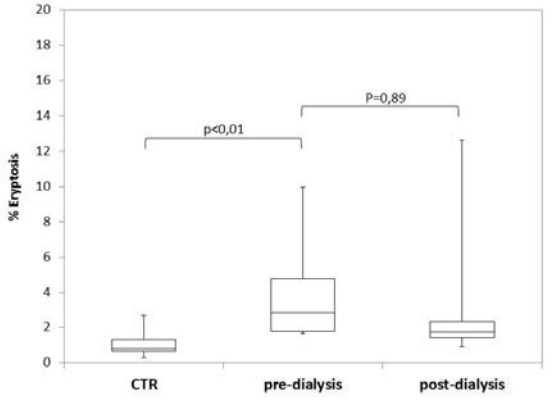
TH-PO835

Suicidal Erythrocyte Death in Hemodialysis Patients Anna Clementi,[1] Grazia Maria Virzì,[2] Alessandra Brocca,[2] Massimo de Cal,[2] Antonio Granata,[1] Claudio Ronco.[2] *[1]Nephrology, Agrigento; [2]Nephrology-IRRIV, Vicenza.*

Background: Even though anemia in ESRD results mainly from the lack of erythropoietin, compelling evidence points to the contribution of accelerated erythrocyte death/eryptosis, which is characterized by phosphatidylserine (PS) exposure at surface, cell shrinkage and cell membrane scrambling. Eryptosis may be stimulated both by uremic toxins and the mechanical stress induced by hemodialysis (HD). We investigated the possible difference in terms of eryptosis levels between healthy subjects and HD patients before and after HD session.

Methods: We enrolled 15 patients (4F, mean age 65±16yrs, 33% with diabetes) undergoing chronic HD and 15 healthy subjects (CTR). Blood samples were collected prior to and after 4h standard HD session. Measurements were made in isolated erythrocytes (RBCs). PS exposure was estimated from AnnexinV binding in flow cytometer.

Results: The percentage of AnnexinV reflecting the percentage of RBCs exposing PS at RBC surface was significantly higher (more than twice) in HD patients than CTR (2.2%; IQR 1.2-4.1 versus 0.8%; IQR 0.7-1.3; p<0.05). The average forward scatter reflecting cell volume was significantly higher in RBCs from HD patients than in CTR. There was no statistically significant relationship between urea levels and eryptosis in HD patients. The percentage of AnnexinV and cell volume were measured prior to and after 4h of HD: no significant differences were observed between pre and postdialytic eryptosis.



Conclusions: Our data suggest that HD may lead to a significant increase in eryptosis, but no differences in its level were observed before and after HD session. Although dialytic procedure is known to be responsible for cytokines and inflammatory mediators release, because of the interaction between blood and circuit lines and filters, it does not seem to induce eryptosis. Further studies are needed to compare different types of HD treatments.

TH-PO836

Deployment of a Dialysis Hospitalization Reduction Program Is Associated with Lower Hospitalization Rates Hanjie Zhang,[1] Dugan Maddux,[2] Karen G. Butler,[2] Len A. Usvyat,[2] Yue Jiao,[2] Brian Scott Ash,[2] John W. Larkin,[2] Terry Ketchersid,[2] Peter Kotanko,[1,3] Franklin W. Maddux.[2] *[1]Renal Research Inst, New York, NY; [2]Fresenius Medical Care North America, Waltham, MA; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: The aim of this study was to investigate the potential effect of a Dialysis Hospitalization Reduction Program (DHRP) on hospital admissions.

Methods: We deployed DHRP to 69 patients between 1/1/2014 and 5/5/2015 in a network of Fresenius Medical Care North America (FMCNA) dialysis clinics. These patients were identified as being at high risk for hospitalization based on FMCNA's data driven predictive modeling efforts and clinical assessments. The DHRP encompasses multiple interventions, targeting malnutrition, non-compliance, mental status issues, fluid overload, and others. Each patient is identified to have one or more "clinical tags"; 88 tags were identified for 69 patients. Interdisciplinary teams were deployed to design and implement interventions. Hospitalization rates were measured 90 days before and after the program.

Results: DHRP was associated with a reduction of all-cause hospitalization from 7.5 to 4.4 per patient year (ppy) (-42 %) (Figure 1A). Interventions targeting patients with "malnutrition" tag were associated with a reduction of hospitalizations from 9.3 to 4.1 ppy (-56%) (Figure 1B).

Figure 1 A. Overall intervention outcomes

	Before	After	Difference
Number of clinical tags	88	88	
Hospital admissions	7.5	4.4	-42%
Hospital days	58	30	-49%
Missed treatments	7.9	7.4	-6%
Albumin (g/dL)	3.52	3.51	0%
Catheters	31%	30%	-3%
Pre-dialysis SBP (mmHg)	146.5	147.1	0%
IDWG (kg)	2.49	2.47	-1%

B. Intervention outcomes targeting malnourished patients

	Before	After	Difference
Number of clinical tags	21	21	
Hospital admissions	9.3	4.1	-56%
Hospital days	76	38	-50%
Missed treatments	4.4	4.1	-7%
Albumin (g/dL)	3.22	3.28	2%
Catheters	43%	34%	-20%
Pre-dialysis SBP (mmHg)	144.2	144.4	0%
IDWG (kg)	2.3	2.34	2%

SBP, systolic blood pressure; IDWG, interdialytic weight gain

Conclusions: DHRP was associated with reductions in hospital admissions and days. Reductions in overall hospital admissions were even higher in patients specifically identified to have malnutrition issues.

TH-PO837

The Long Inter-dialytic Period Is Not Associated with Inferior BP Control in Stable Hemodialysis Patients Mohamed Shantier, Rajneet Singh, Paul Mcdermott, Sami Suleiman, Donal N. Reddan, Louise Giblin, David W. Lappin, Matthew D. Griffin. *Nephrology Dept, Saolta Univ Healthcare Group, Galway, Ireland.*

Background: 3-day-a-week hemodialysis (HD) involves one long (72hr) and two short (48hr) inter-dialytic periods (IDP) with higher death risk after the long IDP. We investigated BP and CV biomarker patterns in clinically stable HD patients to determine whether BP control during the final 24 hrs of the long IDP is inferior to that of the short IDPs.

Methods: In an initial retrospective study, in-center BP readings over 1 month were analyzed for 81 adult HD patients with stable regimen and medical status for ³3 mths. Next, 23 patients completed a prospective study in which ambulatory BP monitoring was performed for the final 24hrs of the long and one short IDP in the same week. Blood was collected for CRP, Troponin T, BNP following each ABPM.

Results: In the retrospective study, mean pre-dialysis systolic and diastolic BP (SBP/DBP) did not differ for the long and short IDPs despite greater weight gain during the long IDP. This observation was confirmed in the ABPM study and applied to both day- and night-time readings. Pre-dialysis CV biomarkers were not significantly higher following the long IDP. Inter-dialytic weight gain showed no correlation with BP indices.

Index	Long-IDP	Short-IDP	P value
24hr SBP (mmHg, mean± SD)	148.4±18	146.8±19.2	0.4
24hr DBP (mmHg, mean± SD)	80.8±10.3	80.5±11.2	0.5
24hr MAP (mmHg, mean± SD)	103.3±11.6	102.6±12.8	0.4
Day-time SBP(mmHg, mean± SD)	150.7±17	147.8±18.2	0.3
Night-time SBP (mmHg, mean± SD)	141.9±24.6	143.3±25.8	0.4
Inter-dialytic weight gain (kg, mean± SD)	2.7±1.4	1.8±0.8	0.002
Pre-dialysis Troponin T(ng/mL,mean± SD)	76±57	72±50	0.4
Pre-dialysis BNP (pg/mL, mean± SD)	9801±10805	8628±9822	0.1
Pre-dialysis CRP (mg/L, mean± SD)	9.5±12	6.6±9	0.2

Conclusions: In stable HD patients, BP control and CV biomarkers were similar during long compared to short IDP despite greater fluid gain. The adverse influence of excessive inter-dialytic fluid gain is unlikely to be mediated directly through a hypertensive effect.

TH-PO838

Notch Signaling in Bone Marrow-Derived FSP-1$^+$ Cells Mediates a Phenotypic Change in Smooth Muscle Cells Leading to AVF Failure Ming Liang,[1,2] Jinlong Luo,[1] William E. Mitch,[1] Jizhong Cheng.[1] *[1]Medicine, Baylor College of Medicine, Houston, TX; [2]Nephrology, Guangzhou Medical Univ, Guangzhou, Guangdong, China.*

Background: sociological and economic costs of failed arteriovenous fistulas (AVF) are well known but mechanisms of AVF losses are controversial. We have shown that smooth muscle cells (SMCs) from anastomosed artery compose of ~50% of neointima cells in AVF. Arterial anastomoses are also infiltrated by bone marrow (BM)-derived FSP-1$^+$ cells, potentially linking FSP-1$^+$ cells to SMC activation. However, whether Notch/RBP-JK signaling involves in BM-derived FSP-1$^+$ cells activation has not been studied. We propose that Notch/RBP-JK activation in BM-derived FSP-1$^+$ cells causes a phenotype-switch of SMCs, resulting in SMC translocation from the artery to the venous anastomosis, forming neointima.

Methods: we created CKD and AVFs in wild type and Notch knock out mice. The role of Notch signaling in activation and function of BM-derived FSP-1$^+$ cells was explored. Activated SMCs were characterized by a loss of differentiation markers plus a gain in proliferation (PCNA+). Using BM transplantation, we examined if FSP-1$^+$ cells lacking RBP-JK in CKD mice would suppress SMC phenotype switch and neointima formation in AVFs.

Results: BM-derived FSP-1$^+$ inflammatory cells in AVFs from CKD mice were 45% greater vs. results in pair-fed, control mice. In the artery anastomosis, increased infiltration of FSP-1$^+$ cells led to loss of SMC differentiation markers, SMMHC, SM-22 and SMA-α. Activation of Notch signaling (N1ICD$^+$ and RBP-JK$^+$) raised expression of cytokines (IL-1β, MCP-1) and growth factors (PDGF-BB, bFGF2 and TGF-b1) in FSP-1$^+$ cells, The cytokines and growth factors caused a SMC phenotype switch (characterized by loss of SMC markers), resulting in SMC migration and proliferation. RBP-JK KO in BM-derived FSP-1$^+$ cells significantly decreased the production of cytokines and growth factors, suppressed SMC activation of and neointima formation in AVFs.

Conclusions: Thus, Notch signaling in BM-derived FSP-1$^+$ cells can induce a phenotypic switch in SMCs stimulating neointima growth. Targeting Notch signaling in FSP-1$^+$ cells could improve AFV function.

Cytoglobin Is Upregulated in Failed Arteriovenous Fistula from Hemodialysis Patients and Exerts Survival Functions in Medial Smooth Muscle and Neointimal Cells David Jourd'heuil, Frances L. Jourd'heuil, Yongfeng Liu, Julia Steppich, Roman G. Ginnan, David J. Conti, Harold A. Singer, Arif Asif. *Center for Cardiovascular Sciences and Nephrology Group, Albany Medical Center, Albany, NY.*

Background: Arteriovenous fistulae (AVFs) suffer significant problems with high incidence of both early and late failures. Interventions that may prolong access patency are still very limited and require strategies that may impair or regress neointimal hyperplasia. In the cardiovascular system, globins such as hemoglobin are thought exclusively to regulate O_2 and nitric oxide (NO) levels. However, recent studies suggest that this model might be incomplete and that non-canonical mammalian globins including cytoglobin (CYGB) have survival functions independent of the regulation of O_2 and NO. Our goal was to understand the function of CYGB in the hyperplastic response associated with AVF failure.

Methods: Histomorphometric, immunostaining, and protein analysis were performed on samples obtained from the venous segments of AVFs collected from patients undergoing surgical access creation/revision. The functional significance of CYGB was studied in vivo in rodent models of injury-induced neointimal formation and in sub-cultured human smooth muscle cells (SMCs) derived from primary placement and revision veins.

Results: CYGB was upregulated in revision compared to primary placement veins with significant expression in both medial smooth muscle and neointimal cells. Injury-induced neointimal formation in vivo was attenuated by CYGB deficiency and associated with increase apoptosis and medial VSMCs loss. Human venous medial and neointimal SMCs derived from failed AVFs maintained high levels of CYGB in culture in contrast to medial SMCs from placement veins. Molecular strategies to modulate CYGB expression levels revealed that CYGB promotes SMC cell survival by inhibiting the mitochondrial pathway of apoptosis.

Conclusions: Our results challenge the current dogma on globin functions and demonstrate a role for CYGB in regulating venous VSMCs survival. Strategies aimed at regulating CYGB anti-apoptotic functions might represent important therapeutic options to control for AVF maturation and limit stenosis.

Identification of Ca2+/CaM-Dependent Protein Kinase (CaMKII) Isoforms and Their Selective Regulation by NADPH Oxidases in Failed Arteriovenous Fistula from Hemodialysis Patients Roman G. Ginnan,[1] Ravi S. Shah,[1] David J. Conti,[3] Arif Asif,[2] David Jourd'heuil,[1] Harold A. Singer.[1] *[1]Center for Cardiovascular Sciences, Albany Medical College, Albany, NY; [2]Div of Nephrology and Hypertension, Albany Medical College, Albany, NY; [3]AMC Surgery Group-Transplantation, Albany Medical College, Albany, NY.*

Background: Placement of an arteriovenous fistula (AVF) provides vascular access for lifesaving hemodialysis to patients with severe and chronic kidney disease. A significant percentage of AVFs initially mature; serve as successful hemodialysis access points; but fail at some later time due to neointimal hyperplasia that occludes the vein. The causative underlying molecular, biochemical, and cellular factors that contribute to AVF failure are incompletely understood. CaMKII is a positive regulator of VSM cell proliferation and migration that results in occlusion of carotid arteries in both mice and rats. Currently, there is little known regarding the role of CaMKII in either physiological or pathophysiological venous function.

Methods: CephaIic veins from patients prior to AVF placement and after AVF failure were obtained. Immunohistochemical studies were performed on OCT embedded frozen sections. Molecular analyses were performed on RNA extracts from these venous segments and protein analyses were performed on protein extracts.

Results: Our results indicate that there is an increase in CaMKIId and CaMKIIg expression in failed AVFs as compared to cephalic vein prior to AVF placement. CaMKII activity is regulated by both phosphorylation and oxidation. NADPH oxidases (Noxs) generate reactive oxygen species (ROS) that increases CaMKII activity. Analysis of failed AVFs shows an upregulation of Nox4 and Nox5. Further studies show an increase in CaMKII activity. Interestingly, our data indicates that only a subset CaMKII isoforms are oxidized under these conditions.

Conclusions: These findings lead us to conclude that increases in [Ca2+] and [ROS] after AVF placement may result in increases of CaMKII expression and sustained activity that contribute to AVF failure. They also identify CaMKII as a rational target for therapeutic manipulation to prevent AVF failure.

Combined RNA seq and gDNA Methylation Analysis for AVF Maturation Begoña Campos, Sonia Bhati, Nikhil Grandhi, Ashish Verma, Amanda B. Naciff-Campos, Gagan Deep Singh, Keith Louis Saum, Mario Medvedovic, Amy Pflum, Timmy C. Lee, Prabir Roy-Chaudhury. *Univ of Cincinnati.*

Background: Early arteriovenous fistula (AVF) failure remains an important cause of hemodialysis vascular access dysfunction. In order to understand the cellular and molecular mechanisms involved in early AVF failure we evaluated the gene methylation profile (epigenetics) in conjunction with the gene expression profile (RNA Seq) from venous segment tissue samples obtained at the time of AVF creation. This approach allows us to identify genes that have altered expression (RNA Seq analysis) as a result of epigenetic changes (DNA methylation). The latter can be induced by different factors, including stress, inflammation, nutrition, metabolism, drugs and infection (all of which are prominent in the biological milieu of patients with CKD and ESRD).

Methods: Genomic DNA (gDNA) and RNA were isolated from venous segments collected at the time of AVF creation. We divided the samples into 2 groups, THICK (n=5) and THIN (n = 5), based on a histological evaluation of the amount of neointimal hyperplasia. Deep sequencing technologies were then used to identify differentially regulated levels of gene expression between the THICK and THIN groups, that also had significant differences in the degree of methylation. Standard bioinformatic techniques were used to identify/interrogate these changes.

Results: We were able to identify a number of genes that were differentially regulated, either at the level of the transcriptome or at the level of DNA methylation (epigenetics) between the THICK and THIN groups. However, we were not able to identify individual genes that had changes in both the RNA Seq and DNA methylation analyses, at a high level of statistical significance.

Conclusions: While we were unable to identify differences in both gene expression and the level of DNA methylation for individual genes, between our two groups (perhaps because of a small sample size), we do believe that these techniques and technologies could be used in larger studies, to dive deep into the mechanisms of AVF failure at a molecular and genetic level.

TH-PO842

Computational Fluid Dynamic Analyses in a Uremic Mouse Model of AVF Stenosis: Of Surgery, Techniques and Computation Begoña Campos,[1] Yang Wang,[1] Yong He,[2] John M. Pearce,[3] Richard Scott Dunn,[3] Keith Louis Saum,[1] Janaka Wansapura,[3] Charles L. Dumoulin,[3] Scott A. Berceli,[2] Prabir Roy-Chaudhury.[1] *[1]Univ of Cincinnati; [2]Univ of Florida; [3]CCHMC.*

Background: Although arteriovenous fistulae (AVF) are the preferred form of vascular access for hemodialysis patients, over 50% of AVFs fail to mature (inability to increase blood flow and diameter adequately to support dialysis). Work performed in our laboratory suggests that AVF maturation failure is due to an interaction between "upstream hemodynamics" and "downstream vascular biology". In order to better elucidate the mechanisms involved in both these processes, we herein describe the techniques needed to develop a shear stress profile within a uremic mouse AVF.

Methods: In order to create a uremic mouse model, C57Bl/6 animals underwent an initial cautery of the left kidney followed 2 weeks later by a contralateral nephrectomy. Four weeks later AVFs were created in the neck. In order to generate different shear stress profiles, we created AVFs between the carotid artery and jugular vein in the following surgical configurations (a) end of carotid artery to end of jugular vein (b) end of jugular vein to side of carotid artery and (c) end of carotid artery to side of jugular vein. Mice were then perfused with a silicone rubber casting agent (Microfil). Fistulae were harvested, stored in 4% paraformaldehyde, and treated with Lugol solution as a micro-CT contrast agent. Each AVF was then scanned using micro-CT imaging to create a 3D reconstruction of AVF geometry. In order to obtain blood flow parameters we have developed an MRI technique that allows us to quantify blood flow within the carotid artery. We then use software to develop a complete shear stress profile in the mouse AVF.

Results: We have described for the first time a hybrid surgery-fluid dynamics approach, which could allow us to identify the differential impacts of different surgical configurations, with or without the impact of uremia on AVF fistula functionality (with the promise of also being able to use genetically manipulated animals in the future).

Conclusions: We firmly believe that teasing out the relative roles of upstream hemodynamics and downstream uremic vascular biology will allow us to identify target(s) for future therapeutic interventions.

TH-PO843

Biodegradable Stents Improve Arteriovenous Fistula (AVF) Maturation Begoña Campos, Yang Wang, Zhangzhang Yin, Keith Louis Saum, Diego Celdran-Bonafonte, Mark J. Schulz, Vesselin Shanov, Prabir Roy-Chaudhury. *Univ of Cincinnati.*

Background: Arteriovenous fistula (AVF) maturation failure is currently a huge clinical problem with no effective therapies. At a pathogenetic level the three main causes of AVF maturation failure are (a) small veins (b) abnormal non-laminar flow profiles and (c) abnormal local endothelial function. We therefore, hypothesize, that the placement of a malleable, biodegradable magnesium based maturation enhancing stent (bMES) within the venous segment, at the time of surgical AVF creation would dilate small veins, optimize the anatomical configuration, and serve as a conduit for the future delivery of therapies to improve local vascular biology during the critical initial 4-8 week period with an absence of long term side effects (no stent after 4-8 weeks).

Methods: bMES were fabricated using pure Mg foil (125 mm) and Mg-Zn alloy wire. Bilateral AVFs were created between the femoral artery and vein of Yorkshire pigs. A bMES was inserted on one side and dilated to 8mm. A control AVF was created on the contralateral side. CT angiograms and ultrasounds were performed to document blood flow and diameter for the control and stented AVF.

Results: Preliminary data documents almost complete degradation of the bMES at 4-8 weeks with an initial increase in diameter of the stented AVFs on CT angiograms at 2 weeks (Figure). Histological examination performed on both the stented and control AVFs did not reveal any evidence of necrosis or inflammation.

Conclusions: These initial results clearly demonstrate technical feasibility and safety for the bMES, and also provide us with an efficacy signal based on our CT angiogram data (Figure). We believe that this technology could significantly reduce the huge morbidity and mortality associated with AVF maturation failure and also expand the patient population considered to be suitable for AVF placement in the future.

Abstract Withdrawn

TH-PO845

Association Between Clinical Outcomes and Type of Vascular Access in Elderly End-Stage Renal Disease Patients Initiating Hemodialysis Kyoung Sook Park, Mi Jung Lee, Tae-Hyun Yoo, Shin-Wook Kang. *Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea.*

Background: Although dialysis initiation via arteriovenous fistula (AVF) is the best strategy in incident hemodialysis (HD) patients. Elderly patients with HD are compelled to use HD catheter (HC) due to maturation failure after AVF operation. Therefore, we investigated the association of vascular access (VA) type and clinical outcomes in elderly incident HD patients.

Methods: A prospective cohort of incident HD patients from the Clinical Research Center for End-stage renal disease in Korea between 2009 and 2013 was used. Patients who were 65 years or older were defined as elderly. The patients were classified into three groups according to VA type at HD initiation. Since the hazard ratio (HR) according to type of VA was not proportional, time-dependent Cox regression analysis was performed to determine all-cause mortality.

Results: Among the 511 enrolled patients, 303 (59.3%) were male and the mean age was 72.3±5.4 years. HD was initiated with AVF, arteriovenous graft (AVG), or HC in 86 (16.8%), 36 (7.0%), and 389 (76.1%) patients, respectively. During a median follow up of 12 months, all-cause death was observed 12 (14.0%) in AVF, 13 (36.1%) in AVG, and 107 (27.5%) in HC. Multivariate time-dependent Cox regression analysis demonstrated that AVG (AVF as reference, HR=1.719, 95% confidence interval [CI]=1.274-2.319, P <0.001) and HC (HR=1.304, 95% CI=1.036-1.640, P=0.023) were significant risk factors for all-cause mortality after adjustment of age, sex, diabetes mellitus, previous cardiovascular disease, timing of referral to nephrologist, hemoglobin, serum albumin, and C-reactive protein levels.

Conclusions: Patients with successful AVF were associated with better survival compared to those with AVG or HC. In addition, survival was comparable between elderly patients initiating HD with AVG and HC. Although vascular problems are common in elderly patients, AVF may be the best strategy to improve clinical outcomes in this population.

TH-PO846

International Variability in Arteriovenous Fistula Maturation and Placement: The Dialysis Outcomes and Practice Patterns Study Ronald L. Pisoni,[1] Lindsay Zepel,[1] Francesca Tentori,[1,2] Yun Li,[3] Jarcy Zee,[1] Richard J. Fluck,[4] Loreto Gesualdo,[5] Hideki Kawanishi,[6] Gültekin Süleymanlar,[7] Bruce M. Robinson.[1] *[1]Arbor Research; [2]Vanderbilt Univ; [3]Univ of Mich.; [4]Nat. Health Service England; [5]Azienda Ospedaliero Univ Consorziale Policlinico; [6]Tsuchiya Gen. Hosp.; [7]Akendiz Univ.*

Background: Prior Dialysis Outcomes and Practice Patterns Study (DOPPS) findings demonstrate international variability in vascular access practices, and association with outcomes. Here we describe international practices in arteriovenous fistula (AVF) placement and predictors of AVF maturation.

Methods: We studied 2,230 patients with an AVF created during DOPPS phases 4-5 (2009–2015) in North America, Europe/Australia-New Zealand (ANZ), and Japan. AVF maturation was defined as access use ≥ 30 days. Generalized estimating equations with a logit link were used to assess predictors of AVF maturation adjusting for country, phase, patient characteristics, and accounting for facility clustering.

Results: No significant association was found between many patient characteristics (e.g., age, diabetes, peripheral vascular disease) and AVF maturation. AVF maturation was more likely for males vs. females (OR = 1.49 [95% CI = 1.25-1.79]) and for AVFs placed in the upper vs. lower arm (OR = 1.40 [95% CI = 1.15-1.70]). Even though upper arm AVFs were more common in North America, AVF maturation was lowest in this region (Figure).

	North America	Europe/ANZ	Japan
N AVFs=	1204	857	318
% AVF Maturation:			
Lower arm =	52%	64%	90%
Upper arm =	64%	70%	82%
Overall =	60%	67%	89%
Mean blood flow (ml/min) =	386	307	198

Conclusions: There is large international variability in site of AVF placement and AVF maturation. Differences in blood flow used (much higher in the US vs. Europe and Japan) may lead to different interpretation of the term "maturation" internationally, and may influence maturation rates.

TH-PO847

Vascular Access in Acute Kidney Injury: Results from the ATN Study

Kavitha Ganta, Yue-Harn Ng, Herbert T. Davis, Mark L. Unruh. *Deapartment of Internal Medicine, Univ of New Mexico, Albuquerque, NM.*

Background: Acute kidney injury requiring renal replacement therapy (RRT) portends a poor prognosis. Currently, the decision regarding catheter placement is based solely on physician discretion. Limited data exist to guide catheter placement. The Acute Renal Failure Trial Network (ATN) study was a multicenter, prospective, randomized trial on the effects of dialysis dose on mortality in critically ill patients. Using data from this study, *we assessed the complications rates and the adequacy of dialysis based on different catheter locations*.

Methods: Baseline characteristics were gathered. The outcomes of interest include catheter related infections, cardiac arrhythmias, excessive bleeding, local thrombosis and dialysis adequacy. Categorical variables were analyzed using Chi-square test while continuous variables were analyzed using the Student T test. The SAS software was used for analysis.

Results: There were 242 (11.7%) subclavian (SC), 951 (46.1%) internal jugular (IJ) and 861 (41.7%) femoral (FC) catheters inserted. The baseline characteristics based on catheter location is shown in Table.1.

Baseline Characteristics	Catheter Location			P
	SC (%)	IJ (%)	FC (%)	
Age	61.3 ± 14.3	61.3 ± 14.7	59.1 ± 15.8	<0.01
Gender (Male)	170 (70.3)	686 (72.1)	618 (71.8)	0.84
BMI	27.3 ± 6.0	28.6 ± 6.0	27.9 ± 5.6	<0.01
Platelet (000/mm^3)	141 ± 138	144 ± 113	130 ± 114	0.04
INR	1.6 ± 0.8	1.7 ± 1.6	1.9 ± 1.8	<0.01
Diabetes	78 (32.2)	286 (30.1)	235 (27.3)	0.23
PVD	75 (31.0)	197 (20.7)	113 (13.1)	<0.01

The rate of bacteremia was comparable between the 3 groups. (5.4% (SC) vs. 3.5% (IJ) vs. 3.5% (FC); p = 0.34) The IJ group experienced more cardiac arrhythmias (2%) compared to the SC (0.8%) and FC (0.5%) group [p = 0.01] while the FC group had more venous thrombosis (0.7%) compared to none in the SC and IJ group [p = 0.02]. Overall, complication rates were low. There was no clinically significant difference in the adequacy of dialysis between the 3 groups.

Conclusions: There was no significant differences in complication rates amongst the 3 catheter locations hence decision on catheter location should be based on operator experience and comfort level.

TH-PO848

Vascular Access at Dialysis Initiation in the United States Renal Data System (USRDS): Strong Agreement Between CMS 2728 Medical Evidence Form and CROWNWeb

Purna Mukhopadhyay,[1] Jeffrey Pearson,[1] Kenneth J. Woodside,[2] Sarah Bell,[2] Ronald L. Pisoni,[1] Douglas E. Schaubel,[2] Kaitlyn Ratkowiak,[1] Rajiv Saran.[2] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Univ of Michigan, Ann Arbor, MI.*

Background: The USRDS has long reported vascular access (VA) at the start of hemodialysis (HD) using the CMS-2728 Form. In 2012, CMS rolled out the CROWNWeb (CW) system to collect clinical treatment and laboratory data monthly for all dialysis patients. As CW data are fully integrated into the USRDS database, it is critical to evaluate the level of completeness and consistency between these two data sources.

Methods: We compared VA used at the first HD session reported on the CMS-2728 form for new ESRD patients in 2013 (n = 96,936) in USRDS database with VA used at the end of the 1st month of HD reported through CW. To evaluate the potential for data lag, we also compared to the 2nd month of HD reported through CW. Completeness and consistency was assessed at the patient level by 2x2 tables. The level of agreement was evaluated by kappa statistics. Logistic regression models were fit to identify patient characteristics associated with the level of agreement.

Results: 89% of patients had at least one monthly VA report in CW among which 0.23% was missing VA data from the CMS-2728 and 32.8% did not have a VA reported in CW for their 1st month of HD. However, completeness of CW data improved when either 1st or 2nd month of HD was considered as only 12.6% of patients did not have a VA reported. Among patients with VA reported from both data sources, kappa statistics was 0.88 using the 1st month of ESRD and 0.84 using first two months of ESRD. Agreement was highest for catheter (97-98%) and lowest for graft (78-81%). Age, sex, race were associated with the level of agreement; Hispanic ethnicity and cause of ESRD were not.

Conclusions: CW data has VA information for the vast majority of patients; however, coverage is not complete and may be lowest at start of ESRD. However, there is very strong agreement in VA reported on the CMS-2728 and in CW. This study also demonstrates near completeness of CMS Form 2728 with respect to VA information at start of HD.

TH-PO849

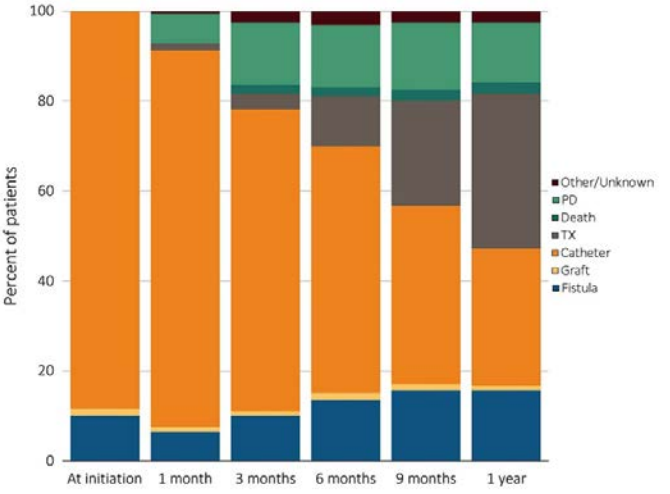
Vascular Access and Trends in Pediatric End-Stage Renal Disease: Results from the USRDS

Brett W. Plattner,[1] Yee Lu,[2] David T. Selewski,[2] Xue Dietrich,[4] Nan Ji,[4] Alissa Kapke,[4] Douglas E. Schaubel,[3] Debbie S. Gipson,[2] Rajiv Saran.[1] *[1]Internal Medicine, Univ of Michigan, Ann Arbor, MI; [2]Pediatrics, Univ of Michigan, Ann Arbor, MI; [3]Biostatistics, Univ of Michigan, Ann Arbor, MI; [4]Arbor Research Collaborative for Health, Ann Arbor, MI.*

Background: Policy to improve outcomes for End-Stage Renal Disease (ESRD) patients (pts) may be less widely adopted in children. We describe vascular access (VA) in incident and prevalent pediatric ESRD pts and examine changes in the first year.

Methods: Pediatric ESRD was defined as 0-17 yrs at diagnosis of ESRD. Data was from the 2728 and CROWNWeb. For pts incident during 2006-2013, data on VA at hemodialysis (HD) initiation (n=2,851) was categorized as catheter only (CVC), AV Fistula (AVF), AV Graft (AVG), CVC with maturing fistula, or CVC with maturing graft. Pts initiating HD between 6/1/2012-12/31/2012 (N=197), were tracked over 12 months. For prevalent pts, AVF & AVG groups include CVC/maturing fistula and CVC/maturing graft,respectively.

Results: From '06-'12, incident pts began ESRD care using HD 39%, PD 36%, and transplant 25%. In 2013, in pts starting HD, 90% had a CVC, an increase from 84% in 2006. CVC was lower for the older pts (<4yrs: 99% vs. 14-17yrs: 83%, p <.05). VA trends over a year in a 7-month incident cohort showed the proportion of CVC decreased from 84% at 1 month to 31% at 1 year, while 16% were using or maturing an AVF. 1% were using or maturing an AVG. 13% of pts transitioned to PD and 35% received a TX by 1 year.



Conclusions: Our analysis confirms the large CVC burden among pediatric HD pts. Conversion to AVF were observed over the first year in an incident cohort where nearly 50% of pts transitioned to PD or TX. Further study will assess the impact of CVC dependence among pediatric ESRD pts with respect to future VA options and patient outcomes.

TH-PO850

In Search of an Optimal Screening Program for Containing Graft Thrombosis

Nicola Tessitore,[1] Giuseppina Pessolano,[1] Valeria Bedogna,[1] Albino Poli,[2] Antonio Lupo.[1] *[1]Emodialisi Borgo Roma, Verona, Italy; [2]Dept Public Health, Verona, Italy.*

Background: K/DOQI guidelines recommend regular screening for >50% stenosis (ST) in graft by surveillance (access blood flow (Qa) &/or static venous pressure ratio (sVPR) or Duplex Ultrasound to reduce the risk of thrombosis. Analysis of the literature suggests that the best predictor of thrombosis is sVPR>0.5, with an area under curve (AUC) of 0.81[95%CI:0.75-0.85] significantly higher than that of Qa<600 ml/min (0.72[95%CI:0.68-0.77]) & ST (0.49[95%CI:0.45-0.53]), but no study has compared vis-a-vis all of the tools.

Methods: To identify an optimal screening program, in 2013 we compared the diagnostic performance of the available tools for incipient thrombosis (within 3 mo) in the same population of 42 grafts (5 forearm loop & 37 straight upperarm), that underwent18 thrombotic episodes.

Results: Qa by Ultrasound Dilution proved to be the best screening tool (AUC:0.81[0.69-0.93]):optimal thresholds between Qa<1000 ml/min(63% sensitivity[SE], 18% false positives[FPR]) & Qa<1200 ml/min (83% SE, 27% FPR). Its AUC was higher than that of ST (0.69[95%CI:0.54-0.84]: 78% SE, 39% FPR), monitoring (0.62[95%CI 0.45-0.79]: 33% SE, 9% FPR), & VAPR (0.58[95%CI:0.42-0.74]:VAPR>0.8:72% SE, 58% FPR). At GLM analysis Qa was the only significant predictor of thrombosis, with 18%[95%CI 7-29] lower risk for each 100 ml/min above a Qa 400 ml/min. From January

2014 onward we adopted a monthly Qa screening program using a Qa<1000 ml/min for stenosis repair & a drop inQa>25% for detecting & repairing restenosis. This led to a significant drop of thrombosis rate from 0.70[95%CI 0.41-1.11] (during the 2012-2013 period in which screening was based on bimonthly VAPR and quarterly Qa measurements and stenosis repair triggered as per guidelines, by a VAPR>0.5 or a Qa<600 ml/min) to 0.11[95%CI 0.01-0.40] event/graft-y (p=0.005), at a comparable elective angioplasty rate (0.71[95%CI 0.46-1.04] vs 0.77[95%CI 0.43-1.27] event/graft-y, p=ns).

Conclusions: Our comparative study suggests that Qa is the best predictor of graft patency & Qa surveillance using a Qa<1000 ml/min threshold allows for appropriate and timely stenosis repair & may contain the risk of thrombosis.

TH-PO851

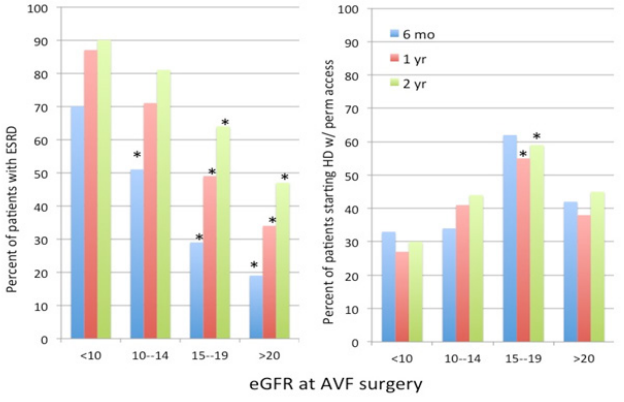
The Impact of eGFR at Pre-HD Access Surgery on the Likelihood of Starting Hemodialysis with a Mature Vascular Access

Alian Albalas, Timmy C. Lee, Michael Allon. *Nephrology Dept, UAB, Birmingham, AL.*

Background: The optimal timing of pre-dialysis vascular access surgery is uncertain. If the access is placed too late, it may not be ready for use; if it's placed too early, it may not be needed. The optimal timing may differ for AVF vs AVG. We evaluated the association of eGFR at access placement with (1) likelihood of starting HD, and (2) likelihood of a mature access at HD initiation.

Methods: We retrospectively queried a prospective computerized access database to identify patients with pre-HD access surgery (301 AVF and 64 AVG placed between 2006-12) with an eGFR recorded on the surgery date. Patients were stratified into 4 eGFR groups (<10; 10-14; 15-19; >20 ml/min). For each patient we determined:(1) whether dialysis was initiated within 2 years, and (2)whether the permanent access was used on the first HD session.

Results: Overall, 208 (or 69%) of pts with pre-HD AVF surgery initiated HD within 2 years, but the proportion varied by eGFR at surgery (90, 81, 64, and 47% for eGFR <10, 10-14, 15-19, and >20 ml/min).



Among the 208 pts with pre-HD AVF who started HD, 47% used the AVF on the first HD session, but the proportion varied by eGFR (30, 44, 59 and 45% for eGFR <10, 10-14, 15-19, and >20 ml/min). Among pts with pre-HD AVG surgery, HD was initiated within 6 months in 90, 62, and 50% for eGFR <10, 10-14, and 15-19 ml/min. The AVG was used for the HD session in 78, 89, and 88% of pts with eGFR of <10, 10-14, and 15-19 ml/min.

Conclusions: There are tradeoffs in the timing of pre-HD AVF surgery. A higher eGFR is associated with a lower likelihood of initiating HD in 2 years, but a higher likelihood that the AVF will be used on the first HD session. The optimal balance is achieved at an eGFR of 15-19 ml/min. In contrast, the optimal timing for pre-HD AVG surgery is an eGFR of 10-14 ml/min. Late placement of an AVG may be a catheter-sparing strategy.[figure]

TH-PO852

Economic Burden to Dialysis Providers of Central Venous Catheter (CVC)-Related Blood Stream Infections (BSI) and Occlusions Among Incident Hemodialysis (HD) Patients

Steven M. Brunelli,[1] Wendy Turenne,[1] Scott Sibbel,[1] John Alan Laich,[1] Antony E. Pfaffle.[2] *[1]DaVita Clinical Research, Minneapolis, MN; [2]CorMedix Inc, Bedminster, NJ.*

Background: Complications of CVCs may have economic consequences for dialysis providers derived from opportunity costs for missed dialysis treatments and increased use of bundled medications. We sought to quantify this financial burden among incident patients at a large dialysis organization (LDO).

Methods: We considered patients who began HD via a CVC between Jan 2013 and Dec 2014. In parallel analyses, patients who developed BSI (N=3269) or occlusion (N=676) during the first 6 months of dialysis were matched to control CVC-HD patients who did not. Missed HD treatment rates and medication utilization were considered from date of BSI/occlusion (or corresponding date for controls) for 180 days or until censoring for death, modality change or loss to follow up. Costs were derived using payor-specific remuneration rates (missed treatments), LDO acquisition costs (IV iron, ESA) and average wholesale prices (antibiotics, thrombolytics). Differences were estimated using linear mixed models including fixed effects for exposure status and month, adjusted for covariates that were imbalanced at baseline.

Results: CVC-related BSI was associated with significantly greater ESA utilization (59,339 vs 49,515 U/month, cases vs controls), IV antibiotic use (41.8% vs 6.0%) and missed HD treatment rate (1.95 vs 1.36 missed treatments/patient-month). This translated to a mean incremental cost of +$397 per patient per month. CVC occlusion was associated with increased thrombolytic use (10.9% vs 4.2%) but no significant difference in costs.

Conclusions: CVC-related BSI is a potent cost driver for dialysis providers with incremental costs of ~$400/month over a 6-month time horizon. No appreciable economic consequences of CVC occlusion were observed.

TH-PO853

Obesity Related Decrease in Intraoperative Blood Flow Is Associated with Maturation Failure of Radiocephalic Arteriovenous Fistula

Jwa-kyung Kim,[1] Sun Ryoung Choi.[2] *[1]Internal Medicine, Dept of Internal Medicine, Kidney Research Inst, Anyang, Korea; [2]Internal Medicine, Shamyook Medical Center, Seoul, Korea.*

Background: Successful arteriovenous fistula (AVF) maturation is often challenging in obese patients. Optimal initial intraoperative blood flow (IOBF) is essential for adequate AVF maturation. This study was conducted to elucidate the effect of obesity on IOBF and radiocephalic AVF maturation.

Methods: Patients who newly created radiocephalic AVF were included (n=252). Obesity was defined as a baseline BMI³25 kg/m², and primary maturation failure was defined as the failure to use AVF successfully by 3 months after its creation. IOBF was measured immediately after construction of AVF using a VeriQTM system.

Results: The mean BMI was 24.1±3.9 kg/m2, and the prevalence of obesity was 31.3%. Particularly, 8.3% (21 patients) were BMI ≥ 30 kg/m2. Primary maturation failure occurred in 100 (39.7%) patients and an IOBF< 190 mL/min was closely associated with the risk of maturation failure (relative risk,3.05; 95% CI,1.52–6.11). Compared to non-obese patients, obese subjects had a significantly higher prevalence of diabetes and elevated hs-CRP levels, whereas diameters of vessels were similar. When the patients were further divided into 3 groups as the BMI <25, 25-29.9, and >30 kg/m2, patients in higher BMI group showed significantly lower IOBF and higher maturation failure rate. According to multivariate analysis, the statistically significant variables that determined maturation failure were obesity, previous vascular disease, increased hs-CRP levels, and IOBF < 190 mL/min.

Conclusions: Obese patients had a significantly lower IOBF, and both obesity and low IOBF contributed to the primary maturation failure of AVF. Obesity-associated inflammation and atherosclerosis might play roles in this association.

TH-PO854

The Impact of Vascular Access on Hemodialysis Patient Survival and Risk Analysis

Ping chin Lai,[1] Le mei Yeh,[1] Yueh hsia Chiu,[2] Ling yin Chiu.[1] *[1]Renal Dept, Chang Gung Memorial Hospital, Taoyuan, Taiwan; [2]Health Care Management, Chang Gung Univ, Taoyuan, Taiwan.*

Background: Hemodialysis is the most common dialysis modality worldwide. However, the impact of different types of vascular access on hemodialysis patient survival has not been investigated in a large scale study. Therefore, we retrospectively reviewed the survival of hemodialysis patients in our center and analyzed the impact of vascular access on their survival. Other potential risk factors were also studied.

Methods: From 2001 to 2010, patients, who aged more than 40 years old and received regular hemodialysis in our center for at least 3 months, were included into this study. A total 916 patients were enrolled. The mean followed up interval were 4.4± 2.5 years. Among them, 51.1% were male, while 48.9% were female. These patients were divided into three groups according to their vascular access. Group A: patients used either native arteriovenous fistula or arteriovenous graft at the all time and dialysis catheter had never been used during the whole study period. Group B: patients used either native arteriovenous fistula or arteriovenous graft as their vascular access most of the time but they had used dialysis catheter at least once during study period. Group C: patients used dialysis catheter as their vascular access and arterioveonus shunt had never been established during the study period. Other survival associated factors were analyzed by using univariate and multivariate factor analysis.

Results: The results showed that group C patients had significantly worst survival rate (P<0.0001). The group B patients also had significantly worse survival rate when compare

with group A patients (P<0.0001). The hazard ratio was 1.71 (1.31-2.24) for group B and 3.56 (2.08-6.08) for group C when compared to group A patients. Multivariate analysis showed that the associated risk factors for patient survival were male sex, diabetes mellitus, low albumin, high hsCRP, and abnormal AST level.

Conclusions: The use of dialysis catheter imposed high risk for patient mortality on top of other associated risk factors. Early establishment of vascular access can eliminate this risk factor and improve patient outcome.

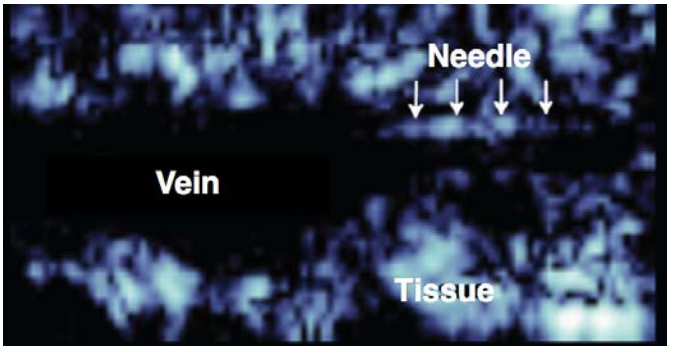
TH-PO855

Early Experience with a Novel Device for Ultrasound-Guided Management and Cannulation of Hemodialysis Vascular Access William D. Paulson,[1] Deborah J. Brouwer-Maier,[2] Lillian A. Pryor,[2] John Jason White,[1] Laura L. Mulloy,[1] Lu Y. Huber,[1] Matthew J. Diamond.[1] *[1]Charlie Norwood VAMC & Georgia Regents Univ, Augusta, GA; [2]Fresenius Medical Care, Waltham, MA.*

Background: The vascular access continues to be the Achilles Heel of dialysis. Methods that facilitate easier management and cannulation of accesses are needed. We describe early experience with a novel ultrasound device.

Methods: The Sonic Window (Analogic Corp, Peabody, MA, USA) is designed to assist management of vessels in a variety of contexts. It differs from conventional ultrasound in that it provides a coronal view of vessels that yields determination of characteristics such as depth and luminal diameter, and assists in cannulation for dialysis. We have initiated a program in 4 FMC dialysis units which is designed to identify its role and limitations.

Results: Two experts in the use of the Sonic Window have trained dialysis staff in the 4 FMC units. Staff have successfully cannulated 33 AV fistulas and synthetic grafts. Set up and use of the device generally adds an extra 1-3 minutes to cannulation time. Staff are able to easily visualize advancement of dialysis needles into the vessel lumen (figure).



We plan to evaluate the following potential uses of the device: 1. Assessing fistula maturation by measuring increase in luminal diameter over time; 2. Evaluating accesses that are difficult to cannulate; 3. Evaluating accesses with low blood flow, or high negative arterial or positive venous dialysis pressure; 4. Identifying alternative access sites for cannulation. Possible disadvantages to be addressed: potential staff & patient reluctance to accept new technology and additional cannulation time, to be assessed in surveys.

Conclusions: Our early experience supports the concept that Sonic Window is a significant advance in managing and cannulating accesses in both routine and difficult situations.

TH-PO856

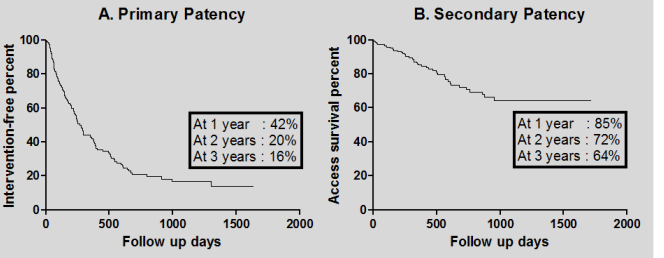
Modifiable Risk Factors Affecting the Outcome Hemodialysis Graft Jee eun Park, Jin Hae Kim, Subin Hwang, Do Hee Kim, Hye Ryoun Jang, Jung eun Lee, Wooseong Huh, Yoon-Goo Kim, Ha Young Oh, Dae Joong Kim. *Nephrology Div, Dept of Medicine, Samsung Medical Center, Sungkyunkwan Univ School of Medicine, Seoul, Korea.*

Background: Arterio-venous graft (AVG) for hemodialysis has poorer outcome than arterio-venous fistula (AVF) with its frequent stenosis and thrombosis. We investigated modifiable risk factors affecting the outcome of AVG.

Methods: A single-center cohort of 254 patients (pts) receiving AVG for hemodialysis access from Sep 2010 to Oct 2014 were included. Demographics, laboratory data, comorbidities, and medications were collected from the medical records. Surgical factors related to AVG operation including the type and diameter of connected vessels, graft site, and type of operation (elective or emergent) were also recorded. End points was the interval from initial access formation to any intervention intended to restore patency (primary patency, days) and the total access survival duration (secondary patency, days).

Results: Data of 225 pts were analyzed. During the follow-up period, 139 (62%) pts received intervention and 45 (20%) pts underwent permanent failure. Survival analyses using Kaplan-Meier method was shown in the figure. In multivariate analysis, primary patency duration was associated with RAS inhibitor (hazard ratio [HR] 1.67, 95% confidence interval [CI] 1.13-2.46), and upper arm graft (HR 0.62, 95% CI 0.40-0.94). Secondary patency duration was associated with serum albumin level (HR 0.28, 95% CI 0.13-0.61), diastolic blood pressure (BP) (HR 0.93, 95% CI 0.89-0.98) and warfarin (HR 5.80, 95% CI 2.04-16.46).

Figure. Survival Curve of AVG



Conclusions: Patients' nutritional status reflected by serum albumin levels and diastolic BP could be modified for favorable outcome of AVG.

TH-PO857

Effects of Diastolic Blood Pressure on the Patency of Brescia-Cimino Arteriovenous Fistula for Hemodialysis Access Yan Yan. *Nephrology Dept, The First Affiliated Hospital of Nanchang Univ, Nan Chang, China.*

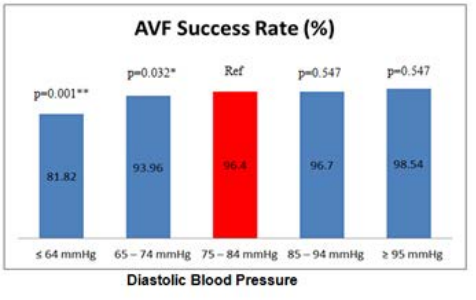
Background: To evaluate the relationship of diastolic blood pressure (DBP) with the patency of the Brescia-Cimino arteriovenous fistula (AVF), and to determine DBP levels that predict the success of this procedure.

Methods: Data was collected from 986 patients with end-stage kidney disease (ESKD) who had Brescia-Cimino AVFs from March 2007 to December 2013. DBP was measured twice a day, at 6 AM and 5 PM, starting 3 days before surgery until 3 days post-procedure. A receiver operating characteristic (ROC) curve was constructed to determine the cutoff value of pre-operative DBP, which predicts an increased chance of AVF patency during the first 7 days after surgery.

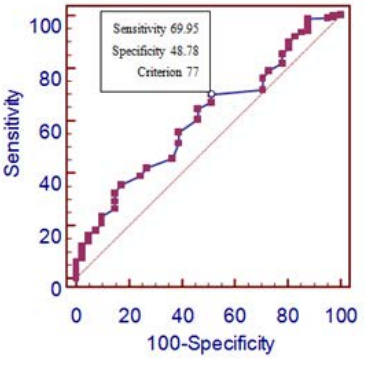
Results: Only41 out of the 986 patients enrolled in this study developed AVF failure within the first 7 days following surgery, resulting in a 95.8% success rate in the procedure. This rate was increased by pre-operative DBP levels ($P = 0.007$). When the cutoff value was 77 mmHg, ROC analysis showed DBP was a pre-operative indicator for predicting AVF patency in the early postoperative period ($P = 0.012$; AUC = 0.607) with a sensitivity of 69.5% and specificity of 48.8%.

Figure

A



B



A: AVF early success rate by preoperative DBP level. **B.** ROC curve of the average diastolic blood pressure level prior to AVF construction. AUC was 0.607 (95% CI 0.576-0.638, $P = 0.012$) when a cutoff value of average DBP was 77 mmHg. * $P < 0.05$, ** $P < 0.01$, *** $P < 0.001$. Ref is comparison object.

Conclusions: A DBP > 77 mmHg prior to surgery may be considered as a key prognostic indicator of the Brescia-Cimino procedure.

TH-PO858

Vascular Access Outcomes following Peritoneal Dialysis to Hemodialysis Transition Timmy C. Lee,[1] Mae Thamer,[2] Qian Zhang,[2] Yi Zhang,[2] Michael Allon.[1] *[1]Univ of Alabama at Birmingham; [2]Medical Technology and Practice Patterns Inst.*

Background: Few studies have evaluated vascular access (VA) use following transition from PD to HD. Our goal was to examine short-term VA utilization following PD to HD transition.

Methods: Using USRDS and Medicare claims data from July 2010-December 2012, we identified 3,565 incident Medicare-insured PD patients who were ³18yrs and initiated dialysis between July 2010-June 2011. Patients had at least one dialysis claim within 90 days of dialysis initiation and were followed for 1 year until one of the following events: switched to HD, kidney transplant, death, or end of follow-up. We used Cox-regression models to examine the association of risk factors and switching to HD, with death and transplantation used as competing events.

Results: 991 (27.8%) patients switched from PD to HD during the 1 year follow-up. Of these, 46% switched to HD within 90 days of dialysis initiation and 66% by 6 months. The median switch time was 114 days (IQR: 32-226). Patients with cardiovascular disease (Adjusted Hazard Ratio (HR) 1.25, 95% CI 1.10-1.43), COPD (HR 1.29; 95% CI 1.01-1.66), and without pre-dialysis nephrology care (HR 1.46; 95% CI 1.21-1.76 versus those with >12 months nephrologist care) were more likely to switch from PD to HD. After switching from PD to HD, 89% used a catheter, 6.6% AVF, and 1.9% AVG. 90 and 180 days after switching to HD, 71% and 50% of patients, respectively, who remained on HD still used a catheter as their VA.

Type of VA	1st Switch	90 Days After 1st Switch*	180 Days After 1st Switch**
N pts Remaining on Hemodialysis	991	709	653
Catheter Only	868 (87.6)	476 (67.1)	299 (45.8)
Catheter with other VA	9 (0.9)	28 (3.9)	27 (4.1)
AVF only	65 (6.6)	130 (18.3)	224 (34.3)
AVG only	19 (1.9)	50 (7.1)	67 (10.3)
Missing	30 (3.0)	25 (3.5)	36 (5.5)

*Transplantation:41; death:127; switched back to PD:114
**Transplantation:50; death:160; switched back to PD:128

Conclusions: The majority of patients transitioning from PD to HD initiate HD with a catheter. 50% dialyze with a catheter at 6 months. This highlights the need for VA planning in patients with failed PD to ensure timely transition to permanent VA.

Funding: Private Foundation Support

TH-PO859

Temporal Trends in Pre-Hemodialysis Vascular Access Creation in Elderly Patients with CKD Timmy C. Lee,[1] Mae Thamer,[2] Qian Zhang,[2] Yi Zhang,[2] Michael Allon.[1] *[1]Univ of Alabama at Birmingham; [2]Medical Technology and Practice Patterns Inst.*

Background: Optimal timing of pre-dialysis vascular access (VA) creation remains unclear. Elderly CKD patients with high co-morbidity are more likely to die before starting HD, so deferring VA creation may be reasonable. We assessed whether nephrologists have started selecting healthier elderly patients for pre-HD VA surgery.

Methods: Using Medicare claims data we identified 3418 elderly patients (aged ≥70 years) with CKD undergoing pre-HD VA creation in 2004 to 2009, and divided them into 3 time cohorts (2004-05, 2006-07 and 2008-09). For each temporal cohort, we assessed the likelihood of initiating dialysis during 2 years of follow-up after VA surgery. We collected data on cardiovascular co-morbidities and cardiovascular events prior to VA surgery and after dialysis initiation to determine if there were significant changes in these variables during the 3 time cohorts.

Results: During the 3 consecutive time periods, the proportion of patients dying before initiating HD decreased by 28%, the proportion surviving without HD increased by 31%, whereas the proportion initiating HD remained constant (p<0.005).

Year of VA Insertion	N of Patients	Initiated HD within 2 Years (%)	Died before HD (%)	Survived without HD(%)
2004-2005	1178	68.0	17.5	14.5
2006-2007	1222	66.0	14.8	19.2
2008-2009	1018	68.5	12.6	19.0

Concomitantly, during the 3 consecutive time periods there was a progressive decrease in patients with history of PVD (66.5 to 59.7%, p<0.005), CHF (47.0 to 35.8%, p<0.005), and prior MI (6.5 to 3.3%, p<0.001). Among patients who initiated dialysis, there was a progressive decrease in the proportion of patients with a CHF (38.8 to 26.0%, p<0.001) or MI (5.4 to 2.6%, p<0.01) event in the first year after dialysis.

Conclusions: From 2004-2009, there has been a progressive decrease in cardiovascular co-morbidities in elderly CKD patients undergoing pre-HD VA surgery, and this has been associated with a decrease in patients dying before HD and in patients with cardiovascular events after starting HD. Clinicians are becoming more selective in pre-HD placement of VA in this patient population.

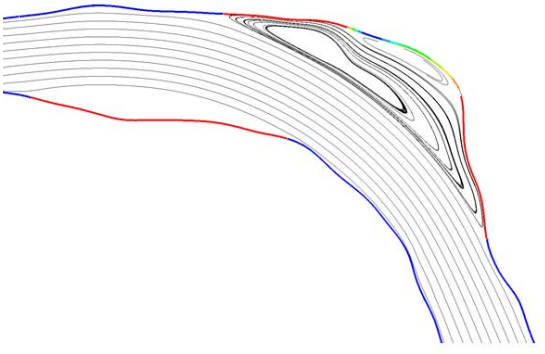
Hemodynamic Changes in Arteriovenous Fistula During Dialysis Mary S. Hammes,[1] Vikash Kumar Sinha,[1] Tom Blicharski,[1] Michael Boghosian,[2] Jane E. Hines,[1] Sydeaka Watson,[3] Kevin Cassel,[2] S.M. Javid Mahmoudzadeh A.[2] *[1]Medicine/Nephrology, Univ of Chicago; [2]Dept of Mechanical, Materials and Aerospace Engineering, Illinois Insitute of Technology; [3]Dept of Public Health Sciences, Univ of Chicago.*

Background: Optimal blood flow velocity (BFV) in arteriovenous fistulas (AVF) to prevent neointimal hyperplasia is yet to be determined. We have hypothesized that changes in BFV and diameter in a brachiocephalic fistula (BCF) are affected by fistula maturation and blood flow induced during hemodialysis.

Methods: Eight subjects with primary BCF participated. Doppler BFV was measured pre-dialysis and during dialysis at 250, 350 and 450 mL/min blood flow for up to 14 months. BFV was measured in the straight portion of the cephalic vein 10 cm proximal to the cephalic arch. The relationship between BFV and diameter was examined using a linear mixed effects model. Computational modeling using venography was performed at 3 and 12 months.

Results: The change in measured diameter and BFV showed an inverse relationship with a significant association at baseline (p<0.0074) and 350 mL/min dialysis blood flow (p<0.0092). The computational model of the cephalic arch in one subject showed a 4 fold increase in Reynolds number with a dramatic recirculation region shown by a swirling eddy at the upper elbow of the arch.



This region, present at baseline and 3 months is much deeper at 12 months and with increased dialysis blood flow rate of 450 mL/min.

Conclusions: In patients with BCF, as the AVF matures and with increased dialysis blood flow, an increase in diameter of the cephalic vein with subsequent decrease in BFV is observed. Increased blood flow during hemodialysis evokes recirculation eddy's which may result in endothelial damage and subsequent intimal hyperplasia unless the arterilized vein is able to adapt and remodel to the pressures and flows that are generated during hemodialysis.

TH-PO861

Arteriovenous Fistula (AVF) Maturation Among Hemodialysis (HD) Patients: Results from the USRDS Rajiv Saran,[1] Sarah Bell,[1] Brett W. Plattner,[1] Douglas E. Schaubel,[1] Sudipta Dasmunshi,[1] Purna Mukhopadhyay,[2] Jeffrey Pearson,[2] Ronald L. Pisoni,[2] Kenneth J. Woodside.[1] *[1]Univ of Michigan; [2]Arbor Research Collaborative for Health.*

Background: AVF are considered the gold standard for HD vascular access, but require time to mature and may not adequately develop, resulting in prolonged central venous catheter (CVC) use. We describe AVF survival from placement until time to first use for prevalent HD patients in the US.

Methods: We examined HD patients with new AVF placements during 2013 using Medicare claims. Failure of maturation was identified by non-use following placement using CROWNWeb (CW) where patient access use is reported monthly by the facility. Patients were followed until end 2014. We assessed the relationship between patient characteristics and time-to-first-use of AVF with a Cox model.

Results: In 2013, 51,561 AVF were placed among 42,160 HD patients followed through 2014. No subsequent evidence of use occurred in 44.3% of the placements. Of successfully used AVF, median time to first use was 113 days. Older age groups were incrementally associated with lower probability of using AVF. Pts in the 0-21 and 22-44yr groups (HRs=1.23 [95% CI=1.06-1.44], and 1.06 [1.03-1.11], respectively), were more likely to use AVFs compared to the 45-64yr group (ref.). Sex (Female; Fig. 1a), race (e.g., Black; Fig. 1b), comorbidity (cardiovascular disease, peripheral artery disease, diabetes, needing assistance or institutionalized status), vintage <1year, CVC and/or AV Graft use at incidence, were also associated with lower probability of AVF use.

Conclusions: We have characterized AVF maturation in a national US sample and identified important associations with multiple patient-level factors. Research is urgently required into the importance of patient, region and practice factors that could improve AVF placement and maturation, decrease CVC use, to improve patient outcomes and experience.

Elderly Age Does Not Affect Long-Term Survival of Non-Transposed and Transposed Upper Extremity Arteriovenous Fistulae Neville R. Dossabhoy,[1,2] Peter Van,[1,2] Renu Gupta,[1,2] Clifton Frilot.[2] *[1]Nephrology, Veterans Affairs Medical Center, Shreveport, LA; [2]LSU Health, Shreveport, LA.*

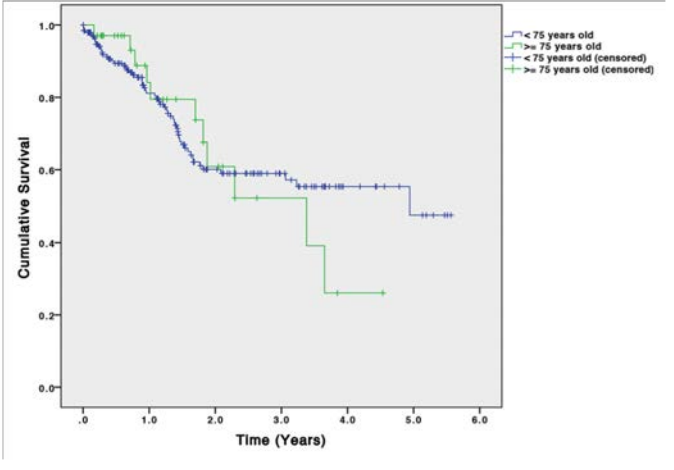
Background: The Fistula First initiative has successfully increased the placement of arteriovenous fistulae (AVF) for vascular access. Some authors have suggested that there is a higher failure rate of AVFs in elderly patients. The purpose of this study was to determine if elderly age influences the overall survival of transposed brachial-basilic fistulae (TBBF) and non-transposed AVFs (NT) placed in the upper extremity (UE).

Methods: Our prospective, computerized clinical database was queried retrospectively to identify the survival outcomes of **all** upper extremity (UE) fistulae placed in CKD and ESRD patients over a 6-year period at our VA hospital. All fistulae were placed by a single surgeon, hence eliminating inter-operator variability. Patient demographics and comorbid conditions were noted from the electronic record. The primary end point was permanent failure of the access. Kaplan Meier survival analysis was performed using SPSS.

Results: 230 UE fistulae were placed, which were categorized into two groups by patient age at the time of AVF placement: < 75 years and 75 years and older. The table shows the distribution by access type and age.

Age	Type of AVF	TOTAL NUMBER OF AVFs	TOTAL NUMBER OF FAILED AVFs
< 75 years	NT	124	40
< 75 years	TBBF	72	19
≥ 75 years	NT	15	6
≥ 75 years	TBBF	19	5

The figure shows that there was no difference in the Kaplan-Meier survival curves for the two age groups when NT and TBBF were analyzed collectively (P=0.833). Furthermore, there was no statistical difference between the survival curves when each group above was analyzed separately (P=0.996).



Conclusions: In conclusion, overall survival was similar for TBBF and NT AVF in our study and was not influenced by elderly age. This finding is contrary to popular opinion and some other reports.

TH-PO863

Peripherally Inserted Central Catheter (PICC) Placement in Hemodialysis Patients with Central Venous Catheters (CVC) Rita L. McGill, Robin Ruthazer, Klemens B. Meyer, Dana Miskulin, Daniel E. Weiner. *Tufts Medical Center, Boston, MA.*

Background: PICC insertion threatens opportunities for AVF creation and may reduce achievement of AVF. Accordingly, we evaluated the incidence of PICC placement in ESRD patients after starting dialysis and in the 2 years prior to starting dialysis, and recognizing that AVF rates are lower in women, whether PICC rates differed by sex.

Methods: After restricting to patients with pre-dialysis Medicare claims, we used CPT codes to ascertain all PICCs placed during the 2 years before HD initiation and up to 12/31/2012 in the subset of adult HD patients entering USRDS in 2010 or 2011 with CVC as sole vascular access. Accounting for censoring due to death and ESRD modality treatment change, and using Poisson regression to adjust for age, race, BMI, diabetes and peripheral vascular disease, we calculated sex-based incidence ratios (IRR) using PICC per 100,000 patient months.

Results: PICC were placed in 2437 (14.6%) of women and 2260 (12.2%) of men.

	Women	Men
N	16686	18494
# PICC placed during the 2 years prior to HD	1983	1469
# PICC placed during first year of HD	1438	1330
# PICC placed after first year of HD	567	532
# PICC TOTAL	3988	3331

Compared to men, crude and adjusted IRR of PICC for female sex were 1.35 [1.28-1.41] and 1.34 [1.27-1.41]. Multiple PICC (range= 2 to 14) were placed in 648/2260 (29%) men and 803/2437 (33%) women who had any PICC.

Conclusions: Despite persuasive indications for PICC avoidance, people dialyzing via CVC frequently receive one or more PICC before and even after starting dialysis. The PICC rate was 35% higher in women, a difference not attenuated by adjustment for demographic and clinical factors. More frequent PICC placement may explain some of the lower fistula rate in women. Eliminating frequent PICC placements in patients with CVC may improve achievement of AVF.

Arteriovenous Fistula Outcomes in an Elderly UK Population Agnes Masengu,[1,2] Jennifer B. Hanko,[1] Alexander P. Maxwell.[1,2] *[1]Regional Nephrology Unit, Belfast City Hospital, Belfast, County Antrim, United Kingdom; [2]Nephrology Research Group, Queen's Univ Belfast, Belfast, County Antrim, United Kingdom.*

Background: The merit of placing arteriovenous fistulas (AVFs) in the elderly is debated in the literature. We sought to investigate AVF outcomes in the population aged ≥ 65 years in our region.

Methods: The Northern Ireland Vascular Access Database incorporates vascular access data on patients with chronic kidney disease stage 4 and 5. The database includes information on all patients ≥ 65 years who had an AVF created during January 2009-December 2014 and had a functional outcome by the 1st March 2015. Functional AVF patency was defined as sustained 2-needle use on haemodialysis for at least 6 sessions. Failure to mature (FTM) was defined by either by clinical examination or failure to sustain 6 sessions of 2-needle dialysis.

Results: During the study period 344 patients ≥ 65 years had an AVF created. One AVF failed immediately, three AVFs were ligated due to steal, 56 patients had not started dialysis by the study end-point and records were incomplete for 30 patients. A total of 254 patients (98% White) remained included for functional AVF patency analysis. Table 1: Clinical Characteristics of Patients ≥ 65 years with AVF Patency Outcomes (n=254)

Clinical Characteristics	Number (%)
Age (mean, median, range)	74, 74, 65-92
Male gender	170 (67)
Diabetes Peripheral vascular disease Ischamic heart disease	102 (40) 30 (12) 102 (40)
Lower arm AVF	134 (53)

A total of 150 AVFs (59%)achieved functional patency and 105 (41%)FTM. Binary logistic regression revealed that a lower arm AVF in this elderly population was associated with FTM (p < 0.001, 0R 0.23, CI 0.13- 0.40).

Conclusions: Given their shorter life-expectancy, the goal of vascular access creation in the elderly should be to create one functional AVF using the best vessels identified. The greater risk of FTM with lower arm AVFs may mean preferential creation of an upper arm AVF if these vessels are better on clinical and ultrasound assessment.

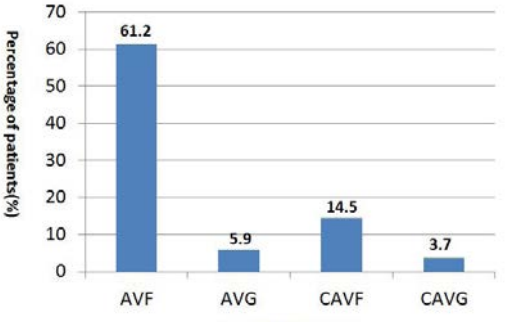
TH-PO865

Type of Vascular Access and Mortality in Japan Toshikazu Ozeki,[1] Shun Minatoguchi,[1] Yukako Ohyama,[1] Hideaki Shimizu,[1] Yoshiro Fujita,[1] Daijo Inaguma.[2] *[1]Nephrology, Chubu Rosai Hospital, Nagoya, Japan; [2]Nephrology, Nagoya Daini Red Cross Hospital, Nagoya, Japan.*

Background: The National Kidney Foundation (NKF) Kidney Disease Outcome Quality Initiative (KDOQI) guidelines have recommended the use of AVFs at dialysis initiation of dialysis. However, it has been reported that the dialysis environment has been significantly different between Japan and the United States, and there are few people who continue hemodialysis with CVCs in Japan. The aim of this study is to examine the association between type of vascular access at dialysis initiation and mortality in Japan.

Methods: This study is retrospective, multicenter, cohort study which data was collected by "Aichi Cohort study of Prognosis in Patients" (AICOPP) newly initiated into dialysis. 18 tertiary care centers in Japan participating in the "AICOPP". This study enrolled 1,525 patients who started maintenance dialysis between October 1, 2011 and March 31, 2014. After exclusion of 129 patients who started peritoneal dialysis or without data, 1329 (87.1%) patients were enrolled. Cox regression was used to determine the effect of access type on total mortality. Type of vascular access was divided into four categories: AVFs, AVGs, CVCs changed to AVF during the course (CAVF), CVCs changed to AVG during the course (CAVG).

Results: This research showed prevalence of type of blood access in Japan.



Under multivariate analysis, CAVGs had a higher risk of mortality compared with AVFs group [hazard ratio (HR): 2.408, p value: 0.003]. No significant differences were observed compared AVFs with AVGs [hazard ratio (HR): 1.466, p value: 0.219] and CAVFs [hazard ratio (HR): 1.223, p value: 0.389].

Conclusions: As it is known, high AVF use was seen in japan. Compared with AVFs, using CVCs changed to AVG during the course is associated with higher risks of mortality.

TH-PO866

Comparison of Arteriovenous Fistula and Arteriovenous Graft on Patient Survival and Access Patency in Non-Elderly versus Elderly Population Hoon suk Park, Min Seok Choi, Woo Jeong Kim, Sung jun Kim, Hyung Wook Kim, Cheol Whee Park, Bum soon Choi, Byung ha Chung, Chul Woo Yang, Dong-Chan Jin. *Div of Nephrology, Dept of Internal Medicine, College of Medicine, The Catholic Univ, Korea.*

Background: Arteriovenous fistula (AVF) is generally known to be the ideal option as a vascular access. However, this consensus can be challenging in elderly population.

Methods: From August in 2008 to April in 2014, 1452 adult incident hemodialysis patients were included from Clinical Research Center registry for ESRD prospective cohort, from 31 centers in the South Korea.

Results: In the whole population, AVF vs. AVG use was associated with the better patient survival only in male ($p < 0.001$) and DM ($p = 0.004$) patients. Multivariate Cox regression analysis showed AVG (vs. AVF; odds ratio [OR] 2.308, 95% confidence interval [CI]: 1.013–4.829; $p = 0.026$), catheter (vs. AVF; OR 10.658, 95% CI: 5.379–21.119; $p < 0.001$) and age (OR 1.035, 95% CI: 1.012–1.058; $p = 0.003$) were significantly associated with poor patient survival. In the elderly patients (≥ 65 years old), the survival benefit by AVF use also existed in only male ($p < 0.001$) and DM ($p = 0.009$) patients, but AVF compared with AVG showed better access patency only in female ($p < 0.001$) and DM ($p = 0.01$) patients. Multivariate Cox regression analysis in the elderly population showed AVG (vs. AVF; OR 3.158, 95% CI: 1.080–9.238; $p = 0.036$), male (vs. female; OR 3.941, 95% CI: 1.031–15.066; $p = 0.045$) and the presence of peripheral vessel disease (OR 4.659, 95% CI: 1.389–15.626; $p = 0.013$) were significantly associated with poor patient survival. AVF showed the survival benefit compared with AVG in the even septuagenarian patients (≥ 70 years old), which is contrast to the previous reports about western population ($p = 0.01$). However, the superior access patency of AVF in comparison with AVG began to decrease from septuagenarian population.

Conclusions: In the Korean septuagenarian patients, AVF placement can be considered because of its survival benefit. However, it seems appropriate that AVG is preferentially placed in the septuagenarian patients with multiple comorbidities.

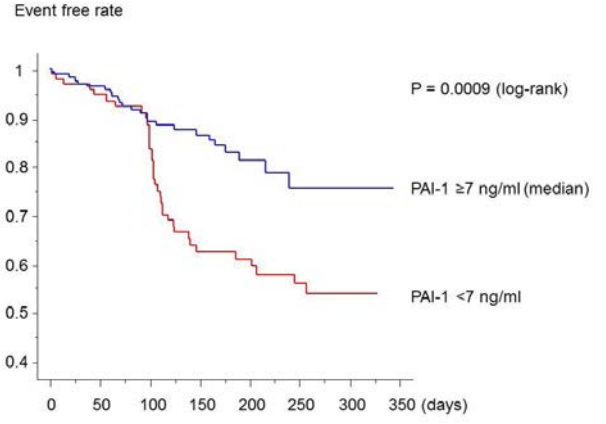
TH-PO867

Abnormality of Fibrinolysis as well as Coagulation Were Associated with Second Patency Rates of Vascular Access in Hemodialyzed Patients Yukiko Hasuike,[1] Naoto Kakita,[2] Takeshi Nakanishi.[1] *[1]Div of Kidney and Dialysis, Dept of Internal Medicine, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan; [2]Vascular Access Center, Tanaka-Kitanoda, Japan.*

Background: Vascular access (VA) is essential for the HD patients. However, VA is often occluded even after the percutaneous-transluminal angioplasty (PTA). There is increasing evidence indicating the importance of the fibrinolysis system (i.e., plasminogen activator inhibitor-1 (PAI–1) level) in the progression of vascular disease. We intended to clarify whether coagulation and fibrinolysis might be associated with VA failure after PTA.

Methods: Blood samples were taken from 262 HD patients at the PTA. Thrombin/anti-thrombin (TAT) as a marker of coagulation, PAI–1, FDP, D-dimer as markers of fibrinolysis system, and laboratory data were measured. Blood flow volume of VA was evaluated by Doppler ultrasonography before PTA. The end point was the re-vascularization or re-operation of VA during the observational period after PTA. The results were analyzed using univariate (Kaplan-Meier methods) and Cox regression analyses.

Results: Age of patients was 70.6±9.7 years, and 121 patients (46.2%) have native arteriovenous fistula (AVF). During follow-up period, re-PTA was performed in 33 patients and re-operation in 28 patients. Native AVF, higher blood flow volume (≥500 ml/min), lower TAT (<3 ng/ml), and higher PAI–1 (≥7 ng/ml) were associated with good patency rates. The Kaplan–Meier analysis showed both higher TAT ($p=0.0026$) and lower PAI–1 (Figure 1) were significantly associated with VA failure. Cox regression analysis revealed that higher TAT (HR 2.140, 95%CI 1.288-3.556, $p=0.0033$) and lower PAI–1 (HR 2.322, 95%CI 1.390-3.880, $p=0.0013$) were related to VA failure event.



Conclusions: The present research indicates that VA failure after PTA might be associated with abnormality in the fibrinolysis system as well as activated coagulation.

TH-PO868

Early Hemodynamic and Geometric Changes in Brachiocephalic Fistula Access Mary S. Hammes,[1] Kevin Cassel,[2] Michael Boghosian,[2] Jane E. Hines,[1] Sydeaka Watson,[3] S.M. Javid Mahmoudzadeh A.[2] *[1]Medicine/Nephrology, Univ of Chicago; [2]Dept of Mechanical, Materials and Aerospace Engineering, Illinois Inst of Technology; [3]Dept of Public Health Sciences, Biostatistics Laboratory, Univ of Chicago.*

Background: An arteriovenous fistula is the optimal vascular access for hemodialysis. A brachiocephalic fistula (BCF) is often placed in the upper arm to provide effective dialysis, but unfortunately cephalic arch stenosis (CAS) commonly develops leading to access failure. We hypothesized that a contribution to fistula failure is low wall shear stress (WSS) resulting from changes that occur in the cephalic arch because of alteration in post-fistula creation hemodynamics.

Methods: Twenty-two subjects with advanced renal failure had BCF placed. The following procedures were performed at mapping (pre-operative) and fistula maturation (8-32 weeks post-operative): venogram, Doppler to measure venous blood flow velocity, and whole blood viscosity. Geometric and computational modeling was performed to determine WSS and other parameters that represent the curve of the cephalic arch. The relationship between parameters was examined using univariate analysis and linear regression.

Results: Blood flow velocity, venous diameter, and regions of low WSS were shown to increase in subjects by the time of maturation ($p < 0.05$). The percent of low WSS was linearly related to an increase in blood flow velocity ($p = 0.01$). Although the mean global measures in curvature and asymmetry remained unchanged from baseline to time to maturation, the change fell for shorter time to maturation and rose for longer time to maturation ($r = 0.52$; $p = 0.01$), crossing the regression line at 15–16 weeks.

Conclusions: The maturation process of an AVF introduces geometric effects in arch curvature and asymmetry. Hemodynamic changes increase the percentage of low WSS regions within the cephalic arch by the time of fistula maturation. Low WSS may contribute to endothelial cell damage, subsequent intimal hyperplasia, and resultant CAS. If this hypothesis remains tenable with further studies, ways of protecting the arch through control of flow during maturation of the fistula, or alternatives to the BCF, may need to be developed.

TH-PO869

Dilator-Assisted Banding and Beyond: Proposing an Algorithm for Managing Dialysis Access-Associated Steal Syndrome Shouwen Wang. *AKDHC Access Centers, Arizona Kidney Disease and Hypertension Center, Phoenix, AZ.*

Background: Dialysis Access-associated Steal Syndrome (DASS) is a major complication of arteriovenous dialysis accesses and its proper management is of critical clinical importance. However, the reported approaches are diverse and general consensus is lacking. Recently, guided banding approaches have gained popularity, as they are minimally invasive. This report analyzes the clinical outcome of Dilator-assisted Banding (DAB), a simple technique initially described by the author for managing DASS.

Methods: This series included 30 patients that underwent DAB for DASS due to excessive dialysis access flow.

Results: Of the 30 patients: 29 had upper arm fistulas or grafts and 1 had a forearm fistula; 23 had arteriogram - 3 of which required angioplasty ± stent for feeding artery stenosis. The DAB procedures included: intraluminal DAB (12/30), extraluminal DAB (14/30) and open fistula reduction plus DAB (4/30). After DAB, the average severity scores of ischemic symptoms was reduced from 2.8 ± 0.4 to 0.2 ± 0.4 for the fistula group (n=24, p<0.001) and from 3.0 ± 0.0 to 1.2 ± 1.2 for the graft group (n=6, p=0.041). Of the 24 patients with fistula, 19 had resolution of ischemic symptoms and 5 had minimal residual symptoms while 3 had finger necrosis that healed after DAB. Of the 6 patients with graft, 2 had resolution, 2 had minimal residual and 2 had no change of ischemic symptoms. These two DAB-ineffective patients underwent proximalization of arterial inflow (PAI) revisions that resulted in resolution of ischemic symptoms. During follow-up of 18.7 ± 14.5 months (range 1-50), all dialysis accesses remained functional. At 24-month post-DAB, the primary patency, primary-assisted patency and secondary patency rates of the fistula group were 72%, 91% and 100%, respectively.

Conclusions: DAB is a simple, effective and versatile approach for managing DASS due to excessive flow, especially in patients with fistula. In patients with failed banding, PAI can be effectively used for rescue. Based on the data in this series and the literature, an algorithm is proposed for managing DASS.

TH-PO870

Outcomes of Vascular Access Creation in Incident Hemodialysis Patients in Singapore Nicholette Goh,[1] Chieh-suai Tan,[2] Shaam Achudan,[1] Yi liang Tan,[1] Kian Guan Lee,[2] Hui-Lin Choong,[2] Tze tec Chong.[3] *[1]National Univ of Singapore; [2]Renal Medicine, Singapore General Hospital; [3]Vascular Surgery, Singapore General Hospital.*

Background: Hemodialysis is the main modality of renal replacement therapy for end-stage renal disease (ESRD) patients in Singapore. Vascular access is critical for effective therapy. This study evaluates the impact of pre-operative vein mapping on vascular access creation in patients newly initiated on hemodialysis in Singapore General Hospital.

Methods: Data of ESRD patients initiated on hemodialysis from January 2010 to December 2012 were retrospectively collected from electronic medical records. 708 patients (mean 62.8 ± 12 years old, 61% male, 71.3% Chinese) who underwent surgical creation of their first vascular access were followed up for a mean of 2.3 ± 1.2 years.

Results: 694 (98%) arteriovenous fistulae (AVF) and 14 (2%) arteriovenous grafts (AVG) were created. Successful AVF cannulation was established in 543 patients (78.2%). After 1 year, 511 (73.6%) remained patent with 43.5% (302/694) primary and 30.1% (209/694) secondary patency. 216 upper arm and 478 forearm AVFs were created. Upper arm AVFs had significantly higher maturation rates (85.0% vs 76.4%, p = 0.011). Pre-operative vein mapping was performed in 42.5% (295/694) of patients. The mean vein diameter was 2.44 ± 0.82mm. Maturation rates with and without vein mapping were 72.2% and 82.7% respectively (p = 0.001). Between vein diameters of <2 and ³2mm, there was no statistical difference in maturation rates (71.3% vs 72.6%; p = 0.887) or median maturation time (66.5 vs 77 days; p = 0.280). There was no statistical difference in maturation rates between veins of <2 and ³2mm in both forearm (p = 0.076) and upper arm AVFs (p = 0.722). On univariate analysis, male gender (p = 0.001) and the presence of good post-operative thrill (p < 0.001) were associated with successful maturation in newly created AVF. AVFs created by trainees also had better maturation rates compared to consultants (83.5% vs 76.2%; p = 0.027).

Conclusions: In conclusion, successful vascular access creation can be accomplished in majority of ESRD patients. This is independent of vein size or the need for pre-operative vein mapping.

TH-PO871

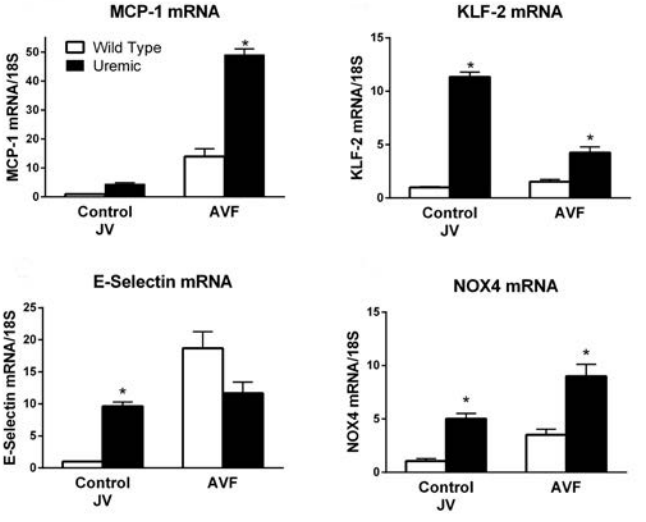
Uremia Induced Gene Expression in a Mouse Model of Arteriovenous Fistula Stenosis Keith Louis Saum, Begoña Campos, Neil Batra, Yang Wang, Prabir Roy-Chaudhury. *Univ of Cincinnati.*

Background: Arteriovenous fistula (AVF) non-maturation remains a huge clinical problem resulting in significant morbidity and mortality. Unfortunately most animal models of AVF stenosis do not incorporate uremia. As a result, the molecular mechanisms by which uremia contributes to AVF dysfunction remain unknown. The aim of this study was to assess the impact of uremia on the expression of genes associated with the pathogenesis of AVF dysfunction using a uremic mouse model of AVF stenosis.

Methods: Mice were made uremic by cautery of one kidney, followed by contralateral nephrectomy. After 4 weeks, an end to side anastomosis was created between the jugular vein and carotid artery. Contralateral vessels served as controls. Vessels were harvested after 14 days, and RNA isolated from the AVF venous segment. Gene expression of different mediators was measured with qPCR. Data was analyzed from control vein; uremic vein; veins of non-uremic AVFs; and veins of uremic AVFs.

Results: Significant upregulation in the expression of monocyte chemotactic protein-1 (MCP1), NADPH Oxidase (NOX4), and E-Selectin were found within the veins of AVFs compared to wild-type control vessels (P<0.017 for each gene). Compared to normal vein, MCP1 expression was increased 4.4, 14.0, and 49.1 fold in uremic vein, the non-uremic AVFs, and uremic AVFs respectfully . Paradoxical increases in Krüppel-like factor-2 (KLF-2) were also seen in uremic vessels compared to wild-type veins (P<0.017).

Conclusions: In summary, marked upregulation of the proteins MCP-1, NOX4, and E-Selectin were seen with uremia, and some of these (MCP-1) were further elevated within the AVF. Of note, the flow sensitive gene KLF2 was also elevated in uremia, but was attenuated in the setting of an AVF. These preliminary findings suggest key pathways by which uremia could exacerbate AVF dysfunction and future targets for the prevention and treatment of AVF maturation failure.



TH-PO872

Chlorhexidine-Impregnated Transparent Dressing for Prevention of Catheter-Related Bacteremia in Hemodialysis Patients: A Quality Improvement Study Vandana Niyyar,[1] Ibironke W. Apata,[1] John Hanfelt.[2] *[1]Nephrology/ Internal Medicine, Emory Univ, Atlanta, GA; [2]Rollins School of Public Health, Emory Univ, Atlanta, GA.*

Background: CRBSI are a major cause of morbidity in HD patients dialyzing with a CVC. A major route of catheter contamination is introduction of organisms from the skin to the catheter. Tegaderm-CHG is a transparent catheter dressing with an integrated gel containing chlorhexidine, designed to combine the benefits of transparent dressings; and the bactericidal and bacteriostatic benefits of chlorhexidine. We conducted a QI project to assess the rates of catheter-related bloodstream infection (CRBSI) in three dialysis units following the introduction of chlorhexidine-impregnated transparent catheter dressings.

Methods: Our study was conducted in two phases. In the first phase (9/12 through 10/13), we introduced the intervention, Tegaderm-CHG, to EDC, one of the three Emory hemodialysis units. EDGB and EDNS were the control sites where standard gauze catheter dressings were maintained. The rates of CRBSI at each dialysis units during the 12-month intervention were compared against the rates of CRBSI for the 12 month pre-intervention period. CRBSI rates were also compared between the dialysis units. The second phase of the study started in 11/ 2013, with the extension of Tegaderm-CHG dressing to EDGB and EDNS (the control sites in Phase 1). Tegaderm-CHG was maintained at EDC.

Results: The three dialysis units were comparable in terms of age, sex, and race of patients. In phase 1, the catheter infection rate (per 1,000 catheter days) in EDC decreased by 51% (pre: 1.69, post: 0.82). At EDGB, the infection rate increased by 12% (pre: 1.80; post: 2.02) while the infection rate increased by 35% (pre: 0.91; post: 1.23) at EDN. However, none of these increases in infection rates were significant (i.e., p > 0.05). The infection rates at EDGB and EDN decreased significantly in phase 2 by 86% (pre: 1.86, post: 0.26), and 53% (pre: 1.89, post: 0.88), respectively. At EDC, the catheter infection rate did not change significantly in phase 2.

Conclusions: The use of Tegaderm CHG dressing was associated with decreased rates of CRBSI at Emory outpatient dialysis units.

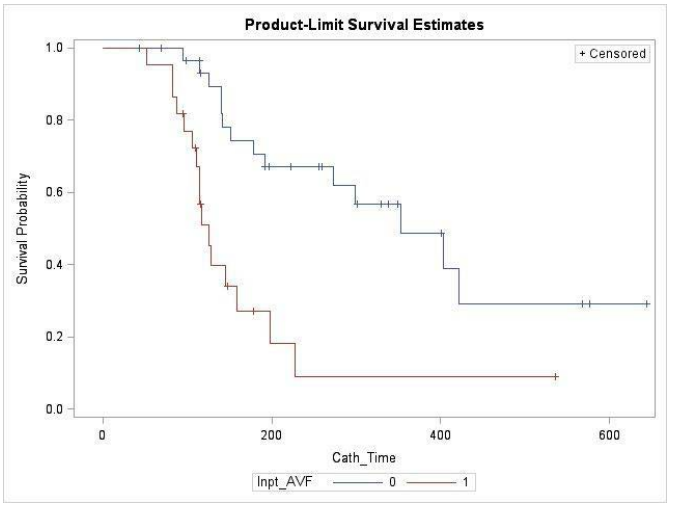
In-Patient Permanent Access Is Associated with Reduced Catheter Time for Emergent Start Hemodialysis Patients Catherine A. Moore,[1] Richard E. Wing,[1] Scott E. Liebman.[1] *[1]Medicine- Nephrology Div, Univ of Rochester, Rochester, NY; [2]Aurora Medical Group, Marinette Menominee Clinic, Marinette, WI.*

Background: Hemodialysis initiation with a tunneled catheter carries increased risk of morbidity and mortality. Conversion from a hemodialysis catheter to permanent access at any time is associated with improved outcomes. This study investigates whether a strategy of placing permanent dialysis access in incident HD patients without permanent access while still hospitalized is associated with reduced exposure to hemodialysis catheters.

Methods: We conducted a retrospective cohort study of ESRD patients initiating Hemodialysis with a catheter while hospitalized at a single University Hospital Medical Center from October 2010 through June 2013. Patients were divided into two groups: those with permanent access placed during the hospitalization (N = 22) vs. those discharged without permanent access (N = 67). Our primary endpoint was removal of the hemodialysis catheter.

Results: Subjects who underwent permanent access placement while still hospitalized had a median catheter exposure time of 114 days compared with 241 days for those who did not. The median time with HD catheter in place was shorter by 127 days in the Inpatient Access group. There was no significant difference in length of hospital stay or early access loss.



Conclusions: The practice of placing permanent access while the patient is still admitted to the hospital is associated with greater likelihood of hemodialysis catheter removal.

TH-PO874

Factors Affecting Haemodialysis Arterio-Venous Fistula Maturation Hannah R. Wilson, Salman Ahmed, Joseph Russell, Nicola Ding, Maggi Steele, Ayesha Irtiza-Ali, David Makanjuola, Nihil Chitalia. *Renal Unit, St. Helier Hospital, Surrey, United Kingdom.*

Background: Arterio-venous fistulae (AVF) are the preferred access for haemodialysis (HD). Many AVFs however, fail to mature. We investigated the factors affecting maturation of AVFs in order to identify any characteristics which were predictive of AVF maturation.

Methods: All AVFs created between 2006 and 2014 were reviewed. Data analysis was performed using GraphPad. AVFs were deemed to have failed to mature if by 90 days post-creation, it was not possible to use them for HD. The patients were divided into 2 groups – those who had the AVF created pre-emptively (group 1) and those already on HD at the time of AVF creation (group 2). Characteristics reviewed were age, gender, ethnicity, co-morbidity score, diabetes status and site of AVF.

Results: There were 1876 AVFs created. 954 in group 1 and 922 in group 2. In group 1, 597 patients started HD; 469 (79%) used their AVF for the 1st HD session. In group 2, 330 (36%) used their AVF within 90 days from creation. Group 1 AVFs were more likely to mature than those in group 2. Co-morbidity scores, age, diabetes status and ethnicity had no impact on AVF maturation rates.

Variable	Mature AVF (n=745)	Non-mature AVF (n=833)	p value
Pre-emptive	415 (55.7%)	241 (28.9%)	*
Non pre-emptive	330 (44.3%)	592 (71.1%)	*
Age in years [mean(SD)]	63 ±15.6	64 ±15.6	ns
Gender	69% M, 31% F	59% M, 41% F	0.0002
Ethnicity Caucasian Asian Afro-Caribbean Not stated	 56% 12% 8% 24%	 55% 13% 9% 24%	 ns
Upper arm AVF	54%	52%	ns
Diabetic	35%	37%	ns
Davies co-morbidity score 0 *(no co-morbidities)* 1 *(1-2 co-morbidities)* 2 *(3 or more co-morbidities)*	 18% 68% 14%	 15% 68% 17%	 ns

**p<0.0001 for percentage of mature AVFs in pre-emptive vs non-pre-emptive groups.*

Conclusions: Our data show that the timing of AVF creation is important; those formed pre-emptively are more likely to mature than those created when the patient is on dialysis. It is possible that the presence of a dialysis line might delay maturation, especially if it is ipsilateral to the AVF.

It highlights the importance of prompt referral to nephrology services so that AVFs can be created in a timely manner.

TH-PO875

Hand Held Ultrasound Device Solves Vascular Access (VA) Cannulation Problems Beth Adams, Vivek Soi, Jerry Yee, Lalathaksha Murthy Kumbar. *Henry Ford Hospital, Detroit, MI.*

Background: The Fistula First Catheter Last workgroup coalition identifies VA cannulation as a fundamental "failure" point in optimizing arteriovenous fistula (AVF) usage. Infiltration from cannulation difficulties result in significant morbidity including loss of VA and cost. Cannulation success is reliant on cannulators' skill and VA characteristics. Surface marking of VA to aid cannulation is frequently used but lacks real time information. Traditional ultrasound devices are expensive and need skilled operators rendering inapt for routine use in hemodialysis units. Sonic Window© (Analogic Ultrasound) is a coronal mode ultrasound device (CMUD) approved for VA cannulation. We present our early experience in using this novel hand held CMUD for real time guidance of AVF cannulation.

Methods: Three patients with cannulation failure defined as inability to achieve 3 needle cannulations leading to tunnel cuffed catheter (TCC) removal were identified. AVF was evaluated initially for 1-2 dialysis sessions with CMUD for course, depth from skin, optimal site for cannulation, needle length and size. Infiltration rates, subsequent procedures and hospitalizations were noted before and after CMUD use and cannulation failure days (days from initial VA clearance for use to TCC removal).

Results:

AVF		Pre-events			Post-events		
Type	Cannulation failure days	Infiltration	Interventions	Hospitalization	Infiltration	Interventions	Hospitalization
Brachio-basilic	210	1	1	6	0	0	0
Brachio-cephlaic	206	3	6	0	0	0	0
Radioce-phalic	153	3	4	0	0	0	0

All 3 AVF were successfully cannulated leading to TCC removal within 21 days of CMUD guidance. CMUD usage resulted in no cannulation related complications and no subsequent revision procedures

Conclusions: CMUD guided cannulation of dialysis access is feasible and safe. Real time ultrasound guidance mitigates cannulation failure and catheter removal.

TH-PO876

Reaching First Dialysis Quickly and Unassisted with Sirolimus Treated Fistulae – Serial Ultrasound Results and Clinical Outcomes
Maria V. DeVita,[1] Eric S. Chemla,[2] Konstantine B. Kipiani,[3] Nutsa K. Beridze,[3] Sriram Iyer.[4] *[1]Nephrology, Lenox Hill Hospital, New York, NY; [2]Vascular Surgery, St. George's NHS Foundation Trust, London, United Kingdom; [3]Vascular Surgery, Georgian Center of Angiology and Surgery, Tbilisi, Georgia; [4]Vascular Therapies Inc, Cresskill, NJ.*

Background: Neointimal hyperplasia (NH) resulting in a flow limiting stenosis within the juxta-anastomotic segment (JAS) of an AV Fistula (AVF), impairs increase in upstream **vein diameter (VD)**, often requires supplementary procedures and prolongs time to 1st cannulation for dialysis (D). Sirolimus delivered locally to the vessel wall can suppress NH and preserve lumen patency ("sirolimus effect").

Methods: 30 pts (29 on D) undergoing AVF surgery [22 Radiocephalic (RCF), 8 Brachiocephalic fistulae (BCF)] received a Sirolimus eluting collagen implant at and around the JAS. 1st cannulation was based on clinical evaluation.

Results: 18 males, mean age 50.8y, 20% diabetic. Analysis excludes 4/22 RCF that thrombosed £2 weeks; 18/22 RCF (88%) and all 8 BCF maintained Primary Patency (PP) prior to first cannulation (mean 49 days); 13 AVF were cannulated ≤6wks, 74% AVF maintained suitability for D with PP at 12mos. Table shows serial Ultrasound results.

Characteristic	Pre op	6-8 hours Post op	2 weeks	4 weeks	6 weeks	8 weeks
RCF (n=18)						
VD Mean (±SD)	2.7 (0.5)	4.4 (0.5)	5.1 (0.8)	5.8 (0.7)	6.1 (0.4)	6.4 (0.4)
VD change from prior time point	-	63%	16%	14%	5%	5%
VD ≥6mm n=		0	2 (11%)	8 (44%)	13 (72%)	18 (100%)
VD ≥4mm n=		14 (70%)	16 (89%)	17 (94%)	18 (100%)	
BCF (n=08)						
VD Mean (±SD)	3.9 (0.6)	5.4 (0.8)	6.8 (0.8)	7.5 (0.9)	7.9 (1.71)	8.45 (1.38)
VD change from prior time point		38%	26%	9%	5%	8%
VD ≥6mm n=		2 (25%)	6 (75%)	8 (100%)		
VD ≥4mm n=		8 (100%)				

Conclusions: 1.Maximum % increase in VD occurred within 8hrs of surgery with gradual continued increments thereafter. 2.At 4, 6 and 8wks, VD of 6mm was attained by 62%, 81% and 100% of the AVF respectively. 3. 26/30 AVF(87%) maintained PP before first cannulation; time to first dialysis for 13 AVF(50%) was ≤6wks and at 12mos 75% were functional with PP. 4.Results signal a "sirolimus effect" and will be tested in an upcoming randomized trial.

Economic Burden to Medicare of Central Venous Catheter (CVC)-Related Blood Stream Infections (BSI) and Occlusions Among Incident Hemodialysis (HD) Patients
Scott Sibbel,[1] Steven M. Brunelli,[1] Abigail Hunt,[1] Wendy Turenne,[1] Antony E. Pfaffle.[2] *[1]DaVita Clinical Research, Minneapolis, MN; [2]CorMedix Inc, Bedminster, NJ.*

Background: Episodes of CVC-related BSI and occlusion in HD patients result in hospitalizations and vascular access-related procedures, with attendant increases in costs. We sought to quantify this burden to the payor among Medicare-enrolled patients at a large dialysis organization.

Methods: Patients received HD via CVC during 2011 and were enrolled in Medicare Parts A and B. In parallel analyses, patients who developed BSI (N=1413) or occlusion (N=793) were matched with controls who did not, on the basis of entry month and incident/prevalent dialysis status. Outcomes were assessed from date of BSI/occlusion (or corresponding date for controls) for 6 months or until censoring for modality change, transfer of care, loss of Medicare benefits or death. Comparisons were made using linear mixed models including fixed effects for exposure status and month, adjusted for covariates that were imbalanced at baseline.

Results: CVC-related BSI was associated with greater rate of hospitalization (incidence rate difference [IRD], 1.07 events/patient [pt]-year) and vascular-related procedures (IRD, 2.87 events/pt-year). Mean per patient per month (PPPM) costs were $2624 higher for BSI patients versus controls, driven primarily by increased inpatient costs. CVC occlusion was associated with modestly greater rate of hospitalization (IRD, 0.29 events/pt-year), but substantively greater rate of ambulatory procedures (IRD, 4.00 events/pt-year). Mean PPPM costs were $2354 greater for occlusion patients versus controls, driven by higher ancillary service and procedure costs.

Conclusions: CVC-related BSI and occlusion are potent cost drivers for Medicare. Risk mitigation strategies to prevent BSIs and occlusions should prove to reduce systemic health care costs.

Arteriovenous Fistula Maturation and Medial Collagen Organization Assessed by Second Harmonic Generation Microscopy
Yan-Ting E. Shiu,[1] Michael Allon,[2] Daniel Pike,[1] CS Jason Tey,[1] Silvio H. Litovsky,[2] Alfred K. Cheung.[1,3] *[1]U of Utah; [2]U of Alabama; [3]VASLCHCS.*

Background: Arteriovenous fistula (AVF) maturation entails vascular dilation to allow increases in AVF blood flow. The required vascular wall distention is likely affected by its microstructure. We hypothesized that the organization of collagen fibers in the medial layer affects vascular dilation and hence AVF maturation. State-of-the-art second harmonic generation (SHG) microscopy and image-analysis algorithms were used to visualize and assess collagen-fiber organization.

Methods: Arteries and veins used for anastomosis were sampled during AVF creation from 128 participants with chronic kidney disease (CKD). Collagen SHG signals in unstained paraffin-embedded tissue sections were acquired under a two-photon microscope at 850 nm excitation, and analyzed for fiber pattern, anisotropy index (AI) and dominant angle (DA) by 3 independent observers blinded to AVF outcomes. AI ranged from 0 (random fiber network) to 1 (completely aligned fiber network). DA ranged from 0° (parallel to lumen) to 90° (perpendicular to lumen).

Results: Arterial and venous medial collagen fibers demonstrated a total of 5 patterns: parallel to lumen, perpendicular to lumen, track, web, or random (Fig. 1). The parallel and perpendicular patterns had a similar AI (~0.3) which was higher than the AI of the other patterns. However, the parallel pattern had a smaller DA than the perpendicular pattern in arteries (18° vs 70°, p=0.001). AVF non-maturation rate was lower in patients with a perpendicular vs parallel arterial fiber network (15 vs 40%, p=0.04). Likewise, AVF non-maturation rate was lower in patients with venous DA >30° vs DA <30° (17 vs 36%, p=0.03).

Conclusions: We have characterized novel vascular medial collagen fiber organization in CKD patients. Moreover, these patterns appear to be associated with the likelihood of AVF maturation.

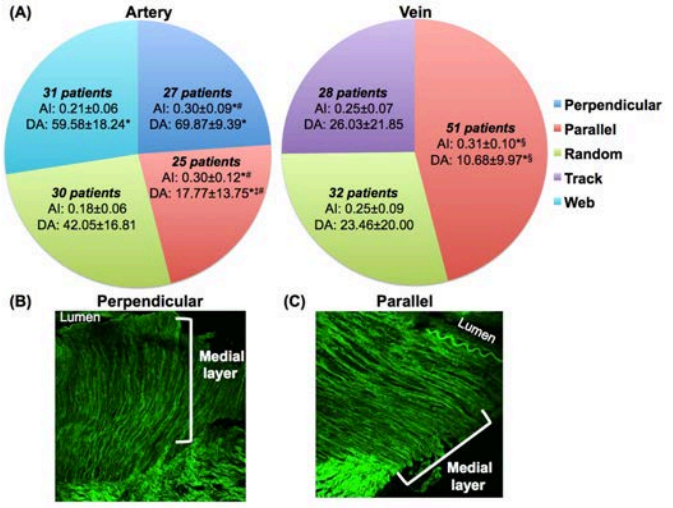

Fig. 1. (A) Characteristics of the medial layers. Data are shown as average ± S.D. Statistical analysis was performed using ANOVA with Bonferroni post-hoc analysis. *P<0.05 when compared to Random in the same pie chart. #P<0.05 when compared to Web. ‡P<0.05 when compared to Perpendicular. §P<0.05 when compared to Track. **(B,C) Representative SHG images of the perpendicular and parallel patterns in the arterial medial layers.**

TH-PO879

Polyurethane Prosthesis for Early Cannulation as an Alternative to Central Venous Catheter Irena Glowinska,[1] Jerzy Glowinski,[2] Jolanta Malyszko.[1] *[1]II Dept of Nephrology and Hypertension, Medical Univ, Bialystok, Poland; [2]Dept of Vascular Surgery and Transplantology, Medical Univ, Bialystok, Poland.*

Background: Autologous arterio-venous fistulae is an optimal vascular access for haemodialysis. Arterio-venous fistula is not faultless and up to 40% of fistulae never mature. In patients with no possibilities to create effective native arterio-venous fistulae haemodialysis with using a proper prosthesis gives a chance to avoid a central venous catheter (CVC).

The aim of the study was to evaluate of usefulness polyurethane prosthesis as an emergency vascular access for haemodialysis.

Methods: The study involved 23 patients, 18 men and 5 women, at 29 – 83 years. Eight patients were in predialysis period , for 17 patients (2 in predialysis) it was a secondary procedure. All patients had implanted AvFlo prosthesis (Nicast, Israel). There were 5 loops in the forearm and 18 straight segments in the arm. Six patients underwent an urgent operation, because of lack of any vascular access. For others it was an elective operation.

Results: The longest observation period was over 36 months. Twenty one grafts were used for hemodialysis within 1-42 days, one prosthesis was removed due to infection, one patient died before initiation of dialysis. All grafts implanted for urgent indications were successfully cannulated within 24 hours. No differences were observed between diabetic and non-diabetic patients.

Conclusions: Implantation of polyurethane prosthesis provides an effective vascular access for dialysis and enables avoidance of CVC. Low infection rate improves the final outcome.

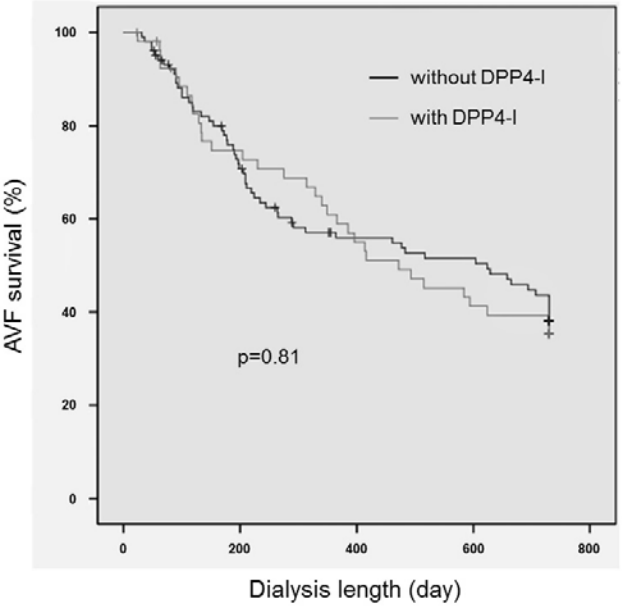
TH-PO880

Impact of DPP-4 Inhibitors on Hemodialysis Vascular Access Dysfunction Hiroki Ito, Yuki Nakamura, Satoru Sanada, Kozo Sato, Atsuhiro Kanno, Yasunori Miyasaka, Mitsuhiro Sato, Yoshio Taguma, Toshinobu Sato. *Nephrology, Japan Community Health Care Organization Sendai Hospital, Sendai, Miyagi, Japan.*

Background: The maintenance of arteriovenous fistula (AVF) is crucial for hemodialysis patients and reduction of complications remains a challenge. Previous reports show that patients with diabetes mellitus are more likely to have AVF dysfunction than those with other underlying diseases. Also, elevated inflammatory cytokine such as IL-6 is known to be associated with AVF dysfunction. Recently, dipeptidyl peptidase 4 inhibitors (DPP4-I) were known to have pleiotropic action including anti-inflammation that decrease IL-6. Thus, we hypothesized that DPP4-I could improve AVF outcome by decreasing inflammatory cytokines.

Methods: The study population included 157 consecutive patients newly starting hemodialysis between 2011 and 2012 with diabetic nephropathy. AVF dysfunction was tracked for 2 years; criteria of which include complete obstruction, insufficient inflow and uniform thrill. AVF survival between patients treated with DPP4-I (n=54) and without DPP4-I (n=103) was investigated using Kaplan Meier and Cox regression analysis. Serum IL-6 level was analyzed by ELISA.

Results: Baseline characteristics were identical between 2 groups in age, sex, blood pressure, body mass index, history of congestive heart failure and coronary artery disease. There was no difference in AVF survival between the groups (DPP4-I: 455±36 vs without DPP4-I: 464±28 days, p=0.81, Log-rank), although serum IL-6 levels were significantly lower in patients with DPP4-I (with DPP4-I: 5.0±1.9 vs without DPP4-I: 10.5±7.2 pg/ml, p=0.03). Among other drugs, no correlation was indicated between AVF dysfunction with insulin, RAS blocker, other antihypertensive drugs nor antiplatelet agents.



Conclusions: DPP4-I did not show any advantage in AVF outcome despite anti-inflammatory effect of lowering serum IL-6 level.

TH-PO881

Drug-Eluting Balloon: New Endovascular Treatment for Haemodialysis Arteriovenous Fistula Carmen Gonzalez corvillo, Alejandro A. Suarez benjumea, Alfonso Lara Ruiz, Mercedes Salgueira lazo. *Nephrology, Virgen Macarena-Rocio, Sevilla, Spain.*

Background: The purpose of this article is to report our experience with drug-eluting balloon(DEB)for the treatment of failing Arteriovenous Fistula(AVF). Mean life expectancy of the vascular acces after the procedure,influence on adequate dialysis parameters postintervention and percentage of complications.

Methods: DEB procedures made in our hospital were evaluated. Main objective was to analyze: a)Reason of consulting and vascular lesion found. b)Hemodialytic arteriovenous shunt type. c)Kt/V, Qb, PV d)Survival of the vascular access at the end of the study e) Complications related to the procedure.

Results: 9 angyioplastic were made by DEB. Mean age:74,6 years, 50% male. 5 left native radiocepahlic fistula and 1 humero-axillary prosthetic.Most of the patients had at least 4 previous interventions. Principal reasson of consultation was low flow,being the most frequent arterial stenosis. No complications were found related to any procedure. Every vascular access is permeable at the actual time, mean life since the intervention: 24 months, being necessary only one reintervention in the target lesion. Blood flow, venous pressure and Kt/V improvement regarding to the basal was observed, after the procedure and at the end of the study.

Conclusions: There is limited experience with the use of drug-eluting balloon in haemodialysis arteriovenous fistula, an increase in average life expectancy of the vascular access with bad prognosis (led to a new vascular access) was found, an improvement on adequate dialysis parameters was observed, preserving vascular system of the patient, decreasing costs and with no complications. More studies would be needed.

TH-PO882

Alteplase Infusion as Rescue Therapy for Central Venous Haemodialysis Catheter Dysfunction Sanjana Gupta,[1] Stephen B. Walsh,[2] Karlene Thomas,[1] Ravindra Rajakariar.[1] *[1]Barts Health NHS Trust; [2]UCL Centre for Nephrology.*

Background: Central venous haemodialysis catheters (CVHC) can become occluded or have poor blood flow (Qb). CVHC complication estimates are 35% and result in hospitalisation and interventional procedures. This study aimed to review alteplase infusion success and patency rates.

Methods: We undertook a retrospective review of all patients that had an alteplase infusion at the Royal London Renal Unit over a 15-month period. Patients had failed an alteplase lock and 4mg alteplase was used in both lumens. Data was collected using the renal database.

Results: There are 1002 haemodialysis patients; 412 dialyse via a CVHC.

Total uses / total patients (n)	94 / 74
Repeat Alteplase, same CVHC n (%)	20 (21)
Median age of CVHC (IQR)	147 days (77 - 300)
Indication (occlusion / Poor Qb) n	31 / 63

CVHC age was statistically different depending on the indication; occluded CVHC age was 124 ± 22 vs 244 ± 27 days for low Qb (p=0.01). Rescued CVHC age was significantly lower than those in whom the alteplase was unsuccessful (147 ± 18.4 vs 269 ± 35.8, p=0.004). In 48% of patients with an occluded CVHC, flow was restored; the remaining 52% required further intervention. Low Qb CVHC success rate was 60% compared to 38% requiring further intervention, 2% were removed (arteriovenous fistula or transplant). There was no significant difference between success rates depending on the indication (p=0.34). Alteplase infusion significantly increased litres processed in subsequent dialysis sessions, in whom the indication was low Qb (6.2 ± 1.16 litres, p < 0.0001). Overall of all infusions undertaken; 1 month patency was 56%, 3 months 45% and 6% removed. No patient had an adverse bleeding event as a result of the alteplase infusion.

Conclusions: Alteplase infusion use is common; approximately once a week in our centre. Interestingly, complete occlusion of CVHC occurs early, possibly suggesting rapid growth of fibrin following insertion. Total litres processed improves after an alteplase infusion in over half of patients. This study demonstrates the safety and success rates of an alteplase infusion, providing evidence for its role prior to replacing the CVHC and importance in saving resources.

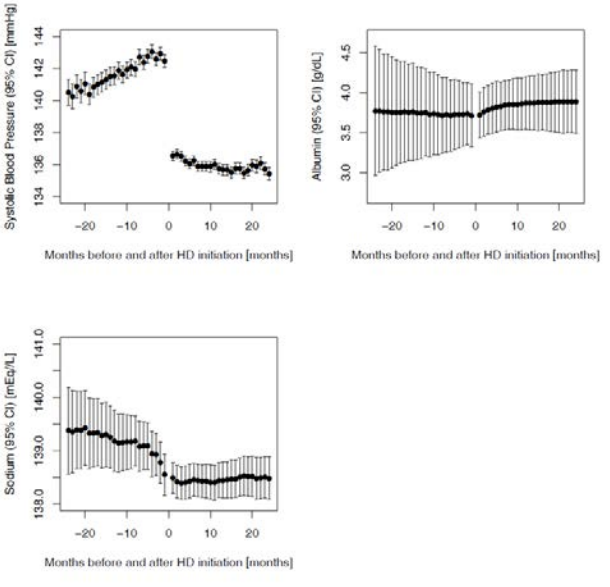
TH-PO883

Temporal Evolution of Parameters Before and After Initiation of Hemodialysis Jochen G. Raimann,[1] John W. Larkin,[2] Carly R. Van Zandt,[2] Len A. Usvyat,[2] Jeroen Kooman,[3] Frank van der Sande,[3] Barbara Cannon,[2] Chad Sowers,[2] Mark Stuart,[2] Terry Ketchersid,[2] Dugan Maddux,[2] Peter Kotanko,[1,4] Franklin W. Maddux.[2] *[1]Renal Research Inst; [2]Fresenius Medical Care North America; [3]Maastricht Univ Medical Center; [4]Icahn School of Medicine at Mount Sinai.*

Background: Little is known about the dynamics of clinical and laboratory parameters during the transition between pre-dialysis chronic kidney disease and end stage kidney disease (ESKD). The goal of our research was to explore the temporal evolution of albumin (Alb), systolic blood pressure (SBP) and serum sodium (SNa) by analyzing monthly data before and after hemodialysis (HD) initiation.

Methods: We analyzed all available data from the de-identified Fresenius Medical Care CKD Data Registry to understand progression of clinical and laboratory markers before and after HD initiation. Average values of Alb, SBP and SNa were compared for 12 months prior and after HD initiation using t-test. To estimate the trends of the average values, we fitted a linear regression function through monthly averages.

Results: We studied 136846 patients (64±14 years, 56% male) over 48 months. Average SBP increased prior to HD initiation (1.2 mmHg/year), immediately decreased following HD initiation, and remained lower for the following 12 months (142.4±22.8 vs. 136.1±23.2 mmHg; P<0.05). Before starting HD, Alb was found to be relatively unchanged, but increased after HD initiation (average Alb increased by 0.14 g/dL per year; levels were slightly higher 12 months after HD initiation [3.7±0.5 vs. 3.8±0.4 g/dL; P<0.05]). Average SNa pre-ESKD had a declining trend (-0.5 mEq/L per year) and was lower compared to the HD period (139.0±3.4 vs. 138.4±3.5 mEq/L; P<0.05).



Conclusions: Our study demonstrates a trend toward improvement in SBP and Alb following HD initiation. The etiology of the SNa decrease after HD initiation requires further investigation.

TH-PO884

Accelerated Arterial Stiffening in Vitamin-K-Antagonist Treated Hemodialysis Patients Christian D. Peters, Krista D Kjaergaard, J. Dam Jensen, Bente Jespersen. *Dept of Renal Medicine, Aarhus Univ Hospital, Aarhus, Denmark.*

Background: Many hemodialysis (HD) patients are treated with vitamin-K-antagonists (VKA) in order to prevent thromboembolic events. A potential side effect to VKA treatment is an increase in soft tissue calcification due to the inhibitory effect of VKAs on the central (liver) and peripheral (e.g. vascular) carboxylation cycle synthesis of several vitamin K-dependant calcification-inhibiting factors. The aim of the present study was to investigate the impact of VKA-treatment on arterial stiffness in a longitudinal, prospective comparative study.

Methods: Seventy-five HD patients from the SAFIR study with urine output >300 mL/day and HD-vintage <1 year were divided into controls (n=67) and VKA-treated (n=8) and followed for one year. The groups were well matched according to age, sex, comorbidity, and intervention (placebo/irbesartan). Arterial stiffness was assessed with carotid-femoral pulse wave velocity (PWV) and pulse wave analysis using the SphygmoCor device.

Results: Blood pressure (BP), PWV, and glomerular filtration rate (GFR) were similar at baseline (controls/VKA-treated) systolic BP: 148±20/145±17 mmHg; PWV: 11.6±3.2/11.0±3.9 m/s; GFR: 5±3/5±3 ml/min/1.73m^2. Dialysis treatment and BP-medication were also similar. During follow up, GFR decreased similarly in both groups (P=0.2). There was no significant difference in BP between the two groups over time although BP tended to decrease more in the controls. PWV decreased in the controls -0.9(-1.4; -0.3) m/s; P=0.004 and increased in the VKA-treated 1.6(0.0; 3.2)m/s; P=0.05. Mean difference after 12 months between the groups (DPWV) was: 2.5(0.7; 4.2) m/s; P=0.006. DPWV remained significant after adjustment for ΔGFR, ΔMAP, age at baseline, and ΔBP-medication: 2.2(0.4; 4.0) m/s; P=0.02. Mean differences after 12 months between the groups in heart rate adjusted augmentation index and time to pulse wave reflection were: 7(-2; 15) %; P=0.11 (AIxHR75) and -14(-27; -2) ms; P=0.03 (TR).

Conclusions: Our findings indicate that VKA-treatment increases arterial stiffening significantly. We speculate that vitamin K-dependant calcification-inhibiting factors in HD patients may be inadvertently affected by VKA treatment.

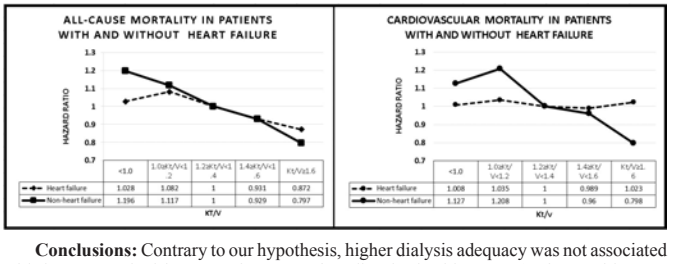
TH-PO885

Associations of Kt/V with Mortality in Hemodialysis Patients by Heart Failure Status Parta Hatamizadeh,[1] Brian Bieber,[2] Keith McCullough,[2] Bruce M. Robinson.[2] *[1]Dept of Internal Medicine, Univ of Michigan, Ann Arbor, MI; [2]Arbor Research, Ann Arbor, MI.*

Background: Kidney failure and heart failure (HF) frequently coexist, a condition called cardiorenal syndrome (CRS). Though HF patients on maintenance hemodialysis (mHD) have high risk of poor outcomes, there is a paucity of data to guide their care. Given the role of uremic toxins in the pathogenesis of CRS, we hypothesized that mortality for mHD patients is lower at higher Kt/V targets.

Methods: Cox regression was used to estimate associations of baseline Kt/V with all-cause mortality (ACM) and cardiovascular mortality (CVM) in phases 1-4 of the Dialysis Outcome and Practice Patterns Study (DOPPS), an international prospective cohort study of mHD patients. Separate models for patients with and without HF (by clinical diagnosis) were stratified by country and DOPPS phase and adjusted for age, gender, race, diabetes and hypertension as comorbidities, dialysis vintage, serum albumin, pre-dialysis systolic blood pressure, and weight. SAS 9.4 was used for analyses.

Results: Among 51,678 mHD patients, mean age was 62.5±14.8 yrs, 41.5% female and 32% had HF. In non-HF patients, Kt/V was inversely associated with ACM and CVM, following a monotonic pattern. In HF patients, the association was similar for ACM but generally flat for CVM. A sensitivity analysis of Kt/V by sex showed a monotonic decline in mortality in women, but little decline at Kt/V >1.4 in men [consistent with prior literature]. HF did not clearly modify associations by sex.



Conclusions: Contrary to our hypothesis, higher dialysis adequacy was not associated with longer survival in HF patients. Confounding by health status (patients with more advanced HF may achieve lower Kt/V because they tolerate dialysis poorly) may be an explanation for this finding. Additional study is needed to identify ways to improve outcomes for these high-risk patients.

Different Impact of Malnutrition-Inflammation and Metabolic Syndrome on Long-Term Mortality and Cardiovascular Events in Hemodialysis Patients Naoki Nakagawa. *Renal Div, Dept of Internal Medicine, Asahikawa Medical Univ, Asahikawa, Hokkaido, Japan.*

Background: Metabolic syndrome confers an increased risk of cardiovascular disease (CVD) in the general population. The relationship between adiponectins, and clinical outcomes in hemodialysis patients remains controversial. We investigated whether adiponectins, biomarkers of inflammation, nutrition status and clinical features predict the mortality of hemodialysis patients for 6 years.

Methods: We measured baseline plasma total and high-molecular-weight (HMW) adiponectins, tumor necrosis factor (TNF)-α, serum high sensitivity C-reactive protein (hsCRP), and clinical characteristics including visceral fat area (VFA) and the Geriatric Nutritional Risk Index (GNRI) in 133 hemodialysis patients.

Results: During the 6-year follow up period, 41 (30.9%) patients died (heart failure, $n = 13$; acute myocardial infarction, $n = 11$; stroke, $n = 2$; infection, $n = 10$; and malignant cancer, $n = 5$). The deceased patients were significantly older, had more prior CVD and diabetes, higher TNF-α and hsCRP levels but lower GNRI. VFA, and total and HMW adiponectin did not significantly differ between the two groups. TNF-α and hsCRP levels and GNRI score were significant for predicting all-cause and cardiovascular mortality in receiver operating curve analyses. The present ROC curve analysis for all-cause 6-year mortality found the predictive value of GNRI for mortality was 96. When stratified by a GNRI score of 96, Cox proportional hazards analyses identified TNF-α as a significant predictor of all-cause mortality (hazard ratio [HR] 1.23; P = 0.038) and hsCRP as a significant predictor of all-cause and cardiovascular mortality (HR, 2.32, P = 0.003; HR 2.30, P = 0.012, respectively) after adjusting for age, sex, diabetes mellitus, and prior CVD, only in malnourished patients.

Conclusions: These results demonstrate that malnutrition and the inflammatory markers TNF-α and hsCRP, but not metabolic markers, including VFA and adiponectins have a significant impact on 6-year all-cause and cardiovascular mortality in hemodialysis patients.

Associations of the Malnutrition-Inflammation Complex Syndrome with Depression Symptoms, Kidney-Disease Targeted Quality of Life Measures and Mortality in a Hemodialysis Population of Predominantly African Descent Marcelo Barreto Lopes,[1] Raissa B. Peixoto,[1] Priscila S. Carvalho,[1] Jean M. Monteiro,[1] Jéssica S. Fernandes,[1] Pedro Guimarães Silva,[1] Luciana Ferreira Silva,[2] Gildete Barreto Lopes,[1] Antonio Alberto Lopes.[1] *[1]Univ Federal da Bahia; [2]Univ do Estado da Bahia, Salvador, BA, Brazil.*

Background: The malnutrition-inflammation score (MIS) has been used to assess protein-energy wasting (PEW), also named malnutrition-inflammation complex syndrome, in maintenance hemodialysis (MHD) patients. Higher MIS has been associated with poorer outcomes in MHD patients but remains unclear if MIS expands the predictive power for outcomes in relation to its ten components and if the published results may be generalized for populations not targeted by previous investigations. We assessed associations of MIS and its components with mortality and patient-reported outcomes, i.e., health-related quality of life (HRQOL) and depression symptoms in a MHD population predominantly of African descent.

Methods: Prospective cohort (PROHEMO) of 632 MHD patients (92% Black or mixed race) treated in Salvador, Brazil. The predictor was MIS (range: 0-30, higher worse) and its ten components. Outcomes were mortality, HRQOL by KDQOL-SF and depression symptoms by CES-D. Multivariable linear regression was used for differences in scores and Cox regression for mortality.

Results: After extensive adjustments for covariates, MIS≥6 was significantly ($P<0.05$) associated with higher mortality (hazard ratio=1.52; 95% CI=1.13, 2.05), higher depression symptoms and poorer HRQOL, including physical, mental and kidney-disease targeted HRQOL scales with differences > 4 points. Four of the 10 MIS components were independently associated with mortality, but not with patient-reported outcomes.

Conclusions: The consistent associations of MIS with mortality, HRQOL and depression symptoms despite the distinct association of MIS components with mortality and patient-reported outcomes support the importance of combining PEW components to assess health status and risks of outcomes in MHD patients. The observed results in a predominantly African descent population expand support to MIS as a valid predictor of outcomes in different MHD populations.

Non-Traditional Risk Factors Predict Atherosclerotic Events in Haemodialysis Patients – Post-Hoc Analyses of the AURORA Trial Marit D. Solbu,[1,2] Geir Mjøen,[3] Patrick B. Mark,[1,4] Hallvard Holdaas,[5] Bengt C. Fellstrom,[6] Alan G. Jardine.[1,4] *[1]Inst of Cardiovascular and Medical Sciences, Univ of Glasgow, Glasgow, United Kingdom; [2]Section of Nephrology, Univ Hospital of North Norway, Tromsø, Norway; [3]Dept of Nephrology Ullevål, Oslo Univ Hospital, Oslo, Norway; [4]Renal and Transplant Unit, South Glasgow Univ Hospital, Glasgow, United Kingdom; [5]Dept of Transplantation Medicine, Oslo Univ Hospital Rikshospitalet, Oslo, Norway; [6]Div of Nephrology, Uppsala Univ Hospital, Uppsala, Sweden.*

Background: Patients on haemodialysis are at high risk for cardiovascular events, but heart failure and sudden death dominate and atherosclerotic events are less common. The AURORA trial was designed to assess the effect of rosuvastatin on myocardial infarction and death from any cardiac cause in haemodialysis patients. We studied predictors of the atherosclerotic, and not all cardiovascular, events in AURORA.

Methods: We readjudicated all deaths and presumed myocardial infarctions according to stricter criteria to separate atherosclerotic from non-atherosclerotic cardiovascular events. The readjudicated atherosclerotic endpoint included non-fatal myocardial infarction, fatal coronary heart disease, non-fatal and fatal non-haemorrhagic stroke, revascularisation procedures and death from ischaemic limb disease. Baseline predictors were assessed for the 2776 participants of the AURORA trial, and step-wise Cox regression analysis was applied.

Results: During a mean follow-up of 3.2 years, 716 patients experienced a readjudicated atherosclerotic event. Baseline phosphate (HR 1.33; 95% CI 1.16-1.53 per 1 mmol/L increase), albumin (HR 0.93; 95% CI 0.91-0.96 per 1g/L increase) and high sensitive CRP (HR 1.07; 95% CI 1.00-1.14 per mg/L increase) were significant predictors in addition to female sex, age, prevalent diabetes and cardiovascular disease. LDL cholesterol was not a significant risk factor.

Conclusions: Even with the use of strict criteria for endpoint definition, non-traditional risk factors, but not lipid disturbances, predicted atherosclerotic events in haemodialysis patients.

Proteomic Studies of Blood Plasma Using 2DE and Mass Spectrometry for Deeper View into the Mechanisms Involved in Atherosclerosis in Chronic Kidney Disease Maria Wanic-Kossowska,[1] Dorota Formanowicz,[2] Elzbieta Pawliczak.[1] *[1]Dept of Nephrology, Transplantology and Internal Medicine, Poznan Univ of Medical Sciences, Poznan, Poland; [2]Dept of Clinical Biochemistry, Poznan Univ of Medical Sciences, Poznan, Poland.*

Background: The exact participation and association of particular risk factors and specific mechanisms that promote cardiovascular complications (CVD) in patients with chronic kidney disease (CKD) remain unclear. The close relationship between CVD and CKD is most likely due to the co-existence of both traditional and novel risk factors. To gain insight into better recognition of the mechanisms of CKD-related accelerated atherosclerosis, a comparative proteomic analyses have been performed.

Methods: Blood samples were taken from 90 patients (CKD1-2, CKD3-4, CKD5), 30 patients with CVD, but without CKD and 30 healthy volunteers. Plasma samples were depleted using affinity chromatography and divided into three fractions: high-abundance protein, low-abundance protein and low molecular weight protein. The first two fractions were analyzed by two dimensional gel electrophoresis and mass spectrometry, the last one has been subjected to direct MS/MS analysis. Differential accumulated proteins were confirmed by selected reaction monitoring analysis.

Results: 49 proteins (13 high and 36 low molecular mass) showed differences in accumulation levels. The proteomic profiles in CKD5 and CVD patients differed in the accumulation of four LAPs the relative accumulations of alfa -2-macroglobulin, second isoform of alfa 1 microglobulin and were higher in CKD5 compared with CVD; fold changes 1.77, 4.14, 2.68 and 1.79, respectively. Moreover, the relative abundances of these proteins were up-regulated in CKD3-4 compared with CVD. CKD1-2 and CVD group differed in the accumulation of apolipoprotein A-4 and apolipoprotein A-1.

Conclusions: Our results definitely indicated similar proteomic profiles in CKD1-2 and CVD patients, in contrast to CVD and CKD5 patients, suggesting that mechanisms of CVD acceleration may be different in initial and advanced stages of CKD. It seems that it is related to chronic inflammation and immune disturbances, typical for CKD.

TH-PO890

Hemodialysis-Induced Release of Microparticles Liina Vassil,[1] Inga Soveri,[1] Fariborz Mobarrez,[2] Tora Almquist,[3] Bengt C. Fellstrom.[1] *[1]Dept of Medical Sciences, Uppsala Univ, Uppsala, Sweden; [2]Dept of Medicine, Karolinska Inst, Stockholm, Sweden; [3]Dept of Clinical Sciences, Danderyd Hospital, Karolinska Inst, Stockholm, Sweden.*

Background: Microparticles (MPs) are 0.1 -1.0 μm vesicles that are released from cells upon activation or during apoptosis. MPs are believed to be involved in the pathophysiology of atherosclerosis and thrombosis. Patients with cardiovascular risk factors have significant MP elevation. Measurements of MPs may uncover new insight into mechanisms behind the severely increased cardiovascular disease (CVD) risk in hemodialysis (HD) patients. The aim was to study whether a hemodialysis session affects MP formation and release.

Methods: Plasma samples from 20 HD patients were drawn before and 1h after the start of a HD session. MPs derived from platelets (CD41+), monocytes (CD14+), endothelial cells (CD62E+), and their expression of phosphatidylserine (PS) and tissue factor (CD142) were analyzed using flow cytometry. P-selectin (CD62P) and CD40 ligand (CD154) were measured on platelet-MPs. In addition, Klotho and the receptor for advanced glycation end products (RAGE) expression were measured on MPs. Paired t-test was used.

Results: Mean age was 73.6 years (range 54-91), 5 patients were female, 14 had central dialysis catheter, 8 patients had diabetes and 14 had CVD.

Marker ($x10^6$/L)	Before HD	1h after start of HD	P-value
Lactadherin (PS+MPs)	3645(1960-9784)	4388(1966-12672)	0.08
Lactadherin + CD41	464(153-2321)	774(169-3000)	0.04
Lactadherin+CD41+CD62P	186(50-1098)	550(70-1369)	0.01
Lactadherin+CD41+CD154	205(33-992)	365(52-1236)	0.05
Lactadherin+CD14	216(175-443)	337(205-584)	0.00
Lactadherin+CD62E a	713 (±233)	845 (±348)	0.03
CD41+CD142 a	467 (±262)	541 (±337)	0.30
CD62E+CD142	135(15-392)	171(26-900)	0.06
CD14+CD142	31(11-121)	58(17-193)	0.00
Klotho a	2260 (±276)	2612 (±414)	0.00
RAGE	154(122-1356)	252(178-1491)	0.00

Mean (± SD) a or Median (range)

Conclusions: The majority of MP levels increase significantly after the start of a HD session. Whether this is driven by patient or dialysis specific factors remains unclear. The clinical significance of MP release during HD needs to be evaluated.

TH-PO891

The Monocyte Subset of CD14+CD16+ Cells Plays a Key Role of Promoting Atherosclerosis in Hemodialysis Patients Miki Nishida,[1] Minoru Ando,[2] Yusuke Iwamoto,[3] Ken Tsuchiya,[1] Kosaku Nitta.[1] *[1]Dept Medicine, Kidney Center, Tokyo Women's Medical Univ, Tokyo, Japan; [2]Tokyo Metropolitan Komagome Hospital, Tokyo, Japan; [3]Saitou Memorial Hospital, Tokyo, Japan.*

Background: Atherosclerosis is closely associated with morbidity and mortality in hemodialysis (HD) patients. The scavenger receptors (SR) in circulating monocytes play a key role in promoting foam cell formation by binding and internalizing oxidized low-density lipoprotein. In addition, heterogeneity of monocytes and macrophage-colony stimulating factor (M-CSF) may facilitate the atherosclerotic process by SR over-expression.

Methods: Subjects included 62 HD patients and 30 healthy controls. Peripheral monocytes were isolated using magnetically labeled Whole Blood $CD14^+$ micro-beads. Transcriptional levels of CD16 and SR-A were measured in monocytes by quantitative real-time RT-PCR, using the comparative threshold (Ct) method. The gene expressions were compared between HD patients and controls, and between HD patients who had cardiovascular disease (CVD) and those who did not. Plasma concentration of M-CSF was measured with M-CSF ELISA kit. Additionally, CD16 protein expression was analyzed by a flow cytometry.

Results: SR-A gene expression was higher in monocytes from HD patients than in those from controls (2.35 vs 1.29, p=0.0006). Moreover, it was higher in HD patients with CVD than in those without (2.79 vs 1.64, p=0.0023). Plasma concentration of M-CSF was 8-fold higher in HD patients than in controls (1173±517.3 vs 152±55.1 pg/ml, p<.0001). It was significantly correlated with the gene expression of SR-A (r^2=0.129, p=0.0007). The CD16 gene expression was higher in $CD14^+$ monocytes from HD patients than in those from controls(1.28 vs 1.07, p=0.0310), and was significantly correlated with the gene expression of SR-A (r^2=0.051, p=0.0467). In a flow cytometry, the proportion of $CD14^+CD16^+$ cells was 2.2-fold higher in HD patients than in controls (34.60 vs 15.85, p=0.0034). In addition, this proportion was related with M-CSF (r^2=0.354, p=0.0118) and SR-A gene expression (r^2=0.540, p=0.0240).

Conclusions: The $CD14^+CD16^+$ cells are important subset of monocytes in HD patients, which may prime and increase SR expressions.

TH-PO892

Active Ghrelin Enhances the Association Between BMI and Clinical Outcome in Hemodialysis Patients Irrespective of Appetite Ilia Beberashvili,[1] Inna Sinuani,[2] Ada Azar,[3] Leonid Feldman,[1] Shai Efrati.[1] *[1]Nephrology, Assaf Harofeh Medical Center, Zerifin, Israel; [2]Pathology, Assaf Harofeh Medical Center, Zerifin, Israel; [3]Nutrition, Assaf Harofeh Medical Center, Zerifin, Israel.*

Background: Ghrelin, a gastric orexigenic peptide, and BMI are known as inversely associated to each other and have both been linked to cardiovascular (CV) risk and mortality in hemodialysis (HD) patients. However, it is unclear whether ghrelin and BMI interact modifying risk of all-cause and CV death in this population.

Methods: We investigated the interactions between BMI and ghrelin as predictors of death over a 3 years of follow-up (median - 28 months, interquartile range - 17-34 months) in 261 maintenance HD patients (39% women, mean age of 68.6±13.6 years).

Results: A significant interaction effect of high ghrelin and high BMI (defined as their levels higher than median) on all-cause mortality was found: crude Cox hazard ratio (HR) for the product termed Ghrelin x BMI was 0.52, with a 95% confidence interval (CI): 0.29 to 0.95 (P=0.04). Across the four ghrelin-BMI categories, the group with high ghrelin and high BMI exhibited the better outcome in both all-cause and cardiovascular mortality (multivariable adjusted hazard ratios were 0.30, 95% CI 0.15 to 0.59, P<0.001, and 0.33, 95% CI 0.13 to 0.86, P=0.02, respectively). Compared to patients from other ghrelin-BMI categorized groups, patients in the high ghrelin-high BMI group were more surprisingly anorexic, were predominantly non-smokers, with lower incidence of diabetes and had higher Kt/V levels. These variables consequently were inserted in all multivariable models. Data analyses carried out by stratifying patients according to ghrelin-fat mass, but not to ghrelin-lean body mass categories, provided similar results.

Conclusions: We observed interactions between high ghrelin and BMI that were associated with decreased mortality risk in our cohort, especially those due to cardiovascular causes. Interestingly, the orexigenic effect of ghrelin does not seem involved in described interaction.

TH-PO893

Serum Procollagen Type I Carboxy-Terminal Propeptide Is Associated with Left Ventricular Hypertrophy and Dysfunction, and May Predict Cardiovascular Event in Incidental Dialysis Patient Sung jun Kim,[1] Hye Eun Yoon,[1] Sungjin Chung,[2] Seok Joon Shin.[1] *[1]Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Incheon, Korea; [2]Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Korea.*

Background: Serum procollagen type I carboxy-terminal propeptide(PICP) is a marker of myocardial fibrosis in hypertensive heart disease.However the clinical significance of this biomarkers is less determined in end-stage renal disease (ESRD) patients. This study was to evaluate the association of predialysis serum PICP levels with echocardiographic markers in ESRD patients.

Methods: Serum PICP, albumin, CRP, iPTH levels were obtained from predialysis blood samples of 123 incidental dialysis patients. Echocardiographic parameters included left ventricular mass index (LVMI) and ejection fraction, ratio of peak early transmitral flow velocity to peak early diastolic mitral annular velocity (E/E' ratio), ratio of peak early transmitral flow velocity to peak late transmitral flow velocity (E/A ratio), and mitral valve-deceleration time (DT).

Results: A direct correlation was found between PICP and Left ventricular mass index (r=0.308, P=0.002), between PICP and E/E' ratio (r=0.236, P = 0.009), between PICP and ratio of peak early transmitral flow velocity to peak late transmitral flow velocity (E/A) (r=0.285, P=0.002). A negative correlation was found between PICP and Left ventricular ejection fraction (r=-0.289, P=0.001), between PICP and mitral valve-deceleration time (r=-0.203, P=0.026). In the multivariate linear regression analysis, the PICP was independently positive associated with LVMI and E/e' and negative associated with Left ventricular ejection fraction. In the multivariate cox regression analysis, previous CV event (HR 15.224, CI 3.26-71.04), and High PICP group (vs low PICP group) (HR 9.478, CI 1.10-81.82) were the significant prognostic factors cardiovascular event.

Conclusions: Serum procollagen type I carboxy-terminal propeptide (PICP) is associated with left ventricular hypertrophy and dysfunction, and may predict cardiovascular event in incidental dialysis patient.

TH-PO894

Associations of Soluble Receptor for Advanced Glycation End Products (s-RAGE) and S100A12 (EN-RAGE) with Mortality in Long-Term Hemodialysis Patients Ji Yong Jung,[1] Eul Sik Jung,[1] Byoungho Choi,[1] Yun Jung Oh,[2] Chungsik Lee,[2] Ae jin Kim,[1] Han Ro,[1] Jae Hyun Chang,[1] Hyun Hee Lee,[1] Wookyung Chung.[1] *[1]Div of Nephrology, Dept of Internal Medicine, Gachon Univ Gil Medical Center, Incheon, Republic of Korea; [2]Div of Nephrology, Dept of Internal Medicine, Cheju Halla General Hospital, Jeju, Republic of Korea.*

Background: Hemodialysis (HD) patients have been associated with vascular calcification and ultimately with high mortality rates. Formerly, we reported association of soluble receptor for advanced glycation end products (s-RAGE) and S100A12 (EN-RAGE) with vascular calcification. We extended our observation whether those biomarkers could be proposed for predicting cardiovascular morbidity and mortality in these subjects.

Methods: This is a prospective observational cohort study in 199 HD patients from extended analyses of our previous study. Serum S-RAGE, S100A12, comorbidities, and other traditional risk factors were also investigated. The cumulative incidences for death using Cox proportional-hazards regression were evaluated in multivariable analyses. A mean observation period was 29 months.

Results: The patients were 57.1 ± 13.7 years of age; 54.3% were male, 49.2% were diabetic, and 36.2% had a history of cardiovascular disease. During the observation period, 27 patients (13.6%) were died. Univariate analysis demonstrated that S100A12 was correlated with diabetes (P = 0.04) and hs-CRP (P = 0.01). In multivariable analyses, serum s-RAGE (HR [hazard ratio], 1.16; 95% CI [confidence interval], 0.61-2.19; P = 0.65) and S100A12 (HR 1.05; 95% CI, 0.62-1.77; P = 0.87) were not associated with mortality in hemodialysis patients, though traditional predictors for mortality including age, history of cardiovascular diseases, serum albumin and serum high-sensitivity C reactive protein (hs-CRP) were related to mortality. Powerful predictors for mortality were age, previous cardiovascular disease and serum albumin level.

Conclusions: Serum S-RAGE and S100A12 may be weak surrogate markers to predict all-cause mortality in patients receiving hemodialysis, even though S100A12 was partly related with diabetes and inflammation.

TH-PO895

Impact of Sodium-Dependent Phosphate Co-Transport, Pit-1, in Peripheral Blood Mononuclear Cells on Cardiac Calcification in Maintenance Hemodialysis Patients

Minwen Ding, Mengjing Wang, Minmin Zhang, Jing Chen. *Huashan Hospital, Fudan Univ.*

Background: Vascular calcification (VC) is an importance risk factor for cardiovascular disease in MHD patients, however, the mechanisms of which are still under investigation. The aims of this study were to explore the risk factors of VC in MHD patients, and to identify the expression of sodium-dependent phosphate co-transporter (Npt) in peripheral blood mononuclear cells (PBMCs) and assess its association with cardiac calcification and its possible impact factors.

Methods: This is a cross-sectional analysis of adult MHD patients who received at least 6-month regular MHD in our dialysis center. The coronary artery calcification (CAC) was measured by cardiac MSCT. The gene expression of Npt in PBMCs was measured by Real-time PCR and we tested serum TNF-α and IL-6 by ELISA. Multivariate logistic analysis was used to determine the risk factors of CAC. Correlation between the gene expression of Npt and other parameters was examined by Pearson relativity analysis.

Results: 1.68 eligible patients were enrolled. 2. Three kinds of Npts were detected in PBMCs of MHD patients. They were typeIINpt,Npt2b,type III Npt,Pit-1 and Pit-2, among which Pit-1 mRNA expression was significantly associated with extent of CAC. 3. The results of the logistic regression analysis were listed in Table 1. 4.Pearson relativity analysis showed Pit-1 mRNA expression of PBMCs was significantly correlated with serum phosphorus (r=0.43, P=0.002), CAC sore (r=0.63, P<0.001) and Pit-2 mRNA expression of PBMCs (r=0.53, P=0.001).

Table 1. Multiple logistic regression analysis of factors associated with CAC score tertile in MHD patients

Variable	Unadjusted		Adjusted	
	OR(95% CI)	P	OR (95% CI)	P
Female gender	0.36	0.037		
Age(y)	1.03	0.062		
Dialysis vintage(m)	1.02	0.007	1.03 (1.01-1.05)	0.003
Smoking	2.38	0.074		
Diabetes mellitus	5.56	0.004	7.14 (0.03-0.75)	0.021
Laboratory parameters				
Ferritin(ug/l)	1.01	0.080		
TNF-α (pg/ml)	1.20	0.019	1.29 (1.01-1.66)	0.044
IL-6 (pg/ml)	1.06	0.030		
Triglyceride(mmol/l)	1.48	0.038		
PBMC Pit-1 mRNA(exp.AU)	1.79	0.055	2.52 (1.08-5.88)	0.032
Therapy				
ACEI/ARB	0.35	0.075		
Lipid-lowing drugs	0.44	0.098		

Longer dialysis vintage (P=0.003), diabetes (P=0.021), higher concentration of serum TNF-α (P=0.044), and Pit-1 mRNA expression of PBMCs (P=0.032) were significantly associated with higher tertile of coronary artery calcification.

Conclusions: Our result showed that longer dialysis vintage, diabetes, higher concentration of serum TNF-α and Pit-1 mRNA expression of PBMCs are the risk factors of CAC in MHD patients. Pit-1 mRNA expression of PBMCs was significantly correlated with serum phosphorus, CAC sore and Pit-2 mRNA expression of PBMCs.

Funding: Government Support - Non-U.S.

TH-PO896

HDL Not as Predictive as apoA-1:apoB Ratio of Dialysis Patients in Predicting Death

Yuji Sato,[1] Shouichi Fujimoto,[2] Tatsunori Toida,[2] Yasuhiro Yamashita,[3] Takashi Iwakiri,[3] Akihiro Fukuda.[1] *[1]Dialysis Div, Univ of Miyazaki Hospital, Miyazaki, Japan; [2]epartment of Hemovascular Medicine and Artificial Organs, Faculty of Medicine, Univ of Miyazaki, Miyazaki, Japan; [3]Dept of Internal Medicine, Div of Circulatory and Body Fluid Regulation, Faculty of Medicine, Univ of Miyazaki, Miyazaki, Japan.*

Background: In dialysis patients, the risk extended by the apolipoprotein profile to all-cause or cardiovascular (CVD) mortality is obscure. Our aim was to investigate the association between the apolipoprotein profile and the incidence of death in chronic dialysis patients.

Methods: A prospective observational study of mortality incidence in dialysis patients was conducted.

Results: Prevalent dialysis patients (n=1088) were enrolled and followed for 4 years. Of the 194 deaths recorded, 82 were of CVD origin. For the regular lipid markers (HDL, non-HDL, and TG), +1 mg/dl of HDL was significantly associated with all-cause mortality [HR and 95% CI, 0.986 (0.974–0.999)] but not for CVD mortality by multivariable Cox analysis adjusted for sex, age, basal kidney disease, dialysis vintage, dry weight, and pre-dialysis systolic blood pressure. For apolipoprotein lipid markers (apoA-1:apoB ratio, apoCIII:apoE ratio, and apoB48:TG ratio), +1 digit of the apoA-1:apoB ratio was significant for all-cause [0.279 (0.102–0.765)] and CVD [0.165 (0.036–0.750)] mortality. When participants were divided into quartiles, the highest quartiles of the apoA-1:apoB ratio were significantly associated with both categories of death when compared with the lowest quartiles by multivariable Cox analysis.

Conclusions: Although controversies persist regarding whether lipids affect the prognosis of dialysis patients, our data revealed that the apoA-1:apoB ratio was significantly associated with all-cause and CVD mortality in dialysis patients.

Funding: Government Support - Non-U.S.

TH-PO897

HDL Subfractions in End-Stage Renal Disease (ESRD) Patients

Anna Gluba-Brzozka, Beata Franczyk-Skora, Jacek Rysz. *Dept of Nephrology, Hypertension and Family Medicine, Medical Univ of Lodz, Poland.*

Background: Chronic kidney disease is a common disease associated with high cardiovascular risk. Recent studies have suggested that HDL not LDL may play the more important role in the progression of atherosclerosis in CKD patients. HDL from CKD patients was shown to become dysfunctional, lose its vasoprotective properties and begin to promote endothelial dysfunction and inflammation.

Methods: The aim of this study was to analyze which HDL fractions were more abundant in ESRD patients and are associated with advanced atherosclerosis. This study included 50 ESRD patients (16 women, 34 men) on dialysis (WAM University Hospital, Lodz, Poland) and 20 healthy volunteers (14 women, 6 men). Blood samples were collected from all subjects and HDL subfractions were analyzed with the use of Lipoprint system. Moreover, all patients had IMT measured.

Results: This study revealed statistically significant differences in HDL subfractions between control and study group: HDL1 [5.6 (2.0-7.1) vs. 13.0 (8.2-15.8), p<0.0001], HDL2 [13.1 (7.8-14.9) vs.17.7 (15.2-21.0), p=0.009], HDL3 [5.5 (0.4-8.6) vs. 9.4 (7.8-11.3), p<0.0001], HDL4 [8.5 (0-10.4) vs.10.6 (9.5-12.0), p=0.003], HDL5 [9.2 (3.3-10.5) vs. 11.4 (9.9-12.1), p=0.01], HDL7 [7.6 (7.2-8.4) vs. 5.3 (4.2-7.2), p<0.0001], HDL8 [8.7 (8.0-9.5) vs. 4.8 (3.5-5.8), p<0.0001], HDL9 [7.0 (5.9-8.2) vs. 3.8 (3.0-4.8), [p<0.0001], HDL10 [15.9 (7.6-28.7) vs. 4.3 (2.6-7.1), p<0.0001] and large HDL [26.5 (17.5-29.2) vs. 40.3 (33.0-47.0), p<0.0001] and HDL Small [30.8 (22.3-43.2) vs. 12.8 (9.4-17.9), p<0.0001]. Significant differences were also observed in HDL1 [9.3 (6.6-12.9) vs. 13.4 (8.7-16.9), p=0.014], HDL6 [20.2 (18.0-23.2) vs.17.6 (15.2-20.1), p=0.020], HDL Large [35.0 (23.7-40.0) vs. 41.4 (33.6-48.0), p=0.017 and HDL Intermediate [50.2 (45.8-51.7) vs.45.8 (40.0-49.1), p=0.017] between HD patients with IMT > 0.9 mm and <0.9 mm].

Conclusions: This study revealed that ESRD influences HDL subfractions. Subfractions of large HDL are more abundant in patients with ESRD while small HDL fraction is more frequent in healthy persons. It is possible that the shift in HDL subfractions may be responsible for the increased risk of atherosclerosis in CKD patients.

TH-PO898

High Non-HDL Cholesterol as an Independent Risk Factor for Coronary Restenosis in Hemodialysis Patients Undergoing Percutaneous Coronary Interventions

Shoko Hasegawa,[1] Toshiaki Nakano,[1] Yasushi Mukai,[2] Yuta Matsukuma,[1] Ryusuke Yotsueda,[1] Akihiro Tsuchimoto,[1] Kiichiro Fujisaki,[1] Kazuhiko Tsuruya,[1,3] Takanari Kitazono.[1] *[1]Dept of Medicine and Clinical Science, Kyushu Univ Graduate School of Medical Sciences, Fukuoka, Japan; [2]Dept of Cardiovascular Medicine, Kyushu Univ Graduate School of Medical Sciences, Fukuoka, Japan; [3]Dept of Integrated Therapy for Chronic Kidney Disease, Kyushu Univ Graduate School of Medical Sciences, Fukuoka, Japan.*

Background: It has been reported that patients with end-stage kidney disease (ESKD) have a higher risk of restenosis after percutaneous coronary intervention (PCI). The aim of this study was to investigate the risk factors of restenosis after PCI in hemodialysis (HD) patients.

Methods: From January 2007 to December 2014, we enrolled 54 consecutive ESKD patients undergoing HD (mean age: 66.5 +/- 10.1 years; 15 women, 39 men; mean HD duration: 3.7 years), who received PCI and follow-up coronary angiography (CAG) after about 6 months. The coronary restenosis was defined by the patient having target lesion revascularization on follow-up CAG.

Results: Of 54 patients who had received PCI, restenosis occurred in 22 patients (40.7%) within 5-12 months after PCI. In the univariable logistic analysis, serum levels of low-density lipoprotein cholesterol/high-density lipoprotein cholesterol ratio, serum levels of non-high-density lipoprotein cholesterol (non-HDL-C), and history of major adverse cardiovascular events (MACE) were significantly associated with the occurrence of coronary restenosis; odds ratio (OR) [95% confidence interval (CI)] was 1.89 [1.02-3.50], 1.22 [1.01-1.47], and 5.79 [1.59-20.99], respectively. In the multivariable logistic analysis, non-HDL-C and the history of MACE were significantly associated with the coronary restenosis; OR [95% CI] was 1.35 [1.08-1.69](per 10 mg/dL increase in non-HDL-C) and 8.55 [1.88-38.85], respectively.

Conclusions: Non-HDL-C was an independent risk factor for the occurrence of coronary restenosis in HD patients undergoing PCI. This result suggests the significance and necessity of strict management of lipid metabolism after PCI in even HD patients.

TH-PO899

Galectin-3 Does Not Correlate within Markers of Cardiac Structure and Function on Cardiac MRI: A Study in Haemodialysis Patients

Lisa E. Crowley,[1] Aghogho Odudu,[1] Saoirse O'sullivan,[2] Christopher W. McIntyre.[3] *[1]Dept of Renal Medicine, Royal Derby Hospital, United Kingdom; [2]Div of Medical Sciences, Univ of Nottingham, United Kingdom; [3]Kidney Clinical Research Unit, London Health Sciences Centre, London, Canada.*

Background: End-stage renal failure patients undergoing haemodialysis (HD) suffer disproportionate rates of death due to heart failure. Accurate tools to help predict those at highest risk are therefore desirable. Galectin-3 is a soluble β-galactoside binding protein secreted by activated macrophages that promotes cardiac fibroblast proliferation, collagen deposition and as a result ventricular dysfunction. Galectin-3 is the only FDA approved test for assessing prognosis in chronic heart failure. Our study explored the relationship between Galectin-3 and cardiac structure and function in a dialysis population.

Methods: We measured Galectin-3 (G3) levels in a multiplex assay (Merck Millipore) in HD patients enlisted in a clinical trial. Results were correlated with tagged cardiac magnetic resonance imaging to assess left ventricular structure and function.

Results: A total of 65 patients had G3 levels taken. The mean age of the cohort was 60±24 years. The overall mean G3 level was 17.7ng/mL±0.07. The mean Left Ventricular Mass Index was 77.09g/m^2±20.4, mean ejection fraction 57.47%±11.7 and mean End-diastolic volume 143.4ml±39.4. In the whole cohort there was no significant correlation between G3 levels and any of the measure of left ventricular structure and function including LVMI (r=-0.22 p=0.24), LVEF (r=0.08 p=0.65) or LVEDV (r=0.012 p=0.94). The previously recommended upper limit of normal for G3 levels is 17.7ng/mL. 32 patients had a G3 level greater than this. In this group the mean G3 level was 23.2ng/mL, however there remained no significant correlations with age (r=0.10 p=0.38), LVEF (r=0.23 p=0.26), LVEDV (r=-0.01 p=0.95), LVMI (r=0.11 p=0.59) or global peak diastolic and systolic strain rates (r=0.3 p=0.14 and r=0.16 p=0.41).

Conclusions: In HD patients, Galectin-3 is not associated with structural and functional markers of systolic dysfunction seen on tagged cardiac MRI. Our results suggest that Galectin-3 does not have a role in risk stratification of this patient group.

TH-PO900

Association of Klotho and FGF23 with Frailty in Patients Initiating Hemodialysis

Sahar Koubar,[1] Esther D. Kim,[2] Dorry L. Segev,[1] Stephen M. Sozio,[1] Larisa Tereshchenko,[3] Lucy A. Meoni,[1] Rulan S. Parekh,[2] Michelle M. Estrella.[1] *[1]Johns Hopkins; [2]Univ of Toronto; [3]Univ of Oregon.*

Background: Frailty at dialysis initiation is associated with higher mortality. Both FGF23 and its co-receptor, klotho, have been implicated in the development of frailty. We aimed to evaluate the independent association of FGF23 and soluble klotho (sKlotho) with frailty in hemodialysis (HD) patients.

Methods: We conducted a cross-sectional study of incident HD patients enrolled in the Predictors of Arrhythmic and Cardiovascular Events in ESRD (PACE) Study. Frailty was defined by ³3 of the following: unintentional weight loss ³10 lbs in prior year, self-reported exhaustion, weakness (by hand grip strength), slowness (by walking distance) and self-reported low physical activity. Logistic regression was used to examine the associations of sKlotho and FGF23 with odds of frailty and frailty subcomponents.

Results: Of 336 individuals, 71% were black; 59% were male. Mean age was 55y. All had hypertension and 56% had diabetes, 38% CAD, and 37% obesity. Median sklotho level was 364.4 pg/ml (IQR 272.5-494.6); mean FGF23 level was 656.2 U/ml (SD: 498). 40% of participants were frail. Adjusting for demographic factors, obesity, Charlson Comorbidity Index, hsCRP, serum albumin and Kt/V, higher sKlotho was associated with lower odds of frailty (Table).

Table. Unadjusted and adjusted association of sKlotho or FGF-23 with odds of frailty

Model	sKlotho, per 1-log pg/mL higher			FGF-23, per 100 ru/mL higher		
	OR	95% CI	P-value	OR	95% CI	P-value
Frailty						
Unadjusted	0.67	0.41 – 1.10	0.12	0.96	0.92 – 1.00	0.06
Adjusted*	0.58	0.33 – 1.01	0.05	0.96	0.91 – 1.01	0.09
Frailty Subcomponents*						
Weight loss ≥10 lbs	1.19	0.65 – 2.18	0.58	0.93	0.88 – 0.98	0.01
Exhaustion	0.53	0.31 – 0.95	0.03	1.04	0.99 – 1.10	0.11
Weakness	0.60	0.33 – 1.08	0.09	1.00	0.95 – 1.05	0.98
Slowness	0.92	0.51 – 1.66	0.78	0.98	0.93 – 1.03	0.43
Low physical activity	0.66	0.38 – 1.13	0.13	1.01	0.96 – 1.06	0.72

*Adjusted for age, gender, race, obesity, Charlson Co-morbidity Index, hsCRP, serum albumin and Kt/V.

This remained robust after also adjusting for FGF23. Conversely, FGF23 was not associated with frailty. In adjusted analyses of the frailty subcomponents, higher sKlotho was only associated with self-reported exhaustion (OR=0.54, 95%CI: 0.30-0.95) while higher FGF23 was only associated with unintentional weight loss (OR=0.93; 95%CI: 0.88-0.98).

Conclusions: sKlotho, but not FGF23, was inversely associated with odds of frailty in incident HD patients, although both hormones appear to be associated with different individual subcomponents of the frailty phenotype.

FGF23 Is Not Associated with Arterial Stiffness in Patients with CKD5D

Kenneth Lim,[1] Stephen M.S. Ting,[2] Daniel Zehnder,[3,4] Thomas F. Hiemstra.[5] *[1]Div of Nephrology, Massachusetts General Hospital, Boston, MA; [2]Dept of Medicine, Heart of England NHS Foundation Trust, Birmingham, United Kingdom; [3]Div of Nephrology, Univ Hospital Coventry and Warwickshire NHS Trust, Coventry, United Kingdom; [4]Div of Metabolic and Vascular Health, Warwick Medical School, Coventry, United Kingdom; [5]School of Clinical Medicine, Univ of Cambridge, Cambridge, United Kingdom.*

Background: Arterial stiffening is thought to be a key determinant of excess Cardiovascular mortality in CKD patients. In CKD, the bone-derived phosphatonin fibroblast growth factor (FGF) 23 is elevated and has been implicated in the development of Cardiovascular disease. In this study, we sought to determine whether FGF23 is a predictor of arterial stiffness in dialysis-dependent CKD patients.

Methods: In this cross-sectional study, we enrolled 352 patients with advanced CKD and 150 healthy controls. Pulse wave velocity (PWV) was recorded by applanation tonometry, and blood pressure and biochemical parameters including plasma intact-FGF23 concentrations determined.

Results: Patients with CKD were significantly younger than controls (46±14 versus 49±11 years, p=0.02), had a higher blood pressure (MAP 97±14 vs 94±10 mmHg, p=0.003), and were more likely to be male (61% versus 49%, p=0.008). CKD patients had significantly higher FGF23 (3095 pg/ml, IQR 612-12726 versus 40 pg/ml, IQR 33-49, p<0.001) and parathyroid hormone (25 pmol/l, IQR 13-56 versus 3.8 pmol/l, IQR 3-5, p<0.001). PWV was elevated in patients with CKD (8 m/sec, IQR 6.9-9.6 vs 7.3m/sec, IQR 6.6-8.4, p=0.0002). In a regression model adjusted for known predictors of PWV, FGF23 did not predict PWV (β=-0.15, p=0.063), but was positively associated with the presence of CKD (p=0.009), age (p<0.001), mean arterial pressure (p<0.001) and heart rate (p=0.001).

Conclusions: In this prospective cohort study, FGF23 did not predict arterial stiffening beyond known risk factors of age, mean arterial pressure, heart rate and the presence of diabetes. Our findings suggest that the excess cardiovascular mortality observed with elevated FGF23 in CKD is not primarily driven by effects on arterial stiffening.

TH-PO902

Differential Association of Fibroblast Growth Factor-23 and Soluble Klotho with Left Ventricular Hypertrophy

Tanya S. Johns,[1] Esther D. Kim,[2] Tessa Kimberly Novick,[3] Lucy A. Meoni,[3] Stephen M. Sozio,[3] Bernard G. Jaar,[3] Larisa Tereshchenko,[4] Rulan S. Parekh,[2] Michelle M. Estrella.[3] *[1]Albert Einstein College of Medicine; [2]Univ of Toronto; [3]Johns Hopkins Univ; [4]Univ of Oregon.*

Background: Fibroblast growth factor-23 (FGF23), a phosphaturic hormone, has been implicated in the pathogenesis of left ventricular hypertrophy (LVH) among patients with chronic kidney disease. Whether FGF23's co-receptor, klotho, is independently associated with LVH is unclear.

Methods: To determine whether soluble klotho (sKlotho) is independently associated with LVH among incident hemodialysis patients, we conducted a cross-sectional study among participants who underwent baseline 2D echocardiograms in the Predictors of Arrhythmia and Cardiovascular Events (PACE) Study. Multivariable logistic regression models with FGF23, sKlotho, and both as primary predictors were constructed to estimate the odds of LVH (defined as LV mass index >116 g/m^2 in men and >104 g/m^2 in women).

Results: Of 391 participants who underwent echocardiogram, 371 and 387 had sKlotho and FGF23 levels available, respectively; 72% had LVH. Mean age was 54 years and 72% were black. All participants had hypertension with mean systolic BP 154 mm Hg. Median volume removed per HD session was 2.6L (IQR: 1.6 – 3.7). FGF23 was not associated with LVH after adjusting for age, race, gender, BMI, systolic BP, serum albumin level, and ultrafiltration volume. In contrast, higher sKlotho was independently associated with lower odds of LVH (OR=0.51 per 1 log higher; 95% CI: 0.29-0.96); this association remained robust with additional adjustment for FGF23 and Charlson Co-Morbidity Index.

Conclusions: sKlotho, not FGF23, is associated with a lower odds of LVH among incident hemodialysis patients.

Table. Association of FGF23 and sKlotho with LVH

	OR	95% CI	P-value
FGF23, per 100 rU/mL higher*	1.03	0.98 – 1.10	0.20
sKlotho, per 1 log pg/mL higher*	0.51	0.28 – 0.96	0.04
sKlotho, per 1 log pg/mL higher¶	0.51	0.27 – 0.95	0.03

*Adjusted for age, race, gender, BMI, systolic BP, serum albumin level, ultrafiltration volume
¶Additionally adjusted for FGF23 and Charlson Co-Morbidity Index

TH-PO903

Predictors of Arterial Stiffness in Incident Hemodialysis Patients

Stephanie M. Toth-Manikowski,[1] Esther D. Kim,[2] Lucy A. Meoni,[1] Bernard G. Jaar,[1] Tariq Shafi,[1] Michelle M. Estrella,[1] Rulan S. Parekh,[1,2] Stephen M. Sozio.[1]
[1]Johns Hopkins Univ; [2]Univ of Toronto.

Background: Premature vascular aging and arterial stiffening characterize CKD progression to ESRD and are associated with increased cardiovascular (CVD) morbidity and mortality. We identified predictors of arterial stiffness over time in HD patients.

Methods: In 339 incident HD patients in the Predictors of Arrhythmic and Cardiovascular Risk in ESRD (PACE) study, we examined the associations of baseline age, sex, race, comorbidities, CVD medications, and dialysis characteristics with longitudinal vascular stiffness measured by carotid-femoral pulse wave velocity (PWV) using generalized estimating equations. Annual change in PWV for up to 3 years was analyzed using linear regression.

Results: Mean age was 54, 58% male, 74% African-American, mean (SD) baseline PWV 10.7 (3.4) m/s, and annual PWV change 0.1 (2.6) m/s. Several factors were associated with higher PWV in univariate and multivariate longitudinal models. None were associated with PWV change.

	Univariate	Multivariate
	β (95%CI)	β (95%CI)

P-value:
*<0.05
†<0.01
‡<0.001
#1st 3 month average

Conclusions: Although PWV did not change significantly over time in incident HD patients, age, male sex, diabetes, and pulse pressure were independently associated with higher PWV. It may be difficult to modify PWV after HD initiation and clinical factors should be optimized prior to starting HD.

TH-PO904

Differences in Risk Factors for Coronary Artery Calcification Between Nondiabetic and Diabetic Hemodialysis Patients

Yoshiko Nishizawa,[1] Sonoo Mizuiri,[1] Kyoka Ono,[1] Mariko Asai,[1] Kazuomi Yamashita,[1] Kenichiro Shigemoto,[1] Kohji Usui,[2] Michiko Arita,[3] Kiyoshi Fujita,[4] Takao Masaki.[5] *[1]Div of Nephrology, Ichiyokai Harada Hospital, Hiroshima city, Japan; [2]Ichiyokai Ichiyokai Clinic, Hiroshima city, Japan; [3]Ichiyokai East Clinic, Hiroshima city, Japan; [4]Ichiyokai Yokogawa Clinic, Hiroshima city, Japan; [5]Dept of Nephrology, Hiroshima Univ Hospital, Hiroshima city, Japan.*

Background: The differences in risk factors for coronary artery calcification between nondiabetic and diabetic hemodialysis (HD) patients have not been fully explored.

Methods: We examined Agatston coronary artery calcium score (CACS) using MDCT, age, sex, presence of diabetes, dialysis vintage, smoking history, administration of phosphate binders, geriatric nutritional risk index (GNRI), HbA1c, serum calcium, phosphate, iPTH, CRP, b2MG, LDL-cholesterol and triglyceride (TG) in 355 HD patients: 242 nondiabetics and 113 diabetics. Factors related to CACS were assessed by multivariate regression analysis using all of the above independent variables. Differences in the above parameters according to quartile (Q) of CACS were also assessed.

Results: Mean age (years), dialysis vintage (months), CACS (H) and serum phosphate (mg/dl) were 63±14 vs. 66 ±12 (ns), 125±100 vs.71±50 months (P<0.01), 1651±2173 vs. 2377±2513 (P<0.05), and 5.3±1.3 vs. 5.0±1.4 (ns) in nondiabetics and diabetics, respectively. Patients with CACS Q4 showed higher prevalence of diabetes (40 vs. 19%), age (68±12 vs. 58±14 years), and CRP (0.7±1.3 vs. 0.2±0.4 mg/dl), but lower iPTH (146±133 vs. 193±131 pg/ml) levels than patients with CACS Q1 (P<0.05), and other parameters were not significantly different except HbA1c. Significant associations were observed between CACS and age (P<0.001, β: 0.21), female(P<0.001, β: -0.21), dialysis vintage (P<0.001, β: 0.31), CRP (P<0.05, β: 0.16), TG (P<0.05, β: 0.15) in nondiabetics. However, CACS was significantly associated only with age (P<0.05, β: 0.30) and HbA1c (P<0.05, β:0.26) in diabetics.

Conclusions: Risk factors for coronary artery calcification differ between nondiabetic and diabetic HD patients, and poor glycemic control is the main factor in the latter.

TH-PO905

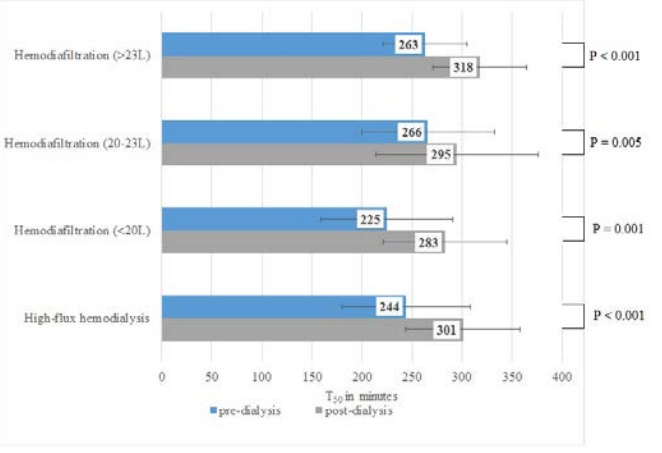
Hemodialysis and Hemodiafiltration Improve Serum Calcification Propensity

Marijke J.E. Dekker,[2] Andreas Pasch,[3] Frank van der Sande,[1] Constantijn Konings,[2] Matthias Bachtler,[4] Mauro Dionisi,[4] Jeroen Kooman,[1] Bernard J. Canaud.[6] *[1]Maastricht Univ Medical Center; [2]Catharina Hospital Eindhoven; [3]Univ Hospital Bern; [4]Calcisco AG; [5]Fresenius Medical Care.*

Background: Calciprotein particles (CPPs) may play an important role in the calcification process. The calcification propensity of serum (T_{50}) is highly predictive of all-cause mortality in chronic kidney disease patients. Whether T_{50} is therapeutically improvable, by hemodialysis (HD) or even further by hemodiafiltration (HDF), has not been studied yet.

Methods: We designed a cross-sectional single center study, and included prevalent patients on HD or HDF. Patients were divided into two groups based on dialysis modality. We included patients on a thrice-weekly schedule, with a dialysis vintage of >3 months and vascular access providing a blood flow rate of >300 ml/min. Calcification propensity of serum was measured by the time of transformation from primary to secondary CPP (T_{50} test), by time-resolved nephelometry.

Results: In total 64 patients were included and, T_{50} was measured in 376 pre- and post-dialysis samples of all in-center dialysis sessions during one week. T_{50} levels improved in both the HD and HDF group with pre- and post-dialysis (mean (SD)) of 244(64)-301(57) and 253(55)-304(61) min respectively (P=0.43). The mean improvement of T_{50} was 26.29% in the HD group and 21.97% in the HDF group (P=0.61). The delta values (Δ) of calcium, phosphate (P) and albumin were equal in both groups. The DT_{50} was mostly influenced by DP (r^2 0.280; P=0.01 HD and r^2-0.239; P=0.02 HDF).



Conclusions: HD and HDF patients present with same baseline vascular calcification risk values pre-dialysis. Calcification propensity is significantly improved during both HD and HDF. T_{50} might be a useful guide to optimize renal replacement strategy to improve the individual calcification risk in dialysis patients.

TH-PO906

Association of Circulating Biomarkers with Vascular Stiffness and Coronary Artery Calcium in Incident Hemodialysis

Esther D. Kim,[1] Stephen M. Sozio,[2] Bernard G. Jaar,[2] Lucy A. Meoni,[2] Michelle M. Estrella,[2] Rulan S. Parekh.[1,2] *[1]Univ of Toronto, Canada; [2]Johns Hopkins Univ.*

Background: Vascular calcification and stiffness are associated with higher mortality in hemodialysis. Studies examining the role of circulating biomarkers – specifically, FGF23, desphospho-uncarboxylated matrix Gla protein (dpucMGP), Fetuin A, osteoprotegerin (OPG), and C-reactive protein (CRP) – in vascular calcification have reported contradictory findings, and the independent association of the biomarkers remains inconclusive.

Methods: In 392 incident hemodialysis patients in the Predictors of Arrhythmic and Cardiovascular Risk End Stage Renal Disease (PACE) study, we examined the associations of baseline FGF23, dpucMGP, Fetuin A, OPG, and CRP with total coronary calcium score (Agatston) at baseline and vascular stiffness (pulse wave velocity [PWV]) at baseline and over 4 study visits. Baseline associations were determined using linear regression and repeated measures over visits were examined using mixed-effects models.

Results: At baseline, higher OPG was associated with increased odds of having a high coronary calcium score (>257), independent of other biomarkers (OR=1.11, 95%CI: 1.06,

1.16). The remaining biomarkers were not associated with high coronary calcium. Higher OPG was associated with higher PWV, and higher FGF23 was associated with lower PWV after adjusting for demographic factors, body mass index, comorbidity index, calcium phosphorus product, systolic blood pressure, and albumin.

Adjusted association with PWV	β (95% CI)
OPG (1 pmol/l)	**0.10 (0.02, 0.19)*†**
FGF23 (100 RU/ml)	**-0.10 (-0.18, -0.02)***
dpucMGP (1-log pm)	0.07 (-0.38, 0.53)
Fetuin A (1 g/l)	-0.79 (-2.77, 1.19)
CRP (1-log µg/ml)	0.02 (-0.27, 0.30)
*P<0.05 †Adjusted for all biomarkers	

OPG and FGF23 remained associated with PWV over follow-up and after additionally adjusting for all biomarkers (β=0.08, 95%CI: 0.01, 0.15 and β=-0.07, 95%CI: -0.13, -0.01).

Conclusions: Several vascular and phosphate biomarkers are associated with vascular calcification at baseline and/or stiffness longitudinally in incident dialysis patients. Further studies assessing interventions on these biomarkers are warranted.

Funding: NIDDK Support

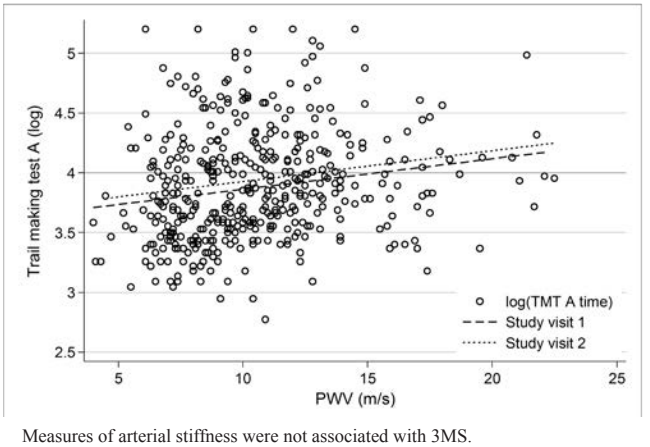
TH-PO907

Association of Arterial Stiffness with Cognitive Impairment in Incident Hemodialysis Esther D. Kim,[1] Lucy A. Meoni,[2] Bernard G. Jaar,[2] Tariq Shafi,[2] Michelle M. Estrella,[2] Rulan S. Parekh,[1,2] Stephen M. Sozio.[2] *[1]Univ of Toronto, Canada; [2]Johns Hopkins Univ.*

Background: Cognitive impairment is common in hemodialysis and places a significant burden on patients and healthcare system. Though vascular stiffness is implicated in the pathogenesis of cerebral microvascular disease, few have examined the relationship between arterial stiffness and cognitive function in dialysis patients.

Methods: This study included 390 incident hemodialysis patients enrolled in the Predictors of Arrhythmic and Cardiovascular Risk in End-Stage Renal Disease (PACE) study. Arterial stiffness was measured using aortic pulse wave velocity (PWV) and augmentation index (AIx). Cognitive function was measured using time to complete Trail making tests A and B (TMT A and TMT B) and the modified mini-mental state exam (3MS) score. Log-linear, Tobit, and logistic regression models were used to examine the baseline association of PWV with TMT A, TMT B, and 3MS, respectively. Changes in the scores over visits and mixed-effect models were used to examine association over time at 1 year follow-up.

Results: At baseline, higher PWV was associated with longer time to complete TMT A after adjusting for demographic factors, reading comprehension score, comorbidity index, systolic blood pressure, and atrial fibrillation (%TMT A=3.12, 95% CI: 0.37-5.87). In the repeated measures analysis, higher PWV was still associated with longer TMT A time (%TMT A=2.05, 95% CI: 0.00-4.11), and higher AIx was associated with longer TMT B time (β=0.80, 95% CI: 0.01-1.58).



Measures of arterial stiffness were not associated with 3MS.

Conclusions: Vascular stiffness isassociated with longer time to complete TMT A and TMT B suggesting that arterial stiffness may lead to subclinical cerebrovascular events and decline in executive function among incident hemodialysis patients.

Close Relationship Between Vascular Endothelial Function and Serum Uric Acid Level in Hemodialysis Patients Makoto Harada,[1] Wataru Tsukada,[2] Yosuke Yamada,[1] Akinori Yamaguchi,[1] Koji Hashimoto,[1] Makoto Higuchi,[1] Yuji Kamijo.[1] *[1]Dept of Nephrology, Shinshu Univ School of Medicine, Matsumoto, Nagano, Japan; [2]Dept of Nephrology and Urology, Ueda Kidney Clinic, Ueda, Nagano, Japan.*

Background: Vascular endothelial function (VEF) impairment is often detected in hemodialysis (HD) patients and has been associated with atherosclerosis and cardiovascular disease (CVD). Although avoidance of VEF impairment is therefore desirable in preventing such complications, the precise factors that influence VEF remain unknown. The present study evaluated VEF for associating factors in HD patients.

Methods: We enrolled 48 patients undergoing maintenance HD at Ueda Kidney Clinic in Japan. No patient had a history of CVD. Reactive hyperemia index (RHI) as evaluated by Endo-PAT (Itamar Medical, Ltd., Caesarea, Israel) was used to asses VEF, whereby a higher RHI was indicative of better function. We also assessed for correlations between the natural logarithm of RHI (LnRHI) and clinical parameters.

Results: The median age of our patients was 67 years, the male-to-female ratio was approximately 2:1, and median LnRHI was low at 0.36. Analysis of Spearman's rank correlation coefficient revealed a significant positive correlation between serum uric acid level (sUA) and LnRHI (rs=0.372, p=0.009). As sUA is influenced by dialysis efficiency and dietary intake, we also performed multivariable linear regression analysis adjusted by age, body mass index, dialysis efficiency by Kt/V, and normalized protein catabolic rate, and observed that sUA was significantly related to LnRHI (B=0.042, 95% CI: 0.007-0.078, β=0.396, p=0.021).

Conclusions: The current study suggests that VEF is closely associated with sUA in HD patients. Although the precise mechanism is unknown, a marked decrease in sUA might be correlated with VEF impairment and should be avoided in individuals undergoing HD.

TH-PO909

Ambulatory Arterial Stiffness Index: An Early Marker of Cardiovascular Disease in Young Hemodialysis Patients Alcia D. Edwards- Richards, Chryso P. Katsoufis, Wacharee Seeherunvong, Nao Sasaki, Marissa J. Defreitas, Gaston E. Zilleruelo, Michael Freundlich, Carolyn L. Abitbol. *Pediatric Nephrology & Cardiology, Univ of Miami/ Holtz Children's Hospital, Miami, FL.*

Background: Cardiovascular disease (CVD)is the leading cause of death in pediatric hemodialysis (HD) patients. Ambulatory arterial stiffness index (AASI) may be an earlier measure of vascular compliance in young patients than pulse pressure (PP). Our objective was to evaluate AASI as a marker of increased vascular stiffness in young HD patients and to compare it with other non-invasive indicators of CVD risk.

Methods: Retrospective review of 24-hour ambulatory blood pressure monitoring (ABPM) was performed in 11 pediatric patients on chronic HD(16±3.6yrs) and dialysis vintage of 32±18 months.AASI was calculated as 1-regression slope of the diastolic over systolic BP. Echocardiogram and bilateral carotid artery ultrasounds were performed to assess left ventricular mass index(LVMI)and carotid intimal medial thickness (cIMT). Carotid artery stiffness indices included distensibility coefficient(DC), stiffness index-β (SI-β) and PP. These were compared with reference values for healthy pediatric controls.

Results: AASI was significantly increased in HD patients compared to controls (0.42±0.1 versus 0.20±0.2;p=0.01).When matched to controls with similar BP's and PP's, the AASI detected increased vascular stiffness independent of PP. cIMT,LVMI, and DC were also significantly increased in HD patients(p<0.01).

Echocardiography & Carotid Ultrasound & 24-Hr ABPM			
Variable	**HD**	**Controls**	**p-Values**
cIMT (mm)	**0.60±0.1**	**0.38±0.1**	**0.01**
LVMI (g/m$^{2.7}$)	**40±9**	**34±11**	**0.01**
DC (kPa^{-1}10^{3})	**43±13**	**53±17**	**0.04**
Stiffness Indexβ	**4.2±10**	**5.3±3**	**0.13**
PP (mmHg) **49±10**		**40±7**	**<0.05**
24-hr PP (mmHg)	**43±9**	**43±5**	**1.00**
AASI	**0.42±0.1**	**0.20±0.2**	**0.01**

Conclusions: Young HD patients demonstrate early surrogate markers of CVD including increased LVMI, cIMT and decreased vascular compliance. Increased AASI detected vascular stiffness that was independent of BP's and PP's. AASI may be an early non-invasive marker of vascular disease in young HD patients that merits further investigation.

TH-PO910

Endovascular Renal Denervation Ameliorates Pathological Left Ventricular Dilatation in Dialysis Patients Neil A. Hoye,[1] J. Christopher Baldi,[1] David L. Jardine,[2] John B.W. Schollum,[1] Gerard T. Wilkins,[1] Luke C. Wilson,[1] Robert J. Walker.[1] *[1]Dunedin School of Medicine, Univ of Otago; [2]Christchurch School of Medicine and Health Sciences, Univ of Otago.*

Background: Endovascular renal denervation (RDN) ameliorates left ventricular hypertrophy and improves contractile function in resistant hypertension. Its cardiac effects on a dialysis population are unknown. We hypothesized RDN would improve blood pressure (BP) control and sympathetic overload, resulting in improved ventricular function.

Methods: Nine dialysis patients with uncontrolled office BP (>140/90mmHg despite two or more agents at maximal tolerated dosages) were recruited into this feasibility study. Office and ambulatory BP monitoring (ABPM) were performed at baseline, one and three months post RDN, along with supine muscle sympathetic nerve activity (MSNA). Echocardiography was performed at baseline and three months. Bilateral RDN was undertaken with an EnligHTN™ catheter.

Results:

	Baseline	1 Month	3 Months	P value
Office Systolic BP (mmHg)	179±28	156±24	152±25	**<0.05**
Office Diastolic BP (mmHg)	90±17	76±13	82±12	0.137
Mean Systolic ABPM (mmHg)	173±19	173±23	166±24	0.544
Mean Diastolic ABPM (mmHg)	92±11	89±13	88±11	0.906
MSNA Burst Frequency (bursts/ min)	59±12	59±15	59±13	0.872
LVIDd (mm)	54±6		50±7	**<0.05**
LV EDV (mL)	168±43		150±42	0.391
LV ESV (mL)	102±41		80±29	0.397
LV EF (%)	41±14		47±11	0.801
LVd mass/BSA (g/m2)	97±16		91±9	0.490
Diastolic Dysfunction Grade	2.0±0.7		1.1±0.4	0.063

Similar to previous, office systolic BP reduced and the effect on ABPM was attenuated. MSNA did not change, a novel finding. Despite lack of change in MSNA, LVIDd reduced with an improving trend in diastolic dysfunction, another novel finding. There was no correlation between change in office systolic BP and ventricular dilatation (R^2=0.255) or dysfunction (R^2=0.034), suggesting BP-independent effects.

Conclusions: RDN in dialysis patients improves office systolic BP and leads to a BP-independent improvement in ventricular dilatation and probably dysfunction. Further controlled studies are warranted in this population.

TH-PO911

Effects of Music and Exercise during Hemodialysis on the Cardiac Autonomic Nervous System Activity Maria Mitsiou,[1] Evangelia J. Kouidi,[1] Vassilios Liakopoulos,[2] Asterios P. Deligiannis.[1] *[1]Laboratory of Sports Medicine, Aristotle Univ of Thessaloniki, Thessaloniki, Greece; [2]Renal Unit, 1st Dept of Internal Medicine, Aristotle Univ of Thessaloniki, Thessaloniki, Greece.*

Background: Cardiac autonomic nervous system (CANS) dysfunction is a common complication in Chronic Kidney Disease (CKD), linked with increased cardiovascular morbidity and mortality. It is known that exercise training during hemodialysis (HD) improves physical function and quality of life in HD patients. Exercise training can suppress the sympathetic over-excitation, restoring the sympathetic (SNS) to parasympathetic nervous system (PNS) balance. Music can positively affect CANS activity. The combination of music and physical training has never been used in CKD. The aim of this study was to investigate the effectiveness of a 6-month, music and physical training combined protocol during HD.

Methods: Heart rate variability (HRV) data were collected from 40 free of any systemic disease HD patients (age 50±14.7 yrs). Patients were randomly assigned to four equally numbered [n=10] groups, employing a joint music and exercise training program for Group A, a sole exercise training program for Group B, a sole music program for Group C and none of the above-mentioned interventions for Group D. At entry and at the end of the study all patients underwent a 6-minute walking test (6MWT) and ambulatory 24-hour Holter monitoring for time- and frequency- domain HRV calculation. The HRV indices obtained were: mean heart rate (HR); standard deviation of NN intervals (SDNN); root mean square of successive differences (RMSSD); proportion of NN50 divided by total number of NNs (pNN50) and very low frequency (VLF).

Results: All indices were significantly better for Group A: 6MWT [F(3,36)=13.095, p=0.000], HR[F(3,36)= 1.910, p=0.145]; SDNN [F(3,36)=11.671, p=0.000]; RMSSD [F(3,36)=12.395, p=0.000]; pNN50 [F(3,36)=45.752, p=0.000]; and VLF [F(3,36)=3.141, p=0.037].

Conclusions: Musical auditory stimulation when jointly used with exercise training during HD has the strongest influence on CANS activity, improving the dynamic interaction between the SNS and PNS. These favorable changes may positively affect cardiovascular morbidity and mortality.

TH-PO912

Temporal Loss of Bone Mineral Density Is Associated with Cardiovascular Diseases in Japanese Patients Starting Renal Replacement Therapy Sawako Kato,[1] Shoichi Maruyama,[1] Bengt Lindholm,[2] Yukio Yuzawa,[3] Yoshinari Tsuruta,[4] Seiichi Matsuo.[1] *[1]Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Japan; [2]Baxter Novum & Renal Medicine Karolinska Inst, Stockholm, Sweden; [3]Nephrology, Fujita Health Univ School of Medicine, Toyoake, Japan; [4]Meiyo Clinic, Toyohashi, Japan.*

Background: Atherosclerosis, vascular calcification and alterations of bone metabolism are common aging disorders, which may be biologically linked via bone-vascular interactions. However, clinical studies on associations of temporal bone loss with cardiovascular disease (CVD) in dialysis patients are limited.

Methods: Seventy-six incident Japanese dialysis patients (46 males, age 60 ± 10 years) were enrolled and followed for a median of 3.8 years (range 1-5.8 years). Bone mineral density (BMD) of the lumbar spine was measured by dual X-ray absorptiometry at baseline and after 1 year.

Results: Baseline BMD, median value 1.05 (0.67-1.56) g/cm^2, negatively correlated to age (rho = -0.28, P = 0.015) and iPTH (rho = -0.14, P = 0.0002). When dividing patients into two groups according to delta BMD (defined as baseline - 1 year), those with high delta BMD had an increased mortality risk (Log rank 6.36, P = 0.012) and time from dialysis initiation to the first CVD event appeared, although not significant, shorter in patients with high delta BMD (Log rank 2.81, P = 0.094). Patients with high delta BMD had a significantly increased relative risk (RR; Cox hazard model) of mortality (10.9, 95% CI; 1.34-250.6) even after adjustments for age, gender, diabetes and smoking,compared with those with low delta BMD. RR of the first CVD event was 5.52 (95% CI; 1.15-7.83) with adjustment for age and gender.

Conclusions: Progressive loss of BMD associated with an increasing risk of CVD and mortality. Whereas in end-stage renal disease patients, BMD may have limited value as predictor of a fracture risk, temporal changes of BMD, potentially reflecting bone-vascular interactions, may be useful as a marker of a CVD risk.

First in Man: Reduction of Inflammation with Medium Cut-Off (MCO) Membranes Daniel Zickler,[1] Ralf Schindler,[1] Markus Storr,[3] Kevin Willy,[1] Bogusz Trojanowicz,[2] Peter Martus,[4] Christof Ulrich,[2] Kristin Liehr,[5] Christian Henning,[5] Torsten Böhler,[3] Marcus A. Glomb,[5] Roman Fiedler,[2] Matthias Girndt.[2] *[1]Dept of Nephrology and Internal Intensive Care Medicine, Charité Univ Medicine, Berlin, Germany; [2]Dept of Internal Medicine II, Martin-Luther-Univ, Halle, Germany; [3]Research & Development, Gambro Dialysatoren GmbH, Hechingen, Germany; [4]Inst for Epidemiology and Applied Biometry, Eberhard-Karls-Univ, Tübingen; [5]Inst for Chemistry / Food Chemistry, Martin-Luther-Univ, Halle.*

Background: High mortality in dialysis patients may be related to reduced clearance of cytokines with conventional dialysis membranes. Attempts to provide a better clearance with high cut-off membranes also leads to albumin loss. A new Medium-Cutoff membrane with better permeability for molecules up to 45 kDa but with limited permeability for albumin was tested clinically for the first time.

Methods: 50 patients were dialyzed with MCO and conventional high-flux (HF) membranes for four weeks following a randomized cross-over design. After the second phase, another 12-week-period was conducted to test for long-term effects. Serum samples were tested for inflammatory effects and cytokine concentrations. Support was granted by the German Federal Ministry of Education and Research (FKZ 13N11796-99).

Results: The primary end point mRNA content of TNF-alpha in leucocytes was reduced to a higher degree and significantly better after 4 weeks on MCO compared to HF membrane (p<0.001). Interleukin-6 mRNA was markedly reduced with MCO (p<0.001). After a significant drop after four weeks of MCO dialysis, albumin concentrations stabilized after 12 weeks.

	Before HF	After HF	Before MCO	After MCO
TNF mRNA Log 10[1]	1.19 ± 0.57 0.03 ± 0.21	1.02 ± 0.49 -0.03 ± 0.18	0.92 ± 0.34 -0.06 ± 0.16	0.75 ± 0.31 -0.16 ± 0.19
IL6 mRNA Log 10[1]	0.86 ± 0.68 -0.18 ± 0.33	0.84 ± 0.67 -0.25 ± 0.34	0.79 ± 0.79 -0.19 ± 0.31	0.60 ± 0.43 -0.32 ± 0.31
Albumin (g/l)	36.6 ± 3.2	37.5 ± 2.7	37.0 ± 3.6	35.2 ± 3.7

[1]Significance testing was based on log transformed values for TNR mRNA and IL6 mRNA. Note that both crossover phases were pooled.

	HF Before extension period	HF After extension period	MCO Before extension period	MCO After extension period
Albumin(g/l)	37.6 ± 2.3	37.9 ± 3.5	35.7 ± 4.5	36.4 ± 3.9

Note that the dialysator before extension period was the dialysator of the 2nd cross over phase.

Conclusions: MCO membranes modulate inflammation in dialysis patients. Albumin concentrations stabilize after an initial drop. These results encourage further investigations with longer treatment periods and clinically relevant endpoints.

Funding: Pharmaceutical Company Support - Gambro, Government Support - Non-U.S.

TH-PO914

Vitamin D and Cardiac Autonomic Tone in End-Stage Kidney Disease: A Blinded, Randomized Controlled Trial Sofia B. Ahmed,[1] Michelle C. Mann,[1] Brenda Hemmelgarn,[1] David A. Hanley,[1] Tanvir Chowdhury Turin,[1] Jennifer M. MacRae,[1] David C. Wheeler,[2] Sharanya Ramesh,[1] Darlene Y. Sola,[1] Derek Exner.[1] *[1]Univ of Calgary, Canada; [2]Univ College London, United Kingdom.*

Background: Importance: End-stage kidney disease (ESKD) patients are at high cardiovascular (CV) risk. Vitamin D deficiency is associated depressed heart rate variability (HRV), a risk factor for CV death. Both vitamin D deficiency and depressed HRV are highly prevalent in ESKD.

Methods: Objective: To determine the effects of activated vitamin D (conventional) compared to activated and nutritional vitamin D (intensive) on HRV (low to high frequency spectral ratio; LF:HF) in patients with ESKD on hemodialysis (HD). **Design:** 2x2 crossover, blinded, randomized controlled trial in outpatient HD units. Fifty-six patients were randomized 1:1 to begin either conventional (0.25mcg alfacalcidiol and placebo 3 times/week) or intensive vitamin D therapy (0.25mcg alfacalcidiol 3 times/week and 50000IU ergocalciferol weekly) for 6 weeks. **Main Outcomes:** HRV is a surrogate index of cardiac autonomic nerve function and independently predicts CV mortality. The primary outcome was the change in LF:HF from the 1st to 6th week HD session. Secondary endpoints included individual changes in LF and HF, parameters of mineral metabolism and renin angiotensin system (RAS) activity.

Results: There was no difference in LF:HF from baseline to 6 weeks for either vitamin D treatment (conventional p=0.9; intensive p=0.07). There were no significant changes in any other measure of HRV, mineral metabolism or RAS activity. On exploratory subgroup analysis, participants who remained vitamin D deficient (25-hydroxyvitamin D<50nmol/L) after treatment had a significant increase in LF:HF (conventional: n=13, p<0.001 vs. insufficient and sufficient groups; intensive: n=8, p<0.001 vs. sufficient group).

Conclusions: Six weeks of treatment with conventional or intensive vitamin D did not alter LF:HF in ESKD patients. However, improved LF:HF was observed in the vitamin D-deficient subgroup. This finding may translate into decreased CV risk and should be considered hypothesis-generating and deserving of further study. **Trial Registration:** ClinicalTrials.gov NCT01774812.

Funding: Private Foundation Support

TH-PO915

The Validity of Left Ventricular Mass as a Surrogate Endpoint for Mortality Outcomes in Chronic Kidney Disease Sunil V. Badve,[1,2] Suetonia Palmer,[3] Giovanni F.M. Strippoli,[4] Matthew A. Roberts,[5] Armando Teixeira-Pinto,[11] Neil Boudville,[6] Alan Cass,[7] Carmel M. Hawley,[1,2] Swapnil Hiremath,[8] Elaine M. Pascoe,[1] Vlado Perkovic,[9] Gillian A. Whalley,[10] Jonathan C. Craig,[11] David W. Johnson.[1,2] *[1]Univ of Queensland; [2]Princess Alexandra Hospital; [3]Univ of Otago; [4]Univ of Bari; [5]Monash Univ; [6]Univ of Western Australia; [7]Menzies School of Health Research; [8]Univ of Ottawa; [9]The George Inst for Global Health; [10]Unitec Inst of Technology; [11]Univ of Sydney.*

Background: Left ventricular mass (LVM) is increasingly used as a surrogate endpoint in trials involving chronic kidney disease (CKD) patients, as intervention-induced reductions in LVM are assumed to lower cardiovascular (CV) risk.

Methods: The aim of this systematic review was to determine the validity of LVM as a surrogate endpoint for all-cause and CV mortality in CKD. Randomized controlled trials evaluating pharmacological and non-pharmacological interventions with follow-up ³3 months were included. The outcomes of interest were LVM change from baseline to last measurement and all-cause and CV mortality. Standardized mean differences (SMD) in LVM change and relative risk of mortality were estimated using random-effects models. Correlations between LVM change and mortality endpoints were summerized across all interventions using a bivariate random-effects Bayesian model together with 95% credible intervals (CrI).

Results: Seventy trials (6420 participants) were eligible. Among 23 interventions, only 3 significantly reduced LVM [erythropoiesis-stimulating agents (SMD -0.13, 95%CI -0.23 to -0.03), renin-angiotensin-aldosterone-system inhibitors (SMD -0.28, 95%CI -0.44 to -0.11) and isosorbide mononitrate (SMD -0.43, 95%CI -0.72 to -0.14)]. There were weak and imprecise associations between LVM change and all-cause mortality (30 trials, 4749 participants, correlation coefficient [r] 0.28, 95%CrI -0.15 to 0.60) and CV mortality (13 trials, 2327 participants, r 0.22, 95%CrI -0.60 to 0.75).

Conclusions: In CKD, it is uncertain whether an intervention-induced LVM change correlates with reduced mortality. Evidence for LVM as a valid surrogate endpoint in CKD is currently lacking.

TH-PO916

Non-Invasive Left Ventricular End-Diastolic Pressure (LVEDP) Measurement in Hemodialysis Patients: A Pilot Study Tariq Shafi, Bernard G. Jaar, Luis F. Gimenez, Alison G. Abraham, Chloe F. Knight, Naya El Hage, Paul J. Scheel, Josef Coresh, Harry A. Silber. *Johns Hopkins Univ.*

Background: Optimal volume status in dialysis patients is difficult to assess. The Valsalva maneuver is recognized as an bedside marker of central volume overload. A novel handheld device that combines finger photoplethysmography with Valsalva maneuver can reliably estimate LVEDP (normal: <12mmHg). (Silber H. PMID: 22389389). The goal of our pilot study is to determine the role of this non-invasive LVEDP measurement in managing volume in hemodialysis patients.

Methods: The LVEDP-Guided Volume Management Study is being conducted at 2 dialysis units in Baltimore. Baseline data collected includes demographics, medical history, KDQOL-36, NYHA dyspnea scale, intra/post dialysis symptoms, predialysis metrics [LVEDP, bioimpedance, blood pressure (BP)] and echocardiogram. We assessed the cross-sectional association of predialysis LVEDP with dyspnea symptoms and intradialytic hypotension (IDH, defined as ³20mmHg drop in systolic BP + nursing interventions).

Results: In the first 28 participants (mean age 56 years, 71% male, 82% black), median (25th, 75th percentiles) for predialysis LVEDP was 14 mmHg (12, 19), interdialytic weight gain (IDWG) was 1.7 kg (0.9, 2.9) and systolic BP was 150 mmHg (133, 164). LVEDP was significantly higher in patients with dyspnea vs. those without. (Mean, 19.9 vs. 14.6; p=0.03). IDH occurred in 5 (18%) patients and all had LVEDP £14 mmHg (Table). The unadjusted odds ratio for IDH per SD decrease in LVEDP was 4.37 (p=0.08). There was no significant association between IDH and predialysis systolic BP or IDWG.

Table: Associations of IDH	IDH		
	No (n=23)	Yes (n=5)	p
Predialysis Factors	Mean (SD)	Mean (SD)	
LVEDP	**16.2 (4.7)**	**11.8 (2.8)**	**0.05**
Systolic BP	153.8 (22.3)	135 (15.5)	0.10
Interdialytic weight gain	1.97 (1.5)	1.92 (0.8)	0.93

Conclusions: Non-invasive LVEDP measurements can identify hemodialysis patients with volume overload associated with symptoms (high LVEDP) and patients at risk for IDH (low LVEDP). Our ongoing study may help confirm these initial findings and define the role of this measurement for volume management in dialysis patients.

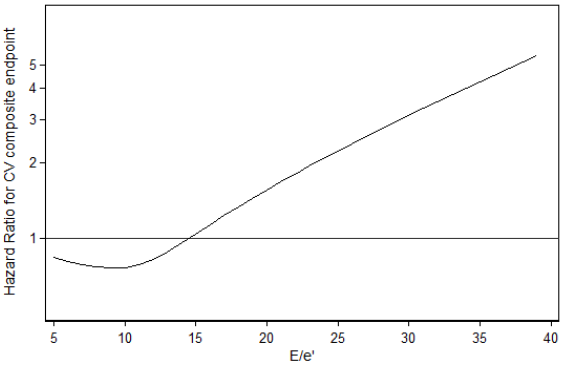
TH-PO917

E/e' Calculated by Tissue Doppler Echocardiography and Cardiovascular Outcome in Incident Dialysis Patients Jongha Park,[1] Jongmin Lee,[1] Kyung sun Park,[2] Sung Hyun Son,[3] Shin-Jae Kim,[1] Jong Soo Lee,[1] Hyun Chul Chung.[1] *[1]Ulsan Univ Hospital, Ulsan, Republic of Korea; [2]Dongkang Medical Center, Ulsan, Republic of Korea; [3]BHS Han-Seo Hospital, Busan, Republic of Korea.*

Background: The ratio of early diastolic peak mitral flow velocity (*E*) to early mitral annulus velocity (*e'*), called *E/e'* is a less volume dependent, non-invasive index to estimate left ventricular (LV) filling pressure. However, the prognostic value of *E/e'* has not been evaluated sufficiently in patients with end-stage renal disease (ESRD).

Methods: The patients who newly started maintenance dialysis therapy between 2009 and 2012, had survived for at least 3 months after dialysis initiation, and had *E/e'* data, were analyzed. *E/e'* was calculated by pulse and tissue Doppler echocardiography. Cardiovascular (CV) composite endpoint comprised hospitalization for heart failure (HF), acute coronary disease (ACD) requiring intervention, ventricular arrhythmia, cerebral infarction or hemorrhage, and CV death. The patients were followed up until 2013.

Results: A total of 206 patients were analyzed (mean age 55.0±13.7 years old, female 51.5%). Median follow-up duration was 29.2 months (range 3.1-61.3). Forty-two CV events occurred during follow-up (15 HF, 17 ACD, 1 cerebral infarction, and 9 CV deaths). Mean *E/e'* was 13.6±5.4 (range 5-39). After adjusting age, sex, diabetes, mean arterial pressure, LV ejection fraction, hemoglobin, serum albumin, C-reactive protein and volume status, one unit increase in *E/e'* ratio was associated with 7% increase in the risk of CV composite endpoint (hazard ratio 1.07, 95% confidence interval 1.02-1.13, p=0.009). Adjusted hazard ratio linearly increased above 15 of *E/e'* in Cox regression with cubic splines.



Conclusions: A higher *E/e'* ratio, reflecting high LV filling pressure which is the main physiological finding of diastolic HF, may be associated with a higher CV risk in patients with ESRD.

TH-PO918

Tallium-201 Washout Rate of Single Photon Emission Computed Tomographic Myocardial Perfusion with Pharmacologic Stress as a Predictor of Mortality in CKD Patients Undergoing Hemodialysis: An Observational, Follow-Up Study Toshihide Hayashi, Nobuhiko Joki, Masaki Iwasaki, Ai Matsukane, Takasuke Asakawa, Yuri Tanaka, Hiroki Hase. *Div of Nephrology, Toho Univ Ohashi Medical Center, Tokyo, Japan.*

Background: Thallium-201 (^{201}Tl) washout rate of single photon emission computed tomography (SPECT) has been reported to correlate with coronary flow reserve which is an index of myocardial microcirculation and be useful to detect coronary artery disease and evaluate the severity. However, the evidence for its use in chronic kidney disease (CKD) has been lacking, and the association between ^{201}Tl washout rate and mortality is unknown. Therefore, a hospital-based, prospective, cohort study was conducted to evaluate the predictive ability of ^{201}Tl washout rate for mortality in CKD patients undergoing hemodialysis.

Methods: A total of 156 patients who had been started on maintenance hemodialysis undergoing pharmacologic stress thallium-201 SPECT within 1 year, 107 men and 49 women, with a median age of 67 years, were studied. The endpoint was defined as all-cause death. The Cox proportional hazards model was used to calculate hazard ratios (HR) and 95 % confidence intervals (CI).

Results: During the mean follow-up period of 3.2 ± 2.4 years, 30 (19.2 %) deaths occurred. The median (interquartile range) of ^{201}Tl washout rate was 45.1 (37.4 - 50.8) %. Cumulative survival rates at 5 years after starting dialysis, with ^{201}Tl washout rate levels above and below the median, were 76.7 % and 63.8 % (p = 0.992, log-rank test), respectively. Overall, the multivariate Cox regression analysis revealed that ^{201}Tl washout rate remained an independent predictor of death after adjusting by confounding variables (HR 0.95, 95 % CI 0.90 to 0.99).

Association of ^{201}Tl washout rate with Death
(Cox proportional hazard model)

		HR (95% CI)	p value
Unadjusted		0.95 (0.93 - 0.99)	0.009
Adjusted	Model 1 a)	0.95 (0.91 - 0.99)	0.018
	Model 2 b)	0.94 (0.90 - 0.98)	0.013
	Model 3 c)	0.95 (0.90 - 0.99)	0.029

Covariates: a) perfusion defect and left ventricular ejection fraction.
b) Model 1 + age, sex, diabetes and cardiovascular disease.
c) Model 2 + serum Alb and CRP.

Conclusions: Among CKD patients undergoing hemodialysis, ^{201}Tl washout rate seems to be useful for predicting death.

Patel,[2] John Graeme Houston,[1] Giles Roditi,[2] Allan Struthers,[1] Alan G. Jardine,[2] Patrick B. Mark.[2] *[1]Div of Cardiovascular & Diabetes Medicine, Univ of Dundee; [2]Inst of Cardiovascular & Medical Sciences, Univ of Glasgow.*

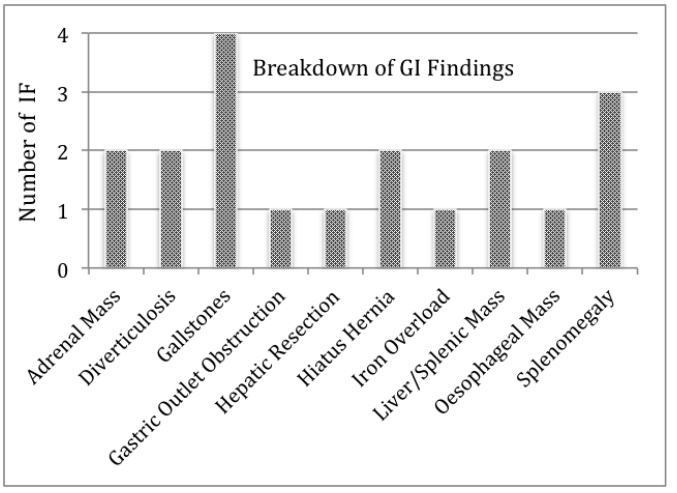
Background: Left ventricular (LV) mass on cardiac magnetic resonance imaging (CMR) is a common end point of clinical trials in nephrology. Incidental findings (IF) on research images have ethical & clinical implications. We retrospectively investigated the incidence of IF in research CMR & reviewed their impact on patient care.

Methods: 161 CKD5 patients underwent CMR for a 2002-2006 research study into transplant assessment. Images were used to assess LV mass & function. In our study a radiologist reviewed the scans for IF. Abnormalities in mass, perfusion or function were not considered IF. The clinical significance of every IF was determined by patient record review.

Results: There were 150 IF. 59% of patients had one or more IF. 68% were extra-cardiac, 56% were new diagnoses.

	Lung/Medi-astinal	Pleural Effusion	GI Tract	Cysts (Not PKD)	Other	Total
Number of IF	11	15	19	50	7	102
New Diagnosis	9	4	12	18	7	50
Should have changed management but clinical course not altered	6	3	1	1	3	14
Identification may have altered clinical course	1	1	3	0	0	5

13% were gastrointestinal.



16 IF were suspicious of malignancy. 17 unidentified IF would have changed patient management if known, but a review of patient records showed these IF had no later clinical impact. In 6 cases earlier identification of an important IF may have improved quality of life or survival.

Conclusions: Without radiology support clinically important IF may be missed on CMR. A suitably trained radiologist should prospectively review all CKD CMR research studies & obtained images. Patients undergoing CMR in trials should be counselled about the frequency & implications of possible IF.

TH-PO920

A Significance of Cardiothoracic Ratio for Mortality in Hemodialysis Patients: The Q-Cohort Study Ryusuke Yotsueda,[1] Masahiro Eriguchi,[1] Shigeru Tanaka,[1] Masatomo Taniguchi,[1] Hideki N. Hirakata,[3] Kazuhiko Tsuruya,[1,2] Takanari Kitazono.[1] *[1]Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [2]Dept of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [3]Nephrology and Dialysis Center, Japanese Red Cross Fukuoka Hospital, Fukuoka, Japan.*

Background: Cardiothoracic ratio (CTR) of chest X–ray is commonly used to determine the volume status in hemodialysis (HD) patients. Thus, the present study was conducted to evaluate the significance of CTR in terms of longitudinal prognosis of HD patients.

Methods: A total of 3,437 Japanese HD patients aged ³18 years were followed for 4 years. Patients were divided into four groups according to quartiles of CTR levels by sex. Risk estimates were calculated by a Cox proportional hazards model, adjusting for potential confounders. We investigated stratified analysis by sex, age, etiology of end–stage kidney disease, history of major adverse cardiac events (MACE) and blood pressure for subanalysis.

Results: The median values (interquartile range) of CTR were 0.49 (0.46–0.53) in male and 0.52 (0.48–0.56) in female. During the follow–up period, 564 patients (16%) died from any causes and the 4 years survival rate decreased significantly with higher CTR levels (p for trend <0.001). Compared with the lowest CTR quartile, the multivariable–adjusted hazard ratios (HRs) for all–cause mortality were 0.89 (95% confidence intervals, 0.66–1.21), 1.41 (1.07–1.86), and 1.52 (1.17–2.00) in subjects with low–intermediate, high–intermediate and highest quartile, respectively. Furthermore, the combination of higher CTR levels and history of MACE or lower blood pressure before HD (systolic blood pressure <140 mmHg and diastolic blood pressure <90 mmHg) synergistically increased the risk of all–cause mortality.

Conclusions: A higher CTR level is closely related to increased mortality in HD patients. This association is more remarkable in patients with history of MACE or without high blood pressure.

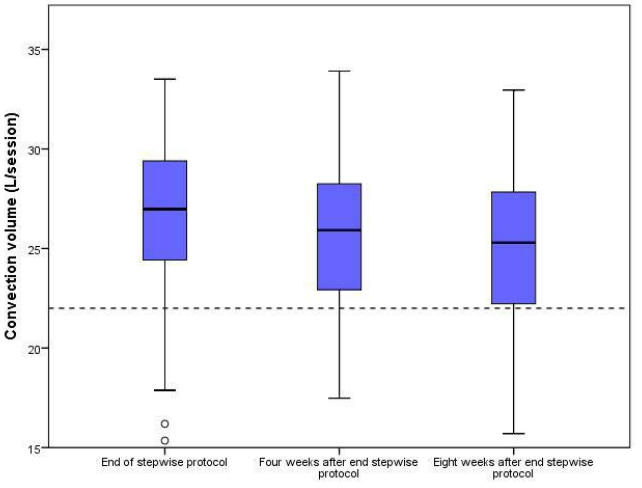
TH-PO921

High Convection Volumes in Postdilution Online Hemodiafiltration (HDF) Are Feasible in the Vast Majority of ESKD Patients Camiel LM de Roij van Zuijdewijn,[1] Isabelle Chapdelaine,[1] Menso Jan Nubé,[1] Peter J. Blankestijn,[2] Constantijn Konings,[3] Tonnis K. Kremer Hovinga,[4] Neelke C. Van Der Weerd,[5] Pieter M. Ter Wee,[1] Muriel P. Grooteman.[1] *[1]Nephrology, VU Univ Medical Center, Amsterdam, Netherlands; [2]Nephrology, Univ Medical Center Utrecht, Utrecht, Netherlands; [3]Internal Medicine, Catharina Hospital, Eindhoven, Netherlands; [4]Internal Medicine, Martini Hospital, Groningen, Netherlands; [5]Nephrology, Academic Medical Center, Amsterdam, Netherlands.*

Background: Available evidence suggests a survival benefit for patients treated with high volume postdilution HDF (hvHDF) when compared to HD. Since these studies are limited by an observational design, we investigated whether hvHDF (>22L/session) is feasible in the majority of patients (>75%).

Methods: A prospective, multicenter study was performed (NCT01877499). HD(F) patients (³18y) were eligible if treated 3x/week for ≥6 weeks. Non-participating eligible patients formed a reference group to examine the representativeness of the study group. Treatment-related determinants of the convection volume were optimized in a stepwise fashion (treatment time [TT] up to 4 hours, blood flow rate [BFR] up to 400 mL/min and filtration fraction [FF] up to 33%). At the end of this protocol (T0) and 4 (T4) and 8 (T8) weeks thereafter, the convection volume was determined.

Results: Baseline characteristics were comparable in participants (n=86) and references (n=58). At T0 and at T4, 79/86 (92%) and 68/86 (79%) patients achieved hvHDF (mean 26.9±3.56 and 26.3±3.36L/session, resp). Hereafter, 2 patients died and 1 was transplanted. 83 patients remained; 66 (80%) reached hvHDF (mean 25.9±3.53L/session, fig 1). Study discontinuation (n=9), TT <4h (n=4) or BFR £300 mL/min (n=4) caused a convection volume <22L/session.



Conclusions: hvHDF is feasible in the vast majority of ESKD patients. As TT remained virtually unaltered, these findings were mainly due to a higher BFR and FF.

TH-PO922

Physical Activity Among Patients with End-Stage Renal Disease: Use of the Exercise Vital Sign Shayna L. Henry,[1] Yi-Lin Wu,[1] John J. Sim,[2] Michael K. Gould.[1] *[1]Dept of Research & Evaluation, Kaiser Permanente Southern California, Pasadena, CA; [2]Dept of Nephrology, Kaiser Permanente Southern California Los Angeles Medical Center, Los Angeles, CA.*

Background: Exercise has been shown to improve physical functioning among ESRD patients. However, ESRD patients report exceedingly low levels of physical activity (PA) with only 13-34% engaging in recommended levels of PA. Although ESRD is characterized by substantial barriers to PA, low PA puts patients at risk for serious complications and higher mortality. Within Kaiser Permanente (KP), patients are administered the Exercise Vital Sign (EVS) – self-reported weekly minutes of PA – during each office encounter. The EVS has been validated in multiple KP regions, with roughly one-third each of the membership reporting no, insufficient, and sufficient PA, or ³150 minutes exercise/week. Although the relationship between EVS reports and cardiometabolic status has been examined, levels of PA reported by ESRD patients using the EVS have not yet been explored.

Methods: EVS reports of all KP patients with a diagnosis of ESRD between January 2013 and July 2014 (N=8,187; Female=3,534, Mean Age=63.3 years) were assessed.

Results: Patients were 25% White, 38% Black, 23% Hispanic, 12% Asian, and the remainder Other, consistent with the regional patient catchment; just over 50% were married. The majority (88%) had comorbid HTN, 65% had comorbid DM, and 37% comorbid CHF. On average, patients had four other comorbid illnesses. During the study period, patients presented for 135,562 encounters. The mean reported PA frequency was 1.4 times per week (SD=2.2), for a mean 12.3 minutes/bout (SD=22.4), or an average of 49.0 minutes/week (SD=103.2) and a median zero minutes/week. The majority of ESRD patients did not achieve sufficient levels of PA during this period; 75% of the sample exercised for ≤60 minutes/week.

Conclusions: Self-reported rates of PA among ESRD patients at KP are critically low. Implications of low PA for cardiovascular and other outcomes as well as for interventions to improve rates of PA in this diverse population will be discussed.

TH-PO923

The Association of RAS Inhibition with Cardiovascular Events in Patients Undergoing Hemodialysis in Japan Masahide Mizobuchi,[1] Hiroaki Ogata,[2] Yoshihiro Onishi,[4] Shingo Fukuma,[3] Tadao Akizawa,[1] Shunichi Fukuhara.[3] *[1]Dept of Nephrology, Showa Univ School of Medicine, Tokyo, Japan; [2]Dept of Internal Medicine, Showa Univ Northern Yokohama Hospital, Yokohama, Japan; [3]Dept of Epidemiology and Healthcare Research, Kyoto Univ Graduate School of Medicine, Kyoto, Japan; [4]Inst for Health Outcomes & Process Evaluation Research (iHope International), Kyoto, Japan.*

Background: Pharmacological inhibition of the renin-angiotensin system (RAS) contributes to cardiovascular protection in predialysis patients. However, definitive evidence of whether RAS inhibition is beneficial on cardiovascular event (CVE) among hemodialysis (HD) patients is lacking. The objective of this study was to investigate the association of RAS inhibitors usage with CVEs in patients enrolled in the Dialysis Outcomes Practice Pattern Study in Japan (J-DOPPS).

Methods: HD patients enrolled in J-DOPPS were eligible for analysis. Association of RAS inhibitors prescription with outcomes including all-cause death, death caused by CVE, and hospitalization due to cardiac failure was investigated by using a multivariable Cox proportional hazards model.

Results: Of the 3848 patients enrolled, 1784 (45 %) patients were treated by RAS inhibitors. The prevalence of male, diabetes, and other anti-hypertensive agent usage was higher in patients with RAS inhibitors compared to those without RAS inhibitors. Dialysis vintage was shorter and systolic blood pressure was higher in patients with RAS inhibitors. After adjusting for potential cofounders by Cox proportional hazards models, we did not find statistically significant associations of RAS inhibitors with all-cause death (HR: 1.19, 95%CI: 0.93-1.53, p=0.16), death caused by CVE (HR: 1.32, 95%CI: 0.80-2.18, p=0.28), and hospitalization due to cardiac failure (HR: 1.30, 95%CI: 0.89-1.89, p=0.18). A similar trend was observed when patients were stratified by the presence or absence of cardiovascular disease history.

Conclusions: RAS inhibition was not associated with CVEs suggesting that RAS inhibition alone is insufficient to reduce the risk of cardiovascular complications. Strategies in addition to RAS inhibition are needed to protect against CVEs in HD patients.

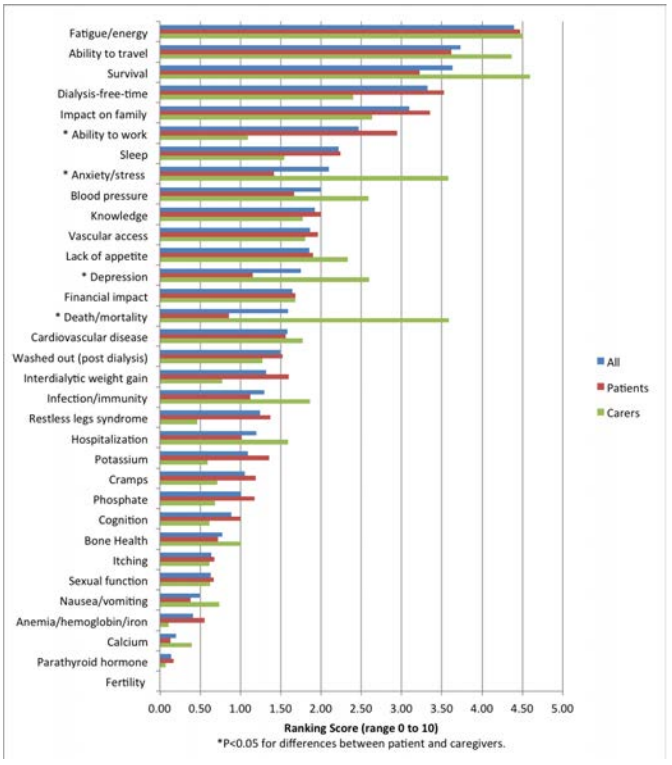
TH-PO924

Patient and Caregiver Priorities for Outcomes in Hemodialysis: A Multinational Nominal Group Technique Study Allison Tong,[1] Rachel Urquhart-Secord,[1] Brenda Hemmelgarn,[2] Braden J. Manns,[2] Kevan Polkinghorne,[3] David C. Harris,[1] Peter G. Kerr,[3] Helen Tam-Tham,[2] Stephanie E. Thompson,[4] Kara Schick-Makaroff,[4] Martin Howell,[1] Jonathan C. Craig.[1] *[1]Univ of Sydney; [2]Univ of Calgary; [3]Monash Univ; [4]Univ of Alberta.*

Background: In the context of clinical trials, researchers have historically selected the outcomes they consider to be important. However, there is a growing awareness that they are often discordant with patient priorities. Efforts to define and report patient-centered outcomes are gaining momentum but have largely been outside of nephrology. We aimed to identify patient and caregiver priorities for outcomes in hemodialysis (HD).

Methods: Structured discussions using a nominal group technique were conducted with patients on HD and caregivers purposively sampled from 5 dialysis units in Australia (Sydney, Melbourne) and Canada (Calgary); who identified and ranked outcomes for HD. A mean rank score out of 10 was calculated for each outcome.

Results: 12 nominal groups involving 82 participants (patients n=58, caregivers n=24) aged 24–88 yrs (mean 58.3) identified 69 outcomes. The top 10 were: fatigue/energy (mean rank 4.4), ability to travel (3.7), survival (defined by patients as daily well-being and coping) (3.6), dialysis-free time (3.3), impact on family (3.1), ability to work (2.5), sleep (2.2), anxiety/stress (2.1), blood pressure (2.0), and knowledge (1.9). Mortality ranked 15th and participants distinguished this from survival. Caregivers ranked mortality, anxiety, and depression higher; patients ranked ability to work higher (P<0.05).



Conclusions: Patient prioritized outcomes are focused on maintaining a quality lifestyle above the usual outcomes in HD trials i.e. death, adverse events, and biological markers. Researchers need to consider interventions that could improve these outcomes, and measure and report patient-relevant outcomes in trials.

TH-PO925

Medicare Advantage (MA) Is Associated with Lower Rates of Mortality versus Medicare Fee-For-Service (MFFS) Among Incident End-Stage Renal Disease (ESRD) Patients Steven M. Brunelli,[1] Carey Colson,[1] Scott Sibbel,[1] Abigail Hunt,[1] Allen R. Nissenson,[2] Mahesh Krishnan.[2] *[1]DaVita Clinical Research, Minneapolis, MN; [2]DaVita HealthCare Partners Inc, Denver, CO.*

Background: Patients with ESRD have a high burden of comorbid illness and are complex to manage and may therefore benefit from programs like MA that facilitate care coordination. Currently, ESRD patients are barred from enrolling in MA after onset of ESRD; however, those already enrolled at the time of ESRD onset may remain enrolled. To understand the potential impact of MA among ESRD patients, we compared mortality rates among patients who began dialysis enrolled with MA versus MFFS.

Methods: Adult patients initiating hemodialysis (HD) or peritoneal dialysis (PD) between 01 Jan 2009 and 30 Jun 2011 and who were enrolled with MA or MFFS as of ESRD onset were considered. MA patients were matched 1:1 to MFFS controls based on initial modality, access type, and propensity score (based on 26 demographic and clinical characteristics). Patients were followed from dialysis initiation until death, transplant, loss to follow up, change in benefits status, or end of study (31 Dec 2011). Mortality rates were compared using negative binomial models. Sensitivity analyses considering early and latent effects were performed using piecewise methods.

Results: Compared to MFFS, MA was associated with lower rates of mortality (64.3 vs 70.7 deaths/100 patient-years; incidence rate ratio, 0.91). Mortality effects were limited to HD patients and were attenuated after the first 24 months of dialysis.

Conclusions: Enrollment in MA was associated with substantially lower rates of mortality during 2009-2011.

Characteristics of Patients Receiving Dialysis at a Comprehensive Cancer Center and Outcomes Ala Abudayyeh,[1] Jai prakash babu Thippaiah Jadegondanahalli,[2] Rima N. Pai,[1] Maria del Pilar Fernandez,[2] Alvin H. Moss.[3] *[1]Section of Nephrology, UT MD Anderson Cancer Center; [2]Nephrology and Hypertension, UT at Houston Medical School; [3]Section of Nephrology, West Virginia Univ School of Medicine.*

Background: With the increasing therapeutic options from the traditional cytotoxic therapies, small molecules for targeted therapies and more recently immunotherapies, cancer patients have been given a massive arsenal to tackle their cancer. With the associated renal toxicities from the chemotherapies, sepsis, infections, antibiotics, and obstruction we are often faced with decisions about the utility of dialysis. This is often the situation in the patients with advanced solid tumors that have failed multiple lines of treatment and are admitted with renal failure necessitating hemodialysis. Our hypothesis for this study is offering dialysis to advanced solid tumor patients will not improve overall survival and is not cost effective.

Methods: All patients diagnosed with Acute Kidney Injury in their last hospital admission with solid tumor and nephrology consult between 01/01/2005 through 12/31/2014 were identified using billing data. Patient demographic data for those records was extracted: date of birth, gender, race, financial class, vital status and last contact date. Our final study cohort is a total of 2,268 unique patient records.

Results: Out of 2,268 patients, 392 patients (17.28%) received dialysis and 1876 patients (82.72%) did not. A total of 1470 patients (64.81%) were discharged alive and 798 patients (35.19%) resulted in a hospital death. The hospital deaths included 269 patients (33.71%) that received dialysis and 529 patients (66.29%) that did not receive dialysis in the hospital.

Conclusions: Our preliminary data indicates that patients who survived their last hospitalization were less likely to have undergone dialysis (8.36%) when compared to patients that died during their last hospitalization (33.71% were dialyzed). Therefore, reaffirming that dialysis in advanced cancer patients would not likely add further benefit to their mortality.

TH-PO927

Emergency Room Utilization by Dialysis Patients: A Population Based Study Claudio Rigatto,[1,2] James M. Zacharias,[1,3] Bing Hu,[4] Brett M. Hiebert,[1] Navdeep Tangri,[1,2] Paul Komenda.[1,2] *[1]Internal Medicine, Univ of Manitoba, Winnipeg, MB, Canada; [2]Renal Health/Dialysis, Seven Oaks General Hospital, Winnipeg, MB, Canada; [3]Renal Health/Dialysis, Winnipeg Health Sciences Centre, Winnipeg, MB, Canada; [4]Manitoba Renal Program, Winnipeg Regional Health Authority, Winnipeg, MB, Canada.*

Background: Patients with kidney failure are frail and have high rates of cardiovascular and infectious comorbidities. As a result, they are heavy users of non-dialysis acute health services such as the emergency department (ED). Despite this, accurate population based data on rates and patterns of ED visits by dialysis patients are lacking. The objective of the current study was to determine rates and patterns of ED utilization by adult dialysis patients vs. the adult general population.

Methods: We linked two large regional databases in Winnipeg, Manitoba, Canada (population 1.3 million), the Manitoba Renal Program Patient Registry and the Winnipeg Regional Emergency Program Admission Discharge Triage database. Data were analyzed for the years 2000-2010. Poisson Regression was used to compare rates.

Results: Over the study period, the linked dataset comprised >2.0 million visits in 1.2 million non- dialysis patients, and 17,738 visits in 3260 dialysis patients. Our key findings were 1) Age and Sex adjusted rates of ER visits were 8.5X higher among dialysis patients [153 vs 18 visits per 100 patient-years, $p<0.001$), with negligible variation year to year over the study period; 2) Rate of ER visits were 25% higher on Mondays and Tuesdays overall; this "post-weekend" risk phenomenon was more pronounced in dialysis patients vs. the general population ($p<0.001$for interaction); 3) among dialysis patients, ER visits were 8X higher during the two weeks before and after initiation of dialysis, reflecting a period of heightened vulnerability for patients with kidney disease.

Conclusions: Our population based rates of ED utilization will help health administrators predict the "collateral" impact of a typical dialysis unit on the health system. Strategies to mitigate the high risk of ED utilization "post weekend" and around the time of transition to dialysis are urgently needed and should be a focus of future health systems research.

TH-PO928

Development of a Clinical Risk Prediction Tool for Six-Month Mortality After Dialysis Initiation Among Older Adults James Wick, Tanvir Chowdhury Turin, Peter D. Faris, Jennifer M. MacRae, Robert G. Weaver, Brenda Hemmelgarn. *Univ of Calgary, Calgary, AB, Canada.*

Background: Early mortality after dialysis initiation is common among older adults. We sought to develop a tool to predict mortality within 6 months of dialysis initiation in an older adult population.

Methods: We linked administrative and dialysis registry data to define a cohort of older adults (age 65+) in Alberta, Canada who initiated chronic dialysis between May 2003 and March 2012. The outcome was all-cause mortality within 6 months of dialysis initiation. Potential predictors included demographics, comorbidities, health-system use,

laboratory measurements and dialysis-related information. We used logistic regression and 10-fold cross validation to identify and validate a model of significant predictors. Model discrimination and calibration were measured by c-statistic and Hosmer-Lemeshow goodness-of-fit respectively. A point system was created based on regression coefficients of predictors in the final model.

Results: 2,211 adults initiated dialysis, of whom 386 (17.4%) died within 6 months. Significant predictors of 6-month mortality were: age ≥80y, vascular access with central venous catheter, baseline eGFR 10-14.9 or >15mL/min/1.73m^2, normal proteinuria, atrial fibrillation, lymphoma and congestive heart failure (CHF). Model discrimination (C-Statistic: 0.73) and calibration (Hosmer-Lemeshow c^2: 6.09; p=0.64) were good. A 40-point scale for 6-month mortality was created based on model coefficients with points assigned based on strength of each predictor as specified in Table 1.

Category		Points
Age	65-79.9	0
	80+	2
Vascular Access	Central Venous Catheter	10
	Arteriovenous Fistula/Graft	0
	PD Catheter	3
eGFR	<10	0
	10-14.9	2
	15+	5
Proteinuria	Normal	6
	Mild	4
	Heavy	0
	Unmeasured	5
Atrial Fibrillation		4
Lymphoma		9
CHF		4
TOTAL		**0 - 40**

Conclusions: We derived and internally validated a clinical risk prediction tool for 6-month mortality for older adults initiating dialysis, using age, vascular access, eGFR, proteinuria, atrial fibrillation lymphoma and CHF as predictors. The results require external validation prior to use in clinical practice. A tool such as this can guide decision making for older adults with kidney failure.

TH-PO929

Coping Strategies and Outcomes Among Hemodialysis (HD) Patients in the DOPPS Elodie Speyer,[1] Hal Morgenstern,[1,2] Peter G. Kerr,[3] Antonio Alberto Lopes,[4] Hugh C. Rayner,[5] Bruce M. Robinson,[1] Ronald L. Pisoni.[1]
[1]Arbor Research, USA; [2]Univ of Michigan, USA; [3]Monash Health & Monash Univ, Australia; [4]Federal Univ of Bahia, Brazil; [5]Birmingham Heartlands Hospital, UK.

Background: Although HD presents numerous psychological and physical challenges for patients, how they cope with dialysis therapy and its impact on quality of life (QoL) and mortality is poorly understood.

Methods: Patients from 6 DOPPS countries completed the Coping Strategies Inventory-Short Form (CSI-SF), which we found to be reliable and valid in those countries for measuring 4 coping strategies: problem-focused engagement (PFE) and disengagement (PFD), and emotion-focused engagement (EFE) and disengagement (EFD); and summary measures of engagement (actions to confront stressors) and disengagement (avoiding exposure to stressors). Outcomes were QoL (from SF-12 and KDQoL-SF), depression symptoms (from the CES-D), and all-cause mortality. Mixed linear and logistic models were used to estimate coping effects, adjusting for country and potential confounders.

Results: The sample included 2,262 HD patients from the US, UK, Australia/New Zealand, Canada, and Sweden in DOPPS4 (2009-11). In general and whatever the instrument, both engagement coping strategies and the summary score were positively associated with better QoL scores and inversely associated with depression symptoms. In contrast, disengagement strategies were inversely associated with better QoL scores and positively associated with depression symptoms. The PFE score was inversely associated with mortality (HR =0.78 per 4 points higher score; 95% CI: 0.66-0.9).

Association between coping strategies and patient-reported outcomes (QoL and depression symptom)

	Coping Scores			Quality of Life measures[¥]		Depression measure[#]
	Mean	Range	IQR[§]	PCS Adjusted difference in means (95% CI)	MCS Adjusted difference in means (95% CI)	Odds Ratio (95% CI) (>10 vs = 10)
Model 1[*]						
PFE	13.6	4-20	4	2.15 (1.5; 2.8)	4.62 (3.9; 5.3)	0.42 (0.36; 0.49)
PFD	11.1	4-20	4	0.03 (-0.6; 0.6)	-1.84 (-2.5;-1.2)	1.43(1.27; 1.61)
EFE	12.0	4-20	4	-0.12 (-0.7; 0.5)	0.02 (-0.6; 0.7)	0.97 (0.86; 1.10)
EFD	5.0	2-10	2	-0.34 (-0.8; 0.2)	-2.37 (-2.9;-1.9)	1.62 (1.46; 1.79)
Model 2[*]						
E	25.6	8-40	7	1.69 (1.1; 2.3)	3.92 (3.3; 4.6)	0.48 (0.42; 0.54)
D	16.1	6-30	6	-0.50 (-1.2; 0.2)	-4.55 (-5.3;-3.8)	2.39 (2.06; 2.77)

[§]IQR=interquartile range
[¥]PCS and MCS=SF-12 physical and mental component summary scores;
 # Analysis modeling the probability that CES-D score>10 (symptom of depression)
**All analyses were adjusted for country*

Conclusions: Engagement strategies appear to be beneficial and disengagement detrimental for HD patients. A better understanding of the coping strategies used by patients may have prognostic implications and may help to improve disease management by providing tailored care for each patient.

TH-PO930

Intradialytic Aerobic Cycling Exercise Improve Inflammation Status, Endothelial Progenitor Cells and Bone Density in Patients with End Stage Renal Disease on Maintenance Hemodialysis Chia-chao Wu,[1] Kuo-cheng Lu.[2]
[1]Div of Nephrology, Dept of Medicine, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan; [2]Dept of Medicine, Cardinal Tien Hospital, School of Medicine, Fu Jen Catholic Univ, New Taipei City, Taiwan.

Background: Inflammation, endothelial dysfunction and mineral bone disease play critical roles of morbidities and mortalities in the hemodialysis (HD) patients. Physical exercise can improve inflammatory status and bone density reverse protein-energy wasting (PEW) and bone loss. We investigate the effects of intradialytic aerobic cycling exercise (IACE) during HD.

Methods: Fourty end-stage renal disease patients undergoing HD will be randomly allocated into an exercise or control group for 3 months. The cycling session consisted of 5 minute warm-up, 20 minutes cycling at desired workload and 5 minutes cool-down during the three weekly dialysis sessions. Biochemical markers, inflammatory cytokines and nutritional status as well as serum endothelial progenitor cells (EPCs) count, bone mineral density and functional capacity were checked.

Results: There were no statistically differences in the baseline characteristics between groups. Biochemical and anthropometric parameters revealed improvement in serum albumin , body mass index and inflammatory cytokines in the exercise group. Statistically significant changes in numbers of CD133/CD34/KDR cells were observed in exercise group, whereas EPCs increased significantly during the study. The patients in exercise group showed a significantly greater 6-minute walk test than at baseline. Subjects who were able to walk faster showed greater increases in EPCs than other subjects. Bone loss at the femoral neck was significantly greater in the control group compared with the exercise group which essentially showed no change. The bone mineral density (BMD) change at the lumbar spine (L1 to L4) was not significantly different between the treatment groups.

Conclusions: In conclusion, an intradialytic aerobic cycling exercise program can decrease inflammation, increase nutritional status and bone mass index, improve 6-minute walk distance, and increase the number of EPCs in HD patients.

TH-PO931

Multicenter Trial of Aerobic Exercise in Maintenance Hemodialysis Patients Misa Miura,[1] Aki Hirayama,[1] Shigeru Owada,[3] Yo Hirayama,[4] Osamu Ito,[2] Masahiro Kohzuki.[2]
[1]Dept of Health, Tsukuba Univ of Technology, Tsukuba, Ibaraki, Japan; [2]Dept of Internal Medicine and Rehabilitation Science, Tohoku Univ Graduate School of Medicine, Sendai, Miyagi, Japan; [3]Asao Clinic, Kawasaki, Kanagawa, Japan.

Background: Hemodialysis patients show reduced physical function and greater risk of arteriosclerosis because of hypertension, metabolic disturbances, and vascular calcification. Meanwhile, exercise training in hemodialysis patients improves fitness, physical function, quality of life, and markers of cardiovascular disease such as arterial stiffness. This study aimed to determine whether aerobic training and electrical stimulation to skeletal muscles for 12 weeks could improve physical function and dialysis efficacy in patients with end-stage renal disease (ESRD).

Methods: This was a multicenter trial. A total of 35 ESRD patients on three occasions (20 males, 15 females; age: 70.2±11.7 years) were randomized to receive 12 weeks of aerobic training exercise during hemodialysis session (Ex-group: n=19), electrical stimulation to the lower limbs (ES-group: n=6), or no specific intervention (Cont-group: n=10). The Borg

scale was used to control the intensity of training. At baseline and study completion, the primary outcome measures were grip strength, quad muscle torque, workout time, activities, dialysis efficacy, HDL, LDL, CRP, IL-6 and blood pressure.

Results: In the Ex-group, handgrip, quad torque, and workout time increased significantly (P<0.05). Dialysis efficacy, HDL-cholesterol, LDL-cholesterol, CRP, and blood pressure on the morning of the dialysis day also improved significantly (P<0.05). These effects were not observed in the Cont-group. In the ES-group, quad muscle torque and dialysis efficacy increased significantly (P<0.05), IL-6 decreased significantly (P<0.05), compared to the other two groups.

Conclusions: In this study, the safety and efficacy of training and electrical stimulation during hemodialysis were confirmed without sudden drop of blood pressure or any other side effects. Therefore, training during hemodialysis session for 12 weeks might improve physical function with specific whole-body effects as well as local effects in ESRD patients.

Glycemic Markers and 2-Year Non-Diabetic Hemodialysis Outcomes from the Glycemic Indices in Dialysis Evaluation Study Mark E. Williams,[1] Neal Mittman,[2] Lin Ma,[3] Julia I. Brennan,[4] Curtis D. Johnson,[4] Franklin W. Maddux,[3] Eduardo K. Lacson.[3,5] *[1]Joslin Diabetes Center, Boston, MA; [2]Kidney Care of Brooklyn and Queens, Brooklyn, NY; [3]Fresenius Medical Care North America, Waltham, MA; [4]Spectra Laboratories, Rockleigh, NJ; [5]Physician, Lexington, MA.*

Background: The ongoing GIDE (Glycemic Indices in Dialysis Evaluation) study includes data on nonDM hemodialysis (HD) patients (confirmed by HgbA1c <6.5%). Because nonglycemic factors may lower HgbA1c levels in ESRD, we previously reported their glycemic status/1-year outcomes using alternative glycemic markers [albumin-adjusted and unadjusted fructosamine (AlbF;F) and glycated albumin (GA) or percent GA (%GA)]. We now report 2-year study data.

Methods: 970 nonDM HD patients from 26 FMCNA facilities with glycemic markers from Jan-March 2013 were followed until April, 2015. Baseline AlbF, F, GA and %GA were used to classify patients as high or low glycemia using thresholds of AlbF≥974µmol/g, F>285µmol/L, %GA>15.7%, and GA>300µmol/L. Standard and Time-dependent (TD) Cox models with case-mix adjustment for age, sex, race, ethnicity, vintage, BMI, HD catheter and baseline comorbidity were used to determine associations between each glycemic index and hospitalization/death risk.

Results: While 1% had HgbA1c>7%, high glycemic status was more commonly detected using F (59%), AlbF (4%), GA (15%) and %GA (29%). Elevated AlbF was significantly associated with 2-year mortality [Standard Cox: Hazard Ratio (HR)=2.53, 95% CI (1.31, 4.92), p=0.006; TD Cox: HR=3.55, 95% CI (1.97, 6.38), p<0.0001] and hospitalization [TD Cox: HR=2.49, 95% CI (1.70, 3.67), p<0.0001]. For all other glycemic markers, no such associations were evident at the proposed thresholds using adjusted analyses in the Cox model.

Conclusions: These data support our previous findings of an association between poor glycemic status (high AlbF) and hospitalization/mortality outcomes in nonDM HD patients. High AlbF-glycemic status may have prognostic implications in nonDM HD patients.

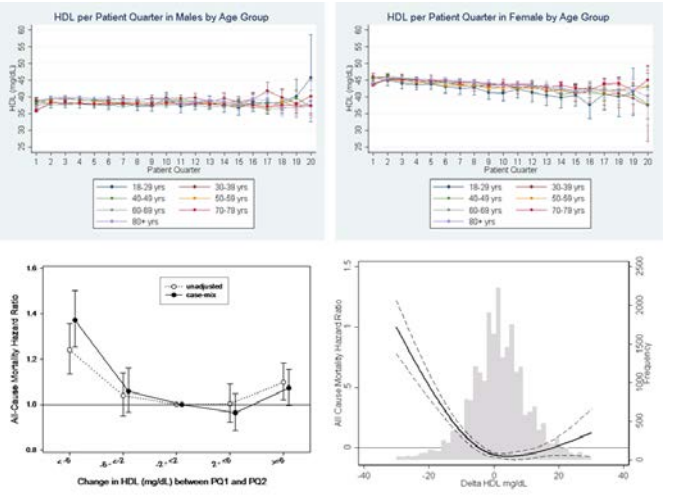
TH-PO933

Association of Change in Serum HDL Cholesterol with Mortality in Hemodialysis Patients: Role of Gender Sheila Mazdyasni,[1] Elani Streja,[1] Tae Hee Kim,[1] Connie Rhee,[1] Steven M. Brunelli,[2] Moti L. Kashyap,[1,3] Nosratola D. Vaziri,[1] Kamyar Kalantar-Zadeh,[1] Hamid Moradi.[1,3] *[1]UC Irvine; [2]DaVita Clin Research; [3]VA Long Beach.*

Background: Elevated high-density lipoprotein cholesterol (HDL) levels, though protective in the general population, can be associated with higher mortality in hemodialysis (HD) patients. Association of HDL change over time with mortality has yet to be examined. Based on previous studies, we hypothesized that upward trends in HDL levels may be associated with higher mortality risk in HD patients.

Methods: We examined HDL change over time in 24,400 incident HD patients receiving care from a large dialysis organization in 2007-2011. Association of delta HDL (HDL change between the 1st and 2nd 91 day interval from dialysis start) and HDL trajectory with all-cause mortality were examined using mixed effect and Cox regression models and adjusted for demographics, comorbidities and baseline HDL. Delta HDL was treated both as a continuous variable using restricted cubic splines and in categories:<-6, -6 -<-2, -2 -<2 (Ref), 2 -<6, and ≥6 mg/dL.

Results: Patients were 65±15 years old, 44% female, 31% black, 66% diabetic with a mean baseline HDL 40.5±13.9 mg/dL and HDL change 1.7±10.4 mg/dL. While male patients had no significant change in HDL over time, females had a significant decrease in HDL (mean -0.6mg/dL/year). A ≥6 mg/dL increase or decrease in delta HDL was associated with a 7% and 37%, respective increase in all-cause mortality compared to reference group. Delta HDL-mortality associations did not differ across gender.



Conclusions: Decreased HDL over time was associated with worse outcomes and increased HDL was paradoxically associated with higher mortality. While HD treatment can be associated with a decrease in HDL, this effect was magnified in younger females. The novel and intriguing role of age and gender in association of HDL and survival needs further evaluation.

Differences in Perceived Kidney Disease Burden on Quality of Life by Race/Ethnicity in a Diverse Cohort of Hemodialysis Patients Anna C. Porter,[1] Rani Gallardo,[2] Linda A. Schiffer,[3] Denise M. Hynes.[2,3,4] *[1]Dept of Medicine, Div of Nephrology, Univ of Illinois Hospital and Health Sciences System, Chicago, IL; [2]Dept of Medicine, Div of Academic General Internal Medicine and Geriatrics, Univ of Illinois at Chicago, Chicago, IL; [3]Inst for Health Research and Policy, Univ of Illinois at Chicago, Chicago, IL; [4]Center of Innovation for Complex Chronic Healthcare, Edward Hines Jr., VA Hospital, Hines, IL.*

Background: Low health-related quality of life (HRQOL) has been well-documented in patients with end-stage renal disease on hemodialysis (ESRD). While African Americans and Hispanics remain at increased risk for ESRD, HRQOL has been less well-described in these individuals compared to non-Hispanic whites.

Methods: Baseline HRQOL data was analyzed for participants enrolled in the Patient-Centered Medical Home for Kidney Disease study (PCMH-KD), a trial of a multidisciplinary, patient-centered primary care intervention in a population of hemodialysis patients at two dialysis facilities in Chicago. The Kidney Disease Quality of Life (KDQOL-36) instrument was used to assess HRQOL at baseline, and the following subscale scores were obtained: Physical, Mental, Burden of Kidney Disease, Symptoms and Problems, and Effects of Kidney Disease.

Results: Baseline data were available for 95 patients. Approximately, 52% of patients were African-American, and 45% were Hispanic. Significant racial/ethnic differences were observed among subscales of self-reported HRQOL.

KDQOL Subscale	Mean Score for African American Participants	Mean Score for Hispanic Participants	P value
Physical	35.8	34.5	>0.05
Mental	51.4	47.1	0.040
Burden	57.4	33.6	<0.001
Symptoms/Problems	76.6	76.0	>0.05
Effects	74.9	66.8	0.048

Conclusions: Hispanic patients with ESRD on HD report disproportionate burden and effects of kidney disease on HRQOL and worse mental HRQOL compared to African American patients with ESRD on HD. Further exploration of these disparities may lead to strategies for improvement of HRQOL in Hispanic patients.

Relative Blood Volume and Mortality in Hemodialysis Patients

Linda H. Ficociello,[1] Paul Balter,[1] Mark Costanzo,[1] Patrice B. Taylor,[1] Claudy Mullon,[1] Robert J. Kossmann.[1] *[1]Fresenius Medical Care North America (FMCNA), Waltham, MA; [2]Renal Research Inst (RRI), New York, NY.*

Background: A quality improvement project on fluid management using Crit-Line® Monitors (CLM) was conducted across multiple RRI facilities. Percent change in relative blood volume (RBV) was measured during routine hemodialysis (HD). Previous analyses of the same cohort have shown associations between RBV reduction and reduced hospital admission rate; the current analysis assesses mortality.

Methods: A retrospective analysis of HD treatments with RBV measurements was conducted over 6 months. RBV was calculated using: RBV= [(Hematocrit$_{(T0)}$/ Hematocrit$_{(T)}$)-1]X100. Average RBV at the end of HD was calculated for 1099 patients (22,579 treatments with RBV). Patient deaths were recorded as part of routine clinic procedures over the same 6 months. Mortality rate per patient month was calculated as #deaths/patient months. Time to death was modeled using Cox proportional hazards model.

Results: Patients were divided into RBV categories by 5% increments and compared on risk of death during the 6 months (Table). There was an increased risk of death with less reduction in RBV. For example, using patients with the greatest reduction in RBV (< -15%) as the reference, patients with the least reduction in RBV by the end of HD had 16 times the risk of death. Modeling time to death, there is a 15% increase risk of mortality for each 1% increase in the end of HD blood volume (p< 0.0001). Similar results were obtained after controlling for age, gender, and race (11% increased risk, p=0.002).

% Relative Blood Volume	Total # Patients	Patient Months	Mortality Rate	Mortality Ratio
≤-15%	47	730	0.004	1 (Reference)
-14.9 to -10%	254	41821	0.006	1.34
- 9.9 to - 5%	507	80408	0.010	2.45
-4.9 to 0%	263	39098	0.017	3.96
> 0%	28	3081	0.068	15.97

Conclusions: In a large cohort of HD patients with relative blood volume measured, patients with less reduction in percent change in relative blood volume at the end of dialysis had higher risk of death over 6 months when compared to patients with greater reduction. These patients may represent a subset of patients at high risk for adverse outcomes and may benefit from fluid management programs.

The Effect of Altitude on Erythropoiesis-Stimulating Agent Dose, Hemoglobin Level, and Mortality in Hemodialysis Patients

Scott Sibbel,[1] Donna E. Jensen,[1] John Alan Laich,[1] Sarb Shergill,[2] Bradley J. Maroni,[2] Steven M. Brunelli.[1] *[1]DaVita Clinical Research, Minneapolis, MN; [2]Akebia Therapeutics, Cambridge, MA.*

Background: Prior studies have shown that hemodialysis (HD) patients residing at high elevations have lower erythropoiesis-stimulating agent (ESA) utilization, possibly due to activation of hypoxia-regulated genes. We sought to better understand the impact of altitude on dosing of anemia medications and mortality following 2011 changes to the US epoetin alfa label and reimbursement policy.

Methods: We studied a cohort of prevalent nonveteran HD patients (vintage >6 months) treated at a large dialysis organization between 1 Jan 2012 and 31 Dec 2012. Patients were compared across categories of altitude for longitudinal hemoglobin (Hb) level, ESA and intravenous (IV) iron dose, and mortality risk using mixed linear models. Associations were adjusted for baseline demographic and clinical characteristics.

Results: Compared to altitude of 0-1499 ft, higher altitude was incrementally associated with higher mean Hb and lower mean ESA dose; mean IV iron utilization did not differ. Altitude >4500 ft (vs 0-1499 ft) was independently associated with lower mortality risk: incidence rate ratio (IRR) was 0.74 with 95% confidence interval (CI) 0.63-0.88.

	Altitude (feet)			
	0-1499 n = 92,490	1500-2999 n = 3118	3000-4499 n = 1659	>4500 n = 2027
ESA utilization, U/treatment Adjusted mean difference (95%CI) [a]	0 (ref)	-324 (-361, -218)	-400 (-519, -316)	-723 (-834, -554)
IV iron utilization, mg/month Adjusted mean difference (95%CI) [a]	0 (ref)	-2.34 (-5.08, 0.40)	-4.62 (-8.79, -0.45)	-2.93 (-7.44, 1.59)
Hemoglobin, g/dL Adjusted mean difference (95%CI) [a]	0 (ref)	-0.01 (-0.04, 0.02)	0.15 (0.11, 0.20)	0.23 (0.19, 0.27)
Mortality Adjusted IRR (95% CI) [a]	1 (ref)	1.07 (0.95, 1.21)	1.05 (0.88, 1.24)	0.74 (0.63, 0.88)

[a] CIs were generated using a bootstrapping method. Bootstrap estimates were generated with 100 replicates, using unrestricted replacement sampling. Adjustments were made for baseline age, race/ethnicity, etiology of end-stage renal disease, postdialysis weight, vintage, vascular access, Charlson comorbidity index, ferritin, Kt/V, and albumin, as well as baseline diabetes, congestive heart failures, coronary artery disease, cerebrovascular disease, cancer, and peripheral vascular disease. Percent of patients using (yes/no) IV iron and ESA were 10% and 13.9% lower, respectively, in the >4500ft vs. 0-1499 ft groups.

Conclusions: Among contemporary HD patients receiving treatment at altitude >1500 ft, higher altitude was independently associated with greater Hb level despite lower ESA doses and comparable IV iron utilization. Altitude of >4500 ft was independently associated with a 26% lower mortality risk.

Achieved Iron Stores and Clinical Efficacy in a Trial of Ferric Citrate as a Phosphate Binder

Kausik Umanath,[1] Molly Mcfadden,[2] Diana I. Jalal,[3] Yoram Yagil,[4] Erwin Antonio Aguilar,[5] Anas Abou-Ismail,[6] Mohammed Sika,[6] Robert M. Niecestro,[7] Mark Koury,[6] Julia Lewis,[6] Tom Greene,[2] Barbara A. Greco,[8] Stephen Z. Fadem,[9] Jamie P. Dwyer,[6] The Collaborative study group.[7] *[1]Henry Ford Hosp; [2]U of Utah; [3]U of CO; [4]Ben-Gurion U; [5]LSU; [6]Vanderbilt; [7]CSG; [8]Baystate Med Ctr; [9]Baylor College of Med.*

Background: Adequate Fe stores are needed for hematopoiesis in ESRD pts on ESA, but optimal Fe stores assuring efficacy/safety are unknown. PO Fe preparations have been unable to do this. In a Ph3 RCT we showed ferric citrate (FC) as a Phos binder ↑Fe stores and ↓IV iron/ESA use. We studied IV iron/ESA use in the trial based on achieved Fe stores.

Methods: 441 pts randomized 2:1 to FC or non-Fe-containing active control (AC) were followed for 52 wks. IV iron use was at a site's discretion while ferritin£1000ng/mL and TSAT£30%. Generalized estimating equations related ↑IV Iron/ESA dose to trailing 4-mo means of ferritin/TSAT to IV iron by randomized group, adjusting for age, sex, black race, CHF and DKD, giving odds ratios (OR) for ESA use >75th %ile (10,611 Units/wk) or IV iron use >median for visits with nonzero dose (47.7 mg/wk) to compare middle and highest TSAT/ferritin tertiles to lowest.

Results: 398 subjects for ESA, 409 pts for IV iron were analyzable. In AC, ORs for ↑ESA dose were 0.63 (0.42-0.95, *p*=0.03) for middle TSAT, 0.53 (0.31-0.93, *p*=0.03) for highest TSAT tertile. FC group was similar, Table 1. Ferritin did not predict ESA dose. In AC, ORs for ↑IV iron dose were 0.51 (0.34-0.78) for middle TSAT, 0.39 (0.20-0.76) for highest TSAT tertile; FC was similar, Table 2. ferritin trended to ↓IV iron use, Table 2.

Table 1. Ability of TSAT and ferritin at higher tertiles to predict ESA usage>75th percentile. TSAT 1-28, ferritin 11-529 are reference groups. AC: active control; FC: ferric citrate

			OR (95% CI)	*p*
TSAT (%)	AC	28-37	0.63 (0.42-0.95)	0.03
		37-83	0.53 (0.31-0.93)	0.03
	FC	28-37	0.68 (0.48-0.97)	0.03
		37-83	0.62 (0.40-0.95)	0.03
Ferritin (ng/mL)	AC	529-825	1.45 (0.84-2.52)	0.18
		825-3212	1.50 (0.79-2.84)	0.22
	FC	529-825	0.92 (0.58-1.48)	0.74
		825-3212	0.90 (0.53-1.54)	0.70

Table 2. Ability of TSAT and ferritin at higher tertiles to predict IV iron use > median use for visits with non-zero dose. TSAT 1-28, Ferritin 11-529 are reference groups. AC: active control; FC: ferric citrate

			OR (95% CI)	*p*
TSAT (%)	AC	28-37	0.51 (0.34-0.78)	0.002
		37-83	0.39 (0.20-0.76)	0.006
	FC	28-37	0.51 (0.35-0.74)	0.0004
		37-83	0.22 (0.13-0.38)	<0.0001
Ferritin (ng/mL)	AC	529-825	0.71 (0.43-1.17)	0.18
		825-3212	0.49 (0.27-0.90)	0.02
	FC	529-825	1.01 (0.68-1.51)	0.96
		825-3212	0.67 (0.38-1.18)	0.17

Conclusions: TSAT predicted ↓IV Iron/ESA, TSAT>37% showing lowest use. In these ranges no TSAT limit existed over which further ↓IV Iron/ESA did not occur. ferritin levels predicted ↓IV Iron, not ↓ESA use. TSAT may better predict ESA responsiveness in ESRD.

TH-PO938

Sotatercept Improves Anemia, Vascular Calcification, and Bone Loss in Patients with End-Stage Kidney Disease on Hemodialysis

John Havill,[1] Nelson P. Kopyt,[2] Daniel W. Coyne,[3] Michael Weiswasser,[4] William T. Smith.[4] *[1]Kidney Specialists of Southern Nevada, Las Vegas, NV; [2]Lehigh Valley Health Network, Allentown, PA; [3]Washington Univ, St. Louis, MO; [4]Celgene Corporation, Warren, NJ.*

Background: This ongoing, randomized, single-blind, placebo (PBO)-controlled study evaluated the pharmacokinetic (PK), safety, and hemoglobin (Hb) effect of sotatercept, an ActRIIA-IgG1 fusion protein ligand trap, in hemodialysis (HD) subjects and explored its effects on vascular calcification (VC) and bone mineral density (BMD) using quantitative computed tomography (QCT).

Methods: Subjects were washed out of erythropoietin-stimulating agent (ESA) effects until Hb was <10 g/dL and randomized to PBO or sotatercept given subcutaneously every 28 days for up to 8 dose cycles. Treatment failures (Hb <9 g/dL) were rescued with ESA or transfusion; intrasubject dose escalation was not permitted. QCT scans of the hip, lumbar spine, and abdominal aorta were obtained at baseline and after the 225-day treatment phase. Interim results are reported for PK, safety, home BP, Hb, VC, and BMD effects in the 0.3, 0.5, and 0.7 mg/kg dose groups.

Results: Among subjects treated with PBO (n=9) or sotatercept 0.3 mg/kg (n=9), 0.5 mg/kg (n=8), and 0.7 mg/kg (n=9), adverse events were mostly mild/moderate, unrelated to study drug, relatively similar in type/severity between groups, and generally consistent with subject medical histories. Two deaths occurred in the PBO group. There were no dose-dependent changes in home BP. In the 225-day treatment phase, Hb was >10 g/dL in 33%, 33%, 63%, and 78% of subjects treated with PBO or sotatercept 0.3, 0.5, or 0.7 mg/kg, respectively. Paired QCTs obtained in 4, 6, 5, and 6 subjects treated with PBO or sotatercept 0.3, 0.5, or 0.7 mg/kg showed <15% progression of VC in 33%, 80%, 80%, and 100%, and >2% increase in femoral neck cortical BMD in 0%, 20%, 40%, and 75%, respectively.

Conclusions: Sotatercept appears to be well tolerated with an acceptable safety profile in HD, without increases in home BP. There are beneficial dose-related responses to sotatercept in Hb, VC, and BMD. A larger dataset, with an ongoing 14-day dose group, will further substantiate these results.

Funding: Pharmaceutical Company Support - Study was sponsored by Celgene Corporation.

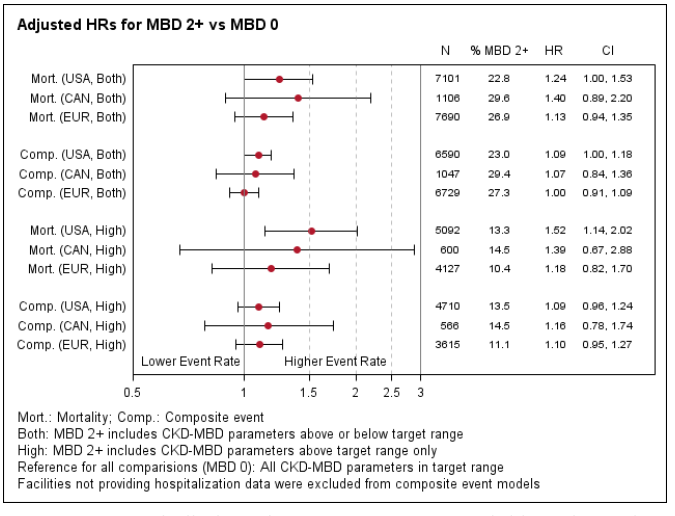
Impact of CKD-MBD Composite Score on Mortality and Hospitalization: Dialysis Outcomes and Practice Patterns Study (DOPPS)

Douglas S. Fuller,[1] Paul Dluzniewski,[2] Kerry Cooper,[2] Brian D. Bradbury,[2] Mark D. Danese,[3] Bruce M. Robinson,[1,4] Francesca Tentori.[1,5] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Amgen, Thousand Oaks, CA; [3]Outcomes Insights, Inc., Westlake Village, CA; [4]Univ of Michigan, Ann Arbor, MI; [5]Vanderbilt Univ, Nashville, TN.*

Background: The biochemistries associated with chronic kidney disease-mineral and bone disorder (CKD-MBD), parathyroid hormone (PTH), calcium (Ca), and phosphorus (P), are physiologically interrelated. We evaluated the impact of combinations of CKD-MBD parameters outside target ranges in HD patients (pts).

Methods: We identified DOPPS 3-5 (2005-2014) pts in the US, Canada, and Europe (France, Germany, Italy, Spain, Sweden, and the UK) with ³12 mos of follow-up. We assessed demographic and clinical covariates in study mos 9-12 and used Cox models to generate disease risk scores (DRS) by region based on pts with CKD-MBD parameters in target (MBD 0; P 3.5-5.5 mg/dL, Ca 8.4-10.2 mg/dL, PTH 150-600 pg/mL) and to compare event rates, adjusted for DRS, of mortality and a composite of death or hospitalization between MBD 0 and pts with 2-3 values outside target (MBD 2+).

Results: MBD 2+ prevalence, primarily due to high PTH and P, was 22.8%, 29.5%, and 26.9% in the US, Canada, and Europe, respectively. PTH above target was higher in the US (52%) compared to Canada (42%) and Europe (28%). Compared to MBD 0, MBD 2+ was associated with moderately higher mortality in the US and Canada but not Europe; MBD 2+ was weakly associated with higher composite rates in all three regions. We observed slightly stronger associations in pts with 2+ MBD labs above target only.



Conclusions: Distributions of CKD-MBD parameters varied by region, perhaps resulting in differential risk of adverse outcomes. Our findings in this international cohort highlight the importance of simultaneous, rather than independent, control of MBD parameters within clinical guidelines ranges.

US DOPPS Practice Monitor: Comparisons with CMS ESRD Databases

Douglas S. Fuller, Lindsay Zepel, Keith McCullough, Brian Bieber, Ronald L. Pisoni, Francesca Tentori, Bruce M. Robinson. *Arbor Research Collaborative for Health, Ann Arbor, MI.*

Background: Since August 2010, the Dialysis Outcomes and Practice Patterns Practice Monitor (DPM; www.dopps.org/DPM) has leveraged its US hemodialysis (HD) sample (now >200 facilities) to provide timely and detailed (>750 data tables) updates on national trends in HD care. Here we compare DPM estimates to available results from end-stage renal disease (ESRD) data sources collected by the Centers for Medicare and Medicaid Services (CMS).

Methods: Pearson correlations (r) were used to compare contemporary trends since Aug 2010 between DPM and the 2014 US Renal Data System Annual Data Report (ADR, through Dec 2012) and the Nov 2014 CMS Claims-Based Monitoring Project (CBMP, through Jun 2014). We also compared monthly DPM estimates with cross-sectional estimates from 2014 CrownWEB (CW; Dec 2013).

Results: DPM trends in ESA use and dose, IV iron use, and hemoglobin levels were highly correlated (r's: 0.89-0.98) with ADR and CBMP trends. Compared to CW, DPM showed slightly higher fistula use, but slightly lower percent of patients with adequate Kt/V and URR values.

Table: Comparisons of US DPM national estimates to CMS ESRD data sources

	Reference Estimate	DPM Estimate (SE)	Pearson *r*
Reference data: USRDS 2014 ADR			
Epoetin dose (u/wk, Dec 2012)	10,490	10,550 (422)	0.96
IV iron use (%, Dec 2012)	61.4%	69.8% (1.9)	0.91
Mean Hb* (g/dl, Dec 2012)	10.6	10.74 (0.04)	0.98
Reference data: CW 2014			
Fistula use (%, Dec 2013)	64.8%	67.5% (1.4)	--
Catheter use (%, Dec 2013)	16.1%	12.6% (0.8)	--
Kt/V ≥1.2 (%, Dec 2013)	97.0%	94% (0.8)	--
URR ≥65% (%, Dec 2013)	96.0%	94% (0.8)	--
Reference data: CBMP Nov 2014			
ESA use (%, Jun 2014)	80.7%	85.6% (1.2)	0.89
Median Hb* (g/dl, Jun 2014)	10.5	10.68 (0.03)	0.96

Abbreviations: DPM, Dialysis Outcomes and Practice Patterns Study Practice Monitor; CMS, Centers for Medicare and Medicaid Services; USRDS, US Renal Data System; ADR, USRDS Annual Data Report; CW, CrownWEB; CBMP, CMS ESRD Claims-based Monitoring Project; Hb, hemoglobin; URR, urea reduction ratio; ESA, erythropoeisis-stimulating agent
*Among ESA-treated patients

Conclusions: DPM reports IV medications use as prescription at the end of the month (before Apr 2012) or anytime during the month (Apr 2012 and after), rather than administration. Thus, estimates for ESA and IV iron utilization each month may be somewhat different due to spontaneous or withheld dosing. Differences with CW cross-sectional estimates may result from differences in calculation methods. DPM includes non-Medicare patients that are not necessarily present in claims-based sources. DPM now includes >4 years of monthly estimates for indicators of US HD care. Although differences in data sources and specifications may influence direct comparisons, DPM data remain an important resource for identifying important trends in HD care before confirmations from CMS ESRD databases are available.

BHC Medical, Janssen, Takeda, Kidney Foundation of Canada (for logistics support), Hexal AG, DGfN, Shire, WiNe Institute, Societa' Italiana di Nefrologia (SIN), PDOPPS Japanese Society for Peritoneal Dialysis, Fresenius Medical Care, Keryx, Private Foundation Support

TH-PO941

Reduced Free Triiodothyronine Is an Independent Predictor of Clinical Outcomes in Hemodialysis Patients with Low Albuminemia

Akihiko Kato,[1] Masafumi Ono,[1] Takayuki Tsuji,[2] Naro Ohashi,[2] Hideo Yasuda.[2] *[1]Blood Purification Unit, Hamamatsu Univ Hospital, Hamamatsu, Shizuoka, Japan; [2]Internal Medicine 1, Hamammatsu Univ School of Medicine, Hamamatsu, Shizuoka, Japan.*

Background: Low free triiodothyronine (fT3) and free thyroxine (fT4) are both related to malnutrition, inflammation and mortality in dialysis patients. Upper-normal thyrotropin (TSH) levels are also associated with a higher risk of total mortality in hemodialysis (HD) patients. However, it remains unclear which of thyroid-related hormones is most useful in predicting clinical outcomes. So, we aimed this study to compare the prognostic value of different hormones in prevalent HD patients.

Methods: We enrolled 339 HD patients (age: 64±13 years old, time on HD: 129±114 months), and measured basal fT3, fT4 and TSH. We then followed the patients for the next 42 months, and assessed the impact of fT3, fT4 and TSH on all-cause mortality and cardiovascular (CV) events or hospitalization. Patients were divided into the 4 groups based on the quartiles of fT4, fT4 and TSH. The associations of basal levels with clinical outcomes were examined with Cox proportional hazards models adjusted for demographic and classical factors and comorbidities.

Results: Mean serum fT3 and ft4 were 2.01±0.37 [0.95-3.73] pg/mL and 0.86±0.20 [0.35-1.67] ng/dL. Serum levels of fT3 and fT4 were lower than those of reference ranges in 85.0% and 56.0% of the patients, respectively. In contrast, TSH levels were within the reference range in most patients (92.9%). Cox hazards analyses revealed that the lowest quartile of fT3 (<1.75 pg/mL) was an independent predictor of all-cause mortality (HR 3.55 [95%CI: 1.17-4.09, p<0.01]), all-cause mortality plus CV events (HR 2.19 [95%CI: 1.53-8.23,, p=0.01]), and all-cause mortality plus hospitalization (HR 2.16 [95%CI: 1.28-3.67, p<0.01]) when compared with those with the top quartile (fT3³0.98 pg/mL). However, the significant impact of low fT3 on prognosis was observed only in patients with serum albumin lower than 3.8 g/dL (n=195). In contrast, serum fT4 and TSH levels did not relate to prognosis.

Conclusions: These findings suggest that low fT3 became an independent predictor of clinical outcomes in HD patients with low albuminemia.

TH-PO942

Low Socioeconomic Status and Co-Morbidity Are Associated with Limited Health Literacy in RRT Patients – Results from the ATTOM Study Dominic Taylor, The ATTOM investigators. *Southmead Hospital, Bristol, United Kingdom.*

Background: Limited health literacy(LHL) is a risk factor for poor outcomes in chronic disease patients. Studies with limited patient numbers in RRT patients associate LHL with low socioeconomic status(SES), comorbidity and ethnicity.

Methods: This cross-sectional study used baseline data from the 'Access to Transplantation and Transplant Outcome Measures'(ATTOM) cohort. ATTOM recruited incident dialysis and transplant patients aged 18-75 years in the UK during 2011-2013 and also wait-listed patients similar to those transplanted(matched controls). Health literacy was measured by the question 'How often do you need someone's help to read instructions, leaflets, or other written material from your doctor or pharmacy?' answered on a scale from 1-Never to 5-Always. LHL was defined as a score greater than 2. The three groups were analysed for associations between LHL and demographics, SES factors and comorbidity, using univariate and multivariate analysis, p<0.05.

Results: 6842 patients were recruited: 2621 incident dialysis (ID), 2262 incident transplant (IT) and 1959 matched controls (MC). 6373/6842(93%) completed the health literacy assessment. Prevalence of LHL was 20% in the ID, 12% in the IT and 15% in the MC group. In univariate analyses, in all groups, English not as first language, Asian ethnicity, low educational level, unemployment, absence of car or home ownership, increased comorbidity by modified Charlson index and mental illness were associated with LHL. In adjusted models, in all groups, the following factors were associated with LHL: English not as first language(OR>3), modified Charlson index (OR 1.2 for each point above zero), low level of education (OR>2 for no qualifications compared to any), unemployment (OR>3.0 compared to employed) and absence of car ownership (OR 1.7). Age and sex were not associated with LHL after adjustment.

Conclusions: In this large nationwide study, low SES and co-morbidity are associated with LHL in patients receiving dialysis or at the point of transplantation, independent of first language. LHL may impact upon patients' ability to engage with shared decision making and their capacity to cope with the burden of disease and treatment.

TH-PO943

Comparing Dialysis Facility Compare (DFC) Star Rating to QIP Payment Categories Claudia Dahlerus,[1] Christopher J. Harvey,[1] Joseph M. Messana,[1] Richard Hirth,[1] Cindy Liao,[1] Natalie Scholz,[1] Tempie H. Shearon,[1] Zezhi (zac) Zhang,[1] K. A. Wisniewski,[1] Casey Parrotte,[1] Ji Zhu,[1] Elena K. Balovlenkov,[2] Joel S. Andress,[2] Yi Li.[1] *[1]Biostatistics, Kidney Epidemiology and Cost Center, Univ of Michigan, Ann Arbor, MI; [2]Centers for Medicare and Medicaid Services.*

Background: CMS star ratings summarize DFC quality measures, giving each facility 1 to 5 stars to help consumers compare facilities. The ESRD QIP, a value based purchasing program, applies performance-based payment reductions. We describe differences between the star rating and QIP payment reduction categories and how each distinguishes average facility performance.

Methods: We obtained the fixed percentile star rating (5-Star 10%, 4-Star 20% 3-Star 40%, 2-Star 20%, 1-Star 10%) and QIP payment reduction for each facility from the Jan 2015 DFC file. We calculated star rating mean final scores (MFS) for each tier and used t-tests to assess differences between adjacent tiers.

Results: Differences in MFS between adjacent star rating tiers are similar (~9 pts, p<.0001) (Table 1). In the QIP system, the difference between payment reduction tiers 0.5% to 2% is small (~1 to 3 pts) and not statistically significant and the difference between the 0.5% and 0% categories is ~15 pts, p<.0001.

Star Rating	Facility N(%)	MFS (SD)	QIP Payment Reduction	Facility N(%)	MFS (SD)
1	563(10)	31.8 (0.2)	**2.0%**	37(0.6)	33.3 (2.1)
2	1127(20)	41.4* (0.1)	**1.5%**	23(0.4)	34.0 (1.6)
3	2255(40)	50.2* (0.1)	**1.0%**	41(0.7)	36.9 (1.4)
4	1127(20)	58.7* (0.1)	**0.5%**	242(3.9)	36.3 (0.6)
5	563(10)	67.7* (0.2)	**0%**	5795(94.4)	50.9* (0.1)

* p<.0001 vs. previous tier

Conclusions: Differences in MFS between adjacent DFC star tiers were larger and potentially clinically meaningful. QIP categories primarily distinguish between the top tier (0% reduction) and all lower tiers (.5% to 2% reduction). Programs evaluating facility performance have different goals, and methods for categorizing quality are informed by these goals. Further research and debate will help inform what is optimal.

TH-PO944

Association of Socioeconomic Characteristics with Readmission Among Dialysis Patients Claudia Dahlerus,[1] John Wheeler,[1] Deanna Chyn,[1] Yanming Li,[1] Richard Hirth,[1] John Kalbfleisch,[1] Jennifer Sardone,[1] Zhi He,[1] Tempie H. Shearon,[1] Joel S. Andress,[2] Elena K. Balovlenkov,[2] Yi Li.[1] *[1]UM Kidney Epidemiology & Cost Center; [2]Centers for Medicare & Medicaid Services.*

Background: CMS recently developed hospital readmissions measures to reflect quality of care provided by nursing homes, long-term care hospitals, inpatient rehabilitation facilities, home health agencies and dialysis facilities. The intent is to encourage care coordination as patients transition between care providers. All measures adjust for patient characteristics. CMS has not adjusted quality measures for patient socioeconomic status (SES), so as not to condone disparities in care delivery. However, not including such adjustments may result in inappropriate assessments about quality of care. We present preliminary analyses assessing the association of SES and readmission among dialysis patients.

Methods: Using 2013 Medicare claims data, we model the probability of readmission, defined as an unplanned readmission within 30 days of a hospital discharge, adjusted for patient characteristics including age, sex, BMI, comorbidities, discharging hospital, and several measures of SES, plus measures reflecting SES of the patient's area of residence.

Results: Patients with Medicare secondary payer (MSP) were less likely to experience a readmission (OR 0.92; CI 0.90-0.93); patients with dual Medicare and Medicaid coverage (OR 1.08; CI 1.08-1.09), unemployed at ESRD incidence (OR 1.07; CI 1.06-1.08) and living in ZIP codes with high unemployment, low education and income disparity were more likely to experience a readmission.

Conclusions: Insurance status and area of residence are strong proxies for SES and are associated with readmissions. MSP, largely reflective of private insurance coverage, can be an indicator of higher SES and perhaps better health. Dual eligibility for Medicare and Medicaid can be an indicator of lower SES, as can being unemployed at ESRD incidence. As interest in risk adjusting for indicators of SES has grown, the association between SES and readmission suggests further analysis may be appropriate. However, caution must be exercised in efforts to distinguish between SES factors that may or may not be related to quality of care.

Funding: Other U.S. Government Support

TH-PO945

Co-Morbidities (CM) Do Not Predict Adverse Outcomes in Peritoneal Dialysis (PD) versus Hemodialysis (HD) in a Multi-Ethnic Asian ESRD Cohort Gek hsiang Lim,[1] Khuan yew Chow,[1] Vathsala Anantharaman.[2] *[1]Health Promotion Board, Singapore; [2]National Univ Health System.*

Background: There is conflicting data on outcomes following HD vs PD. USRDS data for ESRD in 2002-2004 suggested similar outcomes for HD and PD over 5 years of followup. This study evaluated outcomes for HD vs PD from a multi ethnic Asian ESRD population and evaluated the impact of CM on worse outcomes in either modality.

Methods: 3279 HD and 1330 PD patients who were included in the Singapore Renal Registry(SRR) in 2001-2007 and followed up till death or 31 Dec 2012 comprised the study population. Data on patients' demographics, CM and survival were collected. Patients were stratified by age, presence of diabetes(DM) and occurrence of 1 or more vascular(V) vs non-vascular(NV) CM. 5-year survival was compared using Kaplan-Meier and regression analyses.

			Median Survival (Yrs)^		
CM	**Age**	**No.**	**PD**	**HD**	**HR(95% CI)**
0	**All**	999	-	-	1.3(0.9–1.6)
Non-DM	**<65**	1217	11.0	-	1.1(0.9-1.4)
Non-DM+No CM	**<65**	810	-	-	1.0(0.7–1.4)
Non-DM+V		286	7.8	9.1	1.1(0.8–1.6)
Non-DM+NV		121	7.9	-	1.1(0.5-2.6)
Non-DM	**≥65**	496	3.4	4.9	1.5(1.2-1.9)
Non-DM+No CM		189	3.8	6.7	2.1(1.4–3.1)
Non-DM+V		265	3.3	3.9	1.3(1.0–1.8)
Non-DM+NV		42	7.2	3.6	0.6(0.2–1.9)
DM	**<65**	1838	3.2	5.6	1.8(1.6–2.0)
DM+No CM		545	4.8	6.8	1.7(1.3–2.1)
DM+V		1212	2.9	4.9	1.8(1.5–2.0)
DM+NV		81	3.8	7.2	2.1(1.1–2.3)
DM	**>65**	1058	2.2	3.3	1.7(1.5–2.0)
DM+No CM		224	2.4	4.3	1.7(1.2–2.3)
DM+V		802	2.2	3.0	1.7(1.4–2.0)
DM+NV		32	-	4.1	0.5(0.1–3.8)

^ -: Not reached

Results: Overall, survival was comparable for HD vs PD for ESRD patients with no CM(HR:1.3;95% CI:0.9-1.6). Likewise, for non-DM patients <65 years, neither V nor NV CM impacted on outcomes for PD vs HD. However, DM had worse survival on PD regardless of age or presence of V vs NV CM.

Conclusions: Median life expectancy for HD is superior in this Asian population relative to USRDS (SRR vs USRDS: 73.5 vs 38.4 months for HD; 42.8 vs 36.6 months for PD) Of note, outcomes for young, non-DM ESRD patients was comparable between HD and PD. CM did not confer additional risk for adverse outcomes for PD in any subgroup.

TH-PO946

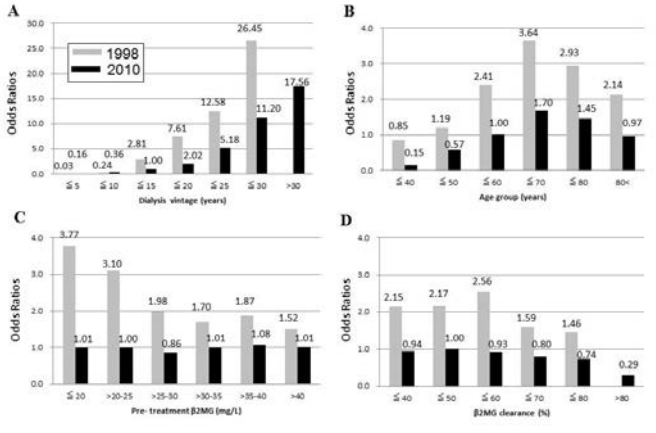
Significance of the Decreased Risk of Dialysis-Related Amyloidosis Now Proven by Results from Japanese Nationwide Surveys in 1998 and 2010

Junichi Hoshino,[1,2] Kunihiro Yamagata,[2] Shinichi Nishi,[3] Kunitoshi Iseki,[2] Ikuto Masakane.[2] *[1]Nephrology Center, Toranomon Hospital, Tokyo, Japan; [2]Committee of Renal Data Registry, Japanese Society for Dialysis Therapy, Tokyo, Japan; [3]Div of Nephrology, Kobe Univ, Kobe, Japan.*

Background: Although dialysis technology greatly improved in recent years, it remained unclear whether those improvements helped decrease the incidence of dialysis-related amyloidosis (DRA). Accordingly, we retrospectively compared the incidence of first-time carpal tunnel surgery (CTS)—as proxy for DRA onset—in two cohorts of hemodialysis patients, the second cohort studied after dialysis methods (especially dialysate quality) had greatly improved.

Methods: We used the 1998 and 2010 Japan Renal Data Registries to compare crude risk of first-time CTS the following year. After adjusting for patient background and laboratory data, odds ratios (ORs) for CTS in the whole cohorts and the populations matched by propensity score for hemodialysis and hemodiafiltration were calculated.

Results: 202,726 patients were analyzed. In the 1998 cohort, 1.77% experienced first-time CTS compared with 1.30% of the 2010 cohort (p<0.001); with 2010 as referent, the adjusted 1998 OR was 2.22 (1.68-2.95). Both crude risks and adjusted ORs were analyzed by dialysis vintage, age, pre-dialysis b2-microglobulin (b2m) and b2m clearance, risk of CTS trending 1.5-2.0 higher in 1998 than 2010.



The reduction was most prominent in patients with longer dialysis vintage, patients who were younger, and those with lower pre-dialysis b2m levels. Similar results were obtained by propensity score-matched analysis. We also found that b2m clearance >80% may reduce risk of CTS.

Conclusions: The incidence of first-time CTS as proxy for DRA decreased significantly from 1998 to 2010. Several factors may have contributed to this decrease, including improved dialysis methods.

TH-PO947

Twice Weekly Hemodialysis and Clinical Outcomes in the China DOPPS

Yucheng Yan,[1] Mia Wang,[2] Jia Qi Qian,[1] Brian Bieber,[2] Mei Wang,[1] Nan Chen,[3] Bruce M. Robinson,[2] Shuchi Anand.[4] *[1]Shanghai Renji Hospital; [2]Arbor Research; [3]Shanghai Ruijin Hospital; [4]Stanford Univ.*

Background: Outcomes related to 2 times weekly hemodialysis (HD),substantially practiced in China, remain understudied. Small, single-center studies have indicated better preservation of residual kidney function (RKF) and similar survival for 2 vs. 3 times weekly HD. We used data from the China Dialysis Outcomes Practice Patterns study (DOPPS) to evaluate survival and hospitalizations by frequency of HD.

Methods: We studied 1433 patients from 45 HD unitsin China (2012-2015). Cox regression was used to model the association of 2 vs. 3 times weekly HD with clinical outcomes adjusting for patient and treatment characteristics.

Results: 270 patients (19%) were undergoing 2 times weekly HD in China. Compared with 3 times weekly HD, patients on 2 times weekly HD were more likely to be female and have shorter time on dialysis (4.3 vs. 2.6 yrs), more urine output, shorter dialysis session length (238 vs. 250 min) and longer travel times to facility. They were less likely to have diabetes or cardiovascular disease. Insurance coverage was similar in the two groups. During follow-up (median=1.7 years), 184 (13%) deaths and 516 (38%) hospitalizations occurred. No differences in mortality or hospitalization were found between the two frequency groups (Table). No interaction was observed with vintage (p=0.43).

Table: Progressive adjustment of mortality with twice weekly dialysis, in China

2 times weekly (vs 3 times weekly)	HR (95% CI)	p
model 1: unadjusted	0.90(0.61-1.33)	0.61
model 2: model 1+patient demographics[a]	0.95(0.63-1.42)	0.79
model 3: model 2+residual kidney function	0.99(0.66-1.50)	0.97
model 4: model 3+insurance	0.98(0.66-1.44)	0.90
model 5: model 4+comorbidities	1.08(0.72-1.61)	0.72
model 6: model 5+ktv, average intra-dialytic weight loss	1.00(0.59-1.69)	0.99
model 7: model 6+labs (hgb, albumin)	1.06(0.61-1.85)	0.84

*1393 patients, 184 events.
[a]age, gender, BMI, standardized, and vintage.

Conclusions: In this multi-center study with well-characterized patient and treatment data, outcomes of 2 vs. 3 times weekly HD were similar. Thus, it is possible that among carefully selected patients 2 times weekly HD may provide acceptable outcomes. An additional study is also need due to residual confounding, small sample size, and the changes in results with progressive adjustments.

TH-PO948

Initiation of a Chronic Kidney Disease Case Manager Program Is Associated with Better Outcomes in Incident Hemodialysis Patients

Joseph A. Kuhn, Patrick Bridge, John W. Larkin, Hao Han, Sheetal Chaudhuri, Len A. Usvyat, Terry Ketchersid, Franklin W. Maddux. *Fresenius Medical Care North America, Waltham, MA.*

Background: The Renal Care Coordinator (RCC) Program places chronic kidney disease (CKD) case managers in the Nephrology Practice to co-manage late stage CKD (4 and 5) patients for an optimal outpatient start to Renal Replacement Therapy (RRT). This program is performed through both physical and virtual RCCs. We compared outcomes in patients starting hemodialysis (HD) who were previously enrolled in the RCC program to CKD patients cared for in the Nephrology practice, but were not in the RCC program.

Methods: All CKD 5 patients who transitioned to end stage renal disease (ESRD) requiring RRT between 1/1/2012 and 10/1/2014 at the nephrology practices that adopted the RCC were analyzed. We compared outcomes in patients enrolled into the RCC program versus patients considered to have a "Timely Referral" for dialysis (i.e. were followed in a

nephrology practice for >4 months before starting RRT), but received no RCC interaction. The access type, albumin (Alb), and hemoglobin (Hgb) was collected at the first outpatient HD treatment. We also computed the rates of hospital days and mortality in the first 120 days of HD.

Results: 1,404 CKD 5 patients were identified for the analysis, where 51% of the population was enrolled in the RCC. Patients in the RCC had a lower % of catheters, higher % of Alb ≥4.0g/dL, and higher % of Hgb 10-11g/dL at the first HD treatment compared to patients with a "Timely Referral", but no RCC care. During a 120 day follow up after initiating HD, patients in the RCC program had significantly lower hospitalization rates.

Table 1. Comparison of parameters in incident HD patients

Patient group	Number of patients	120 Day hospital admissions (ppy)	120 Day hospital days (ppy)	Catheters at start of HD	Hgb 10-11 at start of HD	Alb ≥4.0 at start of HD
TIMELY, Non-RCC	685	1.9	13.7	52.2%	26.9%	21.5%
TIMELY, RCC	719	1.5*	9.3*	31.5%*	30.9%*	27.8%*

P<0.05 (*)

Conclusions: This analysis demonstrates that placement of CKD case managers is associated with better outcomes, including anemia, access type, nutritional status and hospitalizations in the first 120 days of HD.

Funding: Pharmaceutical Company Support - Fresenius Medical Care North America

Extracellular Overhydration Measured by Multifrequency Bioelectrical Analysis Is Associated with Increased Postdialysis Systolic Blood Pressure in Hemodialysis Patients

Hae Yeul Park,[1] Seok-hyung Kim,[1] Ah Ran Choi,[1] Jung eun Lee,[2] Hyung Jong Kim,[3] Hoon Young Choi,[1] Sung-Kyu Ha,[1] Hyeong cheon Park.[1] *[1]Nephrology, Gangnam Severance Hospital, Yonsei Univ College of Medicine, Seoul, Korea; [2]Nephrology, Yongin Severance Hospital, Yonsei Univ College of Medicine, Seoul, Korea; [3]Nephrology, Bundang CHA Hospital, Pochon CHA Univ College of Medicine, Seoul, Korea.*

Background: Postdialytic hypertension is associated with increased morbidity and mortality for hemodialysis (HD) patients. Recent studies suggest that increased postdialysis extracellular volume may account for the rise in postdialysis systolic blood pressure (PDSBP). The aim of this study was to assess the relationship between volume status and PDSBP in HD patients.

Methods: Volume status assessments were performed after mid-week HD using multifrequency bioelectrical impedance (BIA, Inbody S10) in supine position. Demographic and routine biochemical data were collected and pre- and post-dialysis B-type natriuretic peptide (BNP) level was measured (Triage BNP test, Alere).

Results: We enrolled clinically stable 99 HD patients from 3 dialysis centers. Patients were divided into 3 groups based on a fall in SBP of 20mmHg or more (Hypotensive, 24.2%), an increased SBP of 10mmHg or more (Hypertensive, 32.3%), and a stable group (43.4%). The mean age was 55.1±13.3 years in hypotensive, 58.3±11.6 years in stable, and 65.2±7.2 years in hypertensive group. Postdialysis BNP was 267.8±251.1 pg/mL in hypotensive, 669.8±915.9 pg/mL in stable, 1124.2±1197.8 pg/mL in hypertensive group. There were no differences in gender, dialysis prescriptions, and subjective global assessment score among the patient groups. The ECW/TBW ratio was significantly higher in the hypertensive group and positively correlated with PDSBP and delta SBP. The only independent risk factor affecting PDSBP was ECW/TBW ratio after dialysis.

Conclusions: HD patients who demonstrate increase in PDSBP should have their volume status reassessed and target dry weights adjusted using BIA, with emphasis on increased the ECW/TBW ratio.

TH-PO950

Novel Phosphate Binder, Ferric Citrate Hydrate, Can Reduce Serum Phosphate Levels and Doses of Erythropoiesis Stimulating Agents in Japanese Patients on Hemodialysis

Hirotake Kasuga,[1] Ryo Takahashi,[1] Keiko Kimura,[1] Chieko Matsubara,[1] Hitomi Tanimoto,[1] Mari Maseki,[1] Yasuhiko Ito.[2] *[1]Nephrology, Nagoya Kyoritsu Hospital, Nagoya, Japan; [2]Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Japan.*

Background: Ferric citrate hydrate (FC) has been available in Japan as a phosphate binder for patients on dialysis (HD) since 2014 although its effects have not been evaluated in detail in such patients. The present study aimed to determine the effects of FC on serum phosphate levels and anemia control in patients on HD.

Methods: Thirty-eight outpatients (mean age, 62.5 y; male, n = 28 [73.7%]; mean HD vintage, 7.2 y; hypertension, n = 29 [76.3%]; diabetes, n =19 [50.0%]; secondary hyperparathyroidism, n = 15 [39.5%]) on maintenance HD were treated with FC for six months to control hyperphosphatemia. Serum concentrations of phosphate, calcium, hemoglobin, and ferritin levels, transferrin saturation (TSAT), and weekly epoetin (EPO) doses were evaluated.

Results: Mean phosphate levels were significantly decreased from 7.05 ± 1.11 to 6.19 ± 0.91 ($p < 0.00001$), 6.14 ± 1.16 ($p < 0.005$) and 6.01±1.11 ($p < 0.005$) mg/dL at one, three and six months, respectively. Calcium, hemoglobin and ferritin levels did not significantly differ during the same periods. Transferrin saturation was significantly increased (26.7 ± 10.9% vs. 20.0 ± 9.5%, $p < 0.05$) and the weekly EPO dose was significantly decreased (2750 ± 2699 vs. 6801 ± 7406 IU/week, $p < 0.05$) after six months of FC therapy.

Conclusions: FC can decrease serum phosphate levels and the weekly EPO dose. Therefore, FC is useful for treating hyperphosphatemia and renal anemia in Japanese patients on HD.

TH-PO951

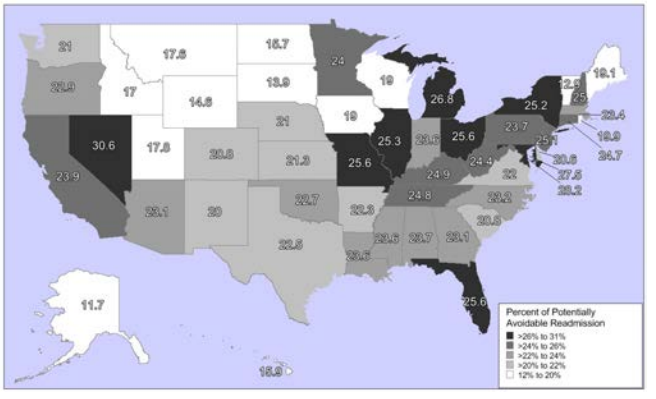
Geographic Variation of Potentially Avoidable Readmissions in Hemodialysis Patients

Daniel W. Ross,[1] Kamyar Kalantar-Zadeh,[2] Steven Fishbane,[1] Anna Mathew.[1] *[1]Div of Nephrology, Hofstra North Shore –LIJ School of Medicine, New York, NY; [2]Harold Simmons Center for Kidney Disease Research and Epidemiology, Div of Nephrology, Univ of California, CA.*

Background: In 2011 in the United States, 36.3% of prevalent hemodialysis patients were readmitted within 30 days of an index hospitalization. These rates are approximately twice that of the general U.S Medicare population. While some readmissions to hospital are unavoidable, it is probable that a substantial number could be prevented. In the present study, we describe inter-state variability in 30-day potentially avoidable readmissions (PAR).

Methods: The United States Renal Data System (USRDS) was used to identify prevalent hemodialysis patients (vintage >90 days) with acute hospitalizations in 2008. Exclusion criteria were transfer to rehabilitation or skilled nursing facility, unknown dialysis start date, and renal function recovery. PAR were identified using a validated, computerized algorithm (SQLape), and displayed geographically by state using Pitney Bowes MapInfo.

Results: 250,606 index hospitalizations were identified, with 37% readmissions within 30 days (n = 84,279). Nationwide, 24% of index hospitalizations were followed by a 30-day PAR (64.9% of all readmissions) (n= 59,803). PAR ranged from 12% to 31% by state. The figure shows the geographic distribution of potentially avoidable readmissions.



Conclusions: There is inter-state variability in PAR among chronic hemodialysis patients and that may be related to regional differences in practice patterns or patient demographics. Further characterization of risk factors associated with PAR is the focus of our ongoing research.

TH-PO952

Unravelling the Relationship Between Mortality, Hyponatremia, Inflammation and Malnutrition in Hemodialysis Patients: Results from the International MONDO Initiative

Marijke J.E. Dekker,[1] Daniele Marcelli,[3] Bernard J. Canaud,[3] Constantijn Konings,[1] Karel M. Leunissen,[2] Nathan W. Levin,[4] Jochen G. Raimann,[4] Frank van der Sande,[2] Len A. Usvyat,[3,4] Peter Kotanko,[4] Jeroen Kooman.[2] *[1]Catharina Hospital Eindhoven; [2]Maastricht Univ Medical Center; [3]Fresenius Medical Care; [4]Renal Research Inst.*

Background: Hyponatremia is a risk factor for mortality in hemodialysis patients. However, it is not well known to which extent comorbidities, such as malnutrition, fluid overload and inflammation are related to hyponatremia and influence the association between hyponatremia and outcomes.

Methods: We studied 8892 patients from the European subset of the MONDO Initiative. Nutritional and fluid statuses were assessed by multifrequency bioimpedance spectroscopy. Based on pre-dialysis fluid status, fluid depletion was defined as an extracellular water volume < -1.0L and fluid overload > +2.5L. Malnutrition was defined as a lean tissue index below the 10th percentile of age- and gender matched healthy controls. Hyponatremia and inflammation were defined as serum sodium levels < 135 mEq/L and C-reactive protein levels >10 mg/L, respectively.

Results: Hyponatremia was predicted by the presence of malnutrition (odds ratio (OR) 1.48 (95%CI 1.30-1.69) and inflammation (OR 1.44 (95%CI 1.26-1.64)), but not by fluid depletion (OR 1.38 (95%CI 0.98-1.93)) or fluid overload (OR 0.99 (95%CI 0.85-1.14)). Malnutrition (hazard ratio (HR) 1.39 (95%CI 1.23-1.58)), inflammation (HR 2.31 (95%CI 2.04-2.62)), fluid overload (HR 2.17 (95%CI 1.90-2.47)) and hyponatremia (HR 1.63 (95%CI 1.39-1.90)) were independent predictors for all-cause mortality.

Conclusions: In hemodialysis patients hyponatremia is associated with malnutrition and inflammation but not with deranged fluid status. Hyponatremia maintained predictive for all-cause mortality after correction for malnutrition, inflammation and fluid status abnormalities. Hyponatremia may aid efforts to identify hemodialysis patients at increased risk of death.

TH-PO953

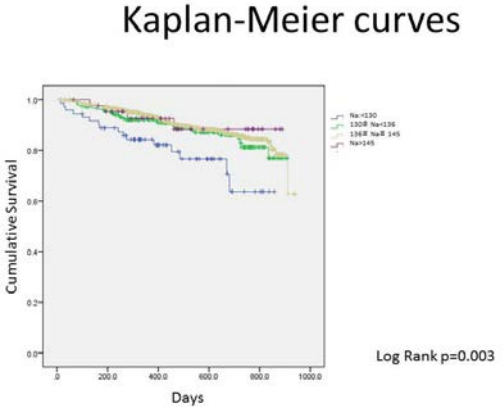
Low Serum Sodium Concentration at the Induction of Maintenance Hemodialysis Predicts Higher Risk of Mortality

Yukako Ohyama,[1] Hideaki Shimizu,[1] Daijo Inaguma,[2] Yoshiro Fujita.[1] *[1]Nephrology and Rheumatology, Chubu Rosai Hospital, Nagoya, Japan; [2]Nephrology, Red Cross Nagoya Daini Hospital, Nagoya, Japan.*

Background: Low serum sodium concentrations are associated with an increased risk of death in the general population because of underlying diseases such as congestive heart failure and cirrhosis. However some papers report hyponatremia itself further increases the mortality risk. The prevalence of hyponatremia and the mortality risk of hyponatremia at the induction of maintenance hemodialysis (HD) haven't been reported before.

Methods: This study is a retrospective cohort study which date was collected from "Aichi Cohort study of Prognosis in Patients" (AICOPP) newly initiated dialysis. After the exclusion of peritoneal dialysis (PD) patients, this study enrolled 1395 patients (mean age; 68 ± 13 years, mean eGFR level; 5.4 ± 2.2 ml/min/1.73m^2) who started maintenance HD between 10/1/2011 and 11/30/2013. We divided the cohort to 4 groups by serum sodium concentration at the induction of HD adjusted by serum glucose concentration(Severe hypo:Na<130, Mild hypo:130£Na<136, Normal :136£Na£145, Hyper:Na>145 mEq/L). The proportional hazard model was used to examine the association between serum sodium level and mortality.

Results: The prevalence of hyponatremia, defined as Na<136 mEq/L and <130 was at 23% and 5%, respectively. During 15.5 months' mean follow up, 159 patients (11%) died. The lowest Na group was significantly associated with higher risk of mortality.(figure1) Patients with serum sodium levels of <130 mEq/L were more likely to have multivariable-adjusted mortality hazard ratios (95% confidence interval) of 2.34 (1.31-4.15) compared to patients with serum sodium levels of 136-145 mEq/L.



Conclusions: Hyponatremia at the induction of HD is an independent predictor of higher risk for mortality.

TH-PO954

Frequency of Hyperkalemia Events in Dialysis Patients in a Large Dialysis Organization

Akeem Yusuf,[1] Yan Hu,[1] Bhupinder Singh,[2] Alex Yang,[2] James B. Wetmore.[1] *[1]Chronic Disease Research Group, MMRF, Minneapolis, MN; [2]ZS Pharma, Inc, Redwood City, CA.*

Background: Hyperkalemia is a major problem in dialysis patients. It is associated with increased risk of cardiac arrhythmias and sudden cardiac death. However, few studies have examined frequency of hyperkalemia episodes in a large population of dialysis patients. We present a characterization of the magnitude of hyperkalemia prevalence in a large hemodialysis population and examine the role of interdialytic interval in its occurrence.

Methods: We derived annual cohorts of hemodialysis patients (2007-2010) from linked DaVita and USRDS databases. Included patients were those receiving thrice-weekly hemodialysis. On a monthly basis, hyperkalemia case was defined as a serum potassium level greater than or equal to 5.5 mEq/L. Hyperkalemia prevalence was calculated as the cumulative number of monthly episodes divided by cumulative follow-up time. Hyperkalemia prevalence was also reported separately by long and short interdialytic interval.

Results: Hyperkalemia prevalence in 2010 was 16.3 per 100 patient-months. Overall, hyperkalemia prevalence was stable between 2007 and 2010. The prevalence of hyperkalemia events occurring on day after the long interdialytic interval was about 2.0 to 2.4 times as high as events occurring on the day after the short interdialytic interval.

		Number of events per 100 patient-months	
		Events on day after	Events on day after
Cohort	Cohort	long interdialytic	short interdialytic
Year	Size	interval	interval
2007	28,769	58.74	28.84
2008	34,785	62.16	27.63
2009	34,567	62.94	26.26
2010	36,879	61.61	26.22

Conclusions: The findings from this study show that hyperkalemia is highly prevalent among hemodialysis patients, especially on the day after the long-interdialytic interval. Further studies are warranted.

Serum Potassium Levels and Mortality in Hemodialysis Patients

Akeem Yusuf,[1] Yan Hu,[1] Bhupinder Singh,[2] Jose A. Menoyo,[2] Alex Yang,[2] James B. Wetmore.[1] *[1]CDRG/MMRF, Mpls, MN; [2]ZS Pharma, Inc, Redwood City, CA.*

Background: Hyperkalemia is common in patients receiving maintenance hemodialysis (HD) and is associated with sudden cardiac death. However, few studies have examined the association between serum potassium (K) level and death in a large population of dialysis patients.

Methods: A cohort of patients receiving thrice-weekly HD in 2010 was constructed using data linked between USRDS and a large dialysis organization (LDO). Patients were followed from first serum K measurement until death, transplant, change in dialysis modality, change in dialysate K concentration, loss of Medicare eligibility, loss to follow up, or Dec 31, 2010. Hyperkalemia was defined by serum K levels 5.5-6.0 mEq/L at 0.1 mEq/L intervals. Time-dependent Cox proportional hazards modeling was used to estimate the association between hyperkalemia occurrence and all-cause and cardiovascular mortality.

Results: Hyperkalemia defined as serum K ≥5.7 mEq/L was associated with all-cause mortality (adjusted hazard ratio [AHR] 1.1, 95% CI 1.01-1.28, P = 0.037, compared to K ≥5.0 mEq/L) after adjustment for demographic and clinical factors in time-dependent models; the AHRs increased progressively as the threshold for hyperkalemia rose (AHRs 1.18, P = 0.014, for K=5.8 mEq/L; 1.29, P = 0.001, for K=5.9 mEq/L; 1.37, P = 0.0002, for K=6.0 mEq/L). The pattern of the point estimates was similar for cardiovascular mortality, although the results did not reach statistical significance (AHRs 1.09 for K=5.7 mEq/L, 1.13 for K=5.8 mEq/L, 1.20 for K=5.9 mEq/L, 1.28 for K=6.0 mEq/L).

Conclusions: Hyperkalemia is associated with all-cause mortality beginning at K level ≥5.7 mEq/L, with mortality risk point estimates increasing in ordinal fashion through K level ≥6.0 mEq/L. A similar pattern was observed in the point estimates for cardiovascular mortality. This study may have identified a threshold at which point serum K becomes dangerous.

A Multicenter, Phase 2/3 Randomized, Double-Blind, Placebo-Controlled Trial of Nalbuphine ER Tablets for the Treatment of Uremic Pruritus: Baseline Population Characteristics Vandana S. Mathur,[1] Jayant Kumar,[3] Paul W. Crawford,[5] Howard Hait,[4] Thomas Sciascia.[2] *[1]MathurConsulting, Woodside, CA; [2]Trevi Therapeutics, New Haven, CT; [3]Renal Medicine Associates, Albuquerque, NM; [4]Biostatistics, Edenridge Consulting, Wilmington, DE; [5]Research by Design, Evergreen Park, IL.*

Background: Uremic pruritus (UP) afflicts 30-40% of hemodialysis patients (HDP) and is associated with greater use of ESA and antibiotics. UP is hypothesized to be centrally-mediated via the reduction in endogenous κ/μ opioid ligand ratio. Nalbuphine ER tablet (NAL), a κ-opioid agonist and μ-opioid antagonist, is being developed for treatment of UP.

Methods: 373 HDP with moderate or severe UP (Numerical Rating Scale, NRS itch intensity scores ≥4.5) were randomized to blinded placebo or NAL (60 or 120 mg BID) X 8-wks.

Results: Worsening itch intensity by baseline NRS quartile was monotonically associated with impaired QOL on all instruments as well as with sleep onset latency, anxiety, and depression, but not with age, gender, BMI, ethnicity, itch duration, iPTH, URR, or Kt/V. Black race appeared to be associated with higher NRS.

Itch Intensity Numerical Rating Scale (NRS) Quartile [N]	Q1 [97] (4.5-5.6)	Q2 [97] (5.7-6.8)	Q3 [104] (6.9-8.0)	Q4 [75] (>8.0)
NRS (0, no itch; 10, worst possible itch)	5.1 (0.4)	6.3 (0.3)	7.5 (0.4)	8.9 (0.6)
White/Black race	53/43%	49/47%	47/53%	44/55%
Self-Assessed Disease Severity Patient Type C [most severely affected]	20%	33%	46%	67%
Skindex-10 (0 - 60) [0 (least); 60 (greatest) QOL impact of pruritus]	26.0 (11.1)	32.4 (13.1)	39.7 (12.4)	43.5 (13.3)
HADS - Depression	5.6 (3.6)	6.1 (3.6)	6.8 (4.0)	7.8 (4.5)
HADS - Anxiety	6.2 (3.9)	7.7 (4.1)	7.7 (4.4)	9.4 (4.6)
Time to fall asleep >60 minutes	20%	22%	36%	42%
iPTH (pg/mL)	492 (451)	336 (304)	433 (334)	463 (439)
Serum phosphate (mg/dL)	5.6 (1.7)	5.4 (1.7)	5.7 (2.0)	5.6 (1.8)
Urea Reduction Ratio (%)	74 (5)	74 (5)	73 (6)	74 (6)
spKt/V	1.6 (0.3)	1.6 (0.3)	1.5 (0.3)	1.7 (0.6)

Conclusions: In addition to the 1° endpoint hypothesis that NAL will reduce itch intensity, the apparent associations between itch intensity and QOL measures at baseline warrant examination by treatment. Unblinded results will be presented.

TH-PO957

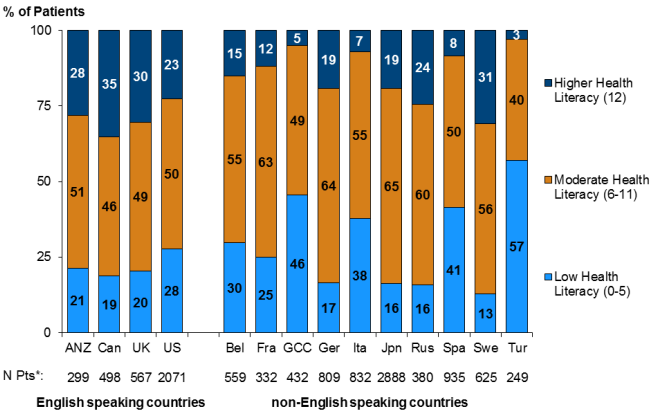
International Variation of Characteristics of Health Literacy and Its Association with Mortality in Dialysis Kerri L. Cavanaugh,[1] Mia Wang,[2] Ken Wallston,[1] Russell Rothman,[1] Ali AlSahow,[3] Patricia De Sequera,[4] Takeshi Hasegawa,[5] Brian Bieber,[2] Bruce M. Robinson,[2] Ronald L. Pisoni,[2] Francesca Tentori.[1,2] *[1]Vanderbilt Univ; [2]Arbor Research; [3]Jahra Hospital; [4]Hospital Infanta Leonor; [5]Fukushima Medical Univ.*

Background: In patients receiving hemodialysis (HD), low health literacy (LHL) has been associated with greater use of emergency care, more hospitalizations and higher mortality. Little is known about the characteristics of LHL in HD patients outside of the United States.

Methods: A total of 11,476 DOPPS participants completed the Brief Health Literacy Screen (BHLS) [0-12]. Descriptive statistics were performed overall and by country. Participant characteristics were examined between three health literacy categories using mixed, GEE, and multinomial logistic models. Cox models were applied to examine associations of LHL with mortality adjusting for the above variables and also potential effects of study phase, country, and facility clustering.

Results: LHL prevalence varied across countries (Figure). LHL was more likely in patients who were older, female, unemployed and in those who had fewer years on HD, lower education, and lower income (all P for trend<0.001). LHL was significantly associated with mortality when examined as a continuous score (HR=1.05; 95%CI=1.03-1.08 for each point decreased) or as a category (HR=1.65; 95%CI=1.28-2.12 Low vs. High), and no interaction with country was observed.

Figure. Distribution of Health Literacy by Country



*Total of 11,476 patients (6,143 from DOPPS 4 2009-2012 and 5,333 from DOPPS 5 2012-2015).

Conclusions: LHL is common worldwide among HD patients. Variability in LHL prevalence across countries may be in part explained by cultural differences as well as health care systems. Vulnerable patients are at highest risk of LHL, and LHL is an independent predictor of mortality. Further examining by country the role of health system practices may help to overcome LHL-related barriers to patient engagement and improve outcomes in hemodialysis.

Evaluation of a Vancomycin Weight-Based Dosing Protocol in Patients Undergoing High-Flux Hemodialysis Katherine Desforges, Marieme N'Diaye, Robert Zoel Bell, Jean-Philippe Lafrance, Vincent Pichette, Michel Vallee. *Nephrology, Hopital Maisonneuve-Rosemont, Montreal, QC, Canada.*

Background: Hemodialysis patients are frequently subject to Gram-positive infections including Staphylococcus aureus and Methicillin-resistant Staphylococcus aureus (MRSA).Vancomycin is an antibiotic of choice in this population to treat these infections.The objective of this project was to validate the performance of a pre formatted individual prescription protocol of vancomycin in its capacity to reach target vancomycin serum concentrations of 10 to 30 mg/L for Gram-positive infections and 15 to 20 mg/L for MRSA infections.

Methods: The records of 84 patients diagnosed with end-stage renal disease undergoing a 4-hour, three times weekly high-flux hemodialysis treatment were analyzed retrospectively. All patients received vancomycin according to a weight-based dosing protocol between 2011 and 2014.Patients < 70 kg received a 1000 mg loading dose followed by a 500 mg maintenance dose at each dialysis session.Patients between 70 and 100 kg received a 1500 mg loading dose followed by a 750 mg maintenance dose.Patients > 100 kg received a 1500 mg loading dose followed by a 1000 mg maintenance dose.

Results: We collected and analyzed 189 dosages of 84 patients.For all assays, 95.2% achieved levels between 10 and 30 mg/L and 50.3% achieved levels between 15 and 20 mg/L.Stratified by weight categories, for the 10 to 30 mg/L target, 93.3% of patients < 70 kg, 100 % of patients between 70 and 100 kg and 89.5% of patients > 100 kg achieved the target serum concentrations.For the 15 to 20 mg/L target, 49.3% of patients < 70 kg achieved the target serum concentrations (mainly below), 61.3% of patients between 70 and 100 kg achieved the target serum concentrations and 31.6% of patients > 100 kg achieved the target serum concentrations (mainly higher, but below 30 mg/L).

Conclusions: The vancomycin weight-based dosing protocol achieved target serum concentrations of 10 to 30 mg/L in 95.2% of patients.However, because half the dosages of patients < 70 kg were below the target of 15 to 20 mg/L, vancomycin bolus and maintenance doses should be adjusted upward in this subgroup.No dose change is suggested in the other subgroups.

Trends in Incident ESRD Counts Initiating Dialysis in Freestanding Facilities Have Regional Variation David T. Gilbertson,[1] Peer Kidney Care Initiative Investigators.[2] *[1]CDRG, MMRF, Minneapolis, MN; [2]Peer Kidney Care Initiative.*

Background: Overall rates of incident end-stage renal disease (ESRD) patients initiating dialysis in freestanding units have stabilized, and the growth in counts of incident ESRD patients begun to slow by the beginning of this decade. We assessed trends in incident ESRD counts from 2004–2011, overall and geographically by the 9 US Census Divisions.

Methods: Data were ascertained from the Centers for Medicare & Medicaid Services ESRD database. For annual incident cohorts, we identified patients with their first outpatient dialysis within 3 months of initiating chronic dialysis in a freestanding facility.

Results: Yearly counts increased through 2010, with an average annual percent increase of 2.7% from 2004 to 2011. Between 2009 and 2011, this average percent increase was relatively unchanged (-0.1%). However, there were regional differences, with the New England Census Division experiencing the largest proportionate decrease in incident patients between 2009 and 2011, while the contiguous Middle Atlantic division averaged the highest increase during the same period by 2011.

Conclusions: Overall trends in dialysis incidence reveal substantial geographic variation that has not been explained, suggesting that an assessment based on overall U.S. counts may mask important regional differences. Whether these trends will continue in the face of increasing diabetes rates, an aging population and shifts in social demographic changes is uncertain and will require more detailed analysis.

TH-PO960

Association of Intradialytic Hypoxemia with Hospitalization and Mortality: Results from a Large U.S. Hemodialysis Cohort Anna Meyring-Wosten,[1] Hanjie Zhang,[1] Xiaoling Ye,[1] Doris H. Fuertinger,[1] Franz Kappel,[2] Mikhail Artemyev,[1] Nancy Ginsberg,[1] Yuedong Wang,[3] Stephan Thijssen,[1] Peter Kotanko.[1,4] *[1]Renal Research Inst, New York, NY; [2]Univ of Graz, Austria; [3]Univ of California - Santa Barbara, CA; [4]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: While intradialytic hypoxemia is recognized since the early days of hemodialysis (HD), its associations with hard clinical outcomes have not yet been assessed.

Methods: We analyzed arterial oxygen saturation (SaO_2) data obtained by Crit-Line™ monitor (CLM) in chronic HD patients treated between 1/2012 and 1/2015. An individual 6-month baseline with at least 10 CLM measurements preceded a 12-month follow-up. Prolonged intradialytic hypoxemia (PIH) was defined as SaO2 ≤ 90% for more than 1/3 of treatment time. Patients were stratified based on the presence or absence of PIH. We conducted Cox proportional hazards analysis with adjustment for age, gender, race, vintage, chronic obstructive pulmonary disease (COPD), congestive heart failure (CHF), diabetes, albumin, hemoglobin, erythropoietin (EPO) dose, neutrophil-to-lymphocyte ratio, interdialytic weight gain, post-HD systolic blood pressure, and ultrafiltration rate.

Results: We studied 983 patients (59% males; 53% whites) with 30.5±12.5 baseline SaO_2 measurements. 100 patients (10.2%) had PIH. PIH patients showed a higher prevalence of CHF and COPD required significantly more EPO, and resembled an inflammatory phenotype. During the follow-up, 2.21 and 1.55 hospitalizations per patient-year were recorded in patients with and without PIH, respectively (P=0.009). Eighty-nine patients died during follow-up. The mortality rate was 24.1 per 100 patient years in the PIH group and 10.2 in the non-PIH group (P=0.0008). Cox proportional hazards analysis corroborated the increased probability of death in PIH patients (hazard ratio 1.98 [95% CI: 1.14 to 3.43]).

Conclusions: Prolonged intradialytic hypoxemia (PIH) is associated with increased risk for hospitalization and mortality. A better understanding of the pathophysiology of PIH, its clinical consequences and its medical management requires future basic and clinical research.

Funding: Pharmaceutical Company Support - Renal Research Institute

TH-PO961

A New Polymethyl Methacrylate Membrane (PMMA) Improves the Membrane Adhesion of Blood Components and Clinical Efficacy Ikuto Masakane. *Yabuki Hospital, Nephrology, Yamagata, Japan.*

Background: Polymethyl methacrylate (PMMA) is a unique dialysis membrane which has protein adsorption property and it has been reported to effective to reduce the pruritus and maintain nutritional status on chronic dialysis patients. The newly launched PMMA membrane (NF) has been modified in order to improve hemo-compatibility as well as maintaining the protein adsorptive capacity. The aim of the current study is to evaluate the solute removal performance, peripheral circulation during dialysis session and clinical efficacy on patient's subjective symptoms in the comparison with conventional PMMA (BG).

Methods: The six subjects were treated with NF and BG for 3 months each in a crossover design. We evaluated the solute removal properties by the clearance of urea, beta-2 microglobulin (B2MG) , removed amount of alpha-1 microglobulin (A1MG) and albumin loss in spent dialysate. The hemo-compatibility was evaluated by changes in platelet count. The peripheral circulation was estimated by the Skin Perfusion Pressure (SPP) by PAD-3000® (Kaneka Medix, Osaka, Japan) Dialysis-related complaints, including itching, distraction, malaise, headache, hypotension, fatigue after dialysis, and appetite, were compared.

Results: The total amount of removal in each urea, B2MG, A1MG and albumin leakage was not different in both NF and BG. During dialysis, the percent changes in platelet count were (for NF and BG, respectively) 97.1% and 86.1% after 15 min of dialysis, 96.5% and 85.1% after 30 min, 97.3% and 88.3% after 1 h, and 99.6% and 90.1% after 4 h. The changes in platelet count during dialysis were significantly smaller with the NF than with the BG. The SPP was well maintained in NF but time-dependently deteriorated in BG. There were no significant differences in any subjective symptoms, but the mean score of the seven items tended to be lower in NF.

Conclusions: The new PMMA (NF) membrane may improve the QOL of chronic dialysis patients by stabilizing the platelet and peripheral circulation.

TH-PO962

Outcomes of Infants Receiving Chronic Peritoneal Dialysis Keia Sanderson,[1] Hongying Dai,[2] Laurel K. Willig,[1] Bradley Warady.[1] *[1]Nephrology, Children's Mercy Hospital, Kansas City, MO; [2]Research Development and Clinical Investigation, Children's Mercy Hospital, Kansas City, MO.*

Background: Outcome data for infants receiving chronic peritoneal dialysis (CPD) is limited and has been reported primarily by small voluntary registries. The impact of treatment era has also been poorly studied.

Methods: The USRDS database was reviewed for demographic features and outcomes of patients who initiated CPD at £12 months of age from 1990-2014.

Results: A total of 1,730 infants (575 £1 month and 1155 >1-12months) who initiated CPD at £12 months from 1990-2014 were identified. Overall, 68% of the infants were male and the most common primary diagnoses were obstructive uropathy (31.8%) and congenital renal dysplasia/hypoplasia (29.9%). Mean age at initiation of CPD was 0.4 months (+/- 0.3 months) in infants £1 month and 5.2 months (+/-3.1 months) in infants >1-12months. Overall, 1066 infants received at least one kidney transplant during the follow up (333 infants £1 month and 733 infants >1-12months. Mean age at first kidney transplant was 2.9 years (+/-1.6yrs) in infants £1 month and 2.5 years (+/-2.15yrs) in infants >1-12months . Crude all cause mortality rates were higher among infants who initiated CPD at £1 month (276 per 1000 persons at 3 years) versus infants who initiated CPD at >1-12 months of age (185 per 1000 persons at 3 years). Mortality rates at 5 years were 28.7% for infants initiated on CPD at £1 month and 20.7% for infants at >1-12 months of age. Multivariable Cox proportional hazards modeling of factors associated with mortality demonstrated a statistically significant adjusted HR of 4.027 (95% CI 3.274-4.952) for initiation era (1990-2000 vs 2001-2014) and an HR of 1.42 (95% CI 1.15-1.744) for age at initiation of dialysis (£1 month vs >1-12months). Patient sex, race, and primary ESRD diagnosis were not significantly associated with mortality in this model.

Conclusions: In the largest cohort of infants on CPD reviewed to date, the probability of mortality among infants initiating CPD in the first year of life appears to be greaterduring the prior initiation era (1990-2000) and greater among infants who initiated dialysis at £1 month of age.

TH-PO963

ESRD from Scleroderma in the United States 1995-2010 Donal J. Sexton, Scott Reule, Robert N. Foley. *Medicine, Univ of Minnesota, Minneapolis, MN.*

Background: Though the management of scleroderma continues to evolve it is unknown whether the burden of ESRD from scleroderma has changed.

Methods: We examined United States Renal Data System data (N = N = 1,557,117) for the years 1995-2010 to calculate incidence rates and outcomes of ESRD due to scleroderma treated with renal replacement therapy (RRT, N=2342).

Results: ESRD rates due to scleroderma in 1995-1996 were 0.6 per million per year in the overall population, with higher rates in age 40-64 (0.9) and ≥ 65 (1.4) years, females (0.8) and African Americans race (0.9). Standardized incidence ratios declined between 1995-1996 and 2009-2010 in the overall population (ratio 0.55), in those aged 40-64 yrs (0.49), 65+ yrs (0.62), in male (0.56) and female sex (0.55), in white (0.6) and AA race (0.37). Characteristics of ESRD from scleroderma included age 40-64 (57.9% Vs. 41.3% yrs.), female sex (76.6% Vs. 45.1%) and white race (78.1% Vs. 65.2%). 74.3 % of patients with scleroderma died over a mean observation period of 3.3 years, while 16.9% were

listed for renal transplant and 10.1% received a renal transplant. With matching for age, sex and race, overall mortality rates were higher in scleroderma cases than controls (22.3 Vs. 15.5 per 100 person-years, P < 0.001). Overall rates of listing for renal transplant (8.4 Vs. 8.5 per 100 person-years, P = 0.92) and rates of transplantation (4.1 Vs. 4.3 per 100 person-years, P = 0.66) were similar in scleroderma cases and controls.

Conclusions: The incidence of ESRD from scleroderma appears to have declined in the United States since 1995. Mortality rates on RRT are higher in scleroderma cases than controls taken from ESRD from other causes. However, listing for and receiving a renal transplant were as likely in scleroderma patients as matched controls.

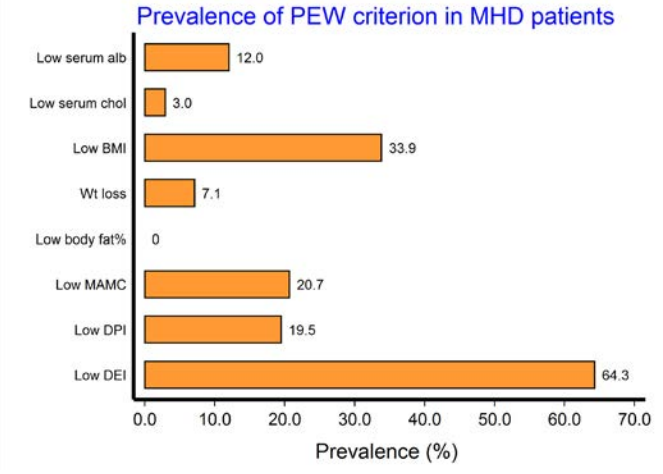
TH-PO964

Prevalence and Mortality Associations of Protein- Energy Wasting Syndrome Criteria in Maintenance Hemodialysis Patients Srini Beddhu,[1,2] G. Wei,[1] Xiaorui Chen,[1] Kalani L. Raphael,[1,2] Robert E. Boucher,[1] Dominique Ferranti,[1] Tom Greene,[1] Michel Chonchol.[3] *[1]U of Utah; [2]VA SLC; [3]UC Denver.*

Background: As the prevalence and mortality associations of protein-energy wasting (PEW) syndrome criteria in the MHD population are not well established, we examined these in 1480 MHD pts in the HEMO Study, a multi-center RCT to examine the effects of dialysis dose and dialyzer flux on mortality.

Methods: The prevalence of International Society of Renal Nutrition and Metabolism panel PEW criterion (listed in the table) at the 12 m follow-up visit were examined. Subsequent mortality associations were examined in Cox models adjusted for demographics, duration of ESRD, Kt/V and flux groups, smoking and alcohol use.

Results: There were 632 deaths / 3390 yrs of follow-up. The prevalence of PEW criterion varied widely: 0% for low body fat% to 64% for low DEI (figure).



Low serum albumin and cholesterol, low BMI, weight loss and low mid-arm muscle circumference (MAMC) were strongly associated with higher risk of mortality (Table 1). However, dietary criteria were not associated with mortality.

PEW Criterion*	All cause mortality HR* (95% CI)
Serum Alb < 3.5 (g/dl)	2.12 (1.68, 2.69)
Serum Chol < 100 (mg/dl)	3.68 (2.46, 5.50)
BMI < 23 (kg/m^2)	1.51 (1.23, 1.86)
Wt loss >10%	1.95 (1.47, 2.58)
Muscle mass category	
Low MAMC[#]	2.00 (1.60, 2.50)
Dietary protein intake (DPI) < 0.60 (g/kg/day)	1.00 (0.80, 1.24)
Dietary energy intake (DEI) < 25 (kcal/kg/day)	0.87 (0.72, 1.05)

*as none had body fat% < 10%, this variable could not be examined, [#]10% or more lower than the 50th percentile of reference population

Conclusions: As there is a wide variability in the prevalence of PEW criteria, the thresholds used in their definition need to be further refined. Dietary variables were not associated with mortality and the validity of these variables as PEW criteria also needs further study.

Funding: NIDDK Support

Primary Care Physician Involvement in the Care of Chronic Dialysis Patients in the U.S. Vahakn B. Shahinian, Deanna Chyn, Yi Li, John Z. Ayanian, Richard Hirth, William H. Herman, Rajiv Saran. *Univ of Michigan.*

Background: Current health reform efforts aimed at improving quality and value center around delivery of good primary care. However, national patterns of primary care physician (PCP) involvement along with a nephrologist in the care of chronic dialysis patients are unknown.

Methods: Patients on chronic dialysis during 2010-11 with Medicare as the primary insurer were identified using US Renal Data System (USRDS) data. PCP involvement was defined based on a claim for an outpatient (non-dialysis) visit with a physician specializing in family practice, general internal medicine or geriatrics. Patients were characterized with respect to two aspects of preventive care: influenza vaccination and diabetes care.

Results: The sample included 179,645 patients, 81,272 of whom were diabetic. In 2010, 59% of patients had evidence of PCP involvement based on ³1 outpatient visit. Patients with PCP involvement were older and more likely to be female, white and with diabetes as cause of ESRD (Table). Rates of vaccination and diabetes care were higher in those with PCP involvement, even after adjustment (ORs: 1.48 [1.45-1.51] for vaccination and 1.53 [1.48-1.58] for a composite of diabetes care).

Patient Characteristics or Delivered Care	PCP Involvement (1+ Visit in 2010)	
	No (n=73,597)	Yes (n=106,048)
Mean age at ESRD (SD)	52.1 (17.0)	57.8 (16.0)
Sex		
Female	40.2	48.7
Male	59.8	51.3
Race		
White	48.6	55.3
Black	45.4	38.3
Other	6.0	6.4
Primary Disease Causing ESRD		
Diabetes	35.8	45.7
Hypertension	31.0	27.7
Glomerulonephritis	15.7	12.0
Influenza Vaccination	59.2	68.4
Diabetes-related care (among diabetic patients)	No (N=29,524)	Yes (N=51,748)
1+ HbA1C test	75.9%	83.5%
1+ Lipid test	65.5%	74.3%
1+ Diabetic eye exam	36.3%	46.3%
All 3 tests	24.1%	33.6%

By a more restrictive definition of ³2 visits in 2010, 47% had PCP involvement; under a looser definition of ³1 visit over 2 years (2010-11), vs 70% had PCP involvement.

Conclusions: Even under the loosest definition of PCP involvement, over one quarter of dialysis patients have no evidence of PCP involvement. Patients with PCP involvement have higher rates of preventive care, but further study should examine the impact on outcomes and costs.

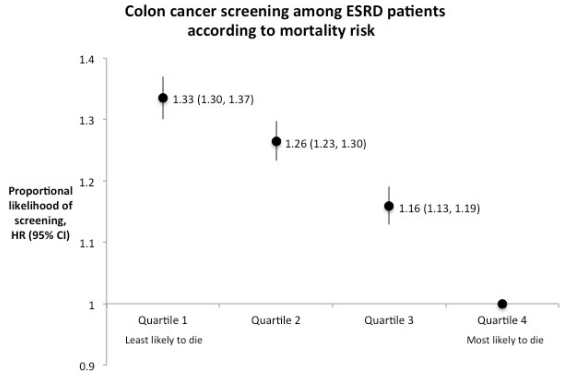
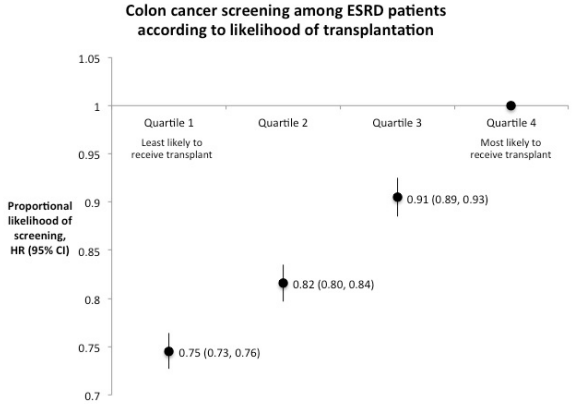
Are We Choosing Wisely? A Study of Colon Cancer Screening Practices Among Dialysis Patients in the United States Christopher A. Carlos,[1] Chi-yuan Hsu,[1] Meda E. Pavkov,[3] Nilka Rios Burrows,[3] Vahakn B. Shahinian,[2] Rajiv Saran,[2] Neil R. Powe,[1] Kirsten L. Johansen.[1] *[1]Univ of California, San Francisco, San Francisco, CA; [2]Univ of Michigan, Ann Arbor, MI; [3]Centers for Disease Control and Prevention, Atlanta, GA.*

Background: Because estimated net gains in life expectancy are very small, the American Society of Nephrology recommended against routine cancer screening in asymptomatic dialysis patients. We aimed to determine how often colon cancer screening is performed in the U.S. and whether colon cancer screening is targeted toward healthier dialysis patients. **Methods:** We performed a retrospective cohort study of patients aged ≥50 years on dialysis between January 1, 2007 and September 30, 2012 using data from the United States Renal Data System (USRDS). Using multivariable Cox regression models, patients were divided into quartiles based on the risk of death and the likelihood of receiving a kidney transplant and, according to these quartiles of risk, we then assessed the likelihood of colon cancer screening (CCS) by fecal occult blood testing, sigmoidoscopy or colonoscopy from Medicare claims data.

Results: Of 391,616 patients, 13% received CCS over a median follow-up of 1.5 years (interquartile range 0.7-2.9). Screening was most common in patients with the lowest mortality risk (16%), compared with 9% of those with the highest mortality risk (HR 1.33;

95% CI 1.30-1.37). Overall, 41% of CCS occurred in those whose risk of death was above the median. Patients least likely to receive a transplant were less often screened (10%) than those most likely to receive a transplant (HR 0.75; 95% CI 0.73-0.76).





Conclusions: Our findings suggest that screening was appropriately targeted to dialysis patients with longer life expectancies and away from those with the lowest chances of receiving kidney transplantation.

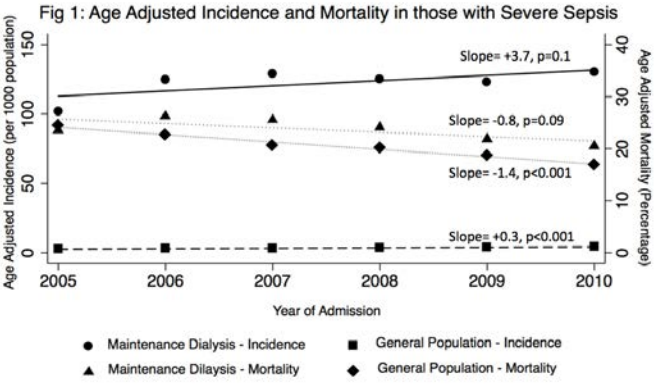
Severe Sepsis Hospitalizations in Those on Maintenance Dialysis – National Trends and Outcomes Ankit Sakhuja,[1] Kianoush Banaei-Kashani,[2] Hatem Amer,[2] Robert C. Albright.[2] *[1]Nephrology, Univ of Michigan; [2]Nephrology and Hypertension, Mayo Clinic.*

Background: Severe sepsis (SS) is a life-threatening condition requiring early diagnosis and management. Incidence of SS is increasing in general population (GP) and mortality is declining; however, epidemiology and outcomes of SS have not been well studied in those on maintenance dialysis (MD). We designed this study to look at incidence and outcomes of SS in those on MD.

Methods: Using Nationwide Inpatient Sample database we included all hospitalizations (age ³20 yr) with SS based on ICD-9-CM codes of severe sepsis, septic shock or blood stream infection with organ dysfunction from 2005 to 2010. Those on MD were identified based on ICD-9-CM codes. Age adjusted incidence of SS and mortality in subgroups was calculated by direct standardization to 2000 standard US population. Linear regression was used to assess trends over time and logistic regression to assess independent effect of MD on mortality.

Results: Of estimated 5,000,152 (95% CI: 4,798,520-5,201,784) hospitalizations with SS, 6.4% were on MD. Unadjusted incidence of SS was 145.4/1000 in MD compared to 3.5/1000 in GP with incidence rate ratio 40.9 (95% CI: 40.8-40.9). Age adjusted incidence of SS seems to be increasing in both subgroups though trend was not significant in MD (Fig 1).



Unadjusted in-hospital mortality is higher in MD (30.3% vs 26.2%; p<0.001). Age-adjusted mortality is decreasing in both subgroups though trend was not significant in MD. Age-adjusted mortality continues to be higher in MD (Fig 1). MD is an independent risk factor for mortality with OR 1.26 (95% CI: 1.23-1.29).

Conclusions: Hospitalizations with SS are over 40 times more common in MD. Mortality is higher in MD and being on MD is an independent predictor of mortality in those admitted with SS. Though incidence of SS seems to be increasing, there is a trend towards decrease in mortality even in MD.

TH-PO968

Trends in Colorectal Cancer Screening in U.S. End-Stage Renal Disease Population Kevin C. Abbott,[1] Chyng-Wen Fwu,[2] Paul L. Kimmel,[1] Paul W. Eggers.[1] *[1]Div of Kidney, Urologic Hematologic Diseases, NIDDK, NIH, Bethesda, MD; [2]Social & Scientific Systems, Inc., Silver Spring, MD.*

Background: Screening for colorectal cancer (CRC) has been recommended for those over 50 years old. Medicare coverage of CRC screening began in 2000. Dialysis patient care is shared by many practitioners, perhaps leading to therapeutic nihilism and insufficient screening. CDC data show almost 2/3 of patients at risk report CRC screening. We determined rates of CRC screening in ESRD hemodialysis (HD) patients, compared to a 5% Medicare sample, and to assess secular trends.

Methods: We used data from the 2001-2011 USRDS to describe trends in percentages of HD patients receiving CRC screening tests per year. We limited our study population to patients with Medicare Part A and B as primary payer to ensure complete Medicare claims data for CRC screening. Current Procedural Terminology /Healthcare Common Procedure Coding System (CPT/HCPCS) codes identified Medicare physician and supplier billing data for screening: colonoscopy (G0105 and G0121), sigmoidoscopy (G0104), and fecal-occult blood test (FOBT; G0107, G0328, and 82270). We compared HD data to a 5% Medicare sample.

Results: Overall, the proportion of HD patients having CRC screening decreased from 6.1% annually in 2001 to 3.5% in 2011 due to decreased use of FOBT. There was a persistent increase in the proportion of patients with colonoscopy or sigmoidoscopy for CRC screening in the 11-year study period, from 0.3% to 1.0% annually. In most years, male, black and age 50-75 patients were more likely to receive colonoscopy or sigmoidoscopy than female, white, and other age subgroups. In 2006, the most recent available comparable year, CRC screening in HD patients was less than that of the general Medicare population; 0.8% vs. 1.6% annually for colonoscopy and sigmoidoscopy, 6.0% vs. 8.1% including FOBT.

Conclusions: Screening for CRC in ESRD HD patients is less frequent than in the general Medicare population, and considerably less than CDC recommendations. Differences in ascertainment methods (CDC uses self-report) may account for most of the disparity from CDC estimates.

Increasing Prevalence of Withdrawal from Dialysis: Trends from 2004-2011 James B. Wetmore,[1] Peer Kidney Care Initiative Investigators.[2] *[1]CDRG, MMRF; [2]Peer Kidney Care Initiative.*

Background: Voluntary withdrawal from dialysis, which frequently occurs when a patient perceives dialysis as having become unduly burdensome, is an area of increasing interest. How early withdrawal, defined as that occurring within 1 year of dialysis initiation, has changed over the past decade has not been fully explored.

Methods: Patients initiating dialysis between 2004 and 2011 were selected from the Centers for Medicare & Medicaid Services End-Stage Renal Disease (ESRD) database. Information on withdrawal was ascertained from the ESRD Death Notification Form by the presence of code 104 ("withdrawal") in the 1st or 2nd position. The unadjusted cause-specific monthly mortality rate (deaths per 100 pt-years) was calculated for patients initiating in each year.

Results: Annual incident counts ranged from 87,174 (2004) to 100,665 (2011). Overall, during the first year of dialysis, the withdrawal rate was highest soon after initiation, peaking at month 2 for all years except 2004. Rates then decreased until approx. month 9, stabilizing through month 12. Additionally, early rates more than tripled over the study period, from 1.9 per 100 pt-years at month 2 in 2004 to 5.9 in 2008 to 6.4 in 2011.

Conclusions: Withdrawal rates are high in the weeks immediately after dialysis initiation, a pattern more marked in recent years. Because patients who withdraw soon after initiation may be suboptimal dialysis candidates, future work should focus on determining whether a tailored approach, designed to identify individual patient goals and present the risks and benefits of dialysis and viable alternatives such as conservative care, might provide optimal patient-centric care.

The Dialysis Sodium Gradient – A Modifiable Risk Factor for Fluid Overload Emilie Trinh, Catherine L. Weber. *Nephrology, McGill Univ Health Centre, Montreal, QC, Canada.*

Background: Fluid overload in patients on conventional hemodialysis is a frequent complication associated with increased hospitalizations, cardiovascular morbidity and all-cause mortality. There are multiple patient and physician-related factors that lead to fluid overload. Individualizing dialysate sodium prescription and minimizing the sodium gap are potential modifiable risk factors.

Methods: We performed a cross-sectional study on 111 prevalent stable conventional hemodialysis patients at the McGill University Health Center. The associations of sodium gradient with various hemodialysis parameters of fluid status including interdialytic weight gain percentage (IDWG%), ultrafiltration (UF) rate, blood pressure (BP), intradialytic hypotension and intradialytic hypertension were analyzed.

Results: The mean serum sodium gradient was 4.6 ± 3.6 mEq/L. with a mean pre-dialysis sodium of 137.4 ± 2.5 mEq/L and a mean dialysate sodium of 142.0 ± 3.0 mEq/L. There was a direct correlation between sodium gradient and interdialytic weight gain percentage ($r=0.49$, $p<0.01$) as well as ultrafiltration rate ($r=0.44$, $p<0.01$). The average sodium gradient was significantly higher in patients with IDWG > 3% (6.36 vs. 3.16 mEq/L, $p<0.01$) and in patients with UF rate > 10ml/kg/h (6.01 vs. 4.23 mEq/L, $p=0.03$). In a univariate logistic regression model, a higher sodium gradient was associated with increased risk of IDWG% > 3% (OR 1.34, $p<0.01$) and increased risk of UF rate >10 ml/kg/h (OR 1.16, $p=0.03$), but there was no associations with intradialytic hypotension (OR 1.01, $p=0.87$) or intradialytic hypertension (OR 1.07, $p=0.21$). Also, no significant associations were found between sodium gradient and blood pressure (pre-dialysis or post-dialysis) or number of antihypertensive medications.

Conclusions: A higher sodium gradient was associated with significant increases in IDWG and UF rate which are associated with poor outcomes. Sodium gradient was not associated with intradialytic hypotensive episodes. With the parameters we measured in this study, it appears that individualizing dialysate sodium prescription to minimize sodium gap leads to less fluid overload in conventional hemodialysis patients.

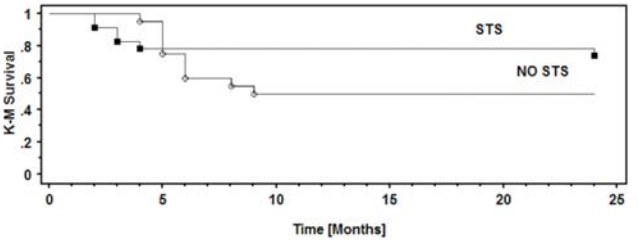
TH-PO971

Calcific Uremic Arteriolopathy: Mortality Outcomes with and without Sodium Thiosulfate Therapy Chamberlain I. Obialo, Alexander Quarshie. *Dept of Medicine, Morehouse School of Medicine, Atlanta, GA; Clinical Research Center, Morehouse School of Medicine, Atlanta, GA, Venezuela.*

Background: Calcific uremic Arteriolopathy (CUA) or Calciphylaxis is commonly seen in patients with end stage kidney disease (ESKD) and carries a high mortality risk. There is no definite therapy for this condition but promising results have been reported in patients treated with intravenous sodium thiosulfate (STS). However, the mortality advantage of therapy with STS over therapy without STS remains unknown.

Methods: We retrospectively reviewed our ESKD patient's records over a 10-year period and identified 45 biopsy confirmed cases of CUA. Associations between patients who received STS therapy and those who did not and various categorical end points were assessed using the Pearson chi-squared tests while differences in continuous end points were examined using Mann-Whitney- U tests. Survival analysis utilized Kaplan-Meier plots. All statistical tests were two-sided, and level of significance set at 0.05.

Results: The mean age of the 45 cases was 63, 60% female, mean body mass index was 34 and mean dialysis vintage was 4 years. Of the 45 cases, 23 (51%) received STS while 22 (49%) did not. The mean level of serum albumin, phosphorus and parathyroid hormone was 2.8 g/dl, 6.7 mg/dl and 989 pg/dl respectively. One –year mortality was 22% in STS vs. 50% in no STS cases, $p = 0.05$. The overall survival of the patients over the 2- year study period was significantly superior in the recipients of STS than in those who did not receive STS, $p = 0.03$.



Patients who did not receive STS were also more likely to have major surgeries than those who received STS, 86% vs. 52%, $p = 0.01$.

Conclusions: Sodium thiosulfate therapy appears to confer both short term and long term survival advantage over no STS. We encourage hospitals and dialysis companies to procure and make this agent more available to physicians.

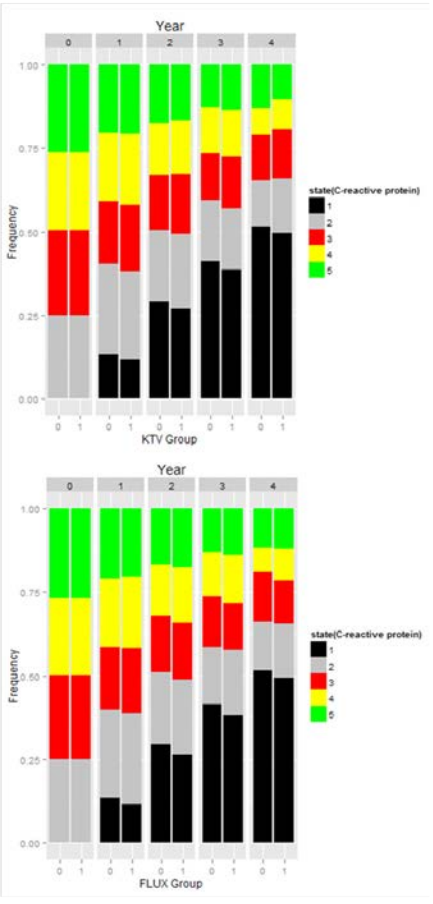
Effect of High-Dose and High-Flux Hemodialysis on Markers of Inflammation in the HEMO Study Kristen L. Nowak,[1] Tom Greene,[2] Jian Ying,[2] Alfred K. Cheung,[2] Michel Chonchol.[1] [1]*Univ of Colorado Denver;* [2]*Univ of Utah.*

Background: Hemodialysis treatment induces markers of inflammation, which could affect clinical outcomes. This study sought to determine whether high-dialysis dose and high-flux dialysis would improve markers of inflammation compared with standard dialysis dose and low flux dialysis.

Methods: The HEMO Study was a randomized multicenter study of the effects of high-dose versus standard-dose and high-flux versus low-flux hemodialysis. Serum high sensitivity C-reactive protein (hs-CRP, pre-specified primary outcome for this set of analyses) and interleukin-6 (IL-6) were measured in stored serum samples in 1,846 HEMO participants. For each inflammatory marker we used a joint multi-state modeling approach to estimate the proportion of patients in 5 ordered states (S) over 3 annual assessments while accounting for mortality: S1=deceased (score=0); S2=alive in highest quartile (score=1); S3=alive in 3rd quartile (score =2); S4=alive in 2nd quartile (score=3); and S5=alive in lowest quartile (score=4). The average rank was computed over 3 yrs of follow-up and compared between the randomized groups.

Results: Randomized patients had high rates of coexisting conditions: 45% had diabetes, and 80% had a history of cardiac disease. Characteristics of the patients in the two dose groups were similar, as were the characteristics of those in the two flux groups. The state distribution of hs-CRP in each year by dose (KTV) group and by flux group for hs-CRP are shown in Figure 1.



hsCRP did not differ significantly between dose (p=0.83) or flux groups (p=0.53). Similar results were obtained for IL-6.

Conclusions: Over 3 years, neither high-dose nor high-flux dialysis exhibited a beneficial effect on markers of inflammation.

TH-PO973

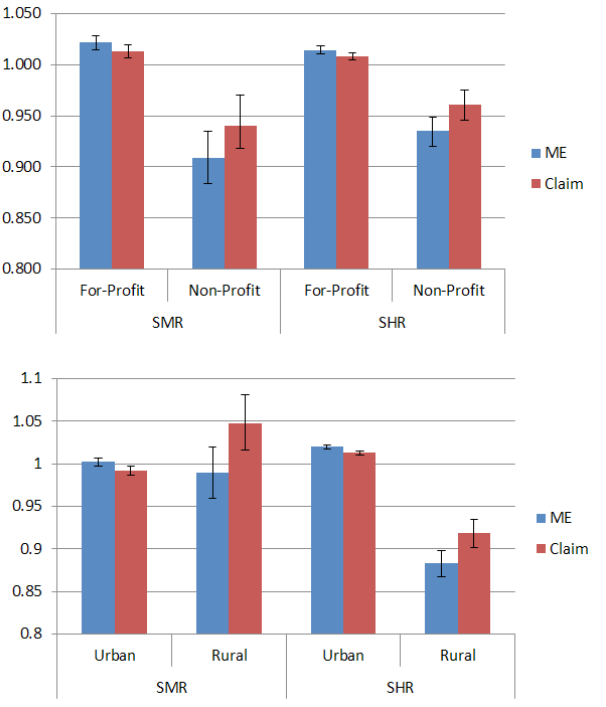
Comorbidity Data Source May Impact SMR/SHR Calculation

Jiannong Liu,[1] Mahesh Krishnan,[2] Jincheng Zhou,[1] Kimberly M. Nieman,[1] Yi Peng,[1] David T. Gilbertson.[1] *[1]CDRG, MMRF, Mpls, MN; [2]DaVita Healthcare Partners, Denver, CO.*

Background: Standardized mortality and hospitalization ratios (SMRs and SHRs) are used to measure dialysis facility performance, with adjustment for demographics and comorbidities derived from the end-stage renal disease (ESRD) Medical Evidence (ME) Report. Sensitivities are low for ME-based comorbidities. We investigated the effect on SMR and SHR calculations by comparing ratios adjusted for claims-based comorbidities.

Methods: Using the USRDS ESRD database, we included US hemodialysis patients who initiated dialysis July 1-December 31, 2006-2010, had Medicare as primary payer, were aged ≥ 66 years, and had no prior transplant (TX). Patients were followed from dialysis initiation to the earliest of death, TX, modality change, or 1 year. SMRs and SHRs were calculated for patients in for-profit/non-profit and rural/urban facilities for ME-based and claims-based comorbidity, separately. Cox models were used for expected number of deaths and piecewise Poison models for expected number of hospitalizations. Agreement of comorbidity between the two sources was measured by a kappa statistic.

Results: 73,950 incident hemodialysis patients were included. Kappas for comorbidity agreement were low, less than 0.5, except for diabetes (0.77). Percent of patients with claims-based comorbidity was similar for for-profit and non-profit facilities; ME-based comorbidity was lower for for-profit facilities. Differences between ME-based and claims-based SMR/SHRs were statistically significant. Compared with ME-based SMR/SHR, claims-based ratios decreased 0.9/0.6% for for-profit and 1/0.7% for urban facilities and increased 3.4/2.8% for non-profit and 5.9/4.1% for rural facilities



Conclusions: Comorbidity data source may impact performance evaluation. The impact is larger for smaller groups, and may increase with prevalent patients included.

TH-PO974

Thematic Analysis of the Medical Records of a National Cohort of Patients Who Initiated Maintenance Dialysis: 2000-2009

Susan P.Y. Wong,[1] Elizabeth Vig,[1] Nilka Rios Burrows,[2] Chuan-fen Liu,[1] Desmond Williams,[2] Paul L. Hebert,[1] Ann M. O'Hare.[1] *[1]Univ of Washington; [2]Center for Disease Control.*

Background: Little is known about how decisions to initiate dialysis take shape in clinical practice.

Methods: We performed a qualitative thematic analysis of the medical records of patients who initiated maintenance dialysis to understand factors that impact decisions to initiate maintenance dialysis as they occur in clinical context. We analyzed key care processes, patient-provider interactions and patient and/or provider concerns and considerations relevant to the decision to initiate dialysis as documented in the electronic medical records of a national random sample of patients for whom the decision to initiate maintenance dialysis was made at the Department of Veteran Affairs between 2000 and 2009 (n=1,691).

Results: We identified three dominant, overlapping themes pertaining to the decision to initiate dialysis: 1) dialysis initiation as *process*, which describes the decision to initiate dialysis as integrated with other treatment decisions and unfolding over time rather than an isolated decision occurring at a fixed point in time; 2) sources of *momentum* for dialysis initiation, which describes factors that appeared to hasten the process of dialysis initiation and included hospitalization for acute illness and efforts to optimize patients' clinical status for future medical interventions; and, 3) *push-pull* dynamics between patients and providers, which describes the sometimes adversarial relationship between patients and providers during the process of dialysis initiation in which patients were often portrayed by providers as "resistant" to dialysis initiation while providers appeared paternalistic and safety conscious in their approach towards treatment decisions.

Conclusions: Our analysis of the medical record underscores the complexity of treatment decisions about dialysis initiation in real-world clinical settings and supports a re-conceptualization of dialysis initiation as a *process* that unfolds over time rather than as a discrete treatment decision occurring at a fixed point in time.

TH-PO975

Trends in 30-Day Readmission Rates in Dialysis Patients During an Era of Medicare Payment Policy Changes, 1996-2012

Allan J. Collins,[1] Peer Kidney Care Initiative Investigators.[2] *[1]MMRF; [2]Peer Kidney Care Initiative.*

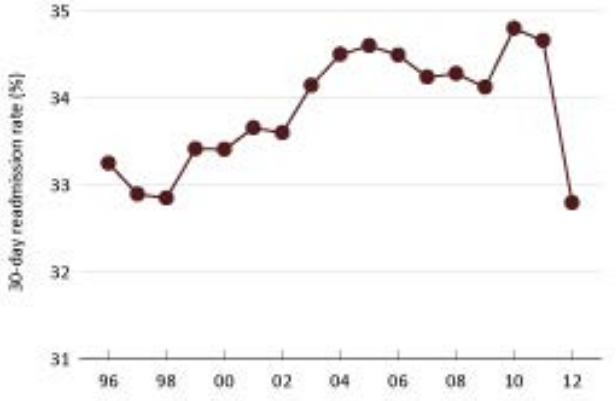
Background: High hospital readmission rates, which may indicate inadequate quality of care and result in unnecessary expenditures, have been a recent focus for Medicare. Medicare has enacted payment-related policy changes: freezing the inpatient payment rate (1997), expanding "disproportionate share" hospital payments (early 2000s), tying

reimbursement for outpatient hemodialysis services to the number of monthly visits (2004), introducing the new Medicare prospective payment system (2011), and instituting the "hospital payment penalty" (2012). Given evidence demonstrating links between these changes and readmission rates in the general population, we sought to examine changes in 30-day readmission rates in dialysis patients 1996–2012.

Methods: Data were obtained from the Centers for Medicare & Medicaid Services End-Stage Renal Disease database. Dialysis patients were assessed for discharges from short-term or critical access hospitals. Thirty-day readmission rates were calculated, without adjustment for differences in patient case-mix or hospital characteristics.

Results: All-cause readmission rates increased modestly over the period studied except for 2012. The nadir was 32.8% in 1998; the rate increased to 34.6% in 2005, fell to 34.1% in 2009, and peaked at 34.8% in 2010. Discharge data in the first 6 months of 2012 showed further decrease (32.8%). In comparison, other studies show that the rate in the general Medicare population was relatively stable 2007-2011 (19.0%), and decreased in 2012 (18.4%).

Conclusions: Thirty-day readmission rates were substantial in dialysis patients compared with general Medicare patients, possibly reflecting case-mix. How public policy changes may have affected potentially avoidable readmissions should be more fully explored. Cause-specific readmission rates might provide a better reflection of quality of care and should be examined.



Funding: Pharmaceutical Company Support - Financial support for Peer is provided by 13 participating dialysis provider organizations: American Renal Associates, Atlantic Dialysis Management Services, Centers for Dialysis Care, DaVita HealthCare Partners, Dialysis Clinic, Inc. TH-PO976

The Impact of Volume Status on Nocturnal Hypoxemia in Patients Undergoing Maintenance Hemodialysis Farhanah Yousaf, Mitesh K. Patel, Sherbeth Marie C. Young, Chaim Charytan, Alla Goldberg, Bruce S. Spinowitz. *New York Hospital Queens, Flushing, NY.*

Background: Hemodialysis patients experience changes in volume status according to hemodialysis schedule. Excess fluid volume may shift to the neck upon assuming a recumbent position during sleep, leading to engorgement of the great veins of neck and peripharyngeal edema. We explored the impact of volume status on nocturnal hypoxemia in the hemodialysis population.

Methods: Following local IRB approval, adult hemodialysis patients who were undergoing regular chronic hemodialysis (HD) for at least 3 months were consented to complete two nights of nocturnal oximetry using Pulsox 300i wristwatch. HD night was defined as the night of HD treatment whereas non-HD night was defined as the night on which no HD was performed. The first hour of recording was deleted in efforts to capture oximetry reading from sleep time only. Motion artifacts and aberrant data were also excluded from the analysis. Oxygen desaturation index (ODI) was defined as the number of desaturations ≥ 3% from baseline lasting ≥ 10 seconds, per hour. Paired t-test was used to compare HD and non-HD night related data.

Results: Twenty HD patients (11 males and 9 females) aged 54 ± 13 years with a mean body mass index of 25.5 ± 4.6 kg/m^2 and neck circumference of 38.4 ± 5.8 cm participated in the study. Mean ODI was 21.2 ± 21.1 on HD night versus 20.0 ± 19.8 on non-HD night (p=0.6) with a mean interdialytic weight gain of 1.9 ± 1.3 Kg. The lowest recorded mean saturation was 76 ± 10 % on HD night versus 73 ± 11 % on non-HD night (p=0.3). Eleven of 20 patients, with a mean interdialytic weight gain of 2.1 ± 1.5 Kg, experienced worsening of ODI on non-HD night (16.9 ± 17.9) versus HD night (11.6 ± 13.8) [p=0.008]. Meanwhile, nine patients, with a mean interdialytic weight gain of 1.5 ± 0.9 Kg, exhibited improvement in ODI on non-HD night (23.8 ± 22.4) versus HD night (32.9 ± 23.1) [p=0.04].

Conclusions: Volume status alone does not explain HD to non-HD variation in nocturnal hypoxemia seen in ESRD population. Both central and obstructive mechanisms are likely involved. Additional research is warranted to further explore this phenomenon and develop preventive strategies.

TH-PO977

Hospital Readmission within 30 Days of Discharge Among Adults Receiving Dialysis Lorien S. Dalrymple,[1] Barbara A. Grimes,[2] Patrick S. Romano,[1] Yi Mu,[1] Danh V. Nguyen,[3] Kirsten L. Johansen.[2,4] *[1]UC Davis; [2]UCSF; [3]UC Irvine; [4]San Francisco VA.*

Background: Hospital readmission is common in adults receiving dialysis. Few studies have examined the timing or causes of 30-day hospital readmission.

Methods: We used the USRDS to examine adults initiating dialysis Jan 2009 trough Dec 2010 who had Medicare as the primary payer. The cohort was followed from day 90 of dialysis for up to one year, with censoring for death, renal recovery or transplant. We classified the principal cause of the index hospitalization and hospital readmission using Clinical Classification Software.

Results: Our cohort consisted of 103,381 patients. During follow-up, 50,639 patients experienced 89,728 index hospital admissions; 5% resulted in in-hospital death. Of the 85,284 live hospital discharges, 25,792 (30%) were associated with 30-day readmission. The median time to readmission was 11 [5, 19] days. Leading causes of readmission by cause of index hospitalization are in Table 1.

Table 1. Causes of 30-Day Readmission

	Causes of Readmission				
Cause of Index Admission	**Leading Cause**	**2nd Leading Cause**	**3rd Leading Cause**	**4th Leading Cause**	**5th Leading Cause**
All-Cause N=89728	Complication of device, implant or graft	Septicemia	CHF	DM	HTN
Complication of device, implant or graft N=14195	Complication of device, implant or graft	Septicemia	DM	CHF	HTN
Septicemia N=6049	Septicemia	Complication of device, implant or graft	DM	Pneumonia	CHF
HTN* N=5380	HTN	Complication of device, implant or graft	CHF	DM	Fluid and electrolyte disorders
CHF† N=5322	CHF	HTN	Complication of device, implant, graft	Fluid and electrolyte disorders	Septicemia
DM†† N=4986	DM	Complication of device, implant or graft	Septicemia	HTN	Complications of surgical procedures or medical care

*HTN: Hypertension with complications and secondary hypertension;†CHF: Congestive heart failure - nonhypertensive; ††DM: Diabetes mellitus with complications

For the 5 most common causes of hospitalization, the principal cause for readmission was in the same category as the initial admission, accounting for 18-32% of readmissions.

Conclusions: Thirty-day hospital readmission in Medicare recipients on dialysis is frequently for a cause related to the initial admission.

Racial/Ethnic and Age Differences in Cause-Specific Deaths Among U.S. Dialysis Patients Alison J. Yu,[1] Keith C. Norris,[2] Alfred K. Cheung,[3] Guofen Yan.[4] *[1]Univ of Southern California; [2]UCLA; [3]Univ of Utah; [4]Univ of Virginia.*

Background: Recent research reported that Hispanics have the lowest all-cause mortality, African Americans (AAs) intermediate, and Whites the highest among U.S. dialysis patients over 30 years old. The objective of this study is to examine whether this risk pattern varied depending on the cause of death.

Methods: The study included 1,255,640 adult incident dialysis patients between 1995 and 2010 in the USRDS, with no prior kidney transplantation. We examined 5 major cause-specific deaths: cardiovascular (CVD), infection, malignancy, others, and unknown. Cause-specific hazards for each cause-specific death were compared among AAs, Hispanics, and Whites for overall and stratified by age groups.

Results: After adjustment for multiple covariates (Table), compared with Whites, in all age groups, Hispanics consistently had lower risks of cause-specific deaths for all major causes examined (HRs<1), while AAs also had lower risks except for the cause of infection, for which AAs had significantly higher risks in age groups of <50 and >80 years (HRs from 1.07-1.94).

Table. Adjusted cause-specific hazard ratios (HRs) for AAs and Hispanics vs. Whites

Age Groups	CVD		Infection		Malignancy		Others		All-cause	
	AA	His-panic	AA	His-panic	AA	His-panic	AA	His-panic	AA	His-panic
18-30	0.99*	0.52	1.94	0.81	0.52	0.60*	1.06*	0.62	1.17	0.60
31-40	0.85	0.61	1.51	0.95*	0.82*	0.65	0.75	0.63	0.97	0.68
41-50	0.74	0.60	1.07	0.79	0.75	0.66	0.59	0.56	0.79	0.63
51-60	0.69	0.63	0.83	0.71	0.86	0.61	0.54	0.56	0.72	0.64
61-70	0.74	0.70	0.84	0.81	0.82	0.62	0.50	0.59	0.73	0.69
71-80	0.78	0.78	0.98*	0.90	0.92	0.70	0.54	0.60	0.78	0.76
>80	0.84	0.84	1.07	1.01*	1.06*	0.89*	0.57	0.65	0.83	0.83

Note: all significant at p<0.05 except the ones indicated by *.

Conclusions: The racial difference observed in all-cause mortality, in which Hispanics have the lowest risk, AAs intermediate, and Whites the highest, was also noted for major cause-specific deaths in most age groups, except for the cause of infection. Both younger and older AAs are at the greatest risk of death due to infection. Further studies are needed to explore the specific reasons responsible for the higher risk of infection-related death in AAs.

Dialysis Therapy and Mortality in Older Heart Failure Patients with Advanced Chronic Kidney Disease: The Kaiser Permanente MATCH Study

David Law, Sijie Zheng, Sharina Belani, Jingrong Yang, Thida Tan, Juan Daniel Ordonez, Susan Kim, Alan S. Go. *Kaiser Permanente Northern California.*

Background: Heart failure (HF) and chronic kidney disease (CKD) often coexist and those with both have much worse outcomes than having either alone, with limited data to guide optimal management. We evaluated the outcome of dialysis therapy in a diverse elderly cohort with HF and advanced CKD.

Methods: In Kaiser Permanente Northern California, a large integrated healthcare system, we identified members ≥70 years with HF and estimated glomerular filtration rate (eGFR) £20 ml/min/1.73 m^2 between 2008-2012 and no prior renal replacement therapy, cancer, cirrhosis or organ transplant. Through 2013, we identified patients who started chronic dialysis and individually matched controls who were alive on the dialysis start date of the matched case along with age, gender, diabetes status, and high-dimensional propensity score to start dialysis. Demographics, clinical features and drug use were obtained from electronic records. We calculated rates of death through 2013 and examined the impact of dialysis on mortality using Cox regression.

Results: We identified 334 eligible HF-CKD cases who initiated dialysis and 899 matched control HF-CKD patients. Mean age was 80.1±4.8 yrs, with 51% women, 33% black and 72% diabetic. Case and control patients were well-matched across characteristics, except for controls being less likely to be Hispanic or have proteinuria, or to receive alpha or calcium channel blockers or thiazide diuretics; and more likely to have prior intracranial bleed, liver disease, dementia and higher blood pressure, hemoglobin and mean eGFR (16.4 vs. 12.0 ml/min/1.73 m^2). Incidence of death was 32 per 100 p-y in combined case and control patients. Among matched patients, after further adjustment for residual differences in patient features, dialysis was independently associated with a 47% lower rate of death (hazard ratio 0.53, 95%CI:0.41-0.67).

Conclusions: In older adults with HF and advanced CKD, dialysis was independently associated with a lower mortality. Randomized trials are needed to determine the net outcomes of dialysis related to both length and quality of life in the elderly with HF and advanced CKD.

Gender, Poverty, and Dialysis Mortality in Adults with Sickle Cell Disease

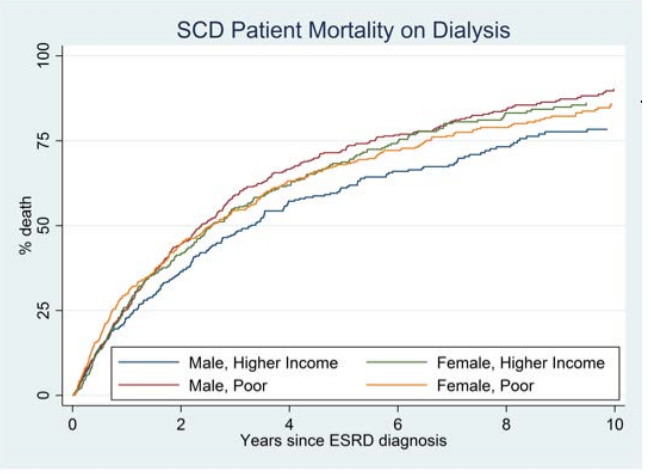
Tanjala S. Purnell, Xun Luo, Carlton Haywood, Sophie Lanzkron, Lauren Marie Kucirka, Sunjae Bae, Morgan Grams, Dorry L. Segev. *Johns Hopkins Univ.*

Background: Chronic dialysis patients with sickle cell disease (SCD) have increased risk of mortality compared with the general US dialysis population. The contributions of gender and neighborhood poverty to dialysis mortality in SCD patients are largely unknown.

Methods: Using USRDS data, we linked all US adults with SCD who initiated dialysis between 1995-2012 with zip-code level US Census neighborhood data. We performed multivariable Cox regression models with adjustment for age, dialysis type, BMI, and diabetes status to compare mortality between men and women, stratified by neighborhood poverty level. Neighborhoods with ³20% of households living below the federal poverty level were defined as poor.

Results: The study cohort included 1,681 SCD patients on dialysis with 52% male, 94.7% black, mean age 42.5, and 55.9% living in poor neighborhoods. 1-, 5-, and 10-year mortality in this population were 26.1%, 67.9%, and 85.5%. Overall, men had similar mortality to women (aHR: 0.96, 95% CI: 0.86-1.07, p=0.45). However, men living in poor neighborhoods had higher risk of death than women (aHR: 1.20, 95% CI: 1.04-1.40, p=0.015). **(Figure 1)** The median survival time from dialysis initiation for poor men with SCD was 2.37 years. In comparison, the median survival time for poor men without SCD was 3.77 years.

Figure 1. Dialysis Mortality in Sickle Cell Disease Patients by Gender and Neighborhood Poverty



Conclusions: Men with SCD who live in poor neighborhoods were at highest risk of death. Efforts to address socioeconomic barriers may be an important target for improving survival in this population.

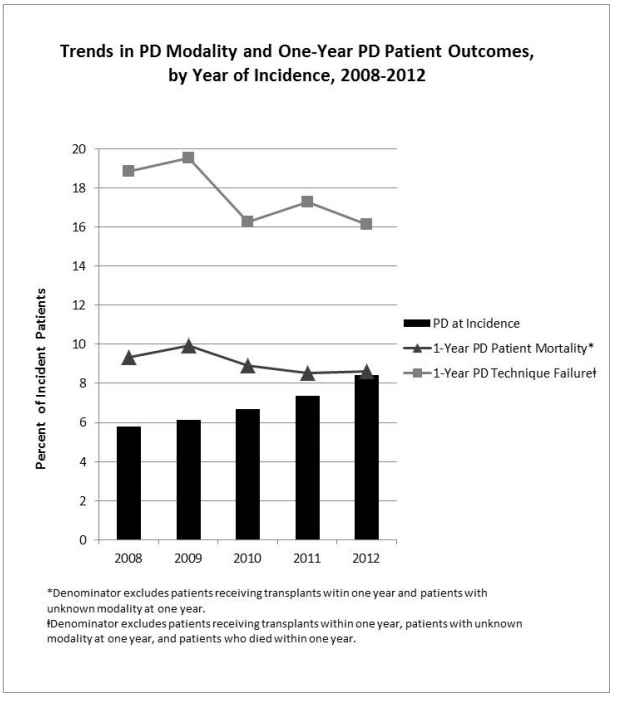
Peritoneal Dialysis (PD) Patient Outcomes Under the Dialysis Prospective Payment System (PPS)

Marc Turenne, Regina M. Baker, Jeffrey Pearson, Chad M. Cogan, Purna Mukhopadhyay, Elizabeth L. Cope. *Arbor Research Collaborative for Health, Ann Arbor, MI.*

Background: The use of PD was expected to be incentivized by the expanded Medicare PPS that was implemented in 2011. There is early evidence under the PPS of additional incident ESRD patients and dialysis facilities using PD (Hirth et al 2013; Turenne et al 2014). More widespread PD use could have implications for PD outcomes due to potential changes in PD selection or in the experience of dialysis providers with PD. This study assessed PD patient outcomes before and after the new PPS was implemented.

Methods: This study included n=36,582 incident ESRD patients for whom PD was identified as the intended initial dialysis modality on the CMS ESRD Medical Evidence Form during 2008-12. We evaluated 1-year PD technique failure and PD patient mortality using data from Medicare claims, the Standard Information Management System, CROWNWeb, and the CMS Death Notification Form. PD technique failure was ascertained when hemodialysis was used for at least 60 days.

Results: Selection of PD increased from 5.8% to 8.4% of incident patients between 2008 and 2012 (see Figure).



During this period, 1-year PD technique failure decreased from 18.8% to 16.1% of patients and 1-year PD patient mortality decreased from 9.4% to 8.6% (see Figure). Outcomes were relatively stable or improving across patient age, race, and Hispanic ethnicity subgroups and for patients in both urban and rural areas.

Conclusions: In the context of expanding PD use under the new PPS, there is no early evidence of worsening overall PD patient outcomes or of growing disparities in PD patient outcomes by demographic group or by urban/rural location. Instead, there were lower levels of PD technique failure and PD patient mortality in the initial years of the new payment system.

TH-PO982

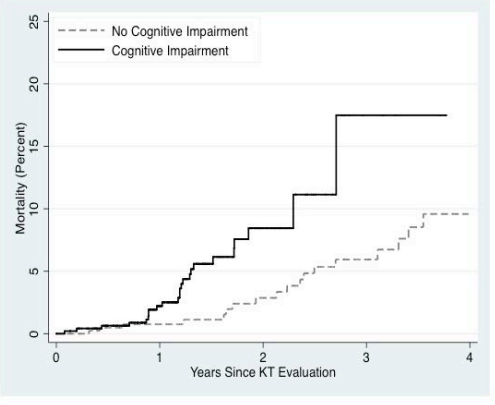
Cognitive Impairment and Mortality in Adults on the Kidney Transplant Waitlist Mara McAdams-DeMarco, Hao Ying, Israel O. Olorundare, Dorry L. Segev. *Johns Hopkins.*

Background: Older adults with poor cognitive function are at increased mortality risk . It is unclear whether ESRD patients of all ages with cognitive impairment are at increased mortality risk of while on the kidney transplant (KT) waitlist.

Methods: 918 ESRD patients being evaluated for and waitlisted for KT (no previous listings) at Johns Hopkins were enrolled in a prospective cohort study (11/2009-5/2014). The Modified Mini Mental Status (3MS), a test of global cognitive function (range 0-100. higher scores represent better function) was assessed at KT evaluation. Global cognitive impairment was defined as 3MS score<80). Mortality risk by 3MS score and cognitive impairment (separately) was estimated using an adjusted Cox proportional hazards model; participants were censored at the waitlist removal, time of KT or administrative end of follow-up.

Results: At KT evaluation, the mean (SD and range) age was 54 (14; 18-86), 57% were male, and 46% were African American. The mean (SD and range) 3MS score was 82.6 (11, 47-100) and 52% were classified as having cognitive impairment. 45 participants died over an average of 1.7 years of follow-up. Mortality risk was greater for adults on the KT waitlist who had worse 3MS scores (1 point decrease in 3MS score: HR=1.05, 95% CI: 1.02-1.08, P=0.003) and those with cognitive impairment (HR=2.51, 95% CI: 1.26-4.99, P=0.009) after adjusting for sex, age, race, education, and dialysis factors. The risk of mortality associated with cognitive impairment was similar for older (age≥65) and younger (age<65) participants (P=0.73).

Waitlist Mortality by Global Cognitive Impairment.



Conclusions: Among adults ESRD patients, impairment in global cognitive function more than doubled the risk of waitlist mortality. A simple screener for global cognitive function scores at the evaluation for first listing would not only identify adults with ESRD who have unrecognized cognitive impairment but also identify a high-risk population.

Indications, Technique, and Outcome of Plasmapheresis in a Large Pediatric Dialysis Center Rainer Büscher, Lübbert Lübbers, Anja K. Büscher, Peter F. Hoyer. *Pediatric Nephrology, Univ of Duisburg-Essen, Pediatrics II, Essen, Germany.*

Background: Plasmapheresis (PP) is a established therapeutic option for various indications in pediatric patients. However, there are only few reports with only little information on clinical outcome.

Methods: We performed a retrospective analysis involving 86 children and adolescents undergoing PP in our pediatric dialysis unit from 1997 to 2013.

Results: Within the observation period, 86 children (41 male), mean age 8.7±3.2 years (3 months to 18.9 years) received PP for a total of 652 sessions (1-33 sessions/patient; mean 6.4±3.1 sessions/patient). Most patients (30.2%) were treated for hemolytic-uremic syndrome (HUS), 18.6% for liver failure and 7.8% for rejection following renal transplantation. Other indications included encephalitis (5.9%), thrombotic thrombocytopenic purpura (4.9%), autoimmune hepatitis (3.9%), rapid progressive glomerulonephritis (3.9%) and nineteen other indications (24.8%). Membrane filtration was used in all patients, fresh frozen plasma (64.7%) the most frequently used substitution fluid and heparin the most frequently used anticoagulant (85.5%). Complications during PE included emesis (17.4%), seizures (13%), hypotension (8.7%), diarrhea (8.7%), mild allergic reactions (4.4%) and headaches (4.4%). All complications could be resolved. Overall, PP achieved full disease remission in 52 patients (60.4%), 14 patients showed a partial response (16.3%) and 20 patients (23.3%) did not respond at all. Among these, 12 patients (15.1%) died within the following 30 days. When stratified by diagnosis, 65% of all HUS patients (n=17/26) achieved complete remission and 5 out of 6 patients with encephalitis (85%) showed no relapse. Only poor results could be achieved in 16 patients with liver failure, where PP was used as bridging therapy prior to liver transplantation (LTX). Ten patients 62.5%) died prior or post LTX and 6 could be successfully transplanted.

Conclusions: Plasmapheresis is a safe method in children with a high efficacy in patients with hemolytic uremic syndrome, neurological autoimmune diseases and other primary renal diseases. Patients with liver failure who receive PP as bridging therapy show an infaust outcome.

TH-PO984

Who Makes the Best Exit Site: Nephrologist or Surgeon? Vaibhav S. Keskar, Mohan B. Biyani, Brian Blew, Jeffrey Warren, Brendan Mccormick. *The Ottawa Hospital, Univ of Ottawa, Ottawa, ON, Canada.*

Background: Buried peritoneal dialysis(PD)catheters are placed months before dialysis is needed and the exit site is created at the initiation of dialysis by the nephrologist. In contrast, the exit site of an unburied catheter is created by the surgeon at the time of insertion. Our PD unit uses both methods of catheter placement. We undertook this study to compare the outcomes of the two methods of exit site creation.

Methods: The charts of all patients who initiation PD between Jan 2012 and Dec 2013 were reviewed. At each clinic visit, exit sites were graded by the PD nurse into standard predefined groups: perfect, good, equivocal and infected. Primary outcome was the frequency of perfect exit sites at 2, 6, and 12 months after initiation of PD. Secondary outcomes were exit site infections, peritonitis and technique failure due to exit site infection.

Results: 119 patients started PD during the period of interest and 114 remained on PD at 2 months. 52 patients had buried catheters exteriorized at the time of starting PD (group A) and 62 patients had unburied catheters (Group B). Group A had more males (71% vs 48%), had higher mean age (65±14 vs 59±15) and had most of the patients as incident dialysis patients. Diabetic nephropathy was the most common underlying disease in either group (61.53% and 51.61%). Group B had a higher frequency of perfect exit sites at 2 months but this difference disappeared by 6 and 12 months. There was a trend towards more exit site infections in Group A but this did not translate into more technique failure.

		Group A (Buried, n=52)	Group B (Unburied, n=62)	p
% of perfect exit sites	2 months	40%	56%	0.02
	6 months	57%	62%	0.34
	12 months	62%	53%	0.65
Exit site infections		8	3	0.06
Tunnel infections		0	1	NS
Peritonitis		6	5	NS
Technique failure		2	1	NS

Conclusions: Buried catheters are less likely to have perfect appearance at two months compared to unburied catheters; however this is no longer significant at six and 12 months. The trend towards more exit site infections with buried catheters suggests that there may be clinical consequences of the tissue trauma at time of exteriorization.Consideration should be given to the use of prophylactic antibiotics at exteriorization.

TH-PO985

Prevention of Peritoneal Dialysis Catheter-Related Infections – A Multicenter Randomized Controlled Trial Mercedes L. Velo, Paula López, Carmen Felipe, Jose Ramon Rodriguez-Palomares, Gloria Del peso, Francisco Javier Ahijado, Fernando Tornero, Mar?a Jose Fernandez Reyes, Ana M. Tato, Maria Rosario Luque, Jose M. Portoles. *Grupo Centro Diálisis Peritoneal, Spain.*

Background: Peritonitis, tunnel and catheter exit site (CES) infections are the most serious complications of peritoneal dialysis (PD). We studied the effect of antibiotic ointment (EUDRAC: 2009-016835-36) on catheter-related infections (CRI) and morbidity.

Methods: Allocation was stratified in blocs of 4/center. Ointment containing 2% colistin, tobramycin, amphotericin B and 4% vancomycin or normal saline were applied to the CES over 1 year. Follow-up period was 3 months after the last dose. Exit site infection (ESI) was defined as erythema, edema or local pain with purulent secretion and positive culture. Antimicrobial therapy was given according to local protocols.

Results: 140 patients were included, 6 didn't meet entry criteria. Characteristics and dialysis parameters of the 65 in the control group (CG) and 69 intervention group (IG) patients were comparable.

	Study	Control
Age, mean (SD)	56.5	58.9
Gender, male, %	65.2	53.1
Diabetes, %	24.6	26.6
Charlson index	3.2	3.3
Prior cardiovascular events, %	27.5	23.4
Time in PD, mean, years	1.3 (1.5)	2 (2.2)
APD/CAPD, %	30.4	25
Residual renal function, ml/min	4.5 (4.4)	6.3 (4.2)
KTv	2.2 (0.6)	2.3 (2.5)

Mean study duration was 0.6 (IG) vs 0.6 (CG) years (ns). 26 episodes of CRI (11 ESI, 4 tunnel, 11 peritonitis) occurred in the CG and 12 in the IG (3 ESI, 0 tunnel, 9 peritonitis) ($p<0.001$). Etiology of ESI was *Staphylococcus aureus* (x7), *Corynebacterium* spp, *Pseudomonas aeruginosa*, *E. coli*, *Serratia* spp., coagulase-negative *S.* (x2) and 1 negative culture in the CG and *S. aureus* (x1), 1 Gram-negative bacillus and 1 negative culture in the IG. Systemic or topical antibiotics were given for ESI in 11 (CG) and 2 patients (IG) ($p<0.01$), respectively. Hospital admissions were 23 (CG) and 15 (IG). Local side effects were significantly increased in the IG.

Conclusions: Local prophylaxis with a broad-spectrum antimicrobial ointment is associated with a significant reduction in ESI and systemic antibiotic use without associated bacterial resistance. Significant local side effects were observed.

TH-PO986

Association Between Plasma Fibroblast Growth Factor-23 and Carotid Artery Atherosclerosis in Peritoneal Dialysis Patients Nanmei Liu. *Jimin Hospital of Shanghai.*

Background: We investigate the association between plasma fibroblast growth factor-23 (FGF-23) level and carotid artery atherosclerosis of 125 stage 5 chronic kidney disease (CKD5) patients, who are doing continuous ambulatory peritoneal dialysis (CAPD) at renal division of Shanghai Jimin Hospital in China.

Methods: A retrospective cohort study of individuals 15 years of age and older, divided into two cohorts according to carotid intima-media thickness (CIMT) : CIMT normal cohort (CIMT<0.9mm) and CIMT thickening cohort (CIMT³0.9mm). Plasma FGF-23 concentrations were determined by ELISA. CIMT thickness and atherosclerotic plaques were measured by carotid ultrasound.

Results: Of the 125 PD patients, the CIMT was thickened in 82 patients (65.6%). Compared with the CIMT normal patients, plasma FGF-23 concentration was significantly increased ($p<0.01$) in the CIMT thickening cohort (Table 1). Linear regression analysis discovered an obvious positive correlation between plasma FGF-23 and CIMT ($r=0.416$, $P=0.006$) (Table 2). Multiple regression analysis indicated that plasma FGF-23 level was independent risk factor for CIMT ($\beta=0.421$, $t=2.607$, $P<0.01$) (Table 3).

Conclusions: The level of plasma FGF-23 was positively correlated with CIMT and played an important role in development of carotid artery atherosclerosis in peritoneal dialysis patients.

Funding: Government Support - Non-U.S.

TH-PO987

Atherogenic Index of Plasma Is Associated with Insulin Resistance in Non-Diabetic Peritoneal Dialysis Patients Mi Jung Lee,[1] Jae Eun Um,[2] Meiyan Wu,[2] Tae ik Chang,[3] Tae-Hyun Yoo.[1] *[1]Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea; [2]Brain Korea 21 PLUS, Severance Biomedical Science Inst, Yonsei Univ College of Medicine, Seoul, Korea; [3]Dept of Internal Medicine, NHIC Ilsan Hospital, Gyeonggi-do, Korea.*

Background: Insulin resistance (IR) is an independent risk factor for cardiovascular morbidity and mortality. Although many factors including uremia, chronic inflammation, and abnormal adipokine levels are known to contribute to the development of IR, the role of pro-atherogenic lipoprotein on IR remains unknown in peritoneal dialysis (PD) patients. Therefore, we investigated the independent association between pro-atherogenic lipoprotein and IR in non-diabetic PD patients.

Methods: We conducted a cross-sectional study in 75 non-diabetic PD patients. Pro-atherogenic lipoprotein was assessed by the atherogenic index of plasma (AIP, log transformed triglyceride to high-density lipoprotein cholesterol ratio). IR was determined by homeostatic model assessment-IR (HOMA-IR). Patients were divided into the higher and lower HOMA-IR group according to the median value of HOMA-IR. Independent association between AIP and HOMA-IR was ascertained by multivariate linear regression analysis.

Results: The mean age of the patients was 52.1±11.2 years, 35 patients (46.7%) were male. The mean value of AIP was 0.38±0.33 and the median value of HOMA-IR was 1.58 (interquartile range, 0.88 to 2.76). AIP was significantly greater in the higher HOMA-IR group (0.25±0.27 vs. 0.53±0.32, $P<0.001$). AIP was negatively correlated with systolic blood pressure ($r=-0.32$, $P=0.005$) and log adiponectin ($r=-0.42$, $P=0.001$) and positively correlated with sagittal abdominal diameter ($r=0.25$, $P=0.033$), residual renal function ($r=0.29$, $P=0.012$), serum albumin ($r=0.26$, $P=0.026$) and log HOMA-IR ($r=0.54$, $P<0.001$). In multiple linear regression analysis, AIP ($\beta=0.251$, $P=0.037$) was independently associated with HOMA-IR after adjustment for confounding factors.

Conclusions: Pro-atherogenic lipoprotein abnormality determined by high AIP might be implicated with development of IR in non-diabetic PD patients.

TH-PO988

Reducing Mortality in CAPD Patients by Statin Yong kyu Lee, Tae ik Chang, Sug kyun Shin. *Nephrology Div, Dept of Internal Medicine, National Health Insurance Corporation, Ilsan Hospital, Goyang, Korea.*

Background: Patients who are on CAPD (Continuous Ambulatory Peritoneal Dialysis) shows higher serum LDL cholesterol and Triglyceride compared to patients who are on hemodialysis. But higher cholesterol level does not seem to effect on raising mortality or cardiovascular morbidity and PD failure. On the contrary, lower serum cholesterol level in CAPD patients tends to raise mortality and morbidity due to poor nutritional status.

Methods: This study is a retrospective study designed to evaluate the effect of cholesterol level, statin on CAPD outcome and mortality. Patients who were on peritoneal dialysis for at least 6 months since March 1st, 2000 were included. A total of 467 patients were enrolled in this study. Patients' biological parameter, biochemical parameter and morbidity/mortality during CAPD maintenance period were collected.

Results: Patients whose initial cholesterol level were above 240 mg/dL shows significantly low CAPD failure rate compared to patients whose initial cholesterol level were below 200 mg/dL (OR= 0.469, p=0.049). Patients whose average LDL-cholesterol during CAPD period were over 100mg/dL showed significantly higher mortality compared to patients whose initial LDL-cholesterol level were below 100mg/dL (OR=1.848, p=0.024). Patients whose compliance to statin during CAPD period was over 80% showed significantly low mortality compared to patients who did not take statin during CAPD period (OD=0.556, p=0.020). Patients showed no significant difference in motality due to total cholesterol, HDL cholesterol levels and patients showed no significant difference in CAPD failure due to HDL/LDL cholesterol, statin usage.

Conclusions: In CAPD patients, serum total cholesterol level should be targeted higher than HD or CKD patients. On the contrary, similar to HD or CKD patients, Statin should be administered and LDL cholesterol should be lowered during CAPD period to lower mortality. To identify the difference in cholesterol mechanism of CAPD patients further, in depth study over adequate cholesterol level in CAPD patients needs to be proceeded.

TH-PO989

Using Daily Remote Biometric Monitoring in Peritoneal Dialysis Susie Q. Lew,[1] Manya Magnus,[2] Neal Sikka.[3] *[1]Medicine, George Washington Univ, Washington, DC; [2]Epidemiology and Biostatistics, George Washington Univ, Washington, DC; [3]Emergency, George Washington Univ, Washington, DC.*

Background: Peritoneal dialysis(PD) requires self-monitoring with daily blood pressure(BP), weight, & physical examination. Patients(Pts) don't always perform procedures or record results. We aim to determine associations between daily remote biometric monitoring(RBM) & clinical and pt satisfaction outcomes.

Methods: Pts were provided with BP monitoring equipment & scale which were capable of announcing the results, transmitting the results via Bluetooth technology to a hub located in the pt's home & via 2G/3G cellular signal to a Telehealth call center. PD nurses viewed results or alerted to abnormal results.

Results: 300 subjects(subjs) from 10 PD units were followed over at least 12 months. Demographics include male (56%), African American(AA)(62%), & median age 56 yrs (IQR 44-64) and 1.86 yrs on dialysis (IQR 0.62-3.73). AA subjs were more likely to use than non-AA (69% vs 55%, $p<0.05$). 51% of subjs used RBM, with 66% consistently using the equipment. RBM was associated with reduced risk of hospitalization (Coef -0.27, SE 0.10, p=0.006). Subjs became increasingly less likely to breach any upper or lower alert threshold (OR 0.995, p=0.004). Subj satisfaction of RBM equipment for BP monitoring was 87% & scale 90%. Rural exceeded non-rural subjs in utilizing RBM (OR 4.77, 95% CI 1.34-16.98, $p<0.02$) Use of RBM was associated with improved perception of confidence with self-care requirements of PD: easier to collect measurements (OR 2.69, 95% CI 1.52-4.76, $p<0.001$); more secure in their measurements (OR 3.28, 95% CI 1.71-6.26, $p<0.001$);getting more support from their PD doctors and nurses (OR 2.03, 95% CI 1.01-4.12, $p<0.05$).

Conclusions: RBM was associated with increased frequency, accuracy, and communication of measurements to medical personnel, enhanced perception of autonomy and confidence in measurements, & reduction of hospitalizations & out of range measurements for BP. RBM was acceptable & satisfactory to PD pts. RBM offers additional tools to support PD pts in maintaining their measurement regimens & reduce negative health outcomes.

TH-PO990

Impact of Patient-Centric Automated Peritoneal Dialysis User-Interface on Operator Learning and Confidence Catherine Firanek, Mary Gellens, James A. Sloand. *Medical Affairs, Baxter Healthcare, Deerfield, IL.*

Background: Automated peritoneal dialysis (APD) is an underutilized therapy for patients with end-stage renal disease (ESRD). The perception patients may not be able to manage their own treatment setups comes into play in choice of this treatment modality. Improvements to cycler technology may help to further simplify therapy for patients,

reducing barriers to uptake. This study aimed to determine whether a cycler-embedded, patient-centric interface offered an enhanced user experience compared to a conventional APD cycler.

Methods: 30 study participants (ages 29-84, mean 50 yrs, 67% male) diagnosed with ESRD were randomized into 2 groups using cycler with patient-centric user interface with advanced technology in development and a conventional APD cycler. Participants evaluated cyclers on 2 non-consecutive days using a different cycler each day. Each participant was given a brief orientation, setup task, training session, break, followed by a setup task and questionnaire. Study results were analyzed via Fisher's exact, Mann-Whitney and Exact binomial tests.

Results: The cycler with patient-centric user interface and advanced technology (in development) scored better on reduced reliance on printed instructions (p<0.0001). Patients committed fewer deviations on the cycler in development vs the conventional cycler (2 of 19 steps vs 14 of 19 respectively) after training (p=0.004), including disinfecting hands (p=0.02) and line handling (p=0.01), and were more confident that they set up the cycler according to specifications (p=0.043). The new cycler scored higher in overall preference among study participants: The cycler with a patient centric user interface was rated easier to learn (p=0.005) and to use (p=0.016), preferable to use (p=0.03), and users felt more confident about using the new cycler at home compared to conventional cycler (p=0.001).

Conclusions: A cycler with embedded, patient-centric interface was rated higher in terms of overall reliance on instructions, task competency, ease of use and learning, preference and overall confidence of using the cyclers. These findings indicate that APD operator learning and confidence can be enhanced with a patient-centric user-interface.

Single-Site Trans-Umbilical Peritoneal Dialysis Catheter Insertion

Mangalakumar Veerasamy. *Nephrology, KMCH, Coimbatore, Tamilnadu, India.*

Background: Traditional laparoscopic peritoneal dialysis catheter placement requires two ports insertion and this could lead to complications like leak and hernia at the port sites. We describe a novel approach of using single-site trans-umbilical ports that is associated with small scar (less than 1cm) and reduced complications.

Methods: Under general anaesthesia pneumo-peritnoeum was created as per standard method. One 10mm port and one 5mm port was inserted through trans-umbilical route to guide peritoneal dialysis catheter insertion. Hernial orifices were inspected and if there was any adhesion present that was released to facilitate free fluid movement. The catheter was inserted through a small incision 1 inch below umbilicus. The catheter was positioned in the pouch of Douglas using lap instrument passed through the trans-umbilical port. The other end of catheter was tunnelled in the standard manner and brought out though the exit site and the titanium adaptors were fixed as usual.To prevent the migration of catheter from the pelvic cavity a trans-facial loop was placed around the catheter(freely mobile but remains in pelvis). Omentum was folded and pulled upwards to the left upper guardant and fixed to anterior abdominal wall using a trans-facial loop. The latter prevented the omentum from wrapping dialysis catheter and causing malfunction. Then the port site was closed in three layers (Video available).

Results: 10 cases underwent catheter insertion with this approach (Male 7, Female 3) and the mean follow up period is 11 months. None of them developed leak or catheter migration or any mechanical complication that might require catheter reposition or change.

Conclusions: Combined method of Single-site port placement, omentopexy and loop fixation of intra-abdominal segment of catheter offers the following advantages -small incision; hence risk of leak when catheter was used early after placement is low. The risk of hernia through port site is reduced and small scar will be welcome to image conscious patients. If there was any adhesion present that could be released with minimal trauma to peritoneal membrane. Placing a loop around the catheter prevented catheter migration. Omental wrapping was prevented by fixing this in the upper quadrant by trans-facial loop.

TH-PO992

Peritonitis and Survival following PD Catheter Insertion in Infants

Joshua Zaritsky, Coral D. Hanevold, Troy Richardson, Jonathan Rodean, John P. Lawlor, Raymond P. Quigley, Alicia Neu, Bradley Warady. *SCOPE Collaborative, CHA, Overland Park, KS.*

Background: Chronic peritoneal dialysis (PD) is the dialysis modality of choice for children. However, there are limited outcome data in those who undergo PD catheter (cath) insertion in the 1st year of life. Using data from the Children's Hospital Association Standardizing Care to Improve Outcomes in Pediatric End Stage Renal Disease (ESRD) Collaborative (SCOPE), we examined peritonitis rates and survival in 156 infants who had a PD cath placed in the 1st yr of life.

Methods: Data on pt demographics, PD cath characteristics, peritonitis risk factors and outcomes from 157 cath insertions from 29 North American pediatric dialysis centers were reviewed and analyzed using chi square test for association or a Wilcoxon rank-sum test.

Results: In hospital and overall peritonitis rates during the 1st year post cath insertion were 1.73 and 0.76 per pt-year, respectively. Gram + organisms were responsible for 38.7% of infections (**figure**); 28% were culture negative. Polycystic kidney disease and pulmonary hypoplasia were more frequent in infants with peritonitis, whereas anuria did not differ between groups (**table**). Use of a curled catheter or plastic adaptor, nephrectomy prior to or concurrent with cath insertion, and G-tube insertion after cath placement were more common in pts with peritonitis, while number of cuffs, surgical technique, cath use within 14 days and cath revision did not differ between groups. Infants with peritonitis had longer initial hospital stays and lower survival compared with those without peritonitis.

	No Peritonitis (N=91)	Peritonitis (N=65)	p
DEMOGRAPHICS (median with IQ range)			
DOL at cath placement	32 (9, 129)	21 (8, 88)	NS
Gestational age (weeks)	36 (34, 38)	37 (34, 38.5)	NS
Weight (KG)	3.3 (2.6, 5.2)	3.3 (2.6, 4.6)	NS
Initial hospitalization (days)	60 (21,90)	83 (48,130)	<0.02
RISKS/OUTCOMES for Peritonitis (% Insertions)			
	No Peritonitis (N=91)	Peritonitis (N=66)	p
Polycystic Kidney Disease	2.2	16.9	<0.01
Pulmonary Hypoplasia/CLD	21.4	36.2	<0.05
Anuria at time of placement	19.1	30.6	NS
Curled Catheter	82.4	95	<0.02
Plastic Adaptor	32.6	48.4	<0.05
Nephrectomy prior/at time of placement	3.6	18.6	<0.01
G-tube insertion after placement	23.1	42.4	<0.03
Single Cuff	33	45	NS
Open surgical placement	60	51	NS
Use w/in 14D	52.5	62.5	NS
Cath revision	18.1	29	NS
Survival: Initial hospitalization	96.7	87.9	<0.03
Survival: 1 Year	95.6	86.3	<0.04

Conclusions: In this large cohort of infants with ESRD, we found a high rate of peritonitis and identified several risk factors associated with peritonitis. Given that peritonitis was associated with increased initial hospital stay and mortality, attention to the potentially modifiable factors is needed.

TH-PO993

Risk Factors for All-Cause Unexpected Hospitalization After Peritoneal Dialysis Catheter Implantation

Zi Li,[1] Zita C. Abreu,[2] Joanne M. Bargman.[2] *[1]Nephrology, West China Hospital, Sichuan Univ, Chengdu, Sichuan, China; [2]Nephrology, Toronto General Hospital Univ of Toronto, Toronto, ON, Canada.*

Background: Implantation of the peritoneal dialysis catheter (PDC), usually an elective procedure, may necessitate unexpected hospitalization due to multiple co-morbidities and inherent instability of the end-stage renal disease patient. This information is important for administrative planning for a PD program. However, information on hospitalization after PDC implantation is limited and details about the reason for hospitalization are lacking.

Methods: We performed a prospective cohort study in consecutive patients who underwent PDC implantation at a single institution from 2007 to 2013. Clinical characteristics of enrolled patients, technique of the implantation procedure and all-cause unexpected hospitalization and morbidity within 14 days after implantation were analyzed.

Results: A total of 246 patients receiving 252 PDC implantations during the 6 years were studied. After 39 procedures (15.5%), patients had an unexpected hospital stay due to operative complications (33.3%), worsening of comorbid disease (35.9%), or a single-night hospital stay for observation (30.8%). Compared to discharged patients, the unexpected hospitalization ones were older (P=0.001), had higher rates of previous episodes of heart failure (P=0.006) and heart disease (P<0.001), had more use of general anesthesia (P=0.046), had more added procedures during the implantation (P=0.02) and had more episodes of flow obstruction and peritonitis (P=0.012 and P<0.001). Multivariable logistic regression showed that age, cardiac morbidity, use of general anesthesia, PDC flow problems and peritonitis after implantation were independent predictors of all-cause unexpected hospitalization.

Conclusions: For the first time, our study has analyzed the rate of unexpected hospitalization after PDC implantation and identified the salient risk factors. Increased focus to identify patients at greatest risk for hospitalization, evaluation of processes of care, and implementation of preventive strategies may be helpful to reduce unplanned hospitalization after catheter insertion.

TH-PO994

Early Mechanical and Infective Complications in First Time Blind, Bedside, Midline Percutaneous Tenckhoff Catheter Insertion with Ultra Short Break-in Period: Setting New Standards

Suceena Alexander,[1] Ninoo G. George,[2] Santosh Varughese.[1] *[1]Nephrology, Christian Medical College, Vellore, Tamil Nadu, India; [2]Nephrology, Billroth Hospitals, Chennai, Tamil Nadu, India.*

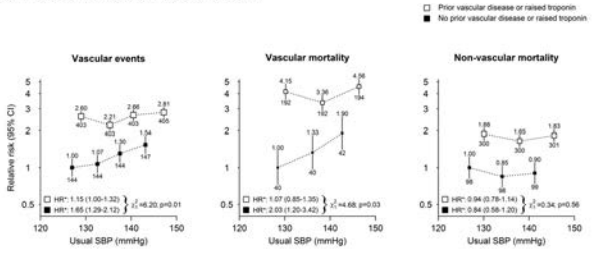
Background: There are no large studies that have looked into ultra-short break-in period with blind, bedside, midline approach of Tenckhoff catheter insertion.

Methods: 284 consecutive adult patients underwent catheter insertion for chronic peritoneal dialysis at our centre from January 2009 to December 2013. Those with history of midline laparotomy scars and hernias were referred for open surgical insertion. 245 patients (86.3%) underwent the percutaneous and 39 patients (13.7%) underwent surgical insertions.

Results: The mean break-in period for the percutaneous group (PG) was 2.68 ± 2.63 days and for the surgical group (SG) was 11.19 ± 6.96 days, p <0.001. Poor catheter outflow was present in 22 (9%) of PG and in 4 (10.3%) of SG (p= 0.80).Primary catheter non-function was present in 24 (9.8%) of the PG and in 4 (10.3%) of the SG (p= 0.73). Catheter survival at one year was 164/241 (89.1%) in the PG. The various outcomes are:

Outcomes	Percutaneous N=245	Surgical N=39	P value
Failed Catheter Insertion,n(%)	2(0.8)	0	0.74
Poor outflow,n(%)	22(9)	4(10.3)	0.8
Dialysate leak,n(%)	16(6.5)	6(15.4)	**0.055**
Mesentric tear,n(%)	2(0.8)	0	0.74
Paralytic ileus,n(%)	0	1(2.6)	**0.01**
Exit site bleeding,n(%)	1(0.4)	0	0.69
Early peritonitis,n(%)	3(1.2)	0	0.49
Overall early mechanical complications,n(%)	40(16.3)	11(28.2)	**0.07**
Primary catheter non-function,n(%)	24(9.8)	4(10.3)	0.73
Mortality,n(%)	68/241(28.2)	17/36(47.2)	**0.02**
Catheter survival at one year,n(%)	164/184(89.1)	29/35(82.9)	0.29
Median patient survival(mts)	43(95%CI:28.5-57.5)	35(95%CI:24-46)	0.60

Figure: Relevance of systolic blood pressure to vascular events and cause-specific mortality, by prior vascular disease or raised troponin



SBP=systolic blood pressure. Relative risks adjusted for age, sex, ethnicity, country, education, smoking status, prior diabetes, renal status, body mass index and treatment allocation. *Average HR per 20 mmHg higher usual SBP across range of values studied (i.e. assuming a log-linear relationship).

Conclusions: The significantly shorter break-in period and smaller wound incisions reduce hospitalization and the need for bridging hemodialysis as well as having good patient and catheter outcomes.

TH-PO995

Comparing Outcomes of Percutaneous Peritoneal Dialysis Catheter Insertion by Nephrologist versus Open Surgical Insertion – Large Single Centre Experience

Louise E. Ross, Bhrigu Raj Sood. *South West Thames Renal and Transplantation Unit, Carshalton, Surrey, United Kingdom.*

Background: Several studies suggest that percutaneous insertion of peritoneal dialysis (PD) catheters by nephrologists improves the uptake of PD. Percutaneously inserted PD catheter has the advantage of being less invasive, removing the need for general anaesthetic, reducing hospital stay, facilitating acute PD, therefore making PD more accessible. There are only a few small studies directly comparing the outcomes of patients who have had a percutaneous versus open method of implantation, with some suggesting poorer outcomes.

Methods: We retrospectively reviewed data on all patients who had a percutaneous or open surgical PD catheter inserted between August 2011 and December 2014 at a single renal centre, to identify the patients who developed an exit site infection (ESI) or episode of PD peritonitis within two and four weeks of catheter insertion. We also looked at patients who developed a functional catheter problem requiring manipulation or replacement of the catheter within the first year. Chi-squared test was used to assess statistical significance.

Results: 276 PD catheters were inserted in the said time period. 152 were inserted percutaneously and 124 with open surgery. There were less ESI (at 2 weeks - 2.6% versus 6.5%; p=0.122, and at 4 weeks – 2.6% versus 10.5%; p=0.007) and less peritonitis (at 2 weeks - 0.7% versus 3.2%; p=0.112, and at 4 weeks – 1.3% versus 5.6%; p=0.044) episodes in the percutaneous versus open surgical group. PD catheters requiring manipulation or replacement within the first year due to a functional problem was comparable in the percutaneously inserted catheters (9.2% versus 12.9%; p=0.327). There were no major complications in the form of viscus perforation or major haemorrhage in either group.

Conclusions: In our study, we found that infection related complications were better with percutaneous PD catheter insertion and mechanical failure rate was comparable to open surgical PD catheter insertion. In our practice we have found that percutaneously inserted PD catheters are a safe means of increasing patient access to PD, enabling more patients to have a home-based therapy.

TH-PO996

Shared Decision-Making in Chronic Kidney Failure: The Retrospection of Early-Stage Dialysis Patients in Germany

Maxi Robinski,[1] Wilfried Mau,[1] Andreas Wienke,[2] Matthias Girndt.[3] *[1]Inst of Rehabilitation Medicine, Martin Luther Univ Halle-Wittenberg, Halle (Saale), Germany; [2]Inst of Medical Epidemiology, Biostatistics, and Informatics, Martin Luther Univ Halle-Wittenberg, Halle (Saale), Germany; [3]Dept of Internal Medicine II, Martin Luther Univ Halle-Wittenberg, Halle (Saale), Germany.*

Background: To date, little is known about the extent to which patients with chronic kidney failure feel involved in decision-making regarding the life-changing dialysis treatment. Previous studies on mortality yielded equivalence of peritoneal (PD) and hemodialysis (HD). However, only 5% of the patients in Germany choose PD, even though many patients are eligible for both options and entitled to receive unbiased counselling.

Methods: In a nationwide multicenter study with federal funding ("CORETH-project"), we surveyed 781 patients on dialysis since 6 to 24 months with regard to their rating of shared decision-making (SDM) with their physician concerning the choice of renal replacement therapy. We used the "Shared Decision-Making Questionnaire" (Kriston et al. 2010), which is a highly reliable and well accepted measure. Furthermore, patients indicated the dominating reason for choosing their treatment as well as their treatment satisfaction (TS). Data were compared between propensity score-matched groups of patients (n_{PD}=n_{HD}=246).

Results: PD patients rated all aspects of SDM (for example, consideration of patient-preferences or shared weighing of options) significantly more positive than HD patients (SDM-total score, p<.0001). PD patients predominantly (73%) indicated their independency as a motivator for the choice, whereas HD patients were largely (30%) subject to medical decisions only. Moreover, compared to HD, PD patients were more satisfied with the information received (p=.013). The SDM- and TS-total scores correlated significantly positive in the matched overall sample (r=.19, p<.0001).

Conclusions: Our findings heighten awareness for an unbiased nephrological counselling-culture and provide indications for a successful SDM-process when choosing dialysis modality. According to the results, an effective SDM can pave the way for dialysis patients' quality of life and treatment success.

Depression and Cognitive Impairment in Peritoneal Dialysis: A Multi-Center Cross-Sectional Study

Jie Dong,[1] Hai-chen Pi,[1] Zuying Xiong,[2] Jinlan Liao,[2] Li Hao,[3] Gui-ling Liu,[3] Ye-Ping Ren,[4] Qin Wang,[4] Li-ping Duan,[5] Zhao-xia Zheng.[5] *[1]Renal Div, Dept of Medicine, Peking Univ First Hospital, Beijing, China; [2]Renal Div, Peking Univ Shenzhen Hospital, Shenzhen, China; [3]Renal Div, The Second Hospital of Anhui Medical Univ, Hefei, Anhui, China; [4]Renal Div, The Second Affiliated Hospital of Harbin Medical Univ, Harbin, Heilongjiang, China; [5]Renal Div, Handan Central Hospital, Handan, Hebei, China.*

Background: Depression and cognitive impairment have been identified as independent risk factors for mortality in peritoneal dialysis (PD) patients. The relationship between depression and cognitive functions in PD patients was investigated in this multi-center cross-sectional study.

Methods: Study design: multi-center cross-sectional study. Setting & Participants: A total of clinically-stable 458 patients who performed PD for at least 3 months from 5 PD units were enrolled in this study. Factor: Depression. Outcomes: Global and specific cognitive impairment. Measurements: Global cognitive function was measured by using the Modified Mini-Mental State Examination (3MS), specific cognitive function by executive function, immediate memory, delayed memory, visuospatial skill and language ability by subtests of Repeatable Battery for the Assessment of Neuropsychological Status. Depression was diagnosed if the depression severity index>0.5 by using Zung's Self-rating Depression Scale.

Results: The prevalence of depression and cognitive impairment evaluated by 3MS were 52% and 28.4% respectively. Patients with mild or moderate/severe depression had higher prevalence of general cognitive impairment, executive dysfunction, impaired immediate and delayed memory. After adjusting for demographic, comorbidity data and clinical parameters, depression scores were independently associated with lower scores of 3MS, immediate and delayed memory, and language ability, and longer completion time of trails A and B. Even mild depression could independently predict higher risk of CI, executive dysfunction, impaired immediate and delayed memory after multivariable adjustments.

Conclusions: Even mild depression plays an important role in global and specific cognitive functions in PD patients.

Funding: Government Support - Non-U.S.

TH-PO998

Proposed Model for the Care of Hospitalized Peritoneal Dialysis Patients
Cynthia R. Christiano,[1] Melanie I. Hames,[1] Pankaj Jawa,[1] Piper J. Hughes,[3] Maria H. Locklear.[2] *[1]Div of Nephrology, Brody School of Medicine at East Carolina Univ, Greenville, NC; [2]Vidant Medical Center, Greenville, NC; [3]Internal Medicine, East Carolina Univ, Greenville, NC.*

Background: Peritoneal dialysis (PD) has been prescribed throughout the United States, yet the optimal model of care for hospitalized PD patients remains unknown. With a growing interest in home modalities and emphasis on quality, it is imperative that we identify an effective and efficient way to care for this patient population during hospitalization.

Methods: We describe a model successfully implemented at Vidant Medical Center (VMC) in 2008. Prior to this date, the primary hospital nurses performed PD care. Due to the high risk, low volume nature of inpatient PD, this resulted in inconsistent care as well as decreased physician, nursing, and patient satisfaction. In 2008, an inpatient PD nursing team was created. This team, consisting of nephrology nurses with specialized PD training, is managed by VMC's self-maintained dialysis unit. Staffed with 2 nurses during the day and 1 at night, they provide 24/7 care throughout the hospital, including the ICU and ED. Responsibilities include patient education, exit site care, catheter flushes, and all manual and automated PD exchanges. Upon discharge, the outpatient unit is contacted to ensure appropriate transition back to the outpatient setting.

Results: This model provides several benefits: 1) PD treatments are consistently completed and charted, 2) Increased physician, nursing, and patient satisfaction, 3) Continuity of care, and 4) Cost reduction (personnel and supplies). Since inception, this team has grown to 13 nurses. During FY2014, 2568 (1572 adult / 996 pediatric) PD treatments were performed, the majority CAPD. To ensure appropriate utilization of nursing resources, most are cross-trained to perform hemodialysis.

Conclusions: In conclusion, the creation of a specialized nursing team has been instrumental in optimizing the care of our hospitalized PD patients. This sustainable model provides effective, efficient care and should be considered for implementation by hospitals providing PD services.

TH-PO999

Elderly Peritoneal Dialysis Compared with Elderly Hemodialysis Patients and Younger Peritoneal Dialysis Patients: Competing Risk Analysis of a Korean Prospective Cohort Study
Hyunsuk Kim,[1] Jung Nam An,[2] Dong Ki Kim,[1] Yong-Lim Kim,[3] Yun Kyu Oh,[2] Chun Soo Lim,[2] Yon Su Kim,[1] Jung Pyo Lee.[2] *[1]Internal Medicine, Seoul National Univ College of Medicine, Seoul, Republic of Korea; [2]Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul, Republic of Korea; [3]Internal Medicine, Kyungpook National Univ School of Medicine, Daegu, Republic of Korea.*

Background: The outcomes of peritoneal dialysis (PD) in elderly patients have not been thoroughly investigated. We aimed to investigate the clinical outcomes and risk factors associated with PD in elderly patients.

Methods: We conducted a prospective observational nationwide adult end-stage renal disease (ESRD) cohort study in Korea from August 2008 to March 2013. Among incident patients (n=830), patient and technical survival rate, quality of life, and Beck's Depression Inventory (BDI) scores of elderly PD patients (≥65 years, n=95) were compared with those of PD patients aged ≤49 years (n=205) and 50~64 years (n=192); and elderly hemodialysis (HD) patients (n=315). The patient death and technical failure were analyzed by cumulative incidence function.

Results: The patient survival rate of elderly PD patients was inferior to that of younger PD patients (P<0.001). However, the technical survival rate was similar (P=0.097). Compared with elderly HD patients, the patient survival rate did not differ according to dialysis modality (P=0.987). Elderly PD patients showed significant improvement in the BDI scores, as compared with the PD patients aged ≤49 years (P=0.003). Low albumin, diabetes and low residual renal function were significant risk factors for the PD patient survival; and peritonitis was a significant risk factor for technical survival. Furthermore, low albumin and hospitalization were significant risk factors of patient survival among the elderly.

Conclusions: The overall outcomes were similar between elderly PD and HD patients. PD showed the benefit in BDI and quality of life in the elderly. Additionally, the technical survival rate of elderly PD patients was similar to that of younger PD patients. Taken together, PD may be a comparable modality for elderly ESRD patients.

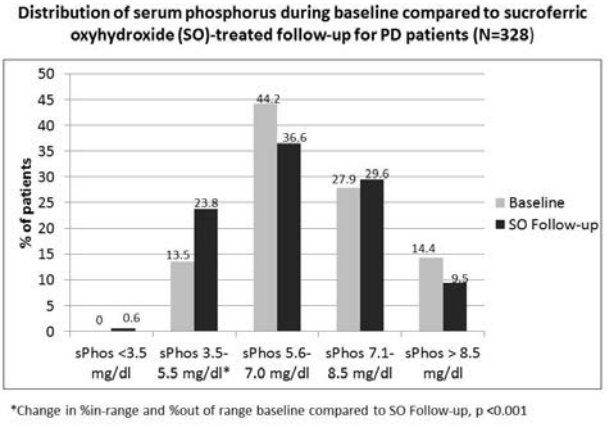
TH-PO1000

Phosphorus Control and Phosphate Binder Pill Burden During Real-World Use of Sucroferric Oxyhydroxide in Peritoneal Dialysis Patients
Linda H. Ficociello, Vidhya Parameswaran, Mark Costanzo, Claudy Mullon, Franklin W. Maddux, Robert J. Kossmann. *Fresenius Medical Care North America (FMCNA), Waltham, MA.*

Background: Achieving serum phosphorus (sPhos) control can be a challenge for dialysis patients (pts). This retrospective database analysis examined the real-world effectiveness of sucroferric oxyhydroxide (SO), an iron-based phosphate binder (PB), in adult peritoneal dialysis (PD) pts.

Methods: A cohort of PD pts prescribed SO as part of routine clinical care at FMCNA clinics was analyzed. Pts had ³1 sPhos measured during SO and had been previously treated with sevelamer, calcium acetate, calcium carbonate or dual therapy. Changes in sPhos, serum calcium (sCa), intact parathyroid hormone (iPTH), transferrin saturation (TSAT), ferritin (FER), and PB pills per day (PPD) were assessed 3-months before SO (baseline) and 3-months during SO (follow-up).

Results: Pts (n=328) were, on average, 53 years old, with a dialysis vintage of 3.9 years. At baseline, 56% of pts used sevelamer, 29% calcium acetate, 11% calcium carbonate, and 5% dual therapy. Pts in-range increased from 13.5 to 23.8% (76% increase). Mean sPhos decreased from 6.92 to 6.67 mg/dl, p<0.001. PB PPD was reduced from 8.4 to 3.8 pills (4.6 fewer pills, p<0.001). There was no significant change in sCa (9.1 to 9.0 mg/dl) or iPTH (535 to 555 pg/ml). TSAT and FER increased from 35.4 to 36.6% and 752.1 to 814.9 ng/ml, respectively. In pts not receiving IV iron (n=127), TSAT and FER did not change significantly (36.3 to 37.3% and 797.9 to 743.3 ng/ml, respectively).



Conclusions: In this large cohort of PD patients prescribed sucroferric oxyhydroxide as part of routine clinical care, a significant reduction in serum phosphorus (p<0.001) and a 76% increase in patients achieving in-range serum phosphorus (p<0.001) was observed. This was accomplished with a mean of 3.8 pills per day, a reduction of 4.6 pills (p<0.001).

Laparoscopic Findings of Visceral Peritoneal Injury in Patients Treated with Neutral pH Peritoneal Dialysis Solution
Yudo Tanno, Nanae Matsuo, Izumi Yamamoto, Yasuyuki Nakada, Ichiro Ohkido, Keitaro Yokoyama, Takashi Yokoo. *Div of Kidney and Hypertension, Dept of Internal Medicine, Jikei Univ School of Medicine, Tokyo, Japan.*

Background: Encapsulating peritoneal sclerosis (EPS) is caused by a visceral peritoneal lesion, i.e., intestinal tract adhesion and encapsulation, it is important to evaluate changes in the visceral peritoneum. It has been reported that there was a decreasing trend of peritoneal injury with the use of PD solution with neutral pH as compared with acidic pH in the histopathological evaluation of the parietal peritoneum; however, there is no report evaluating changes in the visceral peritoneum, which is essentially important and should be evaluated. We previously reported laparoscopic approach for evaluation of EPS (KI 2012) in patients treated with PD solution with acidic pH. In this study, we examined macroscopic findings of the visceral peritoneum in patients treated with neutral pH solution alone for 4 years or more by laparoscopy.

Methods: 19 patients underwent laparoscopy at the time of PD catheter removal. Duration of PD in these patients was 64.5±18.8 months. Clinically, none of these patients had developed EPS by the time of the investigation. The findings of both parietal and visceral peritoneal tissues were categorized according to color changes, presence of neovascularizations and adhesions.

Results: It was found that longer the duration of PD, the worse the peritoneal injury. Although changes in the parietal and visceral peritoneum had heterogeneous distributions, the changes in the visceral peritoneum were milder, showing a discrepancy with the findings of the parietal peritoneum. As compared with laparoscopic findings in patients treated with PD solution with acidic pH, the degrees of color changes, presence of neovascularizations, and adhesions were all mild, however, severe adhesions were noted in patients with a history of PD peritonitis.

Conclusions: Although changes in the visceral peritoneum resulting from the use of PD solution with neutral pH show a decreasing trend as compared with acidic pH, there is a certain level of peritoneal change, suggesting the possibility of progression of peritoneal deterioration by long-term continuous use.

TH-PO1002

***"Composite"* Encapsulating Peritoneal Sclerosis: A New Presentation in a Long Time of Renal Replacement Therapy**
Valerio Vizzardi. *O.U. of Nephrology, Spedali Civili and Univ of Brescia, Brescia, Italy.*

Background: Encapsulating peritoneal sclerosis (EPS) is the more dangerous complication of peritoneal dialysis (PD). The EPS can occur during PD (classic EPS), after kidney transplantation (TX) or rapid shift to hemodialysis (HD) as the mode of renal replacement therapies (RRTs).

Methods: single-center retrospective analysis of PD transplanted patients in 35 years. Evaluation of the characteristics of the EPS presentation.

Results: From July 1979 to December 2014, 173 PD patients underwent kidney transplantation (TX). Were diagnosed 5 cases (2.9%) of EPS: one after 6 months from the TX (typical posttransplant EPS), but the other 4 cases have occurred after more than 20 years of different renal replacement therapy (medium 346±20 months, range 327-366) and at least a long time of TX (medium 227±24 months, range 207-259), also after many years of cessation from the last period in PD. The medium time in PD was 71±31 months (range 36-99). Two patients died after 10 and 41 months after diagnosis, respectively after 332 and 367 months in RRT. In our center during the same period other 21 EPS cases (2.8%) are occurred among the 747 PD patients never transplanted. No cases of EPS was manifested after direct transfer from PD to HD.

Conclusions: in our experience EPS prevalence in transplanted PD patients is not greater than not transplanted PD patients. In patients for many years in RRTs, EPS occurs even after a long time of the cessation of DP, especially after many treatments and long periods in TX. It is possible that the PD is acting only as a side event on the tissues affected by fibrotic processes formed for a long time in RRTs and/or due to the immunosuppressive therapy. To its features this form can be defined "*composite EPS*" and should also be considered in PD patients transplanted since many years.

TH-PO1003

Delta Neutrophil Index Is a Predictive Marker of Catheter Removal in Peritoneal Dialysis Patients with Peritonitis Jae Eun Um,[1] Sul A Lee,[2] Shin-Wook Kang.[1,2] *[1]Severance Biomedical Science Inst, Brain Korea 21 PLUS, Yonsei Univ College of Medicine, Seoul, Korea; [2]Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea.*

Background: Severe and prolonged peritonitis leads to peritoneal membrane failure and is the most common cause of technique failure in patients treated with peritoneal dialysis (PD). Recent studies reported that delta neutrophil index (DNI), which reflects the fraction of circulating immature granulocytes in the blood, is a practical severity marker of infection. This study investigated whether DNI could be a predictive marker of catheter removal in PD patients with peritonitis.

Methods: Patients treated with PD peritonitis at Severance Hospital between January 2012 and January 2015 were enrolled. Demographic data, clinical, and laboratory parameters including DNI were collected at the time of peritonitis. DNI was calculated by automatic analyzer.

Results: A total of 125 PD peritonitis episodes in 92 patients were investigated. The mean age was 59.1±12.0 years and 55 (44.0%) were male. PD catheter was removed in 31 (24.6%) patients. The median value of DNI in patients undergone PD catheter removal was significantly higher compared to that of patients who maintained PD catheters [DNI (interquartile range), 3.30 (0.0-65.0) vs. 0.70 (0.0-22.5), P=0.001]. DNI is significantly associated with percentage of segmented neutrophil (r=0.28) and serum albumin (r=-0.32), and dialysate leukocyte counts (r=0.20), but not with C-reactive protein (CRP) levels (r=0.08). Multivariate logistic regression analysis revealed that DNI was an independent predictor for PD catheter removal in patients with PD peritonitis (odds ratio=1.08, 95% confidence interval=1.01-1.12, P=0.04) after adjustment for serum albumin, CRP, leukocyte count of dialysis effluent, and septic shock. The area under the ROC curve (AUC) of DNI for PD catheter removal was 0.69 (P=0.001), whereas the AUC of dialysate leukocyte count was not statistically significant (0.52, P=0.70).

Conclusions: DNI levels reflected the severity of PD peritonitis. Higher levels of DNI could be an independent predictor for PD catheter removal in patients with PD peritonitis.

TH-PO1004

Peritonitis Rates Among African Americans and Caucasians Undergoing Peritoneal Dialysis Aceela Muqri, Russell Griffin, Eric L. Wallace. *Univ of Alabama at Birmingham.*

Background: African Americans (AA) are under-represented in the prevalent peritoneal dialysis (PD) population in the United States. There is relatively little conclusive data to explain the cause of this. One explanation is that AA may have higher rates of peritonitis than Caucasians leading to increased technique failure. This study aimed to determine if differences between AA and Non-AA rates of peritonitis at the University of Alabama at Birmingham Home Dialysis existed.

Methods: This is a single center retrospective cohort analysis on data from November 2012 to November 2014. Baseline demographics as well as data on peritonitis episodes were analyzed. Peritonitis rate was defined as the absolute number of distinct peritonitis episodes divided by the number of patient months at risk. Relapsing peritonitis episodes were excluded. Chi-square analysis was used to compare baseline categorical variables and independent t test to compare length of time on dialysis. Rates of peritonitis were analyzed with Fischer exact test. Peritonitis free survival, hospitalization free survival and technique failure were analyzed by log rank comparison of Kaplan Meier curves.

Results: Between 2012 and 2014, 90 AA and 70 non-AA were treated at the UAB home dialysis units. Baseline demographics between the two groups were similar in Gender and cause of ESRD (p >0.2 in all causes ESRD). Non-AA were older than AA with an average age of 58 vs 50 respectively (p= 0.003). Average time on dialysis were similar (p =0.27) AA had an 82% increased rate of peritonitis over the time period (RR 1.82, 95% CI 0.99-3.37). This association no longer remained after adjustment for age at time of PD start (RR 1.66, 95% CI 0.89-3.10). There was no interaction with age and race in regards to the rate of peritonitis infection rate (p=0.4637). Technique survival was not different between AA and Caucasians. (p 0.44).

Conclusions: AA when compared to non-AA, trended towards a higher risk of peritonitis than Caucasians. Despite this, technique survival between races did not differ. This study does not support the hypothesis that the underlying cause of decreased prevalent AA PD patients is due to increased technique failure from disproportionate peritonitis rates.

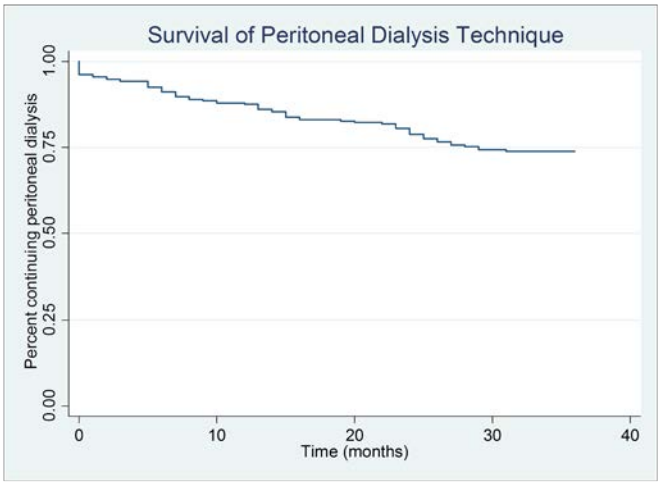
TH-PO1005

Factors Associated with Peritoneal Dialysis Technique Failure: A Single Center Study Anoop Sheshadri, Ramesh Saxena. *Dept of Nephrology, UTSW Medical Center, Dallas, TX.*

Background: To review peritoneal dialysis (PD) technique survival and assess factors associated with PD technique failure at our center.

Methods: We performed a retrospective analysis of 315 patients with PD catheters placed between 01/2001 and 09/2009, reviewing medical records for demographic and clinical information. Primary outcome was PD technique failure, defined as permanent discontinuation of PD due to infectious or non-infectious complications, inadequate dialysis, or miscellaneous factors such as pain. Patients were followed at least 36 months after PD initiation. Survival analysis was performed using Kaplan-Meier methods. Covariates influencing survival were analyzed using Cox proportional hazards regression models.

Results:



There were a total of 70 failures, 31 (44.3%) related to infectious complications, 22 (31.4 %) to non-infectious complications (e.g. obstruction, leaks), 8 (11.4%) to inadequate dialysis, and 9 (12.9 %) to miscellaneous factors. Overall survival at 36 months was 78.81%. Covariates significantly affecting technique failure include prior HD (1.83; 1.14–2.92), non-infectious complications (1.82; 1.28–2.59), DM (1.62; 1.00–2.63), HIV (2.52; 1.01–6.24), peritonitis (1.94; 1.20–3.12), and exit site infections (1.79; 1.09–2.92). Previous abdominal surgeries (.90; .758–1.08) and BMI (1.005; .971–1.04) were not significantly associated with failure.

Conclusions: This is one of the largest single center studies of its type from a US PD program. It shows excellent 3 year PD technique survival, better than reported in similar studies. Our results confirm that diabetes mellitus, PD related infections, and non-infectious mechanical problems are independent risk factors for PD technique failure. Conversely, BMI, abdominal surgeries, and demographic characteristics such as race and gender do not have significant association and should not be considered barriers to PD initiation.

Effect of Early Peritonitis on Clinical Outcomes Kristin M. Corapi,[1] Julia Beth Wenger,[1] Jeffrey Perl,[2] Sharon Nessim,[3] Ishir Bhan,[1] Joanne M. Bargman.[4] *[1]Nephrology, Massachusetts General Hospital, Boston, MA; [2]Nephrology, St. Michael's Hospital, Toronto, ON, Canada; [3]Nephrology, Jewish General Hospital, McGill Univ, Montreal, QC, Canada; [4]Nephrology, Toronto General Hospital, Toronto, ON, Canada.*

Background: Infection is a source of significant morbidity and mortality for peritoneal dialysis (PD) patients. Previous studies suggest that early peritonitis is associated with shorter technique survival; however these studies are limited by small samples, restricted generalizabilty, and a lack of standardized definitions. We used data from a large dialysis database to determine if the timing of the first peritonitis episode is associated with adverse clinical outcomes.

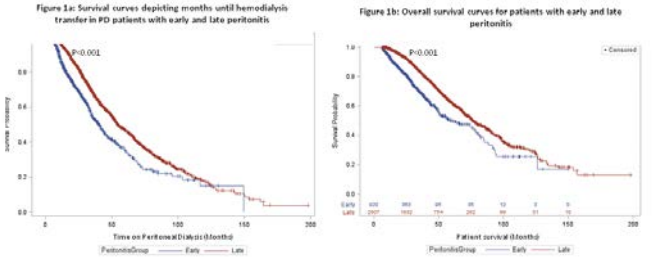
Methods: US and Canadian data from 1996 to 2005 in the Baxter POET (Peritonitis, Organism, Exit sites, Tunnel infections) database was analyzed. Patients who developed peritonitis within 6 months of PD initiation were identified as cases. Controls were patients whose first peritonitis occurred after 6 months. Patients who never developed peritonitis or who were on PD for less than 6 months were excluded. Patients were censored at the time of transplant, transfer to hemodialysis, or death.

Results: 920 cases and 2607 controls were identified.

	Early (n=920)	Late (n=2607)	p value
Age (years)†	57	58	0.7
% Male	54	46	0.6
% on CAPD	66	71	0.006
% with diabetes	47	40	<0.001
% New to PD % Transfer from HD % Other *	50 26 24	49 25 26	0.5

Presented as %, †= mean, * failed transplant or moved from another unit

Patients with early peritonitis had a significantly higher peritonitis rate than controls (1.26 and 0.67 episodes/patient year, p<0.001). Early peritonitis was also associated with shorter technique and patient survival.



Conclusions: Our results suggest that patients with early peritonitis are at increased risk of adverse clinical outcomes such as future infection, technique failure, and death.

TH-PO1007

Underweight Predicts Technical Failure: A Retrospective Cohort Study of Incident Peritoneal Dialysis Patients Xiaoyan Huang, Xiuqin Zeng, Qing Wang, Zibo Xiong, Yumei Liao, Zuying Xiong. *Div. of Nephrology, Peking Univ Shenzhen Hospital, Shenzhen, Guangdong, China.*

Background: Technical failure is more common in peritoneal dialysis (PD) than in hemodialysis. High body mass index (BMI) increases mortality in the general population, but it may improve survival in hemodialysis patients. In PD patients, yet, reports regarding the association of BMI with technical survival are scarce and remain controversial.

Methods: In this retrospective cohort study, 348 incident PD patients (aged 48.2 ± 15.5 years, 62% men) at Peking University Shenzhen Hospital from 2000 to 2014 were included. BMI was calculated with height and weight first recorded within 2 to 6 months after initiation of PD. Patients were categorized according to the World Health Organization recommendation for Asians. All patients were followed until October 31, 2014. Primary outcome was technical failure, defined as death or permanently transferred to hemodialysis. Secondary outcomes included all-cause mortality, cardiovascular and cerebrovascular mortality, occurrence of coronary heart disease and stroke, and incidence of peritonitis. Data were analyzed using Cox proportional hazards models.

Results: BMI in this cohort was 22.1 ± 3.0 kg/m^2. During 2.5 (interquartile range: 1.0-4.0) years, 60 cases of technical failure occurred. Incidence of technical failure was higher in patients with low BMI (13.4/100 person-years) than those with normal BMI (5.2/100 person-years) and with high BMI (6.3/100 person-years). After adjustment of age, sex, education, primary disease, and heart failure, hazard ratios (95% confidence intervals) were 3.60 (1.53, 8.45) and 0.93 (0.49, 1.76) for patients with low and high BMI, respectively, as compared to those with normal BMI. Similarly, the low BMI group had significantly higher rates of total as well as cardiovascular and cerebrovascular mortality than the normal BMI group, but such relationships did not exist in the high BMI group. No associations of BMI with occurrence of coronary heart disease and stroke and incidence of peritonitis were observed.

Conclusions: In incident PD patients, low BMI is associated with technical failure, all-cause mortality, and cardiovascular and cerebrovascular mortality.

Funding: Government Support - Non-U.S.

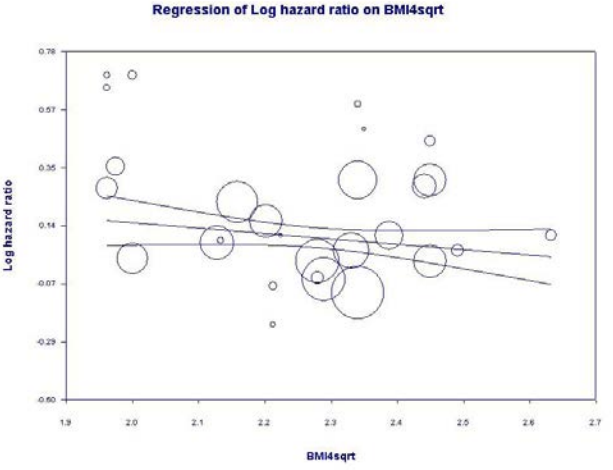
TH-PO1008

The Association Between Body Mass Index and Mortality in Peritoneal Dialysis Patients Jin Ho Hwang,[1] Geun joo Choi,[2] Hyun Kang,[2] Su Hyun Kim.[1] *[1]Internal Medicine, Chung-Ang Univ Hospital, Seoul, Republic of Korea; [2]Anesthesiology and Pain Medicine, Chung-Ang Univ Hospital, Seoul, Republic of Korea.*

Background: Unlike the general population, a higher body mass index (BMI) was consistently found to be a strong predictor of decreased mortality in patients with end-stage renal disease who receive maintenance hemodialysis (HD). This phenomenon has been referred to as the "Obesity paradox" or "reverse epidemiology". Similar tendency has been observed in several studies with peritoneal dialysis (PD) patients, but the studies have reported conflicting results. We conducted this study to evaluate the association between BMI and all-cause mortality in PD patients.

Methods: A systematic search was conducted for published studies in Medline, EMBASE, and the Cochrane library databases from 1970 to April 2015. We identified studies evaluating the impact of BMI on mortality among PD patients. Data of hazard ratios and 95% confidence intervals (CIs) were obtained for respective BMI groups provided by each study. We performed meta-regression analysis using unrestricted maximum likelihood model.

Results: The Medline, EMBASE, and the Cochrane library search provided a total of 3,047 articles. After screening of all titles, 513 abstracts were selected. Finally, 9 cohort studies with 33,090 patients were included in the final analysis. Log hazard ratio for all-cause mortality showed a trend negatively associated with increasing four square root of BMI (slope coefficient: -0.1976, 95% CI -0.4110 to 0.0158, p= 0.0695).



Conclusions: In PD patients, BMI was inversely associated with mortality as in HD patients. Other outcomes such as cardiovascular death, peritonitis incidence, and technical failure will be additionally evaluated.

TH-PO1009

Is Obesity a Poor Prognostic Factor in Incident Peritoneal Dialysis Patients? Hyunjeong Cho,[1] Hyo Jin Kim,[1] Miseon Park,[2] Dong Ki Kim,[1] Kwon Wook Joo,[1] Yon Su Kim,[1] Curie Ahn,[1] Kook-Hwan Oh.[1] *[1]Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea; [2]Clinical Research Inst, Seoul National Univ Hospital, Seoul, Korea.*

Background: Obesity is associated with an increased risk of death in the general population. Previous studies have demonstrated a discrepancy in the impact of body mass index (BMI) on mortality among peritoneal dialysis (PD) patients. We examined the effect of BMI on patient and technique survival in a prospective, incident PD cohort at a single center.

Methods: Subjects who started PD between 2000 and 2012 were enrolled in the study. Demographic and laboratory data were prospectively collected. Patients were categorized into four BMI groups: obese, ³25 kg/m^2; overweight, 23 –24.9 kg/m^2; normal, 18.5 –22.9 kg/m^2 (reference category); and underweight, <18.5 kg/m^2. Patient and technique survival were compared using Cox proportional hazards model.

Results: A total of 632 incident PD patients were included in final analysis. The median follow-up period was 40 months (interquartile range, 19–64 months). In Kaplan–Meier survival curve, patient survival was not statistically different among all BMI categories (p = 0.641, by log-rank test). The hazard ratio (HR) adjusted for age, sex, diabetes, comorbidities, albumin, hemoglobin for patient survival was not significant among BMI groups (p = 0.837). In contrast, technique survival was significantly poorer in obese patients than in patients having a normal BMI (p = 0.029, by log-rank test). The HR for technique failure was significantly greater for obese PD patients in comparison with the reference category [1.8; 95% confidence interval (CI): 1.2 to 2.8; p = 0.008]. The reasons for technique failure included recurrent peritonitis (34%), inadequate dialysis (17%), mechanical problem (17%) and refractory exit-site/tunnel infection (11%) in obese patients.

Conclusions: In our PD patients, patient survival was similar in all BMI categories. Therefore, obese patients should not be discouraged from receiving PD purely on the basis of BMI. However, technique survival was significantly poorer for obese PD patients. Further study is warranted to improve technique survival in obese patients.

TH-PO1010

Phosphate Clearance in Peritoneal Dialysis: Residual Renal Function and Dialysis Modality Carmen Gonzalez corvillo, Mariangeles Rodriguez Perez, Alejandro A. Suarez benjumea, Nuria Areste, Mercedes Salgueira lazo. *Nephrology, Virgen Macarena-Rocio, Sevilla, Spain.*

Background: Evaluate urinary and peritoneal excretion of phosphate and related factors in peritoneal dialysis(PD).Analyze phosphate clearance depending on PD modality and peritoneal membrane type.

Methods: Observational study,in a sample of 37PD patients.Mean age:60±14years.24 patients on APD(16CCPD,8NIPD)13 on CAPD.Mean Kt/V:2.64±0.6.Mean residual renal function(RRF)6.3±4.4ml/min.Transmembranous peritoneal transport:6high(H),26high-average(HA)and 5low-average(LA).Renal and peritoneal phosphate clearance(ultrafiltration(UF)and diffusion(D))was analyzed.Urinary and dialysate P/Cr.Weekly peritoneal P clearance(WPCl).Serum P.PTH.Use and dosage of phosphate binders and vitaminD analogs.

Results: Mean total P clearance:460±192mg/d.Mean renal P clearance:286±201mg/d and mean peritoneal P clearance:211±88mg/d.Mean P clearance through UF:22±15mg/d(9%) and by D 194±85mg/24h(91%).Mean urinary and dialysate P/Cr were0.4±0.15 and 0.59±0.24.Mean WPCl:31.4±13.1L/week.Mean serum P:4.9±1mg/dl and PTH294±166pg/ml.86%of patients were on Sevelamer and 22%calcium based binders.43%were on vita minD(55%calcitriol,45%paricalcitol).Positive correlation between peritoneal P clearance and UF(r=0.45 p=0.004)as well as between RRF and renal P elimination(r=0.83 p<0.001) was observed.WPCl was higher in patients on CAPD than on APD(39,4±7 vs 27.1±13l/week p<0.05)being the main difference patients subjected to continuous vs discontinuous modality(CAPD39.4±7 vs CCPD 31.4±12 vs NIPD 18.4±12 l/weekp<0.001).Regarding to the membrane,WPCl was higher in H patients vs. HA and LA.(46.5±6 vs 28.7±12 vs 27.1±12l/week p<0.05).Negative correlation was detected between WPCl and serum P(r=-0.51p=0.001).Positive correlation was noted between WPCl and P clearance by D(r=0.87p<0.001).

Conclusions: A substantial percentage of daily P elimination took place through urinary excretion,that is why preservation of RRF is crucial.There is a correlation between peritoneal clearance and increase of UF.P removal is higher on continuous modalities,CAPD shows better results.H patients would have better P clearance.Therefore,D would be the main mechanism of P peritoneal elimination,aided by long dwell time.

TH-PO1011

Proteinuria at PD Initiation May Predict Residual Renal Function Loss in the Automated Peritoneal Dialysis Patients Using Biocompatible Solution

Yoshifumi Hamasaki,[1] Kent Doi,[2] Rei Isshiki,[1] Haruki Kume,[3] Masaomi Nangaku,[1] Eisei Noiri.[1] *[1]Nephrology and Endocrinology, The Univ of Tokyo, Tokyo, Japan; [2]Emergency and Critical Care Medicine, The Univ of Tokyo, Tokyo, Japan; [3]Urology, The Univ of Tokyo, Tokyo, Japan.*

Background: Residual renal function (RRF) has a significant impact on the prognosis of dialysis patients. Peritoneal dialysis (PD), especially using biocompatible PD solution (BPDS) with neutral-pH and reduced glucose degradation products, has advantageous to preserve RRF (Kidney Int., 2013). It is still unclear what factors predict RRF loss in the PD patients using BPDS. We investigated the relationship between clinical parameters at PD initiation and the change of RRF in the PD patients using BPDS.

Methods: The data from patients who started PD as their first dialysis modality from 2001 to 2014 at The University of Tokyo Hospital were collected retrospectively. All patients were treated by automated PD (APD) using BPDS. To identify predictors of RRF decline, we analyzed data including clinical parameters measured at PD initiation. Residual GFR was calculated as the average of 24-hour urinary urea and creatinine clearances. The rates of urine volume and residual GFR decline were calculated by the least squares linear regression formula. The outcome of dialysis modality change was defined as switching APD to hemodialysis (HD) or combined therapy of PD and HD due to RRF loss.

Results: 96 patients were analyzed in this study. On multiple regression analysis, the decline rates of urine volume and residual GFR were significantly correlated with proteinuria at PD initiation. When patients were divided into two groups according to urinary protein level, Kaplan-Meier analysis revealed the lower proteinuria group had higher persistence rate of APD and lower rate of dialysis modality change (Log rank; p = 0.001 and 0.004, respectively). On ROC analysis, urinary protein predicted the need of dialysis modality change within 2 years after PD initiation with statistical significance (AUC [95%CI] =0.78 [0.66-0.90]).

Conclusions: Proteinuria at PD initiation may predict RRF loss and the need of dialysis modality change in the APD patients using BPDS.

TH-PO1012

Urgent Start versus Traditional Start Peritoneal Dialysis: Does Race Influence Outcomes?

Vinay Narasimha Krishna, Manish K. Saha, Leslie J. Jackson, Gaurav Jain, Eric L. Wallace. *Univ of Alabama at Birmingham.*

Background: Although urgent start (US) peritoneal dialysis (PD) and traditional start (TS) PD have similar outcomes, it is not known if differences in outcomes exist based on race. The objective of this study was to determine if differences in PD outcomes exist when stratified based on race and type of PD start.

Methods: Retrospective data from an electronic database on incident PD patients collected between November 2012 and March 2015 was analyzed. Patients were analyzed by US vs TS and then stratified into 4 groups: African American (AA) TS, Non-AA TS, AA US and Non-AA US. Chi-square analysis was used to compare categorical variables, while ANOVA was used to compare means across groups. Exact mid-p was used to compare rates of hospitalization, peritonitis and catheter revisions. Survival curves were used to evaluate the probability of hospital free, peritonitis free, and technique survival. Patients were censored in the technique survival analysis for death or transplant.

Results: 114 patients were started on PD during the study period, 33 of which were US. When comparing US to TS, patients were matched for age, gender, and average days on study (All p values >0.05). No significant differences were observed in rates of peritonitis, timing of peritonitis, technique failure, catheter revision or hospitalization rates between TS and US groups. Sub-group analysis based on race stratification showed that age at PD start was younger in AA TS vs Non AA TS (50±13 vs 60±14 years respectively, p=0.003). AA TS patients were 60% more likely to have technique failure than Non-AA US (p=0.03). Non-AA US patients were more likely to be free of hospitalizations than AA TS (p 0.03). Peritonitis rates for AA TS, Non-AA TS, AA US, and non-AA US were 0.3, 0.14, 0.33, 0.36 per patient year respectively; catheter revision rates were 0.49, 0.3, 0.42 and 0.3 per patient year respectively with no significant difference among the subgroups.

Conclusions: There were no significant differences in outcomes among TS and US groups. Sub-group analysis showed that non-AA US patients have the least technique failure and hospitalization rates while AA TS have the worst technique failure and hospitalization rates.

TH-PO1013

Reasons for Dialysis Modality Changes in an Integrated Healthcare System

Leonid Pravoverov, Sijie Zheng, Joanna Mroz. *The Permanente Medical Group, Oakland, CA.*

Background: In-center HD and PD are the 2 most common types of dialysis utilized in US. Few studies have examined characteristics of patients who changed dialysis modality. Kaiser Permanente Northern California is an integrated health care delivery system with 3.7 million members. We retrospectively examined the characteristics and disease burden of patients who switched from modalities.

Methods: Retrospective examination of EMR from Jan 2009 – Oct 2014. Disease burden was assessed by internally developed comorbidity point score, which predicts negative outcomes in the next 12 months, based on documented comorbidities and hospitalizations.

Results: From 2010-2014, dialysis population in our integrated health system increased from 4005 to 4491 patients, and PD population grow from 621 to 1033. In this period, 11% of patients who initiated dialysis switched modality. Majority of modality changes occurred within a year after dialysis initiation. 8% of HD patients switched to PD and 24% of PD patients switched to HD. Majority of patients who switched from **HD to PD** do so within 6 months of initiation. They have **less** comorbidities than those who stay on HD. They have a higher comorbidity score when they switch to PD but lower than repeated score of those who switched from PD to HD. They were younger than those remained on HD. Most patients who switched from **PD to HD** did so within a year. They have **more** comorbidities than those who stay on PD and have a higher comorbidity score when they switch to HD, even higher than the repeat score of those who switch from HD to PD. The difference in co-morbidity scores between the first and second measurement is higher for the PD to HD pattern. They have similar age to those who didn't switch.

Conclusions: Patients who switched from HD to PD remain at approximately the same comorbidity score before and after switch. Comorbidity scores of patients who switched from PD to HD significantly increased, suggesting that change was influenced by decline in their overall condition. In our patient population, the switch from HD to PD is likely a patient's decision, while the switch from PD to HD may be due to inability to continue PD.

TH-PO1014

Impact of Pre-Dialysis Immunosuppressive Treatment Time on Infectious Complications and Survival of Systemic Lupus Erythematosus (SLE) Patients on Peritoneal Dialysis

Junbao Shi,[1,2] Joanne M. Bargman.[2] *[1]Dept of Nephrology, Peking Univ Third Hospital, Beijing, China; [2]Div of Nephrology, Univ Health Network, Toronto General Hospital, Toronto, ON, Canada.*

Background: SLE patients on peritoneal dialysis (PD) have a significant risk of infectious complications and poor outcomes.However, few studies have examined the relationship between pre-dialysis exposure to immunosuppressive (IS)therapy and the outcome on dialysis. The objective of this study was to investigate whether pre-dialysis IS treatment time influences the infectious complications and outcomes of SLE patients on PD.

Methods: Twenty-six SLE patients were treated with PD in a major academic centre from May 1996 to May 2014. Demographics, diagnostic tests and IS treatment, comorbid illnesses, biochemistry and clinical data upon initiation of PD and lupus activity, infective complications, hospitalizations and clinical outcomes during the study period were collected. Three years was chosen as the discriminant between longer and shorter duration of IS therapy.

Results: Two patients were lost to follow-up during the study period. Therefore, a total 24 patients were included for analysis.The SLE patients with longer duration of pre-dialysis IS (n=17) were older than patients with shorter pre-dialysis IS(n=7)(38.6±11.0 vs 27.1±7.8, P<0.05), but there were no significant differences in sex, race, PD duration, PD sub-modality and biochemistry between the two groups(P>0.05).Seven patients died during the follow-up period and all the deaths were from the group with longerpre-dialysis IS time (P<0.05). Three patients died from infections, two patients from cardiovascular disease, and two had sudden death at home. However, there were no significant differences in the incidence of peritonitis, exit site infection, other infections, or hospitalizations.

Conclusions: SLE patients undergoing PD with longer pre-dialysis exposure to IS drugs have a greater mortality that appears to be related to both infectious and noninfectious causes. Although incident to PD, they should be considered a high-risk subgroup.

TH-PO1015

Predicting Peritoneal Dialysis Prescriptions with a Fast Peritoneal Equilibration Test Using PD Adequest

J. Ken Leypoldt,[1] Baris U. Agar,[2] James A. Sloand,[1] Mary Gellens.[1] *[1]Medical Products (Renal), Baxter Healthcare Corporation, Deerfield, IL; [2]Medical Products (R&D), Baxter Healthcare Corporation, Round Lake, IL.*

Background: The fast peritoneal equilibration test (PET) is often used to determine peritoneal membrane transport status, but its accuracy in predicting parameters of peritoneal dialysis (PD) therapy adequacy using computer software, like PD Adequest, has not been quantified. In the current study, the ability of a new version of PD Adequest was

examined to 1) compare mass transfer-area coefficients (MTACs) for urea, creatinine and glucose during fast and standard PETs and 2) use those parameters to predict PD therapy prescription adequacy.

Methods: Data from 104 PD (41 CAPD, 63 APD) patients who underwent a 4-hour standard PET and an overnight exchange with the same glucose concentration were used to determine fluid and solute transport parameters. Calculated MTAC values for standard PET were compared with those for fast PET by using only data obtained at 4-hours during the standard PET and assuming a 200 mL residual volume in the prior exchange. The calculated membrane parameters were used to predict net ultrafiltration (UF), urea Kt/V and creatinine clearance (CrCl), and those predictions of therapy adequacy were also compared with the mean of 3 actual measurements of net UF, Kt/V and CrCl for each patient.

Results: Median urea, creatinine and glucose MTACs were 20.9, 10.1, and 9.1 mL/min during standard PET, and 21.0, 10.1 and 9.0 mL/min during fast PET; the corresponding median absolute difference between MTACs for urea, creatinine and glucose were 0.6, 0.3 and 0.6 mL/min. Comparing predictions using standard and fast PETs, 81% of net UF were within 150 mL, 94% of Kt/V were within 0.1/wk and 93% of CrCl were within 2 L/wk/1.73m^2. The percent of predicted and actual measured values of net UF within 300 mL, Kt/V within 0.2/wk and CrCl within 8 L/wk/1.73m^2 were 44%, 63% and 77% for standard PET and 38%, 64% and 77% using fast PET; these differences were not statistically significant.

Conclusions: These results suggest that the predictions of PD therapy adequacy using PD Adequest are clinically equivalent when either fast or standard PET is employed.

TH-PO1016

The Loss of Residual Diuresis Increases in Eryptosis in PD Patients Grazia Maria Virzì, Carla Estremadoyro, Sabrina Milan manani, Alessandra Brocca, Massimo de Cal, Ilaria Tantillo, Carlo Crepaldi, Claudio Ronco. *Nephrology-IRRIV.*

Background: Anemia in ESRD is attributed to impaired erythrocyte formation due to erythropoietin and iron deficiency. The accelerated clearance of erythrocytes may at least partially be due to enhanced eryptosis, a suicidal death of erythrocytes characterized by cell shrinkage and cell membrane scrambling with phosphatidylserine(PS)-externalization at the erythrocyte (RBC) surface. Exposed PS is recognized by macrophages that engulf and degrade the affected cells.Little is known about mechanisms underlying enhanced eryptosis in ESRD. At least in theory, eryptosis may be stimulated by some uremic toxins. The present study investigated eryptosis in peritoneal dialysis (PD) patients.

Methods: 46 PD patients (31 M, mean age:64±14yrs) and 17healthy subjects (CTR) were enrolled. All measurements were made in isoalted RBCs. PS exposure was estimated from FITC-AnnexinV binding by flow cytometric.

Results: 27 patients were treated with CAPD and 19 with APD. The mean length of treatment was 39±29months. The PS externalization on surface was significantly higher in PD patients than in CTR (2.6%; IQR 1.6-3.7 versus 0.8%; IQR 0.7-1.3 p<0.01). The median percentage of eryptosis showed no significant differences between patients with(n=18) and without diabetes, treated with CAPD or APD and with a negative or positive (n=18) history of peritonitis. Eryptosis showed significantly lower levels in PD patients with residual diuresis (n=23) than in patients without (3.7%, 2.6-5.6 versus 5%, 3.1-16; p=0.03). A significant negative correlation was observed between percentage of eryptosis and Body Composition Monitor-BCM for hydratation status (Spearman's rho=- 0.4, p<0.05). There was no a statistically significant relationship between eryptosis and months of PD, urea, albumin and creatinine levels.

Conclusions: In conclusion, eryptosis has been shown to be significantly higher in PD patients than CTR. Our data suggest that the type and the lengthof PD treatment do not enhance eryptosis. On the contrary, the loss of residual diuresis lead to a significant increase in eryptosis:the residual diuresis may contribute to the elimination of potential uremic toxins that induce increased eryptosis.

TH-PO1017

The Pattern of T Helper Lymphocytes Has No Clinical Implications in Peritoneal Dialysis Patients Gyu Tae Shin, Seirhan Kim, Inwhee Park, Heungsoo Kim. *Dept of Nephrology, Ajou Univ School of Medicine, Suwon, Kyunggi, Korea.*

Background: It has been reported that the imbalance between type-1 T helper lymphocytes (Th1) and type-2 T helper lymphocytes (Th2) exist in uremic patients. Th1 dominance leads to increased cardiovascular risks and Th2 dominance to allergic diathesis and pruritus. In this study, we investigated the pattern of Th lymphocyte differentiation in peritoneal dialysis (PD) patients.

Methods: Peripheral blood mononuclear cells were isolated from venous blood using Ficoll gradient methods. Isolated lymphocytes were stimulated with ionomycin and phorbol myristic acetate in the presence of brefeldin A, and then stained with CD3-, CD8 surface markers, interferon-gamma (IFN-gamma) and interleukin-4 (IL-4) for flow cytometry analysis. CD3-positive/CD8-negative cells were assumed as CD4-positive Th lymphocytes.

Results: We recruited 23 PD patients and 10 healthy controls. Th lymphocytes accounted for 68.9% of total T lymphocytes in PD patients and 72.9% in controls (p=non-significant). IFN-gamma positive T lymphocytes (Th1) accounted for 15.8% of Th lymphocytes in PD patients and 15.3% in controls (p=non-significant). IL-4 positive T ymphocytes (Th2) accounted for 2.6% in PD patients and 2.8% in controls (p= non-significant). The percentage of Th1 or Th2 lymphocytes did not correlate with any of the demographic and laboratory findings including diabetes, PD vintage, PD regimens, Kt/V, left ventricular ejection fractions, serum chemistries and hematologic values. The patients who suffered from cardiovascular diseases (n=6) showed a similar percentage of Th1 and Th2 lymphocytes compared with those who did not (n=17). The patients who had significant pruritus requiring medications (n=11) showed a similar percentage of Th1 and Th2 lymphocytes compared with those who did not (n=12).

Conclusions: The pattern of Th lymphocyte differentiation was similar between PD patients and healthy people, and it did not have an association with clinical findings in PD patients.

TH-PO1018

Hemostatic Profile of Patients on Automated Peritoneal Dialysis by Thromboelastography Thalita Moura Braga, Erica Adelina Guimarães, Rodrigo Souza Adao, Rosilene M. Elias, Hugo Abensur. *Nephrology, Univ de São Paulo, São Paulo, Brazil.*

Background: It's believed that hypoalbuminemia induces hemostatic disorders in peritoneal dialysis (PD) patients. Beside to this the lipid profile may also contributes to atherogenicity. Thromboelastography (TEG®) is a skilled and snapshot method that provides a global hemostasis evaluation. We objective to investigate whether TEG profile of patients in automated PD (APD) reflects the coagulation factors abnormalities and it is influenced by peritoneal transport of small solutes, macromolecules, and lipid profile.

Methods: A cross-sectional study included 15 patients (5 men) with age 43±18 years on APD for 26±15 months. Serum, effluent peritoneal fluid, and urinary values of: urea, creatinine, albumin, and total protein were obtained. Kt/V, ultrafiltration (UF), complete lipid profile, serum coagulation factors, and TEG were also performed.

Results: The TEG revealed that 7 patients were hypercoagulant according to coagulation indices (IC) (2.9±0.6, normal range-NR:-3 to 3) and 14 patients presented high maximum amplitude (MA) (68.1±4.2 mm, NR:27 to 49 mm), that reflects fibrin strength and platelet aggregation. Hypercoagulant patients presented UF less than normal patients (926±499 vs. 1896±750 ml, p=0.01). Accordingly, MA and IC correlated negatively with UF (r=-0.545, p=0.04 and r=-0.725, p=0.002, respectively). Factor IX (high in 8 patients) correlated with non-HDL (r=0.639, p=0.02), LDL (r=0.612, p=0.03), and negatively with HDL cholesterol (r=-0.771, p=0.002). D-Dimer (high in 11 patients) correlated with serum urea (r=0.569, p=0.03) and clot elasticity (G) (r=0.589, p=0.03). Unexpectedly, both fibrinogen (high in 12 patients) and D-dimer did not correlate with protein loss. There were no patients with severe hypoalbuminemia in this sample.

Conclusions: The TEG demonstrates an unfavorable hemostatic profile in PD patients characterized by mainly major platelet aggregation, which corresponds to abnormal dosages of clotting factors and degradation products. This panorama did not depend on protein loss and serum albumin. Lipid metabolism alterations, uremia, and low UF can be implicated in this finding.

TH-PO1019

Dialysate Looses of Vitamin 25(OH)D in a Cohort of Patients Treated with Peritoneal Dialysis Juan Carlos Ramirez-Sandoval, Maria Luisa Safar-Boueri, Jorge Jesus Silva, Olynka Vega-Vega, Ricardo Correa-Rotter, Reynerio Fagundo. *National Medical Sciences and Nutrition Inst Salvador Zubiran, Mexico City, Mexico.*

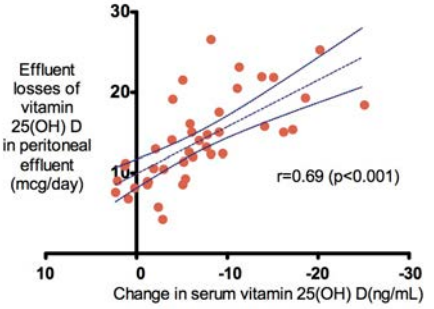
Background: Peritoneal dialysis (PD) is associated with 25(OH)vitamin D deficiency. To our knowledge, there are no cohort studies about 25(OH)vitamin D dialysate looses in PD.Objective: To characterize 25(OH) vitamin D losses in peritoneal effluent (PE) and their relation with changes in serum 25(OH)vitamin D levels during 4 months in a cohort of incident PD patients.

Methods: 52 patients with <6 mths but >1 mth on PD were invited from 2011 to 2014. Those with severe infections, hospitalizations, and oral intake of D3 or D2 during follow up were excluded. Basal vitamin 25(OH) D in 24h PE and serum were measured. After 4 months, a 2nd assessment was performed. The principal outcome was the change in serum vitamin 25(OH) D levels.

Results: 43 patients were included, 22 (51%) men, median age was 39 y (Intercuartile range [IQR] 31-62), 29 (68%) had diabetes and 29 (67%) had some degree of renal residual function during all study. After 4 months of PD initiation, all patients had vitamin 25(OH) D levels <20 ng/mL, 13 of them with levels less than 10 ng/mL.

Characteristics, (n=43) *n(%) or median (IQR)	Initial	After 4 months	p
Serum 25(OH)D, ng/mL	14.2 (10.3-20.2)	8.6 (8-9.3 ng/mL)	<0.001
Peritoneal effluent 25(OH)D, ng/mL losses, mcg/day	13 (9.2-17) *All detectable at this timepoint	10 (6-11) *Not detectable in 35/43	<0.001
PTH, pg/mL	521 (343-845)	590(288-791)	0.6
Ca, mg/dL	9.2 (8.5-9.6)	9.14(8.5-9.5)	0.6
P, mg/dL	4.9 (3.6-6.1)	5.4 (3.8-6.1)	0.3

The mean decrease of vitamin 25(OH)D levels was 5.8 ng/mL/6 months (IQR 2-9.3 ng/mL). Basal PE losses in mcg/day and delta in serum vitamin 25(OH) D had a significant correlation



Conclusions: High effluent losses of vitamin 25(OH) D are observed in patients on PD and may explain very low levels observed during follow up in this cohort.

TH-PO1020

Peritoneal Protein Excretion Was Lower in Nocturnal Intermittent Peritoneal Dialysis as Compared with Continuous Ambulatory Peritoneal Dialysis Not Associated With Peritoneal Transport Status in the Same Individual Hironori Nakamura, Anayama Mariko, Yasushi Makino, Masaki Nagasawa. *Dept of Nephrology, Shinonoi General Hospital, Nagano, Japan.*

Background: Recent studies have reported that peritoneal protein excretion (PPE) during peritoneal dialysis (PD) therapy is associated with cardiac disease and patient survival. However, little is known regarding the extent to which PPE can be influenced by PD prescription or peritoneal transport status.

Methods: The aims of this study were to compare PPE in the same individual with different PD prescriptions of either continuous ambulatory PD (CAPD) or nocturnal intermittent PD (NIPD), and to evaluate the correlation between PPE and dialysate to plasma creatinine ratio (D/P Cr). Seventeen patients, of whom 58.8% were male, were included in the study. A peritoneal equilibrium test was performed and the amount of total protein (TP) loss in the dialysate was measured during CAPD or NIPD therapy in the same patient.

Results: The mean age of the patients was 59.4 ± 18.0 years, body mass index was 21.5 ± 3.4, serum TP (s-TP) was 5.8 ± 0.8 g/dL, serum albumin (s-Alb) was 3.0 ± 0.7 g/dL, C-reactive protein (CRP) was 0.4 ± 0.7 mg/dL, and D/P Cr was 0.76 ± 0.15. During NIPD therapy, PPE was correlated with peritoneal clearance ($\gamma = 0.63$, $p = 0.006$), effluent volume ($\gamma = 0.69$, $p = 0.002$), and PPE to effluent volume ratio ($\gamma = 0.80$, $p = 0.000$), but not with s-TP, s-Alb, CRP, or D/P Cr. During CAPD therapy, PPE was negatively correlated with s-TP ($\gamma = -0.62$, $p = 0.007$) and s-Alb ($\gamma = -0.58$, $p = 0.014$), positively correlated with effluent volume ($\gamma = 0.50$, $p = 0.037$) and PPE to effluent volume ratio ($\gamma = 0.72$, $p = 0.001$), but not with CRP or D/PCr. On comparing NIPD and CAPD, there was no difference in effluent volume (7341 mg vs. 7209 mg, respectively); however, both PPE and PPE to effluent volume ratio were significantly lower during NIPD than during CAPD [5586 mg vs. 7779 mg ($p = 0.004$) and 0.74 mg/mL vs. 1.09 mg/mL ($p = 0.004$), respectively].

Conclusions: The current study demonstrated that PPE and PPE to effluent volume ratio were lower during NIPD than during CAPD in the same individual, independent of the peritoneal transport status.

TH-PO1021

Fungal Peritonitis in the Standardizing Care to Improve Outcomes in Pediatric ESRD (SCOPE) Collaborative Raj P. Munshi,[1] Christine B. Sethna,[3] Sushil Gupta,[2] Samhar I. Al-Akash,[5] John P. Lawlor,[6] Bradley Warady.[4] *[1]Seattle Children's; [2]Kosair Children's Hospital; [3]North Shore-LIJ Medical Group; [4]Childrens Mercey Hospital; [5]Driscoll Childrens Hospital; [6]Children's Hospital Association.*

Background: The SCOPE Collaborative is a multicenter QI initiative with the 1° aim to reduce dialysis catheter associated infections. The objective of this study was to describe the epidemiology of fungal peritonitis (FP) among pediatric patients with an indwelling peritoneal dialysis (PD) catheter enrolled in SCOPE.

Methods: PD characteristics and patient outcome were collected between 10/11-12/14 from 29 centers participating in SCOPE. Data was stratified based on fungal, bacterial/culture-neg peritonitis and no peritonitis. Peritonitis was defined as any episode that was treated for peritonitis. Differences among groups were assessed by chi-square analysis.

Results: Of 880 patients, there were 416 peritonitis episodes of which 37(8.9%) were fungal. 36 individual (median age 28.3 months; 56% male) were responsible for the FP episodes, with 22(59.4%) episodes occurring in patients <2 years of age. 21(56.8%) episodes were preceded by a documented peritonitis episode, with 12(32.4%) of the peritonitis episodes diagnosed within 90 days of the fungal infection. Culture neg (28.6%) and Staph species (23.8%) were the predominant causes of the prior peritoneal infections. Presence of a G-tube (48.3%, p=0.003), vesicostomy (10.3%, p=0.036), upward orientation of the PD catheter exit site (13.3%, p=0.031), and history of touch contamination (10.3%, p=0.027) were more common in children with FP as compared to the other groups. FP resulted in 1(2.9%) death, 33(89.2%) catheter removals, and 29(78.4%) hospitalizations. 1 child (2.9%) had successful treatment of a fungal peritonitis episode while leaving the PD catheter in place.

Conclusions: FP were responsible for 8.9% of peritonitis episodes with the majority of the episodes occurring in children <2 years of age. Additional risk factors included presence of a G-tube, vesicostomy, upward orientation of the exit site and history of touch contamination. The majority of the PD catheters were removed, with a preponderance of patients requiring hospitalization.

TH-PO1022

Relation of Central and Brachial Blood Pressure to Volume Status in Peritoneal Dialysis Patients Yun Jung Oh,[1] Su mi Lee,[2] Ji Yong Jung,[3] So Mi Kim,[4] Chungsik Lee.[1] *[1]Dept of Internal Medicine, Cheju Halla General Hospital, Jeju, Republic of Korea; [2]Dept of Internal Medicine, Dong-A Univ Hospital, Busan, Republic of Korea; [3]Dept of Internal Medicine, Gacheon Univ Gil Hospital, Incheon, Republic of Korea; [4]Dept of Internal Medicine, Jeju Natitonal Univ Hospital, Jeju, Republic of Korea.*

Background: Euvolemia is an important predictor of outcome in peritoneal dialysis (PD), but chronic subclinical volume overload occurs frequently in PD patients. Even though volume overload is associated directly with hypertension, blood pressure (BP) not always reflect volume overload. Central BP has been shown to be a better predictor for target organ damages compared with brachial BP in general population. In this study, we evaluated comparative values of central BP and brachial BP for determining volume status in PD patients.

Methods: We enrolled 52 prevalent PD patients, and accessed volume status using Body Composition Monitor (BCM). Central BP was estimated using radial artery tonometry, and brachial BP measurement at office and 24-hour ambulatory blood pressure monitoring (ABPM) were performed. Volume overload was defined as an overhydration (OH) ³1.1 L.

Results: Average office central systolic BP (cSBP), office brachial systolic BP (bSBP), and ambulatory brachial systolic BP (24-bSBP) were 139.8±26.3, 140.7±19.2, and 142.5±22.0 mmHg, respectively. In overall, 41(78.8%) patients were in volume overload status. A stronger association of central BP with volume overload compared with brachial BP was observed in the receiver operating curve analysis (area under the curve (AUC) of cSBP, bSBP, and 24-bSBP were 0.87±0.06, 0.78±0.09, and 0.83±0.06 respectively). In multivariate analysis adjusted for age, sex, PD vintage, diabetes, and cardiovascular disease, the odds ratio (OR) for central BP (OR 1.110; 95% CI 1.019-1.210) was higher than those for brachial BP (OR 1.085; 95 CI 1.014-1.161 for bSBP and OR 1.094; 95% CI 1.021-1.173 for 24-bSBP).

Conclusions: Office central BP was more strongly related to volume status than out-of-office ambulatory brachial BP as well as office brachial BP, suggesting that central BP was more valuable than brachial BP in assessing volume status in PD patients.

TH-PO1023

Novel Regimen for Intraperitoneal Cefazolin and Ceftazidime in Peritoneal Dialysis Patients Sadudee Peerapornratana,[1] Pisut Katavetin,[1] Pajaree Chariyavilaskul,[2] Talerngsak Kanjanabuch,[1] Kearkiat Praditpornsilpa,[1] Somchai Eiam-ong.[1] *[1]Div of Nephrology, Dept of Medicine, Faculty of Medicine, Chulalongkorn Univ, Bangkok, Thailand; [2]Dept of Pharmacology, Faculty of Medicine, Chulalongkorn Univ, Bangkok, Thailand.*

Background: Current guideline suggested that intraperitoneal (IP) antibiotics should be administered only in a long peritoneal dialysis (PD) dwell (≥6 hours), which is not always practical because the long dwell might result in low ultrafiltration and volume overload. The objectives of this study were to develop a novel regimen for IP antibiotics in short dwell (£2 hours) during the automated PD cycling and examine the dialysate and plasma level of the most used empirical antibiotics for PD-related peritonitis, cefazolin and ceftazidime.

Methods: In the novel regimen, cefazolin and ceftazidime (20 mg/kg each) were added in a 5-liter bag of 2.5% dextrose PD fluid which was placed on the warmer of the PD cycling machine. Another 5-liter bag of PD fluid was connected to the machine, off the warmer. Patients underwent 5 exchanges of 2-liter PD fluid over 10 hours by the PD cycling machine without last fill or additional dwell. Cefazolin and ceftazidime concentrations in plasma and dialysate were determined by high performance liquid chromatography.

Results: Six PD patients without peritonitis were participated in the study. Dialysate cefazolin and ceftazidime were consistently high throughout the PD session in all patients (26-360 mg/L). Plasma cefazolin and ceftazidime exceeded the minimal inhibitory concentration (MIC) for susceptible organisms (8 mg/L) within 2 hours (cefazolin 28.5±8.0 and ceftazidime 12.5±3.4 mg/L at 2 hours), peak at 10 hours (51.1±14.1 and 23.0±5.2 mg/L) and then sustained well above the MIC at 24 hours (42.0±9.6 and 17.1±3.1 mg/L).

Conclusions: The novel regimen for IP cefazolin and ceftazidime in short dwell (£2 hours) during the automated PD cycling could provide adequate dialysate and plasma concentration and would become a standard regimen for peritonitis in PD patients already using PD cycling machine as well as those who temporarily need shorter dwells during peritonitis due to increasing peritoneal solute transport.

TH-PO1024

Is Automated Peritoneal Dialysis Better Than Continuous Ambulatory Peritoneal Dialysis in Quality of Life, Depression, and Renal Treatment Satisfaction? A Prospective Multicenter Propensity-Matched Study

Sun-Hee Park,[1] Hee-Yeon Jung,[1] Sukyung Lee,[1] Ji-Young Choi,[1] Se-Hee Yoon,[2] Jang-Hee Cho,[1] Chan-Duck Kim,[1] Yong-Lim Kim.[1] *[1]Internal Medicine, Kyungpook National Univ School of Medicine, Daegu, Republic of Korea; [2]Internal Medicine, Konyang Univ, Daejeon, Republic of Korea.*

Background: Health-related quality of life (HRQOL) is an important variable in the selection of dialysis modality among incident dialysis patients. However, relative superiority in HRQOL between automated peritoneal dialysis (APD) and continuous ambulatory peritoneal dialysis (CAPD) are not clearly known. The objective of this study was to compare HRQOL, depression, and renal treatment satisfaction over time between APD and CAPD patients.

Methods: Incident patients initiating APD and CAPD were prospectively enrolled from nationwide multicenters in Korea. HRQOL, depression, and renal treatment satisfaction were assessed at 1 and 12 months after the start of dialysis by Kidney Disease Quality of Life Short Form 36 (KDQOL-36), Beck's Depression Inventory (BDI), and Renal Treatment Satisfaction Questionnaire (RTSQ), respectively. The mean changes of scores in APD and CAPD were compared by propensity score matching analysis.

Results: All 260 incident patients starting peritoneal dialysis (PD) from 11 centers were included in this study. A total of 170 patients were matched from 208 patients who completed all questionnaires and did not change PD modality during the 1-year follow-up period. The total scores at 1 month showed better HRQOL for APD than CAPD patients in symptom, patient satisfaction, pain, and social function domains. No differences were observed between the two groups in total scores of KDQOL-36 at 12 months. However, CAPD patients had a significantly greater improvement in symptom and health status domains. A significant improvement also occurred in BDI and RTSQ in CAPD patients.

Conclusions: APD is not better than CAPD in HRQOL, depression, and renal treatment satisfaction during initial first one year on dialysis. The relative positive effect of CAPD compared with APD on improvement of HRQOL, depression, and renal treatment satisfaction was confirmed.

TH-PO1025

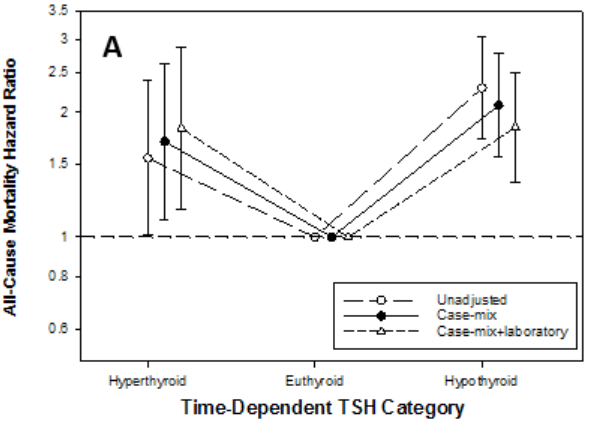
Thyroid Functional Disease and Mortality in a National Peritoneal Dialysis Cohort

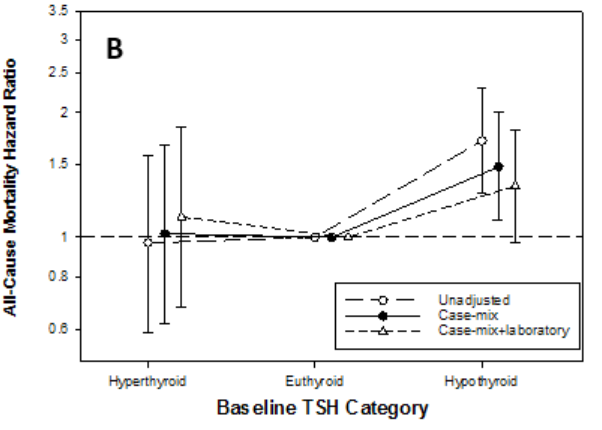
Connie Rhee,[1] Vanessa A. Ravel,[1] Elani Streja,[1] Rajnish Mehrotra,[2] Steven B. Kim,[1] Jiaxi Wang,[1] Danh V. Nguyen,[1] Steven M. Brunelli,[3] Csaba P. Kovesdy,[4] Gregory Brent,[5] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]UW; [3]DaVita Clin Research; [4]UTHSC; [5]UCLA.*

Background: Peritoneal dialysis (PD) patients have a high prevalence of thyroid dysfunction which may be due to 1) peritoneal effluent losses (vast majority of thyroid hormone is protein-bound) and 2) frequent exposure to povidone-iodine cleaning agents leading to iodine-induced hypo- and hyperthyroidism. In the general population thyroid dysfunction is associated with higher risk of cardiovascular (CV) disease and death. There has not been study of the association between hypo- or hyperthyroidism defined by TSH with mortality in PD patients.

Methods: We examined the association of thyroid functional status with all-cause mortality in a 5-year national cohort (1/2007-12/2011) of PD patients with at least one TSH measure. Thyroid functional status was defined as: hyper-, eu-, and hypothyroidism (TSH <0.5, 0.5-5, >5mIU/L). We examined time-dependent and baseline thyroid function to determine short- and long-term exposure–mortality associations, respectively, using Cox models with 3 adjustment levels: unadjusted, case-mix, and case-mix+laboratory adjusted.

Results: Among 1484 patients, 7% and 18% had hypo- and hyperthyroidism, respectively. In time-dependent analyses, hypo- and hyperthyroidism were each associated with higher mortality risk in all 3 Cox models (ref: euthyroidism). In baseline analyses, hypothyroidism was associated with higher death risk in unadjusted and case-mix models, but associations were attenuated to the null in case-mix+laboratory models.





Conclusions: Time-dependent hypo- and hyperthyroidism were each associated with higher mortality, suggesting short-term risk in PD patients. Further studies are needed to determine if CV pathways are implicated, and if thyroid-modulating therapies ameliorate mortality in this population.

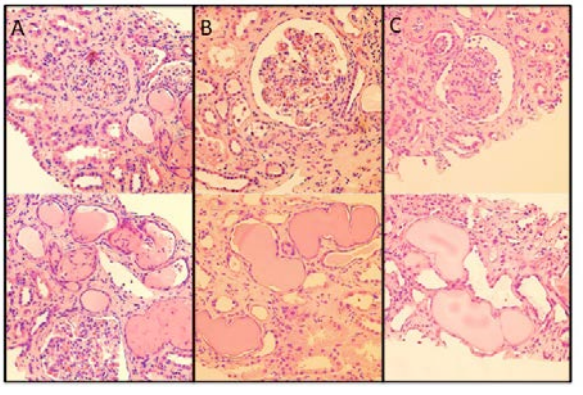
TH-PO1026

A Tale of *APOL1* Mutation and Parvovirus Infection

Sherry Mansour,[1] Whitney E. Besse,[1] Karan Jatwani,[2] Ursula C. Brewster.[1] *[1]Nephrology, Yale School of Medicine, New Haven, CT; [2]Internal Medicine, Government Medical College And Hospital Chandigarh, Nawanshahr, India.*

Introduction: We present a case of a first trimester pregnant woman with nephrotic range proteinuria and fetal demise in the setting of an acute parvovirus infection. Kidney biopsy revealed collapsing FSGS, and exome sequencing revealed mutations in *APOL1*. The relationship between Parvovirus and FSGS is one that clinicians might overlook, and perhaps may play a more prominent role in these progressive cases especially with *APOL1* mutations.

Case Description: 37 yo Caribbean female presented at 8 weeks gestation with progressive swelling. Her daughter developed fifth's disease one month prior. On presentation her BP was 146/95, HR 77 with pitting edema. Her creatinine was 6.3, BUN 43, albumin 1.5, and spot prt/crt 20.8. Parvovirus PCR was 2000 copies. Biopsy demonstrated collapsing FSGS secondary to Parvovirus B19 [Fig 1A 1B]



The hope was that this injury would improve with improvement in titers, so IVIG was started. A follow up PCR showed improvement to 200 copies but she remained nephrotic with proteinuria of 20-60 g. Re-biopsy revealed significant scarring and dialysis was initiated [Fig 1C]. Patient is now being evaluated for transplant. Given the unusual severity of this case, and her possible African ancestry, a genetic susceptibility to podocyte injury was entertained. Whole exome sequencing identified the patient to have two *APOL1* risk alleles.

Discussion: Parvovirus has been linked with collapsing FSGS, and in one study viral PCR was detected in 78% of kidney tissue with this diagnosis. The combination of B19 infection and *APOL1* mutation likely made our patient particularly susceptible to injury. Our case raises the question of how often subclinical parvovirus infection may be involved in collapsing FSGS, and highlights how sudden and devastating it can be to the life of a prior healthy young woman.

TH-PO1027

Podocyte Myeloid Bodies without Confirmed Genetic Mutation in a Female: Fabry's Disease? Pravir V. Baxi,[1] David J. Cimbaluk,[2] David G. Warnock,[3] Robert J. Desnick,[4] William Luke Whittier.[1] *[1]Nephrology, Rush Univ MC, Chicago, IL; [2]Pathology, Rush Univ MC, Chicago, IL; [3]Nephrology, UAB, Birmingham, AL; [4]Genetics, Mt Sinai, New York, NY.*

Introduction: Fabry's disease (FD) is a X-linked lysosomal storage disorder caused by deficient alpha-galactosidase activity. A renal variant has been described with the R363H mutation. Due to random X-chromosomal inactivation, heterozygous females can present a diagnostic challenge. We report a case with a renal limited presentation, biopsy findings characteristic of FD but a negative whole blood DNA analysis.

Case Description: A 46 year-old Hispanic woman was evaluated for proteinuria. She was asymptomatic with no prior medical history or family history, and no exposure to silica, amiodarone, or hydroxychlorquine. Her exam was unremarkable: no neuropathy, skin changes, or corneal dystrophy. SCr was 0.6 mg/dL, UA 2+ protein with P/C ratio of 1.94 g/g. Biopsy revealed diffuse enlargement of the podocytes with a foamy cytoplasm appearance and on EM, prominent podocyte lamellated lipid inclusions with foot process effacement and minimal endothelial deposits.

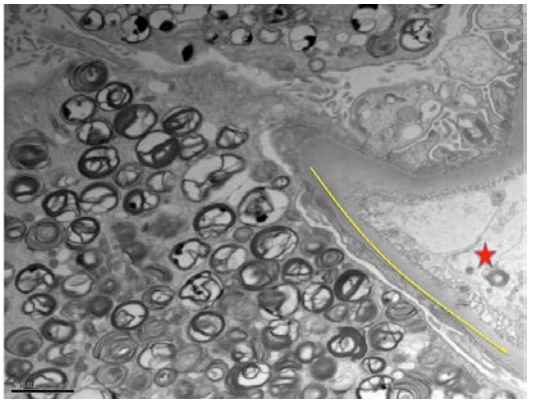


Figure 1: Podocyte myeloid bodies; yellow line denotes foot process effacement, red star shows limited endothelial inclusions. Alpha-galactosidase activity was 0.187 U/L (lower limit of nl) and genomic sequencing of the GLA gene was negative. EKG, Echo, cardiac MRI, and brain MRI with and without gadolinium were nl.

Discussion: We present a pt with renal limited manifestations mimicking FD in the absence of known toxic exposure and a negative whole blood DNA mutation analysis. Treatment with enzyme replacement is not warranted without a positive genetic analysis. This case highlights the variable genotypic and phenotypic presentation, and raises the possibility that tissue-specific mosaicism could explain phenotypic variation in females with Fabry's Disease.

TH-PO1028

Relapsing Thrombotic Microangiopathy following Persistent Intravenous Use of Reformulated Oxycontin Melissa S. Nataatmadja, Dakshinamurthy Divi. *Dept of Nephrology, Gold Coast Univ Hospital, Southport, Queensland, Australia.*

Introduction: Thrombotic microangiopathy (TMA), resembling thrombotic thrombocytopenic purpura (TTP), with normal ADAMTS13 activity has recently been observed in persons injecting Opana ER (oxymorphone), an oral opioid available in the United States. This phenomenon had not been reported outside the US, however, and the mechanism of inducing TMA is not yet known.

Case Description: A 29-year old female presented with hemolytic anemia and thrombocytopenia, with a hemoglobin of 70g/L and platelet count of 17 x 10^9/L. She was treated with therapeutic plasma exchange (TPE) for a working diagnosis of TTP and recovered, with no ongoing TPE requirement. She represented two weeks later, with a hemoglobin of 81g/L, platelets of 8 x 10^9/L, and additional renal impairment. She again commenced TPE and also prednisone. Her ADAMTS13 activity was >94%, atypical hemolytic-uremic syndrome (aHUS) was therefore considered, and genetic testing was ordered. She then admitted to a two-month history of injecting Oxycontin (oxycodone) and for the previous month had been using reformulated Oxycontin. TPE and prednisone were discontinued and she experienced physical and hematological recovery. Genetic testing for aHUS subsequently returned as negative.

Discussion: To our knowledge, this is one of only two documented cases of TMA following IV Oxycontin use, both of which were observed in Australia soon after reformulated Oxycontin replaced original Oxycontin. This report supports polyethylene oxide (PEO), a tamper-proof coating added to the reformulated Oxycontin and Opana ER, as the causative agent, as TMA has now been observed following the use of two different medications but with the same PEO coating. Additionally, our case is the first to demonstrate relapse of TMA following persistent intravenous drug use of either of these medications. Given the rarity of this illness, it is possible that an unidentified genetic or immunologic susceptibility causes some individuals to develop TMA in response to these drugs, whilst others do not. We encourage clinicians to consider IV drug use in all patients presenting TMA, as treatment approach may differ and the role of plasma exchange is not yet clear.

TH-PO1029

Ipilimumab Associated Kidney Injury Andinet Gizaw, Jason M. Kidd. *Nephrology, VCUHS, Richmond, VA.*

Introduction: Melanoma is the most fatal form of skin cancer. Patients without surgically resectable disease require chemotherapy. Ipilimumab; a human monoclonal antibody against anti-CTLA-4 is an Immunomodulation agent, with proven benefit in overall survival in patients with unresectable, advanced (Stage 3,4) Melanoma. Cytotoxic T Cell Lymphocyte Antigen-4 (CTLA-4) is a negative regulator of T –Cell mediated anti-tumor immune response working as immune check points (down regulation). We present a case of acute kidney injury due to interstitial nephritis and minimal change disease from this drug.

Case Description: A 55 year old man with metastatic melanoma with right atrial mass, status post resection, was seen for evaluation of acute kidney injury and nephrotic range proteinuria. He developed lower extremity swelling with rash about 02 weeks after receiving a third dose of ipilimumab. He had a baseline serum creatinine of 1.2mg/dl. At the time of consultation, his serum creatinine was 2.97mg/dl, 9 grams of proteinuria on 24 hours collection and serum albumin of 2.2. He was initially fluid resuscitated, however, creatinine increased to 5.2 mg/dl and he became oliguric. Urine microscopy was without casts and serology markers were negative. Renal biopsy was performed that showed an interstitium with eosinophil rich inflammatory cell infiltration and severe edema. Almost half of glomeruli were globally sclerotic, the others had minimally altered composition. Immunofluorescence was unremarkable. Electron microscopy showed diffuse effacement of podoyte foot processes. He was treated with high dose (2mg/kg) steroid and oral diuretics. Renal function has retuned to his prior baseline and he has subnephrotic proteinuria.

Discussion: This describes a case of nephrotic syndrome and interstitial nephritis related to the monoclonal antibody, Iplimumab. Interstitial nephritis has been described with this drug before. [1]However, this is the first case to our knowledge of the administration of ipilimumab leading to acute kidney injury from interstitial nephritis and severe proteinuria from diffuse podocyte foot process effacement. Prompt recognition of this presentation is necessary to preserve renal function.

[1]"kidney injury related to ipilimumab", Invest New Drugs (2014) 32:769-773.

TH-PO1030

Kappa Light Chain-Associated Crystal-Storing Tubulopathy, Podocytopathy, and Histiocytosis in GI Tract, in a Patient with Multiple Myeloma Michifumi Yamashita,[1,3] Albert Q. Lam,[2,3] Joseph V. Bonventre,[2,3] Vanesa Bijol.[1,3] *[1]Pathology, Brigham and Women's Hospital, Boston, MA; [2]Renal Div, Internal Medicine, Brigham and Women's Hospital, Boston, MA; [3]Harvard Medical School, Boston, MA.*

Introduction: Multiple myeloma manifests with variety forms of kidney disease, such as AL amyloidosis, cast nephropathy, and light chain deposition disease. Among them, crystal-storing disease is a rare entity. We report an interesting case of a patient with extramedullary IgG/κ multiple myeloma, who presented with crystal-storing histiocytosis in GI tract, and subsequently developed crystal-storing tubulopathy and podocytopathy.

Case Description: A 65-year-old man with type 2 DM and HTN was found to have a 1 cm large cecal polyp on screening colonoscopy in 2009. The polyp showed diffuse infiltration by a plasma cell neoplasm and crystal-storing histiocytosis with κ light chain (LC) restriction. At that time, the patient showed intact bone marrow, normal renal function and proteinuria of 0.5 g/24h. He was subsequently closely followed with endoscopy, SPEP, and renal function tests. In 2014, he developed nephrotic range proteinuria (>4g/24h), slightly rising Cre to 1.12 mg/dl, and increased serum free κ LC (216 mg/L). Kidney biopsy was performed, revealing many proximal tubular epithelial cells containing PAS-negative granular materials in the cytoplasm. The glomeruli were unremarkable except for mild mesangial expansion. No significant immune deposits were present in glomeruli or tubulointerstitium, but there was slightly stronger background IF reactivity for κ LC than λ LC on frozen tissue sections. IF studies on protease-digested paraffin sections revealed strong κ LC reactivity of the materials aggregated in the tubular epithelial cells and podocytes, while λ LC was negative. EM revealed extensive intracytoplasmic accumulation of crystalline material of rhomboid and rectangular shapes in proximal tubular epithelial cells and podocytes.

Discussion: LC-associated crystal-storing disease is a rare kidney disease. To our knowledge, this is the first reported case of coexisting crystal-storing tubulopathy, podocytopathy, and histiocytosis in the GI tract in a patient with multiple myeloma.

TH-PO1031

Parvovirus B19-Preceding Collapsing Glomerulopathy in Renal Allograft
Michifumi Yamashita,[1,3] Martina M. McGrath,[2,3] Anil K. Chandraker,[2,3] Vanesa Bijol.[1,3] *[1]Pathology, Brigham and Women's Hospital, Boston, MA; [2]Renal Div, Internal Medicine, Brigham and Women's Hospital, Boston, MA; [3]Harvard Medical School, Boston, MA.*

Introduction: Collapsing glomerulopathy (CG) is a distinct clinicopathologic entity with proliferation of glomerular epithelial cells and capillary collapse. It has been classically associated with HIV infection, but other predisposing conditions and etiologic factors include parvovirus and CMV infections, autoimmune diseases, hematologic malignancies, and certain drugs. The pathomechanism of CG in renal allograft is unclear. Here we report a case of parvovirus infection-preceding CG in allograft.

Case Description: A 72-year-old man with ESRD due to DM and HTN, status post DDRT in June 2014, who presented with rising Cre from 1.6 to 2.0 without viral illness, 3 months after transplantation. The 1st biopsy showed several mesangial deposits with organized spherical substructural organization, averaging 18 nm in diameter, without evidence of allograft rejection. Extensive immunohistochemistry (IHC) workup revealed positive staining only for Parvovirus in mesangial area. 3 weeks after the biopsy, he developed Parvovirus B19 viremia with 4.8×10^9 IU/mL. 6 weeks later, he presented with rising Cre to 3.4, proteinuria 1.5 g/24hr, and improved Parvovirus viremia (3.3×10^5 IU/mL). The 2nd biopsy revealed severe podocyte injury with features of CG: (1) Collapse of the tuft and prominent epithelial cells with intracytoplasmic protein reabsorption granules, (2) extensive effacement of foot process and other degenerative changes of podocytes, and (3) coarse protein reabsorption granules in tubular epithelial cells. Parvovirus could not be detected anymore by EM or IHC.

Discussion: This case clearly showed: (1) for the first time, Parvovirus B19 particles in glomeruli immunohistochemically and ultrastructurally, (2) Parvovirus B19 infection systemically and histologically preceding CG, and (3) when CG developed, serum Parvovirus B19 titer was significantly decreased, and the virus could not be detected in the kidney tissue by EM or IHC. The evidence suggests that the direct or the indirect association between Parvovirus B19 infection and CG in kidney allograft.

TH-PO1032

A Case Report of Obstructive Nephrolithiasis Secondary to Atazanavir
Dina Abdelwahab, Anushree C. Shirali. *Internal Medicine, Section of Nephrology, Yale Univ School of Medicine, New Haven, CT.*

Introduction: Atazanavir, a protease inhibitor used in the management of human immunodeficiency virus (HIV), is associated with crystalluria and nephrolithiasis. While crystalluria is seen in 10-20% of patients on atazanavir treatment, frank nephrolithiasis is less common. We report a case of nephrolithiasis associated with atazanavir in an HIV patient on long-term highly active anti-retroviral therapy (HAART).

Case Description: A 56-year-old male with a past medical history of HIV on HAART, HCV, DM type 2 and proteinuric CKD stage III presented with rise in serum creatinine from 2.6 to 5.7 mg/dL over the preceding year. His CD4+ T-cell count was 514 and his viral load was less than 20 copies/ml on treatment with atazanavir, ritonavir and raltegravir, a regimen that had remained stable for 10 years. He had no history of diabetic retinopathy and his proteinuria was stable around 5.2 gm. Prior abdominal CT imaging had revealed bilateral non-obstructive nephrolithiasis 1 year prior to presentation. Evaluation of the decline in renal function included a CT scan of the abdomen, which showed a left-sided obstructive stone. The patient had no symptoms of renal calculi. He underwent ureteroscopy, laser lithotripsy and stent placement. Stone analysis revealed calculi composed of atazanavir and its metabolites. His HAART regimen was switched to dolutegravir, lamivudine and abacavir. Despite an initial stabilization in creatinine, the patient eventually progressed to ESRD.

Discussion: This case highlights the fact that patients treated with atazanavir may develop nephrolithiasis with chronic therapy. Evaluation of renal disease in patients on atazanavir should include renal imaging for detection of calculi, even in the absence of symptoms, in susceptible patients who have an unexplained drop in GFR. The risk of nephrolithiasis is particularly heightened in patients on ritonavir-boosted atazanavir and those with pre-existing chronic kidney disease. Other types of renal disease associated with atazanavir include acute interstitial nephritis and chronic interstitial nephritis and should prompt kidney biopsy in those patients without evidence of obstructive nephropathy.

TH-PO1033

Paraneoplastic Tumor-induced Osteomalacia (TIO) in Small Cell Carcinoma: First Report of Positive Immunostaining for Fibroblast Growth Factor-23 in Small Cell Carcinoma
Smita Mahendrakar, Hone S. Kaw, Hiba M. Ahmed, Suneet Verma, Mandeep Samra, Jennine Michaud, Donghong Cai, Michael Yudd. *Nephrology, Dept of Veterans Affairs NJ Healthcare System, East Orange, NJ.*

Introduction: We report a case of hypophosphatemia due to Fibroblast Growth Factor(FGF)-23 in small cell carcinoma (SCCA). This is the first reported case of positive immunohistochemical staining for FGF-23 in SCCA.

Case Description: 60 yr old male was admitted with abdominal pain, anorexia and weight loss . Labwork showed normal renal function, serum phosphorus (PO4) 0.8 mg/dl, bilirubin 4 mg/dl, increased LFT's, and elevated fractional excretion of PO4 82%, with high serum FGF-23, 577 RU/ml. No lab findings of Fanconi Syndrome . CT showed pulmonary nodules and a massively enlarged liver with no focal lesions. Liver biopsy showed metastatic SCCA with diffuse sinusoidal pattern. Despite PO4 replacement, hypophosphatemia was difficult to correct. Chemotherapy was started, but patient died in 2 weeks. Tissue sections from the tumor and controls were stained separately using antibodies directed against epitopes comprising amino acid residues located within the C-terminal portion of FGF23.

Discussion: Immunostaining of tumor cells from the lung and liver were positive for FGF-23. This is the first case with documented elevated serum FGF-23 and positive FGF-23 immunostaining of SCCA. Tumor-induced osteomalacia (TIO), is usually associated with benign tumors of mesenchymal origin, rarely with adenocarcinomas or small cell carcinoma. The syndrome is characterized by renal PO4 wasting due to excess FGF-23 from the tumor, leading to hypophosphatemia. There are at least 10 cases of SCCA with phosphate wasting, but without FGF23 levels. Only four cases of TIO with documented elevated FGF-23 associated with tumors other than mesenchymal tumors: 2 cases of stage D2 prostate adenocarcinoma, one with metastatic colon cancer, and one with stage 4 ovarian cancer . All of these were advanced, metastatic disease. Of these, only the metastatic colon adenocarcinoma case was documented by FGF-23 immunohistochemical staining in the hepatic metastases. Our case is the first case of FGF-23-postive immunostaining in tumor cells of small cell CA.

TH-PO1034

Relapse of Kappa Restricted Chronic Lymphocytic Leukemia Associated with a Lambda Restricted Plasma Cell Clone Causing Renal Amyloid
Sunil Rangarajan, James C. Harms, Huma Fatima, Randall S. Davis, Eric L. Wallace. *Univ of Alabama at Birmingham.*

Introduction: Chronic lymphocytic leukemia (CLL) has been associated many glomerular diseases. Rarely, it has been associated with amyloidosis either as the sole clone responsible, or in association with a plasma cell clone possessing the same light chain as the CLL clone, or in very rare cases, a different light chain. We present a case of adult onset nephrotic syndrome secondary to amyloid-lambda light chain due to a small lambda-restricted plasma cell population, temporally associated with a relapse of a kappa-restricted CLL.

Case Description: A 66 year old male, diagnosed with kappa-restricted CLL in 2009 achieved complete remission after 6 cycles of fludarabine, cyclophosphamide and rituximab. 5 years later, he presented with foamy urine, generalized swelling, and weight gain. Serum creatinine was 1.1. Initial spot urine protein / creatinine ratio showed proteinuria of 5g/g which later increased to 10g/g. During the previous year serum albumin fell from 3.8 to 1.5 g/dL and the white blood cell count rose from 7.4 to 30 $x10^3$/cmm. While the lymphocyte frequency rose from 45% to 88%, serum free light chains were 45.1mg/L lambda, 21.5 mg/L kappa with a ratio of 0.48. Kidney biopsy showed AL-amyloidosis with immunofluorescence positive for lambda. Due to discrepancy in the clonality of previous circulating CLL expansion (kappa restricted) and renal amyloidosis (lambda restricted), a bone marrow biopsy was done. This showed a relapse of CLL with low level (<10%) plasma cell dyscrasia. Flow cytometry confirmed that the relapsed CLL population was kappa-restricted while the clonal plasma cell population expressed lambda. After 8 months of treatment with velcade, dexamethasone and revlimid, he showed minimal improvement in proteinuria.

Discussion: Though the co-existence of clonal plasma cells and CLL is known, the temporal association of this patient's nephrotic syndrome secondary to amyloidosis from a unique plasma cell clone expressing a different light chain supports the hypothesis that, in CLL, sharing the same microenvironment as non-tumor cells may activate bystander B-cells to express free light chains and in this case lead to amyloidosis.

TH-PO1035

Recurrent 2,8-Dihydroxyadenine Deposition Successfully Treated with Kidney Transplantation
Paula A. Duran, Mohanram Narayanan. *Div of Nephrology, Baylor Scott & White Healthcare, Temple, TX.*

Introduction: Adenine phosphoribosyltransferase (APRT) deficiency is an autosomal recessive purine metabolism disorder where adenine is oxidized by xanthine dehydrogenase to 2,8–dihydroxyadenine (2,8-DHA), forming insoluble urinary crystals, nephrolithiasis, CKD and ESRD. Literature reveals diagnosis of APRT deficiency is rare before kidney transplantation. Delay in diagnosis and xanthine oxidase inhibitor treatment predisposes to recurrent disease in renal allograft, with allograft loss in over 25% cases. Though APRT is ubiquitous in all cells, extrarenal symptoms are uncommon in affected individuals. Our patient presented with crystalline keratopathy resolving completely after kidney transplantation.

Case Description: 41 y/o Caucasian female with recurrent 2,8-DHA nephrolithiasis since age 23 was maintained on Allopurinol. Clinical course was significant for obstructive uropathy requiring multiple stent placements; continued decrement in renal function and blurry vision, intense photophobia, excessive tearing in both eyes. Corneal examination showed crystalline keratopathy. Genetic analysis indicated patient had mutant APRT alleles inherited from her parents. With progressively declining renal function she was evaluated for preemptive renal transplantation. She received a 0-antigen mismatched deceased donor renal allograft with uneventful post-transplant course. Allopurinol dose was increased to 600 mg daily with complete resolution of disabling visual symptoms. Allograft function has been excellent with nadir creatinine of 0.82 and urine microscopy negative for DHA crystals.

Discussion: APRT deficiency is a rare genetic disorder not readily diagnosed but easily treated with Allopurinol to prevent urinary DHA crystallization. Typical recommended daily dose of Allopurinol is 200-300 mg, but reports from Iceland have shown excellent results in transplant recipients taking 600 mg that lacked statistical significance due to the small sample size. Allopurinol 600 mg should be considered post-transplant to prevent allograft loss. Our patient's post-transplant dose was increased to 600 mg with remarkable resolution of crystal keratopathy and crystalluria while maintaining excellent allograft function.

TH-PO1036

Minimal Change Disease Diagnosing Relapsing Mantle Cell Lymphoma
Juan Calderon, Mark A. Perazella. *Nephrology, Yale Univ School of Medicine, New Haven, CT.*

Introduction: Glomerular lesions are linked with hematologic malignancies, with minimal change disease (MCD) commonly associated with Hodgkin's lymphoma. Diagnosis of the underlying hematologic disorder often precedes development of the glomerulopathy; however, in rare cases, MCD precedes discovery of the lymphoma by several months. We present a case of new onset nephrotic syndrome and AKI in association with undetected relapsing mantle cell lymphoma (MCL).

Case Description: A 74 y/o man with history of stage IV mantle cell lymphoma in remission developed AKI and new onset edema. Chemotherapy completed 1 year prior to presentation induced complete remission on bone marrow and follow-up PET scans. On presentation he denied B symptoms, had no new lymphadenopathy, and only noted decreased appetite. The patient was edematous and hypertensive. Serum Cr was 2.4 mg/dl up from 1.3 mg/dl. High-grade, non-quantifiable urine protein was noted by the lab. Urine sediment was remarkable for numerous granular casts, oval fat bodies, and few uric acid crystals. Serum uric acid was 13.2 mg/dl. Therapy for tumor lysis syndrome was instituted due to concern for relapsing lymphoma in the setting of AKI. However, PET/CT scan was completely normal with no evidence for lympoma. Furthermore, LDH was within normal limits. Kidney biopsy revealed normal glomeruli on light microscopy with acute tubular injury. EM revealed global effacement of foot processes. A diagnosis of MCD with focal tubular injury was made and steroid therapy was started. Peripheral flow cytometry and later a bone marrow biopsy confirmed a 23% tumor burden compatible with relapsed MCL. Targeted chemotherapy for MCL was initiated.

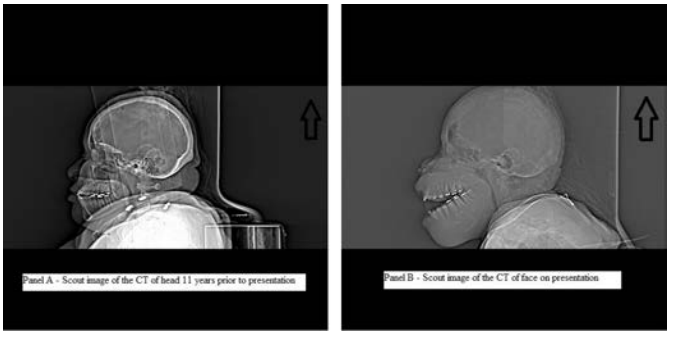
Discussion: We present the first report of MCD associated with relapsing MCL. Oncologic surveillance including PET scan failed to detect reccurrent MCL. BM biopsy and flow study was pursued following the diagnosis of MCD. Initial therapy with steroids alone was associated with a reduction in proteinuria. This improved further with therapy directed at the relapsed MCL suggesting a pathophysiologic relationship between these two disorders. Clinicians must remain cognizant of the possibility of malignancy when a suspicious glomerular lesion develops.

TH-PO1037

Renal Osteodystrophy
Hitarth S. Dave, Daniel E. Carl. *Dept of Internal Medicine, Div of Nephrology, Virginia Commonwealth Univ School of Medicine, Richmond, VA.*

Introduction: It is believed that mineral metabolism changes start as early as stage II chronic kidney disease (CKD). The spectrum of CKD-mineral and bone disorder (MBD) ranges from low-turnover adynamic disease to high-turnover osteitis fibrosa.

Case Description: A 37-year-old female with end-stage renal disease (ESRD), currently undergoing hemodialysis, presented complaining of a 1-day history of inability to eat or drink. Prior to presentation, she had noticed 2-week history of difficulty speaking, and 8-month history of increasing facial size. On presentation, the blood pressure was 180/68 mm Hg, and the oxygen saturation 98% while breathing ambient air. The physical examination revealed significant bony hypertrophy of the maxilla and mandible with edema of the overlying soft tissue. Computed tomographic (CT) scans of the maxilla and mandible showed severe expansion of the mandible and hard palate with complete replacement of the osseous matrix and surrounding mass effect on the maxillary sinuses and oropharynx with narrowing of the airway most severe at the angle of the mandible (Panel B). Panel A shows a scout image of the CT of head done eleven years ago for comparison.



Laboratory data showed calcium 10.2 mg/dL (8.9-10.7 mg/dL), phosphorus 4.7 mg/dL (2.5-4.6 mg/dL), alkaline phosphatase 2784 units/L (0-120 unit(s)/L), intact PTH 5707.8 pg/mL (12-65 pg/mL). She underwent tracheostomy and four-gland parathyroidectomy with autotransplantation in the subcutaneous abdominal tissue. Biopsy of the left maxillary bone revealed osteitis fibrosa consistent with renal osteodystrophy.

Discussion: Hyperparathyroidism can cause extraosseous calcification in arteries, joints, and viscera. Osteitis fibrosa cystica is characterized by increased bone turnover caused by secondary hyperparathyroidism. The prevention of a positive phosphate balance is the mainstay of treatment of high-turnover bone disease.

TH-PO1038

Bevacizumab Nephrotoxicity: Case Report and Literature Review
Girish Singhania, Abhilash Koratala, Azra Bihorac. *Nephrology, Univ of Florida, Gainesville, FL.*

Introduction: Bevacizumab (BCZ), an inhibitor of vascular endothelial growth factor (VEGF), is approved for the treatment of various cancers. We are reporting a case of BCZ induced acute kidney injury (AKI) with proteinuria (PTN) and thrombotic microangiopathy (TMA) and providing a summary of evidence after systematic review of reported cases in literature.

Case Description: A 57-year-old Caucasian woman with no history of kidney disease presented with abdominal pain 4 weeks after completing most recent cycle of BCZ (first dose 2 months before hospitalization) for colon cancer. She presented with new onset of hypertension (HTN), diffusely tender abdomen and a significantly low hemoglobin of 4.6 g/dL. A non-contrast CT showed hemorrhagic pancreatitis. Her serum creatinine at presentation was 2.93 mg/dL (baseline: 0.5 mg/dL). Further workup showed platelets of 45,000/μL, haptoglobin of <10 mg/dL and LDH of 947 U/L. Peripheral blood smear showed 3 schistocytes/hpf. Urinalysis was positive for protein and 4 RBCs/hpf. 24 hour urine had 2.1 gms of protein. Hepatitis panel, ANCA and SPEP were negative. ADAMTS 13 activity was normal. Based on clinical diagnosis of AKI, PTN and TMA related to BCZ, the drug was discontinued and patient was managed conservatively without plasma exchange (PE). The creatinine gradually improved to 1.5 mg/dL while platelet count and hemoglobin returned to baseline at discharge.

Discussion: We identified 24 cases reported in literature with mean age of 62 years. All patients presented with AKI and PTN with 61% being nephrotic range. The onset of PTN ranged from 2 weeks to 28 months after initiation of BCZ. HTN occurred among 62% while TMA among 57% of patients. Most of the patients had partial or complete recovery of AKI and PTN with only 1 patient progressing to end-stage renal disease on follow up ranging from 2 to 33 months. The proposed mechanism of nephrotoxicity is thought to be related to low free VEGF levels leading to endothelial dysfunction and podocyte dysregulation. Treatment includes withholding the drug if PTN exceeds 2g/day or permanent discontinuation for nephrotic syndrome and ACEI or thiazide diuretics for treatment of HTN. Drug induced TMA with normal ADAMTS 13 levels rarely requires PE.

TH-PO1039

5-Oxoprolinuria: A Rare Cause of High Anion Gap Metabolic Acidosis due to Acetaminophen Ingestion
Ardavan Mashhadian,[1,2] Sreesh G. Iyengar,[1,2] Seyed-ali Sadjadi,[2] Lisa Aimee Hechanova.[1] *[1]Nephrology, Loma Linda Univ, Loma Linda, CA; [2]Nephrology, Jerry L Pettis Memorial Veterans Medical Center, Loma Linda, CA.*

Introduction: Acquired 5-oxoprolinuria is a rare cause of high anion gap metabolic acidosis due to excessive acetaminophen ingestion. It largely goes unrecognized because an assay for 5-oxoproline is not widely available. The malnourished and chronically ill women with history of chronic acetaminophen ingestion are commonly affected. Acetaminophen levels are rarely in toxic range.

Case Description: A 57-year-old woman with a history of adiposis dolorosa was admitted for acute osteomyelitis. She was chronically taking acetaminophen containing pain medication. Her hospital course was complicated by anion gap metabolic acidosis and cardiorespiratory failure. Her acetaminophen level was not elevated. Usual causes of anion gap acidosis were ruled out. Finally, a urine organic acid screen showed elevated 5-oxoproline levels. Acetaminophen containing pain medication was stopped, she was given IV hydration and sodium bicarbonate. Her anion gap metabolic acidosis would quickly resolve.

Discussion: Acute and chronic acetaminophen ingestion can lead to high levels of 5-oxoproline. The pathophysiology behind acquired 5-oxoprolinuria has been mostly explained by reduced glutathione in prior case reports. 5-oxoproline is an intermediate in the gamma-glutamyl pathway, the metabolic cycle responsible for creating glutathione and shuttling amino acids into the cytosol. When glutathione levels are diminished, feedback inhibition ceases, causing an overproduction of 5-oxoproline. Sepsis, amongst others etiologies, have been implicated in glutathione depletion. 5-Oxoprolinuria clinically presents with altered mental status. One of the key aspects of diagnosing this disorder is the detection of 5-oxoproline in urine. *N*-acetylcysteine may be an effective treatment that acts to restore intracellular glutathione levels. Extracellular fluid expansion with dextrose containing saline promptly improves symptoms. In conclusion, 5-oxoprolinuria should be considered in any patient with unexplained metabolic acidosis and recent acetaminophen ingestion. Overlooking the diagnosis can be costly.

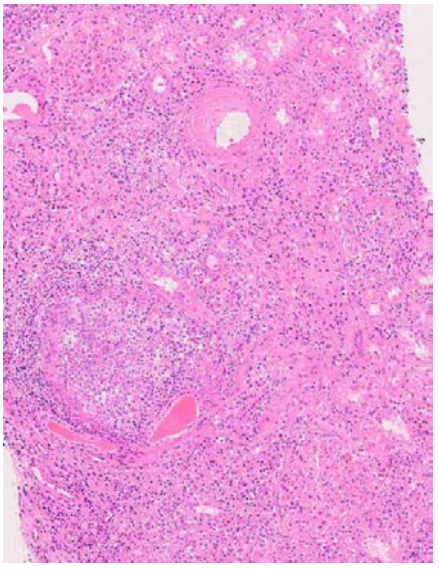
TH-PO1040

Severe Tubulointerstitial Nephritis with Lymphoid Follicles in Sjögren's Syndrome
Maiko Nagata, Takehiko Kawaguchi, Mao Watanabe, Takafumi Yamakawa, Moritoshi Kadomura, Hiroshi Kitamura, Toshiyuki Imasawa. *Internal Medicine, National Hospital Organization Chiba-East-Hospital, Chiba, Japan.*

Introduction: Patients with Sjögren's syndrome (SS) are at increased risk for the development of lymphoma. The prolonged state of immunologic and lymphoid hyperactivity in SS may predispose patients to the development of lymphoid neoplasm. However, biopsy specimens from some of these patients do not meet histologic criteria for frank malignancy. We report a rare case of severe tubulointerstitial nephritis with lymphoid follicles in SS.

Case Description: A 66-year-old woman, who had developed general malaise for a few years, was admitted to our hospital, because of the rapid rise in the serum creatinine

level in the past two months. Four months before the admission, she was found to have hypergammaglobulinemia, and a bone marrow–biopsy specimen revealed no hyperplasia of plasma cells. In the admission, the main laboratory values showed the following values: serum creatinine 1.8 mg/dl, IgG 6634 mg/dl, urinary b_2MG 7829 mg/l, anti-SS-A≥500 U/ml. Renal biopsy showed tubulointerstitial nephritis with marked lymphoplasmacytic infiltration. Most of the cells were plasma cells; some were immature. Immunostain studies showed plasma cells with a polyclonal pattern. Some lymphoid follicles were also present in the interstitial tissue.



Additionally, lip biopsy showed microsalivary gland with concentrated lymphocyte infiltration. Most of the cells were B lymphocytes. Plasma cells with a polyclonal pattern were present in the peripheral germinal centers. Thus, the diagnosis was primary SS. Immunopathologic analysis of renal and lip biopsy specimens showed no features of malignancy. Steroid therapy led to prompt resolution of the infiltration.

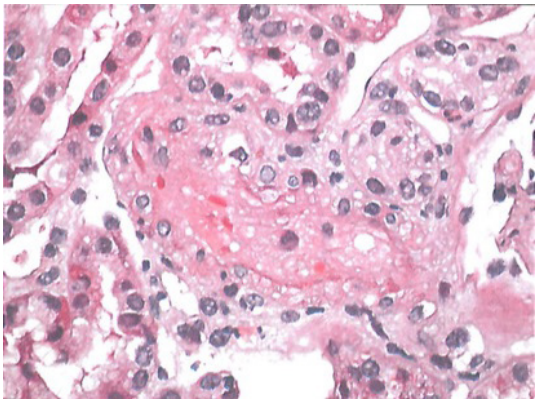
Discussion: This is a rare case of severe tubulointerstitial nephritis with lymphoid follicles in SS. It may show a spectrum of lymphoproliferative disease in SS.

TH-PO1041

Scleroderma Renal Crisis with Normal Blood Pressure and Normal Serum Creatinine Natanong Thamcharoen,[1] Raquel M. Rosen,[1] Vivette D. D'Agati.[2] *[1]Dept of Medicine, Bassett Medical Center, Cooperstown, NY; [2]Dept of Pathology, Columbia Univ College of Physicians and Surgeons, New York, NY.*

Introduction: A serious complication of systemic sclerosis is scleroderma renal crisis (SRC) usually presenting with acute onset of high blood pressure, kidney failure and thrombotic microangiopathy. 10% of patients may not have hypertension known as normotensive scleroderma renal crisis but mostly presenting with elevated creatinine. We introduce a case of scleroderma renal crisis with normal blood pressure and normal serum creatinine.

Case Description: A 61 year-old woman was admitted with dysphagia, proximal muscles weakness and tightening of skin. She was diagnosed with systemic sclerosis from the findings. She later developed oliguria without elevation of creatinine (baseline creatinine 0.4 increased to 0.8). Her blood pressure was in normal range. The urinalysis showed 5-10 cell/HPF of red blood cell, no dysmorphic red blood cell or cast. She had proteinuria of 441 mg/day. Kidney ultrasound did not show abnormalities. Anti-dsDNA, MPO antibody and proteinase-3 antibody were performed, they were all negative. Free light chain disease and amyloidosis were ruled out by normal serum protein electrophoresis and normal free light chain. Kidney biopsy was performed revealing arteriolar mucointimal edema and concentric intimal sclerosis, consistent with thrombotic microangiopathy.



Scleroderma renal crisis was diagnosed according to the pathology result. Lisinopril 20 mg oral daily was started but kidneys continued deteriorating leading to hemodialysis.

Discussion: Recognizing the early signs of kidney injury is important to initiate the treatment scleroderma renal crisis(SRC). Physicians should suspect for SRC once patients have signs of acute kidney injury regardless of elevated blood pressure or creatinine.

TH-PO1042

Acetaminophen Associated 5-Oxoproline Acidosis in an Anuric End-Stage Renal Disease Patient Michael Pham,[1] Leslie F. Thomas,[2] Christine Snozek.[3] *[1]Internal Medicine, Mayo Clinic, Phoenix, AZ; [2]Nephrology, Mayo Clinic, Phoenix, AZ; [3]Laboratory Medicine & Pathology, Mayo Clinic, Scottsdale, AZ.*

Introduction: Also known as pyroglutamic acid, 5-oxoproline is an intermediary in glutathione antioxidant metabolism. Reports of acetaminophen associated 5-oxoproline high-anion gap metabolic acidosis (HAGMA) has been slowly growing in the literature but remains under recognized in clinical practice.

Case Description: A 57 year old male with anuric end-stage renal disease (ESRD) was admitted for confusion and hypotension secondary to sepsis from infected lower extremity ulcers, poor oral intake, and excessive peritoneal dialysis. Laboratory evaluation revealed a depressed bicarbonate level of 17 mEq/L and an elevated albumin-corrected anion gap of 30 mEq/L. Despite correction of an elevated L-lactate with fluid resuscitation and antibiotics, his HAGMA persisted. An exhaustive investigation was unable to find a convincing etiology including commonly attributable organic acids, D-lactate, paraproteinemias, toxic exposures, and medications. Further inquiry revealed a protracted course of therapeutic acetaminophen ingestion with a weighted average daily dose of ³1.3 grams in the four weeks leading to presentation. Serum 5-oxoproline was elevated to >100.0 mmol/L (normal <70.0 mmol/L). Serum acetaminophen was undetectable. All acetaminophen containing medications were subsequently stopped. His clinical course improved with supportive care and he was discharged home. After 5 weeks of acetaminophen cessation, his serum 5-oxoproline normalized to 27.1 mmol/L with anion-gap and bicarbonate levels returning to baseline.

Discussion: To our knowledge, we report the first case of acetaminophen associated 5-oxoproline acidosis in an anuric ESRD patient. Risk factors are thought to be related to glutathione deficiency which in turn favors the 5-oxoproline pathway of the γ-glutamyl cycle and results in accumulation. These risk factors include reactive acetaminophen metabolites, alcohol abuse, malnutrition, sepsis, renal dysfunction, and liver disease. As an under recognized entity in clinical practice, 5-oxoproline should be considered in adults with unexplained HAGMA and the above risk factors.

TH-PO1043

Renal Amyloidosis Associated with Apolipoprotein C-II Deposition Lohit Garg,[1] Gerta Mane,[1] Sami S. Zarouk.[2] *[1]Dept of Internal Medicine, Beaumont Health, Royal Oak, MI; [2]Dept of Nephrology, Beaumont Health, Royal Oak, MI.*

Introduction: A 62-year-old female with no family history of renal disease presented with a creatinine at 2.3 mg/dL and hypertension. Baseline creatinine was 1.2 mg/dL one year prior to presentation and she had 1+ proteinuria on urinalysis 3 years earlier. Serologic work up was negative for ANA, C3, C4, hepatitis B and C, HIV and SLE. Monoclonal gammopathy evaluation showed IgA kappa monoclonal protein as two bands in the beta globulin region. Random urine for protein electrophoresis showed a small amount of IgA and free kappa monoclonal protein. Her random urine for protein/ creatinine ratio was 6.3.

A renal biopsy was consistent with amyloidosis in the mesangium that exhibited apple green birefringence on polarization microscopy after Congo Red staining. Immunofluorescent stains for kappa and lambda light chains were negative. Electron microscopy showed randomly arranged fibrils in the mesangium with features characteristics of amyloid fibrils. Bone marrow biopsy showed 6% plasmacytosis and minimal involvement with amyloidosis. Laser micro dissection and liquid chromatography mass spectrometry (LCMS) were performed on peptides extracted from Congo-red positive dissected areas. LCMS detected high levels of apolipoprotein C-II while analysis for lambda or kappa light chains, transthyretin and serum amyloid A were negative. It was concluded that these findings are unequivocally consistent with apolipoprotein C-II amyloid. Genetic testing was performed by direct sequencing of apolipoprotein C-II and showed mutation in patient as well as her son but not her daughter.

Discussion: Apolipoprotien C-II is a component of very low density lipoprotein and readily aggregates in lipid free conditions to form homogenous amyloid fibrils due to their intrinsic structure. To the best of our knowledge, this is the first case of apolipoprotein C-II renal amyloidosis. This case highlights the importance of performing DNA sequencing of exons of interest and LCMS on known amyloidogenic proteins to accurately diagnose and type the renal amyloidosis, which is critical for prognosis, treatment and genetic counseling.

TH-PO1044

Membranous Nephropathy in a Young Child with IPEX-Like Phenotype and a Novel Foxp3 Mutation Olga Charnaya, Sun-Young Ahn, Asha Moudgil. *Nephrology, Children's National Medical Center, Washington, DC.*

Introduction: Immune dysregulation, polyendocrinopathy, enteropathy, X-linked (IPEX) syndrome typically presents with heterogenous manifestations. The syndrome is characterized by numerous auto-immune diseases due to dysfunction in the *Foxp3* gene, which plays a critical role in maintaining immune tolerance.

Case Description: A 14-month-old male with a history of failure to thrive (FTT), eczema and diarrhea presented with cough and wheezing for 4 months. Pertinent findings on physical exam included weight < 2%ile, length 10%ile, BP 103/83 mmHg, and diffuse wheezing. Laboratory evaluation showed nephrotic range proteinuria (urine protein-to-creatinine ratio of 6.3), low serum albumin 1.8 gm/dL, normal serum creatinine 0.3 mg/dL, elevated LDL cholesterol 195 mg/dl, elevated serum glucose 303-426mg/dl, normal urine calcium-to-creatinine ratio 0.25, low C3 46 and C4 9.7, and negative ANA and anti DNA. Thyroid function tests were normal; islet cell antibodies were elevated at 80 (normal <1.2). A renal biopsy revealed membranous nephropathy with mild mesangial proliferative changes. Upon further evaluation, he was found to have fat malabsorption and numerous food allergies. Genetic sequencing identified a novel missense mutation, c.767T>C leading to substitution of the highly conserved amino acid threonine with methionine at position 256 in the *Foxp3* gene. This mutation was predicted to be deleterious by in silico analysis thereby suggesting the diagnosis of IPEX syndrome. Of note, *Foxp3* protein expression was borderline low. The patient was treated with prednisone and tacrolimus with partial resolution of extra-renal symptoms, improvement in proteinuria and is currently awaiting bone marrow transplant.

Discussion: Infants with IPEX syndrome usually present with auto-immune enteropathy, FTT, eczema, type 1 diabetes mellitus and thyroid dysfunction. Renal involvement is rare and includes proteinuria, hematuria and renal insufficiency. Some children with novel mutations may have partial features as seen in this case. A diagnosis of IPEX should be considered in any male infant or young child with proteinuria in association with systemic features of autoimmunity.

TH-PO1045

Acute Rejection of a Kidney Transplant in a Patient with Common Variable Immunodeficiency Syndrome Omar Mousa Al Nimri, Rakesh Malhotra, Paisit Paueksakon, Beatrice P. Concepcion. *Vanderbilt Univ Medical Center, Nashville, TN.*

Introduction: Common Variable Immunodeficiency (CVID) is a primary immunodeficiency characterized by hypogammaglobulinemia. Clinical manifestations include recurrent bacterial infections, autoimmune disorders, chronic lung disorders, hepatitis and lymphoma. We report a case of a patient with known CVID whose post-transplant course was complicated by acute cellular and humoral rejection which ultimately led to graft loss.

Case Description: A 44 y.o. male with ESRD was diagnosed in 11/2010 with CVID after developing peritonitis. He had a history of recurrent sinopulmonary infections and pneumococcal pneumonia. Immunoglobulin levels were undetectable and B, T and NK cell numbers normal. He was treated with monthly IVIG infusions. In 3/2012, he underwent living unrelated kidney transplantation (KT). Immunosuppression consisted of basiliximab, methylprednisonlone (MP), FK, MMF and prednisone. Baseline creatinine (Cr) post KT was 1.3 mg/dL. In 8/2014 Cr was 3.6 mg/dL. Renal biopsy showed diffuse lymphoplasmacytic infiltrate with edema, frequent tubulitis and interstitial eosinophils. C4d and donor specific antibodies (DSA) were negative. He received IV MP 2.5 g and thymoglobulin 10.5 mg/kg as therapy for acute cellular rejection (ACR), CCTT Type 1. In 9/2014 Cr was 5 mg/dL. Rebiopsy showed resolution of ACR. However, he had chronic vascular rejection, focal acute tubular injury and transplant glomerulopathy with new diffuse (100%) C4d positivity. Class I DSA was positive at moderate levels. He was treated for acute humoral rejection with plasmapheresis and IVIG 2 g/kg. Renal function did not improve. In 11/2014 he was declared ESRD due to uremic symptoms and volume overload.

Discussion: To our knowledge, this is the first reported case of a patient with diagnosed CVID on maintenance IVIG who then underwent KT. The main concern for patients with CVID undergoing KT is the risk of infectious complications. However, this case illustrates that rejection can occur and adequate immunosuppression remains essential. Balancing immunosuppression with the risk of infection can be quite challenging in this patient population, making them high risk for transplantation.

TH-PO1046

Reverse Pseudohyperkalemia in a Patient with Non-Hodgkins Mantle Cell Lymphoma and Chronic Lymphocytic Leukemia Chawmay Aye, Mitesh K. Patel, Farhanah Yousaf, Bruce S. Spinowitz, Alla Goldberg, Ritesh Raichoudhury. *New York Hospital Queens.*

Introduction: Distinguishing pseudohyperkalemia from hyperkalemia is often challenging. Simple pseudohyperkalemia is common and is represented by a falsely increased serum potassium whereas reverse pseudohyperkalemia is characterized by a falsely elevated plasma potassium level. We report a case of reverse pseudohyperkalemia in a patient with non-Hodgkin's mantle cell lymphoma and chronic lymphocyctic leukemia.

Case Description: A 74 year old South Asian female with a past medical history of non-Hodgkin's mantle cell lymphoma (MCL) and chronic lymphocytic leukemia (CLL), presented to the emergency department with a chief complaint of dizziness. She underwent chemotherapy session with Imbruvica one week prior to her presentation. Her initial vital signs included a blood pressure of 105/73, a pulse of 116 beats/min, a respiratory rate of 17, and a temperature of 36.7 degrees Celsius. Physical exam was unremarkable. Her initial hematology panel consisted of a white blood count of 0.82 K/µL, hemoglobin of 10.2 g/dL, and platelets of 40 K/µL. Patient was admitted with neutropenic sepsis and was started on Vancomycin, Meropenem, and Valtrex. Subsequent lab tests revealed a rising serum creatinine of 2 mg/dL and greater. One month into hospitalization, lab results showed a plasma potassium concentration of 8.22 mmol/L and a serum potassium concentration of 5.6 mmol/L. Repeat testing four hours later was consistent and showed a plasma potassium concentration of 7.2 mmol/L and a serum potassium concentration of 5.4 mmol/L. Based on the blood plasma potassium results, the patient received emergent hemodialysis and potassium lowering agents.

Discussion: Reverse pseudohyperkalemia has been reported in adults with CLL but remains relatively an under-recognized entity among clinicians. The mechanisms producing reverse pseudohyperkalemia are unclear but potassium may be released from leukocytes due to heparin-induced cell damage and/or impaired Na-K ATPase activity in the presence of hematological malignancy. Early identification of reverse pseudohyperkalemia is crucial in preventing potassium lowering intervention related morbidity and mortality.

TH-PO1047

An Unusual Presentation of Fibromuscular Dysplasia Omar Mousa Al Nimri,[1] Murray J. Mazer,[2] Margaret L. Burks,[3] Gerald Schulman,[1] Rachel B. Fissell.[1] *[1]Nephrology, Vanderbilt Univ Medical Center, Nashville, TN; [2]Radiology, Vanderbilt Univ Medical Center, Nashville, TN; [3]Internal Medicine, Vanderbilt Univ Medical Center, Nashville, TN.*

Introduction: Fibromuscular dysplasia typically presents in middle aged women, often with hypertension. Depending on which arteries are involved, patients may present with transient ischemic attack, stroke [carotid artery FMD], or intractable hypertension [renal artery FMD]. We report an atypical case of fibromuscular dysplasia (FMD) in a male, that presented with renal infarction and no other symptoms.

Case Description: The patient is a 47yo male with no significant past medical history, including no history of Ehlers-Danlos syndronme or Marfan's syndrome, who developed sudden left flank pain while driving. No urinary symptoms. No tenderness on exam. The pain was so severe that he went to a local ER. Initial evaluation notable for BUN 10 mg/dL, Cr 1.06 mg/dL, urinalysis negative for blood, protein, and white blood cells. CT angiography revealed beading consistent with FMD at the distal main renal artery at the junction of the bifurcating branches, and tapered narrowing and occlusion most likely caused by spontaneous dissection with intramural hematoma, with upper pole infarct.

Subsequent transthoracic echo showed no vegetation or shunt, appearing to exclude embolus from heart or lungs. Hypercoagulable work-up was negative. Patient is being managed conservatively with no anticoagulation, and is doing well. His Cr has drifted down from a peak of 1.16 mg/dL to a new baseline of 0.99 mg/dL, he has not developed hypertension, and his flank pain has resolved.

Discussion: This case is notable because the FMD occurred in a male, and because renal infarction is a rare presentation of FMD. The actual cause of the infarction is most likely arterial dissection, with or without peripheral emboli.

Clotting Filter Might Be an Early Clue to Fat Embolism Syndrome: Case Report and Literature Review Deepak Jasuja, Melissa D. Anderson. *Div of Nephrology, Indiana Univ, Indianapolis, IN.*

Introduction: Non traumatic causes of Fat Embolism Syndrome (FES) have been reported with bone marrow transplantation, osteomyelitis, pancreatitis, alcoholic fatty liver, and with liposuction. Etiology likely is fat particles entering the circulation with damage to capillary beds. Regardless of the mechanism initiating fat embolism, the end result is an intense inflammatory response. In the lungs, this induces lung injury that is indistinguishable from ARDS. FES can cause cerebral edema with raised intracranial pressure along with multi-organ failure and AKI.

Case Description: We present a 40-year-old African American lady who underwent non-myeloablative bone marrow transplant for Myelodysplastic anemia. One week after engraftment she developed sudden onset of respiratory distress leading to a cardio-respiratory arrest. She developed ARDS, multiple organ dysfunction syndrome and CVVH was initiated for oliguric AKI and Metabolic acidosis .Soon after initiating CVVH her filter clotted with white, creamy plaque which cleared after 2 successive filters. Patient met Gurd and Wilson's criteria for diagnosis of Fat Embolism Syndrome. She had abundance of

inflammatory cells on Broncho alveolar lavage including neutrophils and macrophages. Oil Red-O stain (stain for lipid) was performed to quantify macrophages displaying positivity. The initial Prep yielded 5 of 5 and the repeat prep yielded 11 out of 12 macrophages positive for Oil-Red-O. CT brain was performed which revealed large acute strokes with midline shift compatible with subfalcine herniation. No cerebral blood flow was identified on nuclear scan and patient was declared brain dead and terminally weaned.

Discussion: With the absence of specific tests or criteria the diagnosis of FES is dependent on the clinical acumen of the physician. Lipid inclusion in 30-70% of macrophages / inflammatory cells is most suggestive of FES . Only proven treatment is supportive care. We propose that a clotting filter might be an earlier clue to diagnose fat embolism syndrome and sending the filter for pathological analysis looking for lipid laden inflammatory cells is a less invasive approach as compared to quantification using Broncho-alveolar lavage.

TH-PO1049

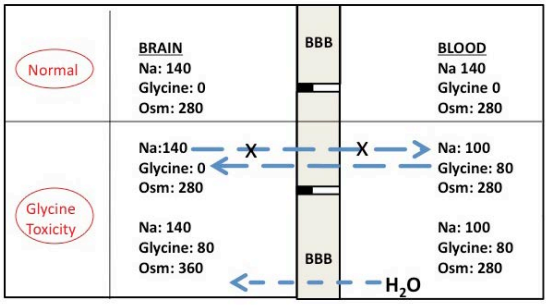
Fatal Hyponatremia with Glycine Solution During Hysteroscopy – Proposal for New Mechanisms of Hyponatremia and Cerebral Edema

Suchita J. Mehta, Subodh J. Saggi, Andrea Roche-Recinos, Man S. Oh. *Nephrology, Suny Downstate, Brooklyn, NY.*

Introduction: We report a fatal case of severe symptomatic hyponatremia and cerebral edema following hysteroscopy.

Case Description: 39 y/o woman underwent 70 mins hysteroscopic myomectomy, 6L of glycine solution used for distension, without documented deficits. 3 hours later she developed pulmonary edema. Hyponatremia of 117mEq/L first noted 4 hours post surgery, baseline normal sodium. Course further complicated by agitation, vomiting, lethargy due to cerebral edema confirmed on C.T. Head 8 hours post-op, remained without brain stem reflexes. Post-op day 2 she also developed central diabetes insipidus. Remained brain dead, extubated and died after 12 days.

Discussion: Hyponatremia with glycine is iso-osmolar occurring as a result of dilution effect since glycine is retained in extra-cellular fluid before its metabolism by glycine cleavage enzyme. Two main questions with our postulated explanations: 1) How does cerebral edema develop with iso-osmolar hyponatremia? 2) Why is hyponatremia often more severe than predicted? Proposed mechanisms:1) Glycine can cross blood brain barrier (BBB) by passive diffusion, as shown in rats and cats. Sodium, however, does not exit brain via BBB as sodium transport across BBB occurs only inward. With glycine toxicity, glycine accumulates in the brain cells after crossing BBB followed by water resulting in brain edema. Possibility of glycine metabolism to ammonia leading to cerebral edema cannot be ruled although high levels were not seen in our case.



2) The greater reduction in serum sodium than expected can be explained by a smaller initial volume of distribution of glycine than the extracellular volume, which is attributed to rapidity of accumulation of glycine solution and the reduced muscle blood flow during surgery.

TH-PO1050

Cytomegalovirus-Induced Atypical Hemolytic Uremic Syndrome After Renal Transplant

Taranpreet Kaur,[1] Andres G. Chiesa-vottero,[2] Leal C. Herlitz,[2] Richard A. Fatica.[1] *[1]Nephrology, Cleveland Clinic; [2]Pathology, Cleveland Clinic, Cleveland, OH.*

Introduction: Atypical hemolytic uremic syndrome (aHUS) may occur as de novo disease and recurrence of primary renal disease in kidney transplant recipients. Causes of de novo HUS includes immunosuppressive drugs, ischemia reperfusion injury, acute humoral rejection, and viral infections. Some patients have a genetic susceptibility to the disease from underlying mutations in the complement regulatory proteins. Cytomegalovirus (CMV) has been rarely reported as a trigger for de novo post-transplant aHUS.

Case Description: A 61 year old male underwent deceased donor kidney transplant for ESRD from presumed FSGS. 1 year following transplant he was admitted with profound diarrhea and weight loss due to CMV colitis and high grade CMV viremia (410,462 copies/ml). His immunotherapy was reduced and he was discharged home on oral valganciclovir with near resolution of symptoms. He was re-admitted 1 week later with nausea, abdominal pain, and acute kidney injury (Creatinine of 3.8 mg/dl, baseline of 1.8 mg/dl). His repeat CMV viral load was significantly better at 70,000 copies/ml. Labs were suggestive of microangiopathic hemolytic anemia: Hb 8 g/dl, platelets 58 K/ul, LDH 586 U/L, haptoglobin <20 mg/dl, and ADAMTS13 activity >67%. He received 4 sessions of plasmaphresis without improvement and required initiation of dialysis. Histologic features of acute and subacute endothelial injury, including segmental fibrin thrombosis of 2 arterioles were present on transplant kidney biopsy. His aHUS genetic panel revealed several mutations in different gene loci but no disease- associated mutation was identified. He was started on eculizimab. His hemolysis labs improved and he was taken off dialysis.

Discussion: CMV infection by way of endothelial injury can provoke aHUS in kidney transplant recipients and possibly be enhanced by genetic predispositions. Postulated mechanisms of CMV endothelial injury include increased leukocyte and platelet adhesion, endothelial expression of Von Willebrand factor, E-selectin, vascular cell adhesion molecule-1, and intercellular adhesion molecule-1. In our case, the aHUS process was halted by use of eculizumab.

TH-PO1051

Acute Interstitial Nephritis from Anti-PD-1 Therapy with Pembrolizumab in Two Patients with Advanced Non-Small Cell Lung Cancer

Heidi Mae G. Timbol, Anushree C. Shirali. *Internal Medicine, Section of Nephrology, Yale Univ School of Medicine, New Haven, CT.*

Introduction: Immune checkpoint inhibition with monoclonal antibodies (mAb) targeted against programmed cell death receptor 1 (PD-1) is emerging immunotherapy for various cancers. Pembrolizumab, an anti-PD-1 mAb, is being used in clinical trials with promising anti-tumor responses, but renal-specific adverse events are not clear. We report 2 cases of acute interstitial nephritis (AIN) in patients who received Pembrolizumab for advanced non-small cell lung cancer (NSCLC).

Case Description: Two female patients, both 69 years of age, with metastatic NSCLC were seen in outpatient nephrology clinic for acute kidney injury (AKI). Both patients were enrolled in a clinical trial with Pembrolizumab, and their cases had been complicated previously by auto-immune adrenalitis. On labs, Patient A had an increase in creatinine to 2.1 mg/dL prior to cycle 16, up from a baseline of 0.9 mg/dL. Patient B had a creatinine peak of 1.9 mg/dL after cycle 6, up from a baseline of 1.1 mg/dL. Medications were significant for long-standing pantoprazole use in both patients. Urine sediment showed many WBC clumps without casts or RBCs. Renal ultrasound was unremarkable. Volume expansion with normal saline and cessation of potential nephrotoxins failed to reverse renal dysfunction in either case. Each patient underwent CT-guided renal biopsy, which showed diffuse AIN. Steroid therapy with prednisone 60 mg/day with a slow taper was started and creatinine improved to baseline.

Discussion: These two cases highlight a new association between AIN and Pembrolizumab, which to the best of our knowledge has not been previously reported. While both patients were on pantoprazole therapy prior to their AKI, this medication was not new. Rather, the time course of AKI best fits with initiation of pembrolizumab. Additionally, their pre-existing drug-related auto-immune adrenalitis suggests a possible auto-immune component to AIN from anti-PD-1 therapy. With increasing use of these agents, clinicians should maintain a high index of suspicion for AIN as a cause of AKI and have a low threshold for kidney biopsy to confirm diagnosis and initiate early treatment.

TH-PO1052

Concurrent Anti-PLA2R and ADAMTS 13 Inhibitor – Coincidence or a Clue to Pathogenicity?

Laith Al-Rabadi,[1] Moshe Shashar,[1] Parikshit Duriseti,[2] Ami Patel,[1] Aala Jaberi,[1] Ashish Upadhyay,[1] Joel M. Henderson,[1] Vipul C. Chitalia,[1] David J. Salant,[1] Laurence H. Beck.[1] *[1]Boston Univ Medical Center; [2]Mamata Medical College, India.*

Introduction: Thrombotic thrombocytopenic purpura (TTP) is a hematologic emergency associated with a decrease in ADAMTS13 activity, most often due to the presence of an inhibitor. Severe proteinuria is an unusual feature of TTP. The concurrent presence of anti-PLA2R and ADAMTS13 inhibitor has never been previously reported until now.

Case Description: Herein, we present a case of a 70 year old male who presented with generalized anasarca. Physical exam was remarkable for BP 180/100, and 2+ peripheral edema. Workup revealed Hgb 7.4, Plt 36, Creatinine1.43**,** LD 742 and undetectable haptoglobin. His peripheral smear showed many schistocytes. These findings were consistent with thrombotic microangiopathy. Urine analysis showed 2+ blood, 3+ protein. Examination of the urinary sediment revealed oval fat bodies, and some RBCs. The patient was started on plasma exchange and prednisone (1 mg/kg). Further studies revealed a serum albumin of 2.2 and urine protein/Cr of 9. Kidney biopsy showed features of membranous nephropathy with many subepithelial deposits flanked by new basement membrane material (spikes). The deposits were immunoreactive for PLA2R, with IgG1 but no IgG4 reactivity. In addition, there was moderately severe arterial and arteriolar sclerosis and segmentally prominent double contour formation in the glomeruli. These vascular changes suggest a primary form of endothelial injury and consistent with chronic thrombotic microangiopathy. VWF protease activity came back as less than 3% with an elevated inhibitor titer of 1.3 (reference <0.4 BEU). Anti-PLA2R was detected in the serum at titer of 40.3 RU/ml. Both were exclusively of the IgG1 subtype by western blotting, atypical of the usual IgG4 predominance for both autoimmune disorders.

Discussion: Although prednisone, plasmapheresis, and supportive therapy have thus far stabilized both diseases, rituximab would be our first choice for more definitive treatment of these concurrent autoimmune disorders. This unique case may help to further our understanding of the mechanistic pathways underlying both of those clinical entities.

TH-PO1053

Carfilzomib Associated Acute Kidney Injury Vladimir Liberman,[1] Vivette D. D'Agati,[2] Naveed N. Masani,[1] Joseph Mattana,[1] James Drakakis.[1] *[1]Medicine, Winthrop-Univ Hospital, Mineola, NY; [2]Pathology, Columbia Univ Medical Center, New York, NY.*

Introduction: Carfilzomib is a selective proteasome inhibitor approved in 2012 for the treatment of relapsed and refractory multiple myeloma. A phase 2 trial of the drug showed an increased serum creatinine in 17.7% of patients but the mechanism has been incompletely understood. We report a case of biopsy proven acute tubular injury one week after carfilzomib administration.

Case Description: A 60 year old man with IgG lambda multiple myeloma who received an autologous stem cell transplant 2 years ago presented to the hospital complaining of shortness of breath and chest discomfort. Physical examination revealed a blood pressure of 141/74, clear lungs, normal heart sounds with no murmurs and pitting edema of both lower extremities. Serum potassium was 6.3 mEq/L and creatinine was 3.4 mg/dL (baseline 0.8 mg/dL). Serum free lambda light chains were 3630 and free kappa light chains were 5.55. The patient had received an injection of carfilzomib 7 days prior to his arrival. He had no other exposure to nephrotoxic medications. Spot urine protein/creatinine ratio was 3g/g with an albumin/creatinine ratio of 140mg/g. Obstruction was excluded by ultrasonography and he received isotonic saline with only minimal improvement in kidney function at which point a kidney biopsy was performed. Renal biopsy showed focal mild myeloma cast nephropathy with diffuse acute tubular injury out of proportion to the sparse casts. The close temporal association with the initiation of carfilzomib suggests that it could have been responsible for the severe tubular injury given no other obvious insults.

Discussion: Carfilzomib has been associated with kidney injury as one of its adverse effects in its phase 2 trial. Most of the kidney injuries were reported as grade 1 or 2 based on the NIH grading system. Grade 3 and 4 renal impairment was reported in 38 patients (7.2%). This case of biopsy proven acute tubular injury suggests a mechanism by which carfilzomib may cause acute kidney injury in patients with multiple myeloma.

TH-PO1054

Podocyte Infolding Glomerulopathy in a Patient of African Decent Laith Al-Rabadi,[1] Cathryn J. Byrne-dugan,[2] David Olafsson,[3] Saif Alrabadi,[4] Laurence H. Beck,[1] Helmut G. Rennke,[2] Stanley D. Crittenden.[1] *[1]Boston Medical Center; [2]Brigham and Women's Hospital; [3]Univ of Iceland; [4]Jordan Univ.*

Introduction: Podocyte infolding glomerulopathy (PIG) is a rare entity primarily described in Japan which is frequently associated with autoimmune diseases like lupus. It is not known whether PIG represents a new disease entity or a transient morphologic state of well-known diseases (i.e. a subset of membranous nephropathy or lupus nephritis). PIG has been exclusively described in Asian populations, with no cases reported in patients of African descent. PIG is distinguished by its histologic features of podocyte membrane infolding into the basement membrane and the formation of microspheres and microtubules. The majority of cases do not contain electron-dense deposits, nor do they show any reactivity with IgG.Here we present the first reported case of PIG in a patient of African descent.

Case Description: A 58 year old Africa female from Ghana with history of systemic lupus erythematosus presented to the nephrology clinic for the evaluation of proteinuria. She was found to have a serum creatinine of 1.5 mg/dL and random urine protein to creatinine ratio of 1.5 g/g. Microscopic examination of the urine sediment did not reveal RBCs or cellular casts. Other notable lab findings include anti nuclear antibody titer of 1:2560 and positive anti double stranded DNA. She underwent kidney biopsy. Light microscopy revealed thickened glomerular peripheral capillary walls, with numerous crater-like defects. Immunofluorescence was negative other than trace IgM and C3 reactivity along the peripheral capillary walls and in the mesangium. No electron dense deposits were found on electron microscopy (EM). However, widespread aggregates of spherical structures within the lamina rara externa and lamina densa along with diffuse invaginations of the podocytes at the subepithelial aspect of the basement membrane, with deposition of spherical microparticles were seen on EM.

Discussion: Further studies are warranted to investigate whether this represents a unique primary disease with a specific underlying pathology or if it is simply a morphologic reflection of a transition point for a previously discovered disease entity.

TH-PO1055

Amyloidosis due to R554L Fibrinogen Aα-Chain Mutation Matthew R. Lynch,[1] Ian Mccoy,[3] Isaac Ely Stillman,[2] Stewart H. Lecker.[1] *[1]Div. Nephrology, Beth Israel Deaconess Medical Center, Boston, MA; [2]Pathology, Beth Israel Deaconess Medical Center, Boston, MA; [3]Medicine, Beth Israel Deaconess Medical Center, Boston, MA.*

Introduction: Cases of systemic amyloid caused by mutations in the fibrinogen A-alpha chain (Afib) were once thought to be quite rare, but may be more common than initially thought. Mutations in Afib leading to hereditary amyloidosis, primarily with renal manifestations, was first described in 1993. A significant minority of Afib amyloid patients have the R554L variant. To date, about 20 such cases have been published. Small sample sizes have limited definitive conclusions regarding genotype-phenotype correlation.

Case Description: A 66-year-old man with a history of hypertension, hyperlipidemia, and prior heavy NSAID use was referred for two years of stable, nephrotic-range proteinuria. Besides lower extremity edema managed with compression stockings, he was asymptomatic. He had no family history of kidney disease. His medications included losartan, torsemide, and simvastatin. His exam was unremarkable except for pitting edema to the knees. Laboratory studies revealed a stable serum creatinine of 1.1 mg/dl. A 24 hour urine protein measured 4180 mg. Urine sediment showed lipiduria but no cells or casts. Testing for hepatitis B and C, HIV, and ANCA was negative. Serum and urine protein electrophoresis showed no monoclonal protein. Renal ultrasonography was unremarkable. Kidney biopsy showed massive glomerular deposition of Congo Red positive and apple-green birefringent material. Liquid chromatography tandem mass spectrometry detected mutant R554L amino acid sequence in the fibrinogen A-alpha chain.

Discussion: Afib patients progress from presentation to ESRD over a mean of 4.6 years with mean survival of 9.3 years after ESRD. Recurrent amyloidosis occurs in renal allografts, but this process takes several years. While orthotopic liver transplantation may cure the amyloidosis by replacing the source of the mutant fibrinogen, the procedure-related mortality is high, making the benefit of preemptive liver transplantation unclear. With increasing recognition of this disease, further investigation into curative therapy is needed.

TH-PO1056

Diabetes Insipidus Induced by Excessive Intake of Melatonin Rahul N. Pawar, Savneek S. Chugh, Amy R. Patel. *Nephrology, Westchester Medical Center, Valhalla, NY.*

Introduction: Melatonin is produced by the pineal gland and regulates the sleep/wake cycle in humans. Specific over the counter melatonin formulations can be used to treat circadian-rhythm-related sleep disorders and age-related insomnia. Acute intoxication of melatonin and its deleterious effects have rarely been reported.

A 24 year old female, with no known medical history, was brought to the hospital for altered mental status and possible drug overdose. Her vital signs were a Tmax of 101.8 F, HR 170, BP 150/103, and a pulse oximetry of 98% on 2L NC. On physical exam, she had mildly dilated and sluggish pupils. Due to an altered sensorium, she was intubated for airway protection. Initial lab tests showed a sodium of 140 mEq/L, potassium 3.9 mEq/L, chloride 113 mEq/L, bicarbonate 25 mEq/L, BUN 8 mg/dL, and a creatinine of 0.6 mg/dL with no osmolar gap, but elevated AST 74 U/L, ALT 37 U/L and creatine phosphokinase of 2,460. Urine toxicology screen was negative for PCP, cocaine, MDMA, and opioids with an undetectable blood alcohol level. On day 1, she developed polyuria with a urine output of more than 13.5 liters, a serum sodium of 147 mmol/L and urine osmolarity of 65 mOsm/kg concerning for diabetes insipidus (DI). CT head and MRI of the brain were negative for intracranial lesions. Despite decreasing the rate of intravenous fluids, her urine output was more than 8L/day. Her urine osmolality increased to 444 mOsm/kg suggestive of a partial central DI. With the administration of DDAVP, her urine output decreased to 2-3L/day. After extubation, the patient reported ingestion of an excessive amount of melatonin for insomnia, but no other medications. She received DDAVP for 4 days with complete resolution of hypernatremia and polyuria.

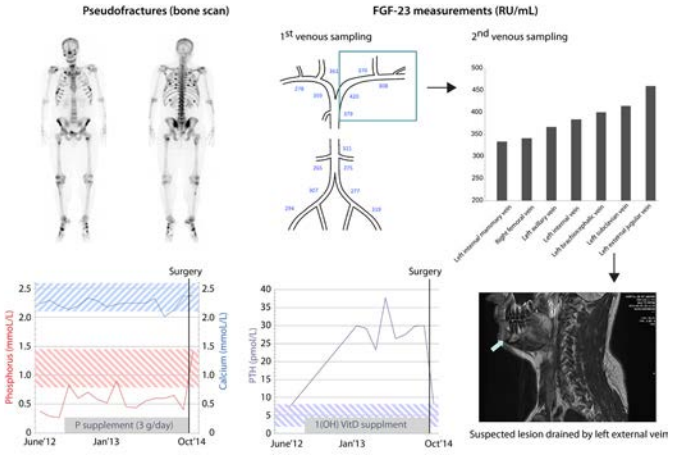
Discussion: Extensive literature review revealed that rat studies show how melatonin regulates the glomerular filtration of both sodium and water. It stimulates sodium tubular transport in the proximal tubules but its receptor or action on the distal tubule is unknown. Only a handful of cases have shown that it can cause polyuria. This rare case of polyuria from the acute ingestion of melatonin, which responded to DDAVP, may suggest its role in causing partial central DI.

TH-PO1057

Localization of Ectopic Fibroblast Growth Factor 23 Production in Tumor-Induced Osteomalacia Using a 2-Step Selective Venous Sampling Method Karyne Pelletier, Veronique Bienvenue, Myriam Lessard, Stephan Troyanov. *Medicine, Hôpital du Sacré-Coeur, Univ of Montreal, Montreal, QC, Canada.*

Introduction: Tumor-induced osteomalacia (TIO) is a rare syndrome characterised by hypophosphatemia, impaired renal phosphate reabsorption and inappropriate reduction of serum 1,25(OH)vitamin D usually caused by benign mesenchymal tumors secreting FGF23. Affected individuals present severe osteomalacia with bone pain, pseudofractures and muscle weakness. Although TIO is cured by the resection of the causative tumor, definitive treatment is often delayed because current imaging techniques (MRI and bone, octreotide and PET scans) fail to localize the offending lesion. We propose localization of ectopic FGF23 tumors using 2-step selective venous sampling method.

Case Description: A 37-year-old patient presented with bone pain and hypophosphatemia. An initial workup showed >75% fractional excretion of phosphate, normal serum calcium and intact PTH, low 25(OH) vitamin D. Peripheral blood FGF23 level was 310 RU/mL (N:19-114). Initial imaging failed to localize an obvious lesion. A 1st venous sampling suggested FGF23 drainage from the left subclavian vein. A second focused sampling pointed to the left external jugular vein. The excision of an initially unsuspected small mandibular lesion cured the patient.



Discussion: A recent cases review (Andreopoulou, J Bone Min Research 2011) supports the benefits of systemic venous sampling in locating FGF23 tumors in TIO. However, up to 30 samples are needed when using a single venous sampling method. Since lesions are small and may arise anywhere, we propose a 2-step approach simplifying the localization of causal lesions.

TH-PO1058

Renal Transplant Dysfunction due to Calcium Casts following Parathyroidectomy Maharajan Raman,[1] Rajkumar Chinnadurai,[1] Grahame N. Wood,[1] Jamil Choudhury,[2] Philip A. Kalra.[1] *[1]Renal Medicine, Salford Royal NHS Foundation Trust, Salford, Manchester, United Kingdom; [2]Cellular Pathology, Salford Royal NHS Foundation Trust, Salford, Manchester, United Kingdom.*

Introduction: Parathyroidectomy for renal hyperparathyroidism can lead to significant drop in calcium levels due hungry bone syndrome, which can lead to seizure, coma or fractures. Current practice is to pre-load patients with hydroxycholecalciferol and calcium supplements to maintain safe calcium levels in the post-operative period. We report a case of calcium cast nephropathy causing significant renal dysfunction following parathyroidectomy.

Case Description: A transplant patient on Cinacalcet for tertiary hyperparathyroidism underwent parathyroidectomy(PTX). Post operatively her calcium levels were managed according to local protocol. Patient sub-acutely developed renal dysfunction and the trends in creatinine(Cr), corrected calcium(C.Ca) and parathyroid hormone levels(PTH) pre and post surgery are shown in the table below.

	Pre PTX	1 month post	2 months post	3 months post	4 months post	6 months post
Cr (umol/L)	113	167	132	169	284	103
C.Ca (mmol/L)	2.73	2.62	2.55	2.71	2.67	2.38
PTH (ng/L)	329	-	54	-	-	-

Virology screen, immunology screen, urine culture, urine PCR, DSA, Cyclosporin levels and renal ultrasound were normal with no change in patients haemodynamic status. Hence a kidney biopsy was performed to identify the cause, which showed evidence of calcium casts with surrounding infllammation with no evidence of rejection. Her steroid dose was transiently increased due to the inflammation seen on the biopsy and all her calcium and hydroxycholecalciferol supplements were suspended, which lead to recovery of her renal function to baseline.

Discussion: Our patient had mild hypercalcaemia prior to parathyroidectomy with a stable renal function and following parathyroidectomy patient developed renal dysfunction despite similar levels of calcium, which can only be explained by iatrogenic calcium supplementation based on the renal biopsy. Perhaps routine monitoring of urinary calcium may help us guide the amount of calcium given to such patients and aiming for lower levels of calcium post parathyroidectomy rather than normal levels may prevent such phenomenon.

TH-PO1059

Severe Ketoacidosis After Bariatric Surgery in a Patient Treated with Canagliflozin Hossein Ghofrani, Christopher C. Wong, Miroslaw Smogorzewski. *Div of Nephrology, Keck Hospital of USC, Los Angeles, CA.*

Introduction: Euglycemic diabetic ketoacidosis is relatively uncommon and is usually caused by starvation and a lack of caloric intake. Sodium-glucose cotransporter-2 (SGLT-2) inhibitors have been very recently implicated as a cause of severe ketoacidosis. We report a case of euglycemic diabetic ketoacidosis in a patient who underwent bariatric surgery while taking an SGLT-2 inhibitor, canagliflozin.

Case Description: A 38 year old male with a history of DM type 2 and morbid obesity presented with fatigue, acute dyspnea, decreased exercise capacity and 2-3 pillow orthopnea for two days. Canagliflozin 300 mg daily was initiated 3 months prior to his current presentation due to poorly controlled DM-2. Ten days prior to his hospitalization, he underwent gastric sleeve bypass surgery and was discharged on post-op day 1. Upon admission in the ICU, his physical exam was benign except for a PR 108/min, RR 29/min, and a normal BP 128/69 mmHg. ABG showed pH 6.9, pCO2 13mmHg, pO2 99mmHg, bicarbonate 5mg/dL. His anion gap was 37, and serum glucose 152 mg/dL, with normal kidney function. Urine toxicology and blood levels of lactic acid and alcohol were negative. Urinalysis revealed pH 5.0, glucose >1000 mg/dL, and ketones>150 mg/dL. During the first day, he received 150 meq of sodium bicarbonate; his canagliflozin was held. He was intubated and started on a regular insulin drip along with 5% dextrose solution. He remained intubated and on an insulin drip for 7 days, receiving a total of 1266 units of insulin and extensive electrolyte replacement; blood glucose never exceeded 200 mg/dL while glycosuria persisted until day 7. C-peptide increased from 0.29 to 2.26 ng/mL. Once anion gap was closed and patient stabilized, he was extubated and weaned off the insulin drip.

Discussion: We present a new case of severe euglycemic DM ketoacidosis, induced by a combination of SGLT-2 inhibitor use and low caloric intake after bariatric surgery. Despite withdrawal of canagliflozin, its effect on glycosuria persisted for 7 days. Considering long biological effect of SGLT-2 inhibitors, they should be stopped weeks before a bariatric surgery to avoid ketoacidosis.

TH-PO1060

Severe Hypercalcemia in Erdheim-Chester Disease: A Rare Clinical Scenario David H. Slade,[1] Esho Georges,[2] Ahmer Farooq,[3] Kavitha Vellanki.[2] *[1]Dept of Medicine, Loyola Univ Medical Center, Maywood, IL; [2]Dept of Nephrology, Loyola Univ Medical Center, Maywood, IL; [3]Dept of Urology, Loyola Univ Medical Center, Maywood, IL.*

Introduction: Erdheim-Chester disease (ECD) is a rare form of histiocytosis with highly variable clinical manifestations. Only a few hundred cases have been reported in the literature to date. It is characterized by proliferation of non-Langerhans cells that can infiltrate all vital organs. Infiltration of the retroperitoneal space and subsequent fibrosis may cause bilateral ureteral obstruction leading to progressive renal failure. Here, we present a case of severe hypercalcemia, work up of which eventually lead to the diagnosis of ECD.

Case Description: A 58 year old Polish male with chronic kidney disease due to obstructive uropathy from bilateral ureteral obstruction was transferred to our center for suspected pyelonephritis. His course was complicated by persistent fevers with repeatedly negative infectious work up and severe hypercalcemia with ionized calcium levels peaking at 1.66 mm/L. Parathyroid hormone levels were appropriately suppressed. Work up for multiple myeloma showed no lytic lesions on bone scan, however, bilateral, symmetric, sclerotic lesions in the distal femurs and proximal tibias were incidentally noted. Based on these findings, ECD was suspected. This was confirmed with bone marrow biopsy which revealed multiple histiocytic and lymphocytic aggregates positive for the histiocyte marker CD68, but negative for CD1a (pathognomonic of the disease). He was subsequently started on BRAF (v-raf murine sarcoma viral oncogene homolog B1) inhibitor, vemurafenib with marked improvement in clinical symptoms. While he received pamidronate for hypercalcemia during the hospital stay, his ionized calcium levels have since normalized and continue to be within normal range 6 months after the initial presentation.

Discussion: In conclusion, ECD is a rare disorder with varied clinical manifestations and diagnosis is often elusive, requiring a high level of clinical suspicion. Although skeletal involvement is seen in 96% of the patients with ECD, there have been no reported cases of hypercalcemia, and our case is the first to report such an association.

TH-PO1061

APOL1 Polymorphisms in Deceased Donors and Primary Glomerular Disease Post-Kidney Transplant: First Case Report Pratik B. Shah, Alexander C. Wiseman, James E. Cooper. *Renal Diseases and Hypertension, Univ of Colorado Medical Center, Aurora, CO.*

Introduction: Genetic polymorphisms in APOL1 (G1/G2) are associated with glomerular disease and ESRD. An emerging issue is whether screening for APOL1 (G1/G2) should be performed in living or deceased kidney donors.

Case Description: A 46 year-old Caucasian male with a history of SLE received a deceased donor kidney transplant. The deceased donor was a 12-year old African American male. 9 months post-transplant, he presented with acute kidney injury following an elective laparoscopic cholecystectomy (CCK). 2 weeks prior to surgery his SCr was at baseline, 1.5 mg/dl with no proteinuria. On postop day 0-CCK, his SCr was 7.9 mg/dl, with spot UPC of 2 g/g Cr, platelet count of 58000, LDH of 2022 U/L, haptoglobin of <14 mg/dl. Renal transplant biopsy showed collapsing glomerulopathy with no evidence of thrombotic microangiopathy or rejection. Plasma CMV PCR was positive at 2340000 copies/ml. The patient's acute kidney injury was attributed to collapsing glomerulopathy in the setting of acute CMV infection. The patient ultimately did not recover kidney function. The patient's deceased donor DNA was analyzed for APOL1 risk variant genotyping and was positive for two APOL1 risk variants: compound heterozygosity for APOL1 G1, c.1024A>G; p.Ser342Gly and APOL1 G2 c.1164delTTATAA. The sister kidney from the same deceased donor had been transplanted to a 63 year old female with ESRD from diabetes. Six months post-transplant, she had new onset proteinuria of 2.5 g/d, and a renal biopsy demonstrated focal segmental glomerulosclerosis (FSGS). Her renal function and proteinuria remain stable 14 months post transplant.

Discussion: To our knowledge, this is the first case report of high risk variant APOL1 in a deceased donor with subsequent primary glomerular disease in both the recipients. This suggests that deceased kidney donor APOL1 genotyping may be informative in predicting graft outcomes. This also highlights the important question of whether routine screening of African American donors for high risk APOL1 variants before renal transplant is warranted. This consideration must be balanced against the significant limitations in kidney availability.

TH-PO1062

Atypical HUS in an Infant due to a Novel Gene Mutation Mohamed Alseiari,[1] Robin Amy Kremsdorf,[2] M. Khurram Faizan.[2] *[1]Rhode Island Hospital; [2]Hasbro Children's Hospital; [3]Hasbro Children's Hospital.*

Introduction: Atypical HUS (aHUS) is a rare genetic renal disease associated with over- activation of the alternative pathway of complement. A variety of mutations have been described in the complement pathways genes in patients with aHUS. We report a case of aHUS with a novel genetic mutation in the Complement Factor B (CFB) gene.

Case Description: 10 months old Caucasian girl who presented with diarrhea, vomiting, and swelling in her extremities and face for 2 weeks preceded by an episode of cough, runny nose with non-bloody diarrhea. Upon presentation her BP was 150/90 mm Hg. Lab data showed Hgb 4.4 g/dl, Platelets, 46 x10exp9/L, Cr elevated to 0.46 mg/dl from baseline of 0.3, Albumin 2.6 g/dl, LDH 632 IU/L, normal ADAMTS13 and C3 level 7.9 mg/dl. Urine revealed 32RBC/hpf with proteinuria, Urine protein Creatinine ratio 19 g/g. Peripheral blood smear revealed schistocytes. Stool was negative for Shiga toxin. Clinical presentation was strongly suggestive of aHUS and patient was treated with Eculizumab. She developed worsening anasarca with neck edema, requiring a tracheotomy after failed intubation. She required RRT for volume management during her hospital course after failing diuretics . Renal biopsy showed acute and chronic thrombotic microangiopathic changes consistent with aHUS. Genetic testing revealed a novel mutation in the complement Factor B gene in the region of binding to Von Willebrand factor. It also showed a heterozygous deletion of CFHR1 andCFHR4. Patient recovered renal function 3 weeks after presentation. C3 remained low after recovery of renal function. RRT was stopped after two weeks and she was discharged on ACEI with Eculizumab every 2 weeks.

Discussion: Gain of function mutations in CFB are extremely rare in aHUS and occur in only 1% to 2% of cases of familial aHUS. There is increased C3b affinity and form hyperactive C3 convertase that is resistant to dissociation, thus increasing C3b formation. Anti C5 Antibody Eculizumab has revolutionized the care of aHUS, improving the overall prognosis of these patients. This case is the first case reported with this novel CFB gene mutation. No long term data avaiable regarding the outcomes of aHUS with Eculizumab therapy.

TH-PO1063

Oxymorphone-Induced Thrombotic Microangiopathy and Acute Kidney Injury Girish Singhania, Shriharsha Kallahalli Jayaramu, Dara N. Wakefield, Amir Kazory. *Nephrology, Univ of Florida, Gainesville, FL.*

Introduction: Intravenous (IV) administration of oral oxymorphone represents an emerging pattern of drug abuse with increasing popularity and unforeseen adverse consequences. Here, we present a case of IV Oxymorphone abuse associated with thrombotic microangiopathy (TMA) and acute kidney injury (AKI).

Case Description: A 32-year-old man with a history of IV drug abuse presented with non-healing left arm wound. Physical examination was unremarkable except for a left forearm abscess. However, laboratory studies revealed a serum creatinine (SCr) of 2.3 mg/dL. He was found to have severe anemia with a Hb level of 5.8 g/dL, platelets of 135,000/μL and evidence of hemolysis (LDH of 579 U/L, undetectable serum haptoglobin, and schistocytes on peripheral blood smear). He had proteinuria of 4.1 gm/day and the urine drug screen was positive for oxymorphone. Serum complement levels were normal as were all other immunologic studies. ADAMTS13 level was >100%. Kidney biopsy showed evidence of TMA supported by glomeruli filled with focal extravasated and crenated RBCs. Immunofluorescence (IF) was negative for immune complex deposition but C4d staining was positive. Conservative management including platelet transfusion, without plasma exchange (PE), was followed by stabilization of renal function.

Discussion: This patient presented with TMA, acute kidney injury, and normal serum ADAMTS13 activity. His urine oxymorphone was positive and he admitted to IV abuse of pulverized oxymorphone pills, which represents an emerging pattern of illicit drug abuse. The mechanism of oxymorphone-induced TMA remains unclear but it is suggested that the drug or some ingredients mixed in it triggers a cascade of immunological pathways leading to TMA. Previously reported cases had negative IF on kidney biopsy but positive C4d staining in this patient implies some degree of complement activation. Although PE was initially used in some cases, it has recently been shown that oxymorphone-induced TMA could successfully be managed without it. Based on this case coupled with previous reports, we suggest that health care providers should inquire about IV Oxymorphone abuse in the setting of unexplained TMA and acute kidney injury.

TH-PO1064

IgG-4 Related Tubulointerstitial Nephritis in a Young Patient with Enlarged Kidneys Valerie Jorge Cabrera,[1] Shirin Shirani,[2] Joni H. Hansson.[3] *[1]Yale Nephrology, Yale School of Medicine, New Haven, CT; [2]Nephrology, Yale New Haven Hospital/St. Raphael Campus, New Haven, CT; [3]Nephrology, Yale New Haven Hospital/St. Raphael Campus, New Haven, CT.*

Introduction: IgG-4 related disease is a recently recognized entity characterized by the infiltration of tissues with IgG-4 positive plasma cells. It occurs more commonly in middle age men and affected organs can be diffusely enlarged, sometimes with nodular lesions that can mimic tumors. We present the unique case of a young patient with a two year history of recurrent cellulitis, parotid gland enlargement, diffuse lymphadenopathy and nephromegaly.

Case Description: A 27 year old African American male presented with a rash and edema of his right lower extremity. He also reported night sweats and weight loss over 4 months. His past medical history included hypertension, recurrent cellulitis, nephrolithiasis, chronic kidney disease of unclear etiology, antithrombin III deficiency and pulmonary embolism. Prior imaging had shown bilateral hilar, retroperitoneal and mesenteric lymphadenopathy. However, lymph node and parotid gland biopsies were non diagnostic. On examination, he was afebrile but tachycardic. Parotid glands were enlarged and cardiovascular, lung and abdominal examination were unremarkable. His creatinine was 2.5 mg/dL, elevated from 1.8 mg/dL without significant proteinuria. A C3 level was 41 mg/dL and C4 was less than 10 mg/dL. An IgG-4 level was elevated to 2045 mg/dL. A renal biopsy was obtained and although the lack of glomeruli was limiting, the tissue revealed a dense plasma cell rich infiltrate in the interstitium consistent with an interstitial nephritis. Immunostains were positive for IgG4 in the infiltrating plasma cells. Treatment was initiated with prednisone 40 mg daily. His creatinine decreased to 1.3 mg/dL with resolution of his symptoms.

Discussion: A number of conditions can lead to kidney enlargement. Diabetes, HIV, amyloidosis and leukemia/lymphoma are commonly included in the differential diagnosis. IgG-4 related disease should also be considered in the differential diagnosis of patients presenting with kidney enlargement and recurrent infections.

TH-PO1065

Karyomegalic Interstitial Nephritis: A Rare Cause of Kidney Disease Lindsay Sanders,[1] Maxwell L. Smith,[2] Ibrahim Qaqish,[1] Sumi Sukumaran Nair,[1] Leslie F. Thomas.[1] *[1]Nephrology and Hypertension, Mayo Clinic Arizona, Phoenix, AZ; [2]Pathology, Mayo Clinic Arizona, Scottsdale, AZ.*

Introduction: Karyomegalic interstitial nephritis (KIN) is a rare, progressive kidney disease associated with Fanconi-associated nuclease 1 (FAN1) mutation as well as exposure to heavy metal, ochratoxin,or viral pathogens. Less than 50 cases have been reported in the literature. Onset of the disease is often in the third decade and may be associated with a history of recurrent upper respiratory tract infections. There is no known treatment.

Case Description: A 45-year-old male was seen for renal impairment first noted at age 40, with a serum creatinine of 1.6 mg/dL (eGFR 53 mL/min/1.73 m^2). He had no known risk factors for chronic kidney disease. His only other personal medical history was for skin changes of his lower extremities consistent with pigmented purpuric dermatosis. He had no known exposures to heavy metals or toxins. He reported renal disease of unclear etiology in one sister. At time of consultation, he had a combined eGFR of 46. Urinalysis and serologic studies were normal, and ultrasound demonstrated kidneys of normal size with echogenic parenchyma. Renal biopsy demonstrated KIN. Significant findings by light microscopy included 1) 8 of 33 glomeruli appearing normal with the remaining 25 glomeruli being globally sclerosed, 2) moderate to severe fibrosis of the tubulointerstitial compartment with associated tubular atrophy, 3) marked pleomorphism of tubular cells with prominently enlarged nuclei, pleomorphic nuclei, and multinucleation, and 4) moderate predominately lymphocytic and plasma cellular inflammatory cell infiltrate. Electron microscopy showed a hypodense chromatin pattern with slight nuclear membrane irregularities.

Discussion: The diagnosis of KIN should be considered especially when there is a family history of kidney disease of unclear etiology. Karyomegalic cells can be found elsewhere in the body, including the brain, lung, and liver. Testing for heavy metals and ochratoxin may be useful. Urine cytology may identify atypical cells. Genetic testing should be considered, including for mutation of FAN1. Literature to date suggests steroid treatment may be of use in some cases.

TH-PO1066

Hypodipsic Hypernatremia: An Unusual Manifestation of Paraneoplastic Syndrome Sahar Siddiqui, Sun-Young Ahn, Asha Moudgil. *Nephrology, Children's National Medical Center, Washington, DC.*

Introduction: Hypernatremia usually results from increased free water losses or impaired thirst perception.

Case Description: A 17-year-old female presented to the emergency room after an episode of syncope while waiting for school bus on a summer morning. She had intermittent episodes of slurred speech over the previous 2 weeks but denied polyuria, polydipsia, dizziness or headaches. She was diagnosed with primary amenorrhea one year ago. Physical Exam: Weight 46 kg (5%ile), height 150 cm (<3%ile), BP 92/58 mmHg and afebrile. She was slow to respond and had slurred speech. She was Tanner III for breast & I for pubic hair. The remainder of her exam was normal. Laboratory evaluation showed hemoglobin 11.2g/dl, hematocrit 37.8%, platelet 100x10^9/L, sodium 177 mmol/l, potassium 4.3 mmol/l, chloride 139 mmol/l, CO_2 32 mmol/l, BUN 55 mg/dl, creatinine 2.5mg/dl, glucose 91 mg/dl, calcium 9.7 mg/dl,serum Osm 375 mOsm/kg, urine Osm 678 mOsm/kg, ADH level 2.2 pg/ml(nl). Urinalysis: specific gravity 1.016, pH 5.5, 1+ protein, trace blood. A renal ultrasound showed a right suprarenal mass which was confirmed to be an adrenal mass on CT scan. Despite adequate intravenous hydration, her hypernatremia persisted. Due to low LH & FSH there was a concern for hypogonadotropic hypogonadism. However, brain MRI was normal. DDAVP was initiated with partial response. The patient underwent a right adrenalectomy; pathology was consistent with ganglioneuroma. At the time of discharge, her serum sodium was 138mmol/l and her serum creatinine 0.8 mg/dl.

Discussion: The cause of hypernatremia in this case was likely an impaired thirst mechanism in a cognitively normal child. Her partial response to DDAVP suggests an additional contribution from partial diabetes insipidus. Essential hypernatremia and an adrenal ganglioneuroma expressing sodium level sensors (Nax) were reported in a 6 year old child by Hiyama et al. (Neuron 2010; 66(4): 508-522). The mechanism of hypernatremia was postulated to be impaired thirst due to antibodies to Nax in the brain. A diagnosis of paraneoplastic syndrome should be considered in a patient with hypodipsic hypernatremia without structural hypothalamic lesions.

TH-PO1067

IgG4 Mediated Isolated Reteroperitoneal Fibrosis Causing Obstructive Uropathy in a Patient with Subclinical Ankylosing Spondylitis Ayman H. Morgan, Vikram Aggarwal. *Internal Medicine/ Nephrology Div, SUNY Upstate Medical Univ, Syracuse, NY.*

Introduction: Retroperitoneal fibrosis is a rare manifestation of systemic autoimmune disease, characterized by the presence of inflammatory and fibrous retroperitoneal tissue that often encases the ureters causing obstructive uropathy. Idiopathic retroperitoneal fibrosis is recently being recognized manifestation of IgG4-related disease. We report a case of histologically confirmed IgG4 related retroperitoneal fibrosis in a patient with subclinical Ankylosing spondylitis . This association has been rarely reported.

Case Description: A 70 year old male with PMH of HTN, diabetes and baseline creatinine of 1.2 mg/dl presented with weakness, vomiting and decreased urine output. Physical examination was unremarkable. Further evaluation revelaed serum creatinine of 13.3 mg/dl and BUN=106 mg/dl. He also has mild hyperkalemia and anion gap metabolic acidosis. Urine analysis was negative for protein or RBC cast. A CT scan of the abdomen and pelvis, showed retroperitoneal mass, Aortitis, ankylosis of SI joint bilaterally with osseous fusion and bilateral mild hydronephrosis. Bilateral nephrostomy tubes were placed with excellent urine output as well as improvement of creatinine to baseline in 48 hours. He subsequently had a CT guided biopsy of the reteroperitoneal mass. Histopathology revealed dense fibrous tissue with significant IgG4 positive plasma cell infiltrate. Immunological workup showed elevated level of IgG4 as well as positive HLA-B27.Hence this obstructive uropathy was confirmed to be due to IgG4 related retroperitoneal fibrosis. He also met the clinical and imaging criteria for Ankylosing spondylitis. Treatment with oral corticosteroids was initiated by rheumatology.

Discussion: Our hypothesis is that the patient had a subclinical Ankylosing Spondylitis which trigged IgG4 mediated disease that lead to retroperitoneal fibrosis which caused bilateral obstructive uropathy. Hence role of ankylosing spondylitis in development of idiopathic retiperitonal fibrosis via IgG4 mediated pathways warrants further consideration and for nephrologists to be aware of this rather unusual presentation.

TH-PO1068

IgG4-Related Tubulo-Interstitial Nephritis with Low Complement C4, Circulating Immune Complexes and an Elevated IgG4, Presenting as Unilateral Hydronephrosis and Prostatitis Cornelius J. Doorenbos,[1] Annemarie A. Van norel,[1] Christiaan F.M. Klok,[2] M.m. Smits,[3] Peter Van den Tillaar.[4] *[1]Nephrology, Deventer Hospital, Deventer, Netherlands; [2]Radiology, Deventer Hospital, Deventer, Netherlands; [3]Pathology, Deventer Hospital, Deventer, Netherlands; [4]Urology, Deventer Hospital, Deventer, Netherlands.*

Introduction: IgG4-Related Disease is characterized by infiltrates of IgG4-positive plasma cells and eosinophils in different organs and is a rare cause of tubulointerstitial nephritis (TIN) and idiopathic retroperitoneal fibrosis.

Case Description: A 67 year old white male had a creatinine increase from 0.90 to 2.06 mg/dl. He had fatigue and dyspnea. Complement C3 was normal, C4 low 0.06 g/l, C1Q-BA 28% (N <8%), but ANA/ENA, DsDNA, AST, ANCA, HBV, HCV and M-protein were negative, IgG4 3.0 g/l (N 0.08-1.40 g/l). Urine showed 3 RBC/HPF, protein 0.36 g, albumin 61 mg per 24h. On ultrasound both kidneys were 13 cm with right sided hydronephrosis and 300 ml urinary retention. CT-Urography showed obstruction of the right ureter at the iliac artery. A bladder catheter and ureteral stent did not improve renal function. A MAG-III scan showed a non-functioning right kidney without hydronephrosis on ultrasound. On revision, the CT showed soft tissue surrounding the aorta and the right iliac artery. A kidney biopsy showed TIN with a dense infiltrate of IgG4-positive plasma cells and eosinophils with impressive fibrosis, a vein showed obliterative phlebitis, consistent with IgG4-related TIN. He was treated with prednisolon 40 mg daily and after 1 week he reported a dramatic clinical improvement, his creatinine decreased to 1.7 mg/dl.

Discussion: Hydronephrosis first dominated the clinical picture, delaying diagnosis, but the low C4, positive C1Q-BA and large kidneys suggested IgG4-related TIN. We found only one report of IgG4-related TIN with hydronephrosis, but that was after urinary tract tuberculosis. Rare cases were reported of IgG4-related segmental ureteritis or prostatitis without TIN and the cases of IgG4-related TIN had no hydronephrosis. The present case is the first with coincident biopsy-proven IgG4-related TIN, ureteral obstruction and prostatitis. Hydronephrosis does not exclude, but may be part of IgG4-related disease.

TH-PO1069

Monoclonal Light Chain Proximal Tubulopathy with Unique Ultrastructural Microtubular Inclusions Hiba M. Ahmed,[1] Hone S. Kaw,[1] Mandeep Samra,[1] Smita Mahendrakar,[1] Suneet Verma,[1] Jennine Michaud,[1] Fang Bu,[2] Nicholas Cassai,[2] Rosemary Wieczorek,[2] Michael Yudd.[1] *[1]Nephrology, Dept of Veterans Affairs (VA) NJ Health System, East Orange, NJ; [2]Pathology, New York Harbor Healthcare System, New York, NY.*

Introduction: Renal disease related to monoclonal gammopathies is common and varied. An uncommon lesion is proximal light chain tubulopathy (PLCT), which may present with Fanconi syndrome (FS) and variable degrees of renal failure. Most have ultrastructural (US) findings of proximal tubule damage with crystalline inclusions of κ LC's within proximal tubular cells (PTC). A minority of PLCT do not have crystals; these may have λ LC restrictions. We describe a patient with a rare finding: PLCT with light chain (LC)-related microtubular inclusions.

Case Description: 74 year old man had progressive CKD over 2 years with serum creatinine 2.1 mg/dl. A serum M spike, 1.0 g/dl of IgGκ, was present. Urine protein, 1200 mg/day, contained 13% albumin, and 45% M spike of IgGκ. No findings of FS. Renal biopsy abnormalities were limited mainly to the proximal tubules (PT). The PTC's were bright red on trichrome stain and showed granular cytoplasmic changes and marked cell shedding. Congo red stain was negative. On immunofluorescence, the cytoplasm of PTC's stained 3-4+ for total Ig and κ. IgG, IgM, IgA and λ were negative. On EM, non-branching microtubules, ranging in size from 26- 36 nm were membrane bound within PT lysosomes. No amyloid filaments or crystalline structures were seen. Bone marrow subsequently showed a low grade B cell lymphoma with clonal κ B cells and small population of κ plasma cells.

Discussion: Two large biopsy reports of monoclonal renal disease found PLCT to be very uncommon, 0.5 – 4%. Most have findings of crystalline inclusions, less without crystals. To our knowledge, there are only 2 other cases with inclusions similar to our findings. Free LC's are freely filtered and rapidly endocytosed into PTC's via the tandem receptors megalin/cubulin for catabolism in the lysosomes. The variable domain of the abnormal LC's may be resistant to proteolysis. Specific characteristics of the LC's and their resistance to metabolism may determine the varied US appearances.

TH-PO1070

IgG1-kappa Monoclonal Membranous Nephropathy Associated with Systemic Lupus Erythematosus Stephen W. Roderer, Anjali A. Satoskar, Tibor Nadasdy, Isabelle Ayoub, Brad H. Rovin, Samir Parikh. *The Ohio State Univ, Columbus, OH.*

Introduction: Monoclonal gammopathy of renal significance is a recently described condition in which monoclonal protein is found in the kidney but often without a circulating clone. This has not been previously associated with SLE. Here, we describe two cases of monoclonal immune deposition causing membranous nephropathy in SLE.

Case Description: Case 1: An 18 year old female with SLE developed nephrotic syndrome with 4g/d proteinuria and normal serum creatinine. Immunofluorescence (IF) on renal biopsy showed diffuse IgG1-kappa staining in the mesangium and along the capillary loops. Lambda staining was negative. Electron microscopy (EM) showedintramembranous and subepithelial electon-dense deposits. Work up for systemic monoclonal gammopathy including bone marrow biopsy was negative. She was diagnosed with IgG1-kappa monoclonal membranous nephropathy associated with SLE. She was treated with mycophenolate mofetil and prednisone and achieved partial remission. **Case 2:** A 38 year old female with SLE developed proteinuria of 2.5g/d and microscopic hematuria. Similar to case 1, IF on renal biopsy showed diffuse granular IgG1-kappa deposition in the mesangium and along the capillary loops. Lambda staining was negative. EM revealed mesangial and subepithelial electon-dense deposits. Work up for a systemic monoclonal gammopathy, including serum and urine immunofixation and serum free light chains was negative. A diagnosis of IgG1-kappa monoclonal membranous nephropathy associated with SLE was made. She was started on an ACEi and prednisone with improvement in proteinuria from 2.5g/d to 800mg/d.

Discussion: These 2 cases represent a newly described form of monoclonal membranous nephropathy associated with SLE. In both cases the monoclonal protein was restricted to the kidney. The pathogenesis is unclear but may be due to autoreactive b-cells producing an abnormal clone locally in the kidney. The clinical significance must still be elucidated but it may impact treatment and long-term outcomes so clinicians caring for SLE patients should be aware of this association. Further, these patients may develop a systemic monoclonal gammopathy, so close monitoring is necessary.

TH-PO1071

IgG1-κ Anti-Glomerular Basement Membrane Disease Jehan Z. Bahrainwala,[1] Afshin K. Hannani,[2] Jonathan J. Hogan.[1] *[1]Renal, Electrolyte and Hypertension Div, Hospital of the Univ of Pennsylvania, PA; [2]Mercer Renal Insts Inc, Trenton, NJ.*

Introduction: Anti-GBM disease is caused by polyclonal IgG that binds to the NC1 domain of the a3 chain of type IV collagen on glomerular and pulmonary capillary walls. It presents with severe glomerulonephritis and/or pulmonary hemorrhage and typically does not relapse. A recent case report described relapsing, necrotizing and crescentic glomerulonephritis associated with linear IgG1-κ antibody staining on IF. Here, we report a second case of this entity.

Case Description: A 38 year old African American woman presented 4 years ago with respiratory (cough, hemoptysis) and gastrointestinal (emesis, diarrhea) symptoms. She had severe AKI (peak Cr 8.6 mg/dL), microscopic hematuria and a urine protein/creatinine ratio (UPCR) of 3.3 g/g. A kidney biopsy showed focal necrotizing and crescentic glomerulonephritis with liner IgG1κ GBM staining and moderate-severe interstitial inflammation. No electron dense deposits were noted on EM. Anti-GBM (ELISA), ANCA and paraprotein studies were negative. She had a C3 level of 76(88-201) mg/dL and a normal C4. She underwent induction therapy with pulse methylprednisolone and oral prednisone 60 mg/day, PLEX x 4 sessions and oral cyclophosphamide (150 mg/day) for 6 months; followed by azathioprine for 1 year. Her Cr improved to 1.2 mg/dL, UPCR to 55mg/g and her hematuria resolved. 4 years after her initial presentation, she developed respiratory symptoms (cough, sinus congestion), RUQ pain, emesis, gross hematuria and AKI (Cr 2.4 mg/dL). A second kidney biopsy again demonstrated focal necrotizing and crescentic glomerulonephritis with liner IgG1κ GBM staining with mild interstitial fibrosis. Her serologic workup was again negative for Anti-GBM antibodies, ANCAs or paraprotein. She was treated with pulse steroids and rituximab 1000 mg IV X 2.

Discussion: This is the second reported case of necrotizing and crescentic glomerulonephritis associated with IgG1-κ anti-GBM antibody. It is unknown if this disease is driven by an underlying autoimmune process or monoclonal gammopathy. Both cases are atypical for classic anti-GBM disease due to their relapsing nature.

TH-PO1072

First Reported Case of Collagenofibrotic Glomerulopathy in a Patient with Multiple Myeloma Arun Rajasekaran,[1] Indraneel Mogarala,[2] Lillian W. Gaber,[3] Jai Radhakrishnan,[4] Ala Abudayyeh.[5] *[1]Internal Medicine, UCF College of Medicine, FL; [2]Div of Renal Diseases & Hypertension, UT- Medical School at Houston, Houston; [3]Pathology, The Methodist Hospital, Houston; [4]Div of Nephrology, Columbia Univ Medical Center, New York; [5]Section of Nephrology, The Univ of Texas MD Anderson Cancer Center, Houston.*

Introduction: Collagenofibrotic glomerulopathy is an extremely rare idiopathic glomerular disease characterized by abnormal accumulation of atypical spiraled and frayed type III collagen fibrils in mesangial and subendothelial areas, and elevated serum procollagen III and hyaluronan levels. Proteinuria (commonest feature), edema, hypertension, and occasional progression to ESRD are commonly seen. We report the first published case of Collagenofibrotic glomerulopathy in Multiple Myeloma.

Case Description: A 54 year old male with recent history of IgG Kappa Multiple Myeloma (May 2011); with underlying CKD stage 3 and baseline Creatinine at 2 mg/dl; in remission status-post autologous stem cell transplant (January 2012) and on Lenalidomide maintenance therapy, presented with proteinuria of 4g. Kidney biopsy revealed Nodular and Focal glomerulosclerosis with IF weakly (+) for IgG, IgA, IgM, c3, c4, c1q, Kappa and Lambda light chains with +3 staining for IgM and c1q. EM showed patchy foot process effacement with massive deposition of collagen-III fibers. The weak and non-specific staining, along with massive collagen-III fiber deposition fitted with the description of Collagenofibrotic glomerulopathy, and made an immune mediated kidney injury less likely.

Discussion: Discussion: Collagenofibrotic glomerulopathy is an extremely rare disease characterized by massive intraglomerular atypical type III collagen fiber deposition. Proteinuria is the cardinal manifestation of this disease. Clinically, patients present with edema and hypertension and often progress to ESRD. Etiology and pathogenesis remains elusive. Most cases are seen in Japan and an autosomal-recessive mode of inheritance has been described. Definitive diagnosis is established by identifying collagen-III fibrils by IF and EM with special staining. No specific treatment is available unfortunately.

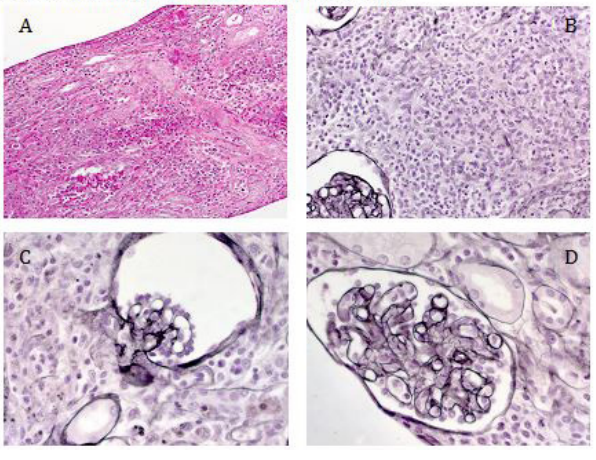
TH-PO1073

Severe Acute Kidney Injury (AKI) with Organomegaly in a 17 Days Old Newborn: When Pathology Makes the Difference Marie-Michele Gaudreault-Tremblay, Catherine Litalien, Natalie Patey, Aicha Merouani. *CHU Sainte-Justine, Montreal, QC, Canada.*

Introduction: Acute tubulointerstitial nephritis (ATIN) is a significant cause of AKI in children and is often due to allergic drug reactions or infections. Diagnosis of ATIN is usually clinical and renal biopsy not routinely performed.

Case Description: A previously healthy 17 days old baby presented with decreased oral intake, vomiting and oligoanuria. His first laboratory results showed an elevated creatinine (1.7mg/dL) with metabolic acidosis, hyponatremia (Na107mEq/L), hyperkalemia (K 8.8 mEq/L) and thrombocytopenia (platelets $16x10^{12}$/L). His urinalysis was abnormal (proteins 3gr/L, WBC >50/hpf, RBC 21-3/hpf, positive nitrites). An ultrasound revealed bilateral kidney enlargement with a heterogeneous parenchyma and hepatosplenomegaly. Intravenous fluid, broad-spectrum antibiotics, calcium chloride and sodium bicarbonate were started. He was intubated for respiratory failure and required dialysis for fluid overload. With worsening of his condition, a kidney biopsy was performed and showed a massive and polymorph infiltrate with destruction of tubular structures [Fig.1, A-B]. Ischemic glomeruli, double glomerular membranes and mesangial oedema [Fig.1, C-D] were observed. Administration of steroids were followed by improvement of his renal function and cessation of dialysis after 6 days. The patient has been disease-free since.

Fig. 1: Renal biopsy in a newborn with severe AKI



Renal biopsy findings were consistent with severe ATIN. The most likely etiology for his ATIN was a urinary tract infection as this patient was not taking any medication and a follow-up cystography revealed a left grade III vesicoureteral reflux.

Discussion: ATIN is rare in neonates and usually drug-induced. This is the first report of a renal biopsy-proven ATIN in a neonate. Even if procedural risks of a renal biopsy are not negligible, it can make the difference in certain cases by dictating appropriate management.

TH-PO1074

AL Lambda Amyloidosis in Kidney Transplant Allograft as a Cause of Massive Nephritic Syndrome with AKI That Responded to Chemotherapy Noaman Siddiqi,[1] Manish K. Saha.[1] *[1]Dept of Nephrology, Univ of Alabama, Birmingham, AL; [2]Dept of Nephrology, Univ of Alabama, Birmingham, AL.*

Introduction: This interesting case showed AL lambda amyloidosis in kidney transplant allograft as a cause of massive nephritic syndrome with AKI that responded to chemotherapy. 51 year old African American female with history of ESRD secondary to APKD s/p DDKT in Oct 2010 with Thymoglobulin induction, maintained on 3 drug immunosuppression including tacrolimus, mycophenolate and prednisone with baseline creatinine of 1.5, presented with anasarca and orthostatic hypotension. Her serum albumin was 1.2mg/d. She underwent extensive investigations including Echo, transplant allograft ultrasound all of which came back unremarkable. She has sudden onset sub nephritic range proteinuria in Aug 2013 which progressed to nephritic range in Feb 2014. She has 34g of protein on a 24h urine collection 90% of which was albumin. Her UPCR gradually got worse from 10 to 32 with worsening in serum Cr from 1.5 to 5.5. She has poor response to IV Lasix with albumin infusion and has severe orthostatic symptoms. Her SPEP and UPAP were negative. Serum IFE was also negative. Urine IFE showed lambda light chain. Serum free light chain showed elevated lambda levels. Due to worsening and explosive proteinuria with worsening anasarca renal allograft biopsy was done that showed lambda AL amyloidosis involving glomeruli, arterioles and arteries along with light chain proximal tubulopathy. Congophilic casts consistent with light chain cast nephropathy. Pt underwent bone marrow biopsy that did not show MM. She was treated with bortezomib combined with cyclophosphamide and dexamethasone and has good response with improvement in orthostatic hypotension, serum albumin level and lambda light chain got normal.

TH-PO1075

Granulomatous Interstitial Nephritis Caused by T-Cell Lymphoma Yoshitatsu Ohara,[1] Namiko Kobayashi,[1,2] Yohei Kono,[1] Tomoharu Yoshimine,[1] Mariko Ichijo,[1] Toshiyuki Hirai,[1] Keiko Suzuki,[3] Takayuki Toda,[1] Michio Nagata,[2] Noriaki Matsui.[1] *[1]Dept of Nephrology, Tsuchiura Kyodo General Hospital, Tsuchiura, Ibaraki, Japan; [2]Renal Pathorogy, Univ of Tsukuba, Tsukuba, Ibaraki, Japan; [3]Dept of Pathology, Tsuchiura Kyodo General Hospital, Tsuchiura, Ibaraki, Japan.*

Introduction: Granulomatous tubulointerstitial nephritis (GTIN) occurs 0.5-1.3% in renal biopsy samples. Granuloma is basically caused by type IV allergy; T cell-mediated mechanism against drug, foreign bodies and microorganisms such as Mycobacterium. We here present, a rare case of GTIN associated with T cell lymphoma.

Case Description: Sixty-year-old man with uncontrolled diabetes complained right chest pain. Chest and abdominal CT revealed multiple abscesses formations in the right lung, right chest wall, liver and right retroperitoneum. Although no distinct bacterium was identified from the liver abscess, the patient was treated by antibiotics, tazobactam/piperacillin(TAZ/PIPC). It was not effective. During the antibiotics treatment, renal dysfunction and skin rashes on extremities occurred. Renal biopsy revealed GTIN with collapsing glomeruli. Light microscopy showed diffuse interstitial inflammatory infiltrates predominantly with mononuclear cells including some atypical cells, which invaded tubular basement membrane resulting impaction of these cells in the tubular lumina. Since drug induced lymphocyte stimulation test (DLST) was positive for TAZ/PIPC, we once diagnosed as drug-induced GTIN in this patient. Despite stopping antibiotics, his renal function was not recovered. Meanwhile, atypical lymphoid cells were detected in the urine cytology and serum soluble IL2 receptor was significantly increased. Immunohistochemistry revealed hypercellularity of monotonous atypical lymphocytes stained with T-cell markers, CD3 and CD5, and then diagnosed as GTIN caused by T-cell lymphoma. Although CHOP chemotherapy induced remission of lymphoma and disappearance of multiple abscess formation, the kidney dysfunction was unimproved.

Discussion: The case reminds us T-cell lymphoma as an additional cause of GTIN.

TH-PO1076

Pauci-Immune Glomerulonephritis and Escherichia Coli Bacteremia: A Mere Coincidence or a True Causal Association? Marwan M. Abu Minshar, Wihib A. Gebregeorgis. *Nephrology, Wayne State Univ S.O.M, Detroit, MI.*

Introduction: Antineutrophil cytoplasmic antibody (ANCA) associated vasculitides are systemic autoimmune diseases affecting small to medium sized blood vessels. Pauci-immune necrotizing glomerulonephritis (GN) is one of the manifestations. Triggering factors for ANCA associated vasculitis are not well-defined. Systemic infections have been implicated in the pathogenesis.

Case Description: A 67 year old patient was admitted to the hospital from a nursing home for a Foley catheter associated Escherichia coli (E. coli) urinary tract infection & bacteremia leading to septic shock and acute kidney injury/acute tubular necrosis with a peak serum creatinine (Cr) of 3.8 mg/dl. She had recently been hospitalized for subarachnoid hemorrhage that was treated conservatively and her serum Cr at that time was 0.9 mg/dl.

She promptly responded to standard treatment of septic shock and her serum Cr improved to 1.6 mg/dl on discharge. Ten days later, she was readmitted to the hospital after a follow up visit to her primary physician where a routine blood work showed her serum Cr to be elevated to 6.8 mg/dl. Urine sediment revealed several RBCs and few granular casts. Anti-myeloperoxidase antibody was positive with a titer of 1:640. Other serological tests were negative. Her renal function declined further and she was initiated on hemodialysis. A renal biopsy was consistent with pauci-immune necrotizing and crescentic GN. She was treated with steroids, intravenous cyclophosphamide and plasmapheresis following which she came off dialysis & her serum Cr stabilized around 1.8 mg/dl.

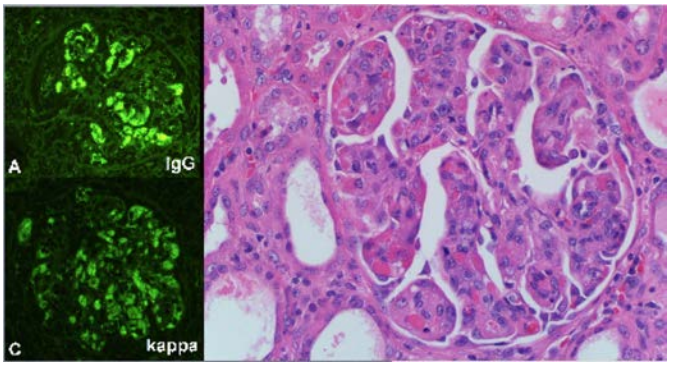
Discussion: Anti-LAMP-2 antibodies, a subtype of ANCA antibodies directed against lysosome-associated membrane protein-2 (LAMP-2) have been reported in patients with pauci-immune necrotizing GN, often in coexistence with anti-PR3 & anti-MPO antibodies. Infections with bacteria that express the bacterial adhesin FimH (mostly E. coli), which has 100% homology with the human LAMP-2 epitope, are believed to trigger autoimmunity via molecular mimicry. In our patient, the onset of ANCA positive necrotizing GN in a close temporal association with E. coli bacteremia suggests a possible causative relationship.

TH-PO1077

Cryoglobulinemic Vasculitis and Glomerulopathy Associated with Chronic Lymphocytic Leukemia Narottam Regmi, Albert Braverman, Swaty Arora, Raavi Gupta, Subodh J. Saggi. *Nephrology, SUNY Downstate Medical Center, Brooklyn, NY.*

Introduction: Cryoglobulinemia manifests as ischemic or occlusive vasculopathy with or without renal involvement. Early stage Chronic lymphocytic leukemia(CLL) has not been reported with vasculitic lesions as its first manifestation. We report a rare case of Stage I CLL with cutaneous,renal and cerebral lesions due to monoclonal Type I cryoglobulinemia.

Case Description: A 60year-old woman presented with abdominal pain due to retroperitoneal hematoma from a ruptured right gonadal artery, which was embolized. Labs included eukocytosis, anemia with mild azotemia.Flow cytometry was consistent with CLL.The patient was readmitted with a serum creatinine of 11.2 mg/dL and proteinuria and required hemodialysis. There were extensive lesions on her lower extremities and a necrotic left forearm ulcer. Renal biopsy revealed membranoproliferative glomerulonephritis with deposition of IgG kappa light chain cryoglobulins as intraluminal hyaline deposits (Figure 1), infiltrates consistent with CLL and thrombi in intrarenal arteries. Biopsy was complicated by hematoma leading to left nephrectomy. Plasmapheresis was initiated for cerebral infarcts related to cryoglobulinemia. Despite leukemia treatment and regular hemodialysis her clinical condition deteriorated and patient expired.



The pathophysiology of GN in CLL is possibly due to glomerular deposition of immune complexes and/or paraproteins.Review of the literature reveals a small number of cases of MPGN associated with CLL and cryoglobulinemia.

Discussion: Vasculitic presentations,bleeding or thrombotic and/or renal failure in the setting of CLL may be manifestations of cryoglobulinemia. Because of potential rapid progression, as in this case, regular urinalysis and testing for cryoglobulins should be considered in all stages of CLL, with possible renal biopsy when cryoglobulinemia and proteinuria are detected.

TH-PO1078

PGNMID in a Patient with Hepatitis C Mohamed Alseiari, Susie L. Hu. *Alpert Medical School of Brown Univ.*

Introduction: Proliferative glomerulonephritis with monoclonal IgG deposits (PGNMID) is infrequently associated with hematological disease but more commonly presents like an immune-complex glomerulonephritis. Few have reported cases associated viral infections such as hepatitis C. We report a case of PGNMID in a patient with active HCV infection.

Case Description: A 56 year-old male with refractory hepatitis C (post treatment with interferon and Ribavirin), HTN and coronary artery disease presented with rising creatinine (peak 5.3 mg/dl) from baseline (0.9 ml/dl a year ago) and no kidney disease in family. He reported months of progressive fatigue, dyspnea on excretion, nausea, vomiting, and dark urine. He endorsed chronic Ibuprofen use for leg pain. On examination BP was normal with clear lungs and no edema. Urinalysis revealed blood but minimal proteinuria with urine protein to creatinine ratio of 0.5 g/g and albumin 4.2 g/dL. Complements were low (C3 83 mg/dL, CH50 <10 U/mL). HCV-RNA quantification was 1.7 million copies. SPEP, plasma light-chains, ANA, ANCA, Anti GBM, HIV, Hep B serologies were normal. Bone survey was negative. Renal biopsy revealed diffuse linear staining of glomerular basement with monoclonal IgG1/Kappa immunoglobulin and endocapillary focal glomerulonephritis, chronic interstitial nephritis with ATN. Renal function did not improve until Prednisone was initiated, down to 3.3 mg/dL. Cyclophosphamide was started after discussion with his gastroenterologist. Antiviral therapy has been delayed until further improvement of renal function.

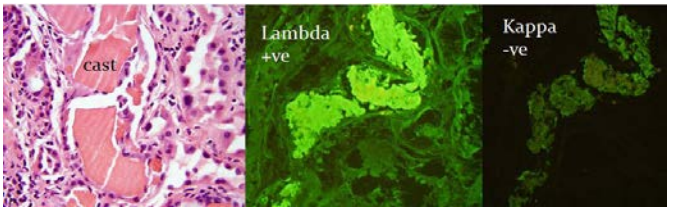
Discussion: We report a case of PGNMID associated with HCV. There are 2 other reports of HCV associated PGNMID however with membranous glomerulonephritis pathology. 30% of PGNMID patients have same heavy- and light-chain isotypes as the glomerular deposits. Membranoproliferative (57%) or endocapillary proliferative (35%) are the most two common histological variants. Nasr et al in a series of 32 patients reported after an average of 30.3 months of follow-up, 38% had complete or partial recovery, 38% had persistent renal dysfunction, and 22% progressed to ESRD. Viral infection such as HCV associated immune disorders could be implicated in the pathogenesis. Currently, there is no consensus regarding the management of this entity.

TH-PO1079

Myeloma Cast Nephropathy with Acute Renal Failure, Skin Rash, Eosiphiluria, and Low Complement C4 Level Mustafa G. Aly,[1] Mamoun Elsir Bashir,[1] Irfan Warraich,[2] Aumyot Prongdong,[1] Weeraporn Srisung.[1] [1]*Internal Medicine, Nephrology Dept, Texas Tech Univ Health Science Center, Lubbock, TX;* [2]*Pathology Dept, Texas Tech Univ Health Science Center, Lubbock, TX.*

Introduction: We here report myeloma cast nephropathy with skin rash, eosinophiluria and low complements which is a very atypical presentation of this renal condition.

Case Description: A 53y Caucasian female was admitted with 3 day confluent erythematous skin rash, acute renal failure with s.Cr 17.6 with a normal baseline renal function of s.CR 0.7mg/dL. Five days prior, she was prescribed cephalexin for root canal infection. Initial diagnosis of acute interstitial nephritis was made but patient didn't respond after stopping antibiotics and steroid course trial. urine exam showed WBC clumps and no casts. Serological biomarkers were done and reported Negative ANA, ANCA, cryoglobulins, Hepatitis B, Hepatitis C and HIV. Complement C4 was low with normal C3. Patient's laboratory workup showed normocytic normochromic anemia and pseudohyponatremia per osmolality check, SPEP and SFLC ordered and was positive for M-spike with free light chain analysis showing predominant Lambda more than 4 g/L. Renal biopsy showed myeloma cast nephropathy.



Bone marrow biopsy confirmed MM with 80% plasma cell. Patient received bortezomib +dexamethasone + cyclophosphamide chemotherapy and her renal function completely improved after being dialysis dependent for about 12 weeks with. Patient is being evaluated for BM transplant after chemotherapy response.

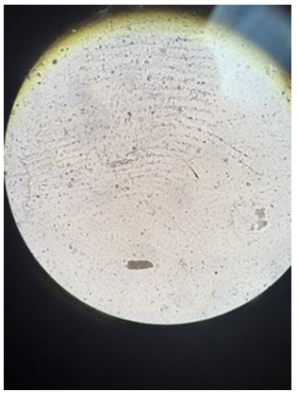
Discussion: Multiple Myeloma can cause renal damage in many ways which sometimes can be misleading and very uncharacteristic. Up to our knowledge, this presentation is quite uncommon in literature and hence we suggest including myeloma related kidney injury in such clinical presentation.

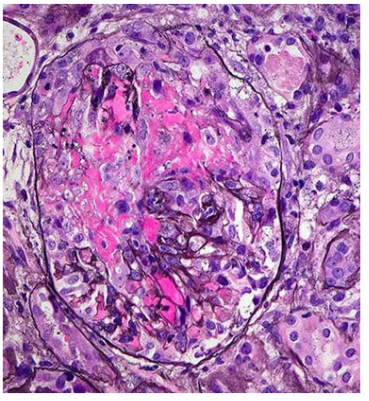
TH-PO1080

A Rare Case with ANCA-Related Necrotizing Glomerulonephritis without Nephritic Features or Systemic Vasculitis Mustafa G. Aly,[1] Faisal Jamal,[1] Maria Gabriela Suarez,[1] Irfan Warraich,[2] Aumyot Prongdong.[1] [1]*Internal Medicine, Nephrology Dept, Texas Tech Health Science Center, Lubbock, TX;* [2]*Pathology Dept, Texas Tech Health Science Center, Lubbock, TX.*

Introduction: We report an atypical and unusual case of ANCA necrotizing glomerulonephritis with no significant nephritic features or systemic vasculitic picture.

Case Description: A 78 year-old African American female with history of controlled hypertension was admitted with diagnosis of pneumonia and renal failure and was treated empirically with antibiotics. Despite antibiotic treatment, she had persistent leukocytosis and pneumonia was ruled out by negative WBC scan and CT chest. Urine had pre-renal pattern and urinalysis was bland twice. Renal ultrasound was unremarkable except for hyperechoic kidneys. Despite aggressive hydration for 10 days, renal function continued to worsen. Patient was never oliguric. Serum biomarkers were checked due to unexplained renal failure which reported negative hepatitis B, C and HIV as well as normal Complement C3, C4, ANA, dsDNA and antiphospholipid panel. Normal SPEP with no M spike. UPEP showed faint IGG monoclonal band in the ALPHA-2 region. SFLC was negative. Bone marrow biopsy showed normal cellularity. Although patient had no obvious systemic vasculitic features, but due to renal failure and persistent non-specific respiratory symptoms, ANCA was checked and was positive for anti-MPO antibodies. Renal biopsy showed pauci-immune acute necrotizing glomerulonephritis (Figure 1) with negative Ant-GBM and immune fluorescence. Patient was treated with cyclophosphamide, high dose steroids and plasmapheresis.





Discussion: The patient had advanced necrotizing GN but never developed nephritic or systemic vasculitic features and UA was persistently bland. The probability of diagnosing ANCA associated GN based upon above clinical presentation was significantly low, making this an unusual case.

TH-PO1081

Bilateral, Multifocal Renal Tumors Diagnosed as Birt-Hogg-Dubé Syndrome Confirmed by Genetic Analysis Seokwoo Park,[1] Sehoon Park,[1] Eunjeong Kang,[1] Hae Il Cheong,[2] Dong Ki Kim,[1] Yon Su Kim,[1] Kwon Wook Joo,[1] Hajeong Lee.[1] *[1]Dept of Internal Medicine, Seoul National Univ Hospital, Seoul, Korea; [2]Dept of Pediatrics, Seoul National Univ Children's Hospital, Seoul, Korea.*

Introduction: Birt-Hogg-Dubé syndrome (BHD) is an autosomal dominant disorder characterized by skin fibrofolliculomas, pulmonary cysts and spontaneous pneumothorax, and renal cancers. The syndrome is caused by germline mutations of the FLCN gene located in 17p11.2 encoding folliculin. The risk of renal cancer is seven times higher in BHD patients. Bilateral, multifocal and chromophobe renal cell carcinoma is characteristic of renal cancers in BHD. Among about 110 pathogenic mutations reported in BHD, only twenty six of them have been associated with renal cancer. In this study, we described a case of 50-year-old woman with chromophobe renal cell carcinoma who had c.1557delT mutation in the FLCN gene which is novel in BHD-associated renal cancer.

Case Description: A 50-year-old-woman presented with flank pain. A CT scan of abdomen showed multifocal tumors in both kidneys. To differentiate the origin of the tumors, a chest CT and a whole body PET-CT were carried out, although there was no other lesion except a few lentiform cysts at basal lungs. Histologic evaluation through a needle biopsy revealed that the mass was chromophobe type renal cell carcinoma**.** The patient underwent partial nephrectomy. Given multifocal distribution of the renal cell carcinoma, we suspected an inherited form of kidney cancer. Although she denied any specific familial history, the cystic change of both lungs and chromophobe renal cell carcinoma pointed towards the possibility of BHD. DNA sequencing of the entire FLCN gene identified a heterozygous c.1557delT mutation in exon 14 [p.Phe(TTT)519Leu(TTA)fs*18].

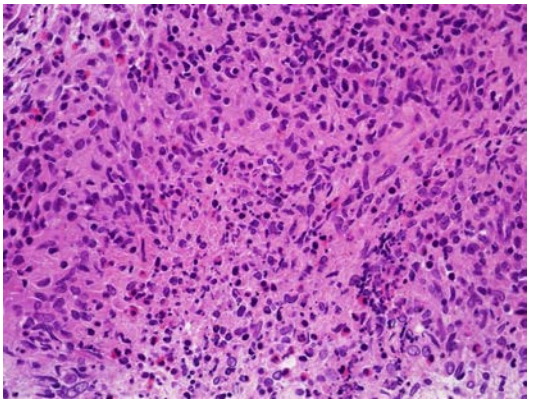
Discussion: Once multifocal renal masses are diagnosed as renal cell carcinoma, histologic subtype, family history and other clinical features should be considered to recognize familial renal cancer syndromes. Multifocal chromophobe renal cell carcinoma should prompt genetic test for BHD even in a patient without typical skin lesion. In our patient, c.1557delT mutation was found out which has been first reported in BHD-associated renal cancers.

TH-PO1082

The First Case of Steroid Responsive Renal Involvement of Mycosis Fungoides without Sezary Syndrome Jinuk Jeong, Kitae Bang, Jongho Shin. *Dept of Internal Medicine, The Eulji Univ School of Medicine, Daejeon, Korea.*

Introduction: Mycosis fungoides (MF) is a mature T cell non-Hodgkin lymphoma with presentation in the skin but with potential involvement of the nodes, bloods and viscera. Renal lymphomatous involvement in MF has received limited attension. We present a rare case of moderate dose steroid responsive lymphomatous renal involment with acure renal injury which occured in solitary kidney.

Case Description: A 39-year-old man presented with fever, right flank pain with a rise of creatinine 10.54mg/dl ,one month prior being 1.4mg/dl. He donated his left kidney 10 years ago. He had recurrent prutitic rash before MF was diagnosed by skin biopsy. 4 years prior to his presentation, he received several different course of chemotherapy, including cyclophosphamide, adriamcin,vincristin, and prednisone (CHOP), alpha-interferon. Ultrasound revealed normal echogenicity with right kidney 14 cm. Urinalysis showed protein 1+, WBC cast and no hematuria. He was treated first with antibiotics in case of acute pyelonephritis. He defervessed within two days, However, his renal function kept declining. Hemodialysis was performed . On the 6th day. Renal biopsy was performed. Renal biopsy showed that Numerous atypical lymphocytes with hyperchromatic, indented, variably sized nuclei were infiltrated in the tubulointerstitium.



After treatment with methyprednisolone 40mg , level of creatinine improved up to baseline.

Discussion: To our knowledge, this is the first report of steroid responsive renal involvement of MF. Renal involvement in non-Hodgkin lymphoma has been reported, including AKI , glomerulonephritiws, and infiltration of renal parenchyma by lymphoma cell. Renal manifestations of MF are especially rare and there are only few cases pulblished to date. But there has been no case which showed steroid response except this case.

TH-PO1083

A Case of Cryoglobulinemic Nephropathy with Successful Childbirth After Recurrent Episodes of Nephrotic Syndrome During Pregnancy Miho Karube, Kazuhito Fukuoka, Yoshihiro Arimura. *The First Dept of Internal Medicine, Kyorin Univ School of Medicine, Mitaka, Tokyo, Japan.*

Case Description: A 35-year-old woman was admitted to our hospital because of massive proteinuria that developed during the third pregnancy. The previous two pregnancies had been terminated because of similar episodes of nephrotic syndrome. No history of hypertension was observed, but during the course she presented cryoglobulinemia, a high titer of RF and low serum complements. The renal biopsy performed 10 days after the third termination revealed MPGN-like lesions with lobulation in glomeruli, double contour of GBM, endotheliosis, and moderate mesangial cell proliferation. Immunofluorescence study showed IgG, IgA, IgM, C3, C4, and C1q all positive mainly along the glomerular capillaries, and subendothelial deposits were confirmed by EM, thus she was diagnosed as cryoglobulinemic nephropathy. Because the histological findings of repeated renal biopsy were not improved two months after the disappearance of proteinuria, treatment with 30 mg/day of PSL was started, followed bv intravenous cyclophosphamide 6 times and plasma exchange, since she had a desire for baby. Finally at the fourth pregnancy, she bore a healthy baby weighing 2,342g on vaginal delivery at 36 weeks despite of recurrent appearance of nephrotic syndrome. After delivery, she was given 30 mg/day of PSL and proteinuria subsided.

Discussion: We experienced a rare case of the type III cryoglobulinemic nephropathy that repeatedly developed nephrotic syndrome during pregnancy, but finally bore a baby after immunosuppressive therapy. The pathogenesis of pregnancy-induced nephrotic syndrome in cryoglobulinemia in this patient was not known, aggressive treatment may be helpful for ameliorating nephropathy, leading to successful delivery.

TH-PO1084

A Case of Glomerular Lipidosis with Type III Hyperlipoproteinemia Exhibiting Nephrotic Syndrome Rei Miura,[1] Kaori Fujimoto,[1] Aya Sakanashi,[1] Tomoaki Onoue,[1] Kengo Kajiwara,[1] Masao Tomita,[1] Taku Miyoshi,[2] Masataka Adachi,[2] Yukimasa Koda,[2] Masashi Mukoyama.[2] *[1]National Hospital Organization Kumamoto Medical Center; [2]Kumamoto Univ.*

Introduction: Lipid deposition and accumulation in glomeruli are sometimes recognized in kidney biopsy specimens, especially in focal segmental glomerulosclerosis and diabetic glomerulosclerosis, but glomerular lipidosis other than such conditions is rarely seen.

Case Description: A 77-year-old woman was admitted to our hospital because of nephrotic-range proteinuria. She was diagnosed as chronic thyroiditis 8 years before, after which she started to have levothyroxine and remained uneventful. Three weeks before coming to our hospital severe edema developed rapidly, and she gained 10 kg of body weight in 6 months. Laboratory examinations showed nephrotic syndrome with mild renal dysfunction (s-Alb 2.1 g/dL, urinary protein 7.97 g/gCr, s-Cr 0.95 mg/dL), marked dyslipidemia (T-Chol 712 mg/dL, TG 1191 mg/dL) and poorly controlled hypothyroidism (TSH 45.2 μIU/mL, free T4 0.83 ng/mL). Genetic test for *APOE* revealed homozygosity of apoE2 and immunoelectrophoresis for lipoprotein showed type III hyperlipoproteinemia. Renal biopsy revealed the presence of intracapillary lipid thrombi and foam cells; electron microscopy demonstrated lipid droplet accumulated mainly in mesangial cells, whereas podocytes, endothelial cells and tubular cells were rather unremarkable. Immunofluorescent studies showed no significant deposits in glomeruli. Intense lipid-lowering therapy with bezafibrate and ezetimibe improved hyperlipidemia, with only a partial effect on proteinuria (~5 g/gCr).

Discussion: We report here a case of glomerular lipidosis associated with type III hyperlipoproteinemia exhibiting nephrotic syndrome. We suggest that hyperlipidemia with glomerular lipid accumulation would have a pathogenic role for glomerulopathy, but other factors might be involved in causing nephrotic syndrome.

TH-PO1085

Successful Treatment of Crescentic Glomerulonephritis (GN) in Hypocomplementemic Urticarial Vasculitis Syndrome (HUVS) Ramchandur Bakhtiani, Mark G. Parker. *Nephrology, Maine Medical Center, Portland, ME.*

Introduction: HUVS is a rare autoimmune systemic disorder characterized by chronic urticaria, low complements and extracutaneous organ involvement. Kidney involvement is not uncommon (50% of cases), usually of benign nature. The glomerular injury pattern varies from mesangial proliferation to membranoproliferative glomerulonephritis (MPGN). Crescentic MPGN in HUVS is rare; only six cases have been reported in world literature, many with poor outcomes. We present a case of crescentic GN successfully treated with substantial remission.

Case Description: A 55-year-old Caucasian female with a previous episode of hives was admitted to hospital with features of both acute nephritic and severe nephrotic syndrome. She had 6 months history of persistent hives, fatigue, fevers, arthralgia, self-limited recurrent angioedema episodes, and generalized lymphadenopathy. Lymph node biopsy displayed reactive hyperplasia. Her serum creatinine was 4 mg/dl, urine protein to creatinine ratio was 23, serum albumin was 1.4 gm/dl and urinary sediment showed > 100 RBCs, > 10 hyaline casts/HPF. Serologic workup was positive for very low C3 andC4 and ANA titer of 1:80. Anti-dsDNA, cryoglobulins, anti-SSA, anti-SSB, chronic hepatitis panel, and workup for paraproteinemia all were negative. C1q levels were undetectable. Anti C1q antibody was not performed. Renal biopsy revealed immune complex crescentic MPGN with IgG, IgA, IgM, C3 and C1q deposits on immunofluorescence. Treatment was started initially with high dose glucocorticoids followed by addition of mycophenolic acid and losartan. Her systemic symptoms and acute kidney injury resolved completely. Nephrotic syndrome improved slowly. After 6 months of therapy her proteinuria decreased to 4.5g per day and serum albumin increased to 3.8 g/dl.

Discussion: Crescentic GN associated with HUVS appears to convey a poor renal prognosis. Based on available information in five of six reported cases, three progressed to end stage renal disease; one had near complete renal recovery and another had partial recovery with persistent nephrotic range proteinuria. Relatively good outcome in our case may aid to our understanding of this uncommon and newly recognized disease process.

TH-PO1086

An Unusually Early Presentation of Pre-Eclampsia David Bennett, Renu Regunathan-Shenk, Maya K. Rao. *Medicine, Div of Nephrology, Columbia Univ Medical Center, New York, NY.*

Introduction: Pre-eclampsia affects approximately 3-6% of pregnancies in the United States. It is defined as new onset hypertension and proteinuria in pregnancy. By definition, it occurs after 20 weeks gestation. However, earlier cases have been reported in the literature.

Case Description: The patient is a 45 y/o woman, 16 weeks + 4 days pregnant with twins (IVF with donor embryo), with a PMHx significant for obesity and borderline HTN who presented with 6 weeks of progressive swelling that had worsened in the past week. 3 weeks prior to presentation, the pregnancy was complicated by worsening hypertension, ranging 140's-160's/90's-100's, for which she was started on labetalol. On presentation, her exam was notable for BP 193/122, 1+ upper extremity edema, 2+ lower extremity edema, and bibasilar crackles on lung exam. On labs, Cr 0.85, 3+ protein on UA (previously negative) with 3 RBC's and 6 WBC's, ~12g of protein on 24hr urine collection, and serum albumin 2.3. Serologic work-up including ANA, C3, C4, HIV, Hepatitis B, Hepatitis C, SPEP, UPEP, and Kappa and Lambda Free Light Chains was negative. Platelet count 202, LDH 334 (elevated), and indirect bilirubin 0.2. AST, ALT, and Alkaline phosphatase were normal. The patient underwent a kidney biopsy which demonstrated subacute glomerular thrombotic microangiopathy with prominent endotheliosis, characteristic of pre-eclampsia. Termination of pregnancy was advised and performed. On post-discharge follow-up, spot urine protein-to-creatinine ratio (in mg/mg) decreased to 1.52 after ~1.5 months, 0.32 after ~3.5 months, and 0.13 after ~6 months. BP improved as well and she is now off anti-hypertensives.

Discussion: This patient had multiple risk factors for pre-eclampsia including age, multiparity, obesity, IVF, and ovum donor pregnancy. Although kidney biopsies are associated with a higher complication rate in pregnant women, they often change management, as was the case for this patient. Given this case and others reported in the literature, the gestational age criteria for the diagnosis of pre-eclampsia should be reconsidered.

TH-PO1087

A Case of Autosomal Dominant Polycystic Kidney Disease and C3 Glomerulonephritis Conor Patrick Moran, Mamoun S. Elawad. *Dept of Nephrology, Altnagelvin Hospital, Western Health and Social Care Trust, Londonderry, United Kingdom.*

Introduction: Autosomal Dominant Polcystic Kidney Disease, (AD-PKD), is the most common form of inherited renal disease. Proteinuria has been reported, however, nephrotic range proteinuria and nephrotic syndrome are rarely reported in the literature. Only 30 cases of patients with AD-PKD and glomerulopathy have been reported. The most common have been FSGS and Membranous Nephropathy. Two cases of Mesangioproliferative Glomerulonephritis and one case of Membranoproliferative Glomerulonephritis have been reported.

Case Description: We present a 47 year old female with Autosomal Dominant Polcystic Kidney Disease with C3 Glomerulonephritis. The patient had been under regular and unremarkable Nephrology clinic follow-up for many years. In March 2014, she presented to with new proteinuria, (Urinary ACR 375.4mg/mmol), and evidence of C3 hypocomplementaemia, (0.3 g/L, normal: 0.8-1.7 g/L). Kidney function was newly impaired, (Creatinine 118, eGFR: 45.3 mL/min/1.73m2). C3 Nephritic factor was normal and a minute Cryoglobulin band was detected. ACE inhibitor therapy was commenced. Renal biopsy showed markedly enlarged and lobulated glomeruli with marked endocapillary proliferation. Widespread thickening of the glomerular basement membranes, (GBM), with numerous double contours was observed. Immunofluorescence revealed strong diffuse coarse positivity for C3 along the GBM with some focal mesangial C3. There was some IgM, but no IgG, in the GBM. In July 2014, there was no clinical response to ACE inhibition. Corticosteroids were commenced, (Prednisolone 1mg/kg), which achieved partial remission, (urinary ACR fell from 650.5mg/mmol to 79.7 mg/mmol), however, in August 2014 she developed nephrotic syndrome requiring aggressive diuretic therapy. Addition of Rituximab therapy induced complete remission of proteinuria, (UACR 25-30 mg/mmol), with normalisation of C3 levels. Renal function remains stable.

Discussion: In a disease where CKD progression is predictable, glomerular pathology can accelerate this decline and histology should be sought. This is the second reported case of AD-PKD associated with Membranoproliferative C3 Glomerulonephritis in the literature to date.

TH-PO1088

To Deliver or Not to Deliver: The Dilemma of a Pregnant Patient with Medullary Cystic Kidney Disease Who Develops Acute Kidney Injury Sweta Carpenter, Rozina B. Ali, Sandeep Aggarwal. *Nephrology, Drexel Univ.*

Introduction: Achieving maternity is quite a challenge for women with chronic kidney disease (CKD). Pregnant patients with CKD of any stage but especially stages 3–5 are at increased risk for fetal loss, prematurity and pre-eclampsia.

Case Description: We present a case of a 31 year old pregnant female with a past medical history of CKD stage 3B secondary to medullary cystic disease (MCD) who presented with acute kidney injury at 31 weeks gestation. Her other co-morbidities include a history of diabetes and idiopathic thrombocytopenia (ITP). On admission, the patient had a creatinine of 2.32 mg/dL and was found to have 7 gm proteinuria. During this pregnancy, her baseline creatinine was 1.6-1.8 mg/dL and prior to pregnancy she had baseline proteinuria of 2 gm. Given her elevated creatinine and degree of proteinuria, there was concern that the patient could have pre-eclampsia. A management dilemma occurred and it was unclear whether the patient should have an emergency C-Section for questionable pre-eclampsia. Unfortunately, the usual markers of pre-eclampsia such as proteinuria, elevated creatinine, hypertension, low platelets, and elevated uric acid levels were all present in our patient. These markers however could be present in our patient due to her underlying medical conditions of CKD, ITP, and MCD. After a multidisciplinary meeting with the obstetrician, nephrology, and hematology occurred, it was felt that the patient truly did not have pre-eclampsia. A key decision was made and she was not induced. Her AKI was attributed to volume depletion and progression of CKD. Her creatinine eventually declined to 1.9-2 mg/dL and her proteinuria decreased to 3-5 grams. The patient is now 34 weeks pregnant and her pregnancy has been maintained. As the weeks progress, there are increased chances of fetal development.

Discussion: Our case highlights that in patients with multiple co-morbidities and CKD, the diagnosis of pre-eclampsia can be challenging. Incorrectly labeling a patient as pre-eclamptic can lead to pre-term delivery and risks to the fetus. A multidisciplinary team effort along with fetal monitoring can help differentiate pre-eclampsia from other diagnoses, prolonging delivery.

TH-PO1089

Development of Aggressive De Novo Henoch-Schönlein Purpura, 10 Years Post-Kidney Transplant Kamel Hatahet,[1] Swati Rao,[1] Avrum Gillespie,[1] Mythili Ghanta,[1] Serban Constantinescu,[1] Xu Zeng,[2] Iris J. Lee.[1] *[1]Nephrology, Temple Univ School of Medicine, Philadephia, PA; [2]Temple Univ School of Medicine, Philadelphia, PA.*

Introduction: Histologic recurrence of IgA deposits in renal allografts is as high as 60% in recipients with primary IgA nephropathy, however significant nephritis presenting as de novo Henoch-Schönlein Purpura (HSP) post-kidney transplant (KT) is rare with only a few cases reported.Our patient had biopsy proven diabetic nephropathy (DN), yet presented with severe HSP with multi-system involvement 10 years post-KT.

Case Description: A 63 y/o Hispanic female with DN received a living related KT in 2005 and was stably maintained on tacrolimus, prednisone, without mycophenolate mofetil (MMF) due to recurrent infections. 10-yrs post-KT, she developed diarrhea, melena and acute renal failure (Cr of 4.19 from 1.5) after completing a course of antibiotics for pneumonia. She developed diffuse purpuric rash and had hematemesis with severe abdominal pain. Abdominal CT scan showed enteritis of the small bowel. EGD demonstrated necrotic lesions in the esophagus and severe ulcerative duodenitis with biopsies showing leukocytic infiltration of vessels, and submucosa. Skin biopsy showed leukocytoclastic vasculitis. Urine had 4+protein, leukocytes, red blood cells, but no casts. Extensive infectious and serologic workup was negative. KT biopsy demonstrated membranoproliferative changes without crescents, coupled with findings of DN and advanced interstitial fibrosis and tubular atrophy. Immunofluorescence showed +4 deposits for IgA and C3 and the patient was diagnosed with HSP. Due to severe GI involvement the patient was treated with pulse

steroids. Given renal fibrosis and comorbidities, no further therapies were pursued. Repeat EGD showed improved duodenal lesions after steroids, however renal function declined and the patient required dialysis.

Discussion: IgA nephropathy histologically recurs post-KT but rarely impacts graft survival. De novo HSP with significant nephritis is infrequently described and treatment strategies in adults with aggressive disease remain unestablished. Interestingly MMF is used for severe HSP in children. Whether lack of MMF maintenance contributed to HSP in our patient remains unknown.

TH-PO1090

Harvoni Induced Acute Interstitial Nephritis Jyotsana Thakkar, Kenar D. Jhaveri, Rimda Wanchoo. *Nephrology, North Shore-LIJ Hospital, NY.*

Introduction: Harvoni is a new combination pill consisting of ledipasvir with sofosbuvir approved by FDA in October 2014 for the treatment of chronic Hepatitis C genotype 1 virus infection. No cases of Acute Kidney Injury (AKI) have been reported with this agent thus far. We report the first case of Harvoni associated biopsy proven acute interstitial nephritis (AIN).

Case Description: A 64 year old AA female with chronic Hepatitis C, hypertension, diabetes mellitus came to our clinic for evaluation of AKI superimposed on chronic kidney disease. Laboratory data revealed serum creatinine of 2.24 mg/dl (baseline Cr 1.5 mg/dl), hypoalbuminemia (3.2 gm/dL) with a spot urine protein/ creatinine ratio of 3.3 (baseline of 1). Her AKI coincided with peripheral eosinophilia. Home medications included hydralazine, lantus, lisinopril and simvastatin. She had recently completed eight weeks of treatment for Hepatitis C with Harvoni and her most recent viral load was undetectable. She denied using any NSAID, antibiotics, PPI or herbal supplements. Physical exam was normal. AKI workup revealed negative ANCA , normal complement, normal serum free immunoglobulin light chain ratio and negative ANA panel.

Patient underwent kidney biopsy. Light microscopy showed 11 glomeruli, 3 were globally sclerosed, 3 had cellular crescents with mesangial nodular matrix expansion and moderate tubular atrophy. Interstitium showed moderate fibrosis with severe lymphocytic inflammation. Immunofluorescent microscopy was normal and electron microscopy showed diffusely thickened glomerular membrane and moderately effaced foot processes. A final diagnosis of acute interstitial nephritis with chronic diabetic nephropathy was made. Her clinical picture, pathology findings and time course of renal impairment coincided with Harvoni use and is suggestive of Harvoni induced AIN. She was initiated on steroid therapy and advised to stop further use of Harvoni. Her renal function is stable with no further deterioration after stopping offending agent.

Discussion: Harvoni has a cure rate of up to 94-100% in patients with Hepatitis C genotype 1. We report first case of biopsy proven AIN with Harvoni. Hepatologists and nephrologists need to be aware of the potential side effect of this novel agent.

TH-PO1091

Thrombotic Microangiopathy Secondary to Smoldering Myeloma: A Form of MGRS Jyotsana Thakkar, Rimda Wanchoo, Kenar D. Jhaveri. *Nephrology, North Shore-LIJ Hospital, NY.*

Introduction: Thrombotic microangiopathy syndrome (TMA) is not a usual presentation of paraproteinemic diseases. We report a case of TMA secondary to smoldering myeloma presenting as monoclonal gammopathy of renal significance (MGRS).

Case Description: A 69 year old male with past history of hypertension, diabetes mellitus, prostate cancer, Chronic Kidney disease (CKD) (baseline creatinine 1.3-1.5 mg/dl), chronic back pain was referred to our clinic for evaluation of CKD. Home medications included enalapril, humalog, pioglitazone and acetaminophen as needed. Physical exam was normal except for elevated BP of 160/80 mmHg. Workup showed serum creatinine 1.5 mg/dl, Spot urine protein/creatinine ratio of 0.2, Hb 15.5 gm/dl and platelets 113K/UL. Serum free light chain ratio was suggestive of elevated IgA kappa light chain and elevated K/L ratio. Bone marrow biopsy showed mild plasmacytosis (10% plasma cell). Skeletal survey was negative for lytic lesion. Patient was diagnosed with smoldering myeloma. Kidney biopsy was done to rule out MGRS.

Light microscopy showed 24 glomeruli, 11 of which were sclerotic. Immunofluorescence was negative. On Electron microscopy, extensive glomerular basement membrane (GBM) duplication with sub endothelial widening was seen. Between the duplicated GBM, two types of electron dense deposits were seen, consisting of short fibrils and well demarcated dense material giving bubbly appearance consistent with thrombotic microangiopathy. Serological workup for secondary causes of TMA including HIV, Hepatitis, CMV PCR, Parvovirus B19 PCR, antiphospholipid antibody, cryoglobulin, complement (C3, C4) , HTLV I/II immunoassay, beta 2 glycoprotein IgA Ab were negative. Given the smoldering nature of MM and the finding of TMA on kidney biopsy with no secondary cause, patient was considered to have MGRS presenting as renal limited TMA and is currently being treated with anti plasma cell agents.

Discussion: Case series of cancer related microangiopathic hemolytic anemia and TTP as initial presentation of multiple myeloma have been described before but not biopsy proven chronic renal limited TMA secondary to smoldering myeloma. We report first case of biopsy proven TMA likely secondary to smoldering myeloma.

TH-PO1092

A Case of Leukocyte Chemotactic Factor 2 Associated Amyloidosis Nada Bader, Saeed Kamran Shaffi. *Nephrology, Univ of New Mexico.*

Introduction: Leukocyte chemotactic factor 2-associated amyloidosis (ALECT2) is a newly described form of nonhereditary amyloidosis. The disease usually presents with chronic kidney disease and bland urinary sediment with variable degrees of proteinuria. We describe a case of a young Hispanic female who presented with nephrotic syndrome without renal insufficiency.

Case Description: A 40 year old Hispanic female with history significant for uncontrolled type 2 diabetes, hypertension and rheumatoid arthritis, was referred to renal clinic for evaluation of nephrotic syndrome. Physical examination revealed periorbital and bilateral lower limb edema. Pertinent diagnostic data are shown in figure1.

Figure 1: Diagnostic Data	
Urinalysis	3+ protein
Urine microscopy	Bland
Spot urine protein/creatinine (g/g)	20
Serum creatinine (mg/dl)	0.5
Serum albumin (g/dl)	1.4
SPEP	No M component
Serum Keppa/Lambda	Normal
Hepatitis panel	Non-reactive
ANA	Non-reactive
Renal ultrasound	Normal kidney size with mild echogenicity

Renal biopsy showed extensive amyloidosis involving the glomeruli, interstitium and arterioles. Immunofluorescence was negative for immunoglobulins and amyloid associated protein. Proteomic typing of the amyloid revealed ALECT2 associated amyloidosis. The patient was started on lisinopril and spironolactone, but her proteinuria failed to improve and she had progressive deterioration of renal function. Two years later, she developed ascites and elevated liver enzymes. Her presentation was concerning for hepatic amyloidosis; therefore, she was transferred to a liver transplant center for further evaluation.

Discussion: Based on two large renal biopsy series, ALECT2 accounts for 2.5-2.7% of all cases of renal amyloidosis. In a multicenter study involving 72 patients with renal ALECT2, 92% were Hispanic, 2.8% were below the age of 50 and 91.4% had a serum creatinine > 1.2mg/dl. One third had nephrotic range proteinuria, but only 10% of all patients presented with nephrotic syndrome. Pathogenesis is not clear. It is postulated that inflammatory processes lead to excessive production of an amyloidogenic variant of ALECT2. Accurate identification of the amyloid protein is essential as disease modifying treatments are available for certain types of amyloidosis.

TH-PO1093

Complement Polymorphisms in Patients with Thrombotic Microangiopathy Associated with Intravenous Abuse of Oral Formulation of Extended-Release Oxymorphone (OPANA-ER) Joe Ghata, Lukas Haragsim, Satish Kumar. *Nephrology, Univ of Oklahoma Health Science Center, Oklahoma City, OK.*

Introduction: In 2012, the CDC reported 15 cases of unexplained renal failure and thrombotic migroangiopathy (TMA) in which all patients reported dissolving and intravenously injecting an oral preparation of oxymorphone (Opana ER) prior to presentation. Since then, 30 additional cases have been reported in the U.S. The mechanism of IV Opana-associated TMA is unclear. ADAMTS13 levels were normal. We report two patients with genetic polymorphisms of complement system proteins as a possible mechanism for Opana-associated TMA.

Case Description: Two patients, a 26 yo WM (Pt 1) and a 38 yo WM (Pt 2) presented with unexplained renal failure (serum creatinine 8.2 and 4.6 mg/dl respectively) in the setting of IV Opana Abuse. Both displayed a hematological constellation of microangiopathic hemolytic anemia, thrombocytopenia, consumed haptoglobin and elevated LDH. Both patients had normal INR/PT/PTT, ADAMTS13 (both > 55%) and fibrinogen levels. ANA, HIV, and hepatitis profiles were negative. Renal biopsy showed intermediate sized vessel TMA in both patients. Both received plasmapharesis for 5 days. Hematological microangiopathy resolved in Pt 2 but persisted in Pt 1. Both remained dialysis dependent. Genetic studies for complement-mediated HUS demonstrated both to be positive for a heterozygous polymorphism (IVSP-78 G>A) within an intron of the membrane cofactor protein (MCP/CD 46) and for a homozygous polymorphism (p.His402Tyr) in the complement factor H (CFH). In addition, both patients had an additional CFH polymorphism (p.Val62Ile; Pt 1 homozygous, Pt 2 heterozygous).

Discussion: Our patients suggest a 2 hit mechanism for IV Opana-associated TMA. Both had polymorphisms in complement system proteins MCP and CFH with a potential predisposition for complement-mediated HUS. The MCP/CD 46 polymorphism has been shown to be enriched in patients with complement-mediated HUS. Polymorphisms in complement system proteins could cause hyperactivation and dysregulation of the complement system and provide a genetic predisposition for thrombotic microangiopathy, with IV Opana abuse acting as a trigger.

TH-PO1094

Acute Kidney Injury due to an Excessive Dose of Rivaroxaban Sandar Win,[1] Kevin G. Lazo,[2] Jordan L. Rosenstock.[1] [1]*Nephrology, NSLIJ/Lenox Hill Hospital, New York, NY;* [2]*Internal Medicine, .*

Introduction: Recently, over-anticoagulation with warfarin has been recognized as a cause of acute kidney injury (AKI) and has been termed warfarin related nephropathy (WRN). We report a patient who developed AKI and gross hematuria while taking the new oral anticoagulant (NOAC) rivaroxaban.

Case Description: A 45 y/o man presented to his physician's office with abdominal pain. Computed tomography (CT) of the abdomen was done and thrombosis of the portal, splenic, and mesenteric vein was identified. He was admitted to the hospital and discharged on rivaroxaban 10mg 2 tablets daily. After 6 weeks, he was given a prescription for rivaroxaban 20 mg tab and told to take 1 tablet daily. He mistakenly took 2 tablets daily. After 5 days, he noticed painless gross hematuria for several days. He reported to his physician's office and his serum creatinine had increased to 2.7 mg/dL from a baseline of 1.5. He had a previous history of splenic vein thrombosis of unclear cause 2 years previously (treated with course of warfarin), hypertension, and diabetes. His medications included metformin, glipizide, gemfibrozil, valsartan, sitagliptin, and rivaroxaban. His vital signs were normal. Physical examination showed splenomegaly but was otherwise unremarkable. Urinalysis revealed many red blood cells with trace proteinuria. The urine protein to creatinine ratio was 257 mg. Serologies were negative and there was no evidence of intravascular hemolysis. Antiphospholipid antibodies were negative as was a hypercoaguable work-up. A bone marrow biopsy was unremarkable and paroxysmal nocturnal hemoglobinuria was ruled out. Renal dopplers were negative for renal vein thrombosis. Renal function remains stable after 3 months. Renal biopsy was not performed in the setting of required anticoagulation and likely diagnosis of anticoagulant related AKI.

Discussion: WRN is a newly recognized form of AKI in the setting of excessive anticoagulation with warfarin. This appears to be the first reported case of a WRN- like AKI due to the NOAC rivaroxaban, and was likely caused but inadvertent doubling of the patient's dose. WRN can often be irreversible and in this patient as well no renal recovery was evident at 3 months.

TH-PO1095

Irreversible Acute Kidney Injury due to Oxalate Nephropathy from Intravenous Vitamin C Tarvinder S. Matharu, Satish Kumar. *Nephrology, Univ of Oklahoma Health Science Center, Oklahoma City, OK.*

Introduction: High doses of vitamin C are widely used in alternative medicine for treatment of cancer, viral illness and fatigue. Vitamin C is metabolized to oxalic acid in the body. High doses of vitamin C have the potential to cause hyperoxaluria, nephrolithiasis and oxalate nephropathy. We report a patient who developed severe, irreversible, acute kidney injury due to acute oxalate nephropathy from high dose intravenous vitamin C.

Case Description: 75 yo male with a history of hypertension, hypothyroidism, and mild pancytopenia, presented to a wellness clinic with fatigue and weight loss. He had a normal metabolic profile except hypercalcemia (corrected Ca, 12 mg/dl). He received IV vitamin C 30 g/d for 7 days. Serum creatinine was 1.3 mg/dl prior to Vitamin C administration. One month following treatment, he was admitted to our hospital with serum Cr 9.1, Na 110, K 3.1, Cl 70, CO2 16, BUN 152, Glucose 131, Ca 8.4, Uric Acid 12.1, CPK 175, Phos 11.9, and Mg 3.3. LFTs were normal. Urine vitamin C level was 40. An abdominal CT revealed diffuse mesenteric and retroperitoneal lymphadenopathy with hepatosplenomegaly and ascites. Liver was without cirrhosis. A renal ultrasound revealed normal sized, echogenic kidneys. Serum free light chains and serum and urine protein electrophoresis were normal. A renal biopsy demonstrated diffuse acute tubular injury and abundant tubular calcium oxalate deposits consistent with acute oxalate nephropathy. Bone marrow biopsy was normal and culture negative. A lymph node biopsy demonstrated diffuse T Cell Lymphoma. Patient was started on dialysis and remained dialysis-dependent at last follow up.

Discussion: Our patient developed severe, irreversible acute kidney injury from high dose intravenous vitamin C. The hypercalcemia was likely a contributing factor for the extensive deposition of calcium oxalate crystals in the kidney. A literature search identified 2 previous reports of oxalate nephropathy from intravenous vitamin C. High dose vitamin C is a common component of alternative medical regimens for cancer and other illnesses. We urge caution in using high dose vitamin C especially in patients with pre-existing renal insufficiency or hypercalcemia.

TH-PO1096

Atypical Hemolytic Uremic Syndrome (aHUS) due to a Novel Sequence Variation of Diacylglycerol Kinase Epsilon (DGKE) Shoba Narayan,[1] Rupa A. Udani,[2] Stefanie Dugan,[2] Matthew W. Anderson,[2] Dorit Ben-Ezer,[1] Kenneth Dale Friedman.[2] [1]*Nephrology, Children's Hospital Orange County, Orange, CA;* [2]*Hematology, Blood Center of Wisconsin, Milwaukee, WI.*

Introduction: aHUS is a congenital disease characterized by hemolytic anemia, thrombocytopenia, and organ dysfunction (e.g. renal failure). Genetic alternations resulting in uncontrolled activation of the complement system are found in 50-60% of aHUS cases. Recently autosomal recessive mutations in DGKE have been identified, indicating that intrinsic abnormalities in the signaling pathways controlling endothelial and platelet procoagulant tendency and podocyte function can also lead to aHUS. Patients with DGKE-associated disease tend to present at earlier age, have nephrotic range proteinuria, fail to respond to eculizumab, and may develop renal failure, but do well after renal transplantation.

Case Description: We identified a novel homozygous sequence variation c.1344C>A, p.N448K in the kinase accessory site of DGKE in a family with aHUS. The index case presented at 1 year of age with nephrotic range proteinuria and hypertension. Renal biopsy at the time revealed TMA. Clinical course was complicated by ongoing proteinuria despite ACE-I and ARB therapies. At age 10, she does not have thrombocytopenia, schistocytes, abdominal or CNS manifestations, as typically noted in patients with complement-mediated aHUS. Genetic testing was resent to identify mutations previously not available to guide further treatment. The patient also carries heterozygous sequence variation ADAMTS13 c.3287G>A, p.R1096H, associated with decreased ADAMTS13 function and is heterozygous for CFHR5. Subsequently, a younger sister presented with hypertension, hematuria and nephrotic range proteinuria. The symptomatic sister is also homozygous for this variant in DGKE and is heterozygous for CFHR5, but lacks the ADAMTS13 variant. Parents and siblings with heterozygous DGKE variants are healthy.

Discussion: This case is the first reported case of a kinase accessory domain of DGKE associated with aHUS. Additional studies are needed to determine the impact of DGKE mutations on the clinical course of patients with aHUS and their appropriate management.

TH-PO1097

Membranoproliferative Glomerulonephritis with Mixed Cryoglobulinemia in Patients with Autoimmune Hepatitis Olorunkemi O. Oluwole, Anand Achanti, Jalal E. Hakmei, Sally Self, Milos N. Budisavljevic. *Nephrology, MUSC, Charleston, SC.*

Introduction: Autoimmune hepatitis (AIH) is frequently associated with extrahepatic manifestations; however, glomerulonephritis is rarely seen. We describe two patients with biopsy proven AIH who developed membranoproliferative glomerulonephritis (MPGN) despite treatment with prednisone and azathioprine. Screening for hepatitis B and C virus was negative and neither patient had SLE.

Case Description: Case 1: A 56 year old female presented with microscopic hematuria (6-10 RBC), proteinuria (6.9 g) and acute kidney injury (creatinine 1.5 mg/dL). Her renal function deteriorated requiring hemodialysis treatment. Serology revealed mixed type III IgG/IgM cryoglobulins. Kidney biopsy showed mesangial proliferation, protein thrombi within capillary loops, reduplication of GBM and mesangial interpositioning, consistent with cryoglobulinemic MPGN. She was treated with plasma exchange and rituximab, with disappearance of cryoglobulins, normalization of urinary findings and resolution of AKI. Case 2:18 year old female presented with proteinuria (1.7 g), hematuria (44 RBC) and serum creatinine 0.8 mg/dl. Mixed type III cryoglobulins consisting of IgG/IgM were detected in the serum. Kidney biopsy revealed mesangial hypercellularity reduplication of GBM with subendothelial, mesangial and scattered subepithelial deposits. She was treated with plasma exchange, one dose of 1000 mg intravenous cyclophosphamide and 1 gram of rituximab 4 weeks later. Treatment led to the disappearance of cryoglobulins and normalization of urinary findings. Serologic tests at presentation are presented in (table 1).

	Case 1	Case 2
C3 (88-201 mg/dL)	27	42.2
C4 (16–47 mg/dL)	<10	<10
ANA (Negative)	Negative	1:160
Anti dsDNA (<30 IU/ml)	20	28.7
RF (0-24 IU/ml)	1770	Negative
ANCA (Negative)	Negative	1:640

Discussion: Patients with AIH should be monitored for proteinuria and active urinary sediment due to the risk of glomerulonephritis, despite treatment with prednisone and azathioprine. MPGN is a rare, but important, complication of AIH. Prompt diagnosis by kidney biopsy and aggressive treatment of AIH associated MPGN with rituximab and/or cyclophosphamide may result in a favorable renal outcome.

TH-PO1098

A Case of Chinese Herb (Aristolochic Acid) Nephropathy Leading to ESRD Complicated by Bladder Cancer Melin Joe Narayan, Bahar Bastani. *Dept of Nephrology, St. Louis Univ, St. Louis, MO.*

Introduction: Chinese Herb (aristolochic acid) Nephropathy, is a rapidly progressive interstitial nephritis leading to ESRD with a high frequency of urothelial malignancy.

Case Description: We report a 59 year old white female who had received Chinese herbs for one and half years before she developed progressive renal insufficiency that over a six month period lead to ESRD requiring hemodialysis. A renal biopsy showed extensive tubular loss and collapse associated with interstitial edema and interstitial fibrosis consistent with the effects of tubular toxic damage caused by aristolochic acid. After one week of hemodialysis, the patient underwent a living unrelated kidney transplant from a friend. Alemtuzumab induction, steroid free maintenance on tacrolimus and mycophenolate (MMF) were started. She had no history of diabetes, hypertension or use of NSAIDS. She underwent monthly urinalysis and screening cystoscopy every six months to rule out urothelial malignancies. Twenty months post transplant she underwent right breast lumpectomy and radiation for intraductal carcinoma. Two and a half years after kidney transplant routine cystoscopy revealed a bladder mass, a biopsy of which showed high grade urothelial carcinoma with squamous differentiation invading into subepithelial connective tissue for which she underwent bilateral native nephrectomy, ureterectomy, cystectomy and transplant kidney ileal loop urinary diversion. One year later the patient was admitted with shortness of breath and was found to have a malignant pleural effusion of unidentified primary which led to her demise. A sample of the Chinese herb that she had used was found to contain aristolochic acid.

Discussion: There has been a high risk of urothelial malignancies associated with Chinese herb/aristolochic acid exposure with 40 - 45% of these patients developing multifocal high grade transitional cell carcinoma leading to a suggestions for either prophylactic bilateral native nephrectomy and ureterectomy at the time of renal transplantation or screening cystoscopies every 6 months to identify early stage urothelial carcinoma. Our patient is a classic example of aristolochic acid associated nephropathy complicated with urothelial cancer.

TH-PO1099

Anti-Tumor Necrosis Factor Therapy – A Trigger for Anti-Glomerular Basement Membrane Disease Carlos Antonio Cortes Sanchez, Hector R. Cordova, Krystahl Z. Andujar. *Medical Service, VA Caribbean Healthcare System, San Juan, PR.*

Introduction: Tumor necrosis factor (TNF) has a key pathological role in diseases such as rheumatoid arthritis (RA). Vasculitis and other autoimmune diseases have been associated with the use of anti-TNF agents such as Adalimumab.

Case Description: A 73-year-old man with of RA, Hypertension, Diabetes Mellitus type 2 and Non-Hodgkin's Lymphoma in remission for 3 years complained of decreased urine output, dark urine, poor appetite, weight loss and peripheral edema for three weeks. He was on chronic low dose Prednisone and Adalimumab intermittently during the previous 21 months. Physical exam revealed bilateral lower extremity pitting edema but no skin lesions. Laboratories showed a serum creatinine of 9.3mg/dl (baseline of 1.3mg/dl). Urinalysis exhibited many RBC's, proteinuria (2+) and pyuria without casts. The clinical picture suggested acute glomerulonephritis. Hemodialysis (HD) was started.

Test	Upon Admission	After Plasmapheresis	After Reexposure to Adalimumab
ANA	1:80 Speckled		
C3/C4	Normal		
Anti-GBM (N < 1.0 AI)	7.9	2.4	4.3
Atypical P ANCA (N < 1:20)	Negative	Negative	Negative
P-ANCA (N < 1:20)	1:20	Negative	Negative
MPO (N < 1.0 AI)	4.6	1.1	2.2
C-ANCA (N < 1:20)	Negative	Negative	Negative
Prot3Ab (N < 1.0 AI)	Negative	Negative	Negative
ASO Titer	Normal		

Serology tests were compatible with Anti-Glomerular Basement Membrane (GBM) Disease. Alveolar hemorrhage was not present. Plasmapheresis therapy decreased anti-GBM titers but there was no recovery of renal function. The patient continued using Adalimumab after discharge. He later returned with hemoptysis due to alveolar hemorrhage, which resolved after the discontinuation of Adalimumab. The patient remained HD-dependent.

Discussion: The temporal association of the illness with anti-TNF therapy and worsening of symptoms upon reexposure suggest an etiologic role of Adalimumab in the development of Anti-GBM Disease in our patient. Patients receiving anti-TNF therapy should have renal function closely monitored to allow early detection of this infrequent but life-threatening side effect.

TH-PO1100

Severe Pauci Immune Crescentic Glomerulonephritis Mimicking ANCA Related Vasculitis Caused by Clinically Silent Dental Abscess Leading to Bacterial Endocarditis Anil K. Chunduri, Maria Saleem Khan, Anthony Alvarado, Tibor Nadasdy, Lee A. Hebert. *Nephrology, OSUMC, Columbus, OH.*

Introduction: Severe crescentic GN is usually categorized based on the cause if it is Anti GBM or IC mediated disease. However, it is not widely appreciated that some instances of pauci immune GN are actually the result of severe occult systemic infections. We present a case of severe pauci immune crescentic GN whose initial assessment for infection was negative. The patient was assumed to have idiopathic AAV and was treated with high dose steroids. Despite no obvious signs of infection, bacteremia was on our differential due to pancytopenia. These findings are rarely common, if ever, associated with AAV.

Case Description: 55 year old male with PMH of CAD presented to an outside hospital with fatigue. Initial labs revealed Hb: 7.6g/dl, WBC; 2.8 K/μL, Plt: 44 K/μ, Creat: 2.26 mg/dl. Infectious work up was negative. Autoimmune workup revealed: ANA positive (1:40), Anti GBM (<0.2), Anti PR3 (0.6), ANCA and Anti MPO: negative. C3 : 77mg/dl↓, C4 :16.9 mg/dl (wnl). Cryoglobulin (<5), Urine PC ratio was 1.2. Further workup included a bone marrow biopsy and kidney biopsy, which was suggestive of pauci-immune crescentic and necrotizing GN. He received treatment with steroids and was discharged on steroid taper. His creatinine upon discharge was 1.5 mg/dl. On follow up his creatinine was elevated to 3.5 mg/dl. He was transferred to our institution. Repeat Infectious work up revealed streptococcus viridians bacteremia, tricuspid and aortic valve endocarditis. A panoramic radiograph of his teeth showed periapical abscess. He was subsequently diagnosed with infection related acute pauci-immune crescentic necrotizing GN. Unfortunately this patient remained dialysis dependent at the time of discharge.

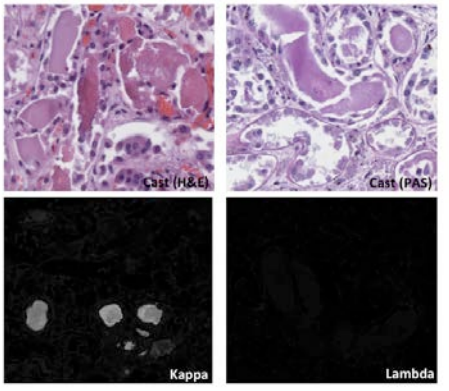
Discussion: It is well established but not widely appreciated that severe pauci-immune crescentic GN can be the direct result of infection. Thorough investigation is warranted even if the initial infectious workup is negative, if the patient does not have a positive response to conventional therapy to improve morbidity and mortality.

TH-PO1101

POEMS Syndrome with Cast Nephropathy Amanda K. Hall,[1] Josephine Abraham,[1] Monica Patricia Revelo Penafiel,[2] Frederic Clayton.[2] *[1]Div of Nephrology and Hypertension, Univ of Utah, Salt Lake City, UT; [2]Div of Pathology, Univ of Utah, Salt Lake City, UT.*

Introduction: POEMS syndrome(**P**olyneuropathy, **O**rganomegaly, **E**ndocrinopathy, **M**onoclonal protein, **S**kin changes) is a plasma cell disorder with peripheral neuropathy and any of the following features osteosclerotic bone, Castleman's disease, increased levels of serum vascular endothelial growth factor(VEGF), organomegaly, endocrinopathy, edema or skin changes. We report a case of POEMS presenting with acute renal failure due to cast nephropathy.

Case Description: A 63-year-old Caucasian female presented with a 3 month history of increasing weakness and was diagnosed with chronic inflammatory demyelinating polyneuropathy. She was also noted to have new onset diabetes mellitus and hypothyroidism. She was treated with intravenous immunoglobulin(IVIG) with minimal response. She was admitted with acute renal failure initially thought to be secondary to IVIG, progressive weakness, and shortness of breath. Serum beta 2 microglobulin was elevated and kappa/lambda ratio was abnormal with Bence-Jones proteinuria. Renal biopsy was deferred as the patient developed respiratory failure, subarachnoid hemorrhage, and a left middle cerebral artery stroke. Comfort measures were initiated. Bone marrow biopsy confirmed multiple myeloma with 20% clonal plasma cells. Autopsy showed hepatomegaly, splenomegaly, and peripheral nerve demyelination with active axonal loss. Renal examination showed cast nephropathy with monoclonal kappa light chains.



These features are characteristic of POEMS given the multiple myeloma with neuropathy, organomegaly, rash and new onset diabetes mellitus and hypothyroidism.

Discussion: POEMS is a paraneoplastic syndrome associated with plasma cell dyscrasia. Polyneuropathy with plasma cell disorder should prompt evaluation for POEMS as outcomes have been excellent with diagnosis and treatment.

TH-PO1102

Acute Interstitial Nephritis Associated with a New Breast Cancer Chemotherapy Regimen Cory Handelsman,[1] Michael T. Tanoue,[2] Amy Kwon,[2] Steven Salvatore,[3] Jeffrey I. Silberzweig.[2,4] *[1]Div of Nephrology, Weill Cornell Medical College; [2]Dept of Medicine, Weill Cornell Medical College; [3]Dept of Pathology, Weill Cornell Medical College, New York, NY; [4]The Rogosin Inst, New York, NY.*

Introduction: Acute interstitial nephritis (AIN) as a direct consequence of chemotherapy is infrequently described. A recent review implicated ifosfamide, tyrosine kinase inhibitors, and pemetrexed as culprits in this process. We describe a case of AIN related to the recently approved chemotherapy regimen of pertuzumab, trastuzumab, and docetaxel for HER-2 positive metastatic breast cancer. While diarrhea, rash, and pruritis are well-known side effects, this report is the first to show AIN as a consequence of this combination regimen.

Case Description: A 69-year-old woman recently diagnosed with HER-2 positive breast cancer and treated with six cycles of neoadjuvant pertuzumab, trastuzumab, and docetaxel was hospitalized for acute kidney injury after two days of diarrhea and vomiting. Admission labs demonstrated leukocytosis to 26,000/uL, serum creatinine of 5.9 mg/dL (baseline of 1.55 mg/dL), and elevated anion gap metabolic acidosis with a lactic acid of 4.5 mmol/L. Urinalysis showed pyuria with occasional granular casts. Fractional excretion of sodium was 1.88%. Renal sonogram showed normal resistive indices with no evidence of hydronephrosis or calculi. Infectious workup, including blood, urine, and stool studies, was unrevealing. Despite aggressive hydration and resolution of diarrhea and vomiting within 48 hours, her renal function worsened; her creatinine peaked at 9.0 mg/dL on hospital day 3. She was non-oliguric throughout the admission. A renal biopsy revealed moderate to marked, diffuse acute and subacute, interstitial inflammation characterized by lymphocytic infiltration with moderate eosinophilia and diffuse tubular injury. Some endothelial injury

was present as well. The patient was diagnosed with AIN secondary to chemotherapy and treated with prednisone. Two weeks later, her symptoms had fully resolved and her serum creatinine had returned to baseline.

Discussion: This is the first documented case of AIN related to combination chemotherapy with docetaxel, pertuzumab, and trastuzumab.

TH-PO1103

Sarcoidosis-Lymphoma Syndrome Presenting with Severe Refractory Hypercalcemia Osita W. Okechukwu,[1] Barry M. Wall,[2] Elvira Gosmanova,[1] Deepak Nandikanti.[1] *[1]Nephrology Div, UTHSC, Memphis, TN; [2]Nephrology Section, VAMC, Memphis, TN.*

Introduction: Sarcoidosis-lymphoma syndrome (SLS) is rare. Sarcoidosis (S) usually precedes lymphoma (L) by many months. Constitutional symptoms and hilar lymphadenopathy are typical initial manifestations of SLS. We report a SLS case presenting with severe acute hypercalcemia and acute kidney injury (AKI).

Case Description: Case Report:A 70 yr-old Caucasian male was hospitalized with symptoms of generalized weakness, poor oral intake, and altered mental status. Examination was significant for dry mucus membranes, depressed mentation, evidence of bilateral pleural effusions, mild ascites, and 2cm well-delineated hyper-pigmented erythematous plaques on anterior chest wall. Laboratory findings included a corrected serum Ca 19.4mg/dL (2 months prior- 9.3mg/dL), ionized Ca 2.5 mmol/L, BUN 56mg/dL, serum creatinine 2.9mg/dL (baseline 1.4 mg/dL),and mild anemia. Further work up revealed suppressed PTH (6.2pg/mL) normal LFT, PTHrP, serum and urine electrophoresis, calcidiol, calcitriol, ACE, CEA, PSA, and TSH. A working diagnosis of hypercalcemia of malignancy was made. Intravenous fluids, calcitonin, prednisone, and low dose pamidronate were initiated; however, hypercalcemia and AKI remained poorly responsive to conservative measures and hemodialysis was required. Skin biopsy of chest wall lesion demonstrated non-caseating granulomatous dermatitis consistent with sarcoidosis. Thoracentesis was performed and pleural fluid cytology showed occasional plasmacytoid/lymphoid cell and polyclonal T-cells on flow cytometry. However, flow cytometry of ascitic fluid was positive for monoclonal B cells.Computed tomography (CT) demonstrated diffuse soft tissue lung masses and abdominal carcinomatosis. Osseous survey was normal. CT-guided omental mass biopsy showed dense fibrous tissue with lymphoplasmacytic infiltrate. The diagnosis of SLS with associated B-cell lymphoma was made. Given poor functional status and widespread disease, the patient and his family opted for hospice care.

Discussion: Severe refractory hypercalcemia leading to AKI is unusual for sarcoidosis and should prompt investigation for concomitant lymphoma.

TH-PO1104

End Stage Renal Disease Secondary to Oxalate Nephropathy in a Patient with Undiagnosed Chronic Pancreatitis Kalyani Chandra, Burl R. Don. *Div of Nephrology, UC Davis Medical Center, Sacramento, CA.*

Introduction: Oxalate nephropathy is a rare, underdiagnosed, devastating disease characterized by extensive oxalate deposition, acute kidney injury and rapid progression to end stage renal disease (ESRD). Secondary hyperoxaluria occurs in enteric disorders associated with increased intestinal oxalate absorption and renal tubular injury. Chronic pancreatitis is a rare cause of oxalate nephropathy.

Case Description: A 66 year-old white man with history of diabetes mellitus, hypertension and recurrent kidney stones, was noted on routine labs to have an elevated serum creatinine level (6.88 mg/dL; baseline 1.17 mg/dL, 6 months prior). He reported having chronic diarrhea, fatigue, loss of appetite and weight loss over the past 6 months. Workup revealed pancreatic calcifications consistent with chronic pancreatitis. Urinalysis and renal ultrasound were normal. Renal biopsy revealed acute tubular necrosis with extensive oxalate deposition. A 24 hr urine collection noted increased oxalate and reduced citrate excretion. Despite a 6 month course of a low oxalate diet, pancreatic enzymes, calcium supplementation, and sodium citrate to alkalinize the urine, the patient's renal function failed to improve, and he is preparing for home hemodialysis.

Discussion: Enteric hyperoxaluria can lead to acute oxalate nephropathy. It has been described in patients with post-gastric bypass surgery and inflammatory bowel disease. There are rare reports noting the association between chronic pancreatitis and oxalate nephropathy leading to chronic kidney disease (CKD) and rarely ESRD. The pathogenesis of hyperoxaluria in chronic pancreatitis remains uncertain, but it is postulated that fat malabsorption may increase free fatty acids that competitively inhibit the formation of calcium oxalate in the GI tract, combined with increased colonic mucosal permeability, leading to hyperoxalemia, hyperoxaluria and oxalate crystallization in the kidney. Treatment remains largely empiric, aiming at decreasing oxalate burden to the kidney as was done in this patient. Oxalate removal with dialysis has not been shown to be beneficial. Oxalate nephropathy can be a late complication of chronic pancreatitis leading to CKD and ESRD.

TH-PO1105

mRNA Expression of Proinflammatory Mediators in Common Variable Immunodeficiency with Granulomatous Interstitial Nephritis: Case Report Giacomo Mori, Giulia Ligabue, Sara De biasi, Milena Nasi, Andrea Cossarizza, Gianni Cappelli. *Univ Hospital - Modena.*

Introduction: Common Variable ImmunoDeficiency (CVID) impact on kidney function is poorly understood.We present a case of a woman, 39years old,affected by CVID, expressing as hypogammaglobulinemia,anemia and chronic kidney failure secondary to granulomatous interstitial nephritis(IN).

Case Description: In 2013 serum creatinine(s-cr)rose from 0.8 to 2.6mg/dl,without urinary abnormalities or signs of inflammation.A kidney biopsy showed an IN,with granulomatous aspects.PolyomaBK,HIV1/2,ParvovirusB19,SV40 resulted negative,urinary PolyomaJC was positive.A PET-CT ruled out occult infections or reactive linphnodes. Pathology of several purple-brownish skin lesions demonstrated a lymphocytic infiltrate and perivascular macrophages containing melanin pigment.ACE level was doubled.A course of metilprednisolone(350mg i.v. for 3 days,followed by oral tapering)was started;anemia improved with iron,vitamins and EPO;s-cr decreased to 1.9mg/dl.Along 2014 relevant metabolic acidosis persisted and s-cr gradually rose to 3.8mg/dl.Before starting a new course of steroids we evaluated mRNA expression of a panel of proinflammatory mediators in circulating monocytes.

Among the considered mediators AIM2,PTGS2 and IL1B genes were overexpressed. AIM2 is central in innate immune response,recognizing cytosolic double-stranded DNA and inducing caspase-1-activating inflammasome formation in macrophages;PTGS(or Cyclooxygenase)is the key enzyme in prostaglandin biosynthesis,with two isozymes:PTGS1(constitutive) and PTGS2(inducible).PTGS2 upregulation leads to the prostanoid biosynthesis involved in flogosis and mitogenesis.IL1B(Interleukin1)is involved in cell proliferation,differentiation and apoptosis.IL1B induces PTGS2,mediating pain hypersensivity.Steroids allowed a regression of s-cr to 2.4mg/dl and of ACE to normality range.

Discussion: Innate immune response over activation could be the cause of a pathologic monocyte-macrophage stimulation responsible for tubulointerstitial damage.Further studies are needed to understand the therapeutic potential of biologic therapy of CVID related interstitial nephritis,with the aim of stopping the inflammatory cascade.

TH-PO1106

Nephrotic Range Proteinuria without a History of Penicillamine Therapy in a Patient with Wilson's Disease Hideki Matsumura,[1] Akira Ashida,[1] Yuko Fujii,[1] Akihiko Shirasu,[1] Hyogo Nkakura,[1] Motoshi Hattori,[2] Hiroshi Tamai.[1] *[1]Pediatrics, Osaka Medical College, Osaka, Japan; [2]Pediatric Nephrology, Tokyo Women's Medical Univ, Tokyo, Japan.*

Introduction: Wilson's disease (WD) is a rare autosomal recessive genetic disorder of copper metabolism, characterized by hepatic and neurological abnormality. Although penicillamine is one of the key drugs for treatment of WD, in rare cases it may have a nephrotoxic effect leading to nephrotic syndrome due to membranous nephropathy. Here, we report a case of WD in a patient who showed nephrotic range proteinuria clinically and focal segmental glomerulosclerosis (FSGS) histologically, without a history of treatment with penicillamine.

Case Description: We treated an 18-year-old girl who had been diagnosed as having WD at the age of 6 years and treated with trientine. She had normal liver function and normal urinalysis parameters. At the age of 16 years, she had developed acute liver failure due to poor drug compliance. Although her liver function subsequently recovered after plasma exchange and medications including zinc and trientine, slight proteinuria began to appear. As the proteinuria increased gradually to within the nephrotic range, we performed a kidney biopsy one year later. The patient had normal blood pressure, no edema, and her body mass index was 26.9. Blood examinations demonstrated no hypoproteinemia, no immunological abnormalities and normal kidney function. Although urinalysis revealed no hematuria, the urine protein:creatinine ratio was increased to 2.98. A kidney biopsy demonstrated perihilar FSGS and arteriolar intimal thickening, without tubular-interstitial or glomerular basement membrane changes. We diagnosed the patient as having secondary FSGS and began administration of an angiotensin receptor blocker.

Discussion: Although the kidney manifestations in WD include aminoaciduria and nephrocalcinosis, these were not observed in our patient. As her symptoms were relatively milder than those of typical FSGS and she had several known causes of secondary FSGS including arteriolar intimal hyperplasia and obesity, our histological diagnosis was secondary FSGS. To our knowledge, this is the first report of histologically confirmed FSGS in a patient with WD.

TH-PO1107

Denosumab for the Treatment of Bisphosphonate Refractory Hypercalcemia of Malignancy Theresa L. Nilson, Tammy Wan, Erik Lawrence Lum. *Div of Nephrology, Univ of California, Los Angeles, Los Angeles, CA.*

Introduction: Hypercalcemia is common in malignancy, occurring in 20-30% of patients. Volume expansion with normal saline is the mainstay of therapy, with the addition of bisphosphonates in cases of severe hypercalcemia. Here we describe a case of bisphosphonate resistant hypercalcemia of malignancy and discuss potential treatment options for refractory cases.

Case Description: A 62 year-old male with T2 paraplegia following a fall 24 years ago presented to the ER for evaluation of a decubitus ulcer. On arrival his vital signs were unremarkable, and physical examination demonstrated a 10x10 cm stage IV decubitus ulcer with purulent drainage and exposed bone. Initial laboratory data demonstrated white blood cell count 18.7, hemoglobin 4.9 g/dL, normal basic metabolic panel and calcium 8.8mg/dL. He was transfused blood products and given antibiotic therapy. Bone biopsy demonstrated invasive squamous cell carcinoma. His calcium increased to 14.1mg/dL with elevated PTHrP 71pg/mL. He was diagnosed with humoral hypercalcemia of malignancy and treated with intravenous normal saline and pamindronate 90mg. His calcium initially reduced to 11mg/dL, but rose again to 13.4mg/dL. He received a second dose of pamindronate, but the calcium continued to rise to 15.3mg/dL. He was given a single dose of denosumab 120mg and his calcium decreased to 9.32 mg/dL over the next four days. The response was sustained without additional need for administration over the next two months before the patient expired due to complications related to his decubitus ulcer.

Discussion: This case illustrates the potential effectiveness of denosumab for the treatment of hypercalcemia refractory to bisphosphonates. Denosumab is a human monoclonal antibody against RANK-Ligand (RANKL) whose use has previously been described for management of hypercalcemia, but required multiple infusions. Recognition of this additional treatment, with effectiveness from a single infusion, is critical in managing refractory hypercalcemia, as the only other known option is hemodialysis. Increasing availability of options for management of refractory hypercalcemia may allow patients to avoid complications associated with hemodialysis.

TH-PO1108

Collapsing and NOS Focal Segmental Glomerulosclerosis (FSGS): Progression Along a Spectrum or Different Diseases? Suzanne L. Katsanos, Patrick H. Nachman, JulieAnne G. McGregor, Volker Nickeleit. *UNC Kidney Center, Chapel Hill, NC.*

Introduction: Minimal change disease (MCD) and some variants of FSGS (tip lesion and not otherwise specified NOS) are thought to represent a histologic spectrum of a similar autoimmune pathogenic process (Habib, R. Proceedings IXth Int Cong of Neph). This contention has never been proven, however. Some cases of MCD are thought to be "unsampled" FSGS. A "transition" from MCD to FSGS is common in steroid-resistant forms (Tejani, A. Nephron 39). It has been proposed that collapsing FSGS is pathogenically and clinically distinct from other FSGS variants based on morphology, demographics, severity of nephrotic syndrome, and renal prognosis. The etiology has not been identified but viral agents, drugs, and cyclosporine toxicity have all been proposed.

Case Description: We present the case of a 37-year-old African American male with a complicated course of nephrotic syndrome. He was diagnosed with biopsy-proven MCD when 9 years old. He was treated with steroids followed by chlorambucil and then cyclophosphamide over the next several years. He was in complete remission off therapy for about 2 years until he re-presented with increased edema, proteinuria (3.8 g/d), hypoalbuminemia, and acute kidney injury (AKI). A repeat biopsy (25 glomeruli) showed FSGS NOS. He was treated with steroids followed by mycophenolate mofetil and cyclosporine, resulting in complete remission. 7 years later, he developed edema, proteinuria (21 g/d) and AKI. Repeat biopsy showed 25 glomeruli demonstrating segmental tuft collapse, activation of endothelial cells, and segmented marked activation and crowding of podocytes consistent with collapsing FSGS. HIV, hepatitis B, and hepatitis C were negative.

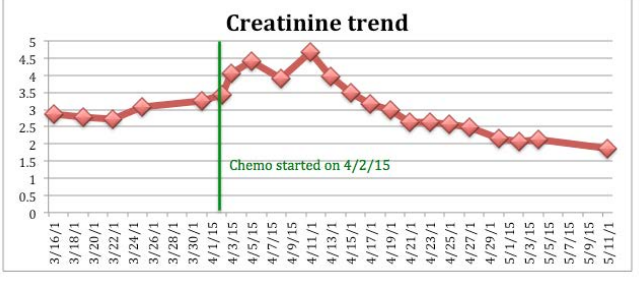
Discussion: The transition from MCD to FSGS NOS is common in the literature. However, the transition from FSGS NOS to collapsing FSGS is rarely reported. This patient's case raises questions about this transition from NOS to collapsing variant. Glomerular undersampling is unlikely given 25 glomeruli were examined each time. This could represent a progressive, patient-related pathogenetic process versus a *de novo* lesion (either related to a viral infection or medication, for example).

TH-PO1109

Lymphoma Associated Monoclonal Cryoglobulinemia in a Patient with Hepatitis C Sangeeta Mutnuri,[1] Marjan Afrouzian,[2] Hania Kassem.[1] *[1]Dept of Nephrology, UTMB, Galveston, TX; [2]Dept of Pathology, UTMB, Galveston, TX.*

Introduction: We present a case of type I cryoglobulinemia and membranoproliferative glomerulonephritis (MPGN) in a patient with hepatitis C infection (HCV), leading to the diagnosis of a marginal zone lymphoma.

Case Description: A 47 year old male with HCV and hypertension presented with two month duration of shortness of breath and decreased urine output. On examination he was hypertensive (blood pressure: 183/111 mm of Hg), had lung crackles, lower extremity edema and hepatosplenomegaly. Laboratory tests were significant for pancytopenia, hypoalbuminemia and an elevated creatinine of 2.8mg/dl (0.8mg/dl four months ago). Urine exam revealed red blood cell (RBC) casts, dysmorphic RBC's and nephrotic range proteinuria (9.5 gm). Immunochemistry revealed elevated rheumatoid factor, hypocomplementemia and cryoglobulinemia. These findings led to a suspicion of HCV induced cryoglobulinemic glomerulonephritis. Kidney biopsy was performed revealing MPGN type III with deposits. Fluorescence microscopy favored Kappa monoclonality. Electron microscopy of the deposits was consistent with cryoglobulins. Serum immunoelectrophoresis also confirmed IgM/Kappa monoclonality. As HCV is more commonly associated with polyclonal cryoglobulinemia this finding of monoclonality prompted a search for malignancy. A bone marrow biopsy showed lymphoid aggregates indicating marrow involvement by marginal zone lymphoma. The patient was initiated on rituximab/dexamethosone based regimen. The creatinine trended down to 1.87 mg/dl.



Discussion: Monoclonal cryoglobulinemia is related to lymphoproliferative diseases whereas HCV is associated with polyclonal cryoglobulinemia. This case stresses the importance of differentiating between the two entities especially in patients with co existing disorders. Making this crucial distinction helps predict the underlying etiology and treatment.

TH-PO1110

A Lupus Nephritis Patient Accompanied with Storiform Fibrosis Characteristic in IgG4-Related Kidney Disease in the Absence of Serum IgG4 Elevation and IgG4-Positive Plasma Cell Infiltration Mamiko Imada, Naoki Takahashi, Daisuke Mikami, Seiji Yokoi, Kenji Kasuno, Hideki Kimura, Masayuki Iwano. *Div of Nephrology, Univ of Fukui, Fukui, Japan.*

Introduction: IgG4-related kidney disease (IgG4-RKD) usually presents as tubulointerstitial nephritis with IgG4-postive plasma cell (PC) infiltration and serum IgG4 elevation. IgG4-RKD has characteristic histological findings called storiform fibrosis and radiological findings showing multiple low-density lesions on contrast-enhanced CT scan. Recently, Hara et al. reported a case of IgG4-negative IgG4-RD (Mod Reumatol, 2014) which had a condition closely mimicking IgG4-RD despite the absence of serum IgG4 elevation and IgG4-positive PC infiltration. Here we report a patient diagnosed with lupus nephritis (LN) with IgG4-negative IgG4-RD.

Case Description: A 59-year-old Japanese man was referred to our hospital with chest pain and mild proteinuria. Thoracic biopsy was performed for abnormal lung shadow and interstitial pneumonia was diagnosed. Although ANA titer was elevated to 2560-fold, anti-DNA, anti-Sm, and anti-SS-A/-B antibodies were all negative. Serum C3 and C4 levels and complement activity were decreased. Serum IgG and IgE levels were elevated, but serum IgG4 level was within normal limits. On contrast-enhanced CT, multiple low-density lesions were observed in kidney. Renal biopsy findings revealed lymphoplasmacytic infiltration with storiform fibrosis and small numbers of eosinophils. Immunostainings revealed CD138- or IgG-positive PC infiltration without IgG4-positive PC. Immunofluorescence microscopy showed granular mesangial positivity for a "full-house" pattern. Electron microscopy disclosed mesangial and subendothelial dense deposition accompanied with virus-like particles. We diagnosed this patient with IgG4-negative IgG4-RD and LN (ISN/RPS II). After administration of 20 mg prednisolone, laboratory data was drastically improved.

Discussion: To our knowledge, this is the first report of a patient with LN and IgG4-negative IgG4-RD. IgG4-negative IgG4-RD may be a chronic burnout phase of IgG4-RD. Further studies gathering similar cases would be needed to clarify whether or not IgG4-negative IgG4-RD is included in a category of IgG4-RD.

TH-PO1111

A Case of Acute Phosphate Nephropathy in a Kidney Transplant Recipient Hetal Shah, M. Lee Sanders, Kelly A. Birdwell, Anthony J. Langone, Paisit Paueksakon, Beatrice P. Concepcion. *Vanderbilt Univ Medical Center, Nashville, TN.*

Introduction: Acute phosphate nephropathy has been described after large doses of phosphate, typically in laxatives and bowel cleansing preparations. We present a case of acute phosphate nephropathy in a kidney transplant recipient who was taking oral phosphorus supplementation for hypophosphatemia.

Case Description: A 26 year-old man with a living related donor kidney transplant in 2011 complicated by recurrent IgA nephropathy with a baseline creatinine of 1.9 mg/dL presented with nausea, vomiting, diarrhea, fatigue and elevated creatinine. Two weeks prior to presentation, he had been started on K-Phos-Neutral 500 mg three times a day for a phosphorus of 1.6 mg/dL. Intact parathyroid hormone (iPTH) was 58 pg/mL. He soon after developed diarrhea and ten days later developed nausea and vomiting. He was found to have a creatinine of 10.4 mg/dL, phosphorus 9.7 mg/dL, calcium 9.6 mg/dL and iPTH 761 pg/mL. Urinalysis had a urine pH of 5, no red blood cells and trace protein. Renal biopsy was performed, and pathology revealed 30 foci of intratubular calcium phosphate crystals with associated acute tubular injury involving 30-40% of tubular profiles, along with known recurrence of IgA nephropathy. The patient underwent acute hemodialysis for oliguric acute kidney injury. Given the high serum phosphorus, he was dialyzed for four consecutive days until phosphorus level was less than 4 mg/dL and did not rebound. Patient was discharged requiring intermittent hemodialysis for an additional three weeks until he demonstrated renal recovery. His new baseline creatinine is 2.2 mg/dL and he has remained off hemodialysis.

Discussion: Hypophosphatemia is common in kidney transplant recipients. Although rare, acute phosphate nephropathy can occur in the setting of phosphorus repletion. This patient also had multiple risk factors, including baseline renal dysfunction, volume depletion and angiotensin receptor blocker use. Acute phosphate nephropathy can potentially lead to irreversible loss of renal function. While no specific treatment exists, in this case, aggressive hemodialysis to decrease serum phosphorus may have played a role in this patient's eventual renal recovery.

TH-PO1112

Unusual Membranous Nephropathy in a Patient with Lupus Iheanyichukwu Ogu, Julia Lewis, Agnes B. Fogo. *Nephrology, Vanderbilt Univ Medical Center, Nashville, TN.*

Introduction: Membranous nephropathy (MN) is an immunologically mediated glomerular disease. Distinguishing between primary and secondary MN is important in guiding diagnosis and treatment. We present a case of a patient with systemic lupus with pathologic features in a repeat biopsy suggestive of primary MN.

Case Description: A 32 year old African American woman presented in 1998 with nephrotic range proteinuria (8g), edema and serum creatinine 0.6. She had negative work up for secondary causes including lupus. Renal biopsy showed mild matrix expansion, diffuse global basement membrane (GBM) spikes, preserved tubulointerstitial compartment; fine granular IgG(3+), C3(1+) IgM(trace), C1q(trace), IgA(negative) capillary loop staining with focal mesangial IgM and C1q staining; numerous subepithelial deposits, 90% foot process effacement, and unremarkable endothelial cells. She was started on an angiotensin receptor blocker but was lost to follow up. In 2011 she was diagnosed with Lupus and in July 2014, had proteinuria (1.9g). Repeat renal biopsy showed persistent MN with features concerning for lupus, with reticular aggregates, mildly increased mesangial matrix and cellularity, and 20% interstitial fibrosis. After referral to our clinic, additional testing on the 1998 biopsy (fig 1,2) showed diffuse global capillary wall Ig G1(1-2+), IgG2(2+), IgG3(negative), IgG4(3+), PLA2R(negative); and the 2014 biopsy (figs 3,4) showed diffuse global granular capillary wall IgG1(2+), IgG2(1-2+), IgG3(negative), IgG4(3+) and PLA2R near global(1-2+) granular capillary loop staining.

Discussion: The PLA2R staining and the dominance of IgG4 currently are consistent with primary MN. The negative PLA2R in 1998 may indicate early disease or epitope change. The mesangial deposits are nonspecific and could possibly represent a low grade lupus-related nephropathy. The presence of reticular aggregates is a marker of high interferon levels in patients with lupus, and does not necessarily mean lupus nephritis.

TH-PO1113

A Case of Proliferative Glomerulonephritis with Monoclonal IgG Deposits Exhibiting Marked Nephrotic Syndrome Who Responded Well to the Renin-Angiotensin System Blockade Alone Yoshihiko Nishiguchi, Hideki Inoue, Tomoaki Onoue, Yutaka Kakizoe, Yuichiro Izumi, Takashige Kuwabara, Taku Miyoshi, Masataka Adachi, Yushi Nakayama, Masashi Mukoyama. *Nephrology, Kumamoto Univ Hospital, Kumamoto, Japan.*

Introduction: Proliferative glomerulonephritis with monoclonal IgG deposits (PGNMID) is a newly recognized entity of glomerulonephritis caused by glomerular deposition of monoclonal IgG. The clinical and pathological features, treatment and prognosis of this entity remain elusive.

Case Description: A 79-year-old woman was admitted to our hospital due to hematuria and marked nephrotic-range proteinuria. Her serum creatinine level was 0.75 mg/dL and urinary protein excretion was 20.8g/g creatinine. Renal biopsy showed a membranoproliferative feature without nodular formation. Immunofluorescence study showed capillary and mesangial deposits of IgG, C1q and C3. Moreover, IgG-kappa deposits were strongly stained and IgG3 deposits were restrictedly stained for IgG heavy-chain subclass analysis. Electron microscopy revealed amorphous electron-dense mesangial and subendothelial deposits. Monoclonal proteins were not detected in serum or urine samples. Serum cryoglobulin titer was negative. Serum free light-chain assay showed a normal kappa/lambda ratio.These findings were consistent with the diagnostic criteria for PGNMID. Considering her age and tolerability, we started monotherapy with angiotensin II receptor blocker. This case showed drastic reduction in proteinuria with stable renal function within several months after the treatment with the renin-angiotensin system (RAS) blockade alone.

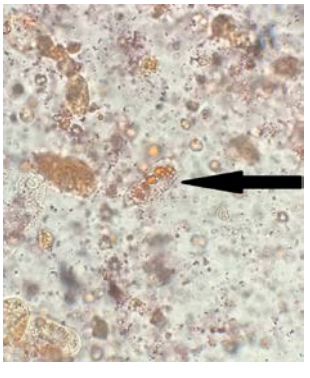
Discussion: We report here an exceptional case of PGNMID associated with the membranoproliferative feature successfully treated with RAS blockade alone, without steroid or other immunosuppressive agents. Further studies are needed to clarify clinical spectrum and prognosis of this newly described disease entity.

TH-PO1114

Brentuximab Induced Renal Steatosis – The Hint Is in the Urine Akhil Hegde, Ronald J. Falk, Abhijit V. Kshirsagar. *UNC Kidney Center, Univ of North Carolina at Chapel Hill, Chapel Hill, NC.*

Introduction: We describe the onset of acute kidney injury (AKI), lipiduria and multi-organ steatosis after the use of Brentuximab, a monoclonal antibody targeting CD30, in patients with recurrent Hodgkin Lymphoma (HL).

Case Description: A 61 year old female with recurrent HL, treated with Brentuximab 180mg (4 and 2 weeks prior to admission), was admitted with a 1-month history of nausea and vomiting. She was found to have AKI, creatinine 1.7 - baseline 0.9 mg/dl, elevated liver enzymes (AST 324, ALT 282 U/L), a urine protein/creatinine ratio of 1.0g with a total cholesterol and HDL of 152 and 32 mg/dl. Urine microscopy revealed numerous free fatty droplets and fatty casts that did not have a maltese cross appearance under polarizing light. Sudan black dye demonstrated positive staining indicating non-cholesterol fat in the urine.



PET/CT imaging did not show malignancy, but revealed severe fatty infiltration of multiple organs not present 4 months earlier. The patient's clinical course worsened and the patient died on hospital day #6. An autopsy revealed hepatomegaly with severe steatosis, fatty infiltration of the pancreas and proximal renal tubular epithelial cell macro/microvesicular steatosis with intra-glomerular lipiduria.

Discussion: The development of AKI, lipiduria, transaminitis and multi-organ steatosis after 2 doses of Brentuximab is concerning for a drug-induced injury. Sudan dye attaches to neutral lipids and is helpful in distinguishing the 2 categories of lipids. Only 2 weeks after the last dose of Brentuximab, the patient was found to have new fatty infiltration and a subsequent autopsy revealed intra-glomerular lipidosis. The first hint to systemic steatosis was the presence oval fat bodies in the urine. Typically, charged lipids have the appearance of a maltese cross under polarizing light, while neutral lipids do not refract polarized light in this manner.

TH-PO1115

Pheochromocytoma: An Unusual Cause of Thrombotic Microangiopathy Induced Acute Kidney Injury in Pregnancy – Wolf in Sheep's Clothing Venkat Sainaresh Vellanki,[1,2] Sachin V. Kodgire,[2] Anila Abraham.[3] *[1]Nephrology, Manipal Superspecialty Hospital, Visakhapatnam, Andhra Pradesh, India; [2]Nephrology, Univ of Toronto, Toronto, ON, Canada; [3]Renal Pathology, Center for Renal and Urological Pathology, Chennai, Tamil Nadu, India.*

Introduction: Hypertensive disorders during pregnancy result in substantial maternal and fetal morbidity. Pheochromocytoma in pregnancy is extremely rare with a reported frequency of 0.002% and 50% maternal and fetal mortality.

Case Description: 25 year old female, 26 weeks of gestation with gestational diabetes presented with antenatal hemorrhage, confusion and uncontrolled hypertension with BP190/124mmHg. Investigations revealed hemoglobin 9 gm/dl, platelets 76000/microliter, serum creatinine 2.4 mg/dl, LDH 245U/L, AST 30U/l, ALT 39U/L, urine dipstick protein 1+. Ultrasound confirmed abruptio placenta and intrauterine death of fetus needing emergency surgical evacuation. She developed intraoperative hypotension needing multiple blood transfusions and ventilatory support. Her renal function worsened needing initiation of hemodialysis. Septic and hemolytic work up were negative. She had paroxysmal episodes of uncontrolled hypertension and flash pulmonary edema needing frequent rescue hemodialysis and parenteral antihypertensives. Renal doppler was negative for renal artery stenosis. CAT scan showed left adrenal mass. Plasma normetanephrine was elevated at 1223 pg/ml suggestive of pheochromoctoma. BP was stabilized with four drugs and surgical resection of the tumor was done. A wedge kidney biopsy showed thrombotic microangiopathy (TMA). The tumor histopathology confirmed pheochromocytoma, positive for chromogranin and synaptophysin staining. Post operative, her creatinine stabilized at 1.6mg/dl, BP and glycemic status returned to normal.

Discussion: Discussion: Pheochromocytoma in pregnancy is an extreme rarity with a frequency of 0.002%. It is often mistaken for other hypertensive disorders of pregnancy. This is the first case report of a patient with acute kidney injury in pregnancy from TMA secondary to pheochromocytoma. Patient made good renal recovery after resection of the tumor.

TH-PO1116

Immune Reconstitution Inflammatory Syndrome and Hypercalcemia with Acute Kidney Injury following Stribild Therapy Christine A. Garcia, Kelly H. Beers, Catherine Miranda, Kamran Karimi, Yezina T Nigatu, Nand K. Wadhwa. *Nephrology/Medicine, Stony Brook Medicine, Stony Brook, NY.*

Introduction: Immune reconstitution inflammatory syndrome (IRIS) is an inflammatory disorder with paradoxical worsening of preexisting infectious processes following HAART in HIV-infected individuals. We describe a case of IRIS following Stribild (elvitegravir, cobicistat, emtricitabine, tenofovir) resulting in hypercalcemia.

Case Description: A 33 year-old woman with acquired immunodeficiency syndrome (AIDS) who had been on Stribild for two months presented to the ED with acute kidney injury with a serum creatinine of 2.93 mg/dL and Ca of 15.2 mg/dL. Her CD4 count was 145 /uL and viral load 35 copies/mL. Four months prior, she was treated with amphotericin for cryptococcal lung infection and Cryptococcemia. One month prior, a right lower lobe mass histology had revealed necrotic tissue with inflammatory cells. On examination, she was alert, in no acute distress, with unremarkable physical examination. Her temperature was 36.7 degrees Celsius, heart rate 72/minute, BP 108/64 mm Hg, respiratory rate 16/minute, and oxygen saturation 100% on room air. Chest X-ray showed an interval decrease in the right lower lobe mass. Serum intact PTH was 9.7 pg/mL. PTHr peptide, SPEP and UPEP were negative. Serum 25 (OH) D was 37 ng/mL, 1,25 $(OH)_2$ D3 was 17 pg/mL, and 24 hour urine Ca was 270 mg. Urine fractional excretion phosphorus was 28% with no glucosuria. She was diagnosed with IRIS and Stribild was discontinued. She was treated with IV fluids and calcitonin with an improvement in her renal function and normalization of her serum calcium over a period of 4 weeks. Lab data summarized.

	Serum Creatinine mg/dL	Serum Ca mg/dL	CD4 /uL	HIV viral load copies/mL
Base level	0.70	9.0	40	119,698
2 weeks on Stribild	1.45	11.8	122	220
8 weeks on Stribild	2.93	15.2	145	35
6 weeks off Stribild	1.00	9.4	93	178,362

Discussion: IRIS is thought to be due to increased T-lymphocyte proliferation after HAART in AIDS patients. IRIS typically manifests as a granulomatous inflammation. Corticosteroids are treatment of choice in IRIS in the setting of excess 1,25 $(OH)_2$ D3. In our case, serum 1,25 $(OH)_2$ D3 was low suggesting possible other mechanisms.

TH-PO1117

IgA-Dominant Postinfectious Glomerulonephritis: A Case Series

Pranjal Sharma,[1] Anitha Vijayan,[2] Tingting Li.[2] *[1]Dept of Internal Medicine, Renal Div, Washington Univ in St. Louis, St. Louis, MO; [2]Dept of Internal Medicine, Renal Div, Washington Univ in St. Louis, St. Louis, MO; [3]Dept of Internal Medicine, Renal Div, Washington Univ in St. Louis, St. Louis, MO.*

Introduction: IgA dominant post-infectious glomerulonephritis (PIGN) is a distinct clinico-pathologic entity that typically occurs in diabetic patients and in association with a recent or active staphylococcal infection**.** Patients usually present with hematuria, proteinuria, and AKI. Renal pathology shows an immune-complex GN with varying light microscopic patterns and IgA-dominance or co-dominance with IgG on immunofluorescence. Here we report the clinical characteristics and outcomes of 10 patients with IgA dominant PIGN.

Case Description: After obtaining approval from the local IRB, retrospective, single-center review of data was performed and 10 patients with IgA dominant PIGN were identified.

Majority was white males, and 6/10 were diabetic. Eight patients had a Staphylococcal infection and one had active Hep C infection. Only 3/10 had low complements. 6/10 required RRT and 4 developed ESRD, of which 2 died at 2 and 5 months after initiation of RRT. Five were left with varying degree of CKD and one was lost to follow up. Three patients were treated with immunosuppression in addition to antibiotics-all had significant improvement in renal function; one patient who was initially RRT-dependent was able to come off dialysis.

Patient	Infection	C3/C4	Hema-turia	Protein-uria/ d	Peak SCr	RRT	Follow Up
1	Hep C	N/N	Y	7.5	1.6	No	CKD
2	MSSA	L/L	Y	0.6	6.9	Y	CKD
3	MRSA/Pseu-domonas	N/N	Y	1.16	3.9	No	NA
4	MRSA	N/N	Y	6.5	5	Y	Died
5	MRSA	N/N	Y	3.7	10.9	Y	CKD
6	MSSA	L/L	Y	1.2	7.5	Y	ESRD
7	MRSA/VRE	N/N	Y	4.1	7	Y	ESRD
8	MSSA	N/N	Y	NA	6.5	Y	Died
9	MRSA	N/N	Y	NA	3.9	No	CKD
10	Clostridium subterminalis	N/L	Y	2.8	5.2	No	CKD

N=Normal;L=Low;Y=Yes

Table 1. Clinical features and outcomes of pts with IgA-dominant PIGN

Discussion: IgA-dominant PIGN is an increasingly recognized disorder that occurs most commonly in diabetic patients with Staphylococcal infections. Overall renal prognosis is poor. Treatment with immunosuppression in addition to antibiotics may be considered.

TH-PO1118

Hematuria in a Young Female: This Was a Hard Nut to Crack

Manish K. Saha, Gaurav Jain. *Nephrology, Univ of Alabama, Birmingham.*

Introduction: Flank pain with hematuria usually indicates urolithiasis but in its absence, renal vascular abnormalities should be considered.

Case Description: A 27-year old female with history of sickle cell trait, was admitted for gross hematuria. She had flank pain at the end of her urine stream but denied associated fever, chills or dysuria. She was treated with ciprofloxacin for presumed UTI but due to weakness she presented to our hospital. Her vital signs were stable and had a normal physical exam. Her hemoglobin was 5 gm/dl, creatinine at 0.6 mg/dl and urinalysis was evident for 3 plus proteinuria with >25 RBC/hpf and >50WBC /hpf. Her total protein to creatinine ratio was 2 and had a negative urine culture. She had normal complement, ANA screen and negative serology work up for autoimmune disease. Renal ultrasound (US) showed 10 cm (right) X 9.5 cm (left) kidneys. Her non-contrast CT abdomen and cystoscopy was non-diagnostic. To further evaluate her hematuria she underwent renal US with Doppler which showed narrowing of the left renal vein at the level of the superior mesenteric artery (SMA) with a peak velocity gradient greater than 10:1, consistent with left renal vein(LRV) stenosis or "nutcracker" syndrome (NCS). She subsequently underwent exploratory laparotomy with evidence of aortic and SMA scissoring compression of renal vein at its confluence with inferior vena cava (IVC). The IVC and left renal vein were mobilized and the compression was relieved. Patient continued to have hematuria with persistent proteinuria for few months postoperatively but eventually had resolution of both hematuria and resolution of proteinuria and hematuria.

Discussion: NCS refers to compression of left renal vein by abdominal aorta and SMA in fork-like fashion resulting in renal and pelvic venous congestion. The usual manifestations are microscopic to gross hematuria, pelvic or flank pain and orthostatic proteinuria .Hematuria results from the rupture of thin blood vessels into the collecting system due to elevated renal venous pressure. Symptomatic patients usually need surgical repair, LRV transposition and renal auto-transplantation in rare cases. NCS is an important differential in patient with hematuria-proteinuria and flank pain in young patients.

TH-PO1119

ANCA Negative Pauci-Immune Necrotizing Crescentic Glomerulonephritis in a Patient with Non Hepatitis C Mixed Essential Cryoglobulinemia

Victor Nwazue,[2] Ji ae Yoon,[1] Balhinder S. Brar.[3] *[1]Medicine, Mercy St Vincent Medical Center, Toledo, OH; [2]Nephrology, Univ of Toledo, Toledo, OH; [3]Nephrology, Mercy St. Vincent Medical Center, Toledo, OH.*

Introduction: Mixed essential cryoglobulinemia (MC) is associated with a hepatitis C infection in 70-90% of patients and presents as membranoproliferative glomerulonephritis or rapidly progressive glomerulonephritis (RPGN) with or without crescents. We report an unusual presentation of type II MC without hepatitis C infection presenting as ANCA negative pauci-immune necrotizing and crescentic glomerulonephritis (CrGN).

Case Description: A 64 year old male presented with AKI (creatinine of 5.4 from a baseline of 0.8 mg/dl, 2 weeks earlier), 12-18 month history of arthralgias, fatigue, joint pains, petechial and purpuric spots on his extremities. His symptoms were exacerbated in the winter months. Lab tests revealed elevated cryoglobulin level (338mg/dL), low C4 (5 mg/dl), positive rheumatoid factor, IgG monoclonal gammopathy (0.37g/dl). MPO ANCA, PR3 ANCA, ANA, hepatitis B and C and HIV serologies were negative. Urinalysis showed 20-50 RBCs, no casts and proteinuria of 2.5 g. Bone marrow biopsy showed < 5% plasma cells and no T cell aberrancy or B cell monoclonality. A kidney biopsy revealed pauci-immune necrotizing CrGN. Electron microscopy (EM) showed no deposits or fibrillar or tubular structures in the glomeruli. The patient was treated with hemodialysis (HD), 5 sessions of plasmaphresis and oral cyclophosphamide for 3 months. He responded to treatment with near complete resolutions of his symptoms and near normalization of kidney function.

Discussion: Pauci-immune CrGN is associated with either microscopic polyangitis or granulomatosis with polyangitis. These can present as RPGN and have either a positive MPO or PR3 ANCA but have no deposits on immunofluorescence and EM. CrGN in patients with MC is an immune complex disease, has distinct immune deposits in glomerular capillaries and fibrillar and tubular structures on EM. Our case was an unusual combination of 2 different pathologically and pathogenically distinct disease entities. To our knowledge this is the first reported case with these unusual manifestations.

TH-PO1120

Fibrillary Glomerulonephritis Presenting as Rapidly Progressive Crescentic Glomerulonephritis

Pallavi D. Shirsat,[1,2] Chyi Chyi Chong,[1,2] Ramesh Marahatta,[1,2] Cherinet S. Adgeh,[1,2] Neville R. Dossabhoy.[1,2] *[1]Dept of Nephrology, Veterans Affairs Medical Center, Shreveport, LA; [2]Dept of Nephrology, LSU School of Medicine, Shreveport, LA.*

Introduction: Fibrillary glomerulonephritis is a rare disease of unclear etiology, known to be associated with malignancy, autoimmune disorders, lymphoplasmacytic disorders and hepatitis C. It is seen in 0.5 to 1.0% of native kidney biopsies.

Case Description: We report a case of a 62 year old Caucasian male veteran who had a past medical history of hepatitis C, hyperlipidemia, s/p coronary bypass, multiple colon polyps s/p colectomy and CKD stage 3. Patient, on a routine follow up appointment, was noted to have rapid worsening of kidney function, with creatinine increase from baseline of 1.4-1.8 up to 3.2 mg/dL. He was also noted to have 24 RBCs per HPF on urine microscopy. Urine protein:creatinine ratio was 4.5. Hepatitis C related membranous glomerulonephritis (GN) was high on the differential list. Hepatitis B and HIV serologies were negative. Complements, cryoglobulins, ANCA and serum protein electrophoresis were within normal limits. Patient underwent kidney biopsy, which showed crescentic GN, with linear pattern immunoglobulin deposition along the GBM (glomerular basement membrane) on light microscopy and immunofluorescence suggestive of anti-GBM disease. However, patient's anti-GBM titer was negative! Electron microscopy showed thickening of GBM due to fibrillary deposits. Similar fibrillary deposits were also seen in the mesangium, with haphazard distribution of fibrils measuring about 15 nm, consistent with fibrillary GN . Congo red stain for amyloid was negative. Patient was also found to have a 2.8 x 2.5 cm well-circumscribed solid & cystic mass in right kidney on ultrasound, suspicious for renal cell carcinoma (RCC). A fine needle aspiration of the mass yielded cells consistent with RCC.

Discussion: Fibrillary GN is known to be associated with malignancy. It can rarely present clinically as rapidly progressive, crescentic GN, and masquerade as anti-GBM disease on immunofluorescence. Electron microscopy and serologic workup are needed to clinch the definitive diagnosis.

TH-PO1121

Pauci-Immune Necrotizing Crescentic Glomerulonephritis as the First Manifestation of Chronic Lymphocytic Leukemia Relapse

J. Saadi Imam,[1] Monia E. Werlang,[1] Tatiana A. Thom,[2] Nabeel Aslam.[2] *[1]Dept of Medicine, Divison of Internal Medicine, Mayo Clinic, Jacksonville, FL; [2]Dept of Medicine, Div of Nephrology, Mayo Clinic, Jacksonville, FL.*

Introduction: The association between hematological malignancy and auto-immune disease is a well-documented phenomenon. Chronic lymphocytic leukemia (CLL) patients have 5-10% risk of developing autoimmune cytopenias, and a rare subset of these CLL patients express anti-neutrophil cytoplasmic antibodies (ANCA) in the setting of a vasculitis. Here, we present a case of a patient with treated CLL whose relapse was identified by the new diagnosis of ANCA-associated pauci-immune glomerulonephritis.

Case Description: A 73-year-old female with history of CLL, status post chemotherapy five years prior, presented with complaints of dyspnea on exertion, fatigue, oral ulcers, hemoptysis, rash, arthralgias, edema, and tea-colored urine for 3 months duration. Exam showed BP 157/94, bibasilar rales and gingival ulcers. Labs showed Hb 5.4g/dL, platelets 113K, WBC 4.6K, S. creatinine 4.4mg/dL. Urinalysis showed 2+ protein, many RBCs and WBCs with granular casts. ANA, anti-PR3 and MPO were strongly positive. Kidney biopsy showed necrotizing crescentic pauci-immune glomerulonephritis in more than 50% of glomeruli. Taking into consideration the patient's prior history of CLL, bone marrow biopsy was performed and showed scattered nodular lymphoid proliferation with flow cytometry confirming relapse of CLL. Given this finding, our patient was treated on the lines of CLL relapse with steroids and rituximab instead of using steroids, cyclophosphamide and plasmapheresis for the treatment of ANCA-associated vasculitis alone.

Discussion: The prevalence of ANCA positivity in CLL patients has been documented to be <2%. In our patient, ANCA-associated pauci-immune glomerulonephritis was the first manifestation of CLL relapse. Discovering CLL relapse mandated a change in the management from the standard treatment of pauci-immune glomerulonephritis to a regimen more appropriate for both conditions. Clinicians should be aware of this rare association of CLL with ANCA-associated vasculitis to choose the most appropriate treatment regimen for these patients.

TH-PO1122

Multiple Recurrences of Anti-GBM Disease: Diagnosis or Treatment Risk Lamya Boujelbane, Patricia Liu, Sana Waheed, Laura J. Maursetter. *Div of Nephrology, Univ of Wisconsin School of Medicine and Public Health, Madison, WI.*

Introduction: Anti-GBM disease is commonly a monophasic illness. We present a case of a woman who had two recurrences of anti-GBM disease after her initial diagnosis in 2001.

Case Description: 33-year-old woman with history of tobacco use was diagnosed with anti-GBM disease after presenting with hematuria. A renal biopsy showed crescentic glomerulonephritis with linear IF staining for IgG. Serum anti-GBM and anti neutrophilic cytoplasmic antibodies (ANCA) levels were undetectable at diagnosis. Five years later, she presented with dyspnea and hemoptysis. She had a hemoglobin of 8.5 g/dL and a chest x-ray suggestive of diffuse alveolar hemorrhage. Her anti-GBM antibody level was 122 AU/ml. She was treated as a relapse of anti-GBM disease and, her anti-GBM antibody had decreased to 0 AU/ml and she had no hematuria. Now at 47 years of age, she presented with dyspnea. Her chest x-ray demonstrated bilateral perihilar opacities consistent with diffuse alveolar hemorrhage and urinalysis revealed 1+ hemoglobin. Anti-GBM antibody was not detected but she was treated for a presumed anti-GBM disease recurrence. With each recurrence of anti-GBM disease, her symptoms resolved with 7 sessions of plasmapheresis, 3 days of IV methylprednisone and 6 months of oral cyclophosphamide 2mg/kg/day. Her creatinine remains low at 0.7 mg/dl but she suffered a complication of osteonecrosis of the knee.

Discussion: Relapses are infrequent in anti-GBM disease but have been reported. Our case is unique because the patient had three episodes of presumed anti-GBM disease. Smoking has been linked to recurrent disease and could have been the trigger in this case. It is interesting that our patient had varying presence of circulating anti-GBM antibodies with each recurrence which poses the question of the accuracy of the diagnosis. One possible explanation is that only local antibodies were reactivated by smoke exposure without a systemic antibody production and we may be missing low level recurrences. An important question is whether the risk of exposure to immunosuppression is higher than the risk of repeat biopsy to confirm diagnosis to avoid treatment related complications.

TH-PO1123

Nephrotic Syndrome, Nodular Glomerulosclerosis and Impaired Glucose Tolerance (IGT) – A Case Report Daniel Taiwo Adeneye, Mary C. Mallappallil, Gary R. Briefel. *Nephrology, Down State Medical Center, Brooklyn, NY.*

Introduction: Diabetic nodular glomerulosclerosis is a recognized complication of overt diabetes but is hardly diagnosed in patients with IGT. Diabetic nephropathy(DN) without overt hyperglycemia vindicates other etiological factors. Pathogenesis of DN is poorly understood but the trigger is still hyperglycemia. Advanced DN without overt diabetes is rare and 3 case reports have been published.This is a 48 yr old AA woman who presented with nephrotic syndrome, renal failure, IGT and renal biopsy with nodular glomerulosclerosis.

Case Description: 48 yr old AA woman referred for elevated creatinine and proteinuria. No gestational diabetes,tobacco,etoh and drug use history. BP -164/77mmgh, Pulse 70/min with pedal edema. BMI-28; fundoscopy not done. Urine protein 3+ and normal sediments, no cast. UPCR- 6G/G. (FPG)-118mg/Dl;Bun - 42mg/Dl, Creatinine 3.9mg/dl, Albumin 2.4mg/Dl, Total protein- 4.6g/dl, Cholesterol- 278mg/dl, LDL 191mg/Dl. Hepatitis B, C, HIV, ANA, C3,C4, SSA, ANCA, Cryoglobulin, Spep/Upep- negative.USS; kidneys 13/12cm,increased echogenicity. biopsy-glomeruli; 25% globally sclerosed, moderate interstitial fibrosis and tubular atrophy. I/F :negative staining for Igm,igg,iga,lamda,kappa, albumin,c3 and C1q. E/M ;no deposits in glomerular capillary walls or mesangium. GBM;diffuse thickening,focal podocytes effacement and nodular mesangial matrix.

Discussion: Nodular glomerulosclerosis is usually seen in advanced DN with overt diabetes after 15yrs in Type I and variable in Type 2. Our patient did not have a prior diagnosis of diabetes. A causal relationship can be established between IGT and DN;nodular glomerulosclerosis found on renal biopsy is usually seen in overt diabetes of long duration. Animal studies have shown that brief postprandial elevation of glucose may trigger renal injury viaTGFb that results in DN. The CKD was advanced and biopsy was undertaken at her insistence even after she was told;it may not impact outcome or treatment.

This was an unexpected learning case that shows that the occurrence of diabetic nephropathy may correlate more with presence and not the intensity or duration of hyperglycemia. Further studies are needed to elucidate this phenomenon.

TH-PO1124

A Case of Catastrophic Antiphospholipid Syndrome Treated with Plasma Exchange Takeyuki Takamura, Fumihiko Furuya, Tetsuharu Oku, Kenichiro Kitamura. *Third Dept of Internal Medicine, Univ of Yamanashi.*

Introduction: Catastrophic antiphospholipid syndrome (CAPS) is characterized by diffuse vascular thrombosis, leading to multiple organ failure within a few days and resulting to poor prognosis. Antiphospholipid syndrome (APS) is an autoimmune thrombotic syndrome with recurrent thrombosis and occurs in both artery and vein, and from large to micro vessels. CAPS is also defined as a fetal variant of APS and develop thrombosis of three different organ systems with histopathologic evidence of multiple small vessel occlusions and high titers of antiphospholipid antibodies. Treatment for CAPS has not been established, and intensive anticoagulation or immunosuppressive therapy is carried out.

Case Description: A 68-year-old female who had been diagnosed as lupus erythematous and APS complicated with multiple cerebral infarctions and treated with 5 mg of oral predonisolone. After her admission, she developed de novo cerebral infarction and colonic perforation with ischemic enteritis. Following a partial colectomy, she developed gram-negative bacteremia, subsequently, multiple strokes, non-ST elevation myocardial infarction, renal failure, and pathological findings with multiple thrombi. These clinical findings indicated that patient's features were consistent with CAPS. She was maintained with anti-bacterial agent, anticoagulant, and predonisolone. However, since renal failure and anuria had continued, she was treated with plasma exchange (PE) and hemodialysis. Thereafter the volume of urine output was gradually increased and her renal function was recovered.

Discussion: We report a case of CAPS with multiple organ failure and successfully treated with anticoagulant, predonisolone, and PE. The clinical manifestation of CAPS depends on the release of inflammatory cytokines from the affected organs by thrombosis and small vessel occlusion. Our patient's successful course could be attributed to beneficial role of PE through the removal of excessive inflammatory cytokines.

TH-PO1125

Acute HIVAN in a HIV-Naïve Patient During Primary HIV Infection and High Viral Load Amit N. Shah, Adam G. Winkler, Claude Bassil, Donald E. Wheeler, Jacques A. Durr. *Div of Nephrology, Univ of South Florida, Tampa, FL.*

Introduction: A hitherto healthy 42 yo AA male felt chilly 6 days earlier. He took a NyQuil and skipped next day's shift for body aches/GI cramps. He improved but again felt bad by HS, 48h later. Next AM in a local ER, his UA showed WBC/RBC, 3+ protein, and a SG of 1.030. Physical exam, chest X-ray, contrast abdominal CT, and eGFR, were normal. He improved and worked full capacity again, but got admitted 48h later after a brief syncope.

Case Description: Vital signs: T 103 °F, BP 100/60 mm Hg, and HR 76 bpm. He had transient mild diarrhea. Serum albumin (Alb) was 2.1 g/dl, creatinine (cr) 2 mg/dl, and WBC 3•103/ml. UA had WBC/RBC and >0.5 g/dl protein. UNa was 21 mmol/l. His urine protein was >12 g/24h. CRP was >2 (<0.5 ng/dl), and ESR 50 mm/h. CPK was 8717 U/l and < half by 48h. Hep B, C, and HIV-1/-2 Ab screens were (-), but (+) for HIV p24 Ag. He had >3•106 HIV copies/ml, and 213 CD4+ cells/ml. US showed normal-sized kidneys, no obstruction, but some cortical echogenicity.

His cr first improved for 72h, but then rose to >8 mg/dl in 1w. Dialysis and HAART were initiated. By then he had edema and Alb was

1.2 g/dl. Renal biopsy showed collapsing GN, podocyte hypertrophy/hyperplasia, microcystic tubular dilatations, 3+ acute tubular injury, 2+ patchy (mostly lymphocytic) infiltrate with focal tubulitis, and no signs of chronicity. Prednisone was added. He seroconverted (HIV-1) 2w after his first chills.

Discussion: Of the case reports of primary renal HIV infection only 2 had biopsy-proven HIVAN. One was HIV Ab (-) but had 700,000 HIV copies/ml (Levin ML et al. 2001); the other was HIV Ab (+) by EIA but not by Western blot, and had 70,000 HIV copies/ml (Szabo S et al. 2002). Both had advanced RF and already other infections. Our patient had normal eGFR until his acute HIV infection. The high HIV Ag load alone, not replication, is the sole likely cause for HIVAN, consistent with the view that a direct toxic effect of some HIV gene product causes podocyte dedifferentiation, since viral particle endocytosis readily occurs in podocytes (as their normal filter cleaning role?), but lack of HIV entry receptors precludes local replication (Khatua AK et al. 2010).

FR-PO001

A Case of Hypercalcemia with Renal Failure: Renal Sarcoid? Eduardo J. Zouain, Isha Gupta, Karim El Hachem, Steven D. Smith, Ira S. Meisels. *Nephrology Dept, Mt. Sinai St. Luke's Hospital and Icahn School of Medicine at Mt. Sinai, New York, NY.*

Introduction: Sarcoidosis is a multisystem granulomatous disease of unknown etiology characterized by noncaseating granulomas in involved organs. Renal involvement occurs in 35-50%, manifested by hypercalciuria, hypercalcemia, nephrocalcinosis, and nephrolithiasis. Granulomatous interstitial nephritis is the most typical histological finding, usually in the setting of systemic disease and rarely in the absence of extrarenal sarcoid.

Case Description: A 54 y/o male presented with AKI superimposed on CKD and severe hypercalcemia (Calcium 13.5mg/dl, Cai=1.7mmol/L, creatinine=7.59mg/dl). Six months prior he had a kidney stone removed at which time his creatinine was 2.4mg/dl with Ca=11 but no further work up was performed. He was taking no medications and complained of back pain. Physical exam was unremarkable. A CT scan was negative for nephrolithiasis or hydronephrosis, chest X-ray revealed no abnormality. He was aggressively treated with IV NS and then Lasix with minimal improvement in the creatinine or the serum calcium. Work up for hypercalcemia included normal serum and urine immunofixation, negative PPD, normal PSA and normal skeletal survey. 25 Hydroxyvitamin D 27.8ng/ml (30-95ng/mL), PTH suppressed at <3pg/ml, total 1, 25 HydroxyVitamin D 79pg/ml (18-72pg/mL), and Angiotensin Converting enzyme 82 (9-67U/L). A formal ophthalmologic exam and PFTs were normal. A diagnostic kidney biopsy was performed.

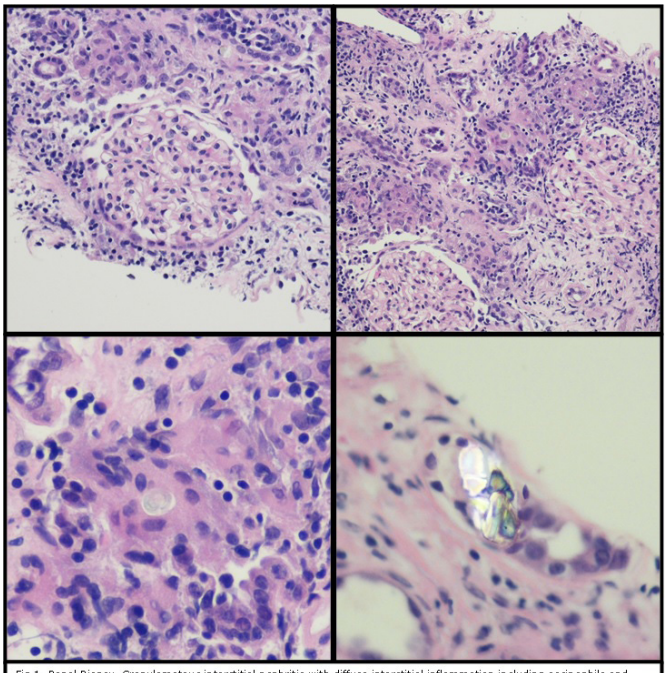


Fig 1. Renal Biopsy. Granulomatous interstitial nephritis with diffuse interstitial inflammation including eosinophils and oxalate crystals. Compatible with Sarcoidosis

Discussion: The diagnosis of sarcoid interstitial nephritis was strongly suggested by the renal biopsy given that other causes of granulomatosis were ruled out. The patient was started on prednisone 60mg/d with rapid resolution of the hypercalcemia and slow improvement in renal function (Creatinine 2.9mg/dl). A slow steroid taper over 1 year is planned.

FR-PO002

Pediatric Chronic Refractory SIADH: Use of Tolvaptan Cristin Kaspar, Nianzhou Xiao, Timothy E. Bunchman, Megan M. Lo. *Pediatric Nephrology, Children's Hospital of Richmond at Virginia Commonwealth Univ, Richmond, VA.*

Introduction: The syndrome of inappropriate antidiuretic hormone (SIADH) is the most common cause of euvolemic hyponatremia in hospitalized patients, and standard therapies can be limited in their effectiveness. Arginine vasopressin receptor antagonists (AVR-A) oral tolvaptan and intravenous conivaptan have been FDA approved in adults, but reports on long-term use in pediatrics are lacking. We report on the dosing and safety of chronic AVR-A treatment in two patients with chronic SIADH. Dosing regimen was extrapolated from current pediatric and adult literature.

Case Description: Case A is a 13 year old, 43.5 kg female with a 12-year history of pituitary astrocytoma treated with an experimental chemotherapy agent. She developed chronic refractory SIADH and was treated with IV conivaptan load and continuous infusion of 0.2-0.5 mg/kg/day, discontinued after 74 hours. Oral tolvaptan for outpatient treatment was then started at 0.7 mg/kg/day (15 mg twice daily) which induced nausea and thirst but [Na+] rose only to 129 mmol/L. Dosage was titrated and weaned off after 82 days. Case B is a 13 year old, 47.3 kg female who developed refractory SIADH as her initial presentation of an olfactory neuroblastoma. She was treated with conivaptan load and infusion of 0.2 mg/kg/day, titrated off after 32 hours. She received tolvaptan starting at 0.15 mg/kg/day and discontinued once the mass was excised after 27 days.

Discussion: Stable tolvaptan dosing was reached at 0.15-0.3 mg/kg/day (7.5 mg daily or twice daily) and weaned to 0.08 mg/kg (3.5 mg) daily or every other day before being discontinued in both patients. Case B had elevation of serum creatinine when on IV conivaptan and fluid restriction. Neither patient had complications of hypokalemia, hypernatremia, or liver dysfunction. Both patients required frequent monitoring of serum sodium and regular titration of dose and oral fluid intake. We recommend starting tolvaptan at 0.15-0.3 mg/kg/day. The use of tolvaptan in an outpatient setting for chronic hyponatremia is safe and effective in adolescent patients with close monitoring.

FR-PO003

Methylmalonic Acidemia: An Unexpected Consult for an Adult Nephrologist: A Case Report Yogita Lakhera, Seyed-ali Sadjadi. *Nephrology, JL Pettis VA Medical Center, Loma Linda Univ School of Medicine, Loma Linda, CA.*

Introduction: Organic acidemias are caused by deficiencies of enzymes involved in the breakdown pathways of amino acids, fatty acids and carbohydrate metabolism. Methylmalonic academy (MMA) is a heterogeneous group of disorders of impaired metabolism of methylmalonic acid. We present a patient with MMA who was admitted with severe metabolic acidosis.

Case Description: A 21 year old male with past medical history of end stage renal disease on peritoneal dialysis, chronic pancreatitis, diabetes mellitus and coeliac diseas presented to emergency room with diarrhea. He denied fever, abdominal pain and vomiting. He was hypotensive. Laboratory tests showed metabolic acidosis with anion gap of 33 mMol/L and absence of leukocytosis. Arterial blood gas result was, pH:7.38, pCO2:18 mmHg, paO2: 108 mmHg and HCO3: 10 mMol/L. Patient was kept NPO and acidosis worsened the next day.

Labs (mMol/L)	Day 1	Day 2	Day of discharge
Na	144	156	133
K	3.9	2.5	3.9
Cl	96	104	89
CO2	15	5	22
Lacate	8.2	20.4	5.5

Initial treatment included fluid boluses with NS, bicarbonate drip and broad-spectrum antibiotics for suspected sepsis. Further history revealed that patient had MMA and then iv fluid was changed to D20NS with insulin drip. He was started on special formula feed for MMA. Daily peritoneal dialysis was continued. Serum ammonia, β-hydroxybutyrate and lipase levels were normal. Blood and stool cultures grew salmonella enteritidis and antibiotics were switched to iv ciprofloxacin and metronidazole. With assistance from metabolic specialist, nephrologist and endocrinologist, patient was treated successfully.

Discussion: MMA is a rare autosomal recessive disorder (incidence of 1:48,000), caused by deficiency of methylmalonyl-CoA mutase or its cofactor, cobalamin. It is associated with anion gap metabolic acidosis, hypoglycemia, ketonuria and hyperammonemia. Metabolic decompensation can occur during episodes of increased catabolism such as prolonged fasting. Treatment of acute illness includes, providing hydration with high caloric supplementation, stopping all protein intake for 1-2 days and reintroduction of a low protein diet later**.** Severe acidosis may require dialysis.

FR-PO004

Congenital Pituitary Stalk Interruption Syndrome (PSIS) Newly Diagnosed in Case of Hyponatremia in the Elderly Kenji Kajitani, Takahito Ito, Kaori Takaori, Yoko Tomiyama, Ikue Nagayama, Masafumi Yamato, Akira Wada, Hirotsugu Iwatani. *Nephrology, Osaka National Hospital, Osaka, Japan.*

Introduction: There are many diseases that cause hyponatremia. Among them, adrenal insufficiency (AI) is important due to its urgency. We present an extremely rare case of elderly-onset AI in congenital PSIS, which is highly suggestive of the mechanism of AI progression.

Case Description: A hyponatremic episode (Na 117 mEq/L) occurred in a 76 year-old Japanese man in conjunction with common cold. Laboratory analyses revealed a low serum cortisol level. He was short-statured, had no hair growth on his axilla and pubis, and had unusual pale pigmentation in skin. He presented with gynecomastia and micropenis. CT scan revealed anorchism. He was not mentally retarded. Serum hormonal analyses showed AI, hypothyroidism, growth hormone deficiency, hypogonadism and hyperprolactinemia. A set of CRH/TRH/GHRH/LHRH stimulation test disclosed hypothalamic panhypopituitarism. Brain MRI visualized severely pressed 2-mm thick pituitary, but not the pituitary stalk, indicating PSIS.

Discussion: We concluded that his PSIS was not an acquired but a congenital anomaly based on his episode of intrauterine growth retardation and anorchism in the light of embryology. In PSIS patients, the functions of pituitary are sometimes maintained even if partially, although hypophyseal portal vessel snaps apart. This is because hypothalamic hormones reach pituitary through the superior hypophyseal artery (SHA), the nutrient artery of both hypothalamus and pituitary. In this case, the echogram of the internal carotid artery, from which SHA branches showed severe atherosclerosis. We speculate that the progression of atherosclerotic changes impaired the blood flow of SHA and then decreased

the delivery of hypothalamic hormones to pituitary, resulting in elderly-onset AI. Thus, blood flow disturbance of SHA can induce AI in PSIS. In conclusion, a congenital disorder can be the cause for elderly-onset adrenal insufficiency. This case suggests that pituitary stalk interruption syndrome should be taken into account as a differential diagnosis for hyponatremia, even in the elderly, especially in short-statured patients.

FR-PO005

A Family Case of Hypoparathyroidism, Deafness, and Renal Dysplasia Syndrome with a Novel Mutation of GATA3 Tomoo Yabuuchi,[1] Shoichiro Kanda,[1] Naoya Morisada,[2] Keiichi Takizawa,[1] Yuji Tomii,[1] Naoto Kaneko,[1] Hirotaka Hama,[1] Eiji Nakano,[1] Norimasa Tada,[1] Kiyonobu Ishizuka,[1] Hiroko Chikamoto,[1] Yuko Akioka,[1] Kazumoto Iijima,[2] Motoshi Hattori.[1] *[1]Dept of Pediatric Nephrology, Tokyo Women's Medical Univ, Shinjyuku-Ku, Tokyo, Japan; [2]Dept of Pediatrics, Kobe Univ Graduate School of Medicine, Chuo-ku, Kobe, Japan.*

Introduction: Congenital anomalies of the kidney and urinary tract (CAKUT), a major cause of end-stage renal disease in children, often present as a systemic disorder with extrarenal symptoms. Extrarenal symptoms and family history are helpful in the genetic diagnosis of CAKUT. We report here a family case of hypoparathyroidism, deafness, and renal dysplasia (HDR) syndrome with a novel mutation of *GATA3*.

Case Description: Soon after birth, a female patient was diagnosed as having bilateral cystic dysplastic kidneys by renal ultrasonography. She also had hearing impairment at the infancy. She received peritoneal dialysis at the age of 3 years and received a cadaveric kidney transplant at the age of 10 years. When she was 14 years old, she visited the emergency department because of acute abdomen. Detailed examinations showed hematometra associated with vaginal atresia. Branchio-oto-renal syndrome was considered as her diagnosis based on her hearing impairment, bilateral cystic dysplastic kidneys, and normocalcemia However, we suspected that she had an HDR syndrome because we found that her mother had hypoparathyroidism after determining a detailed family history. Genetic analysis was approved by the central ethics board of Tokyo Women's Medical University and Kobe University. This analysis showed a novel mutation, c. 1013G>T (C338F) of *GATA3*, the causative gene for HDR syndrome.

Discussion: Our patient did not show any symptoms of hypoparathyroidism. However, based on the family history, we performed a genetic analysis and found a novel mutation of *GATA3.* She was then diagnosed with atypical HDR syndrome. Therefore, determining a detailed family history is important in the precise diagnosis of CAKUT patients.

FR-PO006

Hypocomplementemic Urticarial Vasculitis Syndrome Resistant to Corticosteroid and Plasma Exchange Therapy Yasuhiro Kawai,[1] Kenji Ueki,[1] Yuta Matsukuma,[1] Hiroto Hiyamuta,[1] Akihiro Tsuchimoto,[1] Kiichiro Fujisaki,[1] Kumiko Torisu,[1] Kosuke Masutani,[1] Kazuhiko Tsuruya,[2] Takanari Kitazono.[1] *[1]Dept of Medicine and Clinical Science, Kyushu Univ, Fukuoka City, Japan; [2]Dept of Integrated Therapy for Chronic Kidney Disease, Kyushu Univ, Fukuoka City, Japan.*

Introduction: We present a case of HUVS resistant to corticosteroid and plasma exchange.

Case Description: A 36-year-old Japanese man with the history of diffuse pan-bronchiolitis developed microscopic hematuria, proteinuria, and kidney dysfunction. Percutaneous kidney biopsy was performed at the other hospital, and the diagnosis was non-IgA mesangial proliferative glomerulonephritis. In spite of the administration of angiotensin II receptor blocker, progressive kidney dysfunction was evident. Then he was transferred to our hospital 4 months later. He also had a history of urticarial rash on his leg, and pigmentation was evident at the time of transfer. Urinalysis revealed 3+ proteinuria and 3+ hematuria, and urinary sediment showed red blood cells of 50-99/high power field. Urinary protein/creatinine (Cr) ratio was 2.9 g/gCr. Blood tests revealed a serum Cr level of 2.4 mg/dL, complement (C) 3 level 18 mg/dL, and C4 level 23 mg/dL. We performed kidney biopsy again, and found membranoproliferative glomerulonephritis with crescents. Since additional blood test revealed serum anti-C1q antibodies of 51,965 U/mL, the diagnosis of HUVS was made. We treated him with methylprednisolone pulse therapy followed by oral prednisolone, but his kidney function was unchanged and he developed bacterial pneumonia. Next, we added plasma exchange, and found a temporal decrease in proteinuria accompanied by a decrease of serum anti-C1q antibody level. But his kidney function did not recover, and the level of anti-C1q antibody raised again.

Discussion: HUVS is a small vessel vasculitis associated with recurrent urticarial rash, hypocomplementemia, and anti-C1q antibodies. Safe and effective treatment for HUVS has not been established. Although corticosteroid and plasma exchange showed temporal efficacy, it was impossible to suppress the progressive kidney dysfunction in this case.

FR-PO007

Acquired Fanconi Syndrome in a Patient with Acetaminophen Overdose Deepak Jasuja, Jay B. Wish. *Div of Nephrology, Indiana Univ, Indianapolis, IN.*

Introduction: Acquired Fanconi syndrome is described in patients receiving antiretrovirals, aminoglycosides, platinum compounds and with proximal tubulopathies due to light chain disease/ paraproteinemias. We describe a case of acetaminophen induced acute tubular necrosis (ATN) presenting as Fanconi syndrome with hypophosphatemia, normoglycemic-glucosuria, aminoaciduria, and uric acid, potassium and bicarbonate wasting.

Case Description: A 35 year old woman with borderline personality disorder, depression, alcohol abuse, multiple suicide attempts, and previous acetaminophen overdose was transferred from outside hospital with fulminant hepatic failure secondary to acetaminophen poisoning. Nephrology was consulted for metabolic acidosis and AKI. On exam she was oriented to person only and following minimal commands. She had acute fulminant hepatic failure as evidenced by transaminase elevations, encephalopathy, and coagulopathy. On presentation her serum creatinine was 2.95 which rose over the next 3 days to 9.06. Initial blood gas was consistent with metabolic acidosis and respiratory compensation. Serum potassium (K) was low (2.9-3.5) despite large doses of K supplements. Her K requirements abated when bicarbonate supplementation was discontinued. Acetaminophen level was elevated on transfer at 21 and urine drug screen was positive for opiates and benzodiazepines; toxic alcohols were negative. Serum uric acid was <1.5 mg/dL and phosphorus <1 mg/dL. Glucose was 1-2+ on urinalysis with normal blood glucose. The following amino acids were elevated in her urine: aspartic acid, beta alanine, citrulline, gamma amino acid butyric acid, glutamic acid, leucine, ornithine, prolline, taurine and valine. This was a non-specific pattern of generalized aminoaciduria consistent with proximal tubulopathy and acquired Fanconi syndrome. The patient subsequently recovered renal function and the proximal tubulopathy resolved.

Discussion: It is important for nephrologists to be aware that ATN (in this case acetaminophen induced) can lead to acquired Fanconi syndrome and proximal tubulopathy which seem to resolve as ATN resolves. Aggressive treatment with bicarbonate supplements can exacerbate urinary K wasting and should be avoided.

FR-PO008

Spontaneous Remission of Non-Parasitic Chyluria Hillel Sternlicht,[1] Lakshmi V. Ramanathan,[2] Martin Fleisher,[2] Edgar A. Jaimes,[2] Ilya Glezerman.[2] *[1]Div of Nephrology and Hypertension, Weill Cornell Medical Center, New York, NY; [2]Renal Service, Memorial Sloan Kettering Cancer Center, New York, NY.*

Introduction: Chyluria is a medical condition characterized by the presence of chyle in the urine. The disease is most prevalent in South East Asian countries mostly caused by parasitic (*Wuchereria bancrofti*) infections. Chyluria presents as a cloudy milk-colored urine accompanied by systemic symptoms such as weight loss, fatigue, and rarely, flank pain from retained clots.

Case Description: A 72 year-old woman presented to Nephrology clinic complaining of milky urine (Figure 1) and painless hematuria with clots for two months as well as twenty-pound weight loss. Physical exam was unremarkable. Cystoscopy and urine cytology were unremarkable. Serum albumin was 3.2 g/dL. A urinalysis showed 3+ protein and 50 red blood cells per HPF. Urine sediment had no dysmorphic cells or casts. A 24-hour urine collection revealed 8.8 grams of protein. Chyluria screen was positive for chylomicrons and triglycerides. Midnight blood smears were negative for filarial parasites. Urine culture was negative for mycobacteriae or schistosomas. Serologic studies including IgG western blot for cysticercus and IgG ELISA for filariasis were negative. The rapid plasma reagin (RPR) was also negative. Imaging for a lymphatic leak by lymphoscintigraphy was unrevealing. The patient was managed conservatively and underwent spontaneous remission with disappearance of chyluria several months of her initial diagnosis.

Discussion: The most common cause of chyluria is parasitic infection with granulomatous diseases or structural etiologies less frequently encountered. Sclerotherapy of the renal pelvis is the definitive treatment. Idiopathic chyluria as shown in this case is rare. Conservative management of idiopathic disease may be warranted due to the possibility of spontaneous remission.

FR-PO009

Rebound Hypertension and Hypokalemia After Stopping Drospirenone Kalyani Chandra, Shubha Ananthakrishnan. *Nephrology, UC Davis Medical Center, Sacramento, CA.*

Introduction: Drospirenone is the fourth generation oral contraceptive with antimineralocorticoid effects, which are reported to be generally mild. There have been several warnings issued for drospirenone, in relation to adrenal insufficiency and hyperkalemia. But, no reports thus far of the rebound effects like hypertension (HTN) and

hypokalemia, following the discontinuation of the medication, especially after prolonged use. Review of literature, to our best knowledge, suggests this to be the first case report demonstrating the association between HTN, hypokalemia and drospirenone.

Case Description: A 54 year-old Indian woman, previously normotensive, noted a new rise in home BP to 200/100 mm Hg and presented to the emergency department, where she was also noted to have mild hypokalemia to 3.1 mg/dL. Given the rather new onset of severe HTN and hypokalemia, work-up for secondary causes of HTN was done, which revealed normal aldosterone level (9 ng/dL), low plasma renin activity (PRA) (0.15 ng/mL/hr) and high aldosterone/PRA ratio (60). Looking back into her history, it was noted that, the timing of symptoms was closely related to discontinuing Yasmin® (30 µg ethinyl estradiol and 3 mg drospirenone), which she was taking for over 6 yrs. She was thought to have rebound effect with relatively excess mineralocorticoid activity, precipitated by the abrupt discontinuation of drospirenone. With the introduction of low dose spironolactone, her symptoms significantly improved.

Discussion: Drospirenone (an analogue of spironolactone), which has antimineralocorticoid and antiandrogenic activities similar to endogenous progesterone, counteracts the estrogen-mediated stimulation of the renin-angiotensin-aldosterone system (RAAS). Due to these effects, it has the potential to decrease blood pressure and also cause hyperkalemia. At a dosage that suppresses ovulation, drospirenone induces mild natriuresis, which is followed by compensatory stimulation of the RAAS (comparable to a low sodium diet). When the prolonged ongoing suppression for the RAAS is removed, there might be a potential rebound effect with (relatively) high aldosterone state, resulting in sodium retention, leading to HTN. Spironolactone appears to be useful in this situation.

FR-PO010

Acthar Induced Hypokalemic Metabolic Alkalosis Imran Quyyum, Neil W. Lyman. *Dept of Nephrology, St. Barnabas Medical Center, Livingston, NJ.*

Introduction: Acthar, an ACTH formulation from porcine pituitary gland, is an effective therapy for Membranous Nephropathy (MN). A rare adverse effect of hypokalemic alkalosis has been described in infants only. We present a case report of an 84 y/o Caucasian female who developed severe hypokalemia and metabolic alkalosis with Acthar therapy and concomitant diuretic use.

Case Description: The patient presented with severe bilateral leg edema. Lower extremity doppler was negative for DVT. Echo revealed normal EF. UA showed 4+ protein and 2+ blood. Spot protein/creatinine ratio was 20g. Urine sediment had no RBC casts. Her scr was 1.99 mg/dL. (baseline 1.34 mg/dL). Albumin was 2.3 g/dL. Workup for malignancy was negative. Her serologies were unremarkable and a renal ultrasound was negative. Anti-PLA2 Ab was positive. Renal biopsy was consistent with MN. Acthar therapy was preferred due to her advanced age. Acthar 80 units 2x/week was added to her regimen of furosemide, amiloride, losartan and hydrochlorothiazide. Protein excretion decreased from 20g to 5g. Scr and albumin improved to 1.16 mg/dL and 3.4 g/dL, respectively. Follow up labs revealed potassium of 2.1 mmol/L and serum bicarbonate of 40 mmol/L. Acthar and diuretics were held and K+ was repleted. Acthar at 40 units 2x/week was later restarted due to worsening renal function and proteinuia. However, patient was readmitted three weeks later with K+ of 2.3 mmol/L and bicarbonate of 35 mmol/L which prompted termination of Acthar. She currently remained in partial remission with less than 5g of proteinuria.

Discussion: ACTH increases endogenous steroid production via MelanoCortin Receptor (MCR) type 2. It also exerts direct beneficial effects on podocytes and glomerular cells via other MCR subtypes. ACTH is an effective, alternative therapeutic modality for MN as well as other causes of nephrotic syndrome. Importantly as our case report demonstrated, the concomitant use of ACTH and diuretic therapy can result in severe hypokalemic metabolic alkalosis. Clinicians should closely monitor serum electrolytes after initiating Acthar.

FR-PO011

Polycythemia in a Patient with Bartter's Syndrome and Medullary Nephrocalcinosis Girlie Singian Merdegia. *Medicine, Philippine General Hospital, Manila, Metro Manila, Philippines.*

Introduction: Bartter's syndrome is a tubular salt wasting disorder presenting with severe hypokalemic alkalosis, hypochloremia, and hyperreninemia with normal blood pressure. Medullary nephrocalcinosis in this disorder is an infrequent finding and is still generally unrecognized. Polycythemia is an unusual presentation in patients with renal diseases, but has been described in literature among patients with nephrotic syndrome and distal tubular acidosis. It is noteworthy, however, that reports on secondary erythrocytosis among patients with Bartter's syndrome is lacking. The exact mechanism for the polycythemia is still uncertain, although postulates include hypoxia induced by nephrocalcinosis causes stimulation of oxygen receptors thus increasing erythropoietin secretion, and stimulation of prostaglandin production may be contributory.

Case Description: A 27 year old Filipino male with recurrent bouts of severe hypokalemia since childhood presenting as bilateral lower extremity weakness necessitating recurrent hospital admissions was diagnosed with Bartter's syndrome based on metabolic alkalosis, hypokalemia, hypochloremia, slight hyponatremia with normal serum calcium and magnesium levels. He had normal blood pressure and no frank hypercalciuria. His creatinine was elevated at baseline and his ultrasound revealed normal sized kidneys with bilateral nephrocalcinosis. He has elevated hemoglobin of 190 g/L, slight leukocytosis with no thrombocytosis. JAK2 mutation was negative and a bone marrow biopsy revealed mildly hypercellular marrow with trilineage hematopoiesis, mild plasmacytosis for which polycythemia vera was ruled out. Findings were said to be consistent with a reactive marrow. He underwent as needed phlebotomy and was maintained on potassium replacement, spironolactone and an ace-inhibitor.

Discussion: The association of Bartter's syndrome with medullary calcinosis and secondary erythrocytosis is a rare entity with very limited data in literature. The mechanism leading to secondary erythrocytosis, as well as nephrocalcinosis among patients with Bartter's syndrome remains uncertain. Clinicians should be aware of potential complications of this disorder so as to institute appropriate management.

FR-PO012

Homozygous Deletion of CFHR3-CFHR1 as a Cause for Atypical Hemolytic Uremic Syndrome in a Patient with Systemic Lupus Eyrthematosus Salem Almaani,[1] Tibor Nadasdy,[2] Samir Parikh.[1] *[1]Div of Nephrology, The Ohio State Univ, Columbus, OH; [2]Dept of Pathology, The Ohio State Univ, Columbus, OH.*

Introduction: Thrombotic microangiopathy (TMA) is a rare but devastating condition associated with systemic lupus erythematosus (SLE). In SLE, renal TMA is typically associated with the anti-phospholipid syndrome 9APS) or TTP. Here we report a case of atypical hemolytic uremic syndrome (aHUS) associated with SLE that was confirmed by complement genetic studies and treated successfully with Eculizumab.

Case Description: A 21 year old African American female with a history of SLE and class II+V lupus nephritis was hospitalized after presenting with AKI, thrombocytopenia (TCP), and a microangiopathic hemolytic anemia (MAHA). Initial lab values revealed a serum creatinine of 3.5 mg/dl, platelet count of 58, hemoglobin of 7.3, and LDH of 1484. Plasmapheresis and IV solumedrol was started empirically for presumed TTP and SLE flare. ADAMTS13 enzyme activity was normal and APS antibodies were negative. There was no improvement and the patient was started on dialysis. The patient required multiple blood transfusions as TCP and MAHA persisted. A kidney biopsy was performed and findings were consistent with severe TMA. The patient was empirically started on Eculizumab and after the first dose, TCP improved rapidly, with a platelet counts increase from 77K of 170K. Complement mutation studies were obtained and revealed a homozygous deletion of CFHR3-CFHR1 genes. The patient continued on Eculizumab, and after 4 months she recovered renal function and was liberated from dialysis.

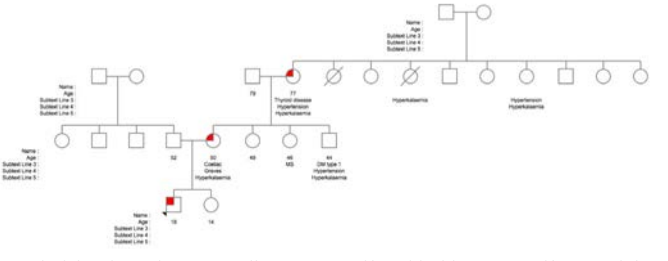
Discussion: This is the first report of aHUS associated with SLE in a patient with an identified complement mutation. Our patient had a homozygous deletion of CFHR3-CFHR1, which has previously been linked to aHUS. CFHR3-CFHR1-deficient plasma is thought to contribute to defective regulation of complement activation on the cell surface and occurs despite the presence of normal factor H and I levels. Treatment with Eculizumab is effective and should be started promptly so disease can be halted and chronic damage limited.

FR-PO013

A Novel Mutation in KLHL3 Gene Causes Familial Hyperkalemic Hypertension Mohd Radzi Rodzlan Akib,[1] Dearbhla Kelly,[1] Xavier Jeunemaitre,[2] Catherine A. Wall.[1] *[1]Nephrology, Adelaide & Meath Hospital, Dublin, Ireland; [2]Département de Génétique et Centre de Maladies Vasculaire Rares Hôpital Européen Georges Pompidou, Paris, France.*

Introduction: Familial hyperkalemic hypertension is an autosomal dominant disorder where mutations in the regulators of the thiazide-sensitive NaCl co-transporter (NCC) cause salt-dependent hypertension. Implicated genes include WNK1, WNK4, KLHL3 and CUL3. These lead to increased activity of the NCC in the distal nephron, excessive chloride and sodium reabsorption, and volume expansion. We describe a novel disease-causing variant in KLHL3 not previously reported in the literature.

Case Description: An 18 year-old man with no prior medical history presented with an incidental finding of serum potassium of 7.3mmol/L. He was hypertensive with blood pressure 150/90mmHg. His mother, maternal uncle and grandmother also had a history of early onset hypertension and unexplained hyperkalemia.



His labs showed serum sodium 139mmol/L, chloride 103mmol/L, creatinine 83mmol/L. His arterial blood pH was 7.37 with bicarbonate 21. His plasma renin activity was suppressed at 0.2ng/ml/H and his serum aldosterone was raised at 534.4pmol/L. The transtubular potassium gradient was 3.87. Genetic analysis of the patient and affected family members revealed a missense mutation affecting exon 13 of the gene KLHL3 (c.1492C >T p.His498Tyr) affecting a residue located in the 5th kelch motif of the protein . The patient was treated with dietary salt restriction and a thiazide diuretic.

Discussion: This man illustrates classic findings in familial hyperkalemic hypertension including hypertension, hyperkalemia, metabolic acidosis and positive family history. Cases such as this give us further insight into the molecular pathophysiology of blood pressure control. KLHL3 gene products play a key regulatory role in distal nephron Na reabsorption and may have potential as anti-hypertensive drug targets.

FR-PO014

Renal Failure Run A-FUOwl: Disseminated Histoplasmosis Eileen Smith, Rajeev Raghavan, Sreedhar A. Mandayam. *Baylor College of Medicine, Houston, TX.*

Introduction: In patients with fever of unknown origin (FUO) and glomerulonephritis, *Histoplasma capsulatum* should be considered.

Case Description: A 37-year-old man presented to the hospital with 3 weeks of fatigue, 15-pound weight loss, intermittent chest pain, dyspnea on exertion and 3 day history of erythematous pruritic rash on his neck. PMH included congenital aortic stenosis with AVR, complicated by endocarditis requiring repeat AVR. Physical exam found splenomegaly and a lacy erythematous rash on the neck and torso. On admission, creatinine was 3.15 mg/dL (baseline 1mg/dL last year) with gross hematuria, and new pancytopenia. Initial work-up for glomerular disease was non-diagnostic. He developed persistent cyclical fevers to 102°F during his hospital stay. Blood cultures, tagged WBC scan and TEE were negative. Kidney biopsy showed numerous electron-dense deposits suggestive of Membrano-Proliferative Glomerulonephritis with active interstitial inflammation. Further history revealed the patient regularly cleaned a chicken coop. An infectious work-up found the patient to be strongly positive for the *Histoplasma capsulatum* urinary antigen. With itraconazole for histoplasmosis and concomitant steroid therapy for glomerulonephritis, he defervesced and his creatinine improved to 1.4 mg/dL.

Discussion: Infection Related Glomerulonephritis (IRGN) is an immune-mediated disease caused by non-renal pathogens. The incidence is higher in developing countries: for example, per 100,000 individuals, the incidence of cases per year is 39 in India and 0.78 in the United States. It is believed that sub-clinical IRGN is common and underdiagnosed. In a study of 1012 kidney biopsies, 10% had evidence of disease, such as subepithelial humps. Hematuria is present in > 80% of cases, and patients usuallly present with Nephritic Syndrome. Endemic mycoses as a cause of glomerular disease in humans are rare. An infection due to *H. capsulatum* can result from inhalation of aerosolized spores after disruption of chicken droppings harboring the fungus. We suspected endocarditis given his cardiac history, and kidney biopsy findings also supported infection. However, the splenomegaly, FUO, and exposure to fowls (FUOwls) established the diagnosis.

FR-PO015

Next Generation Sequencer Driven Exome Analyses Identified a MCKD1 Family with New Mutation Before VNTR Of MUC1 DNA Sequence, Suffering from Mucosal Dysfunctions Satoko Yamamoto,[2] Jun-Ya Kaimori,[1] Masaki Hatanaka,[2] Naotsugu Ichimaru,[1] Shiro Takahara,[1] Hiromi Rakugi,[2] Yoshitaka Isaka.[2] *[1]Dept of Advanced Technology of Transplantation, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan; [2]Dept of Geriatrics & Nephrology, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan.*

Introduction: Hereditary tubulo-interstitial nephritis (h-TIN) is characterized by family history, bland urine, normal size kidney, hyperuricemia, renal fibrosis and gradual renal function loss. MCKD1 type h-TIN is also recognized by the difficulty to identify mutant sequence by conventional Sanger Sequencer or next generation sequencer, because the cytosine insertion mutation locates in the GC rich valuable number tandem repeat (VNTR) region. The mutant MUC1 DNA sequence is supposed to produce truncated type protein, which is inhibited to be trafficked to the cell membrane. Because of the difficulty of identification, there may be lots of unknown symptoms in MDCK1.

Case Description: We identified 5 hereditary TIN patients in a family, three of those are renal transplant recipients, one is under dialysis, and the other was CKD. The CKD patient is 23 y.o female, whose renal function is gradually reducing for 10 years. Now her serum creatinin is over 3. Her renal MRI images showed normal size kidneys with no cysts. The patients are suffering from mucosal dysfunctions including GI ulcer, sinusitis, and dysphagia. We analyzed genome DNA sequence of hereditary TIN family by next generation sequencer driven trio exome analyses. They revealed that the 2 bp deletion mutation were located before VNTR. Interestingly, consequently produced mutant MUC1 protein is a truncated protein with almost the same a.a. sequence repeats with previously reported mutant protein. The results were confirmed in the further analyses of other family members by conventional Sanger sequencer.

Discussion: We could identified the totally new mutation sequence of MDCK1 family, because it located before the GC rich VNTR sequence of MUC1. The newly identified mutant protein showed the almost same a.a. repeats sequence, suggesting these repeat sequence is implicated in the pathophysiology of MDCK1 type h-TIN.

Funding: Government Support - Non-U.S.

FR-PO016

Propofol-Induced Hyperkalemia in a Hemodialysis Patient Ibrahim M. El-Ali, Chandana Shekar, Sarthak Virmani, Ruchir D. Trivedi. *Dept of Medicine, Div of Nephrology, Univ of Connecticut Health Center, Farmington, CT.*

Introduction: Propofol induced hyperkalemia and propofol infusion syndrome are well described in the intensive care literature. Propofol induced sudden cardiac arrest, however, may be under recognized. We report a case in which a large bolus of propofol was associated with an acute increase in serum K^+ precipitating potentially fatal cardiac arrhythmia.

Case Description: 59 y/o male on maintenance hemodialysis (HD), having missed 2 HD sessions, presented with altered mental status and hyperkalemia. Patient required intubation for airway protection. Serum K^+ was 8.2 mEq/L and confirmed with repeat of 8.8 mEq/L. Propofol bolus was used as premedication for intubation followed by infusion at 20 mcg/kg/min. Ventricular fibrillation and cardiac arrest ensued soon after propofol bolus. Patient was managed with repeated calcium chloride bolus totaling 10 grams and urgent hemodialysis. Post-HD Serum K^+ level was 4.5 mEq/L. Repeat K^+ 10 hours after HD, with no other parameters being changed, was 7.1 mEq/L, increasing to 7.9 mEq/L within the next hour. Cardiac monitor showed widening QRS interval. No concurrent evidence of hemolysis, DIC or rhabdomyolysis. No exogenous $K^+$was given. HD was re-initiated emergently to avoid recurrent cardiac arrhythmias. Propofol was discontinued with no recurrence of hyperkalemia.

Discussion: Direct mitochondrial respiratory chain inhibition similar to mitochondrial myopathy is the most plausible explanation for propofol infusion syndrome (PRIS); a rare but significant adverse effect of propofol. Impaired mitochondrial fatty acid metabolism leads to lactic acidosis causing trans-cellular potassium shifts to ECF resulting in hyperkalemia. Rapid rise of serum K^+ is more closely correlated with onset of arrhythmia than absolute K^+ levels. Propofol bolus can also cause sudden worsening of hyperkalemia via depressed beta adrenoceptor-agonist effect and acute transcellular shift of potassium. This complication can be fatal in ESRD patients who may have baseline hyperkalemia. Hence, propofol should only be used with extreme caution in ESRD patient population on HD.

FR-PO017

A CuriouSLE Tangled Case: Systemic Lupus Erythematosis as the Unifying Diagnosis for Fibrillary Glomerulopathy and Toxic Epidermal Necrolysis Kawan A. Swain, Hao Liu, Volker Nickeleit, Patrick H. Nachman. *Nephrology, Univ of North Carolina at Chapel Hill, Chapel Hill, NC.*

Introduction: Fibrillary glomerulopathy is a rare cause of glomerular disease. Most cases are idiopathic but can be associated with autoimmune diseases.

Case Description: 58 yo Caucasian male with a past history of hypertension presented a week after developing an acute erythematous rash associated with fever, encephalopathy, and AKI. This was preceded by an 8 month history of intermittent night sweats, fever, and joint pain. The desquamating rash encompassed >30% BSA with mucosal involvement. Skin biopsy revealed acute vacuolar interface dermatitis consistent with toxic epidermal necrolysis (TEN). Labs showed pancytopenia without evidence of hemolysis. Serum Cr was 2.14 mg/dl (recently 0.9) and urine Protein/Cr was 1.1g. Urine microscopy showed numerous acanthocytes and a few RBC casts. Serologies revealed low C3 and C4, positive ANA 1:640 and ENA screen, but negative ANCA, cryoglobulins, infectious work up and antibodies to ds-DNA, Sm, RNP, Ro/SSA, La/SSB, Jo1 and Scl70. A kidney biopsy showed acute tubular injury and mild mesangial and endothelial proliferation without crescents or tuft necrosis. Immunofluorescence revealed diffuse 1-2+ staining for IgG, IgA, IgM, C3, C1q, kappa and lambda in the mesangium and capillary walls. Electron microscopy showed mesangial and capillary deposits with 20nm non-branching fibrils. Congo red stain was negative and IgG subclass stain did not reveal monoclonality. The findings were classified as a fibrillary glomerulonephritis. After initial methylprednisolone pulse, treatment with oral prednisone and mycophenolate mofetil resulted in resolution of rash, encephalopathy, and recovery of renal function and cell counts. The unifying diagnosis is new onset SLE, with TEN (possibly precipitated by naproxen) and fibrillary glomerulopathy.

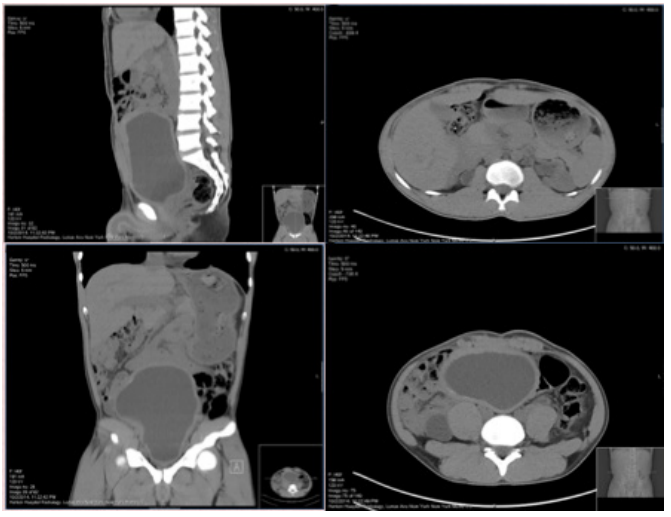
Discussion: This case illustrates an uncommon presentation of an immune complex mediated fibrillary glomerulopathy consistent with SLE in an older male patient who presented with TEN. SLE has been rarely implicated as a cause of SJS/TEN when associated with initial photodistribution, absence of genital involvement, and a prolonged course.

FR-PO018

An Unusual Case of Renal Failure in an Adult: "Prune Belly Syndrome" Juan Antonio Medaura, Jeffrey D. Wallach, Sudhanshu Jain. *Nephrology, Harlem Hospital Center, New York, NY.*

Introduction: Prune Belly Syndrome is a rare congenital disease characterized by hypoplastic abdominal wall musculature, severe urinary tract dilatation and bilateral undescended testes. The complete syndrome is seen only in males affecting 3.8 per 100,000 live births. While the cause is unknown several aspects suggest an influence of genetic factors. Very few patients survive adulthood and all of them progress to ESRD.

Case Description: A 25-year-old male from Burkina Faso presented with a 10-day history of fever, rigors and right-sided flank pain. On exam he was found to have an empty scrotum and a distended bladder. He reported history of several urinary tract infections and urological surgeries during childhood. He was found to have azotemia (Sr. creatinine 10.8 mg/dl and BUN 82 mg/dl) and an eGFR of 8 ml/ min/ 1.73m2. Urinalysis was cloudy with 2+ protein, 3+ leucocyte esterase, 2-5 WBC's and moderate bacteria. Urine culture grew Enterococcus fecalis. CT of the abdomen showed a massively distended urinary bladder with diffuse wall thickening and calcification, severe bilateral hydroureter, mild left hydronephrosis, right renal atrophy.



He received intravenous antibiotics and improved clinically.

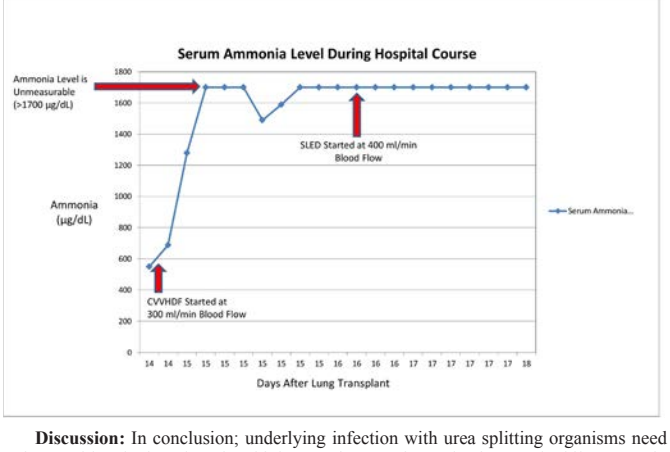
Discussion: Although lower urinary tract and kidney malformations account for 40% of childhood ESRD it is a rare cause of kidney failure in adults. Mutation in the HNF1β gene and homozygous loss-of-function mutation of muscarinic receptor M3 (*CHRM3*) were described. *CHRM3* is the major receptor mediating urinary bladder contraction upon micturition. These patients have normal urethral patency on cystogram and detrusor hyporeflexia with high residual volumes after micturition seen on cystometry, identical to the findings in our report. This diagnosis in a 25 year old is rare, as most patients do not survive until adulthood or they are already ESRD.

FR-PO019

How 'Idiopathic' Is Idiopathic Hyeprammonemia? Esho Georges, Kavitha Vellanki. *Nephrology, Loyola Univ Medical Center, Maywood, IL.*

Introduction: Idiopathic hyperammonemia is characterized by progressive elevations in serum ammonia of unknown etiology, ultimately leading to cerebral edema and death. It is a rare fatal syndrome described in transplant setting; lung transplant recipients having the highest risk. Calcineurin inhibitors are thought to play a role but the exact mechanism is not known. Here we report an unusual case of severe hyperammonemia that has been linked to donor transmitted Ureaplasma infection.

Case Description: A 59 yr old Hispanic man with idiopathic pulmonary fibrosis received bilateral lung transplant at our center. His induction regimen included thymoglobulin and methylprednisolone and was maintained on tacrolimus, mycophenolate and prednisone. His post-operative course was fairly uncomplicated until he was found unresponsive due to seizure on day 14. Work up revealed serum ammonia level of 549 µg/dL. Tacrolimus was discontinued and he was started on lactulose, sodium benzoate, phenyl acetate and broad spectrum antibiotics and started on CVVHDF to help in management of hyperammonemia. Despite all these measures, ammonia levels remained persistently elevated at > 1700 µg/dL (Figure 1) and patient expired within 4 days. At autopsy, bronchoalveolar lavage (BAL) of transplanted lung tested positive for Ureaplasma urealyticum. On further testing, donor's pre- transplant BAL was positive for the same organism. Lysis of urea by Ureaplasma generates free ammonia and when left untreated, can cause hyperammonemia. But the rise in serum ammonia levels of such a magnitude despite aggressive dialysis is unheard of.



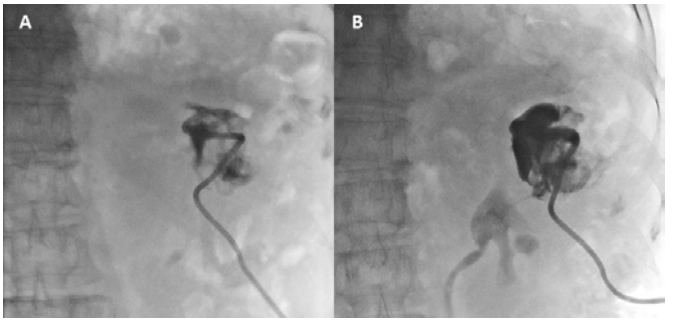
Discussion: In conclusion; underlying infection with urea splitting organisms need to be considered when there is a high rate of ammonia production. And while we are in need of further studies, it may be worthwhile to empirically treat with azithromycin for Ureaplasma infection in so called "idiopathic hyperammonemia".

FR-PO020

Pelvocalyceal Leakage on Ethanol Sclerotherapy for Recurrent Infected Renal Cyst in ADPKD Eunyoung Lee, Joo-Hark Yi, Sang-Woong Han, Ho-Jung Kim. *Divsion of Nephrology, Dept of Internal Medicine, Hanyang Univ Guri Hospital, Guri-si, Gyeonggi-do, Republic of Korea.*

Introduction: Though sclerotherapy has been commonly considered as a valid and safe therapeutic option for symptomatic renal cysts, it's effectiveness in recurrent infected renal cyst in autosomal dominant polycystic kidney disease (ADPKD) is rarely reported.

Case Description: A 76-year-old woman with ADPKD was again admitted by infected (Lt) renal cyst (7.3 cm) on ultrasonography (US) with similar episode, 1 yr ago. She presented with a fever, dysuria and left CVA tenderness. Despite clinical and laboratory improvement with sensitive antibiotics against Klebsiella pneumonia for 14 days, the size of the infected renal cyst was paradoxically enlarged (8.9 cm) on follow-up US. Thus, percutaneous catheter was inserted for drainage and after 1 wk, tubogram showed no evidence of dye leakage (figure1-A). Following complete clinical recovery, absolute ethanol sclerotherapy was performed to prevent further recurrent cyst infection. However, she complained of severe burning pain in low abdomen at the beginning of the procedure. Tubogram dye was shown in pelvocaliceal system and ureter (figure1-B). Sclerotherapy was immediately stopped and saline irrigation was followed. Then, percutaneous catheter was remained into the cyst for further draining, and double-J catheter was inserted at ureteropelvic junction to prevent a ureteral stricture. Then, she underwent uneventful hospital course, and discharged on hospital day 42.



Discussion: Infected renal cyst wall, despite clinical recovery, could consist of already damaged tissue that may be easily broken by ethanol. Through this unexpected adverse complication, we learned that cyst ablation therapy with ethanol may not be an appropriate modality to prevent recurrent renal cyst infection in ADPKD.

FR-PO021

A *CD2AP* Mutation (p.T374A) Associated with Cognitive Decline and Focal Segmental Glomeruloscrlerosis in Young Adulthood Dmitry Tsvetkov,[1] Yoland Marie Anistan,[1] Christian Harteneck,[2] Maik Gollasch.[1] [1]*Charité Univ Medicine Berlin, Nephrology/Intensive Care, Experimental and Clinical Research Center (ECRC) and Max Delbrück Center for Molecular Medicine, Berlin, Germany;* [2]*Dept of Pharmacology and Experimental Therapy, Inst of Experimental and Clinical Pharmacology and Toxicology, Eberhard Karls Univ Hospitals and Clinics, and Interfaculty Center of Pharmacogenomics and Drug Research, Univ of Tübingen, Tubi.*

Introduction: Mutations in CD2-associated protein (CD2AP) gene have been identified in patients with focal segmental glomerulosclerosis (FSGS); however, reports of CD2AP mutations remain scarce.

Case Description: We performed Sanger sequencing in a 32-year old patient with steroid-resistant FSGS presented with a nephrotic syndrome (proteinuria >3.5 g/day). The patient reported that his mother and his only brother also have a kidney disease. Neurological examination showed a remarkable cognitive decline within the last 5 years. Therapy with steroid and low-intermediate doses of cyclosporine A led to a persistent reduction of proteinuria. Serum creatinine levels and glomerular filtration rate (eGFR) did not decline during this treatment.

Discussion: Our patient displayed mild cognitive decline, a phenotypic characteristic not previously associated with CD2AP-associated FSGS. His proteinuria was remarkably reduced by treatment with cyclosporine A. Our findings expand the genetic spectrum of CD2AP-associated disorders and broaden the associated phenotype with the co-occurrence of cognitive decline. Our case shows that cyclosporin A is a treatment option for CD2AP-associated nephropathy.

FR-PO022

Acute Motor and Sensory Axonal Neuropathy-Associated Syndrome of Inappropriate Antidiuretic Hormone Secretion Weeraporn Srisung,[1] Aumyot Prongdong,[1] Pavis Laengvejkal,[2] Camilo Pena,[1] Mustafa G. Aly,[1] Sorot Phisitkul.[1] [1]*Internal Medicine, TTUHSC;* [2]*Neurology, TTUHSC.*

Introduction: SIADH is associated with various conditions including Guillain-Barre' syndrome (GBS). We report a case of SIADH associated with acute motor and sensory axonal neuropathy (AMSAN), a variant of GBS.

Case Description: A 36-year-old man presented with a 6-week history of progressive ascending weakness. Physical examination showed hypovolemia with asymmetric motor weakness, more severe in the LEs, muscle wasting, absent LE reflexes, dysesthesia and no cranial nerve involvement. MRI head/spine was unremarkable. CSF analysis showed albuminocytologic dissociation and ruled out infection. HIV, viral hepatitis and paraproteinemia were absent. Anti GM1 and GQ1b were negative. Nerve conduction study showed axonopathic pattern on motor and sensory fibers bilaterally. AMSAN was diagnosed. He received IV immunoglobulin with gradual improvement of his weakness. On admission, serum chemistry panel showed Na 115 mmol/L with normal Cr. Urine showed Na <20 mmol/L, and specific gravity 1.045. Urine Osm was not available initially. He received NS infusion for volume expansion. Interestingly, Na did not significantly improve after he became euvolemic. Fluid restriction was then tried with mild improvement. Endocrine work-up ruled out hypothyroidism and adrenal insufficiency. Repeat labs showed serum Na 124 mmol/L, urine Na 191 mmol/L and urine Osm 531 mOsm. Hence, SIADH was diagnosed. Other well-established causes of SIADH were ruled out thus AMSAN was believed to be the most likely cause of SIADH. Tolvaptan was started at 15 mg and resulted in significantly increased urine output (300-500 ml/hr). Na increased rapidly so D5W was started to prevent osmotic demyelination syndrome. Tolvaptan was restarted at 7.5 mg 2 days later with good response. He was discharged on tolvaptan 7.5 mg daily with Na 130 mmol/L.

Discussion: Although GBS is a well-established cause of SIADH, but to our knowledge, AMSAN-associated SIADH has only been rarely reported in literature. We suggest that SIADH should be high on the differential diagnosis for hyponatremia in patients with AMSAN, especially in the setting of euvolemia.

FR-PO023

Severe Renal Osteodystrophy as a Result of Fanconi Syndrome Rabie I. Adam-Eldien, Charles W. Heilig. *Nephrology, Univ of Florida, Jacksonville, FL.*

Introduction: Fanconi syndrome is a disease of the proximal renal tubules in which glucose, amino acids, uric acid, phosphate, bicarbonate and other substances are not reabsorbed and lost in the urine.

Case Description: 22 year old African American female with an autosomal dominant Fanconi syndrome. Her disease is clinically manifested by severe rickets and short stature. Her short stature has not responded to growth hormone. She has multiple stress fractures, and she ambulates with a walker. Her disease is manifested chemically by generalized aminoaciduria, hyperchloremic metabolic acidosis, hyperphosphaturia, glucosuria, bicarbonaturia, and proteinuria. Her life compliance with the medication has been poor. She has a gastrostomy tube for medications administration. Her medications include Calcium Carbonate, Neutra-Phos, Rocaltrol, Polycitra and Zantac. Her physical examination showed: Height 98.5 cm, weight 15.8 kg, blood pressure 106/57, pulse 80. She can stand up with hips flexed and her trunk slightly forward because of the anterior and lateral bowing of the femur. She has widening metaphyses of the knees and the wrists. She has ricket changes, ankle prominence, and she has good range of motion. Extremities: Have severe ricket changes. Lower extremities are deformed with prominent femur curve bilaterally. The rest of her exam was unrevealing.

Urinalysis shows glucose 100 mg/dL, ketones 40 mg, blood trace, pH 7, protein greater than 300 mg. Chemistry showed, Sodium 134, potassium 3.4, bicarbonate 13, chloride 114, glucose 142, BUN 5, creatinine 0.6, calcium 7.9, phosphorus 3.8. Osmolality 268. Alkaline phosphatase 865. White count 7.3, hemoglobin 14, hematocrit 41.3, platelets 385.

Discussion: Fanconi syndrome lead to multiple defects and impair proximal tubular reabsorption of glucose, phosphate, amino acids, HCO_3, uric acid, water, K, and Na. It can be caused by a drug or accompanies another genetic disorder. In hereditary Fanconi syndrome, proximal tubular acidosis, hypophosphatemic rickets, hypokalemia, polyuria, and polydipsia usually appear in infancy. If a patient is unable to keep up with the replacement of these substances secondary to compliance or lack of access, adverse permanent skeletal effects might result from that.

FR-PO024

An Unusual Organism with Unusual Renal Manifestations Brian M. Zwecker, Sreedhar A. Mandayam, David Sheikh-Hamad. *Baylor College of Medicine.*

Introduction: Infective endocarditis can cause renal failure due to immune complex mediated glomerulonephritis. We present a case of Nontuberculous mycobacterium (NTM) endocarditis associated with acute glomerulonephritis with tubulointerstitial nephritis.

Case Description: Our patient was a 59 y/o Venezuelan man with a history of cocaine use who presented with generalized weakness, intermittent nausea, and a 40lbs weight loss. He denied taking any medications or illicit drugs for the previous month. On examination, he was afebrile, HR 85, BP 112/43mmHg. Pulmonary exam was unremarkable, and heart auscultation revealed a 3/6 holosystolic murmur at the right upper sternal border. JVP was normal and there was no edema. Serum creatinine was 4.7mg/dL; BUN 56mg/dL; Hemoglobin 8.9g/dL; U/A revealed 2+ protein, 3+ blood, 65 RBCs/HPF, and no casts; Urine Pr/Cr 1.93g/g; HCV IgG positive; HCV PCR negative; low C3; urine drug screen negative. Blood cultures one-day after admission identified Staphylococcus and Corynebacterium species; on hospital day seven the pathogen identification was changed to Mycobacterium chelonae/abscessus complex. Renal biopsy revealed an acute diffuse mesangial proliferative and exudative glomerulonephritis associated with significant tubulointerstitial nephritis. Focal red blood cell casts were also seen on biopsy. TTE revealed a dilated left ventricle with severe aortic insufficiency and possible vegetations. Unfortunately, the patient died on hospital day seventeen from cardiogenic shock.

Discussion: Renal pathology associated with infective endocarditis is rare and typically associated with hematuria, proteinuria, and a mild rise in serum creatinine. Two prior case reports described glomerulonephritis associated with NTM, both of which showed improvement in renal function with treatment of the underlying infection. Additionally, interstitial nephritis in association with NTM has been reported in two immunosuppressed patients. Our case is the first to describe both glomerulonephritis and acute tubulointerstitial nephritis in association with nontuberculous mycobacterium. This serves as a reminder that infectious endocarditis can have varied renal manifestations whether the causative pathogen is common or uncommon.

FR-PO025

Severe Hyponatremia in a Young Patient with Recurrent Abdominal Pain Dimpu M. Patel, Manish K. Saha, Ashita J. Tolwani. *Nephrology, Univ of Alabama at Birmingham, Birmingham, AL.*

Introduction: Acute intermittent porphyria (AIP) is a rare metabolic disorder. Hyponatremia due to syndrome of inappropriate secretion of antidiuretic hormone (SIADH) during acute attacks of AIP requires prompt diagnosis and treatment of both AIP and hyponatremia.

Case Description: A 21yo Asian female presented to the ED with sharp intermittent abdominal and flank pain. Upon arrival to the ED, she had a generalized tonic-clonic seizure requiring intubation for airway protection. Her only medications were trimethoprim-sulfamethoxazole and ibuprofen prescribed 2 days prior. Previous ED visits for similar episodes of abdominal pain included an extensive workup with negative urine drug screen, abdominal CT scan, pelvic ultrasound, and surgical evaluation. Prior episodes were noted to occur during menstruation. Physical examination was unremarkable apart from tachycardia. Laboratory data was significant for sodium 113mEq/l, urine osmolality 282 mOsm/kg, and serum osmolality 225 mOsm/kg. Renal function, cortisol, TFTs, LFTs, and CBC were normal. Her hyponatremia was initially corrected slowly with 3% saline and later with sodium chloride tablets after a diagnosis of SIADH was made. The constellation of recurrent abdominal pain and unexplained cause of SIADH in a young menstruating female led to the diagnosis of AIP. Studies sent for AIP demonstrated elevated urine total porphyrin 3,374 (normal 0-300 nmol/24 hr), urine porphyrin 115 (normal 0-4 mg/24hr), 5-aminolevulinic acid (ALA)–delta 79.8 (normal < 7mg/24hr), and RBC protoporphyin 162 (normal 0-80 mcg/dl). She was treated with a carbohydrate based diet and avoidance of medications known to precipitate an acute attack.

Discussion: AIP results from a deficiency of PBG deaminase, leading to accumulation of ALA and PBG. Acute abdominal pain and involvement of supraoptic nuclei of hypothalamus by the metabolites may trigger constant ADH secretion. Rarely renal and gastrointestinal sodium loss may also cause hyponatremia. Our patient likely had an acute attack triggered by her pain crisis, sulfonamide antibiotic and her menstrual cycle. In the appropriate clinic setting in young patients with hyponatremia, AIP should be considered in the differential diagnosis.

FR-PO026

A Case of Solute Diuresis Muhammad K. Qaseem,[1] Elizabeth A. Gilliams,[1] James L. Bailey.[1] *[1]Emory Univ School of Medicine, Atl; [2]EUH.*

Introduction: Polyuria is a common manifestation of many primary medical disorders. Here we present a case of Arigininosuccinate Lyase Deficiency(ASLD)who presented with altered mental status and later developed polyuria.

Case Description: A 24-year old male with history of ASLD was admitted to the Intensive Care Unit (ICU) for altered mental status with an ammonia level of 347mcmol/L. He was started on Ammonia Scavenger therapy with Ammunol(arginine, Na-benzoate and Na-phenylacetate). On hospital day 10 he developed hypokalemia, hypernatremia and polyuria of 5L. His labs are listed below.

Day-1	Day-14
Na=140 mmol/L	Na=148 mmol/L
K=3.8 mmol/L	K=2.6 mmol/L
Cl=112 mmol/L	CL=118 mmol/L
CO2= 20 mmol/L	CO2=26 mmol/L
Creatinine = 0.68 mg/dL	Creatinine= 0.5 mg/dL
BUN= 3 mg/dL	BUN= 2 mg/dL
Ammonia= 347 mcmol/L	Ammonia= 47 mcmol/L

Urine studies showed urine Sodium of 253mmol/L,urine Potassium of 59mmol/L,urine chloride of 175 mmol/L,urine anion gap of 137,urine osmolality of 637 mOsm/kg and urine Creatinine of 63 mg/dL with a 5.3L of urine in 24 hours. He was receiving ½Normal Saline, Ammunol and Total Parenteral Nutrition(TPN). It was recommended to decrease the dose of ammunol to decrease the non-measured anions in the urine,stopping ½normal saline and change the TPN to have less solute load. With these interventions his urine output and hypokalemia improved to almost back to normal.

Discussion: Argininosuccinate lyase activity results in the breakdown of argininosuccinic acid to arginine and fumarate. ASLD can result in severe hyperammonemia. Treatment of acute decompensations with hyperammonemia involves discontinuing oral protein, using intravenous arginine and ammonia scavenging therapy. Polyruria in ASLD could be due to different mechanisms such as low BUN leading to poor urine concentrating ability with loss of free water or due to solute diuresis. Our patient's high urine osmolality and high urine sodium indicated a mechanism other than Diabetes insipidus. After the solute content was decreased his urine osmolality decreased significantly along with his urine output. Hypokalemia also improved. Management of solute diuresis in this case was to reduce the solute intake of the patient but first and foremost requires an accurate diagnosis.

FR-PO027

Life Threatening Hypokalemia and Metabolic Alkalosis Related to Paraneoplastic Cushing's Syndrome Chyi Chyi Chong,[1] Pallavi D. Shirsat,[1] Ramesh Marahatta,[1] Cherinet S. Adgeh,[1,2] Neville R. Dossabhoy.[1,2] *[1]LSU Health Science Center, Shreveport; [2]VA Medical Center, Shreveport.*

Introduction: Paraneoplastic Cushing's syndrome (CS) develops secondary to tumoral ATCH and less often CRH production. Classical stigmata of CS are often absent, and purple striae and buffalo hump are uncommon. Hypokalemia associated with metabolic alkalosis are more common with ectopic ACTH. We report a case of severe hypokalemia with metabolic alkalosis related to ectopic ACTH production.

Case Description: A 58 y/o African American male presented with complaints of feeling unwell, weight loss and frequent diarrhea for at least one month. On admission, he was noted to be hypertensive with BP 157/87 mmHg. On physical exam, patient had mild wheezes at bases. Laboratory data was significant for Na 144 mEq/L, K 1.1 mEq/L, Cl 82 mEq/L, HCO3 50 mEq/L, BUN 14 mg/dL and Cr 1 mg/dL . Blood gas revealed pH 7.34, PCO2 92 mmHg, PO2 92.4 mmHg and HCO3 47 mmol/L. Pt unfortunately developed acute respiratory failure requiring intubation shortly after albuterol nebulizer treatment. He was also receiving Diamox in ICU. He required potassium supplement on average of 120 meq per day (Maximum 300 meq/day). Once diarrhea resolved and with discontinuation of Diamox, patient was still noted to be hypokalemic. Urine electrolytes performed: Na 31 mmol/L, K 107 mmol/L, Cr 41 mg/dL. Additional lab data: Renin <0.15 ng/ml/hr, Aldosterone <1 ng/dl, ACTH level 126 pg/ml and 24hr urine cortisol 3846 mcg. In addition, patient has positive dexamethasone suppression test. CT abdomen and pelvis performed - suggestive of metastatic disease with lesions in liver, left adrenal gland and bone. He had liver biopsy, which revealed neuroendocrine carcinoma. Patient was started on Spironolactone and Triamterene for hypokalemia, and Ketoconazole to decrease ACTH and cortisol level. Potassium supplement requirement decreased to 40 meq/day.

Discussion: This is a rare case of paraneoplastic CS associated with neuroendocrine carcinoma. Early recognition and appropriate treatment for this syndrome are important, although overall clinical outcome remains poor.

FR-PO028

Overcorrection of Hyponatremia Secondary to Diuresis in Postpartum Maria Berenice Nava,[1] Maya K. Rao.[2] *[1]Div of Nephrology, Columbia Univ, New York, NY; [2]Div of Nephrology, Columbia Univ, New York, NY.*

Introduction: Previous case reports have described hyponatremia in pre-eclampsia particularly with twin gestations. Overcorrection in the post-partum period is a potential risk and complicates management.

Case Description: Case report.

30 yo woman G1P0 with intrauterine insemination with triplets presented at 30 weeks gestation with pre-eclampsia and nephrotic syndrome for emergent cesarean section. On presentation she was hypertensive, massively edematous found to have a serum sodium of (sNa) 126 mEq/L (no prior values), serum creatinine 0.5 mg/dl, albumin was 2.4 g/dl. Urine osmolarity was 159 mOsm/kg and the serum osmolarity was 263 mOsm/kg, urine sodium 21mmol/L. Spot urine protein:creatinine ratio 3.5 grams. By POD 2, her sNa decreased to a nadir of 119 mEq/L and spot protein: creatinine ratio was 0.458 grams, free water restriction was started. She soon began to auto-diurese (2.6L in 4hrs) resulting in a rise in sNa to 127 mEq/L in 5 hrs with a urine osmolality of 159 mOsm/kg. She was started on DDAVP to slow down correction and sNa levels were checked every 4 hours. Her subsequent sodium levels remained at 127 mEq/L over the next 12 hrs. On POD # 3 her sNa corrected to 133 mEq/L, she continued to have a urine output of 200-300 ml/hr, therefore D5W was initiated and DDAVP was again administered. Her urine output decreased to <100ml/hr on POD#4, urine osmolality was 217 mOsm/kg, therefore D5W was discontinued. She received 4 additional doses of DDAVP. The patient was ultimately discharged on POD#10 with a sNa of 143 mEq/L and off DDAVP.

Discussion: Hyponatremia in pre-eclampsia with nephrotic syndrome has been reported in the literature and is thought to be secondary to low effective circulating plasma volume. In this case, we report rapid correction of serum sodium post-delivery likely due to volume redistribution and removal of ADH stimulus. Awareness of potential rapid correction and frequent monitoring of serum sodium is important in order to intervene early and prevent consequences of rapid sodium correction. Serum sodium post-delivery should be monitored very closely in cases such as these.

FR-PO029

Severe Hypocalcemia in a Hemodialysis Patient Manish K. Saha, Maria E. Taylor, Alian Albalas, Denyse Thornley-Brown. *Nephrology, Univ of Alabama, Birmingham.*

Introduction: Severe hypocalcemia in a hemodialysis patient is rare in the absence of parathyroidectomy ,vitamin D deficiency or calcimimetic drugs.

Case Description: A 58 year-old man was found to have severe asymptomatic hypocalcemia (5.9 mg/dL) with prolonged QTc (547 ms) four weeks after starting hemodialysis. He had a history of prostate cancer treated with radical prostatectomy, bisphosphonates and a GNRH analogue. Serum calcium prior to starting hemodialysis was 8.6 mg/dL; serum albumin 3.2 gm/dL, PTH 352 pg/mL, 25OH-Vitamin D2 <4ng/mL, 25OH-Vitamin D3 12 ng/ml, and phosphorus 6.3 mg/dL. His intravenous doxecalciferol dose was titrated to 20 mcg thrice weekly; oral calcium carbonate and 1,25-dihydroxycholecalciferol were titrated up. Dialysate calcium concentration was increased to 3.5 mEq/L. However, despite these measures, pre-dialysis calcium was 6 mg/dL. On further review, it was found that he had been started on denosumab six weeks prior to initiation of hemodialysis for bone pain due to skeletal metastases. Desonumab is a monoclonal antibody against RANKL (receptor activator of nuclear factor kappa-B ligand). Tumor cells in patients with skeletal metastases stimulate osteoblast to secrete RANKL, which stimulate osteoclast to promote osteolysis and increase calcium levels. Even after replenishing Vitamin D stores, our patient continues to need higher dialysate calcium.

Discussion: Common causes of hypocalcemia in dialysis patients include: vitamin D deficiency, autoimmune or surgical hypoparathyroidism, severe hyperphosphatemia due to tumor lysis or rhabdomyolysis and medications such as cinacalcet. Desonumab is an easily overlooked cause of hypocalcemia. Our patient had Vitamin D deficiency but had normal calcium level prior to starting denosumab. It is important to replete vitamin D and calcium stores prior to initiating denosumab in patients with chronic kidney disease as they may have resistance to standard therapy for hypocalcemia. It is also recommended to check calcium levels regularly while on this medication.

FR-PO030

Central Diabetes Insipidus with Pituitary Atrophy from Chronic Lithium Use Joe Ghata, Satish Kumar. *Nephrology, Univ of Oklahoma Health Science Center, Oklahoma City, OK.*

Introduction: Lithium use is commonly associated with nephrogenic diabetes insipidus (NDI) and rarely with central diabetes insipidus (CDI). The mechanism of Lithium associated CDI is unclear. We report a patient on chronic lithium therapy who developed CDI and partial NDI and who had atrophy of posterior pituitary atrophy on MRI.

Case Description: A 62 yo woman with diabetes mellitus 2 for 5 years, hypertension for 10 years, and bipolar disorder on lithium for 40 years was admitted to the ICU for altered mental status. ROS was negative for nausea, vomiting, diarrhea, acute intoxication or infectious prodrome. Physical exam was normal; she was clinically euvolemic. Urine output was 4-8 l/d and a serum Na was 178 mEq/l. Serum creatinine was 4.84 mg/dl, elevated from a baseline of 1.5 in 2012. Urine osmolality (U osm) was < 100 mosm/l. Intravenous D5W at 200 ml/h caused improvement in serum creatinine to 1.7 mg/dl but minimal reduction in serum Na. Water restriction produced a submaximal rise (<250 mosm/l) in U osm from 157 to 176. ADH levels were undetectable by RIA when serum Na was 165-175. Intravenous desmopressin produced submaximal elevation in urine osmolality from 80 to 153 (91.25%), consistent with partial NDI (U Osm < 250 mosm/l) and partial CDI (>15 to 99%). MRI demonstrated atrophy of the posterior pituitary, with non-specific volume loss, straightening of the infundibulum, and absence of bright spot corresponding to the posterior pituitary. Final diagnosis was both partial central and nephrogenic DI associated with lithium use. Eunatremia was eventually achieved with intranasal DDAVP and liberal fluid intake.

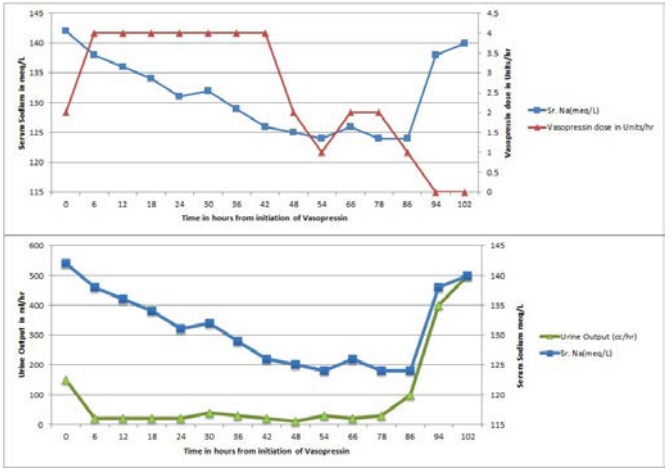
Discussion: This is the first report of radiological evidence of posterior pituitary atrophy with lithium-associated central DI. Possible mechanisms of posterior pituitary atrophy may include "burn-out" from chronic hypersecretion of ADH caused by lithium induced nephrogenic diabetes insipidus or autoimmune hypophysitis from circulating autoantibodies developed in response to chronic high ADH levels.

FR-PO031

Iatrogenic Hyponatremia Isha Gupta, Eduardo J. Zouain, Karim El Hachem, Anip Bansal, Steven D. Smith, Germaine Z. Chan. *Dept of Nephrology, Mt. Sinai St. Luke's Hospital, New York, NY.*

Introduction: Vasopressin acts in the kidney via V2 receptors to regulate water resorption and on the vasculature via V1 receptors to regulate smooth muscle tone. It is often used in the management of shock, but rarely causes hyponatremia in hemodynamically unstable patients. We present here a case of a man who developed marked hyponatremia during vasopressin infusion.

Case Description: A 58 year old man with history of hypertension and coronary artery disease was admitted to intensive care unit for un-witnessed cardiac arrest. He was intubated and started on vasopressin and norepinephrine for cardiogenic shock. His lab data on admission revealed normal serum sodium, blood urea nitrogen and creatinine. His inpatient course was significant for development of hyponatremia within 2 hours of initiation of vasopressin infusion. Patient's sodium dropped from 142 meq/L(normal range 136-146 meq/L) to lowest value of 124 meq/L associated with oliguria (urine output 20ml/hr). With cessation of vasopressin, urine output increased significantly to 500ml/hr and serum sodium increased from 124 meq/L to 142 meq/L. Dextrose infusion was started to prevent overly rapid correction. Please refer to graph for the changes in the serum sodium and urine output with vasopressin infusion over time. Patient had normal cortisol levels and thyroid function.



Discussion: Vasopressin does not usually result in hyponatremia when used in management of shock. Possible explanations include lack of renal responsiveness secondary to renal hypoperfusion/acute kidney injury, or lack of intake of hypotonic fluids. In this case, the patient developed marked hyponatremia in setting of preserved renal function.

FR-PO032

Hyperkalemia Secondary to Octreotide Use in a Patient with Normal Kidney Function Dron P. Bhandari, Jyotsana Thakkar, Hitesh H. Shah. *Nephrology, Hofstra North Shore-LIJ School of Medicine, Great Neck, NY.*

Introduction: Octreotide, a somatostatin analogue works by reducing blood levels of a variety of hormones (e.g. growth hormone, insulin) and chemical messengers (e.g. gastrin, vasoactive intestinal peptide). Octreotide therefore has been used as an effective medication for the treatment of sulphonylurea-induced hypoglycemia, acromegaly, VIPoma and carcinoid syndrome. Octreotide-induced hyperkalemia has rarely been reported in the literature. We report a patient with normal renal function who developed hyperkalemia secondary to octreotide use.

Case Description: A 70-year-old male with long standing history of DM (since 20 years), HTN, and metastatic neuroendocrine pancreatic cancer was referred by his oncologist for evaluation of severe hyperkalemia (serum potassium level of 6.6 mmol/L). Patient was diagnosed with pancreatic neuroendocrine tumor approximately 2 years prior to his presentation for which he underwent Whipple procedure. He was also receiving subcutaneous octreotide monthly for nearly 1.5 years prior to his presentation. There was no history of kidney disease or any urinary complaints. Other medications included aspirin, insulin, creon, levothyroxine and HCTZ. BP was normal and patient was noted to have bilateral lower extremity pitting edema on examination. Other labs done 5 days prior to presentation showed normal serum bicarbonate (25 mmol/L) level, normal serum creatinine (1.23 mg/dL) level, and elevated serum glucose (263 mg/dL) level. On reviewing medical records, our patient was noted to have chronic and persistent hyperkalemia over the previous six months that was medically managed by intermittent oral sodium polystyrene and low potassium diet. All other causes of hyperkalemia were clinically excluded. Serum potassium normalized after receiving medical management and holding octreotide treatment.

Discussion: We present a rare case of octreotide-induced hyperkalemia in a patient with normal renal function. We believe that hyperkalemia in our patient occurred as a result of octreotide-induced insulin suppression and resultant impaired cellular potassium uptake. Based on our experience, one should be aware of this potential life-threatening side-effect of octreotide therapy.

FR-PO033

Hypercalcemia and Acute Kidney Injury due to Immune Reconstitution Syndrome in an HIV Patient on HAART and MAC Therapy Anand Achanti, Omar M. Shahateet, Karl Berthold Pembaur, Nithin Karakala, Juan Carlos Q. Velez. *Nephrology, Medical Univ of South Carolina, Charleston, SC.*

Introduction: Hypercalcemia can occur in HIV-infected patients due to several conditions such as granulomatous diseases, lymphomas, and solid tumors. HIV patients are also susceptible to causes found in the general population, such as primary hyperparathyroidism, medications, and vitamin D supplementation.

Case Description: A 48 year old male with history of HIV and disseminated *Mycobacterium avium complex* (MAC) was sent to the hospital after being found to have a serum calcium of 15.5 mg/dl and serum creatinine of 5.8 mg/dL on routine labs. His only complain was weakness. Five months prior to presentation, patient had an adjustment of his highly active antiretroviral therapy (HAART) with a viral load of 76,000 copies/mL, CD4 count of 36/CUMM, serum calcium of 9.6 mL/dL, and serum creatinine of 2.6 mg/dL at that time. Previous renal dysfunction was caused by interstitial nephritis diagnosed 6 weeks prior. Patient reported increased compliance to his newregimen for several weeks prior to presentation, reflected by an increase in CD4 count of 138 /CUMM earlier and undetectable viral load upon presentation. Workup for hypercalcemia included: low PTH of 5.8 pg/mL, low PTH-rp of 0.7 pmol/L, and a high 1,25 Vitamin D of > 200 pg/mL. Serum and urine protein electropheresis showed a restricted kappa light chain band, but serum kappa/lambda ratio and bone marrow biopsy were normal. Imaging was negative for lymphoma. The patient was managed with volume repletion, prednisone 60 mg/d, and IV pamidronate 60 mg with gradual improvement of his calcium to 8.8 mg/dL and creatinine to 2.8 mg/dL in 9 days. Steroids were tapered and the patient remained stable 6 months later.

Discussion: Our patient developed acute kidney injury secondary to severe hypercalcemia, likely due to renal vasoconstriction and volume depletion superimposed over interstitial nephritis. The etiology of hypercalcemia was likely immune reconstitution syndrome caused by the restoration of HAART. In patients with HIV and AIDS with history of granulomatous disease, it is important to monitor for hypercalcemia when initiating HAART therapy or adjusting therapy.

FR-PO034

Hypocalcemia in Severe Malnutrition, and Acute Pancreatitis Veils Vitamin D Intoxication Kamran Karimi, Catherine Miranda, Yezina T. Nigatu, Kelly H. Beers, Nand K. Wadhwa. *Nephrology, Stony Brook Univ Medical Center, Stony Brook, NY.*

Introduction: Although vitamin D has a wide therapeutic index, a routine use of high doses of vitamin D intake can cause toxicity. We report a case with severe hypocalcemia likely due to malnutrition and pancreatitis related to alcoholism followed by hypercalcemia from vitamin D toxicity.

Case Description: A 43 year-old woman with alcoholism was admitted with rhabdomyolysis and alcohol induced acute pancreatitis. On initial examination she was in moderate distress with altered mental status and diffuse abdominal pain. Her blood pressure was 102/67 mmHg, heart rate 136/min and temperature 38.3°C. Her lab data revealed WBC 54.71 mm^3, Hb 16.9 g/dL, PLTs 186 mm^3, serum Na 129 mEq/L, K 3 mEq/L, bicarbonate 19 mEq/L, BUN 32 mg/dL and creatinine 1.3 mg/dL, Ca 4.4 mg/dl, Mg 1.1 mg/dl, phosphorus 1.7 mg/dL, CPK 1089 IU/L, albumin 2.9 g/dL. She received intravenous Ca, Mg, K and phosphorus in addition to oral supplements. On day 4, her serum Ca was 8.7 mg/dl, albumin 2.5 g/dl, phosphorus 4.0 mg/dl and K 3.9 mmol/l without any supplement. Her serum Mg remained low and continued to receive oral and intravenous Mg supplements. Serum Ca was not checked between days 9-14 of her hospitalization. On day 15, her serum Ca was 12.8 mg/dl, ionized Ca 6.4 mg/dl, vitamin D 25OH 370 ng/ml, vitamin D 1-25 OH_2 149 pg/ml and intact PTH 11.8 pg/ml. Her TSH, T4, ACE and vitamin A levels were normal. Her 24 hours urine revealed Na 140 mmol, K 70 mmol, creatinine 1110 mg, UN 4.1 g, Ca 462 mg, Mg 403 mg , phosphorus 931 mg. She admitted taking vitamin D 50,000 units daily for many months for her psoriasis on her own. Her hypercalcemia was treated and her serum calcium stabilized over one week to 9.4 mg/dl while her vitamin D 25OH and vitamin D 1-25 OH_2 remained elevated over the next 6 weeks.

Discussion: Her unusual presentation of hypocalcemia masked vitamin D toxicity till she resumed regular nutrition. Her hypocalcemia was likely related to malnutrition due to chronic alcoholism and possible calcium deposition due to acute pancreatitis. With proper nutrition during her hospitalization and improvement of her underlying condition led to hypercalcemia due to vitamin D toxicity.

FR-PO035

Re-Defining the Speed Limit in Osmotic Demyelination Syndrome? Mahrukh Rizvi, Rebeca D. Monk. *Nephrology, Univ of Rochester Medical Center, Rochester, NY.*

Introduction: Osmotic demyelination syndrome (ODS) is a severe, debilitating, possibly fatal neurological condition that results from rapid correction of severe chronic hyponatremia. Imaging reveals central pontine myelinolysis (CPM). Potential added risk factors for ODS include Sodium (Na) < 120 mmol/L, alcoholism, malnutrition and liver transplant. Current recommendations advise raising serum sodium by less than 9 mmol/L in 24 hours. We present a case of ODS in a patient presenting with severe hyponatremia corrected at a maximum rate of 8meq/dL in 24 hrs.

Case Description: A 37 year old man with a history of alcohol abuse was sent in to the hospital by police after a car accident for jaundice. He endorsed two weeks of worsening jaundice and right upper quadrant (RUQ) pain. Admission vital signs were stable. Physical exam revealed marked jaundice, abdominal distention and RUQ pain. Work up revealed severe alcoholic hepatitis with cirrhosis and metabolic derangements including a Na of 105 mmol/L, chloride of 69 mmol/L, urea nitrogen of 45 mg/dL, creatinine of 2.13 mg/dL with unknown baseline. 3% saline with ddAVP was initiated for cautious correction of severe hyponatremia. Na incresaed at the desired rate, with maximum of 8 mmol/L over 24 hours on day 1. Hospital course was complicated by altered mental status on day 3 for which he was initiated on CIWA. Over the course he had protracted encephalopathy with difficulty moving bilateral lower extremities, trouble swallowing and dysarthria. On day 9 of his stay, a magnetic resonance imaging of the brain was obtained revealing CPM.

Discussion: Defining a safe rate of serum sodium correction that the brain can tolerate has been difficult. It has evolved to more cautious values over the past few decades. Our case adds to the available pool of data in the literature shedding further light on what may be "overcorrection." Despite strict observance of therapeutic guidelines, a maximum correction of 8 mmol/L proved to be a sizeable enough increment to lead to ODS. This leads to reconsideration of a "safe" speed limit. Treatment should be tailored to individual patients and sodium corrected at a rate as low as possible, especially in the presence of other risk factors for ODS.

FR-PO036

A Case of Axenfield-Rieger Syndrome Presenting with Elevated Serum Bicarbonate Rudrick V. Ledesma, Maureen E. Brogan, Venkata Buddharaju, Rahul N. Pawar, Rajat Lamba. *Westchester Medical Center, NY.*

Introduction: Elevated serum bicarbonate can be often misdiagnosed as metabolic alkalosis leading to improper management. Chronic resipratory acidosis caused by central hypoventilation can lead to elevated bicarbonate secondary to renal compensation. We present a case of central hypoventilation caused by cerebello-pontine lesion in a patient with Axenfield-Reiger syndrome (ARS).

Case Description: A 25 yo man with PMH of glaucoma, developmental delay, schizoaffective disorder sent to the ED for respiratory failure. He was seen earlier in renal clinic for evaluation of elevated serum bicarbonate. He was complaining of fatigue and insomnia. Arterial blood gas was done and showed a pH of 7.30, pCO2 of 79, PO2 of 63 and HCO3 of 38.9. He was eventually admitted for further management. While in the hospital, he continuously needed bilevel positive airway pressure. Chest ultrasound showed little to no movement of his diaphragm. EMG was negative. PFT was suboptimal as he wasn't able to follow the instructions. MRI brain showed a mass on his right cerebello-pontine angle. He was also diagnosed with ARS during his hospital stay. The mass was resected and progressive improvement was observed in his respiratory status. He was eventually weaned off bilevel positive airway pressure and was discharged home without any need for respiratory support.

Discussion: Elevated serum bicarbonate can often pose a diagnostic challenge. Evaluation should start with an ABG which would differentiate a primary metabolic alklaosis from a renal compensation of respiratory acidosis. Differential diagnoses for respiratory acidosis include central hypoventilation, primary lung pathology, neuromuscular disease and airway pathology. Central hypoventilation could be secondary to lesions in the respiratory center. ARS presents as a spectrum of developmental disorders resulting from abnormal migration and differentiation of neural crest cells with both ocular and systemic manifestations. The regions in the brain that are usually affected are forebrain and pituitary gland. Our case is interesting as he had ARS with epidermoid cyst which we believe has led to central hypoventilation and elevated bicarbonate as compensatory mechanism.

FR-PO037

Signet-Ring Cell Carcinoma Presenting as Frequency of Urination Haya Waseem Siddiqi, Daniel E. Carl, Todd W. Gehr. *Nephrology, Virginia Commonwealth Univ, Richmond, VA.*

Introduction: Urinary tract obstruction may occur at any site in the urinary tract and is important to recognize early since it is readily reversible if quickly corrected.

Case Description: 45 year old male with obesity, history of gastric bypass surgery, hypertension and obstructive sleep apnea who presented to our institution for evaluation of frequency of urination. He developed progressively worsening frequency of urination, occurring every hour during the day and night for 3 months prior to presentation. During this time, his serum creatinine was 1.6 mg/dL. He had been seen multiple times by an Urologist and Primary Care Providers outside our institution, and was diagnosed with prostatitis despite negative urine cultures and no pyuria. During the work up, an out-patient CT scan revealed mild bilateral hydroureter and mild left hydronephrosis. Furthermore, an office cystoscopy revealed diffuse inflammatory cystitis of the bladder and no definitive bladder outlet obstruction. Over the ensuing 3-4 weeks, he developed acute kidney injury, with a serum Cr that peaked at 6mg/dL. This prompted an admission to an outside facility. He was again found to have mild bilateral hydroureter, however, ureteral stents were attempted, but unsuccessful. A repeat cystoscopy revealed severely inflamed bladder tissue, the ureterovesical junction was not visualized, and urinary bladder biopsy was done. Patient was transferred to VCU for placement of percutaneous bilateral nephrostomy tubes by interventional. He had successful stent placement by IR followed by post obstructive diuresis treated with intravenous fluid hydration in the form of saline. His AKI improved as did the hydronephrosis evident on follow-up imaging study. His serum Cr improved to 1.3 mg/dL and repeat CT scan with intravenous contrast was obtained for staging which showed circumferential bladder wall thickening with asymmetric soft tissue prominence along the right anterior dome most consistent with bladder neoplasm. Outside pathology report was consistent with signet cell carcinoma of bladder.

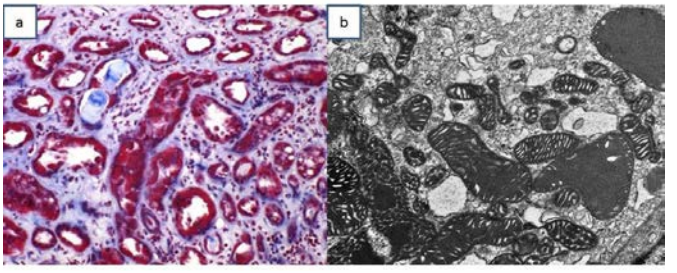
Discussion: Signet-ring cell carcinoma a rare bladder tumor can result in acute kidney injury secondary to bilateral ureteral obstruction.

FR-PO038

A Case of Tenofovir-Induced Nephrotoxicity Keerti K. Bhanushali, Girish Singhania, Abhilash Koratala, Radhika Vemuri, William L. Clapp, Dara N. Wakefield, Saraswathi Gopal. *Nephrology, Univ of Florida, Gainesville, FL.*

Introduction: Tenofovir (TFV) is a nucleotide reverse-transcriptase inhibitor used for treatment of HIV and hepatitis B. Most studies suggest that TFV has only a modest effect on estimated glomerular filtration and severe nephrotoxicity is uncommon. We describe a case of severe renal failure and mitochondrial tubulopathy related to TFV.

Case Description: A 55-year-old woman with HIV on TFV for several years, presented with vomiting and abdominal pain for 4 days. Physical exam was unremarkable. Laboratory data showed BUN 65 mg/dL, creatinine 9.07 mg/dL (baseline: normal), bicarbonate 12 mmol/L, glucose 137 mg/dL, HIV RNA: 21 copies/mL and CD4: 292 cells/uL, glycosuria and proteinuria (157mg/24 hours). Serological tests for autoimmune processes were negative. Kidney biopsy showed proximal tubule (PT) injury and eosinophilic oval cytoplasmic inclusions on trichrome stain (fig. a) with no definite glomerular or mesangial abnormalities. Electron microscopy (EM) showed PT cells with cytoplasmic swelling, loss of membrane integrity, accumulation of enlarged dysmorphic mitochondria with intra-cristal widening and the matrix appearing as electron-dense bands, and focal loss of cristae (fig. b) consistent with mitochondrial injury (MI) seen in TFV nephrotoxicity. Despite discontinuing TFV, she remained dialysis dependent.



Discussion: Currently available data supports renal safety of TFV in HIV patients. Severe renal dysfunction has only been reported sporadically. Although nucleoside reverse transcriptase inhibitors (adefovir) are known to impair mitochondrial replication by interfering with DNA polymerase-γ, evidence linking TFV specifically to MI is limited. Our case implies that TFV can cause significant renal failure and MI. Monitoring renal function and urinalysis during TFV treatment is key for early detection of nephrotoxicity.

FR-PO039

A Case of Severe Hypomagnesaemia in a Patient Treated with Trastuzumab Saifullah Kazi, Ghulam Akbar, Paul Robbins. *Nephrology, Lankenau Medical Center, Wynnewood, PA.*

Introduction: A case of invasive ductal carcinoma that was treated with chemotherapy including Trastuzumab found to have severe hypomagnesemia requiring very aggressive repletion strategies.

Case Description: A 36 y/o non-alcoholic female with past medical history of hypertension well controlled on diet therapy, was diagnosed with invasive ductal carcinoma of the breast requiring initiation of chemotherapy with docataxel and carboplatin with Trastuzumab. She received a total of 6 cycles of chemotherapy every three weeks and Trastzumab 2gm weekly infusions. After completion of chemotherapy, the dose of Trastuzumab was increased to 6gm per infusion every three weeks. Her serum magnesium level which was 2.1mg/dl in the beginning of chemotherapy was noted to be low at 0.5mg/dl when she presented with generalized weakness to the hospital six months into the treatment. At this time, she had completed her chemotherapy 2 months ago and now on Trastuzumab only. She was on lasix and proton pump inhibitors at that time, both of which were stopped immediately. However her serum magnesium remained low between 0.6-1.0 mg/dl persistently for next few months requiring intravenous infusions every week. On repeated testing, fractional excretion of magnesium remained high indicating renal magnesium wasting. Although patient was hypokalemic initially, it corrected immediately after stopping loop diuretics and remained normal ruling against tubulopathies such as Gitelman or Barter syndrome. She remained hypomagnesemic despite completing one year course with Trastuzumab. She is receiving once a week intravenous infusions of magnesium and oral supplements three times a day and serum magnesium remains at 1.4-1.5mg/dl.

Discussion: Trastuzumab is a human epidermal growth factor (HER-2) inhibitor which belongs to the family of epidermal growth factor receptor (EGFR). EGFR is involved in increasing the magnesium absorption in the distal nephron by increasing the transcription of the genes regulating TRPM6 channels. Hypomagnesemia has been well reported in other EGFR inhibitor with Cetuximab used in colon cancer and Erlotinib used in lung cancer, but not reported in patients taking Trastuzumab, especially after escalating to higher doses.

FR-PO040

Capecitabine Induced Acquired Bartter's-Like Syndrome Eric A. Kirk, Jennifer Thompson, Juan Carlos Q. Velez, Nithin Karakala. *Nephrology, MUSC, Charleston, SC.*

Introduction: Many forms of chemotherapy carry a risk of electrolyte abnormalities. Capecitabine is an antimetabolite of the fluoropyrimidine carbamate class of chemotherapeutic agents. Phase I and II trials have reported hypomagnesemia, hypokalemia and hypocalcemia as isolated electrolyte imbalances, and there are case reports of isolated hypomagnesemia and reports of a relatively large number of patients with hypokalemia. A Fanconi like pattern of electrolyte disorders has also been reported with capecitabine.

Case Description: A 68 year old female with neuroendocrine pancreatic cancer treated with capecitabine and temozolomide developed back spasms and was found to have severe hypokalemia (2.4mmol/L), hypomagnesemia (0.7mg/dL) hypocalcemia (6.4mg/dL) and metabolic alkalosis (bicarbonate 30mmol/L) in the absence of vomiting or diarrhea 5 weeks after starting a 2 week course of capecitabine (1400mg/m^2 divided twice daily). She had evidence of renal salt wasting with sodium 256.5mEq, potassium 51.8 mEq,and calcium 500mg in a 24 hour urine collection. No evidence of hypoparathyroidism, with intact PTH 67.3pg/mL, 1,25 hydroxy vitamin D was 33pg/mL. Further capecitabine therapy was withheld. 24 hr urine collection was completed 1 week later with decreased renal loss of sodium, potassium and calcium and normalization of electrolytes.

Discussion: We present a case of life threatening hypokalemia caused secondary to capecitabine. As the patient had metabolic alkalosis it was unlikely that the patient had Fanconi's as described in some case reports. Our case is unique as this patient developed a combination of hypokalemia, hypocalcemia, hypomagnesaemia and metabolic alkalosis

caused by capecitabine. The patient exhibited Bartter's like physiology with increased renal loss of potassium, calcium, and magnesium and evidence of metabolic alkalosis. Unlike the proximal tubulopathy associated with capecitabine, the pathophysiology of acquired Bartter's with is unknown but could be caused by direct inhibition of apical NaKCC or ROMK, or activation of the calcium sensing receptor on the basolateral surface in the thick ascending loop of Henle.

FR-PO041

Uncommon Case of Severe Hypercalcemia After Renal Transplantation Rapeepat Lekkham, Gitana Bradauskaite. *Nephrology, Einstein Medical Center, Philadelphia, PA.*

Introduction: Following renal transplantation, hypercalcemia is frequently caused by persistent hyperparathyroidism, but other causes should be kept in mind. We report a case of hypercalcemia after renal transplant from unregulated extrarenal 1,25-dihydroxyvitamin D synthesis from disseminated tuberculosis and cryptococcosis.

Case Description: The patient was a 59-year-old male with unknown etiology of ESRD who received a living unrelated kidney transplant. He was stable on low dose immunosuppressive agents for history of BK virus infection. At 10 months post-transplant, the patient diagnosed with disseminated cryptococcosis with granulomatous mesenteric mass and positive serum cryptococcal antigen. High dose oral fluconazole was started. 10 days later, he readmitted with severe hyponatremia, severe hypercalcemia (corrected serum Ca peak at 14.72 mg/dl) and acute renal failure (serum Cr peak at 5.8 mg/dl from baseline 1.6 mg/dl). The iPTH level was suppressed to 2.8 pg/ml. The serum $1,25(OH)_2D$ level was elevated and levels of 25(OH)D fell. Serum phosphate rose and ALP levels were elevated. PTH-related peptide was negative. Serum immunoelectrophoresis with immunofixation showed slightly elevated IgG kappa monoclonal gammopathy with normal ratio of free kappa and lambda light chain. Kidney biopsy revealed acute tubular necrosis, no evidence of granulomatous or lymphoproliferative disease. CT chest revealed right upper lobe mass with calcified granuloma at lung base. Culture from lung biopsy showed strongly positive for Mycobacterium Tuberculosis. Anti-tuberculosis drugs were started and mycophenolate mofetil was held. Elevated calcium levels were unresponsive to calcitonin, fluid neither diuretic. After his sputum AFB became negative, the oral prednisone was increased to 20mg/day. Hypercalcemia and hyperphosphatemia normalized upon one month follow up and remained stable until finished 6 months course of anti-tuberculosis drugs and the creatinine returned to baseline.

Discussion: Unlike persistent hyperparathyroidism, underlying diseases of PTH independent hypercalcemia after renal transplantation like a granulomatous disease can lead to significant morbidity and mortality. Early recognition and prompt treatment is necessary.

FR-PO042

Treatment of Malignancy-Associated Hypercalcemia with Low Calcium Hemodialysis Yields Several Benefits for Cancer Patient Rozina B. Ali, Akshatha Rao, Suzanne Boyle, Jesse M. Goldman. *Div of Nephrology and Hypertension, Drexel Univ College of Medicine, Philadelphia, PA.*

Introduction: Hypercalcemia of malignancy can be fatal. In literature, primary treatment remains forced saline diuresis while dialysis is seldom considered. We present a case of severe, refractory hypercalcemia associated with diffuse large B-cell lymphoma that was treated with low calcium (Ca) hemodialysis (HD).

Case Description: A 56 year-old male presented with 3 weeks of weakness and confusion. Labs noted a serum creatinine (Cr) of 1.45mg/dL, Ca of >18mg/dL, and ionized Ca of >2.3. Urine microscopy had pigmented granular casts. Cause of acute kidney injury (AKI) was attributed to hypovolemia, acute tubular necrosis and Ca-induced vasoconstriction. He had a PTH of 7pg/ml, PTH-rp of 2.1pmol/l, vitamin D 25,OH of 25.4ng/ml and 1,25OH of 18.6pg/ml . Non-contrast CT chest demonstrated diffuse lymphadenopathy with LN biopsy showing diffuse large B-cell lymphoma. On day 1, patient received several liters of normal saline, calcitonin, and pamidronate. Despite maximal medical therapy, he had delirium, persistent AKI with Cr peak to 2.6 mg/dL and elevated Ca at 15mg/dL. On days 3, 4, and 5, he received consecutive 4-hour sessions of intermittent HD with low Ca (2meq/L) dialysate using a 0180 high flux dialyzer with blood flow of 400mL/hr. On day 6, Ca decreased to 10.4 mg/dL and mental status improved. He received induction chemotherapy on day 13 with cyclophosphamide, doxorubicin, rituximab, and vincristine. At discharge, Cr was 1.66mg/dL and Ca level was 12mg/dL.

Discussion: Management of refractory severe hypercalcemia with low Ca HD is potentially underutilized. Conventional methods of management have therapeutic and temporal limitations. We found low Ca HD to be a useful adjunctive tool for treatment in our case of malignancy-related severe hypercalcemia. With low Ca HD, care must be taken to avoid hypotension from volume depletion and vasodilation from high Ca flux. Our patient tolerated dialysis without adverse events. Adding low Ca HD to other treatment modalities likely contributed to rapid symptom improvement and mitigation of further Ca-mediated renal injury, allowing for timely chemotherapy induction.

FR-PO043

A Curious Case of PPI Induced Renal Magnesium Wasting Minesh Rajpal, Taranpreet Kaur, Reejis Stephen, Fahad Saeed. *Cleveland Clinic, Cleveland.*

Introduction: Proton pump inhibitors (PPI) are known to impair absorption of magnesium (Mg) by inhibition of transient receptor potential melastatin-6 (TRPM6) and TRPM7 channels on the intestinal epithelium. We present a case of PPI induced hypomagnesaemia from renal Mg wasting.

Case Description: 41 year old female with history of thyroidectomy for cancer, parathyroidectomy, hypothyroidism, and gastro-esophageal reflux disease (GERD) referred to our nephrology clinic for severe symptomatic hypokalemia for a decade. She has poor appetite and weighs around 330 pounds but denies vomiting or diarrhea. Home BPs is low 90's /60's mmHg. She denies licorice, diuretic or excessive alcohol use. She was adopted as a child with unknown family history. She was admitted for further work up. Her serum potassium (K) was 3.5 and Mg was 1.2. 24 hour urine collection was done and levels of sodium, K, Mg and aldosterone were found to be 48 mmol, 21 mmol, 49.6 mmol, and 7.5 ng/dl respectively. Fractional excretion of Mg using the formula FEMg = 100 * (UrineMg * PlasmaCr) / (0.7 * PlasmaMg * UrineCr) was 121% confirming renal Mg wasting. Her serum bicarbonate of 22mmol/L and absence of salt wasting ruled out Gitelman syndrome. Review of medications revealed that she was chronically on esomeprazole 40 mg daily for presumed GERD. Esomeprazole was stopped, and with continued magnesium supplementation her repeat K and Mg were within normal range as outpatient. Repeat 24 hour urinary Mg was pending at the time of abstract submission.

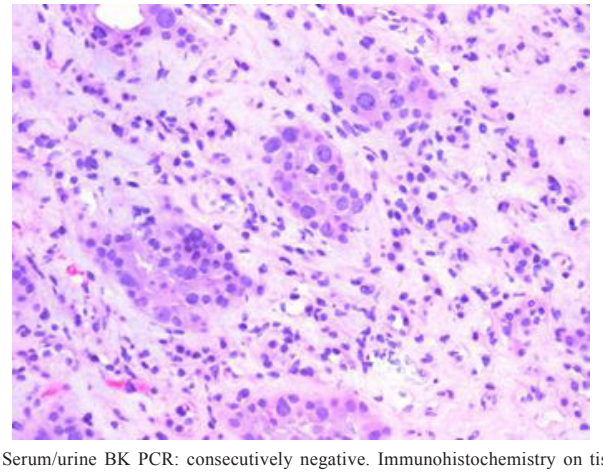
Discussion: The kidneys are highly efficient organs in Mg conservation with most of filtered Mg being reabsorbed in the thick ascending limb of the loop of Henle. It is speculated that patients who develop hypomagnesaemia on long-term PPI treatment may harbor one or more heterozygous mutation(s) of the gene TMPR6, FXYD2, KCNJ10, or KCNA1 involved in the modulation of Mg reabsorption in the distal nephron, leading to diminished efficiency of the encoded protein(s). This situation could involve a continuous low-grade Mg leak and facilitate the development of Mg depletion when combined with factors that decreases intestinal magnesium absorption.

FR-PO044

Viral Inclusions Excluding BK: Case Report of JC Virus Renal Allograft Nephropathy Deanne Leonard,[1] Cherise M. Cortese,[1] Xochiquetzal J. Geiger,[1] Lynn D. Cornell,[2] D. Jane Hata,[1] Mary B. Prendergast.[1] *[1]Mayo Clinic, Jacksonville, FL; [2]Mayo Clinic, Rochester, MN.*

Introduction: JC virus, a DNA polyomavirus, infects 70-80% of asymptomatic adults with clinical significance in immunocompromised hosts; known for causing progressive multifocal leukoencephalopathy, a fatal disease resulting in demyelination from infected oligodendrocytes. The paucity of data on JC virus nephropathy makes it essential to report this case.

Case Description: 76 year old male with diabetes mellitus and end stage renal disease underwent a deceased donor kidney transplant with basiliximab induction and a standard steroid taper. He experienced self-limited diarrhea with negative work up. Maintenance immunosuppression included mycophenolate mofetil, prednisone and tacrolimus, with levels 4.5-8.2. Serum CMV PCR: negative. Year 1, serum creatinine: 1.4mg/dL, urine protein to creatinine ratio 0.05 gm, negative urinalysis. Allograft biopsy: normal glomeruli, 5% tubular atrophy, mild tubulitis not meeting criteria for rejection and several large medullary viral inclusions but minimal plasma cells, C4D negative.



Serum/urine BK PCR: consecutively negative. Immunohistochemistry on tissue sections: positive for BK (SV40 T antigen which cross reacts with JC). In-situ hybridization for JC and BK viruses: positive in medullary tubular epithelial cell nuclei. Reduction in immunosuppression resulted in renal improvement.

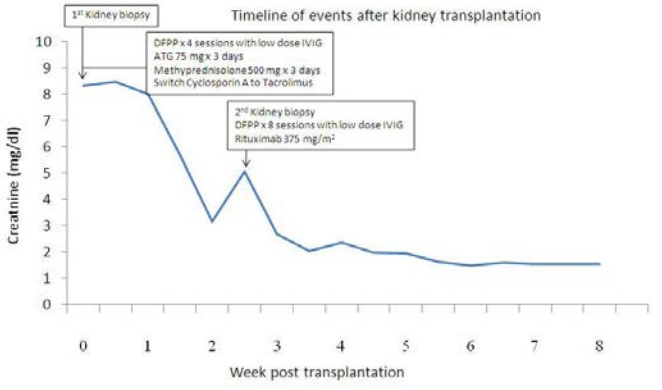
Discussion: Kantarci et al, 2011 summarized only 9 cases ever in existence. It is important to note that the scarcity of cases results in a small pool of patients from which to draw direct correlations. This case emphasizes the importance of other polyoma viruses in biopsy positive "BK" with minimal plasma cells and negative serum/urine thus broadening the differential on viral nephropathy and emphasizing the existence of non BK viral nephropathy.

FR-PO045

Successful Treatment of Anti-Angiotensin II Type 1 Receptor Antibodies Associated with Refractory Antibody-Mediated Rejection and Acute Cellular Rejection in Kidney Transplantation: A Case Report Punlop Wiwattanathum, Atiporn Ingsathit. *Nephrology Unit, Faculty of Medicine Ramathibodi Hospital, Mahidol Univ, Bangkok, Thailand.*

Introduction: Angiotensin II type 1 receptor (AT1R) antibody has been proved that it can be detrimental to kidney allograft. Similar to HLA-antibody, patients who have AT1R antibody are at risk for rejection and poor allograft outcome. There is no standard treatment in this situation but the aim is to remove pathologic antibodies and suppress antibodies production. Outcomes after treatment are unsatisfied and not well established. Herein we present a successful treatment kidney transplant pateint who experienced AT1R antibody associated rejection.

Case Description: A 50-year-old male with hypertension and ESRD underwent a disease donor kidney transplantation using a graft from acute kidney injury donor with peak serum creatinine of 1.24 mg/dl. No intraoperative complication occurred, urine flow rate of 300 ml/hr was observed immediate postoperative but abruptly decreased to 20 ml/hr at 8 hours posttransplantation. Acute rejection was suspected, thus allograft biopsy was done. The histopathological findings were compatible with acute cellular rejection combined with antibody-mediated rejection (ABMR). AT1-R antibody was detected at level of 15.0 u/ml. Anti-rejection therapies were offered with steroid, IVIG, plasmapheresis, anti-thymocyte globulin and rituximab. At 8 weeks posttransplantation, rejection was well controlled with stable serum creatinine of 1.5 mg/dl.



Discussion: Although AT1R antibody associated rejection has rarely been reported, the outcomes after rejection are unsatisfied. Early detecting rejection and rapid antibody removal seem to be the most effective treatment that prolong allograft function in present time. There are limited and controversial data about long term graft survival by treating patient with angiotensin receptor blocker.

FR-PO046

Hemodiafiltration for Hepatic Encephalopathy Induced by Budd-Chiari Syndrome in a Patient with End-Stage Kidney Disease Takuya Wakamatsu, Suguru Yamamoto, Takeshi Nakatsue, Junichiro J. Kazama, Ichiei Narita. *Div of Clinical Nephrology and Rheumatology, Niigata Univ Graduate School of Medical and Dental Sciences, Niigata, Japan.*

Introduction: Budd-Chiari Syndrome (BCS) is defined as portal hypertension caused by obstruction of the inferior vena cava at the liver. Severe BCS induces hepatic encephalopathy, and has known to be exacerbated during hemodialysis (HD) treatment in end-stage kidney disease (ESKD) patients, probably due to lowering branched-chain amino acid (BCAA)/aromatic amino acid (AAA) ratio and reducing blood flow in the portal vein. Hemodiafiltration (HDF) has been proposed be effective for some dialysis-related complications due to better removal of middle sized uremic toxins and preservation of plasma osmolality, compared with HD. Here, we present a patient with ESKD who developed hepatic encephalopathy after progression of BCS, which was ameliorated by HDF.

Case Description: The patient was a 36-year-old woman complaining of a consciousness disorder. She was diagnosed with BCS as a consequence of antiphospholipid syndrome presented at 21 years of age. Her kidney function impaired gradually, and progressed to ESKD. After initiation of HD, transient loss of consciousness due to hepatic encephalopathy occurred frequently. After her blood purification therapy was changed to online HDF, her hepatic coma improved dramatically (West Haven grade, 0.07±0.27 vs. HD, 0.95±1.11). Compared with HD, increased the removal of AAAs (phenylalanine: 43.6% vs. HD, 10.7%; tyrosine: 73.0% vs. HD, 35.3%), contributing to the increased BCAA/AAA ratio was observed after HDF session.

Discussion: In this case, hepatic encephalopathy was worsened by HD treatment in a patient with ESKD due to BCS, and was improved by HDF, with increased removal of AAAs. Hepatic encephalopathy is thought to be exacerbated by HD due to portal systemic bypass or shunting and/or perturbation of the amino acid profile. Tryptophan, one type of AAA, has especially a high protein-binding rate (50%-80%), and only a small amount of protein-bound tryptophan is removed by HD. Therefore, one of the reasons why HDF ameliorates hepatic encephalopathy is increased removal of protein-bound AAAs, leading to increased BCAA/AAA ratio.

FR-PO047

De Novo Lupus Nephritis in a Stable Kidney Transplant Recipient Laura Panarey, Karthik M. Ranganna, Alden Michael Doyle. *Div of Nephrology & Hypertension, Drexel Univ Hahnemann Hospital, Philadelphia, PA.*

Introduction: De Novo Lupus Nephritis (LN) is an exceedingly rare complication in kidney transplant recipients, previously reported only twice, neither recipient noted to have clinical manifestations of SLE. The scarcity of autoimmune disease in this population is not fully understood, but has been attributed to the maintenance immunosuppression used to prevent allorecognition and rejection.

Case Description: Herein, we present de novo LN in a 55-year-old woman with post streptococcus glomerulonephritis and HTN; 28 years status-post living-related kidney transplant. The patient had no personal or family history of autoimmune disease at time of transplant. Three years ago, she began complaining of episodic carpo-pedal spasm and scleritis; laboratory abnormalities included mildly low albumin and stable 1g proteinuria. Medications were stable and no potentially provocative antigens, vaccines or transfusions, were given during this period. Immunosuppression included cyclosporine and low dose prednisone. Seven months ago, the patient developed malar rash and hemo-proteinuria prompting immunological studies and kidney allograft biopsy. Anti-nuclear, double stranded DNA, smith and histone antibodies were all strongly positive with low serum complement levels. Serum creatinine increased by 0.5 mg/dL from baseline; urine protein to creatinine ratio revealed nephrotic range proteinuria peaking at 9.6grams. Immunofluorescence revealed granular "full house" pattern, C4d negative; Electron microscopy revealed intramembranous deposits. The patient was treated with high dose prednisone, continued cyclosporine and addition of mycophenolate mofetil.

Discussion: Although rare, de novo auto-immune disease should be considered for transplant patients despite maintenance immunosuppression.

FR-PO048

Atypical Hemolytic Uremic Syndrome Allograft Outcome in the Post Eculizumab Era Laura Panarey, Karthik M. Ranganna, Alden Michael Doyle. *Divsion of Nephrology & Hypertension, Drexel Univ Hahnemann Hospital, Philadelphia, PA.*

Introduction: Atypical Hemolytic Uremic Syndrome (aHUS) is an exceedingly rare etiology of renal failure; recurrent forms of HUS are often linked to underlying viral illness or particular classes of immunosuppression in transplant recipients. Exceedingly rare are genetic etiologies of aHUS for which transplantation is undesirable due to very high recurrence rates of disease.

Case Description: Herein we describe a case of misdiagnosis; 78 year old man initially diagnosed with rapidly progressive glomerulonephritis (RPGN) by kidney biopsy developed anuria necessitating hemodialysis. The patient had no family history of kidney disease. Immunological work-up negative for Anti-nuclear or cytoplasmic antibodies; complement deemed within normal limits. Pt received a living-unrelated kidney transplant from a 40 year old healthy donor. Standard induction solumedrol and thymoglobulin. Initiation of maintenance calcineurin inhibitor (CNI), steroid, antimetabolite. Favorable outcomes were observed, creatinine 1.77 mg/dL and urine output upon discharge. One week post-transplant, patient was observed to have increased creatinine, peak 4mg/dL, not amenable to discontinuation of CNI or typical offending agents; prompting renal biopsy. Histologically Thrombotic Microangiopathy (TMA), C4d (-) observed and deemed comparable to native biopsy slides. Laboratory studies confirmed aHUS: (-) ADAMSTS13; low lactate dehydrogenase, elevated haptoglobin; peripheral smear shistocytes. Negative viral studies including Shiga toxin. Pt was treated with high dose solumedrol, plasma exchange and eculizumab; resolution of kidney function, creatinine 1.88 mg/dL, month post-transplant period. Interim six month follow-up, with twice monthly eculizumab reveal no recurrent TMA on biopsy; despite bouts of acute kidney injury related to CNI levels or volume fluctuations.

Discussion: aHUS, as presented above, may be misdiagnosed and therefore present at the time of post-transplant recurrence. With the advent of treatment, alternative pathway complement inhibitor eculizumab; a high degree of suspicion must be maintained when managing post-transplant dysfunction.

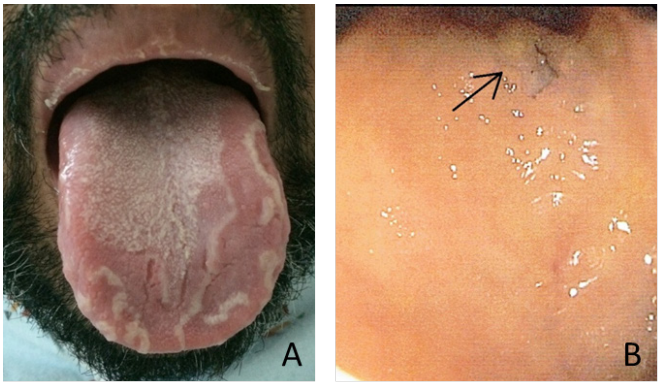
FR-PO049

An Unusual Manifestation of Disseminated Histoplasmosis in a Renal Transplant Patient Kana N. Miyata, Lilly M. Barba. *Nephrology, Harbor-UCLA Medical Center, Torrance, CA.*

Introduction: Disseminated histoplasmosis is rare but can develop in immunocompromised patients. We present a case of histoplasmosis presenting as fever of unknown origin with oral and gastrointestinal (GI) manifestations.

Case Description: The patient is a 42 year-old man with ESRD secondary to unclear etiology, who had a living related renal transplant from his cousin 4 years ago in Mexico. He was born in El Salvador, moved to California at age 7, and had traveled to Mexico and Cuba (last travel 1 year ago). His post-transplant course was complicated by antibody mediated rejection and borderline acute cell mediated rejection 2 years ago, for which he was successfully treated with IVIG, plasma exchange, and rituximab. His medication included tacrolimus, MMF, and prednisone. He presented with 2-3 weeks of fever and mild abdominal pain after unsuccessful treatment with ciprofloxacin. He had fever of 38.7

°C, painless tongue ulcers (Fig.A), and mild periumbilical tenderness. CT chest/abdomen showed multiple lung nodules, mild mediastinal lymphadenopathy, and a severe wall thickening of the distal loop of ileum. Colonoscopy revealed an 8 mm ulcer at terminal ileum (Fig.B), whose pathology was positive for intracellular *Histoplasma capsulatem*. Urine histoplasma antigen was positive. He improved soon after oral itraconazole was started.



Discussion: This is an unusual case of disseminated histoplasmosis. Histoplasmosis is most commonly diagnosed in the first year after transplant. Fever, fatigue, and dry cough are the most common presenting symptoms, and GI manifestations are recognized clinically in less than 10% of cases. Post-transplant histoplasmosis remains a rare event with only 1 case per 1000 person-years but the mortality is as high as 10%. We should maintain a high index of clinical suspicion to diagnose and treat it properly.

FR-PO050

Successful Strategy for Management of Anuric Acute Kidney Injury Complicated by Severe Hyponatremia Using Continuous Venovenous Hemodialysis Rahul N. Pawar, Rajat Lamba, Amy R. Patel, Venkata Buddharaju, Michael D. Klein. *Nephrology, Westchester Medical Center, Valhalla, NY.*

Introduction: Anuric acute kidney injury (AKI) with hyponatremia presents a therapeutic challenge. Hemodialysis (HD) using a standard Na^+ bath can cause excessive correction of $[Na^+]$, and a risk of osmotic demyelinolysis. We report the controlled correction of hyponatremia via continuous venovenous HD (CVVHD) against a standard bath using an infusion of dextrose 5% in water (D5W) to blunt the $[Na^+]$ shift.

An 83 year old man with respiratory failure developed altered mentation and oliguria. Labs demonstrated severe hyponatremia with $[Na^+]$ 119 mEq/L, $[K^+]$ 6.8 mEq/L, and AKI with BUN 46 mg/dL, creatinine 3.08 mg/dL. Emergent renal replacement therapy (RRT) was required, but HD would have risked overly rapid correction of $[Na^+]$. Instead, we started CVVHD with a $[Na^+]$ 140 mEq/L bath. The dialysate rate was 2 L/hr and blood flow rate was 200 cc/min. Net target was zero, with all drips included in the calculation. We simultaneously infused D5W at 100 cc/hour. $[Na^+]$ was monitored every 4 hrs. The D5W was held if the CVVHD was stopped for any reason. The D5W was to be increased if the $[Na^+]$ rise was > 0.5 mEq/hr or 6 mEq in 24 hrs. It was to be reduced if the correction was suboptimal. The patient's $[Na^+]$ rose from 118 mEq/L to 125 mEq/L on day 1, 125 mEq/L to 131 mEq/L on day 2, and reached 137 mEq/L by day 3. The patient was then safely converted to HD .

Discussion: CVVHD is a safer option for RRT than HD in the setting of severe hyponatremia, but low Na^+ CVVHD dialysate is not available. Some have suggested adjusting the dialysate $[Na^+]$ using sterile water to achieve the desired $[Na^+]$ prior to treatment. This may produce a predictable response in $[Na^+]$, but there are concerns for infection and/or dosing error which makes this strategy problematic. Reducing dialysate or effluent flow, though effective, often results in unacceptable clearances. We demonstrated, that CVVHD with a standard Na^+ bath, a separate D5W drip, and strict monitoring of $[Na^+]$, can yield a predictable response in $[Na^+]$, obviating the cumbersome and risky point of care manipulations of the dialysate formula.

FR-PO051

Case Report: Renal Squamous Cell Carcinoma of a Native Kidney After Renal Transplant Adam Daniel Jakes,[1] Poonam Jani,[2] Mini Menon,[3] Kate Adams,[4] Matthew Edey,[3] Stewart Fleming,[5] Sunil Bhandari.[3] *[1]Dept of Renal Medicine, Hammersmith Hospital, London, United Kingdom; [2]Hull York Medical School, Hull, United Kingdom; [3]Dept of Renal Medicine, Hull Royal Infirmary, Hull, United Kingdom; [4]Dept of Infection & Tropical Medicine, Castle Hill Hospital, Hull, United Kingdom; [5]St. James's Univ Hospital, Leeds, United Kingdom; [6]Cellular and Molecular Pathology, Ninewells Hospital, Dundee, United Kingdom.*

Introduction: Renal squamous cell carcinoma is a rare primary tumour of the kidney, which rapidly invades local structures and has a poor prognosis. Presentation is usually non-specific and is associated with renal stone disease and chronic infection. We present a case of squamous cell carcinoma of a native kidney in a renal transplant recipient, which has not previously been described in the literature.

Case Description: A 46-year-old white male with previous renal stones and recurrent urinary infections underwent a right nephrectomy and subsequent renal transplantation due to failure of the remaining kidney. Five years post-transplant, an abdominal ultrasound scan was performed due to recurrent urinary infections and ongoing pyuria. This was reported as normal, but he later developed a discharging sinus in his left flank. A CT scan revealed a tracking peri-nephric abscess with an associated cystic lesion of the left kidney. A left nephrectomy was performed and histological examination suggested an invasive squamous cell carcinoma of the renal pelvis. The patient later required major surgery for chronic infection, and further imaging revealed metastatic disease, resulting in the decision to manage palliatively.

Discussion: Renal transplant recipients are three-four times more likely to develop a malignancy than the general population. The patient also had renal stone disease and recurrent urinary infections; further increasing his risk of developing this condition. Abdominal ultrasound was unhelpful and only a later CT scan revealed the underlying malignancy. Given the non-specific nature of the symptoms and the poor prognosis, healthcare professionals should have a lower threshold for diagnostic imaging in these patients. This should be expedited if there is a persistent abnormality on urinalysis.

FR-PO052

A Case of Hydronephrosis due to Adenovirus Hemorrhagic Cystitis following Peripheral Blood Stem Cell Transplantation for Malignant Lymphoma Rio Noto,[1] Hideki Yokoi,[2] Akihiro Yoshimoto,[1] Motoko Yanagita.[2] *[1]Clinical Nephrology, Kobe City Medical Center General Hospital, Kobe, Hyogo, Japan; [2]Nephrology, Kyoto Univ Graduate School of Medicine, Kyoto, Japan.*

Introduction: In patients receiving stem cell transplantation (SCT), adenoviral infections are associated with mortality and morbidity. Cystitis is the most common clinical presentation of adenoviral urinary tract infection, which unusually causes inflammation of the upper urinary tract. We report a rare case of adenoviral ureteritis accompanied by hydronephrosis after autologous peripheral blood SCT.

Case Description: A 50-year-old male, who had undergone SCT 4 months ago for the treatment of nasal-type extranodal NK/T cell lymphoma and received tacrolimus as prophylaxis for graft-versus-host disease, developed fever, right back pain and dysuria. Computed tomography (CT) showed perirenal and periureteral fat heterogeneity and dilation of the right ureter. He was diagnosed as pyelonephritis caused by ureteral stones (already dropped), but antibiotics did not relieve symptoms. In addition, he exhibited a left solitary pulmonary mass, which was diagnosed as Mycobacterium avium complex (MAC) infection by lung needle biopsy. Cystoscopy and retrograde pyelography revealed hemorrhagic cystitis and right ureteral stenosis, where a catheter was placed. Viral PCR test was performed for differentiating hemorrhagic cystitis, and adenovirus was detected both in urine and in blood. Symptoms and abnormal findings on CT were improved by the placement of a catheter and the decrease of tacrolimus dosage.

Discussion: Differential diagnoses were urothelial carcinoma, recurrence of malignant lymphoma, retroperitoneal fibrosis and disseminated MAC disease. Urine cytology result was negative for malignancy. Gallium scintigraphy excluded recurrence of malignant lymphoma. Fat heterogeneity disappeared after catheter placement, suggesting that malignant lymphoma and retroperitoneal fibrosis were unlikely. MAC was not detected from blood and urine cultures. Clinical course and laboratory data indicated that inflammation of adenoviral hemorrhagic cystitis spread to the right ureter, leading to ureteral stenosis and hydronephrosis in an immunocompromised patient after SCT.

FR-PO053

Unusual Cause of Thrombocytopenia in a Dialysis Patient Rahul N. Pawar, Savneek S. Chugh, Amy R. Patel, Rudrick V. Ledesma, Rajat Lamba. *Nephrology, Westchester Medical Center, NY.*

Introduction: Hemodialysis (HD) is an invasive treatment with many adverse effects, thrombocytopenia being one of them. Most of the cases of thrombocytopenia on dialysis are related to the use of heparin creating auto-antibodies leading to heparin induced thrombocytopenia (HIT). Here we report a case of severe thrombocytopenia, which was initially thought to be due to HIT, but later revealed to be secondary to a specific dialyzer membrane.

An 81 year old female started on HD 2 months prior for progressive CKD was sent to the ED for excessive bleeding around the tunneled catheter site and a platelet (PLT) count of 27 K/uL. When she was first started on inpatient HD, she was found to be thrombocytopenic and heparin autoantibodies were weakly positive so she was started on argatroban. At the 1st outpatient HD unit, her PLT count increased to 200 K/uL. After transferring to a 2nd outpatient HD center, her PLT count, once again, dropped to 27 K/uL along with recurrent bleeding at the catheter site. This prompted investigation of heparin exposure as a cause, but it was revealed that the patient never received heparin during any of her treatments. Despite being restarted on argatroban, her PLT count remained in the 20 K/uL range. The serotonin release assay was negative. It was noted that the hospital and the 2nd outpatient unit both used a F160NR dialyzer, different from the dialyzer used in the first outpatient unit. With the suspicion of a possible dialyzer reaction, the membrane was switched from F160NR to Gambro Revaclear. Her PLTs increased to 125 K/uL in 4 days. Discharge instructions indicated that the patient must use a Revaclear dialyzer. A week later, repeat PLT count was noted to be 200 K/uL.

Discussion: This case demonstrates a rare dialyzer reaction, in which a specific dialyzer membrane leads to severe thrombocytopenia and bleeding. It has been postulated that complement activation might have a role, but this patient had normal complement levels

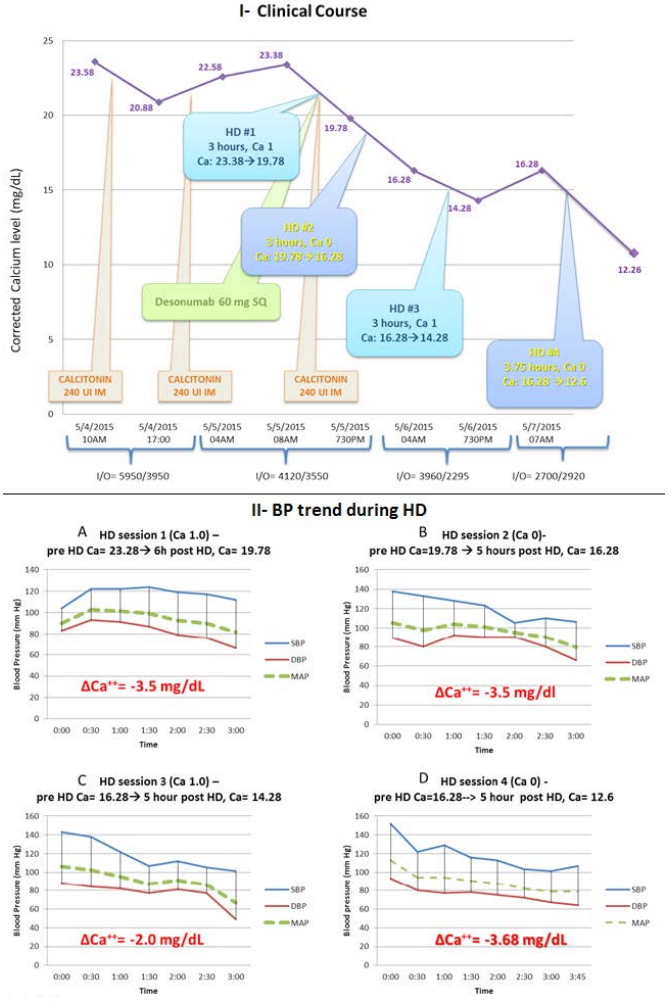
and a negative coombs test. Heparin induced reactions are still the most common etiology of thrombocytopenia in HD patients, but other causes, such as a dialyzer reaction should be considered as part of the initial differential.

FR-PO054

Calcium Free Dialysis for Hypercalcemic Crisis Karim El Hachem, Eduardo J. Zouain, Isha Gupta, Anip Bansal. *Nephrology, Mt Sinai- St Luke's Hospital, New York, NY.*

Introduction: Hypercalcemic crisis, a potentially life-threatening condition, has been defined as a calcium of 14 mg/dl or more with evidence of multi-organ dysfunction including cardiovascular, renal or CNS involvement. We describe a case of hypercalcemic crisis due to primary hyperparathyroidism treated with low calcium/calcium free dialysis.

Case Description: A 62 year old healthy man was brought by his wife to the ED for lethargy, worsening confusion over 3 days, weight loss and constipation. On exam, he was hemodynamically stable, had flat jugular veins and dry mucous membranes. His corrected calcium was 23.58 mg/dL with a creatinine of 3.60 mg/dL. He was aggressively hydrated with normal saline and received a total of 2 doses of Calcitonin 240 IU IM with no improvement in his mental status or in his calcium levels. He was then given Denosumab 60 mg SQ and underwent a 3 hour session of low calcium dialysis (Ca bath 1.0 mEq/L). During the treatment, he was given NS boluses in addition to his maintenance NS 250 cc/hr to avoid hypotension. He subsequently underwent 3 additional treatments (Treatments 2 and 4- using calcium free dialysate and Treatment 3- using Ca 1.0 mEq/L) that were well tolerated. Following his 2nd treatment, his mental status improved significantly. After his 4th treatment, his calcium was 12.26 mg/dL. His intact PTH level was 1324 pg/mL. A Sestamibi thyroid scan showed a large left parathyroid mass. The patient underwent surgical resection of a 13 gm parathyroid adenoma after which his calcium normalized to 9.8 mg/dL. His clinical course and a blood pressure trend during hemodialysis is reported below.



Discussion: Calcium free dialysis and the use of low calcium dialysate was tolerated with no hemodynamic instability. Aggressive hydration is important to maintain tolerability. It can be safely used as a bridge to definitive surgical treatment in the setting of primary hyperparathyroidism.

FR-PO055

Antineutrophil Cytoplasmic Antibody Crescentic Allograft Glomerulonephritis following Sofosbuvir Therapy Shilpa Gadde. *Nephrology, Tulane Univ, New Orleans, LA.*

Introduction: Sofosbuvir is used for the treatment of hepatitis C virus infection. We report first case of ANCA/RPGN following Sofosbuvir in a kidney transplant recipient.

Case Description: 51 yo male had a living unrelated donor kidney transplant, received alemtuzumab induction, and tacrolimus and mycophenolate maintenance. sCr was 1.4, 1 week after transplant. 12 weeks post-transplant, sCr was 2.0; renal biopsy showed ATN and tubular isometric vacuolization. Tacrolimus was replaced with cyclosporine. His sCr stabilized at 1.6. He had HCV genotype 1a and high viral load. At week 40 after transplant, he was started on ribavirin and sofosbuvir. At 12 weeks of HCV treatment, sCr was 3.7. UA with 30 protein and 131 RBCs, and PCR was 0.6. Allograft biopsy showed TMA. Therefore, sofosbuvir, ribavirin and cyclosporine were stopped. He was started on prednisone and continued on mycophenolate. His sCr was at 2.4. 70 weeks after transplant (30 weeks after initiation of sofosbuvir and ribavirin treatment), he had a sCr of 4.3 and PCR of 5. Urinalysis showed >500 of protein, 70 RBCs. Biopsy showed cellular crescents in glomeruli with pauci-immune IF. EM had normal GBM with subendothelial "fluff". p-ANCA titer was 1:320 and MPO ab >100. He was diagnosed with p-ANCA associated crescentic GN in the allograft. The patient was treated with solumedrol, cyclophosphamide and a course of plasmapheresis. He later started HD and Rituximab was added. He remains dialysis-dependent despite of our efforts in treating his RPGN.

Discussion: Renal biopsy showed 3 different pathologies. Initiallly tubular toxicity of tacrolimus. After sofosbuvir and ribavirin, he had TMA, we stopped his HCV treatment, although the concurrent cyclosporine use was implicated. 30 weeks after the initiation of sofosbuvir and ribavirin therapy he had ANCA-associated crescentic GN. Ribavirin had no reported cases of ANCA vasculitis. Sofosbuvir was approved in 2013 and we suspect it as likely cause of ANCA vasculitis. Therefore, our case represents the first case of drug-associated ANCA vasculitis in an allograft kidney. Further drug monitoring is necessary to elucidate the degree of association and possible causal effect of sofosbuvir and p-ANCA vasculitis.

FR-PO056

Malignant PEComa Post Combined Kidney and Pancreas Transplantation Rapeepat Lekkham, Mauricio Alexander Pedroza, Gitana Bradauskaite, Daranee Chewaproug. *Medicine, Nephrology, Albert Einstein Medical Center, Philadelphia, PA.*

Introduction: Perivascular epitheliod cell tumors or clear cell "sugar" tumor or PEComas is a very rare mesenchymal neoplasm. The biological behavior of such tumors can range from benign to malignant. We report the first case of primary renal malignant PEComas with lung metastasis after combined kidney and pancreas transplantation.

Case Description: The patient was a 44-year-old Hispanic female with a history of DM type I with living related kidney transplant back in 1998 and followed by a pancreas transplant in 1999 with transplant pancreatectomy and retransplant of the second pancreas in 2010. Her immunosuppressive agents were mycophenolic acid, prednisone and tacrolimus. Fifteen years post-kidney-transplant, she developed fever with chronic cough for a month. CT of the chest revealed multiple, bilateral, solid, non-cavitating pulmonary masses with mediastinal lymphadenopathy. CT of the abdomen showed right native kidney mass measured 5.8x5.8x8 cm. Right lower lobe lung biopsy showed perivascular epitheliod cell neoplasm. The PEComas of the lung are traditionally considered benign. To investigate the nature of the renal mass, the patient underwent right open radical nephrectomy. Again, the right nephrectomy pathology showed malignant PEComa, 10 cm with pure epitheliod with carcinoma-like growth pattern, involving the entire kidney. The tumor is histologically identical to the patient's lung mass and confirms that the kidney mass is the primary tumor and the lung tumor is a metastasis. The patient also found metastatic osteolytic lesions involved pelvis, proximal femurs, cervical and thoracic spines. After confirmed the diagnosis of malignant PEComas, mycophenolic acid was stopped. She was started on Temsirolimus 25 mg intravenous weekly, tacrolimus was changed to rapamycin and continue with oral prednisone. Unfortunately 3 weeks later patient became unresponsive, cardiac arrest and passed away.

Discussion: Although the majority of PEComas is recognized as benign, but in the immunocompromised patient, especially with a history of multiple solid organ transplants like in our patient, the tumor could be presented in advance and aggressive way with fatal outcomes.

FR-PO057

A Case of Post-Transplant Kaposi Sarcoma Treated with Combination Chemotherapy and mTOR Inhibitor Nadeen J. Khoury, Dina Abdelwahab, William S. Asch. *Internal Medicine/Nephrology, Yale Univ School of Medicine, New Haven, CT.*

Introduction: Kaposi sarcoma is a viral-induced malignancy caused by human herpes virus 8. Clinical presentation varies from minimal mucocutaneous disease to extensive organ involvement. We present a case of transplant-associated visceral Kaposi sarcoma without cutaneous manifestations treated with sirolimus and liposomal doxorubicin.

Case Description: A 43 y old African American male with history of ESRD s/p deceased donor kidney transplant in 2013 induced with alemtuzumab, maintained on tacrolimus, mycophenolate and prednisone was admitted with worsening shortness of breath and productive cough. His course was complicated by hypoxemic respiratory failure requiring intubation. He received broad-spectrum antibiotics initially and his anti-

proliferative was held. His exam was unremarkable except for an exophytic gingival lesion on his right mandible. His kidney function was at baseline. Imaging revealed diffuse lung and liver nodularities with bulky lymphadenopathy. An axillary lymph node biopsy was performed and was consistent with Kaposi sarcoma (HHV8+). Tacrolimus was stopped and the patient was transitioned to the mTOR inhibitor: sirolimus. He was initiated on liposomal doxorubicin after extubation with significant improvement in metastatic disease after four cycles. His renal function remained stable on sirolimus and prednisone.

Discussion: Post-transplant malignancies are common and constitute a major burden. Adjustment of immunosuppression is the mainstay of therapy in these cases. It is standard of care to switch from calcineurin inhibitors to sirolimus upon the diagnosis of Kaposi sarcoma. However, there's no literature regarding chemotherapy in transplant-associated Kaposi sarcoma. Most of the available data is from the AIDS population that we extrapolated to our patient. His bulky disease triggered us to explore aggressive therapy. Combination chemotherapy and sirolimus seem to be a good therapeutic strategy that should be considered in cases of disseminated post-transplant Kaposi sarcoma.

FR-PO058

Warfarin-Related Nephropathy in a Kidney Transplant Patient Nadeen J. Khoury,[1] Gilbert W. Moeckel,[2] Mark A. Perazella.[1] *[1]Nephrology, Yale Univ, New Haven, CT; [2]Dept of Pathology, Yale Univ, New Haven, CT.*

Introduction: Anticoagulant-related nephropathy is a new entity manifesting as AKI in the setting of excessive anticoagulation. Initial cases were related to warfarin use; however, more recently AKI is reported with direct thrombin inhibitors. We present biopsy-proven warfarin-related nephropathy (WRN) in a transplant patient on anticoagulation for atrial fibrillation with INR<2.

Case Description: A 69 y old man with hypertension, atrial fibrillation (on warfarin), T2DM and ESRD s/p living unrelated kidney transplant with baseline sCr 2.0 mg/dl (on cyclosporine, mycophenolate and prednisone) presented with nausea, vomiting and abdominal pain. Acute cholecystitis was diagnosed and percutaneous cholecystostomy drainage performed. Initial labs revealed leukocytosis and AKI on CKD with sCr: 2.7 mg/dl. INR was 1.8. Urinalysis revealed 3+blood, 2+ protein with 179 RBCs/HPF, urine sediment 1-2 RBC casts/LPF. Transplant kidney ultrasound was unremarkable. Complements were normal. Urine microscopy demonstrated persistent RBC casts and kidney biopsy was performed. Acute tubular injury with numerous occlusive RBC casts suggestive of WRN was observed. Kidney function slowly improved but sCr remained above baseline upon discharge. Warfarin was resumed due to high stroke risk.

Discussion: Our patient's presentation with AKI in the setting of acute cholecystitis raised the possibility of sepsis-induced AKI. However, the presence of microscopic hematuria and numerous RBC casts suggested a glomerular process. Biopsy suggested WRN developing in the setting of CKD and anticoagulation. Our case is somewhat unusual given the INR<2. Most cases of WRN have an INR>3. However, the patient had risk factors that have been linked to WRN including CKD, diabetes mellitus and hypertension. Interestingly, INR levels several months prior were all consistently below 2 yet the patient had 2 bleeding episodes requiring hospitalizations (GI bleed and thigh hematoma) suggesting an underlying bleeding predisposition. It is reasonable to consider WRN in cases of unexplained AKI with RBC casts in a patient with INR<3 in the presence of other risk factors and bleeding tendency.

FR-PO059

Successful Preemptive Kidney Transplantation Using Rituximab Induction in a Patient with Focal Segmental Glomerulosclerosis and Nephrotic Syndrome – Case Report Aureliusz Kolonko, Grzegorz Piecha, Andrzej Wiecek. *Dept of Nephrology, Transplantation and Internal Diseases, Medical Univ of Silesia, Katowice, Poland.*

Introduction: Focal segmental glomerulosclerosis (FSGS) recurs in 30% of patients receiving their first kidney transplant and often leads to graft loss. In the past, patients with FSGS and overt nephrotic syndrome were rarely transplanted, mostly due to the worries about its relapse. Rituximab (RTX), an anti-CD20-specific monoclonal antibody, was previously reported to be valuable option in resistant nephrotic syndrome and in relapsing FSGS after second kidney transplantation. Hereby, we present a successful first kidney transplantation of a young patient with FSGS and full-blown nephrotic syndrome, treated with RTX induction.

Case Description: The patient is a 24-year-old woman, who developed nephrotic syndrome at the age of 4. FSGS was confirmed early by renal biopsy, she was treated with cyclosporine A, mycophenolate mofetil (MMF), and steroids, with no remission. She was referred to preemptive, deceased donor kidney transplantation despite of 10 g/day proteinuria. She received induction therapy with two doses of RTX (375 mg/m^2) at day 0 and 7, followed by tacrolimus 5 mg BID, MMF 500 mg BID, and steroids therapy after transplantation. We observed immediate kidney graft function and protein-absent diuresis since 6th day post-transplant. Pre-transplant soluble urokinase plasminogen-type activator receptor (suPAR) serum concentration was 4550 pg/mL, it decreased to 2191 pg/mL at day 13th and was 2073 pg/mL at 6 months posttransplant. Steroids were tapered and discontinued at 10 months post-transplant. Twenty months after transplantation serum creatinine is 0.8 mg/dL and no proteinuria is observed.

Discussion: Successful kidney transplantation in a patient with pretransplant overt nephrotic syndrome secondary to FSGS, using rituximab as an induction therapy strongly suggest the need for larger clinical trials in such patients.

FR-PO060

Black Appearing Peritoneal Effluent Manjunath Ramaiah, Carol Motes Headley, Geeta G. Gyamlani, Adnan Naseer, Barry M. Wall. *Nephrology, Veterans Affairs Medical Center, Memphis, TN.*

Introduction: Endoscopic tattooing with India ink is a useful and safe tool for localizing small colorectal lesions.

Case Description: 60 year old man with End Stage Renal Disease due to Lupus Nephritis on Continuous Ambulatory Peritoneal Dialysis (CAPD), developed black effluent from the peritoneal dialysis drain bag following screening colonoscopy. Findings included an ulcerated tumor occupying 25% to 49% of the colon circumference. There was no evidence of bleeding and multiple forceps biopsies were taken. The tumor area was marked with tattoos using 3 injections (5 ml each) of India ink. He resumed CAPD and noticed his dialysate effluent was "black". He presented to the ER with nausea, vomiting and black colored peritoneal fluid. Examination revealed a mildly tender abdomen without rebound or guarding. Vitals were stable and he was afebrile. CT scan of abdomen revealed small amount of free intraperitoneal air consistent with his peritoneal dialysis. Peritoneal effluent cell count was elevated at 0.619 K/ul and WBC count of 5.5 K/ul. His presentation was consistent with peritonitis (cloudy dark gray/black peritoneal effluent and elevated cell count)and empiric antibiotics were initiated with vancomycin, cefepime and metronidazole. Within 48 hours the peritoneal effluent was clear (cell count down to 0.105 K/uL). The effluent culture grew Escherichia coli and Providencia Stuartii. Dialysate remained normal. At the time of partial colectomy performed one month later, dark dye was still visible on mesenteric transverse colon, but no abscess was identified.

Discussion: Complications associated with India ink tattooing include abscesses, inflammatory pseudotumor, focal peritonitis and peritoneal staining, most of which have been attributed to inadequate dilution or sterilization of the India ink. Dye spillage into the peritoneal cavity has been reported to occur at a rate between 2.4% and 13%. This occurrence has been attributed to injection technique (deep), and the possibility of transmural movement of the dye. In our patient the development of black appearing dialysate and bacterial peritonitis with gram-negative organisms is consistent with microperforation of the colon during the tattoing procedure.

FR-PO061

Sevelamer-Induced Colonic Injury – A Unique Case of Gastrointestinal Bleeding in End Stage Renal Disease Patient Nivin Haroon,[1] Unnikrishnan Ponnamma Kunjan Pillai,[2] Zeenat Yousuf Bhat.[1] *[1]Internal Medicine/ Nephrology, Wayne State Univ, Detroit, MI; [2]Internal Medicine/ Nephrology, Indiana Univ Ball Memorial Hospital, IN.*

Introduction: End stage kidney disease patients experience significant morbidity and mortality. One common complication in this population is Gastro-intestinal bleeding(GIB) and common causes of GIB are platelet-dysfunction, anticoagulation use, Angiodysplasias and malignancies. Also medications like Sodium-polystyrene-sulfonate can cause direct mucosa damage. We report a case of GIB in Hemodialysis-patient attributed to Sevelamer-induced colonic-ulceration.

Case Description: 56Y/O ESRD-Hemodialysis patient with multiple comordities including hypertension, systolic cardiac-dysfunction, Atrial-fibrillation, H/o Breast Cancer s/p mastectomy/chemo(2005),presented to the hospital with passage of bright red blood per rectum,accomapanied with syncope and shortness of breath. Her medications included Amiodarone, Aromasin, baby-Aspirin, Carvedilol, Diltiazem, Pantoprozole, Sevelamer, Cinacalcet. Her clinical examination was unremarkable(including neurologic exam)except for palor. Orthostatic vital signs not checked due to dizziness, Significant labs findings were-hemoglobin-5.7mg/dl, Serum Potassium-5.5meq/L,BUN and Serum-Creatinine 46mg/dl and 8.5mg/dl respectively and INR-1.1. CT head- no acute abormalities, Mesenteric angiogram-no source identified, Endoscopic-Gastro-duodenoscopy- normal, colonoscopy-no active bleeder, multiple diverticulosis+. Bleeding scan showed activity near the hepatic flexure. She underwent emergent right-hemicolectomy for the continued bleeding. Pathology report showed metastatic Carcinoma involving proximal Colon, Colonic-Mucosa inflamed and ulcerated,cluster of organophilic Fish scale like crystals suggestive of Sevelamer crystals were noted in colonic mucosa. Patient improved post surgery.

Discussion: There is only handful of literature on the Sevelamer colonic toxicity. This case highlight the fact that with widespread use of sevelamer in dialysis patient, physicians should be aware of this entity. Our understanding of Sevelamer-associated mucosal injury is limited and there are no known prevention strategies available.

FR-PO062

Successful Eculizumab Therapy in De Novo Atypical Hemolytic Uremic Syndrome in a Renal Transplant Recipient Adil Mohammad Hazara, Matthew Edey, Martin Chanayireh, Sunil Bhandari. *Hull and East Yorkshire Hospitals NHS Trust, Hull, United Kingdom.*

Introduction: The use of terminal complement inhibitor eculizumab has not been well described in the treatment of de novo atypical hemolytic uremic syndrome (aHUS) post renal transplantation.

Case Description: We present a 47 years old female with end-stage renal disease due to reflux nephropathy who had received a living-donor renal transplant from her sister 18 months previously. Her maintenance immunosuppression medications included tacrolimus 6mg twice daily, mycophenolate sodium 720mg (AM) and 360mg (PM), and prednisolone 5mg on alternate days. She presented with 2 day history of diarrhea, vomiting and dehydration. Admission biochemistry revealed stage III acute kidney injury with a serum creatinine of 640 µmol/l (baseline 90 µmol/l). She was anemic (Hb 90 g/l) and

required multiple blood transfusions. Her trough tacrolimus level was raised at 22 ng/l. Stool microscopy and culture was negative for shiga-toxin producing bacteria. Blood film showed red cell fragments; serum lactate dehydrogenase was raised at 752 u/l. ADAMTS-13 activity was normal. Renal biopsy was consistent with thrombotic microangiopathy. Complement genetic analyses (factors H, I, B and MCP tested) did not reveal any pathogenic mutations. Anti-factor H antibodies were negative. She was treated, first with four cycles of plasma exchange and then commenced on eculizumab at 900mg infusion weekly for first four doses and then 1200mg fortnightly. Her renal and anemia parameters rapidly normalised.

Fig 1. Changes in serum creatinine at the time of diagnosis (arrow), with plasma exchange (PEx) and following eculizumab treatment.

Discussion: Eculizumab has been used successfully in treatment of aHUS in our patient who had developed this condition de novo. Uncertainties still remain regarding the duration of treatment and long-term efficacy.

FR-PO063

Lowering of Dialysate Conductivity Stopped a Painful Sickle Cell Crisis in a ESRD Patient

Amit N. Shah, Jacques A. Durr. *Div of Nephrology, Univ of South Florida, Tampa, FL.*

Introduction: Deoxy Hg-S gelation in sickle cell disease (SCD) is highly temperature-sensitive, and causes RBC sickling that impairs capillary flow and cause painful crises (Embury SH, PMID 15280086). On O_2 loss, the rate of gelation has a lag inversely related to the 30th power of its concentration (Hofrichter J, 4531026), and is in the range of capillary transit and circulatatory times. Within limits, RBCs behave like perfect osmometers (Ponder E, 16994612). This led to claim that as RBC shrink during medullary transit Hgb-S concentrates and sickling leads to papillary necrosis and hypostenuria in SCD (Perillie PR, 13942410), Similarly, some claimed that induced hyponatremia treats SCD crisis (Rosa RE, 6999348), others did not (Charache S, 7296001).

Case Description: A 42 yo SCD ESRD patient is admitted ~ once a month for severe pain crisis that last for several days and are not relieved by oxycodone, dilaudid, nasal O_2, or IV fluids, and not due to low dry weight. Her baseline HgB is 5-6 g/dl, and P_{Na} is stable at ~ 140 mmol/l. One of us was in the dialysis unit as she had a severe crisis, and had exhausted all resources. We asked for permission to lower her dialysate Na by 5-8 mmol/l.

This abolished her pain within ~10 min. She says that this was the first time something helped.

Discussion: We wish to call our colleagues' attention to this case, as SCD patients with ESRD and painful crises are not uncommon, and since an ingenious method (Du E, Proc Natl Acad Sci USA. 2015 Feb 3; 112(5): 1422–1427) is now available that allows to study RBC sickling kinetics during a mimicked capillary transit, under controlled conditions of temperature, tonicity, O_2 tension, pH, etc. There was a strong correlation between sickling and MCHC-S concentration, and MCV. However, the slope was negative between cell velocity and cell volume ($R = -0.89$, $P < 0.001$). This method should help resolve which factor predominates during RBC swelling induced by acute hypotonicity: the desired decrease in Hg-S concentration, or undesired decrease in RBC velocity in the capillaries (low O_2 tension). Our observation should trigger controlled studies. Would decreasing the dialysate temperature also have a positive effect?

FR-PO064

Hemophagocytic Lymphohistocytosis Associated Nephrotic Syndrome Caused by Cytomegalovirus Infection in a Renal Transplant Recipient

Gaurav Agarwal,[1] Abolfazl Zarjou,[1] Todd M. Stevens,[2] Shikha Mehta.[1] *[1]Div of Nephrology, Univ of Alabama at Birmingham; [2]Dept of Pathology, Univ of Alabama at Birmingham, Birmingham, AL.*

Introduction: Hemophagocytic lymphohistocytosis (HLH) is a life threatening syndrome representing severe uncontrolled inflammatory reaction caused by hypercytokinemia and excessive immune activation. It is rare in solid organ transplantation and caries a mortality of 47%.

Case Description: 31 year old black man with end stage kidney disease who was status post deceased donor kidney transplant, received induction with alemtuzumab and was maintained on prednisone, mycophenolate mofetil and tacrolimus. He presented 4 months post-transplant with diarrhea and fever and was diagnosed with CMV disease with a viral load of 2.7 million copies/ml. He had acute kidney injury with serum creatinine (Cr) of 3.3 mg/dl. Despite 2 weeks of adequate antiviral therapy with IV ganciclovir and reduction of immunosuppression, patient continued to have high grade fever, worsening pancytopenia, AKI and developed new onset nephrotic range proteinuria of 15.5 gms/24 hrs. Kidney allograft biopsy revealed characteristic CMV inclusion bodies within glomerular endothelial cells and diffuse foot process effacement consistent with acute CMV glomerulopathy. There was no evidence of focal segmental glomerulosclerosis, thrombotic microangiopathy or rejection. He had pancytopenia, elevated ferritin level (15,605 ng/ml), transaminitis, hypertriglyceridemia, elevated LDH and D-dimer. Patient met the clinical criterion for HLH. His nephrotic syndrome was attributed to HLH associated with CMV infection. Treatment was started with anakinra 100 mcg subcutaneously daily. Patient responded to the therapy with initial decline in serum Cr to 2.4 mg/dl. At 2 months follow up, proteinuria has improved to 2.1 g/g, ferritin to 1875 ng/ml, but Cr remains elevated at 3.6 mg/dl.

Discussion: Most cases of HLH in kidney transplant recipients are triggered by CMV infection or other herpesviruses. This is a unique case of HLH and nephrotic syndrome caused by CMV infection which is likely secondary to cytokine storm and histiocyte proliferation. Treatment with anakinra could be beneficial in these patients.

FR-PO065

BK Nephropathy in Allogeneic Stem Cell Transplant Recipient without Thrombotic Microangiopathy and Graft-Versus-Host Disease: A Unique Observation

Rima N. Pai,[1] Maria del Pilar Fernandez,[2] Jai Prakash Babu Thippaiah Jadegondanahalli,[2] William F. Glass,[3] Sairah Ahmed,[4] Ala Abudayyeh.[1] *[1]Section of Nephrology, UT MD Anderson Cancer Center; [2]Nephrology and Hypertension, UT-Houston Medical School; [3]Pathology, Ut-Houston Medical School; [4]Dept of Stem Cell Transplantation, UT MD Anderson Cancer Center.*

Introduction: BK virus is emerging as an important pathogen in allogeneic stem cell transplant (SCT) recipients and more prevalent in patients of Graft versus Host Disease (GVHD) and Thrombotic microangiopathy (TMA).Due to immunosuppression, different drugs and/or drug combinations have been associated with BK nephropathy such as tacrolimus. BK virus causes chronic kidney disease, ureteral stenosis and hemorrhagic cystitis in stem cell transplant patients leading to increase mortality and long hospital stay. We present a unique case of BK nephropathy that has occurred in patient who was asymptomatic and without any co-infections, TMA, or GVHD. The patient was tapered off tacrolimus which showed improvement in the BK viral urine and serum load.

Case Description: A 31-year- old female with history of Acute Myeloid Leukemia (AML) underwent an allogeneic stem cell transplant a year ago. Patient was treated with 4 cycles of Fludarabine, IDArubicin, CYTarabine (FIA) and sorafenib regimen. Post-transplant course was complicated by GVHD of gastrointestinal tract and skin (Grade I) .Patient was maintained on tacrolimus and later tapered off .She remained asymptomatic; however, kidney function worsened with elevated creatinine at 1.8. BK Serum viral Load of 10,800 was seen. Therefore, renal biopsy was done which was consistent with BK nephritis. With limited effective therapeutic options, immunosuppression by tacrolimus was tapered off and Leflunomide was started showing a decrease in viral load and creatinine stabilizing to 1.37.

Discussion: A definitive diagnosis of BK nephritis is confirmed with a kidney biopsy. BK nephropathy is an important and often overlooked cause of chronic kidney disease in allogeneic stem cell transplant patients. This case report helps to recognize the much needed development of guidelines in detection and treatment of BKV for early intervention.

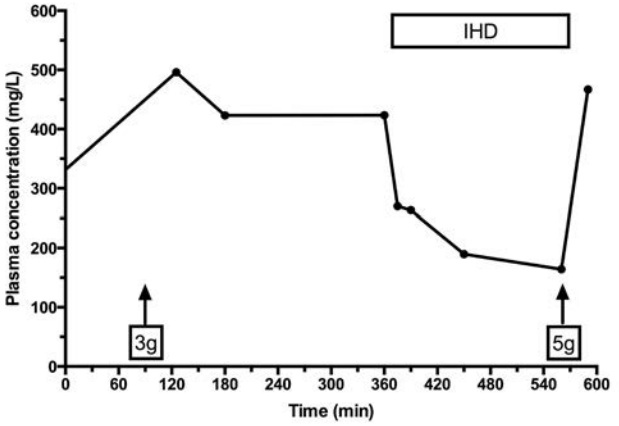
FR-PO066

Pharmacokinetics and Total Removal of Fosfomycin in a Patient with Chronic Kidney Failure Undergoing Haemodialysis

Julius Schmidt, Jan T. Kielstein. *Nephrology, Medical School Hannover, Hannover, Germany.*

Introduction: Fosfomycin shows bactericidal activity against various gram-positive, gram-negative and anaerobic pathogens, including antibiotic resistant S. aureus. However, dosing of fosfomycin in critically ill patients undergoing renal replacement is based on scarce data.

Case Description: A female chronic dialysis patient (76 years, BMI 20) was admitted to our hospital due to distinct dorsalgia. Computed tomography of the lumbar spine unveiled spondylodiscitis of the thoracic vertebrae 11/12. A punch biopsy of the affected bone region showed focal osteomyelitis. As the patient was allergic to penicillin, antibiotic therapy with clindamycin and fosfomycin sodium (8 g per day, 3 g before, 5 g after IHD session) was initiated. Maximum plasma concentration after the 3 g infusion was 496 mg/L. IHD led to a distinct reduction of fosfomycin plasma levels of 61%, with a dialyzer clearance of 75 ml/min. The total amount of fosfomycin in the total collected dialysate was 2430 mg. C_{max} after the additional administration of 5 g of fosfomycin after IHD treatment was 467 mg/L.



Discussion: Fosfomycin dosing guidelines in dialysis patients are based on publications from the 1970s and 1980s. These publications indicate a high elimination of fosfomycin during hemodialysis with a dialyzer clearance of 60 ml/min. Modern dialysis even exceeds these clearance rates, as seen in this case report (75 ml/min). The large amount of fosfomycin in the total spent dialysate indicates the need for an additional dose after dialysis therapy. About 81% of the admitted dose of fosfomycin was found in the dialysate. This suggests, that intermitted hemodialysis can decrease fosfomycin serum levels beyond ranges, where minimal inhibitory concentrations in bone spongiosa can be achieved. Therefore, fosfomycin dosage after hemodialysis seems crucial to provide sufficient drug concentrations.

FR-PO067

Tumoral Calcinosis – A Rarely Seen Complication in Dialysis Patients Lathika Raakesh, Raakesh Hassan, Christopher C. Wong, Chong Parke. *Nephrology, Univ of Southern California, Los Angeles, CA.*

Introduction: Tumoral calcinosis is characterized by solitary or multiple painless, periarticular soft-tissue calcium deposits. Tumoral calcinosis was first described by Giard and Duret in 1898 and 1899. There are two categories, a familial variant also called Teutschlaender disease and Secondary tumoral calcinosis also called Uremic tumoral calcinosis.

Case Description: Case : 50 year old female with end stage renal disease secondary to hypertension presented for evaluation of painful left shoulder mass. She has been on dialysis for 12 yrs. Has multiple painful swellings on her hands, elbow and feet. States that her shoulder mass appeared 2 years ago and has progressively increased in size. Also complained excruciating pain causing trouble carrying out her daily activities. Her surgical history significant for a right neck dissection for a neck mass, parathyroidectomy and a remote history of partial thyroidectomy. Physical examination significant for multiple soft immobile nodular swellings on the left shoulder, dorsum of left foot, right elbow and index finger. Mass on the left shoulder about 12 X 10 cm in size, immobile, tender and firm to palpation. The swelling on the right elbow non tender to palpation and the one on the right index finger involved the distal and proximal interphalangeal joints Imaging studies showed nodular swellings with significant calcification. Excision of the left shoulder mass showed exudation of a chalky white material. Pathology results were consistent with tumoral calcinosis.

Discussion: Secondary tumoral calcinosis is associated with high serum Ca X P in dilaysis patients, secondary or tertiary hyperparathyroidism, aluminium intoxication and vitamin D overload. These lesions are painless but massive swellings can cause mechanical limitation, pain and neurovascular symptoms due to compression of adjacent structures. Management includes dietary phosphate restriction, noncalcemic phosphate binders, intense dialysis with a low-calcium dialysate and calcimimetics. Surgical excision is indicated in symptomatic lesions. Parathyroidectomy recommended in patients with persistently elevated PTH levels. Tumoral calcinosis resolves after successful renal transplantation.

FR-PO068

Palate Nodule in a Hemodialysis Patient: A Long and Winding Road Until Diagnosis Precil Diego Miranda de Menezes Neves,[1] Ramaiane Aparecida Bridi,[1] Rosilene M. Elias,[1] Fábio Luiz de Menezes Montenegro,[1] Rosa M.A. Moyses.[1,2] *[1]Nephrology, Univ of São Paulo, Sao Paulo, Brazil; [2]Univ Nove de Julho-UNINOVE, Sao Paulo, Brazil.*

Introduction: Secondary hyperparathyroidism (SHPT) is a common condition in end-stage renal disease patients. We highlighted a complication that usually affects long bones, a brown tumor (BT). We report a case of a patient with SHPT, with a palate nodule, which diagnosis investigation led to a BT of maxilla.

Case Description: A 25 years-old female, previously hypertensive, who returned to hemodialysis after her kidney transplant fails. She was referred to our CKD-MBD service with a 3-month history of a progressively enlarging submucosal nodule with hard consistency on her posterior left palate. The mass was painful since the beginning, and presented progressive growth. She had no fever, neither consumptive symptoms nor palpable lymph nodes. Before coming to our service, she was referred to a maxillofacial surgery service, where a computed tomography (CT) and a biopsy were requested, as no initial suspected diagnosis was done. CT disclosed a lytic bone lesion located in alveolar process of maxilla, measuring 3.0 X 2.5cm, and damaging the superior molar roots, producing a bulging in the left maxillary sinus, nasal cavity and palate. Microscopy view evidenced the presence of multinucleated giant cells among ovoid and fusiform mesenchymal cells, large amount of hemorrhage and trabecular of lamellar bone tissue, being compatible with Brown Tumor. On review of her case, she confirmed that Sevelamer 1,6g thrice a day, but the administration of Vitamin D analogs was not possible due to hyperphosphatemia. Her serum intact Parathormone levels were 1,500pg/ml, Vitamin D 36ng/ml, ionized calcium: 4,8mg/dl, phosphorus: 6,1mg/dl. Technetium sestamibi parathyroid scan revealed hyperactive glands at both superior thyroid lobes and at the low cervical region. The patient was submitted to total parathyroydectomy, and the lesion is progressively decreasing despite of other modalities of treatment.

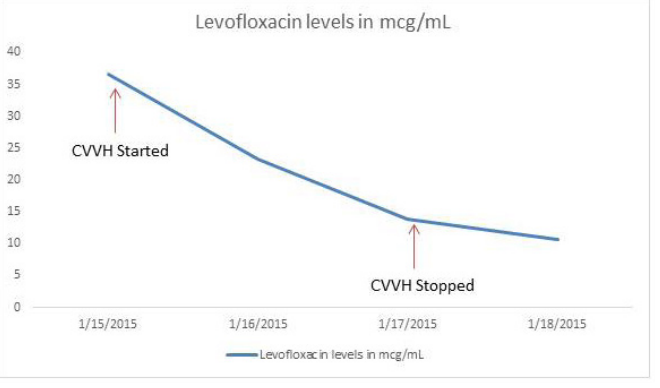
Discussion: Brown Tumors must be kept in mind as a differential diagnosis in patients with SHPT even when these lesions are located in unusual sites such as the maxilla.

FR-PO069

A Case of Levofloxacin Toxicity Treated with Continuous Veno-Venous Hemofiltration Karl Berthold Pembaur, Jennifer Thompson, Nithin Karakala. *Nephrology, MUSC, Charleston, SC.*

Introduction: Levofloxacin is a commonly prescribed antibiotic. Multiple adverse events such as central nervous system and cardiovascular toxicity have been described. Cardiovascular toxicity, namely QT prolongation when present can be particularly dangerous and requires urgent management. Aside from stopping the drug there is paucity of data regarding other urgent treatment modalities such as CRRT when potential toxicity is suspected.

Case Description: A 53 year-old African American female with a history of ESRD on peritoneal dialysis (PD) for 2 years was admitted for concern of levofloxacin toxicity. She had been admitted to an outside hospital and discharged approximately 1 week prior to presentation with a levofloxacin prescription for presumed bronchitis. During initial evaluation, she admitted to taking levofloxacin 500 mg every 8H for the preceding 5 days. She admitted she had been performing PD every other day as she was concerned she was volume depleted. After 3 days she developed nausea, vomiting, left heel pain, left hand tremor, and palpitations. She had not performed peritoneal dialysis since the onset of her symptoms. Her initial physical exam was consistent for left hand tremor and Achilles tendon tenderness. Her QTc upon initial evaluation was 534. Serum levofloxacin level was ordered and a decision was made to start continuous veno-venous hemofiltration (CVVH) to increase clearance of levofloxacin. CVVH was stopped after clinical recovery of her symptoms and normalization of QTc. Her initial levofloxacin level was 36.65 mcg/mL (normal therapeutic range 8-12 mcg/mL) and serum levels were followed for the duration of treatment every 12 hours. Below is a graphical trend of her levofloxacin levels.



Discussion: Levofloxacin toxicity represents a unique and dangerous clinical challenge. This case report shows successful and effective treatment of critical toxicity with the use of CVVH.

FR-PO070

Utility of Cystatin C in the Setting of Urinoma Lilian Saro-Nunez,[1] Amrei Aufderheide,[3] Alan Perlman.[1,2] *[1]Nephrology, Weil Cornell Medical College, NY, NY; [2]Rogosin Inst, NY, NY; [3]Technical Univ, Munich, Germany.*

Introduction: Urinomas (i.e. presence of urine outside of the urinary tract) are common in the setting of urologic/pelvic surgery. Due to the resorption of extravasated urinary constituents such as urea nitrogen and creatinine, determination of renal function is typically confusing and often leads to the false impression of acute renal failure, a situation referred to as pseudo-renal failure. We describe the superior precision of cystatin C (CysC) vs serum creatinine (SCr) in estimating renal function in a patient with urinoma.

Case Description: 79 yo M with a history of urinary retention requiring a chronic indwelling Foley catheter presented with catheter obstruction leading to bladder rupture and apparent acute renal failure. Presenting SCr was 5.8mg/dl (baseline 1.5mg/dl). A cystogram was consistent with urinoma. Treatment of the bladder leak consisted of urinary catheter replacement and he maintained urine output of > 2L/24h for several days. SCr decreased to 2.9mg/dL. A second episode of catheter obstruction subsequently occurred resulting in a significant increase of the extraperitoneal bladder leak and acute rise of creatinine to 4.6mg/dL. After placement of a larger catheter, his SCr decreased to 1.7mg/dL. During the second episode of urine leakage, simultaneous CysC levels were obtained. In contrast to

the marked variation of SCr during the onset and resolution of the urinoma, CysC levels demonstrated greater stability, increasing modestly from 1.6mg/L to 2.0mg/L during onset, followed by return to near baseline level of 1.7mg/L upon catheter replacement. CysC based eGFR values using CKD-EPI demonstrated similar relative stability, decreasing from 39 to 29mL/min during the recurrent bladder rupture, followed by an increase to 36 mL/min after recatheterization. In contrast, the eGFR decline based upon SCr-based CKD-EPI equation was notably labile declining from 20 to 11mL/min during episode then increased to 38mL/min with treatment.

Discussion: These findings imply superiority of CysC over SCr in estimating renal function in patients with urinoma and pseudo-renal failure. Discordant estimates of eGFR between CysC and SCr may be indicative of urinoma.

FR-PO071

Two Cases of Nonocclusive Mesenteric Ischemia Triggered by Intradialytic Hypotension in Patients on Maintenance Hemodialysis Norihiko Morisawa, Izumi Yamamoto, Yasuyuki Nakada, Yusuke Okabayashi, Yudo Tanno, Ichiro Ohkido, Takashi Yokoo. *Dept of Internal Medicine, Div of Nephrology and Hypertension Jikei Univ School of Medicine, Tokyo, Japan.*

Introduction: Among dialysis patients, non-occlusive mesenteric ischemia (NOMI), defined as diffuse intestinal ischemia without any organic blood vessels occlusion, is rare (1%patient-year) but has a very high mortality (56-90%). The factors associated with mortality from this disease include age, diabetes, hypertension, intradialytic hypotension, atherosclerosis, medications, etc. Early diagnosis and treatment are important for improving survival in patients with this disease.

Case Description: We here report two cases of NOMI, who were triggered by hypotension during hemodialysis. Case1: A 52-year-old man who had a low left ventricular ejection fraction after myocardial infarction showed intradialytic prolonged hypotension. On physical examination, he was hypotensive with diffuse abrupt abdominal tenderness. The laboratory investigation showed a high white blood count of 20,000. Case 2: A 88-year-old woman on maintenance hemodialysis for 5 years had hemorrhagic shock. On physical examination, she was also hypotensive with mild abdominal tenderness. The laboratory investigation showed a high white blood count of 16,000. We performed multiple detector computed tomography (MDCT) and found patent mesenteric vessels in both cases. Subsequent surgical procedure revealed the necrosis of terminal ileum in case 1 and autopsy revealed necrosis of cecum in Case 2. Finally, we diagnosed them as having NOMI. The former underwent surgical procedure and was discharged alive from the hospital but the latter was dead.

Discussion: Considering the fact that NOMI is very high mortarity disease, early diagnosis must be important. However, a diagnosis of this disease is very difficult because clinical manifestations are nonspecific. We speculated that the profile of hemodialysis is very similar to that of risk factors, therefore, we should evaluate patients who showed intradialytic hypotension with abdominal pain using multiple detector computed tomography.

FR-PO072

Aggressive Renal Cell Carcinoma in a Renal Allograft Hafiz Ali Sroya, Antonia Harford. *Nephrology, UNM, Albuquerque, NM.*

Introduction: Kidney cancers arising in renal allografts are very rare and most publications focus on cancers in native kidneys of transplant recipients. We are reporting a case of a renal cell carcinoma (RCC) arising 14 years post-transplant.

Case Description: A 46-years old man with a history of ESRD due to diabetic nephropathy underwent hemodialysis for one year prior to receiving a Living Un-Related Renal Transplant from his brother –in law, a 36 yo healthy male in 2001. The patient had immediate graft function post-transplant and was maintained on MMF, Cyclosporine and Prednisone. He underwent renal allograft biopsy in 2004 for a gradual decline in renal allograft function; this biopsy showed chronic transplant glomerulopathy. The patient had very gradual decline in renal allograft (CKD G3bA1) until Jan 2015, when he developed mild lower abdominal pain over several weeks. Imaging including abdominal US and CT revealed a 14 X 12 X 12 cm mass arising from the transplant kidney with extensive regional adenopathy involving the right common iliac vein and IVC with evidence of lung metastasis. Biopsy showed RCC, clear cell type with extensive necrosis. The venous involvement precluded surgical excision. The patient was treated with sunitinib. Several weeks later, he developed extensive bilateral pulmonary embolism treated with heparin infusion and IVC filter. Soon after the initiation of the heparin infusion he developed severe hematuria. Alcoholic embolization of the tumor was then performed. Immunosuppressive medications were tapered and the patient returned to hemodialysis.

Discussion: Characteristics of *de novo* kidney allograft RCCs are currently unknown. These tumors can be de novo or transmitted by the donor and differentiation between these 2 modes of transmission may be difficult. The most common reported histologic type of graft tumor is papillary carcinoma; clear cell type as in our case is less usual. Tumors occurring in renal transplants are usually incidental, asymptomatic, low grade and small but may be symptomatic or with vague clinical picture, high grade, aggressive and very large size as in our case. Frequent and continued surveillance imaging of both the renal allograft and native kidneys is paramount.

FR-PO073

A Case of Acute Allograft Rejection Combined with BK Virus-Associated Nephropathy Bernice Kim, Soo Ryeong Ryoo, Kyung Soo Kim. *Div of Nephrology, Dept of Internal Medicine, Dongguk Univ Ilsan Hospital, Goyang, Republic of Korea.*

Introduction: Rejection and BK virus-associated nephropathy (BKVAN) are major causes of renal allograft dysfunction. Treatment can be difficult when both conditions coexist, because potent immunosuppression is required in acute rejection and reduction of immunosuppressive agents is essential in BKVAN. We present a case of acute allograft rejection combined with BKVAN.

Case Description: A 41-year-old male with end stage renal disease because of hypertensive nephrosclerosis received a deceased donor renal transplantation. Immunosuppressive therapy was started with mycophenolate mofetil, tacrolimus, methylprednisolone, and anti-thymocyte globulin. On post-operative day (POD) 19, serum creatinine (sCr) level was 1.89 mg/dl but was elevated to 2.4 mg/dL on POD 25. Diffuse C4d staining in peritubular capillaries was noted on kidney biopsy and acute antibody-mediated rejection was diagnosed. Plasmapheresis was initiated and intravenous immunoglobulin (IVIG) and rituximab were administered. After 10 days of treatment, sCr was decreased to 1.5 mg/dL. Additional episodes of sCr elevation occurred and more sessions of plasmapheresis and IVIG administration were done, but sCr was elevated to 2.48 mg/dL on POD 67. Decoy cells were detected on urine cytology and high levels of viruria and viremia were found on polymerase chain reaction for BK virus DNA. On second kidney biopsy, findings of acute cellular rejection were noted and viral inclusion bodies in tubular epithelium were seen, suggestive of BKVAN. For treatment of BKVAN, reduction of immunosuppressive agents and administration of IVIG and leflunomide were performed. Steroid pulse therapy was done in regard of acute cellular rejecton. Despite therapy, his renal function did not recover completely and sCr was elevated to 3.2mg/dL on POD 138.

Discussion: It is difficult to treat when BKVAN and acute rejection coexist. In our patient, IVIG and leflunomide was administered and immunosuppression was reduced for BKVAN while steroid pulse therapy was performed for acute rejection, but his allograft function deteriorated. Studies are required to optimize the management of these difficult cases.

FR-PO074

Decreased Ultrafiltration in an End-Stage Renal Disease Patient with Sickle Cell Anemia: A Potential Strategy to Facilitate Kidney Transplantation Ekamol Tantisattamo,[1] Siwadon Pitukweerakul,[2] Praveen Ratanasrimetha.[3] *[1]Nephrology, Northwestern Univ; [2]Presence St. Francis Hospital, Evaston; [3]Faculty of Medicine Siriraj Hospital, Mahidol Univ, Bangkok, Thailand.*

Introduction: Sickle cell crisis (SC) leads to mortality and morbidity in sickle cell anemia(SCA) patients. Volume depletion is a common precipitating cause. Volume overload may require increasing ultrafiltration(UF). We report a case of SCA woman with acute kidney injury (AKI) who suffered from recurrent episodes of SC and acute hemolytic anemia requiring blood transfusions after hemodialysis(HD) was initiated. She became more sensitized from blood transfusions. Decreased UF reduced episodes of SC and blood transfusions.

Case Description: A 39-year-old African American woman with a longstanding history of SCA presented with a severe episode of SC complicated by AKI requiring chronic HD 5 years ago. Since starting HD, she had more episodes of SC from once a year up to every other month and required more blood transfusions. She presented for a pre-kidney transplant evaluation. Her panel reactive antibody(PRA) increased from 28 and 0 to 44 and 10, for class I and II, respectively. Upon interview, she has HD 3 times/week. Her estimated dry weight was 62 kg and intradialytic weight gain was 2-2.3 kg. She sometimes had intradialytic hypotension with BP of 90s/50s. As concern for over UF being a potential cause of volume depletion and subsequently precipitating SC, the UF was decreased. She had fewer episodes of SC and blood transfusions. She remained on the kidney transplant waiting list with this HD prescription and stable hemoglobin.

Discussion: Our patient presented with more frequent episodes of SC after HD initiation. Intradialytic hypotension indicates intravascular volume depletion which subsequently precipitating SC and hemolytic anemia. Volume management in SCA patients with ESRD is challenging and critical to avoid intravascular volume depletion. SC and acute hemolysis may be surrogate markers of over UF. Avoiding over fluid removal can prevent SC, acute hemolysis, and blood transfusion which potentially increases immunological barrier for kidney transplantation from sensitization.

FR-PO075

Recurrent Catastrophic Antiphospholipid Syndrome Treated with Eculizumab in a Peritoneal Dialysis Patient Karl W. Schoenholzer,[1] Marianna De Francesco,[1] Giulia Bedino,[1] Josua Van den Berg,[2] Silvio Pianca.[1] *[1]Nephrology and Dialysis Div, Ospedale Regionale di Lugano, Lugano, Switzerland; [2]Interventional Radiology Div, Ospedale Regionale di Lugano, Lugano, Switzerland.*

Introduction: Catastrophic Antiphospholipid Syndrome (CAPS) is a severe variant of Antiphospholipid Syndrome (APS), a systemic autoimmune disease characterized by multiple arterial and/or venous thromboses in presence of elevated titers of antiphospholipid antibodies (aPL). These autoantibodies, promote thrombosis by activating endothelial cells and platelets. We describe a case of a clinical remission in recurrent CAPS via inhibition of terminal complement with Eculizumab in a Peritoneal Dialysis (PD) patient.

Case Description: A 48-year-old man has shown recurrent CAPS characterized by diffuse arterial thromboses in the heart, kidneys, liver and lungs, confirmed by positivity of aPL. Angiography revealed a bilateral subclavian arterial thrombosis, a right iliac arterial stenosis that was treated with a stent and a left renal arterial occlusion. The patient's renal function was decreased until End Stage Renal Disease, secondary to chronic thrombotic microangiopathy, and PD therapy was started.During 14 months, our patient presented 8 recurrent episodes of disease with pulmonary involvement characterized by multiple alveolar hemorrhages in concomitance with liver necrosis (biopsy proven) and miocardial ischemia. The patient was treated with high-dose pulse corticosteroids (methylprednisolone 500 mg/day for 3 days) followed by prednisone (1 mg/Kg/day), plasma exchange (5 series with a total of 74 sessions), IV immunoglobulin (400 mg/Kg/day for 5 days), IV Rituximab (initial therapy and maintenance after 6 months), clopidogrel, aspirin and anticoagulation. Despite this standard therapy, we did not observe a sustained remission.

Discussion: After a review of the literature, we decided to administer Eculizumab, a monoclonal antibody against complement C5, that blocks and prevents the generation of the prothrombotic and proinflammatory molecules $C5_a$ and membrane attack complex $C5_b$-9. The patient has been in remission with long-term Eculizumab treatment and anticoagulation therapy, without further thrombotic events during 1 year of follow-up.

Funding: Private Foundation Support

FR-PO076

A Case Report of Post-Transplant Lymphoproliferative Disorder in Kidney Allograft Dina Abdelwahab, Nadeen J. Khoury, William S. Asch. *Div of Nephrology, Yale Univ, New Haven, CT.*

Introduction: Renal tumors are rare in transplanted kidneys. Nephrectomy is the traditional approach for renal masses. We are reporting a renal mass that was found to be post-transplant lymphoproliferative disorder in the renal allograft which we chose to biopsy instead of using traditional surgical resection.

Case Description: A 63 year old female with past medical history of renal cell carcinoma in native kidney treated by right nephrectomy, ESRD secondary to MPGN status post living donor kidney transplant presented with abdominal pain, fever and diarrhea. Ultrasound of renal allograft showed a solid appearing 4.8x5.6x4.3 cm mass in the upper pole of the transplanted kidney which was predominantly homogenous with internal vascularity; MRI revealed a 6.2x 4.9 x4.5 cm mass with solid enhancing and non-enhancing components within the transplanted kidney concerning for renal cell carcinoma . Given her previous history of RCC there was an increased concern for recurrence. Nephrectomy would have been the traditional approach but that would have meant sacrificing her allograft and initiating hemodialysis. The mass was biopsied and pathology revealed post-transplant lymphoproliferative disorder. Microscopic description showed a small kidney portion with tubules and glomeruli overrun by a dense lymphoid infiltrate. Immunohistochemical stains revealed that the large atypical cells were positive for CD20, Bcl-2, Mum-1 and CD30 but negative for BCL-6, CD10 and CD138. C-myc stained approximately 10-20% of cells and Ki-67 30-40%. In situ hybridization for Epstein Barr virus encoded RNA(EBER) was positive. Patient received 6 cycles of R-CHOP, follow-up MRI showed decrease in mass size.

Discussion: The biopsy of renal tumors for the diagnosis of small masses has not been widely adopted despite recent safety reports with advanced techniques and physicians' expertise. It has been shown to be safe and reliable and should be considered in all patients with small masses especially in transplanted kidneys to decrease the risk of unnecessary surgical intervention.

FR-PO077

Renal Replacement Therapy for Severe Hyponatremia (PNa 99mEq/L), Using 5% Dextrose Solution Infusion Method Masataka Hasegawa, Takuya Fujimaru, Yuki Heath, Fumika Taki, Miyuki Futatsuyama, Masahiko Nagahama, Yasuhiro Komatsu. *Nephrology, St. Luke's International Hospital, Tokyo, Japan.*

Introduction: Dialysis therapy for patients with severe hyponatremia poses risk of osmotic demyelination syndrome due to rapid correction of serum sodium concentration. To prevent rapid correction, low sodium dialysate or filtration fluid can be used; however, dialysate sodium concentration needs to be changed frequently as patient's serum sodium concentration rises. Instead of using low sodium dialysate, infusion of 5% dextrose solution (D5W) to the dialysis circuit after dialyser/hemofilter can adjust the serum sodium concentration of returning blood to the desired level (D5W infusion method). We successfully treated a patients with severe hyponatremia, who required dialysis therapy for severe hyperkalemia and acute kidney injury (AKI), using continuous venovenous hemofiltration (CVVH) with D5W infusion method.

Case Description: A 46 year-old women presented to the emergency department with confusion and dysarthria, due to severe hyponatremia (PNa 99mEq/L). She also had anuric AKI (creatinine 10mg/dL), heperkalemia (K 7.7mEq/L) with ECG changes (widened QRS complex), and metabolic acidosis (pH 7.0, pCO2 7.7, HCO3- 1.9mEq/L). After admission, supportive therapy including fluid resuscitation, insulin with glucose and sodium bicarbonate failed to improve hyperkalemia and AKI. Decision of dialysis therapy was made, but to avoid rapid correction of serum sodium concentration, we started CVVH using D5W infusion method. CVVH using standard filtration fluid (Na conc. 140 mEq/L) was started (QB 100mL/min, Qf 1000mL/hr), with continuous infusion of D5W (rate: 400mL/hr) to the CVVH circuit after hemofilter. By adjusting the infusion volume of D5W, sodium concentration of returning blood can be adjusted to the desired level; if the correction rate is fasterthan expected, D5W infusion rate can beincreased. After 24 hours of CVVH, her serum sodium level increased to 108mEq/l. She recovered completely from hyponatremia and AKI without any sequelae.

Discussion: CVVH using D5W infusion method is safe and effective treatment modality for patients with severe hyponatremia requiring dialysis.

FR-PO078

Performing Chronic Hemodialysis Therapy in a Patient with Total Artificial Heart Simona Pozzoli, Marco Simonini, Federico Pappalardo, Chiara Lanzani, Teresa Arcidiacono, Maria Teresa Sciarrone Alibrandi, Donatella Spotti, Paolo Manunta, Stefano Tentori, Giorgio Slaviero. *San Raffaele Scientific Inst, Italy.*

Introduction: Total Artificial Heart (TAH) is an implantable artificial heart usually used as a temporary bridge till heart transplantation. Recently a review showed that bleeding (47%), AKI requiring hemodialysis (40%) and infection (33%) are the most common complications following implantation of a TAH. Currently there are no data in the literature on long term renal function outcome and on management of ESRD related complications. We present our experience on a patient with TAH in chronic hemodialysis therapy.

Case Description: A 55 years old Caucasian man was admitted on 1st March 2012 at our Hospital ER with cardiogenic shock for AMI with rupture of the papillary muscle. His medical history included hypertension and dyslipidemia in good pharmacological control. On 9th March TAH has been implanted in order to replace the lost heart function. From the day of admission to ICU, the patient developed oliguric AKI and CRRT was started. Subsequently, the patient was switched to four times a week haemodialysis. To maintain an appropriate circulating volume for the operation of cardiac device, atrial filling pressures were maintained between 5-5.5 mmHg and 6.0-6.5 mmHg in the right and left atrium respectively. At the same time it was decided to record the change of hematocrit which the patient was subjected during the dialysis sessions (via Blood Volume Monitor (BVM)) in order to identify the critical BVM value for the functioning of the cardiac device. In this way we were able to manage the patient's dialysis sessions even once he was discharged from the hospital with the portable version of TAH.

Discussion: This patient received dialysis therapy four times a week in order to maintain a more content and constant weight till March 2015, when he underwent to combined heart and kidney transplantation. To the best of our knowledge this is the longer case of continuous dialysis therapy in a patient with total artificial heart. Total Artificial Heart is confirmed to be a valid therapeutic option for those patients waiting for heart transplantation even for long periods of time.

FR-PO079

Severe Varicella Zoster Virus Encephalitis and Retinal Necrosis in a Renal Allograft Recipient Jean Luc Franck, Srijita Mukherjee, Tina Thomas, Sharon M. Graves. *Nephrology, Emory Univ, Atlanta, GA.*

Introduction: Varicella zoster virus infection (VZV) has devastating potential complications and should be considered more often for testing by clinicians. Our case reflects the need to maintain a higher degree of suspicion for VZV by clinicians treating the immunosuppressed population.

Case Description: A 31-year-old man underwent living related renal transplantation in 2008 for chronic glomerulosclerosis. The clinical course was uneventful until January 2015, when he was diagnosed with grade IA rejection after admitting to four months of nonadherance to his prescribed immunosuppression regimen, consisting of tacrolimus, mycophenolate mofetil, and prednisone. The rejection was addressed with pulse IV steroids and resumption of his oral immunosuppressant regimen. Over the next four months, the patient sought medical attention for worsening and persistent occipital headache. Lumbar puncture was performed and suggested a viral etiology.MRI imaging was performed and revealed a large cerebellar infarct and diffuse vasculitis. Upon transfer to our institution, the patient underwent emergent neurosurgical correction of acute obstructive hydrocephalus with decompressive craniotomy. Polymerase chain reaction (PCR) testing in the cerebrospinal fluid was positive for VZV. The patient was started on acyclovir and steroids for treatment of VZV encephalitis and diffuse vasculitis. Ophthalmologic evaluation revealed retinal necrosis of the left eye, with PCR testing of the anterior chamber fluid also positive for VZV. After four weeks of acute care, the patient is currently in rehabilitation.

Discussion: Varicella Zoster Virus infection requires timely diagnosis and treatment for positive outcomes in the immunosuppressed patient. Clinical presentation can vary dramatically, from subtle rash to encephalitis. Therefore, clinicians caring for immunosuppressed patients should more routinely consider VZV as part of the differential diagnosis. Our case raises several questions including consideration for lengthening duration of VZV prophylaxis in allograft recipients and consideration for resuming VZV prophylaxis when resuming immunosuppression after extended periods of nonadherance.

FR-PO080

Hemodialysis Related Acute Thrombocytopenia During Pregnancy Nikulkumar Chaudhari, Belinda Bun Jim, Anjali Acharya. *Dept of Nephrology, Jacobi Medical Center, Bronx, NY.*

Introduction: Thrombocytopenia is not uncommon during pregnancy. It could be multifactorial and range from a mild asymptomatic condition to severe thrombocytopenia with fetal effects.

Case Description: A 29 year old woman with hypertension, CKD-IV from primary FSGS, presented at 10th week of gestation. Intermittent hemodialysis had to be initiated at 20th gestation week. Thrombocytopenia developed as described in the table below.

Relation of Hemodialysis	Platelet Count
Pre-dialysis	215,000-239,000
After 1st HD with Fresenius Optiflux Dialyzer	152,000
After 2nd HD	119,000
After 3rd HD	75,000
After 4th HD	82,000
Prior to 5th HD	48,000
Holding HD for next 3 days without any intervention	Gradually increased to 121,000
Re-started and continued HD with Exeltra Dialyzer	150,000-220,000

Patient was not on antiplatelet agents and panel for HIT antibodies was negative. Patient remained asymptomatic throughout hospitalization. Hematological evaluation ruled out all routine causes of thrombocytopenia during pregnancy such as gestational thrombocytopenia, preeclampsia, HELLP, TTP/ITP and autoimmune causes. Given the chronological correlation of platelet decrease and hemodialysis it was concluded that thrombocytopenia was likely hemodialysis related. Patient was switched from a Fresenius dialyzer optiflux to Exeltra 210 high flux dialyzer.

Discussion: Complement activation, anti-coagulation use, exposure of blood to the roller pump, dialysis tubing, micro-bubbles, and use of cellulose membrane are potential causes of dialysis related thromocytopenia. In addition, sterilization techniques have shown to have a differential impact. A major difference between the two dialyzers used was the technique of sterilization. Electron beam radiation used in the Fresenius dialyzer might affect membrane integrity or physical properties that could lead to platelet activation, aggregation, or adsorption causing thrombocytopenia, which is not seen with gamma sterilization. Thrombocytopenia is an important, if rare, complication of hemodialysis that should be considered in the differential diagnosis of thrombocytopenia in pregnancy. Dialysis associated thrombocytopenia may occur despite the use of biocompatible membranes.

FR-PO081

A Rare Case of Nephrocalcinosis Caused by Hereditary Renal Hypouricemia Three Months After Kidney Transplantation Yo Komatsuzaki,[1] Izumi Yamamoto,[1] Yasuyuki Nakada,[1] Yusuke Okabayashi,[1] Takafumi Yamakawa,[1] Akimitsu Kobayashi,[1,2] Takahito Niikura,[1,2] Yudo Tanno,[1] Ichiro Ohkido,[1] Hiroyasu Yamamoto,[1,2] Keitaro Yokoyama,[1] Takashi Yokoo.[1] *[1]Dept of Internal Medicine, Div of Nephrology and Hypertension Jikei Univ School of Medicine, Tokyo, Japan; [2]Dept of Internal Medicine, Div or Nephrology and Hypertension Atsugi City Hospital, Kanagawa, Japan.*

Introduction: Renal hypouricaemia (MIM: 220150) is a syndrome that involves a defect in urate transporter1 (URAT1) for urate reabsorption at the brush border of the proximal tubule. Nephrocalcinosis and exercise-induced acute renal failure are two major complications affecting renal function. A C889T mutation in SLC22A12 encoding URAT1 is the rare mutation in Japanese. Here we report a rare case of nephrocalcinosis caused by hereditary renal hypouricaemia three month after kidney transplantation.

Case Description: A 41-year-old man had undergone living-related kidney transplantation because of Henoch–Schönlein purpura nephritis. Three month protocol biopsy showed several localized nephrocalcinosis determined by either von kossa or de Galantha's stain (staining for urate crystals). The evaluation for nephrocalcinosis showed hypouricaemia at 1.9 mg/ dl with a high fractional excretion of uric acid at 26.8% (normal range, 6–10%). DNA direct sequencing followed by restriction fragment length polymorphism showed that both the recipient and donor were heterozygous for C889T. This mutation induce stop codon, therefore subsequent immunostaining were performed using antibody to C terminals of URAT1 and found that of immunoreactivities were partially deleted. We finally diagnosed him as having hereditary renal hypouricemia. We directed them to avoid hard exercise, drink plenty of water, and alkalize their urine for the long term renal survival.

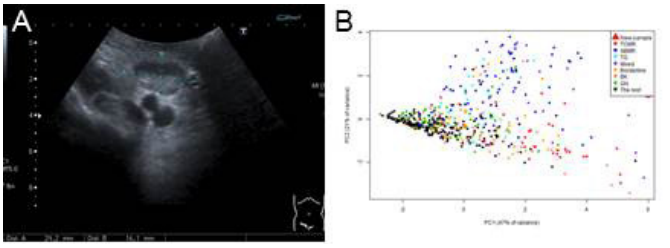
Discussion: Renal hypouricemia is a rare but have the possibilities to affect renal function. The patient did not show hypouricemia during hemodialysis because an anuric dialyzed patient with hereditary renal hypouricemia does not eliminate uric acid. Nephrocalcinosis could be a characteristic feature suspicious of renal hypouricemia. DNA direct sequencing and immunostaining help to diagnose renal hypouricemia.

FR-PO082

An Unusual Cause of Lymphadenopathy in a Renal Transplant Patient Anna Bertram,[1] Marcus Hiss,[1] Jan H. Braesen,[2] Philip F. Halloran,[3] Gunilla Einecke.[1] *[1]Nephrology and Hypertensiology, Hannover Medical School, Hannover, Germany; [2]Pathology, Hannover Medical School, Hannover, Germany; [3]Alberta Transplant Applied Genomics Centre, Univ of Alberta, Edmonton, Canada.*

Introduction: We report an uncommon cause of lymphadenopathy in a kidney transplant patient.

Case Description: The 28y old male patient presented 10y after living donor kidney transplantation with painful inguinal swelling. He had returned to dialysis 8 months ago after graft failure due to antibody-mediated rejection (AMR), which had been unsuccessfully treated with plasmapheresis, intravenous immunoglobulins, and rituximab between 10/2013-03/2014. To sustain diuresis, immunosuppression was continued with tacrolimus (trough level 7ng/mL) and 5mg prednisolone. At presentation, no local injury was detectable, and the patient denied systemic symptoms. Work-up including MRI revealed enlargement of inguinal and iliacal lymph nodes on his right side. Laboratory results showed elevated inflammatory parameters (CRP 120 mg/L; PCT 1.0 µg/L; leukocytes 13.2/nL). Tacrolimus trough level was 3.7 ng/mL, EBV-DNA in plasma was detectable at low values (3200 IU/mL). To rule out PTLD, biopsy of a 3 cm inguinal lymph node (fig.1B) was performed. However, histology showed lymphangiitis and no sign of malignancy. Because the allograft in his right Fossa iliaca was tender, we performed a biopsy, as well, although ultrasound showed signs of chronic damage. Histology revealed severe ongoing cellular and AMR. Molecular analysis of the biopsy confirmed an unusually severe form of AMR with intense inflammation (fig.1B). Due to the clinical symptoms, we performed transplant nephrectomy. Inguinal lymphadenopathy regressed rapidly, and the patient made a full recovery.



Discussion: This case illustrates that severe allograft rejection, confirmed on histopathological and molecular level, can in rare cases present with pronounced lymphadenopathy.

FR-PO083

Prevnar 13 Associated Immune Thrombocytopenic Purpura in a Renal Transplant Recipient Sagar Gupta, Daniel C. Brennan. *Renal, WashU, St. Louis, MO.*

Introduction: ACIP recommends all adults with immunocompromising conditions should receive PCV13 to prevent invasive disease caused by 13serotypes of *S.pneumoniae.* We describe here a case of ITP associated with Prevnar13 administration in a renal allograft recipient,which is the first reported case of its kind.

Case Description: A 77 year old Caucasian male presented with chief complaint of increased bruising at insulin injection sites for one week.There was no history of fever,abdominal pain,diarrhea,bleeding episodes,neurological deficits,new medications or insect bites.He had ESRD secondary to hypertension and DM2.He received a living unrelated kidney allograft 22mo ago.He was on tacrolimus,MMF,prednisone,MMF later discontinued indefinitely due to BK viremia.Family history was non-contributory. Medications included allopurinol,ASA,statin,bactrim,carvedilol,insulin glargine and aspart,prednisone and tacrolimus.He received Prevnar13 1 month ago.Exam showed normal vital signs and petechial rash in the areas of insulin injections.Lab testing resulted in Hb 11.7 & WBC 7.7(baseline) and platelet 3000 (baseline 140).BUN 31 and Cr1.50 (baseline). PT,PTT,LDH and haptoglobin were normal.No schistocytes seen.Infectious workup was negative and ADAMTS-13 activity resulted at 102%. The isolated thrombocytopenia was diagnosed as ITP and was attributed to the Prevnar 13 vaccine.He was started on pulse dose steroids and IVIG.He received 6 units platelets with counts increasing to 94000, later discharged on a prednisone taper.Weekly blood counts showed improvement to his baseline of 140,000 in 3 weeks.

Discussion: PCV13 contains the *S.pneumoniae* serotypes' capsular polysaccharide covalently linked to an immunogenic carrier protein resulting in a T cell– dependent antigen,causing a T helper-cell response.The pathogenesis of ITP involves antibody production driven by CD4-positive helper T cells reacting to platelet surface glycoproteins. Antibodies formed during viral or bacterial infections may also cross-react with normal platelet antigens (a form of molecular mimicry).Isolated cases of ITP have been reported but are relatively rare.Our case is further unique to occur in a pt on immunosuppression with a calcineurin inhibitor and corticosteroids.

FR-PO084

Placement of a Tunneled Hemodialysis Catheter in the Superior Vena Cava for Multiple Central Venous Occlusions Qinghua Yin, Tianlei Cui, Li Zhou, Ping Fu, Fang Liu. *Div of Nephrology, West China Hospital of Sichuan Univ, Chengdu, Sichuan, China.*

Introduction: A tunneled hemodialysis catheter is essential for dialysis access when the use of a functioning arteriovenous fistula is not possible. In extreme situations of multiple central venous occlusions, it remains a challenge to establish durable vascular access. Unconventional routes to the central veins are typically used. We successfully performed placement of a tunneled hemodialysis catheter in the superior vena cava (SVC) with fluoroscopic guidance in a hemodialysis patient with multiple central venous occlusions due to repeated catheterization. We report on a feasible option for hemodialysis patients with multiple central venous occlusions.

Case Description: A 49-year-old diabetic male who had been diagnosed with ERSD one year prior came to our medical center because of temporary catheter occlusion.CT venography revealed occlusion of the bilateral brachiocephalic, internal jugular and the common femoral veins, and central venography showed occlusion of the bilateral jugular and innominate veins.Guided by ultrasound, a percutaneous transhepatic route, as described by Duncan et al[9], was developed, which was applied to SVC venography and provided access for a 5F indwelling catheter, which was used to locate the distal end of

the SVC (Figure 2A). The puncture point of the skin was beneath and 0.5-1.0 cm outside of the junction of the right clavicle and head of the sternocleidomastoid, and the direction of the subcutaneous tunnel was along the distal end of the SVC, which was marked by a 5F indwelling catheter. Under fluoroscopic guidance, a micro-21G needle (Cook) was used to puncture the stump occlusion of the SVC; dark red blood was drawn when the micro-21G needle (depth approaching 15 cm) met the 5F indwelling catheter. Additionally, under anteroposterior and lateral fluoroscopic guidance, a 21G needle was punctured into the SVC (Figure 2B-C), and the tunneled hemodialysis catheter (cuff to tip 23 cm, Bard) was then exchanged with a 0.035-inch guide wire in the SVC. Chest radiography showed positioning of the hemodialysis catheter tip into the right atrium (Figure 2D). CT showed that the needle did not enter the chest.

FR-PO085

Crystal Nephropathy in a Kidney Transplant Recipient due to Excessive Consumption of Oxalate Rich Diet and Vitamin C Sudheer Muduganti,[1] Padmavathi Mali,[2] Sandesh Parajuli,[1] Maha A. Mohamed.[1] *[1]Nephrology, Univ of Wisconsin School of Medicine and Public Health, Madison, WI; [2]Internal Medicine, Marshfield Clinic, Marshfield, WI.*

Introduction: Acute kidney injury due to crystal nephropathy has been reported mainly in patients with gastrointestinal (GI) malabsorption or GI surgery. We present a rare case of crystal nephropathy in the kidney transplant recipient (KTR) without obvious GI risk factors.

Case Description: 68 year old obese female, who is living-unrelated KTR for five years, with a stable post-transplant course and a baseline serum creatinine (scr) of 1.1 mg/dl, presents to our hospital with tiredness and diarrhoea for one week. She had extensive work up in the past for chronic diarrhoea which is described as "soft stool". 24 hour fecal fat, serum amylase and serum lipase were normal. Upon presentation, scr was 7.1 mg/dl, which prompted us to perform an allograft kidney biopsy demonstrating multiple oxalate crystals deposited in the renal tubules. Reviewing her history further revealed that she was consuming 3 gm vitamin C (over the counter) daily for the last one month. Her preferred diet always consisted of oxalate rich foods (spinach). Renal functions improved in one month (scr 2mg/dl) with hydration, discontinuation of vitamin C, and changes in dietary habits. Urine studies obtained after one week of treatment showed normal urine calcium, low urine oxalate and citrate.

Discussion: Oxalate nephropathy can occur from hyperoxaluria due to ingestion of oxalate rich diet or substances which metabolize to oxalate like vitamin C or from enteric causes like malabsorption. In our patient, we ruled out enteric causes and determined oxalate nephropathy was secondary to ingestion of oxalate rich diet and excess vitamin C. Renal functions improved with modification of diet, hydration and discontinuation of offending agents. Although vitamin C and high oxalate diet are rare causes of oxalate nephropathy in patients with normal renal function, it may cause significant nephropathies in KTR. KTR patients therefore, should follow low oxalate diet and avoid excessive vitamin C even with normal renal functions to avoid development of crystal nephropathy.

FR-PO086

The Conundrum of Dry Weight in a Pregnant Dialysis Patient Sweta Carpenter, Akshatha Rao, Sandeep Aggarwal. *Nephrology, Drexel Univ.*

Introduction: The frequency of pregnancy in women of child bearing age who are on dialysis ranges from 0.3-1.5% per year. When a dialysis patient does become pregnant, nephrologists become extra vigilant to ensure a successful outcome for both mother and child. An important question that often arises is how to adjust a patient's dry weight as pregnancy progresses.

Case Description: We present a case of a 23 year old pregnant dialysis patient who was admitted to the hospital with shortness of breath at 26 weeks gestation. She had a past medical history of a miscarriage, hypertension, and a failed deceased donor renal transplant. At her outpatient dialysis unit, she was being dialyzed 6 times per week. Her dry weight was increased by 1.5 kg during the first trimester and during the second trimester by 1 pound a week to account for normal pregnancy weight gain. On this admission, her weight was 113.5 kg and her estimated dry weight was 114 kg. Her vital signs on admission revealed that she was mildly hypertensive with a blood pressure of 150/94 and her oxygen saturation was 90% on room air. After other etiologies were excluded, it was determined that the patient's hypertension and hypoxia were due to volume overload despite the patient being below her expected dry weight. A fetal monitor was placed on the patient and she was dialyzed for three consecutive days with a net ultrafiltration of 7 liters. There were no signs of fetal distress during volume removal on the monitor. A uterine artery doppler was also performed and showed no signs of hypoperfusion to the fetus during dialysis. Subsequently, the patient's shortness of breath and hypertension resolved. Upon discharge, her new dry weight was 108 kg, which was 6 kg below her expected dry weight. The patient delivered a baby weighing 5.4 lbs at 37 weeks with Apgar scores of 8 and 9 at 1 and 5 minutes, respectively.

Discussion: In a pregnant dialysis patient, it is difficult to distinguish between normal pregnancy weight gain and extra fluid. A fetal monitor and uterine artery doppler during dialysis are useful tools that nephrologists can employ to titrate ultrafiltration goals. Better volume management in turn could avoid pre-term delivery.

FR-PO087

A Rare Cause of AKI in a Renal Transplant Recipient Ronald Brian Vigo,[1] Sandra Barrow,[1] Lillian W. Gaber,[2] Wadi N. Suki.[1] *[1]Nephrology, Houston Methodist Hospital, Houston, TX; [2]Pathology, Houston Methodist Hospital, Houston, TX.*

Case Description: We present a 66 year-old African American woman who underwent pre-emptive living related donor kidney transplant for ESRD secondary to DMII and hypertension. She had immediate graft function and was discharged on the fourth post-operative day with Na 136 mEq/L, K 3.5 mEq/L, Cl 102 mEq/L, total CO_2 19 mEq/L, creatinine 1.3mg/dL and urine pH 7.0. Baseline renal biopsy was normal. Her medications on discharge included Prograf, Cellcept, Prednisone, Bactrim, Valcyte and sodium bicarbonate. She presented 10 days later with complaints of nausea, and vomiting as many as 10 times. Serum chemistries revealed the following: Na 136 mEq/L, K 5.0 mEq/L, Cl 95 mEq/L, and total CO_2 20 mEq/L, consistent with a high-anion gap metabolic acidosis (AG 21). Serum creatinine was 1.3 mg/dL and urinalysis revealed a urine pH of 7.5, pyuria and bacteriuria. Urine culture grew E. Faecalis and renal transplant ultrasound was normal. She was started on IV antibiotics and IV fluids, including sodium bicarbonate. The following day, her chemistries revealed her anion gap metabolic acidosis had resolved, with total CO_2 rising to 27 mEq/L. However, serum creatinine increased to 1.8 mg/dL, and continued to rise further despite treatment. A renal allograft biopsy was performed. Microscopic examination of the biopsy revealed widespread nephrocalcinosis with calcium-phosphate deposition. PTH at the time was 255 pg/mL, Ca 8.5 mg/dL, iP 4.1 mg/dL and fractional excretion (FE) of Ca 0.15%, FEiP 29%, and urine anion gap was 29.

Discussion: We propose that our patient had developed post-transplant RTA, given the presence of non-anion gap metabolic acidosis, low K, and urine pH of 7.0 in the immediate post-transplant period. Positive urine anion gap is suggestive of decreased ammonium excretion (although it should be confirmed with measurement of the urine osmolal gap and urinary P_{CO2}). The combination of high urine pH, as a consequence of bicarbonate administration and decreased bicarbonate reabsorption, in conjunction with hyperparathyroidism and consequent increase phosphate excretion, provided the perfect medium for calcium phosphate precipitation.

FR-PO088

A Rare Case of Rabbit Anti-Thymocyte Globulin Induced Disseminated Intravascular Coagulation Vasanthi Balaraman,[1,2] Anup Patel.[1] *[1]Dept of Renal Transplant, Saint Barnabas Medical Center, Livingston, NJ; [2]Dept of Nephrology, Newark Beth Israel Medical Center, Newark, NJ.*

Introduction: Rabbit anti-thymocyte globulin (RATG) is a purified polyclonal immunoglobulin used for induction therapy in renal transplantation. Adverse effects include cytokine release syndrome, leukopenia, thrombocytopenia and serum sickness. We report a rare case of renal transplant recipient who developed severe coagulopathy and post-operative bleeding in whom RATG was used for induction.

Case Description: A 61 year old female with end stage renal disease received a deceased donor renal transplant. RATG (2 mg/kg) was initiated intraoperatively. Over the ensuing 2 hours, the patient became hemodynamically unstable with excessive bloody output from the surgical site drain. Exploration of the renal transplant revealed diffuse oozing from surrounding tissues but no bleeding from the arterial or venous anastomosis. Labs revealed an elevated prothrombin time of 27.0 sec, thrombin time of 36.4 sec, INR of 2.5 and d-dimer greater than 5250 ng/ml, reduced fibrinogen level of 135 mg/dl and platelet count of 66000/cmm. The RATG infusion was stopped. Multiple units of packed red blood cells, platelets, fresh frozen plasma and cryoprecipitate were transfused. There was persistent bloody output. A reexploration revealed persistent diffuse oozing which required packing of the transplant bed. On postoperative day 4, the patient's condition improved.

Discussion: We suspect Disseminated Intravascular Coagulation(DIC) may be secondary to RATG in our case. The donor biopsy showed no evidence of DIC. Other causes including calcineurin inhibitors, hyperacute rejection and sepsis were ruled out. Only a few case reports of RATG induced coagulopathy exist in the literature. Weber et al reported 12 hematopoietic stem cell transplant patients having coagulopathy after using RATG therapy. These cases had elevated D-dimer, tissue factor, thrombin-antithrombin III complex, and thrombomodulin, but had no bleeding, thromboembolic or vaso-occlusive complications. We contemplate that DIC is a rare but potential life threatening complication of RATG induction and awareness of this potential complication is important.

FR-PO089

A Page Transplant Kidney Supreet Sethi, Shalini Bumb, Scott Leonard Sanoff. *Div of Nephrology, Dept of Internal Medicine, Duke Univ Health System, Durham, NC.*

Introduction: Page kidney occurs by extrinsic compression of the renal parenchyma from a hematoma or a mass, leading to activation of the renin-angiotensin-aldosterone system and resulting in systemic hypertension.

Case Description: A young-adult male,with ESRD of uncertain etiology underwent living related kidney transplantation 3-months prior to presentation. His post-transplant serum creatinine (SCr) stabilized around 1.3-1.5mg/dl. He was maintained on a 3 drug immunosuppressive regimen including tacrolimus, prednisone and myfortic. The patient presented to the hospital with pain over allograft site and low grade fever.He reported an altercation with a family member without clear direct trauma to his right lower quadrant graft, but admitted to blunt trauma to his right flank region in a shoving match.Patient was hypertensive with blood pressures in the 170-180/100-110 mm Hg range. Labs revealed a SCr of 4.1mg/dl, potassium of 5.7mmol/L, hemoglobin of 10.8g/dl from a baseline of 12g/

dl, and WBC of 15,000/uL. Urinalysis was bland.The patient was given a dose of solumedrol 500mg due to concerns for rejection.US of the transplant kidney showed a 2.2 x 10.5 x 4.1cm subcapsular fluid collection exerting a mass effect on the transplanted kidney, concerning for sub-capsular hematoma. The main renal artery and vein were patent, but the resistive indices were elevated within the arcuate renal arteries.Cross-sectional imaging of the abdomen confirmed a moderate sized renal transplant subcapsular/perinephric hematoma. The patient was managed conservatively and by hospital day 3, the renal function started improving. The patient was discharged with a SCr of 2.1mg/dl on hospital day 4 on his home regimen of amlodipine and labetalol.Most recently his SCr was 1.4mg/dl.

Discussion: The clinical syndrome of Page kidney in a kidney allograft due to subcapsular/perinephric hematoma following trauma or biopsy is characterized by acute hypertension with a concomitant acute decrease in kidney function. Our cases illustrates that this syndrome may occur without a history of direct trauma to the kidney, and that despite severe acute kidney injury, can be managed conservatively in some cases, with a good long term outcome.

FR-PO090

Black Colored Dialysate: A Rare Complication of Peritoneal Dialysis due to Cholecystitis Yi Li,[1] Basmah A. Abdalla,[2] Pang-Yen Fan.[2] *[1]Dept of Internal Medicine, Univ of Massachusetts Medical School; [2]Dept of Nephrology, Univ of Massachusetts Medical School.*

Introduction: We report a rare complication of black colored dialysate in a patient with ESRD on peritoneal dialysis (PD) with acute cholecystitis.

Case Description: A 73 year old man was undergoing peritoneal dialysis for ESRD secondary to obstructive uropathy. He presented with black discoloration of his PD effluent, preceded by persistent abdominal pain and fever. Exam was notable for abdominal tenderness and a clean PD catheter exit site. Peritoneal fluid analysis was consistent with peritonitis. Contrast CT showed a distended indistinct gallbladder with punctate stones and an ill-defined wall. No biliary obstruction or dilatation identified. There was no evidence of pancreatitis and serum lipase level was 12. Subsequent HIDA scan was consistent with acute cholecystitis. A total bilirubin from PD effluent was 14.6mg/dL and serum bilirubin was only 0.8mg/dL. Both blood cultures and PD fluid cultures were negative. He received empiric antibiotics and a percutaneous cholecystostomy tube was placed and similar turbid dark fluid was aspirated from his gallbladder.

Discussion: Dark colored dialysate has been reported in hemorrhagic and non-hemorrhagic pancreatitis. Acute bile leak or choleperitoneum is a recognized complication of cholecystectomy due to extrahepatic bile duct rupture or due to gall bladder rupture in patients without ESRD. There are few reports of biliary peritonitis due to intrahepatic bile duct rupture spontaneously and in the setting of cholelithiasis. An ascitic fluid bilirubin level of > 6mg/dL with an ascitic fluid/serum bilirubin ratio of >1.0 has been shown to correlate with choleperitoneum. The black colored PD effluent in our patient represented a biliary leak likely from increased permeability of the gallbladder wall or microperforation in the setting of non-perforated cholecystitis or from an unidentified intrahepatic bile duct rupture. In conclusion black colored PD effluent should prompt investigation for gall bladder disease and/or pancreatitis. Peritoneal fluid and serum bilirubin levels and lipase levels can aid in making a diagnosis.

FR-PO091

NK Cell Lymphoproliferative Disorder(PTLD) Associated with Pure Red Cell Aplasia in a Renal Transplant Recipient Treated with ATG – A Case Report and Literature Review Daniel Taiwo Adeneye, Amarpali Brar, Fasika M. Tedla, Nabil Sumrani, Devon John. *Nephrology, Suny Downstate Medical Center, Brooklyn, NY.*

Introduction: PRCA can be idiopathic or secondary to parvovirus infection,SLE,thymoma or lymphoma.PTLD are lymphoid proliferations that develop following immunosuppression for solid organ transplantation.While they are predominantly B cell PTLD, few NK/T cell PTLD have been published. Secondary PRCA may resolve with treatment of the underlying disorder while PRCA occurring in the setting of Nk/T cell PTLD (due to T cell inhibition of marrow erythroid cells) are treated like idiopathic PRCA as immunologically mediated disease.This is the first published report of PRCA associated with NK cell PTLD in a 41yr old renal transplant recipient.

Case Description: This is the first published report of PRCA associated with NK cell PTLD in a 41 year old renal transplant recipient.

A 41year old woman with ESRD from lupus nephritis,received living related renal transplant 9 years ago; admitted with hemoglobin of 5.6 g/dl with normal WBC count and platelet count. Patient had well-functioning allograft with serum Cr of 1.5.There was no evidence of joint swelling , rash, or alopecia. No proteinuria, RBC, WBC or cast on urine analysis. Serum Protein was 4.9 g/dl , Albumin 2.7 g/dl. LDH, haptoglobin, DS DNA,ANA,C3,C4,hepatitis B,C, HIV,Parvo virus PCR, EB PCR, free kappa/Lamda were normal. MCV was 95.9 fL. Peripheral smear showed many normal lymphocytes with normal count. Bone marrow biopsy showed normal lymphocyte population, many macrophages but absence of erythroid precursors. Flow cytometry revealed increased NK 56(-) ,CD3 - ,CD8+ cells. Renal allograft Ultrasound, CT Chest and CT abdomen were normal. This patient had her last epogen in 2003 and anti- EPO antibody induced PRCA though possible is very unlikely. Patient received 2 units of packed red cells and Anti-Thymocyte globulin (ATG) daily for 5days. She was continued on tacrolimus with stable hemoglobin with no further need for transfusion.

Discussion: We present a case of PRCA in a renal transplant recipient due to NK cell lympho proliferative disorder which was successfully treated with ATG .

FR-PO092

New-Onset Diabetes After Transplantation in a Pediatric Patient with Congenital Anomalies of the Kidney and Urinary Tract: The Role of Hepatocyte Nuclear Factor 1β Naoto Kaneko,[1] Naoya Morisada,[2] Keiichi Takizawa,[1] Tomoo Yabuuchi,[1] Hirotaka Hama,[1] Norimasa Tada,[1] Eiji Nakano,[1] Shoichiro Kanda,[1] Kiyonobu Ishizuka,[1] Hiroko Chikamoto,[1] Yuko Akioka,[1] Kazumoto Iijima,[2] Motoshi Hattori.[1] *[1]Dept of Pediatric Nephrology, Tokyo Women's Medical Univ, Tokyo, Japan; [2]Dept of Pediatrics, Kobe Univ Graduate School of Medicine, Kobe, Japan.*

Introduction: Congenital anomalies of the kidney and urinary tract (CAKUT) are the most frequent cause of end-stage renal disease (ESRD) in children. New-onset diabetes after transplantation (NODAT) is one of the major complications following kidney transplantation (KTx). Mutations of hepatocyte nuclear factor 1β (HNF1B), a transcriptional factor involved in the development and maintenance of several organs, cause a multi-system disorder, including CAKUT, diabetes, liver dysfunction. We report a pediatric patient with renal hypodysplasia carrying a novel mutation of *HNF1B* who developed NODAT and liver dysfunction.

Case Description: The patient was a 14-year-old girl. She was diagnosed with bilateral hypodysplastic kidney in the newborn period. At the age of 3 years, she received living-related KTx from her mother preemptively. At the age of 4 years, a steroid pulse for acute rejection resulted in development of diabetes mellitus (NODAT). At the age of 13 years, she complained of acute right flank pain and fever. Laboratory data showed elevated transaminase levels and computed tomography showed malformation of the bile duct. The causes of NODAT were initially thought to be steroid and tacrolimus. However, based on her clinical features, including CAKUT, NODAT, and liver dysfunction, screening for a mutation of *HNF1B* (approved by the central ethics board of Tokyo Women's Medical University and Kobe University) was performed. Direct sequencing identified a novel splicing mutation of HNF1B, c.344+2T>C.

Discussion: CAKUT is the leading cause of ESRD in children and HNF1B is the most frequently mutated gene of CAKUT. Therefore, the contribution of HNF1B mutations to development of NODAT appears to be large in the field of pediatric KTx. An oral glucose tolerance test and screening for HNF1B mutations may be advisable before KTx in pediatric CAKUT patients.

FR-PO093

Acute Kidney Injury from Biopsy Proven Oxalate Nephropathy in a Combined Kidney and Lung Transplant Recipient Minesh Rajpal, Reejis Stephen, Brian R. Stephany. *Cleveland Clinic, Cleveland.*

Introduction: Acute oxalate nephropathy (AON) is a rare, but well reported cause of acute kidney injury (AKI) in patients with cystic fibrosis (CF) after lung transplant. We report the only known case of late AON of a transplanted kidney in a combined kidney and lung transplant patient without CF after undergoing medical and surgical management of infective endocarditis.

Case Description: A 62 year old Caucasian male with a remote history of Hodgkin's disease complicated by radiation-induced pulmonary fibrosis and aortic stenosis underwent a simultaneous double lung transplant and bioprosthetic aortic valve replacement (AVR) in February 2013. His post operative course was complicated by recurrent bronchopneumonias secondary to MSSA requiring prolonged oxacillin as well as ESRD secondary to presumed unrecovered acute tubular necrosis (ATN).The patient subsequently underwent a successful living unrelated kidney transplant from his wife in October 2014 with baseline creatinine of 1.4mg/dl. Unfortunately, he developed E. faecalis bacteremia secondary to urosepsis and subsequent finding of multivalvular endocarditis with superior vena cava involvement. This was treated with a prolonged antibiotic course, but recurrent admissions thereafter for CHF and cardiorenal AKI necessitated a redo AVR along with mitral valve replacement and tricuspid valve repair, "Commando Procedure" on 3-9-2015. Immediate post-operative AKI occurred and was thought due to ATN given the presence of muddy brown casts on sediment exam along with hemodynamic instability requiring temporary intra- and post-operative vasopressor support. Anuric AKI persisted for four weeks leading to a surveillance kidney biopsy to investigate for superimposed rejection. Notable histologic findings were tubular injury consistent with ATN, but more prominent was that of extensive calcium oxalate deposits consistent with AON.

Discussion: In summary we report the first known case of AKI due to AON in a lung and renal transplant recipient after infective endocarditis requiring prolonged antibiotics and the Commando heart procedure. Though the clinical presentation mimics ATN it is important for clinicians to include AON in the differential diagnosis.

FR-PO094

Pax2 and PTIP Regulate AVPR2 Expression in the Inner Medulla Sanjeevkumar R. Patel, Saji Abraham. *Internal Medicine, Univ of Michigan, Ann Arbor, MI.*

Background: In mammals, Pax genes encode developmental regulatory proteins that specify cell lineages and tissues in metazoans and Pax2 is essential for kidney development. Upon binding to DNA through the conserved paired-domain, Pax proteins can recruit both activating and repressing complexes that imprint distinct patterns of histone methylation associated with either gene activation or silencing. Expression of Pax2 persists in the medulla of the adult kidney, where it is proposed to prevent apoptosis in response to increased osmolality. Deletion of the Pax2 interacting protein PTIP in the inner medulla of

mice results in a concentrating defect in part related to a reduction of AVPR2 expression. As Pax proteins interact with PTIP, and Pax2 expression persists in the inner medulla, we hypothesized that Pax2 and PTIP are required for AVPR2 expression.

Methods: In IMCD-3 cells with control, Pax2 or PTIP deletion, we determined Pax2 and AVPR2 expression at the mRNA and protein level in response to normal and elevated osmolality. By ChIP analysis, we identified sites of Pax2 and PTIP enrichment on the AVPR2 promoter and determined changes in histone modifications, PolII occupancy in both IMCD cells and in murine medullary tissue.

Results: Pax2 mRNA peaks 8 hours after an increase in osmolality, Pax2 protein peaks at 12 hours, and AVPR2 mRNA after 20 hours. Pax2, PTIP and the HMT activation complex localize to a 100 bp fragment of the AVPR2 promoter, resulting in increases in activation marks, recruitment of PolII to this locus and an increase in gene expression in both cell lines and murine tissue. We identify the minimal promoter that Pax2 binds to and drives expression of the AVPR2 locus. Deletion of this 100 bp region of DNA results in lack of gene expression in the absence and presence of Pax2. Deletion of PTIP results in loss of gene expression even though Pax2 localizes to the promoter region, as histone activation marks are not increased and PolII is not recruited to this locus.

Conclusions: Thus, Pax2 and PTIP both regulate the expression of AVPR2 in the murine inner medulla and in cells derived from this tissue. Pax2 provides the locus specificity for PTIP recruitment of the HMT activating complex and gene expression.

Adenine Downregulates NKCC2 and AQP2 in the Rat Kidney and Causes Early Nephrogenic Diabetes Insipidus Hassane Amlal, Rose P. Webster, Ingrid Fernandes dos Santos. *Internal Medicine, Univ of Cincinnati, Cincinnati, OH.*

Background: Long-term feeding of adenine is extensively used to develop animal models of chronic renal failure with metabolic features resembling those observed in humans. However, the mechanisms by which adenine induces renal failure are poorly understood.

Methods: In this study, we examined the early effects of adenine (ADN) feeding on water metabolism and renal function in rats placed in metabolic cages. Rats were fed control diet or diet supplemented with 0.25% or 0.50% ADN, or 0.50% adenosine ad libitum with free access to dH_2O, and monitored daily for food intake, water balance and urine osmolality, and euthanized for blood an kidney collections after 7 days.

Results: ADN-treated rats exhibited a sharp polyuria and polydipsia and decreased urine osmolality as early as 3 days, and the magnitude of these effects is dose-dependent. Further, ADN caused a significant reduction in food intake and body weight at 0.50% but not at 0.25%. None of these physiologic parameters was altered by adenosine treatment. dDAVP treatment induced a significant increase in urine osmolality in control but not in ADN-treated rats. Immunoblotting experiments demonstrated a sharp reduction in AQP2/actin proteins ratio in the cortex (-75%), Outer medulla (-65%) and inner medulla (-80%) of kidneys of ADN-treated vs. control animals. The results also demonstrated that the abundance of NKCC2/actin proteins ratio was reduced to zero in the kidney outer medulla of ADN-treated vs. control rats. Blood chemistry of ADN-treated rats was normal except for a significant 3.8-fold increase in BUN, as compared to control rats. When rats were fed adenine diet supplemented with 7% NaCl, their BUN was corrected to normal level, but still exhibited a significant reduction in urine osmolality.

Conclusions: In conclusion, adenine acts on renal tubules as a signaling molecule and causes nephrogenic diabetes insipidus, likely by directly downregulating NKCC2 and AQP2 in the kidney. The combination of renal fluid loss and decreased food intake likely plays an important role in the development of early acute renal injury that progresses to chronic kidney disease in long-term periods of adenine treatment.

FR-PO096

AMPK Activation Increases Urine Concentrating Ability in a Rat Model of Congenital Nephrogenic Diabetes Insipidus Orhan Efe, Huiwen Ren, Lauren M. Larocque, Janet D. Klein, Jeff M. Sands. *Medicine, Renal Div, Emory Univ School of Medicine, Atlanta, GA.*

Background: The urine concentration mechanism is primarily regulated by vasopressin which activates NKCC2 and urea transporters to generate a hypertonic interstitium that promotes water reabsorption through AQP2. Congenital nephrogenic diabetes insipitus (NDI) is caused by vasopressin V2 receptor (V2R) mutations. Present treatment options are limited. We studied AMPK as an alternate pathway to stimulate transporters involved in urine concentration.

Methods: Tolvaptan (10 mg/kg/day), a selective V2R antagonist, was given by oral gavage to rats for 4 days,+/- metformin (800 mg/kg/day). Urine volume and osmolality were measured daily. Following sacrifice, kidneys were dissected into inner medullary tip, base and outer medulla, and UT-A1, AQP2, and NKCC2 were analyzed by Western blot. Immunohistology was used to localize AQP2, pAQP2, pAMPK, and NKCC2.

Results: Tolvaptan was used to produce a rat model of NDI. Urine volumes of tolvaptan-treated rats increased 105% within 24 h. Metformin was used to stimulate AMPK as a candidate NDI treatment. Metformin decreased urine volume by 110% back to control levels in 3 days. Urine osmolality in control rats (mean: 2107 mOsM) was significantly decreased by tolvaptan (mean: 1303 mOsM, $p<0.05$) and restored to near control levels by metformin (mean: 2335 mOsM, $p<0.05$). Metformin increased protein abundance of IM tip UT-A1 by 61% in tolvaptan treated rats ($p<0.05$). IM tip AQP2 was also increased 44% but failed to reach statistical significance ($p=0.057$). In contrast, IM base UT-A1 and AQP2 protein levels were not changed with AMPK stimulation. Outer medullary NKCC2 abundance was increased 117% with AMPK stimulation in control rats ($p=0.004$) but not in V2R-blocked rats. Immunohistochemistry showed that AQP2 and p-AQP2-Ser256 appear to be localized on the cell membrane with acute and chronic AMPK stimulation, both in control and V2R-blocked rats.

Conclusions: AMPK stimulation in V2R-blocked rats is able to reduce the urine concentrating defect by increasing UT-A1 and AQP2. These results indicate that specific AMPK pathway activators might provide a promising treatment for congenital NDI.

HYAL2 Disruption Leads to Impaired Urinary Dilution Capacity in Mice Vanessa Colombaro,[1] Inès Jadot,[1] Anne-Emilie Decleves,[1,2] Isabelle Habsch,[1] Bruno Flamion,[1] Nathalie Caron.[1] *[1]Molecular Physiology Research Unit-URPHyM, Univ of Namur, Namur, Belgium; [2]Laboratory of Experimental Nephrology, Univ Libre de Bruxelles, Bruxelles, Belgium.*

Background: Hyaluronan (HA) is a glycosaminoglycan present in high amount in the inner medulla of the kidney but almost absent in the cortex. Hyaluronidase 2 (HYAL2) is one of the two major hyaluronidases acting synergistically to degrade HA. Recently, it has been shown that *Hyal2*$^{-/-}$ mice display HA accumulation in the kidney. Renal HA content is known to vary with hydration status. Therefore, our study was set up to characterize the renal excretory capacities and renal water handling in response to water deprivation and acute water loading in *Hyal2*$^{-/-}$ mice.

Methods: Experiments were performed in *Hyal2*$^{-/-}$ mice and in their wild-type controls. After appropriate acclimation, water deprivation was performed during 24 hours. The capacity to excrete a water load was tested on an hourly basis for the next 6h after i.p. injection of 2 ml of sterile water. Diuresis and urinary osmolarity were measured. HA concentration was measured in the kidney tissue and its distribution through the different kidney zones was examined using immunohistochemistry. Expressions of aquaporin 2 (AQP2) and p-Ser 256 AQP2 were also assessed using immunohistochemistry and immunobloting.

Results: After water deprivation, *Hyal2*$^{-/-}$ mice showed the same ability to concentrate urine as the *Hyal2*$^{+/+}$mice. On the other hand, *Hyal2*$^{-/-}$ mice had a significant delay in the diuretic response induced by an acute water loading. As for renal HA content, *Hyal2*$^{-/-}$ mice maintained higher HA concentration than *Hyal2*$^{+/+}$mice after both water deprivation and acute water loading. HA was present around tubules in all kidney zones including cortex. Plasma AVP levels, kidney AQP2 and kidney p-Ser AQP2 expressions were increased after water deprivation and decreased after acute water loading to the same extent in KO and WT mice.

Conclusions: HYAL2 deficiency and/or increased renal interstitial HA delays the diuretic response to acute water loading without any increase in plasma AVP or collecting duct AQP2 expression.

FR-PO098

Phosphorylated AQP2 and NR3a Reduce NSAID-Induced Urine Concentration Defect Huiwen Ren,[1,2] Baoxue Yang,[2] Patrick A. Molina,[1] Jeff M. Sands,[1] Janet D. Klein.[1] *[1]Medicine, Renal Div, Emory Univ School of Medicine, Atlanta, GA; [2]Pharmacology, School of Basic Medical Sciences, Peking Univ, Beijing, China.*

Background: Vasopressin increases urine concentration through activation of aquaporin-2 (AQP2) in the collecting duct. Nonsteroidal anti-inflammatory drugs (NSAIDs) block PGE2 synthesis, and may suppress AQP2, producing a urine concentrating defect. NR3a can regulate cellular Ca^{2+} entry and may influence AQP2 trafficking.

Methods: We treated rats with a nonselective NSAID, ibuprofen, and a COX-2-selective NSAID, meloxicam, daily for 2 weeks. We assessed urine osmolality and volume, and monitored p-AQPs by Western blotting. NR3a$^{-/-}$ mice were used to examine if NR3a has a protective role.

Results: Both NSAIDs significantly increased urine output and decreased urine osmolality by days 7 - 14. Meloxicam significantly reduced total AQP2 in inner medulla (IM) tip to 64% and base to 63% of control. Ibuprofen decreased total AQP2 in IM tip to 70% of control, with no change in base. Meloxicam significantly increased the ratios of p^{256}-AQP2 and p^{261}-AQP2 to total AQP2 in IM tip (to 44% and 40%, respectively). Ibuprofen increased the ratio of p^{256}-AQP2 to total AQP2 in IM tip but did not affect p^{261}-AQP2/total AQP2. Both NSAIDs increased p^{264}-AQP2 and p^{269}-AQP2 ratios in tip and base. Ibuprofen increased UT-A1 levels in IM tip, but not base. NR3a, present in rat IM tip and base, was significantly increased in the meloxicam and ibuprofen treated IM bases (37% and 20%, respectively), but unchanged in IM tip. AQP2 and UT-A1 abundances were decreased both in wild type (AQP2: to 76%, UT-A1: to 62%) and NR3a-/- mice (AQP2: to 52 %, UT-A1: to 33%) by ibuprofen treatment. Meloxicam did not show any changes either in wild type or in NR3a$^{-/-}$ mice. Notably, ibuprofen treatment caused AQP2 and UT-A1 to decrease more in NR3a$^{-/-}$ mice than in wild type mice.

Conclusions: We conclude that NSAIDs reduce AQP2 abundance contributing to decreased urine concentrating ability. In compensation, p-AQP2 increases, resulting in increased AQP2 membrane insertion. The beneficial effects of NR3a may reflect the altered Ca^{2+} entry that could be limiting dephosphorylation of AQP2 and promoting improved water homeostasis.

FR-PO099

The Role of Klotho in Renal Sodium and Water Transport Talita R. Sanches,[1] Fernanda O. Coelho,[1] Lectícia Jorge,[1] Leticia U. De Castro,[1] Makoto Kuro-o,[2] Lucia Andrade.[1] *[1]Div of Nephrology, Univ of Sao Paulo, Brazil; [2]Jichi Medical Univ, Japan.*

Background: Klotho (Kl), a transmembrane protein hormone, counteracts aging. Aging is often paralleled by dehydration, which could promote age-related disorders, because it decreases renal Kl protein abundance, as well as increasing plasma osmolarity, antidiuretic hormone (ADH), aldosterone, and 1,25 vitamin D. ADH and aldosterone decrease Kl transcription in HEK293 cells and are elevated in the sera of Kl knockout mice. We explored the effects of Kl deficiency on renal transporters.

Methods: 8-12 week old male $Kl^{+/+}$, $Kl^{+/-}$ and $Kl^{-/-}$ mice (n=6/group) were fed standard mouse chow and given ad libitum access to tap water. We evaluated serum levels of Na, K, Cl, Mg, creatinine and urea. We immunoblotted for sodium/hydrogen exchanger isoform 3 (NHE3), renal outer medullary potassium channel (ROMK), the Na-K-2Cl cotransporter (NKCC2), alpha subunit of the epithelial sodium channel (αENaC) and aquaporin 2 (AQP2) in kidney membrane fractions; and for phosphorylated glycogen synthase kinase 3 beta (pGSK3β) in cytoplasmic fractions.

Results: Data are mean±SEM.

	Kl +/+	Kl+/-	Kl-/-
Body weight (g)	25.1±3.4	24.5±3.0	9.5±2.2[a]
Na (mEq/L)	148±0.6	144±0.6	157±2.3[a]
K (mEq/L)	4.6±0.2	4.2±0.1	4.2±0.4
Cl (mEq/L)	114±1.4	111±1.5	121±4.0[a]
Mg (mg/dl)	1.6±0.1	1.7±0.0	2.5±0.1[a]
Urea (mg/dl)	50.5±3.3	52.0±2.1	101.6±7.8[a]
Creatinine (mg/dl)	0.1±0.0	0.1±0.0	0.12±0.02
NHE3*	99.1±1.1	92.5±2.2	58.2±4.5[a]
ROMK*	99.3±2.4	92.5±4.7	20.5±4.8[a]
NKCC2*	97.5±1.1	97.8±1.4	130.6±10.7[a]
αENaC*	99±0.4	98±0.9	48±4.9[a]
AQP2*	98.5±0.8	98.3±0.4	133.5±2.2[a]
pGSK3β*	100±0.7	98.3±0.7	60.3±1.3[a]

[a]$p<0.05$ vs. $Kl^{+/+}$ and $Kl^{+/-}$; *% $Kl^{+/+}$ protein expression

Conclusions: In Kl knockout mice, there seems to be normal regulation of NKCC2 and trafficking of AQP2 to the apical plasma membrane in response to ADH. However, Kl knockout mice present reduced sensitivity to elevated plasma aldosterone levels with no increase in αENaC or ROMK protein expression. A lack of Kl can deregulate the adaptive response. (FAPESP).

Urine Aquaporin-2: Improvement in ELISA Measurements by Alkali Pre-Treatment and Mechanisms of the Secretion Sei Sasaki,[1,3] Yoko Saijo,[2] Yasukazu Ohmoto,[2] Fusako Iwata,[2] Daisuke Koga,[2] Takayuki Shimada,[3] Masaki Sakai,[3] Yasuko Tanaka,[3] Kenichi Ishibashi,[3] Kiyonori Katsuragi.[2] *[1]Nephrology, Tokyo Medical and Dental Univ, Tokyo, Japan; [2]Research and Development and Inst of Biomedical Innovation, Otsuka Pharmaceutical Co Ltd, Tokushima, Japan; [3]Medical Physiology, Meiji Pharmaceutical Univ, Tokyo, Japan.*

Background: Vasopressin-regulated water channel, aquaporin-2 (AQP2) is excreted in urine in the form of extracellular vesicles (mostly exosomes). Urine AQP2 has been measured in many clinical water-balance disorders as a potential biomarker for diagnosis and prognosis. However, despite such a clinical application, fluctuations of the measured values in ELISA were sometimes observed depending on storage conditions, and basic mechanisms of urinary AQP2 excretion are still largely unknown. We characterized urinary excretion of AQP2 by using a highly sensitive and specific ELISA system for human AQP2, which has been developed by us.

Methods: Human urine samples from healthy subjects were measured by a sandwich ELISA. Effects of maneuvers to disrupt the exosome membranes mechanically (freezing and thawing at different temperatures) and chemically (treating with alkali and detergents) prior to ELISA were examined. Stably AQP2-transfected MDCK cells were grown on permeable support and excretion of AQP2 to the medium was measured.

Results: 1. Urine samples stored at 4ºC or -80ºC did not show significant AQP2 values in ELISA, whereas those stored at -25ºC for more that 2 weeks provided the values. Urine samples treated with 0.4N NaOH/0.5% Triton X-305 showed the consistent and comparable values to those stored at -25ºC, indicating the need of disruption of the exosome membranes. 2. Supernatants of 200,000g ultracentrifugation contained less than 0.5% of AQP2 of original urine samples. 3. In the culture, AQP2 concentration was more than 10 times higher in apical medium compared to basolateral, and apical AQP2 excretion was stimulated with 3h-incubation of 10^{-5}M forskolin and 100mM NaCl.

Conclusions: Almost all urine AQP2 is enclosed in exosomes, and pre-treatment of alkali (0.4N NaOH) allows consistent ELISA measurements. Mechanisms of urinary excretion of AQP2 can be examined in culture system.

FR-PO101

Inhibition of EGFR Activity Induces Aquaporin 2 Phosphorylation and Increases Water Reabsorption in Lithium Treated Mice Pui Cheung, Naohiro Nomura, Anil V. Nair, Hua Ann Jenny Lu, Richard Bouley, Dennis Brown. *Medicine, Massachusetts General Hospital, Boston, MA.*

Background: Impairment of vasopressin (VP) receptor type 2 signaling in the kidney is detrimental to water homeostasis. However, strategies targeting cAMP signaling to treat diseases associated with water balance have so far been unsuccessful in humans, prompting a search for alternative pathways that modulate AQP2 trafficking.

Methods: The effect of erlotinib (Erl) oral gavage in a lithium induced nephrogenic diabetes insipidus mouse model was analyzed by measuring urine volume and osmolality. The effect of Erl on aquaporin 2 trafficking and expression in kidneys was studied by immunostaining and western blot analyses. EGF and Erl regulation of AQP2 trafficking and phosphorylation were studied using selective kinase inhibitors and phospho-specific antibodies on AQP2-expressing LLC-PK1 cells.

Results: EGF alone had only a subtle effect on AQP2 trafficking, but it exerted a significant antagonizing effect on VP-induced AQP2 phosphorylation and membrane accumulation. Conversely, erlotinib (Erl), an EGFR inhibitor, led to a VP-independent increase of apical AQP2 accumulation in collecting ducts, and significantly reduced urine volume by more than 40% after 4 days of treatment in lithium-induced NDI mice. Erl enhanced AQP2 plasma membrane localization in cells by increasing AQP2 exocytosis and decreasing endocytosis. This effect was cAMP, cGMP, and PKA independent. Despite apparently bypassing cAMP pathways, Erl resulted in AQP2 phosphorylation in a dose dependent manner at serine 256, an essential step in VP-induced AQP2 membrane accumulation. We propose that EGF has a tonic inhibitory effect on VP action, and that relief of such inhibition enhances AQP2 phosphorylation and results in membrane accumulation.

Conclusions: We showed a crosstalk between EGF and VP in the modulation of AQP2 trafficking. EGFR inhibition increases AQP2 membrane expression bypassing the canonical VP/cAMP/PKA pathway and ameliorates lithium-induced NDI in mice. This study improves our understanding of the diversity of mechanisms that regulate water reabsorption in the body, and uncovers a novel pathway for potential therapeutic targets for NDI.

ChIP-seq Analysis of Genomic Binding Sites for the Transcription Factor Elf1 in mpkCCD Cells Hyun Jun Jung, Viswanathan Raghuram, Jae Wook Lee, Mark A. Knepper. *Systems Biology Center, NHLBI, NIH.*

Background: Collecting duct cells selectively express a number of transport proteins (aquaporins and ion channels) vital to water and electrolyte balance. Previous studies of tissue-specific gene expression in collecting duct cells have implicated Ets family transcription factors (TFs)(Yu et al. PNAS 2009;106:2441). We integrated data from prior proteomics and transcriptomics studies of mouse mpkCCD cells using Bayes' Rule to create a probability-based ranking of all known TFs with regard to likelihood of a role in collecting duct-specific gene expression. Among the top-ranked TFs were several Ets family TFs including Elf1.

Methods: To identify genomic binding sites for Elf1 in mpkCCD cells, we carried out ChIP-seq analysis using an antibody successfully employed in the *Mouse ENCODE Project*. The mpkCCD cells were treated with the vasopressin analog dDAVP (100pM) for 24 hr prior to crosslinking and chromatin immuno-precipitation (ChIP) (n=3). DNA libraries were prepared from immunoprecipitated DNA and sequenced using an Illumina HiSeq 2000 sequencer to identify TF-enriched genomic regions. Control ChIP was carried out with nonspecific IgG.

Results: The analysis (MACS peak-calling software) identified >2000 binding sites seen in all three replicates and not seen in IgG-only controls. The identified sites mapped to within 2000 bp of annotated transcription start sites (TSSs) of several genes whose transcript abundances were previously demonstrated to be regulated by vasopressin including *Id3*, *Txnip*, *Jun*, *Sat1* and *Spag1* (Khositseth et al. Mol Cell Proteomics 2011;10:M110). There was no Elf1 binding in the vicinity of any aquaporin or any ENaC subunit, indicating that any role of Elf1 in regulating these targets is likely to be indirect. However, Elf1 binding was mapped to additional TFs that are predicted to bind within 1000 bp upstream of TSSs for aquaporin-2, β-ENaC or γ-ENaC (Genomatix motif analysis). These TFs were *Creb1*, *Gata3*, *Sox4*, *Junb*, *Sp1*, *Sp3*, *Gabpa*, *Nfkb1*, *Hmbox1*, *Rreb1* and *Rxra*.

Conclusions: These data provide an initial step in identification of the transcriptional network that determines cell-type-specific expression in renal collecting duct cells.

FR-PO103

Deletion of Aquaporin 11 in Transgenic Mice prior to Post-Natal Day 12 Results in Proximal Tubule Injury and Cyst Formation Søren Nielsen,[1] Mads Vammen Damgaard,[1,2] Michael R. Rutzler,[1] Robert A. Fenton,[2] Aleksandra M. Rojek.[2] *[1]Dept of Health Science and Technology, Aalborg Univ, Aalborg, Denmark; [2]Dept of Biomedicine, Aarhus Univ, Aarhus, Denmark.*

Background: AQP11 is expressed in the proximal tubule (PT). Neonate *AQP11* KO mice show PT vacuolization and cysts, resulting in renal failure and death. This study examined; 1) whether AQP11 deficiency at specific stages of kidney development is important for PT injury and cyst formation; 2) if cysts are closed structures or dilations of PT; 3) the role of metabolic challenges on PT injury and cyst formation.

Methods: Tamoxifen-inducible *AQP11* KO mice were generated.

Results: Deletion of *Aqp11* at post-natal (PN) day 2, 4, 6, 8, 10, 12 or 21 was investigated alongside neonate total *Aqp11* KO mice. PT cell vacuolization and tubular cysts developed only in mice where *Aqp11* gene disruption was instigated before PN day 12. Aqp11 gene deletion after PN week 3 did not result in PT injury or cyst formation. Similarly, 3 weeks of metabolic stress induced by repeated fasting (16hrs) / re-feeding (2hrs) of PN day 21 induced *Aqp11* KO mice or total neonate AQP11 KO mice resulted in PT cytoplasmic vacuoles but not PT cysts. IP injection of biotinylated-dextran (10kDa) in adult, neonatally induced *Aqp11* KO mice revealed endocytotic uptake in both cystic and PT epithelium. Thus apparent cysts were continuous with PT hence representing PT dilations. This was confirmed by serial sectioning and digital 3-D tracing of PT cysts in adult, neonatally induced *Aqp11* KO mice. Electron microscopy of PT in kidneys from adult neonatally induced *Aqp11* KO mice revealed dilated RER and extensive authophagosomes.

Conclusions: 1) AQP11 deficiency prior to PN day 12 leads to PT cell injury and severe PT tubular dilatation. 2) *Aqp11* gene deletion after full kidney development results in normal PT morphology, and only present with PT injury in response to metabolic challenge. 3) Apparent cysts represent PT dilations and are not closed cysts. Conclusion: AQP11 deficiency prior to PN day 12 sensitizes PT cells of the developing kidney to cellular injury and causes severe PT dilations thus revealing a novel mechanism for PT cyst formation.

Involvement of NADPH Oxidase 2 in the Kidney Injury of Aquaporin-11 KO Mouse Yuya Hoshino,[1] Hiroko Sonoda,[1] Kenichi Ishibashi,[2] Masahiro Ikeda.[1] *[1]Veterinary Pharmacology, Univ of Miyazaki, Miyazaki, Japan; [2]Medical Physiology, Meiji Pharmaceutical Univ, Tokyo, Japan.*

Background: Aquaporin-11 (AQP11), the latest member of the AQP protein family to be described, is an intracellular AQP. Several in vivo studies have shown that AQP11 deficiency causes kidney injury characterized by the formation of multiple cysts. Recentry, this kidney injury was reported to be related to the production of reactive oxygen species (ROS). However, the underlying molecular mechanism is largely unknown.

Methods: In this study, we examined the mechanism by which AQP11 deficiency induces ROS production using PCR array, real-time PCR, immunoblotting, and immunohistochemistry techniques. Also, a pathway analysis was performed with the results from the gene expression analysis.

Results: Immunohistochemistry studies showed that the number of 8-hydroxy-2'-deoxyguanosine-positive cells in renal interstitium was increased in AQP11 KO mice in comparison with wild-type mice. In parallel, immunoblotting analysis showed the increased levels of renal protein carbonylation in the KO mice. The NADPH oxidase (NOX) enzyme family is important sources of ROS and so far, six members (NOX1, NOX2, NOX3, NOX4, DUOX1, DUOX2) have been identified in mouse. Among them, real-time PCR analysis showed that renal NOX2 mRNA level was markedly increased in the KO mice. Furthermore, mRNAs for the assembly factors (p40phox, p47phox, p67phox) for NOX2 in the kidney were dramatically up-regulated in the KO mice. Immunoblotting analysis revealed that renal NOX2 protein expression was significantly increased in the KO mice. Immunohistochemistry showed that NOX2-positive cells were observed in renal interstitium.

Conclusions: These data strongly suggested that increased ROS production in AQP11 KO mice was mediated by NOX2, leading to the kidney injury.

Intracellular Vacuoles in the Kidney of AQP11 Null Mice May Simulate the Cisplatin Nephrotoxicity Kenichi Ishibashi, Ichiru Akinaga, Takashi Kusano, Sei Sasaki, Yasuko Tanaka. *Medical Physiology, Meiji Pharmaceutical Univ, Kiyose, Tokyo, Japan.*

Background: Nephrotoxicity is a major side effect of cisplatin in chemotherapy. Despite years of research, the mechanism underlying cisplatin nephrotoxicity remains unclear and effective renal protective approaches during chemotherapy are still unavailable. Pathologically, cisplatin nephrotoxicity is characterized by cell injury with multiple intracellular vacuoles in the proximal tubule which are very similar to the kidney phenotype of AQP11 null mice before the polycyst development. We speculated that cisplatin may inhibit the function of AQP11 to induce intracellular vacuoles.

Results: As the importance of caspase (Casp) 12 in cisplatin nephrotoxicity has been reported in the literature (J Am Soc Nephrol. 16: 1985, 2005), the expression of Casps was examined by real-time PCR in the kidney of AQP11 null mice with intracellular vacuoles, i.e. two weeks after birth. Casp3/Casp8 for apoptosis were not induced, while Casp12 for ER stress were strongly induced by 9 folds and Casp1/Casp4 for inflammation by 6/7.5 folds. We next examined the effect of cisplatin on AQP11 expression in the kidney. The real-time PCR showed the decrease of AQP11 expression by half in mice kidney at three days after 20 mg/g BW i.p. cisplatin with almost normal renal function. When AQP11 hetero-mice were challenged with the same cisplatin treatment, the renal parameters were increased: (hetero/wild) BUN 159.1/53.4 mg/dl, Cr 0.33/0.17 mg/dl, UA 3.13/2.0 mg/dl. We next searched for the interventions which enhance AQP11 expression in the kidney. Two-day dehydration decreased the AQP11 mRNA expression while three-day glucose 5g/kg BW i.p. or 1g/kg BW D-cysteine p.o. increased the AQP11 mRNA expression. We then treated AQP11 hetero-mice with the D-cysteine p.o. daily for three days after the cisplatin i.p. The increase of BUN by cisplatin was attenuated.

Conclusions: The results suggests that AQP11 may play an important role in the development of cisplatin nephrotoxicity. The enhancing the AQP11 expression in the kidney will be a renoprotective strategy in cisplatin nephrotoxicity.

Development of a Model on Chronic SIADH: Effect of Water Challenge and Treatment on Behavior, Learning, Memory and Brain Edema Marta Tejedor, Ana Durán Vila, Carmen Grande, Margarita Fernández, Teba González, Maria Melendo, Ana Morales, Cristina Vila, Juan Carlos Jado, Ignacio Lizasoain, Alberto Tejedor Jorge. *Nephrology, Hospital_Gregorio_Marañon, Madrid, Spain.*

Background: AIM: to develop a model on chronic SIADH and study the effects of acute water overload on behavior, brain edema and response to treatment.

Methods: We induced chronic SIADH by daily injection of ddAVP and water over a 3-5 day period to balb-c mice. We induced acute on chronic SIADH by giving an acute i.p. water challenge of 5% of body weight. We assessed behavioral changes by filming spontaneous activity in cages and under controlled conditions in a Morris water maze. We studied brain edema by means of continuous Percoll gradients to fraction grey and white brain substance. We administered tolvaptan to evaluate their effects in the abovementioned conditions.

Results: ddAVP administration alone was able to induce significant changes in spontaneous behavior despite minimal changes in natremia (3mEq/l). These changes were earlier and more severe if a chronic water overload was given. Overall, learning and memory improved over time with training, measured by times of resolution ($p=0.004$) and trajectory ($p=0.002$) in a water maze. This was more evident in the control group than in the SIADH group (learning ($p=0.06$), memory ($p=0.08$)). The mean trajectory length to resolve the maze was 185±55 cm in the control group, 360±44 cm in SIADH with no acute water overload ($p<0.05$) and 808±94 cm in SIADH with an acute water challenge of 5% ($p<0.05$). Treatment with tolvaptan significantly shortens the length of the trajectory to nearly baseline values. The SIADH group who received a 5% water challenge developed significant brain edema which was reversed by tolvaptan. No significant changes were seen in animals who did not receive the water challenge. An acute water overload of 5% in SIADH was equivalent to a 10% one in controls, as shown by similar worsening in the water maze.

Conclusions: ddAVP injection alone is enough to induce subtle behavioral changes, even in the absence of significant hyponatremia. Acute on chronic SIADH significantly worsens brain edema and resolution of a water maze, and such changes can be reverted by tolvaptan.

FR-PO107

Warburg-Like Proliferation Underlies Lithium-Induced Nephrogenic Diabetes Insipidus Theun de Groot, Peter M.T. Deen, Mohammad Alsady. *Dept of Physiology, Radboud Univ Medical Center, Netherlands.*

Background: Lithium is the first-choice medication for treatment of bipolar disorders and is used by 0.1% of the western population. Unfortunately, lithium treatment is associated with development of severe renal side effects. In approximately 50% of treated patients, lithium causes a urinary concentrating defect, which develops in ~20% of patients into symptomatic Nephrogenic Diabetes Insipidus (NDI). This disorder is characterized by polyuria and polydipsia and is caused by downregulation of AQP2 water channels in principal cells of the renal collecting duct. Furthermore, lithium induces proliferation of these cells *in vitro* and *in vivo*. Cell proliferation is often characterized by aerobic glycolysis (Warburg effect). Here, we investigated whether lithium may induce Warburg-like aerobic glycolysis and whether inhibition of this Warburg effect may rescue lithium-induced-NDI (Li-NDI).

Methods: Polarized mouse cortical collecting duct (mpkCCD) cells were cultured as a 2D transwell model and exposed to lithium chloride on the apical side (10 mM) and basolateral side (1 mM) to mimic clinical conditions in patients. C57BL6/J mice were fed a normal rodent diet or a diet with lithium chloride in a concentration of 40 mmol/kg of chow. During the last 48 hours of the experiment, mice were housed in metabolic cages in order to determine water intake and urine output/osmolality during the last 24 hours.

Results: Lithium induced proliferation of mpkCCD cells as shown by increased levels of the proliferation markers PCNA and cyclin D1. In addition, lactate and succinate, main products of the Warburg effect, were both increased in lithium-treated mpkCCD cells and mice. This was accompanied by a decrease in the ratio of phospho-pyruvate dehydrogenase pPDH/PDH, confirming the induction of aerobic glycolysis by lithium in mice. Interestingly, inhibition of lithium-induced glycolysis with 2-deoxyglucose (2DG) attenuated lithium-induced AQP2 downregulation in mpkCCD cells.

Conclusions: Our results reveal that lithium induces aerobic glycolysis in mpkCCD cells and mice. Targeting of aerobic glycolysis with 2-deoxyglucose rescued lithium-induced AQP2 downregulation and may represent a potential therapy for Li-NDI.

RNA-seq Profiling of the Cortical Collecting Duct in Vasopressin Escape

Jae Wook Lee,[1] Carolyn M. Ecelbarger,[2] Mark A. Knepper.[1] *[1]NHLBI, NIH, Bethesda, MD; [2]Georgetown Univ, Washington, D.C.*

Background: Vasopressin escape is a protective mechanism that limits hyponatremia in the syndrome of inappropriate antidiuresis (SIADH). Using RNA-seq, we investigated transcriptomic changes in microdissected cortical collecting duct (CCD) of rats undergoing vasopressin escape.

Methods: Male Sprague-Dawley rats (120-160 g) were placed on continuous dDAVP (5 ng/hr) infusion for 5 days, and received either a high water load (50 mL/d, "escape") or a normal water load matching insensible losses plus urine output (25 mL/d, "control"). Rats were sacrificed at day 1, 2, and 4, and 4 mm of CCDs were collected by manual microdissection. RNAs were processed into cDNA libraries and 50-bp paired-end reads were obtained using an Illumina platform. Reads mapping to Ensembl genes were counted for differential-expression analysis.

Results: Sequence depths were 40-65 million reads, with 80% of reads mapping to Ensembl genes. At day 2, 180 transcripts were downregulated and 339 transcripts were upregulated at a false discovery rate < 0.1. Consistent with increased water excretion in vasopressin escape, transcripts of aquaporin-2 and aquaporin-3 were significantly downregulated at day 1, 2 and 4. Among downregulated transcripts were transcription factors (*Hes1*, *Hmx2*, *Hoxb5*, *Hoxb6*, *Hoxb7*, *Jun*, and *Tox3*) and a cyclin-dependent kinase inhibitor (*Cdkn1b*). Among upregulated transcripts were proteins involved in cell division, such as centromere proteins (*Cenpa*, *Cenpf*, *Cenpl*, and *Cenpt*); cyclins (*Ccna2*, *Ccnb2* and *Ccdn1*); a cyclin-dependent kinase (*Cdk1*); components of DNA replication machinery (*Pold3* in DNA polymerase complex; *Mcm2*, *Mcm3*, *Mcm4*, *Mcm6*, and *Mcm7* in MCM replicative helicase complex; *Orc5* in origin recognition complex); polo-like kinase 1 (*Plk1*); and forkhead box protein M1 (*Foxm1*). GO terms related to cell division were enriched in upregulated transcripts ("cell cycle phase", adjusted $p=8\times10^{-23}$; "mitosis", 2×10^{-13}). Immunohistochemistry showed PCNA-positive cells in CCD of escape rats but none in control rats.

Conclusions: RNA-seq revealed that increased rate of cell division may be an activated mechanism involved in remodeling of the CCD to restore water homeostasis as a part of the renal adaptation to SIADH.

Silencing of the Kinome Identifies a Novel Modulator of Aquaporin-2 Trafficking

Hana Cernecka,[1] Dorte Faust,[1] Kerstin Zuehlke,[1] Marc Wippich,[2] Katina Lazarow,[2] Martin Neuenschwander,[2] Jens Peter von Kries,[2] Enno Klussmann.[1] *[1]Anchored Signalling, Max Delbrück Center for Molecular Medicine in the Helmholtz Association, (MDC), Berlin, Germany; [2]Leibniz-Inst für Molekulare Pharmakologie (FMP), Campus Berlin-Buch, Berlin, Germany.*

Background: Arginine vasopressin (AVP)-dependent water reabsorption requires the redistribution of aquaporin-2 (AQP2) from intracellular vesicles into the plasma membrane of renal principal cells. Despite identification of several proteins participating in the control of AVP-dependent AQP2 trafficking, the molecular mechanisms underlying the AQP2 redistribution are largely unknown. The aim of this study was to identify proteins controlling the localization of AQP2 and thereby to elucidate molecular mechanisms underlying the AQP2 translocation.

Methods: We established a large-scale siRNA screening using mouse collecting duct cells, stably expressing human AQP2. The expression of 719 kinases was knocked down and the AQP2 localisation was analysed by automated immunofluorescence microscopy. Generated images were analysed automatically to quantitatively evaluate cellular phenotypes in an unbiased approach by utilizing CellProfiler. Machine learning in combination with advanced statistical and computational techniques were applied.

Results: The screening revealed 13 genes whose expression was relevant for the AQP2 redistribution. One of them is a recently identified member of the cyclin-dependent kinase family. Its knockdown blocks the AQP2 translocation and simultaneously increases the AQP2 protein abundance.

Conclusions: Our approach contributes to understanding the molecular mechanisms underlying the control of AQP2 trafficking and to identify potential therapeutic targets for the treatment of diseases caused by or associated with aberrant AVP-mediated water reabsorption such as diabetes insipidus or heart failure.

The Circadian Clock in the Kidney Controls Several Essential Metabolic Pathways

Svetlana Nikolaeva,[1,2] Camille Ansermet,[1] Gabriel Centeno,[1] Robert Koesters,[3] Sylvain Pradervand,[4] Olivier Bonny,[1,5] Dmitri Firsov.[1] *[1]Pharmacology and Toxicology, Univ of Lausanne, Lausanne, Switzerland; [2]Sechenov Inst of Evolutionary Physiology and Biochemistry, St. Petersburg, Russian Federation; [3]Univ Pierre et Marie Curie, Paris, France; [4]Genomic Technologies Facility, Univ of Lausanne, Lausanee, Switzerland; [5]Service of Nephrology, CHUV, Lausanne, Switzerland.*

Background: The circadian clock is the central mechanism for regulating body metabolism and energy homeostasis. However, the role of the intrinsic renal circadian system in the control of renal and/or systemic metabolic pathways remains elusive.

Methods: A combined metabolomic/transcriptomic approach was performed on plasma or kidney tissue samples obtained from mice devoid of the molecular clock in renal tubular cells ($Bmal1^{lox/lox}$/Pax8-rtTA:LC1Cre mice/ cKO mice).

Results: We found that cKO mice exhibit significant changes in several essential metabolic pathways, including (i) increased renal arginine production resulting in the increased plasma arginine and asymmetric dimethylarginine levels; (ii) significantly increased arginase activity in the PST resulting in the increased renal polyamines production and increased plasma urea levels; (iii) increased plasma levels of several phosphatidylcholine and sphingomyelin species; and (iv) a significant reduction in plasma carnitine levels, paralleled by a significant decrease in the expression levels of Slc22a5 (OCTN2) transporter involved in the apical carnitine reabsorption in the proximal tubule. Transcriptome analysis revealed a significant reduction in expression levels of all transcripts encoded by the mitochondrial genome as well as of a great number of nuclear transcripts encoding proteins involved in the mitochondrial oxidative phosphorylation. In parallel kidneys from cKO mice exhibited a significant decrease in the NAD/NADH ratio suggesting an increased glycolysis and/or decreased mitochondrial function.

Conclusions: These results suggest that the local renal circadian clock control a variety of metabolic processes both on the intra-renal and systemic levels.

Mouse Monocarboxylate Transporter 9 Functions as a Urate Transporter

Promsuk Jutabha, Naoyuki Otani, Motoshi Ouchi, Naohiko Anzai. *Dept of Pharmacology and Toxicology, Dokkyo Medical Univ School of Medicine, Mibu, Tochigi, Japan.*

Background: Monocarboxylate transporter 9 (MCT9/SLC16A9) has been suggested to be involved in the onset of hyperuricemia or gout by genome-wide association studies (GWAS). Since no experimental data about MCT9 function has been reported, we tried to clarify its physiological roles.

Methods: The expression of SLC16A9 was investigated by quantitative RT-PCR (qRT-PCR) against human tissue cDNAs. Using oocyte expression system, we injected mouse MCT9 (mMCT9) cRNA to perform the functional characterization of mMCT9.

Results: qRT-PCR showed that the mRNA expression of MCT9 is quite higher in kidney than other tissues. Its expression is also found in spleen, ovary, pancreas, prostate and testis. *Xenopus* oocytes expressing mMCT9 mediated the transport of [^{14}C]urate in Na^+-, Cl^- and voltage-independent manner. Radiolabelled urate uptake via mMCT9 was not inhibited by 2.5 mM unlabelled urate and was not *trans*-stimulated by intracellularly-injected monocarboxylates (counterions for URAT1) nor dicarboxylates (counterions for OATs).

Conclusions: Here, we suggested, for the first time, that MCT9 functions as a low affinity urate facilitatory transporter in kidneys.

Mutation in the Creatine Transporter MCT12 Causes Low Plasma Level and Increased Fractional Excretion of Guanidinoacetate but Not Glucosuria

Nasser Dhayat,[1] Alexandre Simonin,[1] Giuseppe Albano,[1] Ganesh Pathare,[1] Christine Deisl,[1] David Mordasini,[1] Bruno Vogt,[1] Barbara Kloeckener,[3] Daniel G. Fuster.[1] *[1]Div of Nephrology, Hypertension and Clinical Pharmacology, Univ of Bern, Bern, Switzerland; [2]Inst of Medical Molecular Genetics, Univ of Zürich, Zürich, Switzerland.*

Background: A heterozygous mutation (c.643C>A; p.Q215X) in the creatine transporter gene MCT12 (also known SLC16A12) was recently identified as the cause of a syndrome with juvenile cataracts, microcornea and glucosuria in a single family. While the MCT12 mutation co-segregated with the eye phenotype, poor correlation with the glucosuria phenotype questioned a pathogenic role of the mutation in the kidney.

Methods: We undertook a detailed phenotypic investigation of the index family and performed complementary in vitro studies.

Results: Here we show that MCT12 resides on basolateral membranes of proximal tubules. Patients with MCT12 mutation exhibit reduced plasma levels and increased fractional excretion of guanidinoacetate, but normal creatine levels, suggesting that MCT12 may function as a guanidinoacetate transporter in vivo. However, functional studies in Xenopus oocytes revealed that MCT12 transports creatine but not its precursor guanidinoacetate. This indicates that impaired MCT12-mediated cellular creatine efflux affects guanidinoacetate homeostasis indirectly, e.g. by an increase of the cellular creatine concentration, which is known to inhibit guanidinoacetate synthesis. Genetic analysis revealed a separate, hitherto undescribed heterozygous mutation in SGLT2 (c.265G>A; p.A89T) in the family that segregated with the renal glucosuria phenotype. When overexpressed in HEK293 cells, the mutant SGLT2 transporter is not efficiently translocated to the plasma membrane and displays greatly reduced transport activity.

Conclusions: Our data indicate that MCT12 functions as basolateral exit pathway for creatine in the proximal tubule. Heterozygous mutation of MCT12 affects systemic levels and renal handling of guanidinoacetate. Furthermore, our data reveal the presence of a digenic syndrome in the index family with simultaneous MCT12 and SGLT2 mutation. Thus, glucosuria is not part of the MCT12 mutation syndrome.

FR-PO113

NaDC1 Knockout: Effects on Blood Pressure and Urine pH Federico Jose Teran,[1] Weitao Huang,[1] L. Lee Hamm,[1,2] Kathleen S. Hering-Smith.[1] *[1]Nephrology, Tulane Univ School of Medicine, New Orleans, LA; [2]Research, SLVHCS, New Orleans, LA.*

Background: NaDC1 reabsorbs filtered citrate (Cit); thus its regulation is important in preventing calcium nephrolithiasis. Importantly NaDC1 reabsorbs other Krebs cycle intermediates such as succinate (Suc) and αKG. Recently Suc and αKG have been found to be important in paracrine signaling as their luminal presence stimulates distal nephron G-protein coupled receptors GPCR91 and GPCR99 respectively. Luminal Suc via GPCR91 has been found to stimulate renin release; while αKG via GPCR99 stimulates bicarbonate secretion by type B intercalated cells. The purpose was to determine whether knockout of NaDC1 produces hemodynamic or urine pH changes that might be anticipated by activation of these receptors.

Methods: Adult NaDC1 KO, heterozygous (Het), and wild-type mice (WT), under normal or acid diet for 72 hr, were studied using standard clearance techniques. After anesthesia direct measurements of hemodynamic parameters were determined in real time. Urine, blood and tissue were collected for measurement of Suc, Cit, αKG, and pH.

Results: NaDC1 KO produced 2, 4, and 10-fold increases in urinary Suc, Cit, and αKG, respectively. There was substantial residual reabsorption of Cit and Suc in KO mice, indicating other transporters involved in reabsorption of these substrates. Despite the increase in urinary αKG there was no significant increase in urine pH (normal or acid diet); in fact on normal diet urine pH was lower in KO mice (5.41 ± 0.04 vs 5.90 ± 0.13 WT; $p < 0.001$). The lower urine pH in KO mice on normal diet may be a response to loss of potential bicarbonate in the form of increased Krebs cycle intermediate excretion. There was no change in the ability of KO animals to excrete ammonia. In regard to potential hemodynamic effects mediated by NaDC1 KO and increased urinary Suc, no change in MAP was determined comparing WT, Het or KO either on normal or acid diet.

Conclusions: In sum, NaDC1 is responsible for significant reabsorption of filtered αKG and Suc, but knockout of NaDC1 does not impair acid-base homeostasis or BP changes on normal or acid diets.

FR-PO114

The Ablation of Dendritic Cells Prevents the Upregulation of the Intrarrenal Renin-Angiotensin System and Renal Sodium Transporters in Response to Angiotensin II and High Salt Diet Patricio A. Araos,[1] Daniel E. Hevia,[1] Carolina E. Prado,[2] Eugenia L. Fuentes,[1] Rodrigo Pacheco,[2] Luis F. Michea.[1] *[1]Univ de Chile, Chile; [2]Fundación Ciencia y Vida, Chile.*

Background: Blood pressure depends on the renal sodium reabsorption mediated by the tubular transporters that are modulated by the intrarenal renin–angiotensin system (iRAS). Angiotensin II (AngII) and a high salt diet (HS) cause hypertension (HT) and the upregulation of the iRAS and sodium transporters. Our previous studies showed that the ablation of Dendritic Cells (DC) in mice prevented the development of HT in response to AngII+HS. In the present study, we evaluated if the ablation of DCs alters the modulation of the iRAS and tubular sodium transporters by AngII+HS.

Methods: CD11c.DOG mice, for selective loss of DCs ($CD11c^{Hi}$) cells after Diphteria Toxin (DT) injection, received vehicle, AngII+HS (AngII, 450 mg Kg/day+1% NaCl in drinking water) or AngII+HS+DT (DT, 8ng/g) during 14 days; Paired WT mice received vehicle, AngII+HS or AngII+HS+DT. We measured blood pressure (days 0, 4, 8, 14), and at day 14 we harvested tissues to measure the abundance of renal DCs ($MHC\text{-}II^{+}$ and $CD11c^{+}$) by inmunofluoresce, the iRAS, the sodium-proton exchanger 3 (NHE3), the sodium-chloride cotransporter (NCC) and the Epithelial Sodium Channel (αENaC) by qRT-PCR and Western blot.

Results: The injection of DT prevented the development of HT in response to AngII+HS only in CD11c.DOG mice. CD11c.DOG and WT mice showed increased abundance of DCs in the cortex (peritubular); Only the CD11c.DOG mice showed a sharp reduction of renal DCs after DT injection. Both, in WT as in CD11c.DOG mice the administration of AngII+HS increased the iRAS (in fold of induction: Angiotensinogen, 1.5; Angiotensin converting enzyme, 1.9; and Angiotensin II receptor type I, 5), NHE3, NCC and αENaC (in fold of induction: 4.2; 6; 2), respectively vs vehicle–treated mice ($p<0.05$; n=5-9). The injection of DT concomitant to AngII+HS prevented the changes in sodium transporters and iRAS in CD11c.DOG mice ($p<0.05$ compared to AngII+HS; n=5-9).

Conclusions: We conclude that DCs are required for the modulation of iRAS and tubular sodium transporters by AngII+HS.

FR-PO115

Splenectomy Differentially Affects Angiotensin-II and L-NAME Murine Models of Hypertension Joseph C. Gigliotti, Sylvia Cechova, Thu H. Le. *Univ of Virginia.*

Background: The immune system plays a major role in animal models of hypertension (HTN) and end-organ damage. However, few studies have assessed the role of lymphoid organs in the pathogenesis of HTN. We have shown previously that prior splenectomy (SPLX) significantly alters tissue inflammation; however the effect of SPLX on HTN remains unclear. Therefore, the objective of the current study is to determine whether prior SPLX influences the development of HTN in 2 different mouse models.

Methods: Mice underwent SPLX or sham surgery 7 days prior to the induction of HTN using angiotensin-II (AngII, 400ng/kg*d) or nitric oxide synthase inhibition using L-NAME (30mg/kg*d). Systolic blood pressure (SBP) was measured by tail-cuff manometer daily and mice were euthanized 14 days after induction of HTN. Heart weight/body weight (H/BW) ratios were calculated and kidney leukocyte infiltration was analyzed by flow cytometry.

Results: Mice with prior SPLX+AngII had significantly lower (P=0.03) SBP at both week 1 (148±7) and week 2 (135±7) as compared to Sham+AngII (174 and 173±7mmHg). Similarly, SPLX+AngII mice had significantly smaller (P=0.007) H/BW (4.3±0.3) as compared to Sham+AngII treated mice (5.2±0.4mg/g BW). Interestingly, no difference was observed in renal $CD45^{+}$ (9.8±3 vs $10.6\pm3x10^{5}$ cells/g, P=0.64) or $CD3^{+}$ T-cell infiltration (8.8±0.2 vs $9.6\pm0.1x10^{4}$ cells/g, P=0.64) between the Sham+AngII and SPLX+AngII treated mice, respectively. Furthermore, SPLX did not appear to influence the development of L-NAME HTN. SPLX+L-NAME mice had similar P=0.84) SBP (145±4mmHg) as the Sham+L-NAME group (146±4mmHg, n=6) after 2 weeks. Relative heart weights were also similar (P=0.45) between SPLX+L-NAME (4.9±0.2) and Sham+L-NAME treated mice (4.8±0.3mg/g BW).

Conclusions: Our data suggests that the full pressor response to AngII is dependent on the spleen. However, the effect of the spleen appears to be independent of renal inflammation. Moreover, the protective effect of the spleen is specific to AngII-dependent HTN and does not appear to be generalizable to all mouse models of hypertension. Further studies are needed to understand the physiological link between lymphoid organs (such as the spleen), renal inflammation, and the development of chronic HTN.

FR-PO116

Salt Overload Promotes Severe Renal Injury and Activates AngII, Renal NF-κB and Other Components of Innate Immunity in a Model of Arterial Hypertension Victor F. Avila, Orestes Foresto-Neto, Simone CA Arias, Camilla Fanelli, Flavia G. Machado, Mariliza V. Rodrigues, Claudia R. Sena, Viviane D. Faustino, Lisienny CT Rempel, Gizely CS Moreira, Vivian L. Viana, Denise M. Malheiros, Jose E. Krieger, Roberto Zatz, Clarice K. Fujihara. *Univ of São Paulo, São Paulo, Brazil.*

Background: Hypertension (HTN) develops in rats that received the NF-κB inhibitor pyrrolidinedithiocarbamate (PDTC) during lactation. High salt (HS) and uninephrectomy (UNx) aggravate HTN, increase renal AngII and lead to severe renal injury. Here, we further investigated the mechanisms of renal injury and the effect of Losartan (L) in this model.

Methods: Munich-Wistar pups received PDTC ($PDTC_{lact}$) or no treatment (C) during lactation. At 10 wks of age, all rats underwent UNx and were divided in: **C**, given normal salt diet (NS); **$PDTC_{lact}$**, given NS; **$PDTC_{lact}$+HS**, given HS; **$PDTC_{lact}$+HS+L**, given HS and L, 50 mg/kg/d. After 3 mo, we assessed: tail-cuff pressure (TCP, mmHg), glomerulosclerosis (GS), interstitial collagen 1 (COL), arteriolar lesions (AL), interstitial AngII+, macrophages (Mø) and lymphocytes (Ly), cells/mm^2, TLR4 and nuclear NF-KB (x C), and serum IL-6 (pg/mL).

Results:

	C	$PDTC_{lact}$	$PDTC_{lact}$+HS	$PDTC_{lact}$+HS+L
TCP	144±2	167 ± 3^{a}	195 ± 4^{ab}	163 ± 5^{ac}
GS%	2±1	1±1	12 ± 2^{ab}	7 ± 2^{abc}
AL%	0±0	1±1	17 ± 5^{ab}	10 ± 4^{ab}
AngII+	2±1	2±1	7 ± 1^{ab}	4 ± 1^{abc}
Mø	33±3	34±4	140 ± 21^{ab}	42 ± 7^{c}
Ly	37±3	43±4	141 ± 25^{ab}	65 ± 8^{abc}
COL%	2.8±0.2	2.8±0.4	7.3 ± 1.2^{ab}	3.5 ± 0.5^{c}
NF-κB	1.0±0.2	1.7±0.4	2.6 ± 0.5^{a}	0.9 ± 0.3^{c}
IL-6	23±3	32±3	40 ± 4^{a}	28 ± 1^{c}
TLR4	1.0±0.1	1.5±0.4	2.9 ± 0.7^{ab}	0.9 ± 0.2^{c}

Mean±SE, $^{a}p<0.05$ vs C, $^{b}p<0.05$ vs $PDTC_{lact}$, $^{c}p<0.05$ vs $PDTC_{lact}$+HS

HS+UNx led to severe HTN and renal/vascular injury, intense Mø/Ly infiltration, increased AngII+ and TLR4, and NF-κB activation, with increased plasma IL-6, all correlating positively with TCP. L strongly attenuated renal damage, normalizing renal TLR4, renal NF-κB and plasma IL-6.

Conclusions: In $PDTC_{lact}$, renal injury caused by HS+UNx involves activation of renal AngII and innate immunity, including the NF-κB system. FAPESP/CNPq.

Interleukin-6 Inhibition Attenuates Hypertension and Proteinuria in Dahl Salt-Sensitive (SS) Rats Shireen Hashmat,[1] Justine M. Abais-Battad,[2] Hayley Lund,[2] Scott K. Van Why,[1] David L. Mattson.[2] *[1]Pediatrics, Medical College of Wisconsin; [2]Physiology, Medical College of Wisconsin, Milwaukee, WI.*

Background: The infiltration of T lymphocytes in the kidney accompanies hypertension and renal damage in Dahl SS rats. Pharmacological or genetic reduction of T cells attenuates hypertension and renal damage in SS rats fed high salt. An examination of the infiltrating T cells in the kidney demonstrated that interleukin 6 (IL-6) mRNA levels are >50-fold higher in T cells isolated from the kidney in comparison to circulating T cells. IL-6 is a pro-inflammatory cytokine which positively correlates with hypertension in humans.

Methods: Experiments were performed to assess the potential role of IL-6 in Dahl SS hypertension by administering goat anti-rat IL-6 neutralizing antibody (anti-rIL-6; 4 µg /day, IP; R&D Systems, Minneapolis, MN) or normal goat IgG control (4 µg/day, IP) for 11 days.

Results: The MAP and urine protein excretion rates (Upro) were similar between the groups of SS rats (n=13-16/group) when fed low salt (0.4% NaCl) chow. Following 11 days of high salt (4.0% NaCl), the rats receiving anti-rIL-6 demonstrated a significant reduction in immunoreactive IL-6 in the renal medulla compared to control group (954±133 pg/ml vs 1802±336 pg/ml). Moreover, the increase in MAP following 11 days of 4.0% NaCl intake was significantly attenuated in treated (MAP=138±3 mmHg) vs the control group (MAP=149±3 mmHg). The Upro as a marker of renal damage was also significantly attenuated in treated (193±17 mg/day) vs control group (252±20 mg/day). To investigate mechanisms of action, a flow cytometry analysis of infiltrating immune cells in the kidney (n=4-5/group) was performed. The total number of leukocytes (CD45+) was significantly lower in the treated vs the control group averaging $4.8\pm0.5\times10^6$ vs $6.8\pm0.5\times10^6$ cells/kidney. The total number of monocytes and macrophages (CD11b/c+) was significantly lower in the treated vs the control group by 31%. The total number of T cells and T regulatory cells were not different among the groups.

Conclusions: The present studies indicate that IL-6 may participate in the development of SS hypertension and end-organ damage by mediating the infiltration of leukocytes into the kidney.

High Salt Affects Toll-Like Receptor-Induced Gene Expression in Macrophages David Severs, Martin Hoogduijn, Alexander H. Danser, Robert Zietse, Ewout J. Hoorn. *Internal Medicine, Erasmus Medical Center, Rotterdam, Netherlands.*

Background: High dietary salt intake is a major risk factor for cardiovascular disease. A high-salt (NaCl) diet increases NaCl concentrations in the skin. In the skin, macrophages respond to high NaCl by the osmosensitive transcription factor NFAT5 and promote NaCl efflux via lymph vessels. Other effects of NaCl on local macrophages have remained largely elusive. Recent evidence suggests that NFAT5 also regulates multiple Toll-like receptor (TLR)-induced genes such as NOS2, TNF and IL6 in macrophages, independently of osmotic stress. We aimed to investigate the effects of NaCl-generated hypertonicity on the expression of these genes in TLR-activated macrophages.

Methods: We simulated the hypertonic skin microenvironment by culturing macrophage-like RAW 264.7 cells in NaCl-induced hypertonic media (340-480 mOsm/kg) and compared this with normotonic media (320 mOsm/kg). After 1 to 24 hours of stimulation with lipopolysaccharide (LPS) or Zymosan A, a TLR2 ligand, we measured nitrite production, and analyzed TLR response genes by quantitative RT-PCR, and p38-MAPK, NFAT5, and NOS2 by immunoblot.

Results: NaCl significantly and dose-dependently increased nitric oxide (NO) production (2-fold), NOS2 mRNA (3-fold) and NOS2 protein expression (2.25-fold) in LPS- and Zymosan A-stimulated cells. In contrast, equiosmolar mannitol or urea did not affect expression levels. NaCl also increased LPS-induced p38 phosphorylation and total NFAT5 protein expression. Similarly, NaCl increased TNF mRNA expression 1.25-fold. Remarkably, NaCl significantly downregulated LPS-induced expression of CCL5 (4-fold), IL6 (2.4-fold) and IL12b mRNA (3.5-fold).

Conclusions: Elevated concentrations of NaCl, comparable with those found in the skin after high dietary salt intake, amplify expression of NOS2 and TNF in TLR-stimulated macrophages. This effect is likely mediated via p38 and NFAT5. Increases in NOS2 and TNF expression were paralleled by a sharp decline in mRNA expression of other proinflammatory genes. Modulation of TLR-mediated macrophage activation by NaCl may be relevant both for the physiological response to high dietary salt and salt-sensitive hypertension.

FR-PO119

Indoxyl Sulfate Upregulates Aortic Expression of (Pro)renin Receptor by Reactive Oxygen Species and Activation of AhR/NF-κB Pathway in Vascular Smooth Muscle Cells Maimaiti Yisireyili,[1] Toshimitsu Niwa.[2] *[1]Cardiology, Nagoya Univ Graduate School of Medicine, Nagoya, Aichi, Japan; [2]Faculty of Health and Nutrition, Shubun Univ, Ichinomiya, Aichi, Japan.*

Background: Chronic kidney disease (CKD) is considered major causes of death in cardiovascular disease (CVD) patients. (Pro)renin receptor (PRR) is significantly expressed in the kidney of CKD and vascular system. In this study we aimed to clarify the role of indoxyl sulfate (IS), a uremic toxin, in PRR activation in rat aorta and human aortic smooth muscle cells (HASMCs).

Methods: CKD rats and IS-administrated rats were subjected for in vivo experiments. Human aortic smooth muscle cells (HASMCs) was treated with or without indoxyl sulfate.

Results: Immunohistochemistry showed increased expression of PRR and renin/prorenin in aorta of CKD rats and IS-administrated rats compared with normal rats. IS elevated the expression of PRR and prorenin in HASMCs. N-acetylcysteine, an antioxidant, and diphenyleneiodonium, an inhibitor of nicotinamide adenine dinucleotide phosphate oxidase, suppressed IS-induced expression of PRR and prorenin in HASMCs. Knock down of organic anion transporter 3 (OAT3), aryl hydrocarbon receptor (AhR) and nuclear factor-κB p65 (NF-κB p65) with small interfering RNAs inhibited IS-induced expression of PRR and prorenin in HASMCs. Knock down of PRR inhibited cell proliferation and tissue factor expression induced by not only prorenin but also IS in HASMCs.

Conclusions: IS promotes aortic expression of PRR and renin/prorenin through OAT3-mediated uptake, production of reactive oxygen species, and activation of AhR and NF-κB p65 in vascular smooth muscle cells.

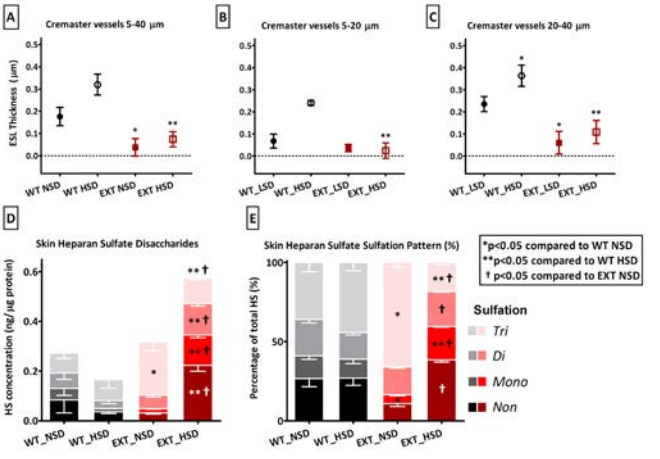
Role of Skin and Endothelial Surface Layer Heparan Sulfates in Blood Pressure Regulation Rik Hg Olde Engberink,[1] Naomi Van Vlies,[2] Bert-jan Van den Born,[3] Ed van Bavel,[4] Liffert Vogt.[1] *[1]Nephrology, AMC, Amsterdam, Netherlands; [2]Laboratory of Genetic Metabolic Disease, AMC, Amsterdam, Netherlands; [3]Vascular Medicine, AMC, Amsterdam, Netherlands; [4]Biomedical Engineering and Physics, AMC, Amsterdam, Netherlands.*

Background: Besides the skin, the endothelial surface layer (ESL) contains many glycosaminoglycans (GAGs) that can osmotically inactivate Na^+ and may affect blood pressure (BP). EXT genes regulate heparan sulfate (HS) polymerization, the predominant ESL GAG. In mice with heterozygous loss of EXT1 and EXT2 (EXT), and wildtype (WT) mice, we investigated the role of HS in the skin and ESL in BP regulation after an acute and chronic NaCl load.

Methods: We investigated BP effects of a 7-d normal (0.3%, NSD) and high (8.0%, HSD) NaCl diet, with tail cuff measurements, and an acute 1.8% NaCl load (8 µl/g) with intracarotid measurements. We used intravital microscopy to estimate ESL thickness in <40 µm cremaster vessels on both diets. We used high performance liquid chromatograph-mass spectrometry to measure skin HS disaccharide concentration.

Results: Baseline BP was equal in WT and EXT mice (p=0.9), with no difference between NSD and HSD. Relative to WT, acute NaCl infusion increased BP in EXT mice (p=0.02), while heart rate remained equal (p=0.5). After a NSD and HSD, EXT mice had a 78% reduction of ESL thickness compared to WT mice (Fig A). HSD increased ESL thickness in WT, especially in 20-40 µm vessels, but not in EXT mice (Fig BC). Skin HS concentration and sulfation patterns were equal between diets in WT mice (Fig DE). On NSD, EXT mice had more highly sulfated HS compared to WT (Fig DE). EXT mice on a HSD had the highest skin HS concentration, of which most were low-sulphated.



Conclusions: An intact ESL is pivotal to prevent a BP increase during acute NaCl excess. Skin GAGs may be particularly important to prevent detrimental NaCl effects on the long-term, especially when the ESL is damaged.

Functional and Dynamic Microcompartmentation of Cav-1/TRPV4/K_{Ca} in Caveolae of Endothelial Cells Andreas Hofmeister, Sybelle Goedicke-Fritz, Anuradha Kaistha, Ivica Grgic, Joachim Hoyer. *Dept of Internal Medicine and Nephrology, Philipps-Univ Marburg, Marburg, Germany.*

Background: Ca^{2+}-activated K^+ channels (K_{Ca}) play an important role in the endothelium-dependent hyperpolarization and regulation of vascular tone and blood pressure. For activation, K_{Ca} depend on an increase of intracellular calcium which is largely mediated by Ca^{2+}-permeable cation channels including the transient receptor potential V4 (TRPV4). It has been proposed that K_{Ca} and Ca^{2+}-permeable cation channels may be clustered in localized positions within the cell membrane to form functional units and that caveolae may constitute the scaffolding for such microcompartmental organization.

Methods: Here, we sought to elucidate the composition and functional relevance of these microcompartments in vitro and in vivo.

Results: We show that TRPV4 and small-conductance $K_{Ca}2.3$ are enriched in caveolae of human microvascular endothelial cells. Using immunoprecipitation, immunocytology and superresolution microscopy, we found a caveolae-dependent association between caveolin-1, TRPV4 and small conductance $K_{Ca}2.3$, but not intermediate conductance $K_{Ca}3.1$, in endothelial cells under static condition. Mechanical stimulation of cells via exposure to shear stress led to a partial de-novo colocalization of $K_{Ca}3.1$ with Cav-1 and TRPV4. In a mouse model of genetic Cav-1 deficiency, we found significantly reduced K_{Ca}-mediated currents as determined by patch-clamping in carotid artery endothelial cells (CAEC) from Cav-$1^{-/-}$ mice compared to wildtype. Functionally, Cav-1 deficiency was associated with impaired endothelium-derived hyperpolarizing factor (EDHF)-mediated vasodilation in response to shear stress and acetylcholine.

Conclusions: In summary, our findings provide evidence for a dynamic microcompartmentation of TRPV4/K_{Ca} in caveolae of endothelial cells and highlight the importance of Cav-1 for endothelial K_{Ca} functions and flow-induced vasodilation.

FR-PO122

Adenosine A1 Receptor Exacerbates Water-Sodium Retention in Deoxycorticosterone Acetate-Salt Hypertensive Mice Janet Yanqing Mei,[1] Xiaoxiao Shi,[1] Dongli Tian,[1] Xiaoyan Peng,[1] Wei Chen,[2] Limeng Chen.[1] *[1]Nephrology Dept, Peking Union Medical College Hospital, Beijing, China; [2]Cardiology Dept, Peking Union Medical College Hospital, Beijing, China.*

Background: Water-sodium retention is the key change in salt sensitive hypertension. Adenosine A1 receptor (A1AR) engages in tubuloglomerular feedbacks; its activation is followed by increased secretion of atrial natriuretic peptides (ANP) in the heart. We aim to study the function of A1AR in water-sodium retention.

Methods: DOCA-salt hypertensive model was established by removal of left kidney, implantation of a DOCA pellet (200mg, 60-day release), and feeding with high salt diet (8%NaCl). Arterial blood pressure and heart rate were measured by tail-cuff method. Urine samples were collected using metabolic cage. The CD73 (an adenosine synthetase), A1AR, ANP and Corin (a protease cleaves pro-ANP, producing ANP) mRNA expression were measured by real-time PCR.

Results: Wildtype DOCA-salt mice showed higher blood pressure (124.7±20.3 vs. 105.8±14.1 mmHg, $P<0.01$), slower heart rate (562.0±90.8 vs. 681.5±90.1, $P<0.01$), and increase in 24h urine output (3606±2359 vs. 1399±752 ml, $P<0.01$). The adenosine pathway was activated in DOCA-salt mice evidenced by increased CD73 (2.22 and 17.7 times increased expression in kidney and heart, $P=0.034$ and 0.001) and A1AR expression (2.54 and 11.12 times increased expression in kidney and heart, $P=0.032$ and 0.009). The cardiac mRNA expression of ANP and Corin were also significantly higher in DOCA-salt mice (176.67 and 30.93 times increased expression, $P=0.030$ and 0.005). The $A1AR^{-/-}$ mice showed no significant changes in blood pressure or heart rate between DOCA-salt and sham group. The elevation in 24h urine output (7003±3742 vs. 3606±2359 ml, $P=0.031$) and 24h urine sodium excretion (1246.5±860.0 vs. 149.7±48.9 mmol/d, $P=0.028$) was more prominent compared to wildtype DOCA-salt mice. There was no change in either ANP or Corin mRNA expression.

Conclusions: A1AR may exacerbate water-sodium retention in salt sensitive hypertension. The reduction in glomerular hyperperfusion and hyperfiltration through tubuloglomerular feedback possibly outweighs the up-regulation of Corin and subsequent ANP expression.

Dietary Fructose Increases Renal Sympathetic Nerve Activity in Response to High Salt Diet in Awake Freely Moving Rats Noreen F. Rossi,[1,2] Kevin L. Gordish,[1,3] Pablo A. Ortiz,[1,3] William H. Beierwaltes.[1,3] *[1]Physiology, Wayne State Univ School of Medicine, Detroit, MI; [2]Nephrology, John D. Dingell VA Medical Center, Detroit, MI; [3]Hypertension Research, Henry Ford Health Systems, Detroit, MI.*

Background: High consumption of fructose containing foods is increasingly prevalent. Fructose intake is associated with metabolic syndrome including hypertension. Fructose upregulates renal Na and Cl transport and induces neuroexcitation, both of which may increase blood pressure. Here we tested the hypothesis that fructose-fed rats fed a high salt diet will have higher plasma renin activity (PRA), renal sympathetic nerve activity (RSNA) and mean arterial pressure (MAP) than glucose-fed rats on similar diet.

Methods: Male Sprague Dawley rats were instrumented for telemetric MAP and RSNA measurements. They were placed on 20% glucose (GF) or 20% fructose (FF) in their drinking water and 0.4% NaCl diet for 10 days then switched to 4% NaCl diet with further monitoring. RSNA recordings were obtained using LabChart 7 Pro. Rats were also subjected to air jet stress and nasopharyngeal reflex testing.

Results: Baseline MAP was similar in both groups, but was 20 mmHg higher in FF vs GF rats after high salt diet ($P < 0.05$). Baseline integrated RSNA did not differ between GF and FF rats. RSNA decreased in GF rats to 0.961 ± 0.182 mV.s after high salt diet. In contrast, integrated RSNA increased from 1.199 ±0.245 to 1.600 ± 0.231 mV.s after high salt intake in FF rats ($P < 0.05$ vs high salt GF rats). Air jet stress and nasopharyngeal reflex responses in MAP and RSNA in GF rats were as expected and brief but in FF rats both responses were significantly greater and sustained for a longer period of time. High salt suppressed. PRA by only 40% in FF rats: 2.05 ± 0.27ng Ang I/ml/hr (high salt) vs 3.48 ± 0.45 ng Ang I/ml/hr (baseline; $P < 0.05$).

Conclusions: We found that the expected suppression of RSNA by high salt diet is completely reversed into stimulation with high fructose diet. The suppression of PRA by high salt diet is blunted and the response to acute stressors enhanced, thus suggesting increased RSNA is a critical component of fructose-induced salt-sensitive hypertension.

A 20% Fructose Diet Enables Low Concentrations of Angiotensin II to Activate Sodium Transport in the PT via Protein Kinase C (PKC) Pablo D. Cabral, Jeffrey L. Garvin. *Physiology & Biophysics, Case Western Reserve Univ, Cleveland, OH.*

Background: Consumption of high-fructose corn syrup is implicated in the development of hypertension but the mechanisms are poorly understood. The proximal tubule (PT) reabsorbs ~70% of the filtered fluid, Na and most of the bicarbonate via Na/H exchanger 3. Enhanced PT transport is implicated in many forms of hypertension. Angiotensin II (Ang II), atrial natriuretic peptide (ANP) and dopamine regulate Na transport. Enhanced effects of Ang II and decreased actions of ANP and dopamine in the PT may cause salt-sensitive hypertension. Hypothesis: A 20% fructose diet enables low concentrations of Ang II to activate Na transport in the PT via protein kinase C (PKC).

Methods: We isolated and perfused PTs from Sprague Dawley rats that were fed either a control or a 20% fructose diet for 1 week. NHE activity was measured as the recovery of intracellular pH after an NH_4Cl acid pulse using the pH-sensitive dye BCECF. The rate of pH recovery was measured in Fluorescent Units per second (FU/sec).

Results: Ang II (10^{-12}M) did not stimulate NHE under normal conditions. When rats were fed a 20% fructose diet, this concentration stimulated NHE activity from 0.6±0.1 to 1.3±0.1 FU/sec ($p<0.002$;$n=5$). In the presence of the PKC inhibitor Gö6976 (10^{-7}M), Ang II was unable to stimulate NHE activity (from 1.9±0.6 to 1.2±0.2 FU/sec;$n=12$). The dopamine 1 receptor agonist fenoldopam (10^{-6}M), decreased NHE activity to the same extent in PTs from rats fed either a control or a 20% fructose diet (-0.6±0.2 vs -1.1±0.4 FU/sec;$n=5$). ANP (10^{-8}M) also decreased NHE activity to the same extent in PTs from rats fed either a 4% NaCl diet or a 4% NaCl plus 20 % fructose diet (-0.9±0.4 vs -1.1±0.5 FU/sec;$n=12$).

Conclusions: A 20% fructose diet enables low concentrations of Ang II to activate Na transport in the PT via PKC without affecting the inhibitory effects of dopamine and ANP on NHE activity in the PT. These results may partially explain the mechanism by which a fructose diet induces hypertension.

FR-PO125

Megalin-Dependent Intrarenal Generation of Angiotensin II Induced by Podocyte Injury Taiji Matsusaka,[1] Fumio Niimura,[1] Akira Nishiyama,[2] Akihiko Saito,[3] Motoko Yanagita,[4] Iekuni Ichikawa.[1,5] *[1]Tokai Univ School of Medicine, Japan; [2]Kagawa Univ School of Medicine, Japan; [3]Niigata Univ School of Medicine, Japan; [4]Kyoto Univ School of Medicine, Japan; [5]Shinsyu Univ, Japan.*

Background: We previously demonstrated that podocyte injury enhances glomerular filtration of liver-derived angiotensinogen (Agt) and renal angiotensin(A)II generation and that filtered Agt is reabsorbed by proximal tubular cells dependently on megalin. In the present study, we tested whether megalin is involved in intrarenal AII generation.

Methods: For this purpose, we generated proximal tubule specific megalin knockout (KO) mice by crossing megalin-loxP, Ndrg1-Cre, and Kap-Cre mice. Renal AII contents were measured by radioimmunoassay.

Results: In megalin KO mice (n=12), renal megalin mRNA was decreased to 2.5% of that in control mice (n=16). Renal Agt staining was markedly diminished, with increase in urinary Agt in KO mice. However, renal AII levels were similar between KO and control mice (108±11 vs. 101±17 fmol/g). We next tested the effect of megalin KO on AII generation in the kidney with abnormally increased filtered load of Agt in mice with podocyte-specific injury, by crossing with NEP25 mice. Control NEP25 mice (n=10) showed markedly intense renal Agt staining and enhanced renal AII level (450±61). Megalin KO/NEP25 mice (n=12) showed diminished renal Agt staining and significantly attenuated renal AII level (119±23, $p<0.01$). KO/NEP25 mice showed similar renin and Agt mRNA, and more preserved Ace mRNA in the kidney.

Conclusions: These indicate that, in podocyte injury, abnormally increased filtered load of Agt is reabsorbed via megalin by proximal tubular cells and induces the inappropriate activation of intrarenal renin-angiotensin system, which may be involved in the progression of tubulointerstitial damage secondary to podocyte injury.

FR-PO126

Ciliary Neurotrophic Factor Deficiency Protects from Cardiovascular Death in Angiotensin II-Induced Hypertension Ivo Quack,[1] Yuriko Mori,[2] Sebastian Alexander Potthoff,[1] Magdalena Woznowski,[1] Eva Koenigshausen,[1] Lorenz Sellin,[1] Lars C. Rump,[1] Johannes Stegbauer.[1] *[1]Nephrology, Univ Hospital Duesseldorf, Duesseldorf, Germany; [2]Nuclear Medicine, Univ Hospital Duesseldorf, Duesseldorf, Germany.*

Background: It has been shown that the JAK 2 / STAT3 signaling cascade modulates Ang II (Ang II)-dependent hypertension. The ciliary neutrophic factor (CNTF) is an interleukin-6-like cytokine so far known for mediation of survival and differentiation of neuronal cells via JAK2 / STAT3. This study focuses on the role of CNTF in Ang II-dependent hypertension.

Methods: Two weeks after uninephrectomy, Ang II osmotic minipumps (1000 ng/min/kg BW) were implanted in CNTF-KO and age-matched C57/Bl6J male mice (WT). Blood pressure (BP) were measured for 3 weeks by radiotelemetry, starting one week before implantation. Histological and mRNA analysis were performed at the end of the observation period. Renal vascular function was evaluated in the isolated perfused kidney.

Results: At baseline systolic BPs were similar in CNTF-KO and WT mice (119±2 vs.124±1 mmHg). CNTF deficiency significantly attenuated BP increase under Ang II infusion (week 1: 139±3 vs. 153±3 mmHg; week 2: 151±5 vs. 168±4 mmHg; n=19; $P<0.01$). Strikingly, in the CNTF-KO group signifcantly less animals died of cardiovasular causes (4,2% (KO) vs. 29,2% (WT $P<0.05$). In accordance, end organ damage (cardiac hypertrophy, renal vascular fibrosis and tubulo-interstitial damage) was attenuated in the CNTF-KO group. In the isolated perfused kidney, pressor response to Ang II was significantly attenuated in CNTF-KO mice. Administration of CNTF (0.5nM) nearly restored the Ang II dependent pressor response. This effect was mediated through a JAK2/STAT3 dependent pathway as static (0.1μM), a selective STAT3 inhibitor abolished the CNTF induced increase in pressor response in kidneys of CNTF-KO. On cellular basis, CNTF induced phosphorylation of STAT3 and MYPT in VSMCs.

Conclusions: Better survival and less end organ damage strongly suggest that CNTF has a major impact on blood pressure regulation. CNTF seems to modulate the Ang II induced vasoreactivity via a JAK2 / STAT3 dependent mechanism. Thus, CNTF might qualify as therapeutic target in hypertension.

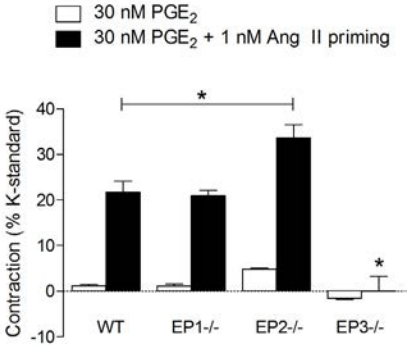
FR-PO127

Angiotensin II AT1 Receptor Potentiates Prostaglandin E2 Vasoconstrictor Effects Maria Palazzo Kraemer,[2] Fred S. Lamb,[3] Richard M. Breyer.[1] *[1]Div of Nephrology and Hypertension, Dept of Veterans Affairs and Vanderbilt Univ, Nashville, TN; [2]Dept of Biochemistry, Vanderbilt Univ, Nashville, TN; [3]Dept of Pediatrics, Vanderbilt Univ, Nashville, TN.*

Background: Prostaglandin E_2 (PGE_2) is a key modulator of blood pressure and arterial tone. It usually has vasodepressor effects however under certain circumstances can act as a vasopressor. Recent reports demonstrated that sub-threshold concentrations of KCl and phenylephrine augment PGE_2-mediated constriction in rat femoral arteries, however the effects of angiotensin II (Ang II) on PGE_2-mediated contraction are unknown.

Methods: Wire myography was performed on femoral arteries isolated from WT or EP deficient mice.

Results: PGE_2 had no effect on mouse femoral arteries at doses up to 1 μM. Pretreatment of arterial rings with 1 nM Ang II potentiated PGE_2-evoked constriction in a dose dependent manner ($AUC_{untreated}$ 1.784±0.353, $AUC_{Ang\ II}$ 23.27±9.820,$P<0.05$). To identify the relevant E-Prostanoid (EP) receptor, femoral arteries from EP1, EP2, and EP3 receptor null mice were tested. Arteries isolated from $EP1^{-/-}$ or $EP2^{-/-}$ but not $EP3^{-/-}$ mice responded to PGE_2 after Ang II priming. Pretreatment of arterial rings with 1 μM losartan, an AT1 angiotensin receptor antagonist, blocked PGE_2-induced constrictor effects primed with Ang II (% KCl, Ang II 21.72 ± 5.296, Ang II + losartan 3.025 ± 1.046, n=3). No constriction was observed in Ca^{2+}-free buffer; re-addition of extracellular Ca^{2+} to the arterial bath restored PGE_2-induced contractions (n=5). The Rho-kinase inhibitor Y-27632 blocked contraction (n=3).



Conclusions: Taken together these data are consistent with angiotensin AT1 and prostaglandin EP3 receptors mediating a synergistic Ca^{2+}/Rho-kinase-dependent contractile response. The synergistic interaction of Ang II and PGE_2 may have physiological relevance in the context of hypertension.

FR-PO128

Angiotensin II Increases Uromodulin Expression and Excretion in Rats Independent of Blood Pressure and Alterations in Tubular Reabsorption Magali Araujo, William J. Welch, Gabriel A. Cordeiro dos Santos, Daurea M. Vieira Paiva, Christopher S. Wilcox. *Medicine, Georgetown Univ, Washington, DC.*

Background: Increased uromodulin (UMOD) has been associated with salt-sensitive hypertension and chronic kidney disease. Evidence suggests that UMOD regulates the trafficking and activity of the Na-K-2Cl cotransporter (NKCC2) and the inward-rectifier type potassium channel (ROMK), the two main transporters involved in Na^+ reabsorption by the TAL. Angiotensin II (AngII) increases net TAL Na^+ transport and Na^+ apical entry; however its interaction with UMOD remains elusive. We hypothesized that ANG II interacts with UMOD to modulate Na^+transport.

Methods: Sprague-Dawley rats (n=5) were infused with a subpressor dose of AngII (100ng/kg/min) or vehicle for 3 days. Blood pressure (BP) was measured by telemetry. On day 2, rats were placed in metabolic cages for 24 h and urine was collected for UMOD and Na/K measurements. On day 3, proximal and distal reabsorption were measured by renal micropuncture and the renal medulla was harvested for determination of UMOD expression by western blot.

Results: Blood pressure was unchanged after 3 days of AngII (veh: 89±3, AII: 81±1mmHg). AngII treated rats had significantly increased UMOD excretion compared with control rats (Veh: 17.63± 2.19, AII: 28.09±3.6, mg/24h, $p<0.05$). Sodium excretion was unchanged (veh: 3.46±0.6 AII: 3.38±0.6 mmol/24h). There were no changes in proximal fractional reabsorption (Veh: 57±2%, AII: 59±0.6%) and distal fractional reabsorption (Veh: 83±3%, AII: 87±2%). UMOD expression in the renal medulla was 3 fold higher in AngII treated rats compared to vehicle rats.

Conclusions: Our data demonstrate that AngII increases UMOD expression and excretion independent of blood pressure and alterations in tubular reabsorption. These results suggest that the interaction of AngII with UMOD precedes Na^+ transport alterations and therefore can be an important mechanism involved in the development of hypertension.

FR-PO129

Effects of Systemic Deletion of Angiotensin Receptor-Binding Molecule on the Aging Kidney Kazushi Uneda, Kouichi Tamura, Hiromichi Wakui, Akinobu Maeda, Kengo Azushima, Sona Haku, Ryu Kobayashi, Masato Ohsawa, Yoshiyuki Toya, Satoshi Umemura. *Dept of Medical Science and Cardiorenal Medicine, Yokohama City Univ Graduate School of Medicine, Yokohama, Japan.*

Background: The renin-angiotensin system plays a key role in the maintenance of cardiovascular and renal homeostasis, principally via appropriate activation of the angiotensin II type 1 receptor (AT1R). On the other hand, exaggerated activation of AT1R signaling would exert detrimental effects, such as various aging-related diseases including renal dysfunction. We previously identified an AT1R-associated protein (ATRAP/*Agtrap*), which is a molecule directly interacting with the AT1R. Accumulating results indicate that ATRAP exerts functionally selective inhibition on exacerbated AT1R activation in response to pathological stimuli. The present study was performed to investigate pathophysiological significance of ATRAP in aging-related phenotypes by employing systemic ATRAP-knockout mice (ATRAP-KO mice).

Methods: ATRAP-KO mice and their wild-type control mice (WT mice) were fed the standard diet and maintained until death to estimate their life spans. Their growth (body weight change and appearance) and physiological parameters (blood pressure, caloric intake and glucose and lipid metabolism) were also analyzed. Furthermore, aging-related organ damages in the hearts, aortas and kidneys were examined in young (3 to 4 months old) and aged (22 to 25 months old) mice in both groups.

Results: There was no difference in the growth between two groups. In addition, ATRAP-KO mice did not show any evident alteration of physiological parameters. However, the life span of ATRAP-KO mice was significantly shorter than that of WT mice (KO vs WT; median life span, 100.4 weeks vs 123.1 weeks, log-rank test, $P<0.001$). By further analysis we found no significant difference in cardiovascular aging-related phenotype between two groups. On the other hand, renal fibrosis was exacerbated in aged ATRAP-KO mice compared to aged WT mice.

Conclusions: In the present study, ATRAP-KO mice showed accelerated renal fibrosis with shortened life span. Therefore, ATRAP deficiency seems to exacerbate the aging-related renal fibrosis and to inhibit the longevity.

FR-PO130

Effects of Deficiency of Angiotensin Receptor-Binding Molecule on Blood Pressure Regulation in Chronic Kidney Disease Ryu Kobayashi, Kouichi Tamura, Hiromichi Wakui, Kengo Azushima, Sona Haku, Kazushi Uneda, Kotaro Haruhara, Kohji Ohki, Sho Kinguchi, Masato Ohsawa, Yoshiyuki Toya, Satoshi Umemura. *Dept of Medical Science and Cardiorenal Medicine, Yokohama City Univ Graduate School of Medicine, Yokohama, Kanagawa, Japan.*

Background: The renin-angiotensin system plays a key role in the maintenance of cardiovascular and renal homeostasis, principally via appropriate activation of Ang II type 1 receptor (AT1R). On the other hand, exaggerated activation of AT1R signaling would exert detrimental effects, such as promoting various aging-related diseases including chronic kidney disease (CKD). We previously identified an AT1R-associated protein (ATRAP/*Agtrap*), which is a molecule directly interacting with the AT1R.Accumulating results indicate that ATRAP exerts functionally selective inhibition on exacerbated AT1R activation in response to pathological stimuli. The present study was performed to investigate pathophysiological significance of ATRAP in mice model of CKD by employing systemic ATRAP-knockout mice (ATRAP-KO mice).

Methods: ATRAP-KO mice and their wild type control mice (WT mice) were subjected to 5/6 nephrectomy (Nx) as CKD model. To examine the effects of ATRAP deficiency, blood pressure and other parameters were measured in ATRAP-KO mice and WT mice after 5/6 Nx.

Results: At baseline, blood pressure was similar in ATRAP-KO and WT mice. In ATRAP-KO mice, blood pressure increased from 2 to 8 weeks after 5/6 Nx and was significantly higher than that in WT mice (ATRAP-KO vs WT; systolic blood pressure at 4 weeks after 5/6 Nx, 124±2 mmHg vs 107±1mmHg, $P<0.01$). With respect to the mechanism of elevated blood pressure in ATRAP-KO mice after 5/6 Nx, plasma volume was significantly higher in ATRAP-KO mice than in WT mice after 5/6 Nx, in spite of no significant difference in creatinine clearance between two groups after 5/6 Nx.

Conclusions: Although ATRAP-KO mice show similar blood pressure and renal function with WT mice in normal condition, ATRAP-KO mice exhibited significantly

increased blood pressure and plasma volume after 5/6 Nx compared with WT mice. Therefore, endogenous ATRAP may exert a protective function against pathological blood pressure elevation in CKD.

FR-PO131

In Vivo Action of Angiotensin II Type 1a Receptor in Renal Injury Induced by Deoxycorticosterone Acetate-Salt Hypertension Mikako Hisamichi,[1] Atsuko Ikemori,[1,2] Takeshi Sugaya,[1] Daisuke Ichikawa,[1] Kenjiro Kimura,[3] Yugo Shibagaki.[1] *[1]Div of Nephrology and Hypertension, Dept of Internal Medicine, St. Marianna Univ School of Medicine, Kawasaki, Japan; [2]Dept of Anatomy, St. Marianna Univ School of Medicine, Kawasaki, Japan; [3]Dept of Internal Medicine, Tokyo Takanawa Hospital, Tokyo, Japan.*

Background: The AT1a receptor plays a major role in the renal action of Ang II and is expressed in vascular smooth muscle cells of the afferent arterioles.In this study, we investigated the morphological change in deoxycorticosteron acetate (DOCA)-salt hypertensive pathology in order to confirm the in vivo function of the AT1a receptor against renal damage due to hypertension.

Methods: To examine urinary L-type fatty acid binding protein (L-FABP) as an indicator of tubulointerstitial damage, we used human L-FABP chromosomal transgenic mice (L-FABP$^{+/-}$ AT1a$^{+/+}$) and L-FABP transgenic mice in addition to disrupting the AT1a receptor gene (L-FABP$^{+/-}$ AT1a$^{-/-}$). L-FABP$^{+/-}$ AT1a$^{+/+}$ and L-FABP$^{+/-}$ AT1a$^{-/-}$ mice were administered DOCA tablets plus 1% NaCl water for 28 days.

Results: In the DOCA salt hypertensive model with L-FABP$^{+/-}$ AT1a$^{+/+}$ (L-FABP$^{+/-}$ AT1a$^{+/+}$-DOCA), slight expansion of the glomerular area and tubulointerstitial damage were observed, but not glomerular sclerosis. In the AT1aknockout mice administered DOCA-salt (L-FABP$^{+/-}$ AT1a$^{-/-}$-DOCA mice), glomerular sclerosis with expansion of the mesangial area was found, and the degree of tubulointerstitial damage was more severe compared to L-FABP$^{+/-}$ AT1a$^{+/+}$-DOCA mice. Both urinary albumin and L-FABP levels were significantly higher in the L-FABP$^{+/-}$ AT1a$^{-/-}$-DOCA mice than in the L-FABP$^{+/-}$ AT1a$^{+/+}$-DOCA mice. This renal damage induced in the L-FABP$^{+/-}$ AT1a$^{-/-}$-DOCA mice was significantly attenuated by reduction of blood pressure using Hydralazine. Activation of the AT1a receptor may contribute to myogenic response of the afferent arteriole involved in the renal autoregulatory mechanism.

Conclusions: In conclusion, kidneys without AT1a receptors exhibited an increased vulnerability to hypertension, and therefore activation of the AT1a receptor inhibited the transmission of the elevated systemic pressures to the glomeruli.

FR-PO132

Renal Blood Flow and Oxygenation During Renin-Anigotensin-Aldosterone System Activation – Two Sides of the Same Coin? René van der Bel,[1] Aart J. Nederveen,[2] Bram F. Coolen,[2] Wouter V. Potters,[2] Hein J. Verberne,[3] Liffert Vogt,[1] Erik Stroes,[1] C.T.P. (Paul) Krediet.[1] *[1]Internal Medicine, AMC, Univ of Amsterdam, Netherlands; [2]Radiology, AMC, Univ of Amsterdam, Netherlands; [3]Nuclear Medicine, AMC, Univ of Amsterdam, Netherlands.*

Background: In chronic kidney disease, renal hypoxia and renin-angiotensin-aldosterone system (RAAS) activation may augment each other. Although renal oxygenation (RO) measured by Blood Oxygen Level Dependent (BOLD) MRI is not correlated to Glomerular Filtration Rate (GFR), recent data suggest that RO relates to inter-individual variation in RAAS activity. To further explore this we measured the effects of Angiotensin II (Ang-II) on renal blood flow (RBF) and RO in healthy humans.

Methods: After a 30 min baseline phase, 8 healthy volunteers (age 19-22 years) were subjected to continuous Ang-II infusion at 0.3, 0.9 and 3.0 ng/kg/min for 12 minutes per dose. RO and RBF were assessed by BOLD and phase contrast MRI, respectively (Ingenia 3.0T, Philips Healthcare). Off-line, R2* values were calculated for cortex and medulla, via mono-exponential fitting to multi-echo 2-dimensional fast field-echo data (TR 140 ms; FA 70°; min TE 2 ms; DTE 5 ms; 16 echoes; voxel 1.2 mm^2 by 4 mm). RBF was calculated in the proximal renal artery after manual vessel segmentation. During a second visit (n=6), GFR and Effective Renal Plasma Flow (ERPF) were measured by ^{125}I-thalamate and ^{131}I-hippuran clearing test during equal Ang-II infusion.

Results: Mean arterial blood pressure increased from 83.0±2.85 at baseline to 91.3±3.76 mmHg (p=0.002). RBF decreased dose dependently from 11.1±2.08 to 8.05±1.02 (p=0.02) ml/s. GFR and ERPF both decreased (10±7.1%, p=0.016; 24±4.5%, p<0.001). RBF and ERPF measurements strongly correlated (R = 0.75 p<0.001). There was a trend towards a cortical R2* increase by 7.2±3.76% (p=0.014); medullar R2* did not change. Cortical DR2* and DRBF inversely correlated (R=0.42, p=0.044). Cortical DR2* and ΔGFR correlated (R=0.48, p=0.017).

Conclusions: Ang-II causes a dose dependent DRBF. The observed DRO seem to differ between cortex and medulla. Only for the cortex BOLD may provide an index of tissue perfusion.

FR-PO133

Chloride Contributes to Hypertension and Renal Injury in Aldosterone-Salt Treated Rats Takahiro Yamauchi, Shigehiro Doi, Toshiki Doi, Kensuke Sasaki, Toshinori Ueno, Ayumu Nakashima, Takao Masaki. *Dept of Nephrology, Hiroshima Univ Hospital, Hiroshima, Japan.*

Background: Aldosterone-salt treatment is known to induce renal inflammation and plays an important role in the development of renal fibrosis as well as elevation in blood pressure.In addition to sodium, chloride has recently been reportedly to be involved in renal damage, raising the possibility that sodium-bicarbonate may ameliorate renal injury and hypertension in rats treated with aldosterone. This study investigated the role of chloride on renal damage and hypertension by comparing rats treated with aldosterone in combination with either sodium chloride or sodium carbonate.

Methods: Following a left nephrectomy, 8-week-old male Sprague-Dawley rats were implanted with a osmotic infusion mini-pump and then allocated to the following 3 groups; 1) drinking a 1% NaCl solution with aldosterone infusion (NaCl-aldosterone treated group), 2) drinking a 1% $NaHCO_3$ solution with aldosterone infusion ($NaHCO_3$-aldosterone treated group), and 3) drinking water with vehicle infusion. Blood pressure levels were measured weekly by the tail cuff method. After 6 weeks, the rats were sacrificed and their renal tissues examined by immunoblotting and immunohistochemistry.

Results: The NaCl-aldosterone group had higher blood pressure levels than the $NaHCO_3$-aldosterone group. Protein expression of αENaC and Pendrin in the membrane fraction was also increased in the NaCl-aldosterone group compared with the $NaHCO_3$-aldosterone group. In addition, the NaCl-aldosterone group had high protein levels of NCC and phosphorylated NCC in the whole protein and membrane fractions. On the other hand, the expression of inflammatory (CD3, CD68, IL17A, IL-23 receptor) and fibrotic markers (α-smooth muscle actin, collagen1) were greater in the NaCl-aldosterone group.

Conclusions: These findings suggest that chloride plays an important role in the development of NaCl-aldosterone-induced hypertension and renal injury.

FR-PO134

RAGE-DNA Aptamer Improves Aldosterone-Induced Renal Injury Possibly via Inhibition of Rac1-MR Axis in Mice with Hypertensive Nephropathy Kensei Taguchi,[1] Sho-ichi Yamagishi,[2] Yuichiro Higashimoto,[3] Yosuke Nakayama,[1] Katsuhiko Asanuma,[4] Seiji Ueda,[1] Kei Fukami.[1] *[1]Div of Nephrology, Dept of Medicine; [2]Dept of Pathophysiology and Therapeutics of Diabetic Vascular Complications; [3]Dept of Chemistry, Kurume Univ School of Medicine, Kurume, Japan; [4]Div of Nephrology, Kyoto Univ Graduate School of Medicine, Kyoto, Japan.*

Background: Advanced glycation endproducts (AGEs) stimulate the generation of reactive oxygen species (ROS) and subsequently enhance various intracellular pathways through the interaction with receptor for AGEs (RAGE). Although AGEs-RAGE axis has been mainly investigated in diabetic nephropathy, its pathophysiological role in hypertensive nephropathy (HN) is unknown. In addition, recent evidence has suggested that aldosterone (aldo)-mineralocorticoid receptor (MR) system plays a crucial role for the pathogenesis of HN. In this study, we examined whether AGEs-RAGE system could interact with aldo-MR axis in deoxycorticosterone acetate(DOCA)-induced HN in mice. Further, we explored the inhibitory effects of DNA-aptamer directed against RAGE (RAGE-aptamer) on the progression of HN.

Methods: Uninephrectomized 8-week-old C57Bl/6J male mice were divided into three groups; 4% salt diet (control), 4% salt diet with DOCA (50mg), and DOCA with hydralazine (Hyd). RAGE-aptamer constructed by SELEX method was continuously administrated with osmotic mini pump.

Results: DOCA elicited-UAE was independent of blood pressure. Renal ROS generation, RAGE protein expression and plasma carboxymethyl lysine (CML) levels were elevated in DOCA/salt mice. RAGE was colocalized MR in podocytes by immunohistological analysis. Further, GTP-bound Rac1 activation and MR overexpression were observed in DOCA/salt mice. DOCA-elicited increase in UAE, renal ROS generation and RAGE expression, plasma CML levels were improved by RAGE-aptamer independent of blood pressure. Interestingly, RAGE-aptamer suppressed GTP-bound Rac1 activity and MR overexpression in DOCA/salt mice.

Conclusions: AGEs-RAGE axis and Rac1-MR pathway could be correlated with each other, which could lead to podocyte injury in HN. RAGE-aptamer may be a novel therapeutic strategy for the progression of HN.

FR-PO135

Dipeptidyl Peptidase-4 Inhibitor Ameliorates the Aldosterone-Induced Renal Fibrosis Kang-Yung Peng, Vincent Wu. *Dept of Internal Medicine, National Taiwan Univ, Taipei, Taiwan.*

Background: Renal fibrosis is considered a common outcome of a wide variety of chronic kidney diseases with diverse causes. However, no antifibrotic agent has been approved in clinical practice yet. In this study, we examined the effect of dipeptidyl peptidase-4 (DPP-4) inhibitor against renal fibrosis induced by aldosterone.

Methods: Human proximal tubular epithelial cells (HK2) were used to examine the inhibitory effect of DPP-4 inhibitor on aldosterone induced epithelial-mesenchymal transition (EMT). Besides, aldosterone infusion mice were used to evaluate the effect of DPP-4 inhibitor, linagliptin, on aldosterone induced renal fibrosis. Expression of TGF-β, OPN and molecules involved in EMT were examined using western blot and immunohistochemistry. Renal fibrosis was determined by Masson's trichrome staining.

Results: *In vitro* studies showed that aldosterone significantly increases the expression of TGF-β, OPN and markers of EMT in HK2 cells, while these effects were abolished in that treated with DPP-4 inhibitor. Similarly, the aldosterone-infused mice exhibited severe kidney fibrosis. The expression of TGF-β, OPN, vimentin and α-SMA were induced by aldosterone, and oral DPP-4 inhibitor ameliorated the kidney fibrosis and lessened the increase in fibrotic proteins without significant changes in blood pressures.

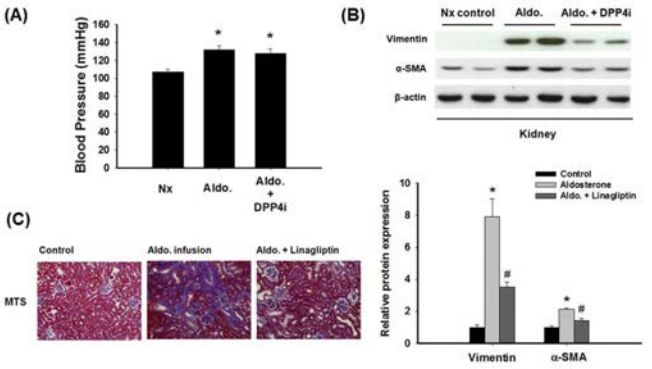

Figure. Effect of DPP4 inhibitor on aldosterone induced renal fibrosis

Conclusions: In this study, our results suggest that DPP-4 inhibitor possesses anti-EMT effect to ameliorate the aldosterone-induced renal fibrosis, which may partly attribute to regulating TGF-β/OPN pathways. These findings may guide us in therapeutic strategies for aldosterone-induced renal fibrosis.

FR-PO136

G-Protein-Coupled Receptor 40 Mediates the Regulation of Epithelial Sodium Channel by Epoxyeicosatrienoic Acid Signaling Seong Kwon Ma, Ha Yeon Kim, Chang Seong Kim, Eun Hui Bae, Soo Wan Kim. *Internal Medicine, Chonnam National Univ Medical School, Gwangju, Republic of Korea.*

Background: Epoxyeicosatrienoic acid(EET) plays diverse functions including cellular proliferation, anti-inflammation and vasorelaxation. Although it has been demonstrated that EET also regulate epithelial sodium channel (ENaC), the potential functional receptor mediating the biological effect of EET has remained elusive. In the present study, we investigated the role of GPR40 mediating ENaC regulation of EET in mouse cortical collecting duct (M1-CCD) cell line.

Methods: M1-CCD cells were cultured with aldosterone in the absence or presence of 14,15-EET. In addition, M1-CCD cells treated with aldosterone were cultured in the absence or presence of GW9110, a GPR40 antagonist.

Results: The mRNA and protein of ENaC-α and GPR40 were endogenously expressed in the M1-CCD cells as well as the cortical collecting ducts of murine kidney. Treatment with aldosterone increased the protein expression of ENaC-α and mineralocorticoid receptor (MR). These changes were abolished by 14,15-EET treatment, and treatment with 14,15-EET increased the phosphorylation of ERK1/2. Inhibition of GPR40 by treatment with GW9110 enhanced the aldosterone-induced upregulation of ENaC-α and MR, while decreased ERK1/2 phosphorylation.

Conclusions: In conclusion, EET inhibits aldosterone-induced ENaC activation by the inhibition of MR and activation of ERK1/2. GPR40 inhibition augmented the aldosterone-induced ENaC activation by the activation of MR and inhibition of ERK1/2. These findings suggest that GPR40 mediated the ENaC regulation by EET signaling.

FR-PO137

The Extra Renal Effect of Hydrochlorothiazide on Systemic Blood Pressure: Role of Vasodilation in Volume Depleted States Saeed Alshahrani,[1] Jack Rubinstein,[2] Min Jiang,[2] Sharon L. Barone,[2,3] Jie Xu,[2] Kamyar A. Zahedi,[2,3] Manoocher Soleimani.[1,2,3] *[1]Pharmacology, Univ of Cincinnati, Cincinnati, OH; [2]Internal Medicine, Univ of Cincinnati, Cincinnati, OH; [3]Research Services at VA Hospital, Cincinnati, OH.*

Background: Thiazides are specific inhibitors of the Na^+-Cl^- Co-transporter (NCC) in the distal nephron, and the most commonly used diuretics for the treatment of mild hypertension. The mechanism of hypotensive action of thiazides is not clear. The accepted belief is that the primary effect of thiazides is through the enhancement of salt excretion; however, several studies point out the extra renal effects of thiazides. The blood pressure response to thiazides requires an initial volume loss of about 1.5 kg, which it is not observed in individuals who are ingesting a high-salt diet.

Methods: Balance studies were performed in age/sex-matched wild type and NCC deficient mice. The blood pressure was measured using computerized tail cuff method. Cardiac functions were analyzed by echocardiography.

Results: Hydrochlorothiazide (HCTZ) significantly reduces systemic blood pressure when NCC KO mice are volume-depleted and their renin-angiotensin system (RAS) is activated, however, it had no effect on blood pressure of salt replete NCC KO mice. The reduction in blood pressure in salt depleted animals was dramatic, happened within hours after HCTZ and occurred in the absence of any increase in salt excretion, indicating its extra-renal origin. Echocardiography showed no significant changes in cardiac output in response to HCTZ. The antihypertensive effects of HCTZ were abrogated in the presence of a blocker of large conductance Ca+2 activated K+ (BK) channels, Paxilline. Western blots demonstrated significant enhancement of BK expression in vascular system of salt depleted, NCC-deficient mice.

Conclusions: Our results indicate that vasoconstriction secondary to RAS activation amplifies the extra-renal hypotensive action of HCTZ through vasodilation irrespective of the status of its renal target. Patients on a combination diuretic regimen such as furosemide and HCTZ are at increased risk of hypotension and kidney hypoperfusion subsequent to systemic vasodilation by HCTZ.

Mitochondrial Oxidative Stress-Activated Renal Local RAS Promotes the Expression and Function of NCC in Proteinuric Kidney Disease Songming Huang,[1,2] Yibo Zhuang,[1] Guixia Ding,[1] Zhanjun Jia,[1,2] Aihua Zhang.[1,2] *[1]Nephrology Dept, Nanjing Children Hospital, Nanjing Medical Univ, Nanjing, China; [2]Nanjing Key Laboratory of Pediatrics.*

Background: The fluid retention and hypertension are common complications of kidney diseases, whose pathogenic mechanisms remain elusive.

Methods: Kidney tissues from mice subjected to albumin overload via i.p injection for 12 days and renal biopsy specimens were analyzed.

Results: Following albumin overload, we found a striking increase of Na^+-Cl^- cotransporter (NCC) expression by 2.3-fold in mouse kidneys determined by Western blotting and qRT-PCR. To evaluate NCC function in these mice, NCC inhibitor hydrochlorothiazide (10mg/kg) was administered via a single i.p injection. In agreement with NCC upregulation, the response to hydrochlorothiazide was significantly enhanced in albumin overloaded mice. Considering the established role of renin-angiotensin system (RAS) in regulating sodium transporters, we examined key components of RAS and found a striking elevation of angiotensinogen (AGT) and angiotensin converting enzyme (ACE) by 2-3 folds in line with enhanced urinary AngII excretion. In proteinuric patients, we also observed 4-fold upregulation of NCC and remarkable stimulation of ACE detected by immunohistochemistry in accord with significantly increased urinary Ang II output. To further investigate the role of RAS in NCC upregulation, we did primary culture of renal tubular cells and observed that albumin directly increased NCC paralleled with significant induction of AGT, ACE, and Ang II. Strikingly, administration of specific ACE inhibitor captopril to the cells remarkably abolished albumin-induced enhancement of NCC and RAS components. Additionally, albumin overload significantly reduced mitochondrial superoxide dismutase (SOD2) by 60%, and administration of a SOD2 mimic (MnTBAP) entirely abolished the stimulation of NCC, AGT, and ACE in mice with albumin overload.

Conclusions: The findings demonstrated an important role of albuminuria in upregulating NCC expression via a mitochondrial oxidative stress-initiated stimulation of renal local AGT/ACE/Ang II, which may contribute to the fluid retention and hypertension in proteinuric kidney disease to some extent.

Funding: Government Support - Non-U.S.

FR-PO139

Prophylactic and Therapeutic Tenapanor Are Vascular Protective in a Rat Model of CKD Ann-Cathrine Jönsson-Rylander,[1] Margareta Behrendt,[1] Craig F. Plato,[2] Denise L. Schwabauer,[2] Peter J. Greasley.[1] *[1]AstraZeneca R&D, Mölndal, Sweden; [2]Plato Biopharma Inc., Denver, CO.*

Background: Tenapanor (AZD1722), an inhibitor of the Na^+/H^+ exchanger NHE3, reduces absorption of gut sodium and phosphate. It is being developed for renal and constipation-related indications.

Methods: 5/6 nephrectomized Sprague Dawley rats were fed 4% NaCl chow to induce salt-sensitive arterial hypertension. Oral tenapanor (1 mg/kg/day) was initiated either at the start of NaCl intake (prophylactic; Px) or 2 weeks later (therapeutic; Tx), and was administered for up to 6 weeks. Disease controls (DCs; vehicle-treated) and healthy controls (HCs; sham operated, normal chow) were included to enable assessment of disease progression. Systemic hemodynamics and urinary and plasma biomarkers were assessed every 2 weeks. *Ex vivo* vascular function (isometric tension recording) or arterial stiffness (pulse wave velocity) was evaluated at 2 and 6 weeks.

Results: Compared with DCs, rats in the Px and Tx groups had reduced urinary albumin, protein, sodium and phosphorus excretion ($p<0.05$), and looser stools. Systolic, diastolic and mean BP increased in DCs but were normalized in the Tx group. Arterial stiffness was reduced by Px and Tx tenapanor ($p<0.05$). Compared with HCs, DCs had impaired aortic vasoconstrictor and vasodilator function at 2 weeks ($p<0.05$) and significant endothelial dysfunction at 6 weeks. Px tenapanor normalized, and Tx tenapanor attenuated arterial hypertension, vascular stiffness, vasoconstrictor and endothelium-dependent and independent vasodilator function (Table).

	ΔEC_{50} (denuded vs intact endothelium)[a]		EC_{50} (intact endothelium)[b]	Pulse wave velocity change
	Phenylephrine (nM)	Nitroprusside (nM)	Acetylcholine (nM)	
HCs	187.5±49.3	0.5±0.2	11.9±1.21	–
DCs	12.7±3.2*	15.4±2.7*	80.3±8.7*	75.4%*
Tx tenapanor	102.7±28.6†	2.8±0.9†	10.3±1.38†	−60.7%†
Px tenapanor	120.5±25.3†	1.06±0.3†	8.15±0.71†	−81.9%†

*$p<0.05$ vs HCs; †$p<0.05$ vs DCs; [a]Mean±SEM; [b]Mean±SD.
DCs, disease controls; HCs, healthy controls; Px, prophylactic; Tx, therapeutic; EC_{50}, half maximal effective concentration.

Conclusions: Tenapanor prevented most of the maladaptive consequences in a rat model of renal insufficiency-induced salt-sensitive arterial hypertension and CKD. The benefit of Tx treatment was similar to that elicited by Px use, suggesting disease modification.

Urinary Exosome Profiling in Thiazide Induced Hyponatremia

Sarath Kiran Channavajjhala,[1] Theresa Peltz,[3] Wenjing Jia,[1] Ian Hall,[1] Kevin O'Shaughnessy,[2] Matthew A. Bailey,[3] James W. Dear,[3] Mark Glover.[1] *[1]Div of Therapeutics and Molecular Medicine, Univ of Nottingham, United Kingdom; [2]Clinical Pharmacology Unit, Univ of Cambridge, United Kingdom; [3]Centre for Cardiovascular Science, Univ of Edinburgh, United Kingdom.*

Background: Thiazides are one of the most widely used and cost-effective class of anti-hypertensive medication. Thiazide-Induced Hyponatremia (TIH) is one of their major adverse effects and the leading cause of drug-induced hyponatremia requiring hospitalization. *A priori* TIH must result from excessive saliuresis and/or water reabsorption. The water and electrolyte transporter composition of urinary exosomes (UE) reflects their cellular origin and are a promising way to study renal dysfunction. This study assessed the expression of AQP2 and NCC in the UE of TIH patients.

Methods: 100 patients admitted to hospital with severe TIH donated urine samples during acute TIH and at two months post thiazide cessation. Matched normonatremic controls were recruited both on and off thiazides (groups 1 & 2 respectively). UE from a representative sample of each patient group were isolated and AQP2 and NCC were evaluated by Western blotting and Nanoparticle Tracking Analysis (NTA). AQP2 and NCC expression was normalized by urinary creatinine. Immunoblots were also corrected for total protein and results expressed as units of optical density/Ucr.

Results: Westerns showed that UE expression of AQP2 was higher in cases during acute TIH compared to convalescent (32.93 vs 28.71, $P<0.01$) and compared to control groups 1 & 2 (15.61 and 15.09 respectively, $P<0.001$). NCC expression was lower in TIH patients acutely compared to convalescent (17.72 vs 31.86, $P<0.05$) and compared to both control groups (30.32 and 31.17, $P<0.05$). NTA also demonstrated increased AQP2 expression in acute & convalescent TIH.

Conclusions: This study highlights the utility of UE analysis to probe the molecular pathophysiology of TIH. Increased AQP2 and reduced NCC expression suggests that TIH results from increased water reabsorption and sodium wasting in the distal nephron. TIH studies may further understanding of renal physiology and inform the design of new thiazide medicines less prone to cause hyponatremia.

Epigenetic Modulation of Renal Arterioles Induced by DOCA-Salt Loading in Mice

Hiroyuki Inoue, Kazutoshi Miyashita, Masaaki Sato, Kentaro Fujii, Aika Hagiwara, Masanori Tamaki, Hiroshi Itoh. *Internal Medicine, School of Medicine, Keio Univ, Tokyo, Japan.*

Background: The relationship between salt intake and development of hypertension is familiar; however, the mechanism for the onset has not been fully revealed. Our previous report showed that the medial hypertrophy of renal arterioles after transient salt loading in spontaneous hypertensive rat caused lasting elevation in blood pressure. The present study investigated the significance of epigenetic modulation of the gene expressions which are relevant to the medial hypertrophy after transient salt loading.

Methods: Male 6 week old C57bl6 mice were implanted deoxycorticosterone acetate (DOCA) pellets and given drinking water containing 1% NaCl for 2 weeks for generation of salt-induced hypertension. The blood pressure was measured by a tail-cuff method during and after the transient salt loading. Histological examinations of the kidney were performed during and after the salt loading. Gene expressions in the kidney such as matrix metalloproteinases (MMPs), which promote the medial hypertrophy, were quantified. Epigenetic modulation of the genes were analyzed.

Results: Transient salt loading caused elevation in blood pressure during the loading period. Blood pressure after stopping salt-loading was also significantly higher than that before salt loading. Salt loading caused medial hypertrophy of renal arterioles, and it remained after stopping salt loading, as to cause lasting renin elevation. Real time PCR revealed that MMP2 and MMP9 were increased during the salt loading. CGN5, CBP and p300, which are histone acetyltransferases, were elevated. Sirt1, Sirt3, HDAC1 and HDAC5, which are histone deacetylases, were decreased. Histone H3K9 and H4K16 acetylations in the MMP2 gene were enhanced by the salt loading.

Conclusions: The lasting medial hypertrophy and renin elevation after transient salt loading were suggested to be caused by the increased expression of MMPs along with augmented histone acetylations by the salt loading. Increased expressions of acetyltransferases along with decreased expressions of Sirts and HDACs by transient salt loading would be involved in the enhancement of the histone acetylations.

Radio-Frequency Catheter-Based Renal Denervation in Hypertensive Sheep with Chronic Kidney Disease Impairs Responses to Hemorrhage

Reetu R. Singh,[1] Karen M. Moritz,[2] Kate M. Denton.[1] *[1]Physiology, Monash Univ, Clayton, VIC, Australia; [2]School of Biomedical Sciences, The Univ of Queensland, St. Lucia, QLD, Australia.*

Background: Renal sympathetic nerves modulate kidney function and blood pressure (BP). Trials using catheter-based renal denervation (cDNX) in hypertensive patients yielded results both in support of and, against its efficacy in lowering BP. A critical question is whether cDNX has adverse consequences, in situations of clinical challenge, such as hemorrhage in denervated patients where intact nerves would be required. This study examined consequences of cDNX 1) on BP and renal function and 2) on reflex activation of sympathetic nerve activity (SNA) in hypertensive sheep with chronic kidney disease (CKD).

Methods: Sheep with established hypertension and renal dysfunction (CKD group) with an appropriate control group were used. At 10 months of age, some animals underwent cDNX (CKD-cDNX; control-cDNX) while the remaining underwent sham procedure (CKD-intact; control-intact). At 2 months post-cDNX, BP, renal function, and plasma renin activity (PRA) were assessed before, during and after hemorrhage (20% blood volume withdrawn over 15 minutes).

Results: CKD sheep had higher BP compared to all groups but CKD-cDNX sheep had similar BP to control sheep. Basal renal function was not further reduced. In response to hemorrhage, BP fell in all groups but the greatest decrease occurred in CKD-cDNX. In Control-intact sheep this fall in BP gradually recovered, associated with increase in PRA reflecting an increase in reflex SNA. In contrast, in Control-cDNX and CKD-cDNX groups, PRA did not increase and BP did not recover reflecting an absence of increase in reflex SNA.

Conclusions: cDNX effectively reduced BP at 2 months post-cDNX in previously hypertensive sheep but had no effect on renal function. However, the lack of reflex activation of neural mechanisms observed during hemorrhage suggest, that cDNX may impair a patient's ability to adequately respond to physiological challenges.

Interleukin-10 Mediates the Renoprotective Properties of Mesenchymal Stem Cells-Derived Extracellular Vesicles in Porcine Metabolic Syndrome and Renal Artery Stenosis

Alfonso Eirin,[1] Xiang-yang Zhu,[1] Christopher M. Ferguson,[1] Scott Riester,[2] Andre J. Van Wijnen,[2] Amir Lerman,[3] Lilach O. Lerman.[1,3] *[1]Divs of Nephrology and Hypertension, Mayo Clinic; [2]Orthopedic Surgery, Mayo Clinic; [3]Cardiovascular Diseases, Mayo Clinic, Rochester, MN.*

Background: Mesenchymal stem/stromal cells (MSCs) are immunomodulatory and have unique potential to restore the renal microvasculature, but may generate safety concerns. MSC-derived extracellular vesicles (EVs) emerged as a novel non-cellular alternative. Using a swine model of metabolic syndrome (MetS) superimposed on renal artery stenosis (RAS) we tested whether intrarenal injection of EVs attenuates renal injury and if this capacity is mediated by their cargo of the anti-inflammatory cytokine IL-10.

Methods: MetS pigs were studied after 16 weeks of RAS untreated or treated 4 weeks earlier with a single intrarenal delivery of labeled EVs harvested from autologous MSCs ($2.5x10^5$/Kg) with or without pre-silenced IL-10 (IL-10 knock-down). Lean and MetS Sham served as controls (n=7 each). Single-kidney renal blood flow (RBF) and glomerular filtration rate (GFR) were studied in-vivo, and microvascular architecture (micro-CT) and fibrosis ex-vivo.

Results: EVs were detected in the stenotic-kidney 4 weeks after injection. RBF and GFR, which increased in MetS compared to Lean, fell in MetS+RAS, but improved in EV-treated pigs (Table). EVs also improved cortical microvascular density and renal fibrosis (Figure). Yet, these renoprotective effects were blunted in pigs treated with IL-10 depleted EVs.

Conclusions: Intrarenal delivery of MSC-EVs improves renal structure and function in chronic experimental MetS+RAS, partly mediated by their cargo of IL-10. These observations suggest that EV-based regenerative strategies might be useful for patients with MetS+RAS.

Role of Mitochondrial Dysfunction and ROS Production in Ang II-Induced NLRP3 Inflammasome Activation Wen Yi, Liu Yiran, Tang Taotao, Bi-Cheng Liu. *Inst of Nephrology, Southeast Univ, Nanjing, Jiangsu Province, China.*

Background: The type 1 angiotensin (AT1) receptor plays an important role in maintaining blood pressure. Previous studies suggested that the activation of immune responses by angiotensin (Ang) II during hypertension may aggravate renal damage. NLRP3 inflammasome activation promotes renal inflammation and contributes to chronic kidney damage. Further investigation should be performed to explore the correlation between the RAS and NLRP3 inflammasome activation, and possible mechanisms.

Methods: C57BL/6 AT1R-/- and NLRP3-/- mice underwent left nephrectomy followed 1 week for recovery. Blood pressure measurements were recorded at baseline and following 4 weeks of chronic Ang II or saline infusion. At the end of the experiment, the kidney were harvested and fixed. AT1R siRNA and mitoTEMPO treatment were performed before the Ang II stimulation in HK2 cells. The expression levels of NLRP3 inflammasome and mitochondrial dysfunction were measured.

Results: Ang II significantly induced kidney injury and NLRP3 inflammasome activation. Mitochondria swelling and fragmentation were observed by transmission electron microscope. AT1-/- blocked Ang II-induced hypertension, inhibiting the mitochondrial dysfunction and NLRP3 expression. Deficiency of NLRP3 attenuated kidney injury in hypertension with no significant influence to blood pressure. In vitro studies showed that Ang II stimulation increase the mitochondrial damage and NLRP3 activation in dose- and time- dependent manner. AT1R silence effectively blocked Ang II-induced damage. MitoTEMPO attenuated the activation of NRLP3 inflammasome through clearance of reactive oxygen species (ROS). Moreover, Ang II-induced mitochondrial dysfunction was markedly inhibited by silence of NLRP3.

Conclusions: Ang II stimulation induces NLRP3 inflammasome activation through AT1a receptor. Ang II-induced NLRP3 activation is mediated by mitochondrial dysfunction, with overproduction and accumulation of ROS. NLRP3 inflammasome activation plays an important role in kidney injury, and blocking it can be a potential therapeutic target for hypertension-associated kidney damage.

The Endoplasmic Reticulum Stress Inhibitor 4-Phynelbutyric Acid Prevents the Development of Essential Hypertension in Young Spontaneously Hypertensive Rats Safaa Naiel,[1] Chao Lu,[2] Jeffrey G. Dickhout.[1,2] *[1]Medicine, McMaster Univ, Hamilton, ON, Canada; [2]St. Joseph's Healthcare Hamilton, Hamilton, ON, Canada.*

Background: Essential Hypertension is the leading global risk factor for premature death. This complex multifactoral disease has no known cause and has been shown to contribute to the progression of chronic kidney disease (CKD). Mechanistically both Endoplasmic Reticulum (ER) stress and the Unfolded Protein Response (UPR) have been implicated in the pathobiology of this disease. A small molecular chaperone, 4-phenynelbutyric acid (4-PBA), is known to inhibit ER stress. In our previous studies, we found that 4-PBA is able to lower blood pressure in animal models of hypertension. It remains unclear however if ER stress is a cause of hypertension or a consequence.

Methods: Young spontaneously hypertensive rats (SHR) were used in this study and Wistar Kyoto (WKY) rats were used as its normotensive control. High blood pressure begins to develop in the young SHR at 4-weeks of age. Radio-telemetry transmitters (HD-X11 transmitter, Data Sciences International) were implanted to monitor blood pressure development, heart rate and ECG activity in both SHR and WKY. SHR and WKY were both randomized into 4-PBA (1 g/kg/day) or vehicle groups at 4-weeks of age to determine if ER stress inhibition would prevent the development of hypertension. Resistance vessels, such as mesenteric arteries and renal arteries were collected after 8 weeks and analyzed for specific ER stress markers using real-time polymerase chain reaction (RT-PCR).

Results: 4-PBA treatment significantly lowered systolic, diastolic and mean arterial pressures in the SHR rats, but not in the WKY rats. 4-PBA treatment also significantly abolished pre-hypertensive tachycardia in the SHR. Additionally, 4-PBA significantly prevented the expression of UPR markers CHOP and GRP78 in SHR resistance blood vessels.

Conclusions: ER stress appears to play a causative role in the development of hypertension. Novel pharmacological strategies aimed at ER stress inhibition might represent useful therapeutic tools for people with a high risk of developing hypertension and progressive CKD. *Funding:* Government Support – MOP-133484.

Macrophage Endothelin-B Receptors Clear Endothelin-1 and Regulate Blood Pressure Neeraj Dhaun. *Queen's Medical Research Inst, University of Edinburgh.*

Background: Hypertension is common. Its cause remains unclear in the majority of those affected. Recent data suggest that macrophages (MΦ) contribute to, and protect from, hypertension. Endothelin-1 (ET-1) is the most potent endogenous vasoconstrictor with additional pro-inflammatory properties. The effects of ET-1 on MΦ biology are not well studied.

Methods: To examine the interactions between the ET and MΦ systems we administered incremental doses of intravenous ET-1 to CD11b-diphtheria toxin receptor (DTR) mice given diphtheria toxin (DT) and to mice lacking ET_B receptors solely on myeloid cells ($LysMET_B^{-/-}$). We also cultured bone marrow derived MΦ (BMDM) from both these mice and human monocytes *in vitro*. Finally, we examined BP and the ET system in patients receiving MΦ depleting and non-depleting therapy.

Results: MΦ depletion or loss of function – Cd11b-DTR mice given DT a*nd* $LysMET_B^{-/-}$ mice – were not associated with a difference in baseline BP or endothelial dysfunction. In both, administration of ET-1 resulted in an exaggerated hypertensive response compared to controls. At a dose of ET-1 1nmol/kg the maximal change in BP was ~2-fold greater in MΦ deficient mice compared to control groups. *In vitro*, mouse BMDM and human MΦ possess both ET_A and ET_B receptors. Whereas stimulation of mouse and human MΦ with exogenous ET-1 did not polarize MΦ to a classical or alternative phenotype, both displayed chemokinesis to ET-1. This was reduced by selective ET_A and completely blocked by ET_B receptor antagonism.BMDM stimulation with LPS/INFγ led to an increase in the concentration of ET-1, an effect that was blocked by phosphoramidon, an inhibitor of endothelin converting enzyme. Importantly, using pharmacological and gene targeting studies we show a novel clearance mechanism for ET-1 through ET_B receptor mediated dynamin-dependent endocytosis present in both murine and human MΦ. Finally, patients receiving MΦ depleting therapy we show that BP is higher and the ET system more activated than in those receiving non-depleting therapies.

Conclusions: Overall, these data suggest that MΦ and ET-1 may play an important role in BP control and potentially have a critical role as a therapeutic target in hypertension.

FR-PO147

Role of the Myeloid Endothelin-B Receptor in Angiotensin II Mediated End-Organ Damage Neeraj Dhaun. *Inst de Recherche, PARCC, Inserm, Paris.*

Background: Hypertension is common and in the majority of cases its cause remains unknown. Recent interest has focused on the role of macrophages (Mϕ) in blood pressure (BP) regulation. Endothelin-1 (ET-1) is the most potent endogenous vasoconstrictor mediating its effects through two receptors – the endothelin-A receptor (ET_A) and endothelin-B (ET_B) receptor. The ET_B receptor has a specific role in ET-1 clearance. We investigated the role of the Mϕ ET_B receptor in a model of angiotensin II (Ang II)-mediated end-organ damage.

Methods: Mϕ ET_B receptor deficient mice ($LysMET_B^{-/-}$) and controls were exposed to Ang II infusion for 6 weeks under a high salt diet. We assessed BP *via* telemetry, cardiac structure and function and endothelial function by Doppler ultrasound, end-organ injury and plasma and urine ET-1.

Results: At baseline, components of BP did not differ between groups and increased similarly with Ang II. Whereas after 6 weeks of Ang II $LysMET_B^{-/-}$ and controls had similar left ventricular hypertrophy and cardiac insufficiency, endothelial function was better in $LysMET_B^{-/-}$ at both baseline and after Ang II (% dilation of basilar artery in response to CO_2, $LysMET_B^{-/-}$ *vs.* controls: baseline: 20 *vs.*11%, p<0.01; at 6 weeks: 11 *vs.*0%, p<0.01). Baseline renal function and proteinuria did not differ between groups. After Ang II, $LysMET_B^{-/-}$showed similar renal function compared to controls but less proteinuria (urine albumin:creat, mg/mmol: 208±10 *vs.* 530±25, p<0.01), glomerulosclerosis (34±2 *vs.* 61±4%, p<0.001), and fewer renal Mϕ compared to controls (F4/80 staining per high power field, $LysMET_B^{-/-}$ *vs.* controls: 1.1±0.7 *vs.* 3.2±0.5%, p=0.02), although similar levels of $CD3^+$ T cells. Plasma ET-1 was no different at baseline but increased more in $LysMET_B^{-/-}$with Ang II *vs.* controls after 6 weeks Ang II: 3.7±0.7 *vs.*1.4±0.2pg/ml, p=0.03). Urine ET-1 was similar baseline and 6 weeks.

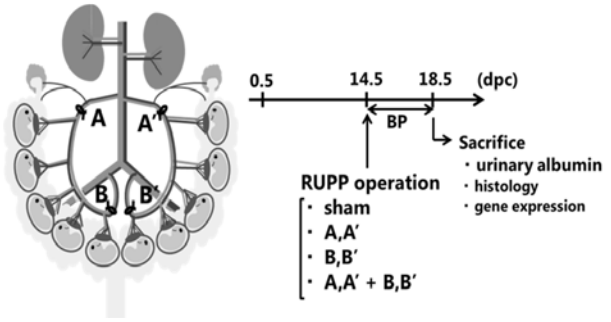
Conclusions: Deletion of the Mϕ ET_BR is associated with a blunting of the effects of systemic Ang II infusion as reflected by less endothelial dysfunction, reduced inflammation and end-organ damage. The mechanisms for these effects are the focus of ongoing research.

FR-PO148

A Novel Reduced Uterine Perfusion Pressure (RUPP) Model of Preeclampsia in Mice Tomofumi Fushima,[1] Yuji Oe,[2] Emiko Sato,[1,2] Sadayoshi Ito,[2] Hiroshi Sato,[1,2] Nobuyuki Takahashi.[1,2] *[1]Graduate School of Pharmaceutical Sciences, Tohoku Univ, Sendai, Miyagi, Japan; [2]Div of Nephrology, Endocrinology, and Vascular Medicine, Tohoku Univ, Sendai, Miyagi, Japan.*

Background: Preeclampsia (PE) is a pregnancy-related hypertension with proteinuria that typically develops after 20 weeks of gestation. PE is caused by a reduction in uterine blood flow due to abnormal trophoblast invasion of the spiral arteries. The ischemic placenta releases anti-angiogenesis factors such as sFlt-1, leading to maternal hypertension and proteinuria. The reduced uterine perfusion pressure (RUPP) model is widely used in rats, but not in mice, hindering the clarification of genetics of PE. The aim of the present study is to establish a novel PE model using an improved RUPP method in mice.

Methods: As shown in the Figure.1, uterine vessels of pregnant ICR mice were ligated at 14.5 dpc, and BP, renal phenotype and pregnancy outcome were analyzed.



Results: RUPP in mice increased blood pressure. B,B' ligation mice showed increased urinary albumin excretion, mesangial expansion and endotheliosis as shown by the reduction of glomerular open capillary area. RUPP increased the risk of miscarriages and premature deliveries, and significantly reduced fetal weights at 18.5 dpc compared to those of sham mice.

Conclusions: We developed a novel RUPP mouse model that recapitulates the phenotype of PE. This model is expected to be useful for investigating pathogenesis pf PE and evaluating its new therapies.

FR-PO149

Sildenafil Treatment Is Protective against Progression of Renal Injury in the Preeclamptic Dahl Salt Sensitive Rat Ellen Elizabeth Gillis, Jennifer N. Mooney, Michael R. Garrett, Jennifer M. Sasser. *Pharmacology and Toxicololgy, Univ of Mississippi Medical Center, Jackson, MS.*

Background: Preeclampsia, a hypertensive disorder of pregnancy, is characterized by transient glomerular damage and increased risk for kidney disease later in life. Recent studies in our lab have identified the Dahl salt sensitive (Dahl S) rat on a 0.3% NaCl diet as a spontaneous model of superimposed preeclampsia. We hypothesized that sildenafil treatment would result in an improvement in renal function during the preeclamptic pregnancy exhibited by the Dahl S rat.

Methods: Female Dahl S rats (n=4-9) were mated, and rats were randomly divided into control and sildenafil treated groups. Sildenafil was administered to the treated group via food on gestational days 10-20 at a dose of 50 mg/kg/d. Rats were placed in metabolic cages on gestational day 19 for 24-hr urine collection, and blood and tissues were harvested on gestational day 20. Urinary protein excretion, nephrin excretion, and plasma and urinary creatinine concentrations were measured by Bradford assay, Exocell ELISA, and the picric acid method, respectively. Kidney sections were stained with Masson's trichrome, and glomeruli were measured (n=20 per rat) and analyzed using Nikon software.

Results: Sildenafil treatment significantly improved renal function, as observed in the increase in creatinine clearance and corresponding decrease in plasma creatinine (Table, *p<0.05 vs control). Treated rats exhibited less renal injury, with a significant decrease in proteinuria and nephrinuria during late pregnancy (Table). Histological analysis showed that the treated rats did not exhibit glomerulomegaly during pregnancy compared to the untreated controls (Table).

Conclusions: This study provides preclinical evidence that sildenafil prevents the progression of renal injury during preeclampsia.

Recessive Mutations of the Interaction Partners, *TENC1*, *DLC1* or *MAGI2*, Cause Nephrotic Syndrome in Humans Shazia Ashraf,[1] Jia Rao,[1] Merlin Airik,[1] Svjetlana Lovric,[1] Jennifer A. Lawson,[1] Weizhen Tan,[1] Carolin Sadowski,[1] Werner Lukas Pabst,[1] Daniela A. Braun,[1] Heon Yung Gee,[1] Richard P. Lifton,[2] Martin Zenker,[3] Friedhelm Hildebrandt.[1,4] *[1]Div of Nephrology, Boston Children's Hospital, Boston, MA; [2]Dept of Genetics, Yale Univ School of Medicine, New Haven, CT; [3]Inst of Human Genetics, Univ Hospital Magdeburg, Magdeburg, Germany; [4]HHMI.*

Background: Identification of monogenic causes of nephrotic syndrome (NS) has furthered the understanding of its pathogenesis. However, many genes and disease mechanisms remain unknown.

Methods: We performed homozygosity mapping (HM) and whole exome sequencing (WES) in individuals of consanguineous families with NS to identify the underlying mutations. To identify additional families, we performed microfluidic PCR (Fluidigm Access Array™) and next generation sequencing (NGS) to screen worldwide cohort of ~2000 individuals with severe NS.

Results: By WES in consanguineous family A1358, we identified a homozygous missense mutation (p.R292Q) in the *TENC1* (*Tensin-2*) gene in an amino acid residue conserved since *Ciona intestinalis*. By microfluidic PCR and NGS, we detected additional mutations in *TENC1* in three unrelated families with NS. Later, we also discovered mutations in 2 different families with NS in *DLC1* gene, a known binding partner of *TENC1*. Interestingly, most of the individuals with *TENC1* or *DLC1* mutations had steroid sensitive NS or histologically showed biopsy of MCNS. Furthermore, in 2 families with NS and neurological impairment, we identified 2 different homozygous truncating mutations in *MAGI2* gene. Deficiency of Tenc1 or Magi2 has been previously shown to cause NS in mice. By Co-IP, we now show that TENC1 and DLC1 interact with MAGI2 in HEK293T cells and these interactions are abrogated in one of the MAGI2 mutant. Knockdown of TENC1, DLC1 or MAGI2 in cultured podocytes exhibited an altered podocyte migration rate. Immunoflorescence microscopy showed that TENC1 and DLC1 colocalize with phosphotyrosine at the focal adhesions in cultured human podocytes.

Conclusions: We, thus, identified mutations of *TENC1*, *DLC1* and *MAGI2* as three novel single-gene causes of NS revealing a potential new pathogenic pathway for NS.

FR-PO151

Mutation of *DHTKD1* Can Cause Nephrotic Syndrome with Neurological Impairment and Ketoadipic Aciduria Weizhen Tan,[1] Shazia Ashraf,[1] Svjetlana Lovric,[1] Jia Rao,[1] Merlin Airik,[1] David Schapiro,[1] Daniela A. Braun,[1] Heon Yung Gee,[1] Martin Zenker,[2] Friedhelm Hildebrandt.[1,3] *[1]Div of Nephrology, Boston Children's Hospital, Harvard Medical School, Boston, MA; [2]Inst of Human Genetics, Univ Hospital Magdeburg, Magdeburg, Germany; [3]Howard Hughes Medical Inst, Chevy Chase, MD.*

Background: Steroid-resistant nephrotic syndrome (SRNS) is the second most frequent cause of end-stage kidney disease in children. Identification of single-gene causes of SRNS has furthered the understanding of its pathogenesis. However, additional genes and disease mechanisms remain obscure. To identify a new causative gene for SRNS with neurological impairment, we combined homozygosity mapping (HM) and whole human exome sequencing (WES).

Methods: In two siblings (of consanguineous parents) with SRNS, neurological impairment, and ketoadipic aciduria, HM yielded 8 segments of homozygosity by descent with a cumulative genomic length of ~485 Mb. We performed WES in both siblings to identify the underlying single-gene disease-causing mutation.

Results: WES in this consanguineous family detected a homozygous missense mutation (p.Val296Met) in the *DHTKD1* (*dehydrogenase E1 and transketolase domain containing 1*) gene in an amino acid residue that is evolutionary conserved to prokaryotes (*Saccharomyces cerevisiae*). The mutation segregated with the affected status in this family and was absent from the 1,000 genomes project and Exome Aggregation Consortium (ExAC) databases. DHTKD1 functions as a 2-oxoglutarate-dehydrogenase E1 component and plays an important role in energy production in mitochondria through the tricarboxylic-acid cycle. Mutations in *DHTKD1* have previously been identified as cause of 2-aminoadipic and 2-oxoadipic aciduria via impaired turnover of decarboxylation 2-oxoadipate to glutaryl-CoA[1]. [1] Danhauser K. et al., *Am J Hum Genet*, 91:1082-1087, 2012.

Conclusions: We identified a recessive mutation of *DHTKD1* as a novel single-gene cause of SRNS with neurological impairment and ketoadipic aciduria. Further genetic and functional studies will shed light on the involvement of this protein in the pathogenesis of NS and will provide a further step in understanding the disease mechanism.

Genes Encoding Nuclear Pore Outer Ring Components *NUP85*, *NUP107*, and *NUP133* Are Mutated in Patients with Nephrotic Syndrome

Svjetlana Lovric,[1] Weizhen Tan,[1] David Schapiro,[1] Shazia Ashraf,[1] Daniela A. Braun,[1] Jia Rao,[1] Richard P. Lifton,[2] Heon Yung Gee,[1] Friedhelm Hildebrandt.[1,3]
[1]Div of Nephrology, Boston Children's Hospital, Harvard Medical School, Boston, MA; [2]Dept of Genetics, Yale Univ School of Medicine, New Haven, CT; [3]Howard Hughes Medical Inst, Chevy Chase, MD.

Background: Steroid resistant nephrotic syndrome (SRNS) almost invariably progresses to end-stage kidney disease. Although more than 30 single-gene causes of SRNS are known, a large proportion of SRNS remains unexplained. Recently, mutations in genes encoding proteins of the nuclear complex (NPC), *NUP93* and *NUP205* were identified as novel causes of nephrotic syndrome. Study of these proteins has implicated SMAD signaling in the pathogenesis of nephrosis.

Methods: To identify additional novel causes of nephrotic syndrome, we performed a candidate screen of 17 nuclear pore complex (NPC) genes in an international cohort of >900 individuals with SRNS via microfluidic multiplex PCR (Fluidigm Access Array™) and next generation sequencing (Illumina MiSeq™).

Results: In two families we identified two homozygous missense mutations, p.A477V and p.R645W, (conserved to *S. cerevisiae*) in the NPC outer ring protein *NUP85*. We then sequenced the exons of 1,000 additional families in genes encoding other outer ring proteins and found mutations in *NUP107* (1 family, p. Y889C, conserved to *C. elegans*) and *NUP133* (2 families, p.S974R and p.R231G, p.L1055S, conserved to *D. rerio)*. Although the structure resolution of the NPC 3D complex is incomplete, we modeled the interacting portions of the Y-subcomplex proteins *NUP107* and *NUP133*. Two of the mutations, p.S974R in *NUP133* and p.Y889C in *NUP107*, are located in the interacting alpha helix between the two proteins. 5 of 6 families demonstrated FSGS on biopsy.

Conclusions: As a novel cause of SRNS we identified mutations in 3 different NPC outer ring proteins *NUP85*, *NUP107*, and *NUP133* that form an integral part of the Y-subcomplex. Further functional studies are needed to illuminate how the defect of NPC contributes to the pathogenesis of nephrotic syndrome.

Defining the Genetic Epidemiology of a Phenotypically Well-Characterized Adult-Onset Focal and Segmental Glomerulosclerosis Cohort

Moumita Barua,[1] Daniel C. Cattran,[1] Heather N. Reich,[1] Michelle A. Hladunewich,[6] Mark Leung,[2] Weili Li,[3,4] Andrew D. Paterson,[5] York P. Pei.[1]
[1]Nephrology, Toronto General Hospital, UHN, Toronto, ON, Canada; [2]Biology, Univ of Waterloo, Waterloo, ON, Canada; [3]The Centre for Applied Genomics, Hospital for Sick Children, Toronto, ON, Canada; [4]Dalla Lana School of Public Health, Univ of Toronto, Toronto, ON, Canada; [5]Genetics and Genome Biology, Hospital for Sick Children, Toronto, ON, Canada; [6]Nephrology, Univ of Toronto, Toronto, ON, Canada.

Background: The genetic epidemiology underlying adult-onset sporadic FSGS has not been well characterized and rigorous correlation of rare genetic forms of disease with clinical outcomes is also lacking. We defined the genetic epidemiology of the phenotypically well characterized sporadic and familial Toronto GN FSGS cohort using next-generation sequencing.

Methods: We have ascertained the clinical information and performed whole exome sequencing in adult-onset disease of 90 sporadic FSGS cases, 41 steroid-sensitive nephrotic syndrome (SSNS) cases and 22 families with FSGS. A variant in a known FSGS gene was called disease-causing if it was novel or had a MAF £1% for dominant and recessive genes, respectively, in 1000 genomes project, NHLBI exome sequencing project and ExAC; compound heterozygosity was consistent with reported inheritance pattern for that gene; segregated in affected family members; and called damaging by at least two *in silico* prediction programs or affected highly conserved residues.

Results: In 7 of 90 sporadic FSGS cases, a disease-causing mutation was found in the following genes: *WT1*, *TRPC6*, *PAX2* and *COL4A5*. No mutations in the known FSGS genes were identified in 41 SSNS cases. In contrast, in 4 of 23 autosomal dominant and recessive families with FSGS, a disease-causing mutation was identified in the following genes: *INF2*, *TRPC6*, *LMX1B* and *ADCK4*. Mutations in the known FSGS genes were found in 7.8 and 17.4% of sporadic and familial cases of adult-onset disease, respectively, but none were discovered in patients with SSNS.

Conclusions: Our results are consistent with extensive genetic heterogeneity in FSGS. We will test the association of rare variants with phenotype. Clinical outcomes will be described.

A Novel Mouse Mutant with a Point Mutation in Laminin α5 Exhibits Chronic Nephrotic Syndrome

Sara Falcone,[1] Thomas Nicol,[1] Cheryl Scudamore,[2] Frederick W.K. Tam,[3] Charles D. Pusey,[3] Jeffrey H. Miner,[4] Steve Dm Brown,[1] Paul K. Potter.[1]
[1]Mammalian Genetics Unit, MRC Harwell, Harwell, Oxfordshire, United Kingdom; [2]Mary Lyon Centre, MRC Harwell, Harwell, Oxfordshire, United Kingdom; [3]Renal Section, Imperial College, London, United Kingdom; [4]Renal Div, Washington Univ, St. Louis, MO.

Background: Diseases associated with ageing pose an increasing social and financial burden on society and represent an imperative for research in the biomedical sciences. We are undertaking the first large-scale project to investigate the interaction between genetic variation and the pleiotropic effects of ageing, employing random mutagenesis and phenotyping to generate new models of late onset or age-related disease.

Methods: Mutant mice are being aged to 18 months and undergo comprehensive phenotyping across a wide range of disease areas at several time points throughout the life of the mice. To date we have identified lines with a variety of late onset phenotypes which are being characterised in detail.

Results: Mutant mice were identified at 6 months of age with elevated creatinine and urea levels, which reached end stage renal failure at approximately 10 months of age. Mapping and whole genome sequencing identified a *Lama5* ^{E884G} mutation in the L4a domain of *Lama5*. Time course studies of *Lama5* ^{E884G} homozygotes showed reduced serum albumin (18.0 ± 1.2 vs 24.9 ± 3.1, g/l, mean SD) and proteinuria from 12 weeks of age with a gradual loss of renal function over time. Affected mice also have significantly elevated cholesterol levels and a progressive nephropathy leading to diffuse glomerular fibrosis, dilated protein filled tubules and pigment deposition suggesting this is a model of nephrotic syndrome. The mutation does not affect expression of the LAMA5 protein within the glomerular basement membrane.

Conclusions: We have identified a novel mouse mutant with a missense mutation *Lama5* resulting in nephrotic syndrome. Recent patient sequencing data suggests LAMA5 mutations are associated with focal segmental glomerulosclerosis (Chatterjee et al, PLoS One, 8:e76360) and we are investigating this in our model. Other models of late-onset renal disease are also being investigated.

Exome Sequencing Suggests a Role for Nephron Number in FSGS

Adele Mitrotti,[1] David Fasel,[1] Yifu Li,[1] Monica Bodria,[1] Landino Allegri,[3] Gerald B. Appel,[1] Jai Radhakrishnan,[1] Loreto Gesualdo,[4] Gian Marco Ghiggeri,[5] Richard P. Lifton,[2] Ali G. Gharavi,[1] Simone Sanna-Cherchi.[1]
[1]Medicine, Columbia Univ Medical Center, New York, NY; [2]Genetics, Yale, New Haven, CT; [3]Medicine, Univ of Parma, Parma, Italy; [4]Medicine, Univ of Bari, Bari, Italy; [5]Medicine, Gaslini Children Hospital, Genova, Italy.

Background: Exome sequencing is a powerful tool to identify disease-causing mutations. Identification of novel genes for dominant FSGS has proven difficult.

Methods: We performed exome sequencing in 41 patients from 31 families affected by FSGS. Exome sequencing was conducted on Illumina HiSeq2500. Annotations were conducted with semi-automated scripts developed in the lab.

Results: We detected diagnostic variants for FSGS in 4 genes in 5/31 families (16%): TRPC6, INF2, LMX1B, and LAMB2. We detected two variants of unknown significance in FSGS-associated genes (EMP2, INF2). We detected 7 variants in additional 6 patients (19%) in genes that predispose to different kidney diseases when mutated (FN1, SIX5, COL4A4, FRAS1, FREM1, FREM2, UMOD). While these conditions can represent phenocopies of FSGS, it is possible that genes involved in renal development predispose to proteinuria and adaptive FSGS.

Prot + small kidneys	FREM1	nonsynonymous	CAKUT (Fraser syndrome related)	p.A1173S	0.0008949
FSGS	UMOD	nonsynonymous	Medullary cystic kidney disease	p.T614N	novel
FSGS	FREM2	missense	Unilateral renal agenesis, and Frem-2 related Fraser syndrome	p.G2144A	0.000008284

Analysis of the remaining 20 families (65%) did not reveal any gene with rare segregating mutations present in multiple independent families.

Conclusions: Mutations in genes known to be associated to FSGS are identified in a small proportion of cases. Mutations in genes involved in GBM assembly or kidney development can result in defects that present as FSGS. These findings can point to a correct genetic diagnosis and the identification of mutations in genes involved in CAKUT suggests that glomerular sclerosis could be the manifestation of a maladaptive reaction to reduced nephron mass from birth.

Role of CD2AP Mutations in Steroid Resistant Nephrotic Syndrome Revisited – New Insights from Next Generation Sequencing Ania B. Koziell,[3] Katrina Soderquest,[3] Andrey S. Shaw,[1] Michael A. Simpson.[2] *[1]Immunology and Pathology, Washington Univ School of Medicine, St. Louis, MI; [2]Genomics Medicine Group, King's College London, London, United Kingdom; [3]Experimental Immunobiology, King's College London, London, United Kingdom.*

Background: Steroid Resistant Nephrotic Syndrome (SRNS) is a rare disease icharacterised by glomerular filter malfunction. Analysis of inherited cases has identified mutations in >50 genes. However, clinical data can be limited and the true pattern of inheritance difficult to verify. In light of recent advances in next generation sequencing (NGS) and rare disease genetics, we re-examined CD2AP, a gene considered to cause autosomal dominant SRNS in early life.

Methods: In-house whole exome sequencing (WES) data on 200 deeply phenotyped SRNS patients was tested to assess the ability of CD2AP mutations to act as autosomal dominant. All protein altering CD2AP variants detected with a MAF < 0.05 were selected for further examination in the Exome Aggregation Consortium (ExAC) database. Samples with likely pertinent variants in CD2AP were also analysed for causal mutations in other SRNS genes.

Results: Variants with a frequency of > 1 in 1000 in the ExAC database were considered unlikely to cause autosomal dominant SRNS based on frequency of SRNS in populations. Two rare CD2AP variants remained after filtering but one case also demonstrated a rare heterozygous non-synonymous disease causing variant in SYNPO (allele frequency 0.0002179 in ExAc, non-homozygous) and the other a variant in NPHS2 (not seen in ExAc). SYNPO interacts with CD2AP and combined, these genes causes FSGS in mice. The NPHS2 variant neighboured a mutation linked previously to bigenic heterozygosity with CD2AP in SRNS.

Conclusions: Some heterozygous CD2AP variants occurred in normal controls or were detected co-incident disease causing variants. This indicates that mutations behaving as a dominant negative in a small number of cases may in fact demonstrate more complex inheritance on interrogation of a larger cohort. Computational analysis of WES provides a useful adjunct to rapidly examine and ascertain actual heritability in rare disease populations, especially in seemingly sporadic cases.

FR-PO157

Chemical Chaperone 4-PBA Is Not Nephroprotective in Experimental Podocin Nephropathy Tanja Tamara Wlodkowski,[1] Mansoureh Tabatabaeifar,[1] Geraldine Mollet,[2] Corinne Antignac,[2] Franz S. Schaefer.[1] *[1]Pediatric Nephrology Div, Heidelberg Univ Hospital, Germany; [2]Inserm U983, Hopital Necker, France.*

Background: 4-PBA has been demonstrated to improve protein trafficking from ER to plasma membrane and function of mutant ΔF508-CFTR protein in cystic fibrosis. In hereditary nephrotic syndrome the most common NPHS2 (podocin) mutation, R138Q, leads to retention of podocin in the ER and therefore to defective intracellular protein trafficking. In order to investigate beneficial effect of chemical chaperone in podocin nephropathy, we administered 4-PBA to knock-in mice carrying this mutation. Analogous to human disease, these mice develop heavy proteinuria, podocyte loss, focal segmental glomerulosclerosis and progressive renal failure.

Methods: In C57BL/6 mice with $Nphs2^{Flox/R140Q}Cre^{+}$, hemizygosity for mutant podocin was induced by tamoxifen injection. From the time of induction the animals (n=5) received 4-PBA added to the chow (200 mg/kg/d) or remained untreated (Co). Weight, blood pressure and proteinuria were monitored weekly. Biochemical and histopathological changes were examined after 4 weeks of treatment.

Results: All animals developed massive proteinuria (116% of untreated controls). Hypoalbuminemia at 4 weeks was slightly ameliorated (21.1 (Co) vs. 24.7 g/dl; n.s.). Serum urea, cholesterol and creatinine levels were deteriorated by 4-PBA treatment. Podocyte loss (podocytes per glom: (53% (Co), 69% (4-PBA) of healthy animals, n.s) and glomerular sclerosis index (1.75(Co), 1.82(4-PBA) were unchanged, whereas an increase in tubulointerstitial fibrosis was noted in 4-PBA treated animals (1.36 (Co) vs. 3.82 (4-PBA).

Conclusions: In an in vivo model of hereditary podocin nephropathy, prophylactic 4-PBA treatment showed no beneficial effect on proteinuria and podocyte loss but aggravated tubulointerstital fibrosis and renal failure. Our findings argue against a nephroprotective action of 4-PBA in this hereditary podocytopathy.

FR-PO158

Prominent Renal Complications in the c.80A>G in MMACHC Gene Fang Wang, Xiaoyu Liu, Huijie Xiao, Yong Yao, Jie Ding, Yanqin Zhang. *Dept of Pediatrics, Peking Univ First Hospital, China.*

Background: Cobalamin C defect is a clinically heterogeneous disease caused by mutations in the *MMACHC* gene. The aim of the present study was to delineate renal phenotype in Chinese children with Cobalamin C defect.

Methods: Detailed clinical data were collected and analyzed, and all coding exons of *MMACHC* gene were PCR-amplified and sequenced from genomic DNA.

Results: Four unrelated Chinese children (1 female, 3 male) with unexplained microscopic hematuria and proteinuria were included. The onset age of renal symptoms ranged from 9 months to 4 years. Two patients had nephrotic-level proteinuria in their initial visit, and renal dysfunction was detected in 2 patients in 3 months and 6 years after onset, respectively. Only 1 patient had hypertension in 6 years after onset. All patients had moderate anemia, and megaloblastic anemia was detected in 2 patients. None of 4 patients had thrombocytopenia or pancytopenia. One of 4 patients had mild development backward. Four patients had hyperhomocysteinemia, and 2 of 4 patients presented with remarkable elevated urinary methylmalonic acid. Renal biopsy in 3 patients showed thromboticmicroangiopathy. Mutations in *MMACHC* gene was found in four patients. Two patients were a compound heterozygote for c. 658_660delAAG andc.80A>G, one patient was a compound heterozygote for c.609G>A and c.80A>G, and one patient was a homozygote for c.80A>G. Three patients were in follow up. After vitamin B12 [in the form of hydroxycobalamin (OHCbl), i.m.], folic acid and L-carnitine betaine supplementation, urine protein became negative in 2 patients and reduced in 1 patient, and renal function in 1 patient was improved. In all 3 patients, hemoglobin increased to normal, plasma homocysteine decreased and still was abnormal. In 2 patients with remarkable elevated urinary methylmalonic acid, the level of urinary methylmalonic acid was normal in 1 patient and decreased in another patient. Blood pressure of the patient with hypertension was well-controlled using calcium channel blocker.

Conclusions: Prominent renal complications can be found in c.80A>G in *MMACHC* gene, and treatment resulted in improvement of renal and hematological signs.

Funding: Government Support - Non-U.S.

FR-PO159

The Susceptible Human Leukocyte Antigen Class II Genes and the Encoding Amino Acid Residues on Major Histocompatibility Complex Molecules to Primary Membranous Nephropathy Li-jun Xie,[1,2] Zhen Qu,[1] Zhao Cui,[1] Gang Liu,[1] Yun-hua Liao,[2] Ming-hui Zhao.[1] *[1]Renal Division, Peking Univ First Hospital, Beijing, China; [2]Div of Nephrology, the First Affiliated Hospital, Guangxi Medical Univ, Nanning, China.*

Background: Primary membranous nephropathy (MN) is an organ-specific autoimmune disease. M-type phospholipase A2 receptor (PLA2R) appears to be the specific target antigen, which needs to be presented by major histocompatibility complex (MHC) class II molecule. In genome wide association studies, risk alleles at PLA2R1 loci and single nucleotide polymorphism (SNP) (rs2187668) within HLA-DQA1 closely associate with the disease. However, the full association of HLA class II genes and MHC molecule amino acids has not been investigated in MN.

Methods: We genotyped 860 Chinese individuals, including 261 primary MN patients and 599 healthy controls, for DRB1, DQA1, DQB1 and DPB1, 4 digits resolution HLA alleles, and extracted the encoding amino acid sequences from IMGT/HLA database. Circulating anti-PLA2R antibody was detected in all patients.

Results: We found that DRB1*1501 (OR=3.49, $P=1.77\times10^{-21}$) and DRB1*0301 (OR=3.44, $P=3.46\times10^{-10}$) were two independent risk alleles for MN. In patients with positive anti-PLA2R antibodies, DRB1*1501 (OR=6.06) and DRB1*0301 (OR=4.92) showed even higher risk for the disease. The SNP (rs2187668) is the tag SNP of DRB1*0301. After conditioning on DRB1*1501 and DRB1*0301, no other HLA allele showed significant association with MN. At amino acid level, the most significant and independent associations were mapped to amino acid position 13 ($P=5.78\times10^{-25}$) and position 71 ($P=7.99\times10^{-25}$) on MHC DRβ1 chain. After conditioning on these positions, no other amino acid position showed significant association with MN. Alanine on position 71 and Arginine on position 13 were encoded by DRB1*1501; lysine on position 71 was encoded by DRB1*0301. These amino acids were susceptible to MN and showed positive association with the presence of anti-PLA2R antibodies (P=0.001).

Conclusions: We concluded that two alleles of HLA class II genes, and the encoding three amino acid residues on two positions at the epitope-binding pockets of MHC DRβ1 chain, were responsible for higher risk to MN.

Funding: Government Support - Non-U.S.

FR-PO160

Somatic Mosaicism and Variant Frequency Detected by Next Generation Sequencing in X Linked Alport Syndrome Naohiro Kamiyoshi,[1] Kandai Nozu,[1] Tomohiko Yamamura,[1] Takeshi Ninchoji,[1] Yuko Shima,[2] Koichi Nakanishi,[2] Norishige Yoshikawa,[3] Kazumoto Iijima.[1] *[1]Pediatrics, Kobe Univ Graduate School of Medicine, Kobe, Hyogo, Japan; [2]Pediatrics, Wakayama Medical Univ, Wakayama, Japan; [3]Pediatrics, National Center for Child Health and Development, Tokyo, Japan.*

Background: Alport syndrome is a hereditary disorder of type IV collagen, characterized by chronic kidney disease progressing to end-stage renal disease, sensorineural hearing loss, and ocular abnormalities. Approximately 85% of Alport syndrome patients show X-linked inheritance (XLAS) and variants in the type VI collagen, a5 gene (*COL4A5*), which encodes the type IV collagen α5 chain. Although male patients with XLAS usually develop end-stage renal disease before 30 years of age, some male patients show a milder phenotype and develop end-stage renal disease later in life. However, the molecular mechanisms associated with this milder phenotype have not been fully identified.

Methods: We genetically diagnosed 186 male patients with suspected XLAS between January 2006 and August 2014. Genetic examination involved: (1) extraction and analysis of genomic DNA using polymerase chain reaction and direct sequencing using Sanger's method for all patients; and (2) next-generation sequencing to detect variant allele frequencies for four patients who suspected somatic mosaic variants.

Results: We identified somatic mosaic variants in the *COL4A5* in four patients. Interestingly, two of these four patients with variant frequencies in kidney biopsies or urinary sediment cells of ≥50% showed hematuria and moderate proteinuria, while the other two with variant frequencies of <50% were asymptomatic or only had hematuria.

Conclusions: *De novo* variants can occur even in asymptomatic male cases of XLAS resulting in mosaicism, with important implications for genetic counseling. This is the first study to show a tendency between the variant allele frequency and disease severity in male XLAS patients with somatic mosaic variants in *COL4A5*. Although this is a very rare status of somatic mosaicism, further analysis is needed to show this correlation in a larger population.

FR-PO161

A New Non-Invasive Method to Examine Collagen α5(IV) Expression Using Plucked Hair Follicles: Analysis of an X-Linked Alport Family with a Novel COL4A5 Splice Region Variant Andrew F. Malone, Steven Daniel Funk, Jeffrey H. Miner. *Renal Div, Dept of Medicine, Washington Univ, St. Louis, MO.*

Background: Alport syndrome is a hereditary disease caused by mutations in COL4A5 in 85% of cases. Many different mutation types in this gene have been described. Levels and patterns of type IV collagen deposition are variable in the glomerular basement membranes of Alport kidneys. As COL4A5 is also expressed in the skin, we sought to characterize COL4A5 deposition in the basement membrane of plucked hair follicles from a family with a novel COL4A5 variant as a way of confirming the functional significance.

Methods: Whole-exome sequencing was done on the proband of a family with biopsy (renal and skin)-confirmed Alport syndrome. Sanger sequencing was performed on all affected family members and a married-in unaffected individual. Immunofluorescence microscopy was performed on whole mount and sectioned hair follicles co-stained with monoclonal antibodies to collagen a2 and α5(IV). Staining intensity between males and females, affecteds and unaffecteds, was analyzed.

Results: Family WU1 is a 3 generational family with chronic kidney disease secondary to Alport syndrome. Affecteds are in each generation, and both males and females are symptomatic. Whole-exome sequencing of affected individual 3227 revealed a novel splice region variant c.1780-6T>G in *COL4A5*. There were no other potentially pathogenic variants found in COL4 or other podocyte genes. This variant was confirmed by Sanger sequencing and segregated with disease. Reduced and abnormal expression of COL4A5 protein was confirmed in affected family members by immunofluorescence microscopy of hair follicles.

Conclusions: We confirmed linkage of a novel splice region variant in COL4A5 to Alport syndrome in a family with a typical X-linked inheritance pattern; this variant may be pathogenic. We developed and validated a new approach to characterize the expression of COL4A5 protein using immunofluorescence microscopy of plucked hair follicles. Furthermore, we demonstrated variability of COL4A5 expression between patients in this family, suggesting intermittent failure of splicing and/or variable lyonization in females.

FR-PO162

X-Linked Alport Dogs Demonstrate Mesangial Filopodial Invasion of the Capillary Tuft as an Early Event in Glomerular Damage Sabrina D. Clark,[1] Mary B. Nabity,[1] Rachel Cianciolo,[2] Brianna M. Dufek,[3] Dominic E. Cosgrove.[3] *[1]Veterinary Pathobiology, Texas A&M Univ, College Station, TX; [2]Veterinary Biosciences, The Ohio State Univ, Columbus, OH; [3]Genetics, Boys Town National Research Hospital, Omaha, NE.*

Background: X-linked Alport syndrome (XLAS), caused by a mutation in the type IV collagen COL4A5 gene, accounts for approximately 80% of the cases of human Alport syndrome. Dogs with XLAS have a similar clinical progression. Prior studies in autosomal Alport mice demonstrated early mesangial cell invasion as the source of laminin 211 in the glomerular basement membrane (GBM), leading to proinflammatory signaling. Thus far, these findings have not been confirmed in a large animal model.

Methods: XLAS dogs and unaffected littermates were monitored with serial clinicopathologic data and renal biopsies. Biopsies were obtained at the onset of microalbuminuria (MA), overt proteinuria (urine protein:creatinine (UPC) > 2), onset of azotemia, moderate azotemia, and at euthanasia. Glomeruli were analyzed by immunohistochemistry.

Results: With disease progression, XLAS dogs showed a progressive decrease in renal function (based on serum creatinine, symmetric dimethylarginine (SDMA), UPC, and iohexol clearance) and increase in interstitial fibrosis and glomerulosclerosis (based on light microscopy and/or immunostaining for aSMA and fibronectin). The only identifiable structural abnormality at the time of MA was segmental multilamination of the GBM observed on transmission electron microscopy (TEM), which was more extensive when overt proteinuria developed. Co-localization studies showed that mesangial laminin 211 and integrin α8β1 accumulate in the GBM, which was identified with laminin β2. This was first observed when overt proteinuria developed and coincided with evidence of mild cellular interpositioning on TEM, consistent with invasion of the capillary loops by mesangial cell processes.

Conclusions: These findings confirm, in a large animal model, the induction of mesangial filopodial invasion of the glomerular capillary tuft leading to the irregular deposition of mesangial laminin 211 as an early initiating event in Alport glomerular pathology.

Drug Repurposing for the Treatment of Experimental Alport Syndrome Vanessa R. Williams,[1] Ana Konvalinka,[2] Xuewen Song,[2] Eun Hui Bae,[3] Fei Fang,[1] Rohan John,[4] York P. Pei,[2] James W. Scholey.[1,2] *[1]Inst of Medical Science, Univ of Toronto, Canada; [2]Div of Nephrology, Univ of Toronto, Canada; [3]Internal Medicine, Chonnam National Univ Medical School, Korea; [4]Pathology, Univ of Toronto, Canada.*

Background: Alport Syndrome (AS) is a hereditary nephropathy caused by mutations in genes that encode type IV collagen, leading to progressive injury and eventually end-stage renal disease. Currently there are few effective therapies for AS. Therefore we applied a drug repurposing strategy, utilizing data on drugs currently approved for use in humans, to identify a novel AS treatment.

Methods: 129/SvJ *Col4a3*$^{-/-}$ (KO) and wild-type (WT) mice were studied at 4 and 7 weeks (N = 8/group). Histological analyses of formalin-fixed mouse kidney sections were performed. Plasma and 24-hour urine samples were collected. Global gene expression profiling of RNA from renal cortex was performed with the Affymetrix Mouse Gene 2.0 ST Array. Significance Analysis of Microarrays (SAM) was used to identify differentially expressed genes. *In silico* drug repurposing with the Connectivity Map (CMAP) was used to identify drugs expected to effectively treat murine AS.

Results: Mice with AS developed a progressive rise in albuminuria and serum creatinine. These changes were associated with glomerulosclerosis and tubulointerstitial fibrosis. SAM was used to generate a disease signature of differentially expressed genes, comparing 7-week-old KO versus WT mice. The disease signature was used to query the CMAP. Vorinostat, a lysine deacetylase inhibitor, was the top drug predicted to reverse the signature. KO mice were treated with vehicle or vorinostat daily from 4 to 7 weeks of age. Vorinostat treatment induced hyperacetylation of kidney lysine residues. This was associated with reduced albuminuria, decreased aSMA protein expression, and reduced gene expression of inflammatory cytokines.

Conclusions: *In silico* drug repurposing identified a novel therapeutic approach to AS. *In vivo* testing of the putative therapy showed that vorinostat exerts a renoprotective effect. Further studies will better define the mechanisms underlying the protective effect of this novel therapy.

***KCTD1* Mutations in Scalp-Ear-Nipple ('Finlay-Marks') Syndrome: A Further Cause of Thin Basement Membrane Nephropathy** Dongmao Wang,[1] Peter Diakumis,[2] Melanie Bahlo,[2] Deb J. Colville,[1] Judith A. Savige.[1] *[1]Medicine, The Univ of Melbouren (Melbourne Health), Melbourne, VIC, Australia; [2]Bioinformatics, WEHI, Melbourne, VIC, Australia.*

Background: Scalp-Ear-Nipple syndrome is an ectodermal dysplasia, with a scalp defect, prominent ears and absent breasts. It results from mutations in *KCTD1*, an inhibitor of the transcription factor, AP2. AP2 regulates the expression of the collagen IV a3 and a4 chains, which are major components of the glomerular, corneal and retinal basement membranes. This study characterised the clinical phenotype in Scalp-Ear-Nipple syndrome and how mutations caused disease.

Methods: Two unrelated families with Scalp-Ear-Nipple syndrome were examined by a renal physician and an ophthalmologist. One family member provided a skin biopsy that was used to derive a fibroblast cell line. Urine specimens from two family members were used to study the expression of the collagen IV a3 and a4, and laminin a5 and b1 transcripts. The ER size was measured using immunohistochemistry before and after treatment with PBA, a chemical chaperone.

Results: Seven family members had developed renal cysts and impaired renal function by late adulthood, and all 14 who were examined had astigmatism. A renal biopsy demonstrated a thinned glomerular membrane. One individual had a thinned cornea and the two who were examined with optical coherence tomography had a small optic disc, and thinned retinal nerve fibre layer.

There was reduced transcription of the collagen IV a3 and a4 chains in the urine. The fibroblast cell cultures confirmed reduced laminin transcripts. ER size was increased in the fibroblast cells in vitro but 4PBA chaperone treatment reduced ER size. However no KCTD1 mutations were identified in 20 individuals with Thin membrane nephropathy and no COL4A3/COL4A4 mutations nor in 20 individuals with familial astigmatism.

Conclusions: The clinical features of Scalp-Ear-Nipple syndrome are due to *KCTD1* mutations that affect basement membrane collagen IV and laminin expression. Chemical chaperones represent a potential treatment to delay renal failure.

FR-PO165

Podocyte Globotriaosylceramide (GL3) Accumulation in Fabry Disease Is Influenced by Age and Genotype Behzad Najafian,[1] Camilla Tøndel,[2] Einar Svarstad,[2] Michael L. West,[3] Michael Mauer.[5] *[1]Univ of Washington; [2]Univ of Bergen; [3]Dalhousie Univ; [4]Univ of Washington.*

Background: Podocyte injury plays a key role in Fabry nephropathy, a major complication of Fabry disease. Identification of factors affecting podocyte injury may help to understand the pathophysiology of Fabry nephropathy. We studied effects of age and gendotype on podocyte GL3 accumulation in Fabry patients.

Methods: Kidney biopsies from 55 male Fabry disease patients, age 25 [4-65] (median [range]) years were studied using electron microscopic stereology. Podocyte GL3 volume

density [Vv(GL3/Podo)] was estimated and correlated with age and GLA mutation. The latter, known in 38 of these patients, included 35 classical, 2 cardiac variant (N215S) and one late onset (R363H) GLA mutation.

Results: There was a wide range of Vv(GL3/Podo) among the patients, 0.41 [0.003-0.58]. Vv(GL3/Podo) increased linearly with age in younger patients up to age 30 years (r=0.56, p=0.001), but plateaued thereafter, varying within the narrow range of 0.35-0.58. There were 4 outliers, ages 37-50 with low Vv(GL3/Podo) (range 0.003-0.22), including patients with N215S (n=2) and R363H mutations and one patient whose GLA mutation was unavailable. Vv(GL3/Podo) directly correlated with urine albumin creatinine ratio (r=0.67, p=0.02) and foot process width (r=0.49, p=0.05) in males younger than 30 years. Volume density of podocytes per glomerulus was inversely correlated with age (r=-0.69, p=0.0001) across the age range with no plateauing, suggestive of continuous podocyte loss.

Conclusions: The fraction of podocyte cytoplasm filled with GL3 inclusions increase with age up to about age of 30 in Fabry males with classical GLA mutations and is associated with podocyte injury and albuminuria. Plateauing of podocyte GL3 volume density after age of 30 is suggestive of a threshold beyond which GL3 accumulation may not be compatible with podocyte survival. The clinical progression of Fabry nephropathy beyond age 30 in FD males with classical mutations could be reflected in other podocyte parameters such as podocyte hypertrophy and/or loss. Thus further studies are underway to explore these possibilities.

FR-PO166

Outcomes of Patients Over 65 in the Canadian Fabry Disease Initiative Study Michael L. West,[1] Daniel G. Bichet,[2] Aneal Khan,[3] Joe T. Clarke,[4] Sandra Sirrs,[5] Steve Doucette,[6] Christiane Auray-Blais,[7] Kaye Lemoine.[8] *[1]Medicine, Dalhousie Univ, Halifax, NS, Canada; [2]Medicine, Univ of Montreal, Montreal, QC, Canada; [3]Genetics, Univ of Calgary, Calgary, AB, Canada; [4]Emeritus, Univ of Toronto, Toronto, ON, Canada; [5]Medicine, Univ of British Columbia, Vancouver, BC, Canada; [6]Dept of Community Health and Epidemiology, Dalhousie Univ, Halifax, NS, Canada; [7]Pediatrics, Univ of Sherbrooke, Sherbrooke, QC, Canada; [8]Nursing, Nova Scotia Health Authority, Halfax, NS, Canada.*

Background: The Canadian Fabry Disease Initiative (CFDI) is a multicentre prospective study of outcomes with enzyme replacement therapy (ERT) in Fabry disease. ERT has been shown to be of benefit in reducing Fabry cardiac and renal disease. There is uncertainty as to the benefits of ERT in older patients. We compared outcomes of ERT in patients over 65 years of age with the overall CFDI population.

Methods: Patients are reviewed every 6-12 months as to clinical status. ERT is provided every 2 weeks according to national guidelines with intravenous dose agalsidase alfa (0.2 mg/kg) or agalsidase beta (1.0 mg/kg). Cardiovascular risk factor modification is promoted with use of ASA, statins and ACEi/ARB. Clinical outcomes are defined as stage 5 CKD, stroke/TIA, acute deafness, cardiac arrest, CHF, arrhythmia, unstable angina, MI, PTCA, pacemaker/ICD, AVR/CABG and death.

Results: As of Jan 2015, 429 subjects were enrolled. There were 51 patients over 65 y, 68.6% female, and 60.8% on ERT with mean age 71.8 y. There were no differences in mean age, cardiac variant genotype, or time in the CFDI between those on ERT and those not. Compared with patients not on ERT, those on ERT had lower eGFR, greater proteinuria and higher LVMI at both baseline and 6 y later. Three patients not on ERT had 5 clinical events, prevalence 15%, no deaths with clinical event rate of 1/34.5 patient years. Twenty patients on ERT had 5 deaths, 38 clinical events, prevalence 64.5% and clinical event rate of 1/9.3 patient years. Death was more likely in females 21% vs. males 8.3%. Patients over 65 y had greater prevalence of cardiac indications for ERT than the overall CFDI population. Time to first clinical event was earlier in those on ERT (p=0.003).

Conclusions: Older patients with Fabry disease continue to have clinical events, mainly cardiac, despite ERT but appear to be living longer. Use of the Canadian Fabry Disease guidelines appears to successfully target high-risk older patients. ERT use in this subgroup appears to be of benefit.

A Founder Haplotype of APOE-Kyoto Mutation Associated with Lipoprotein Glomerulopathy Zhangxue Hu. *Dept of Nephrology, West China Hospital, Chengdu, Sichuan, China.*

Background: Lipoprotein glomerulopathy (LPG) is a rare dominant inherited kidney disease with incomplete penetrance, histological characterized by the formation of intraglomerular lipoprotein thrombi. Their main clinical manifestation includes proteinuria, the elevated level of serum triglyceride and apolipoprotien E (apoE). Approximately 15 APOE mutations associated with LPG have been reported so far, the most common being APOE-Kyoto mutation. Our previous study revealed the largest population of LPG from a county 200 kilometer near Chengdu city, in Sichuan province, China. All these patients shared APOE Kyoto mutation in e3 allele, which suggests that the APOE-Kyoto mutation spread from one founder.

Methods: we enrolled 26 patients with LPG from twenty-six unrelated Chinese families who were diagnosed by renal biopsy. After informed consents were obtained from them and their families, APOE mutation was detected by PCR-RFLP with Aor51HI, and a haplotype analysis of APOE was carried out by DNA sequencing using the method of TA cloning.

Results: We investigated the haplotype of APOE allele from twenty-six unrelated LPG families, and found the haplotype of APOE-Kyoto mutant allele was identical, and was likely derived from haplotype 1 of APOE3; as for the counterpart APOE allele, the haplotype of counterpart APOE allele was not identical. Also, we identified a new haplotype of APOE4 named 32.

Conclusions: The haplotype of APOE-Kyoto mutation allele associated with LPG in the narrow country was identical, suggesting that mutation is common in chinese patients through a founder effect. And patients didn't have a common haplotype of counterpart APOE allele as the asymptomatic carriers, which association with the onset of LPG isn't known. To the new haplotype 32 of APOE4, its clinical value isn't clear now.

Eleven Pregnancies in Four Women with Atypical Hemolytic Uremic Syndrome Martina M. Gaggl,[1] Christof Aigner,[1] Zoltan Prohaszka,[2] Gere Sunder-Plassmann,[1] Alice Schmidt.[1] *[1]Dept of Medicine III, Div of Nephrology and Dialysis, Medical Univ of Vienna, Vienna, Austria; [2]IIIrd Dept of Internal Medicine, Research Laboratory, Semmelweis Univ, Budapest, Hungary.*

Background: Pregnancy activates the maternal alternative pathway of the complement system due to presentation of paternal antigens. In females with atypical Hemolytic Uremic Syndrome (aHUS) – a disease of the complement regulatory proteins and C3 – each pregnancy can trigger life-threatening disease episodes.

Methods: Data were collected from patients with aHUS, enrolled in the Viennese TMA Cohort. Pregnancies occurred between 2002 and 2015.

Results: We report 11 pregnancies in 4 women (table 1). Two had an established diagnosis of aHUS prior to the first pregnancy (case 2 and 3). Case 1 presented with end-stage renal disease due to TMA (biopsy-proven) 12 months after her first delivery and case 4 presented postpartum after her uncomplicated first delivery. In 8 pregnancies females received preventive plasma infusions (PI, 200-1600 mL) 2 to 4 weeks apart. After kidney transplantation case 1 received a maintenance therapy (PIs once a month), which was intensified during the II. pregnancy to every other week. Two pregnancies (case 1 III., case 4 III.) are currently ongoing without evidence of a disease flare so far. Nine pregnancies went without any complication and the offspring are healthy. One pregnancy (case 3, III., without PIs) resulted in an intrauterine fetal death at gestation week 36, but without signs of TMA in the mother.

Age at renal transplant (yrs)	25	-	26	-
Number of pregnancies	3	2	3	3
Age at I. pregnacy	18	19	29	20

Conclusions: Our case series underscores the fact that the recommendation to avoid pregnancies in aHUS is questionable. The strategy to prevent disease episodes with plasma infusions might be superior to primary monitoring and initiation of treatment in acute disease episodes.

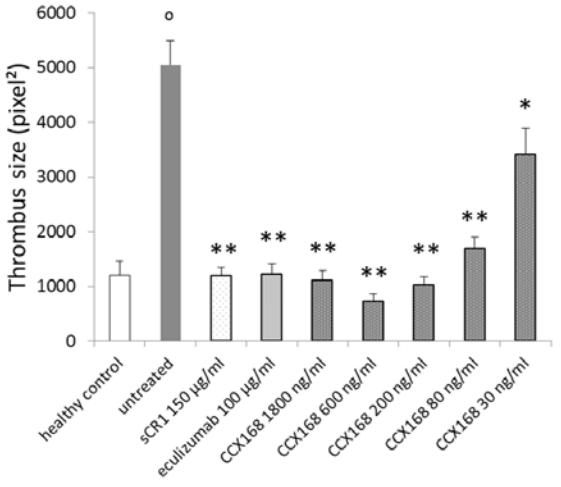
Orally Administered Complement 5a Receptor Inhibitor CCX168 Development in Atypical Hemolytic Uremic Syndrome Miriam Galbusera,[1] Sara Gastoldi,[1] Valentina Portalupi,[1] Elena Mondo,[1] Pirow Bekker,[2] Thomas J. Schall,[2] Marina Noris,[1] Giuseppe Remuzzi.[1] *[1]Mario Negri Inst; [2]ChemoCentryx.*

Background: The orally administered complement 5a receptor (C5aR) inhibitor CCX168 is in Phase 2 development for antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis, atypical hemolytic uremic syndrome (aHUS), and IgA nephropathy. The anaphylatoxin C5a is a potent neutrophil attractant involved in neutrophil priming and activation as well as inducing endothelial cell injury. The latter causes increased neutrophil and platelet adhesiveness, leading to thrombosis, one of the hallmarks of aHUS. We report here progress in the aHUS program.

Methods: In an ex vivo thrombus formation system, serum from aHUS patients induces thrombus formation on microvascular endothelial cells. CCX168 was compared with the anti-C5 antibody eculizumab and soluble complement receptor 1 (sCR1) in this assay.

Results: CCX168 resulted in a dose-dependent inhibition of thrombus size.



° P<0001 vs control; * P<0.05, ** P<0.0001 vs untreated. 200 ng/mL CCX168, equal to trough plasma levels achieved with 30 mg CCX168 twice daily (b.i.d) in patients, showed maximal inhibition of aHUS serum-induced thrombus formation, comparable to sCR1 and eculizumab at 100 mg/mL, the trough level observed in aHUS.

Conclusions: CCX168 was effective in reducing aHUS-induced thrombus formation, similarly to eculizumab and sCR1. A Phase 2 study was launched. Ten patients with aHUS who are on dialysis are treated with CCX168 30 mg b.i.d. for 15 days. The primary aim is to evaluate whether in vivo CCX168 treatment dampens the ex vivo prothrombogenic properties of serum from these patients. Secondary outcome measures include the effect of CCX168 on biomarkers of complement, soluble thrombomodulin and VCAM-1, platelet count, hemoglobin, LDH, neutrophil count, and the pharmacokinetic profile of CCX168.

Whole Exome Sequencing Reveals Mutation of *PAPLN* as a Novel Cause of Congenital Abnormalities of the Kidney and Urinary Tract (CAKUT) Jing Chen,[1,6] Asaf Vivante,[1,6] Julian Jakob Schulz,[1] Shirlee Shril,[1] Stefan Kohl,[1] Daw-yang Hwang,[1] Richard P. Lifton,[2,3] Elijah O. Kehinde,[4] Velibor Tasic,[5] Friedhelm Hildebrandt.[1,3] *[1]Dept of Medicine, Boston Children's Hospital, Harvard Medical School, Boston, MA; [2]Dept of Human Genetics, Yale Univ School of Medicine, New Haven, CT; [3]Howard Hughes Medical Inst, Chevy Chase, MD; [4]Dept of Surgery, Kuwait Univ, Safat, Kuwait; [5]Dept of Pediatric Nephrology, Univ Children's Hospital, Skopje, Macedonia, The Former Yugoslav Republic of; [6]These authors contributed equally to this work.*

Background: Congenital anomalies of the kidney and urinary tract (CAKUT) are the most common cause of chronic kidney disease in children. Knowledge from animal models suggests that single gene mutations in genes governing kidney and urinary tract development may lead to CAKUT in humans. However, the genetic pathogenesis of human CAKUT remains mostly elusive.

Methods: To identify novel monogenic causes of CAKUT we applied homozygosity mapping with whole exome sequencing (WES) to 36 families with CAKUT. Then we investigated a worldwide cohort of ~1,600 families with CAKUT with a barcoded array based multiplex exon PCR (48x48 Fluidigm Access Array™) and next generation sequencing (Illumina MiSeq™).

Results: In a consanguineous family with isolated CAKUT we detected a homozygous protein truncating mutation (p.Arg480*) in the *PAPLN* gene by WES. *PAPLN* encodes papilin, a component of the extracellular matrix (ECM) that plays a role in ECM development and interacts with ADAMTS metalloproteases. Papilin contains several thrombospondin type I domains homologous to ADAMTS-1, in which mutations leads to very distinct CAKUT phenotype in mice.

Conclusions: We identified a recessive truncating mutation in *PAPLN* as a novel monogenic cause of CAKUT, suggesting that CAKUT in humans may result from disruption of ECM degradation and turn over.

Whole Exome Sequencing Identifies Mutations in *TUBAL3* as a Novel Cause of Congenital Abnormalities of the Kidney and Urinary Tract (CAKUT) Shirlee Shril,[1,6] Asaf Vivante,[1,6] Jan Halbritter,[1] Jing Chen,[1] Julian Jakob Schulz,[1] Stefan Kohl,[1] Daw-yang Hwang,[1] Elijah O. Kehinde,[2] Richard P. Lifton,[3] Martin Zenker,[4] Friedhelm Hildebrandt.[1,5] *[1]Dept of Medicine, Boston Children's Hospital, Harvard Medical School, Boston, MA; [2]Dept of Surgery, Kuwait Univ, Safat, Kuwait; [3]Dept of Genetics, Yale Univ School of Medicine, New Haven, CT; [4]Dept of Human Genetics, Otto von Guericke Univ, Magdeburg, Germany; [5]Howard Hughes Medical Inst, Chevy Chase, MD; [6]These authors contributed equally to this work.*

Background: Congenital anomalies of the kidney and urinary tract (CAKUT) are the leading cause of end-stage kidney disease in children. The morphogenesis of kidney and urinary tract is modified by genetic mutations that lead to CAKUT. Identifying these mutations will not only provide a deeper insight on disease mechanisms but also aids in improving diagnosis. *TUBAL3* was identified as a potential candidate gene for causing CAKUT.

Methods: Homozygosity mapping with whole exome sequencing(WES) was performed in 20 consanguineous families with CAKUT from India. Homozygous recessive mutations within the homozygous region were further evaluated as the strongest candidates. Furthermore, we screened an additional cohort of 900 patients with CAKUT for additional mutations with a barcoded array based multiplex exon PCR (48x48 Fluidigm Access Array™) followed by next generation sequencing (Illumina MiSeq™) All identified mutations were confirmed by Sanger sequencing.

Results: A homozygous truncating mutation (p.Tyr179*) in the gene *TUBAL3* was identified in the consanguineous Indian family A3838 using WES. We then independently detected another mutation homozygously (p.Gly10Ser) in the gene *TUBAL3* in a family A1347 of Kurdish descent. *TUBAL3* (Tubulin, alpha-like 3) is a protein coding gene and is very conserved across species. Tubulin is the major constituent of microtubules.

Conclusions: We identified recessive mutations in *TUBAL3* as a novel single-gene cause of CAKUT. Futher genetic information and functional studies will help understand disease mechanisms and the role of TUBAL3 in the pathogenesis of CAKUT.

Association of PAX2 and Other Gene Mutations with the Clinical Manifestations of Renal Coloboma Syndrome Kengo Furuichi,[1] Toshiya Okumura,[2] Yasuyuki Shinozaki,[2] Yasunori Iwata,[2] Norihiko Sakai,[1] Takashi Wada.[2] *[1]Div of Blood Purification, Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Japan; [2]Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Japan.*

Background: Renal coloboma syndrome (RCS) is characterized by kidney hypoplasia or dysplasia and abnormality of the optic nerve. Diagnosis of RCS is based on the morphological examination of the kidney, ophthalmologic findings, and family history. Approximately 170 cases with *PAX2* gene mutations have been reported in cases with RCS worldwide. However, around 50% cases of RCS have no mutation in *PAX2 gene*.

Methods: To investigate the incidence and effects of mutations of *PAX2* and 25 related genes, 26 patients with RCS were screened using next-generation sequence analysis, and candidate mutations were confirmed using Sanger sequencing. The correlation between mutations and clinical manifestation was evaluated.

Results: Thirty patients, including two family cohorts (n = 5 and 2), 19 patients with sporadic RCS, and 4 coloboma only control cases were evaluated in the present study. Screening the sequences of *PAX2* and 25 other genes identified 46 nonsynonymous single nuclear changes and 9 indels, Among these candidate gene abnormalities, eleven *PAX2* mutations, including four novel mutations, were confirmed using Sanger sequencing, as were mutations in *CHD7*, *SALL4*, *KIF26B*, and *SIX4*. A *SALL4* mutation was detected in one patient, and *CHD7*, *KIF26B*, and *SIX4* mutations were detected in another patient, of which*KIF26B* mutation is novel. Kidney function and proteinuria were more severe in patients with *PAX2* mutations than in those without themutation. Moreover, the coloboma score was significantly higher in patients with *PAX2* gene mutations. Three out of five patients with *PAX2* mutations had focal segmental glomerulosclerosis diagnosed from kidney biopsies.

Conclusions: Our data indicate that *PAX2* mutation is a key mutation in RCS and may make a major contribution to the pathogenesis of kidney and eye abnormalities. However, other factors and gene mutations may play a role, and further human and animal studies will be required to define the mechanism of pathogenesis of RCS.

FR-PO173

Whole Exome Sequencing Identifies a Mutation in *TTC25* as a Novel Monogenic Cause of Congenital Anomalies of the Kidney and Urinary Tract (CAKUT) Julian Jakob Schulz,[1] Asaf Vivante,[1] Jing Chen,[1] Shirlee Shril,[1] Elijah O. Kehinde,[2] Friedhelm Hildebrandt.[1,3] *[1]Dept of Medicine, Boston Children's Hospital, Harvard Medical School, Boston, MA; [2]Dept of Surgery, Kuwait Univ, Safat, Kuwait; [3]Howard Hughes Medical Inst, Chevy Chase, MD.*

Background: Congenital anomalies of the kidney and urinary tract (CAKUT) cover a wide range of renal malformations which account for most cases of pediatric CKD. So far more than 30 monogenic CAKUT-causing genes have been identified. However, for most cases the underline genetic cause is still unknown.

Methods: To identify causative genes for CAKUT we investigated consanguineous families with CAKUT by applying whole exome sequencing (WES) combined with homozygosity mapping.

Results: In one family we detected a homozygous loss-of-start mutation in the gene *TTC25* (tetratricopeptide repeat-containing 25). This mutation (p.Met1Thr; c.2T>C) was present in an affected child that had a posterior urethral valve, vesicourethral reflux and bilateral hydronephrosis. TTC25 plays a role in ciliogenesis, pronephric cilia function and signal transduction in the sonic hedgehog pathway (Hayes, J. M. *et al*., 2007. Dev. Biol. 312: 115; Xu Y *et al*., 2015. PLOS ONE 10(4): e0124378). The latter has been shown to coordinate bladder as well as urethra formation in mice (Haraguchi R *et al*., 2007. Development 134(3):525; Haraguchi R *et al*., 2012. PLOS ONE 7(7): e42245).

Conclusions: By WES and homozygosity mapping we identified *TTC25* as a novel monogenic CAKUT-causing gene if mutated.

Phenotypic Analysis of a Cohort of Patients with Hepatocyte Nuclear Factor 1 Beta (HNF1β) Mutations and Correlation with Established Scoring Systems

Emma Kaye Montgomery,[1] John Andrew Sayer.[1,2] *[1]Renal Services Centre, Newcastle Hospitals NHS Foundation Trust, Newcastle upon Tyne, Tyne and Wear, United Kingdom; [2]Inst of Genetic Medicine, International Centre for Life, Newcastle Univ, Newcastle upon Tyne, Tyne and Wear, United Kingdom.*

Background: Hepatocyte nuclear factor 1 beta (HNF1β) mutations may lead to a wide spectrum of clinical phenotypes including developmental defects of the kidney, pancreas, liver, and Mullerian duct. HNF1β mutations account for Renal Cysts and Diabetes (RCAD) syndrome. We reviewed patients with known HNF1β mutations to determine the range of phenotypes and identified if these patients would have been detected based on established scoring systems.

Methods: We selected patients who had been screened for HNF1β mutations from 2009 to 2014 within our hospital. Serum magnesium, potassium, urate and creatinine levels were noted as well as renal morphology based on imaging. All positive and negative patients for HNF1β mutations had their phenotypes quantified and correlated with published HNF1β scoring systems and screening criteria.

Results: 135 patients were screened over 5 years. The cohort included 17 patients from 10 families with confirmed HNF1β mutations. The majority of these patients had CKD stage 3, with a mean creatinine of 144 umol/L. Only 35% of mutation positive patients had both renal cysts and diabetes. 57% of patients had hypomagnesaemia, 50% of the patients had hyperuricemia and 4 patients had clinical symptoms of gout with 75% of these patients presenting with gouty symptoms before the age of 30. Using a published HNF1β scoring system, 16 patients reached a threshold score of >8, sufficient for a presumed diagnosis, validating the sensitivity of the scoring system in our cohort. Based on alternative screening criteria, all 17 patients would have been identified for screening.

Conclusions: The majority of patients with HNF1β mutations demonstrated hypomagnesaemia (50%), hyperuricaemia (53%) and deranged liver function tests (59%). RCAD remains a misnomer and patients with HNF1β mutations have a wide phenotypic spectrum, with only one third having renal cysts and diabetes. The use of a HNF1β scoring/screening system will help to improve detection rates.

CTNS Gene Mutations and Variants in Adult Hemodialysis Patients

Craig B. Langman,[1] Paul C. Grimm,[2] Elena N. Levtchenko,[3] Krishna R. Polu.[4] *[1]Feinberg Sch Med, Northwestern U; [2]Stanford U. Sch. of Med; [3]Univ of Leuven; [4]Raptor Pharmaceuticals, Novato, CA.*

Background: Nephropathic Cystinosis (NC), a rare, systemic, autosomal recessive disease due to *CTNS* gene mutations causes end-stage renal disease (ESRD). While most cases of NC are recognized in infancy (95%), late-onset NC with ESRD is rare but might be under-diagnosed. NC is rarely diagnosed in African-Americans (AA). **Objective**: To identify *CTNS* mutations and possible pathogenic variants (Δ) in a representative sample of ESRD patients (pts) in the US.

Methods: Genomic DNA was extracted from whole blood from 4007 adult hemodialysis pts from the Davita biorepository. Fluidigm's Access Array IFC was used for the *CTNS* target enrichment. Enriched DNA was sequenced on the Hiseq 2500 using 2 x 100bp read length.Reads were mapped to the human genome version hg19 using the BWA aligner. Mutations and Δ were called using both GATK and Samtools and confirmed by Sanger sequencing.

Results: 16 pts had homozygous (HoZ) and 52 pts had compound heterozygous (HTZ) *CTNS* sequence Δ. 1/68 pts had a known diagnosis of NC (W138X). In HoZ pts, 6 had known mutations in CTNS (V42I;5/6 were AA) consistent with NC. 9 had upstream promoter mutations (UPM) (7 with -294C>T and 2 with -295G>C, a mutation locus with known disease association), and 3 of these pts were AA. In 52 HTZ *CTNS* sequence Δ, 2 AA pts had UPM. The other 50 had combinations of changes in the *CTNS* coding sequence & promoter region.

Conclusions: The unexpected frequency of *CTNS* gene mutations & Δ suggest that late-onset NC may be underrecognized in ESRD. These *CTNS* alterations need further study to determine pathogenicity and association with NC. In addition, *CTNS* mutations & Δ in AA sub population signals a need for evaluation for a diagnosis of late onset nephropathic cystinosis in ESRD.

Sixteen Monogenic Genes Cause 20% of Early-Onset Urinary Stone Disease

Jennifer A. Lawson,[1] Daniela A. Braun,[1] Heon Yung Gee,[1] Jan Halbritter,[1] Shirlee Shril,[1] Weizhen Tan,[1] John Andrew Sayer,[2] Danko Milosevic,[3] Michelle Baum,[1] Velibor Tasic,[4] Friedhelm Hildebrandt.[1,5] *[1]Nephrology, Boston Children's Hospital, Boston, MA; [2]Inst of Genetic Medicine, Newcastle Univ, Newcastle upon Tyne, United Kingdom; [3]Dept of Pediatric Nephrology, Univ of Zagreb Medical School, Zagreb, Croatia; [4]Medical Faculty Skopje, Univ Children's Hospital, Skopje, Macedonia, The Former Yugoslav Republic of; [5]Howard Hughes Medical Inst, Chevy Chase, MD.*

Background: Urinary stone disease (USD) is a prevalent condition that affects 10-15% of adults in their lifetime. It is associated with high morbidity due to colicky pain, the necessity for surgical intervention, and sometimes progression to chronic kidney disease. In recent years, multiple monogenic causes of USD have been identified. However, the prevalence of each monogenic gene has yet to be systematically studied in a pediatric urinary stone cohort.

Methods: To determine the percentage of cases that can be explained molecularly by mutations in 1 of 30 known urinary stone genes, we conducted a high throughput exon sequencing analysis in an international cohort of consecutively recruited individuals from three renal stone clinics. The cohort consisted of 143 individuals under 18 year of age, with nephrolithiasis (n=123) or isolated nephrocalcinosis (n=20).

Results: We detected likely causative mutations in 16 of 30 analyzed genes, leading to a molecular diagnosis in 20% (29 of 143) of affected individuals; 14 of the 32 detected mutations were not previously described as disease causing (43.8%). We show that mutations in recessive genes are more likely to cause infantile onset disease, whereas mutations in dominant genes are more likely to manifest later.

Conclusions: We present the first exclusively pediatric cohort examined for monogenic causes of urinary stone disease, and our data demonstrates that important therapeutic and preventative measures may result from mutational analysis in individuals with early-onset USD.

FR-PO177

Mild Inhibition of Alanine-Glyoxylate Aminotransferase Translation as a Possible Treatment of Primary Hyperoxaluria Type I

Roman Lyakhovetsky,[1] Yaacov Frishberg,[1] Bodo B. Beck,[2] Ruth Belostotsky.[1] *[1]Pediatric Nephrology, Shaare Zedek Medical Center, Jerusalem, Israel; [2]Inst of Human Genetics, Cologne, Germany.*

Background: Primary hyperoxaluria type 1 (PH1) is a kidney stone disease, often leading to ESRD, caused by absence, deficiency or mistargeting of the liver peroxisomal alanine-glyoxylate aminotransferase (AGT), encoded by *AGXT*. The most frequent mutation G170R, responsible for 30% of PH1 cases in Caucasians, results in aberrant mitochondrial localization rather than catalytic inactivity. Modulating AGT maturation and folding has long been perceived as a therapeutic approach. Yet, numerous attempts over the years failed to rescue AGT mutants. We propose mild translational inhibition as a novel approach to improve folding and localization of AGT mutants.

Methods: The antihelminthic FDA-approved drug emetine, was used as a translation inhibitor. To ensure selective and specific discrimination between the mitochondrial (major) and the peroxisomal (minor) subpopulations of mutated AGT we developed the *GlowAGT* assay based on the recently described self-assembly split GFP approach.

Results: Using *GlowAGT,* WT-AGT but not G170R-AGT was detectable by GFP fluorescence, although both variants were visible by indirect immunofluorescence. Long-term treatment with low concentrations of emetine showed statistically significant increase of fluorescent subpopulation of G170R-AGT. GFP fluorescence was exclusively co-distributed with the peroxisomal staining in all cases.

Conclusions: We have developed and applied successfully *GlowAGT* as a unique self-assembly split-GFP-based assay for detecting peroxisomal subpopulation of AGT. Using *GlowAGT* we show that mild translation inhibition by emetine is a novel therapeutic approach for PH1 caused by AGT misfolding/mislocalization

FR-PO178

Functional Analysis of CLCNKB Mutations Causing Bartter Syndrome Type III Yohan Bignon,[1] Mathilde Keck,[1] Stéphane Lourdel,[1] Rosa Vargas-Poussou,[2] Jacques Teulon,[1] Olga Andrini.[1] *[1]Metabolisme et Physiologie Renales, Centre de Recherche des Cordeliers, UPMC, Paris, France; [2]Dept of Human Genetics, Hopital Europeen Georges Pompidou, Univ Paris 5, Paris, France.*

Background: Bartter Syndrome type III is a human autosomal recessive disease characterized by salt wasting, hypokalemic metabolic alkalosis and secondary hyperaldosteronism. Therefore, patients affected by Bartter syndrome type III display polyuria, polydipsia, dehydration, nephrocalcinosis and failure to-thrive. The disease is caused by inactivating mutations in the CLCNKB gene encoding for the ClC-Kb Cl- channel that is present in the distal nephron, where it mediates the basolateral step of Cl- absorption [2]. In this study, we have investigated the functional consequences of five previously reported pathogenic ClC-Kb missense mutations (A204T, A210V, P216L, G424R, G437R [3]).

Methods: We characterized the electrical activity, total protein expression, surface expression and subcellular localization of mutated forms of ClC-Kb in X. laevis oocytes and mammalian cell lines.

Results: Currents produced by G424R and G437R ClC-Kb channels were reduced by 50%, in proportion to membrane targeting without any change in total protein abundance. A210V and P216L mutants did not produce any current but their membrane insertion was only partially reduced (50-80%). Protein abundance of A210V was decreased by half. Conversely, that of P216L was comparable to WT ClC-Kb, suggesting that the P216L mutation might alter channel gating. Finally, A204T seems to be electrically functional, rather well inserted into the plasma membrane and protein level is comparable to that of wild-type ClC-Kb.

Conclusions: In conclusion, the loss-of-function of ClC-Kb mutants is the result of different molecular defects including lower stability of the mutant protein, impaired membrane targeting and altered channel gating.
