Background: Increased blood pressure variability (BPV) is associated with lower neurocognitive test (NCT) performance in adults. We previously studied children with chronic kidney disease (CKD), who are at risk for cognitive dysfunction and increased BPV. However, little is known about the impact of increased BPV on cognition in children with CKD.

Methods: Children 6-18 years enrolled in the prospective NIH-sponsored Chronic Kidney Disease in Children (CKiD) study had NCT including WASI Matrix Reasoning, parent BRIEF, CPT-II, Digit Span, and Verbal Fluency. Casual BP visit-to-visit BPV was assessed by SD (BPV-SD) and average real variability (ARV), and 24-hour ambulatory BP monitoring by SD of wake and sleep periods. For unadjusted analyses, test scores of the subjects with BPV in the upper tertile were compared to that of subjects in the lower tertile. Multiple linear regressions were used to evaluate the relation between BPV and NCT scores, adjusting for BP index, sex, age, maternal education, race, BMI %ile, estimated GFR, % of life with CKD, nephrotic proteinuria, and low birth weight.

Results: Depending on the task, 121- 511 subjects had both BP and NCT results available. In unadjusted analysis, subjects with increased visit-to-visit systolic BPV scored lower on Verbal Category Switching (3rd vs 1st tertile of BPV-SD, 8.4 ± 2.7 vs 9.8 ± 3.0, $p = 0.004$; of ARV, 8.6 ± 3.0 vs 9.7 ± 2.5, $p = 0.009$). There was no effect of increased visit-to-visit BPV or ambulatory BPV on any other task. In adjusted analyses, increased visit-to-visit systolic BPV remained significantly associated with lower Verbal Category Switching scores for BPV-SD (β=-0.28, 95% CI:-1.34, -0.15) and there was a trend for ARV (β =-5.7, 95%CI:-1.16, 0.03).

Conclusions: Increased visit-to-visit systolic BPV was independently associated with decreased Verbal Category Switching scores in children with CKD. These results suggest that children with CKD may have difficulties with set shifting that are related, in part, to increased BPV. Further study is needed to determine the significance of this isolated result.

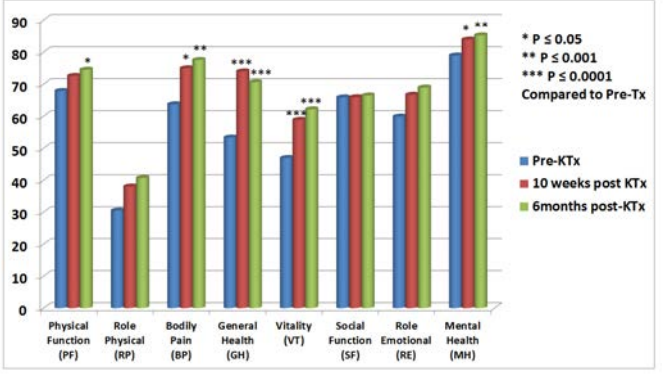
Rapid Post-Transplant Improvement of HRQOL in Older Kidney Recipients Kristian Heldal,[1,2] Kjersti Lønning,[2,3] Tomm Bernklev,[2,4] Nanna von der Lippe,[2] Anna Reisaeter,[3] Anders Hartmann,[2,3] Marit helen Andersen,[3] Karsten Midtvedt.[3] *[1]Clinic of Internal Medicine, Telemark Hospital, Skien, Norway; [2]Inst of Clinical Medicine, Faculty of Medicine, Univ of Oslo, Oslo, Norway; [3]Clinic of Cancer, Surgery and Transplantation, Oslo Univ Hospital, Rikshospitalet, Oslo, Norway; [4]Research Unit, Telemark Hospital, Skien, Norway.*

Background: It is widely accepted that health-related quality of life (HRQOL) is significantly compromised in patients with ESRD. In adults, kidney transplantation (KTx) is known to improve HRQOL. In older recipients there is a lack of studies measuring the effect of KTx on HRQOL. The aim of this study was to measure HRQOL longitudinally in enlisted patients >65 years of age, from pre-transplant and until 6 months after KTx.

Methods: Patients >65 years listed for transplantation at our centre were asked to complete the SF36 questionnaire at enlisting and thereafter every 6 months until KTx. Post transplant, the patients received a new SF36 form after 10 weeks and 6 months.

Results: A total of 180 patients have been included from Jan 2013. Mean age at enlisting was 70.6 years (65.0-81.8) and 68% were male. By the end of May 2015, 100 patients were transplanted and 59 of them had completed both pre- and post-transplant questionnaires. Mean time from completing the first pre-tx questionnaire to transplantation was five months. When comparing the scores for the last SF36 pre-tx with 6 months post-tx, there was a statistical significant increase of the mean scores for **GH (**53-71), **PF (**68-74), **BP (**64-78), **VT** (53-71) and **MH** (79-85). There was also a tendency towards improved scores for **RP** and **RE**, while the **SF** score was unchanged.



Conclusions: Our preliminary findings indicate that older patients report a significant improved HRQOL measured by SF36 already 10 weeks after KTx and the status remains stable after 6 months. Longer follow-up is warranted.

L-Carnitine Improves Cognitive and Renal Functions in a Rat Model of Chronic Kidney Disease Zaher Anis Armaly,[2] Adel Rafik Jabbour,[1] Avi Avital.[3] *[1]Dept of Nephrology, Bar Ilan Univ, E.M.M.S. Hospital, Nazareth, Israel; [2]Dept of Biochemical Laboratory, E.M.M.S. Hospital, Nazareth, Israel; [3]Behavioral Neuroscience Lab, Dept of Physiology, Rappaport Faculty of Medicine, Technion and The Emek Medical Center, Haifa, Israel.*

Background: Over the past decade, the prevalence of chronic kidney disease (CKD) has reached epidemic proportions. L-Carnitine, considered as the "gatekeeper" responsible for admitting long chain fatty acids into mitochondria. L-Carnitine synthesis and turnover are regulated mainly by the kidney and its levels inversely correlate with serum creatinine (SCr) of normal subjects and CKD patients. Previous studies showed that L-Carnitine administration to elderly improves and preserves cognitive function. Yet, there are no clinical intervention studies that investigated the effect of L- Carnitine administration on cognitive impairment evidenced in CKD patients.Thus, we investigated the effects of L-Carnitine treatment on renal function and cognitive performance in a rat model of progressive CKD.

Methods: Animals were subjected to right unilateral nephrectomy combined with 2/3 of left kidney ligation. Sham operated rats served as controls. Following 14-days recovery period, animals were randomly assigned into two treatment conditions: treatment with saline (sham n=7; CKD n=9) or L-Carnitine (250 mg/kg) (sham+car n=7 ; CKD+car;n=8) by daily intraperitoneal injections, for 8 consecutive weeks. Then all rats were sacrificed, blood samples and remnant kidney were collected, for biochemical and histological analysis, respectively.Two way shuttle avoidance test was used to assess the effects of CKD and L-Carnitine treatment on cognitive-related behavior.

Results: We found that all CKD animals exhibited renal dysfunction, as indicated by elevated sSCr, BUN, and histopathological abnormalities. L-Carnitine treatment of CKD rats significantly reduced SCr and BUN, attenuated renal hypertrophy and decreased renal tissue damage. In addition, in the two way shuttle avoidance learning, CKD animals showed cognitive impairment which recovered by the administration of L-Carnitine.

Conclusions: Administration of L-Carnitine in a rat model of CKD, significantly improved cognitive and renal functions.

SA-PO736

Being a Relative to Patients with Chronic Kidney Disease – Experiences of Participation in Care and Treatment Hanne Agnholt,[1] Jette Kristiansen,[2] Mona Kyndi Pedersen.[3] *[1]Dept of Nephrology, Aalborg Univ Hospital, Aalborg, Denmark; [2]Univ College of Northern Denmark, Aalborg, Denmark; [3]Clinic for Internal Medicine, Aalborg Univ Hospital, Aalborg, Denmark.*

Background: Studies concerning the lives of patients with chronic kidney disease have focused on the patients, and not the relatives. However, relatives share and are affected by the same consequences as the patient with regard to changes in everyday life, roles in the family and mutual relationship. The purpose of the study was to gain insight into and understanding of the needs of the relatives of patients with chronic kidney disease with regard to their ability to provide support in everyday life, and the expectations of the relatives of participation in care and treatment.

Methods: A qualitative study based on four focus group interviews with four to eight relatives in each group (in total 27 relatives). The groups were formed according to the age and gender of the relatives as well as their relation to the adult patient with chronic kidney disease.

Results: The study demonstrated how relatives provide substantial support to the patient both in everyday life and in care and treatment**.** In relation to the patient, it was a constant challenge for relatives to find the balance between supporting and taking over. They expressed a need for recognition by both the close relations and the health care professionals as well as a need for sharing their experiences with other relatives in the same situation. The analysis identified six themes: 1. Different needs and possibilities for support and participation. 2. Finding balance between disease and everyday life. 3. Emotional pressure. 4. The importance of recognition. 5. Need for regaining energy, and 6. Collaborating with health care professionals.

Conclusions: When collaborating with the relatives with regard to care for patients with chronic kidney disease, the health care professionals should actively recognize the patient support that the relatives already provide in everyday life. Initiatives of participation in care and treatment should be based on collaboration and the needs, expectations and possibilities of both the patient and the relatives.

SA-PO737

CKD(3-5) Affects Endurance, Strength, Balance and Fine Motor Skills which Are Not Detectable by Questionnaire Naomi D. Clyne,[1] Matthias Hellberg,[1] Peter Hoglund.[2] *[1]Clinical Sciences Lund, Nephrology, Lund Univ, Lund, Sweden; [2]Laboratory Medicine, Clinical Pharmacology, Lund Univ, Lund, Sweden.*

Background: Physical functions are impaired in dialysis patients. It is unclear which functions are affected and how they decline in the course of CKD. This study investigated the effects of declining GFR (CKD 3-5) on measured physical functions, self perceived physical functioning and well-being.

Methods: In this cross sectional analysis 101 patients (40 women, 61 men; mean age: 67±13 years, median GFR: 21 (9-41) ml/min/1.73m^2) were tested with 6 Minutes Walk (6-MWT), Isometric Quadriceps Strength (IQS), Functional Reach (FR) and Picking-up (PUT). Self perceived physical functioning and well-being were assessed by KDQOL-SF™. GFR was measured with Iohexolclearance and comorbidity by Davies´index. Multivariable linear regression analyses were employed including the following explanatory variables: GFR, age, sex, comorbidity and the interaction between sex and age.

Results: Significant associations were found between decline in GFR and endurance (6-MWT; p=0.039), strength (IQS; p=0.035), balance (FR; p=0.024) and fine motor skills (PUT; p=0.015) as well as by the patients' perceived domains in the KDQOL-SF™ of effects- (p=0.023) and burden (p=0.016) of kidney disease and social support (p=0.006) after having taken the explanatory variables into account. There were significant associations between the KDQOL-SF™ domains role physical and emotional well-being and 6-MWT (p=0.018; p=0.018, respectively) and IQS (p=0.005; p=0.045, respectively), but these were dependent on age, sex and comorbidity and not driven by GFR.

Conclusions: Physical functions comprising endurance, strength, balance and fine motor skills were impaired relatively early in the course of CKD (3b-5), seemed to progress with declining GFR and could be detected by easy to perform physical function tests. The relationship between self perceived physical functioning and well being, respectively, with measured endurance and strength, respectively, were driven by age, sex and comorbidity but not by decline in GFR. The only domains that descriminated for GFR associated infuelnce were effects- and burden of kidney disease and social support.

SA-PO738

The Prevalence of Cognitive Impairment in Chinese Peritoneal Dialysis Patients Chi-bon Leung, Cheuk-Chun Szeto. *Dept of Medicine and Therapeutics, Prince of Wales Hospital, Shatin, Hong Kong.*

Background: Cognitive impairment is common amongst patients with chronic kidney disease and may be associated with excessive morbidity in dialysis patients. This study determines the prevalence and risk factors of cognitive impairment in Chinese peritoneal dialysis (PD) patients.

Methods: We studied 178 prevalence PD patients (103 males). Cognitive impairment was screened by the 10-item Abbreviated Mental Test (AMT) questionnaire. We also determined patients' comorbidity load, dialysis adequacy, residual renal function, nutritional status, and degree of frailty.

Results: The mean age was 60.7 ± 11.7 years; vintage of dialysis 42.5 ± 44.1 months. Average AMT score was 9.3 ± 1.3. The AMT score is closely associated with age (r =

-0.398, p < 0.0001). AMT score also has a modest but significant correlation with Charlson's comorbidity index (r = -0.192, p = 0.010), subjective global assessment score (r = 0.153, p = 0.041), malnutrition inflammation score (r = -0.212, p = 0.004), serum albumin level (r = 0.184, p = 0.024), and frailty index (r = -0.199, p = 0.008), but not with vintage of PD, dialysis adequacy, or residual renal function. When defined as a AMT score <7, 14 patients (7.9%) had cognitive impairment.

Conclusions: Cognitive impairment is not uncommon amongst Chinese PD patients. Frailty and malnutrition are the major risk factors of cognitive impairment in our cohort, while comorbidity load and dialysis adequacy have little effect.

SA-PO739

Neurocognitive Functioning and Association with Clinical Outcomes in Adults with End-Stage Kidney Disease: The COGNITIVE-HD Study

Giovanni F.M. Strippoli.[1,2,3,4] *[1]On behalf of the COGNITIVE-HD Study Investigators*; [2]Diaverum Medical Scientific Office; [3]Univ of Bari; [4]Univ of Sydney.*

Background: Cognitive impairment and neurocognitive disorder have been associated with increased mortality in the general population. Whether dialysis patients have specific patterns of cognitive dysfunction, or whether cognitive function is associated with activities of daily living and durability of dialysis treatment remain poorly understood.

Methods: The COGNITIVE-HD study will provide detailed neuropsychological assessments of cognitive function among hemodialysis patients to characterize age- and education-adjusted prevalence and patterns of cognitive impairment and the associations with physical and social functioning and clinical outcomes including cardiovascular events at 12 months. The COGNITIVE-HD study is a prospective, longitudinal, population study of 751 adults conducted in 20 dialysis centers in Italy. A detailed battery of comprehensive testing for executive function, visuospatial function, language, learning and memory, personality traits, and complex attention has been carried out by a trained psychologist at baseline to assess for presence of cognitive impairment and to evaluate the pattern of cognitive deficits, and any association between cognitive impairment and activities of daily living.

Results: Preliminary analyses have been conducted on the Mini Mental State Examination (MMSE) evaluation of cognitive function among 702 participants (mean age 68.2 years, 60% men). 50% had normal cognitive function (MMSE score 27-30), 22% had mild cognitive impairment (score 26-24). 198 patients (28%) had MMSE results compatible with dementia (score <24), of whom 51%, 48% and 1% had mild, moderate and severe impairment respectively.

Conclusions: The COGNITIVE-HD is a population-based study of cognitive function involving dialysis patients that has the potential to inform candidate interventions for treatment trials of cognitive impairment in the setting of advanced kidney disease. *List of study investigators: S Palmer, M Ruospo, A Iurillo, V Saglimbene, P Natale, O Barulli, L Gargano, AM Murgo, C Loy, JC Craig, DW Johnson, M Tonelli, J Hegbrant, C Wollheim, G Logroscino and GFM Strippoli.

SA-PO740

Lower Renal Function Predicts Poorer Performance in Specific Domains of Neurocognitive Function in Older Hypertensive Men

Stephen L. Seliger,[1,2] Jason Kisser,[3] Jamie Giffuni,[2] Leslie I. Katzel,[1,2] Shari R. Waldstein.[3] *[1]Medicine, U Maryland Sch Medicine; [2]GRECC, VA Maryland Healthcare System; [3]Psychology, U Maryland Baltimore Co.*

Background: CKD has been associated with lower cognitive performance, especially in older adults. However, the specific pattern of functional deficits is uncertain, and many prior reports have not accounted for common vascular risk factors of ageing such as hypertension.

Methods: We tested neurocognitive functions using a multi-item test battery among older (60+) community-dwelling hypertensive males with stage 2-4 CKD (n=108) and without CKD (n=68). Subjects were free of stroke and dementia. GFR was estimated using the MDRD equation. Multiple linear regression was used to compare those with and without CKD, and to estimate associations of eGFR and proteinuria with cognitive functions, adjusting for demographics and potential confounders (education, depression, blood pressure, hemoglobin, fasting glucose, smoking, alcohol use, and BMI).

Results: Mean age was 69.1±7.4 years, mean SBP 134+/-18 mm Hg, and 47% were African-American; mean eGFR was 42.9.±14.5cc/min/1.73m^2 among those with CKD. Among all subjects, lower eGFR was linearly associated with worse performance on tests of attention, non-verbal memory, visuospatial ability, manual dexterity, and language fluency after multivariable adjustment (Table). In contrast, those with stage 2-4 CKD as a group did not differ from controls in cognitive performance after adjustment for confounders, nor was proteinuria correlated with cognitive test performance.

Adjusted associations (β) of estimated GFR with neurocognitive function

Cognitive Test	Functional Domains	Standardized β	p-value
Logical Memory Immediate	Verbal Memory & Learning	0.07	0.388
Logical Memory Delayed	Verbal Memory	0.048	0.56
Visual Reproductions Immediate	Non-verbal Learning & Memory	0.175	0.019
Visual Reproductions Delayed	Non-Verbal Memory	0.13	0.099
Grooved Pegboard (dominant)	Motor Speed, Manual Dexterity	-0.161	0.039
Grooved Pegboard (non-dominant)	Motor Speed, Manual Dexterity	0.005	0.948
Digit Span, Forwards	Simple attention	0.179	0.029
Digits Span, Backwards	Concentration, Working Memory	-0.041	0.591
Trails A	Psychomotor Speed,	-0.119	0.076
Trails B	Complex attention, set-shifting	-0.039	0.574
Stroop Color Word	Response Inhibition	0.104	0.234
Judgment of Line Orientation	Visuospatial Ability	0.144	0.05
Symbol Digit Substitution	Psychomotor Speed	0.099	0.179
Verbal Fluency	Language Fluency	0.168	0.038
Category Fluency – Animals	Language Fluency	-0.009	0.913
Category Fluency – Supermarket	Language Fluency	0.138	0.106

Conclusions: Among older men, those with primarily mild-moderate CKD and HTN do not have lower cognitive function compared to hypertensive controls after accounting for common cognitive risk factors. However, across a range of GFR, lower renal function is associated with worse performance in specific domains of cognitive function.

SA-PO741

Neurocognitive Function and Psychiatric Disorder in Children with Chronic Kidney Disease from the KNOW-Ped CKD Cohort Study (Korean Cohort Study for Outcome in Patients with Pediatric Chronic Kidney Disease)

Kyoung Hee Han,[1] Eujin Park,[2] Yo Han Ahn,[2] Seong Heon Kim,[3] Joo Hoon Lee,[4] Young Seo Park,[4] Hee Gyung Kang,[2] Hae Il Cheong,[2] Curie Ahn,[5] Il-Soo Ha.[2] *[1]Dept of Pediatrics, Jeju National Univ School of Medicine, Jeju, Republic of Korea; [2]Dept of Pediatrics, Seoul National Univ Children's Hospital, Seoul, Republic of Korea; [3]Dept of Pediatrics, Pusan National Univ Children's Hospital, Yangsan, Republic of Korea; [4]Dept of Pediatrics, Asan Medical Center, Univ of Ulsan College of Medicine, Seoul, Republic of Korea; [5]Dept of Internal Medicine, Seoul National Univ Hospital, Seoul, Republic of Korea.*

Background: We determined whether pediatric chronic kidney disease (CKD) is associated with neurocognitive impairment and psychiatric disorder from the KNOW-PedCKD cohort study in Korea.

Methods: A total of 322 children (M:F 218:104) enrolled from seven major pediatric nephrology centers of Korea from July 2010 to December 2013 were the subject of this study. Neurocognitive function and psychiatric status of pediatric CKD patients were evaluated using Wechsler intelligence scale for children, Child Behavior Checklist, ADHD Rating Scale-IV, State-Trait Anxiety Inventory, Child Depression Inventory and Parental bonding instrument-Korean version.

Results: Verbal, performance and full scale IQ were lower in younger age and congenital anomalies of the kidney and urinary tract as a cause of CKD. More than 10 percent of school-age children with CKD presented significant emotional distress including somatization (15%), attention problems (15%) and anxiety (12%). Impact of progression of CKD on their neurocognitive function and psychiatric status will be investigated in KNOW-PedCKD as follow-up study.

Conclusions: In young patients with CKD and those with multiple congenital problems in addition to CKD suffer from low intelligence and psychiatric disorder. Pediatric CKD patients with low intelligence and psychiatric disorder need close attention and developmental training techniques. **Acknowledgement.** This work was supported by the Research Program funded by the Korea Centers for Disease Control and Prevention (2013E3301600, 2013E33081601).

Awareness of Kidney Disease Is Associated with Depressive Symptoms: NHANES 2005-2010

Shayan Shirazian, Robert Diep, Joseph Mattana, Ritika Sharma, Rose Calixte. *Winthrop Univ Hospital.*

Background: Depressive symptoms are common in patients with chronic kidney disease (CKD). The purpose of this study was to define variables associated with depressive symptoms in patients with CKD including awareness of CKD diagnosis.

Methods: We used data from the National Health and Nutrition Examination Surveys (NHANES) 2005-2010. Non-pregnant subjects age >20 with CKD stage 1-4, who completed both an awareness of kidney disease questionnaire and a Patient Health Questionnaire (PHQ-9) were included. Three outcome groups were defined: 1) minimal depressive symptoms (PHQ-9 score 0-4), subthreshold depressive symptoms (PHQ-9 score 5-14) and severe depressive symptoms (PHQ-9 score > 14). All analyses were performed with appropriate

weighting. Chi-square and unpaired t-tests defined significant differences between outcome groups. Multivariable logistic regression defined variables independently associated with subthreshold depressive symptoms. Significance was defined as p£0.05.

Results: Of the 2500 subjects with CKD that met study criteria, 21.8% had subthreshold depressive symptoms and 3.3% had severe depressive symptoms. Multivariable predictors of subthreshold depressive symptoms included female gender, lower education, lower income, single marital status, Mexican and Black race, diabetes, elevated diastolic blood pressure, smoking, cardiovascular comorbidity and awareness of kidney disease. 6.4% of subjects were aware they had CKD. CKD awareness was significantly associated with subthreshold, but not severe, depressive symptoms in univariable analysis (OR 1.76, CI 1.10-2.80). In multivariable analysis, the association between awareness of CKD and subthreshold depressive symptoms remained significant (p=0.05). There was a significant interaction between awareness and stage 1 CKD on subthreshold depressive symptoms (OR 8.25, CI 2.24-30.63), and between awareness and female gender on subthreshold depressive symptoms (OR 2.19, CI 1.09-4.38).

Conclusions: Awareness of kidney disease is significantly associated with subthreshold depressive symptoms. This association is possibly mediated by distress caused by CKD diagnosis. Increased psychosocial support, especially in early stages of CKD, may be warranted.

SA-PO743

Vitamin D Deficiency Is Significantly Associated with Depression in Chronic Kidney Disease Patients Jong Hyun Jhee, Sul A. Lee, Hyung Jung Oh, Jung Tak Park, Seung Hyeok Han, Shin-Wook Kang, Tae-Hyun Yoo. *Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea.*

Background: Recent studies have reported significant associations between vitamin D deficiency and depression in the general population. Although both vitamin D deficiency and depression are common features in chronic kidney disease (CKD) patients, the association between these two prevalent factors in this patient population remains poorly elucidated. Therefore, the association between vitamin D deficiency and depression in CKD patients was investigated.

Methods: The data from the Korean National Health and Nutritional Examination Survey between 2010 and 2012 were used. A total of 495 patients with estimated glomerular filtration rate ≤60 mL/min/1.73m^2 were enrolled. Vitamin D deficiency was defined as 25-hydroxyvitamin D3 [25(OH)D3] levels £10 ng/mL. Patients were dichotomized by the presence of vitamin D deficiency. Depression was determined by the EuroQOL-5D (EQ5D) questionnaire. Independent association between vitamin D deficiency and depression was evaluated by multivariate logistic regression analysis.

Results: The mean age was 71.2±9.3 years, and 257 patients (51.9%) were female. The median 25(OH)D3 levels were 17.9 (13.9-22.7) ng/mL. The prevalence of depression in CKD patients was higher compared to the general population (14.3% vs. 11.1%, P=0.031). In addition, the prevalence of depression was significantly higher in patients with vitamin D deficiency than those without vitamin D deficiency (27.0% vs. 13.3%, P=0.022). Multivariate logistic regression analysis showed that vitamin D deficiency was a significantly independent predictor of depression after adjusting for age, sex, alcohol, body mass index, hypertension, diabetes mellitus, anemia, suicidal idea, EQ5D index, and serum parathyroid hormone levels (odds ratio=6.27, 95% confidence interval=1.57-25.05, P=0.009).

Conclusions: Depression was highly prevalent in CKD patients. Vitamin D deficiency was a significantly independent predictor of depression in CKD patients. Therefore, determining vitamin D levels might be helpful to predict depression in these patients.

SA-PO744

Comparison of Prevalence and Predictors of Fatigue in Advanced Chronic Kidney Disease and Cancer Patients Manisha Jhamb,[1] Sanah Parvez,[2] Khaled Abdel-Kader,[3] Mark L. Unruh,[2] Jennifer L. Steel.[1] *[1]Univ of Pittsburgh; [2]Univ of New Mexico; [3]Vanderbilt Univ.*

Background: Although >50% of patients with advanced CKD report fatigue, its presence, predictors and consequences are under-appreciated by renal providers. We compared the symptom burden among CKD/ESRD patients to those with advanced hepatobiliary cancer (CA).

Methods: In 237 patients with advanced kidney disease (35% CKD stage 4-5, 65% ESRD) and 606 with advanced CA, patient-reported symptoms and health-related quality of life (HRQOL) were assessed using validated fatigue, pain, sleep quality, depression and HRQOL questionnaires. Chi-square and ANOVA were used to test between group differences and linear regression was employed to test predictors of fatigue.

Results: In unadjusted analyses, CKD patients reported statistically (but not clinically) less fatigue, similarly poor sleep quality, and significantly lower prevalence of depression and pain as compared to CA patients. Lower levels of fatigue were strongly associated with higher HRQOL in both groups (r=0.80, p<0.001 in CKD; r=0.67, p<0.001 in CA). Depression was significantly associated with higher levels of fatigue for both groups (p<0.001 for both). Poor sleep quality was associated with higher fatigue in both groups (r= -0.40, p<0.001 in CKD; r= -0.27, p<0.001 in CA). Similarly, in both groups, more pain was associated with higher fatigue (r=0.41, p<0.001 for MOS SF-36 pain score in CKD; r= -0.48, p<0.001 for BPI in CA). Using linear regression, and including those factors significantly associated with fatigue, 29% of the variance in CKD and 31% in CA cohort was explained by depression, sleep and pain.

	CKD/ESRD (n=237)	Cancer (n=606)	p-value
Age (yrs)	54.7 ± 14.9	61.6 ± 10.9	<0.001
Males	152 (64.2%)	391 (64.6%)	0.91
FACIT-F score	34.5 ± 11.2	32.7 ± 12.1	0.05
Clinical levels of depression*	61 (25.7%)	242 (41.7%)	<0.001
PSQI Sleep Quality score	7.7 ± 4.3	7.3 ± 4.1	0.32
Clinical Levels of Pain**	47 (18.7%)	157 (31%)	<0.001

# questionnaires used - Functional Assessment of Chronic Illness Therapy –Fatigue (FACIT-F), Brief Pain Inventory or the Medical Outcomes Short-Form 36 pain subscale, Pittsburgh Sleep Quality Index, Center for Epidemiological Studies-Depression scale or the Patient Health Questionnaire-9 or Beck Depression Inventory, MOS SF-36 or FACT-Hepatobiliary.
$ presented as Mean± SD for continuous and n(%) for categorical variables
*based on clinical cut offs for BDI, PHQ, and CES-D
**one SD below or above the mean for SF 36 Pain or BPI respectively

Conclusions: Patients with advanced CKD experienced similar levels of fatigue and poor sleep quality as those with advanced CA. Sleep, depression, and pain were significant predictors of fatigue in these chronically ill patients.

SA-PO745

Urinary Incontinence Is Common Among Adults with Chronic Kidney Disease (CKD) and May Impact Patient Compliance with Diuretics Mitul Natu Patel, David J. Leehey, Kavitha Vellanki, Vinod K. Bansal, Julia Koval, Linda Brubaker, Neelam Balasubramanian, Jasmin Sandhu, Anuradha Wadhwa, Holly J. Kramer. *Nephrology, Loyola Univ Medical Center, Maywood, IL.*

Background: Urgency urinary incontinence (UUI) is a stigmatized condition that may be common among adults with CKD due to the older age and high prevalence of comorbidities (obesity and diabetes) that increase risk for UUI in this population. Diuretics, which are commonly used for hypertension management, may exacerbate UUI symptoms. However, the impact of UUI on diuretic compliance has not been previously assessed in adults with CKD.

Methods: This pilot study recruited 89 adults with non-dialysis dependent stage 3-5 CKD who are prescribed diuretics for hypertension management. All participants provided written informed consent. Study participants completed the Morisky Medication Adherence Scale (MMAS), a validated questionnaire for hypertension medication compliance with scores ranging from 0 (poor adherence) to 11 (excellent adherence). Participants were asked "Do you ever avoid taking the diuretic (water pill) because it increases the urge to urinate or because it makes you urinate before reaching the toilet?" Information on UUI prevalence and nocturia was collected using standardized, validated questions for urinary symptoms.

Results: The mean age of the participants was 71 years, 54% were male and 71% were white. Overall, UUI was present in 44%, and 93% reported nocturia (waking at night to urinate) and 33% reported severe nocturia (waking 3 or more times to urinate). Overall 17% reported ever not taking their diuretic due to urinary urgency and this was significantly more frequent among those with UUI vs. those without UUI (32% vs. 6%; P = 0.002). Compared to patients who do not avoid diuretics, patients who reported ever avoiding diuretics showed significantly lower median values of medication adherence scores (7.0 vs. 10.0; P< 0.001) and were less likely to to have a blood pressure < 140/90 mmHg at the clinic visit (53% vs. 72%; P < 0.05).

Conclusions: UUI is common among older adults with CKD and may negatively impact compliance with diuretics and blood pressure management.

Validation of a Patient-Perceived Symptom Score for Chronic Kidney Disease Stephanie A. Brown,[1] Freya Tyrer,[2] Amy L. Clarke,[1] Laetitia H. Lloyd-Davies,[1] Andrew G. Stein,[3] Carolyn Tarrant,[2] Alice C. Smith.[1] *[1]Leicester Kidney Exercise Team, Univ of Leicester, Leicester, United Kingdom; [2]Dept of Health Sciences, Univ of Leicester, United Kingdom; [3]Univ Hospitals of Coventry and Warwickshire, United Kingdom.*

Background: Chronic Kidney Disease (CKD) is associated with a range of symptoms, even at relatively early stages. There is increasing recognition of the importance of the patient symptom experience for clinical management and quality of life, but validated symptom scores are lacking. We have refined and validated an existing draft CKD symptom questionnaire listing 11 common renal symptoms plus lines for additional symptoms not included in the list.

Methods: Validation was undertaken in 4 phases. In Phase 1, 219 patients with CKD1-5 not requiring renal replacement completed the draft questionnaire to identify the most common symptoms in this population. Phase 2 explored cognitive validity via semi-structured interviews with 11 patients, after which the draft questionnaire was refined. Phase 3 was a focus group with 5 patients, to review and further refine the updated questionnaire. Phase 4 was content validity testing: the questionnaire was sent to 16 external expert clinicians for assessment of relevance, clarity and comprehensiveness.

Results: Phase 1 identified 13 common symptoms, and Phases 2 and 3 confirmed symptom selection and refined the wording used to describe them. The symptom descriptions finalised were: itching, sleep disturbance/insomnia, loss of appetite, feeling tired, pain in bones/joints, poor concentration/mental alertness, loss of libdo/erectile dysfunction, loss of muscle strength/power, shortness of breath, cramp/muscle stiffness, restless legs/difficulty keeping legs still, need to urinate more often, feeling cold. In Phase 4, 14 of 16 experts responded (87.5%). 10 of the 13 symptoms had "excellent" or "good" evaluation scores, and the content validity index of the whole questionnaire was 0.81, falling within the recommended threshold.

Conclusions: This work has provided a new, validated symptom score for the early/pre-dialysis CKD population, which can be used as a patient reported outcome measure in both clinical management and research.

SA-PO747

Impact of Psychosocial Factors in Advanced Chronic Kidney Disease on Wait-Listing for Transplantation Sanjeev Akkina, James P. Lash, Jason Roy, Boyang Chai, Michael J. Fischer, L. Lee Hamm, Peter D. Hart, Chi-yuan Hsu, Yonghong Huan, Anne M. Huml, Radhakrishna Reddy Kallem, Manjula Kurella Tamura, Anna C. Porter, Ana C. Ricardo, Sylvia E. Rosas, Raymond R. Townsend, Peter P. Reese, Meera Nair Harhay. *CRIC Study Group Investigators.*

Background: Transplantation (Tx) is generally regarded as the best option for renal replacement therapy. However, few patients with CKD are listed for Tx when eligible. We examined the association between psychosocial factors in patients with advanced CKD and wait-listing for kidney Tx.

Methods: The study population includes 803 individuals with an eGFR of less than or equal to 20mL/min/1.73m2 (advanced CKD) in the Chronic Renal Insufficiency Cohort study. The primary predictors were health related quality of life (HRQOL) and depressive symptoms assessed within 24 months prior to reaching the eGFR inclusion criteria using the Kidney Disease QOL (KDQOL)-36 survey and the Beck Depression Inventory (BDI), respectively. The primary composite outcome was wait-listing or transplantation (WLT). Cox proportional hazards models were used to examine the association between low HRQOL (³1 SD below the cohort mean) and BDI (³11) with WLT.

Results: Of the 803 subjects, 380 (47%) were wait-listed including 120 that proceeded to Tx. Compared to individuals who were not WLT, those in the WLT group were more likely to be younger, male, have no history of cardiovascular disease, and have proteinuria > 300mg/day (p <0.01). After adjustment for demographic and clinical variables, a low Mental Component Summary (MCS) score was associated with a lower likelihood of WLT (Table). There was no association between the BDI or other QOL measures with WLT.

Predictor	Adjusted Model (HR, 95% CI)
BDI ≥ 11	0.88 (0.69-1.12)
KDQOL (≥1 SD below the cohort mean)	
-Mental Component Summary	**0.73 (0.56-0.95)**
-Physical Component Summary	0.92 (0.69-1.24)
-Symptoms/Problems	0.97 (0.71-1.32)
-Burden of Kidney Disease	0.82 (0.61-1.09)
-Effect of Kidney Disease on Daily Life	0.94 (0.69-1.28)

Conclusions: Lower MCS scores were associated with lower likelihood of WLT. Further work is needed to evaluate the impact of poor mental QOL in advanced CKD and how it might influence wait-listing.

Perspectives on Pregnancy in Women with Chronic Kidney Disease Allison Tong,[1] Mark A. Brown,[2] Wolfgang C. Winkelmayer,[3] Jonathan C. Craig,[1] Shilpa Jesudason.[4] *[1]The Univ of Sydney; [2]St. George Hospital; [3]Baylor College of Medicine; [4]Royal Adelaide Hospital.*

Background: Women with chronic kidney disease (CKD) often have difficulty achieving pregnancy, and are at increased risk of adverse pregnancy outcomes. Given the medical, ethical and emotional complexities of pregnancy in CKD, the clinical approach should involve explicit consideration of women's values; of which there are sparse data. We aimed to describe the beliefs, values, and experiences of pregnancy in women with CKD, to inform pre-pregnancy counseling and pregnancy care.

Methods: Semi-structured interviews were conducted with 41 women aged 22-56 years with advanced chronic kidney disease, from two renal units in Australia. Transcripts were analyzed thematically.

Results: Six themes were identified: bodily failure (conscious of fragility, noxious self, critical timing, suspended in limbo); devastating loss (denied motherhood, disempowered by medical catastrophizing, resolving grief, barriers to parenthood alternatives, social jealousy); intransigent guilt (disappointing partners, fear of genetic transmission, respecting donor sacrifice, medical judgment); rationalizing consequential risks (choosing survival, avoiding fetal harm, responding to family protectiveness, compromising health, decisional ownership, unjustifiable gamble); strengthening resolve (hope and opportunity, medical assurance, resolute determination, reticent hope); and reorientating focus (valuing life, gratitude in hindsight).

Conclusions: Decisions surrounding pregnancy in the context of chronic kidney disease require women to confront uncertainties about their own survival, disease progression, guilt towards their family and kidney donor, the outcomes of their offspring, and genetic transmission. Communicating the medical risks of pregnancy to women with chronic kidney disease must be carefully balanced with their values of autonomy, hope, security and family. Informed and shared decision making that is sensitive to women's priorities as identified in this study can contribute to improved pregnancy, health and psychosocial outcomes in this vulnerable population.

SA-PO749

Nrf2 Activator, Resveratrol, Ameliorates Aging-Related Progressive Renal Injury Eun Nim Kim, In-Ae Jang, Ji Hee Lim, Min Young Kim, Byung Ha Chung, Cheol Whee Park, Chul Woo Yang, Yong-Soo Kim, Yoonsik Chang, Bum Soon Choi. *Div of Nephrology, Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Seoul, Republic of Korea.*

Background: The senescence markers of kidney have been shown to cause many changes in the energy metabolism. Two important issues in aging kidney are mitochondria dysfunction and oxidative stress. Nrf2 activator, Resveratrol may prevent inflammation and oxidative stress by activating SIRT1 and Nrf2. We examined that Resveratrol can potentially ameliorates the cellular condition, such as renal injury due to cell oxidative stress and mitochondria dysfunction caused by aging.

Methods: Male 19-month-old C57/BL6 mice were used in this study. Resveratrol (0.04%) was provided to old mice for 6month. We compared histological change, oxidative stress, and aging-related protein expression in the kidneys between Resveratrol treated old-mice group (RSV) and vehicle old-mice group (VH).

Results: In our study, expression of Nrf2 in nuclear (1 ± 0.1 fold vs. 2 ± 0.4 fold; p < 0.01 vs. VH) was increased in RSV. Expression of SIRT1 (1 ± 0.2 fold vs. 1.31 ± 0.11 fold; p < 0.05 vs. VH) was increased in RSV. p-AMPK/Total AMPK ratio expression (1 ± 0.1 fold vs. 1.79 ± 0.2 fold; p < 0.01 vs. VH) was increased in RSV compared with VH. RSV group displayed decreased albuminuria and Creatinine clearance increased with RSV. There were decreases in mesangial volume, tubulointerstitial fibrosis and collagen IV in RSV. Immunohistochemistry of F4/80 expression in glomerulus and tubule were decreased in RSV compared with VH. Also, TGF-β was decreased in RSV. Urine isoprostane and 8-OHdG excretion decreased with aging. Antioxidant enzyme, HO-1 (1 ± 0.08 fold vs. 1.6 ± 0.1 fold; p < 0.001 vs. VH) and NQO-1 (1 ± 0.06 fold vs. 1.3 ± 0.1 fold; p < 0.01 vs. VH) were increased in RSV compared with VH.

Conclusions: These results suggest that activation of Nrf2 may benefit aging-related renal injury related with SIRT1 and AMPK activation by reducing oxidative stress. Pharmacologically targeting Nrf2 signaling molecules may reduce the pathologic changes of aging in the kidney.

SA-PO750

Dual Agonist of Nuclear Hormone Receptor Farnesoid X Receptor and G Protein Coupled Receptor TGR5 Exhibits Calorie Restriction Mimetic Effects in Aging Mice Xiaoxin Wang,[1] Evgenia Dobrinskikh,[1] Yuhuan Luo,[1] Luciano Adorini,[2] Moshe Levi.[1] *[1]Univ of Colorado Denver; [2]Intercept Pharmceutical Company.*

Background: Previous studies have shown that calorie restriction (CR) in mice and in rats prevent age-related proteinuria and glomerulosclerosis. We have observed an age-related decrease in renal nuclear hormone receptor farnesoid X receptor (FXR; NR1H4), and G protein-coupled receptor TGR5 (GPBAR1 or GPR131) expression. In contrast, renal FXR and TGR5 expression are increased by CR in the aging mice. FXR and TGR5 expression are also increased in the long-lived Ames dwarf mouse. The purpose of the present study was to determine if activation of FXR and TGR5 in the kidneys of ad lib fed aging mice have similar effects to CR.

Methods: We studied 5 month old ad lib fed, 24 month old ad lib fed, 22 months old ad lib fed mice treated with the dual FXR/TGR5 agonist INT-767 for 2 months, and compared them to lifelong 24 month old CR mice.

Results: Treatment of 22 month old ad lib fed aging mice with FXR/TGR5 dual agonist INT-767 for 2 months decreases albuminuria, TGF-β expression, and fibronectin accumulation in aging mice. INT-767 stimulates mitochondrial biogenesis, increases mitochondrial DNA content, and mitochondrial transcription factors Nrf-1 and Tfam in the aging kidney. INT-767 also increases the expression of SIRT1, PGC-1α, and ERRα mRNA, as well as PGC-1α and SIRT3 protein abundance. INT-767 activation of the mitochondrial NAD-dependent deacetylase SIRT3 restores its targets MCAD and acetyl-IDH2 to normal levels, which are important for regulation of mitochondrial fatty acid β-oxidation as well as mitochondrial redox status. Furthermore, INT-767 increased expression of NAMPT and Nrk1, enzymes involved in synthesis of sirtuins substrate NAD.

Conclusions: Our results therefore indicate that activation of FXR and TGR5 in the aging kidney reverses most of the age-related changes and the effects of FXR and TGR5 are similar to beneficial effects achieved by lifelong CR.

SA-PO751

ESRD in Nonagenarians in the United States, 1995 Through 2010
Donal J. Sexton, Scott Reule, Robert N. Foley. *Medicine, Univ of Minnesota, Minneapolis, MN.*

Background: Patients in their 90's are increasingly being considered for maintenance dialysis, comprehensive epidemiological data could help with decision making.

Methods: We used US census data and data for patients who initiated maintenance dialysis between 1995 and 2010 (N=1,557,117) to examine trends in ESRD for those aged 90 to 99 years (N=14,289).

Results: The rate of ESRD in 1995-1996 was 0.6 per million per year in those aged 90-99 years respectively. Standardized incidence ratios (SIRs) rose between 1995 and 2010 both overall (SIR 2.8), and individually in males (2.89), females (2.7) white (3.1) African American (1.93) and other races (2.43). Median survival was 10.7 months. "Unspecified renal failure" was the most common reported cause of ESRD (62.6%), followed by "diabetes mellitus type 2" (15.89%), "ATN without recovery" 3.47%, "GN (not histologically examined)" 3.18%, "renal artery stenosis" 2.44% and other 12.44%. Causes of death included; Cardiac deaths 42.4%, Infection 12.07%, Withdrawal of dialysis/ Uremia 10.16%, Stroke/Intracranial Hemorrhage 3%, Cachexia 2.99%, Cancer 2.45%, Other 12.03% and Unknown 14.89 %. Mortality fell over time, AHR (95% CI) 0.79 (0.72, 0.87) in 2009-2010 vs 1995-1996. Factors associated with a higher likelihood of death included; ischemic heart disease (AHR 1.13), AV graft (AHR 1.36 vs AV fistula), or venous catheter for hemodialysis vascular access (AHR 1.7 vs AV fistula), shorter pre-dialysis nephrology care (AHR 1.37), higher eGFR at dialysis initiation (AHR 1.13), serum albumin < 3.5 g/dl (AHR 1.34), cerebrovascular disease (AHR 1.21), peripheral vascular disease (AHR 1.14), cancer (AHR 1.08), inability to ambulate (1.43) or transfer (1.59), "ATN without recovery" as primary cause of ESRD (AHR 1.11 vs "renal failure not specified").

Conclusions: ESRD in nonagenarians has risen over the period of observation in the United States. Rising prevalence may be attributable not only to rising incidence but to falling mortality also.

SA-PO752

Impact of Geriatric Multi-Morbidity Versus Medical Multi-Morbidity on Quality of Life in Older CKD Patients
Christine Liu,[1,2] Jamie Giffuni,[3] Kieran Reid,[2] Leslie I. Katzel,[3] Stephen L. Seliger,[3] Daniel E. Weiner,[2] Roger A. Fielding.[2] *[1]Boston Univ, Boston, MA; [2]Tufts Univ, Boston, MA; [3]Univ of Maryland, Baltimore, MD.*

Background: Geriatric conditions are constellations of signs and symptoms not always linked to a disease, such as cognitive impairment and fatigue; geriatric conditions are associated with worse quality of life (QoL). Older adults with CKD are likely to have geriatric multi-morbidity (GM), defined as ³2 geriatric conditions. Medical multi-morbidity (MM) is also common in this population and affects QoL. We compared the impact of GM to MM on QoL in older CKD patients.

Methods: We used baseline data from an ongoing trial of excercise in persons ≥55 years with stage 3b-4 CKD. For GM, persons were defined with 1) cognitive impairment if Montreal Cognitive Assessment <26; 2) poor physical function if Short Physical Performance Battery ≤7; 3) dizziness as reported by Memorial Symptom Assessment Scale; 4) fatigue if responded ≥"good bit of time" to feeling worn out on Short Form-36 (SF-36); and 5) chronic pain if ≥"moderate" pain on SF-36. For MM, hypertension, diabetes, CAD, and COPD were self-reported, and depression was defined as Beck Depression Inventory ³15. QoL was measured with the SF-36. Linear regression adjusting for age, sex, race, site, BMI, and eGFR was utilized.

Results: Of 72 persons (31% women, mean age 68.6±7.8 years, mean eGFR 33.3±9.8 ml/min/1.73m²), 49% (35) had GM and 76% (55) had MM. GM was associated with lower scores in all SF-36 subdomains (all p< 0.05). MM was associated with lower scores in two SF-36 subdomains (both p<0.05).

Conclusions: In older adults with CKD, geriatric multi-morbidity is common and likely affects QoL.

Standardized βs of the associations of geriatric multi-morbidity and medical multi-morbidity with SF-36

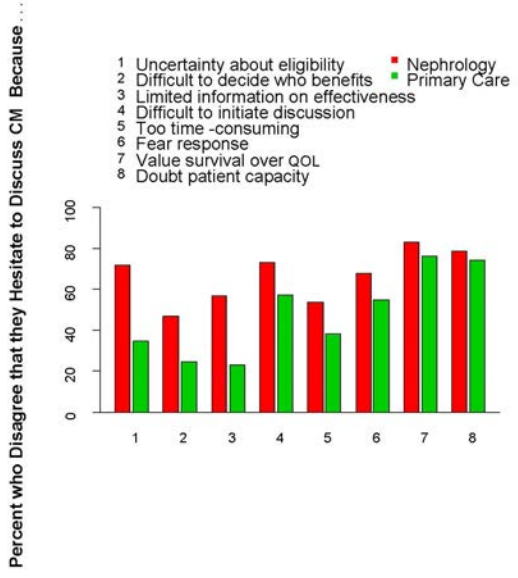
A Survey of Provider Knowledge, Attitude, and Practices Surrounding Conservative Management for Patients with Advanced Chronic Kidney Disease
Sanah Parvez,[1] Khaled Abdel-Kader,[2] V. Shane Pankratz,[1] Mi-Kyung Song,[3] Mark L. Unruh.[1] *[1]Div of Nephrology, Univ of New Mexico; [2]Div of Nephrology, Vanderbilt Univ; [3]Adult and Geriatric Health Div, School of Nursing, Univ of North Carolina.*

Background: Despite the potential benefits of conservative management (CM), discussing CM as a viable treatment option rarely occurs. Several factors might contribute to this but no studies in the U.S. have described them. The purpose of this survey was to describe nephrologists' (NEPHs) and primary care providers' (PCPs) knowledge, attitudes, and practices of CM for patients with advanced CKD.

Methods: We developed a survey based on the relevant literature to include items assessing knowledge, attitudes, and self-reported practices of CM for patients with advanced CKD. We then conducted a web-based cross sectional survey between April and May 2015. We used the American Medical Association's Physician Masterfile to identify NEPH and PCPs practicing in the U.S.

Results: 431 (67.6% NEPHs, 32.4% PCPs) providers completed the survey. The respondents were, on average, white, predominantly male, and in their 30s and 40s. A majority of both PCP (83.5%) and NEPH respondents (78.2%) reported that they were likely to discuss CM with their older advanced CKD patients. Self-reported number of patients managed conservatively was at least >11 patients for 30.6% NEPHs and 49.2% of PCPs. As shown in the figure where a higher percent demonstrates a lower barrier, the major barriers to CM discussions identified by NEPHs and PCPs significantly differed.



There were significant differences in knowledge across the groups with PCPs reporting significantly more uncertainty about survival rates with CM.

Conclusions: Both NEPH and PCP are comfortable with discussing CM with their patients. PCPs have less certainty regarding patient selection for CM and report feeling less informed about outcomes of CM.

Which Therapeutic Project for Elderly Reaching ESRD? Patient's Characteristics and Outcomes
Coraline Fafin,[1] Cécile Couchoud,[2] Cecile M. Vigneau,[3] Olivier Moranne.[1] *[1]Nephrology, CHU Nice, Nice, France; [2]REIN Registry, Agence de Biomédecine, St. Denis La Plaine, France; [3]Nephrology, CHU Pontchaillon, Rennes, France.*

Background: The KDIGO guidelines recommend referral for planning RRT in people at risk of kidney failure. Treatment without dialysis in ESRD patient is another therapeutic option especially in elderly. The objective of our study is to describe the therapeutic projects declared by nephrologist and associated patient's characteristics and outcomes in a prospective design.

Methods: 573 patients over 75 y/o (82±5 y/o) with eGFR below 20 (14 ± 4) were included by nephrologists in 2009 and followed 4 yrs (Moranne et al 2012). At baseline, we recorded social, clinical characteristics and therapeutic project declared by nephrologist. The first project was considered at the second visit as Postponed decision about dialysis (STAB), decision to start Dialysis when required (DIAL), Non-dialysis made by nephrologist (NDne) or at patient's request (NDpt). During follow-up, we evaluated the dialysis start and death before dialysis and compared patient's characteristics and incidence of these events according to the therapeutic projects.

Results: The therapeutic project was STAB in 234 patients (41%), DIAL in 216 pts (38%), NDne in 66 (12%) and NDpt in 55 (10%). Patients were older in ND group, with more women for NDpt and more comorbidities for NDne (dementia, active malignancy,

CVD, less physical autonomy). After 4 yrs follow-up, the number of death before dialysis and dialysis start were 10%/85% for DIAL, 42%/34% for STAB, 67%/20% for NDpt and 95%/2% for NDne respectively. There was significantly more emergency start for the NDpt group starting nevertheless dialysis. In all groups, the main reasons declared by nephrologist to start dialysis were: eGFR level, fluid overload and weight lost.

Conclusions: In this population, we observed many patients with stable conditions and high risk mortality which anyway raises the issue of dialysis options and care organization. Although some patients expressed their willingness not to start dialysis at one point or another, it could nonetheless occur but with worst condition. On the contrary, if the dialysis option isn't retain by the nephrologists, it will not occur.

SA-PO755

Specific Prognosis Factors of Death and Dialysis Start for Elderly Patients Reaching ESRD in the Prospective PSPA Cohort Study

Coraline Fafin,[1] Cécile Couchoud,[2] Cecile M. Vigneau,[3] Olivier Moranne.[1] *[1]Nephrology, CHU Nice, Nice, France; [2]Agence deBiomedecine, REIN, St Denis de la Plaine, France; [3]Nephrology, CHU Pontchaillon, Rennes, France.*

Background: The death before dialysis start is high in elderly patients reaching ESRD and the treatment without dialysis is another option. We need to better predict the outcomes of this specific population and identify prognosis factors to improve strategies of care. The objective of our study is the identification of prognosis factors of dialysis start or death before dialysis in a multicenter prospective cohort of elderly reaching ESRD.

Methods: 573 patients over 75 y/o (82±5 y/o) and with eGFR below 20 (eGFR14 ± 4 mL/min/1.73m²) were included by nephrologist in 2009-10 (Moranne et al 2012). At baseline, we recorded social and clinical characteristics, laboratory test and medications. Information about death or dialysis status is available for all patients after 4 years follow-up. Prognosis factors for dialysis start or death before dialysis were quantified with subdistribution hazard ratios using proportional hazard regression models constructed according to Fine and Gray to take account competiting risks.

Results: After 4 yrs follow-up, 274 patients (48%) started dialysis and 223 (39%) died. Compared to patient still alive without dialysis, the variables independently associated with higher risk of death prior to dialysis are: higher age, male, diabetes, lower eGFR, behavioural disorder, less mobility, cerebrovascular disease, cardiac heart failure, active malignancy and anemia. The variables associated to higher probability of dialysis start are: lower age, male, lower eGFR, high blood pressure, hyperphosphatemia, higher proteinuria, chronic respiratory disease, cerebrovascular disease and less behavioural disorder or active malignancy.

Conclusions: We observed a higher probability of dialysis start than death before dialysis in this population of elderlies included by nephrologists. We identified specific prognosis factors that could discriminate the risk of starting dialysis or died before dialysis to help organisation of the CKD 5 care in elderly patients.

SA-PO756

Ageing and Decreased GFR: A 1,249,388 Elderly Population-Based Study

Regina C.R.M. Abdulkader,[1] Emmanuel A. Burdmann,[1] Yeda Aparecida Oliveira Duarte,[2] Maria Lucia Lebrao,[2] Dirce M.T. Zanetta.[2] *[1]Div of Nephrology, Univ of Sao Paulo Medical School, Sao Paulo, SP, Brazil; [2]Epidemiology, School of Public Health of the Univ of Sao Paulo, Sao Paulo, SP, Brazil.*

Background: GFR decreases with ageing and so a low GFR in old people might occur due to a physiologic process instead of being a mark of disease. However, comorbidities can superimpose on this process, and reduce GFR by a pathologic course. This study aims to assess the frequency of isolated low GFR without coincident diseases in a geriatric population in a developing country megalopolis.

Methods: A multistage cluster sampling (1,353 inhabitants) was used in order to obtain a sample representative of the elderly population of São Paulo megalopolis (1,249,388 inhabitants aged ≥60 years). Participants answered a survey on socio-demographic factors and health and had urine and blood samples collected. GFR < 60 ml/min/1.73m² (estimated by the abbreviated MDRD equation) was defined as low and presence of hematuria or proteinuria as kidney damage. Data are presented as weighted proportion or means and standard errors. Comparisons were made by chi-square with Rao-Scott correction or t-test.

Results: Individuals with GFR < 60 (19.8%) were older (75 ± 1 vs. 69 ± 1 y, p<0.001), had lower education level, more hypertension, diabetes and cardio-vascular disease and more kidney damage (35% vs 15%, p<0.001), when compared with the group with GFR ≥ 60. In the low GFR group only 25% of the individuals had no simultaneous diseases and no kidney damage.

Conclusions: Low GFR was associated with kidney damage and/or coincident chronic diseases that might affect the kidneys in this population. These data strongly suggest that in this group of geriatric individuals low GFR is indicative of renal disease. Funding: Government Support - Non-U.S (FAPESP, Ministério da Saúde, Brasil).

Indoxyl Sulfate, a Representative Uremic Toxin, Suppresses Myogenic Differentiation: Implication in Uremic Sarcopenia

Chih-Kang Chiang,[1,2] Un Iong Ao,[1] Yuan-Siao Chen,[1,2] Shing-Hwa Liu.[1] *[1]Inst of Toxicology, College of Medicine, National Taiwan Univ, Taipei, Taiwan; [2]Depts of Integrated Diagnostics and Therapeutics and Internal Medicine, College of Medicine, National Taiwan Univ, Taipei, Taiwan.*

Background: Sarcopenia (or muscle wasting) is a common feature of the uremic phenotype and predisposes this vulnerable patient population to increased risk of comorbid complications, poor quality of life, frailty and premature death. Accumulation of uremic toxin would be the most significant difference between health and uremic subjects. We hypothesized that indoxyl sulfate (IS), a representative protein-bound uremic toxin, might disturb skeletal myotube differentiation and contribute to sarcopenia in uremic patients.

Methods: The mouse myoblast cell line C2C12 was applied to evaluate myotube differentiation and signaling. Cell viability evaluated by MTT assay. Cell morphology was observed by microscope. Hematoxylin and eosin staining morphologically analyzed the multinucleated myotube formation. The expressions of myogenic differentiation markers and related signaling proteins were determined by Western blotting.

Results: We first investigated the non-lethal concentration of IS by MTT assay, and found IS level less than 1mM without significant cellular toxicity as compared with control group. In order to development the protocol, we confirmed myotubes were visibly formed throughout 4 days of differentiation first. IS significantly attenuated the number of myotubes and the percentage of mature myotubes. Furthermore, IS significantly and dose-dependently decreased the expression of MyoD, Myogenin and myosin heavy chain, which is the representative markers of slow and fast myofiber phenotype, both in translational and transcriptional level. The molecular signals of myotube differentiation were also disturbed by IS treatment.

Conclusions: These findings suggest that IS, a uremic toxin, dysregulates myotube differentiation in C2C12 cells. This is the first time to provide additional evidence that IS might contribute to the development of sarcopenia in uremic patients. Further explore wound give the light to provide potential therapeutics in uremic sarcopenia.

Attitudes, Experiences and Perspectives of Elderly Kidney Transplant Recipients: Thematic Synthesis of Qualitative Research

Jule Pinter,[1] Camilla Sara Hanson,[1] Jonathan C. Craig,[1] Jeremy R. Chapman,[1] Klemens Budde,[2] Fabian Halleck,[2] Allison Tong.[1] *[1]Univ of Sydney; [2]Charité - Universitätsmedizin Berlin.*

Background: Kidney transplantation offers improved survival and quality of life in an increasing number of elderly patients with end-stage kidney disease. However, elderly kidney transplant recipients may face unique challenges due to a higher burden of comorbidity, greater cumulative risk of immunosuppression-related complications, and increasing frailty. We aimed to describe the perspectives of elderly kidney transplant recipients.

Methods: Electronic databases were searched to April 2015. Thematic synthesis was used to analyze the findings.

Results: 41 studies involving more than 120 kidney transplant recipients aged 60 yrs and over were included (29 studies did not specify number of patients aged ≥ 60 yrs). We identified 6 themes. *Regaining strength and vitality* meant valuing the marked physical and psychosocial improvements in daily functioning and life participation. *Extending life* was the willingness to accept an organ, including an extended criteria kidney, to prolong survival. *Debt of gratitude* entailed a need to be consciously appreciative towards their donor whilst knowing they were unable to repay their sacrifice. *Moral responsibility of maintaining health* motivated adherence to medication and lifestyle recommendations out of an ethical duty to protect their gift and prolong graft survival. *Disillusionment with transplant* reflected disappointment and exasperation at having to contend with *side effects and* adverse events such as cancer, and residual physical limitations. *Finality of treatment option* reflected an acute awareness that their current transplant may be their last and some would not return to dialysis if the transplant failed.

Conclusions: Kidney transplantation reverses deterioration of functioning and well-being that patients experienced whilst on dialysis. However, elderly transplant recipients may have anxieties about debilitating adverse events, comorbidities, and a sense of vulnerability that the current transplant may be their last. Addressing these concerns in the care of elderly kidney transplant recipients may improve treatment outcomes in this growing population.

SA-PO759

New Perspectives on the Evolution of Quality of Life and Depression Among Hemodialysis Patients

Christiane Hegedus Karam, Nadia Guimaraes-Souza, Adriano Luiz Ammirati, Maria C.C. Andreoli, Thais Nemoto Matsui, Fabiana Dias Carneiro, Rosana Cardoso, Ana Merzel Kernkraut, Bento C. Santos. *Nephrology, Hospital Albert Einstein, São Paulo, Brazil.*

Background: Hemodialysis is the most common treatment for patients with chronic kidney disease. Five to 22% of those also have a psychiatric condition. The objective of this study was to evaluate the quality of live perception and depression symptoms in three groups of age (<65, 65-75, e >65 y.o.).

Methods: This was a retrospective observational study. Clinical and social demographic data were collected from clinical records. The Kidney Disease Quality of Life and Beck depression inventory were used to assess quality of life and depression symptoms.

Results: 104 patients were included. 68.3% were man, 71.2% married, 91.3% Caucasian and 44.2% were in productive life period. A relation between quality of life-score and time in dialysis was observed (p=0.0118, CI -0.0023; 0.0003). Patients younger than 65 y.o. showed more favorable results, such as general health perceptions, emotional well-being, energy/fatigue, pain and dialysis staff encouragement. Patients between 65 to 75 y.o. showed lower energy/fatigue index (11.98; CI -22.93; -1.02) and a reduction of 18.97-points (IC -33.97; -3.98) for emotional well-being. A 15.04-point (CI -27.21; -2.87) and a 14.78-point (-26.46; -3.10) reduction, for patients between 65-75 y.o. and for older than 75 years, respectively, was observed in physical function. Burden of kidney disease had a reduction of 13.29 (-25.40; -1.18) and sexual function reduced 69% (27%; 87%) in 65-75 y.o. patients. Patients older than 75 years had a significant increase in quality of social interaction (17%; CI: 1%;36%) and an increase of 16% (CI 3% -30%) in social support. Depression correlated with time in hemodialysis (p = 0.0007; CI 0.14%; 0.55%). For each month an increase of 0.35% on depression symptoms was found.

Conclusions: For patients younger than 65 years hemodialysis treatment represents a rehabilitation possibility. Patients over 75 years had significant increase on social support and social interaction. Patients 65 to 75 y.o. had worse perception of quality of life.

Fibroblast Growth Factor 23 and the Risk of Infection-Related Hospitalization in Older Adults: The Cardiovascular Health Study

Kristen L. Nowak,[1] Traci M. Bartz,[2] Lorien S. Dalrymple,[3] Joachim H. Ix,[4] Ian H. De Boer,[2] Bryan R. Kestenbaum,[2] Michael Shlipak,[5] Pranav S. Garimella,[6] Michel Chonchol.[1] *[1]Univ of Colorado Denver; [2]Univ of Washington; [3]Univ of California Davis; [4]Univ of California San Diego; [5]Univ of California San Francisco; [6]Tufts Medical Center.*

Background: Fibroblast growth factor 23 (FGF23) may inhibit 25-hydroxyvitamin-D-1α-hydroxylase (CYP27B1) in monocytes. We hypothesized that higher circulating FGF23 would lead to an increase in serious infection risk because FGF23 decreases the intracrine production of 1,25-dihydroxyvitamin D ($1,25(OH)_2D$), which consequently reduces production of cathelicidins.

Methods: Plasma C-terminal FGF23 concentrations were measured in 3141 Cardiovascular Health Study participants. Cox proportional-hazards models were used to examine the association between FGF23 levels and the first infection-related hospitalization (multivariable models adjusted for demographics, co-existing illnesses, body mass index, tobacco use, albumin, estimated glomerular filtration rate, urine albumin creatinine ratio, C-reactive protein, and IL-6). We tested whether associations differed by the presence of chronic kidney disease (CKD) (eGFR; >60 [n=2309] or ≤60 ml/min/1.73m^2 [n=832]).

Results: Participants were 78±5 years, 60% females, and the median serum FGF23 level was 70 [IQR 53, 99] pg/mL. During a median follow-up of 15.7 years, 1162 (37%) had an infection-related hospitalization. In the adjusted models, participants in the highest quartile of FG23 (compared to the lowest) had a higher risk of infection (hazard ratio [HR] 1.33; 95% confidence interval [95% CI], 1.10-1.60). The association was stronger for those participants with CKD (HR 1.27; 95% CI 1.11-1.46 per doubling of FGF23) than in those without CKD (HR 1.07; 95% CI 0.98-1.17 per doubling of FGF23; p-value for interaction: 0.06). The addition of serum calcium, phosphorus, vitamin D and PTH into the statistical models did not attenuate these associations.

Conclusions: In ambulatory elders, higher serum FGF23 levels were independently associated with the risk of first infection-related hospitalization. This association appeared stronger in the setting of CKD.

SA-PO761

Characteristic of the Elderly Patients in the Chronic Renal Insufficiency Standards Implementation Study (CRISIS) Cohort Compared to Their Younger Cohort A Descriptive Analysis

Maharajan Raman, Darren Green, James Ritchie, Thilini Nishani Abeygunaratne, Smeeta Sinha, Philip A. Kalra. *Renal Medicine, Salford Royal NHS Foundation Trust, Salford, Manchester, United Kingdom.*

Background: CKD in the Elderly is associated with high mortality and slower rate of progression to ESRD. Identifying the characteristics of this phenotype and modifying their risk may reduce the burden of death but this can be challenging due to the heterogeneity of the disease in this group.

Methods: The CRISIS cohort of 2706 participants was divided into four groups based on their age. Descriptive statistical analysis was performed using SPSS and in between group significance was calculated using one way ANOVA or Chi-Square test.

Results: Essential characteristics of the cohort are shown in the table below.

	<55years	55-<65years	65-<75years	>75years	P value
Number	644	507	823	732	
Age*(years) Male(%) Current Smoker(%)	43.2± 8.9 56.4 19.7	60.5± 2.8 63.9 15	70± 2.8 64 12.2	80.2± 3.7 64.5 5.2	0.000 - -

Death(%)	11.1	21.8	42.2	52.5	0.000
Co-Morbidity(%) >1 Vascular co-morbidity >1 Non-Vascular co-morbidity Diabetes	 3.3 2.8 19.2	 12.2 7 37.2	 19.8 5.5 39	 22.6 7.7 33.2	 0.000 0.001 0.000

*mean±SD

Conclusions: The group aged >75 years had the highest incidence of death and accumulation of co-morbidities . We aim to develop a risk prediction model to identify the characteristics of this phenotype, which may help in modifying their risk.

SA-PO762

Muscle Strength Rather Than Muscle Mass Is More Important in Evaluating Physical Function in Elderly Patients with Predialysis Chronic Kidney Disease

Yasuhiro Taki,[1] Koji Hiraki,[2] Keita Uehara,[1] Hiroo Kawarazaki,[1] Tsutomu Sakurada,[1] Yugo Shibagaki.[1] *[1]Dept of Nephrology and Hypertension, St. Marianna School of Medicine, Kawasaki, Kanagawa, Japan; [2]Dept of Rehabilitation Medicine, St. Marianna School of Medicine, Kawasaki, Kanagawa, Japan.*

Background: Recently, physical function has been reported to be strongly associated with prognosis of patients with chronic kidney disease (CKD). Sarcopenia is well described in CKD patients on dialysis especially of the elderly and is known to be associated with reduced physical function, but whether this is the case in elderly predialysis CKD is undetermined.

Methods: We enrolled consecutive 85 elderly patients (age over 60) with predialysis CKD (estimated GFR:eGFR < 60 ml/min/1.73m2)in outpatient nephrology clinic at St Marianna University Hospital. We evaluated kidney functional parameters, muscle mass by bioimpedance, muscle strength by dynamometer (hand grip, knee extension) and 4-meter walking speed in these participants.

Results: Average age was 74 years old, 76% were men, 33% had diabetes mellitus (DM) and average eGFR was 28.6ml/min/1.73m2. Patients were divided into those with eGFR<30 or >30. After adjustment for age, gender and history of DM, hand grip strength (–4.36, 95%CI;-0.85~-7.85), knee extension strength (-5.62, 95%CI;-2.28~-8.97) and 4-meter walking speed (-0.12, 95%CI;-0.02~-0.22) were significantly reduced in those with eGFR<30. However, there was no difference in muscle mass (-0.23, 95%CI;-0.68~0.23).

Conclusions: In conclusion, muscle strength and walking speed but not muscle mass declined along with progression of CKD. Thus, it seemed more important to check muscle strength and walking speed rather than muscle mass when evaluating physical function in elderly patients with predialysis CKD.

SA-PO763

Lower Muscle Endurance, Strength and Quality Are Associated with Greater Risk of Functional Limitations in Older Adults with CKD Baback Roshanravan,[1] Kushang V. Patel,[3] Linda F. Fried,[2] Ian H. De Boer,[1] Cassianne Robinson-Cohen,[1] Anne B. Newman,[2] Bryan R. Kestenbaum.[1] *[1]Medicine/Nephrology, Kidney Research Inst - Univ Washington, Seattle, WA; [2]Univ of Pittsburgh, Pittsburgh, PA; [3]Univ of Washington, Seattle, WA.*

Background: Chronic kidney disease is associated with inflammation and insulin resistance contributing to fatigue and muscle weakness. The association of muscle endurance, strength, and quality with functional limitation among persons with CKD is unknown.

Methods: We studied 186 participants with eGFRcys<60 at the year 3 Health ABC visit. Participants were excluded if unable to complete >90% of quadriceps isokinetic fatigue testing. Quadriceps endurance was defined by total work using isokinetic dynamometer. Quadriceps strength was measuring by isometric torque. Leg lean mass (leglm) was measured using DXA. Muscle quality was defined by specific work (work/leglm) and specific torque (torque/leglm). Outcome was incident persistent severe lower extremity limitation (PSLL) based on 2 consecutive reports of having a lot of difficulty or inability to walk 1/4 mile or climb 10 steps without resting. We used competing risks regression.

Results: Participants had a mean age 76.2 ±3yrs, eGFRcys of 49.2 ±10. None had mobility disability. There were 82 PSLL events over a median 6 years. After adjustment each 1-SD lower quadriceps isokinetic work and isometric maximal torque were associated with a 1.38 fold (95% CI 1.04, 1.85, P=0.028) and 1.43 fold (95% CI 1.01, 2.03 P=0.045) greater risk of PSLL, respectively. Leg lean mass was not associated with PSLL (P=0.12).

	Unadjusted SHR	Adjusted SHR
Isokinetic Work (Joules)	1.26 (0.99, 1.61)	1.38 (1.04, 1.85)*
Specific work (Joules/kg)	1.32 (1.06, 1.64)*	1.38 (1.09, 1.76)+
Isometric Torque (N*m)	1.37 (1.04, 1.79)*	1.43 (1.01, 2.03)*
Specific Torque (N*m/kg)	1.46 (1.10, 1.94)+	1.42 (1.04, 1.93)*

Per 1-SD difference
Adjusted for demographics, comorbidity, activity, cognitive function, statins & bicarbonate, ±leg lean mass
*P<0.05, +P<0.01

Conclusions: Among older adults with CKD free of mobility disability, lower muscle endurance, strength, and quality are independently associated with greater risk of severe lower extremity limitation.

Efficacy and Safety of Exercise Training in Patients with Predialysis Chronic Kidney Disease Yugo Shibagaki,[1] Koji Hiraki,[2] Takashi Yasuda,[1] Kenjiro Kimura.[1] *[1]Div of Nephrology and Hypertension, St. Marianna Univ; [2]Div of Rehabilitation, St. Marianna Univ.*

Background: Efficacy and safety of exercise training has not been well studied in patients with predialysis chronic kidney disease (CKD). Since we have reported in elderly patients with predialysis CKD that there was a significant reduction in muscle strength and short-term exercise did not damage kidney, we conducted a randomized controlled trial to elucidate the long-term efficacy and safety of exercise in this population.

Methods: Study design was a randomized controlled trial. Thirty six male elderly patients with CKD stage 3-4 seen at the outpatient nephrology clinic at St. Marianna University Hospital agreed to participate in the study with written informed consent. We randomly divided them into intervention (I) group and control (C) group. Patients with I group were adised to walk fast for 30 minutes a day or 10,000 foot steps a day and was trained to do muscle training for upper/lower extremities at every clinic visit for 12 months. Patients with C group did not received exercise advice. Both groups received conventional drug therapy for CKD and were checked the daily foot steps by pedometer. Primary outcome was the change in estimated glomerular filtration rate (eGFR) and secondary outcomes were the changes in muscle strengths by dynamometer (hand grip and knee extension).

Results: There were no difference in baseline characteristics (demographic, kidney functional parameter, hemoglobin and serum albumin level) with average age of 68.7±6.8 years and eGFR of 39.0±11.6 ml/min/1.73m^2. Change in eGFR were not different at 12 months among both groups . Muscle strength in knee extension increased in I group (0.65±0.17kgf to 0.70±0.17kgf in knee extension) but not in C group (0.66±0.15 to 0.62±0.13kgf) (0.65±0.17kgf to 0.70±0.17kgf in knee extension) but not in C group (0.66±0.15 to 0.62±0.13kgf), which showed statistically significant difference. Change in muscle strength in hand grip also showed the difference between the groups.

Conclusions: Only the advise on exercise training could increase the physical activity and muscle strength without compromising kidney function in the elderly patients with predialysis CKD.

SA-PO765

Determinants of Impaired Cardiorespiratory Fitness in Older Adults with CKD Stephen L. Seliger,[1,2] Jamie Giffuni,[2] Roger A. Fielding,[3] Eamon F. Fleming,[3] Christine Liu,[4,6] Leslie I. Katzel,[1,2] Kieran Reid,[3] Sushrut S. Waikar,[5] Andrew M. Well,[6] Daniel E. Weiner.[3] *[1]Medicine, U Maryland Sch of Medicine; [2]GRECC, VA Maryland Healthcare System; [3]Tufts Univ Sch of Medicine; [4]Boston Univ Sch of Medicine; [5]Brigham and Women's Hospital; [6]Emory Univ School of Medicine.*

Background: Chronic Kidney Disease (CKD) may be associated with impaired cardiorespiratory fitness (CRF). We examined methods of estimating CRF in CKD and identified factors associated with CRF.

Methods: We measured peak aerobic capacity (VO_2peak) using a modified Graded Exercise Treadmill Test (GXT) in 71 older adults with CKD stage 3b-4 in an ongoing exercise clinical trial. GFR was estimated with the CKD-Epi equation. Linear regression was used to examine factors associated with VO_2peak. Resting VO_2 was measured prior to GXT in seated position. Metabolic Equivalents of Task (MET, oxygen consumption during exercise relative to rest) was estimated at peak exercise based on GXT stage and compared to actual achieved METS.

Results: Mean age was 68.4±7.7 years, with 61% African-Americans, 30% women; mean eGFR was 33±11 ml/min/1.73m^2 and mean Hb 12.3±1.6 g/dL. Mean VO_2peak was 17.4±5.4 ml/kg/min, which was 31±17% lower than expected based on normative values (p<0.001). In a multivariate model including demographics and co-morbidity, lower hemoglobin - but not GFR - was associated with lower VO_2peak (Table). Albuminuria did not correlate with VO_2peak.

Covariate	Standardized β	p-value
Age	-0.25	0.005
African-American	0.08	0.3
Male	0.41	<.001
Diabetes	0.01	0.9
Cardiac Disease	-0.25	.002
Body Mass Index	-0.47	<.001
GFR	0.09	0.3
Hemoglobin	0.19	0.025

Estimated METS: Mean achieved METS was 5.6±1.8. Although there was low bias for estimated vs. achieved METs (mean difference, -0.45), precision and accuracy were poor, with only 35% of predicted values within 1 MET of achieved values, and nearly one third of estimated values >30% different from achieved.

Conclusions: Among older adults with CKD stage, CRF as reflected by VO_2peak is markedly impaired. Lower hemoglobin, obesity, and prevalent cardiac disease are associated with worse aerobic capacity. The use of estimated METS during treadmill testing poorly estimates actual aerobic capacity.

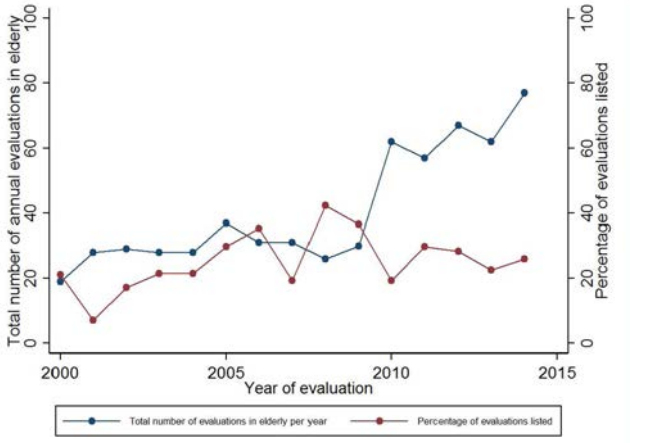
SA-PO766

Access to Kidney Transplantation and Outcomes of Those Listed for Kidney Transplant in Elderly Pritika Shrivastava, Ankit Sakhuja, Diane M. Cibrik, Abhijit S. Naik. *Div of Transplant Nephrology, U Michigan, Ann Arbor, MI.*

Background: Data suggests that patients above 70 years of age (>70 y.o.) with ESRD derive a benefit from kidney transplant (KT). We report our single center experience of access to transplant and outcomes for those >70 y.o. listed for KT. We used the number of evaluations in a year and rate of acceptance after evaluation as surrogate markers for KT access in elderly.

Methods: We assessed the rate of acceptance for KT and its trends over the years for those >70 y. o. between 2000-2014. Linear regression was used to assess trends over time. Differences in rates of listing stratified by diabetes status, KT rates among those approved for listing by diabetes status and mortality among those transplanted vs waitlisted was assessed.

Results: Over 15 year period, we evaluated 612 elderly patients (pts). 25.3% of those evaluated were approved to be listed for transplant. There were 9 patients who were evaluated twice of those 5 were approved for listing the second time and two got transplanted. There was 300% increase in annual evaluation of the elderly from year 2000 to 2014 and trend towards increased acceptance rate of those evaluated (slope=+0.82, p=0.12).



The acceptance rate was lower in diabetics compared to non-diabetics (18.2% vs 32.0%; p=0.001). 38.0% of listed pts have been transplanted and the rate of transplant did not differ by diabetes status. Of those transplanted 59.3% had living donors. Mortality among those transplanted was 64.4% in comparison to 87.3% of those waitlisted (p=0.001).

Conclusions: Only a fourth of those >70 evaluated for KT were accepted for listing, though there has been some improvement in the acceptance rate for listing over time. Acceptance rate was significantly lower among elderly diabetics. Mortality though improved remained significantly high for transplant vs waitlisted patients.

SA-PO767

P-Cystatin C Improves GFR Estimation in Older People Karin Werner,[1] Anders G. Christensson,[2] Mats Pihlsgård,[1] Sölve Elmståhl.[1] *[1]Dept of Geriatrics, Lund Univ, Malmo, Sweden; [2]Dept of Nephrology and Transplantation, Lund Univ, Malmo, Sweden.*

Background: There is a need for validation of commonly used cystatin C and creatinine based formulas for eGFR (estimated glomerular filtration rate) in the older segment of the general population for all levels of kidney function.

Methods: Markers used for eGFR estimation were P-Cystatin C and P-Creatinine. Measured GFR (mGFR) adjusted to body surface area was performed by a single sample iohexol clearance in 112 participants, aged 70-100 years old from the population-based cohort "Good Aging in Skåne". The participants were selected to cover a wide range of kidney function and to obtain an even distribution regarding sex and age. The timing of the sample depended on eGFR (eGFR >50, 25-50, and >25 at 4, 7, and 24 hours respectively). Formulas using both markers (CKD EPI combined, Lund-Malmo combined, BIS2), only creatinine (CKD EPI creatinine, MDRD) and only cystatin C (CKD EPI cystatin C) were compared. The analysis included bias (median difference: mGFR-eGFR), precision (IQR: interquartile range of the differences), accuracy (P30: percentage of estimates ±30% of mGFR) as well as accuracy (P30) above and below mGFR 45.

Results: There were 57 women and 55 men. Mean age was 82 years and mean GFR 55 ml/min per 1.73m^2. Results are presented in the table.

eGFR	CKD-EPI comb	Lund-Malmo	BIS2	CKD-EPI creatinine	MDRD	CKD-EPI cystatin C
Median difference (ml/min per 1.73m^2)	3.3	4.2	6.1	-0.5	2.9	6.1
IQR (ml/min per 1.73m^2)	7.9	8.4	12.6	10.5	11.6	8.8
% P30	96	95	94	86	84	93
% P30 mGFR>45	99	96	93	92	91	92
% P30 mGFR<45	92	92	95	73	70	95

Conclusions: All the formulas that include cystatin C performed well in this Swedish cohort with a mean age above 80. This confirms that it is safe to use either of those formulas in our older patients across a wide spectrum of kidney function. However, the formulas based solely on creatinine are not reliable enough below GFR 45. Further sub-analysis can demonstrate detailed performance for males and females respectively, for all CKD-stages and for smaller age-intervals.

Funding: Government Support - Non-U.S.

SA-PO768

Factors Associated with Early Death After Dialysis Initiation Among Elderly CKD Patients Fahad Saeed, Susana Arrigain, Jesse D. Schold, Joseph V. Nally, Sankar D. Navaneethan. *Nephrology, Cleveland Clinic.*

Background: There are limited studies examining prognosis for elderly CKD patients following dialysis initiation. Herein, we evaluated the factors associated with poor one year survival after dialysis initiation among elderly CKD patients at our institution.

Methods: We studied 621 CKD patients≥65 years from an EMR based CKD registry linked to the USRDS data. We retrospectively analyzed factors associated with one year mortality after dialysis initiation including: age, sex, race, presence of diabetes, hypertension, BMI, stroke, CHF, COPD, malignancy, peripheral vascular disease , depression, alcohol use, smoking, presence of AVF, pre-dialysis serum albumin and potassium.

Results: In our study, 224 (36%) patients died within the first year of dialysis initiation. Results from the Cox proportional model showed that older age and CHF were associated with early deaths, while higher albumin, presence of AVF and HTN were associated with a lower hazard of early death.

Conclusions: CHF and older age in the pre-dialysis setting are associated with higher 1-year mortality after dialysis initiation. These prognostic data need to be presented to geriatric CKD patients while discussing renal replacement therapy options.

Table. Multivariable Cox model of 1 year mortality among elderly CKD patients

Parameter	Hazard Ratio (95%CI)

Differential Significance of Prognostic Factors for 6-Month and 3-Year Mortality in Elderly Patients on Hemodialysis Koji Harada,[1] Azusa Izumiya,[1] Tomohiro Kawamura,[1] Juri Tsukahara,[1] Koichi Sumida,[1] Yukinari Yamaguchi,[1] Yasuhiro Akai.[2] *[1]Dept of Nephrology, Rakuwakai-Otowa Hospital, Yamashina, Kyoto, Japan; [2]Center for Postgraduate Training, Nara Medical Univ, Kashihara, Nara, Japan.*

Background: As the population of elderly people has been growing, the number of older chronic kidney disease patients commencing renal replacement therapy (RRT) is increasing. The survival advantage of RRT may be counterbalanced by the burden of treatment and its negative effect on quality of life in the elderly, and old age is no longer seen as a contraindication to RRT. Therefore, it is important to evaluate survival factors in this population. We conducted this study to investigate prognostic factors for mortality in elderly patients starting hemodialysis (HD) for end-stage renal disease (ESRD).

Methods: This is a single-center, retrospective cohort study from January 2009 to December 2014. In total, 90 ESRD patients commencing HD were enrolled. All the patients were aged 65 years or older. Six-month and 3-year survival rates and prognostic factors for mortality were evaluated.

Results: The mean follow-up period was 21.7±18.3 months. The 6-month and 3-year survival rate were 94.0% and 66.9%, respectively. Age, unplanned initiation of HD, presence of heart failure, high value of estimated GFR on starting HD, Charlson comorbidity index (CCI), and Eastern Cooperative Oncology Group Performance Status scale (ECOG-PS) were associated with 3-year mortality, whereas only the presence of heart failure and ECOG-PS were significant predictors of 6-month mortality. There was no significant difference in 6-month mortality rate between patients aged ≥ 80 and < 80. On the other hand, 3-year mortality rate of ≥ 80 year-old patients was significantly higher than that of < 80 (≥ 80: 53.3% vs < 80: 14.2%, p = 0.0004).

Conclusions: There is a variation of significance among different prognostic factors according to the duration of life after starting hemodialysis. The presence of heart failure and ECOG-PS predicted short-term mortality among elderly ESRD patients starting HD. These results might help clinical decision making when nephrologists consider commencing HD for elderly ESRD patients.

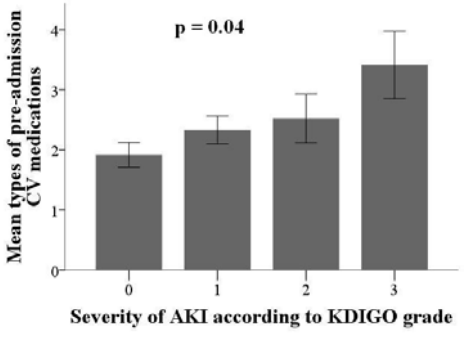
SA-PO770

Cumulative Cardiovascular Polypharmacy Is Associated with the Risk of Geriatric Acute Kidney Injury Chia-Ter Chao,[1] Hung-Bin Tsai.[2] *[1]Dept of Medicine, National Taiwan Univ Hospital Jin-Shan Branch, New Taipei City, Taiwan; [2]Dept of Traumatology, National Taiwan Univ Hospital, Taipei, Taiwan.*

Background: Polypharmacy is common in the elderly due to multiple morbidities. However, the effect of polypharmacy on renal outcomes is rarely recognized. We investigated the effect of cardiovascular polypharmacy on acute kidney injury (AKI) in elderly patients.

Methods: We used the Taiwan National Health Insurance PharmaCloud system to investigate the relationship between cumulative cardiovascular medications in the 3 months prior to admission and risk of AKI in the elderly at admission to general wards. Community-dwelling elderly patients (>60 years) were prospectively enrolled and classified according to the number of pre-admission cardiovascular medications. Cardiovascular polypharmacy was defined as use of 2 or more relevant medications.

Results: We enrolled 152 patients, 48% with AKI (based upon Kidney Disease Improving Global Outcomes [KDIGO] classification) and 64% with cardiovascular polypharmacy. The incidence of AKI was higher in patients taking more cardiovascular medications (0 drugs: 33%; 1 drug: 50%; 2 drugs: 57%; 3 or more: 60%; p = 0.048). Patients with higher KDIGO grades also took more cardiovascular medications (p = 0.04).



Multiple regression analysis showed that patients who used 1 or more cardiovascular medications had increased risk of AKI at admission (1 drug: odds ratio [OR] = 1.63, p = 0.2; 2 drugs: OR = 4.74, p = 0.03; 3 or more drugs: OR = 5.92, p = 0.02), and that cardiovascular polypharmacy increased the risk of AKI (OR 2.58; p = 0.02). Each additional cardiovascular medication increased the risk for AKI by 30%.

Conclusions: We found that elderly patients taking more cardiovascular medications had increased risk for adverse renal events. Interventions that reduce polypharmacy may be able to reduce the incidence of geriatric AKI.

Low Bicarbonate Associates with Higher Mortality Independent of pH in Healthy Older Individuals: The Health, Aging, and Body Composition Study Kalani L. Raphael,[1] Rachel A. Murphy,[2] Michael Shlipak,[3] Suzanne Satterfield,[4] Hunter K. Huston,[1] Anthony Sebastian,[3] Deborah Sellmeyer,[5] Kushang V. Patel,[6] Anne B. Newman,[7] Mark J. Sarnak,[8] Joachim H. Ix,[9] Linda F. Fried.[7] *[1]Univ of Utah; [2]Univ of British Columbia; [3]Univ of California San Francisco; [4]Univ of Tennessee; [5]Johns Hopkins Univ; [6]Univ of Washington; [7]Univ of Pittsburgh; [8]Tufts Medical Center; [9]Univ of California San Diego.*

Background: Low serum [HCO_3^-] associates with higher mortality in CKD. The purpose of this study is to determine if [HCO_3^-] associates with all-cause mortality independent of systemic pH in healthy older persons.

Methods: Data were analyzed from the Health, Aging, and Body Composition Study, an observational study of black and white adults aged 70-79 years followed from 1997-2014. Arterialized venous blood gas measurements were obtained in 2,287 individuals. Participants were grouped into one of 3 [HCO_3^-] categories: <23.0 (low), 23.0-27.9 (reference group), and ³28.0 mEq/L (high). Mortality hazard ratios (HR) in the low and high [HCO_3^-] groups were compared to the reference group using Cox models adjusted for demographics, eGFR, albuminuria, COPD, smoking, and pH. Multiplicative interaction terms tested whether CKD status modified the relationship between [HCO_3^-] categories and mortality.

Results: The mean age was 76 years, 51% were female, and 38% were black. The mean pH was 7.41, mean [HCO_3^-] was 25.1 mEq/L, 11% had low and 10% had high [HCO_3^-]. The mean eGFR was 82.1 ml/min/1.73m²; 12% had CKD. During follow-up (mean 10.3 years), 1,326 (58%) participants died. The adjusted all-cause mortality HR was 1.24 (95% CI, 1.02-1.49) in the low [HCO_3^-] category and 1.03 (95% CI, 0.84-1.26) in the high [HCO_3^-] category compared to the reference group. CKD status did not modify the association between [HCO_3^-] and mortality (p=0.74).

Conclusions: Healthy older persons with low [HCO_3^-] have higher mortality risk than those with normal [HCO_3^-] independent of pH and potential confounders. High [HCO_3^-] does not associate with higher mortality. The potential health benefits of normalizing low [HCO_3^-] in generally healthy older persons should be investigated.

SA-PO772

Low Urinary Creatinine Excretion Is a Valid Surrogate for Frailty in Patients with Advanced Chronic Kidney Disease Harmke Polinder-Bos,[1] Hakan Nacak,[2] Friedo W. Dekker,[2] Stephan J.L. Bakker,[1] Carlo A. Gaillard,[1] Ron T. Gansevoort.[1] *[1]Internal Medicine, Univ Medical Center Groningen, Groningen, Netherlands; [2]Epidemiology, Leiden Univ Medical Center, Leiden, Netherlands.*

Background: Muscle wasting is a key component of frailty, which is highly prevalent in advanced stages of chronic kidney disease (CKD). Whether low urinary creatinine excretion (UCrE), a marker of low muscle mass, is a valid surrogate for frailty in this population is unknown. We studied cross-sectional associations between frailty and a low UCrE in patients with CKD stages 4 and 5 (not on dialysis).

Methods: 2748 healthy individuals of the general population were included to define low UCrE. Low UCrE was defined as height-indexed UCrE below the age- and sex-specific 5th percentile. In a CKD population including 320 and 967 participants of the resp. PREPARE-2 and NECOSAD studies, associations of frailty, the individual components that define frailty, and frailty-associated variables with low UCrE were evaluated using multivariate logistic and linear regression models. Frailty was defined as a composite construct including self-reported poor physical functioning, exhaustion, low physical activity, and underweight.

Results: In the general population with a median age of 46 years, median UCrE was 9.8 mmol/day for women and 14.3 mmol/day for men, compared to 7.0 mmol/day and 9.5 mmol/day in CKD patients, respectively. In the CKD patients with a median age of 63 years, low UCrE was found in 38%. Frailty, and the individual components that define frailty, were associated with a low UCrE, independent of comorbidities (OR frailty = 2.19 [1.28-3.77], p=0.005). Of the frailty-associated variables, lower hemoglobin and albumin levels, and higher parathyroid hormone levels were associated with low UCrE. Adjustment for GFR attenuated the associations of frailty, and the individual components that define frailty with low UCrE, except for underweight.

Conclusions: Low UCrE is a valid surrogate for frailty, independent of comorbidities. Low UCrE is strongly determined by a lower kidney function, suggesting that reduced kidney function induces changes in muscle mass and performance leading to frailty.

SA-PO773

Oral Anticoagulation and Kidney Function in Elderly Antonios Douros,[1] Elke Schaeffner,[2] Olga Jakob,[3] Reinhold Kreutz,[1] Natalie Ebert.[2] *[1]Clinical Pharmacolology, Charité; [2]Nephrology, Charité; [3]Clinical Epidemiology, Charité.*

Background: In the past years new oral anticoagulants (NOACs) were approved expanding our pharmacological arsenal. Data on their utilization in elderly compared to vitamin K antagonists (VKA) are scarce and the impact of kidney function (KF) on NOAC use in a population with declining glomerular filtration rate (GFR) is of great interest. The present study investigates anticoagulant use and KF in people ≥ 70 years.

Methods: Individuals included in the analysis were participants of the Berlin Initiative Study (BIS). BIS is a population-based prospective cohort study initiated in 2009 in Berlin, Germany, to evaluate KF in people ≥ 70 years. Medication was assessed through personal interviews and coded using the Anatomical Therapeutic Chemical Classification System. For GFR estimation we used the CKD-EPIcr equation. Predictor analysis was conducted via logistic regression.

Results: Figure 1 illustrates the percentage of drug use for the three NOACs and phenprocoumon, the most common VKA in Germany, over the course of 4 years.

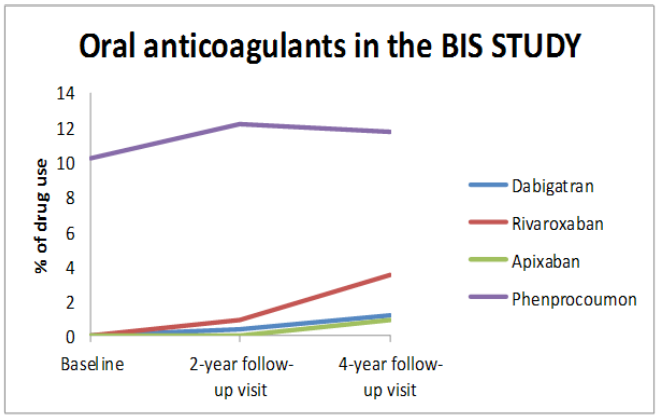

Table 1 shows the characteristics of patients for each oral anticoagulant group during the 4-year follow-up visit (01/2014-04/2015).

	Phenprocoumon (n=153)	**Dabigatran (n=14)**	**Rivaroxaban (n=46)**	**Apixaban (n=12)**
Age mean±SD (years)	84±6	87±4	84±5	85±5
Female sex n (%)	62 (41)	4 (29)	24 (52)	9 (75)
eGFR$_{CKD-EPI}$ < 60ml/min/1.73m² n (%)	64 (42)	3 (21)	16 (35)	5 (42)
Myocardial infarction n (%)	27 (18)	3 (21)	8 (18)	1 (9)
Stroke n (%)	17 (11)	3 (21)	0 (0)	2 (17)

The probability of dabigatran use rose with increasing age (+12%), and the probability of phenprocoumon use rose in case of eGFR < 60 ml/min/1.73m² (+54%) or male sex (+82%).

Conclusions: Our data show that also in the elderly NOAC use increased over the past years. Characteristics such as age, sex or KF had an impact on the choice of oral anticoagulation.

SA-PO774

Can Morbidity Predict Mortality in Dialysis Patients? Kathryn Ducharlet,[1] Vijaya Sundararajan,[2] Nuala Barker,[1] Jodie L. Burchell,[2] Robyn G. Langham.[1] *[1]Dept of Nephrology, St. Vincent's Hospital, Fitzroy, Victoria, Australia; [2]Dept of Medicine, Melbourne Univ, Fitzroy, Victoria, Australia.*

Background: Symptom management and quality of life (QOL) in dialysis patients is increasingly important in determining treatment approach and outcome research. This study identified symptoms, QOL, functional status in dialysis patients, determining if symptom burden had an impact on mortality.

Methods: A single-centre cross-sectional study was undertaken in dialysis patients with median follow up time 10 months. Patients completed surveys incorporating POS-S renal, WHOQOL-BREF and Karnofsky Performance scale. A Log rank test determined the risk of death based on symptom severity.

Results: 112 patients were recruited; 67 hemodialysis, 10 home/nocturnal hemodialysis and 35 peritoneal dialysis patients, average age 66 years, 66% male. Patients had high symptom burden (median POS-S score 13 (inter-quartile range (IQR 9, 22)) and reduced total QOL 4 (IQR 3,4), health satisfaction 3 (IQR 2,4) and performance status 60 (IQR 50,70). A log rank analysis was performed on 104 POS-S renal responses with 8 deaths during the study. A significant impact of pain, shortness of breath, nausea, mouth problems, drowsiness, poor mobility and skin changes on survival was found.

Symptom	Number (%) n = 112	Log rank test (Chi²) n=104
Pain	82 (73%)	10.56*
Shortness of breath	72 (64%)	8.18*
Weakness	98 (88%)	1.62
Nausea	44 (39%)	9.54*
Vomiting	25 (22%)	9.49*
Poor appetite	58 (52%)	3.53
Constipation	62 (55%)	3.06
Mouth problems	38 (34%)	16.29**
Drowsiness	68 (61%)	8.22*
Poor mobility	76 (68%)	12.28*
Itching	70 (63%)	3.95
Difficult sleeping	89 (79%)	9.02
Restless legs	57 (51%)	8.05
Feeling anxious	62 (55%)	6.01
Feeling depressed	52 (46%)	3.13
Diarrhoea	68 (61%)	3.40
Skin Changes	28 (25%)	60.37***

*P<0.05, **P<0.01 ***P<0.001

Conclusions: This study demonstrated high symptom burden, reduced functional status and QOL in dialysis patients. Patients with severe pain, weakness, shortness of breath, nausea, mouth problems, drowsiness, poor mobility and skin changes were more likely associated with higher mortality risk. Symptom identification and management may help predict and improve patient QOL outcomes in dialysis patients.

SA-PO775

Outcomes of Cardiopulmonary Resuscitation in Maintenance Dialysis Patients Based on CPR Characteristics Haris Farooq Murad, Fahad Saeed. *Cleveland Clinic Foundation.*

Background: Cardiopulmonary resuscitation (CPR) is associated with high rates of mortality, especially in patients with end stage renal disease (ESRD). Previous studies have reported an in-hospital mortality rate of up to 75% in ESRD patients undergoing CPR. There are no large studies to date on how individual CPR characteristics relate to the long term outcomes in these patients. Herein, we aimed to answer this question.

Methods: By an EMR inquiry, we identified all the adult patients (³18years) who had underwent CPR from January 2006 to December 2014, and then selected patients who were on maintenance dialysis. We conducted a chart review of CPR characteristics and its association with the hospital discharge survival. We studied following variables: initial rhythm, duration of CPR, in-hospital versus out of hospital CPR and the use of hypothermia protocol.

Results: We studied a total of 497 ESRD who had undergone CPR. Sixty eight percent of our patients had expired in the hospital post-CPR. Pulseless electrical activity (PEA) was the most common initial rhythm (51.4%), followed by ventricular arrhythmias (19.6%) and asystole (19.2%). In-hospital mortality was the highest (76.8%) for patients with asystole . Mortality rates at the time of discharge were 73.3% for PEA and 57.7% for patients with ventricular arrhythmias respectively. Fifty six percent of patients who underwent therapeutic hypothermia died in the hospital as compared to 68.9% of those who did not undergo a cooling protcol. CPR duration of greater than 10 minutes was associated with higher in-hospital mortality (76.1%) as compared to patients who had CPR for less than 10 minutes (40.9%). Patients who had undergone out of hospital CPR (by paramedics or bystanders), 72.2% died before discharge; while 68.9% of patients who underwent CPR in the hospital expired during the same hospitalization. The average length of stay for patients who were alive at discharge was 17 days.

Conclusions: CPR in dialysis patients is associated with high mortality rates.It is possible to predict hospital discharge survival of patients with cardio-pulmonary arrest based on the CPR characteristics.

SA-PO776

End of Life Care Preferences in Maintenance Dialysis Patients Haris Farooq Murad,[1] Muhammad Adil Sardar,[1] Syed Zamrak Khan,[1] Sara N. Davison,[2] Fahad Saeed.[1] *[1]Cleveland Clinic Foundation; [2]Univ of Alberta.*

Background: Dialysis patients have an annual mortality rate of 20-25%. A previous Canadian study comprising mainly of Caucasian patients has shown that patients are interested in active involvement in end of life care discussions and majority would want to know their prognosis on dialysis. In this Caucasian predominant cohort, approximately 50% chose to be DNR. It is not known if patients' preferences on end of life care are any different in a racially more diverse cohort of patients in the U.S.

Methods: We collected data on 423 out of 440 dialysis patients from 7 dialysis facilities in the U.S. using self-reported questionnaires.

Results: Our study included 28.1% Caucasian and 66.7% African American patients. Eighty three percent of the patients felt that their QOL was an important determinant in guiding their future care plans, and 72.3% of patients reported that they need to have frequent discussions about their QOL with their nephrologist. Only 35.4% of patients actually get information about their health and well-being from their nephrologists. Only 8.6% of patients had a discussion with any Physician, nurse or social worker regarding end of life care during the past 12 months. Notably, 74.2% of our participants reported that they would like to have such discussions with their health care providers. Sixty seven percent of the patients wished to be full code. Fifty six percent of the patients preferred to die at home versus 20.4% wanted to die in a hospice facility and 13.4% in a hospital. Only 23.6% of patients knew about palliative care.

Conclusions: There is a need to have more dialogue between patients and their nephrologists regarding end of life care preferences, and it is necessary to develop policies and practices that would help address this need.

SA-PO777

"So I had No Choice": Perceptions of Dialysis Decision-Making Among Older Adults Keren Ladin,[1] Daniel E. Weiner.[2] *[1]Occupational Therapy, Tufts Univ, Medford, MA; [2]Medicine, Tufts Univ Medical School, Boston, MA.*

Background: Multiple treatments are available to older patients with advanced chronic kidney disease. However, poor communication about available treatment options may result in a mismatch between patient preferences and treatment choice.

Methods: Semi-structured in-depth interviews were conducted with a purposive sample of 26 dialysis patients aged 65 and older at two dialysis clinics in the Greater Boston area. Trained researchers conducted, audiotaped and transcribed interviews. Applying grounded theory, interviews were and analyzed in an iterative process to identify emergent codes. Codes were discussed using consensus and organized into themes.

Results: Twenty-six patients participated in the interview. Mean age was 77±9 years; 50% were men, 19% African American and 58% diabetic. Median vintage was 28 (17, 39) months. Four major themes with associated subthemes were identified. The first, "Deciding to start dialysis" revealed that only two patients conceptualized dialysis initiation as a choice. Patients were seldom informed of conservative management, and many had unanswered concerns about trade-offs among treatment choices. The second theme, "Experience with dialysis", included positive and negative physical, emotional, and social consequences of dialysis and logistics of care. While many reported greater than anticipated levels of pain, fatigue, and frustration over transportation costs and time spent, others reported substantial benefits, including increased longevity and the ability to achieve life goals. The third theme, "Patient Role", revealed patients tied self-worth to meeting clinical goals. Finally, "End-of-life (EOL) preferences and conversations" revealed that most patients had not discussed EOL with their clinical team and or with loved ones.

Conclusions: Many older patients who treated with dialysis do not perceive that they had a choice when making their dialysis decision. Initiating dialysis may contradict patients' EOL preferences, and many desire greater information and more discussions with clinicians. Older adults' preferences and experiences with dialysis vary, underscoring the importance of patient involvement in decision-making.

SA-PO778

Improving Advance Care Planning in Elderly Outpatients with Chronic Kidney Disease – A Quality Improvement Initiative Ritu K. Soni,[1] Jane O. Schell.[1,2] *[1]Section of Palliative Care and Medical Ethics, Univ of Pittsburgh Medical Center, Pittsburgh, PA; [2]Renal-Electrolyte Div, Univ of Pittsburgh Medical Center, Pittsburgh, PA.*

Background: Despite a high annual mortality rate in patients with advanced chronic kidney disease (CKD), advance care planning (ACP) is underutilized. A minority of dialysis patients complete advance directives (AD). Timely ACP ensures that patients' preferences for future care are respected and is associated with less intensive care at end of life. We sought to introduce ACP and increase documentation of AD in older outpatient CKD patients.

Methods: This quality improvement study was conducted over 15 weeks in older outpatients at the University of Pittsburgh Kidney Clinic. The intervention included training and supporting the CKD nurse educator to introduce and encourage ACP completion. Inclusion criteria were age older than 65 years and referral to the CKD education session. The CKD nurse educator was assigned the role of asking whether each patient had AD and a designated healthcare power of attorney (HPOA). The nurse additionally offered every eligible patient the *Five Wishes* AD form and documented their responses.

Results: Of the 110 patients who underwent CKD education over a period of 15 weeks, 52 (47.2%) were eligible. Thirty-one of 52 (59.6%) patients already had AD and 32 of 52 (61.5%) had a HPOA. Thirteen of 52 (25%) were interested in reviewing the *Five Wishes* AD form although 2 of them had already completed an AD. The AD and HPOA screening information was documented by the nurse educator in 59.6% and 61.5% patients respectively. One patient had an AD scanned in the electronic records and one patient requested referral to the Renal Supportive Care clinic for continuation of ACP discussions.

Conclusions: We report a successful nurse educator based quality improvement initiative to increase AD documentation in older nephrology outpatients. Our data suggest that although many of these patients have previously completed AD, these preferences are not documented in the medical chart. A nurse educator based intervention is effective in improving documentation rates of AD.

SA-PO779

Trends in Inpatient Intensive Procedures in the Last Six Months of Life Among Medicare Beneficiaries Treated with Maintenance Dialysis, 2000-2011 Nwamaka Denise Eneanya,[1] Susan M. Hailpern,[2] Ann M. O'Hare,[2] Manjula Kurella Tamura,[3] Ronit Katz,[2] Yoshio N. Hall.[2] *[1]Div of Nephrology, Massachusetts General Hospital, Harvard Medical School, Boston, MA; [2]Kidney Research Inst, Univ of Washington, Seattle, WA; [3]Geriatric Research and Education Clinical Center, VA Palo Alto Health Care System, Palo Alto, CA.*

Background: Many US dialysis patients undergo intensive procedures intended to prolong life such as mechanical ventilation, cardiopulmonary resuscitation or feeding tube placement at the very end of life. Little is known about trends over time in use of intensive procedures in this population.

Methods: We examined temporal trends in receipt of inpatient intensive procedures in the last 6 months of life by age and race among 601,942 adult Medicare beneficiaries treated with maintenance dialysis who died between January 1, 2000 and December 31, 2011.

Results: From 2000 to 2011, inpatient admissions during the last six months of life increased slightly from 89% to 90%. Among those admitted, there was a marked increased in the use of intensive procedures ranging from 38% in 2000 to 44% in 2011. Intensive procedures at the end of life were more common among black vs. white patients (50% to 57% vs. 34% to 39%) and among younger vs. older patients (50% to 61% for those < 55 years vs. 27% to 26% for those 85+ years).

Proportion of hospitalized decedents receiving an intensive procedure in the last 6 months of life during 2000-2011.

	Whites	
Age grp	Outcomes	Total N
19-54	15,812	30,368
55-69	44,115	98,592
70-84	68,940	204,925
85+	12,334	52,715
All	141,201	386,600

	Blacks	
Age grp	Outcomes	Total N
19-54	16,911	28,010
55-69	30,411	52,867
70-84	31,212	61,171
85+	4,914	11,788
All	83,448	153,836

In adjusted analyses, racial differences in receipt of intensive procedures were most pronounced at older ages (black vs. white aOR [95% CI]; 1.38 [1.33-1.42] in patients < 55 years, 2.48 [2.38-2.59] in patients 85+ years).

Conclusions: From 2000 to 2011, a growing number of Medicare beneficiaries treated with maintenance dialysis received intensive procedures during the final months of life. These procedures were most common and increased most dramatically in younger patients while racial differences were most pronounced in older patients.

Funding: NIDDK Support

SA-PO780

Will Nephrologists Implement an Advance Directives Program in Their Patients? (Quality Improvement Program) Ali Mohammed Habeeb, Sheldon W. Tobe. *Nephrology, Sunnybrook Health Sciences Centre, Toronto, ON, Canada.*

Background: Mortality remains high among patients on dialysis. Advanced age and multiple co-morbidities are the majors predictors for increasing mortality. ADs extend patients' autonomy and are the best tool to inform about a patient's preferences for health care decisions when they become unable to make such decisions. Chronic dialysis patients have been shown to want to discuss ADs in the past.

Methods: We reviewed 215 chronic in-center hemodialysis patients at Sunnybrook Health Sciences Centre from March to April 2015 by the dialysis unit social workers for any documents related to ADs (like Living wills, Substitute Decision Maker (SDM) and CPR forms). Only 2 patients had ADs in their charts (**1.0%**). When this data has presented to the Nephrologists they agreed that ADs should be discussed with their patients and that this was a quality improvement issue. Will the staff nephrologists change their practice behaviour and begin to ask their hemodialysis patients about ADs and document the discussion?

Results: As part of the process to discuss Ads, the unit's social workers distributed a pamphlet for the patients with simple and explicit definitions and advantages of AD and also provided explanations about the contents of the pamphlets. The Staff Nephrologists were educated about the importance and advantages of ADs in their patients and were asked to start discussing the issues with their patients. The Nephrologists will also be educated about how an AD discussion might go and how to document the results of the discussion. In 3 months, a review of the patients' charts will again look for any documented ADs. We will also study the response of individual dialysis staff and their participation in completing and discussing the ADs. We will assess the potential barriers for not completing ADs by the dialysis unit staff and by patients and attempt to address these barriers.

Conclusions: Expected Outcome: Based on the Prochaska model we are anticipating the dialysis staff are now in the contemplation stage and we are aiming to observe the progression in their behavior to more advanced stages of behavior and try to find out what are the barriers that prevent the progression.

SA-PO781

Current Practice of Advance Care Planning in Australia and New Zealand

Rachael L. Morton,[1] Lucy Spencer,[2] Allison Tong,[1] Carol A. Pollock,[1,2] Karen M. Detering,[4] Josephine M. Clayton.[1,3] *[1]The Univ of Sydney, Australia; [2]Royal North Shore Hospital, Australia; [3]HammondCare Palliative Care Service, Australia; [4]Austin Health, Australia; [5]On behalf of Univ of Technology Sydney Collaborators.*

Background: Recent guidelines emphasise the need to improve advance care planning (ACP) for patients with chronic kidney disease (CKD). Little is known about current ACP practice in Australian/New Zealand renal centres. We aimed to describe current practice and barriers to ACP from the perspective of renal clinicians.

Methods: A cross-sectional survey was administered online to nephrology nurses, nephrologists and social workers between May 2014 and January 2015. Survey questions covered the topics of experience, skills, comfort and knowledge regarding ACP, workplace policies and procedures concerning ACP, perceived barriers and facilitators to ACP, and perceived need for new CKD-specific ACP programs and materials.

Results: 375 participants completed the survey, mean age 48 years, from renal centers in all Australian states and territories and New Zealand. 57% indicated that ACP was performed in their workplace on an ad-hoc basis; 22% reported that there was a formal program; 13% reported that ACP hardly ever occurred; and 8% were unsure.61% reported that ACP was done poorly, 32% well, and 7% were unsure. Perceived barriers to ACP included patient/family discomfort with the topic (84% of respondents), difficulty engaging families and lack of clinician expertise (83% each), lack of clinician time (82%), health professional discomfort (72%), cultural/language barriers (65%), environmental problems such as lack of space (61%) and lack of formal policy/procedures (60%). Whilst discouragement from colleagues or managers was identified as a barrier in only 19% of cases, narrative comments on the survey emphasised the gate-keeping role played by nephrologists.

Conclusions: ACP in Australian/New Zealand renal centres is subject to health system, provider and patient related barriers. Given the volunteer effect associated with online surveys, our study may underestimate the need for ACP support. Targeted interventions are needed to improve ACP in Australian and New Zealand renal centres.

SA-PO782

Nephrology Leadership Required to Address Unmet Palliative Care Needs in Dialysis Centers

Alvin H. Moss,[1] Stacey Culp,[1] Dale Lupu,[2] Cheryl Arenella,[2] Nancy C. Armistead.[3] *[1]Medicine, West Virginia Univ School of Medicine, Morgantown, WV; [2]Daleview Associates, Silver Spring, VA; [3]Mid-Atlantic Renal Coalition, Richmond, VA.*

Background: Because of high symptom burden, numerous comorbidities, and shortened life expectancy, dialysis patients are increasingly recognized as appropriate candidates for early and continuous palliative care.

Methods: In 2013 the Coalition for Supportive Care of Kidney Patients conducted an online survey of dialysis professionals and administrators using ESRD Network and Renal Physicians Association email lists to determine perceptions about how well patient palliative care needs are met. Differences among disciplines were assessed by chi-squared testing and one-way ANOVA.

Results: The 487 respondents included 41 nephrologists, 152 nurses/physician assistants, 199 social workers, and 95 dialysis center administrators. There was a significant difference by discipline in reported unmet palliative care needs for symptom management, care coordination, and family bereavement support, with administrators least likely to view each need as unmet (all $p < .02$). In rating possible barriers to providing high quality palliative care in their centers, mean scores differed by discipline for 7 items, and nephrologists were most likely and administrators least likely to perceive them as barriers (all $p < .05$). "Guidelines to help with decision-making in seriously ill patients" was selected as the top priority for change by each discipline (37% overall, p=.47 by discipline). Nephrologists were most likely to be aware that a dialysis guideline already existed and to have used it (43.9% vs 3.3% RN/PA vs 10.6% MSW vs 8.5% administrator, $p < .001$).

Conclusions: Nephrologists report more unmet palliative care needs, barriers, and resources than the administrators who oversee dialysis centers. Because the respondents were self-selected, a study limitation, the results likely underestimate unmet palliative care needs. To better address palliative care needs, nephrologists need to lead interdisciplinary collaborations, including administrators, to implement palliative care pathways already established in evidence-based clinical practice guidelines.

SA-PO783

Hospice and Race for End-of-Life Care in U.S. Dialysis Patients

Robert N. Foley,[1] Scott Reule,[1] Donal J. Sexton.[2] *[1]Div of Nephrology, Univ of Minnesota, Minneapolis, MN; [2]Div of Medicine, National Univ of Ireland, Galway.*

Background: While hospice use is increasingly used for end-of-life care in dialysis patients, we hypothesized that important racial disparities may be present.

Methods: To address this hypothesis, we examined USRDS files to characterize end-of-life care for deaths occurring between 2006 and 2011.

Results: During this 5-year period, the proportion of deaths in hospice increased from 14.7% to 24.2%; grouped by age at death, the following trends were observed: < 65 years-11.5% to 15.0%; 65 to 79 years-19.1% to 26.1%; 80-89 years-24.9% to 34.3%; ≥ 90 years-25.9% to 39.6%. As shown in the accompanying Table, associations of hospice use among decedents included more recent calendar year, older age and female sex. Hospice use varied substantially with race: compared to whites, adjusted odds ratios of hospice use were 0.56, 0.56 and 0.57, respectively, in patients of African American, Native American and Asian race.

Conclusions: While end-of-life care in hospice settings is growing rapidly in the US, substantial, unexplained racial disparities exist.

Candidate Variable	Comparator	Adjusted Odds Ratio
Death in 2008	2006	1.18
Death in 2009	2006	1.27
Death in 2010	2006	1.39
Death in 2011	2006	1.51

Palliative Care Perspectives of Latinos with End-Stage Renal Disease

Lilia Cervantes,[1,2] Stuart L. Linas,[1,2] Stacy M. Fischer.[1] *[1]Dept of Medicine, Univ of Colorado, Denver, CO; [2]Dept of Medicine, Denver Health and Hospital, Denver, CO.*

Background: Latinos are the fastest growing minority and have a nearly 2-fold faster progression from chronic kidney disease to end-stage renal disease (ESRD). Despite the high symptom burden and mortality suffered by patients with ESRD, there is limited palliative care research and Latinos are underrepresented in existing palliative care studies. The purpose of our study is to provide the first description of the Latino palliative care perspective.

Methods: Observational descriptive survey of adult English and Spanish speaking Latinos with ESRD from a safety-net hospital and two private dialysis centers. We modified Davison's 2010 End of Life Care Preferences and Needs Survey to include known barriers to palliative care in the Latino community. The survey was translated to 3rd grade Spanish and then back-translated to English.

Results: Participants (n=61) had a mean age of 59 years ± 12, mean Charlson Comorbidity Index of 6.5 ± 2.5, and a dialysis vintage mean of 43.3 months ±44.8. The majority (77%) spoke Spanish and reported limited understanding of hospice and palliative care. We found that 60 (98%) want to be informed about their prognosis and 55 (90%) want to be prepared and plan ahead; however, only 16 (26%) had discussed prognosis and only 10 (16%) had discussed end-of-life care with their nephrologist. The majority of participants stated that it was their doctor's choice (68.8%) to start dialysis; however, few (14.7%) regret the decision to start dialysis. Participants reported a preference to have advance care planning conversations on a routine basis (86.8%), after starting dialysis but before becoming ill (85.2%), and while receiving dialysis (47.5%) or at home (37.7%). Participants want their family have a central role in medical decision-making (93.4%) and care-giving (95%).

Conclusions: Our findings provide the first description of the palliative care perspectives of a predominantly Mexican Latino population with ESRD. By understanding the palliative care perspectives and barriers experienced by Latino patients with ESRD, we can move toward a value-based and patient-centered model of palliative care.

Symptom Burden Amongst Latinos with End-Stage Renal Disease

Lilia Cervantes,[1,2] Stuart L. Linas,[1,2] Stacy M. Fischer.[1] *[1]Dept of Medicine, Univ of Colorado, Denver, CO; [2]Dept of Medicine, Denver Health and Hospital, Denver, CO.*

Background: All patients with end-stage renal disease (ESRD) experience a high symptom burden. Although Latinos represent 19% of the US ESRD community, little research is available on their symptom burden. The purpose of our study was to provide the first description of symptom burden prevalence and severity amongst Latinos with ESRD.

Methods: Observational descriptive survey of adult English and Spanish speaking Latinos with ESRD from a safety-net hospital and two private dialysis centers. We used Davison's ESAS-r: Renal tool which measures physical and psychological symptom distress and contains 11 symptom items on a Likert scale of 0-10. Moderate = 4-6 and severe = 7-10. We asked three questions about symptom treatment preferences.

Results: Participants (n=61) had a mean age of 59 ±12 years, mean Charlson Comorbidity Index of 6.5 ±2.5, and a dialysis vintage mean of 43.3 ±44.8 months. The majority were born in Mexico (90.2%), spoke Spanish only (77%), and had a less than high school education (72.2%). Overall, Latinos experience a substantial symptom burden with a mean of 6.8 ± 2.9 symptoms of which 5.1 ±2.8 are moderate or severe symptoms. Tiredness

was experienced by 83.5% of patients and reported as moderate or severe by 67.2%. Pain was present in 65.6% and moderate or severe in 49.1%. Depression was reported by 55.7% and anxiety by 49.1% and moderate or severe in 49.2% and 39.3%, respectively. The majority (78.6%) of patients reported lack of well-being and feeling drowsy (70.5%). With respect to medication preferences, our cohort prefers Western Medicine (77.1%) over traditional curandero (22.9%) medicine and is agreeable (77.1%) to taking a few more medications if it meant all symptoms could be controlled. Our Latino cohort prefers (88.5%) to have their physical symptoms (e.g. pain, nausea) treated by nephrology staff.

Conclusions: Latinos with ESRD suffer from a debilitating symptom burden and over half of the symptoms are amenable to symptom directed therapy. Our findings support the early identification and treatment of physical symptoms by nephrology staff.

Care of the 'Failing HD Patient': Role of a Supportive Care Register Tracy Maryan, Maria Da Silva-Gane, Suresh Mathavakkannan. *Renal Unit, Lister Hospital, Stevenage, Hertfordshire, United Kingdom.*

Background: Older dialysis patients (>70) often have significant comorbidities, that worsen with duration on HD. Continuation of dialysis often occurs at the expense of frequent illness episodes. There is a progressive decline in cognitive and physical function that exacerbates dialysis. We had introduced a Supportive Care Register (SCR) in 2012 to identify 'failing dialysis patients' based on their physical performance scores. We attempted to understand whether being on the SCR enabled better patient care when these patients were admitted with inter-current illnesses.

Methods: Data was collected from Patient Administration System (PAS) and Renal IT database in a large Tertiary (non-transplanting) Renal Unit serving a catchment population of 1.2 million. Data maintained in the SCR was reviewed. Total number of HD patient admissions to the acute renal service in 2013 were obtained with analysis of demographics, length of stay (LoS) and outcomes at discharge. Patients who were admitted were checked against the SCR entries.

Results: 287 out of the 409 total HD patients were admitted (123 F, median age 68 years, 590 episodes) with 137 of these patients being admitted more than once. The LoS was 9 days. 49 patients died in 2013 (28M; 76±16 yr; vintage 60 m; LoS 18±12 $p<0.05$). 28 patients died in hospital or at home/hospice following withdrawal of dialysis and institution of palliative care. 16 patients had died following severe acute illness. Five patients died at home. 18/28 patients were on the SCR and had discussions relating to ongoing and future dialysis therapy and advanced and preferred place of care planning prior to their last admission in the clinic setting. Seven patients had proceeded to discussions regarding resuscitation.

Conclusions: In conclusion, establishment of a SCR for dialysis patients with declining functional capacity and significant comorbidities allows for an early identification of patients at risk of physical and functional decompensation. Once identified, establishing a dialogue in the OP dialysis setting about future care needs and expectations allows for a more integrated care approach when patients decompensate to the point of being unable to continue dialysis.

SA-PO787

A Descriptive Study of Home Palliative Service Utilization and Care Trajectory Among Patients Dying on Dialysis Gihad E. Nesrallah,[1] Stephanie Dixon,[2] Marnie MacKinnon,[3] Sarah E. Bota,[2] Jade S. Hayward,[2] Erin Arthurs,[2] Peter G. Blake,[3] Amit X. Garg,[2] Sara N. Davison.[5] *[1]Nephrology Program, Humber River Hospital, Toronto, ON, Canada; [2]Inst for Clinical Evaluative Sciences, London, ON, Canada; [3]Ontario Renal Network, Toronto, ON, Canada; [4]Ottawa Health Research Inst, Ottawa, ON, Canada; [5]Faculty of Medicine, Univ of Alberta, Edmonton, AB, Canada.*

Background: Palliative care service use and outcomes among Ontario's dialysis recipients remain uncharacterized.

Methods: We conducted a descriptive, retrospective, cohort study of 5,507 patients who died while receiving or withdrawing from chronic dialysis (hemodialysis or peritoneal dialysis) in Ontario, between January 1, 2010 and December 31, 2012. Data sources included the Ontario Renal Reporting System, the Canadian Organ Replacement Register, the Home Care database, and other linked administrative health datasets. The date of death served as the index date, and we examined patterns of service use in the prior 365 days. We present selected measures of health service use and outcomes.

Results: Cohort characteristics at death, expressed as median (IQR) or percent of cohort included: 75 (16) yrs old, 3.0 (5) yrs on dialysis, 42% female, 65% had diabetes, 14 (4) Johns Hopkins ACG (comorbidity score). Final dialysis modality was 85% centre HD, 1% home HD, 4% PD, 10% missing. During the last year of life, 11.3% received at least one palliative care service in the home, and 17.5% withdrew from dialysis in the last 30 days of life. In the last 14 days of life, 44% of patients had an emergency department (ED) visit and 36% had an ICU visit. ED and ICU visits were less frequent among patients who had received home palliative services in the last year of life. Place of death was ICU in 33%, and acute care hospital (without ICU) in 32%, while only 3.6% of patients died at home. Patients with home palliative care services in the last year of life had a greater frequency of death at home (15 vs. 2%) compared with those who did not.

Conclusions: Home palliative care services may not be used optimally by dialysis patients in Ontario. Further studies are needed to understand barriers to accessing palliative care services and to improve service planning and delivery.

SA-PO788

Ventilator Dependent Dialysis Patients Jack Rubin. *Los Amaeios.*

Background: We have started treating ventilator dependent patients at our dialysis unit and wish to share our results.

Methods: Chart review was done on all ventilator dependent patients treated at our unit.

Results: All data are shown mean ± sd. To date we have treated 19 patients (8F/11M) aged 71 ± 14 years with a mean time on dialysis of 90 ± 102 days. These patients were on dialysis prior to coming to us a mean 741 ± 1046 days. Seven were started within 2 months of their catastrophic event. Mean last available KT/V 1.5 ± 0.3, weight 152 ± 41 pounds, dialysis time 194 ± 21 minutes, bun 90 ± 20, creatinine 4.5 ± 1.5 Hemoglobin 9 ± 1 g%, albumin 3 ± 0.5 g%, pre-albumin 18 ± 9 mg%, calcium 9.2 ± 0.6 mg% and phosphorus 3.4 ± 1.3 mg%. Four patients were transferred a mean of 71 ± 54 days because of insurance issues. 7 are on dialysis 97 ± 137 days and 8 have died after 94 ± 95 days on dialysis. There were no apparent differences in the parameters listed above between those transferred for insurance reasons, those who died and those still receiving treatment. 7 patients were non communicative, 7 were diabetic, 2 had a fistula and the rest catheters, 3 had atrial fibrillation and all a history of hypertension and congestive heart failure. Deaths were caused by gastrointestinal bleeding (1) and sepsis (7).

Conclusions: These non verbal non communicative patients are receiving aggressive end-of-life care fostered in some cases by unrealistic family expectations and in other instances by state conservators who prefer treatment until death so that outpatient withdrawal of dialysis and comfort care is not a realistic option. There are two groups - vintage patients and new to dialysis patients with a catastrophic event. The goal should be to educate families on the consequences of dialysis for the patient so that they do not start or allow withdrawal of dialysis after a defined trial. Upon taking on treatment of this group of patients the dialysis unit should anticipate a lower star rating in the benchmarks as most are on catheters and are frequently admitted for infection, bedsores or pulmonary complications. To sustain these selected patients requires a dedicated staff of nurses, respiratory technicians and ambulance services.

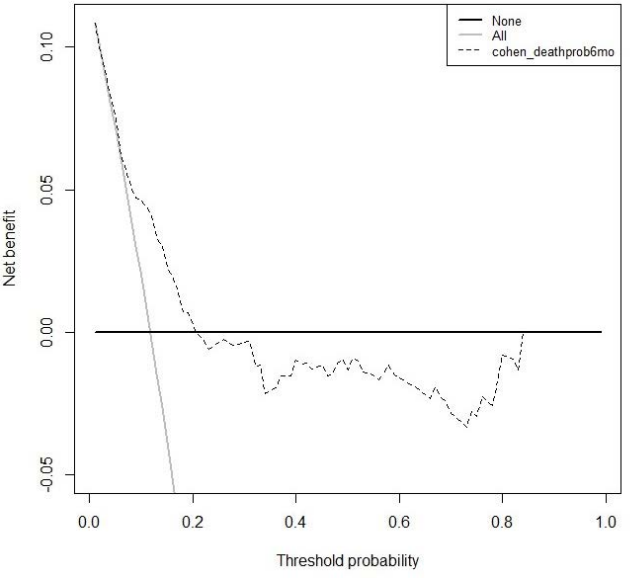
SA-PO789

External Validation of a Prediction Model for 6-Months Mortality Risk (MR) in Patients on Hemodialysis Adeera Levin,[1,2] Brian Forzley,[1] Helen Chiu,[2] Lee Er,[2] Ognjenka Djurdjev,[2] Mohamud A. Karim,[1] Rachel C. Carson,[1] Gaylene M. Hargrove,[1] Dan J. Martinusen.[3] *[1]Dept of Medicine, Faculty of Medicine, UBC; [2]BC Provincial Renal Agency; [3]Island Health Authority, BC, Canada.*

Background: End-Stage Renal Disease (ESRD) is associated with poor prognosis. Clinicians must be prepared to address end-of-life issues; hence, identifying patients at higher MR is recommended. We aimed to validate a 6-month MR prediction model for prevalent hemodialysis patients derived by Cohen et al. (2010) in a Canadian cohort and assess its clinical utility.

Methods: 375 prevalent dialysis patients in two regions of BC, Canada, were followed for 6 months. Data including serum albumin (ALB), age, peripheral vascular disease and dementia captured when the surprise question (SQ) was asked were used to validate the 6-month MR model. Model performance was evaluated through discrimination, calibration and decision-curve analysis.

Results: The observed mortality was 13.3% at 6-months. The model had reasonable discrimination (c-stat=0.70) but poor calibration (slope=0.46 [95% CI: 0.24, 0.69]) in our data. Decision curve showed added value of the model for threshold probabilities of 8%-20% (= 12-42% fewer false-positive death), but no more beneficial to "treat-all" for probability <8% and "treat-none" for probability >20%.



Exploratory analysis showed that only SQ (OR=2.3, 95% CI 1.05, 4.97) and ALB (OR=0.22, 95% CI 0.10, 0.46) were associated with 6-month MR. Simpler models appeared to perform equally well.

Conclusions: The existing prediction model by Cohen et al. has reasonable discrimination but over-estimated the number of deaths and may require recalibration of model coefficients. The model may guide advance care planning conversations, but caution is required when applying this model in clinical decisions. A simpler model may enhance feasibility for use. Further research is needed prior to utilizing the model to predict death.

SA-PO790

Identifying Advanced Chronic Kidney Disease Patients with Same Survival Under Conservative Care versus Dialysis Csaba P. Kovesdy,[1,2] Miklos Zsolt Molnar,[1] Jennie Jing,[3] Melissa Soohoo,[3] Jun Ling Lu,[1] Elani Streja,[3] Lawrence Agodoa,[4] Kevin C. Abbott,[4] Paul W. Eggers,[4] Kamyar Kalantar-Zadeh.[3] *[1]Univ of Tennessee Health Science Center, Memphis, TN; [2]VA Medical Center, Memphis, TN; [3]Univ of California, Irvine, CA; [4]NIH/NIDDK, Bethesda, MD.*

Background: It is unclear if dialysis offers advantages over conservative care in certain patients with advanced CKD who do not have rapidly deteriorating kidney function.

Methods: From 659,546 US veterans with CKD we identified 9,273 who transitioned to dialysis, and 6,136 who reached eGFR<15 ml/min1.73m^2, but did not start dialysis. We matched these groups for their eGFR slope and for the last eGFR prior to ESRD, and restricted analyses to patients with no rapid pre-ESRD progression (defined as a slope of -5 to <0) and pre-ESRD eGFR of 10 to 14.9. We examined all-cause mortality using time-stratified Cox models (by 1-year increments) to account for non-proportionality of hazards.

Results: Of 1,026 veterans included in the analysis, 651 patients did not, and 375 patients did initiate dialysis. Baseline age, gender, race, eGFR slope and last eGFR, and comorbidities were similar in the dialysis vs. no dialysis groups. Overall, 624 patients died over a median follow-up of 1.5 years. Patients on dialysis experienced lower mortality in the first year (HR, 95%CI: 0.25, 0.17-0.36, p<0.001) and in year 2 (0.67, 0.52-0.87, p=0.003). Among patients who survived at least 2 years (28% of the original cohort), the risk of death associated with dialysis was 28% higher but not statistically significant (1.28, 0.94-1.75, p=0.12) during the subsequent time period. In this latter group baseline slopes were flatter (-2.1(1.3) vs. -1.9(1.2)), but their other characteristics were similar to the overall cohort.

Conclusions: Among patients with eGFR 10-15 ml/min/1.73m^2 and no rapid loss of kidney function, transition to dialysis was associated with survival advantage over a two year time period. However, in 28% of the patients conservative management was not associated with worse mortality. Better characterization of patients who may benefit from conservative management warrants additional studies.

SA-PO791

Enteric Dialysis – Stabilization of the Gut Microbiome using Probiotics and Prebiotics (Gut-Kidney Connection) Natarajan Ranganathan,[1] Eli A. Friedman.[2] *[1]Research and Development, Kibow Biotech Inc, Newtown Square, PA; [2]Downstate Medical Center, State Univ of New York, Brooklyn, NY.*

Background: Recent scientific evidence from the human microbiome project has revealed that the trillions of gut microbiome exceed the human microbiome by a factor of 10. There are just 23,000 human genes as against the 3.3 million genes coded by the gut microbiome. This complex microbiome has a major role to play in health and diseases. Scientific evidence has shown that the imbalance in the ratio of this complex microbial community leads to dysbiosis a cause for various diseases. The use of beneficial microbes-probiotics and prebiotics is generally well recognized towards digestive, gut and immune health. However, novel and niche application of probiotics and prebiotics as a dietary supplement in stabilization of Gut Microbiome towards Chronic Kidney Disease (CKD) is relatively new. Many independent reviews in various scientific journals have reflected on various topics such as gut Microbiome, its dysbiosis, impact of the altered intestinal characteristics including small bowel bacterial overgrowth, newer uremic toxins, adsorbent drugs and several observational small scale clinical studies from Kibow and many others.

Methods: "Renadyl" a synbiotic dietary supplement was studied in randomized clinical trials in CKD 3 and 4 and ESRD patients. Other oral therapies for removal of uremic toxins include the use of keto acids and charcoal sorbents.

Results: Our studies using Renadyl for "Enteric Dialysis" showed reduction in levels of various uremic toxins like urea and indoxyl glucuronide. Levels of CRP also decreased with improved quality of life.This demonstrates the potential restoration of the gut microbiome dysbiosis with the use of specific strains of probiotics.

Conclusions: The use of a well-researched, clinically documented and safe probiotic/prebiotic dietary supplement formulation has the potential to safely perform continuous 24h/7d uremic toxin removal and thus stabilize the gut Microbiome and its dysbiosis. Hence, the concept of **"Enteric Dialysis"** with continuous removal of uremic toxins may be the future key to providing an alternative **HOPE** for renal failure population.

SA-PO792

Charcoal Hemoperfusion in the Treatment of Pruritus in Cholestatic Liver Disease Wonngarm Kittanamongkolchai, Ziad El-Zoghby, Nelson Leung. *Nephrology, Mayo Clinic, Rochester, MN.*

Background: Pruritus is a distressing symptom in a considerable proportion of cholestatic patients and few of them do not respond to conventional treatment. Charcoal hemoperfusion (CH) is an extracorporeal technique to eliminate albumin-bound substances that are accumulated during cholestasis by the passage of blood through a column containing activated charcoal. Several case reports have shown significant reduction of bilirubin in mechanical jaundice and neonatal hemolytic jaundice. However, the published data of CH for the treatment of resistant pruritus in cholestatic patients is scarce.

Methods: Procedure code "Charcoal hemoperfusion" was used to identify patients who received charcoal hemoperfusion at Mayo Clinic, Rochester from 1/1/2000 to 5/1/2015.

Results: Thirteen patients were identified. All patients had failed conservative treatment and 2 of them had not responded to plasmapheresis. A median of 5(1-9) sessions for a total of 20(1-33) hours were performed. CH resulted in a significant decrease of pruritus in 9 patients (69%). 2 patients did not have significant relief and 2 patients did not pursue further treatments after having adverse reaction during the first session. Median pruritic score significantly decreased from 9/10 (9-10) to 4/10 (0-9) posttreatment (p=0.004). Duration of symptom free period ranged from 8 to 46 days (median 18 days) in 6 patients who returned for follow up. 6 patients (46%) experienced adverse reactions described in Table 1.

Table 1.

Sex (M/F)	4/9
Age	53 (12-68)
Diagnosis	
Primary sclerosing cholangitis	5
Failed liver transplant	3
Primary biliary cirrhosis	1
Cirrhosis	2
Others	2
AST (U/L)	125 (47-267)
ALT (U/L)	121 (38-357)
ALP (U/L)	457 (126-1544)
Number of sessions	5 (1-9)
Total treatment hours	20 (1-33)
Duration of symptom free (days)	18 (8-46)
Complications	
Fever and rigor	2
Pain (head, chest, back)	4
Bleeding	2
Nausea	1
Hypotension	1
Lightheadedness	1

	Pre-treatment	Post-treatment	p-value
Pruritic score (0-10)	9 (9-10)	4 (0-9)	0.004
Total bilirubin (mg/dL)	2.9 (0.6-13.5)	2.9 (0.5-13.8)	0.3
Hemoglobin (g/dL)	11.5 (8.6-13.3)	11.1 (8.8-13.4)	0.3
Leukocyte (X10^9/L)	6.9 (2.2-18.3)	6.7 (1-16.4)	0.8
Platelet (X10^9/L)	237 (64-522)	148 (25-380)	0.004

*Data represented in median(min-max)

Conclusions: Charcoal hemoperfusion is an effective therapy for refractory cholestatic pruritus. However, the improvement is not sustainable and the short benefit should be balanced with the invasive nature of the therapy and the relatively common adverse reactions.

SA-PO793

Strict Adherence to Medicaid InterQual® Criteria Increases Adverse Events and Health Care Utilization in Undocumented Dialysis Patients S. Jawad Sher, Melissa D. Anderson, Ranjani N. Moorthi, Sharon M. Moe, Michael T. Eadon. *Medicine, Indiana Univ, Indianapolis, IN.*

Background: Current estimates suggest there are 6000 undocumented ESRD patients in the US that may be ineligible for scheduled hemodialysis. To meet emergency Medicaid requirements, hospitals have sought creative ways to treat undocumented patients. We present data from an undocumented cohort as it progressed through a succession of three periods with different dialysis criterion.

Methods: This is a retrospective evaluation of a prospective cohort of 20 undocumented ESRD patients. The patients were followed over 3 consecutive periods (P1, P2, P3) each of 2 months duration. In P1, patients received twice weekly dialysis. In P2, patients were dialyzed based on strict emergent InterQual® Criteria. In P3, emergent criteria included long interdialytic interval as an additional justification. Adverse outcomes, utilization, and dialysis adequacy in P2 and P3 were compared to P1.

Results: The mean age of the cohort was 35.9 y, 30% were female, 45% were employed, and none were US citizens. Emergent dialysis (P2&P3) was associated with increased biochemical abnormalities (peak K+, mean BUN and serum bicarbonate) as compared to P1 scheduled dialysis (P < 0.05). Emergent dialysis (P2&P3) was associated with an increase in nights hospitalized and ICU days (Fig1). Strict adherence to InterQual® Criteria (P2) was

associated with increased adverse events with a composite OR for intubation, bacteremia, NSTEMI, ICU admit, and death of 48 (5.9-391.2) compared to P1. P2 charge estimates increased from P1 ($357,501 v $202,326 per person per year, P<0.001).

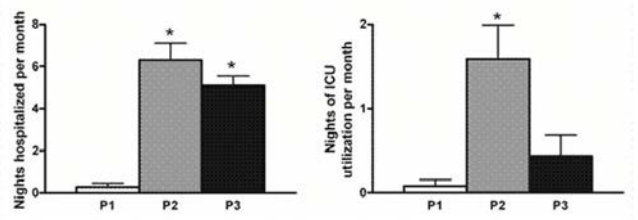

Fig. 1 – Hospital utilization per patient per month. * = P <0.05.

Conclusions: Strict adherence to InterQual® Criteria increases adverse events and healthcare cost per patient. We must determine better alternatives to emergent dialysis which minimize cost, while maintaining dignity, safety, and quality of life.

SA-PO794

Factors Associated with Withdrawal of Care (WOC) in Maintenance Dialysis Patients Fahad Saeed, Robert Butler, Jesse D. Schold. *Nephrology, Cleveland Clinic.*

Background: There is paucity of data on factors leading to WOC in dialysis patients. We studied this question by using the NIS dataset, 2005-2011.

Methods: We studied the following six major primary diagnoses: MI, cardiogenic shock, sepsis, stroke, CPR and coma. Effect of age, sex, race, hospitals' profit status and comorbidities were assessed on WOC status. We studied 836563 dialysis patients' admissions,and WOC occurred in 68152 patients.

Results: Male sex, African American and Latino races, smoking, obesity, psychosis and anemia carried lower odds of WOC. Primary diagnoses of CPR, coma, MI, cardiogenic shock, and sepsis; and co-morbidities such as CHF, dementia, HTN, CA, liver disease, paralysis, chronic lung disease,DM, weight loss were associated with higher odds of WOC. Odds of WOC were increased by approximately 6 % per year of patient age.Teaching hospitals had higher odds while private hospitals carried lower odds of WOC status.

Conclusions: Age, non-profit hospital status, coma, metastatic malignancy and weight loss are the most significant factors associated with WOC among dialysis patients. These prognostic data should be considered while treating such patients.

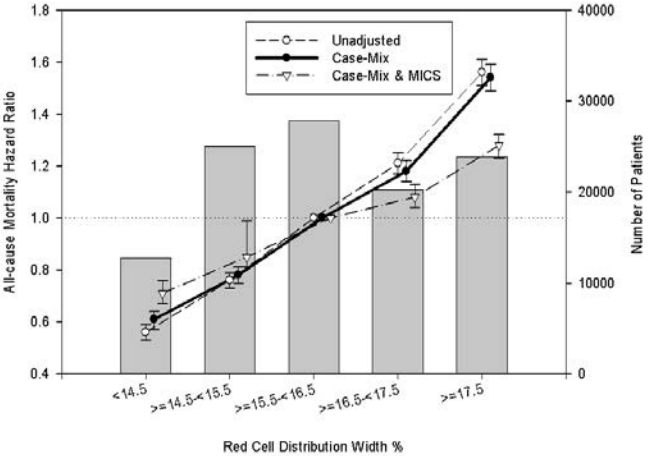
Red Cell Distribution Width and Mortalityin Incident Hemodialysis Patients Tania Vashistha,[1] Elani Streja,[1] Miklos Zsolt Molnar,[2] Connie Rhee,[1] Steven M. Brunelli,[3] Hamid Moradi,[1] Tae Hee Kim,[1] Vanessa A. Ravel,[1] Melissa Soohoo,[1] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]UTHSC; [3]DaVita Clinical Research.*

Background: Red cell distribution width (RDW) is a measure of red blood cell size and variability that is often used as an indicator of iron-deficiency anemia. Although RDW has recently been found to be associated with mortality in the general population, few studies have examined this association in hemodialysis (HD) patients.

Methods: We examined the association of RDW with all-cause mortality in a cohort of 109,675 incident HD patients from a large dialysis organization during 2007-2011 using Cox proportional hazards regression with adjustment for case-mix (demographics, comorbidities covariates) and markers of malnutrition and inflammation (MICS). RDW was divided into 5 categories <14.5, 14.5-<15.5, 15.5-<16.5, 16.5-<17.5, and ³17.5 %.

Results: The mean age (mean±SD) of the cohort was 63±15years old and included 44% females, 58% diabetics, and 31% African Americans. Higher baseline RDW was linearly associated with higher all-cause mortality risk in both unadjusted and fully adjusted models.



Conclusions: Higher RDW is associated with higher mortality risk in HD patients. It is unclear whether RDW is a risk factor for mortality or an epiphenomenon of underlying biological and metabolic imbalances across RDW categories. Further studies are needed to confirm the findings generated from our study and to determine the mechanisms underlying the RDW-mortality association.

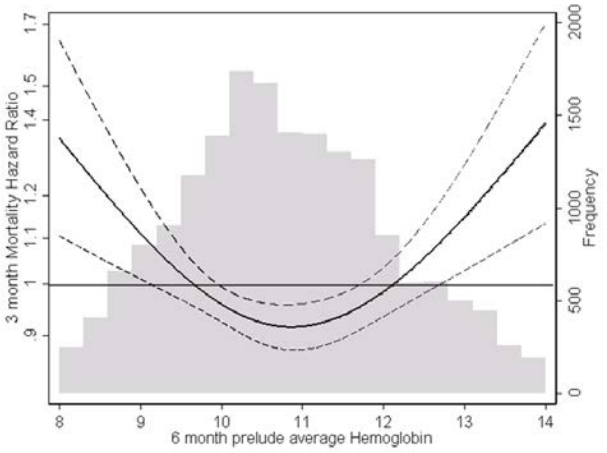
SA-PO796

Association of Pre-ESRD Hemoglobin with Early Post-ESRD Mortality Among U.S. Veterans: A Transition of Care in CKD Study Melissa Soohoo,[1] Connie Rhee,[1] Vanessa A. Ravel,[1] Elani Streja,[1] Jennie Jing,[1] Danh V. Nguyen,[1] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]UTHSC.*

Background: Patients with chronic kidney disease (CKD) are often afflicted with anemia. Previous studies have shown that low hemoglobin (HGB) is associated with pre-dialysis mortality in non-dialysis dependent CKD patients, yet the association of HGB levels in the immediate period preceding dialysis (prelude) and early post-dialysis mortality remains unknown. We hypothesized that lower HGB levels are associated with higher post-transition survival in comparison to higher HGB levels.

Methods: We investigated 18,555 US veterans who initiated dialysis between 10/2007-9/2011 and had at least 1 HGB measurement during the 6 month prelude period before dialysis transition. 6 month averaged HGB was used as a continuous predictor of early post dialysis all-cause mortality occurring in the first 3 months after initiation using restricted cubic spline models and Cox proportional hazard regressions. The models were adjusted for age, gender, race, ethnicity, region and primary cause of ESRD.

Results: The analytic cohort was a mean±SD age of 68±11 yrs, among whom 30% were African-American, 7% Hispanic and 50% had diabetes as the cause of ESRD. The 6 month prelude HGB average was 10.9±1.6 g/dL. Prelude HGB exhibited a U-shaped association with 3-month post-ESRD all-cause mortality; patients with a 6 month prelude HGB average between 10-11.5 g/dL had better survival, whereas patients with HGB measurements <9 g/dL or >13 g/dL had higher mortality (Figure).



Conclusions: HGB during the 6 month prelude period prior to dialysis initiation exhibited a U-shaped association with all-cause mortality in the immediate interval post-dialysis with the best survival when HGB was between 9 and 11 g/dL. These results confirm the findings of earlier clinical trials, and support current therapeutic paradigms for management of pre-ESRD anemia.

Higher Serum Ferritin Levels are Associated with Better Survival in the HEMO Study Anna Jeanette Jovanovich,[1,2] Eugene J. Nuccio,[2] Alfred K. Cheung,[3,4] Tom Greene,[4] Michel Chonchol.[2] *[1]Denver VA Medical Center; [2]Univ of Colorado Denver; [3]VA Salt Lake City; [4]Univ of Utah.*

Background: Ferritin is an important indicator of total body iron stores and has been shown to prevent ox-LDL-induced oxidative injury in endothelial cells. Studies regarding the relationship between serum ferritin levels and all-cause mortality in chronic hemodialysis patients are conflicting. The purpose of this study was to determine the relationship between higher serum ferritin levels and death among participants in the Effect of Dialysis and Membrane Flux in Maintenance Hemodialysis (HEMO) trial.

Methods: We studied the association of serum ferritin and iron levels with all-cause mortality among 1799 subjects from the HEMO trial. Cox regression models adjusted for important confounding variables including demographics, comorbidities, treatment assignment, smoking, and albumin.

Results: Mean age was 58±14 years, 56% were female, and 63% were black. Median (IQR) ferritin and iron levels were 249 (2-497) ng/mL and 50 (5-78) µg/dL, respectively. Over a mean follow-up of 2.84 years, there were 582 deaths. Among subjects with levels in the highest quartile compared to the lowest quartile, both ferritin and iron were significantly associated with reduced all-cause mortality in adjusted analyses, odds ratio (OR) 0.67 (95% CI, 0.46-0.97) and OR 0.60 (95% CI, 0.42-0.85), respectively.

Conclusions: Among subjects participating in the HEMO trial higher serum ferritin and iron levels were associated with reduced mortality. We hypothesize that ferritin may play an important role in protecting the endothelium from oxidative stress-induced damage.

Anemia in Chronic Kidney Disease Patients Could Be Linked to Indoxyl Sulfate Levels Denise Mafra,[1] Natalia Alvarenga Borges,[1] Milena Barcza Stockler-Pinto,[2] Amanda F. Barros.[2] *[1]Medical Sciences Graduate Program, Federal Univ Fluminense, Brazil; [2]Cardiovascular Sciences Graduate Program, Federal Univ Fluminense, Brazil.*

Background: Indoxyl sulfate (IS) is a uremic toxin derived from the action of colon bacteria in dietary tryptophan. This toxin is related to many complications for chronic kidney disease (CKD) patients, including anemia. The aim of this study was to verify the relationship between IS plasma levels and anemia in hemodialysis (HD) patients.

Methods: This transversal study included 18 HD patients (50% men, 54.2 ± 11.6 yrs, BMI 26.3 ± 4.7kg/m^2, time on dialysis 51 (30-52) months, all patients received the same dose erythropoietin per week). Routine laboratory parameters were measured, the total IS plasma levels were quantified with high-performance liquid chromatography (HPLC) and protein C reactive (CRP) levels analyzed by Immunoenzymatic Assay. Statistical analyzes were performed with SPSS version 19.0.

Results: The mean of hemoglobin was 11.0 ± 1.28 g/dL and hematocrit of 34.2 ± 3.0%. The mean of IS plasma levels was 23.9 (10.3 - 100.9) mg/L and CRP 3.1 (1.3 – 8.6) mg/dL. Multivariate linear regression analysis adjusted for age, sex, time on HD, albumin, BMI, CRP revealed that serum hemoglobin (β = -0.62; p = 0.01) was independently and negatively associated with IS levels.

Conclusions: This study provided evidence that IS seems be associate with anemia in HD patients and therapeutic strategies in the clinical care to reduce uremic toxins levels may be effective to management of anemia in HD patients.

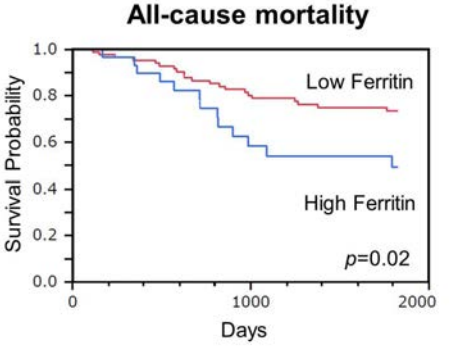
High Ferritin Level Above 100 Ng/Ml Is Associated with Poor Clinical Outcomes in Maintenance Hemodialysis Patients Raku Son,[1] Takuya Fujimaru,[2] Takeshi Kimura,[3] Masataka Hasegawa,[2] Yuki Heath,[2] Fumika Taki,[2] Miyuki Futatsuyama,[2] Masahiko Nagahama,[2] Yasuhiro Komatsu.[2] *[1]Internal Medicine, St. Luke's International Hospital, Tokyo, Japan; [2]Nephrology, St. Luke's International Hospital, Tokyo, Japan; [3]Center for Clinical Epidemiology, St. Luke's International Univ, Tokyo, Japan.*

Background: Ferritin is a well-known marker of iron deficiency anemia, but the target ferritin level in maintenance hemodialysis (MHD) patients still remains controversial among countries. This study is to examine the association of baseline ferritin level and clinical outcomes.

Methods: We retrospectively collected data of 116 patients on MHD at St Luke's International Hospital for 60 months. Ferritin level above 100 ng/ml was defined as high ferritin (HF) group and the rest as low ferritin (LF). The primary end point was all-cause mortality. The secondary endpoints included cardiovascular events and positive blood cultures. Cox proportional hazard analysis was performed as multivariate analysis.

Results: Of the 116 patients (age 65.3±13.4, 70% of males), 29 patients belonged to HF and 87 to LF. During the follow-up (median 60 months, IQR 24.1-60 months), 22 patients (18.9%, 13 in HF and 9 in LF) died. In Kaplan-Meier survival curves, HF showed significantly poor survival compared with LF (p= 0.02).



After adjusting age, sex, vintage of hemodialysis and past medical history of diabetes mellitus, hazard ratio (HR) of HF was 2.60 (95% confidence interval 1.25-5.24, p=0.01). The multivariate analysis for cardiovascular events revealed a similar result with statistical significance (HR 2.65, 95% confidence interval 1.07-6.31, p=0.04). For positive blood cultures, HR of HF was 1.81, although not statistically significant (p=0.17).

Conclusions: In MHD patients, ferritin level above 100 ng/ml increases all-cause mortality and cardiovascular events.

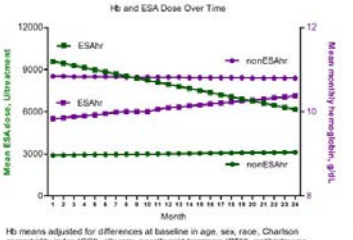
SA-PO800

Erythropoietin-Stimulating Agent (ESA) Hyporesponse (ESAhr) Is Associated with Persistently Elevated Mortality Among Hemodialysis (HD) Patients Jiacong Luo,[1] Donna E. Jensen,[1] Sarb Shergill,[2] Bradley J. Maroni,[2] Steven M. Brunelli.[1] *[1]DaVita Clinical Research, Minneapolis, MN; [2]Akebia Therapeutics, Cambridge, MA.*

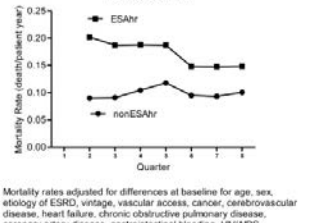
Background: Prior studies have examined the association between ESAhr and outcomes among HD patients. However, none has been conducted using contemporary data nor with a definition of ESAhr that is relevant in contemporary practice, specifically following 2011 changes to the US ESA labels and reimbursement policy.

Methods: We retrospectively studied a cohort of prevalent (vintage >6 months) HD patients from a single large provider (N=98,972) for 24 months (2012-2013). ESAhr was defined as 2 consecutive bimonthly hemoglobin (Hb) measures <10 g/dL with erythropoietin dose >7700 U/treatment. Patients were categorized as of 1Q2012 and followed longitudinally. Associations between ESAhr and mortality were determined using generalized estimating equations adjusting for baseline characteristics.

Results: At baseline, 12,361 (12.5%) patients qualified as having an ESAhr. Mean ESA dose was initially 3-fold greater in ESAhr than control patients and remained 2-fold greater by the end of study.



Hb means adjusted for differences at baseline in age, sex, race, Charlson comorbidity index (CCI), albumin, parathyroid hormone (PTH), antibiotic use, peripheral vascular disease, hypertension, HIV/AIDS, gastrointestinal bleed, coronary artery disease, chronic obstructive pulmonary disease, heart failure, cancer, vascular access, vintage, and etiology of ESRD. ESA means adjusted for differences at baseline for sex, age, race, etiology of ESRD, vintage, vascular access, cancer, PTH, albumin, and CCI.



Mortality rates adjusted for differences at baseline for age, sex, etiology of ESRD, vintage, vascular access, cancer, cerebrovascular disease, heart failure, chronic obstructive pulmonary disease, coronary artery disease, gastrointestinal bleeding, HIV/AIDS, peripheral vascular disease, IV antibiotic use, dry weight, ferritin, transferrin saturation percent, PTH, albumin, IV vitamin D utilization, and CCI.

Initially, mean Hb level was approximately 1 g/dL lower among ESAhr patients and remained 0.4 g/dL lower through the end of study. During follow-up, ESAhr was associated with a greater adjusted risk of mortality vs nonESAhr (control referent). Incidence rate ratios (95% confidence interval) ranged from 2.24 (1.93-2.60) in the 2nd quarter to 1.48 (1.18-1.84) in the 8th quarter.

Conclusions: Using a contemporarily relevant definition, ESAhr at a single point in time is potently and persistently associated with greater ESA utilization, lower Hb levels, and higher mortality risk.

SA-PO801

Impact of ESAs and Iron on Survival in Hemodialysis Patients: Which Is the Best, Which Is the Worth? Jacques B. Rottembourg,[1] Alain Guerin.[2] *[1]Dept of Nephrology, Hôpital de la Pitié, Paris, France; [2]Hemodialysis Units, Diaverum, Paris, France.*

Background: Appropriate anemia management for Hemodialysis (HD) patients (Pts) is still challenging. Intravenous (IV) iron and erythropoiesis-stimulating agents (ESAs) are the main thérapies, with conflicting outcomes. In the unit, pts were treated over the last seven years, cumulative doses of ESAs (darbepoetin alfa [DA]), converted in µg per session, and IV iron (iron-sucrose [IS]),converted in mg per session, were exactly constantly reported. Survival depending on the cumulative dose of each product and both products together was calculated using the Kaplan Meier methodology.

Methods: 300 incident HD pts (67% male) mean[M] (SD) age at start 59,7(16.3) years, were treated for 100,430 dialysis sessions [S], receiving all over 1,192,250 µg of DA, and 1,794,050 mg of IS. M Hb level was 11.55(0.77) g/dL, M TSAT 37.1(8.5)%, and M ferritin 562(322) µg/L. The M DA dose injected was 12.91(9.90) µg per S.The M IS dose injected was 20.91(11.57) mg per S.Expressing the separate doses of DA and IS received by the pts in three categories for each product, we obtained 9 categories of pts, depending on whether they received low, middle, or high doses of ESA and IS per S: M doses were [5.4(2.6), 10.8(3.3), 25.1(14.8)µg] for ESA, [12.5(4.5), 18.4(3.4), 32.3(11.9) mg] for IV iron respectively.

Results: Survival was expressed at 1000, 2000, and 3000 days (d):

	ESA-Low	p	ESA-Middle	p	ESA-High
Iron-Low	50 Pts 1000 d : 100% 2000 d : 96% 3000 d : 70%	P< 0.012	39 Pts 1000 d : 91% 2000 d : 74% 3000 d : 35%	P=NS	36 Pts 1000 d : 92% 2000 d : 61% 3000 d : 40%
	p=NS		p=NS		p=NS
Iron-Middle	39 Pts 1000 d : 100% 2000 d : 90% 3000 d : 77%	P< 0.001	49 Pts 1000 d : 96% 2000 d : 57% 3000 d : 24%	P = NS	31 Pts 1000 d : 88% 2000 d : 46% 3000 d : 33%
	p=NS		p< 0.05		p< 0.001
Iron-High	29 Pts 1000 d : 95% 2000 d : 79% 3000 d : 75%	P< 0.004	41 Pts 1000 d : 93% 2000 d : 10% 3000 d : 0%	P= NS	53 Pts 1000 d : 67% 2000 d : 31% 3000 d : 0%

The better survival was obtained in the group of low ESA and low IV iron, the worth was high ESA and high IV iron. Survival is better with low ESA, whatever is the IV iron dose injected. High ESA dose, whatever IV iron dose is injected, seems to be worth.

Conclusions: Because the majority of patients on HD receives ESA and IV iron, rigorously conducted and adequately powered clinical trials studying the cumulative doses of ESA and IV iron, reflective of present-day practice, are greatly needed.

SA-PO802

Relationship Between Statin Prescription and Erythropoietin Stimulating Agent (ESA) Hyporesponsiveness in Hemodialysis (HD) Patients: Results from the Japan Dialysis Outcomes and Practice Patterns Study (JDOPPS) Takeshi Hasegawa,[1,5] Junhui Zhao,[2] Douglas S. Fuller,[2] Brian Bieber,[2] Yun Li,[3] Jarcy Zee,[2] Hal Morgenstern,[3] Masaomi Nangaku,[4,5] Bruce M. Robinson,[2] Norio Hanafusa.[4,5] *[1]Fukushima Medical Univ Hospital, Fukushima City, Fukushima, Japan; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Univ of Michigan, Ann Arbor, MI; [4]The Univ of Tokyo, Tokyo, Japan; [5]Anemia Working Group of JDOPPS, Japan.*

Background: Statins are widely used in HD patients and have pleiotropic anti-inflammatory and anti-oxidative effects, but the latest guideline is advising against starting its use in this population. Hypothesizing that statins could be used as adjuvant treatment for renal anemia, we examined the association between statin prescription (Rx) and ESA hyporesponsiveness (ESAHYPO) in Japanese HD patients (pts) prescribed ESAs.

Methods: We included 3,208 pts in 178 HD facilities dialyzed 3x/week for ≥4 months from JDOPPS phases 3-5. Statin Rx was reported at baseline. ESAHYPO was defined in the next 4 months as a binary indicator (mean hemoglobin (hgb) <10 g/dL and mean ESA dose >7,500 units/wk) and separately as ESA resistance index (ERI, mean ESA dose/ [post-dialysis body weight*mean Hgb]). We used adjusted logistic and linear regressions to evaluate the associations.

Results: 16.1% of pts reported statin Rx at study entry; 8.8% were classified as ESAHYPO during follow-up. Compared to pts without statin Rx, pts with statin Rx had lower odds of ESAHYPO. Similarly, ERI was lower for statin Rx vs. no statin Rx (adjusted mean ratio [95%CI] = 0.93[0.88, 1.00] in model 3).

Table: Association of statin prescription with subsequent ESA hyporesponsiveness

			Odds Ratio of Hgb < 10, ESA > 7500 for Statin Users vs. Non-Users (95% CI)[a]		
Statin Rx	N Pts	N Events	Model 1[b]	Model 2[c]	Model 3[d]
+	516	35	0.71(0.49,1.02)	0.66(0.45,0.97)	0.70(0.47,1.03)
-	2692	246			

a. ESA and Hgb are averaged over the four months after baseline.
b. Model 1: Adjusted for DOPPS phase
c. Model 2: Adjusted for model 1 + age, gender, vintage, 11 summary comorbidities and post dialysis weight
d. Model 3: Adjusted for model 2 + Kt/V, treatment time, hospitalization within 3 months, IV iron prescription, CRP, albumin, TSAT, ferritin
A ratio of 1: 200 was used to convert darbepoetin to the equivalent epoetin dose.

Conclusions: Our results suggest that statins may reduce ESAHYPO in HD pts. Causal inference is limited by the observational design and unmeasured compliance with statin Rx. The applicability of this finding to non-Japanese populations merits further study, as reported statin Rx is low in JDOPPS.

25(OH)D Deficiency Contributes to the Erythropoietin Hyporesponsiveness in Patients on Maintenance Hemodialysis Pu Lei, Daqing Hong, Fei Deng, Li Wang. *Nephrology, Sichuan Academy of Medical Sciences & Sichuan Provincial People's Hospital, Chengdu, Sichuan, China.*

Background: The aim of this study was to identify the factors that contribute to erythropoietin hyporesponsiveness in patients on maintenance hemodialysis (MHD).

Methods: demographic data , hemoglobin, dose of erythropoetin, biochemical indicators and other related indicators of 80 MHD patients were collected and analyzed retrospectively. They were followed up for 12 moths. Erythropoietin resistance index (ERI) was used to evaluate the response to erythropoietin in patients on MHD.The ERI was calculated dividing the weekly weight-adjusted (kg) dose of ESA (IU) by the hemoglobin level (g/dL). Logistic regression study was used to determine the key variables which might be independently associated with erythropoietin hyporesponsiveness in MHD patients.

Results: Mean erythropoietin resistance index (ERI) for the entire study population was 16 U/kg/week/g/dl. 26% patients were erythropoietin hyporesponsive. Patients were divided into two groups according to ERI: ERI<25IU/week/kg/g/dl and ³25IU/week/kg/g/dl. In ERI³25 U/kg/week/g/dl cases, the proportion of female gender was higher, hemoglobin and 25(OH)D were significantly lower than that of patients with ERI<25 U/kg/week/g/dl. In addition, comparing with ERI<25 U/kg/week/g/dl patients, body mass index(BMI) and serum cholesterol were slightly lower in ERI³25 U/kg/week/g/dl patients(p=0.05). Logistic regression study adjusted gender, dialysis periods, BMI, Kt/v, serum cholesterol, serum albumin, and alkaline phosphatase, indicating an independent association between 25(OH) D deficiency and the erythropoietin hyporesponsiveness(HR:4.590, 95%CI:1.277~16.503).

Conclusions: Erythropoietin hyporesponsiveness is prevalent among MHD patients. Female gender and malnutrition are associateed with erythropoietin hyporesponsiveness. 25(OH)D deficiency is the main risk factor for erythropoietin hyporesponsiveness. Improving 25(OH)D deficiency and malnutrition may increase the response to erythropoietin treatment in MHD patients.

SA-PO804

Incidental Findings on 15 Fluorodeoxyglucose Positron Emission Tomography Along with Low Dose Computerized Tomography (FDG PET CT) Scans Among Clinically Stable Haemodialysis with Erythropoietin Stimulating Agent (ESA) Hypo Responsiveness (ESA-R) Tarun Kaushik, Stanley Fan, Neringa Vilimiene, Muhammad M. Yaqoob. *Nephrology (*Contributed equally), Barts Health Cardiovascular Biological Research Unit and Barts Health NHS Trust, United Kingdom.*

Background: Burden of comorbidities is high among hemodialysis (HD) patient. Underlying infective focus or occult malignancy is always of concern when clinically stable patients have ESA-R (ESA resistance index of ≥6.5 IU/kg body weight/Hb gm/dl per week).

Methods: Patients with similar characteristics were recruited as a part of an on-going clinical trial, which also included whole body FDG PET CT scan at baseline and at six month. Any clinically significant finding was reported to clinical team for further action. We were therefore in a unique position to report incidental findings in this cohort of patients.

Results: Out of total 111 scans 31% showed pathological tracer uptake including suspected malignancy. 2 patients with confirmed malignancy had to be suspended from on going living donor kidney transplant work up. 4 patients needed antibiotics and 1 had anti TB therapy. 7 patients needed appropriate invasive investigations for confirmatory diagnosis. There was no association between elevated CRP around time of scan and pathological tracer uptake (P=0.468)

Imaging	Initial	Follow up	Total
Number of scans	62	49	111
Pathological tracer uptake	20	15	35
Suspected malignancy	9	1 (new)	10
Lung nodule	0	1	
Inflammatory / infective lymphadenopathy	4	1 (old)	
Colonic polyp (non malignant)	1		
Infected renal cyst	1		
Infected sebaceous cyst	1		
Renal cell carcinoma	1		
Papillary carcinoma of thyroid	1		
Confirmed malignancy (new)	2	2 (old)	2
Pathological uptake (other)	11	11	22
Arthropathy	2	2	
Sialadenitis	2	1	
Access related infection	1	1	
Gastric mucosal uptake	2	3	
Lung changes	3	2	
Lymphadenopathy	0	1	
Other	1	1	

Conclusions: This observation confirms occult disease burden among this study group which otherwise would have been undetected and may have seriously impacted patient outcome. We recommend that HD patients with ESA-R should be regarded as high risk and further work is needed to devise easily accessible monitoring tools as part of their management.

SA-PO805

Serial Hepcidin Concentrations in Incident and Prevalent Hemodialysis Subjects Relating to ESA Response Michael E. Brier,[1] Michael Merchant,[1] Xiaolan Zhang,[2] Jonathan Himmelfarb,[3] Brad H. Rovin,[2] Jon B. Klein.[1,4] *[1]Medicine, Univ of Louisville, Louisville, KY; [2]Medicine, Ohio State Univ, Columbus, OH; [3]Medicine, Univ of Washington, Seattle, WA; [4]Robley Rex VA Medical Center, Louisville, KY.*

Background: Hepcidin is a key regulator of iron metabolism and alterations in levels may contribute to an apparent erythropoietin (EPO) resistance. The purpose of the current study was to determine the effect of incident vs. prevalent subjects on hepcidin concentrations at a single point in time and serially up to 6 months.

Methods: We collected blood for hepcidin measurement in 257 prevalent and 33 incident hemodialysis subjects from 2 locations (Louisville and Washington). Repeated blood samples were collected for up to 6 months in 66 prevalent and 33 incident subjects.A total of 752 hepcidin measurements were performed. Additionally we collected EPO dose, hemoglobin (HB), TSAT, and Ferritin. Hepcidin-25 peptide was measured by EIA (Bachem Group) and values are reported as ng/ml.

Results: Hepcidin concentrations in Incident subjects were higher (191±141) vs. Prevalent subjects (151±102, p=0.043) and in Females (n=93, 169±109) vs. Males (n=151, 140±97, p=0.015). There was no difference by Race p=0.948 (African American n=132, 150±106; Caucasian n=95, 151±101; Asian n=10, 154±78; Other n=7, 173±96). Forty five prevalent and 11 incident subjects did not require EPO (EPO naive) for anemia for 6 months prior to Hepcidin measurement. ANOVA of hepcidin by Incident (p=0.018) and EPO naive (p=0.006)showed significant differences (Incident EPO Naive 156±96; Incident EPO 206±161; Prevalent EPO Naive 97±86; Prevalent EPO 164±101). Hepcidin concentrations remained constant in Incident subjects for the first 6 months of dialysis (p=0.913). (Month 1-6; 190, 153, 180, 178, 176, 166).

Conclusions: Differences in Hepcidin concentration exist between Incident and Prevalent hemodialysis subjects as well as Males and Females. Increased Hepcidin concentrations in Incident subjects are maintained for at least the first 6 months in dialysis. Those subjects that are naive to EPO have the lowest Hepcidin concentrations and may provide evidence for the usefulness of Hepcidin as a therapeutic target.

SA-PO806

Female Gender Is Associated with Higher Degree of Erythropoietin Hyporesponsiveness in Maintenance Hemodialysis Patients Daqing Hong, Fei Deng, Li Wang. *Nephrology, Sichuan Academy of Medical Sciences & Sichuan Provincial People's Hospital, Chengdu, Sichuan, China.*

Background: To investigate the difference of erythropoietin hyporesponsiveness between female and male patients.

Methods: 310 MHD patients (163 male and 147 female) were enrolled with their demographic information, comorbities, erythropoietin dosage, hemoglobin, dry body weight, ferrtin and Kt/V collected between Jan, 2014 and Mar, 2014. ERI was calculated to study the response to erythropoietin treatment. Covariates were analyzed to compare the relationship between gender and erythropoietin hyporesponsiveness.

Results: The ERI index was higher in female patients than male patients(28.8±16.0 vs. 20.2±12.3 U/kg/week/g/dl, P<0.05) . Hb was lower and Kt/V was higher in female patients than in male patients(P<0.05). There were no difference in age, ferritin, and PTH between male and female patients(P<0.05). The mean dosage of erythropoietin was higher in female than in male patients(14934±6927U vs. 13353±7554U,P>0.05). Patients were divided into 3 groups according to the tertiles of ERI and no difference was found in PTH, ferritin, Kt/V and age among the three groups.

Conclusions: Female hemodialysis patients are associated with higher degree of erythropoietin hyporesponsiveness. Special attention must be paid to them when treatment strategy is made to treat anemia.

SA-PO807

Oral Vitamin C Supplementation Reduces Erythropoietin Requirement in Hemodialysis Patients with Functional Iron Deficiency Tanjim Sultana, Maria V. DeVita, Michael F. Michelis. *Medicine, Lenox Hill Hospital, New York, NY.*

Background: Functional iron deficiency (FID) is a major cause of erythropoietin (Epo) hyporesponsiveness and persistent anemia in dialysis patients. Vitamin C acts as a reducing agent and enhances mobilization of the ferrous form of iron to transferrin thus increasing its bioavailability. High dose intravenous vitamin C has been shown to decrease the Epo requirement and improve hemoglobin levels in previous studies.This route has its downside regarding difficulty of use, higher cost and associations with increased oxalate levels and inflammatory markers. Use of oral vitamin C has been limited due to the concerns of low bioavailability and patients compliance to medication. This study assessed the effect of low dose oral vitamin C on Epo dose requirements in stable hemodialysis patients with functional iron deficiency.

Methods: This prospective study included 22 stable hemodialysis patients with functional iron deficiency defined as transferrin saturation (Tsat) <30 % and ferritin levels of >100 mcg/L with Epo requirement of ≥ 4000 u/HD. Patients received oral vitamin C 250 mg daily for three months. Epo dose was adjusted according to unit protocol depending on the hemoglobin level. Hemoglobin, iron and Tsat levels were recorded monthly. None of these participants received iron or renal vitamin supplementation during the study period.

Results: The mean Epo dose was reduced in fifteen participants by 867±1356u/HD (p=0.03). In seven responders there was 33 % reduction in Epo dose from their base line. No ill effects of oral vitamin C were observed. Despite adjustment of Epo dose, hemoglobin level was significantly increased from 10.1± 0.6 mg/dL to10.7± 0.6 mg/dL (p=0.03).There were no significant change in Tsat and ferritin levels.

Conclusions: Daily low dose oral vitamin C supplementation reduced Epo dose requirements in hemodialysis patients with functional iron deficiency. Despite concerns regarding oral vitamin C absorption in dialysis patients this study indicates Vitamin C is well tolerated and effective.

SA-PO808

The Greatly Misunderstood Erythropoietin Resistance Index Yossi Chait,[1] Sahir Kalim,[3] Joseph Horowitz,[1] Christopher V. Hollot,[1] Elizabeth D. Ankers,[3] Michael J. Germain,[2] Ravi I. Thadhani.[3] *[1]UMass; [2]WNE Renal & Transplant Assoc; [3]MGH.*

Background: The use of erythropoiesis stimulating agents (ESAs) to treat anemia in end stage renal disease remains controversial due to reported associations with adverse events. Many studies introduce so-called ESA resistance indices (ERIs) to characterize a patient's resistance to ESA.

Methods: We use retrospective data from a cohort study of incident hemodialysis patients (n=8924). ERI is defined as average weekly erythropoietin (EPO) dose (IU) per kg body weight (EPOwt) per average hemoglobin (Hgb) (g/dl)) over a 3-month period. Linear regression was used to describe the relationship between ERI and EPOwt. Logistic (Cox proportional hazards) regression modelled the relationship between 1-year mortality (survival time) and albumin, age, and either ERI or EPOwt.

Results: ERIs were strongly linearly related with EPOwt (r=0.98) but weakly correlated with 1/Hgb (r=0.44). Associations between covariates and mortality based on two logistic regression models differing only by a single covariate, EPOwt or ERI, were almost identical (figure 1) ; the same was found for Cox proportional hazards models (Table 2).

Table 1: Logistic regression of death on covariates albumin, age, and X, where X = log(ERI) (Model A) or X = log(EPOwt) (Model B). OR: odds ratio, Sens: sensitivity, Spec: specificity.

	Model A		Model B	
	OR (95% CI)	P-value	OR (95% CI)	P-value
Albumin	0.320 (0.278-0.369)	< 2e-16	0.312 (0.270-0.359)	< 2e-16
Age	1.035 (1.029-1.040)	< 2e-16	1.034 (1.029-1.040)	< 2e-16
X	1.380 (1.239-1.536)	4.22e-09	1.330 (1.188-1.489)	7.2e-07
	AUC=0.72, Sens=0.65, Spec=0.67		AUC=0.72, Sens=0.64, Spec 0.68	

Table 2: Cox proportional hazard regression results with covariates albumin, age, and X = log(ERI) (Model A) or X = log(EPOwt) (Model B). HR: hazard ratio.

	Model A		Model B	
	HR (CI) (P-value)	P-value	HR (CI) (P-value)	P-value
Albumin	0.357 (0.317-0.403)	(< 2e-16	0.348 (0.309-0.392)	< 2e-16
Age	1.032 (1.027-1.037)	(< 2e-16)	1.032 (1.027-1.037)	< 2e-16
X	1.343(1.219-1.479)	2.17e-09	1.301 (1.175-1.441)	4.29e-07

The area under the ROC curve (AUC) was changed by <1% when covariates ERI or EPOwt were removed from the logistic regression model (AUC = 0.71, sensitivity = 0.66, specificity = 0.65.).

Conclusions: ERIs are strongly linearly related to weight-adjusted EPO doses by a "universal" (i.e., not patient specific) formula, hence are merely surrogates of EPO dose. Because true resistance must depend on both the input, (EPO) and its effect (Hgb increase over endogenous Hgb level), ERI appears to be a poor marker of resistance. EPO dose itself, even though a statistically significant covariate, does not substantially strengthen the association between mortality and albumin and age as assessed by logistic or Cox regression.

SA-PO809

Evaluation of Iron Deposition by MRI in the Heart and Liver in End Stage Renal Disease Patients on Hemodialysis

Rhea Bhargava,[1] Ibrahim Saeed,[3] Joseph S. Soltys,[4] Omkar U. Vaidya.[2] *[1]Dept of Internal Medicine, Univ of Missouri- Kansas City, Kansas City, MO; [2]Dept of Nephrology and Hypertension, Univ of Missouri- Kansas City, Kansas City, MO; [3]Dept of Cardiovascular Diseases, Mid America Heart Inst, Saint Luke's Hospital, Kansas City, MO; [4]Dept of Cardioascular Imaging, Cardiovascular Imaging Technologies, LLC, Kansas City, MO.*

Background: Anemia is highly prevalent in patients with chronic kidney disease and its management is one of the key components of treatment in this population. 2011 introduced the bundling system which led to increased use of parenteral iron to treat anemia in this population. There has been significant controversy regarding our current model of iron and whether this leads to iron overload and increased mortality.

Methods: Retrospective evaluation of patients with end-stage renal disease on hemodialysis who had a cardiac MRI for clinical reasons to evaluate for iron deposition in the heart and liver. Exclusion criteria: Porphyria cutanea tarda, chronic liver disease, hemochromatosis,sideroblastic anemia , thalassemia. Inclusion criteria:End stage renal disease and received a cardiac MRI after 3-5 years of hemodilaysis.

Results: Average total dose of venofer dose before cardiac MRI was 3500 mg. Average ferritin level :695 ng/ml. Average iron saturation : 34%. All patients receiving IV iron had hepatic iron deposition. No correlation was seen between ferritin or iron saturation and hepatic iron deposition. A weak relationship was noted between the total iron dose and hepatic iron deposition.

Conclusions: These data suggest that even though we still use iron markers like ferritin and iron saturation for treatment of anemia in ESRD patients,this may not have a correlation with iron deposition in the liver. Significant iron deposition was not noted in the myocardium. MRI can be a useful modality to evaluate iron overload in this population. Larger studies are needed to evaluate this issue and to formulate an ideal way of intravenous iron dosing in ESRD patient on hemodialysis.

SA-PO810

Achieved Iron Stores and Clinical Safety in a Trial of Ferric Citrate as a Phosphate Binder

Kausik Umanath,[1] Barbara A. Greco,[2] Molly Mcfadden,[3] Diana I. Jalal,[4] Sean D. Barry,[5] Simin Goral,[6] Mohammed Sika,[7] Robert M. Niecestro,[8] Mark Koury,[7] Julia Lewis,[7] Tom Greene,[3] Jamie P. Dwyer,[7] The Collaborative study group.[8] *[1]Henry Ford Hosp; [2]Baystate Med Ctr; [3]U of Utah; [4]U of Colo; [5]LSU Health; [6]U of PA; [7]Vanderbilt; [8]CSG.*

Background: Adequate Fe stores are needed for hematopoiesis in ESRD pts on ESA, but optimal Fe stores assuring efficacy/safety are unknown. PO Fe preparations have been unable to do this. In a multicenter phase 3 RCT we showed ferric citrate (FC) as a Phos binder ↑Fe stores and ↓IV iron/ESA use. We studied subjects' safety in this trial based on achieved Fe stores.

Methods: 441 subjects randomized 2:1 to FC or non-Fe-containing active control were followed for 52 wks. IV iron use was at a site's discretion while ferritin£1000 ng/mL and TSAT£30%. Serious adverse events (SAE), ferritin and TSAT were studied using time-dependent Cox regression, relating trailing 3-mo running means of ferritin/TSAT to subsequent SAE. 1° outcome was composite of CV, ID, GI and Hepatobiliary SAE. Clinical classes of ferritin/TSAT were used, adjusted for age, sex, black race, DKD and prior CVD.

Results: 437 subjects were analyzable. No baseline Δ among groups existed. TSAT 30-50% protected against future SAE, Table 1, but not so for any ferritin category, Table 2. Hazard ratio (HR) for 1° outcome per 10 unit Δ in TSAT was 0.81 (0.66-0.99, p=0.045) with adjustment for ferritin, and HR per 400 unit Δ in ferritin was 1.16 (0.9-1.48, p=0.23) with adjustment for TSAT. Sensitivity analyses, adjusted for baseline Alb and Phos, and introducing a 1-mo lag to address ?confounding by ferritin as acute phase reactant, showed no Δ in result.

Table 1. TSAT<30% is referent.

TSAT, %	HR	95% CI	p
30-50	0.56	0.37-0.86	0.007
>50	0.9	0.46-1.75	0.76
Adjusted for Ferritin			
30-50	0.58	0.37-0.88	0.012
>50	0.91	0.45-1.86	0.8

Table 2. Ferritin< 500 ng/mL is referent.

Ferritin, ng/mL	HR	95% CI	p
500-1000	0.8	0.52-1.23	0.3
>1000	0.85	0.47-1.55	0.6
Adjusted for TSAT			
500-1000	0.87	0.56-1.34	0.53
>1000	0.94	0.5-1.79	0.86

Conclusions: TSAT 30-50% appears to be protective vs <30%. No TSAT upper limit was evident. There were no SAEs at ferritin. Fe stores across the range studied did not risk at levels, and TSAT associated with ¯risk of ID, CV and GI SAEs.

SA-PO811

Paricalcitol, Klotho and Renal Anemia in Hemodialysis Patients

Miguel Uriol Rivera,[1] Sheila Cabello Pelegrin,[1] Gonzalo Gómez Marqués,[1] Manuel Luque-Ramírez.[2] *[1]Nephrology, Son Espases Univ Hospital, Palma de Mallorca, Islas Baleares, Spain; [2]Endocrinology, Ramón y Cajal Univ Hospital, Madrid, Spain.*

Background: Low Klotho levels, a protein linked to aging, is associated with an increase in the eryptosis process(programmed red-cell death). Chronic Kidney Disease is considered as a state of Klotho deficiency. We evaluate the association between plasma sKlotho levels with iron and hematologic parameters, and the influence of paricalcitol on their changes.

Methods: Data were obtained from the MIR-EPO study (EudraCT: 2009-015511-40). Chronic hemodialysis patients were stratified as a function of paricalcitol use(Group A) or not(Group B). Erythropoietin-stimulating agents (ESA) and iron supplementation were administered in order to maintain hemoglobin(Hb) between 10.5 and 12.0 g/dl and transferrin saturation(TSAT) ≥ 20%. After a 3-month titration period, sKlotho was measured(month 3 and 6 of follow-up) by ELISA. The changes in sKlotho from month 3 to 6 (Δ) and their associations with iron metabolism and hematologic parameters as a function of paricalcitol use were assessed.

Results: A total of 31 patients were evaluated(Group A: 23; Group B: 8). Intact parathyroid hormone(iPTH) levels and ESA doses did not change during the study. Mean sKlotho levels decreased at month 6 compared to month 3 in the whole group of patients(527 vs 474 pg/ml; P=0.001). After adjustment for iPTH and globular sedimentation rate, mean sKlotho levels in the Group A were higher than those observed in the Group B throughout the study(537 versus 401 pg/ml, P=0.005). Δ sKlotho correlated with Δ serum iron(r:0.42, P=0.020) in the Group A of patients. A cubic regression model showed that Δ sKlotho strongly explained Δ serum iron in these subjects(F:9.5, R^2:0.64, P=0.001). Δ sKlotho were also associated with changes in iron supplementation (r: -0.47, P = 0.030) in the Group A of patients. In the Group B, a direct correlation between Δ sKlotho and Δ red blood cell count was found (r: 0.73, P = 0.030).

Conclusions: Soluble Klotho is associated with iron metabolism in hemodialysis patients. Higher soluble Klotho levels may be a novel beneficial effect of paricalcitol use on renal anemia.

SA-PO812

Influence of the Paricalcitol on Iron Metabolism in Hemodialysis Patients

Miguel Uriol Rivera,[1] Juan Rey Valeriano,[1] Aina Obrador,[1] Manuel Luque-Ramírez.[2] *[1]Nephrology, Son Espases Univ Hospital, Palma de Mallorca, Islas Baleares, Spain; [2]Endocrinology, Ramón y Cajal Univ Hospital, Madrid.*

Background: Interleukin-6(IL-6) and hepcidin may play a role in the pathogenesis of iron functional deficiency(IFD). The influence of the Paricalcitol in IFD is not known.

Methods: Data were obtained from the MIR-EPO study(EudraCT:2009-015511-40). Chronic hemodialysis patients were stratified as a function of paricalcitol use(Group A) or not(Group B). Erythropoiesis-stimulating agents(ESA) and iron supplements were administered in order to maintain hemoglobin(Hb) between 10.5 and 12.0 g/dl and transferrin saturation (TSAT)³20%. After a 3-month titration period, plasma IL-6 and hepcidin were measured(month 3 and 6 of follow-up) by ELISA. The changes in IL-6 and hepcidin levels from month 3 to 6 (Δ) and their associations with iron metabolism and hematologic parameters as a function of paricalcitol use were assessed.

Results: A total of 31 patients were evaluated(Group A:23; Group B:8). Intact parathyroid hormone(iPTH) and ESA doses did not change throughout the study. We found no correlation between ΔIL-6 and ΔHepcidin(r:-0.10,P=0.640). However, ΔIL-6 correlated with DTSAT(r:-0.40,P=0.030). After adjustment for iPTH and globular sedimentation rate, mean IL-6 levels in Group A were lower than in Group B(8 versus 22 pg/ml,P=0.010). IL-6 levels decreased in the whole group of patients throughout the study, but these changes correlated with an increase in serum iron and TSAT only in the Group A. Hepcidin decreased in the whole group of patients throughout the study as well. Correlation between ΔHepcidin

and ΔHb(r:-0.49,P=0.010) was found in the whole group of patients. Interestingly, mean hepcidin levels were higher in Group A than in Group B(992 vs 494 pg/ml,P=0.050) during the study. In the Group A, ΔHepcidin correlated with ΔHb(r:-0.55,P=0.030).

Conclusions: IL-6 and hepcidin are likely related to different iron pools (functional and storage, respectively) since no correlations between their changes were found. Paricalcitol therapy showed an unexpected increase in iron availability for erythropoiesis that might be associated with changes in IL-6 and hepcidin levels.

SA-PO813

48 Week Open Label Safety Extension Study with Ferric Citrate Demonstrates Favorable Safety Profile in Subjects Not on Intravenous Iron: A Post-Hoc Analysis

Bryce Foote, Lisa Loram, Luke S. Acree, Adam Schayowitz. *Keryx Biopharmaceuticals, Boston, MA.*

Background: Ferric citrate (FC) is an iron-based phosphate binder approved for the control of serum phosphorus levels in patients with chronic kidney disease on dialysis. The Phase 3 pivotal trial in subjects with ESRD demonstrated FC to effectively control serum phosphorus but also significantly increased serum iron parameters. This 48 –week open label extension study to the Phase 3 pivotal trial was conducted to demonstrate long-term safety of ferric citrate. The primary data have been reported previously.

Methods: Subjects from the pivotal FC RCT (NCT01191255) who completed the active control period and, if eligible, the placebo control period were eligible to enroll in the safety extension trial. 79% had a time lag between participation in the RCT and this trial. The primary outcome was safety as assessed by lab data and adverse events (AE). 168 subjects enrolled. 166 received a dose of FC. The data presented are a post-hoc analysis of 98 of the 166 subjects that did not receive IV iron for the duration of the 48-week trial. Safety data regarding changes in serum iron parameters and treatment emergent AEs by system organ class are presented.

Results: Of the 98 subjects included in this analysis, 71 subjects were randomized to FC in the previous Phase 3 trial and 27 to the AC group. Table below shows the changes in TSAT and serum ferritin over the 48 wk period. Data presented as mean (SD).

Time (wk)	TSAT (%)	Serum ferritin (ng/mL)
0	34.5 (14.1)	772 (378)
12	37.9 (16)	891 (458)
24	38.1 (15.9)	904 (450)
36	41.7 (19.1)	961 (517)
48	40.9 (19)	872 (417)

83% of subjects experienced at least one treatment emergent adverse event with the most common being gastrointestinal disorders (40%) and infections and infestations (37%).

Conclusions: Subjects receiving ferric citrate and no IV iron demonstrated serum phosphorus control over the 48 wk study period, and an increase in TSAT and serum ferritin. The increase in TSAT did not exceed 45% in subjects receiving ferric citrate and no IV iron, which might suggest that ferric citrate is absorbed but the risk of excessive iron absorption is low.

SA-PO814

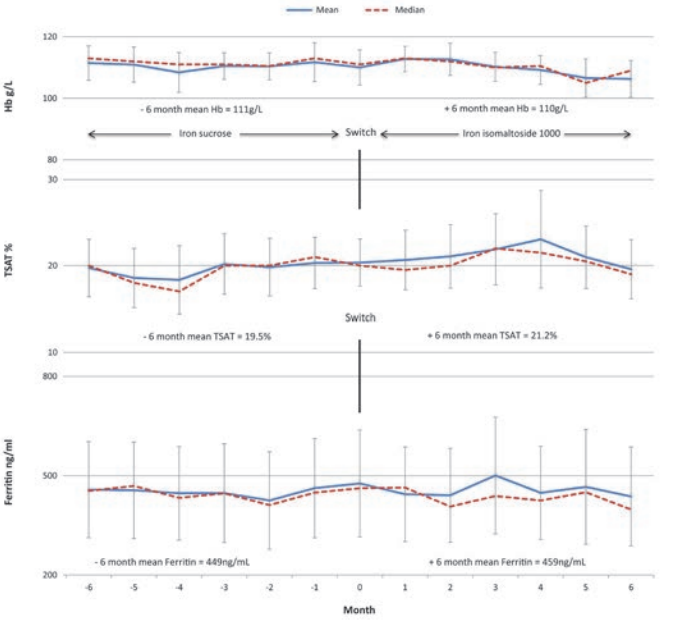
Iron Isomaltoside: A Novel Intravenous Iron Preparation for Hemodialysis

David Jackson, Christopher Brown, Grant Sugiura, Rachel S. Ashcroft, Ashraf I. Mikhail. *Nephrology, ABM Univ Health Board, United Kingdom.*

Background: Diafer® (iron isomaltoside) is newly licensed in Europe for iron deficiency anaemia in CKD patients on dialysis. It is thought the controlled-release matrix minimises free iron; possibly reducing side effects. Little is known about the efficacy & safety of Diafer in clinical practice. This study aims to assess the impact of this novel formulation on anemia parameters in prevalent hemodialysis (HD) patients previously maintained on iron sucrose.

Methods: Data was collected for 13 months; 6 month pre-switch (iron sucrose), 1 month crossover, & 6 month post-switch (iron isomaltoside). All patients received dialysis for ≥ 3 months before evaluation, excluding potential bias of iron loading doses. For both preparations, patients received intradialytic bolus doses of 100mg at frequencies dependant on individual requirements as per current practice.

Results:



n= 51 pts	Iron Sucrose		Switch	Iron Isomaltoside		Sig
Parameter	Mth -6 to -1		Mth 0	Mth +1 to +6		
	Mean	Median	Mean	Mean	Median	
Hb (g/l)	111	112	110	110	111	N
Ferritin (ng/ml)	449	447	477	459	435	N
TSAT (%)	19.5	19.0	20.4	21.2	20.0	Y
ESA (U/wk)	7868	6000	7980	7053	6000	Y
Iron (mg/mth)	202	200	186	168	200	Y
CRP (mg/l)	14	7	15	18	8	Y

The percentage of patients maitaining Hb target (100-120g/L) was 71% with iron sucrose & 70% with iron isomaltoside. No adverse drug reactions were observed. No metallic tastes were reported with Diafer administration. The CRP rise during months 1-6 was imparted by 2 infections & 1 amputation.

Conclusions: Iron isomaltoside maintains Hb stability & adequate iron status in HD patients when incorporated into current practice. While these data suggest Diafer may reduce ESA & iron requirements, further analyses are necessary to validate these findings. Whether the potential to reduce labile iron with iron isomaltoside impacts on clinical outcomes is yet to be determined.

SA-PO815

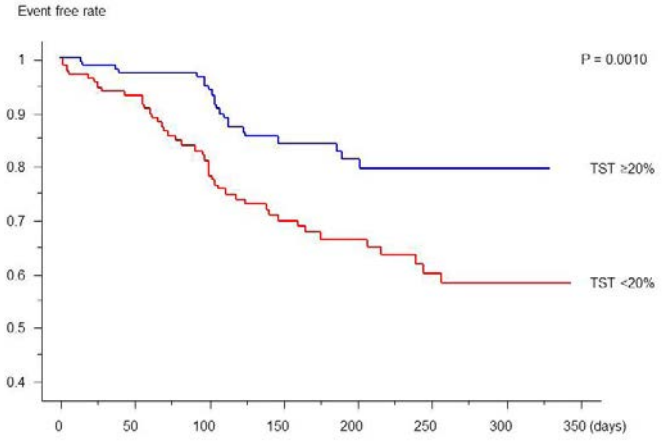
Low Iron Availability May Influence on Second Patency Rates of Vascular Access in Patients on Hemodialysis

Yukiko Hasuike, Wataru Fukao, Takeshi Nakanishi. *Div of Kidney and Dialysis, Dept of Internal Medicine, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan.*

Background: Vascular access (VA) is essential for the patients on HD. However, VA failure is often occurred even after percutaneous-transluminal angioplasty (PTA). Iron is important for normal vascular physiology, and insufficient iron availability can lead to various vascular dysfunction. The purpose of this study was to examine the factors affecting VA patency after PTA, including iron availability and oxidative stress.

Methods: Blood samples were taken from 281 HD patients at the PTA. Routine blood chemistries and factors related to iron metabolism (transferrin saturation rate (TST), ferritin), oxidative stress (advanced oxidation protein products (AOPP), 8OHdG, GSH/GSSG), and inflammation (high-sensitive CRP, interleukin-6, tumor necrosis factor-α, pentraxin-3) were measured. The end point of study was the re-vascularization or re-operation of VA during the observational period after PTA. Cox proportional hazards models for the end point was used.

Results: 133 patients (47.3%) had native arteriovenous fistula. During follow-up period, re-vascularization was performed in 34 patients and re-operation in 31 patients. The patients with VA failure had higher numbers of leukocytes and platelet, significantly lower TST, and a tendency of higher AOPP compared with the patients without VA failure. There was no significant difference in other factors between the patients with and without VA failure. The Kaplan-Meier analysis showed lower TST (‹20%) was associated with VA failure (p=0.0010, (figure 1)).



Cox regression analysis also revealed that lower TST (hazard ratio 2.316, 95% confidence interval 1.385-3.873, p=0.0014) was related to VA failure.

Conclusions: TST ‹20% was associated with the poorest event-free patency of VA after PTA. Low Iron availability might affect the second patency rates of VA.

SA-PO816

Triferic Has a Safety Profile Similar to Placebo: An Integrated Safety Analysis of Phase 2 and 3 Studies Vivian H. Lin, Raymond D. Pratt, Carrie D. Guss, Ajay Gupta. *R&D, Rockwell Medical Inc, Wixom, MI.*

Background: Triferic is a novel soluble iron compound delivered via the dialysate to prevent iron deficiency and maintain hemoglobin in CKD-HD patients.

Methods: The Triferic clinical program included 3 large placebo-controlled efficacy studies lasting 36 to 48 weeks (Controlled Studies), one large placebo-controlled short-term safety study, 3 open-label (OL) safety studies of up to 48 weeks, and 3 small controlled early Phase 2 studies. Patients randomized to Triferic in the 2 pivotal controlled studies who completed the randomized treatment and transitioned to the OL study received Triferic for up to 72 weeks.

Results: Exposure-adjusted most frequent adverse event rates (AE) are presented in the table below.

	Controlled Studies		All Studies
Adverse Events	**Triferic**	**Placebo**	**All Triferic**
Subjects (N) **PYE (Patient Year)** **Total TEAE (N)**	**346** **159** **2089**	**345** **161** **2081**	**1411** **780** **10766**
	Events/100 Patient-Years of Exposure		
Procedural hypotension	291.5	290.6	226.6
AVF Site Complication	35.3	39.1	39.7
Headache	34.6	21.1	33.2
Nausea	29.6	34.8	36.4
Dizziness	28.3	20.5	28.0
HD-induced Symptom	27.7	25.5	68.1
Cough	26.4	18.0	17.2
Diarrhea	25.8	31.1	33.0
Muscle Spasms	22.7	26.7	19.6

Discontinuations and exposure-adjusted AE were similar to placebo in the controlled studies with no increase in the OL studies. The exposure-adjusted mortality rate in the Controlled Triferic group was 7.9/100 PYE, compared to 7.2/100 PYE in placebo. The mortality rate in the All Triferic group was 6.5/100 PYE. No deaths occurred during Triferic administration and none were attributed to Triferic. There were no reports of anaphylaxis in over 100,000 individual doses of Triferic. Suspected hypersensitivity reactions, vascular access thrombotic events, composite cardiovascular events and systemic or serious infections were also similar between the Triferic and placebo groups.

Conclusions: Triferic was well tolerated in long-term controlled and OL studies. Triferic, administered at each treatment, maintained Hgb and iron balance compared to placebo. The safety profile in short and long-term studies supports a favorable benefit-risk profile for use as a maintenance iron therapy for CKD-HD patients.

SA-PO817

Structural, Physical and Functional Characterization of Ferric Pyrophosphate Citrate (FPC, Triferic), A Novel Iron Compound for Pharmaceutical Applications Ajay Gupta,[1] Garry J. Handelman,[2] Raymond D. Pratt.[1] *[1]R&D, Rockwell Medical Inc., Wixom, MI; [2]Univ Massachusetts, Lowell, MA.*

Background: Ferric pyrophosphate citrate (FPC) is the first iron compound approved for parenteral administration that is not an iron-carbohydrate complex. FPC has a molecular mass of about 1313 Da, and high solubility of FPC in aqueous solutions allows its administration via the dialysate.

Methods: FPC is a complex iron salt in which Fe^{3+} is bound to pyrophosphate (PPi) and citrate by coordinate covalent bonds. Extended X-ray absorption fine structure (EXAFS) spectroscopy showed that the Fe in FPC is in the ferric (Fe^{3+}) state and does not complex with sulfate. EXAFS analysis demonstrated that Fe forms a stable complex with 6 O atoms at 2.02 Å in the first coordination sphere and with 2 P and 4 C atoms at 3.22 Å and 2.98 Å, respectively, in the second coordination sphere. FPC demonstrates stability in both the solid and solution forms.

Results: The uptake rate of FPC iron by human apo-transferrin was measured *in vitro* by monitoring absorbance at 471 nm. At an identical set of conditions we observed 75% Tf saturation in <10, 15, and >9 x 10^4 sec for Fe(NTA), FPC and Fe(citrate), respectively. We conclude that Tf loading from FPC is rapid and of similar magnitude to that from ferric nitriloacetic acid, but over four orders of magnitude faster than from ferric citrate. The observed rapid binding kinetics allows for facile Fe^{3+} uptake by transferrin for transport to the bone marrow for hemoglobin synthesis. Pharmacokinetic studies of FPC administered IV to healthy volunteers demonstrate dose-proportional kinetics with a t½ of approximately 1.4 hours. No non-transferrin bound iron has been detected at TSAT levels of up to 100%.

Conclusions: FPC is a novel iron compound that is ideally suited as a maintenance treatment for CKD 5HD patients. FPC replaces ongoing iron losses and maintains hemoglobin. The small doses of iron and the lack of a carbohydrate shell contribute to the favorable safety profile. FPC represents a new paradigm for rational iron replacement in patients on chronic hemodialysis.

SA-PO818

Proton Pump Inhibitors and CYP2C19 Are Associated with Iron-Deficiency Anemia in Hemodialysis Patients: A Cross-Sectional Study Akio Nakashima,[1] Ichiro Ohkido,[1] Keitaro Yokoyama,[1] Mitsuyoshi Urashima,[2] Takashi Yokoo.[1] *[1]Div of Nephrology and Hypertension, Dept of Internal Medicine, Jikei Univ School of Medicine, Tokyo, Japan; [2]Div of Molecular Epidemiology, Jikei Univ School of Medicine, Tokyo, Japan.*

Background: Hyporesponsiveness to erythropoiesis stimulating agents (ESA) is an important phenomenon in dialysis patients. As chronic proton pump inhibitor (PPI) use reduces gastric acid secretion, it seems possible that chronic PPI use might lead to iron malabsorption and anemia. In addition, PPI is mainly metabolized by cytochrome P_{450} (CYP) enzymes, particularly CYP2C19, in the liver. The genotypes of CYP2C19 affect the pharmacokinetics and pharmacodynamics of PPI. However, there is no study investigating the relationship between PPI use and anemia status that includes the effect of CYP2C19 genotype in hemodialysis patients.

Methods: This cross-sectional cohort study analyzed 1350 hemodialysis patients. DNA was isolated from leukocytes in peripheral blood. We used polymerase chain reactions and direct sequencing to analyze CYP2C19 genotypes. We analyzed anemia status with and without PPI usage, including the association with CYP2C19 genotypes.

Results: PPI use was associated with a significantly lower mean serum hemoglobin concentration. Iron and TSAT were also lower in PPI users. ESA dosage was significantly higher in patients receiving PPIs(mean [SD] PPI: 3685 [3288] IU/week; non-PPI: 2899 [2734] IU/week; P<0.001), and multiple regression analysis indicated a significant relationship between PPI use and ESA dosage(β: 494.1 P=0.011). CYP2C19 genotypes were significantly associated with iron status and anemia. Multiple regression analysis demonstrated that CYP2C19 poor metabolizer (PM) type was significantly associated with ESA dosage in PPI users (β: 901.1 P=0.036).

Conclusions: In this study, we found that PPI use is associated with iron status and anemia in hemodialysis patients. Among the dialysis patients receiving PPIs, CYP2C19 genotype was associated with hemoglobin levels, ESA dosage, and iron status.

SA-PO819

A 4-Week Dose Response Study of the Hypoxia Inducible Factor-Prolyl Hydroxylase Inhibitor GSK1278863 in Japanese Anemic Hemodialysis Subjects Yukihiro Endo,[1] Tomoko Kohno,[1] Yukiko Imai,[1] Natsumi Kawase,[1] Katsutoshi Hara,[1] John J. Lepore,[2] Alexander Ralph Cobitz.[2] *[1]GlaxoSmithKline, Tokyo, Japan; [2]GlaxoSmithKline, King of Prussia, PA.*

Background: Hypoxia inducible factor (HIF)-prolyl hydroxylase inhibitors, such as GSK1278863, are an emerging class of oral agents for treatment of anemia associated with chronic kidney disease (CKD). Dose response of GSK1278863 for anemia correction in Japanese hemodialysis-dependent (HDD) subjects is reported.

Methods: We evaluated the relationship between GSK1278863 dose and hemoglobin (Hgb) response in Japanese HDD subjects with anemia of CKD in a 4-week, randomized, double-blind, placebo-controlled study (funded by GlaxoSmithKline). Subjects on thrice weekly hemodialysis for at least 8 weeks and with Hgb of 8.5-10.5 g/dL after stopping their

erythropoiesis stimulating agent for at least 2 weeks were randomized to placebo or to 4 mg, 6 mg, 8 mg or 10 mg of GSK1278863 once daily. The primary endpoint was Hgb change from baseline at Week 4. Other endpoints included circulating levels of erythropoietin (EPO), vascular endothelial growth factor (VEGF) and hepcidin.

Results: A total of 97 subjects were randomized, and 86 subjects completed the study. Mean Hgb at baseline ranged from 9.68 g/dL to 9.92 g/dL across the treatment groups. After 4-week treatment, GSK1278863 produced dose-dependent increases in mean Hgb from baseline (placebo: -1.41 g/dL; 4 mg: -0.28 g/dL; 6 mg: -0.01 g/dL; 8 mg: 0.54 g/dL; 10 mg: 0.97 g/dL). A posterior distribution from Bayesian four parameter Emax model estimated that 2.0 mg, 3.9 mg and 8.7 mg doses would, on average, lead to achieve placebo corrected increases in Hgb over 4 weeks of 0.5 g/dL, 1.0 g/dL and 2.0 g/dL, respectively. Dose-dependent increases in EPO and decreases in hepcidin were observed across the GSK1278863 groups, while no trends of increase in VEGF were observed in any groups. All AEs were reported as single instances in any treatment groups except nasopharyngitis, and no trends in AEs were noted. There were no deaths in the study.

Conclusions: This study demonstrated that GSK1278863 produced dose-dependent elevations in Hgb concentration in Japanese HDD subjects across the dose range tested.

SA-PO820

A Three-Year Study of an ESA Treatment Algorithm for Patients with Renal Anemia: Stable Hb Levels Obtained with Twice-Monthly Administration of CERA (Second Report)

Teruhiko Maeba, Shigeru Owada. *Internal Medicine, Asao Kidney Clinic, Kawasaki, Japan.*

Background: Treatment of renal anemia in hemodialysis(HD) patients requires an adequate ESA dosage to maintain stable Hb levels. Guidelines in Japan recommend determining ESA dosage based on Hb levels measured twice a month. An algorithm for the administration of continuous erythropoietin receptor activator (CERA) has been prepared and implemented to treat patients on HD. The 2-year study results were previously reported during the ASN Kidney Week 2014 (TH-PO 820).

Methods: Based on the algorithm, CERA was administered for 1 year to 102 HD patients being treated with rHuEPO. After the 1st year, the algorithm was reviewed, and some cases of fluctuating Hb levels because of terminating and restarting CERA administration were found. Therefore, the algorithm was revised. Consequently, CERA administration was continued for another 2 years. The target Hb level was 10.5–11.0 g/dl, and Hb levels, CERA dosage, Erythropoietin Resistance Index (ERI), and iron dosage were investigated. CERA was administered once every 2 weeks, and the dosages were changed within a range of 25 mg/dose based on Hb levels. The standard iron dosage was not changed during the evaluation period.

Results: Hb levels at the baseline and 1, 2, and 3 years after the baseline measurement were 10.9 and 11.1, 11.2, and 11.2 g/dl, respectively. The corresponding CERA dosages, administered every 2 weeks, were 62 ± 16, 38 ± 25 , 36 ± 23, and 33 ± 21 mg, respectively, and ERI values were 0.11 ± 0.04, 0.06 ± 0.05, 0.06 ± 0.04, and 0.06 ± 0.04, respectively. To reduce fluctuations in Hb levels to a possible extent, terminating CERA administration was avoided. Serum ferritin levels gradually decreased from 147.9 ± 122.1 at the baseline to 112 ± 95, 88 ± 67, and 67 ± 47 ng/ml in the 1st, 2nd and 3rd years, respectively, and weekly iron dosage decreased from 13± 1.5 at the baseline to 11 ± 2.6 and 11 ± 2.4 mg in the 2nd and 3rd years, respectively.

Conclusions: Three years of twice-monthly CERA administration, based on the algorithm, could maintain stable Hb levels, improve ERI, and reduce iron dosage. Twice-monthly CERA administration based on the algorithm effectively controlled anemia in HD patients.

SA-PO821

Continuous Erythropoiesis Receptor Activator (CERA) for the Anemia of Chronic Kidney Disease (CKD): A Meta-Analysis of Randomized Controlled Trials

Valeria M. Saglimbene,[1] Suetonia Palmer,[2,3] Giovanni F.M. Strippoli.[1,3] *[1]Diaverum Medical Scientific Office; [2]Univ of Otago Christchurch; [3]Cochrane Kidney and Transplant.*

Background: Targeting high hemoglobin levels with erythropoiesis-stimulating agents (ESA) leads to adverse effects in people with chronic kidney disease (CKD). Whether there are treatment differences between different ESA agents is uncertain.

Methods: We did a systematic review of randomized controlled trials evaluating treatment effects of CERA compared with other epoetins (darbepoetin alfa and epoetin alfa or beta) or placebo/no treatment, in people with any stage of CKD. We systematically searched Cochrane databases. Results were expressed as risk ratios (RR) and their 95% confidence intervals (CI) for dichotomous outcomes, and mean difference and 95% CI for continuous outcomes using random-effects meta-analysis.

Results: 17 studies involving 5397 participants were eligible. Studies compared CERA with epoetin (n=8 studies), darbepoetin (n=5), differing frequency (n=2) and dose (n=4). Compared to epoetin and darbepoetin CERA had similar effects on mortality, hypertension, need for blood transfusion and iron therapy.

Outcome	Relative Risk (95% CI)	
	CERA vs epoetin	CERA vs darbepoetin
Mortality	1.06 (0.72-1.55)	1.10 (0.73-1.65)
Hypertension	1.01 (0.86-1.18)	1.00 (0.73-1.36)
Need for blood transfusion	0.94 (0.68-1.30)	0.64 (0.30-1.37)
Iron therapy	1.03 (0.91-1.15)	0.99 (0.95-1.03)

In two studies of low-moderate risk of bias, CERA significantly improved quality of life as measured by SF36. Data were sparse for differing frequency of administration and dose. Evidence for treatment effects of CERA was absent among children and particularly limited for kidney transplant recipients. Studies included in this review were generally at high or unclear risk of bias.

Conclusions: There is no evidence that CERA has different effects on patients-centered outcomes compared to epoetin or darbepoetin among adults with CKD. CERA may improve health-related quality of life, but further high quality trials are needed. Its effects in children with CKD and kidney transplant recipients remains poorly understood.

SA-PO822

Risks of Long-Term Management for Anemia, Cardiovascular Disease (CVD) Death and Risk Factors for Heart Failure in Maintenance Hemodialysis

Hajime Hirano,[1] Haruhito Azuma,[1] Hideaki Shima.[2] *[1]Blood Purification Center, Osaka Medical Collage, Takatsuki, Japan; [2]Nephrology, Osaka Medical Collage, Takatsuki, Japan.*

Background: In this study, to evaluate the various outcome factors, the effects of improvement in anemia in patients treated with hemodialysis on the vital prognosis were evaluated focusing on changes after enrollment.

Methods: This retrospective study was conducted with 201 outpatients with hemodialysis at our Blood Purification Therapy Center and our other related hemodialysis facilities from March 2005 to February 2007 (24 months, 136 males and 65 females, age: male: 59.4 years old, female: 59.8 years old, overall: 59.5 years old). Using CVD death and hospitalization due to heart failure as outcomes, 2-year risk of CVD death was analyzed by logistic regression model with surviving patients. In addition, to assess anemia, changes over a long time after start of observation were evaluated.

Results: The multivariate analysis reveled 3 factors for CVD death risk including smoking history (OR: 9.06 [95%CI: 1.86~44.0, p=0.006]), history of ischemic heart disease (OR: 3.82 [95%CI: 1.19~12.25, p=0.024]) and hypercalcemia. (OR: 1.77 [95%CI: 1.00~3.13, p=0.049]). Similarly, the risk factors for heart failure were smoking (OR:3.11 [95%CI:0.78~12.36, p=0.101]) and history of ischemic heart disease (OR: 5.03 [95%CI: 1.46~17.33, p=0.010]), and history of ischemic heart disease was the only significant variable in the final step.

Conclusions: The factors that influence the risk of CVD death included smoking, history of ischemic heart disease and hypercalcemia. The risk factors occurring heart failure included history of IHD, and it was shown that the effects of smoking and history of IHD on prognosis were stronger than the effects of anemia. The evaluation of changes in Hb over time revealed that the low Hb sustained for a long time would increase the risk. In addition, the risk of death was high in the high-dose rHuEPO group suggesting the risk in the low rHuEPO response patients.

SA-PO823

Anemia Management in ESRD Patients Admitted to the Hospital

Priyanka Govindan, Arjun V. Sharma. *Dept of Nephrology, Univ of Washington Medical Center, Seattle, WA.*

Background: Anemia was twice as prevalent in people with CKD (15.4%) as in the general population (7.6%). The prevalence of anemia increased with stage of CKD, from 8.4% at stage 1 to 53.4% at stage 5. Anemia can be managed successfully with appropriate investigations and therapy in the ESRD population. The aim of the study was to see how appropriate the management of anemia was in our hospital in patients on dialysis and to identify areas for improvement.

Methods: Selected patients were those with ESRD on hemodialysis and peritoneal dialysis that underwent in- hospital dialysis at the University of Washington Medical Center from July 1st 2014 to Sep 30th 2014. The patients who had been undergoing dialysis for less than 12 weeks were considered to have AKI and were excluded from the analysis. In addition, the patients who underwent dialysis only in the Intensive Care units were excluded. The data was collected from the electronic medical records of the individual patient charts. Gender, Age, Anemia status, Lowest Hemoglobin , Iron panel, Reticulocyte count were noted in addition to treatment with iron, blood transfusions and ESA.

Results: A total 145 dialysis patients were identified and 65 of them had both ESRD and anemia. 73.86% of these patients were found to be anemic by KDIGO. Patients in the 60-69 age range had the largest number of anemia with a total of 20 falling in this category. 18 patients had a Hemoglobin between 7.0-7.9. Among the anemic patients 48.5% did not have an iron panel checked and 86.4% did not have a reticulocyte count checked. 40% of those with a Hb < 6 mg /dl had an iron panel checked. In patients with Hemoglobin of less than 11 31% were treated with ESA at least once during their hospital stay. 36.36% received transfusions. 50% of the patients who received blood transfusions did not have an iron panel.

Conclusions: Routine investigations for the management of anemia are being missed regularly. Worse anemia was associated with fewer investigations. We suspect that the management of anemia in patients with ESRD can be improved with more comprehensive labs and therapy. • We intend to follow up with an intervention involving the EMR making it easier to work up anemia in the hospital.

SA-PO824

Variability in Hemoglobin (Hb) Levels in Hemodialysis (HD) Patients in the Current Era David T. Gilbertson,[1] Yan Hu,[1] Yi Peng,[1] Sarb Shergill,[2] Bradley J. Maroni.[2] *[1]CDRG/MMRF; [2]Akebia Therapeutics, Inc.*

Background: Hb variability in dialysis patients has been characterized using a number of methods. The majority of this work occurred prior to the 2011 change in CMS reimbursement policy and ESA labels. We therefore examined Hb variability and patient demographics from current data and compared the results to those obtained prior to implementation of these policy changes.

Methods: We used CMS ESRD data to define a cohort of chronic HD patients who were alive from Apr 1 through Dec 31, 2012. Using a method from Ebben et al. (CJASN 1:1205-1210, 2006), monthly Hb values were categorized as low (L), intermediate (I), and high (H), where L and H were based on monthly Hb values below or above the 25th and 75th percentiles, respectively. Variability was then classified based on the Hb categories during a 6-month period, resulting in 6 categories of variability (see figure legend).

Results: The figure compares the percentage (%) of patients in each Hb variability group in 2004 compared to 2012. The 25th and 75th percentiles in the 2012 data were 10.2 and 11.5. Corresponding 2004 values were 11 and 12.5. Similar % of patients were observed in 2004 and 2012 for the LL and IH categories. A higher % of patients was consistently intermediate (II) in 2012 than 2004 (9.5% vs. 6.0%), whereas a larger % was observed for LI and a smaller % for LH. Compared to the overall 2012 cohort, II patients were older (mean=65.2), and LL or HH patients were younger (mean=58.2 and 57.8). LL had the highest % who were black (48.8%).

Conclusions: While Hb levels have decreased during the last few years, Hb variability is still present. The lower % of patients in the LH group is consistent with a narrowing of the overall Hb distribution. Further studies are needed to assess the association of variability with outcomes in the current era.

SA-PO825

Prevalence and Predictors of Naturally Occurring Normal Hemoglobin Concentration in Hemodialysis Patients Zakaria Abdulnabi, Veeda O. Landeras, Shalini Bumb, Abdulah Alrifai, Jay B. Wish, Peter B. De Oreo, Thomas H. Hostetter, Mirela A. Dobre. *Case Western Reserve Univ, Cleveland, OH.*

Background: Epidemiological data and clinical observations suggest that erythropoietin producing cells exist even in ESRD kidneys. A small subset of ESRD patients have naturally occurring normal hemoglobin levels, without the use of blood transfusions or erythropoietin stimulating agents (ESA), but limited data exists in this field. The aim of this study was to evaluate the prevalence and predictors of naturally occurring hemoglobin concentration ≥ 12 mg/dl in hemodialysis patients.

Methods: This analysis is a retrospective chart review of ESRD patients receiving hemodialysis at Centers for Dialysis Care in East Cleveland, OH, from April-September 2013. Data collected included demographics, cause of renal disease, co-morbidities, duration of ESRD, dialysis access, indices of dialysis adequacy, systolic blood pressure, hemoglobin level, PTH, albumin, calcium, phosphorus. Multivariable regression models were used to identify independent associations with the outcome of interest.

Results: In this cohort of 449 community dialysis patients, the prevalence of naturally occurring hemoglobin level ³12 mg/dL, without the use of ESA, was 5.3%, slightly higher than previous reports of around 2%. In unadjusted analyses, compared to ESRD patients with a hemoglobin level ³10 mg/dL maintained with the use of ESA, the patients with naturally occurring hemoglobin ³12 mg/dL were more likely to be younger, male, with an arteriovenous fistula, longer dialysis vintage, lower systolic blood pressure and higher serum albumin level. In adjusted analyses, male sex, serum albumin and systolic blood pressure remained statistically significantly associated with naturally occurring hemoglobin concentration ³12 mg/dL (OR 3.66(95%CI 1.11-12.06); 14.10(2.21– 90.11); and 0.98(0.96 – 0.99), respectively).

Conclusions: In this sample of community dialysis patients, male sex, serum albumin and systolic blood pressure were the strongest predictors of naturally occurring higher hemoglobin concentration. Further studies to evaluate the mechanisms underlying these associations, including factors stimulating sites of extrarenal erythropoiesis are warranted.

Estimation of Pre-Dialysis Hemoglobin Concentration Using the Crit-Line® Monitor Stephan Thijssen, Hanjie Zhang, Doris H. Fuertinger, Peter Kotanko. *Renal Research Inst, New York, NY.*

Background: Pre-dialysis laboratory measurements of hemoglobin (Hb) are generally used for anemia management. In some clinics, bi-weekly or even weekly Hb measurements are performed for this purpose. The Crit-Line® Monitor (CLM) provides Hb non-invasively and continuously during hemodialysis (HD), but initial readings early during HD are systematically lower than pre-HD laboratory values due to hemodilution caused by the priming fluid. We present a method of correcting CLM Hb for hemodilution.

Methods: Pre-HD reference Hb (Hb_Spec) was measured by Spectra East Laboratories. Hb obtained by CLM (Hb_CLM) was averaged between minutes 4 and 6 after start of the HD treatment. The difference between the two (Hb_Spec - Hb_CLM) was estimated as $\Delta Hb = (V\_sal * 0.5 \wedge (t\_CLM/t\_1/2\_sal) - V\_UF) * Hb\_CLM/BV$, with V_sal = amount of priming fluid (saline) infused at start of HD, t_crit = time point of Hb_CLM measurement (5 min into HD), t_1/2_sal = plasma half life of infused saline (20 min, adapted from ATC Consensus Statement, 2004), V_UF = cumulative ultrafiltration volume up until t_crit, and BV = pre-HD blood volume (obtained by estimating post-HD BV via Nadler equation (using post-HD weight, sex, height), then dividing by end-HD relative blood volume and subtracting V_sal). Corrected Hb_CLM was calculated as $Hb\_corr = Hb\_CLM + \Delta Hb$.

Results: 5,731 HD treatments from 952 chronic HD patients in the USA were analyzed. Without correction, Hb_CLM was found to be systematically lower than Hb_Spec by on average 0.425 g/dL (SD 0.59 g/dL). After correction for hemodilution, the difference (Hb_corr - Hb_Spec) was reduced to -0.068 g/dL (SD 0.59 g/dL).

Conclusions: When applying a correction for the hemodilution caused by infusion of the priming fluid at the start of HD, the corrected Crit-Line® Hb is nearly identical on average to the pre-HD Hb measured by a reference laboratory. More and more clinics are employing Crit-Line® Monitors for fluid and anemia management. Crit-Line® Hb corrected in this way may be used for anemia management, which could reduce blood draws and costs.

SA-PO827

Hemodialysis (HD) Patients Who Can Maintain Fair Hb Level (>10g/dl) without Iron or Erythropoietin (Epo) Administration Showed Higher Serum Soluble Transferrin Receptor(sTfR) and Normal Epo, Vitamin C (VC) Levels Noriko Saito,[1] Kazuhide Saito,[2] Tetsuo Morioka,[1] Hisaki Shimada,[1] Kozo Ikarashi,[1] Yutaka Tsubata,[1] Shunsuke Sakai,[1] Shigeru Miyazaki.[1] *[1]Nephrology, Shinraku-en Hospital, Niigata, Japan; [2]Urology, Niigata Univ, Niigata, Japan.*

Background: HD patients have severe anemia and their Hb levels were recommended to be maintained at greater than 10g/dl using iron and Epo supplementation. Certain HD patients showed Hb levels over 10g/dl without iron or Epo. This time, we studied erythropoiesis and iron metabolism markers in these patients in order to analyze the background mechanism.

Methods: 21 HD patients who could maintain Hb level at 10g/dl and greater without iron or Epo for more than 3 months(G1) were enrolled in this study. 23 HD patients with Hb level less than 10g/dl without iron or Epo for more than 2 months(G2) and 30 healthy volunteer(GN) were also enrolled as control. Blood samples were collected before HD and Epo, hepcidin(HPC), sTfR, VC and standard hematological parameters were examined. The data are indicated as median(interquartile range).

Results: 1. In G1, ferritin(20(14-36) ng/ml), transferrin saturation(14(8-19)%), HPC(0.7(0.2-4.5)ng/ml) were significantly lower than those in both GN and G2, respectively. The percentage of hypochromic RBCs(%HypoHe)(2.7(1.5-4.8)%) was higher than those of GN and G2. 2. MCV values were not significantly different in all three groups. 3. sTfR level, a marker of erythropoietic activity, of G1(30.0(22.1-36.5)nmol/L) was significantly higher than those of GN and G2. 4. Epo level(7.3(5.1-15.2)mIU/mL), reticulocytes(12(9-15)‰) and VC(6.8(2.8-23.4)μg/mL) of G1 were not significantly different from those of GN, whereas significantly higher than those of G2, respectively. 5. In G1, negative correlation was revealed between VC and %HypoHe($r = -0.437$, $p=0.048$), whereas positive correlation between %HypoHe and sTfR($r=0.816$, $p<0.001$). By multivariate analysis, %HypoHe was the predictor of sTfR($\beta=0.834$, $p<0.001$).

Conclusions: HD patients with fair Hb level revealed higher sTfR, %HypoHe and normal Epo, MCV, VC and low HPC levels. These results indicated that iron utilization of these patients was upregulated and this may participate in the maintenance of erythropoiesis.

SA-PO828

Acute Effects of Erythropoietin Administration on Blood Pressure in Dialysis Patients Nawf Hamad Al-Gublan, Kristin M. Corapi, Ishir Bhan. *Nephrology, Massachusetts General Hospital, Boston, MA.*

Background: Erythropoiesis-stimulating agent (ESA) doses are often held in patients with end stage renal disease (ESRD) because of hypertension. However, missed doses may exacerbate anemia of chronic disease. The acute effects of ESA on blood pressure are unknown. We hypothesized that ESA administration during dialysis would not be associated with a significant change in blood pressure.

Methods: With institutional review board approval, we retrospectively reviewed the medical records of 100 hemodialysis patients who were admitted to our hospital between 1/2013-4/2015. All patients in this study were prescribed, and received, ESA's during dialysis. Patients were excluded if dialyzed in the ICU, received vasopressors, were treated for hypertensive urgency (>180/110 mmHg), initiated on hemodialysis, or only underwent ultrafiltration without dialysis. Blood pressure just prior to and 2 hours after ESA were compared using a paired t-test.

Results: The mean age was 61.6 years (±12.8), 42% were male, 66% were Caucasian, 16% African-American, and 10% Asian. Mean change in blood pressures immediately prior to ESA administration and 2 hours after are summarized.

	Pre-Dialysis	Just Prior to ESA	2 Hours Post ESA	Mean Change (95% CI)	
SBP	136±25	132±27	128±25	-4.5 (1.74)	p=0.008
DBP	68±11	67±10	66±11	-1.2 (0.25)	p=0.18

No statistically significant increase in SBP or DBP was noted. In fact, we observed a significantly lower SBP 2 hours after ESA dosing. In a subgroup analysis of patients with an SBP > 160 immediately prior to ESA administration, an even greater decrease in SBP was noted 2 hours after ESA compared to a subgroup with an SBP < 160 (p=0.004). No significant relationship existed between dose of ESA and effect on blood pressure (SBP, p=0.52; DBP, p=0.95).

Conclusions: We demonstrated a decrease in systolic blood pressure 2 hours after ESA administration with no significant change in diastolic blood pressure. Withholding EPO during dialysis due to hypertension may be unnecessary.

SA-PO829

Serum Ferritin Predicts Mortality Regardless of Inflammatory and Nutritional Status in Incident Peritoneal Dialysis Patients Meiyan Wu,[1] Kyoung Sook Park,[2] Hyung Jung Oh,[2] Jung Tak Park,[2] Seung Hyeok Han,[2] Tae-Hyun Yoo,[2] Shin-Wook Kang.[1,2] *[1]Severance Biomedical Science Inst, Brain Korea 21 PLUS, Yonsei Univ College of Medicine, Seoul, Korea; [2]Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea.*

Background: Serum ferritin levels have been proposed as a prognostic factor in hemodialysis (HD) patients, due to its close relationship with inflammation and malnutrition. Since iron supplementation methods and factors affecting nutritional status are somewhat different from those of HD patients, the impact of serum ferritin on clinical outcomes was investigated in incident peritoneal dialysis (PD) patients.

Methods: A prospective cohort of 408 PD patients from the Clinical Research Center for End-Stage Renal Disease was selected. Patients were divided into three groups according to tertiles of Ln ferritin concentrations (group 1: <4.69 ng/mL, group 2: 4.69-5.58 ng/mL, group 3: >5.58 ng/mL). Cox proportional hazard analysis was performed to determine the independent prognostic value of serum ferritin levels for all-cause mortality.

Results: The mean age was 51.2±13.2 years and 236 (57.8%) were male. During a median follow-up of 25 months, 46 (11.3%) patients died. Univariate Cox analysis revealed that the mortality risk was significantly higher in group 2 [hazard ratio (HR)=2.65, 95% confidence interval (CI)=1.11-6.34, P= 0.029] and group 3 (HR=3.16, 95% CI=1.33-7.48, P=0.009) compared to group 1. Moreover, multivariate Cox proportional hazard models revealed that Ln ferritin was independently associated with an increased risk of all-cause mortality (per 1 ng/mL increase, HR=1.94, 95% CI=1.31-2.88, P=0.001), even after adjustment for variables representing inflammatory and nutritional status.

Conclusions: Higher serum ferritin level was a significant independent risk factor for all-cause mortality regardless of systemic inflammation and nutritional status. Therefore, determining serum ferritin levels could be a useful marker to predict clinical outcomes in incident PD patients.

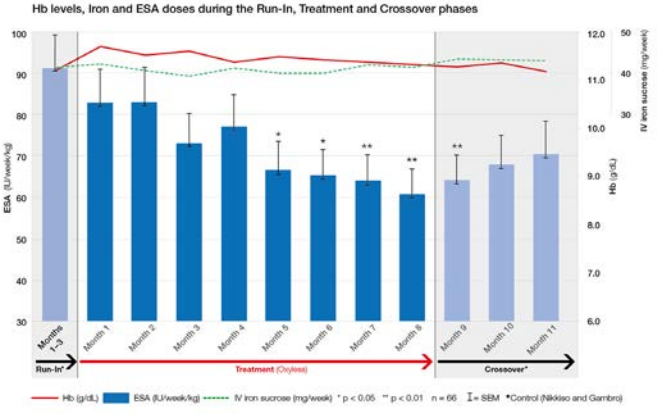
SA-PO830

Improving Anemia Therapy in Hemodialysis Patients: Interim Results of a Clinical Audit Iain C. Macdougall,[1] Antonio Sousa,[2] Carlos Andrade,[2] Erika Schümann,[3] Thomas Ryzlewicz,[4] Franz Ferdinand Becker,[4] Amelia Fairburn-Beech,[4] William Kilgallon.[4] *[1]Renal Unit, King's College Hospital, London, United Kingdom; [2]Fundação Renal Portuguesa, Portalegre, Portugal; [3]Via Medis, Riesa, Germany; [4]Oxyless Ltd, London, United Kingdom.*

Background: An earlier pilot audit (ASN 2013, PUB200) suggested that the use of a novel bloodline (Oxyless), which reduces the contact between blood and air, could improve the efficiency of Erythropoietin Stimulating Agent (ESA) therapy by prolonging red cell survival. The aim of this investigation was to explore this effect in a larger population.

Methods: Patients (n=110; >18 years, HD ≥ 3 months via AV fistulae) were entered into a 16-month open label, single crossover audit following a 3 month Run-In. Patients reverted to control bloodlines (Nikkiso/Gambro) in the Crossover phase after treatment with Oxyless. Hemoglobin (Hb) levels, IV iron sucrose and ESA doses were reported.

Results: Data analysis was conducted on 66 patients from two clinics. Twenty six patients dropped out due to transplantation and intercurrent events, death (n=14) and clinic transfers (n=4). Hb was maintained over the Treatment phase (11.22-11.34 g/dL). Mean ESA doses reduced by 34% (p<0.01) at month 8, equal to 1,909 IU/week/patient. IV iron dose did not change significantly during the audit.



Patients of a shorter dialysis vintage (<4 years, n=35) showed a greater reduction in ESA usage (-42%, p<0.01) compared with those of a longer vintage (>4 years, n=31, -23%). By month 11 (Crossover) ESA doses increased by 9.7 IU/week/kg; 32% of the reduction seen during Treatment.

Conclusions: The reduction in ESA doses observed during Treatment, and the initial reversal in the Crossover, suggest that this novel bloodline can improve anemia therapy in HD patients. The audit design increases the confidence in the data validity. These results could have clinical and financial benefits for HD service delivery.

First in Human Feasability Study Assessing the Tablo Hemodialysis System Luis E. Morales-Buenrostro,[1] Jose Antonio Nino-Cruz,[1] Javier Zúñiga-Varga,[1] Juan M. Ardavin Ituarte,[1] May L. Yau,[2] Luis Alvarez.[3] *[1]Dialysis Dept, Nefros Investigacion SC, Mexico City, DF, Mexico; [2]Outset Medical Inc, San Jose, CA; [3]Palo Alto Medical Foundation, Menlo Park, CA.*

Background: Self-care, at home or in-center, is a must for patients who want more independence and control, or have geographical or mobility constraints. Widespread adoption of this modality requires an easy to use dialysis machine with real-time water treatment capabilities. We conducted a first in human feasibility study to assess the safety and performance of the TABLO™ Hemodialysis System, that may meet these requirements.

Methods: We enrolled 5 patients receiving hemodialysis 3 times/week, with a well-functioning fistula or high-flow catheter. Primary outcomes of measure were Kt/V and adverse events.

Results: A total of 27 treatments in 5 patients were analyzed. Patients had the following characteristics: 40% female (n=2), mean age of 50 years, weighed 66 kg, height of 160 cm, 40% (n=2) fistula, 60% (n=3) high-flow catheter, average treatment time of 183 minutes, average fluid removal of 0.57 L, 80% (n=4)had an unknown etiology of ESRD, and 20% (n=1) had hypertension. Heparin was administered in 52% of treatments. The average single pool Kt/V was 1.4. One patient had only one treatment and was withdrawn from the study due to commute issues. Subjects were monitored during dialysis treatment by in-center staff, per institutional protocol. Only one interdialytic event, mild headache, was reported. In total, 3 subjects reported cramping (n=6/27 treatments) and 1 had hypotension (n=1/27 treatment). There were no unanticipated adverse events, serious adverse events or deaths in the study.

Conclusions: The TABLO™ Hemodialysis system was safe and showed good performance during treatments with shorter times, minimal fluid removal and heparin utilization. The standards of conventional dialysis were maintained without serious adverse events related to the device. The incorporation of an integrated water treatment module and touchscreen with animated step by step instructions was extremely easy to use. This system will allow self-care access, both in-center and at home, in a larger number of patients.

The Big Red Kidney Bus: Mobile Holiday Dialysis Peter G. Kerr,[1] Lesley Ross,[1] Jo M. Fairbairn,[2] Anne C. Wilson.[2] *[1]Nephrology, Monash Health, Clayton, Vic, Australia; [2]Kidney Health Australia, South Melbourne, Vic, Australia.*

Background: The availability of hospital based hemodialysis for those wishing to travel is scarce and often results in restricted opportunities for patients on dialysis to have a holiday. The Kidney Health Australia (KHA) and Monash Health (MH) Big Red Kidney Bus Project (BRKB) offers patients the ability to dialyse on the BRKB whilst on holiday at one of a range of Victorian tourist destinations.

Methods: The aim of the BRKB Project is to provide safe, fully staffed mobile haemodialysis care, to enable people, their families and carers to take a break. KHA owns the bus, manages the bookings and markets the BRKB nationally. MH, a regional health care provider oversees the clinical assessment and treatment and provides medical supervision, dialysis nurses and renal technicians.

The BRKB is a modified bus accommodating 3 hemodialysis machines, dialysis chairs and complete water treatment. Typically, holiday dialysis on the BRKB operates across 2 sessions per day, 6 days per week duplicating the dialysis parameters of the patients' home unit. The bus is driven to and parked at caravan parks around Victoria for 6-week periods, during which time patients may book in for dialysis sessions. Their accommodation is up to them to decide on – with the option of using cabins in the parks or local motels (or their own caravans).

Results: Since its inaugural visit in October 2014, 148 different patients have taken advantage of the BRKB. The bus has visited 6 sites around the State and has site bookings for the next 10 months. Participating holidaymakers were overwhelmingly positive about the service. They found the booking system easy to use. The dialysis service on the bus was delivered to the standard of care experienced at their home units. The professionalism of the nursing staff and friendliness was commended and all participants would recommend the service to others in need of hemodialysis. Most had actively recommended the service to others.

Conclusions: The BRKB is a unique project that provides patients with the opportunity to dialyse on the bus while taking a much-needed holiday.

Patient and Caregiver Values, Beliefs and Experiences when Considering Home Dialysis as a Treatment Option: A Semi-Structured Interview Study Rachael C. Walker,[1] Kirsten Howard,[4] Rachael L. Morton,[1] Suetonia Palmer,[2] Mark R. Marshall,[3] Allison Tong.[1] *[1]Univ of Sydney; [2]Univ of Otago; [3]Middlemore Hospital, New Zealand; [4]Univ of South Australia.*

Background: Home dialysis is associated with higher quality of life and economic benefits to health care systems compared with facility dialysis. However, little is known about the decision-making process of patients when considering home dialysis as a treatment option.

Methods: This semi-structured interview study aimed to describe patient and caregiver values, beliefs and experiences when considering home dialysis, to inform policy and practice strategies that align with patient preferences. We conducted semi-structured interviews with adults with CKD Stage 4-5D (on dialysis <1 year) and their caregivers, treated in 3 nephrology centers in New Zealand. Transcripts were analyzed thematically.

Results: 43 patients (18 pre-dialysis, 13 peritoneal dialysis, 4 home hemodialysis and 9 facility hemodialysis) and 9 caregivers participated. We identified 5 themes related to decision-making when considering home dialysis; lacking decisional power (complexity of information, limited exposure to home dialysis, feeling disempowered, deprived of choice, pressure to choose); sustaining relationships (maintaining cultural involvement, family influence, trusting clinicians, minimizing social isolation); reducing lifestyle disruption (sustaining employment, avoiding relocation, considering additional expenses, seeking flexible schedules, creating free time); gaining confidence in choice (guarantee of safety, depending on professional certainty, reassurance of peers, overcoming fears); and maximizing survival.

Conclusions: Patients feel disempowered when choosing home dialysis and make decisions that sustain their relationships, maintain lifestyle values and maximize survival. Confidence in their modality decision is gained by medical professional and peer support combined with overcoming safety concerns. Pre-dialysis programs that address these patient experiences may support home dialysis as a treatment option.

Patient Experiences of Training and Transition to Home Hemodialysis: A Longitudinal Mixed Methods Study Camilla Sara Hanson,[1,2] Jeremy R. Chapman,[3] Jonathan C. Craig,[1,2] David C. Harris,[3,4] Lukas K. Kairaitis,[4] Mary ann Nicdao,[4] Mary Mikaheal,[4] Allison Tong.[1,2] *[1]School of Public Health, The Univ of Sydney, Sydney, NSW, Australia; [2]Centre for Kidney Research, The Children's Hospital at Westmead, Sydney, NSW, Australia; [3]Centre for Transplant and Renal Research, Westmead Hospital, Sydney, NSW, Australia; [4]Dept of Renal Medicine, Westmead Hospital, Sydney, NSW, Australia.*

Background: Home hemodialysis (HD) can offer better survival and quality of life outcomes compared with in-centre HD. However, psychosocial barriers such as fears of needles and medical isolation may limit home HD uptake. This study aims to describe patients' perspectives on training and transition to home HD; to inform strategies to optimize home HD programs.

Methods: Three semi-structured interviews were conducted prospectively with 20 patients before, during and after home HD training at an Australian renal unit. The CHOICE satisfaction survey was administered during the first and final interview. Transcripts were analyzed thematically.

Results: We identified six themes: persevering despite trepidations (intimidation of machinery, acquiescing to fatal risks, reconciling cannulation fears, dispelling concerns of neglect, tolerating concessions); optimizing learning pathway (practicing problem solving, learning from mistakes, grasping technical complexity, minimizing cognitive overload); developing confidence (believing in own abilities, depending on caregiver partnership, faith in crisis support); interrupted transition momentum (lacking individual attention, language barriers, installation delays, illness and complications, acclimatizing to new conditions); noticing immediate gains (reclaiming normality, satisfying self-sufficiency, personalizing treatment regime); depleting resources and energy (exhaustion, draining financial reserves, imposing caregiver burden). There was no significant change in satisfaction with care after commencing home HD.

Conclusions: Individualized home HD training fosters confidence and competency in patients; however patients may face anxiety and exhaustion with medical responsibilities. Ensuring access to respite, medical assistance, and psychosocial support may alleviate treatment burdens for patients commencing home HD.

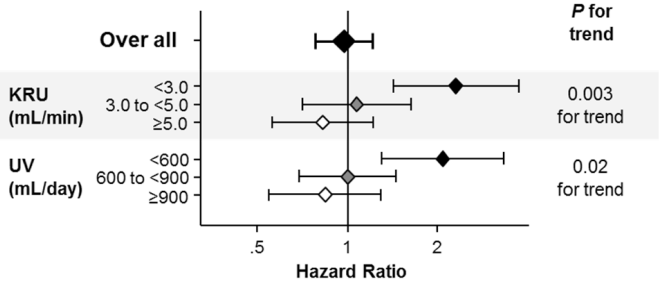
SA-PO835

Incremental Hemodialysis, Residual Kidney Function, and Mortality Risk in Incident Hemodialysis Patients Yoshitsugu Obi,[1] Elani Streja,[1] Connie Rhee,[1] Vanessa A. Ravel,[1] Alpesh Amin,[1] Csaba P. Kovesdy,[2] Rajnish Mehrotra,[3] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]UTHSC; [3]UW.*

Background: We have previously reported that an incremental hemodialysis regimen (e.g., dialysis initiation at twice weekly) was associated with more preserved residual kidney function over a year of dialysis therapy (WCN 2015, Cape Town). Here, we compared survival between the incremental vs. conventional regimen.

Methods: In a longitudinal cohort of 33,277 patients who initiated maintenance hemodialysis over four years (1/2007-12/2010) and survived the first year, 364 patients treated with the incremental regimen were matched to 4,797 patients treated with the conventional regimen on age, gender, race, the use of central venous catheter as blood access, and a history of congestive heart failure at the initiation of dialysis. The incremental hemodialysis regimen was associated with ≃20% higher residual renal urea clearance (KRU) and 24-hr urine volume (UV) after 1 year of dialysis initiation. We then examined survival after the first year.

Results: Patients were 69±12 years old, 39% female, 13% non-Hispanic Black, and 64% diabetic. Median KRU and UV were 4.74 (IQR, 3.23-6.65) mL/min/1.73m^2 and 1,150 (IQR, 800-1,650) mL/day, respectively. Baseline KRU and UV modified the association between the incremental regimen and mortality; the incremental regimen was associated with higher mortality in patients with KRU <3.0 mL/min/1.73m^2 or UV <600 mL/day, but not in those with higher levels of KRU and UV.



Conclusions: Among incident hemodialysis patients with substantial RKF, incremental hemodialysis may be a safe transitioning regimen associated with greater preservation of RKF, whereas in patients without substantial RKF it should be avoided.

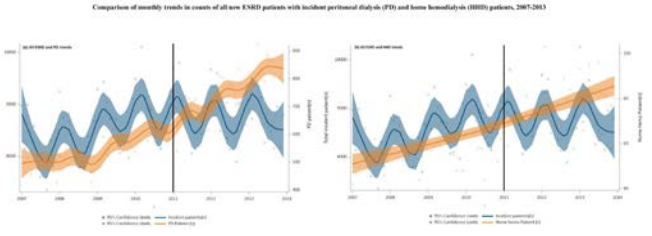
Seasonal Trends in Dialysis Initiation and Rising Home Dialysis: Results from the USRDS Hui Liu,[1] Yang Jiao,[2] Douglas Lehmann,[2] Richard Hirth,[3] Yi Li,[2] Rajiv Saran.[1] *[1]Dept of Internal Medicine, Univ of Michigan, Ann Arbor, MI; [2]Dept of Biostatistics, Univ of Michigan, Ann Arbor, MI; [3]Dept of Health Management and Policy, Univ of Michigan, Ann Arbor, MI.*

Background: Motivated by increasing interest in home dialysis and incentive for it in the bundled payment system, we examined incident trends in home dialysis use in the United States Renal Data System (USRDS).

Methods: Using USRDS data (2007-2013), monthly counts of all new ESRD cases in the US, as well as incident home hemodialysis (HHD) and incident peritoneal dialysis (PD) patients were tracked. Incident HHD patients were those who started HHD within 90 days of entry into an ESRD program and incident PD patients those who started PD as their initial modality.

Results: In 2013, over 55% of US facilities offered only in-center HD, 24.7% both HD and PD and 13.5% offered HD, PD and HHD. Figure 1 shows trends in monthly ESRD and PD utilization in the US during 2007-2013. The incidence rate of ESRD has been stable since 2010, but the number of new PD starts has risen steadily since 2009 and has somewhat further accelerated since 2011. Figure 1 also shows a seasonal trend for new ESRD and PD starts: incident ESRD cases tend to peak in the first 3 months of the year, while new PD starts tend to peak by mid-year. Rising HHD use is evident since 2007, without seasonal variation. A substantial variation in the annual growth rate of PD is notable across the states.



Conclusions: We report steadily rising home dialysis use in the US, both HHD and PD, since 2007 and 2009, respectively. This rise predates the implementation of the bundled payment system in 2011, although PD use seems to be rising faster since 2011. Research into this seasonality in ESRD incidence and the impact of rising home dialysis use are warranted.

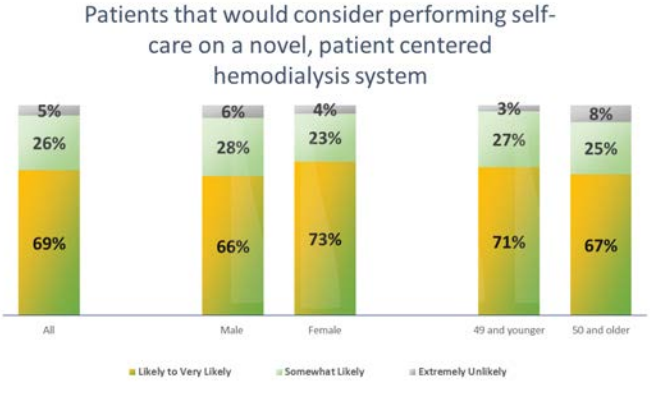
Understanding Barriers to Home-Based and Self-Care In-Center Hemodialysis May L. Yau,[1] Luis Alvarez,[2] Michelle Carver,[1] Geoffrey A. Block,[3] Glenn Matthew Chertow.[4] *[1]Outset Medical, Inc, San Jose, CA; [2]Sutter Health, Menlo Park, CA; [3]Denver Nephrology, Denver, CO; [4]Stanford School of Medicine, Palo Alto, CA.*

Background: Despite superior outcomes and lower associated costs, few patients with end stage renal disease undergo selfcare (SC) or home hemodialysis (HHD). Few studies have examined patient and physician barriers to SC and HHD and the degree which innovative technology might facilitate adoption.

Methods: We surveyed 250 in-center patients (pts) receiving hemodialysis and 51 board-certified nephrologists to identify key barriers to adoption of SC and HHD.

Results: Overall, 172 (69%) pts reported that they were "likely" or "very likely" (figure 1) to consider SC hemodialysis if they were properly trained on a new hemodialysis system designed for SC.



Nephrologists believed that pts were capable of performing dialysis-relevant tasks, including: weighing themselves (98%), wiping down the chair and machine (84%), clearing alarms during treatment (53%), taking vital signs (46%), and cannulating vascular access (41%), but thought that patients would not be willing to do the same.

Description of tasks	% of patients CAPABLE to be more involved	% of patients WILLING to be more involved
Weigh themselves	98%	69%
Wipe chair/machine after treatment	84%	34%
Clear alarms during treatment	53%	31%
Take/record vitals	45%	29%
Document/monitor treatment	43%	27%
Collect supplies	41%	27%
Cannulate their access	41%	16%
Set up machine	35%	19%
Administer medications	31%	26%
Take down machine	22%	21%

Reasons that nephrologists believe pts are hesitant to pursue SC do not correspond to reasons reported by patients.

Conclusions: SC and HHD offer several advantages to patients and dialysis providers. Overcoming real and perceived barriers with new technology, and education will be required for these modalities to gain traction in the coming years.

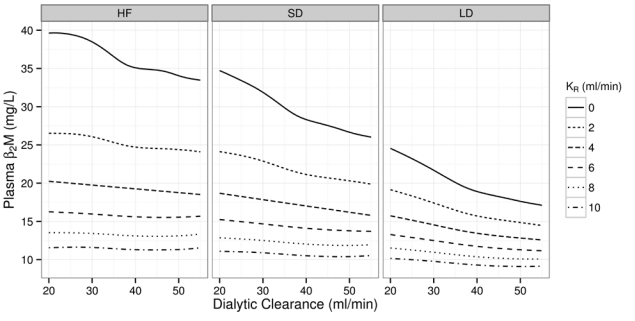
SA-PO838

Dialyzer Clearance, Residual Renal Function and Middle Molecule Levels in Daily Dialysis Christos Argyropoulos, Maria-Eleni Roumelioti, Mark L. Unruh. *Internal Medicine, Div of Nephrology, UNM-HSC, Albuquerque, NM.*

Background: Beta 2 Microglobulin (B2M) has emerged as a predictor of cardiovascular morbidity, mortality and LVH in patients with CKD and ESRD. Daily dialysis leads to higher B2M removal and has been associated with improvements in LVH and mortality in randomized trials. It is not known how B2M levels vary with dialysis membrane clearance (Kd) in daily dialysis regimes.

Methods: We adopted a population kinetic model (PKM) for the intraindividual variability in the generation, distribution and extrarenal removal of B2M (ASN 2014,SA-PO969). We used the PKM to simulate B2M concentrations in patients dialyzed with HF membranes in thrice weekly or daily sessions. For the latter we applied the intervention protocols for Short (SD) and Long Daily (LD) dialysis utilized in the FHN trials. The impact of Kd relative to residual renal function (RRF) on B2M was examined across the three dialysis modalities.

Results: B2M was lower in SD or LD relative to thrice weekly HF dialysis irrespective of RRF; the highest differences from HF (Δ, 95%CI were obtained in anuric pts: 7.5, 7.4-7.62 (SD) and LD 17.2, 17-17.4 mg/dl. The modelled average B2M relative to Kd is shown:



There were significant interactions ($p<0.001$) between modality and RRF, as well as modality and Kd. A Kd of 60 ml/min resulted in lower B2M in LD and SD v.s. HF patients.

Modality	RRF (ml/min)	ΔB2M (mg/l) KD (60 v.s 20 ml/min)	LCI	UCI
HF	0	6.8	6.7	7.6
SD	0	8.2	7.5	8.9
LD	0	8.6	7.8	9.2

The differences between lower and higher dialyzer clearances were minimal (<1.1 mg/dl) at higher RRF irrespective of modality.

Conclusions: In simulations, higher dialyzer clearance is associated with lower plasma B2M in patients on daily dialysis, especially at lower levels of RRF. Whether these differences translate to improved cardiovascular outcomes should be confirmed in clinical studies.

SA-PO839

Wessex Kidney Centre Experience of Nocturnal Home Haemodialysis Using the NxStage Sytem One Venkat Gangaram, Amanda Jane Laird, Laura Hignell, Natalie L. Borman. *Renal Medicine, Wessex Kidney Centre, Queen Alexandra Hospital, Portsmouth, United Kingdom.*

Background: Wessex Kidney Centre (WKC) Portsmouth established Home Haemodialysis (HHD) programme in 2009. In the absence of an in-house technician and limited capital the programme was set up using NxStage system one (NSO). WKC has now established a rapidly growing HHD programme using exclusively NSO, trained 97 patients to date includes nocturnal therapy.

Results: A total of 18 patients have received NHHD with mean time of 12.3 months (range 1 to 31). All patients dialyse alternate nights processing 40-60 litres using dual needling access and a single bolus of Enoxaparin Sodium. Patients have regular transonic monitoring of their access and home visits. Two NHHD patients successfully dialyse alone. The mean age is 47.7 years (range 26 to 80), 78% male, 94% Caucasian with mean BMI 26.9. The Access used was AV fistula 56%, AV graft 22% and CVC 22% of patients. 14 patients changed from short daily HHD (SDHHD), 3 patients from in centre Haemodialysis and 1 from Peritoneal dialysis. Laboratory parameters have been favourable as shown below.

	C.Ca Mmol/L	PO4 Mmol/L	K Mmol/L	Hb g/l	Alb g/l	Ca-PO4 $mmol^2/L^2$	sKt/V
Pre-NHHD (N=18)	2.4	1.6	4.9	11.3	35	3.8	2.44
6 months (N=14)	2.4	1.4	4.7	12.3	36	3.3	2.57
12 months (N=10)	2.4	1.36	4.6	12.3	36	3.0	2.50

Retention has been excellent with one patient returning to in-centre HD after 25 months of HHD. Two patients switched to SD HHD as it more suited to their lifestyle and five patients have been transplanted. Pill burden has reduced, with less or no phosphate binders (mean number of binders reduced from 6 to 2) and a 40 % reduction in antihypertensive medications after 12 months. Patients experience has been excellent with self reported improvements in quality of life including facilitating return to employment. A number of patients have successfully travelled taking their NSO both within UK and abroad.

Conclusions: In Conclusion, NHHD using NSO is a viable alternative for HHD patients with our data suggesting good clinical outcomes. Patients have improved quality of life and with less pill burden, flexibility and more opportunity to engage in social activities.

SA-PO840

Current and Future Training of Home Haemodialysis Nurses Ruth Silverton,[1] Philippa Catherine Brown,[1] Paul Laboi,[1] Nicola Thomas.[3] *[1]Dept of Renal Medicine, York Hospital, United Kingdom; [2]School of Health and Social Care, London South Bank Univ, United Kingdom.*

Background: The UK National Institute for Health and Care Excellence recommend that >10% of dialysis patients be treated by home haemodialysis (HHD), however only 4.1% of patients in the UK are undergoing this modality. Success with HHD can be attributed to a supportive health policy, formal infrastructure, committed individuals and home dialysis experience; providing a patient-centred approach. Lack of nursing expertise is reported as a barrier to home dialysis for 30% of units. A 2010 survey by the Australian HOME network revealed insufficient resources in dialysis units to provide support and education to patients. A potential barrier to HHD in the UK is specific training for renal nurses on the facilitation of shared or self-care.

Methods: The extent of current training provision for dialysis nurses in order to educate patients in home therapies/shared care was evaluated via an online survey. A link to the survey was sent to the British Renal Society database and the survey was available online for 1 month. There were 63 respondents.

Results: Over 76% of respondents (n=48) had worked in renal care for >10 years, with a third (n=21) receiving more than 5 days of structured training in how to teach self care. The majority of this training (51%) was as part of an 'in-service programme', with just over half (53%) of all nurses surveyed feeling adequately prepared for educating patients. The preferred mode of further training was face to face at a national event (38%), with a quarter (n=14) citing e-learning as the preferred option.

Conclusions: Data from the survey highlights a lack of adequate, standardised training for HHD nurses, demonstrating the need for a structured programme that ensures up-to-date best practice. As a result, we plan to pilot a specific HHD training scheme that involves patients and carers in curriculum planning and delivery, with content including; assessment of patients' learning styles, how to facilitate shared decision-making with patients, and how to evaluate effectiveness of the HHD programme.

SA-PO841

Daily Hemodialysis in France: Patient's Characteristics, Trajectories, and Treatment Modalities Adelaide Pladys,[1,2] Sahar Bayat,[1] Cécile Couchoud,[3] Cecile M. Vigneau.[1,4] *[1]French School of Public Health, Rennes, France; [2]Univ Rennes 1, Rennes, France; [3]French Biomedecine Agency, Saint Denis La Plaine, France; [4]CHU Pontchaillou, Rennes, France.*

Background: Increased weekly frequency of hemodialysis (HD) sessions should have positive effects on the control of several biological data of end stage renal disease patients. However, a recent study observed contradicting results in terms of survival compared to previous ones. Patients included in this study came mainly from France where knowledge about daily hemodialysis (DHD) practices is poor. In this context, the aim of this study was to describe the characteristics of French patients in DHD, the treatment modalities and the individual trajectory before starting such a program.

Methods: Were included all patients ³18 y/o who started DHD between 2003 and 2012 in France. Bioclinical and treatment characteristics were extracted from the French Renal Epidemiology and Information Network (REIN registry) then described and compared by groups using Chi-square tests.

Results: 753 patients were included in the study. According to the median age (64 years), two groups of patients were distinguished: old group (≥64 years) characterized by lots of comorbidities such as diabetes (48% *vs* 29%, p<0.0001), active malignancy (17% *vs* 10%, p<0.0001), ³1 cardio-vascular disease (80% *vs* 41%, p<0.0001) compared to the younger one (<64 years). At the 31/12/2013, 30.4% of the young patients underwent renal transplantation and 69% of the old ones were died. The main regimen observed was HD 6x/week with sessions' duration of 3 hours. Among these patients, 496 started with other dialysis modality before switching to DHD (sDHD) and 257 started directly with DHD (dDHD). Before starting DHD, 81% of sDHD patients were in HD 3x/week and 5.4% had ³1 modality change. dDHD patients initiated DHD in urgent condition for 57% of them and 92.6% underwent DHD in centre.

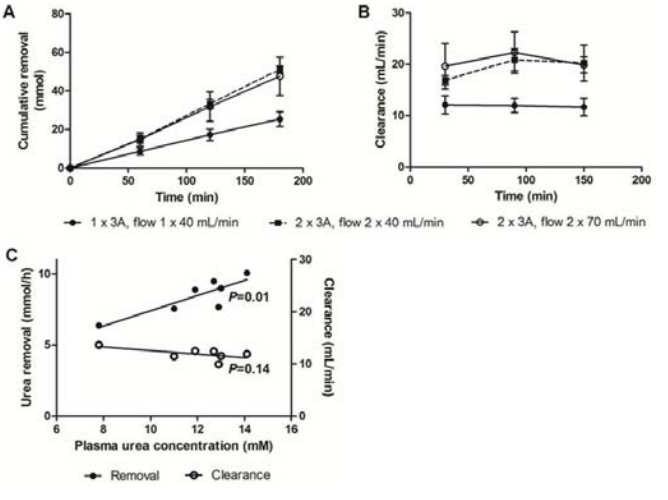
Conclusions: DHD in France is addressed both to old patients with lots of comorbidities who died rapidly and to young patients in better medical conditions who accessed more to renal transplantation. DHD regimens are various and depend of patients' characteristics and previous trajectories.

SA-PO842

In Vivo Urea Removal by Electro-Oxidation in a Wearable Dialysis Device Maarten Wester,[1] Frank Simonis,[2] Diënty Hazenbrink,[1] Jaap A. Joles,[1] Karin G. Gerritsen.[1] *[1]Nephrology and Hypertension, Univ Medical Center Utrecht, Utrecht, Netherlands; [2]Nanodialysis BV, Oirschot, Netherlands.*

Background: In EU consortium NEPHRON+ a wearable dialysis device is being developed that can offer prolonged dialysis by continuous regeneration of a small volume of dialysate. A major challenge is the removal of urea, since the daily urea production is high and removal by adsorption difficult. Electro-oxidation (EO) seems attractive since electrodes are durable, small and inexpensive. Here, we studied in vivo urea removal by EO in a hemodialysis model in goats.

Methods: An EO-unit containing 10 graphite electrodes for EO and sorbent beads for K+ and PO43- removal was incorporated in a dialysate circuit in series with activated carbon (AC;25g/unit). 3 Ampère (A) was applied using 1 EO-unit (1x3A;N=7) or 2 EO-units in parallel (2x3A;N=7). Healthy goats were instrumented with a CVC, heparinized blood was pumped (110mL/min) during 3hrs over a 0.2m2 Polyflux dialyzer and dialysate was recirculated over the EO unit in counter current direction (40mL/min for 1x3A; 2x40mL/min and 2x70mL/min for 2x3A; total dialysate volume 100mL (1 EO-unit) or 150mL (2 EO-units)). Urea was infused to achieve higher urea concentrations.



Results: Urea removal and clearance were 8.4±1.5mmol/h and 11.9±1.6 mL/min, respectively, using 1 EO unit (Fig. A,B) and remained stable during consecutive hours. Use of 2 units in parallel doubled the removal of urea and caused a 1.6-fold increase in urea

clearance. Increase of the dialysate flow did not further increase urea removal. Urea removal was dependent on urea plasma concentrations (Fig.1C). Limited release of ammonia/-um was observed (0.16±0.03 mole per removed mole of urea).

Conclusions: EO by graphite electrodes combined with AC shows promising urea removal in vivo. Research aimed at increasing the efficacy and biocompatibility testing is warranted.

SA-PO843

Unplanned "Crash" Home Dialysis Starts: Single Center Experience from a University Hospital in the United States Kristen P. Tamura,[1] Jose A. Morfin.[2] *[1]Nephrology, UC Davis Medical Center, Sacramento, CA; [2]Nephrology, UC Davis Medical Center, Sacramento, CA.*

Background: There is a high incidence of starting dialysis from the hospital to the in-center unit, and frequently these starts are unplanned and unexpected ("crash"). To this end, we sought to implement an educational program to identify patients suitable for a home dialysis modality, unplanned home hemodialysis (UHHD) and unplanned peritoneal dialysis (UPD).

Methods: We performed an retrospective observational analyses on patients who were started on dialysis from January 2013 to April 2015 in a diverse patient population admitted to UC Davis Medical Center in Sacramento, CA. We devised a systematic and comprehensive screening educational program to provide all modality options. We identified patients suitable UHHD, and UPD, both which were transitioned to a home dialysis training program upon discharge. Clinical characteristics and outcomes were compared to groups who had a standard start home dialysis (SHHD, SPD) during the study period. Our measured outcomes include the following: average training days, interval of technique failure rate (patient drop out), access status and complications, infections, hospitalizations and mortality in the first 90 days.

Results: Preliminary results reveal the groups tended to have similar demographic profiles with the average age for patients starting an unplanned home dialysis 51.5 years of age, 60% non-white race, but with a trend toward more males at 59% compared to standard starts.

Group	# Subject	Training Days Mean	90 Days Drop Out Number	180 Day Drop out Number	% Retention at 12 months
U HHD	9	19.6*	1	02	77.7*
S HHD	27	21.8	3	2	75.7
U PD	10	9.2+	3	0	70.0+
S PD	28	10.5	6	2	71.4

*not statistically sig.between UHHD vs SHHD
+not statistically sig.between UPD vs SPD

Conclusions: In this small representative sample, UHHD and UPD was a viable option for programs to consider for the transition of new dialysis patients from the hospital to the outpatient setting. We found similar outcomes in comparison to patients starting home dialysis training in a traditional standard way. Education and screening of home dialysis therapies should be promoted in the hospital setting.

SA-PO844

Quality of Life After 1 Year of Nocturnal Home Hemodialysis Is Comparable to Quality of Life After Renal Transplantation Anna A. Bonenkamp,[1] Franka E. Van reekum,[1] Marianne C. Verhaar,[1] Brigit C. van Jaarsveld.[2] *[1]Nephrology & Hypertension, Univ Medical Center Utrecht, Utrecht, Netherlands; [2]Nephrology, VU Univ Medical Center, Amsterdam, Netherlands.*

Background: Quality of life (QOL) is an important outcome measure for pts with ESRD. Several studies found improved QOL in Nocturnal Home Hemodialysis (NHHD) compared to conventional HD (CHD). There are no studies comparing QOL in NHHD vs Tx. Therefore, some pts on NHHD hesitate whether or not to apply for a place on the renal transplant (Tx) waiting list. The aim of this study is to assess the difference in QOL between NHHD and Tx after 1 yr of follow up.

Methods: Data were obtained from the ongoing NOCTX-study, which evaluates the 3-yr progression of coronary atherosclerosis in pts treated with CHD, PD, NHHD and Tx. In this study, QOL was measured with the Kidney Disease QOL-SF questionnaire at baseline (<3 mo after start) and after 1 yr in NHHD (n=22; 5-7x/wk, 6-8 hr HD; all Tx-waitlisted) and Tx (n=30). Composite scores (Physical = PCS, Mental = MCS) and disease related domains were used. One yr results were analyzed with an unpaired t-test.

Results: Pts (n=52) were 50±12 yr, 67% male and median duration of RRT was 37±31mo. Baseline characteristics were comparable between the groups. PCS was 46±9 in NHHD and 44±8 in Tx group at baseline; follow up PCS was 44±7 and 47±9 respectively (p=0.13). MCS at baseline was 53±9 vs 53±8 and 50±12 vs 52±9 after 1 yr (NS). Compared to NHHD, Tx-pts scored better on the domain 'Effects of kidney disease' (75±18 vs 86±14 p=0.01). Sexual function had a remarkably good response rate (90%) and equal scores between NHHD and Tx (69±34 and 75±27 p=0.55). In other KDQOL domains no significance was observed.

Conclusions: This is the first study to compare QOL between Tx-pts and wait-listed NHHD-pts. Physical and Mental Composite Scores were similar. In disease specific domains, Tx and NHHD scored not significantly different except for the domain 'Effects'. These data support an important role for NHHD as an alternative to renal transplantation.

SA-PO845

Association of Vascular Access Type with Mortality, Hospitalization, and Transfer to In-Center Hemodialysis in Patients Undergoing Home Hemodialysis Matthew B. Rivara,[1] Melissa Soohoo,[2] Elani Streja,[2] Miklos Zsolt Molnar,[3] Alfred K. Cheung,[4] Ronit Katz,[1] Onyebuchi A. Arah,[5] Allen R. Nissenson,[6,7] Jonathan Himmelfarb,[1] Kamyar Kalantar-Zadeh,[2] Rajnish Mehrotra.[1] *[1]Kidney Research institute, Seattle, WA; [2]Harold Simmons Ctr for Kidney Dis Research & Epidemiology, Univ of California Irvine Med Ctr, Irvine, CA; [3]Div of Nephrology, Univ of Tenn Health Science Ctr, Memphis, TN; [4]Div of Nephrology, Univ of Utah, Salt Lake City, UT; [5]Epidemiology, Fielding School of Pub Health, Los Angeles, CA; [6]DaVita, Inc., El Segundo, CA; [7]David Geffen Sch of Med at UCLA, Los Angeles, CA.*

Background: In individuals undergoing in-center hemodialysis (HD), use of central venous catheters (CVCs) is associated with worse clinical outcomes compared to use of arteriovenous access. However, it is unclear whether a similar difference in vascular access type risk is present in patients undergoing home HD, as these patients have higher dialysis treatment frequency and lower rates of exposure to sources of nosocomial infection.

Methods: We examined the associations of vascular access type with all-cause mortality, hospitalization, and transfer to in-center HD in patients who started home HD from 2007-2011 in 464 facilities in 43 states in the United States. We analyzed the data using competing-risks hazards regression with vascular access type at the start of home HD as the primary exposure in a propensity score-matched cohort (1052 patients; 526 with CVC, 526 with arteriovenous access).

Results: Compared to arteriovenous access use, CVC use was associated with increased risk for mortality (hazard ratio [HR] 1.78; 95% confidence interval [95% CI] 1.21 to 2.61) and hospitalization (HR 1.38; 95% CI 1.19 to 1.59). CVC use was not associated with increased risk for transfer to in-center HD (HR 1.07; 95% CI 0.81 to 1.40). The results of analyses in the entire unmatched cohort (2481 patients), with vascular access type modeled as baseline exposure at start of home HD or as a time-varying exposure, were similar.

Conclusions: In a large nationally representative cohort of home HD patients, CVC use was associated with increased risk for mortality and hospitalization.

SA-PO846

Time to Transplant Associates with Home Dialysis Modality Rita Suri,[1,3] Gihad E. Nesrallah,[2] Lihua Li,[3] Lakshman Gunaratnam.[3] *[1]Centre de Recherche, Centre Hospitalier de l'Univ de Montréal, Univ of Montreal, Montreal, QC, Canada; [2]Humber River Hospital, Toronto, ON, Canada; [3]Nephrology Div, Western Univ, London, ON, Canada.*

Background: We recently showed that prevalent end-stage renal disease patients starting home daily hemodialysis (DHD) have reduced cardiovascular and infection-related hospitalization risk compared to those starting peritoneal dialysis (PD). As current hospitalization precludes being active on the transplant wait-list, we investigated whether DHD patients receiving home DHD would be more likely to be transplanted than those receiving PD.

Methods: We matched 2997 adults starting home daily hemodialysis (DHD) in a single US dialysis provider's facilities from 2004-2011, to 2997 contemporaneous USRDS patients starting PD by US state and propensity-scores. Demographics, comorbidities (form 2728 and hospitalization codes), and outcomes were ascertained from USRDS. We used Cox regression stratified on matched sets censoring for death, and competing risk analysis using Fine's approach for stratified data, to compare times to transplantation between groups.

Results: Baseline variables were balanced between groups after matching, with standardized differences <10%. During 12,558 years of follow-up (mean 2.1±1.4 yrs), 514 DHD and 428 PD patients were transplanted. DHD patients were 19% more likely to be transplanted than PD patients (DHD 8.2 vs PD 6.8 per 100 patient-yrs; HR 1.19, 95%CI 1.05–1.35, p=0.012). Competing risk analysis accounting for death and follow-up losses yielded a HR of 1.18 (95%CI 1.04–1.33, p=0.010). Time to wait-listing did not differ between groups (HR 0.97, 95% CI 0.90–1.06, p=0.54), but once waitlisted, PD patients were significantly more likely to be permanently removed from the wait-list (PD 14.2% vs. DHD 10.2%, RR 1.39 (95%CI 1.09–1.78), p=0.008).

Conclusions: In this prevalent cohort, home DHD patients were more likely to be transplanted than matched PD patients, and less likely to be permanently removed from the wait-list during follow-up. Mean times to wait-listing were similar, suggesting that the groups were well-matched at baseline. Further study is needed on the factors responsible for the differential transplantation rates observed in home DHD and PD patients.

Spectrum of Mutations in *PKD1* and *PKD2* Genes in 100 Unrelated Italian Pedigrees with ADPKD – Sanger Sequencing *versus* Next Generation Sequencing (NGS) Maddalena Gigante,[1] S. Diella,[1] Matteo Accetturo,[2] Paola Pontrelli,[2] Giovanni Stallone,[1] Giuseppe Grandaliano,[1] Loreto Gesualdo.[2] *[1]Univ of Foggia, Foggia, Italy; [2]DETO, Univ of Bari, Bari, Italy.*

Background: ADPKD is caused by mutations in *PKD1* or *PKD2* genes. Although, clinical studies and case reports describing one or few ADPKD families have been reported in Italian population, to date a comprehensive molecular study is still lacking.

Methods: *PKD1* and *PKD2* genes were analyzed in 150 Italian ADPKD patients from 100 unrelated pedigree - the largest Italian cohort analyzed to date in a single study - using Sanger sequencing and NGS. The potential pathogenicity of the newly identified variants was evaluated by combining different *in silico* methods.

Results: We identified the largest number of definitively and probable pathogenic mutations (*n*=78) reported in a single study in Italian population, achieving an overall detection rate of 90%. 55 mutations *(*52 *PKD1* and 3 *PKD2)* have not been previously described, expanding the spectrum of known ADPKD mutations. We identified 12 *de novo PKD1* mutations in sporadic patients without family history, providing a definitive diagnosis of ADPKD. We found the largest number of *de novo* mutations reported in a single study (15%) demonstrating, for the first time, that the prevalence of *PKD1 de novo* mutations may be underestimated. 4/32 *PKD1* mutations were found in ³2 unrelated Italian patients, a sign of founder effect. 20 patients were analyzed by NGS: we confirm the presence of a nonsense *PKD1* mutation and the lacking of clear pathogenic mutations in 3 patients previously analyzed by Sanger, and the presence of definitively/probable pathogenic mutations in the 17 not previously genotyped patients. All NGS results have been confirmed by Sanger sequencing, achieving sensitivity and specificity of 100%.

Conclusions: Our data provide important new advances in the molecular diagnostics of ADPKD: (i) describe for the first time new potential founder mutations in Italy; (ii) report the largest number of *de novo* mutations identified in a single study and (iii) provide a new NGS method with a detection rate comparable to Sanger sequencing but with significantly lower cost and reduced turnaround time.

The Use of Screening MR Angiography in Patient with ADPKD Claudine Christiaens, Ruben Poesen, Dirk R. Kuypers, Bert Bammens, Bjorn Meijers. *Nephrology, Univ Hospitals Leuven, Belgium.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is associated with the development of intracranial aneurysms and an elevated risk of hemorrhagic stroke (HS). It is suggested that screening MR angiography reduces the incidence of hemorrhagic stroke. Current screening criteria include positive aneurysmal history in relatives, neurological symptoms and planned major surgery. The efficacy of these screening criteria has, however, not been fully evaluated.

Methods: We performed a single-center retrospective analysis of all ADPKD patients followed at the University Hospitals Leuven, between January 1990 (date of the first MR angiography) and August 2014. Baseline demographics and occurrence of screening criteria, screening MR angiography, intracranial aneurysm and hemorrhagic stroke were evaluated.

Results: We identified 865 patients with ADPKD. Those who were seen at least three times (n=627, median age 51y, 49% males) were included for analysis. Mean duration of follow up was 11.6 years. In this cohort, current screening criteria were met in 183 ADPKD patients (29.2%). Of these, 136 (74.3%) had screening MR angiography. In patients with no MR angiography, presence of screening criteria was associated with an elevated risk of hemorrhagic stroke (12.8% vs. 4.0%, P 0.02). Use of MR angiography in patients with screening criteria was related with a lower risk of hemorrhagic stroke during follow-up (2.2% vs. 12.8%, P 0.01).

Conclusions: In patients with ADPKD, current screening criteria for intracranial aneurysm are associated with an 3-fold elevated risk for future hemorrhagic stroke and performing MR angiography seems effective in reducing this risk.

SA-PO849

Influence of Genotype on ADPKD Progression in the HALT PKD Cohort Christina M. Heyer,[1] Kaleab Z. Abebe,[2] Vicente E. Torres,[1] Ronald D. Perrone,[4] Marie C. Hogan,[1] William E. Braun,[5] Godela M. Brosnahan,[3] Peter G. Czarnecki,[6] Charity G. Moore,[7] Peter C. Harris,[1] Dana Miskulin,[4] The HALT PKD Investigators.[8] *[1]Mayo Clinic, Rochester, MN; [2]U of Pittsburgh, Pittsburgh, PA; [3]U of Colorado, Denver, CO; [4]Tufts, Boston, MA; [5]Cleveland Clinic, Cleveland, OH; [6]Brigham and Women's Hospital, Boston, MA; [7]Carolina's Health Care System, Charlotte, NC; [8]7 Sites.*

Background: We assayed here the influence of the ADPKD disease gene (*PKD1* or *PKD2*) or *PKD1* mutation type (truncating or non-truncating) on the rates of renal disease progression over 5 years in the HALT PKD cohort.

Methods: *PKD1* mutation type was divided into strength groups: truncating (MSG1), and more or less penetrant non-truncating (MSG2 and MSG3). Correlations were made between gene type/MSG and changes in eGFR or height adjusted total kidney volume (htTKV).

Results: PKD1 patients had a faster eGFR decline than PKD2 (3.3 vs. 1.87 ml/min/1.73m²/yr; P<0.0001) but the rate of htTKV increase did not differ (6.44 vs. 6.81%/yr; P=0.42). Baseline PKD1 htTKV was larger than PKD2 (733, 557ml/m; P=0.0001) and so PKD1 kidneys expanded to a greater extent (268, 217ml/m/5yr; P=0.0001). Rates of change in eGFR or htTKV did not differ between PKD1 MSG3 and MSG1 (P=0.15 and 0.70), but MSG3 baseline kidneys were smaller relative to MSG1 and MSG2 (611, 753, 777ml/m; P=0.004) and so the volume increase was less (221, 262, 277ml/m; P=0.004). PKD2 patients were less likely to reach a study endpoint (death, ESRD or 50% eGFR decline; P=0.0003), but there was no difference between PKD1 MSG1, 2, 3 (P=0.61). Patients with no mutation detected, had a slower increase in htTKV (4.84%/yr; P=0.008 vs. PKD1). The study showed a difference in TKV increase between the low and standard blood pressure groups (5.6 vs. 6.6%/yr; P=0.006). The magnitude of difference was similar when restricted to PKD1 MSG1 (5.7 vs. 6.7%/yr; P=0.0518) or PKD1 MSG1 and 2 (5.8 vs. 6.6%/yr; P=0.0543), but not significant in the smaller populations.

Conclusions: PKD1 MSG3 kidneys are smaller but not because they grow more slowly; possibly because they have less early cysts, similar to PKD2 vs. PKD1. Since genic and allelic effects do not alter progression rates, restricting analysis by genetic factors did not improve significance.

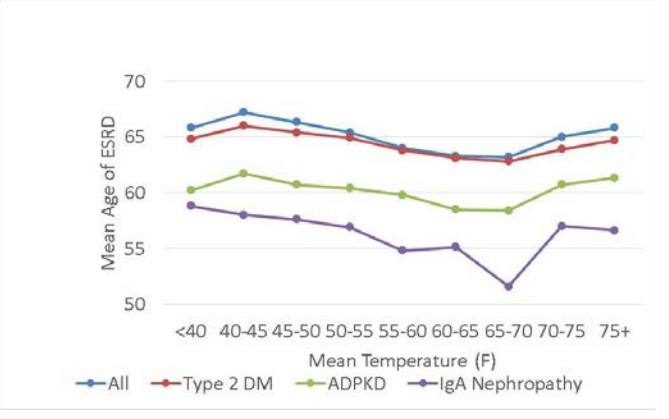
SA-PO850

Climate Temperature Affects the Age of End-Stage Kidney Disease in Autosomal Dominant Polycystic Kidney Disease (PKD) Marwan M. Abbas,[1] Michael E. Bleyer,[1] Elizabeth Swain,[1] Kendrah O. Kidd,[1] Gregory B. Russell,[2] Anthony J. Bleyer.[1] *[1]Section on Nephrology, Wake Forest School of Medicine, Winston-Salem, NC; [2]Biostatistical Sciences, Wake Forest School of Medicine, Winston-Salem, NC.*

Background: Vasopressin receptor 2 antagonists decrease cyst size in PKD. We postulated that patients in hotter climates would have more concentrated urine, and this would affect the age of ESRD in PKD.

Methods: We obtained demographic data and cause of ESRD on 1,332,402 individuals who had their first occurrence of ESRD between ages 30 and 90 between 1971 and 2012 from the US Renal Data system (USRDS). We obtained annual mean temperatures from 1990 to 2010 for US weather stations and linked a participant's zip code to the nearest weather center. We correlated the mean age of onset of ESRD for PKD and other causes of ESRD with 5 degree temperature intervals. We created a multivariate model for PKD patients, with the dependent variable age of ESRD and independent variables race, gender, year starting dialysis, residual GFR at start of ESRD, annual median income by patient zip code, and temperature as discrete variables in 5 degree intervals.

Results: Figure 1 shows the mean age of onset of ESRD by disease. Cold and warm temperature extremes were associated with increasing age of ESRD for PKD, but also other diseases.



Variable	Type III SS	F value	p value
Temperature	11156	8	<0.0001
Gender	3076	18	<0.0001
Race	30783	45	<0.0001
Median income by zip code	25287	150	<0.0001
GFR at start of ESRD	79568	472	<0.0001
Year starting ESRD	82317	488	<0.0001

The multivariate model showed that temperature had a minimal effect on age of ESRD compared to other variables in the model.

Conclusions: There was a U-shaped relationship for age of ESRD according to temperature that was present in PKD and other diseases. However, in a multivariate model, climate temperature had a minimal effect on age of ESRD in PKD.

SA-PO851

Urinary Biomarkers and Prediction of Disease Progression in Autosomal Dominant Polycystic Kidney Disease A. Lianne Messchendorp, Esther Meijer, Wendy Ellen Boertien, Niek F. Casteleijn, Edwin M. Spithoven, Ron T. Gansevoort. *Nephrology, UMCG, Groningen, Netherlands.*

Background: The variable disease course of ADPKD underlines the importance of predicting disease progression especially since therapeutic options are now available. Conventional risk markers (age, gender, GFR, total kidney volume (TKV)) lack sensitivity, are expensive or time consuming to measure. We therefore investigated whether easy to measure urinary markers can predict disease progression and have additional value to conventional risk markers.

Methods: At baseline tubular damage and inflammatory markers were measured in 24-hr urine; albumin, IgG, KIM1, NAG, b2MG, H-FABP, MIF, NGAL and MCP-1. Kidney function was estimated (eGFR by CKD-EPI) and measured (mGFR by (125)I-iothalamate), and TKV by MRI. Disease progression was expressed as annual change in eGFR, mGFR, and height-adjusted (ht)TKV. Multivariate linear regression was used to assess the predictive ability of the markers above conventional risk markers.

Results: Included were 104 ADPKD patients, 40±11yrs, 39% female, eGFR 77±30, mGFR 79±29 ml/min/1.73m^2 and htTKV 852 (510-1243) mL/m. During a follow-up of 3.8±1.2 yrs, annual change in eGFR was -3.2±3.0, in mGFR -3.0±3.0 mL/min/1.73m^2 and in htTKV 6.2±5.9%. b2MG and MCP-1 were associated with annual change in eGFR (St. β=-0.23, p=0.02; St. β=-0.38, p<0.001 resp.) and mGFR (St. β=-0.24, p=0.03; St. β=-0.24, p=0.03 resp.), even when adjusted for conventional risk markers, but not with annual change in hTKV. Similar results were obtained when patients with an eGFR≥60 mL/min/1.73m^2 were selected. Combined b2MG and MCP-1 had an added predictive ability for annual change in eGFR (R^2=0.178 vs. 0.324, p=0.008) and in mGFR (R^2=0.134 vs 0.217, p=0.07). The best predictive model for annual change in eGFR included age, htTKV, MIF, b2MG and MCP-1 (R^2=0.343, p=0.025), and for annual change in mGFR, gender, b2MG, NGAL and MCP-1 (R^2=0.211, p=0.5).

Conclusions: b2MG and MCP-1 both predict disease progression, and had an added predictive value on top of conventional risk markers. These markers have therefore potential to serve as a predictive tool for clinical practice.

SA-PO852

The Novel Surrogate Marker of Autosomal Dominant Polycystic Kidney Disease (ADPKD) – Urinary Copeptin Satoru Muto,[1] Yan Lu,[1] Haruna Kawano,[2] Shigeo Horie.[2] *[1]Urology, Teikyo Univ School of Medicine, Tokyo, Japan; [2]Urology, Juntendo Univ, Graduate School of Medicine, Tokyo, Japan.*

Background: Experimental studies suggest a detrimental role for Arginine vasopressin (AVP) in the pathogenesis of autosomal dominant polycystic kidney disease (ADPKD). Copeptin consists of the C-terminal portion of Pro-AVP and has been shown to be a reliable and stable substitute for circulating AVP concentration. In contrast to serum or plasma, urinary proteins do not undergo detectable degradation by endogenous proteases after voiding. It is unknown, however, whether urinary copeptin concentration are associated with disease severity in patients with ADPKD.

Methods: Serum and Urinary copeptin concentration were measured by immunoassay in ADPKD patients with CKD stage ≤ 4. We compared our measurements with clinical parameters including estimated Glomerular Filtration Rate (eGFR), Total Kidney Volume (TKV), and height-adjusted TKV (htTKV). Logarithmic transformation of all variables was performed to fulfill the requirement of equal distribution of the residuals.

Results: We included 50 patients in this study (24 females and 26 males; mean age: 49.3 years).The median eGFR and TKV were 53.2 ml/min/1.73 m^2 (interquartile range: IQR; 29.4 - 68.45) and 1138.1 ml (IQR; 814.7 - 2065.0), respectively. The median urinary copeptin level was 12.19 (IQR; 6.91 - 22.32) ng/ml. We could show the positive-correlation between u-copeptin and plasma copeptin but without significant relationship (p = 0.198). Although there are no significant correlations between plasma copeptin and eGFR (R = -0.245, p = 0.227), there are significant correlations between plasma copeptin and htTKV (R = 0.458, p = 0.019) and TKV (R = 0.465, p = 0.017). On the other hand, Urinary copeptin/u-Cr was statistically associated with the various markers of disease severity in ADPKD (positively with TKV (R = 0.351, p = 0.014,), htTKV (R = 0.383, p = 0.008) and negatively with eGFR (R = -0.304, p = 0.036).

Conclusions: In ADPKD subjects, a higher urinary copeptin concentration is associated with disease progression, suggesting that urinary copeptin may be a surrogate marker to detect deisease severity renal prognosis in ADPKD.

SA-PO853

The Burden of Tolvaptan Treatment for Autosomal Dominant Polycystic Kidney Disease (ADPKD) Satoru Muto,[1] Haruna Kawano,[2] Masaki Kimura,[1] Shigeo Horie.[2] *[1]Urology, Teikyo Univ School of Medicine, Tokyo, Japan; [2]Urology, Juntendo Univ, Graduate School of Medicine, Tokyo, Japan.*

Background: Last year, Japan became the first country in the world to approve tolvaptan for the treatment of Autosomal Dominant Polycystic Kidney Disease (ADPKD). Because tolvaptan has powerful diuretic effect, patients have to take huge amount of water to prevent dehydration. We evaluated the burden of tolvaptan treatment on patients with ADPKD.

Methods: This study targeted Japanese patients with ADPKD on tolvaptan. An initial dose of tolvaptan was 60 mg. Estimated glomerular function rate (eGFR) and total kidney volume (TKV) were measured at regular intervals. The burden of tolvaptan treatment was evaluated by visual analog scales. Statistical analysis was performed using analysis of variance.

Results: We included 40 patients (male: 28, female: 12). The median age was 46.5 years (interquartile range: IQR 24 - 69 yr.). The median baseline eGFR was 43.4 ml/min/1.73m^2 (IQR: 26.9 – 58.8) and the median baseline TKV was 1,917 ml (IQR: 1,378 - 2,905). The median starting dosage of tolvaptan was 60 mg (IQR: 30 – 60) and the median treatment period was 8 months (IQR: 6 - 11). We observed no statistical variations in eGFR (p = 0.787) and TKV (p = 0.561) during treatment. There were no significant changes in VAS scores for general fatigue (p = 0.817), anorexia (p = 0.393), back pain (p = 0.682), and abdominal distention (p = 0.607) during treatment. Although analysis of variance demonstrated that aquaretic burden including thirst and dry skin were significantly increased after Tolvaptan treatment (p = 0.003), 35 % (n = 14) of patients did not completely sense thirst at al during treatment, and 42 % (n = 17) of patients spontaneously improved without any additional treatment or tolvaptan withdrawal.

Conclusions: Although analysis of variance demonstrated that aquaretic burden including thirst and dry skin were significantly increased after Tolvaptan treatment, almost third of the patients did not completely sense thirst at al from beginning of Tolvaptan treatment, and the remaining third part of patients spontaneously improved.

SA-PO854

Adapted PKDOC Disease Predicts Actual Progression of Autosomal Dominant Polycystic Kidney Disease in TEMPO3:4 Frank S. Czerwiec,[1] Jaime Blais,[1] Jf Marier,[2] Nathalie H. Gosselin,[2] Thomas Peyret,[2] Vicente E. Torres,[3] Arlene B. Chapman,[4] Berenice Y. Gitomer,[5] Steven Thomas Broadbent,[6] Dana Miskulin,[7] Ronald D. Perrone.[7] *[1]Otsuka PDC, Rockville, MD; [2]Pharsight, Montreal, QC, Canada; [3]Mayo Clinic, Rochester, MN; [4]U. Chicago, Chicago, IL; [5]U. Colorado, Denver, CO; [6]Critical Path, Tucson, AZ; [7]Tufts MC, Boston, MA.*

Background: The Polycystic Kidney Disease Outcomes Consortium (PKDOC) has submitted for FDA and EMA concurrence, the use of total kidney volume (TKV) as a prognostic biomarker to enrich autosomal dominant polycystic kidney disease (ADPKD) trials for patients likely to display progressive decline in renal function and progression to end-stage renal disease (ESRD). A disease progression model linking TKV growth (with baseline covariates of age and eGFR) to longitudinal eGFR was constructed using a combination of PKDOC datasets including ADPKD patients with TKV data collected over 30 years of follow-up.

Methods: This report uses baseline data for placebo subjects from the TEMPO 3:4 ADPKD clinical trial to support this approach to disease progression modelling by comparing model predicted and observed TKV and eGFR. Simulations were performed by utilizing the PKDOC model with subject-specific baseline TKV and eGFR measurements from subjects enrolled in TEMPO 3:4.

Results: Bias (mean of the relative error) and precision (square mean of relative error) of TKV and eGFR were derived to assess the predictive performance of the PKDOC model. The model resulted in very robust predictions of TKV and eGFR with mean (95% CI) bias values of 2.98% (1.1-5.1) and 3.03% (1.4-4.7), respectively. Mean (95% CI) precision on TKV and eGFR were 42.9% (19.1-68.7) and 37.9% (34.0-43.4), respectively. The coefficient of determination (r^2) for observed and model predicted TKV and eGFR data were 0.957 and 0.877, respectively.

Conclusions: The disease progression model developed with PKDOC data and applied to the TEMPO placebo dataset demonstrated excellent predictive power for TKV and eGFR. This demonstrates the utility of the disease model in prognosis and potential for evaluation treatment effects.

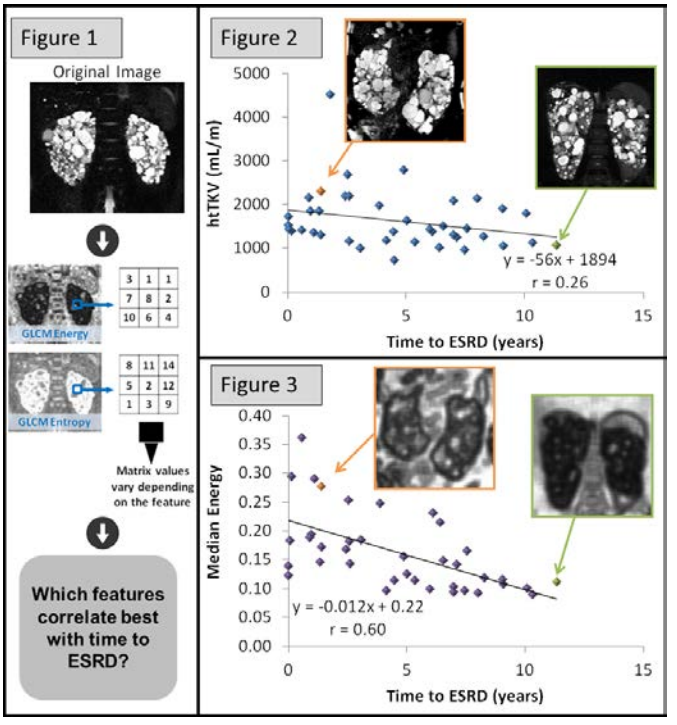
SA-PO855

Polycystic Kidney Disease Imaging Biomarkers – The Texture of Things to Come Timothy L. Kline, Panagiotis Korfiatis, Marie E. Edwards, Joshua D. Warner, Maria V. Irazabal, Peter C. Harris, Bernard F. King, Vicente E. Torres, Bradley J. Erickson. *Mayo Clinic.*

Background: Medical imaging is essential for polycystic kidney disease (PKD) diagnosis, monitoring, and outcome prediction. Research studies use total kidney volume (TKV) as an imaging biomarker to follow the progression of PKD. However, TKV overlooks underlying structural and functional complexities of the kidneys. We hypothesize that texture analysis may provide quantifiable measurements of renal tissue structure to improve patient outcome prediction.

Methods: A retrospective cohort of 20 patients (38 exams) was identified who had imaging prior to reaching end-stage renal disease (ESRD). Image texture features were generated from the baseline MR images and analysis of the correlation to known time-to-ESRD was performed. A total of 18 texture features were computed for each MRI scan. The analysis workflow is shown in Fig. 1.

Results: Texture features were well correlated to time-to-ESRD and many individual texture features outperformed height-adjusted TKV (htTKV) as shown in Figs. 2 and 3. Example T2 MRIs and their corresponding *energy* image feature (measure of heterogeneity) for two different patients with markedly different times-to-ESRD are also shown for comparison. In addition, *entropy* (measure of image randomness) and *gray-level non-uniformity* (measure of neighboring pixel similarities) were also found to be well correlated (r-values of 0.66 and 0.73, respectively).



Conclusions: We present the first use of texture analysis for PKD assessment. Results are promising in terms of identifying new imaging biomarkers that correlate with disease progression. This approach could function as a surrogate to more difficult imaging methods (e.g., quantitative MRI) and costly analysis (e.g., cyst segmentation). It is likely that combining texture analysis with other patient data will allow for substantial improvements to PKD prognosis.

Funding: NIDDK Support, Other NIH Support - Research reported in this poster was supported by NCI grant U01 CA160045 (QIN) and the National Institute of Diabetes and Digestive and Kidney Diseases under NIH Grant/Award Number 5 P30 DK090728 04 Mayo Translational PKD Center (MTPC).

SA-PO856

Accuracy of Traditional and Novel Renal Filtration Markers for Estimating GFR in ADPKD Patients Stephen L. Seliger,[1] Charalett E. Diggs, MSN,[1] Thomas C. Dowling,[2] Robert Christenson,[3] Terry J. Watnick.[1] *[1]Medicine, U Maryland Sch Medicine, Baltimore; [2]Ferris State Univ; [3]Pathology, U Maryland Sch Medicine, Baltimore.*

Background: The best method for estimating GFR in ADPKD is unclear. Changes in tubular handling of filtration markers may affect estimating equation accuracy.

Methods: Among 51 adults with ADPKD and eGFR >20 cc/min/1.73m^2,we measured GFR using iohexol plasma clearance (iGFR,) serum creatinine (SCr, IDMS-traceable assay), Cystatin C (CysC, Dimension VISTA assay) and beta-trace protein (BTP, immunonephelometric assay, Siemens). We estimated GFR (eGFR) using validated equations based on SCr (CKD-Epi$_{Cr}$, MDRD), Cystatin-C (CKD-Epi$_{cys}$), both CysC and SCr (CKD-Epi$_{Cr+Cys}$) or SCr and BTP (White equation). We compared the bias, precision, overall accuracy, and classification (for iGFR<60 cc/min/1.73m^2) of each estimating equation.

Results: Mean age was 51±12 years, 71% were female, 84% Caucasian, and mean iGFR was 68.4+/-34.2 cc/min/1.73m^2. Of the 5 equations, the CKD-Epi$_{cysc}$ had the highest bias (overestimating GFR), lowest precision and accuracy, and was least sensitive for detection of low iGFR (Table). The CKD-Epi$_{Cr}$ and BTP/SCr-based White equations had least bias and highest precision. Sensitivity and specificty were not significantly different between the SCr- and BTP-based estimating equations. (Table)

Performance Characteristic	Bias	Precision	Accuracy		Sensitivity	Specificity
Statistic	Mean Difference	Inter-quartile range of Difference	P30[1]	RMSE[2]	for iGFR<60	
CKD-Epi$_{Cr}$	0.8 (-4.5, 6.0)	-9.2, 9.3	76.5%	18.7	84%	88%
MDRD	5.6 (-11.0, -0.2)	-19.5, 4.6	76.5%	19.5	88%	85%
CKD-Epi$_{cysc}$	17.7 (12.2, 23.2)	2.2, 27.8	51.0%	19.1	52%	100%
CKD-Epi$_{Cr+cysc}$	9.0 (4.1, 13.9)	-3.9, 18.2	74.5%	17.1	68%	96%
White$_{BTP+Cr}$	-0.5 (-5.8, 4.9)	-9.3, 12.3	70.6%	18.4	80%	88%

1. P30 represents proportion with of GFR estimates that are within 30% of measured GFR.
2. Smaller values indicate higher accuracy

Conclusions: In ADPKD patients, cystatin-based GFR equations may over-estimate true GFR, in contrast to the lower bias observed in the general CKD population. The SCr-based CKD-Epi equation performed best overall among 5 equations. The utility of equations utilizing beta-trace protein deserves further investigation.

SA-PO857

Statins, ADPKD Severity and Progression in the TEMPO 3:4 ADPKD Clinical Trial Vicente E. Torres,[1] Ron T. Gansevoort,[2] Ronald D. Perrone,[3] Olivier Devuyst,[4] Arlene B. Chapman,[5] Eiji Higashihara,[6] Wen Zhou,[7] John Ouyang,[7] Jaime Blais,[7] Frank S. Czerwiec.[7] *[1]Mayo; [2]U Groningen; [3]Tufts U; [4]U Zurich; [5]U Chicago; [6]Kyorin U; [7]Otsuka.*

Background: In ADPKD, low HDL and high LDL cholesterol are associated with faster total kidney volume (TKV) increase and eGFR decline. A randomized controlled trial (RCT) of pravastatin in children showed lower TKV expansion without effect on renal function.

Methods: Exploratory post-hoc analysis of TEMPO 3:4 (3-year RCT of tolvaptan in relatively early but progressive ADPKD, age 18-50 yrs, TKV ≥750 ml, eCrCl ≥60 ml per minute) to examine whether use of statins might have affected ADPKD progression. Linear mixed-effect models that adjust for gender, age and baseline TKV and eGFR were used to compare TKV and eGFR slopes between groups.

Results: Patients randomized to placebo using statins were older, had larger TKV and lower eGFR at baseline, and their TKV and eGFR slopes were steeper compared to statin nonusers (Table). Similarly, patients randomized to tolvaptan using statins were older and had lower eGFR, with a non-significant trend to larger TKV compared to statin non-users; however, there was no difference between TKV and eGFR slopes of statin users and nonusers randomized to tolvaptan. Statin use did not affect a composite end point of clinically relevant ADPKD events in the placebo (HR=1.013, P=0.91) or tolvaptan (HR=0.954, P=0.65) group.

	Placebo (n=484)			Tolvaptan (n=961)		
Statin use	No	Yes	P	No	Yes	P
N	416	68	---	827	134	---
Sex (% male)	51.0	57.4	0.33	49.7	62.7	0.005
Baseline age (yrs)	38.5	40.9	<0.001	38.0	41.8	0.025
Baseline eGFR (ml/min/1.73 m^2)	83.5	73.9	<0.001	82.4	74.8	0.003
Baseline TKV (ml)	1638	1848	0.039	1678	1867	0.067
eGFR slope (ml/min/1.73 m^2/yr)	3.57	4.54	0.058	-2.74	-2.64	0.76
TKV slope (%/yr)	5.76	7.10	0.033	3.90	4.29	0.42

Conclusions: Older patients with more advanced and/or severe ADPKD are more likely to be treated with statins. Placebo patients using statins progressed faster; tolvaptan slowed progression and annulled the difference between statin users and nonusers.

Systems Biology of Polycystic Kidney Disease Kelly A. George,[1,2] Herve Husson,[3] Ramya Kalyana Kumar,[2] Vishal S. Vaidya,[1,2] Oxana Beskrovnaya,[3] Jagesh V. Shah.[1,2] *[1]Laboratory of Systems Pharmacology, Harvard Medical School, Boston, MA; [2]Renal Div, Brigham and Women's Hospital, Boston, MA; [3]Genzyme Corp, Framingham, MA.*

Background: Polycystic kidney disease (PKD) is a group of hereditary disease states characterized by cystic kidneys and often accompanied by other manifestations such as cystic liver and hypertension. PKD occurs in 1 in 500 people, usually resulting from a dominant mutation in one of two genes, PKD1 or PKD2. There are no treatments for PKD and it is the leading genetic cause of renal failure. Numerous studies have identified pathways that are misregulated in PKD but targeting these individual pathways has not led to a successful therapeutic intervention or molecular biomarker.

Methods: To identify potential biomarkers and develop a systems-level understanding of PKD, we are using transcriptomics, and quantitative proteomics and phospho-proteomics to evaluate the state of cystic and normal kidneys in a mouse model of PKD. Kidney cysts also induce injury to the surrounding tissues, confounding any analysis of the "cystic state". In an effort to separate the injury signature from the cystic signature, we are also evaluating the state of the injured kidney using a folate model of acute kidney injury and fibrosis. The multi-kinase inhibitor Roscovitine has been shown to prevent cystogenesis in mouse models of PKD but its mechanism of action remains unknown. To gain insight into the mechanism(s) of Roscovitine and to identify biomarkers that change with treatment, we are also using the above "omic" strategies using kidneys from mice following treatment.

Results: From the transcriptomic experiments, we have a list of potential biomarker candidates that are currently being tested by qPCR in mouse tissue at various stages of disease progression. Phosphorylation at motifs for CDKs, CK1, CaMK, and others are reduced in kidneys treated with Roscovitine. The primary transcription factor family found to be suppressed with Roscovitine treatment is the E2Fs, likely a result in the loss of CDK signaling.

Conclusions: These experiments will not only provide candidate biomarkers for PKD progression, but will also yield a deeper understanding of the state of the cystic kidney.

Prognostic Enrichment Strategies in the TEMPO 3:4 ADPKD Clinical Trial

Maria V. Irazabal,[1] Jaime Blais,[2] Ronald D. Perrone,[3] Ron T. Gansevoort,[4] Arlene B. Chapman,[5] Olivier Devuyst,[6] Eiji Higashihara,[7] Wen Zhou,[2] John Ouyang,[2] Frank S. Czerwiec,[2] Vicente E. Torres.[1] *[1]Mayo Clinic; [2]Otsuka PDC; [3]Tufts MC; [4]UMC Groningen; [5]U. Chicago; [6]U. Zurich; [7]Kyorin U.*

Background: An image classification of ADPKD based on diffuse (class 1) vs asymmetric (class 2) cyst distribution along with estimated cyst growth determined by age and height-adjusted total kidney volume (htTKV, subclass A-E) has been proposed for prognostic enrichment by excluding patients with a lesser risk for progression (classes 1A-B and 2).

Methods: This enrichment strategy was compared, post-hoc, to exclusion criteria used for TEMPO3:4 to examine tolvaptan effects on ADPKD progression in patients with early but progressive renal disease (18-50 year-old, TKV ≥750 ml, eCrCl ≥60 ml/min).

Results: 1436 TEMPO 3:4 subjects with baseline MRIs were classified, finding only 10% class 2 or 1B and no 1A subjects. TEMPO3:4 enriched categories 1C-E (90%) compared to the published cohorts (62%, Irazabal 2014 JASN). TKV and eGFR slopes steepened from class 1B to 1E (both P<0.001, Table).

Class: N (%)	2: 42 (3.1)		1B: 96 (7.4)		1C: 474 (37)		1D: 441 (34)		1E: 220 (18)	
	TKV	eGFR	TKV	eGFR	TKV	eGFR	TKV	eGFR	TKV	eGFR
Placebo	2.48	-1.66	3.25	-2.10	5.12	-3.59	6.62	-3.89	7.75	-4.93
Tolvaptan	2.27	-1.34	1.23	-1.79	1.79	-2.32	3.03	-2.99	4.96	-3.46
P-value	0.88	0.75	0.023	0.64	< 0.001	< 0.001	< 0.001	0.007	< 0.001	< 0.001

Tolvaptan effects on TKV and eGFR slopes was greater in classes 1C to E. Originally, tolvaptan blunted TKV and eGFR slopes from 5.51% to 2.80% and from -3.70 to -2.78 ml/min/1.73m^2 per year (both P<0.001), and lowered the risk for a composite endpoint (CE) of clinical progression events (hazard ratio [HR] 0.87, p=0.0095, Torres 2012 NEJM). Removing class 1A-B and class 2 patients from the trial, marginally improved estimates of tolvaptan effects on TKV and eGFR slopes 5.78% to 2.91% and -3.93 to -2.82 ml/min/1.73 m^2 per year (both P<0.001), and the CE endpoint (HR 0.84, p=0.0032).

Conclusions: Prognostic enrichment strategies using kidney morphology can enhance ADPKD trials for rapidly progressing patients, increasing power and reducing costs. Refinements of imaging criteria can improve the probability of success of future clinical trials.

SA-PO860

Prognostic Enrichment Design in Clinical Trials for ADPKD: The HALT PKD A Trial

Maria V. Irazabal,[1] Kaleab Z. Abebe,[2] Kyongtae Ty Bae,[2] Ronald D. Perrone,[3] Arlene B. Chapman,[4] Robert W. Schrier,[5] Alan S.L. Yu,[6] William E. Braun,[7] Theodore I. Steinman,[8] Michael F. Flessner,[9] Vicente E. Torres.[1,10] *[1]Mayo Clinic; [2]U. of Pittsburgh; [3]Tufts U.; [4]U. of Chicago; [5]U. of Colorado; [6]Kansas U.; [7]Cleveland Clinic; [8]Beth Israel Deaconess; [9]NIH-NIDDK.*

Background: Patients with mild ADPKD phenotype are less likely to be informative in clinical trials. An image classification into typical (diffuse cyst distribution) class 1A → E (determined by age and height adjusted total kidney volume, (TKV) and atypical (asymmetric cyst distribution) class 2 has been proposed for prognostic enrichment design in clinical trials with recommendations to exclude class 1A and 2 and follow-up class 1B patients to more precisely define their risk for progression.

Methods: Post-hoc analysis of HALT-PKD A, (RCT of rigorous vs standard BP control on TKV increase and eGFR decline; eGFR>60 ml/min/1.73 m^2) to investigate the performance of this classification for prognostic enrichment design.

Results: 551 participants were classified by 2 raters (98.2% agreement) into class 1A (6.2%), 1B (20.3%), 1C (34.1%), 1D (22.1%), 1E (11.8%), and 2 (5.4%). TKV increase and eGFR decline became steeper from class 1A → 1E (both P<0.0001). HALT PKD A had shown slower TKV increase, faster eGFR decline in the first four months (F0-5) and marginally slower eGFR thereafter (F5-80), without a significant overall (F0-80) effect with rigorous BP control. To ascertain the ability to detect an effect of rigorous BP control in imaging classes of increasing severity, we grouped classes1A and 2 (lowest severity), 1B and 1C (intermediate severity), and 1D and 1E (highest severity). Beneficial effects on TKV increase and eGFR decline were detected only in class 1D and 1E.

	Class 1A & 2 (n=64)			Class 1B & 1C (n=300)			Class 1D & 1E (n=187)		
BP	TKV %/yr	F0-80 eGFR ml/min/yr	F5-80 eGFR ml/min/yr	TKV %/yr	F0-80 eGFR ml/min/yr	F5-80 eGFR ml/min/yr	TKV %/yr	F0-80 eGFR ml/min/yr	F5-80 eGFR ml/min/yr
Standard	4.61	-1.16	-1.39	6.20	-2.47	-2.63	7.80	-4.37	-4.44
Low	4.20	-1.20	-0.98	5.47	-2.84	-2.67	6.44	-3.57	-3.36
P-value	0.64	0.94	0.44	0.11	0.15	0.88	0.033	0.051	0.011

Conclusions: Strategies for prognostic enrichment such as the image classification should be used in the design of RCTs for ADPKD to increase their power and reduce their cost.

SA-PO861

Long-Term Safety Profile of Tolvaptan in Japanese ADPKD Patients

Eiji Higashihara,[1] Shigeo Horie,[2] Yoshifumi Ubara,[3] Satoru Muto,[4] Kikuo Nutahara,[5] Ichiei Narita,[6] Tadashi Okada.[7] *[1]ADPKD Research, Kyorin Univ School of Medicine, Tokyo, Japan; [2]Urology, Juntendo Univ Graduate School of Medicine, Tokyo, Japan; [3]Nephrology Center, Toranomon Hospital, Tokyo, Japan; [4]Urology, Teikyo Univ School of Medicine, Tokyo, Japan; [5]Urology, Kyorin Univ School of Medicine, Tokyo, Japan; [6]Clinical Nephrology and Rheumatology, Niigata Univ Graduate School of Medical and Dental Sciences, Niigata, Japan; [7]Clinical Development, Otsuka Pharmaceutical Co., Ltd., Osaka, Japan.*

Background: Tolvaptan was first approved in Japan for autosomal dominant polycystic kidney disease (ADPKD) based on results of the Tolvaptan Efficacy and Safety in Management of Autosomal Dominant Polycystic Kidney Disease and Its Outcomes 3:4 trial (TEMPO) to evaluate 3-year efficacy and safety. **Purpose:** Examine adverse drug reactions (ADRs) of tolvaptan for up to extended 3 years after TEMPO in Japanese ADPKD patients.

Methods: This open-label study was conducted in 135 patients participating in the preceding TEMPO. Doses of tolvaptan were adjusted from 60 to 120 mg/day.

Results: Main ADRs, thirst (77%), pollakiuria (57%), polyuria (38%), and hyperuricemia (15%) were noted during up to 3 years. In TEMPO, hepatic function-related ADRs were observed more frequently for tolvaptan than for placebo early during treatment. In this study, 8 patients (6%) experienced >3-fold increases above upper limits of normal serum ALT or AST 3 to 9 months after tolvaptan initiation, but all recovered after tolvaptan cessation. Of these 8 patients, 7 had been allocated to placebo in TEMPO. However, the residual one patient allocated to tolvaptan similarly had shown increased serum ALT in TEMPO. None of the 8 patients met Hy's Law criteria. No ADRs besides those seen in TEMPO were newly observed in this study.

Conclusions: Hepatic function-related ADRs occurred early during treatment and were reversible. Tolvaptan was thus indicated to be a promising drug for treatment of ADPKD for up to 6 years while carefully monitoring ADRs including hepatic function abnormalities.

Pregnancy Outcome in Articipants in the HALT PKD Clinical Trials

Arlene B. Chapman,[1] Kaleab Z. Abebe,[2] Marie C. Hogan,[3] Charity G. Moore,[2] Susan Spillane,[2] Theodore I. Steinman,[4] Kyongtae Ty Bae.[2] *[1]U of Chicago; [2]U of Pittsburgh; [3]Mayo Clinic; [4]Beth Israel Deaconess; [5]Halt Investigators.*

Background: ADPKD is the most common hereditary disease. Fertility rates are not impaired in ADPKD women, however, preexisting hypertension and proteinuria associate with increased maternal and fetal complications. In the HALT PKD trials, 38 pregnancies occurred despite counseling and review with participants. We now present maternal and fetal outcomes from these pregnancies.

Methods: In a secondary analysis, data regarding maternal and fetal outcomes and complications of reported pregnancies were obtained including spontaenous abortions, delivery types and still births. Data collection relied on completion of protocol case report forms, followup of hospital discharge summaries and patient based reports if available.

Results: In HALT A and B, 203 and 89 women were premenopausal. In all pregnancies, study medications were stopped immediately or before the pregnancy began. 36 pregnancies occurred in 30 women with 6 experiencing 2 pregnancies. 26 women experienced 32 pregnancies in Study A (12.8%) and 4 occured in 4 women in Study B (4.5%). In study A baseline TKV was 871.5+502.9 mls, and GFR was 104.3+17.5 mL/min. In Study B, baseline GFR was 51.6 9.3 ml/min. Information on pregnancy outcome was not available in 3 pregnancies (2 LTFU and 1 pregnant at the end of study). In 33 pregnancies, 58% resulted in a live birth (100% in HALT B). In the remainder, 7 spontaneous and 2 therapeutic abortions, 1 ectopic and 1 stillbirth occurred. Two C-sections, one for pre-eclampsia and one pre-term delivery was reported.

Conclusions: In this secondary analysis of HALT Study A and B, 10.3% of premenopausal women became pregnant despite ongoing counseling and informaed consent regarding the need to avoid becoming pregnant. A high spontaneous abortion rate was noted with a conservative live birth rate estimate of 58%. Pre-eclampsia, preterm delivery and ectopic pregnancy, all known to associate with ADPKD, occured in 9% of pregnancies. No direct evidence for fetal injury due to telmisartan or lisinopril exposure was noted.

Funding: NIDDK Support

Renal Concentrating Capacity and Copeptin Concentration in Patients with ADPKD and IgA Nephropathy with Impaired Renal Function
Debbie Zittema, Niek F. Casteleijn, Stephan J.L. Bakker, Casper F.M. Franssen, Ron T. Gansevoort. *Nephrology, Univ Medical Center Groningen, Groningen, Netherlands.*

Background: ADPKD patients have an impaired maximal urine concentrating capacity (Umax). Whether this is an aspecific effect of renal function impairment, or specific for ADPKD is yet unknown. We hypothesized that ADPKD patients have a more severely impaired Umax in comparison with non-ADPKD renal disease patients, which leads to an exaggerated vasopressin (AVP) response that may be damaging to the kidney.

Methods: 15 ADPKD (eGFR<60) and 15 IgAN patients, matched for age, sex and eGFR, underwent a water deprivation test to determine Umax. Urine and plasma osmolality (Uosm and Posm), albuminuria (ACR) and plasma copeptin (surrogate marker for AVP in pmol/L), were measured at baseline and after water deprivation (average 17 hours). Height adjusted total kidney volume (htTKV) was measured by MRI.

Results: Umax was lower in ADPKD compared with IgAN patients. Upon water deprivation Posm increased in ADPKD (p=0.003), but not in IgAN (p=0.1), whereas copeptin increased in both groups similarly (ADPKD: p=0.001; IgAN: p=0.02). Copeptin after water deprivation was negatively associated with Umax in both groups (ADPKD: R=-0.72, p=0.002; IgAN: R=-0.70, p=0.004). In ADPKD, copeptin and albuminuria were correlated after water deprivation (R=0.71, p=0.003), independently of eGFR or htTKV. Furthermore, htTKV in ADPKD was associated after water deprivation with Posm (R=0.52, p=0.048), copeptin (R=0.58, p=0.03) and Umax (R=-0.54, p=0.04).

	ADPKD	IgAN	p-value
Baseline			
eGFR	43±9	44±14	0.74
Posm	289±5	294±10	0.14
Uosm	378±157	498±144	0.04
Copeptin	14.0 (6.6-29.1)	11.9 (7.3-26.1)	0.98
Umax			
Posm	293±6	295±10	0.51
Uosm	533±138	642±148	0.046
Copeptin	26.6 (12.8-43.0)	20.7 (10.3-43.0)	0.84

Conclusions: ADPKD patients have a lower Umax compared with IgAN patients with similar renal function. Remarkably, this is not accompanied with an exaggerated increase in AVP. Notwithstanding, ADPKD severity was associated with stronger increases in Posm, copeptin and albuminuria during water deprivation. This suggests that in ADPKD water deprivation may be deleterious and should be avoided.

SA-PO864

Total Abdominal Organ Volume Is a Major Risk Factor for Malnutrition in Ambulatory Patients with Autosomal Dominant Polycystic Kidney Disease
Hyunjin Ryu,[1] Hyosang Kim,[2] Hayne C. Park,[3] Hyunsuk Kim,[1] Kook-Hwan Oh,[1] Young-Hwan Hwang,[4] Curie Ahn.[1] *[1]Internal Medicine, Seoul National Univ Hospital, Seoul, Korea; [2]Asan Medical Center; [3]Armed Forces Capital Hospital, Seongnam; [4]Eulji General Hospital.*

Background: In Autosomal dominant polycystic kidney disease (ADPKD), malnutrition may develop as renal function decreases and abdominal organ volume enlarged. In this study, we evaluated the nutritional status of outpatient ADPKD patients by using subjective global assessment (SGA) and investigated the risk factors for malnutrition.

Methods: In this single center, cross sectional study, anthropometric and laboratory data including serum creatinine (sCr), albumin, and cholesterol were collected, and total kidney and liver volume were measured. Total abdominal organ volume was defined as the sum of total kidney and liver volume and adjusted by height (htTAV).

Results: A total of 288 patients (47.9%) were included and mean age was 48.3±12.2 years. Mean estimated glomerular filtration rate (eGFR) was 65.3 ± 25.3 mL/min/1.73m^2. Mean SGA score was 6.6±0.6. 168 patients (58.3%) were in chronic kidney disease stage 1 or 2, 99 (34.4%) stage 3 and 21(7.3%) stage 4. Total 21 patients (7.3%) were mild to moderately malnourished (SGA 4-5) and 63 patients(21.7%) were at risk of malnutrition (SGA 6). There was no difference in SGA score distribution with sex. Physical scores related to nutritional status in total and male were age, height, weight and body mass index. However none of these parameters were related in female. Lower hemoglobin level and poor renal function were related with low SGA score in total and male but only decreased renal function was related in female. In contrast, higher htTAV was consistently correlated with lower SGA score, even in subjects with eGFR ≥ 45 mL/min/1.73m^2. Subjects with htTAV ³2,340 ml/m showed 8.7-fold higher risk of having malnutrition, after adjusting for sex, age, hemoglobin, albumin and sCr.

Conclusions: Nutritional risk was detected in 30% of ambulatory patients with ADPKD and relatively preserved renal function. Intraabdominal organ growth in ADPKD may affect the nutritional status independently from the renal deterioration.

SA-PO865

Tyrosine Kinase Inhibitor Tesevatinib for Patients with Autosomal Dominant Polycystic Kidney Disease
Anjay Rastogi,[1] Mitchell H. Rosner,[2] Irina Barash,[10] Theodore I. Steinman,[3] Ziad El-Zoghby,[4] Saul Nurko,[5] Seth Goldberg,[6] Ashraf El-Meanawy,[7] Mireille El Ters,[8] Maria Roche,[9] Mark S. Berger.[9] *[1]UCLA; [2]UVA; [3]Beth Israel Deaconess; [4]Mayo Clinic; [5]Cleveland Clinic; [6]Washington Univ; [7]Med College Wisconsin; [8]KU Med Center; [9]Kadmon Corp.; [10]Mount Sinai Beth Israel.*

Background: Tesevatinib (formerly KD019) inhibits both epidermal growth factor receptor (EGFR) and SRC. It decreases cyst growth and slows the decline in renal function in BPK mouse & PCK rat PKD models. In oncology trials the most common adverse events (AEs) were EGFR inhibitor AEs of acneiform rash and diarrhea. The 1/2-life of approx. 60 hrs allows for schedules other than daily dosing.

Methods: This study evaluated the safety and tolerability of tesevatinib at several doses and schedules. Eligibility used Ravine criteria for autosomal dominant polycystic kidney disease (ADPKD) in patients (pts) aged 18-55 years with eGFR ≥ 50 mL/min/1.73 m^2.

Results: 46 ADPKD pts were enrolled into 5 dose/schedule cohorts. At 150 mg/day, 3/5 pts had moderate rash occurring during the first 28 days that was not tolerated and led to study discontinuation for 2. The tolerability of intermittent dosing schedules using 150 mg (Mon, Wed, Fri or Mon, Thu) was improved over 150 mg/day, but 1 case of severe rash occurred. QTc prolongation to ≥485 ms occurred in 2 pts on 100 mg/day, and 1 pt on 150 mg MWF. The most common AEs overall in preliminary safety data were diarrhea (36%), rash (33%), nausea (29%), and asymptomatic CPK increase (24%). Other AEs included asymptomatic mild amylase elevations (21%).

Dose/Schedule	No. Pts	Gender (M)	Median Age (Yrs)	Median TKV (mL)
50 mg/day	9	3	39	1308
100 mg/day	8	5	37	1525
150 mg/day	5	2	41	1094
150 mg MWF	14	4	36	1344
150 mg MT	10	4	37	795
Total	46	18	38 (19-55)	1138 (411-3873)

Conclusions: Tesevatinib 150 mg in various schedules was associated with skin rash that was not well tolerated. A rate of QTc prolongation not acceptable for chronic use was associated with tesevatinib 100 mg/day. Tesevatinib 50 mg/day appears to be a well tolerated dose in patients with ADPKD, although some acneiform rash occurs. In order to confirm the safety profile at 50 mg/day, an additional 20 pts are being enrolled.

Funding: Pharmaceutical Company Support - Kadmon Corporation

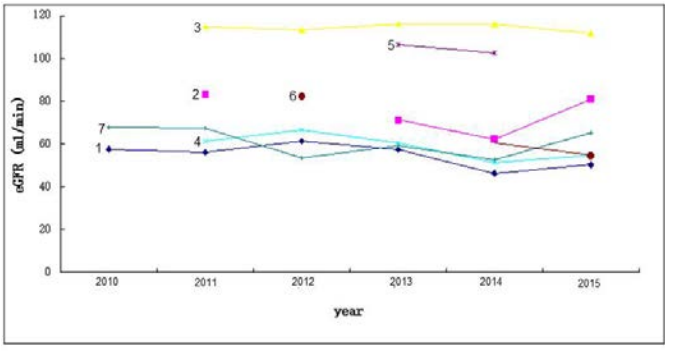
SA-PO866

Retrospective Analysis of Changes in Renal Function in Patients with PKD and Diabetes on Metformin
Jinyu Zhang,[1] Anju Yadav,[2] Lawrence Ward,[1] Kenneth R. Hallows,[3] JingJing Zhang.[2] *[1]Internal Medicine, Thomas Jefferson Univ, Philadelphia, PA; [2]Renal Div, Thomas Jefferson Univ, Philadelphia, PA; [3]Renal Div, Keck School of Medicine of USC, Los Angeles, CA.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) affects approximately 600,000 Americans. The cystic fibrosis transmembrane conductance regulator (CFTR) chloride channel participates in secretion of cystic fluid whereas the mammalian target of rapamycin (mTOR) pathway drives proliferation of cyst-lining epithelial cells. CFTR and mTOR are both negatively regulated by AMP activated protein kinase (AMPK). Metformin, a commonly used diabetes medication,activates AMPK. In two mouse ADPKD models, metformin produced a significant decrease in kidney cystic index relative to controls. Therefore, metformin may provide clinical benefit in PKD patients.

Methods: IRB-approved data collection of patients with PKD and diabetes from office visits between 3/1/2010 and 2/28/2015 were analyzed. Estimated GFR (eGFR) was calculated by using CKD-EPI formula. The ACEI/ARB usage was also recorded.

Results: One-hundred forty-nine patients with PKD were identified during a 5-year period. Of these patients, 13 also had a diagnosis of diabetes. Of these 13 patients, 1 patient was lost to follow up. Four patients have had a kidney transplant with the development of diabetes following transplantation. Eight patients had both PKD and diabetes – 7 were on metformin at some time whereas 1 had never. Regarding this groupof PKD patients on metformin, we present data on renal function trend measured by eGFR.



eGFR trend in 7 patients with PKD and diabtes who took metformin

Time on metformin:

1. 2012-2015	4. 2012-2015	7. 2012-2015
2. 2013-2015	5. 2014	
3. 2011-2015	6. 2014-2015	

Time on ACEI/ARB:

1. 2011-2015	4. 2015	7. 2011-2015
2. 2014	5. 2015	
3. 2011-2015	6. 2014-2015	

Conclusions: Renal function did not change significantly during the period that patients were on metformin. We will continue to observe these patients and accumulate more patients with PKD and diabetes but not on metformin to see if metformin is beneficial in PKD patients.

SA-PO867

11Beta-Dichloro Inhibits Cyst Progression in an Adult ADPKD Model
Sorin V. Fedeles,[1] Bogdan I. Fedeles,[3] Yasunobu Ishikawa,[1] Rachel Gallagher,[1] John M. Essigmann,[3] Stefan Somlo.[1,2] *[1]Dept of Internal Medicine, Yale School of Medicine, New Haven, CT; [2]Dept of Genetics, Yale School of Medicine, New Haven, CT; [3]Dept of Chemistry, M.I.T., Cambridge, MA.*

Background: ADPKD is the most common monogenic disorder for which no effective therapy exists. We have previously shown that the novel antitumor agent 11β-dichloro specifically induced apoptosis in *Pkd1* null cells (ASN 2013 FR-OR100). Administration of 11β-dichloro resulted in amelioration of cystic disease in the *Pkd1*$^{fl/fl}$;*Pkhd1-Cre* neonatal ADPKD model. In the current work we explored the pathways involved in the pro-apoptotic effect of 11β-dichloro and investigated whether the beneficial effect seen in the early model is also present in an adult inducible *Pax8*^{rtTA};*TetO-cre*; *Pkd1*$^{fl/fl}$ model which is more akin to the human disease.

Methods: *Pax8*^{rtTA};*TetO-cre*; *Pkd1*$^{fl/fl}$ mice were induced with doxycycline for 2 weeks beginning at P28. 11β-dichloro was administered by IP injection at a dose of 10 mg/kg, 3 times a week for 12 weeks beginning from P42; At the end of treatment the kidneys were harvested for analysis.

Results: 11β-dichloro treated adult mice resulted in a decrease in KW/BW ratio as compared to vehicle injected controls (2.6±0.1 vs. 6.1±0.4); There was no difference in body weight between treated and control. These changes were accompanied by a decrease in the cystic index (29%±1.5 vs. 49%±1.4), BUN (41±2.4 vs. 83±2.7), and creatinine (0.18±0.007 vs. 0.37±0.02). 11β-dichloro specifically increased apoptosis in cyst-lining cells but not in wild-type. UPR and ROS have been implicated as potential drivers of the 11β-dichloro-dependent pro-apoptotic phenotype. We found that upregulation of the UPR marker XBP1s and its transcriptional targets *BiP* and *Erdj4* was specific to the *Pkd1* null cells compared with wild-type, *in vitro* and *in vivo*. Treatment with 11β-dichloro increased mRNA levels of the antioxidant genes catalase and *SOD1* specifically in the *Pkd1* cystic kidneys and not in vehicle-treated kidneys.

Conclusions: 11β-dichloro specifically induces UPR, ROS, and apoptosis in cystic vs. wild-type kidneys. In an adult inducible cystic model, the compound ameliorates polycystic disease progression and improves kidney function.

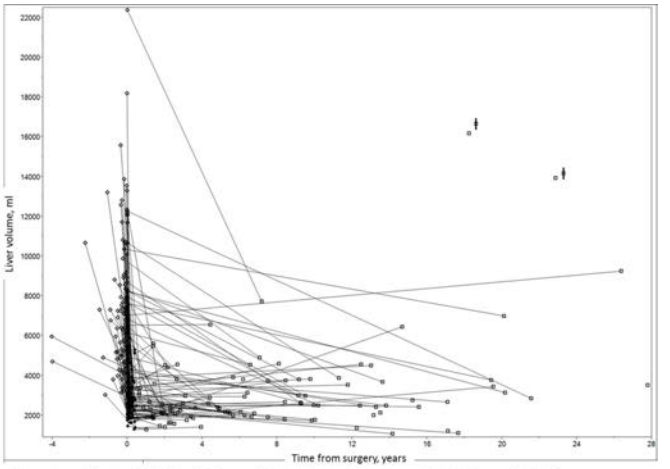
Outcomes of Combined Partial Hepatectomy and Cyst Fenestration for Massive Polycystic Liver Disease
Fouad T. Chebib,[1] Amber Harmon,[1] Maria V. Irazabal,[1] Yeon Soon Jung,[1] Marie C. Hogan,[1] Patrick S. Kamath,[1] Vicente E. Torres,[1] David M. Nagorney.[2] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Dept of Surgery, Mayo Clinic.*

Background: Partial hepatectomy and cyst fenestration (PHCF) selectively provides clinical benefit in highly symptomatic patients Polycystic Liver Disease (PLD). This study aims to ascertain whether the reduction in liver volume achieved by PHCF is sustained long-term.

Methods: Clinical data was retrieved from the electronic records in all PLD patients who underwent PHCF between 1985 and 2014. Preoperative Liver volumes (LV1), postoperative (LV2) and late follow up (LV3) were measured from MR or CT images.

Results: Among 186 patients who underwent PHCF, 91% were Caucasian women with ADPKD with a mean age of 49 years. Major peri-operative complications (Clavien III/IV) occurred in 24% of the patients. Operative mortality (<90 days) was 2.7% with one death from liver failure. Overall survival was 95%, 90%, 76.5% and 59% at 1, 5, 10 and 15 years respectively. Imaging records for volumetry were unavailable in 37 patients. Of the remaining 149 patients, 30 patients had imaging for one LV, 65 for two LV and 54 for all three LV. Median LV was 6812 ml preoperatively and 2502 ml after PHCF leading to a median postoperative liver volume reduction of 61%.



ǂ Two patients without available LV1 and LV2 images had marked recurrent hepatomegaly 23 and 26 years after PHCF

At follow-up (mean 7.8 years), median LV was 2500 ml. Interestingly, 29 out of 61 patients with available LV2 and LV3 showed further regression in LV upon follow up (median -14.8%); while the rest showed mild growth of 9.5%. Overall volumetric comparison of preoperative to follow-up liver imaging showed sustained liver volume reduction (median 60%).

Conclusions: Sustained long-term reductions in LV after PHCF can be achieved in selected patients with severe, highly symptomatic PLD. In our experience, liver-related death and subsequent liver transplantation are infrequent after PHCF.

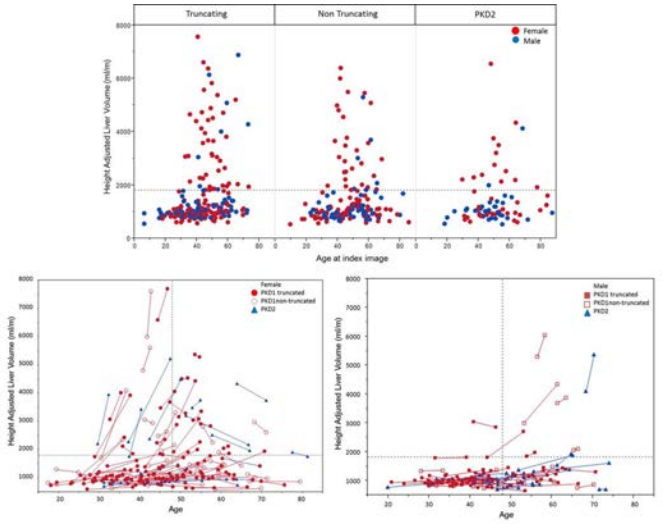
SA-PO869

Effect of Genotype on the Severity and Volume Progression of Polycystic Liver Disease (PLD) in Autosomal Dominant Polycystic Kidney Disease (ADPKD)
Fouad T. Chebib,[1] Yeon Soon Jung,[2] Christina M. Heyer,[1] Maria V. Irazabal,[1] Marie C. Hogan,[1] Peter C. Harris,[1] Vicente E. Torres,[1] Ziad El-Zoghby.[1] *[1]Div of Nephrology, Mayo Clinic, Rochester, MN; [2]Kosin U.*

Background: PLD is the most common extrarenal manifestation in pts with ADPKD. Here we analyzed the influence of genotype and gender on the severity of PLD.

Methods: Clinical data was retrieved from electronic records in a large cohort of pts who were mutation screened, determined to be PKD1 or PKD2 and had available CT or MR liver imaging during 2000-2014 at the Mayo Clinic (n=445). Liver volumes (LV) were measured by stereology on axial images and adjusted to height (HtLV).

Results: Among the 445 pts, 220 (49.5%) had truncating *PKD1*, 153 (34.4%) nontruncating *PKD1* and 72 (16.1%) *PKD2* mutations. Compared to nontruncating *PKD1* and *PKD2*, pts with truncating *PKD1* were younger at time of first imaging (43.6 vs 47.6 and 50.4; p<.001), had lower median survival time to ESRD (62.4 vs 66.9 and 81.4; p<.001,Log-Rank), and larger kidney volumes (785 vs 614 and 548 ml/m; p<.001). LV in pts with *PKD1* truncating, *PKD1* nontruncating and *PKD2* were not different (HtLV 1039, 1076 and 1058 ml/m, respectively;p=.53). Female pts had larger HtLV compared to males (1104 vs 1019 ml/m; p<.001). Annualized median liver growth rates were 1.65, 1.74 and 1.2% for truncating *PKD1*, nontruncating *PKD1* and *PKD2*, respectively (p=.75). Females younger than 48 had higher annualized median growth rates compared to those older than 48 (2.65 vs 0.09%;p<.001). When adjusting for age, gender and baseline LV, growth rate remained unaffected by the ADPKD genotype.



Conclusions: In contrast to the renal phenotype, ADPKD gene type or *PKD1* mutation type were not significantly associated with the severity or growth rate of PLD in ADKPD pts. This finding, along with the demonstrated gender influence, indicate that modifiers beyond the disease gene significantly influence this phenotype.

SA-PO870

Eligibility for Renal Transcatheter Arterial Embolization in Patients with Autosomal Dominant Polycystic Kidney Disease Tatsuya Suwabe, Yoshifumi Ubara, Junichi Hoshino, Rikako Hiramatsu, Kenmei Takaichi. *Dept of Nephrology, Toranomon Hospital, Tokyo, Japan.*

Background: In patients with ADPKD, massive renal enlargement is a serious problem. Renal transcatheter arterial embolization (TAE) is effective for reducing renal volume, but there is large variation of its effectiveness and the reasons remain unclear. We investigated factors influencing the renal volume reduction rate (RVRR) for one year after TAE.

Methods: All patients with ADPKD who received renal TAE at Toranomon Hospital from 2006 to 2013 were enrolled. We calculated RVRR by the calculation formula (1 - renal volume at each time after TAE / renal volume before TAE)*100, and analyzed factors affecting RVRR. We also compared sequential change of large cysts (>5cm), by classified them into four groups as cysts with wall thickening (>4mm), cyst with acute hemorrhage, normal cysts, and the others.

Results: 449 patients (228 men, 221 women, mean age; 57.0 ± 9.1 years) were enrolled. The RVRR at 1 year after TAE ranged from 3.9 to 84.8%, and the least squares mean RVRR calculated using mixed model was 45.73% (95% confidence interval [95% CI]; 44.36 to 47.10%). Multivariate analysis using mixed model revealed that large cysts with wall thickening (regression coefficient: -5.830, 95% CI: -9.140 to -2.520, p=0.0006), age(/5years) (-0.847, -1.073 to -0.621, p<0.0001), dialysis duration(/12months) (-0.115, -0.193 to -0.037, p=0.0039), systolic blood pressure(/10mmHg) (0.283, 0.065 to 0.501, p=0.0109), and number of microcoils used for renal TAE (1.333, 0.784 to 1.882, p<0.0001) had a significant influence on the RVRR. Among large cysts, only cysts with wall thickening did not decrease in volume. Significantly more microcoils were needed to achieve complete renal artery occlusion in patients with younger age and less dialysis duration.

Conclusions: Cyst wall thickening had an important influence on cyst volume reduction. Renal TAE was more effective in patients who were younger, had shorter dialysis duration, or had hypertension, parameters that might be associated with cyst wall stiffness. Renal artery narrowing may occur in older patients or those on longer dialysis, which might contribute to renal TAE being less effective in these patients.

SA-PO871

Patient Reported Health Related Quality of Life in ADPKD: Analysis from OVERTURE Dorothee Oberdhan,[1] Arlene B. Chapman,[2] Ronald D. Perrone,[3] Andreas L. Serra,[4] Jason C. Cole,[5] Wen Zhou,[1] Holly Krasa,[1] Jaime Blais,[1] Frank S. Czerwiec.[1] *[1]Otsuka Pharmaceutical Development & Commercialization, Inc., Rockville, MD; [2]Univ of Chicago, Chicago, IL; [3]Tufts, Boston, MA; [4]Univ of Zürich, Zürich, Switzerland; [5]PPD, San Diego, CA.*

Background: ADPKD imposes a burden on health-related quality of life (HRQoL). Few studies have systematically examined the impact of renal and extra-renal symptomatology on patient's HRQoL. The purpose of this analysis was to capture disease specific burden across all disease stages while determining specificity and sensitivity of existing and new HRQoL instruments.

Methods: The impact of disease progression on HRQoL in 3,409 ADPKD subjects involved in the OVERTURE observational study were evaluated by patient report outcomes (PRO) questionnaires, including the ADPKD-IS, ADPKD-UIS, BPI, EQ-5D, and SF-12v2. HRQoL was assessed by comparing subjects in CKD2-5 to subjects in CKD1 at baseline. Magnitude of change of 0.2, 0.5 and 0.8 standard deviations (SD) represent small, moderate and large effects on HRQoL. Other measures of disease severity, including TKV, were assessed independently.

Results: HRQoL in ADPKD was impacted at different disease stages depending on the sensitivity and specificity of the PRO used. The disease-specific ADPKD-IS scale distinguished physical, emotional and fatigue related burden as early as CKD3. Similarly, the SF-12 PCS scale was able to distinguish burden by CKD3. The SF-12 MCS and EQ5D were not sensitive to disease progression until CKD5. The impact of disease burden prior to ESRD was driven by specific questions focused on physical activity, anxiety, and exhaustion. Subjects reported being bothered by the shape of their abdomen in an independent question as early as CKD3 which associated with larger kidney volumes (htTKV > 635mL/m).

Conclusions: Studies to date have had limited success in their attempt to characterize HRQoL in ADPKD patients by using general health surveys. Disease specific instruments better capture the burden experienced by patients in earlier stages of ADPKD prior to gross kidney enlargement and effects associated with ESRD and dialysis.

SA-PO872

Fibroblast Growth Factor 23, Renal Progression and Death in Patients with Autosomal Dominant Polycystic Kidney Disease Michel Chonchol, Berenice Y. Gitomer, Xuan Cai, Tamara Isakova, Isidro B. Salusky, Renata C. Pereira, Myles S. Wolf. *Div of Renal Diseases and Hypertension, Univ of Colorado Denver.*

Background: No prospective studies examined fibroblast growth factor 23 (FGF23) and clinical outcomes among individuals with autosomal dominant polycystic kidney disease (ADPKD). We tested the hypotheses that higher serum FGF23 is a risk factor for kidney disease progression and mortality in adults with ADPKD.

Methods: We measured intact FGF23 levels (Kainos) in stored baseline serum samples in 1,002 patients who participated in the HALT-PKD randomized controlled trial of two different blood pressure control strategies. We used Cox proportional-hazards models to examine the associations between continuous levels and quartiles of iFGF23 and the primary composite endpoint of time to a 50% reduction in estimated glomerular filtration rate (eGFR) from baseline, end stage renal disease (ESRD) or death.

Results: At baseline, participants had a mean age of 42 ± 10 years, mean eGFR of 71.4 ± 26.4 mL/min/1.73m^2, mean serum phosphate of 3.4 ± 0.5 mg/dL, and median (IQR) iFGF23 of 52.6 (38.6 – 73.7) pg/mL. During a median follow-up of 5.6 years, 226 patients (22.6%) reached the composite endpoint. After adjusting for demographic factors, traditional cardiovascular risk factors, baseline eGFR, and randomized treatment group in Cox proportional hazards models, ascending quartiles of FGF23 were associated with a stepwise increased risk for the composite endpoint (HR 1.0 [reference], 1.54 [95% CI, 0.69 - 3.47], 2.92 [CI, 1.38 - 6.19], and 3.41 [CI, 1.61 - 7.22]). Similar results were obtained when FGF23 was examined on a continuous scale (HR 1.94 [95% CI, 1.39 - 2.69] per 1 SD lnFGF23 increase).

Conclusions: Higher serum FGF23 is an independent predictor of kidney disease progression and death in adults with ADPKD. Further studies are required to determine the mechanisms underlying these relationships and to test whether interventions that reduce FGF23 levels might be renoprotective.

SA-PO873

Natural History of Polycystic Liver Disease in the HALT ADPKD Cohort Marie C. Hogan,[1] Kaleab Z. Abebe,[2] Susan Spillane,[2] Frederic F. Rahbari-Oskoui,[3] Godela M. Brosnahan,[4] Charity G. Moore,[2] Vicente E. Torres.[1] *[1]Mayo C for the HALT PKD Study Group; [2]UPitt; [3]Emory; [4]U Col.*

Background: Although hepatomegaly in polycystic liver disease (PLD) is common, few studies have evaluated natural history & factors associated with progression. **Goal:** Examine change in height adjusted liver volume (htLV) & factors influencing progression in participants in HALT-PKD-A randomized clinical trial.

Methods: Baseline PLD group (mild (htLV<1000ml;n=240) moderate (1000-1800ml; n=271) & severe (>1800ml; n=28; 81% female)) & follow up htLVs, quality of life (QOL:SF36), influence of telmisartan (T) vs placebo (P) on progression were assessed (n=558, age 15-49y, eGFR > 60 ml/min). We assessed factors influencing htLVs such as treatment group, age, gender, genotype (in separate models) & factors influencing progression over time were examined using linear mixed models.

Results: Annual htLV growth rates were 0.76, 0.91,& 1.08% (P=NS) in the mild, moderate, & severe groups, respectively (figure 1). Neither baseline age or genotype associated with annual htLV increase. There were strong negative relationships of eGFR (p=.02) & serum albumin (p=.0003) with htLV. Prior pregnancy & higher parity (both age adjusted) associated with htLV but not with progression over time. Increases in HtLV were associated with increased rates of fatigue/weakness (p=0.003) and declines in SF-36 physical functioning over time (p=0.02). Progression was independent of drug assignment (T 0.89% vs P 1.07% p.a.;p=NS) & BP target (low 0.81 vs std. 1.15% p.a. p=NS).

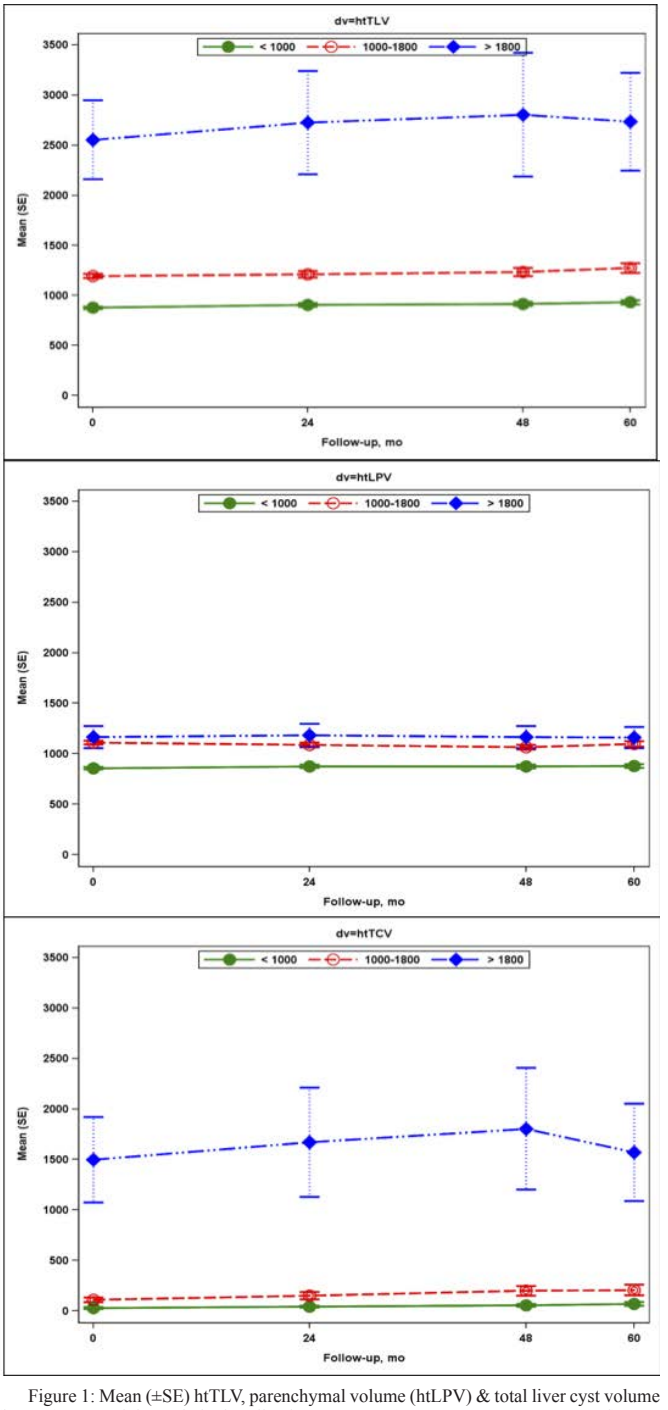

Figure 1: Mean (±SE) htTLV, parenchymal volume (htLPV) & total liver cyst volume (htTCV) at month in study by baseline htTLV group (<1000, 1000-1800, >1800ml).

Conclusions: HtLVs increased in HALT-A participants over time, correlated with fatigue/ weakness and were associated with measurable continued declines in SF36 QOL subdomains.

Towards Personalised Medicine – Treating a Renal Ciliopathy

Shalabh Srivastava,[1] Simon Ramsbottom,[1] Sophie Saunier,[2] Colin Miles,[1] John Andrew Sayer.[1] *[1]Nephrology, Inst of Genetic Medicine, Newcastle Univ, Newcastle upon Tyne, United Kingdom; [2]Laboratory of Inherited Kidney Diseases, Imagine Inst, Paris, France.*

Background: Renal ciliopathies are genetic disorders presenting with nephronophthisis, cystic kidneys or cystic dysplasia.Pathogenesis of ciliopathies may include altered signalling or defective DNA damage response. Due to the huge genetic/phenotypic variability in ciliopathies it is pertinent to explore the most important contributor to individual phenotypes. We investigated disease mechanisms of a patient with Joubert Syndrome aiming to provide a personalised medicine approach to treatment.

Methods: We identified a family with 2 affected siblings with a ciliopathy phenotype. Ciliopathy gene panel sequencing followed by Sanger sequencing and segregation analysis was undertaken to provide a molecular genetic diagnosis. We established Human Urine derived Renal Epithelial Cell (HUREC) cultures from one sibling and a control. Cultured cells where characterised and their response to therapeutic agents quantified.

Results: The siblings exhibited a cerebro-retinal-renal phenotype with renal corticomedullary cyst formation and progressive renal failure. Panel sequencing followed by Sanger sequencing confirmed biallelic mutations in *CEP290* (c.2817G>T, p.K939N; c.2848insC, p.Q950Pfs*6) in both affected patients. The c2817G>T is located in the last base of exon 25 and is predicted to lead to a splicing defect. There was no difference in mitosis or centriole numbers in control and proband's cells. Control cells formed spheroids in 3D culture (100%) whilst the proband's cells showed a defect in spheroid forming index (17%) and absent primary cilia. In the proband cells there was a rescue of spheroid forming index in response to treatment with hedgehog agonists SAG(smoothened agonist) (67%) and purmorphamine (75%) and a rescue of primary cilia.

Conclusions: In a family with a ciliopathy we have confirmed a molecular genetic defect in *CEP290*. Using HURECS we have characterised, at a personalised medicine scale, the cellular defect. This data suggests that renal ciliopathies may have potential therapeutic targets and investigation through individual HUREC based model is an exciting new development.

SA-PO875

Effect of Metformin on the Progression of Autosomal Dominant Polycystic Kidney Disease

Godela M. Brosnahan,[1] Michel Chonchol,[1] John R. Holmen,[2] Eugene J. Nuccio,[1] Berenice Y. Gitomer.[1] *[1]Univ of Colorado; [2]Intermountain Healthcare, Salt Lake City, UT.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is a common inherited disorder resulting in end-stage renal disease (ESRD), without an approved treatment. In an animal model of ADPKD metformin therapy resulted in amelioration of cystic renal growth. We sought to determine whether patients with ADPKD and type 2 diabetes treated with metformin had slower progression to ESRD than similar patients treated with other antidiabetic drugs.

Methods: We conducted a population-based cohort study of adult patients with ADPKD and type 2 diabetes between January 1/2000 and December 31/2014. We identified 322 adults with ADPKD and type 2 diabetes, of whom 119 were treated with metformin only and 203 with other antidiabetic agents. Among these we identified 31 subjects treated with metformin only who could be matched for age, sex, race, history of hypertension and coronary artery disease, and baseline renal function to 31 subjects not treated with metformin. The primary outcomes were incident ESRD and all-cause mortality.

Results: The median age of the enrolled participants was 61 years, 45% were women. Approximately 74% and 26% had a history of hypertension and myocardial infarction, respectively. The baseline MDRD-eGFR in participants receiving and not receiving metformin was 49±12 and 47±14 mL/min/1.73m^2 (p=0.70).After a median follow-up of 4.5 years, incident ESRD occurred in 29% and 16% of those not exposed and exposed to metformin, respectively, with a OR of 2.13 (95% CI 1.10-3.46; p=0.02). Deaths occurred in 32% and 26% of those not exposed and exposed to metformin, with a OR of 1.37 (95% CI 0.5-2.47; p=0.60).

Conclusions: Metformin therapy may slow progression to ESRD in ADPKD adults with type 2 diabetes compared to other antidiabetic drugs. Because metformin has an excellent safety record, a trial to slow the progression of ADPKD in the absence of diabetes is warranted.

SA-PO876

Frequency and Reasons for Hospitalization Among ADPKD Patients with GFR >25 mls/min

Dana Miskulin,[1] Kaleab Z. Abebe,[5] Ronald D. Perrone,[1] Marie C. Hogan,[2] Frederic F. Rahbari-Oskoui,[3] Peter G. Czarnecki,[4] Susan Spillane,[5] Arlene B. Chapman,[6] Robert W. Schrier,[7] Vicente E. Torres,[2] Charity G. Moore.[5] *[1]Tufts Medical Center, Boston; [2]Mayo Clinic, Rochester; [3]Emory Univ, Atlanta; [4]Brigham and Women's Hospital, Boston; [5]Univ of Pittsburgh; [6]Univ of Chicago; [7]Univ of Colorado.*

Background: There is a paucity of data about the frequency and causes of hospitalization in Autosomal Dominant Polycystic Kidney Disease (ADPKD).

Methods: Information about hospitalizations was prospectively collected in the HALT-PKD Studies, 2 multi-center trials involving people with ADPKD and GFR>60 ml/min (Study A) and GFR 25-60 ml/min (Study B). The primary diagnosis was designated after review of discharge summaries and independently adjudicated by a committee.

Results: Total patient years (ptyrs) of follow-up in the 558 Study A patients and 486 Study B patients were 3147 and 2506. The incidence rate (IR) of all-cause hospitalization in Study A and B, respectively, was 67.7 and 123.3 per 1000 ptyrs, which compares to 80.3 and 118.0 , in respective age-matched general populations (*CDC/NHDS National Hospital Discharge Survey, 2010*). The IRs in Study A and B, respectively, for cardiovascular-related hospitalization were 7.0 and 18.1 per 1000 ptyrs, and for ADPKD-related hospitalization (primary diagnosis kidney or liver cyst pain, infection or hemorrhage, pyelonephritis, kidney stones or cerebral aneurysm) were 12.7 and 26.7 per 1000ptyrs. The most common primary diagnoses are listed in the table.

Table 1: Most Common Reasons for Hospital Admission*

Study A (eGFR >60 ml/min)		Study B (eGFR 25-60 ml/min)	
Primary Diagnosis	IR/1000ptyrs	Primary Diagnosis	IR/1000ptyrs
Acute pyelonephritis/Cyst infection	3.18	Abdominal Pain	9.58
Abdominal Pain (undiagnosed/unspecified)	2.86	Kidney Cyst Hemorrhage	5.99
Chest Pain	2.54	Chest Pain	5.59
Kidney Cyst Pain (w/o hemorrhage, infxn)	2.54	Kidney Cyst Pain (w/o hemorrhage,	5.19
Kidney Cyst Hemorrhage	2.22	Acute Pyelonephritis/Cyst	4.79
Nephrolithiasis	2.22	AKI All Causes	4.79
Suicide Ideation/Attempt	2.22	Liver Cyst Pain	3.99
Atrial Fibrillation	1.91	Nephrolithiasis	3.99
Liver Cyst Pain	1.91	Osteoarthrosis Lower Leg	3.19
Acute Appendicitis	1.59	Fever Undetermined Origin	3.19

*Excluding Pregnancy; Abbreviations: IR Incidence Rate; AKI Acute Kidney Injury; w/o without; infxn infection; ptyrs patientyears

Conclusions: As compared with the respective age-matched general US populations, hospitalization rates were lower in ADPKD patients with GFR>60mls/min and higher in patients with GFR 25-60 mls/min. PKD-related complications were more common than cardiovascular related diagnoses as the primary reason for hospitalization in both Study A and B.

Funding: NIDDK Support, Private Foundation Support

SA-PO877

Effect of Statins on the Progression of Autosomal Dominant Polycystic Kidney Disease (the HALT PKD Investigators) Godela M. Brosnahan,[1] Kaleab Z. Abebe,[2] Frederic F. Rahbari-Oskoui,[3] Charity G. Moore,[2] Kyongtae Ty Bae,[2] Robert W. Schrier,[1] Jared J. Grantham.[4] *[1]Univ of Colorado; [2]Univ of Pittsburgh; [3]Emory Univ; [4]Univ of Kansas.*

Background: ADPKD is the most common hereditary disease resulting in end-stage renal failure (ESRD), without an approved treatment. In a small randomized trial comparing pravastatin for 3 years (y) with placebo in 110 patients age 8-22 y, the statin group experienced a slower rate of renal enlargement. No large trial has tested the effect of statins in ADPKD adults.

Methods: We performed a secondary analysis of the HALT PKD trials, categorizing participants into 3 groups based on statin use: 1) never users, 2) less than 3 y, and 3) at least 3 y of use. For subjects in Study A (n=558, age 15-49 y, eGFR > 60 ml/min/1.73m^2) we compared the percent change in height-adjusted total kidney volume (htTKV), in height-adjusted total liver volume (htTLV) and the rate of decline in eGFR between the 3 statin use groups. For participants in Study B (n=486, age 18-64 y, eGFR 25-60 ml/min/1.73m^2) we compared time to composite endpoint of death, ESRD or 50% decline in eGFR. Follow-up was 5-8 y.

Results: In HALT Study A only 59 subjects used statins for > 3y and 37 for < 3y. There was no difference in the rate of annual htTKV increase (6.41%, 7.11%, 5.97%; p=NS) or htTLV growth (1.02%, 1.15%, 0.65%; p=NS) between the 3 groups, after controlling for sex, age, and treatment arms. The rate of eGFR decline was faster in group 2 (4.07 ml/min/y) than in groups 1 and 3 (2.93 and 2.82 ml/min/y; p=0.015), after adjusting for the more favorable baseline characteristics of group 1 (more females, younger age, higher baseline eGFR). In Study B 118 subjects used statins for > 3y and 76 for < 3y. There was no difference in time to endpoint between the 3 groups.

Conclusions: In this secondary analysis of the HALT PKD trials,statin therapy for 3 years did not slow the rate of renal or liver enlargement or of eGFR decline in ADPKD adults, but these results are limited by the small numbers of statin users in Study A, different statin drugs and doses, and non-randomized allocation to groups.

SA-PO878

Assessment of a Dosage-Sensitive Mutational Network for PKD in a Large Cohort of Patients with Early and Severe Forms of Polycystic Kidney Disease Carsten Bergmann,[1,2] John Devane,[2] Steffen Neuber,[1] Eva Decker,[1] Uyen Tran,[3] Oliver Wessely,[3] Elisabeth B. Ott.[2] *[1]Center for Human Genetics, Bioscientia, Ingelheim, Germany; [2]Renal Div, Univ Hospital, Freiburg, Germany; [3]Cellular & Molecular Medicine, Cleveland Clinic.*

Background: ADPKD patients with early and severe disease manifestations only make up a minor proportion, but are crucial for a better understanding of PKD. Affected families have a high recurrence risk for babies with a severe clinical course often resulting in perinatal death. Especially in prenatal cases the diagnostic distinction between different forms of PKD and other ciliopathies can be difficult and illustrates the need for more comprehensive genetic testing.

Methods: An accurate genetic diagnosis is crucial for genetic counselling, prenatal diagnostics and the clinical management of patients. To this end, we established a sequence capture based NGS approach targeting 95 genes for cystic and polycystic kidney disease. This includes *PKD1,* which - due to the presence of pseudogenes - is difficult to test. As an additional advantage over conventional Sanger sequencing we were able to detect copy number variations. The biological significance of some of the detected alleles were subsequently tested by *in vitro* and *in vivo* studies using a range of animal models including zebrafish, *Xenopus* and mice.

Results: We analysed a cohort of 309 patients exhibiting early and severe PKD. In a considerable percentage of patients we did not detect just one single mutated gene/allele, but additional mutations *in trans*. Notably, this proportion increased, the more severely the patients were affected. The affected genes were not limited only *PKD1, PKD2* or *PKHD1*. In particular, a subgroup of patients with non-syndromic disease harboured mutations in genes typically related to ciliopathies such as nephronophthisis, Joubert, Meckel, and Bardet-Biedl syndrome. Finally, we used zebrafish, *Xenopus* and mice to validate some of our findings in terms of a functionally proven dosage-sensitive network.

Conclusions: This study is the most comprehensive analysis performed so far and points towards a general and underestimated concept for the modification of disease gene expression.

SA-PO879

Determinants of Progression in Early Autosomal Dominant Polycystic Kidney Disease - Is It Blood Pressure or Renin-Angiotensin-System Blockade? The HALT PKD Trial Godela M. Brosnahan,[1] Kaleab Z. Abebe,[2] Charity G. Moore,[2] Theodore I. Steinman,[3] Frederic F. Rahbari-Oskoui,[4] Susan Spillane,[2] Kyongtae Ty Bae,[2] Robert W. Schrier.[1] *[1]Univ of Colorado; [2]Univ of Pittsburgh; [3]Beth Israel Deaconess; [4]Emory Univ.*

Background: The HALT PKD Study A (558 subjects age 15-49 years, eGFR > 60 ml/min/1.73m^2) showed that intensive control of systolic blood pressure (SBP) to 95-110 mmHg was associated with a slower rate of kidney volume growth compared to standard control (SBP 120-130 mmHg). It is unclear whether this result was due to lower BP per se or to greater blockade of the renin-angiotensin-aldosterone system (RAAS) by allowing higher drug doses in the low BP group.

Methods: We performed a secondary analysis of HALT PKD Study A categorizing participants into 3 groups based on lisinopril (L) and telmisartan (T) dosage at 4 months, after initial dose titration: 1) high, defined as L 40 mg + T 80 mg daily, 2) middle (everyone not high or low) and 3) low, defined as L < 20 mg + T < 40 mg daily. We compared the percent change in height-adjusted total kidney volume (htTKV) and the rate of eGFR decline between the 3 groups during follow-up for 5-8 years.

Results: Participants in the high dose group (n=51) were more likely male and assigned to the low BP arm; they had higher baseline BP and lower eGFR at 4 months than subjects in the mid- (n=272) and low-dose (n=165) groups.After adjustment for age, sex, genotype, target BP (low or standard), and eGFR at 4 months, there was no significant difference in the rate of kidney growth (5.63, 6.40 and 5.83%/yr) or eGFR decline (3.00, 2.94 and 3.29 ml/min/yr) between the low, middle and high dosage groups.

Conclusions: In this secondary analysis of HALT Study A in young ADPKD adults, a higher dosage of RAAS blocking drugs was not associated with a slower rate of htTKV growth or of eGFR decline, after adjustment for allocation to intensive BP control. Low BP appears to be the main determinant for reducing kidney volume growth.

SA-PO880

The Short Term Effect of Tolvaptan for CKD Stage4 Autosomal Dominant Polycystic Kidney Disease Haruna Kawano,[1,2] Satoru Muto,[2,3] Shigeo Horie.[1,2] *[1]Urology, Juntendo Univ Graduate School of Medicine, Tokyo, Japan; [2]Urology, Teikyo Univ, Tokyo, Japan; [3]Endowed Course for the Study of Polycystic Kidney Disease, Juntendo Univ Graduate School of Medicine, Tokyo, Japan.*

Background: In Japan, the treatment of tolvaptan, a V2 receptor antagonist, started from March 2014. Indication criteria of tolvaptan for ADPKD treatment in Japan is adult patient with more than 750ml total kidney volume (TKV) and more than about 5%/year increasing rate of TKV. It is contraindication to use tolvaptan for patients with eGFR<15ml/min/1.73m^2. It is recommended to reduce dose of tolvaptan for patients with CCr<30ml/min. However, the treatment effect for patients with CKD stage 4 is still unknown. So, we evaluated the short time efficacy of tolvaptan treatment for patients with CKD stage 4.

Methods: Thirteen patients (5 females and 8 males, mean age; 52.5 years) with ADPKD who started tolvaptan at our hospitals from April 2014 to April 2015 were analyzed in this study. Although our standard starting dose of tolvaptan for patients with good renal function is 60mg/day, we administered 15mg/day for patients with eGFR<25ml/min/1.73m^2 patients. Patients were measured eGFR and TKV at the commencement of treatment and at 1.5 and 6 months later.

Results: The baseline median eGFR and TKV were 21.8 ml/min/1.73m^2 (range; 17.1-28.9) and 2,810ml (range; 1.031-5,847), respectively. The change of median eGFR from baseline at 1.5 months and at 6 months were -0.36 ml/min/1.73m^2 (p=0.39) and -1.80 ml/min/1.73m^2 (p=0.04), respectively. The change of median TKV from baseline at 1.5 months and at 6 months were -132ml (p=0.39) and +12ml (p=0.93), respectively. One female patient and one male patient temporally stopped their treatment at 3 months and at 6months because of their eGFR decreased to lower than 15 ml/min/1.73m^2. Hepatic toxicity, hypernatremia, and the other severe adverse events were not detected.

Conclusions: No severe adverse events were occurred and 85% of CKD stage4 patients could keep treatment for 6 months without CKD progression. Tolvaptan was safe and tolerable for ADPKD patients with CKD stage 4 in lower dose.

SA-PO881

Estimation of Total Kidney Volume in Autosomal Dominant Polycystic Kidney Disease Edwin M. Spithoven,[1] Maatje D.A. van Gastel,[1] A. Lianne Messchendorp,[1] Niek F. Casteleijn,[1] Ron T. Gansevoort.[1] *[1]Internal Medicine, Nephrology, UMC Groningen; [2]On behalf of the DIPAK Consortium, Netherlands.*

Background: Measuring total kidney volume (TKV) in autosomal dominant polycystic kidney disease (ADPKD) by magnetic resonance image (MRI) and manual tracing is time consuming. Two alternative MRI methods have recently been proposed to estimate TKV ($eTKV_{ELLIPSOID}$ and $eTKV_{PANK}$) which require less time.

Methods: ADPKD patients with a wide range of kidney function were included, if they had an approved T2 weighted MRI. A test set of 10 MRIs was used for assessing reproducibility, 220 for cross-sectional analyses and 48 for longitudinal analyses with a follow-up of three years. mTKV was used to assess Irazabal risk categories, reclassification was calculated for $eTKV_{ELLIPSOID}$ and $eTKV_{PANK}$. Measured TKV (mTKV) was manually traced, $eTKV_{ELLIPSOID}$ was calculated as advised in literature as $\pi/6$ * ($length_{coronal}$ + $length_{sagittal}$)/2 * width * depth/1000 and $eTKV_{PANK}$ as midslice x number of slices covering the kidney x 0.624 or 0.637 for the left and right kidney, respectively.

Results: In the test set, intra- and inter-coefficients of variation were low; mTKV 1.8% and 2.3%, $eTKV_{ELLIPSOID}$ 3.9% and 6.3%, and $eTKV_{PANK}$ 3.0% and 3.4%. Duration of analyses were respectively 55, 5 and 15 minutes. In cross-sectional analyses baseline kidney volumes (liters) were 1.96 (1.28-2.82) for mTKV, 1.93 (1.25-2.82) for $eTKV_{ELLIPSOID}$ and 1.81 (1.17-2.62) for $eTKV_{PANK}$, the latter both significantly different from mTKV (p=0.004 and p<0.001 respectively). Bias was low and precision high for repeated mTKV (0.2%±3.2%), $eTKV_{ELLIPSOID}$ (1.4%±9.2%) as well as $eTKV_{PANK}$ (4.6±7.6%). In longitudinal analyses, no significant differences were observed between percentage change in mTKV (16.7±17.1%) compared to change in $eTKV_{ELLIPSOID}$ (19.3±16.1%) and $eTKV_{PANK}$ (17.8±16.1%). Both methods resulted in limited reclassification in Irazabal risk categories; 6.7% for $eTKV_{ELLIPSOID}$ and 9.8% for $eTKV_{PANK}$.

Conclusions: Both methods to estimate TKV perform relatively well compared to mTKV, and detect similar changes in TKV over time. Since $eTKV_{ELLIPSOID}$ requires less time than $eTKV_{PANK}$, we suggest this method should be preferred in clinical care.

SA-PO882

Genetic Background Radically Alters Disease Progression in the Pkd1$^{RC/RC}$ Model Diana L. Escobar, Katharina Hopp, Cynthia J. Sieben, Peter C. Harris. *Mayo Clinic, Rochester, MN.*

Background: Studies in ADPKD patients and PKD mouse models have shown that genetic background influences the disease phenotype. Here, we evaluated the phenotype of the homozygous Pkd1: p.R3277C (RC) model in three new backgrounds: BalbC, 129S6, and F1 (C57BL6 X BalbC) and compared them to C57BL6.

Methods: To characterize the cystic disease burden, Pkd1$^{RC/RC}$ animals were inbred into three different strains and aged to 3 months (m). At this time point %Kidney Weight/Body W, BUN levels, kidney cyst index were used to compare disease severity.

Results: Already at this early stage of cyst progression (3m) genetic background significantly affects the severity of the disease in the Pkd1$^{RC/RC}$ model with %KW/BW significantly higher in the BalbC (3.31) and 129S6 (3.12) backgrounds compared with F1 (1.92; P<0.0001,<0.001) or C57BL6 (1.74: both P<0.0001). However, BUN levels did not deviate from the physiological norm at this early stage of the disease in any of the backgrounds. In respect to cyst index, 129S6 (21.87%) and BalbC (19.47%) animals had a greater disease burden compared to F1 (3.71%; both P<0.0001) and C57BL6 (5.24%; both P<0.0001) animals. No significant difference was found between 129S6 and BalbC mice (P=0.47). Histological analysis showed a distribution of variously sized cysts in the medulla and cortex in BalbC and large cysts mainly in the medulla in 129S6, which contrasted with small cysts mainly in the cortex in F1 and C57BL6 (figure 1). Immunofluorescence at 3m in all backgrounds showed the majority of cyst had a collecting duct (CD) origin, however some cysts were negative for the nephron markers LTA-AQP1 (PT), AQP2-DBA (CD).

Conclusions: This study highlights the role of genetic background in cystic disease progression in the Pkd1$^{RC/RC}$ model. Due to the more rapid progression and severe cystic burden, the BalbC and 129S6 models may be more suitable for PKD pre-clinical testing.

Influence of Kidney Volume on Progression to Advanced Stages of Chronic Kidney Disease in Autosomal Dominant Polycystic Kidney Disease (ADPKD) Alan S.L. Yu,[1] Jared J. Grantham,[1] Arlene B. Chapman,[3] Kyongtae Ty Bae,[2] Doug Landsittel,[2] Chengli Shen,[2] Vicente E. Torres,[4] Michal Mrug,[5] Peter C. Harris,[4] Frederic F. Rahbari-Oskoui,[6] Michael F. Flessner,[7] William M. Bennett.[8] *[1]U Kansas; [2]U Pittsburgh; [3]U Chicago; [4]Mayo Clinic; [5]UAB Birmingham; [6]Emory U; [7]NIH; [8]Legacy Good Samaritan Med Ctr.*

Background: The Consortium for Radiologic Imaging Studies of Polycystic Kidney Disease III (CRISP III) is the continuation of a longitudinal cohort study of patients with ADPKD designed to identify predictors of CKD progression and kidney failure. Cyst enlargement and hence increase in kidney volume is believed to be on the causative pathway that leads to decline in GFR and kidney failure.

Methods: In 241 patients, height-adjusted total kidney volume (htTKV) was determined by MRI at baseline, and serial GFR determined by corrected iothalamate clearance and serum creatinine estimating equations.

Results: After a mean follow-up of 11.1 years, 59.8%, 32.1% and 21.6% of subjects reached CKD stage 3, 4 and 5. In multivariable logistic regression analysis, baseline htTKV was an independent predictor for the development of CKD stages 3, 4 and 5 by the final visit, after correction for age, sex, race, BMI, and baseline GFR. Similar results were obtained whether CKD stage was determined using iothalamate clearance, MDRD eGFR, or CKD-Epi eGFR. The estimated htTKV at age 18 yr was also predictive of subsequent CKD stage 3.

[a]Determined by iothalamate GFR
[b]Per 100 mL/m

	htTKV at baseline[b]		htTKV at age 18 yr[b]	
Endpoint[a]	OR (95% CI)	p value	OR (95% CI)	p value
CKD stage 3	1.35 (1.20, 1.53)	< 0.001	1.16 (1.01, 1.32)	0.026
CKD stage 4	1.33 (1.18, 1.51)	< 0.001	1.05 (0.86, 1.27)	0.86
CKD stage 5	1.41 (1.23, 1.63)	< 0.001	1.02 (0.81, 1.27)	0.87

Conclusions: Kidney volume measured by MRI at a single timepoint is a powerful predictor for the development of advanced stages of CKD over the ensuing 11 years. Consistent with prior analyses, greater kidney volume is strongly associated with higher rates of CKD progression, further supporting the notion that cyst enlargement is the primary cause of GFR loss and kidney failure.

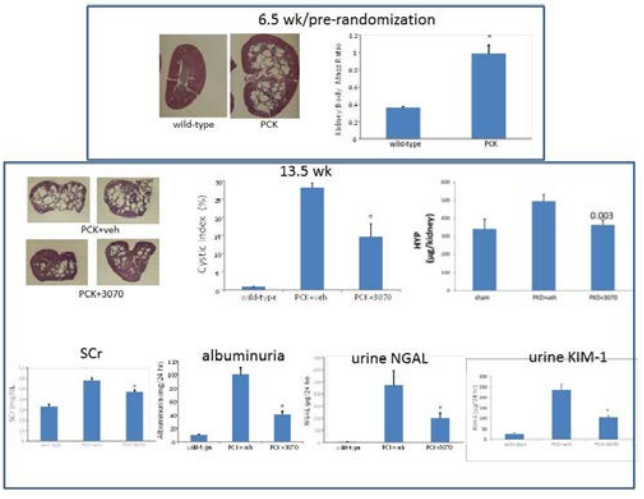
Therapeutic Effects of the Fibrokinase Inhibitor ANG3070 in Polycystic Kidney Disease Prakash Narayan, Liming Zhang, Bin Duan, Jingsong Li, Ping Zhou, Siobhan McCormack, Latha Paka, Itzhak D. Goldberg. *Angion Biomedica Corp.*

Background: Aberrant receptor tyrosine kinase signaling has been implicated in cyst expansion, renal interstitial fibrosis, increased kidney volume and reduced renal function in polycystic kidney disease (PKD). We investigated the effects of a novel, orally bioavailable, small molecule fibrokinase inhibitor, ANG3070, in experimental PKD.

Methods: Male PCK rats (PCK/CrljCrl-pkhd1pck/Crl) were rats were randomized to vehicle or ANG3070 (25 mg/kg, BID, PO) at 6.5 weeks of age following confirmation of frank disease and sacrificed at 13.5 weeks. Age-matched male Sprague-Dawley rats served as wild-type controls.

Results: ANG3070 has no effect on mean arterial pressure. In PCK rats with diseased kidneys (figure1), randomization to ANG3070 treatment was therapeutic, reducing cystic index, renal interstitial fibrosis (hydroxyproline (HYP), albuminuria and other urine biomarkers of renal injury and serum creatinine (* p<0.05).



Conclusions: With ongoing investigational new drug enabling toxicology studies suggesting a large safety index, these data support the continuing development of ANG3070 for PKD, a disease currently without cure.

SA-PO885

Extended Follow-Up of the Consortium for Radiologic Imaging Studies of Polycystic Kidney Disease (CRISP III): The Predictive Value of Height Corrected Total Kidney Volume (htTKV) for the Future Development of CKD Stages 3a, 3b, 4 and 5 After Ten Years Follow-Up in Autosomal Dominant Polycystic Kidney Disease (ADPKD) Arlene B. Chapman,[1] Chengli Shen,[2] Alan S.L. Yu,[3] Michal Mrug,[4] Frederic F. Rahbari-Oskoui,[5] Vicente E. Torres,[6] Jared J. Grantham,[3] Michael F. Flessner,[8] Kyongtae Ty Bae,[2] Doug Landsittel,[2] Peter C. Harris,[6] William M. Bennett.[9] *[1]U of Chicago; [2]U of Pittsburgh; [3]U of Kansas; [4]Univ of Alabama Birmingham; [5]Emory Univ; [6]Mayo Clinic; [7]National Insts of Health; [8]Legacy Good Samaritan Hospital.*

Background: CRISP III is a longitudinal observational cohort study of 241 ADPKD individuals now extending beyond 10 years. Measures of cyst burden by magnetic resonance imaging (MR) provide an accurate assessment through measures of htTKV. We have shown previously that baseline htTKV predicts CKD stage 3 after 8 years. We now evaluate whether baseline htTKV can predict CKD Stage 3a,3b, 4 and 5 after 10 years of followup.

Methods: Participants underwent protocol visits including MR imaging, iothalamate clearance and serum creatinine measurements. Baseline htTKV was evaluated in its capacity to predict later CKD stages both individually and in a multivariable model that includes age, race, gender, and baseline iothalamate clearance. Receiver operator characteristic area under the curves (AUROC) were developed for reaching CKD stage 3a, 3b, 4 or 5 after a minimum of 10 years of followup.

Results: At 10 years, 59.8%, 32.1% and 21.6% of patients had reached CKD stage 3,4 or 5. Baseline htTKV alone predicts CKD stage 3 in 10 years with a ROC of 0.85 and an optimal TKV cut point of 470 ml/m. Multivariable analysis assessing future CKD Stage 3a, 3b, 4 and 5 at 10 years demonstrated a ROC of 0.89, 0.87, 0.90, and 0.89 respectively.

Conclusions: HtTKV is a powerful predictor of the development of all advanced stages of CKD within 10 years with an optimal htTKV of 470 ml/m for CKD Stage 3.

Alterations in Renal Oxylipins in Models of Polycystic Kidney Disease: Potential for Cyclooxygenase Inhibition for Disease Treatment Harold M. Aukema,[1,2] Jessay Gopuran Devassy,[1,2] Md Monirujjaman,[1,2] Tamio Yamaguchi,[1,2] Amir Ravandi.[3] *[1]Human Nutritional Sciences, Univ of Manitoba, Winnipeg, MB, Canada; [2]CCARM, St. Boniface Research Hospital Research Centre, Winnipeg, MB, Canada; [3]Inst for Cardiovascular Sciences, St. Boniface Research Hospital Research Centre, Winnipeg, MB, Canada.*

Background: In both the Han:SPRD-*Cy* rat and the *pcy* mouse, prostanoids formed via the cyclooxygenase (COX) pathway are elevated, while oxylipins produced via the lipoxygenase (LOX) and cytochrome P450 (CYP) pathways are reduced. Importantly, inhibiting the formation of the elevated COX oxylipns with selective (NS-398) or unselective (aspirin) COX inhibitors reduces the progression of disease in the Han:SPRD-*Cy* rat, suggesting their potential use in the treatment of nephronophthisis. It is not known, however, whether renal oxylipins are altered in orthologous models of human polycystic kidney disease (PKD).

Methods: Renal oxylipins were examined in orthologous models of autosomal dominant (AD) and autosomal recessive (AR) PKD. *Mx1Cre^{+}Pkd1$^{flox/flox}$* mice (ADPKD1) were injected with saline or pI:pC at 5 weeks of age, and control and diseased kidneys were obtained at 21 weeks of age. Control and diseased kidneys from *Pkd2$^{WS25/-}$* mice (ADPKD2) and PCK (ARPKD) rats were obtained at 16 weeks of age. Over 100 oxylipins were analyzed by LC/MS/MS.

Results: In *Mx1Cre^{+}Pkd1$^{flox/flox}$* mice with disease, renal levels of the COX metabolites, prostaglandin (PG)E_2 and 6-keto-$PGF_{1\alpha}$ were elevated by 35 and 59%, respectively. In *Pkd2$^{WS25/-}$* mice, PGE_2, 11β-PGE_2, $PGF_{2\alpha}$, PGD_2, and 6-keto-$PGF_{1\alpha}$ were elevated in diseased kidneys by 43, 49, 46, 67 and 136%, respectively. In the PCK rat model of ARPKD, PGE_2 and 6-keto-$PGF_{1\alpha}$ were elevated by 38 and 50%, respectively. In all three models, although not as consistent as the COX oxylipin changes, LOX and CYP oxylipins were generally lower, which is similar to findings in the Han:SPRD-*Cy* rat and *pcy* mouse.

Conclusions: The elevated renal COX oxylipins in these PKD models are consistent with other cystic kidney disease models. This suggests that COX inhibition with common drugs such as aspirin or selective COX inhibitors may be beneficial in PKD, as it is in other models of cystic kidney diseases.

Hepatorenal Fibrocystic Diseases in Children Eujin Park,[1] Yo Han Ahn,[1] Hee Gyung Kang,[1,2] Hye Won Park,[3] IL-Soo Ha,[1] Hae Il Cheong.[1,2] *[1]Dept of Pediatrics, Seoul National Univ Children's Hospital, Seoul, Korea; [2]Research Coordination Center for Rare Diseases, Seoul National Univ Hospital, Seoul, Korea; [3]Dept of Pediatrics, Seoul National Univ Bundang Hospital, Seongnam, Korea.*

Background: Hepatorenal fibrocystic diseases (HRFCDs) are a group of monogenic disorders characterized by developmental abnormalities involving the liver and kidney. In this study, we performed genotype and phenotype analyses of children with HRFCDs to determine the distribution of underlying diseases.

Methods: A total of 36 children with HRFCDs were recruited, with genetic tests performed in 22 patients and 14 patients diagnosed clinically as having autosomal recessive polycystic kidney disease (ARPKD).

Results: In children with HRFCDs, ARPKD was the most common disease (16/36, 44.4%) followed by nephronophthisis 13 (NPHP13, 11/36, 30.6%) and Meckel–Gruber syndrome type 3 (MKS3, 4/36, 11.1%). Renal function deteriorated faster in children with NPHP13. The main hepatic pathology was Caroli disease in the NPHP13 patients, while most other patients had Caroli syndrome or congenital hepatic fibrosis. Of note, three of four MKS3 patients had an accompanying choledochal cyst. No ARPKD patients had other organ involvement, while several NPHP13 patients had ocular and/or neurodevelopmental involvement. In contrast, all MKS3 patients had severe ocular and neurodevelopmental involvement.

Conclusions: NPHP13 is a major disease belonging to HRFCDs, and thorough evaluation of its clinical features, including kidney, liver and other organ involvement, may aid in the differential diagnosis of HRFCD.

SA-PO888

Identifying Genetic Modifiers in Severe Polycystic Liver Disease (PLD) by Whole Exome Sequencing (WES) Amirreza Haghighi,[1] Young-Hwan Hwang,[2] Ning He,[1] Kairong Wang,[1] Winnie Y. Chan,[1] Xuewen Song,[1] Joost P.H. Drenth,[3] York P. Pei.[1] *[1]Div of Nephrology, Univ of Toronto, Toronto, Canada; [2]Div of Nephrology, Eulji Univ College of Medicine, Seoul, Korea; [3]Dept of Gastroenterology and Hepatology, Radboud Univ, Nijmegen, Netherlands.*

Background: Severe PLD (sPLD) is a rare and poorly understood phenotype seen in ADPKD and ADPLD. Mutations of *PRKCSH* or *SEC63* in ADPLD reduce functional polycystin-1 dosage by decreasing endoplasmic reticulum (ER) protein-processing and aggravates cystic disease severity in-vivo (Nat Genet 43: 639-647, 2011). We hypothesize that rare mutations in ER pathway genes may modify PLD.

Methods: We performed WES using Illumina HiSeq2000/2500 with SSV4/5 capture kit in 88 patients (24 affected discordant sib-pairs and 7 affected concordant sib-pairs for sPLD and 27 sporadic cases). All sPLD patients had a liver span >25 cm by CT/MRI or >3x normal liver volume. In addition to genome-wide analysis, we performed focused analysis on 168 ER genes. Standard algorithms for sequence alignment, base calling, and QC filtering were applied to identify rare deleterious variants of high and moderate impact as predicted by PolyPhen-2, Sift, Mutation Assessor, Mammalian and Vertebrate nucleotide-level conservation, and Combined Annotation Dependent Depletion.

Results: Overall, we achieved a mean target coverage of 108X with 90% of targeted exomes having >30X read depth. We identified 4,696 rare deleterious variants that segregated with PLD disease severity in at least one family. From them, we found 7 non ER genes (T*TN*, *DNAH10*, *DNAH14*, *HMCN2*, *NEB*, *OBSCN* and *ADAMTS8*) with rare variants that segregate in 4 to 6 families each and 8 ER genes (*WFS1*, *UGGT1*, *UGGT2*, *SEC24D*, *SEC23B*, *EIF2AK4*, *ATF6B* and *RPN1*) with rare variants that segregate in at least one family and 3-4 sporadic sPLD cases.

Conclusions: Our results suggest extensive genetic heterogeneity with no one single gene accounting for a large proportion of sPLD cases. Future studies with expanded sample size will help to identify promising candidate genes for follow-up functional studies. Identification of genetic modifiers of sPLD has the potential to improve risk prediction and treatment of this unusual complication.

TOSCA – TuberOus SClerosis Registry to Increase Disease Awareness: Renal Manifestations of Tuberous Sclerosis Complex John C. Kingswood,[1] Anna C. Jansen.[2] *[1]Sussex Kidney Unit, Royal Sussex County Hospital, Brighton, United Kingdom; [2]Pediatric Neurology Unit, UZ Brussel, Brussel, Belgium.*

Background: Renal manifestations are the most common cause of morbidity and mortality in adult patients with tuberous sclerosis complex (TSC). The aim of the TuberOus SClerosis registry to increase disease Awareness (TOSCA) is to understand the various manifestations of TSC. The baseline data of renal manifestations in the overall TOSCA cohort are presented here.

Methods: Patients diagnosed with TSC were enrolled in TOSCA from 170 sites across 31 countries worldwide. Patients will be followed up for up to 5 years with interim analysis performed every year.

Results: Baseline core data from 2093 patients were entered in the registry as of September 30, 2014 (cut-off date for the 2nd interim analysis). Median age at consent was 13 years (0-71). Renal angiomyolipomas were reported in 987 (47.2%) patients. Median age at diagnosis of angiomyolipoma was 13 years (0-67). Of the 946 (95.8%) patients with ongoing renal angiomyolipomas, 396 (41.9%) had multiple and bilateral lesions, 329 (34.8%) had lesions > 3 cm, and 204 (21.6%) had growing lesions. Symptoms/signs associated with renal angiomyolipomas, reported either individually or in combination with others, were elevated blood pressure (48 [5.1%]), microscopic hematuria (35 [3.7%]), hemorrhage (47 [5.0%]), impaired renal function (36 [3.8%]), and pain (51 [5.4%]). Renal angiomyolipomas were treated in 274 (27.8%) patients; major treatment modalities included embolization in 98 (35.8%) and mammalian target of rapamycin (mTOR) inhibitors in 78 (28.5%) patients. Other renal features reported were renal malignancy (24 [1.1%]), multiple renal cysts (477 [22.8%]), polycystic kidneys (73 [3.5%]), and impaired renal function (43 [2.1%]).

Conclusions: The prevalence of renal angiomyolipomas of 47.2% in our cohort compared to 80-85% in the literature probably reflects their young mean age. Despite this the intervention rate was high, emphasizing the need for active surveillance. This is the largest cohort of patients with TSC ever reported, thus TOSCA is a powerful tool to delineate the natural history of TSC.

Sirolimus Reduces Fundamentally the Vascular and/or Muscular Components of Angiomyolipomas and Can Be Neoadjuvant to Partial Nephrectomy in Tuberous Sclerosis Complex Patients with Multiple and Large Tumors Associated with Surgical Risk Elieser H. Watanabe,[1] Fernando I. Yamauchi,[2] Hilton M. Leao-Filho,[2] William C. Nahas,[3] Luiz F. Onuchic.[1] *[1]Nephrology, Univ of Sao Paulo, Sao Paulo, SP, Brazil; [2]Radiology, Univ SP, Sao Paulo, SP, Brazil; [3]Nephrology, Univ SP, Sao Paulo, SP, Brazil.*

Background: Renal angiomiolipomas (AMLs) are commonly associated with tuberous sclerosis complex (TSC). Because AMLs may complicate with lethal hemorrhage, invasive intervention is preconized for high-risk lesions. These procedures, however, imply in potential loss of functional renal mass and operatory risk, particularly in TSC patients with multiple and bilateral involvement. Since AML pathogenesis is based on the loss of mTOR inhibition, clinical trials have evaluated and shown efficacy of mTOR inhibitors (mTORi) to reduce tumor size. Such studies, however, were not capable of proving mTORi long-term benefit. Given that tumor size is an independent predictor of renal function decline after partial nephrectomy, we hypothesized that pre-surgical treatment with mTORi might be beneficial.

Methods: In this retrospective study we report the effects of neoadjuvant therapy with the mTORi sirolimus in TSC patients with multiple/large AMLs undergoing nephron sparing surgery (NSS).

Results: As expected, sirolimus decreased tumor volume (-32.9±30.8%, n=22 from 9 patients, serum level of 10.4+1.3 ng/mL; p<0.001). This reduction occurred essentially due to the non-fatty compartment decrease (-56.2±33.1%; p<0,001) while the fatty component showed no significant variation. A lower rate of early operatory complications was found in the treated compared to the non-treated group (0%, n=7 *vs* 43%, n=6; p<0,05). Such complications included mostly intraoperatory bleeding (75%). Long-term complication rates did not differ between the groups. Sirolimus was well tolerated and no serious adverse event was reported.

Conclusions: Our data indicate that sirolimus acts fundamentally at the vascular-containing compartment, suggesting that it may decrease the bleeding risk. In addition to its potential benefit as neoadjuvant therapy for large/multiple AMLs undergoing NSS, our findings revealed that the use of sirolimus was safe and reduced surgical complications.

The ARegPKD Registry Study – Initial Clinical Characterization of an International ARPKD Cohort Kathrin Ebner,[1] Gema Ariceta,[2] Carsten Bergmann,[3,4] Heiko Billing,[5] Reinhard Buettner,[1] Ali Duzova,[6] Heike Goebel,[1] Dieter Haffner,[7] Thomas Illig,[7] Augustina Jankauskiene,[8] Djalila Mekahli,[9] Bruno Ranchin,[10] Anja Christine Sander,[11] Sara Testa,[12] Lutz Thorsten Weber,[1] Dorota Wicher,[13] Elke Wuehl,[14] Franz S. Schaefer,[14] Max Liebau.[1] *[1]Univ Hospital of Cologne, Germany; [2]Univ Hospital Vall d'Hebron, Barcelona, Spain; [3]Bioscientia Center for Human Genetics, Ingelheim, Germany; [4]Univ Hospital of Freiburg, Germany; [5]Univ Hospital of Tuebingen, Germany; [6]Hacettepe Univ, Ankara, Turkey; [7]Hannover Medical School, Germany; [8]Center for Pediatrics, Univ Hospital of Vilnius, Lithuania; [9]Univ Hospital of Leuven, Belgium; [10]Univ de Lyon, Bron, France; [11]Univ of Heidelberg, Germany; [12]Fondazione IRCCS Ca Granda Ospedale Maggiore Polic, Milano, Italy; [13]The Children's Memorial Health Inst, Warsaw, Poland; [14]Univ Hospital of Heidelberg, Heidelberg, Germany.*

Background: Autosomal recessive polycystic kidney disease (ARPKD) is the rare form of polycystic kidney disease presenting in early childhood. There is unexplained phenotypic heterogeneity. Current therapeutic approaches continue to be largely opinion-based and symptomatic.

Methods: ARegPKD is an international, mostly European, pro- and retrospective, observational study in both pediatric and adult ARPKD patients to generate a deeply-characterized ARPKD cohort. Using web-based questionnaires regarding patients' clinical data in combination with associated biobanking and reference histology ARegPKD will characterize long-term ARPKD courses and set roots for future translational research.

Results: In June 2015 63 centers have registered and more than 130 patients have been included (57,6 % male; median age at inclusion 7,6 years; number of follow-up visits up to 17). Here we present data on general patient characteristics, genetic testing, renal and hepatic phenotype putting a special focus on the peri- and postnatal period (prenatal findings, ventilation modalities, sonographical findings, laboratory values).

Conclusions: ARegPKD aims to deeply characterize ARPKD patients in order to provide evidence base for clinical treatment decisions and contribute to the understanding of this severe renal disorder of early childhood.

SA-PO892

The Effect of Sodium Nitrite on Central and Peripheral Hemodynamics, Vasoactive Hormones, GFR and Sodium Excretion in Healthy Subjects Jeppe B. Rosenbaek, Safa Al Therwani, Janni Majgaard Jensen, Frank H. Mose, Erling B. Pedersen, Jesper N. Bech. *Univ Clinic in Nephrology and Hypertension, Holstebro Hospital and Aarhus Univ, Denmark.*

Background: Recent research has shown that sodium nitrite is readily converted to nitric oxide (NO) by enzymes in vivo and exerts vasodilation. Previous studies based on nitric oxide synthase inhibition indicates a natriuretic effect of nitric oxide. The purpose of the present study was to examine the effects of sodium nitrite on central and peripheral blood pressure, heart rate, fractional sodium excretion and GFR.

Methods: In a single blinded, crossover, placebo controlled dose-response study 12 healthy subjects were treated, in a randomized order, with placebo (isotonic NaCl) or one of three doses of sodium nitrite 40, 120 or 240 mg/kg/hour for two hours. Each examination was preceded by 4 days standardized diet. Subjects were supine and water loaded throughout the day. Before, during and after sodium nitrite administration we measured diastolic, systolic and mean arterial blood pressure (DBP, SBP and MAP), heart rate, plasma renin, angiotensin II and aldosterone, GFR by chrome-EDTA clearance, fractional sodium excretion and urinary excretion rate of nitrite and nitrate (NO_x).

Results: Fractional sodium excretion were reduced by 0.25% 95%CI (0.02;0.47) by the lowest dose, 0.24% (-0.12;0.59) by the intermediate dose and 0.32% (0.06;0.59) by the highest dose compared to placebo. The highest dose of sodium nitrite reduced SBP by 4.5 mmHg (0.5;8.5), DBP by 3.8 mmHg (0.9;6.7), MAP by 4.0 mmHg (1.2;6.8) and increased P-renin concentration by 17.6% (2.9;32.2), P-angiotensin II by 21.8% (4.6;38.9) and urinary excretion rate of NO_x by 95% (59;132) compared to placebo. There was no effect on heart rate, GFR or aldosterone.

Conclusions: In supine, water loaded subjects a two hour infusion of 240 mg/kg/hour sodium nitrite exerts an antinatriuretic and BP lowering effect. The rise in urinary excretion rate of NO_x suggests an increased bioavailability. The activation of the renin-angiotensin-aldosterone system (RAAS) could either be mediated directly by nitrite/NO or by baroreceptor reflex. The antinatriuretic effect might, at least partially, be mediated by the RAAS.

The Spatial Destribution of Metabolites Determined by Imaging Mass Spectrometry in the Kidneys of Rats Treated with Furosemide

Hyo-jung Choi, Euijung Park, Tae-Hwan Kwon. *Dept of Biochem and Cell Biol, Sch of Med, Kyungpook Natl Univ, Taegu, Korea.*

Background: In the kidney, metabolic processes vary among the cortex (COR), outer medulla (OM), and inner medulla (IM), and the concentrations of metabolites are different according to the kidney zones. We aimed to examine the regional differences of the significantly changed metabolites in the kidneys of rats treated with loop diuretics by exploiting the matrix-assisted laser desorption/ionization (MALDI) and imaging mass spectrometry (IMS).

Methods: Osmotic minipumps were implanted in male Sprague-Dawley rats to deliver 12 mg/day of furosemide (s.c.). Vehicle-treated control rats (n = 14) and furosemide-treated rats (furosemide rats, n = 15) were maintained in metabolic cages for 6 d on a fixed daily amount of rat chow (15 g/220 g bw/rat) with free access to water intake.

Results: At day 6, higher urine output (32 ± 4 vs. 9 ± 1 ml/day) and lower urine osmolality (546 ± 44 vs. 1,677 ± 104 mOsm/KgH_2O) were observed in furosemide rats. Extracts of COR, OM, and IM were analyzed by UPLC/Q-TOF MS. The filtered peaks in UPLC/Q-TOF MS were subjected to multivariate analysis, revealing a clear differentiation between the two groups. UPLC-QTOF-MS identified significant changes of metabolites, including acetyl carnitine, betaine, carnitine, choline, dehydrocarnitine, and glycerophosphorylcholine (GPC). Next, significant changes of metabolites were also identified by IMS and MALDI-TOF/TOF, including choline compounds (choline, phosphocholine, phosphocholine derivatives and GPC), carnitine compounds (carnitine, dehydrocarnitine, aceyl carnitine and acyl carnitine) and betaine. Importantly, the spatial distribution and relative quantitation of identified metabolites were analyzed by IMS. Choline compounds were increased in COR and OM, but decreased in IM from furosemide rats. Carnitine compounds were increased in COR and IM in furosemide rats. Betaine and GPC were decreased in OM and IM in furosemide rats.

Conclusions: Taken together, IMS applied to the kidney sections successfully provides the spatial distribution and relative quantitation of significantly changed metabolites in the kidneys of furosemide rats.

SA-PO894

Bicarbonate Supplementation Improves Vascular Function in Patients with Chronic Kidney Disease: A Pilot Study

Jessica B. Kendrick,[1,2] Emily Decker,[1] Kristen L. Nowak,[1] Michel Chonchol.[1] *[1]Univ of Colorado Denver, Aurora, CO; [2]Denver Health Medical Center, Denver, CO.*

Background: Metabolic acidosis, as reflected by a low serum bicarbonate level, is associated with increased risks of endothelial dysfunction, hypertension and death. Metabolic acidosis induces inflammation and endothelin-1, both of which contribute to vascular dysfunction. Whether alkali therapy improves vascular function in patients with chronic kidney disease (CKD) is unknown.

Methods: Seven subjects (5 men and 2 women) with stage III/IV CKD and serum bicarbonate level: 16-22 mEq/L completed a pilot, prospective, open-label, crossover study of 14 weeks duration examining the effect of oral sodium bicarbonate supplementation on endothelial function. The primary endpoint was change in brachial artery flow mediated dilation between treatment and control conditions. Each period was 6 weeks in duration with a two-week washout period in between. Patients were treated with oral sodium bicarbonate tablets two to three times per day for goal serum bicarbonate of ≥ 23 mEq/L.

Results: The mean (SE) age and eGFR was 59 (3.3) years and 21.9 (2.6) ml/min/1.73m^2, respectively. The mean (SE) serum bicarbonate level increased after sodium bicarbonate administration from 18.4 (0.7) mEq/L to 23.7 (0.9) mEq/L. The mean (SE) serum bicarbonate level did not change in the control arm. Blood pressure control was similar between the two conditions. Brachial artery flow-mediated dilation was 42% higher after 6 weeks of sodium bicarbonate replacement (3.78 ± 1.58 to 5.35 ± 1.31%) whereas it decreased by 14% during control conditions (3.51 + 0.53 to 3.01 + 0.91%).

Conclusions: Bicarbonate supplementation in patients with CKD and low serum bicarbonate levels results in improved vascular function. Large randomized trials need to be performed to determine if treatment with alkali therapy can reduce cardiovascular disease in patients with CKD.

SA-PO895

Tenofovir-Related Distal Tubular Acidosis in HIV Infected Patients

Tamara Cunha, Talita Mourao Loyola, Carlos Perez Gomes, Maurilo Leite. *Dept of Nephrology, Federal Univ of Rio de Janeiro, Rio de Janeiro, Brazil.*

Background: Tenofovir disoproxil fumarate (TDF) is a nucleoside reverse transcriptase inhibitor extensively used worldwide and is now the most prescribed drug on Highly Active Antiretroviral Therapy (HAART).TDF toxicity is mainly targeted at the proximal tubule, and in severe cases can cause Fanconi Syndrome or acute kidney injury. Despite this, there are no studies evaluating other types of tubular toxicity. This study evaluated the presence of distal renal tubular acidosis (dRTA) in HIV patients on HAART.

Methods: Sixty one HIV patients older than 18 years on treatment with HAART for more than 6 months and GFR estimated by CKD-EPI equation greater than 45 ml/min/1.73m2 were evaluated. They were divided into two groups: 31 used HAART that included TDF and 30 used HAART with no current or previous use of TDF. They were submitted to fluid restriction for 12 hours and received 40mg of furosemide and 0.1mg of fludrocortisone, following the acidification test proposed by Walsh *et al* (2007).We measured serum bicarbonate and the following parameters: hourly urinary pH (0h to 4h) by potentiometry, urinary ammonium (uNH4+) by spectrophotometry and urinary titratable acidity (uTA) by NaOH (0h and 4h).The diagnosis of dRTA was established when the urinary pH was higher than 5.3 in all measurements.

Results: There was no significant difference between the groups in terms of age, gender, ethnicity, CD4 count or eGFR. The prevalence of dRTA was 6% in the group without TDF and 26% in TDF group (p=0.04). In both groups, patients without dRTA showed increase in uNH4+ (p=0.05 and p=0.009, respectively) and in uTA (p=0.04 and p=0.05, respectively), unlike patients diagnosed with dRTA that showed no significant increase neither in uNH4+ (p=0.44 and p=0.34, respectively) nor in uTA (p=0.52 and p=0.11, respectively). In all cases with dRTA, the serum bicarbonate was normal, featuring an incomplete presentation.

Conclusions: The prevalence of incomplete dRTA in patients using TDF was significantly higher than the group not using the drug. This is the first study suggesting a possible association between TDF and dRTA. Subsequent studies will be necessary to corroborate this hypothesis.

SA-PO896

Comparison of Acid-Base Disorder Between Patients Undergoing Ileal Neobaldder and Ileal Conduit

Jung-woo Noh,[1] Eunjung Kim,[1] Ja-Ryong Koo.[1] *[1]Internal Medicine, Nephrology, Hallym Univ Medical Center, Hallym Kidney Research Inst, Seoul, Korea; [2]Internal Medicine, Nephrology, Hallym Univ Medical Center, Hallym Kidney Research Inst, Seoul, Korea; [3]Internal Medicine, Nephrology, Hallym Univ Medical Center, Hallym Kidney Research Inst, Seoul, Korea.*

Background: Since the 1980s, the orthotopic ileal neobladder(INB) has been as an new option by eliminating the need for a cutaneous stoma and urostomy appliances of ileal conduit(IC). Although this method has improved patients' quality of life, frequent incidence of metabolic acidosis(MA) have been reported. We compared occurrence of MA in INB group to IC group, and searched for risk factors affecting MA.

Methods: We conducted a retrospective study in 95 patients who underwent radical cystectomy and urinary diversion from January 2001 to December 2014 at Hallym University Medical Center. Patients who have any illness such as severe pulmonary disorder, take any medication that could lead to MA and sepsis were excluded. Acid-base balance and renal function were compared between INB and IC groups. MA was defined as a venous sample bicarbonate level of less than 21 mmol/L.

Results: MA was detected in 74.2% and 69.7% within 7 days(p=0.64), and in 31% and 14.8% at 1 month(p=0.1) after operation in INB and IC group. But cases on bicarbonate therapy were significantly more in INB group(p=0.02). Serum HCO3 levels(p=0.05) and base excess(p=0.02) were significantly lower in INB group in spite of more cases on bicarbonate therapy. Acute kidney injury(AKI) at 1 month was higher in INB group(p=0.008). Serum creatinine concentrations were significantly correlated with bicarbonate levels. Multiple logistic analysis showed that 1 mg/dl increase of serum creatinine level result in a 5.38-fold higher risk of MA (95% confidence interval, 1.14-25.3; P = 0.03). Patients without AKI, MA was detected in 13.5% in INB group, 12% in IC group at 1 month(p= 1.0).

Conclusions: Despite there being no statistical difference, INB group may more easily develop MA compared with IC group especially in patients with elevated serum creatinine concentrations. In addition, a close association between the serum creatinine level and the degree of MA was observed in both groups.

SA-PO897

Screening for Hyperlactatemia: Relationship Between the Anion Gap and Serum Lactate in Hypovolemic Shock

Richard M. Treger,[1,2] Tristan Grogan,[2] David Elashoff,[2] Craig Anderson,[3] Scott Rudkin.[3] *[1]Nephrology, VHAGLA, LA, CA; [2]Medicine and Statistics Core, UCLA, LA, CA; [3]Emergency Medicine, UCI, Irvine, CA.*

Background: In lactic acidosis (LA), a discrepancy between the increase in serum anion gap (AG) and serum lactate concentration has been noted. Previous studies evaluated patients in the Intensive Care Unit with established LA. No study has examined the relationship between AG and serum lactate within the first hour of the development of LA, specifically the sensitivity and specificity of an elevated AG for predicting hyperlactatemia.

Methods: Data were obtained prospectively from adult trauma patients at a single level 1 trauma center. Venous samples were drawn prior to initiation of intravenous fluid resuscitation.

Results: 117 patients with elevated serum lactate levels (>2.1 mmol/L) were included. The sensitivity of an elevated AG (> 10) to reveal hyperlactatemia was only 43% whereas specificity was 84%. Sensitivity improved if the upper limit of normal AG was lowered and with increasing levels of serum lactate. (Table 1). The correlation between the AG and serum lactate level yielded an R^2 of 0.30 ($p < 0.001$) and the slope of this relationship was 0.29 ± 0.58 (95% confidence interval 0.23-0.35).

Table 1: Sensitivity and specificity from use of the AG as an indicator of hyperlactatemia for specific AG and lactate level thresholds

Sensitivity/Specificity		Threshold for increased lactate concentration			
		>2.1	>5	>8	>10
Threshold for Anion Gap	<6	0.92/0.25	0.96/0.15	1.00/0.14	1.00/0.14
	<8	0.74/0.57	0.84/0.39	0.88/0.37	1.00/0.37
	<10	0.43/0.84	0.60/0.70	0.88/0.68	1.00/0.68
	<12	0.24/0.98	0.48/0.88	0.63/0.85	0.67/0.85

Conclusions: Within the first hour of the development of LA due to hypovolemic shock, the AG was not a sensitive indicator of an elevated serum lactate level, but it was fairly specific. The sensitivity and specificity of the AG as an indicator of hyperlactatemia is consistent with prior studies examining later stages of LA. The AG increased to a greater extent than the serum lactate and approximately 70% of the change in AG could not be explained by increases in serum lactate. Our results suggest that other anions contribute to the AG in LA.

SA-PO898

The Δ Anion Gap/Δ Bicarbonate Ratio in Early Lactic Acidosis: Time for Another Delta? Richard M. Treger,[1,2] Tristan Grogan,[2] David Elashoff,[2] Craig Anderson,[3] Scott Rudkin.[3] *[1]Nephrology, VHAGLA, LA, CA; [2]Medicine and Statistics Core, UCLA, LA, CA; [3]Emergency Medicine, UCI, Irvine, CA.*

Background: The ratio of Δ anion gap and Δ bicarbonate ($\Delta AG/\Delta HCO_3$) is used to detect co-existing acid-base disorders in patients with high AG metabolic acidosis. Classic teaching holds that in lactic acidosis (LA), the $\Delta AG/\Delta HCO_3$ is 1:1 within the first 60 minutes of onset (despite limited human data) and subsequently rises to 1.8:1. This study examined the $\Delta AG/\Delta HCO_3$ within the first hour of the development of LA.

Methods: Data were obtained prospectively from adult trauma patients at a level 1 trauma center. Venous samples were drawn prior to intravenous fluids.

Results: 108 patients were included. 63 patients had normal serum lactate levels (£2.1 mM) with a mean AG of 7.1, the value used to calculate subsequent ΔAG values. $\Delta AG/\Delta HCO_3$ was calculated for 45 patients who had elevated serum lactate levels (>2.1 mM). The mean $\Delta AG/\Delta HCO_3$ for all patients with elevated serum lactate levels was 1.86 (SD 1.40). The correlation between ΔHCO_3 and ΔAG showed a 95% prediction interval of ±6.15 (Figure 1).

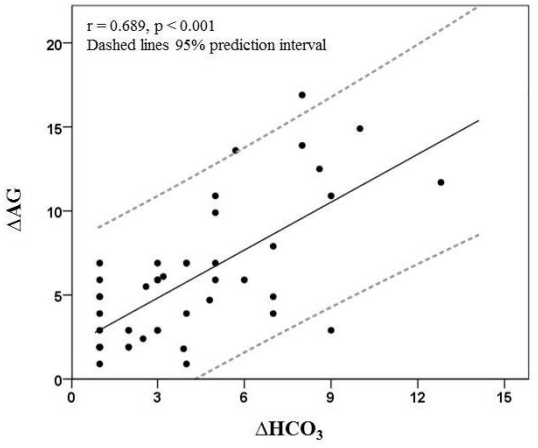

Figure 1: Correlation between ΔHCO_3 and ΔAG

Conclusions: The mean $\Delta AG/\Delta HCO_3$ was 1.86 within the first hour of the development of LA due to hypovolemic shock, confirming a small prior human study. This contradicts the traditional belief that in LA the $\Delta AG/\Delta HCO_3$ is 1:1 within the first 60 minutes. The classic 1:1 stoichiometry is based on animal models (in which lactic acid is infused into the extracellular [EC] space, facilitating EC buffering of protons by bicarbonate), while our results demonstrate a higher initial $\Delta AG/\Delta HCO_3$ ratio in early endogenous LA in humans (which originates intracellularly, resulting in intracellular buffering of protons while lactate is predominantly distributed in the EC fluid). The wide 95% prediction interval suggests that $\Delta AG/\Delta HCO_3$ should be used cautiously in the diagnosis of mixed acid-base disorders.

SA-PO899

Blood Lactate as a Predictor for Mortality in Sepsis Patients with Lactic Acidosis Treated Sodium Bicarbonate: A Retrospective Analysis Su Mi Lee,[1] Eu Gene Jeong,[1] Dongyeol Lee,[2] Hansae Kim,[2] Sung Hyun Son,[3] Yun Jung Oh,[4] Young Ki Son,[1] Seong Eun Kim,[1] Won Suk An.[1] *[1]Dept of Internal Medicine, Dong-A Univ, Busan, Republic of Korea; [2]Dept of Internal Medicine, Bong Seng Memorial Hospital, Busan, Republic of Korea; [3]Dept of Internal Medicine, BHS Hanseo Hospital, Busan, Republic of Korea; [4]Dept of Internal Medicine, Cheju Halla General Hospital, Cheju, Republic of Korea.*

Background: Recent studies have reported that blood lactate level in the critically ill patients is associated with in-hospital mortality, but the use of lactate level to monitor and guide therapy remains under investigation. In this study, we evaluated the efficacy of blood lactate level as a predictor for mortality in sepsis patients with lactic acidosis treated with sodium bicarbonate.

Methods: We conducted a single center analysis from May 2011 through April 2014. We retrospectively analyzed 109 sepsis patients with lactic acidosis treated with sodium bicarbonate.

Results: Among the 230 patients with lactic acidosis treated with sodium bicarbonate, we finally included 109 patients (47.4%) with lactic acidosis caused by sepsis. The non-survivors had lower albumin levels (P=0.009), higher SOFA and APACHE II scores (P=0.002, P=0.047, respectively), and higher blood lactate level at 6 hours, 24 hours, and 48 hours after checking the initial lactate level (P=0.002, P<0.001, P=0.001, respectively). In particular, decrement of at least 10% in lactate clearance for the first 6 hours, 24 hours, and 48 hours of treatment were more dominant in non-survivors than survivors. Lactate clearance at 6 hours, 24 hours, and 48 hours was significantly associated with mortality after adjustment for confounding variables, including age, gender, CRP, albumin, SOFA and APACHE II scores, ventilator care, CRRT, and use of inotropic (HR: 2.201, 95% CI: 1.197–4.046, P=0.011; HR: 3.948, 95% CI: 1.269–12.281, P=0.018; HR: 4.970, 95% CI: 1.679–14.710, P=0.004, respectively).

Conclusions: Serial blood lactate levels monitoring is useful in terms of predicting mortality rather than single initial lactate or maximum lactate levels in sepsis patients with lactic acidosis treated with sodium bicarbonate.

SA-PO900

D-Lactate: It's All in the Gut Muhammad Deen, Roohi Khan. *Dept of Nephrology, CHI St. Luke's Health, Houston, TX.*

Background: D-Lactic acidosis is a rare form of lactic acidosis that can occur in patients with short bowel syndrome.

Methods: 88 yo M with PMH significant for HTN and small bowel obstruction s/p sub total small bowel resection presented to the ED with complains of nausea, vomiting, constipation, loss of appetite, altered mental status and decreased urinary output.

On admission:

Vitals: Blood pressure: 115/68 mmHg, Pulse: 80/min, Temperature: 98.5 F and SpO2: 92%.

Examination: Distended abdomen with no peripheral edema.

Imaging: CT abdomen revealed dilated bowel loops but no bowel obstruction or free air in the abdomen/pelvis.

Labs: Na: 134mmol/L, K: 4.5mmol/L, Cl: 108mmol/L, CO2: 16mmol/L, BUN: 45mg/dL, Creatine: 1.6mg/dL and Albumin 2.3g/dL. ABG: pH: 7.42, pCO2 : 31mmHg, HCO3 : 19mmHg. He was found to have anion gap metabolic acidosis with a non-anion gap metabolic acidosis. Venous lactate: 1.11 mmol/L (Normal 0.5- 2.2 mmol/L). Serum D-lactate was drawn revealing an elevation at 4.15mmol/L – thus confirming the diagnosis of D-lactic acidosis.

Treatment: Patient received IV fluids with bicarb. PO Flagyl was started and constipation was also treated. His neurological status along with his acidosis subsequently improved.

Diagnoses of anion gap metabolic acidosis in the setting of D-Lactic acidosis was made due to bacterial over growth because of his past history of small bowel resection.

Conclusions: The diagnosis of D-lactic acidosis should be promptly considered in patients with malabsorptive disorder such as short bowel syndrome or following a jejunoileal bypass especially when no other cause of anion gap metabolic acidosis is found. Diagnosis is confirmed by a special enzymatic test measuring serum D-Lactate. Treatment involves a low-carbohydrate diet, sodium bicarbonate infusion to correct acute acidemia and antibiotics to minimize D-lactate producing bacteria.

SA-PO901

Customized Base Solutions for Treatment of Acute Acidosis Thomas G. Mason,[1,2] Jeffrey A. Kraut.[3] *[1]Dept of Chemistry and Biochemistry, Univ of California, Los Angeles, CA; [2]Dept of Physics and Astronomy, Univ of California, Los Angeles, CA; [3]Medical and Research Services VHAGLA Healthcare System, UCLA Membrane Biology Laboratory, and Div of Nephrology, VHAGLA Healthcare System and UCLA Geffen School of Medicine, Los Angeles, CA.*

Background: Acute acidosis is associated with cell dysfunction and increased mortality. Intravenous administration of hypertonic sodium bicarbonate ($NaHCO_3$) does not improve cellular function or clinical outcome. This is attributed to undesirable generation of CO_2, which decreases intracellular pH, and also to undesirable osmotic stress. Thus, designing a base that can raise pH without generating CO_2 or producing osmotic stress would address an unmet need.

Methods: Theoretical modeling has been performed using Mathematica software to determine equilibrium ion concentrations in mixed strong-weak base solutions. If these solutions have a significant proportion of strong base yet lower concentration, they are predicted to raise blood pH without generating CO_2 or producing large osmotic stress. Strong bases examined include disodium carbonate (Na_2CO_3) and sodium hydroxide (NaOH); these were mixed with $NaHCO_3$. Acid-base parameters were measured in acidified canine blood mixed with the base solutions in a closed system using a blood gas analyzer. Treated blood was examined using an optical microscope.

Results: A near-isotonic base solution containing Na_2CO_3:$NaHCO_3$ at a ratio of 3:1 is predicted to raise blood pH without increasing CO_2 or causing osmotic stress. Addition of this base to acidified blood raised blood pH while reducing CO_2. By contrast, $NaHCO_3$ raised blood pH, but also generated CO_2. Examination of red blood cells exposed to the former 3:1 solution revealed no evidence of osmotic stress. Mixed base solutions of NaOH and $NaHCO_3$ are also promising as a lower sodium alternative.

Conclusions: Mixed strong-weak base solutions, rather than hypertonic $NaHCO_3$, can raise blood pH and serum bicarbonate levels, minimize osmotic stress, and limit CO_2 generation. A 3:1 mixture of Na_2CO_3 : $NaHCO_3$ well below 1 M concentration appears to be effective in this regard.

SA-PO902

Chloride Alterations in Hospitalized Patients: Prevalence and Outcome Significance

Qi Qian, Charat Thongprayoon, Wisit Cheungpasitporn. *Medicine/ Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: Chloride (Cl) plays a fundamental role in the maintenance of serum osmotic pressure, acid-base balance, and cellular health. Cl channels are expressed in almost all cells in the body. Dysfunctions in the Cl channel result in a broad spectrum of diseases. Cl alterations in hospitalized patients have not been comprehensively studied in recent years.

Methods: We conducted a retrospective study of adult (³18 years old) hospital admissions at Mayo Clinic over a period of three years (2011 to 2013). Patients without admission Cl (£24hr of admission) were excluded. Outcome measures included all-cause mortality, length of hospital stay and discharge disposition.

Results: 76,719 unique patients from a total of 147,358 hospital admissions were enrolled. 55,523 (72.4%) had repeat Cl measurements within 48 hours. Admission serum Cl in the range of 105-108 mmol/L was found to be optimal based on hospital mortality. 60.6% (n=48, 999) had admission Cl<105 mmol/L, and 13% (n=11,999) >108 mmol/L. Cl <100 or >108 mmol/L independently predicted poor outcomes including hospital death, longer length of hospital stay, and being discharged to a care facility. 17.1% (n=13,089) of the patients had anion gap >12 mmol/L; their hospital mortality, when compared to those with anion gap £12 mmol/L, worsened progressively with rising Cl. Further examination of Cl evolution within 48 hours of admission showed Cl increase to be an independent predictor for hospital mortality. Further, the magnitude of Cl increase was inversely associated with days of patient survival.

Conclusions: Non-optimal serum Cl values are common in hospitalized patients. Cl alterations are independent predictors for poor clinical outcomes. Post-admission Cl increase not only predicted hospital mortality but also inversely correlated with length of patient survival. These results indicate that more attention should be paid to Cl value. Further prospective and randomized studies are needed to determine whether avoidance of post-admission Cl increase would improve patient survival.

SA-PO903

A Retrospective Review of Paediatric Patients with Bartter and Gitelman Syndrome

Patrick Walsh, Marc Bienias, Detlef Bockenhauer. *ICH, UCL, London, United Kingdom.*

Background: Bartter and Gitelman syndrome are rare autosomal recessive disorders of renal salt handling. They are characterized by disturbed electrolyte and acid-base homoeostasis with potentially severe complications. Currently little is known about the long-term disease course and best treatment is controversial. We performed a retrospective case review to investigate the long-term disease course of patients with a diagnosis of Bartter/Gitelman syndrome.

Methods: Demographic and Laboratory data was recorded at presentation, and ages 1,2,3,4,5,10 and 15.

Results: 42 patients with a genetic diagnosis of Bartter/Gitelman were reviewed with a median follow up of 7.85 years (Range 0 -18 Years).

Genotype	Number of patients	Age at Presentation	Gestational Age	Nephrocalcinosis (% of patients)	GFR <90ml/min/ 1.73m2 at last follow – up (Schwartz)	Albuminuria (>2.5 Females 3.5 Males mg/mmol)	Average Height at last follow-up (Z-score)
1	6	Day 7	30.3	100	6	2	-1.2
2	10	0.8 Years	32.0	70	9	1	-1.82
3	14	2.7 Years	37.4	7	4	11	-1.28
4	1	Day 1	32.0	0	1	1	N/A
Gitelman	11	5 Years	39.4	9	1	0	-0.93

Bartter 1&2 presented earliest with prematurity and deranged electrolytes. All of the Bartter 1 patients and 70% of Bartter 2 had evidence of nephrocalcinosis on their first ultrasound. Hypomagnesaemia (<0.7mmol/L) was seen in 11/14 Bartter 3 and 8/11 Gitelman patients; Hypomagnesaemia developed over time and was seen earlier in Bartter 3 (3.8 years) than in Gitelman (7.9 years). Obvious complications of hypokalaemia were only seen in one patient with Bartter 3 (despite potassium levels <2.5mmol/L in 10 patients) in the form of hypokalaemic paralysis; he was admitted twice at age 2 and 3 (Potassium 1.7 & 1.5 respectively). Decreased GFR was present in all Bartter 1 and 90% of Bartter 2 at last follow-up. 3 patients with Bartter 3 developed nephrotic range proteinuria and one demonstrated biopsy evidence of FSGS.

Conclusions: The overall prognosis during childhood was good. Final heights were within the normal range and no child developed ESRD. Albuminuria was common in Bartter 3, indicating the need for long-term monitoring of renal function. Interestingly, hypomagnesaemia is often absent at presentation and develops over time in both Bartter 3 and Gitelman.

SA-PO904

Urine Calcium to Magnesium Ratio Aids to Diagnose Gitelman's Syndrome without Hypocalciuria and Receiving Intravenous Magnesium Administration

Chih-Jen Cheng,[1,2] Shih-Hua P. Lin,[1,2] Ming-Tso Yan.[2,3] *[1]Tri-Service General Hospital; [2]National Defense Medical Center; [3]Cathay General Hospital.*

Background: Although hypocalciuria is widely used to distinguish Gitelman's syndrome (GS) from Bartter syndrome (BS), several patients with GS actually have not hypocalciuria and may be clinically misdiagnosed as BS. Intravenous magnesium administration to correct hypomagnesemia, another distinct finding in GS can significantly enhance urine calcium excretion and unmask the preexisting hypocalciuria. Because renal Mg^{2+} wasting is characteristic in GS, we hypothesize that urine Ca^{2+}/Mg^{2+} ratio may be superior in diagnosing GS.

Methods: One hundred forty three Taiwanese GS patients (M:F =87:56, age 25 ± 10) with definite SLC12A3 mutations was enrolled. Nine cBS patients with CLCNKB mutations and 15 healthy subjects were enrolled as disease and normal control, respectively. Intravenous $MgSO_4$ was administered (elemental Mg 0.35 mmol/kg) in 8 GS patients with hypocalciuria. Relevant blood laboratory and at least two urine collection for all electrolytes excretion were determined. Hypoclaciuria was defined as urine Ca/Cr ratio less than 0.1 mmol/mmol.

Results: Fourteen (9.8%) of 143 GS patients did not have hypocalciuria (Ca^{2+}/Cr ratio 0.28 ± 0.09 mmol/mmol) and exhibited no significant difference in blood parameters compared with GS patients without hypocalciuria. Although their urine Ca^{2+}/Cr ratio was significantly lower than that in cBS (0.51 ± 0.18 mmol/mmol), there was still overlapping between them. Notably, urine Ca^{2+}/Mg^{2+} ratio was significantly lower in GS than cBS without overlap (0.46 ± 0.12 vs 1.57 ± 0.53 mmol/mmol, p< 0.001). Acute $MgSO_4$ administration in GS patients markedly enhanced urine Ca^{2+} excretion (Ca^{2+}/Cr ratio 0.05 ± 0.01 to 0.64 ± 0.01 mmol/mmol, p < 0.001). However, urine Ca^{2+}/Mg^{2+} ratio (0.21 ± 0.01 mmol/mmol) remained much lower than healthy subjects (1.35 ± 0.63 mmol/mmol, p<0.001) and cBS.

Conclusions: Urine Ca^{2+}/Mg^{2+} ratio may be a good index to help diagnose GS without hypocalciuria and even receiving intravenous Mg^{2+} administration.

SA-PO905

A Blunted Response to Thiazide Diuretics Is Not Specific for Patients with Gitelman Syndrome

Anneke Bech, Jack F. Wetzels, Tom Nijenhuis. *Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands.*

Background: In Gitelman syndrome (GS), a defective sodium-chloride co-transporter (NCCT) in the distal tubule classically leads to hypokalemia and hypomagnesemia. A challenge with thiazide diuretics, testing the functional presence of NCCT, has been shown to differentiate GS from Bartter syndrome (BS) and normal controls. However, the performance of the thiazide test in renal magnesium wasting disorders other than GS and BS has not been studied.

Methods: Eleven patients who presented to our clinic between 2010-2014 with renal magnesium wasting and in whom a thiazide test was performed were included. An abnormal test result is defined as a maximal change of fractional chloride excretion (ΔFeCl) < 2.3% [Colussi 2007]. The thiazide test in eight volunteers in our clinic showed a mean maximal ΔFeCl 3.12 ± 0.48% with the lowest value being higher than 2.3%. Additional DNA mutation analyses were performed.

Results: Three patients had a mutation in SLC12A3 (GS), one patient had a compound mutation in CLCNKB and KCNJ1 (BS), 1 patient had a mutation in FXYD2 and five patients had a deletion of one HNF1β allele. The patients with GS showed a blunted response, the patient with BS showed a normal response, the patient with a FXYD2 mutation showed a blunted response and the patients with HNF1β mutations showed different responses to thiazide diuretics.

	Mutation	Maximal Δ FeCl (%)
GS	c.1315G>A, exon 10	0.12
GS	c.602-16G>A, intron 4	0.18
GS	815T>C and 1670 C>T, exon 6	0.86
BS	CLCNKB: c.88C >T, exon 2 KCNJ1: c.1070 T>C, exon 5	6.10
FXYD2	c.115G>A	0.66
HNF1β	deletion one allele	0.01
HNF1β	deletion one allele	1.41
HNF1β	deletion one allele	1.48
HNF1β	deletion one allele	2.40
HNF1β	deletion one allele	3.90
unknown diagnosis	unknown	2.43

Conclusions: A blunted response to thiazide diuretics is not specific for GS and can also be found in other renal magnesium wasting disorders, such as caused by mutations in FXYD2 or HNF1β. Still, the thiazide test could prove to be a valuable tool for research and phenotyping patients, and increase our understanding of the pathophysiological processes and the interrelationship between transcription factors, transporters and ion channels.

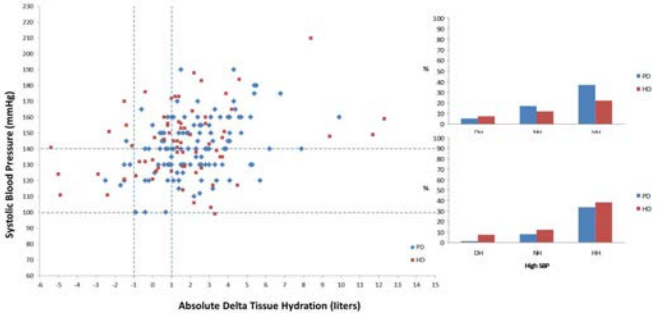
Assessment of Hydration Status by Bioimpedance Spectroscopy in Peritoneal and Hemodialysis Patients from a Single Center Sara Samoni,[1,2] Luis Ignacio Bonilla,[1] Carla Estremadoyro,[1] Alessandra Spinelli,[1] Salvador Roberto Lopez,[1] Faeq Husain-Syed,[1] Carlo Crepaldi,[1] Alessandra Brendolan,[1] Claudio Ronco.[1] *[1]IRRIV, Vicenza; [2]Sant'Anna School of Advanced Studies, Pisa.*

Background: Fluid overload(FO)is frequent in peritoneal dialysis(PD)and hemodialysis(HD)pts.Despite the identified correlation between systolic blood pressure(SBP)and FO,some conditions,i.e.vascular stiffness and heart failure,can cause a significant proportion of pts to fall out from this model.Our aim was to assess the relationship between hydration status(HYD)and SBP in PD and HD pts.

Methods: We enrolled all DP and HD pts of our center.HYD was evaluated by bioimpedance spectroscopy using Body-Composition-Monitor(BCM Fresenius Medical Care)and expressed by the absolute delta tissue hydration(ADTH).BCM and SBP were measured during routine ambulatory visits in DP pts.In HD pts,measurements were done before the intermediate HD treatment based on a 3-treatment per week program.We considered normohydrated(NH),hyperhydrated(HH)and dehydrated(DH)pts with ADTH -1/+1,>+1,<-1,respectively.We defined normal(NSBP),high(HSBP)and low SBP(LSBP) with values of 100-140,>140,<100mmHg,respectively.Considering both parameters,we subdivided the cohort into 9 groups.Continuous variables were expressed as means±SD for normally distributed data and compared with t-test.

Results: We enrolled 188 pts,120 DP,68 HD pts.Mean SBP was 141±18 and 144±22mmHg,respectively.Mean ADTH was 2.2±2 in PD and 1.6±3.1L in HD pts.Among NSBP,the percentage of HH pts was significantly higher in PD than HD pts(p=0.04)while among HSBP,the HD pts were more DH than PD pts(p=0.02).



Conclusions: We found that measurement of SBP is not sensitive to assess the HYD in PD and HD pts.We also found that PD pts with NSBP tend to be more HH than HD pts. We suggest that SBP should not be used alone as a marker for HYD in PD and HD pts,it should always be accompanied by other tools.

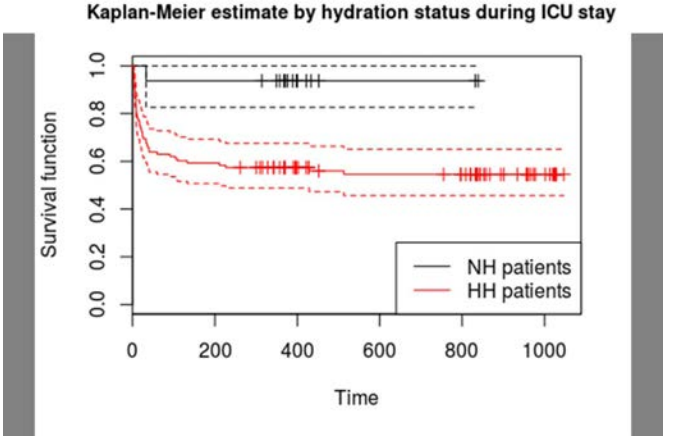
SA-PO907

Impact of Hydration Status, Assessed by Bioelectrical Impedance Vector Analysis, on Mortality in Critically Ill Patients Sara Samoni,[1,2] Valentina Vigo,[3] Luis Ignacio Bonilla,[1] Gianluca Villa,[1] Silvia De Rosa,[1] Federico Nalesso,[1] Fiorenza Ferrari,[1] Alessandra Brendolan,[1] Carlo Donadio,[3] Claudio Ronco.[1] *[1]IRRIV, Vicenza; [2]Sant'Anna School of Advanced Studies, Pisa; [3]Univ of Pisa, Pisa.*

Background: Clinical trials have shown a positive correlation between fluid overload and adverse outcomes in pts admitted to intensive care unit(ICU).Currently,there is not a non-invasive method that can provide an accurate and timely assessment of whole body hydration status.Our aim was to evaluate the impact of hyperhydration,assessed by bioelectrical impedance vector analysis (BIVA),on ICU mortality in critically ill pts.

Methods: This is a prospective,dual-center study.We included 125 ICU pts with an ICU stay of 72 hrs or more.Anthropometric, medical history and laboratory data were collected. Assessment of hydration status was performed by BIVA,using a single frequency analyzer,at the baseline and daily for a period of 72-120 hrs.Pts were considered normohydrated(NH) or hyperhydrated(HH)if BIVA hydration level was 72.7%-74.3% or >74.3% of fat-free body mass,respectively.

Results: The logistic regression analysis performed found a significant correlation between ICU mortality and maximum hydration level reached in observation period,either in patients with or without acute kidney injury(p<0.001).



Conclusions: Our findings confirm and expand literature data about the correlation between hyperhydration and ICU mortality.Despite the importance of this problem,there are currently few methods to assess hydration status in critically ill pts.BIVA has been shown to be safe,non-invasive,easy to use and it may predict mortality,thus we suggest its routinely use in ICU pts.Randomized clinical trials are needed to define the precise role of BIVA in the goal-directed fluid management of critically ill pts in ICU.

SA-PO908

Sleep-Disordered Breathing Is Not Associated with Body Fluid Volume in Chronic Hemodialysis Patients Takahiro Masuda,[1,2] Yumi Kijima,[2] Chuji Sekiguchi,[2] Yasuharu Miyazawa,[2] Eiji Kusano,[3] Yasushi Asano,[4] Daisuke Nagata.[1] *[1]Div of Nephrology, Deparment of Medicine, Jichi Medical Univ, Shimotsuke, Tochigi, Japan; [2]Nasu-Minami Hospital, Nasukarasuyama, Tochigi, Japan; [3]Japan Community Health Care Organization Utsunomiya Hospital, Utsunomiya, Japan; [4]Japanese Red Cross Koga Hospital, Koga, Ibaraki, Japan.*

Background: Sleep-disordered breathing (SDB), characterized by nocturnal intermittent hypoxia, is frequent in patients with chronic hemodialysis (CHD). Fluid retention may promote SDB in these patients, but the detailed information is lacking.

Methods: Eighty-eight CHD patients in Nasu-Minami Hospital and Japanese Red Cross Koga Hospital were included in this study (male: 62.1%, age: 68.1 ± 11.5 years, body mass index: 21.7 ± 3.1, duration of CHD: 5.3 ± 5.9 years, diabetes mellitus: 50.0%). Overnight pulse oximetry and bioimpedance spectroscopy (InBody) for the assessment of body composition were performed after dialysis on a dialysis day. Patients were divided into three groups according to 3% oxygen desaturation index (3%ODI) assessed by pulse oximetry: normal (3%ODI<5), mild SDB (5£3%ODI<15) and severe SDB (15£3%ODI). We investigated the relationship between severity of SDB and body composition including body fluid volume.

Results: Sixty patients (68.2%) were classified into the SDB group (mild SDB 40 [45.5%] and severe SDB 20 [22.7%]). Fat mass (relative to body weight) in the SDB group was significantly higher than in the normal group (normal 24.3±8.5%, mild SDB 29.7±8.0%, severe SDB 30.2±9.2%, P=0.018). After adjusting for age, gender, diabetes mellitus, hemoglobin and serum albumin in a logistic regression analysis, SDB was independently associated with increased fat mass (odds ratio 1.22; 95% confidence interval 1.10–1.38: P< 0.01). Total body water, intracellular water and extracellular water were similar among the three groups.

Conclusions: SDB is associated with increased fat mass, but not body fluid volume in CHD patients. Further studies are needed to evaluate some factors that can explain the high frequency of SDB in CHD.

Association Between Brain Natriuretic Peptide and Fluid Volume Imbalance Between Intra- and Extracellular Water in Patients with Chronic Kidney Disease Yasushi Ohashi, Reibin Tai, Toshiyuki Aoki, Shizuka Kobayashi, Atsushi Aikawa, Ken Sakai. *Dept of Nephrology, School of Medicine, Faculty of Medicine, Toho Univ, Tokyo, Japan.*

Background: Malnourished and elderly patients with chronic kidney disease (CKD) may be susceptible to a extracellular volume overload due to a decreased intracellular volume capacity. We assume that excessive fluid volume is redistributed on the basis of the baseline fluid volume balance when they are exposed to fluid accumulation.

Methods: Using bioimpedance analysis, body fluid composition was measured in 129 patients with CKD from 2013 to 2015 and was separated into three components – (a) free water mass consisting of muscle, fat, and minerals, (b) intracellular water (ICW) content, and (c) extracellular water (ECW) content. Participants was also measured brain natriuretic peptide levels at the time of the body fluid composition measurement. The relationship between the ratio of ECW to ICW and brain natriuretic peptide was examined.

Results: Patients with higher log-transformed plasma level of brain natriuretic peptide was more likely to be older and have lower body mass index (BMI), glomerular filtration rate (GFR), and serum albumin levels and higher proteinuria. In body fluid composition analysis, the brain natriuretic peptide levels increased along with a decrease in all contents of free water mass consisting of muscle, fat, and mineral (r = -0.49, P < 0.001), ICW content (r = -0.34, P < 0.001), and ECW content (r = -0.25, P < 0.01). By the steeper decreased free water mass and ICW content than the decreased ECW content in those patients, the percentage of ECW in body weight increased, and the ratio of ECW to ICW had a positive correlation with the brain natriuretic peptide levels (r = -0.58, P < 0.001). In multivariate analysis, age, BMI, GFR, the ECW/ICW ratio remained independently associated with the brain natriuretic peptide levels.

Conclusions: Brain natriuretic peptide is elevated in leaner and elderly patients with fluid volume imbalance between intra- and extracellular water. Fluid volume imbalance between intra- and extracellular water may express a reserve capacity for fluid volume overload and impact on cardiac preload.

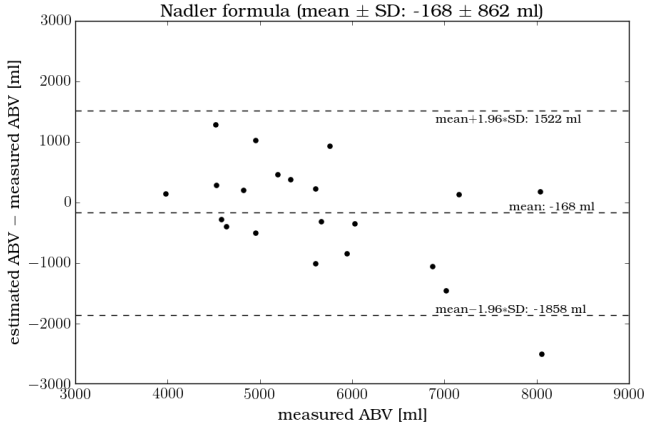
SA-PO910

Blood Volume Estimation in Hemodialysis Patients Doris H. Fuertinger,[1] Line Malha,[2] Peter Kotanko,[1] David S. Goldfarb,[2] Stephan Thijssen.[1] *[1]Renal Research Inst, New York, NY; [2]New York Harbor VAMC and NYU Langone Medical Center, New York, NY.*

Background: Anthropometric formulas used to estimate absolute blood volume (ABV) are generally derived from healthy subjects. Most hemodialysis (HD) patients have an expanded ABV prior to HD, rendering these formulas inappropriate for estimation of pre-HD ABV (pre-ABV). Here, we compare the performance of several ABV formulas, used in conjunction with Crit-Line data, for assessment of pre-ABV.

Methods: We assume that post-HD ABV is closer to normal ABV, which we calculated based on height, sex and post-HD weight using several published formulas. Pre-BV was then calculated from post-HD blood volume using pre- and post-HD Hct measured by Crit-Line®. The calculated pre-ABV was then compared to pre-ABV measured immediately before HD using ^{131}I-labeled albumin dilution.

Results: We compared 27 formulas for ABV estimation in 21 patients (♀: 3, mean ± SD: age 59 ± 14.7 years, height: 170.7 ± 10 cm, post-HD weight: 82.2 ± 16.7 kg). None of the equations showed good agreement with the measured data. The Nadler formula yielded the most accurate results (Fig 1). As exemplified in Fig 1, the equations yield a systematic trend in bias, with reasonable accuracy for ABV between 5-6 L but progressive underestimation and increasing heteroscedasticity towards higher ABV (caused by fluid overloaded patients).



Conclusions: Anthropometric equations such as the Nadler formula show reasonable accuracy (albeit unsatisfactory precision) for patients with close to normal end-HD ABV, but they fail in non-euvolemic patients. Their validity in HD patients depends on the patients' fluid status, which varies widely; hence their undifferentiated use in this population should be discouraged. More accurate and precise estimates of ABV would require a more sophisticated approach incorporating fluid status information, e.g. from bioimpedance.

SA-PO911

Impact of Hospital-Associated Hypernatremia on Outcomes in an Unselected Patient Population: A Retrospective Cohort Study Nicolaos E. Madias, Evangelos Tsipotis, Bertrand L. Jaber. *Internal Medicine, St. Elizabeth's Medical Center, Boston, MA.*

Background: Although hypernatremia has been associated with an increased risk of adverse outcomes, the majority of available studies have examined selected populations questioning the generalizability of their results to unselected patients.

Methods: The discharge data of 20,072 unselected adult patients admitted to a tertiary care facility over a 7-year period were analyzed. Based on the crude relationship between [Na^+] and mortality, hypernatremia was defined as [Na^+] > 142 mEq/L. Patients with community-acquired hypernatremia (CAH) and those with hospital-acquired hypernatremia (HAH) were compared to patients with normonatremia at presentation ([Na^+] of 138-142 mEq/L) in terms of in-hospital mortality, length of stay (LOS), and discharge disposition. Furthermore, patients with CAH in whom hypernatremia worsened during hospitalization (HAggH) were compared to those without aggravation. Multivariable logistic and negative binomial regression analyses were conducted.

Results: CAH occurred in 20% of hospitalized patients and was associated with an adjusted odds ratio (OR) of 1.67 (95% confidence interval [CI] 1.38, 2.01) for in-hospital mortality, and 1.44 (95% CI 1.32, 1.56) for discharge to a short-/long-term care facility, and an adjusted 10% (95% CI, 7%-13%) increase in LOS. HAH developed in 25.9% of hospitalized patients and was associated with an adjusted OR of 3.17 (95% CI 2.45, 4.09) for in-hospital mortality, and 1.45 (95% CI 1.32, 1.59) for discharge to a facility, and an adjusted 49% (95% CI 44%, 53%) increase in LOS. HAggH developed in 8.9% of patients with CAH. Compared to patients with CAH and no further increase in [Na^+]s, HAggH was associated with greater risk of in-hospital mortality (adjusted OR 1.84; 95% CI 1.32, 2.56) and discharge to a facility (adjusted OR 1.90; 95% CI 1.49, 2.41), and an adjusted 13% (95% CI 4%-23%) increase in LOS.

Conclusions: All forms of hypernatremia encountered in unselected hospitalized patients are independently associated with increased in-hospital mortality and heightened resource consumption.

SA-PO912

Utility of Urine/Plasma Osmolality Ratio for Assessing Volume Status in Hyponatremia Sho Hasegawa, Maki Shibata, Takehiro Sugiyama, Fumihiko Hinoshita. *National Center for Global Health and Medicine, Tokyo, Japan.*

Background: Assessing volume status is critical for managing hyponatremia. Physical examination (P/E) and laboratory data are often used for the assessment, but the utility of each parameter has not been validated in hyponatremic patients. A body composition monitor (BCM) uses bioimpedance spectroscopy and can quantify extracellular water (ECW) and volume excess or deficiency. Here, we examined which parameter is superior in assessing volume status of hyponatremic patients, using BCM data as the reference standard.

Methods: We enrolled hospitalized patients (n=41) with hyponatremia (<130 mEq/L) at our institution and conducted P/E, laboratory tests and BCM measurement. Patients with high plasma osmolality (>275 mOsm/kg) were excluded (n=5). We used %ECW (ratio of volume excess or deficiency to ECW) derived from BCM data as the reference standard of volume status. First, patients were divided into overhydration (%ECW>0%, n=29) and dehydration (%ECW<0%, n=7) groups. Clinical signs obtained from P/E and parameters of volume status such as serum albumin (Alb), serum uric acid (UA), urine chloride, urine/plasma osmolality ratio (U/P Osm), UUN/BUN, BUN/creatinine, U/P creatinine, FENa, FEUN and FEUA were compared between the groups by Fisher's exact test or Mann–Whitney U–test. Next, we performed univariate and multiple linear regression analyses to identify associations between each parameter and %ECW.

Results: U/P Osm was significantly higher in dehydration than in overhydration (median: 2.0 vs 1.3, p=0.01), but other parameters and clinical signs showed no significant differences. Univariate regression analysis showed that Alb (β=-7.1±3.2, p=0.04), U/P Osm (β=-11.4±3.1, p=0.001), UUN/BUN (β=-0.3±0.1, p=0.01) and U/P creatinine (β=-0.10±0.03, p=0.01) were associated with %ECW. Since UUN/BUN and U/P creatinine strongly correlated with U/P Osm, we conducted multiple regression analysis using only Alb and U/P Osm. Results showed that compared with Alb (β=-7.7±2.7, p=0.007), U/P Osm (β=-12.0±2.9, p=0.0002) was more strongly associated with %ECW.

Conclusions: U/P Osm is superior to other commonly used parameters and clinical signs for assessing volume status in hyponatremic patients.

SA-PO913

Sodium Concentrations of Body Fluid Losses: A Systematic Review
Matthew Kaptein,[1] Divya Sreeramoju,[2] John Kaptein,[3] Elaine Kaptein.[1]
[1]Nephrology, LAC+USC Medical Center, Los Angeles, CA; [2]Medicine, Presence Saint Joseph Hospital-UIC, Chicago, IL; [3]Southern California Permanente Medical Group, Los Angeles, CA.

Background: Unexplained wide ranges and discrepancies of sodium concentrations [Na+] have been noted for different body fluids. This has led to use of "cumulative fluid balance" regardless of composition, which cannot account for specific water and sodium requirements. Appropriate water and volume management may be facilitated by an accurate and detailed knowledge of water and sodium composition of body fluid losses and gains.

Methods: We performed a systematic review of [Na+] of body fluids lost in adult humans. Particular attention was paid to gastric fluid with high and low acid states, diarrhea due to different mechanisms, and peritoneal, pleural and wound fluids. Inclusion criteria were met for 106 full-text articles.

Results: [Na+] are fluid-specific and consistent. Mean [Na+] were statistically lower for acidic (mean+SD:44+12mEq/L) than for alkaline (55+13mEq/L) gastric fluid; the difference is not clinically relevant. [Na+] are higher for bile (184+24mEq/L) or pancreatic fluid (156+3mEq/L) than all other body fluids, and similar for intact small bowel (119+14mEq/L) and ileostomy outputs (116+25mEq/L). Specific mechanisms for diarrhea are associated with different [Na+]. [Na+] were significantly greater for cholera (128+18mEq/L) and lower for osmotic-induced (28+16mEq/L) than all other causes. Among osmotic diarrheas, sorbitol-induced [Na+] was higher (63+17mEq/L) than for carbohydrate malabsorption (43+20mEq/L), lactulose (26+19mEq/L), Idolax (16+13mEq/L) and polyethylene glycol (13+7mEq/L). Among secretory diarrheas [Na+] for idiopathic causes (53+22mEq/L) was lower than for neuroendocrine and villous tumors (75+13mEq/L) or non-osmotic laxatives (88+33mEq/L). Pleural, peritoneal, and edema fluid had [Na+] (137+13mEq/L) similar to plasma. [Na+] for sweat was 44+17mEq/L.

Conclusions: This is the first in-depth review of verifiable sodium concentrations of body fluids most commonly lost in hospitalized patients. We propose that these losses be replaced with appropriate water and sodium content of enteral and parenteral fluids to correct and avoid dysnatremias and perturbations of volume status.

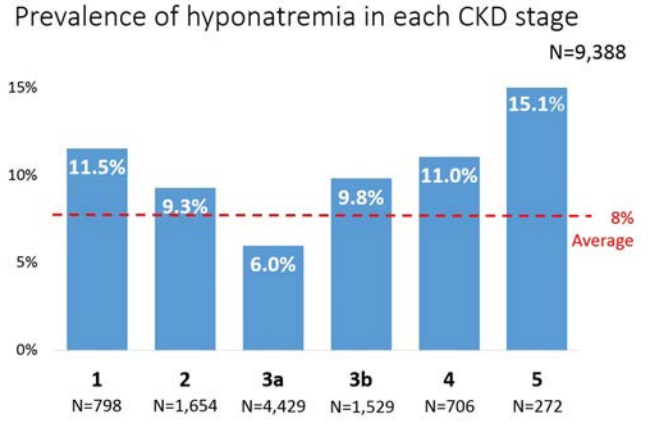
SA-PO914

Hyponatremia in CKD: The Prevalence and Risk Factors
Masahiko Nagahama,[1] Daiki Kobayashi,[2] Fumika Taki,[1] Takuya Fujimaru,[1] Masataka Hasegawa,[1] Yuki Heath,[1] Yasuhiro Komatsu.[1] *[1]Nephrology, St. Luke's International Hospital, Tokyo, Japan; [2]Center for Clinical Epidemiology, St. Luke's International Hospital, Tokyo, Japan.*

Background: Kidney is a vital organ regulating water and sodium homeostasis, and it is plausible that patients with CKD are more prone to develop hyponatremia due to diminished urinary dilution ability, reduced solute intake, and/or medication which affects free water clearance. However, the prevalence and risk factors of hyponatremia among CKD patients have not been elucidated. The aim of the present study is to clarify the prevalence and risk factors contributing to hyponatremia in CKD patients.

Methods: Among 32,438 patients who visited our outpatient clinic between 2011 and 2014, 9,388 patients met the criteria of CKD, which is defined as either eGFR ≤60 ml/min/1.73m² or the presence of proteinuria. Dialysis and transplant patients were excluded. Risk factors for hyponatremia were sought using multivariate logistic regression.

Results: Prevalence of hyponatremia (serum Na£135mEq/L) was 8% in all CKD patients. Among moderate and severe CKD (stage 3, 4 and 5, N=6397), the prevalence of hyponatremia is increased as CKD progresses.



On univariate analysis, patients developing hyponatremia in moderate and severe CKD were older (P<0.01), female sex (P<0.01), diabetic (P<0.01) and more likely to have decreased eGFR (P<0.01). Multivariate logistic regression analysis identified CKD stage (OR:1.7-2.4, P<0.01), diabetes (OR:1.4, P<0.01) and renin-angiotensin-aldosterone system (RAS) inhibitors (OR:0.68, P<0.01) as independent risk factors for hyponatremia in moderate and severe CKD.

Conclusions: The present study shows that the prevalence of hyponatremia was 8% in CKD patients, and development of hyponatremia is correlated with progression of CKD in moderate and severe CKD. Worsening CKD and Diabetes are risk factors, while RAS inhibitors are protective for hyponatremia in CKD.

SA-PO915

Mild Hyponatremia on Admission Is Associated with Sepsis and Increased Mortality in Patients Presenting with a Hip Fracture
Juan Carlos Ayus,[4] Armando Luis Negri,[2] Michael L. Moritz,[3] Nora Angelica Fuentes.[1] *[1]Hospital Italiano, Buenos Aires, Argentina; [2]Inst de Investigaciones Metabolicas, Argentina; [3]Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA; [4]Renal Consultant's of Houston, Houston, TX.*

Background: Hyponatremia is associated with an increased risk of falls and hip fractures in the elderly (JAMA 281: 2299-2304, 1999). Moreover, sepsis is a frequent cause of death in patients with hyponatremia (AJKD 65:435-442, 2015).We assessed if hyponatremia on admission was associated with sepsis and increased mortality in patients presenting with a hip fracture.

Methods: A cohort study in adult patients admitted with a traumatic hip fracture and at least one serum Na performed at admission. Hyponatremic (H), Na < 135 mEq/L, and normonatremic (N) patients were evaluated for complications occurring within 30 days of surgery, length of hospital stay, readmission rate, in-hospital mortality and mortality during 1 year follow-up. An unadjusted and adjusted odds ratio (OR) and hazard ratio (HR) were calculated for in-hospital mortality and 1 year mortality. Adjustments were made for age, gender, propensity score for hyponatremia, CVA, CHF, ischemic heart disease, arrhythmias, thromboembolic disease, sepsis and dementia.

Results: 1571 patients were included of whom 366 (23.2%) were hyponatremic (Na 132 ± 4 mmol/L vs 138 ± 3; p <0,001). Length of stay was 8 days in H vs. 7 days in N (p=0.053). There was in increased incidence of sepsis in hyponatremic patient, 9.8% in H vs. 6% in N (p<0.01) OR 1.7 (CI95%: 1.13-2.6). In-hospital mortality was significantly higher in H vs N patients (19.9 vs 14.7%; p= 0.016), with an un-adjusted OR of 1.45 (95% CI 1.07-1.96) and an adjusted OR of 1.15 (95% CI 0.84-1.6). Readmissions were 15.8% for H vs. 12.9% for N (p=0.14). One-year mortality was greater in H vs N patients (15.4 vs. 6.8%; p <0.001), with an un-adjusted HR of 1.8 (95% CI 1.4-2.35) and an adjusted HR of 1.45 (95% CI 1.1-1.9).

Conclusions: Mild hyponatremia at admission is associated with sepsis and increased in-hospital and late mortality in patients presenting with a hip fracture.

SA-PO916

Characteristics of Tolvaptan Trial in Korean Patients with SIADH
Joo-Hark Yi,[1] Eunyoung Lee,[1] Sang-Woong Han,[1] Kyung Pyo Kang,[2] Ha Yeon Kim,[3] Soo Wan Kim,[3] Hoon Young Choi,[4] Sung-Kyu Ha,[4] Gheun-Ho Kim,[5] Yang Wook Kim,[6] Kyung-hwan Jeong,[7] Sug Kyun Shin,[8] Ho-Jung Kim.[1] *[1]Hanyang Univ Guri Hosp.; [2]Chonbuk Natl. Med. Sch.; [3]Chonnam Natl. Med. Sch.; [4]Yonsei Med. Sch.; [5]Hanyang Med. Sch.; [6]Kyung Hee Med. Sch.; [7]Haeundae Paik Hosp.; [8]NHIS Ilsan Hosp., Republic of Korea.*

Background: This clinical study, a multicenter trial in 8 tertiary hospitals in Korea, was carried out to evaluate changes in serum sodium (Na) during 11 days on tolvaptan (TLV) daily and at the 7th day after stopping TLV in SIADH patients (pts) (<135 mEq/L).

Methods: A total of 39 pts (M:F, 23:16; age, 71±11.3 yrs) without neurologic symptoms were studied from Jun 1, 2013 to Dec 31, 2014. All pts received 15 mg/d of TLV as the initial dose and then further increased to 60 mg/d as needed in the hospital.

Results: Serum Na (mEq/L) increased prominently from baseline during first 24 hrs (127±4.3 vs 134±3.8, p<0.01), but gradually to day 4 (134±3.8 vs 136±3.6, p<0.01), and then maintained a plateau until discontinuation of TLV at day 11 (137±4.5). The changes in serum sodium (DsNa) from the baseline were 2.8±3.3 in 4 hrs, 5.9±4.1 in 8 hrs, and 6.8±4.2 in 24 hrs, respectively. The correlation between DsNa/24 hrs and baseline Na was significant (r=-0.613, p<0.01). When hyponatremia was stratified into 3 groups, mild (I, 130-134, n=12), moderate (II, 125–129, n=18), and severe (III, £124, n=9) groups, DsNa in III (11.1±4.8) during first 24 hrs was significantly higher than II (6.4±2.5, p<0.05) and I (4.3±3.3, p<0.01). Also, those of DsNa/24 hrs ≥8 mEq/L (n=18) compared to <8 (n=21) had significantly lower baseline serum creatinine (0.56 vs 0.73 mg/dL), Wt (53 vs 60 kg), BMI (21 vs 23), and body surface area (1.54 vs 1.63) (all, p<0.05). Then, serum Na after discontinuation of TLV for 1 wk was similar to the baseline (127±4.3 vs 129±8.6, p=NS). All pts underwent successfully this trial more than 24 hrs, but 4 pts were withdrawn due to rapid correction (1) and nausea (3).

Conclusions: Tolvaptan is effective and well tolerated in Korean with SIADH. However, Korean patients, particularly those with smaller frame and severe hyponatremia (<125 mEq/L), could be vulnerable to rapid correction by usual initial dose of Tolvaptan 15 mg.

Risk Factors for the Development of Thiazide-Induced Hyponatremia
Kyle John Laporte, Milagros Zegarra, Melissa Rohrich, William Newman. *Fargo VAHCS, Fargo, ND.*

Background: Thiazide and thiazide-like diuretics are commonly utilized for management of hypertension. However, thiazide diuretics are one of the most common causes of drug-induced hyponatremia. Previous studies have pointed to potential risk

factors that may lead to the development of thiazide-induced hyponatremia, but there is still much uncertainty surrounding their role in predisposing patients to the development of hyponatremia. With an increasing prevalence of hypertension, thiazide utilization will likely continue to increase. Thus, the ability to discern potential risk factors for the development thiazide-induced hyponatremia may offer significant clinical value.

Methods: A retrospective study was conducted on 450 veterans of the age >18 years with hypertension treated with a thiazide/thiazide-like diuretic (chlorthalidone, hydrochlorothiazide, indapamide, metolazone) between March 2004 and November 2014 at the Fargo VA Health Care System.

Results: 404 patients met inclusion criteria. 15 % (n=63) of patients developed hyponatremia during treatment period with thiazide therapy. Average time to development of hyponatremia was 2.6 years (+3.3) from index date. Mean Charlson comorbidity scores were higher for those who developed hyponatremia (4.59 vs. 2.90; $p < 0.001$). Incidence of hyponatremia was found to be higher in patients who were active tobacco users (24.8% vs. 11.3%; $p<0.001$). Although there was no significant difference in serum creatinine and eGFR between groups, a statistically significant difference in eGFR was found to exist when comparing pre-thiazide eGFR to post-hyponatremia eGFR in those who developed hyponatremia (71 vs. 66; p=0.030). Patients who developed hyponatremia also had a lower serum albumin (3.78 vs. 3.95; p=0.033), and a lower BMI (30.1 vs. 31.8; p=0.035). All other values obtained were similar between groups.

Conclusions: Higher comorbidity index and tobacco use are positive predictors for the development of hyponatremia in patients treated with thiazide/ thiazide-like diuretics.

SA-PO918

Persistent Hyponatremia at 72 Hours in Cancer Patients with Severe Hyponatremia Is Associated with Mortality Independent of Cancer Stage Vesh Srivatana,[1] Xian Wu,[2] Edgar A. Jaimes,[3] Ilya Glezerman.[3] *[1]Div of Nephrology, NYP-Weill Cornell Medical Center, New York, NY; [2]Div of Biostatistics, Weill Cornell Medical College, New York, NY; [3]Renal Service, Memorial Sloan Kettering Cancer Center, New York, NY.*

Background: Hyponatremia is a common problem and a known independent risk factor for mortality in cancer patients. The impact of rate of correction of sodium on mortality is unknown. The study aim was to determine if the rate of correction in cancer patients with severe hyponatremia (Na < 120 mEq/L) is linked to 90 day mortality.

Methods: Patients with a Na < 120 mEq/L were identified from the Memorial Sloan Kettering Cancer Center database from June 1, 2009 until June 30, 2014. 195 patients were identified. 55 patients were excluded from analysis because less than 72 hours after admission they either died (4), had no follow up data (16), were discharged (21), or made comfort care (14). The final cohort consisted of 140 patients who stayed in the hospital for at least 72 hours and had serial measurements of serum Na.

Results: The mean initial serum Na was 116.7 ± 3.0 mEq/L, the median rate of correction was 6 mEq/L with interquartile range 3-9 mEq/L in the first 24 hours, and the overall 90 day mortality was 39.3%. No patients with Na correction >8 mEq/L in the first 24 hours (n=54) developed osmotic demyelination syndrome. In patients who died within 90 days, the mean serum Na at 72 hrs was 128.3 ± 4.4 mEq/L compared to 130.5 ± 4.9 mEq/L in survivors ($p<0.01$). When adjusting for cancer stage and rate of correction in a multivariate Cox model, serum Na < 130 mEq/L at 72 hrs was independently associated with 90 day mortality with adjusted HR 2.62 (1.47-4.64, $p<0.001$).

Conclusions: Cancer patients with severe hyponatremia are at heightened risk for 90-day mortality independent of cancer stage and rate of Na correction if their serum Na at 72 hrs is < 130 mEq/L. Based on this finding we recommend that cancer patients with severe hyponatremia should be corrected to >130 mEq/L at 72 hrs.

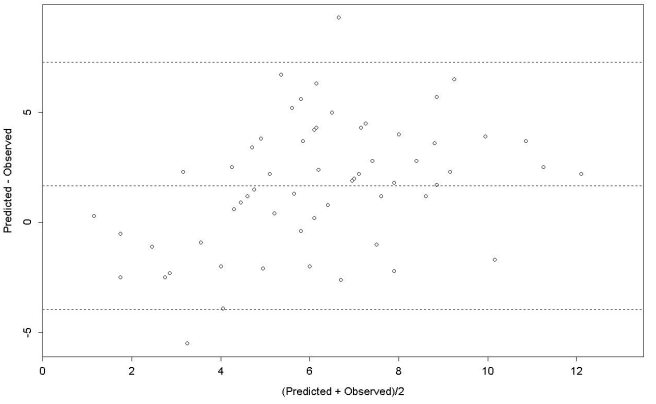
SA-PO919

Hyponatremia Correction Using CRRT: Does Kinetic Modeling Avoid Overcorrection? Saurabh Dasgupta,[1] Lenar T. Yessayan,[2] Balazs Szamosfalvi,[2] Sevag Demirjian.[1] *[1]Nephrology, Cleveland Clinic, Cleveland, OH; [2]Nephrology, Henry Ford Hospital, Detroit, MI.*

Background: Hyponatremia is the most common electrolyte abnormality in inpatients. It must be corrected at a gradual rate of < 8 in 24 hrs to minimize the risk of central pontine myelinosis, which can be effectively achieved in patients with renal failure by CRRT. Sodium (Na) kinetic models can predict end dialysis water. A simplified single pool fixed volume kinetic model may be applicable when net Na generation (G) is ~0 mEq/h. Our goal was to measure the correlation of predicted rate of correction by the formula to that observed in ICU patients with hyponatremia treated with CRRT.

Methods: 66 critically ill subjects with serum Na <130 at time of CRRT initiation were retrospectively identified. Median age was 60, and 52% were male. The predominant CRRT modality was CVVHD (97%), using dialysate Na of 140 mmol/L in most patients (92%) with average cumulative dose of 61L, delivered over median duration of 23.2 hrs. Predicted Na correction in the first 24 hours was calculated using a single pool fixed volume kinetic model. The values were then compared to actual measured serum Na using simple correlation, and Bland-Altman plot.

Results: The correlation factor was calculated to be 0.49 with a p value <0.001. The Bland Altman plot (figure) showed a mean difference of 2 mmol/L between the observed and predicted delta Na values, with a trend for overestimation of Na correction as delta sodium levels increased.



Conclusions: In conclusion, observed serum Na correction rates are slower than that predicted by the simplified Na kinetic model, and err on the side of overestimation (avoid overcorrection). The feasibility to verify the model with empiric data is limited because of practical difficulties in estimating Na generation from fluid intake and output and the ability to ascertain TBW in critically ill patient.

SA-PO920

Hemoglobin Level (Hb) Biases the Measurement of Plasma Sodium (Na) by the Direct Ion-Selective Electrode (ISE) Method Andrea Roche-Recinos,[1] Robert H. Barth,[2] Philip Goldwasser.[2] *[1]SUNY Downstate, Brooklyn, NY; [2]VA NY Harbor Healthcare System, Brooklyn, NY; [3]VA NY Harbor Healthcare System, Brooklyn, NY.*

Background: Na is measured by indirect ISE (iNa) or direct ISE (dNa), on chemistry (chem) and gas panels, respectively. A spurious difference between these assays (DNa = iNa – dNa) can be confusing to the clinician. We recently quantified the negative effect of serum total protein (TP) on iNa (NDT 2015). Red cells have been suggested to interfere with dNa, but both positive and negative interference have been reported (Bijster 1983). In the present study, we examined the effect of gas panel Hb on DNa.

Methods: The data were 772 pairs of closely-timed chem and gas panels (<20 min. apart; median 4 min.), retrospectively collected from our critical care units, excluding hemolyzed/turbid samples, with 1 pair per patient. We used multivariate adjustment for 3 known effects on DNa—TP, bicarbonate (tCO_2), and the chem-gas panel glucose difference (ΔGlu)—and polynomial contrast to test for linear and non-linear trends.

Results: Mean (±SE) values were: Hb, 11.4±0.09 g/dL; DNa, 2.3±0.08 mEq/L. DNa rose across Hb categories (Table); trend analysis showed only a significant linear trend ($p<.04$). By simple regression, DNa rose 0.06 mEq/L per g/dL rise in Hb ($p <.05$); this estimate of the Hb effect is confounded, however, as Hb also correlated ($p<.001$) with TP, tCO_2, and ΔGlu. After adjusting for these confounders, the trend of adjusted DNa across the categories became clearer (Table), with, again, only the linear trend being significant ($P<10^{-4}$). By multiple linear regression with the same covariates, DNa rose 0.15±0.03 mEq/L per g/dL rise in Hb ($p<10^{-6}$).

Hb Category	Hb mean	N	ΔNa, unadjusted	ΔNa, adjusted
<6	5	17	1.4±0.4	1.2±0.5
6-7.9	7.2	43	1.8±0.3	1.5±0.3
8-9.9	9.1	166	2.3±0.2	1.9±0.2
10-11.9	11	240	2.4±0.1	2.4±0.1
12-13.9	12.9	185	2.4±0.2	2.6±0.2
14-15.9	14.8	82	2.5±0.3	2.8±0.2
≥16	17	39	2.6±0.3	3.1±0.3

Conclusions: Increasing Hb spuriously decreases dNa and increases DNa. A linear correction for this artifact can reduce the discordance between iNa and dNa, promoting their interchangeable use.

SA-PO921

HHV-6 Encephalitis Resulting in Cerebral Salt Wasting and Hyponatremia Jonathan A. Ducastel, Uday S. Nori. *Internal Medicine and Nephrology, Ohio State Univ, Columbus, OH.*

Background: Hyponatremia is a common electrolyte abnormality that can be associated with hypo-, hyper-, or euvolemic states. Low circulating volumes secondary to extra-renal losses, fluid overload states, and syndrome of inappropriate ADH are some of the more common causes of hyponatremia. One consideration that is uncommon and often overlooked is cerebral salt wasting (CSW). CSW is defined as "renal loss of sodium during intracranial disorders leading to hyponatremia and a decrease in the extracellular fluid volume." It occurs in the setting of cerebral injury, most commonly associated with subarachnoid

hemorrhage, but also documented with other disorders of central nervous system. The mechanism of CSW is not completely understood, but is believed that a cerebral injury can lead to impairment of the sympathetic outflow causing primary natriuresis leading to hypovolemia and sodium depletion.

Methods: Here we describe a case of CSW in a patient with human herpes virus-6 (HHV-6) encephalitis. The patient was a 29 year old male with a history of AML who presented with increasing confusion. He was found to have hyponatremia with a sodium of 126 mmol/L, a urine osmolality of 615 mOsm/kg, and a urine sodium of 144 mmol/L. On exam, he had evidence of hypovolemia with dry mucus membranes and orthostatic hypotension. He was initially treated with normal saline IV fluids. He had increasing diuresis with fluid resuscitation, with 6 liters of urine output on hospital day 1. The patient was continued on IV saline with the addition of oral salt supplements and started on fludrocortisone for suspected CSW. His hyponatremia improved and by hospital day #5 was 133 mmol/L. CT and MRI imaging of the head and brain were unremarkable for acute changes or pathology. A serum HHV-6 PCR showed 13,960 copies. He was treated with IV foscarnet with normalization of the serum and CSF PCR within 10 days.

Conclusions: This case is important because the diagnosis of CSW is often confused with SIADH, as both share similar diagnostic criteria such as elevated urine sodium concentration and urine osmolality. The important clinical distinction is the patient, despite having a hypovolemic state would have polyuria and renal sodium wasting.

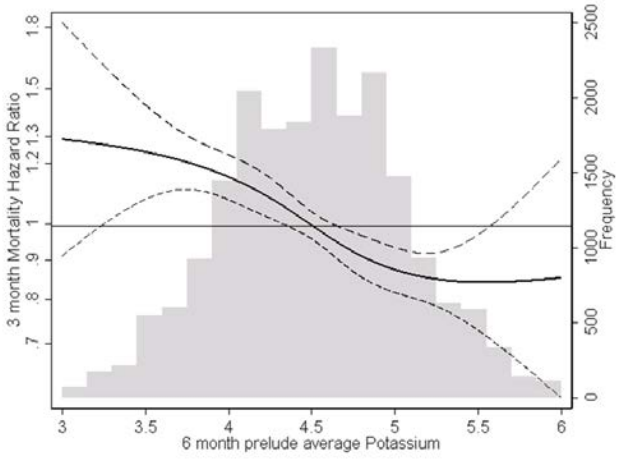
SA-PO922

Association of 6-Month Pre-ESRD Potassium with Immediate Post-ESRD Survival: A Transition to CKD Study Melissa Soohoo,[1] Connie Rhee,[1] Vanessa A. Ravel,[1] Elani Streja,[1] Jennie Jing,[1] Rajiv Saran,[2] Bruce M. Robinson,[2] Yi Li,[2] Danh V. Nguyen,[1] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]UM-KECC; [3]UTHSC.*

Background: Previous studies of the association between serum potassium level and mortality in dialysis patients have suggested that a range of 4.6-5.3 mEq/L portends greatest survival in this population. However, the optimal potassium range in the immediate pre-ESRD prelude period among pre-dialysis CKD patients transitioning to ESRD is not known. We hypothesized that a similar pre-ESRD serum potassium range is also associated with higher survival in this population.

Methods: We investigated a cohort of 20,404 US veterans who initiated dialysis between 10/2007-9/2011 and had at least 1 potassium measurement during the last 6 month period before ESRD transition (6 month-prelude). We examined the association of 6 month averaged potassium as a continuous predictor of all-cause mortality and early post dialysis mortality occurring in the first 3 months after transition using restricted cubic splines and Cox proportional hazard models adjusted for age, gender, race, ethnicity, geographic region and primary cause of ESRD.

Results: The analytic cohort had a mean±SD age of 68±11 years old, among whom 30% were African-Americans, 7% Hispanic and 50% had diabetes as the leading cause of ESRD. The potassium level in the prelude period was 4.5±0.6 mEq/L. Lower potassium levels (3.5-4.0 mEq/L) in the prelude period was associated with highest mortality in the first 3 months after transitioning to dialysis whereas potassium in 4.5-5.5 mEq/L range conferred the greatest early survival.



Conclusions: Lower serum potassium measurements during the final months prior to transition to ESRD are associated with higher early mortality. Whether pre-ESRD potassium should be kept between 4.5 and 5.5 mEq/L in the immediate pre-dialysis transition period warrants additional studies.

SA-PO923

Antihypertensive Medications and the Prevalence of Hyperkalemia in a Large Healthcare System Alex R. Chang,[1] Yingying Sang,[2] H. Lester Kirchner,[1] Kunihiro Matsushita,[2] Shoshana Ballew,[2] Josef Coresh,[2] Morgan Grams.[2] *[1]Geisinger Health System; [2]Johns Hopkins Bloomberg School of Public Health.*

Background: The association of outpatient medication use with patterns and prevalence of hyperkalemia has not been rigorously examined.

Methods: We evaluated the association between baseline antihypertension medications [angiotensin converting enzyme-inhibitors (ACEi), angiotensin receptor blockers (ARB), beta-blockers, loop/thiazide diuretics, and K-sparing diuretics] with the frequency and pattern of mild (K>5 mmol/L) and severe hyperkalemia (>6 mmol/L) over a 2 year window in 342,342 outpatients in the Geisinger Health System based on medication prescription orders. Patterns of hyperkalemia were classified as: never, transient (1-time), intermittent (>1-time but <50% of the time), and persistent (≥50% of the time). Analyses were adjusted for demographics, eGFR, systolic blood pressure, diabetes, and history of cardiovascular disease. Interactions between medication types with hyperkalemia risk were also tested.

Results: Potassium levels were checked >=1 time/yr in 53% of the cohort; 4% had levels checked >=5 times/yr. Overall, 7.4% had >=1 episode of mild hyperkalemia; 0.4% had an episode of severe hyperkalemia. Among the different classes of antihypertensives, K-sparing diuretics had the strongest associations with both mild and severe hyperkalemia, followed by ACEis and then beta blockers, which were associated only with mild hyperkalemia (Figure). ARBs had similar effect size to beta blockers but were not statistically significant. Thiazide/loop diuretics were protective against mild hyperkalemia but not severe hyperkalemia. There were no consistent interactions between types of antihypertensive medication for risk of hyperkalemia.

Conclusions: Mild hyperkalemia is relatively common and associated with the use of ACEis and K-sparing diuretics but not ARBs in this single healthcare system.

SA-PO924

Wide Range in Variation in Serum Potassium in Hyperkalemic Patients with CKD, Response to a Fixed 60 mEq Potassium Diet David A. Bushinsky,[1] Martha Mayo,[2] Dahlia Garza,[2] Yuri Stasiv,[2] Daniel J. Wilson,[2] Charles Dumond,[2] Lance Berman,[2] Murray Epstein.[3] *[1]Univ of Rochester; [2]Relypsa, Inc; [3]Univ of Miami.*

Background: Serum K(s-K^+) levels are affected by diurnal variation, fasting/feeding cycles, and medications. In this study we characterized the differences in inter-individual variation in s-K^+ on a random diet prior to entry and the effect of a controlled K^+ diet on s-K^+ levels in hyperkalemic (HK) pts with CKD (stage 2-4) on stable doses of RAASi, during the run-in phase of a treatment trial.

Methods: A total of 27 pts with s-K^+ ≥5.5 to ≤6.2 mEq/L were monitored in a clinical research unit. At baseline pts were fed a 60 mEq K^+, 100 mEq Na^+ diet. S-K^+ was measured at baseline and at prespecified intervals for the next 72 h. We calculated individual difference (maximum-minimum) in s-K^+ at each time point for the remaining observation period to determine variation in s-K^+.

Results: Mean s-K^+ at baseline was 5.86±0.22 mEq/L and rose to 5.94±0.17 mEq/L at 72 h following the start of the fixed K^+ diet. Over 72 h, 6/27 pts had "low" (0.0–0.2 mEq/L), 9/27 "moderate" (0.3–0.4 mEq/L), and 12/27 "high" (0.5–1.1 mEq/L) variation in s-K^+. Variation in s-K^+ decreased at each time point over the 72-h period of observation on the controlled diet (**Table**).

Conclusions: A wide range of inter-individual variation in s-K^+ occurred in HK pts with CKD on RAASi who were on an uncontrolled diet prior to entry. Variation decreased significantly after 24 h on a 60 mEq K diet. These findings have implications for management of pts with HK and CKD, and for interpreting clinical trials assessing directional change in s-K^+ with an intervention.

Table. Variation in s-K+ (max-min) over 72 h during run-in on a 60 mEq K+ diet, n=27							
Time	baseline	+10 h	+24 h	+36 h	+ 48 h	+62 h	+71 h
Mean±SD Δ in s-K+, mEq/L	0.44± 0.24	0.42± 0.24	0.39± 0.24	0.34± 0.24	0.29± 0.21	0.15± 0.12	0.12± 0.09
P-value*	-	0.0830	0.0027	0.0001	0.0001	<0.0001	<0.0001

*Comparing values from baseline to values at +10, +24, +36, +48, +62 and +71 h via paired t-test with Bonferroni correction (α=.05; P ≤0.0083 is significant).

SA-PO925

Best EKG Criteria for Hyperkalemia in Chronic Hemodialysis Patients Muzzaffar Hussain, Jamrs R. Cook, Gregory Lee Braden. *Dept of Medicine, Baystate Medical Center/Tufts Univ School of Medicine, Springfield, MA.*

Background: To date the effects of hyperkalemia(HK) on the EKG of chronic hemodialysis(CHD) patients(pts) are inconsistent. We studied the EKGs of 128 consecutive CHD pts with clotted grafts or fistulas. EKGs from 46 HK pts > 5.5 mEq/L were compared to 82 pts with normal potassum (NK) levels < 5.5 mEq/L. Pts with RBBB or LBBB or cardiac events within 3 months were already excluded. There were no differences between HK and NK pts for dialysis duration, causes for ESRD, cardiac disease or serum levels of Na, Ca, HCO3, or phosphorus.

Methods: EKG analysis included: the height & width of the P waves, the T waves in V4 & the T waves in Lead 2, the time intervals of PR, QRS, QT, QTc, PR/QT, PR/QTc, & slopes of ascending & descending T waves in Lead 2 & V4. For the first time ever in HK CHD pts, the EKG measurements in 32 HK pts with complete data were compared to their NK EKGs obtained 3 to 6 months from the HK event.

Results: Univariate stats between the 46 HK & 82 NK pts showed 4 differences in mean values: V4 T wave height 4.0 vs 2.9 mm, Lead 2 T wave height 2.7 vs 2.0 mm, & the V4 T wave ascending (.03 vs .02) and descending slopes (.04 vs .03). Multivariate analysis for all clinical & EKG findings between HK & NK pts found only the increased height of the T wave in V4 was significant, p<.05. In contrast , the EKG analysis of the HK pts to their NK EKGs revealed more differences: higher T wave height in V4, 5.0 vs 3.7 mm, higher T wave height in Lead 2, 4.0 vs 2.7 mm, shorter width of T wave in V4 , 2.4 vs 4.1 ms or Lead 2, 2.1 vs 4.1 ms , longer PR 188 vs 167 ms , & steeper slopes in the T waves in Lead 2 and V4. Regression analysis of the change in potassium from NK to HK to each EKG measurement showed that the only significant correlation was to the width,(r = -.433, p=.007) & height of the T wave in V4, r= .333, p=.03. In these HK CHD pts T wave tenting in V4 was now present in 56 %.

Conclusions: We conclude: 1) Comparison of a NK EKG to a HK EKG in CHD pts significantly helps to confirm HK EKG changes in CHD pts. 2) A shortened width and an increased height of the T wave in V4 are the most important HK EKG changes in CHD pts.

SA-PO926

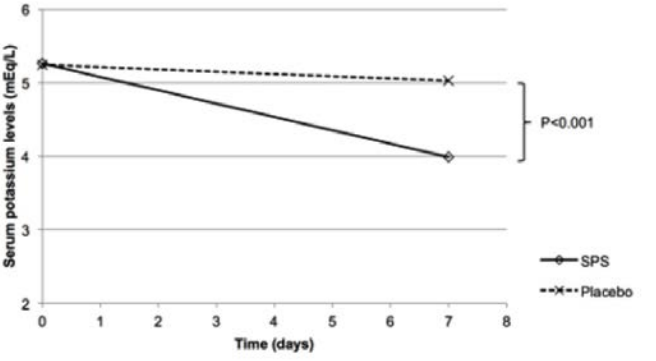
Sodium Polystyrene Sulfonate for the Treatment of Mild Hyperkalemia in Chronic Kidney Disease: A Randomized Clinical Trial Katherine Desforges, Laurence Lepage, Anne-Claude Dufour, Jessica Doiron, Katia Handfield, Robert Zoel Bell, Michel Vallee, Michel Savoie, Sylvie Perreault, Louis-Philippe Laurin, William Beaubien-Souligny, Vincent Pichette, Jean-Philippe Lafrance. *Hopital Maisonneuve-Rosemont, Montreal, QC, Canada.*

Background: Hyperkalemia affects up to 10% of patients with chronic kidney disease (CKD). Sodium polystyrene sulfonate (SPS) has long been prescribed for this condition even though evidence is lacking on its efficacy for the treatment of mild hyperkalemia over several days.

Methods: The aim of this double-blind, randomized trial was to evaluate the efficacy of SPS in the treatment of mild hyperkalemia (5.0 to 5.9 mmol/L) in pre-dialysis outpatients. We randomly assigned 33 patients on stable medication to receive either SPS or placebo 30g orally once a day for 7 days. Patients had to be on stable medication to be eligible for the study. The primary outcome was the comparison between study groups of the mean difference of serum potassium levels between the day following the last dose of treatment and baseline.

Results: The mean duration of treatment was 6.9 days. SPS was superior to placebo in the reduction of serum potassium levels (mean difference between groups of -1.04 mmol/L; 95%CI: -1.37 to -0.71). A higher proportion of patients in the SPS group tended to attain normokalemia (defined as a serum potassium level of at least 3.5 mmol/L and less than 5.0 mmol/L) at the end of their treatment compared to the placebo group (73% vs 38%, P=0.07). Patients in the group treated with SPS had an increase in hypomagnesemia, hypocalcemia, constipation and nausea compared to the control group.

Conclusions: SPS is superior to placebo in the treatment of mild hyperkalemia over seven days in CKD patients. Its use was generally well tolerated in our study population, but does require monitoring of gastrointestinal side effects and electrolytic disorders.



Funding: Private Foundation Support, Government Support - Non-U.S.

SA-PO927

Assessment of Systemic Absorption of Sodium Zirconium Cyclosilicate (ZS-9): Blood and Urine Zr Concentration in Dogs During a 9-Month Oral Toxicity Study Fiona Stavros, Henrik S. Rasmussen, Bhupinder Singh, Jose A. Menoyo. *ZS Pharma, Inc., Coppell, TX.*

Background: Hyperkalemia (HK; potassium [K^+] ≥5.1 mEq/L) is a common and potentially life-threatening electrolyte disorder often occurring in patients with chronic kidney disease, heart failure and diabetes. Sodium zirconium (Zr) cyclosilicate (ZS-9), a potential HK therapy, is a selective K^+ ion trap containing covalently bound Zr atoms within an insoluble 25µm particle. Zr has a long history as an inert substance used in biomedical implants and dialysis, and is present in normal diets and household items. Systemic absorption of Zr is expected to be minimal given the low solubility and particle size of ZS-9. Here we present Zr concentration data from urine and whole blood samples from ZS-9 treated dogs to assess systemic absorption of long-term, high-dose ZS-9.

Methods: Beagle dogs received Control (n=10/sex) or high-dose ZS-9 (2000 mg/kg/day, n=10/sex). Blood samples were collected by venipuncture at baseline, and Weeks 6, 13, 26, and 39. Urine samples were collected directly from the bladder at necropsy (Week 39) and recovery (Week 43). Zr levels in Control and ZS-9 treated dogs were determined using inductively coupled plasma mass spectrometry with a lower limit of quantification (LLOQ) of 10 ng/mL (ppb) for both whole blood and urine. The analytical method was designed to measure the presence of both free Zr and ZS-9 bound Zr.

Results: Zr was below the LLOQ in all dog urine samples (N=28) and in all but one Control group whole blood sample (N=226). The one dog in the Control group had a blood Zr level of 10.9 ng/mL at Week 26.

Treatment Group	ZS-9 Dose Level (mg/kg/day)	Blood Zr concentration >LLOQ, n (N=226)	Urine Zr concentration >LLOQ, n (N=28)
Control	0	1	0
High ZS-9	2000	0	0

Conclusions: There was no detectable Zr or increase in Zr in blood and urine samples following 39 weeks of 2000 mg/kg/day ZS-9 treatment; equivalent to a human dose of ~65 g/day. Zr was detected in one non ZS-9 treated animal. These results demonstrate an absence of systemic ZS-9 absorption after long-term, high-dose treatment in beagle dogs.

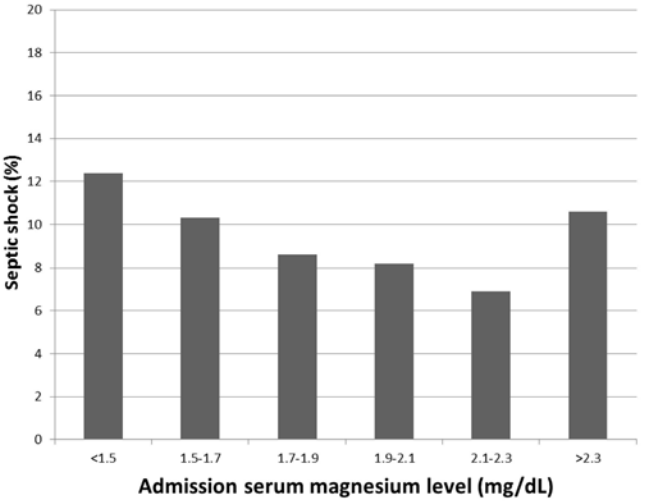
Admission Hypomagnesemia Linked to Septic Shock in Patients with Systemic Inflammatory Response Syndrome Wisit Cheungpasitporn,[1] Charat Thongprayoon,[2] Stephen B. Erickson.[1] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Internal Medicine, Bassett Medical Center, Cooperstown, NY.*

Background: The association between admission serum magnesium (Mg) levels and risk of developing septic shock in patients with systemic inflammatory response syndrome (SIRS) is limited. The aim of this study was to assess the risk of developing septic shock in hospitalized patients with SIRS with various admission Mg levels.

Methods: This is a single-center retrospective study conducted at a tertiary referral hospital. All hospitalized adult patients with SIRS at admission who had admission Mg available from January 2009 to December 2013 were analyzed in this study. Admission Mg was categorized based on its distribution into six groups (<1.5, 1.5 to 1.7, 1.7 to 1.9, 1.9 to 2.1, 2.1 to 2.3, and >2.3 mg/dL). The primary outcome was septic shock occurring after hospital admission. Logistic regression analysis was performed to obtain the odds ratio of septic shock of various admission Mg levels using Mg with lowest incidence of shock, 2.1 to 2.3 mg/dL as the reference group.

Results: Of 2,589patients with SIRS enrolled, septic shock occurred in 236 patients (9.1%). The lowest incidence of septic shock was when serum Mg was within 2.1-2.3 mg/dL. A reverse-checkmark curve emerged demonstrating higher incidences of septic shock

associated with both hypoMg (<2.1) and hyperMg (>2.3). After adjusting for potential confounders, hypoMg (<1.5 mg/dL) was associated with an increased risk of developing septic shock with odds ratios of 1.86 (95% CI 1.07-3.27).



Conclusions: Patients with SIRS and hypoMg (<1.5mg/dL) at the time of admission had increased risk of developing septic shock during hospitalization.

SA-PO929

Risk Factors for Calcium-Alkali Syndrome in Post-Surgical Hypoparathyroidism

Sayaka Kuroya, Masahiko Yazawa, Naoto Tominaga, Yugo Shibagaki. *Nephrology and Hypertension, St. Marianna Univ, Kawasaki, Kanagawa, Japan.*

Background: Post-surgical hypoparathyroidism is a common complication of total thyroidectomy. Patients complicated by permanent hypoparathyroidism often require either or both calcium or vitamin D supplement therapy to maintain serum calcium levels, and long-term therapy can lead to calcium-alkali syndrome (CAS). We examined the incidence rate, magnitude, and risk factors of CAS in patients being treated for post-surgical hypoparathyroidism.

Methods: We retrospectively observed 27 patients with neck tumors who had undergone total thyroidectomy with total parathyroidectomy without autotransplantation between January 2010 and October 2013 at St. Marianna University Hospital. All patients received calcium lactate and alfacalcidol. Medical records were reviewed for historical, clinical, laboratory and imaging data. Definitions were as follows: hypercalcemia, corrected serum calcium (cCa) ³10.0 mg/dL; acute kidney disease (AKD), either or both >50% increase in serum creatinine (sCr) or >35% decrease in estimated glomerular filtration rate (eGFR); and metabolic alkalosis, difference in serum sodium (sNa) and serum chloride (sCl) >38. Data were expressed as mean ± standard deviation (SD). For statistical analysis, the paired t test, Student's t test, and chi-square test were used to compare two matched variables when appropriate. P<0.05 was considered statistically significant.

Results: Average duration between surgery and reaching peak cCa level was 392.7 ± 403.8 days, with levels peaking at 11.1 ± 1.5 mg/dL. All patients tended to have significantly higher cCa and sCr levels and difference in sNa and sCl after surgery than at baseline (p<0.01). Nineteen patients (70.3%) had hypercalcemia, 9 (33.3%) had AKD, and 7 (36.9%) had CAS. Calcium lactate dosage was significantly associated with hypercalcemia and AKD (p<0.01). Higher doses of alfacalcidol tended to increase incidence of hypercalcemia and AKD, although not significantly so.

Conclusions: CAS in post-surgical hypoparathyroidism was common, and dosage of calcium supplement was correlated with CAS. cCa levels and kidney function should be closely monitored in patients with post-surgical hypoparathyroidism.

SA-PO930

Body Temperature Rise in the Cell-Free and Concentrated Ascites Reinfusion Therapy Is Correlated to Albumin Concentration Rather Than the Interleukin-6 Levels in the Ascites

Noriaki Maruyama, Masanori Abe, Kazuyoshi Okada. *Div of Nephrology, Hypertension and Endocrinology, Dept of Internal Medicine, Nihon Univ School of Medicine, Tokyo, Japan.*

Background: There is a fever as a side effect of Cell-free and Concentrated Ascites Reinfusion Therapy (CART). Cytokines in ascites after concentration is thought to be involved in the generation of heat after intravenous injection. To examine the fever related factors, we examined the relationship between inflammatory cytokines levels, total protein (TP), albumin (ALB) in peritoneal fluid and the heating after intravenous injection.

Methods: In this study, we have measured interleukin-1β (IL-1β), interleukin-6 (IL-6), TP, ALB concentration in the ascites fluid before and after concentrated, and observed vital changes in the patient before and after intravenous injection. A total of 8 patients with refractory ascites were studied.

Results: IL-1β was detected in ascites prior to concentration of the two cases, it could not be measured in the other specimen. IL-6 is present in high concentrations in all ascites before concentration (mean 4218.75 pg/mL), it was further increased after concentration (mean 6508.75 pg/mL). Although body temperature rise was observed after the intravenous injection of concentrated ascites in six out of eight, IL-6 concentration in the ascites fluid (r = 0.61063; P = 0.114), the total dose of IL-6 (r = 0.06755; P = 0.436), dose rate(r = 0.2876; P = 0.244) was no obvious correlation between the body temperature rise. On the other hand, respectively in the TP concentration and the ALB concentration of ascites, it was found correlated with body temperature rise after intravenous injection. In particular, a strong correlation between the ALB concentration and the increase in body temperature was observed (r = 0.8033; P < 0.01).

Conclusions: The correlation of body temperature rise after intravenous injection and IL-6 is weak, while the correlation between the concentrated ALB and body temperature rise was very strong. From these results, we considered that any substance bound to the ALB or ALB itself are associated with elevated body temperature.

SA-PO931

Contrast-Related Hyponatremia: What We Could Be Missing

Christine Joy C. Junia, Kalyani Perumal. *Internal Medicine, John H. Stroger Jr. Hospital, Chicago, IL.*

Background: Hyponatremia is a commonly encountered electrolyte abnormality. Long-established algorithms outline etiology and management guiding physicians to prevent neurologic sequelae. Close electrolyte monitoring is emphasized in acute hyponatremia due to higher morbidity and mortality. Contrast-related hyponatremia is an etiology of acute onset hyponatremia that is not routinely monitored and may easily be missed.

Methods: A 76 year-old woman with hypertension, diabetes and chronic kidney disease (CKD) III, eGFR of 44 was admitted for asthma exacerbation and received beta-agonist nebulizers and oral prednisone. Her home medications-Amlodipine and Insulin were restarted. She was tachypneic and wheezing, the rest of the physical exam was normal. Laboratory tests on admission: Na 135 meq/L, K 4.4 meq/L, BUN 11 mg/dL, Creatinine 1.2 mg/dL, and normal urinalysis. An elevated D-Dimer prompted evaluation with CT Chest with contrast Omnipaque 350 (840 mosm/kg) to rule out pulmonary embolism. Her symptoms improved, however her sodium dropped from 135 to 122 meq/L 48 hours after chest CT, creatinine 1.4 mg/dL. Work-up revealed plasma osmolality of 297 mosm/kg, osmolal gap of 30. On the 4th and 5th hospital day, sodium levels were stable at 125 meq/L and 124 meq/L respectively. Her sodium on Day 8 improved to 133 meq/L without any intervention.

Conclusions: The 2014 USRDS data reports a rise in prevalence of CKD III from 4.5 to 6.0 percent. Primary care doctors manage 80 to 90 percent of these patients. There is a simultaneous rise in diagnostic imaging. Over the past decade, CT Scan use in the emergency departments has increased over 200-300%. There are a few case reports of contrast-related hyponatremia, occurring mostly in patients with advanced CKD with eGFR<30. A consistent finding was the acute onset and an average drop in sodium of 12 meq/dL. Contrast hypertonicity generates a fluid shift and a dilutional effect on extracellular sodium. This is usually offset by osmotic diuresis that is impaired in chronic kidney disease. Our case highlights contrast-related acute hypertonic hyponatremia in the setting of mild kidney disease, a high-risk patient population that may benefit from post-diagnostic electrolyte monitoring.

SA-PO932

A Role for NHE3 in Renal Sodium and Acid-Base Handling in the Early Proximal Tubule and Further Downstream Segments

Akira Onishi,[1] Yiling Fu,[1] Panai Song,[1] Meinrad Busslinger,[2] Manoocher Soleimani,[3] Isabelle Rubera,[4] Michel Tauc,[4] Volker Vallon.[1] *[1]Div of Nephrology, UC San Diego & VA San Diego Healthcare System, La Jolla, CA; [2]Research Inst of Molecular Pathology, Vienna, Austria; [3]Dept of Medicine, Univ of Cincinnati, Cincinnati, OH; [4]Univ de Nice Sophia Antipolis, Nice, France.*

Background: Systemic Na+/H+ exchanger 3 (NHE3) knockout in mice lowered blood pressure (BP) and induced metabolic acidosis, however, the role of intestine vs kidney and early proximal tubules (PT) vs downstream segments is unclear.

Methods: Male mice with floxed NHE3 expressing Cre recombinase under the control of i) the SGLT2 promoter to knockdown NHE3 in the early PT (SGLT2-Cre/NHE3$^{fl/fl}$, n=10) or ii) the Pax8 promoter for knockdown along the entire tubular system (Pax8-Cre/NHE3$^{fl/fl}$, n=9) were compared with corresponding Cre-negative controls (n=10 and 7). Blood and spot urine samples were collected, BP measured by automated tail cuff and arterial cannulation, and GFR by inulin clearance.

Results: Urine Na/creatinine (cr) ratios were higher in Pax8-Cre/NHE3$^{fl/fl}$ vs controls (40±5 vs 28±2, P<0.05) but not significantly different in SGLT2-Cre/NHE3$^{fl/fl}$ vs controls (31±2 vs 27±3). Urine pH and HCO_3-/cr ratio were strongly increased in Pax8-Cre/NHE3$^{fl/fl}$ vs controls (7.83±0.11 vs 6.44±0.22; 15.5±3.1 vs 0.55±0.34, each P<0.01), and only modestly higher in SGLT2-Cre/NHE3$^{fl/fl}$ vs controls (6.50±0.15 vs 6.12±0.13, P=0.07 and 0.45±0.20 vs 0.14±0.03, P=0.16). Urine pH and HCO_3- were significantly higher in Pax8-Cre/NHE3$^{fl/fl}$ vs. SGLT2-Cre/NHE3$^{fl/fl}$ (each P<0.05). Blood pH and HCO_3- were not different between any groups. Based on the stronger phenotype, BP and GFR were determined in Pax8-Cre/NHE3$^{fl/fl}$ and their controls and found to be similar. Urine protein/cr ratios were doubled in both knockdown mice vs their controls (Pax8-Cre: 32±3 vs 17±2; SGLT2-Cre: 22±2 vs 10±1, each P<0.01).

Conclusions: Tubule-specific NHE3 knockdown increased urine pH and excretion of sodium, HCO_3- and protein without metabolic acidosis. Comparison of the Cre models is consistent with a role of NHE3 in urinary acidification and reabsorption of sodium and bicarbonate in the early PT as well as in further downstream segments.

SA-PO933

Effect of NBCe1 Deletion on Renal Ammonia Metabolism I. David Weiner,[1,2] Mary E. Handlogten,[1] Gunars Osis,[1] Hyun-Wook Lee,[1] Jill W. Verlander.[1] *[1]Renal Div, Univ of Florida, Gainesville, FL; [2]Nephrology Section, NF/SGVHS, Gainesville, FL.*

Background: Metabolic acidosis typically increases renal ammonia excretion, but people with proximal renal tubular acidosis (pRTA), despite the associated metabolic acidosis, do not have increased ammonia excretion. Genetic forms of human pRTA typically involve the proximal tubule bicarbonate transporter, NBCe1. Based on these observations, we postulated that NBCe1 has a role in renal ammonia metabolism that is in addition to its role in bicarbonate reabsorption.

Methods: We used previously reported mice with NBCe1 deletion. Because -/- mice have 100% mortality between d10-21, we studied mice at d8±1. Wild-type (WT), heterozygous (HET) and homozygous knock-out (KO) mice were generated by breeding HET male and female mice.

Results: Serum HCO3 was 26.4±1.0 in WT, 19.8±1.9 in HET, and 10.3±0.6 mM in KO mice (P<0.05). Thus, NBCe1 deletion causes metabolic acidosis at d8. Although acidosis normally increases ammonia excretion, NBCe1 deletion decreased spontaneous ammonia excretion: 275±44, 212±11 and 94±69 mmol/g creatinine in WT, HET and KO mice, respectively (P<0.01). Serum Na and K were unchanged. Urine pH was 5.3±0.2, 4.8±0.1 and 4.2±0.1 in WT, HET and KO mice, respectively (P<0.01), indicating intact urine acidification and no ongoing HCO3 loss. NBCe1 deletion did not alter urine osmolality significantly (WT, 596 ± 74; HET, 693 ± 51; and, KO, 726 ± 34 mOsm/kg H2O; P=NS), which, in combination with intact urine acidification, suggests intact collecting duct function. The regulation of multiple proteins involved in ammonia metabolism was atypical of acidosis. NBCe1 deletion decreased expression of PDG and PEPCK and increased expression of the ammonia recycling enzyme, glutamine synthetase. This pattern is the exact opposite of that expected with acidosis. Expression of the TAL ammonia transporter, NKCC2, and the collecting duct ammonia transporters, Rhbg and Rhcg, was unchanged.

Conclusions: We conclude: 1) NBCe1 deletion significantly alters proximal tubule ammonia metabolism, leading to decreased urinary ammonia excretion; and, 2) NBCe1, in addition to its role in HCO3 transport, may have an important role in ammonia metabolism.

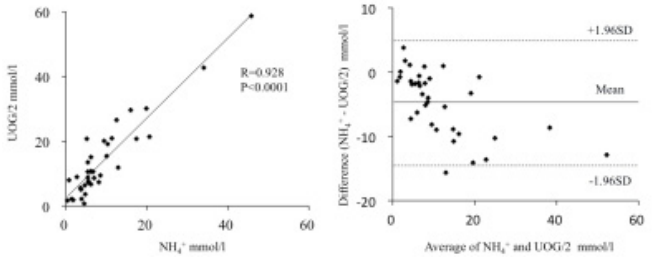
Assessing Urine Ammonium Concentration by Urine Osmolal Gap in Chronic Kidney Disease Takuya Fujimaru, Yasuhiro Komatsu, Takuya Shuo. *Nephrology, St. Luke's International Hospital, Tokyo, Japan.*

Background: Acidemia is one of the risk factor for end stage kidney disease and mortality for patients with chronic kidney disease (CKD). Although ammonium is the crucial component of renal acid excretion, measurement of urine ammonium concentration (NH_4^+) is not routinely available in most hospital laboratories. To estimate NH_4^+, urine osmolal gap (UOG = urine osmolality – [2(Na^+ + K^+) + urea + glucose]) is calculated and the formula (NH_4^+ = UOG/2) has traditionally been used. However, studies evaluating it in CKD patients are scarce. The present study aims to assess the relationship between NH_4^+ and UOG in CKD patients.

Methods: Spot urine samples were collected from 36 patients with CKD in our hospital (24 males, age 41-96 years, serum creatinine 0.9-12.4 mg/dl). We measured urine pH, Na^+, K^+, Cl^-, urea, glucose and NH_4^+. NH_4^+ was measured by colorimetric assay (modified Fujii-Okuda method). The Bland-Altman plot was used to evaluate the agreement between NH_4^+ and UOG/2.

Results: NH_4^+ ranged from 0.3-45.8 mmol/l (median, 6.2 mmol/l). UOG/2 correlated positively and significantly with NH_4^+ (r=0.928, p<0.0001).



The mean difference between UOG/2 and NH_4^+ was 4.7 mmol/l, and the 95% limits of agreement were -5.0 mmol/l and 9.6 mmo/l.

Conclusions: UOG is an accurate method to estimate NH_4^+ in CKD patients and can be used to assess urinary acidification ability in CKD patients.

SA-PO935

Vacuolar H^+-ATPase Regulation by 14-3-3 Proteins Nuria M. Pastor-Soler,[1] Mohammad M. Al-bataineh,[3] Hui Li,[1] Vivek Bhalla,[2] Kenneth R. Hallows.[1] *[1]Medicine, Div of Nephrology, Keck School of Medicine of USC, Los Angeles, CA; [2]Medicine, Div of Nephrology, Stanford School of Medicine, Palo Alto, CA; [3]Medicine, Renal-Electrolyte Div, U. of Pittsburgh School of Medicine, Pittsburgh, PA.*

Background: The vacuolar proton-ATPase (V-ATPase) is highly expressed at the apical membrane of type A intercalated cells (ICs) in the collecting duct. This pump mediates proton transport across a membrane often against a gradient. Defects in V-ATPase function can lead to renal tubular acidosis. In kidney cells we showed that the metabolic sensor AMP-activated protein kinase (AMPK) phosphorylates the V-ATPase A subunit at Ser-384. AMPK regulates some transport proteins by inhibiting their function and promoting their ubiquitination and degradation. These mechanisms are likely important for inhibition of membrane transport during cellular metabolic stress. We noticed that Ser-384 exists within a 14-3-3 binding motif. Dimeric 14-3-3s bind to phosphorylated sites on target proteins and modulate protein function. We hypothesized that phosphorylation by AMPK and an additional kinase modulate A subunit binding to 14-3-3 proteins and A subunit ubiquitination.

Methods: We used transient transfections of V-ATPase A subunit mutants in Clone C ICs, followed by immunoprecipitation and immunoblotting.

Results: We have preliminary evidence that phosphorylation at Ser-384 and a new "Site III" in the V-ATPase A subunit are required for 14-3-3 binding. For example, 14-3-3 binding to the A subunit increased when we used a phosphomimetic mutant (Ser-to-Asp) at Site III compared to the WT sequence at that site, and this binding was is not dependent of the presence of the AMPK activator AICAR. Furthermore, AICAR increased A subunit ubiquitination as compared to untreated cells.

Conclusions: We propose that V-ATPase A subunit binding to 14-3-3s promotes its ubiquitination and degradation. These pathways are downstream of phosphorylation of the A subunit at Ser-384 by AMPK and at Site III by another unidentified kinase. Our results link downregulation of the V-ATPase to metabolic depletion in kidney epithelial cells.

Albuminuria Enhances Renal NHE3 Expression via the Activation of Mitochondrial Oxidative Stress/RAS Axis Aihua Zhang,[1,2] Yibo Zhuang,[1] Guixia Ding,[1] Songming Huang,[1] Zhanjun Jia.[1,2] *[1]Nephrology Dept, Nanjing Children Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China; [2]Nanjing Key Laboratory of Pediatrics.*

Background: Renal sodium–hydrogen exchanger 3 (NHE3) plays a known role in the reabsorption of bicarbonate and fluid. As a result, NHE3 is thought to be important in acid base balance and vascular volume homeostasis. The present study was to investigate the role albuminuria in regulating renal NHE3 expression as well as the underlying mechanisms.

Methods: An albumin overload mouse model was established by i.p injection of albumin. The mouse kidney tissues and kidney biopsy specimens from proteinuric patients were analyzed.

Results: Following 12-day albumin overload, we found that albuminuria increased NHE3 expression by 2-fold in mouse kidneys determined by Western blotting and qRT-PCR. Considering the known role of renin-angiotensin system (RAS) in modulating renal sodium transporters, we examined key components of RAS and found a striking elevation of angiotensinogen (AGT, +2.1 folds), angiotensin converting enzyme (ACE, +3.3 folds), and urinary antgiotensin II (Ang II, +70%) output determined by Western blotting or ELISA. In proteinuric patients, we detected a 1.9-fold upregulation of NHE3 and 3-fold increase of ACE by immunohistochemistry in line with a 2-fold increment of urinary Ang II excretion. To further investigate the role of RAS in upregulating NHE3, we performed primary cultures of renal tubular cells and observed that albumin directly enhanced NHE3 accompanied by stimulated AGT/ACE/Ang II cascade, which was entirely abolished by ACE inhibitor captopril, indicating a key role of RAS in mediating albuminuria effect on NHE3 upregulation. More interestingly, albumin overload significantly induced mitochondrial oxidative stress evidenced by reduced mitochondrial superoxide dismutase (SOD2, -60%) and elevated ROS production. Notably, a SOD2 mimic (MnTBAP) completely normalized NHE3 upregulation and activated AGT/ACE/Ang II cascade in mice with albumin overload.

Conclusions: These results suggest that albuminuria is of vital importance in upregulating renal NHE3 expression in proteinuric patients via mitochondrial oxidative stress-initiated stimulation of AGT/ACE/Ang II cascade.

SA-PO937

ATP6v1b1 Haploinsufficiency Lead to a Mild Incomplete Renal Tubular Acidosis (RTA) in Mice Soline Bourgeois, Carsten A. Wagner. *Inst of Physiology, Univ of Zurich, Zurich, Switzerland.*

Background: Mutations in ATP6V1B1 gene in man is considered as an autosomal recessive disease and lead to distal RTA by dysfunction of the B1 subunit of H-ATPase in type A intercalated cells. B1 subunit ablation in mouse causes also distal RTA with a decrease in ammonuria and alkaline urine pH.

Methods: Here we investigated on littermate mice whether ATP6v1b1+/- mice also develop acid-base disturbances during an acute and chronic acid challenge performed by 0.2 M HCl added to powdered standard food.

Results: ATP6v1b1+/+ (WT) and +/- (HET) mice exhibited no difference in their blood and urine parameters under baseline conditions. During the acid challenge, while ATP6v1b1-/- mice (KO) developed alkaline pH and low ammoniuria with hypercalciuria, HET mice showed no difference in their urine data over the whole acid load compared to WT mice. However, eventhough, HET mice did not exhibit low blood pH, as KO mice, they had a lower bicarbonatemia, higher chloremia and lower pCO2 compared to WT mice at the end of the acid challenge. Both KO and HET mice drank more than WT mice over the acid load with a tendency to urinate more. After 4 days of acid load, subcellular localization of the a4 and B2 subunits of H-ATPase were not different within the 3 strains of mice and WT and HET mice exhibited the same localization of B1 subunit. However, western blot analysis of B1 and B2 expression in renal membrane fractions revealed a 2-fold decrease of B1 and B2 protein expression in HET mice compared to WT mice and no difference in the expression of B2 protein in KO mice compared to WT mice while B1 protein was totally absent from KO kidneys.

Conclusions: In conclusion, 1) HET mice developed a mild incomplete RTA during an acid challenge, undetectable regarding urine parameters. The RTA is partly compensated by the respiration and an increase in water consumption. 2) B2 subunit does not compensate for the decrease in B1 expression both in HET kidney tissues and seems to be inhibited by acid load.

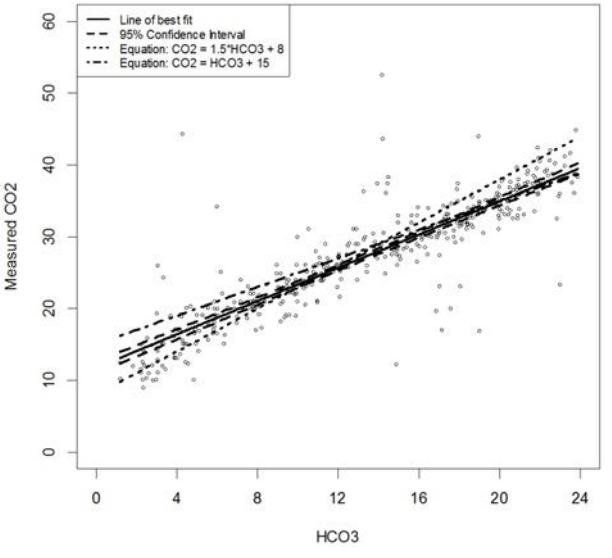
Bedside Rule (pCO2=HCO3+15) Is Reliable in Predicting Respiratory Response in Metabolic Acidosis with Bicarbonate Levels of More Than 7 meq/L Mohammad Kazem Fallahzadeh, Michael Emmett. *Dept of Internal Medicine, Baylor Univ Medical Center, Dallas, TX.*

Background: There is controversy about the reliability of the bedside rule (pCO2=HCO3+15) in prediction of respiratory response in metabolic acidosis. The aim of our study was to compare the accuracy of the bedside rule with Winter's equation in predicting respiratory response in metabolic acidosis.

Methods: We extracted the measured bicarbonate and pCO2 levels of 382 patients with metabolic acidosis from the previously published articles evaluating the respiratory response to metabolic acidosis. We calculated the predicted levels of pCO2 by bedside rule and Winter's equation for each patient. Then we compared the accuracy of these formulas in predicting the respiratory response to metabolic acidosis.

Results: As demonstrated in the figure 1, the values calculated by bedside equation (pCO2=HCO3+15) appear to be a reliable predictor of respiratory response in HCO3 levels of more than 7 meq/L, as compared with the line of best fit and Winter's equation.



Conclusions: Our results show that bedside rule (pCO2=HCO3+15) is reliable in predicting respiratory response in metabolic acidosis with HCO3 levels of more than 7 meq/L.

TSS-Seq Analysis of Low pH-Induced Gene Transcripts in the Intercalated Cells of the Collecting Ducts Yuichiro Izumi,[1] Koji Eguchi,[1] Terumasa Nakagawa,[1] Yushi Nakayama,[1] Hideki Inoue,[1] Yutaka Kakizoe,[1] Takashige Kuwabara,[1] Hiroshi Nonoguchi,[2] Masashi Mukoyama.[1] *[1]Dept of Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Japan; [2]Dept of Internal Medicine and Education & Research Center, Kitasato Univ Medical Center, Japan.*

Background: Metabolic acidosis is caused by acute and chronic kidney disease due to the decrease of acid excretion in the intercalated cells of the collecting duct in the kidney. Although the effect of acidosis on renal function has been examined *in vivo*, direct effect of low pH on the intercalated cells has not been investigated.

Methods: We employed Transcription Start Site-Sequencing (TSS-Seq) to provide low pH-induced gene transcripts in a rat intercalated cell line (IN-IC cells). Two biological replicates were used for the analysis. Cells were grown in a FBS-free DMEM/F12 overnight and incubated in an isotonic solution for 24h in which pH was adjusted either to 7.4 or 7.0, then total RNA was extracted. cDNA library for CAGE (Cap Analysis Gene Expression) was created. Deep sequencing was performed by Illumina HiSeq2500 sequencer. TopHut 2 software was used to map TSS-Seq reads. RECLU was used to identify differentially expressed transcripts. Gene Ontology (GO) analysis was carried out using the Database for Annotation, Visualization and Integrated Discovery (DAVID).

Results: 278 differentially expressed transcripts were identified. 261 transcripts were upregulated and 17 were downregulated. Among them, 225 upregulated and 13 downregulated transcripts were corresponded to known protein products. GO analysis of Biological Processes and Molecular Functions showed 9 clusters of the GO terms with high enrichment score (> 1.5) such as regulation of transcription, dephosphorylation, and enzyme-linked receptor protein signaling pathway. The upregulated transcripts included Jak2, Pten, and Gsk3a, that are involved in renal fibrosis and urine concentration mechanism.

Conclusions: The results suggest that metabolic acidosis could regulate the function of intercalated cells and further exacerbate the renal fibrosis.

SA-PO940

Narrowing the Gap Between the Anion Gap and the Strong Ion Gap Kenrick Berend,[1] Andrew L. Lundquist.[2] *[1]Nephrology, St. Elisabeth Hospital, Willemstad, Curacao, Netherlands Antilles; [2]MGH Div of Nephrology, Massachusetts General Hospital, Boston, MA.*

Background: Despite its importance in understanding acid-base pathophysiology, many physicians do not understand the concept of the strong anion gap. The core of the Stewart acid-base approach is the "strong ion gap" (SIG). The concept of SIG is similar to the AG, but the main difference is that Stewart uses more strong ions and the contribution of albumin and phosphate are adjusted for the pH. Because SIG gives a more precise picture of the ion balance than the AG, one may postulate that it provides a more accurate analysis of acid-base disturbances. The exact differences, however, are not established. This paper will give insight into the difference between the anion gap and the strong anion gap and provide an adjusted formula for the anion gap to replace the need for the strong anion gap.

Methods: The change of the strong ion gap (SIG) and the albumin-corrected anion gap (AG_c) were calculated at a wide range of albumin, phosphate and pH levels.

Results: At a low albumin level of 1 to 3 g/dl and decreased pH from 6.9 to 7.3, the contribution difference of albumin in AG_c and SIG will be maximally -0.97 to 0.51 mEq/L. In metabolic alkalosis (pH up to 7.6) and hypoalbuminaemia (1 to 3 g/dl), the AG_c differs less than 2 mEq/L with SIG. There is a linear relationship of the serum phosphate and the ionic contribution of SIG: at a pH of 6.9, the $phosphate_{SIG}$ is 1.66 times higher and at a pH of 7.6, 1.86 higher. In metabolic alkalosis and moderate hyperphosphatemia, the ionic contribution to the anion gap will increase, but less than 1 mEq/L.

Conclusions: SIG and AG_c are almost identical across a wide range of values, particularly when albumin and phosphate levels are low. The pH adjusted serum phosphate level in the SIG is about 1.76 higher, with a confidence interval of + 0.5 mmol/L. The anion gap will be more precise and incorporate the major components of the SIG when using the equation: $[Na^+]$ - $[Cl^-]$ - $[HCO_3^{2-}]$ - 2.5 [albumin, in g/dL] – 1.76 [phosphate], with an arbitrarily set reference range of 1 +/- 5 meq/L.

SA-PO941

V-ATPase in Luminal Membrane of Renal Proximal Tubule Requires B2 Subunit and CLC-5 for Its Full Functional Activity Nobuhiko Sato,[1] Motonobu Nakamura,[1] Atsushi Suzuki,[1] Masashi Suzuki,[1] George Seki,[2] Shoko Horita.[1] *[1]Nephrology, The Univ of Tokyo Hospital, Tokyo, Japan; [2]Yaizu City Hospital, Shizuoka, Japan.*

Background: Using an isolated rat proximal tubule (PT) primary culture system, we have previously shown that the activity of basolateral Na/HCO3 co-transporter (NBCe1) was preserved for 36 hours. Furthermore, gene silencing with siRNA enabled us to identify the signaling pathways involved in insulin-mediated NBCe1 stimulation (Nakamura M, Kidney Int, 2015). However, it remains unknown whether this technique is applicable to analysis of PT luminal transporters.

Methods: Freshly isolated mouse PT was attached to a glass coverslip with Cell-Tak glue and the lumen was exposed with a broken glass capillary. BCECF was used to measure intracellular pH (pHi). While the cariporide-insensitive luminal NHE activity was determined by the rates of pHi decrease in response to Na removal, the bafilomycin-sensitive V-ATPase activity was determined by the rates of pHi recovery in Na-free solution. These experiments were also performed after PTs were cultured overnight in the presence of siRNA against V-ATPase B2 subunit or CLC-5.

Results: The luminal NHE activity was at least partially preserved in isolated PT primary culture (0.89+/-0.08 vs 0.45+/-0.07 pH unit/min). The hypotonicity (210 mOsm)-stimulated V-ATPase activity was also largely preserved in PT primary culture (0.50+/-0.05 vs 0.32+/-0.04 pH unit/min). Overnight treatment with siRNA against B2 subunit or CLC-5 largely suppressed the V-ATPase activity by 81% and 70%, respectively, without affecting the luminal NHE activity. We also confirmed that transfection of wild-type CLC-5 into HEK293 cells not only decreased endosomal pH as estimated by ratiometric VAMP2-pHluorin but also induced the plasma membrane V-ATPase activity stimulated by hypotonicity (0.01+/-0.01 vs 0.59+/-0.07 pH unit/min).

Conclusions: These data revealed for the first time to our knowledge that the luminal V-ATPase in PT requires both B2 subunit and CLC-5 for its full functional activity. The requirement of CLC-5 may be a common feature of mammalian V-ATPase, either expressed in endosome or plasma membrane.

The Mechanistic Target of Rapamycin Regulates Solute Transport in Renal Tubules

Nasir A. Shah,[1] Davide Pietro Cina,[2,3] Tuncer Onay,[2,3] Vera Eremina,[4] Chengjin Li,[4] Aline Martin,[2] Yashpal S. Kanwar,[2,5] Susan E. Quaggin.[2,3] *[1]Mater Health Services North Queensland, James Cook Univ, Townsville, Queensland, Australia; [2]Medicine, Div of Nephrology, Northwestern Univ, Chicago, IL; [3]Feinberg Cardiovascular Research Inst, Northwestern Univ, Chicago, IL; [4]Lunenfeld-Tanenbaum Reseawrch Inst, Mount Sinai Hospital, Toronto, ON, Canada; [5]Pathology, Northwestern Univ, Chicago, IL, Canada.*

Background: Inhibitors of the mechanistic target of rapamycin (MTOR inhibitors) belong to a family of drugs with potent immunosuppressive, anti-angiogenic and anti-proliferative properties. Despite their clinical potential, their use in humans has been hampered by a significant incidence of proteinuria and electrolyte disturbances. Although some studies suggest Mtor may play a role in regulating renal solute transporter expression and function, the exact mechanisms underlying these changes are largely unknown.

Methods: In this study we examine the contribution of MTOR inhibition in the renal tubules to the development of proteinuria and electrolyte disturbances by generating an inducible *Pax8*-driven, tubule-specific *Mtor* knockout mouse (*Mtor* Pax8-iKO).

Results: Loss of *Mtor* in the renal tubular epithelium resulted in increased 24-hour urine volume, diminished urine osmolalitiy, and renal failure. Despite elevated 24-hour urine albumin, Ca^{2+}, and Mg^{2+} *Mtor* Pax8-iKO mice were both hypercalcemic and hypermagnesemic. Histologically, *Mtor* Pax8-iKO mice exhibited generalized tubular atrophy with focal cystic dilations of the distal and cortical collecting tubules, and interstitial fibrosis. Immunohistochemistry showed decreased expression of aquaporin-2 (Aqp2), Calbindin D 28k (Calb1), and the sodium-potassium-chloride cotransporter (Nkcc2). Increased expression of the transient receptor potential cation channel subfamily V member 5 (Trpv5) was also noted.

Conclusions: Taken together, our results suggest that MTOR is a key player in maintaining electrolyte balance by modifying the expression, and function of solute transporters in the renal tubular epithelium.

SA-PO943

High Mobility Group Box 1 (HMGB1) Inhibits HCO_3^- Absorption in Medullary Thick Ascending Limb (MTAL) Through Receptor for Advanced Glycation End Products (RAGE)-Rho-Rock1-Mediated Inhibition of Basolateral Na^+/H^+ Exchange

Bruns A. Watts, Thampi George, David W. Good. *Univ TX Med Branch, Galveston, TX.*

Background: HMGB1 is a damage-associated molecule that is released extracellularly in response to infection or injury and plays a role in mediating kidney dysfunction in sepsis and sterile inflammatory disorders. Recently we showed that basolateral HMGB1 inhibits HCO_3^- absorption in perfused rat MTALs through a RAGE-dependent pathway additive to TLR4-ERK-mediated inhibition by LPS. Here we examined signaling and transport mechanisms involved in inhibition by HMGB1.

Results: Inhibition of HCO_3^- absorption by HMGB1 was eliminated by the Rho-associated kinase (ROCK) inhibitor Y27632 and by a specific inhibitor of Rho, the direct activator of ROCK. HMGB1 increased ROCK1 activity in dissected inner stripe of outer medulla, a preparation that accurately reproduces changes in MTAL signaling proteins. Activation of ROCK1 by HMGB1 was eliminated by the RAGE antagonist FPS-ZM1 and by inhibition of Rho. Addition of a direct Rho activator reduced basal HCO_3^- absorption rate and prevented inhibition by HMGB1. The Rho and ROCK inhibitors had no effect on inhibition by bath LPS. The Rho-ROCK1 pathway regulates NHE1 and we have shown that inhibition of NHE1 decreases MTAL HCO_3^- absorption secondarily through cytoskeleton-dependent inhibition of apical NHE3. Inhibition of HCO_3^- absorption by HMGB1 was eliminated by bath amiloride, 0 Na^+ bath, and the F-actin stabilizer jasplakinolide, three maneuvers that selectively prevent inhibition of HCO_3^- absorption mediated through NHE1. Bath amiloride and jasplakinolide did not affect inhibition by bath LPS.

Conclusions: We conclude: 1) HMGB1 inhibits HCO_3^- absorption in the MTAL through a RAGE-Rho-ROCK1 pathway coupled to inhibition of NHE1; 2) this pathway functions in parallel with the LPS-TLR4-ERK pathway to impair MTAL HCO_3^- absorption. Thus, during sepsis, endogenous damage-associated molecules and exogenous bacteria-associated molecules act directly and independently to inhibit MTAL HCO_3^- absorption through different receptor signaling and transport pathways. The RAGE-Rho-ROCK1 pathway is a potential target to attenuate sepsis-induced renal tubule dysfunction.

Identification of IQGAP-1 as a Pendrin-Binding Protein in the Kidney

Jie Xu,[1] Sharon L. Barone,[2] Kamyar A. Zahedi,[1,2] Manoocher Soleimani.[1,2] *[1]Center on Genetics of Transport and Epithelial Biology, Dept of Medicine, Univ of Cincinnati, Cincinnati, OH; [2]Research Services, VA Medical Center, Cincinnati, OH.*

Background: Networks of interacting proteins are crucial for all levels of cellular function.The Slc26 family of anion transporters [Slc26a3 (DRA), Slc26a5 (prestin), Slc26a6 (PAT-1), and Slc26a9] form multi-protein complexes with cytoskeleton, anchoring proteins, PDZ adaptor proteins, CFTR and/or protein kinases, which impart regulatory signals on these isoforms. No information is available on proteins that interact with pendrin (Slc26a4).

Methods: A yeast two hybrid system was employed to screen a mouse kidney cDNA library with a pendrin C-terminal fragment as bait. A total of 6×10^3 interacting clones were identified, out of which 14 clones were confirmed to be positive when screened for β-gal expression. Plasmids from these clones were purified and their interaction with pendrin was confirmed.

Results: Our experiments identified IQGAP-1 as a pendrin C-terminus binding partner. IQGAP-1 is a scaffolding protein that binds and/or stabilizes ezrin, CDC42 and RAC1, and interacts with cytoskeletal and cell adhesion molecules. In the kidney, IQGAP-1 is strongly expressed in the DCT, CNT, CCD and podocytes. IQGAP-1 has also been shown to control tight junction formation through recruitment of claudin. Our results indicate that IQGAP-1 co-localizes with pendrin on the apical membrane of B-intercalated cells. IQGAP-1 is also detected on the basolateral membrane of A-intercalated cells in CCD. Functional studies in HEK293 cells demonstrated that the co-transfection of IQGAP-1 and pendrin increased pendrin-mediated Cl^-/HCO_3^- exchange activity by more than 60%. Confocal microscopy showed more abundant plasma membrane expression of pendrin in the presence of IQGAP-1.

Conclusions: These studies demonstrate the interaction of IQGAP-1 and pendrin in B-intercalated cells, as well as the stimulatory role of IQGAP-1 on pendrin activity. We propose that pendrin interaction with IQGAP-1 is important in the regulation of CCD function and physiology, and that disruption of this interaction contributes to altered pendrin trafficking and/or activity in pathophysiologic states.

SA-PO945

Regulation of Rhcg by Aldosterone in Intercalated Cells of the Collecting Ducts

Koji Eguchi, Yuichiro Izumi, Terumasa Nakagawa, Yushi Nakayama, Hideki Inoue, Yutaka Kakizoe, Takashige Kuwabara, Masashi Mukoyama. *Dept of Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan.*

Background: Acid-base balance is regulated by aldosterone which stimulates acid secretion in the intercalated cells of the collecting ducts of the kidney. Rhesus blood group C glycoprotein (Rhcg) is an ammonia transporter which cooperates with H^+-ATPase to secrete H^+ in the intercalated cells. *In vivo* experiments have shown that metabolic acidosis and hypokalemia, that change plasma aldosterone level, increases and decreases the expression of Rhcg, respectively. Direct effect of aldosterone on the regulation of Rhcg has not been examined.

Methods: We examined the effect of aldosterone on the regulation of Rhcg. Membrane fraction of the whole kidney was extracted from mice that were continuously administered aldosterone (40μg/body/day) or vehicle for a week. To further examine the effect of aldosterone on the regulation of Rhcg in the intercalated cells, mRNA, whole cell protein, and membrane fraction were extracted from IN-IC cells (a rat intercalated cell line) after the treatment with aldosterone (10^{-6} M) for 24 h. The Rhcg mRNA and protein expressions were measured by real-time PCR and Western blotting, respectively. The expression of serum and glucocorticoid-regulated kinase 1 (Sgk1) mRNA was also measured in IN-IC cells.

Results: Administration of aldosterone increased the expression of Rhcg protein in membrane fraction of the whole kidney. In IN-IC cells the expressions of Rhcg and Sgk1 mRNAs were 1.3- and 3.2-fold greater, respectively, in cells treated with aldosterone (10^{-6}M) than in cells with vehicle. The expression of Rhcg protein in whole cell extract was not changed by the treatment with aldosterone. However, the expression of Rhcg protein in membrane fraction was 3.2-fold greater in cells treated with aldosterone than in cells with vehicle.

Conclusions: The results suggest that aldosterone regulates membrane accumulation of Rhcg possibly through the activation of Sgk1.

SA-PO946

Role of Adenylyl Cyclase 6 in Regulation of Urinary pH

Søren Brandt Poulsen,[1,2,3] Robert A. Fenton,[3,] Timo Rieg.[1,2] *[1]Dept of Medicine, UCSD, La Jolla, CA; [2]VASDHS, San Diego, CA; [3]Dept of Biomedicine, Aarhus Univ, Aarhus, Denmark.*

Background: Adenylyl cyclase isoform 6 (AC6) is expressed in all renal tubular segments and catalyzes the synthesis of cAMP. We have previously reported that AC6 knockout (AC6-/-) mice have a urinary concentration defect, a mild Bartter syndrome and secondary hyperparathyroidism. A recent study (Am J Physiol Renal Physiol. 2012;303(6):F812-20) determined that cAMP can increase pendrin protein (Cl^-/HCO_3^- exchanger) abundance. We therefore hypothesized that AC6-mediated cAMP formation was important for urinary pH regulation.

Methods: AC6 wild-type (WT) and AC6-/- mice (n=6/genotype) were challenged with $NaHCO_3$ in their drinking water for a period of 8 days. As daily fluid intake is double in AC6-/- mice, the $NaHCO_3$ was reduced by 50% in this genotype (0.14 mol/l vs. 0.28 mol/l in WT). Urine was collected daily; blood was collected under baseline conditions and at the end of the 8 day experimental period. Mice were euthanized, one kidney processed for Western blotting (pendrin, H^+-ATPase B1 subunit and NBCe1), and the other kidney was perfused *in vivo* and processed for immunohistochemistry.

Results: Baseline urinary pH was significantly lower in AC6-/- vs. WT mice (6.5±0.2 vs. 7.7±0.2, $P<0.05$) which was associated with higher blood pH (7.44±0.01 vs. 7.41±0.01, $P<0.05$). At the end of the experimental period urinary pH was comparable between genotypes (8.3±0.4 vs. 8.3±0.4, *NS*) and no significant change in blood pH was observed (7.45±0.01 vs. 7.43±0.01, $P<0.05$ vs. WT). NBCe1 protein abundance was not different, whereas pendrin and H^+-ATPase B1 subunit were 1.8 and 1.5-fold higher in AC6-/- vs. WT, respectively ($P<0.05$). The number of pendrin positive cells/mm^2 (WT: 32±2 vs. AC6-/-: 28±2) in the renal cortex was not different between genotypes.

Conclusions: Our results imply a role for AC6 in expression of pendrin and H^+-ATPase B1 subunit and subsequently regulation of urinary pH. The increase in urinary pH in AC6-/- mice can only be achieved, or is the consequence of, higher pendrin abundance; however, this effect is independent of pendrin distribution changes. Further studies are needed to determine the signals causing baseline differences in urinary pH.

Prediction of the Development of Delayed Graft Function Using Acute Kidney Injury Criteria in Deceased Donor Kidney Transplantation

Jeong Ho Kim,[1] Bum Soon Choi,[1] Cheol Whee Park,[1] Chul Woo Yang,[1] Yong-Soo Kim,[1] Young Soo Kim,[2] Byung Ha Chung.[1] *[1]Internal Medicine, Seoul St. Mary's Hospital, Seoul, Korea; [2]Internal Medicine, Uijeongbu St. Mary's Hospital, Uijeongbu, Korea.*

Background: There is no clear consensus on the definition of acute kidney injury (AKI) in deceased donor. In this study, we determine the discriminative ability of the Kidney Disease: Improving Global Outcomes (KDIGO) compared to the Acute Kidney Injury Network (AKIN) criteria for the prediction of the development of delayed graft function (DGF) and allograft outcome in deceased donor kidney transplantation (DDKT).

Methods: We analyzed 285 kidney transplant recipients who took kidney from 228 deceased donors. We calculated the AKI stage of deceased donor according to the AKIN and KDIGO criteria and compared the predictability for the development of DGF and the change of allograft function.

Results: For 2 classification systems, DGF developed more frequently in the AKI group than non-AKI group ($P < .05$) and allograft function assessed by the Modification of Diet in Renal Disease (MDRD) equation showed a significantly deteriorating pattern at 2 weeks and 1, 3, 6, 12 months after kidney transplantation compared to that in the non-AKI group ($P < .05$, comparison at each time point). In the Receiver-Operating Characteristic(ROC) curve analysis, the KDIGO criteria showed better prognostic accuracy of the prediction of the development of DGF compared to the AKIN criteria (area under the curve = 0.72 versus 0.62; $P < .05$).

Conclusions: In DDKT, the KDIGO criteria may be more useful for predicting the development of DGF compared to the AKIN criteria.

SA-PO948

Impact of Cold Ischemia Time on Graft Failure and Death

Douglas F. Arbetter,[1] Mariana C. Chiles,[1] Prativa Baral,[1] Geoffrey K. Dube,[1] Russell J. Crew,[1] Heather K. Morris,[1] Jai Radhakrishnan,[1] David J. Cohen,[1] Stephen O. Pastan,[2] Rachel E. Patzer,[2] Sumit Mohan.[1] *[1]Dept of Medicine, Columbia Univ College of Physicians & Surgeons, New York, NY; [2]Dept of Medicine, Emory Univ School of Medicine, Atlanta, GA.*

Background: Patient and graft survival post kidney transplant (KT) are influenced by an interaction of multiple factors, including organ quality, preservation and cold ischemia time (CIT). Several small studies have suggested that even small increases in CIT adversely impact patient and graft outcomes. In this analysis we assess the impact of increasing CIT on patient and graft survival in the US.

Methods: We identified 75,660 first-time adult KT recipients, who received a deceased donor (DD) kidney from 2000-2011 in SRTR. Pearson's chi-square tests of independence and Kruskal-Wallis tests were performed to test for association between CIT and mortality, graft failure. Cox proportional hazard analyses, adjusting for donor factors (age, gender, serum creatinine, cause of death), recipient factors (age, dialysis duration, PRA status, HLA mismatch), machine perfusion, and specified effect measure modifiers, were performed to estimate the hazard of either event occurring given CIT.

Results: 60.7% of our cohort was male, and 31.4% were black. Mean age was 52.2±13.0 years and average CIT was 18.2±9.2 hours. By univariate analysis, CIT was associated with an increase in risk of both death-censored graft failure and mortality (both HRs=1.006; p<0.0001). Adjusting for covariates and effect measure modifiers, the relationship between CIT and recipient mortality risk and death-censored graft failure were both attenuated (HR=1.000; p=0.9692 and HR=0.997; p=0.7479, respectively) suggesting that each additional hour of CIT did not significantly increase the risk of graft failure or death.

Conclusions: Our results suggest that increases in CIT do not adversely impact patient and allograft outcomes following DDKT and should not be used to decline organ offers.

SA-PO949

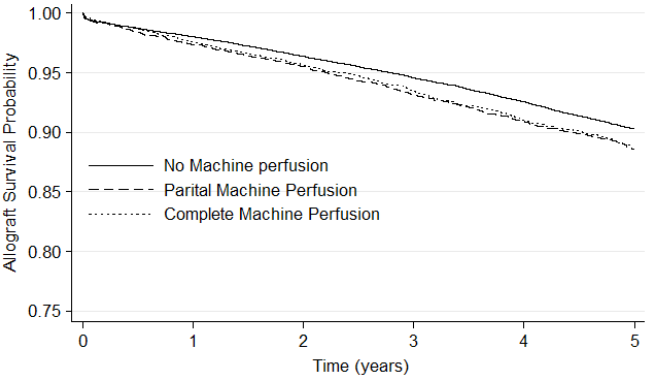
Impact of Hypothermic Machine Perfusion on Outcomes following Kidney Transplantation

Prativa Baral, Mariana C. Chiles, Douglas F. Arbetter, Russell J. Crew, Geoffrey K. Dube, Heather K. Morris, Hilda E. Fernandez, David J. Cohen, Sumit Mohan. *Columbia Univ.*

Background: Patient and allograft outcomes following deceased donor kidney transplantation (DDKT) are thought to be influenced by the intrinsic quality of the organ at procurement and any superimposed subsequent injury that occurs during cold preservation (CP). Hypothermic machine perfusion (HMP) is used in an attempt to decrease injury from CP especially for organs that have extended periods of cold ischemia. We analyzed the impact of complete, partial or no HMP use during CP on patient and graft survival following DDKT.

Methods: We identified 75,660 first-time adult renal transplant recipients, who received a DD kidney from 2000-2011 in SRTR. Pearson's chi-square tests of independence and Kruskal-Wallis tests were performed to test for association between HMP and mortality, graft failure, and delayed graft function (DGF). Cox analyses, adjusting for donor factors (age, gender, creatinine, cause of death), recipient factors (age, dialysis duration, PRA, HLA mismatch), CP time, and specified effect measure modifiers, were performed to estimate the hazard of either graft failure, or DGF occurring given HMP.

Results: On unadjusted analyses, compared to no HMP use, kidneys that received HMP for some or all of their CP time were less likely to experience DGF (OR=0.82, p=<.0001 & OR=0.77, p=<.0001) but more likely to experience allograft failure (HR=1.19, p=<.0001 & HR=1.20, p=<.0001, figure 1). On multivariable analyses, the use of HMP was associated with a lower incidence of DGF (OR=0.70, p=<.0001 & OR=0.59, p=<.0001) but continued to be associated with a higher risk of allograft failure even after adjusting for CIT and the lower DGF (HR=1.11, p= 0.023 & HR=1.26, p=0.002).



Conclusions: HMP improves short term outcomes by lowering rates of DGF but is associated with reduced long-term allograft survival.

SA-PO950

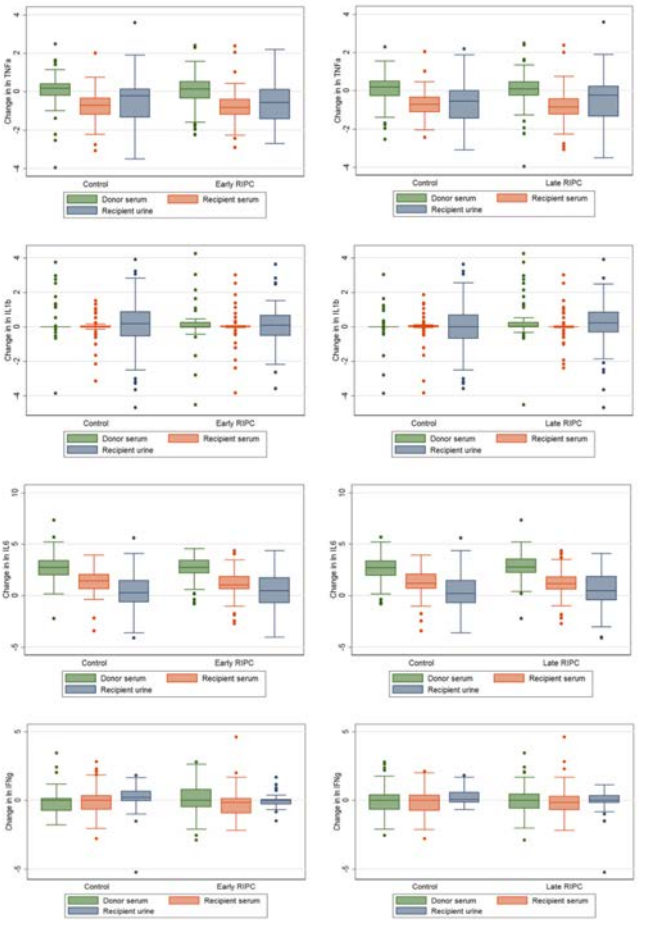
The Impact of Remote Ischaemic Preconditioning (RIPC) on the Inflammatory Response following Live Donor Kidney Transplantation

Kristin Vibeke Veighey,[1] Madhur P. Motwani,[2] Jennifer Nicholas,[3] Raymond Macallister.[2] *[1]Wessex Kidney Unit, Portsmouth Hospitals NHS Trust, United Kingdom; [2]UCL Centre for Clinical Pharmacology & Therapeutics, Univ College London, United Kingdom; [3]Clinical Trials Unit, London School of Hygiene and Tropical Medicine, United Kingdom.*

Background: Ischaemia reperfusion (IR) injury at transplantation contributes to organ damage that limits allograft longevity. Animal studies have demonstrated a reduction in circulating proinflammatory cytokines following RIPC, which may contribute to tissue protective effects. REPAIR demonstrated a trend towards improved live donor kidney function following RIPC. We investigated the effects of RIPC on serum and urinary cytokines in this study.

Methods: 406 adult live donor/recipient pairs were recruited. Pairs were randomised using a factorial design to either: sham RIPC, early RIPC (immediately pre-surgery), late RIPC (24 hours pre-surgery) or dual RIPC. Donor and recipient received the same interventions (active or sham RIPC). Serum from donor and recipient and urine from recipients was analysed at baseline and on day 2 for pro-inflammatory cytokines IL-1ß, IL-6, IFN-γ and TNFα, using multiplex ELISA. All analyses were conducted using linear regression adjusted for baseline (pre-treatment) values of the cytokine and indicator variables for early and late treatment group. Cytokine values were log transformed before analysis to account for skewed distribution.

Results: There was no difference in the expression of serum cytokines in donor serum or recipient serum and urine between baseline pre-surgery and day 2 post surgery.



From top: TNFα, IL-1ß, IL-6, IFN-γ; graph on left = early RIPC, right = late RIPC.

Conclusions: In this large randomised trial, there was no evidence that RIPC attenuated the inflammatory response to transplant surgery in blood or urine.

SA-PO951

Remote Ischaemic Preconditioning (RIPC) Provides a Sustained Improvement in eGFR following Live Donor Kidney Transplantation: Four Year Follow-Up in the REPAIR Study Kristin Vibeke Veighey,[1] Jennifer Nicholas,[2] Steven Robertson,[2] Raymond Macallister.[3] *[1]Wessex Kidney Unit, Portsmouth Hospitals NHS Trust, United Kingdom; [2]Clinical Trials Unit, London School of Hygiene and Tropical Medicine, United Kingdom; [3]UCL Centre for Clinical Pharmacology & Therapeutics, Univ College London, United Kingdom.*

Background: Ischaemia reperfusion (IR) injury sustained at transplantation contributes to organ damage that limits allograft longevity. The REnal Protection Against Ischaemic Reperfusion in transplantation (REPAIR) study demonstrated a weak effect of early RIPC on the primary outcome iohexol glomerular filtration rate (GFR) at 1 year (adjusted mean difference 3.08 ml/min/1.73m^2; 95% CI -0·89 to 7.04; p=0.13), but stronger evidence of an effect on eGFR at 1 year (difference 4.98; 95% CI 1.13 to 8.29; p=0.011),reflecting a potentially clinically important improvement of kidney function. There was no evidence that late RIPC alone had any benefit at 1 year. RIPC was safe and well tolerated. We used data from up to 4 years follow-up to examine the medium term effects of early and late RIPC on eGFR.

Methods: 406 adult live donor/recipient pairs were recruited and randomised using a factorial design to either: sham RIPC, early RIPC (immediately pre-surgery), late RIPC (24 hours pre-surgery) or dual RIPC (early and late RIPC). Donor and recipient received the same interventions (active or sham RIPC). The primary outcome was iohexol GFR at 12 months. eGFR up to 5 years post transplantation was an important secondary outcome.

Results: Provisional analysis of eGFR data up to 48 months suggested a sustained benefit of early RIPC and possible emergence of benefit of late RIPC. The mean (SD) 55.8 (23.0) in control vs 57.4 (20.4) in early RIPC at 2 years; 51.7 (18.6) vs 57.7 (21.3) at 3 years; and 51.8 (19.8) vs 60.5 (24.3) at 4 years. The mean (SD) in control vs late RIPC were 55.8 (20.4) vs 57.4 (22.9) at 2 years; 52.8 (19.8) vs 56.8 (20.5) at 3 years; and 52.4 (21.7) vs 59.7 (22.8) at 4 years.

Conclusions: The benefit of early RIPC on eGFR that was demonstrated at 1 year appears to be sustained during medium-term follow up, reflecting a potentially clinically important improvement of kidney function.

SA-PO952

Low Expression of the Messenger RNA TLRs 2-4,9 from Peripheral Blood Mononuclear Cells of the Kidney Recipients May Indicate Previous Delayed Graft Function Slawomir C. Zmonarski, Katarzyna Madziarska, Miroslaw Banasik, Maria Magott, Marian Klinger. *Nephrology and Transplantation Med., Medical Univ, Wroclaw, Poland.*

Background: The Toll-like receptors (TLR) 2-4,9 are engaged in the pathogenesis of acute renal injury. Earlier studies demonstrated that 24 hrs. after transplantation (KT), the expression of the messenger RNA (mRNA) TLR4 of peripheral blood mononuclear cells (PBMC) from patients (pts) with delayed graft function (DGF+) was lower than in recipients of kidneys without DGF (DGF-). The aim of study was to examine whether the reduced expression of TLR2-4,9 mRNA is a more permanent phenomenon associated with DGF.

Methods: Each of the 151 KT pts was more than 1 month after KT (from 1 to 128 months). Within this group: in 117 pts blood sample was taken for more than 3 months after KT, 45 pts experienced DGF, 13 DGF+ pts was HBcAb positive (DGF+HBc+). Control group (Con.) included 38 healthy volunteers. TLR2-4,9 mRNA expression (expr.) from PBMC was assessed by polymerase chain reaction (real-time PCR) and analyzed in terms of DGF and clinical course.

Results: KT DGF+ pts had generally lower TLR2-4,9 mRNA expr. than KT DGF- pts (TLR2: p=0,06; TLR3; p= 0,021; TLR4: p=0,07; TLR4 > 3 month after KT: p=0,032; TLR 9 ,p= 0,027). TLR3 mRNA of DGF+HBc+ pts was: lower (p=0,046) than DGF+HBc, lower (p=0,013) than DGF-ATN- and lower (p=0,008) than Con. TLR9 mRNA of DGF+HBc+ was lower (p=0,0002) than Con. In multiple regression analysis low expr. of TLR mRNA 2-4,9 was associated with the occurrence of DGF in the past.

Conclusions: Lower than typical expression of TLR 2-4,9 mRNA seems to be a permanent feature of peripheral blood mononuclear cells of the recipient of the transplanted kidney who experienced delayed graft function. Hepatitis B seems may be associated with additional decline of TLR3 and TLR9 mRNA expression. TLR3,4,9 mRNA expression could potentially be used as an indicator of the likelihood of delayed graft function.

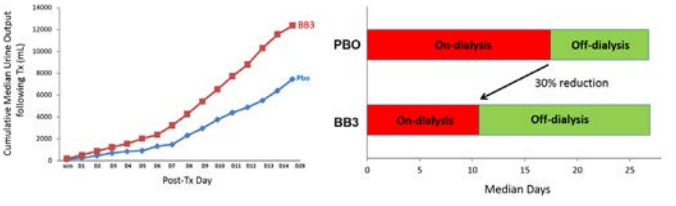
SA-PO953

BB3, a Hepatocyte Growth Factor-Like Small Molecule, Improves Outcome in Kidney Transplant Recipients with Delayed Graft Function Jonathan Bromberg,[1] Matthew R. Weir,[2] A. Osama Gaber,[3] Matthew Cooper,[4] Mark Laftavi,[5] Barry Browne,[6] Bo Zhang,[7] Prakash Narayan,[7] Michael A. Yamin,[7] Itzhak D. Goldberg,[7] Weizhong Cai.[7] *[1]Div of Transplant Surgery, Univ of Maryland School of Medicine, Baltimore, MD; [2]Div of Nephrology, Univ of Maryland School of Medicine, Baltimore, MD; [3]The Methodist Hospital, Houston, TX; [4]MedStar Georgetown Univ Hospital, Washington, DC; [5]Transplant Center at Erie County Medical Center, Buffalo, NY; [6]BNMG, San Diego, CA; [7]Angion Biomedica Corp, Uniondale, NY.*

Background: Duration of delayed graft function (DGF) portends poor short- and long-term renal function and graft survival. We studied the safety and efficacy of BB3, a small molecule with HGF-like activities, dosed starting 24 hr post-transplant (Tx) in patients with reduced urine output (UO) in a double-blind Phase 2 study.

Methods: Patients producing <50 cc urine/hr over 6-8 h post-Tx were randomized (2:1) to BB3 (2 mg/kg IV QD X 3 d) or placebo (PBO). An interim analysis was performed on 12 BB3- and 7 PBO-treated patients.

Results: BB3 was safe and well-tolerated. BB3 reduced the median time to produce 1.2L UO/24 hr from > 28 d to 7.5 d, increased the % of patients reaching this UO within 28 d from 43% to 83%, increased cumulative UO (figure), decreased median duration of dialysis (figure), decreased % on-dialysis days during Days 7-28 (14.2% to 7.1%) and during Days 14-28 (10.9% to 3.6%), reduced median SCr, reduced BUN, and shortened median hospital stay (7 d to 5.5 d). BB3 reduced serum CRP and NGAL.



Conclusions: BB3 administered ~24 hours post-Tx significantly reduced severity of DGF in patients presenting with reduced UO. Confirmation of these results in a Phase 3 trial may translate to improved long-term outcome, decreased Tx costs, increased use of marginal organs, and a shorter waitlist.

DSA Monitoring and Treatment in Kidney Transplant Recipients

Monica Grafals,[1] Alexander Gilbert,[1] Olga A. Timofeeva.[2] *[1]Medstar Georgetown Transplant Inst, Georgetown Univ, Washington, DC; [2]Histocompatibility Laboratory, Georgetown Univ, Washington, DC.*

Background: The development of DSA monitoring is a new technique to detect antibodies in kidney transplant recipients. We previously showed that patients that developed de novo DSA (dnDSA) suffer a 35% graft loss. Because of this we have developed a protocol for treating patients that have developed dnDSA post kidney transplant.

Methods: Since the implementation of this treatment protocol on September 12, 2014, there have been 9 patients that have developed dnDSA after renal transplantation.

	LOW RISK	INTERMEDIATE RISK	HIGH RISK
DSA Criteria	DSA detectable only at titers less than 1:16 -AND- DSA which is c1q negative	DSA detectable at titers equal to or greater than 1:16 -OR- DSA which is c1q positive	DSA detectable at titers equal to or greater than 1:16 -OR- DSA which is c1q positive
Clinical Criteria	No biopsy findings of acute rejection (either ACR or AMR) -AND- Stable serum creatinine (within 25% of baseline)	No biopsy findings of acute rejection (either ACR or AMR) -AND- Stable serum creatinine (within 25% of baseline)	Biopsy findings consistent with ACR or AMR -OR- An acute rise in creatinine greater than 25% from baseline
Treatment Plan	NONE	IVIg 1 gram/kg x2 doses given on day #1 and #2 Rituximab 375 mg / meter^2 x2 doses given on day#1 and day #8	Plasmapheresis x5 sessions (every other day) Bortezomib 1.3 mg/ meter2 on days #1, 4, 8, 11. IVIg 1 gram/kg after the last plasmapheresis session.
Assessment of Treatment	N/A	Check DSA 1 month after start of treatment.	Check DSA on day #14, repeat renal biopsy 3-4 weeks after start of treatment.
Measures of Success	N/A	DSA becomes negative for c1q	DSA becomes negative for c1q -AND- Repeat biopsy shows resolution of earlier changes.

Results: Four of the patients that developed dnDSA were in the low risk category and in 3 of them the DSA has cleared. The 4th patient has a DSA against DP1 with an MFI of 1587 that has remained stable. All of these patients have a GFR>45 cc/min. Three patients were in the intermediate risk category. One of them has a creatinine of 3, BK viremia and he has a DSA against A1 with an MFI of 3150 which has been stable. Another patient in this group developed CMV viremia and his DSA became negative after treatment. The third patient just received treatment for DSA this past month and follow up DSA is not available at this time. Two patients were in the high risk category and both of them received treatment and their GFRs are >45 cc/min and their DSAs have become undetectable and weak respectively.

Conclusions: Since the development of dnDSA post kidney transplant is associated with worse graft outcomes, implementation of treatment protocols is necessary for kidney transplant patients. This preliminary data shows that treatment for dnDSA with this protocol seems to succesfully treat the antibodies.

SA-PO955

On the Patterns of Early De Novo DSA Development in Kidney Transplant Recipients in the First 6 Months After Alemtuzumab Induction

Chelsea Estrada, Yezina T Nigatu, Heesuck Suh, Frank Darras, Mersema Abate, Edward P. Nord. *Nephrology and Transplantation, Stony Brook Medicine, New York.*

Background: The presence of de novo DSA (dnDSA) is associated with antibody mediated rejection and suboptimal graft outcomes. The incidence of dnDSA post renal transplant varies according to immunosuppression protocols, screening, and detection methods, and ranges from 5-25%. A higher incidence of dnDSA after alemtuzumab (AL) has been observed. We sought to characterize the expression of early dnDSA development after AL induction in renal transplant recipients.

Methods: Consecutive kidney transplant recipients were screened for dnDSA from 7/1/2014 to 4/30/2015. DnDSA was detected by single antigen beads and luminex technology at months 1, 2, 3 and 6. Mean Fluorescent Intensity (mfi) > 500 was considered positive. Induction consisted of AL with rapid steroid withdrawal, and maintenance immunosuppression was with tacrolimus and mycophenolate mofetil.

Results: A total of 47 renal transplants, 13 from living donors and 34 from deceased, were performed from 7/1/14 to 4/30/15 and followed for 5.1 +/- 2.9 months (range 1-9). Of these, 17 developed dnDSA (36.2%) in the first 6 months; 7 class I, 7 class II and 3 both. Class I was detected at months 1 (6), 2 (2), 3(1) and 6 (1). Class II was detected at months 1 (3), 2 (3), 3(2) and 6 (2). Median class I mfi was 1,081 (range 535- 2,787), and class II was 2,299 (range 502- 11,301). In 9/17 (52.9%) patients (5 class I and 4 class II) with peak mfi < 2,500, dnDSA resolved (5) or decreased (4) without intervention. Four patients with class II dnDSA found at month 6 (2) and month 2 (2) with peak mfi 2,600 - 11,000, were treated with plasmapheresis, IVIG, and rituximab, preemptively. Of these, 2 dnDSA resolved, 1 remained high but creatinine is stable and 1 had worsening renal function but no evidence of AMR on biopsy. Five patients with rising dnDSA, and stable creatinine are being followed.

Conclusions: In this cohort, dnDSA developed in 36.2% of recipients, with the majority developing in months 1 and 2 (76.5%). Despite the high rate of dnDSA detection, most resolved or decreased without change in immunosuppression or early deleterious effects to graft function.

SA-PO956

Low Level Class I or II Donor HLA-specific Antibodies Do Not Correlate with the Concurrent Presence of Antibody Mediated Injury on Biopsy

Chelsea Estrada, Catherine Miranda, Heesuck Suh, Frank Darras, Edward P. Nord, Mersema Abate. *Nephrology and Transplantation, Stony Brook Medicine, New York.*

Background: Pre-transplant and de novo donor HLA-specific antibodies (DSA) have been identified as risk factors for adverse outcomes in renal transplantation, causing antibody-mediated graft injury and acute antibody mediated rejection (ABMR) and transplant glomerulopathy (TG). With improved detection techniques, DSA recognition is increasing but there is no consensus on the definition of DSA positivity. While low level pre-transplant DSA has been associated with the future occurrence of ABMR, low level DSA on the day of indication biopsy is of unclear significance.

Methods: All sera were tested for DSA using single antigen beads with Luminex technology on the day of indication renal transplant biopsy from 7/1/2015- 5/21/2015. DSA level <500 mfi were considered negative, between 500-1500 mfi low level and >1500 mfi high level. Acute ABMR and TG histology met Banff 2013 criteria. In this cohort, induction was with alemtuzumab and rapid steroid withdrawal, and maintenance immunosuppression was with tacrolimus and mycophenolate mofetil. Chi square analysis was used to assess the association between low and high levels of DSA and biopsy findings of antibody mediated injury.

Results: Fifty-three consecutive indication kidney transplant biopsies were performed from 7/1/2014- 5/21/2015. Of these 12 had evidence of ABMR (2 acute, 8 TG and 2 both). Six of the 8 patients with TG alone did not have DSA. At the time of biopsy, 12 class I (6 low and 6 high level) and 13 class II (3 low and 10 high level) were detected.

DSA	AMR/TG n=12 (%)	No AMR/TG n=41(5)	P value
Class I Low	1(8)	5(12)	0.97
Class I High	3(25)	3(7)	0.09
Class II Low	0(0)	3(7)	0.51
Class II High	5(42)	5(12)	0.02
None	7(58)	34(83)	0.05

Conclusions: 1. The presence of high level class II DSA was significantly associated with the concurrent biopsy finding of antibody medicated injury. 2. Of greater significance, the presence of class I DSA or low level class II DSA did not correlate with pathologic findings.

SA-PO957

Characteristics of Kidney Transplant Candidates with and without Antibody against Angiotensin II Type 1 Receptor (AT1R-Ab)

Mary Carmelle Philogene,[1] S.M. Bagnasco,[2] Annette M. Jackson,[1] Mary S. Leffell,[1] Andrea A. Zachary.[1] *[1]Medicine, Johns Hopkins Univ, Baltimore, MD; [2]Pathology, Johns Hopkins Univ, Baltimore, MD.*

Background: In this study we sought to determine whether baseline characteristics of kidney transplant candidates when correlated with presence of AT1R-Ab are predictive of transplant outcomes.

Methods: 122 renal transplant recipients were tested for presence of AT1R-Ab using quantitative ELISA (CellTrend GmbH, Germany). Patient demographics were obtained from the hospital electronic record under an approved IRB.

Results: Patients were categorized according to AT1R-Ab levels: positive >17 Units/ml (30%); borderline 10-17 Units/mL (34%), negative <10 Units/mL (36%). There were fewer females (31% versus 61%, 55%) and African Americans (14% versus 24%, 16%) in the AT1R-Ab >17 Units/ml group compared to the other two groups. The presence of AT1R-Ab has been associated with development of inflammation and fibrosis; therefore, we examined AT1R-Ab among patients categorized by the following diseases: IgA nephropathy, glomerulosclerosis, lupus nephritis, FSGS, and membranoproliferative glomerulonephritis. We found no correlation between these diseases and AT1R-Ab levels (38%, 29% and 30%, respectively; p=0.7). We also found no association with diagnosis of hypertension and AT1R-Ab levels (16%, 17%, 18%). The most significant difference between the three groups was a higher percentage of positive patients among those who received more than one kidney transplant (78%, 22%, 45%; p= 0.001). Post transplantation, sixty-one patients were biopsied to investigate graft dysfunction. There were more patients in the borderline and positive AT1R-Ab groups who were evaluated for graft dysfunction compared to the negative group (65%, 54% versus 34%) although this did not reach statistical significance. Importantly, the AT1R-Ab positive and borderline groups had fewer HLA antibody positive patients compared to the AT1R-Ab negative group (54%,50%, 87%; p<0.001).

Conclusions: The only pre-transplant characteristic linked to presence of AT1R-Ab in patients who are being evaluated for kidney transplantation is the incidence of previous transplant.

Effect of B-Cell Activating Factor (BAFF) Inhibition (LY2127399; Tabalumab) on Highly Sensitized Patients with End Stage Renal Disease awaiting Transplantation Muhammad Ahmad Mujtaba,[1] Wendy Komocsar,[3] Milagros D. Samaniego-Picota,[4] Eric Nantz,[3] Jayne Hague,[3] Melissa D. Anderson,[2] Benita K. Book,[2] Nancy G. Higgins,[2] Tim E. Taber.[2] *[1]Nephrology, Univ of Texas Medical Branch, Galveston, TX; [2]Transplant Nephrology, Indiana Univ School of Medicine, Indianapolis, IN; [3]Bio-Medicines, Eli Lilly and Company, Indianapolis, IN; [4]Nephrology, Univ of Michigan Health System, Ann Arbor, MI.*

Background: B cell activation factor (BAFF) is critical in B-cellmaturation. Inhibitionof BAFF represents an appealing target for desensitization of highly sensitized end stage kidney disease patients.

Methods: We conducted a Phase 2a, single-arm, open-label exploratory study investigating the effect of tabalumab (BAFF inhibitor) in ESRD patients with cPRAs >50%. The treatment period had a total duration of 24 weeks. Eighteen patients received tabalumab, at a dose of 240-mg subcutaneous (SC) at Week 0 followed by 120-mg SC at 4-week intervals for 5 more months. Patients were then followed for an additional 52 weeks. Blood samples were analyzed for HLA antibodies, BAFF levels, serum immunoglobulins, T and B cell subsets at specified time intervals during the treatment and follow-up periods. Pre and post treatment tonsil and bone marrow biopsies were also performed.

Results: Significant reductions in cPRAs were observed at week 16(p=0.043) and at week 36(p=0.004), however the absolute reductions were small (<5%). Overall factor effect at week 76 compared to baseline was significant (p=0.04). Mean BAFF levels increased during treatment, reflecting binding to tabalumab and decreased in the follow-up period remaining slightly above baseline at week 76. Expected changes in B cell subsets and reductions in immunoglobulins were observed. Two tabalumab-related serious adverse events occurred (pneumonia and worsening of peripheral neuropathy) while the most common other adverse events were injection-site pain and hypotension. Three patients received a matched donor cadaveric transplant during the study follow up.

Conclusions: BAFF inhibition resulted in statistically significant,but not clinically meaningful reduction in the cPRA from baseline.

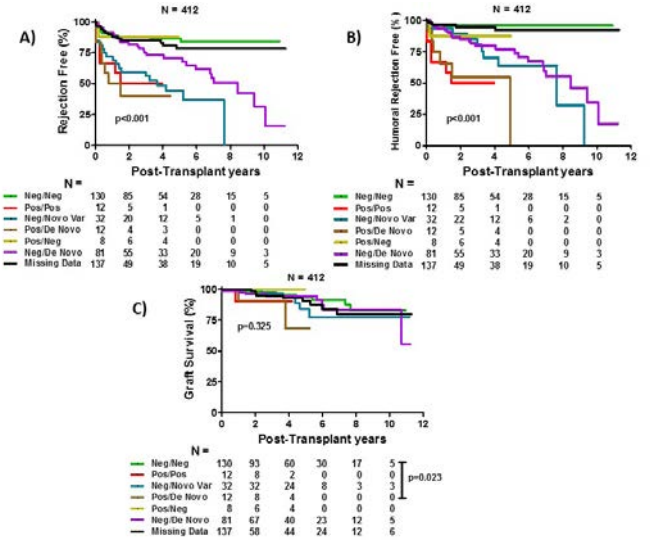
Behavior and Impact of Donor-Specific Antibodies Before and After Kidney Transplant Araminta Guichard-Romero, Lluvia A. Marino-vazquez, Mayra Lopez, Natalia Castelan, Adrian De santiago, Norma O. Uribe-uribe, Josefina Alberú, Luis E. Morales-Buenrostro.

Background: Pre- and post-transplant DSA increases the risk for acute rejection, humoral rejection and graft loss. Every year a 5% of patients will develop DSA but other patients turn negative. It is unclear how the behavior of pre-transplant DSA under immunosuppression and their clinical impact is. This study evaluate the relationship between *de novo* DSA and the outcome of kidney transplantation, and whether the development of these antibodies is related to pre-transplant DSA status.

Methods: Prospective cohort study. From Jan/2004-Dec/2014 a total of 519 kidney transplant were performed. For analysis we include 412 with DSA determination plus negative Flow-Crossmatch (in DSA-positive cases). We classified the patients in 7 groups according to pre-/post-transplant DSA: 1)Neg/Neg (n=130) 2)Neg/*De Novo* (n=81) 3)Neg/*De Novo*-Variable (multiple changes in DSA, n=32) 4)Pos/Pos (same DSA, n=12) 5)Pos/*De Novo* (n=12) 6)Pos/Neg (n=8) 7)Without DSA post-transplant measure (n=137). The outcomes analyzed were graft and patient survival, acute rejection (AR), humoral rejection (AMR), and graft function by MDRD.

Results: From 412 patients, 58 patients (14.1%) had pre-transplant DSA. Patients with Pos/Pos or Pos/*De Novo* DSA had higher and earlier AR and AMR rate, followed by Neg/*De Novo*-Variable and Neg/*De Novo*, as you can see in the figure A) and B) respectively. For graft loss only those with Pos/*De Novo* was higher than Neg/Neg (Figure C). Interestingly, those who are Pos/Neg had similar outcomes than Neg/Neg.



Conclusions: Staying with the same DSA or developing De Novo-DSA after transplantation, regardless what the pretransplant condition was, were associated with development of AR, AMR, and graft loss.

SA-PO960

Course of Anti-HLA Antibodies After Induction Therapy with Rituximab in Renal Transplantation Luuk Hilbrands,[1] Wil Allebes,[2] Martijn W.f. Van den hoogen,[3] Irma Joosten,[2] Marije C. Baas.[1] *[1]Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands; [2]Laboratory Medicine, Radboud Univ Medical Center, Nijmegen, Netherlands; [3]Nephrology, Erasmus Medical Center, Rotterdam, Netherlands.*

Background: B-cell depletion protocols have shown to reduce donor-specific antibodies against HLA (DSA) and chronic antibody mediated rejection. We aimed to study the effects of rituximab as a single-agent induction therapy on the titers of pre-existent or de novo DSA and non-DSA after renal transplantation and relate this to rejection free and overall graft survival.

Methods: We collected sera in participants of a prospective double-blind randomized study on the efficacy and safety of the prophylactic use of one dose of rituximab, added to standard immunosuppressive treatment (prednisolone, tacrolimus and mycophenolate mofetil) in comparison with standard immunosuppressive treatment alone in renal transplantation (www.clinicaltrials.gov, NCT00565331).

Results: 280 patients were included (142 received placebo, 138 rituximab). Anti-HLA antibodies (Ab) were determined in serum taken pre-transplant and 12 and 24 months after transplantation. Serum was analysed pre-transplant and at 12 months from 126 placebo and 119 rituximab treated patients. Pre-existent anti- HLA Ab were present in 24/126 (19.0%) patients in the placebo group and in 20/119 (16.8%) patients in the rituximab group (P<0.05). In the placebo and rituximab treated patients HLA class I Ab disappeared in 55.6% and 50% and HLA class II Ab in 23.5% and 57%, respectively (P=0.06). At 12 months, 11 (8.7%) placebo treated patients and 4 (3.4%) ritixumab treated patients (NS) developed de novo HLA Ab. 10/245 (4.1%) had de novo HLA class I Ab: 6 (4.8%) and 4 (3.4%) in the placebo and rituximab treated patients, respectively (NS). 12/245 (4.9%) had de novo HLA class II Ab: 9 (7.1%) in the placebo group and 3 (2.5%) in the rituximab group (P=0.09).

Conclusions: Induction therapy with rituximab compared to placebo does not significantly influence the course of anti-HLA Ab at 12 months, however it possibly decreases the levels of pre-existent class II anti-HLA Ab and inhibits the formation of *de novo* class II anti-HLA Ab.

SA-PO961

Benefit of Desensitization with Rituximab from the Viewpoint of Anti-A/B Antibody Titer and Pathological Findings in ABO-Incompatible Kidney Transplantation Kazuhide Saito, Shiro Takahara, Norio Yoshimura, Atsushi Aikawa, Shohei Fuchinoue, Takashi Yagisawa, Kazunari Tanabe, Yoshihiko Watarai, Motohide Shimazu, Kunio Morozumi, Kota Takahashi. *Japan ABO-incompatible Transplantation Committee, Japan.*

Background: We conducted a multicenter prospective clinical study in ABO-incompatible kidney transplantation (ABOi-KT) without splenectomy (UMIN000006635). To evaluate the benefit of desensitization with rituximab (R), we investigated the data of this study from the time course change of anti-A/B antibody (ab) titer and sequential pathological findings.

Methods: Desensitization protocol included low dose MMF and steroid started 28 days before and CNI started a few days before surgery. R 375 mg/m^2 was administered at day -14 and day -1. Minimum 2 sessions of plasma exchange were done for anti-A/B ab removal before transplant, and basiliximab was administered on day 0 and day 4. Anti-A/B

ab titer and eGFR were sequentially evaluated, 0 hr, 1 hr and protocol biopsies (4 weeks after transplant) were also sequentially performed as possible. Pathological specimens were centrally diagnosed by 3 pathologists.

Results: 18 pts received ABOi-KT. One-year pts and grafts survival were both 100%. The desensitization with R was well tolerated. Average anti-A/B ab (IgG) titer at baseline was 48.15x and decreased to 19.72x immediately before surgery, maintaining until the end of the study. In pts whose sequential pathological specimen available showed positive C4d deposition in 1/13 at 1 hr and 11/16(69%) at protocol biopsy. No pts developed AMR related to anti-A/B abs except for one who experienced AMR with anti-HLA ab (Banff 07 type II). Her anti-A/B ab titers were slightly higher than the others (4x-32x). Pathological findings included arteriosclerosis in 8, nephrocalcinosis in 1, IF/TA (grade 1) in 1 and suspicious CNI acute nephrotoxicity in 1. Two pts showed C4d+ without other pathological signs.

Conclusions: In this series, anti-A/B ab titers were successfully decreased and no AMR occurred other than 1 caused by anti-HLA ab, whereas C4d deposition was detected in 69% of pts by protocol biopsy. Our desensitization protocol was confirmed both pathologically and clinically safe and effective for ABOi-KT.

Post-Transplant BAFF Levels Do Not Predict the Development of Anti-HLA Antibody in Kidney Transplant Recipients

Ji Won Min,[2] Bum Soon Choi,[1,2] Cheol Whee Park,[1,2] Chul Woo Yang,[1,2] Yong-Soo Kim,[1,2] Byung Ha Chung.[1,2]
[1]Transplant Research Center, Seoul St. Mary's Hospital, College of Medicine, The Catholic Univ of Korea, Seoul, Korea; [2]Div of Nephrology, Dept of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic Univ of Korea, Seoul, Korea.

Background: It is well known that pre-transplant B cell activating factor (BAFF) levels are associated with the development of de novo anti-HLA antibodies and also antibody mediated rejection post-transplant. However, the clinical significance of BAFF values at allograft rejection has not been determined. In this study, we investigated the clinical significance of pre and post-transplant BAFF levels measured when indication biopsy was done.

Methods: In 130 kidney transplant (KT) recipients who required allograft biopsy due to an increase in serum creatinine, we checked for anti-HLA antibodies using Luminex single antigen assay, and measured BAFF levels using ELISA kits. In 78 of these patients we also measured pre-transplant BAFF and anti-HLA antibody levels. We investigated the relationship between pre-transplant, post-transplant and delta BAFF levels and the occurrence of anti-HLA antibodies.

Results: Pre-transplant BAFF levels showed significant association with pre-transplant sensitization, represented by positive PRA, high PRA , and presence of HLA-DSA. They also showed positive association with early rejection (rejection within 6 months from KT). Post-transplant BAFF levels showed significant association with pre-transplant sensitization, but did not show association with anti-HLA antibodies and positive donor-specific antibodies at the time of biopsy. We did not find any association between post-transplant BAFF levels and cumulative allograft survival, allograft biopsy results, Banff scores and microvascular inflammation scores.

Conclusions: In conclusion, pre-transplant BAFF levels are associated with pre-transplant sensitization and are useful in predicting allograft rejection. But post-transplant BAFF levels measured at the time of indicated biopsy are not associated with the appearance of de novo HLA-DSA, allograft rejection, biopsy findings and other allograft outcomes.

SA-PO963

Effectiveness of Bortezomib (BT) in the Treatment of Antibody Mediated Rejection (AMR) Among Pediatric Kidney Transplant Recipients (pKTx)

Sarah J. Kizilbash,[1] Donna J. Claes,[2] Isa Ashoor,[3] Ashton Chen,[4] Sara E. Jandeska,[5] Raed Bou Matar,[6] Jason Misurac,[7] Katherine Twombley,[8] Priya Verghese.[1] *[1]Pediatric Nephrology, Univ of Minnesota; [2]Cincinnati Children's Hospital; [3]Children's Hospital New Orleans; [4]Wake Forest Univ; [5]Rush Univ; [6]Cleveland Clinic; [7]Indiana Univ; [8]Medical Univ of South Carolina.*

Background: AMR has a poor prognosis despite a number of therapeutic options. BT is increasingly being utilized in adults but there are limited data on its safety and efficacy in pKTx with AMR.

Methods: Multicenter retrospective case series including all pKTx who received BT for biopsy proven AMR, from 2008-2015, at 8 centers within Midwest Pediatric Nephrology Consortium.

Results: Twenty-four pKTx from 8 centers were treated with BT for AMR. In addition to BT, 75% were treated with rituximab, 79.2% with plasmapheresis and 91.7% with IVIG. 62.5% were males, 45.8% were white, and 41.7% were African American. Two-thirds were deceased donor recipients, and mean age at transplant was 11.1 years (SD 5.19). Obstructive uropathy and dysplasia comprised 50% of the underlying diseases. At the time of transplant, 82.2% of patients had 0.0% panel reactive antibodies. Mean estimated GFR (eGFR) prior to AMR was 49.6 (SD 12.1). Prevalence of donor specific antibodies (DSA) and changes in eGFR are shown in table 1.

	Class 1 DSA	Class 2 DSA	Mean eGFR (ml/min/1.73m^2)
Initiation of BT	66.7%	91.7%	40.1
3 months after BT	40.0%	75.0%	37.8
6 months after BT	27.8%	76.5%	36.7

Side effects were documented in 54% of patients and most commonly included leukopenia, anemia, and hypertension. Less frequent side effects included hepatitis, headaches, vomiting, and rashes. Mean time to follow up after BT was 1.3 years (SD 0.96). At the end of follow up, patient survival was 100% and 17/24 patients (70.8%) had functioning grafts.

Conclusions: BT was used to treat AMR in pKTx without life-threatening side effects. The 6-month patient and graft survival were excellent. The efficacy and safety of bortezomib for pKTx AMR should be evaluated in randomized clinical trials.

SA-PO964

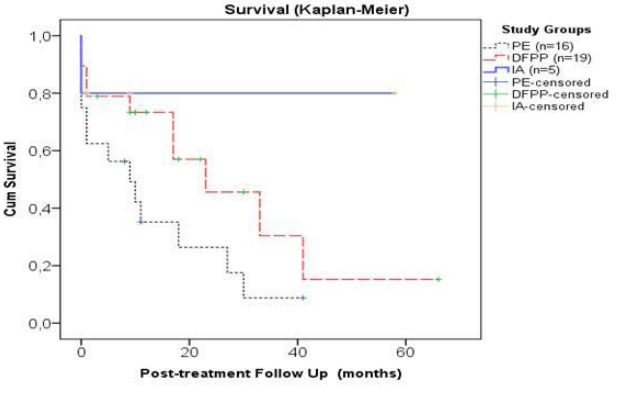
Immunoadsorbtion Is Efficient in the Treatment of Late Antibody Mediated Rejection

Yasar Caliskan,[1] Yasemin Ozluk,[2] Halil Yazici,[1] Aydin Turkmen,[1] Alaattin Yildiz,[1] Mehmet S. Sever.[1] *[1]Div of Nephrology, Dept of Internal Medicine, Istanbul Faculty of Medicine, Istanbul, Turkey; [2]Dept of Pathology, Istanbul Faculty of Medicine, Istanbul Faculty of Medicine, Istanbul, Turkey.*

Background: Plasmapheresis (PP) with IVIG, was proposed as a useful treatment for antibody mediated rejection (ABMR). As an alternative to plasma exchange (PE), double filtration plasmapheresis (DFPP) and immunoadsorption (IA) represent an attractive strategy for antibody depletion. We investigated whether PE or DFPP or IA is effective in the treatment of late ABMR.

Methods: 40 renal tx recipients diagnosed as biopsy confirmed ABMR at a mean time of 70±40 months after tx were included. Patients were randomly assigned to PE (n=16) or DFPP (n=19) or IA with protein A (n=5). The study groups were similar regarding age, gender, donor type, eGFR at randomization and post-tx follow-up time. Donor specific antibody (DSA) was positive in 62.5% of PE, 73.6% of DPFF and 100% of IA groups (p=0.25), and C4d was positive in 75%, 68% and 60% (p=0.79), respectively. All patients received 2 g/kg IVIG and Rituximab 375 mg/m^2.

Results: Tubulointerstitial scarring (ci+ct) (p=0.81), microcirculation inflammation (g+ptc) (p=0.38) and transplant glomerulopathy (cg) (p=0.21) scores were similar. However, the mean total inflammation (ti) score of IA group (2.60±0.55) was significantly higher than PE (1.69±0.70) and DFPP (1.79±0.71). The rates of graft loss were as follows; PE; 13/16 (81.3%), DFPP; 10/19 (52.6%) and IA; 1/5 (25%) (p=0.03). The graft survival was significantly higher for IA than PE (p=0.01). There was a tendency of better graft survival in DFPP compared to PE group (p=0.07). *Kaplan-Meier survival analysis revealed* better overall survival for IA than for PE and DFPP (p=0.03).



Conclusions: Even though limited by small patient numbers, this trial suggests efficiency of IA in the treatment of late ABMR.

SA-PO965

Pre-Transplant Phospholipase A2 Receptor Autoantibody Concentration Is Associated with Recurrence of Membranous Nephropathy Post-Kidney Transplantation

Hasan Fattah,[1] Gaurav Gupta,[1] Dhiren Kumar,[1] Luis F. Quintana,[2] Anne L. King,[1] Rivka Ayalon,[3] Laurence H. Beck.[3] *[1]Nephrology, Virginia Commonwealth Univ, Richmond, VA; [2]Nephrology, Hospital Clínic de Barcelona, Barcelona, Spain; [3]Nephrology, Boston Univ, Boston, MA.*

Background: Idiopathic membranous nephropathy (iMN) has been associated with anti-phospholipase A2 receptor autoantibody (PLA2R-Ab) both in the native kidneys as well as in the setting of recurrence (rMN) post-kidney transplant (txp). Previous studies that have assessed pre-txp PLA2R-Ab for the prediction of rMN have yielded variable results. Many of these studies have been limited by the use of variable immunosuppressive protocols among patients, different ELISA assays as well as method of diagnoses (surveillance vs indication biopsies).

Methods: Sixteen consecutive txp patients with a history of iMN were tested for pre-txp PLA2R-Ab. ELISA titers (Euroimmun, NJ, USA) >14 RU/ml were considered positive, as per manufacturer instructions. All patients received similar post-transplant immunosuppression. A receiver operating characteristic (ROC) analysis was performed after combining data from Quintana et al. (n=21; Transplantation Feb 2015) to determine a PLA2R-Ab concentration which could predict rMN.

Results: Six (out of 16; 37%) patients had biopsy-proven rMN at a median of 3.2 years post-txp. Of these, 5/6 (83%) had a positive PLA2R-Ab pre-txp with a median of 82 RU/ml (range=31-1500). The only patient who had rMN with a negative PLA2R-Ab was later diagnosed with non-Hodgkin's lymphoma. 100% (n=10) patients with no evidence of rMN (median follow-up=5 years) had negative PLA2R-Ab though one patient did have a borderline titer of 13.8 RU/ml. Patients with rMN were treated with rituximab and had an improvement in proteinuria from a median of 6g/d to 0.6g/d. Among the patients with rMN and positive PLA2R-Ab, titers fell to a median of 4 RU/ml at most recent follow-up. In a combined ROC analysis (n=37) a pre-txp PLA2R Ab>29 RU/ml predicted rMN with a sensitivity of 85% and a specificity of 92%.

Conclusions: Pre-transplant PLA2R-Ab could be a useful tool for the prediction of rMN. Patients with rMN in the absence of PLA2R-Ab should be screened for occult malignancy.

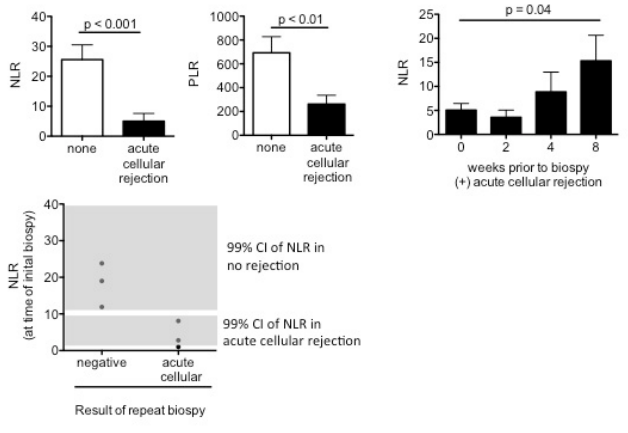
SA-PO966

Neutrophil-to-Lymphocyte and Platelet-to-Lymphocyte Ratio Predict Acute Allograft Rejection David S. Wheeler,[1] Scott Blumhof,[1] Manjula Balasubramanian,[2] Janani Rangaswami.[3] *[1]Internal Medicine, Albert Einstein Medical Center, Philadelphia, PA; [2]Pathology, Albert Einstein Medical Center, Philadelphia, PA; [3]Delaware Valley Nephrology and Hypertension Associates, Philadelphia, PA.*

Background: Currently, allograft biopsy is gold standard for diagnosing rejection however there is intense interest in identifying non-invasive biomarkers. The goal of this study is to determine whether the neutrophil-to-lymphocyte ratio (NLR) or the platelet-to-lymphocyte ratio (PLR) correlate with acute allograft rejection.

Methods: This single center retrospective case-control study examined all kidney transplant biopsies conducted at Einstein Medical Center from Jan 2013 through Dec 2014. Biopsies were stratified for rejection (acute cellular, borderline, negative). The NLR and PLR was calculated from routine laboratory studies obtained at various time points preceding the biopsy.

Results: Of the 102 "for cause" biopsies, 37.3% showed clear evidence of acute rejection and 18.6% were boarderline. NLR and PLR obtained within the week prior to the biopsy showed a significant reduction (4-fold and 3-fold respectively) in patients with acute cellular rejection. This reduction in NLR and PLR preceded the biopsy by 2-4 weeks suggesting a rejection prodome. Interestingly, NLR at the time of boarderline biopsy accurately predicted rejection status on subsequent biopsy conducted within 8 weeks.



Conclusions: NLR and PLR are highly sensitive biomarkers for acute rejection which become positive prior to other clinical manifestations. Furthermore, in cases of boarderline biospies NLR accurately predict the result of subsequent biospies. The inclusion of NLR and PLR could revolutionize allograft rejection evaluation by reducing the need for biopsies and providing additional insight in cases where the biopsy is non-diagnostic.

SA-PO967

Transitional B Cell T1/T2 Ratio Is a Prognostic Marker for Human Renal Allograft Deterioration Aravind Cherukuri,[1] D. Rothstein,[1] Richard J. Baker.[2] *[1]Univ of Pittsburgh; [2]Univ of Leeds.*

Background: Human transitional B cells (TrB) may play a significant role in auto and alloimmune disease. We previously showed that TrB express a high IL10:TNFα ratio and that this ratio fell with acute rejection. TrB are comprised of less mature T1 and more mature T2 cells.

Methods: We characterized the cytokine expression of T1 vs. T2 cells (identified by differences in CD24&CD38 expression) and investigated the utility of T1/T2 ratio as a biomarker for allograft deterioration (graft loss or 50% decline in eGFR).

Results: While both T1 and T2 cells expressed similar IL10, T1 cells expressed less TNFα and had a higher IL10:TNFα ratio. Thus T1 TrBs represent the B subset with the most anti-inflammatory profile. T1 cells were found to fall in rejection (resulting in lower T1/T2 ratio), contributing to the change in IL10:TNFα ratio. When analysed in a test set of 84 renal transplant patients, T1/T2 ratio was a strong predictor of allograft deterioration over a 5 year follow-up (ROC AUC 0.84, P<0.001). In a multivariate Cox model, T1/T2 ratio was independently associated with allograft deterioration (HR 4.8 95% CI 1.3-17.8, P=0.02). T1/T2 ratio was examined 2 years post-transplant in a prospective validation set of 97 stable patients derived from a steroid avoidance RCT comparing alemtuzumab (n=51) or basiliximab induction (n=46). T1/T2 ratio was a strong predictor of outcome over the next 5 years (ROC AUC 0.82, P<0.001) and was independently associated with allograft deterioration (HR 26.6, 95% CI 3.1-227.3, P=0.003). In both the test and validation sets, T1/T2 ratio was a much stronger predictor of graft deterioration than traditional markers like eGFR (test set, eGFR ROC AUC 0.76 vs. T1/T2 ratio 0.84, Z statistic 0.97; validation set, eGFR ROC AUC 0.64 vs. T1/T2 0.82, Z statistic 1.92), or the detection of DSA (test set, DSA ROC AUC 0.68 vs. T1/T2 ratio 0.84, Z statistic 2.9; validation set, DSA ROC AUC 0.66 vs. T1/T2 0.82, Z statistic 2.35).

Conclusions: We demonstrate a distinct subset of TrB (T1) characterized by an anti-inflammatory cytokine profile. A decrease in T1:T2 ratio (due to selective loss of T1 cells) is a strong prognostic biomarker for subsequent renal allograft deterioration.

The Pre-Transplant Ratio of T Regulatory Cells to Effector/Memory CD8+ T Cells Is Correlated with the Development of Acute Rejection Kentaro Sugisaki, Qizhi Tang, Sang-Mo Kang. *Surgery, Medical Center, Univ of California, San Francisco, San Francisco, CA.*

Background: Acute rejection (AR) or renal allografts are a major predictor for the development of chronic allograft nephropathy (CAN) and subsequent graft loss. Although clinical risk factors for the development of AR have been identified, few techniques exist to individually stratify patients for the risk of AR and provide a rational basis for the tailoring of immunosuppression regimens. Over the past two decades, regulatory T cells (Treg) have been identified and subsequently shown to be critical to the prevention of autoimmunity as well as the prevention on organ allograft rejection in numerous models. In parallel, the identification of various T lymphocyte subsets has been greatly refined, allowing a more precise quantitation and correlation with outcomes.

Methods: We hypothesized that Treg abundance pre-transplant could predict for the development of acute rejection in patients undergoing de novo renal transplantation.We prospectively enrolled 76 renal transplant patients undergoing first transplant from August 2013 toMarch 2014. We excluded patients undergoing second transplants, desensitization protocols, or involved in other clinical trials. Venous blood samples from all recipients at transplant date were isolated the peripheral blood mononuclear cells (PBMCs) and stored. We analyzed the samples in batches and normalized cell surface and intracellular staining using a standard control, using a NAVIOS flow cytometer (Beckman Coulter). All recipients were followed for a minimum of 1 year for the development of biopsy proven rejection.

Results: 12 recipients experienced AR. The pre-transplant ratio of Treg and Effector memory (EM) CD8 (Treg/EM CD8) T cells was significantly lower in patients who developed rejection, as compared to patients who did not experience rejection (45 recipients). Other T cell subsets were not associated with the development of acute rejection.

Conclusions: Our data suggests that the pre-transplant ratio of Treg/EM CD8 T cells may identify patients at increased risk of AR and should encourage larger scale studies to validate and quantify the magnitude of risk as well as to assess covariables.

The Association of Th17 Cell Phenotype with Chronic Allograft Dysfunction in Kidney Transplant Recipients Byung Ha Chung, Hyunseon Kim, Chul Woo Yang. *Internal Medicine, Seoul St. Mary's Hospital, Seoul, Korea.*

Background: The purpose of this study is to determine the significance of the Th17 cell pathway in the progression of chronic allograft dysfunction.

Methods: We investigated the expression of T cell phenotype in long-term stable kidney transplant recipients (KTRs)(LTS, n=67), chronic allograft dysfunction group (CAD, n=52), and also in three control groups (early stable KTRs (ES, n=28), end stage renal disease (ESRD, n=45), and healthy control (HC, n=26)).

Results: The percentage of Th17 cells out of $CD4^+$ T cells and the proportion of IL-17 producing cells out of effector memory T cells showed a significant increase in the CAD group compared to the LTS group and other control groups ($P < 0.05$). In addition, The percentage of $CCR4^+CCR6^+/CD4^+$ T cells and IL-17 producing cells out of $CCR4^+CCR6^+CD4^+$ T cells was higher in the CAD group than in the LTS group ($P<0.05$). However, the percentage of Th1, Th2, and regulatory T cells did not differ significantly between the CAD and LTS groups ($P > 0.05$). Also, the serum level of IL-17, IL-33, and RAGE, and the expression of IL-1beta, RAGE, and HMGB1 mRNA showed an increase in the CAD group compared to the LTS group. Lastly, IL-17 induced acute and chronic injury in the human proximal renal tubular epithelial cell line in a dose-dependent manner.

Conclusions: In conclusion, we found the activation of the Th17 cell pathway in patients with chronic allograft dysfunction. The results of this study suggest that Th17 pathway may have a role in the progression of chronic allograft injury.

SA-PO970

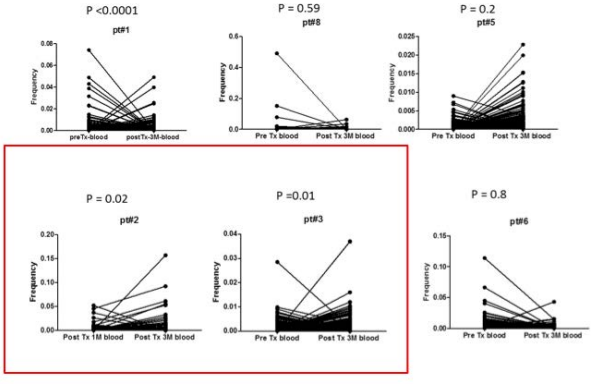
Quantitative Characterization of T Cell Repertoires in Kidney Transplant Patients Houda Alachkar,[1] Martin B. Mutonga,[1] Taigo Kato,[1] Sowjanya Kalluri,[3] Vikas Vujjini,[2] Yusuke Nakamura,[2] Nada Alachkar.[2] *[1]Univ of Chicago; [2]Johns Hopkins Univ; [3]Kendall Medical Center.*

Background: Acute and chronic T cell mediated rejection remains a major cause of kidney graft failure. Despite the significant decrease in early acute rejection due to current potent immunosuppressions, long-term graft survival remains unsatisfactory. Thus, characterization of the T cell repertoire and the kinetic of the expanded clones in transplant (Tx) patients may shed a light on our understanding of the T cells' role in graft rejection.

Methods: We collected blood and urine samples from (46) patients before Tx, and at sequential time points post Tx and at time of T cell mediated rejection. We utilized next generation sequencing approach to characterize T cell receptor (TCR) repertoire. Sequencing using the illumina miSeq was performed on cDNA synthesized from RNA extracted from patients' samples. This approach enables to track each expanded TCR clone in the graft at 3 months post Tx, back to their first appearance in blood and urine samples obtained pre or 1 month post Tx. We also measured the RNA expression levels of CD8, CD4, FOXP3, Granzyme and Perforin in blood samples (N=43).

Results: Only patients with acute T cell mediated rejection (n=2) had TCR repertoires defined by the top 10 TCR clones appeared at any time point in blood, showed significant expansion in blood at 3 month post Tx compared with that at 1 month post Tx (P=0.01 and 0.02). CD8, FOXP3, Granzyme and perforin RNA levels were significantly higher in samples obtained from patients with rejection compared to that in patients with no rejection (P£0.02).

Fig.4: Pattern of changes of CDR3 Frequencies in Blood of Kidney Transplant Patients



Conclusions: Our study provides valuable comprehensive longitudinal analyses that define the kinetics of each TCR beta clone, and the changes in diversity of CDR3. This approach allows for identification of the expanded T cell clones that are possibly associated with graft rejection.

SA-PO971

Critical Apparaisal of the New Banff Criteria for Chronic Antibody-Mediated Rejection in the Real Life Setting Isabelle Houde, Isabelle Côté, Mohsen Agharazii, Sacha A. De Serres. *Renal Div, Quebec Univ Health Center, Laval Univ, Quebec City, QC, Canada.*

Background: Significant changes in the criteria for chronic active antibody-mediated rejection (CAABMR) were made at the 2013 meeting, which is of major concern for clinical management. Here we compared the 2007 *vs.* 2013 criteria with regards to clinical outcomes.

Methods: Single-center, observational retrospective cohort study of all patients who received an indication biopsy between January 2006 and October 2014, during which EM evaluation, ptc scoring and C4d scoring by IH and IF was routinely performed. Patients were included if they met the criterion 1 for CAABMR: score cg1a>0, cg1b>0 or severe peritubular capillary basement membrane multilayering. GN, immune deposits, HCV+ status or suspicion of TTP-HUS were excluded. The endpoint was a composite of doubling of serum creatinine and death-censored graft loss.

Results: 123 patients were included. 18% met the full 2007 criteria, whereas an additional 18% fulfilled the full 2013 criteria. Only 25% of patients met the 2007 criterion #2-C4d, in contrast to 82% for the 2013 criterion #2-microvascular injury (MVI): 67% were C4d-positive and 55% were g+ptc positive, with substantial overlap. 45 patients experienced the endpoint at a median of 22mo post-biopsy. Overall, only a 2013 diagnosis of CAABMR was associated with the endpoint (adjusted HR=2.5 [1.2-5.2] for 2013 *vs.* HR=1.6 [0.7-3.8] for 2007 diagnosis). Adjusted Cox modelling revealed that the 2013 criterion #2-MVI was more strongly associated with the endpoint than the 2007 criterion #2-C4d (HR=4.0 [1.1-14.1] vs. HR=2.3 [1.03-5.3]). When the 2013 criterion #2 was dissected by component, the C4d-component was significant (HR=2.5 [1.1-5.4]), but not the g+ptc (HR=1.1 [0.5-2.3]).

Conclusions: Compared to the 2007 criteria, applying the 2013 criteria here doubled the proportion of patients with CAABMR. Importantly, it improved the association with clinical outcomes.

SA-PO972

Tissue Expression of Aquaporine 2 Is Correlated to Urine Output and Allograft Function in Sensitized Kidney Transplant Patients Luis Eduardo Becker,[1] Martin G. Zeier,[1] Christian Morath.[1] *[1]Nephrology, Univ of Heidelberg, Germany; [2]Pathology, Univ of Heidelberg, Germany.*

Background: Salt and water disturbances often occur during acute kidney allograft dysfunction contributing to graft failure, but this condition has still been poorly investigated in the setting of alloreactivity. We evaluated the tissue expression of aquaporins (AQP1, AQP2) and of the epithelial sodium channel (ENAC) in kidney allograft biopsies from transplant patients with high immunological risk.

Methods: Eigthy-six kidney transplant biopsies from thirty-three sensitized patients were divided into three groups according to the clinical context an possible pathological correlates as follows: time-zero (N=9), protocol (N=9) and indication (N=68) biopsies. The indication biopsies were further divided into three subgroups, according to the presence or absence of acute tubular necrosis or acute rejection. Normal kidney tissue samples (N=6) served as controls. Immmunohistochemical expression of AQP1, AQP2 and ENAC was analyzed with assistance of an image software.

Results: We observed a significantly lower AQP1 expression in time-zero and indication biopsies with rejection compared to controls (7.7±2.0% and 9.1±0.6% vs. 14.3±2.9% of area positively stained; P=0.03 and P=0.04 respectively). AQP2 expression was significantly lower in patients with an indication biopsy when compared to controls and protocol biopsies (2.1±0.2% vs. 4.4±0.7 and 4.0±0.5% of area positively stained, P=0.05 and P=0.005, respectively). For ENAC, a lower expression in indication biopsies compared to controls was seen (P=0.04). Both AQP1 and AQP2 tissue expressions were significantly correlated to the urine output (r=0.45 and r=0.32; P=0.001 and P=0.02, respectively), and AQP2 was correlated to the MDRD-glomerular filtration rate at the time of biopsy (r=0.23; P=0.05).

Conclusions: Our findings can partially confirm previous experimental data showing downregulation of AQP1 expression after ischemia-reperfusion injury and during rejection. AQP2 downregulation seems to be rejection-independent occurring during deteriorating or poor kidney graft function.

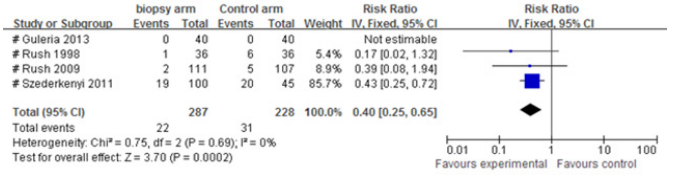
SA-PO973

The Utility of Protocol Biopsy in Renal Recipients: Meta Analysis and Systematic Review Guga Suri. *Kidney Disease, The First Affiliated Hospital of Zhejiang Univ, Hangzhou.*

Background: To evaluate the value of protocol biopsy in patients after renal transplantation.

Methods: Searches were applied to the following electronic database:Medline, Embase Database, Cochrane Library. Randomized controlled trails evaluating the value of protocol biopsy for renal allograft recipients were included. Data were extracted independently by two reviewer.The risk of bias of included studies was assessed by the the Cochrane collaboration's tool for assessing risk of bias.

Results: 5 RCTs were included. Long term graft loss was significantly reduced (RR 0.40,95%CI 0.25 to 0.65, P<0.001) (figure 1) by protocol biopsy after renal transplantation.



Protocol biopsy may reduce the long term serum creatinine (WMD 38.21, 95% CI 54.83 to 21,60, p<0.00001).For renal recipients whose basal immunosuppression is CNI (tacrolimus or cyclosporine), protocol biopsy can significantly improve the long term eGFR (SMD 0.78, 95% CI 0.51 to 1.05, P<0.00001).However, for those whose basal immunosuppression is tacrolimus, this effect is not notable. Protocol biopsy seems to have no significant beneficial effect of reducing clinical acute rejection episodes.

Conclusions: Treatment of subclinical rejection detected by protocol biopsy can significantly improve the graft survival and may improve the allograft function.

SA-PO974

Longitudinal Biopsy Findings Among Children, Adolescents, and Young Adult Renal Transplant Recipients from a Southeastern USA Cohort Jonathan Alexander Miles,[1] Panupong Hansrivijit,[2,3] Katherine D. Westreich,[3] Evan Zeitler,[3] Randal K. Detwiler,[3] Maria E. Ferris.[3] *[1]East Carolina Univ, Greenville, NC; [2]Chulalongkorn Univ, Bangkok, Thailand; [3]UNC at Chapel Hill, Chapel Hill, NC.*

Background: Longitudinal procedure history in children, adolescent, and young adult renal transplant recipients needs to be characterized based on their primary cause of end-stage renal disease (ESRD). It is known that pediatric patients are a high risk group for transplant failure. Elucidating potential factors for transplant failure in this group is important for protecting valuable renal transplants.

Methods: Clinical, demographic and pathological records of patients who received a renal transplant at age ≤ 30 years of age and who underwent transplant biopsies between 2000 and 2014 at the UNC Hospitals were analyzed. This cohort was classified based on

the primary cause of ESRD as either glomerular or non-glomerular. Demographics, number of biopsies (total and adjusted for graft years), and transplant failure (rates and cause) were compared between the two groups.

Results: We enrolled 179 patients; 105 (58.7%) were male; 67 (38%) African American, 92 (51%) Caucasian, and 20 (11%) other race. Their mean age at transplant was 18.7 ± 8.2 years and 98 (55%) had a glomerular cause of ESRD. This cohort underwent a total of 505 graft biopsies. Comparing patients with glomerular vs. non-glomerular conditions, we found no significant differences in cellular or humoral rejections (p=0.430); mean number of biopsies (3.0 ± 1.9 glomerular; 2.7±1.9 non-glomerular; p=0.289); mean number of biopsies per year for failed transplants (p=0.702), current functioning grafts (p=0.090); time to a failed transplant (p=0.476); or age at time of transplant (p=0.136).

Conclusions: In this single institution cohort of children, adolescents and young adults, we found no statistical differences in renal biopsy findings regarding number of biopsies and transplant failure. This high risk age group shows no different longitudinal graft survival based on primary cause of ESRD. More analysis will follow.

Prospective Study of Risk Factors and Impact of Subclinical Rejection (SCR) and Acute Clinical Rejection (ACR) in Renal Transplant Recipients

Rajil B. Mehta,[1] Puneet Sood,[1] Aravind Cherukuri,[1] Shan Shan Chen,[1] Chethan M. Puttarajappa,[1] Christine Wu,[1] Nirav A. Shah,[1] Parmjeet S. Randhawa,[2] Sundaram Hariharan.[1] *[1]Starzl Transplantation Inst, Univ of Pittsburgh Medical Center, Pittsburgh, PA; [2]Dept of Pathology, Univ of Pittsburgh Medical Center, Pittsburgh, PA.*

Background: The long term outcomes of subclinical rejection (SCR) remain unclear. The current study evaluated the risk factors for SCR at 3 mths and followed up renal function upto 1 year in pts with SCR, ACR and no rejection.

Methods: We prospectively followed 340 pts who underwent an ABO compatible kidney transplant between Jan 2013 and Sep 2014. Eight pts were excluded. All patients received induction therapy with either thymoglobulin (95%) or Basiliximab for induction, CNI/MPA for maintenance therapy and rapid steroid withdrawal by day 7. Protocol biopsies were performed 3 months post transplant. Based on this, they were divided into 4 groups. Grp 1 - pts with SCR; Grp 2 - pts with normal biopsy; Grp 3 - pts with ACR; Grp 4 - pts with no biopsy. Banff classification was followed for biopsy grading. Steroids, thymoglobulin and PP/IVIG were used as indicated for the treatment of rejection.

Results:

	Grp 1 (SCR)	Grp 2 (Normal Bx)	Grp 3 (ACR)	Grp 4 (No Bx)	p value
	44/236 (18.6%)	159/332	33/332 (9.9%)	96/332	
Age (yrs)	50+/-16	52+/-15	48+/-15	55+/-12	0.07
Sex (M/F)	28/16	100/59	15/18	52/44	**0.048**
Race (W/O)	34/10	126/33	25/8	80/16	0.07
CIT (mins)	474+/-327	409+/-386	396+/-316	510+/-380	0.16
DGF (Y/N)	13/31	17/142	5/28	21/75	**0.01**
HLA mm	4.1+/-1.5	3.9+/-1.7	4.25+/-2	3.96+/-1.8	0.7
HLA DR mm	1.23+/-0.7	1.12+/-0.7	1.41+/-0.7	1.31+/-0.7	0.08
DSA (Y/N)	11/27	23/109	9/24	13/73	0.18
PRA I	6.7+/-17	6.5+/-19	7.9+/-19	14+/-37	0.13
PRA II	10.8+/-26	14.8+/-29	7.1+/-22	12.6+/-27	0.48
Cr 3m	1.52+/-0.4	1.42+/-0.5	1.69+/-0.48	1.33+/-0.46	**0.0064**
Cr 6m	1.52+/-0.5	1.46+/-0.5	1.54+/-0.37	1.26+/-0.42	**0.012**
Cr 1yr	1.6+/-0.46	1.5+/-0.77	1.66+/-0.48	1.38+/-0.63	0.20
Banff Gr (Bord/IA or >)	25/75	NA	27/73	NA	

Conclusions: 1. Incidence of SCR and ACR around 3 mths was 18.6% and 9.9% respectively 2. Significant risk variables for SCR/ACR were female recipients and DGF 3. No difference in renal function was noted between the groups at 1 year.

SA-PO976

Histological Scoring System Predicts Renal Outcome of Post Transplantation Acute Tubular Necrosis

Tobias Pieters, Lucas Falke, Tri Q. Nguyen, Marianne C. Verhaar, Roel Goldschmeding, Maarten B. Rookmaaker. *Nephrology and Pathology, UMC Utrecht, Netherlands.*

Background: Acute Tubular Necrosis (ATN) is a common cause of Delayed Graft Function (DGF) after renal transplantation (RTX). Currently no histological model is available to predict renal outcome. Recovery of ATN is the result of the balance between damage and repair. In this study we evaluated the predictive value of immunohistochemical parameters of renal damage and regeneration and compared these to an accepted clinical prediction model for cadaveric renal transplantation.

Methods: We included 25 patients that underwent cadaveric RTX with DGF caused by ATN only, as shown in a renal biopsy 1 week after RTX. Biopsies were evaluated for histological tubular damage (atrophy, edema, casts, vacuolization), DNA damage (γH2AX staining) and apoptosis (cC3 staining). Regeneration was assessed by staining for stem cell marker CD133 and proliferation marker Ki67. Clinical parameters for renal outcome were collected as previously described in the Deceased Donor Score (DDS). The relation between these parameters and renal outcome, defined as eGFR at 6 months, was assessed using regression or one-way ANOVA. A corrected analysis for regenerative markers was performed to eliminate potential confounding by the amount of renal damage.

Results: The histological damage score significantly predicted renal outcome (R:-0.52 P:0.01), whereas the DDS only tended to correlate with renal outcome (F:3.12 R: P:0.05). Neither staining for DNA damage, nor for apoptosis could predict renal outcome (R:-0.24 P:0.91 and R:-0.16 P:0.44 respectively). In addition, the investigated parameters for regeneration (CD133 and Ki67) did not predict renal outcome (R:-0.25 P:0.23 and R:-0.10 P:0.63 respectively), also not after correction for renal damage.

Conclusions: We are the first to show that histological parameters can predict renal outcome of post transplantation ATN. Importantly, our histological damage score correlated better with renal outcome than the DDS. Despite the crucial role of regeneration in recovery after ATN, no relation was found between stem cell marker CD133, proliferation marker Ki67 and renal outcome.

Histopathological Changes and Graft Survival of Long-Term Kidney Allograft in Alport Syndrome: A Single-Center Experience in Japan

Yasuyuki Nakada,[1] Izumi Yamamoto,[1] Akimitsu Kobayashi,[1] Yudo Tanno,[1] Hiroyasu Yamamoto,[1] Masayoshi Okumi,[2] Hideki Ishida,[2] Takashi Yokoo,[1] Kazunari Tanabe.[2] *[1]Div of Nephrology and Hypertension, Dept of Internal Medicine, The Jikei Univ of Medicine, Tokyo, Japan; [2]Dept of Urology, Tokyo Women's Medical Univ, Tokyo, Japan.*

Background: Patients with Alport syndrome (AS) commonly develop progressive kidney dysfunction due to a hereditary type IV collagen deficiency, which results in an abnormality in the glomerular basement membrane (GBM). Recurrent glomerulonephritis does not occur in transplanted kidneys, and the allograft survival rate in these patients is similar to that in patients with other renal diseases. Several studies have shown that the type IV collagen of the GBM originates from the recipient's bone marrow–derived cells. Therefore, we postulated that recurrent glomerulonephritis could occur locally and should influence the long-term allograft survival. In this study, we investigated graft survival and histopathological changes in renal allograft recipients with AS, focusing particularly on whether the expression of GBM type IV collagen is altered.

Methods: We collected data on the clinical characteristics of 19 renal allograft recipients who had been diagnosed with AS. All data were obtained from a database at the Department of Urology, Tokyo Women's Medical University. Graft survival was evaluated using the Kaplan–Meier method and compared with a control group (n = 18). We assessed the double staining of a2 and α5 using frozen specimens obtained from long-term allograft survival samples.

Results: The graft survival rate was not statistically different between patients with AS and controls (log-rank $p = 0.2240$). Immunoreactivity to α5 antibody in four patients exhibiting long-term allograft survival showed strong linear positivity and no GBM abnormalities. In the case of chronic active antibody-mediated rejection, the immunoreactivity to anti-a2 antibodies increased in the mesangium and subendothelial space.

Conclusions: These results suggest that the GBM type IV collagen structure was histopathologically maintained for the long term after kidney transplantation, indicating better kidney graft survival in patients with AS.

SA-PO978

Histological Assessments from Kidney Transplant Biopsies: An Explorative Post Hoc Analysis of ZEUS 5 Year Data Ute Eisenberger,[2] Claudia Sommerer,[1] Ingeborg A. Hauser,[1] Frank Lehner,[1] Rudolf P. Wuthrich,[2] Petra Reinke,[1] Anja Susanne Mühlfeld,[1] Katharina M. Heller,[1] Rolf A. Stahl,[1] Heiner H. Wolters,[1] Klemens Budde,[1] Martina Porstner,[3] Oliver Witzke,[1] Wolfgang Arns.[1] *[1]ZEUS Study Group, Germany; [2]ZEUS Study Group, Switzerland; [3]Novartis Pharma, Germany.*

Background: Analysis of pathologists' assessments and histological data allow for deeper insight on patient outcome when combined with investigators final clinical diagnoses. Here we present 5 year data from de novo kidney transplant (KTx) recipients after conversion to an everolimus(EVR) based regimen and withdrawal of CNI therapy vs. continued CNI regimen.

Methods: Post hoc analysis of histological and pathologists' assessments from ZEUS, a prospective, open-label, controlled, multi-center study. At mo 4.5 post Tx 300 KTx patients (pts) were randomized to either EVR + enteric coated-mycophenolate sodium (EC-MPS; n=154) or cyclosporine (CsA) + EC-MPS (n=146). After 12mo interventional study, observational follow-up (FU) on pts safety and efficacy was performed until mo60 post Tx. As per study protocol, graft core biopsies were indicated by suspected rejection episode. Biopsies were read and interpreted by local pathologists.

Results: Total number (nr) and mean nr of biopsies per patient performed are overall similar in both groups until mo60. Nr of pts with at least one rejection (as per final clinical diagnosis) was slightly higher in CNI group vs EVR group. Nr of pts with BPAR was higher in the EVR group especially due to mild, early acute rejections (mostly BANFF IA and IB). Nr of pts with histological evidence of chronic/sclerosing allograft nephropathy was similar in both groups (both 10%), C4D staining positivity was found slightly higher in the EVR group (11% EVR vs 7% CNI), however, pts with evidence of antibody mediated rejection was higher in the CNI group (2% EVR vs 4% CNI), same for CNI-induced toxicity lesions (16% EVR vs 23% CNI).

Conclusions: Data from histological assessments together with investigator reported final clinical pts outcome show that an EVR-based regimen with early elimination of CNI-therapy is as safe and efficacious as standard CNI-therapy offering the opportunity to reduce cumulative CNI-induced toxicities on the allograft.

SA-PO979

Endothelial Microvesicles as a Biomarker of Antibody-Mediated Endothelial Injury Erik Stites,[1] Moglie Le quintrec,[2] Brandon Renner,[1] Jennifer Laskowski,[1] Karissa Fetrow,[1] Joshua M. Thurman.[1] *[1]Univ of Colorado Health Sciences Center, Aurora, CO; [2]Transplantation Rénale, Hôpital Lapeyronie, Montpelier, France.*

Background: Endothelial injury and inflammation are hallmark histopathologic features of antibody-mediated rejection (AMR) in renal transplantation. Antibodies against HLA on the endothelial cells activate the complement system via the classical pathway. The diagnosis of AMR is dependent upon pathologic examination of renal biopsy tissue. A clinical need exists for a noninvasive method for diagnosing AMR. Endothelial cells constitutively release sub-micron vesicles called microvesicles into the circulation, but the release of microvesicles is altered in response to a variety of stimuli. The aim of this study was to evaluate the effect of antibody binding and subsequent complement activation on the production of endothelial microvesicles *in vitro* and to explore endothelial microvesicles from human samples as a potential biomarker of AMR in renal transplant recipients.

Methods: We have developed an *in vitro* model of AMR using immortalized human endothelial cells (HMEC-1) and a monoclonal murine antibody against human HLA class I molecules (W6/32). We analyzed antibody binding and complement deposition with immunohistochemistry and flow cytometry. Microvesicle analysis was performed using flow cytometry.

Results: We have shown that W6/32 antibody binds HMEC-1 cells and activates the classical complement pathway upon exposure to normal human serum. This leads to deposition of complement split products on the cell surface (analogous to C4d deposition in biopsies from patients with AMR) and increased release of endothelial microvesicles. Furthermore, anti-HLA antibody (W6/32), C3, and C4 were deposited on the surface of the microvesicles.

Conclusions: Our results suggest that AMR will lead to an increase in production of microvesicles by the renal endothelium, and AMR-associated microvesicles will have surface-bound IgG and C4d. We have obtained human plasma samples from renal transplant recipients with AMR and healthy controls, and we are currently examining the potential of endothelial microvesicles as a biomarker of AMR.

SA-PO980

Dual Leukocyte/Endothelial Stain for Assessment of Endocapillary Inflammation in the Renal Allograft A. Rosenberg,[1] Jonathan Levi,[2] S.M. Bagnasco,[1] Naima Carter-Monroe.[1] *[1]JHU; [2]NIDDK.*

Background: The pathologist's assessment of renal allograft rejection relies on the evaluation of the pattern of involvement by inflammatory cells. The Banff criteria for renal allograft rejection now includes semiquantitative evaluation of inflammation involving peritubular capillaries (ptc), glomeruli (g), arterial intima (v), tubulitis (t), interstitium (i) and total renal parenchyma (ti) have been elaborated as indices of antibody (g and ptc) versus cell-mediated rejection (v, t, i and ti). Accurate assessment of these various compartments can be difficult and their reproducibility a particular challenge.

Methods: We evaluated a dual pan-leukocyte marker (LCA) and a vascular endothelial marker (CD34) immunohistochemical stain as an ancillary tool for evaluating intravascular (g and ptc) vs tubulointerstitial inflammation. Nineteen cases underwent blinded review of the dual stain.

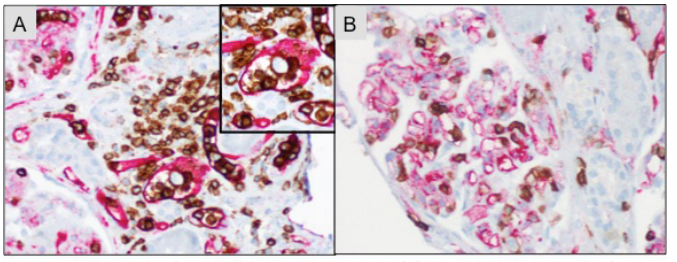

Figure: Dual leukocyte/endothelial stain highlighting in (A) peritubular capillaries (red)and leukocytes (brown); also highlighting in (B) glomerular capillaries (red) and leukocytes. Both dual CD34/LCA immunoperoxidase: Panel A (400x, 600x insert), Panel B (400x)

Results: Overall, good concordance was present between cases originally scored g3 and those meeting criteria on dual stain (9/10), but lesser agreement for cases originally scored g2 with only 1/9 (11%) meeting the same criteria on dual stain. Most cases (4/5) originally scored as ptc2 continued to meet criteria on dual stain, but approximately 35% (5/14) of cases originally scored as ptc3 met criteria for either ptc1 or ptc2 on dual stain.

Conclusions: Dual LCA/CD34 IHC aided the evaluation quantization of inflammatory infiltrate in renal allograft rejection, possibly allowing finer and more reproducible discrimination between ptc and i scores and identifying the extent of glomerulitis. Annotation of whole slide images will be performed to yield a quantitative metric for ptc on a continuous scale for comparison to the current quantized scale. Implementation in larger cohorts and in a consensus setting will be needed to determine improvement in the diagnostic and prognostic yield of the current Banff-based biopsy assessment.

Intragraft Granzyme-B Is Associated with Chronic Renal Transplant Glomerulopathy Narayan Prasad,[1] Brijesh Yadav,[1] Vikas Agarwal,[1] Dharmendra Bhadauria,[1] Raj K. Sharma.[1] *[1]Nephrology, SGPGIMS, Lucknow, UP, India; [2]Immunology, 1.*

Background: Chronic transplant glomerulopathy (CTG) and Interstitial fibrosis and tubular atrophy (IFTA) are two major causes of chronic allograft loss. CTG is often associated with either C4d deposition or, circulating donor specific antibody. Pathogenesis of IFTA is unclear. We aimed the study to determine the role of CD3+CD8+Gzm-B+ Cytotoxic T cells in pathogenesis of CTG and IFTA and to determine its significance as peripheral blood signature of CTG.

Methods: Total 58 (CTG 20, IFTA 28 and stable functioning graft SGF 10) living donor renal transplant recipient were recruited. Patients were categorized into 3 group based on Banff's 2007. We analyzed peripheral blood cytotoxic T cell by flow cytometry, Granzyme-B mRNA transcript in renal biopsy tissue by Taqman real time PCR and soluble Granzyme B level by ELISA.

Results: Age of patients in CTG, IFTA, and SGF group was 41.8±12.7; 36.50±8.34, 46.28±8.65 years; post transplant period at biopsy 63.92±41.0, 51.71±3.06, 70.0±15.42 months; Creatinine at biopsy 2.38±0.84, 2.30±0.86, 1.41±0.33 mg/dl, and daily urine protein 2.67±0.73, 2.22±1.96, 0.22 ±0.060 g; respectively. Peripheral blood CD3+CD8+ T cell frequency was 17.20±6.61% in CTG; 17.39±5.78% IFTA; and 13.20±1.02% SGF respectively (p=0.436). Peripheral cytotoxic T cell frequency (CD3+CD8+Gzm-B+) was significantly low in CTG group (12.62±1.68%), as compared to IFTA (16.44±4.09%), (p=0.012) and SGF 26.35±2.95% (p=0.001). Intragraft mRNA of Granzyme-B in CTG was 3.05 fold high as compared to SGF. In IFTA intragraft Gzm B mRNA was 2.26 fold high compared to SGF(p<0.001). Soluble serum Granzyme B level was significantly high in CTG (423.7±135.20; p<0.001),as compared to IFTA(249.5±73.05; P<0.001), and SGF (91.88±30.89) pg/ml. This suggests that sequestration of cytotoxic T cells into graft resulted in low circulating cytotoxic cells and increased intragraft Gzm-B+ cells leading to Granzyme-B dependent injury and CTG.

Conclusions: Low peripheral blood cytotoxic T cell (CD3+CD8+Gzm-B+) frequency and high intragraft mRNA transcript of Granzyme-B in CTG suggest role of cytotoxic T cells in CTG. Lower circulating CD3+CD8+Gzm-B+ Cytotoxic T cells can be peripheral blood signature for CTG.

Molecular Features of Kidney Transplant Biopsies with Interstitial Fibrosis/ Tubular Atrophy in the Presence of Sterile Leukocyturia Maria Ajaimy, Enver Akalin. *Einstein-Montefiore Transplant Center, Albert/Einstein College of Medicine, Bronx, NY.*

Background: We hypothesized that sterile leukocyturia could reflect an increased intragraft immune activity and investigated gene expression profiles of transplant kidney biopsies of patients with sterile leukocyturia comparing to patients without leukocyteuria.

Methods: We identified 15 normal transplant kidney biopsies without leukocyturia (Group I) and 33 biopsies with non-specificinterstitial fibrosis/tubular atrophy (IFTA) for gene expression profiling. Of the 33 biopsies with IFTA, 24 patients had no sterile leukocyturia (Group 2) and 9 patients had sterile leukocyturia (Group 3). Biopsies with a diagnosis of acute or chronic rejection, recurrent or de novo glomerular disease, or polyoma nephropathy were excluded. Sterile leukocyturia was defined by the presence of leukocytes in the urine (>10μL) without bacterial growth in urine culture. The urinalysis was done within 1 month before or after the biopsy. The gene expression profiles were studied by Affymetrix HuGene 1.0 ST expression arrays.

Results: There was no difference in terms of age, race, and sex, type of transplant, previous history of transplantation or acute rejection, donor characteristics, panel reactive antibody levels and immunosuppressive treatment between the Groups 2 and 3. Both groups also had similar acute and chronic Banff allograft injury scores. There was no statistically significant difference in gene expression profiles between the Groups 1 and 2.When Group 3 biopsies were compared to the Group 1 and 2 biopsies, significantly increased gene transcripts associated with cytotoxic and regulatory T cells, and macrophages (P-value for significance <0.05). There was a trend towards increased interferon-gamma and rejection associated transcripts but no statistically significant difference in expression of B-cell or natural killer cell associated transcripts.

Conclusions: The biopsies of the patients with sterile leukocyturia showed increased expression of gene transcripts associated with T cells indicating heightened intragraft immune activity. Those patients might require close monitoring of their allograft function.

SA-PO983

Elevated Glomerular Mechano-Growth Factor and Vascular Endothelial Growth Factor in Chronic Allograft Nephropathy Is Associated with Activation of Erk1/2 Yongxin Gao,[1] Raafat Farag Makary,[2] Carmela B. Monteiro,[2] Leighton R. James,[1] Charles W. Heilig.[1] *[1]Medicine, Univ of Florida College of Medicine-Jacksonville, Jacksonville, FL; [2]Pathology, Univ of Florida College of Medicine-Jacksonville, Jacksonville, FL.*

Background: We previously identified increased GLUT1 glucose transporter, Mechano-Growth Factor (MGF) and Vascular Endothelial Growth Factor (VEGF) in human Chronic Allograft Nephropathy (CAN) kidneys which demonstrate glomerulosclerosis. Here we investigated a glomerular signaling pathway, Erk1/2, with potential to mediate effects of MGF and VEGF on extracellular matrix (ECM) genes. We employed IHC with specific antibodies to assess protein expression for MGF, VEGF and phospho-Erk1/2 (active Erk1/2) in human CAN kidneys vs. Normal Control kidneys.

Methods: This study involving examination of archived renal biopsy samples was approved by the Institutional IRB. N = 6 for each group of renal transplant - and native kidney biopsies. Immunolabelling of human CAN and Normal Control paraffin-mounted kidney sections was performed for assessment of selected proteins with specific antibodies, by use of immunoperoxidase staining. Scoring of glomerular immunolabelling for individual proteins was 0 – 4+ for semiquantitation. Data were normalized to open glomerular tuft area. P < .05 was considered significant in statistical analyses.

Results: Glomerular MGF protein was increased 3.9-fold in CAN kidneys vs Normal Control kidneys, P <.0001. Glomerular VEGF was elevated 3.0-fold in CAN vs Normal Control kidneys, P < .0001. Both of these growth factors have potential to signal via Erk1/2 to ECM expression. Glomerular Erk1/2 activation (i.e. phospho - Erk1/2) was examined and found to be increased 4.3-fold in CAN vs Control, P<.0001.

Conclusions: Human CAN, characterized by excessive glomerular MGF and VEGF expression, involved enhanced activation of Erk1/2 in the glomeruli. This provides a mechanism by which these glucose-responsive growth factors may induce glomerular ECM production and glomerulosclerosis. Therefore, MGF and VEGF activation of Erk1/2 may contribute to progressive glomerulosclerosis and renal failure in CAN.

Microarray Analysis of Interstitial Fibrosis/Tubular Atrophy in Kidney Transplant Recipients Using Formalin-Fixed, Paraffin-Embedded Renal Biopsy Tissue Sanjeev Akkina,[1] Vishal K. Varma,[2] Michael J. Walsh,[2] Suman Setty.[2] *[1]Medicine/Nephrology, Univ of Illinois at Chicago, Chicago, IL; [2]Pathology, Univ of Illinois at Chicago, Chicago, IL.*

Background: Interstitial fibrosis/tubular atrophy (IFTA) is a common and complex cause of kidney transplant failure that is difficult to predict. Early identification of progressive IFTA (pIFTA) may lead to alternative therapies that may attenuate irreversible injury. In this study, we used formalin-fixed, paraffin-embedded (FFPE) renal biopsy specimens with microarrays to conduct differential gene expression studies to identify predictors of IFTA in kidney transplant recipients.

Methods: We identified 22 individuals with multiple protocol biopsies within the first 3 years after transplant. Glomeruli and blood vessels were removed using laser capture microdissection and the remaining tissue was used for mRNA extraction. Affymetrix Primeview arrays were prepared using standard protocols. IFTA was determined by using image masking in Histolab to quantify the cortical interstitial fraction. pIFTA was defined as a 0.5% absolute increase in the interstitial fraction per month between serial biopsies. Data analysis was conducted using R 3.0.2 and Bioconductor 2.22. Significance was defined as an unadjusted $p<5 \times 10^{-5}$.

Results: Of the 22 subjects in this study, 9 had pIFTA while the remaining 13 were considered stable IFTA (sIFTA). At baseline, the eGFR was 60.5 vs 58.5mL/min/1.73m2 (p=0.79) and log(Urine Albumin) was 3.44 vs. 3.17 (p=0.72) for the sIFTA and pIFTA groups, respectively. The baseline fibrosis was higher in the sIFTA group (18%) compared to the pIFTA group (13%, p=0.04). Using linear modeling, 3 of the top 6 differentially expressed probes at baseline were mapped to metaloothionein 1X and 2A. Paired analysis of serial biopsies did not reveal any significant differences between sIFTA and pIFTA.

Conclusions: Microarray analysis of FFPE specimens show that pIFTA is associated with the differential expression of multiple genes prior to phenotypic changes. Prospective investigation of these genes is needed to determine if these are predictive of pIFTA.

Pathological Analysis for Transplant Nephrectomy – 124 Consecutive Cases in a Single Center Study Over 10 Years Masaki Muramatsu,[1,2] Abigail Lee,[1] Atsushi Aikawa,[2] Carmelo Puliatti,[1] Muhammad M. Yaqoob,[1] Michael Sheaff.[1] *[1]Nephrology, Transplantation and Cellular Pathology, The Royal London Hospital, London, United Kingdom; [2]Nephrology, Toho Univ Faculty of Medicine, Tokyo, Japan.*

Background: Transplant nephrectomy (TNx) is performed for several indications. This study evaluates in depth histological analysis of TNx specimen.

Methods: We identified all cases at the Royal London Hospital between 2004 and 2014. The indication for TNx was divided into four groups: 47 cases with acute graft loss without significant blood flow (AGL); 44 cases of suspected ongoing rejection or graft intolerance syndrome (Rej/GIS); 24 cases with infection (INF); and 9 miscellaneous reasons (MIS). We examined the histological changes in detail and specifically looked at the artery, vein and ureter.

Results: AGL was less likely to have tubulointerstitial changes, but 74.5% had necrosis. In the AGL group, the majority of cases scored zero for t, i, ct and ci. Neutrophil rich arteritis at renal and small arteries was observed in 29.8% and 19.2%. Venous thrombosis was found in 61.7%. All cases in the Rej/GIS group showed ct3 and ci3 and 40.9% showed t3 and i3. Glomerulitis was observed in 52.3% and cg was detected in 75.1%. Arteritis of small and renal arteries was detected in 70.5% and 59.1%. C4d expression was present in 54.1%. Nearly 70% showed ureteric inflammation. Variable cellular infiltrate comprising of lymphocytes, plasma cells and eosinophil were seen in all cases. In the INF group, 66.7% (t1-3) and 79.2% (i1-3) were observed, and ct3 and ci3 were detected in 66.7%. Glomerulitis was rare although allograft nephropathy was detected in 62.5%. All cases had intimal thickening of small and renal arteries but arteritis was unusual. Lymphocyte and plasma cell were common at interstitium and ureter, but plasma cell, neutrophil and eosinophil rarely appeared at vascular lesions. In the MIS group, histological changes were minor.t3, i3, g1-3, arteritis and venulitis were not detected.

Conclusions: The histological changes were similar and specific within the TNx groups but different between the groups. A failed graft often showed substantial immunological response. In depth histological analysis may aid management of subsequent grafts.

MiRNAs as Novel Biomarkers for Transplanted Patient's Evolution Esperanza Macarena Rodriguez serrano,[1] Cristina Galeano,[2] Edurne Ramos,[1] Elisa Conde,[1] Laura Martín-Gómez,[1] Sara Gimenez-Moyano,[1] Maria Laura Garcia-Bermejo,[1] Fernando Liano.[2] *[1]Biomarkers and Therapeutic Targets Unit, IRYCIS; [2]Nephrology, Ramon y Cajal Hospital.*

Background: : Transplanted patients evolution and outcome is dependent on many factors including allograft function, vascular homeostasis and immunogenicity. Up to this moments, apart from creatinine renal biopsy, there are no quantifiable and accurate biomarkers to predict the evolution of the allograft and the receptor, what would enable clinicians to improve the transplanted patient's management. Our group has validated a combination of serum miRNAs as accurate biomarkers for AKI from ischemic aetiology, including: miR-127, miR-101, miR-210, miR-126, miR-146a, miR-26b, miR-29a, miR-10a, miR-93 and miR-27a. Here we have determine the expression of these miRNA in serum from kidney donors and receptors and correlate this expression with clinical parameters of allograft evolution, including ATN development, delayed graft function, rejection and vascular complications.

Methods: For this purpose, serum sample from brain death donors and receptors along pos-transplantation period (6h, 1,2,3,4,5, 6 and 7days and 1,3,6 months) in 30 transplanted patients form our Hospital. After RNA extraction from serum, the combination of miRNAs has been determined by qRT-PCR and correlation with clinical data has been established using SPSS.

Results: The expression of these 10 miRNAs in serum samples from donors did not exhibited significant differences among them. This combination neither correlate with immediate delay graft function because NTA or immunological rejection. However, some of the miRNAs correlate with long term evolution of transplanted patients in terms of non-optimal graft function and they also discriminate patients with also exhibited renal vascular alterations.

Conclusions: In summary we have identified miRNAs that correlates with long term evolution of transplanted patients. These information could be useful for improve transplanted patient management in the context of personalized patient handling.

Plasma MicroRNA 17 Host Gene Protein level Cluster and Tumor Necrosis Factor-Alpha (TNF-α) in Patients with Renal Transplantation: Relation to Allograft Function and Survival Hayam A. El Aggan,[1] Sabah Abdel Hady Mahmoud,[2] Mohamed Mohamed Saker.[1] *[1]Internal Medicine, Faculty of Medicine, Alexandria, Egypt; [2]Medical Biochemistry, Alexandria, Egypt.*

Background: Chronic allograft dysfunction (CAD) remains the leading cause of late graft loss after kidney transplantation. MicroRNAs (miR) are small (19-25 nucleotides) noncoding RNAs that regulate gene expression of diverse biological processes. The polycistronic miR-17~92 cluster is comprised of six miRs and its primary transcript may also encode for a polypeptide of 70 amino acids designated as the *miR-17 host gene* (*MIR17HG*) protein. So the aim of this work was to evaluate the plasma levels of *MIR17HG* protein,an index of miR-17~92 cluster activity, and the plasma level of tumor necrosis factor-alpha (TNF-α) in patients with renal transplantation in relation to renal allograft function and survival.

Methods: This study included 45 subjects; they were divided into three groups each 15, renal transplant patients with stable renal function (Group I), with CAD (Group II) and healthy subjects as controls (Group III). Quantitative determination of plasma levels of *MIR17HG* protein and TNF-α were performed using enzyme linked immunoassay (ELISA). Blood urea, serum creatinine and estimated glomerular filtration rate (eGFR), urinary albumin/urinary creatinine ratio and C-reactive protein (CRP) were done. Resistive index (RI) was calculated. Renal biopsy was done in patients with CAD.

Results: MIR17HG protein and TNF-alevels were significantly higher in renal transplant especially patients with CAD than the controls. In patients with renal transplantation MIR17HG protein and TNF-alevel were positively correlated with each other and with serum creatinine, urinary albumin/creatinine ratio and CRP and was negatively correlated with e-GFR. The degree of fibrosis in renal biopsy was positively correlated with MIR17HG protein, TNF-α levelsand RI ($P<0.05$).

Conclusions: MIR17HG Protein and TNF-alpha plasma levels can be served as circulating biomarkers for early detection of renal allograft dysfunction and follow up of patients with renal transplantation. They can act as a pro-fibrotic factor and denoting ongoing inflammation in the pathogenesis of CAD.

SA-PO988

Polymorphisms of IL17 and CXCL9 Genes, but Not AIF1 Gene, Affect Early Kidney Allograft Function After Transplantation Leszek Domanski, Karolina Kloda, Ewa Kwiatkowska, Kazimierz Ciechanowski. *Clinical Dept of Nephrology, Transplantology and Internal Medicine, Pomeranian Medical Univ in Szczecin, Szczecin, Poland.*

Background: Kidney transplantation outcome is determined by immunological and non-immunological factors, both the donor and the recipient dependent. There are reports suggesting that AIF1, IL17 and CXCL9 genes polymorphisms might influence the post-transplant immune response, and thus kidney function. Therefore the aim of this study was analysis of association between 8 AIF1, IL17 and CXC9 genes polymorphisms and creatinine concentrations up to 1 year after transplantation.

Methods: The study enrolled 269 Caucasian renal transplant recipients (165 males, 104 females, mean age 47.63 ± 12.96 years). Blood samples were collected for genetic analysis and creatinine concentrations evaluation 1, 3, 6, and 12 months after kidney transplantation. The analysis regarded rs2269475, rs2736182 and rs2259571 within AIF1 gene, rs2275913 within IL17A gene, rs2397084, rs11465553 and rs763780 within IL17F gene and rs3733236 within CXCL9 gene. Genotyping was performed using RT-PCR and PCR-RFLP methods.

Results: Creatinine concentrations 1, 3, 6 and 12 months after transplantation differed between the rs2275913 within IL17A gene promoter polymorphism genotypes and were higher among GG homozygotes (GG vs. GA+AA p=0.03, p=0.08, p=0.06 and p=0.03 respectively). In regard to rs2397084 IL17F gene polymorphism, creatinine concentrations differed between the genotypes 1, 2 and 6 months after transplantation and were higher among TT homozygotes (TT vs. CC p=0.02, p=0.02 and p=0.09 respectively). Creatinine concentrations 3, 6 and 12 months after transplantation differed between the rs3733236 CXCL9 gene polymorphism genotypes and were higher among GG homozygotes (GG vs. GA +AA p=0.07, p=0.048 and p=0.02 respectively). There were no significant differences between the studied AIF1 gene polymorphisms genotypes.

Conclusions: Polymorphisms of IL17 and CXCL9 genes, but not AIF1 gene, affect early kidney function after transplantation. These preliminary results indicate that there is a need of genome-wide association studies scoping on genes implicated in the immune response after transplantation.

SA-PO989

Urinary K Cadherin Predicts Renal Allograft Dysfunction Seema Jain,[1] Ekram Nabi,[1] Sharirose Abat,[2] Rajeshwar Ramkhelawon,[2] Sarah Yates,[1] Iain Macphee,[2] Mysore K. Phanish,[1] Mark E. Dockrell.[1] *[1]South West Thames Inst for Renal Research, Epsom and St Helier NHS Trust, London, United Kingdom; [2]St. George's Univ NHS Trust, United Kingdom.*

Background: Renal transplantation is currently the optimal form of renal replacement therapy, however graft attrition remains a problem. Current non-invasive detection methods are insensitive and irreversible damage has often occurred at the time of detection. This study investigates the relationship between urinary Albumin (Alb), Retinal Binding Protein (RBP), N-Acetyl-β-D-glucosaminidase (NAG) activity and a novel marker, K cadherin (KCAD), and graft dysfunction 12 months after implantation.

Methods: 62 renal transplant recipients were recruited into a prospective longitudinal study. Urine was collected 3 months after transplantation. Decline in graft function was defined as a greater than 5ml/min/1.73m^2 fall in eGFR from 3 to 12 months after transplantation. Urine was analysed for NAG by enzymatic colorimetric assay, KCAD and RBP by in-house ELISA and Alb by immunoturbidimetry. Values were expressed after indexing for urinary creatinine concentration. Statistics were performed using GraphPad Prism 6 Linear regression analysis.

Results: 18% of patients had a decline in graft function. Of these, 64% tested positive for significant albuminuria (ACR>3mg/mmol), 73% for RBP, 100% for NAG and 45% for KCAD. Further analysis showed that NAG, RBP and Alb had high sensitivity but low specificity. KCAD had a sensitivity of 0.46 and a specificity of 0.75. All markers correlated positively with a decline in eGFR. However, KCAD had the strongest correlation (R^2=0.2), compared with Alb (R^2=0.17), NAG (R^2=0.05) and RBP (R^2=0.01).

Conclusions: This cohort study demonstrates that, when compared to conventional markers Alb, RBP and NAG, the novel marker KCAD has a higher specificity and correlation with patients who lose graft function after one year. The presence of the proximal tubule cadherin in the urine may be a prognostic indicator for patients who go on to develop chronic allograft dysfunction, and may occur due to the excretion of KCAD by proximal tubules in response to fibrogenic stimuli. Further analysis is required to evaluate this.

SA-PO990

Detection of Endothelial Cell Specific Molecule-1 According to Allograft Status After Kidney Transplantation Se Yun Kim,[1] Kyung-Hwan Jeong,[2] Yu Ho Lee,[1] Tae Won Lee,[2] Chun-Gyoo Ihm,[2] Shin Yeong Lee,[2] Yang Gyun Kim,[1] Sang Ho Lee,[1] Da Wun Jeong,[1] Ju-Young Moon.[1] *[1]Kyung Hee Univ Hospital at Gangdong; [2]Kyung Hee Univ Hospital.*

Background: To investigate whether urine and plasma Endothelial Cell Specific Molecule-1 (ESM-1) level could differentiate rejection from non-rejection in kidney transplantation (KTP) recipients, we compared ESM-1 levels according to allograft status.

Methods: We measured plasma and urine ESM-1 in 77 patients with underwent KTP. The concentration of ESM-1 was analyzed by enzyme linked immunosorbent assay (ELISA). According to allograft status, Groups are divided stable, long-term good survival, immune tolerance, acute cellular rejection (ACR), acute antibody-mediated rejection (AMR) and chronic AMR.

Results: Plasma ESM-1 was not significantly different between all groups according to allograft status (p=.424). Whereas, urine ESM-1 was significantly different between groups according to allograft status (p<.001). Urine ESM-1 was higher in both ACR and acute AMR as well as chronic AMR than stable status. Patients with acute AMR showed significant higher level of urine ESM-1 compared with patients with ACR (p<.05). Area under the curve (AUC) for differentiating acute AMR from ACR was 0.744 (p=0.01).

Conclusions: Urine ESM-1 may reflect endothelial injury of allograft and it could be used to differentiate the patient with acute AMR from ACR.

SA-PO991

Noninvasive Diagnostic and Predictive Value in Renal Transplant Recipients by Measurement of Urine BCA-1 Dajin Chen. *Kidney Disease Center, The First Affiliated Hospital, College of Medicine, Zhejiang Univ, P.R.China.*

Background: To investigate the relationship between early-stage renal acute rejection and the level of BCA-1 in urine, explore the diagnostic value and noninvasive monitoring in early stage after transplantation by measurement of urine BCA-1.

Methods: 145 patients were enrolled between January 2006 and October 2009., including 49 with biopsy-proved acute rejection, 58 patients with stable renal function and no abnormal histological findings, 9 patients with biopsy-proven acute tubular necrosis and 29 patients with biopsy-proven chronic allograft nephropathy. Additionally, urinary samples were also collected from 40 healthy controls. Urinary concentration of BCA-1 was determined by an enzyme-linked immunosorbent assay technique in 145 renal allograft recipients and 40 healthy controls.

Results: Patient with acute rejection excreted urinary BCA-1 at a significantly higher level (8.1±2.1, 95%CI: 3.9-12.4 pg/μmol creatine) than levels of patients with No-AR and healthy controls (P<0.001). Patients with acute tubular necrosis excreted urinary BCA-1 at a significantly lower level(2.52±0.57, 95%CI: 1.21-3.84pg/μmol creatinine)than levels of patients with acute rejection. ROC curve was constructed to determine the discriminatory power of BCA-1 levels for diagnosis of acute rejection. The area under ROC curve was 0.881 (95%CI: 0.811-0.951), at a cut point of 0.23 pg/μmol creatine, the sensitivity was 81.6% and the specificity was 87.9% (P<0.001). Patients with acute humoral rejection had significantly higher urinary BCA-1 concentration than patients with acute celluar rejection (24.2±6.68, 95%CI: 9.5-38.9pg/μmol creatinine vs 2.91±0.65, 95%CI: 1.6-4.22 pg/μmol creatinine, P=0.0002).ROC curve was constructed to determine the discriminatory power of BCA-1 levels for diagnosis of acute humoral rejection. The area under ROC curve was 0.867 (95%CI: 0.725-1.005),at a cut point of 8.3 pg/μmol creatine, the sensitivity was 75% and the specificity was 91.9%.

Conclusions: The monitoring of BCA-1 in urine may be a new and noninvasive approach for detection acute rejection as well as useful to discriminate the type of rejection.

SA-PO992

B Cell Attracting Chemokine 1 in Urine Is a Biomarker of Acute Humoral Rejection Wenhan Peng, Jianghua Chen. *Kidney Disease Center, The First Affiliated Hospital, College of Medicine, Zhejiang Univ, Hangzhou, Zhejiang, China.*

Background: Presently, there are no noninvasive approaches which can be directly applied to clinical diagnosis of acute rejection (AR) or distinguish type of rejection in renal transplant recipients. The aim of this study was to construct diagnostic models of biomarkers in urine of patients with ARor acute humoral rejection (AHR) in renal transplant recipients.

Methods: Concentration of nine biomarkers in urine of 81 patients with AR and 167 patients with stable renal function (No-AR) was determined by ELISA technique. Firstly, by discriminant analysis, we screened a number of biomarkersto construct the diagnostic models for AR and AHR. Secondly, another 102 patients with No-AR and AR were analysed to test the accuracy of the diagnostic model.

Results: Four biomarkers were selected to set up the diagnostic model of AR.or No-AR. Based on the model of AR, 84.3% patients were correctly diagnosed. Two biomarkers were selected to set up the complementary diagnostic model of AR. Based on the two model of AR, 100% patients with No-AR and 96.3% patients with AR were correctly diagnosed. Only B cell attracting chemokine 1 (BCA-1) was selected for the diagnostic modelfor AHR or acute cellular rejection (ACR). Rejection type of 81.5% patients with AR were correctly classfied.Another 102 patients tested the accuracy of the diagnostic models. Diagnostic accuracy of AR or No-AR and AHR or ACR were 100% and 95.4% respectively.

Conclusions: Urinary BCA-1 was a valuable biomarker for determining AHR. These diagnostic models might directly identified AR and types of AR.

Funding: Government Support - Non-U.S.

^{18}FDG-PET/CT Imaging in Suspected Acute Renal Allograft Rejection Pierre Lovinfosse,[2] Laurent E. Weekers,[1] Catherine Bonvoisin,[1] Christophe Bovy,[1] Stéphanie M.j.g. Grosch,[1] Jean-marie H. Krzesinski,[1] Roland Hustinx,[2] Francois Jouret.[1] *[1]Nephrology, Univ of Liege Hospital, Liege, Belgium; [2]Nuclear Medicine, Univ of Liege Hospital, Liege, Belgium.*

Background: The diagnosis procedure for kidney transplant recipients (KTR) with suspected acute rejection (AR) relies on needle biopsy. Still, noninvasive tests to predict nonrejection would be useful to save selected patients from undergoing inessential biopsy. AR is associated with a recruitment of activated leukocytes into the transplant, which are characterized by a high metabolic activity and an increased uptake of glucose analog, ^{18}Fluoro-deoxy-glucose (^{18}FDG). Thus, ^{18}FDG-Positron emission tomography coupled with computed tomography (PET/CT) may help noninvasively distinguish nonrejection from AR.

Methods: From January 2013 to February 2015, we prospectively performed 32 ^{18}FDG-PET/CT in 31 adult KTR with suspected AR who underwent a biopsy. Biopsies were categorized as "normal", "borderline", "AR" or "others" according to Banff classification. PET/CT imaging was performed within 201 ± 18 minutes after i.v. administration of 3.2 ± 0.2 MBq/kg of ^{18}FDG, before any modification of immunosuppression. The mean standard uptake values (SUV) of both upper and lower renal poles were measured, with no threshold activity.

Results: Biopsies were diagnosed as "normal", "borderline", "AR" or "others" in 8, 10, 8 and 6 (including 3 polyoma-BK néphropathies) cases. AR was antibody-mediated in 1 case, whereas Type I, II and III cellular AR were found in 5, 1 and 1 cases, respectively. Mean SUV reached 1.5 ± 0.2, 1.6 ± 0.3, 2.9 ± 0.8, 2.2 ± 1.2 in each category. Mean SUV of biopsy-proven AR was significantly higher than "normal" cases ($p<0.01$). No difference was found between "normal" vs. "borderline", or between "AR" vs. "others" histopathology. Still, a positive correlation between mean SUV and acute composite (g+i+t+v+ptc) Banff score was found, with a coefficient of 0.70 ($p<0.001$). Sensitivity and specificity of ^{18}FDG-PET/CT in detecting pathological biospies were respectively 92.3 and 36.8, with a mean SUV threshold at 1.4.

Conclusions: ^{18}FDG-PET/CT imaging may help discriminate nonrejection, thereby avoiding unnecessary transplant biopsy in KTR with suspected AR.

High Remnant-Like Particle-Cholesterol Is a Risk Factor of Worsening Graft Function in Japanese Kidney Transplant Recipients Makoto Tsujita. *Transplant Surgery, Nagoya Daini Red Cross Hospital, Japan.*

Background: Many factors cause dyslipidemia after kidney transplantation.Low density lipoprotein cholesterol (LDL-C) has been focused to reduce cardiovasucular disease(CVD),but residual risk factors such as triglyceride(TG), remnants or small dense LDL-C are also important to reduce CVD. We investigated whether residual risk factors affected graft function in kidney transplant recipients.

Methods: This study is a retrospective cohort study at a single center. Three hundred and seventy seven kidney transplant recipients (male 223) in more than six months after transplantation were enrolled. TG, Remnant-like particle-cholesterol (RLP-C), non-high density lipoprotein cholesterol(HDL-C), LDL-C/apoB, eGFR(estimated glomerular filtration rate), Urine protein /day (UP), Body Mass Index (BMI) and other parameters at baseline were measured and we studied the association of residual risk factors with kidney fuction. DeGFR meant the difference between eGFR at baseline and eGFR 1year after enrollement (eGFR 1y).Data are shown as n(%), mean (SD) or median (interquartile).

Results: Patients' characteristics of this study is shown.

Figure 1.

Patients' characteristics of this study (n=377)	
Age (years)	51.0 (13.2)
Gender (male) (n)	223 (59.1%)
Vintage after transplantation (months)	45.0 (24.0, 81.5)
Systoric BP (mmHg)	124.4 (12.1)
DMN (n)	39 (10.3%)
BMI (%)	21,9 (3.79)
Hb(g/dl)	12.6 (1.4)
cCa (mg/dl)	9.6 (0.5)
IP (mg/dl)	3.3 (0.6)
iPTH (pg/ml)	105.7 (73.8)
T-cho (mg/dl)	187.5 (31.0)
HDL-C (mg/dl)	63.5 (18.2)
non HDL-C (mg/dl)	124.0 (24.6)
TG (mg/dl)	117.3 (57.2)
LDL-C (mg/dl)	100.5 (23.0)
RLP-C (mg/dl)	5.0 (2.4)
Apo B (ug/ml)	78.5 (15.2)
LDL-C/ApoB	1.3 (0.2)
eGFR at baseline (ml/min/1.73m2)	41.6 (12.2)
eGFR 1y (ml/min/1.73m2)	41.9 (12.5)
Urine protein (g/day)	0.1 (0.3)
Cycrosporine use (n)	263 (69.8%)
Tacrolimus use (n)	107 (28.4%)
statin use (n)	204 (54.1%)
ARB use (n)	199 (52.8%)
β blocker use (n)	49 (13.0%)

Mean age (years) was 51.0 (13.2), median vintage after kidney transplantation (months) was 45.0 (24.0, 81.5), and mean BMI (kg/m^2)was 21.9 (3.79). DeGFR were associated with age ($r=0.12$, $p=0.02$), BMI ($r=0.12$, $p=0.02$), TG ($r=0.12$, $p<0.001$), UP ($r=0.15$, $p=0.004$), RLP-C ($r=0.21$, $p<0.001$). Multivariate analysis showed that High RLP-C was the associated with worsening graft function.

Conclusions: High RLP-C is a risk factor of worsening graft function in Japanese kidney transplant recipients.

SA-PO995

The Modification of Erythrocyte Membrane Fatty Acid Contents According to Kidney Transplantation: Prospective Study Young Ki Son,[1] Sung Hyun Son,[2] Dongyeol Lee,[3] Hansae Kim,[3] Eu Gene Jeong,[1] Su Mi Lee,[1] Yun Jung Oh,[4] Won Suk An,[1] Seong Eun Kim.[1] *[1]Dept of Internal Medicine, Dong-A Univ Hospital, Busan, Republic of Korea; [2]Dept of Internal Medicine, BHS Han Seo Hospital, Busan, Republic of Korea; [3]Dept of Internal Medicine, Bong Seng Memorial Hospital, Busan, Republic of Korea; [4]Dept of Internal Medicine, Cheju Halla General Hospital, Cheju, Republic of Korea.*

Background: Modifications of erythrocyte membrane fatty acid (FA) contents may effect on cellular function or transmembrane receptors. The high erythrocyte membrane oleic acid contents are related with acute coronary syndrome. It is known that kidney transplanted recipients have lower cardiovascular event than dialysis patients. Therefore, we prospectively evaluated whether erythrocyte membrane FA contents were modified after kidney transplantation (KTP).

Methods: We recruited 22 kidney transplanted recipients from September 2011 through May 2014. Blood samples were obtained just before KTP and at 6 months after KTP. The erythrocyte membrane fatty acid contents were measured by gas chromatography.

Results: The mean ages were 45.3±10.9 years. The erythrocyte membrane contents of omega-3 FA (10.1±3.9 vs. 5.5±3.63, $p<0.001$), omega-6 FA (26.6±6.2 vs. 20.7±7.7, p=0008), arachidonic acid (11.6±4.1 vs. 7.7±4.7, p=0.001), eicosapentaenoic acid (1.4±0.7 vs. 0.7±0.5, $p<0.001$), docosahexaenoic acid (2.0±0.8 vs. 1.2±1.0, p=0.001), omega-3 index (7.9±3.2 vs. 4.1±2.7, $p<0.001$) were significantly higher but erythrocyte membrane contents of total saturated FAs (44.9±8.0 vs. 52.6±9.4, p=0.003), total monounsaturated FAs (17.2±1.6 vs. 19.9±2.2, $p<0.001$), total trans FAs (0.9±0.3 vs 1.1±0.2, p=0.011), oleic acid (15.7±1.5 vs. 18.0±1.9, $p<0.001$), and omega-6/omega-3 ratio (3.1±1.4 vs. 4.6±1.7, p=0.14) were significantly lower at 6 months after KTP.

Conclusions: FA contents of erythrocyte membranes including increased omega-3 FAs, decreased oleic acid and omega-6/omega-3 were significantly modified after KTP. These changes of erythrocyte membrane FA contents may effect on lower cardiovascular event rate in kidney transplanted recipients compared to dialysis patients and further studies are necessary to confirm these effects.

SA-PO996

Diffusion Impairment Measured by Functional MRI Correlates with Allograft Fibrosis After Kidney Transplantation in Patients with Delayed Graft Function Jan H. Braesen,[1] Abedalrazag Ahmad Khalifa,[1] Faikah Gueler,[2] Frank Lehner,[4] Wilfried Gwinner,[2] Dagmar Hartung,[3] Hermann G. Haller,[2] Katja Hueper.[3] *[1]Inst for Pathology, Hannover Medical School, Hannover, Germany; [2]Clinic for Nephrology, Hannover Medical School, Hannover; [3]Inst for Diagnostic and Interventional Radiology, Hannover Medical School, Hannover; [4]Clinic for General, Abdominal and Transplant Surgery, Hannover Medical School, Hannover, Germany.*

Background: Functional MRI parameters derived from diffusion weighted (DWI) and diffusion tensor imaging (DTI) correlate with renal fibrosis and cell infiltration in experimental studies. Aim of this study was to investigate these non-invasive techniques in patients with delayed graft function (DGF) and to correlate diffusion parameters with renal function and renal histology of allograft biopsies.

Methods: 33 patients with initial graft function between day 4 and 11 after kidney transplantation and 31 patients with DGF were examined on a 1.5 Tesla MRI. DTI and DWI sequences were acquired and apparent diffusion coefficient (ADC) and fractional anisotropy (FA) were calculated. Kidney biopsies were available in 26 patients and analysed for acute rejection (Banff), amount of fibrosis, inflammatory infiltrates, and tubular injury as well as edema.

Results: ADC was significantly reduced in patients with DGF compared to patients with initial function. Similarly, FA, representing the degree of directed diffusion along anatomical structures such as tubules, collecting ducts and vessels, was impaired in DGF patients. ADC and FA positively correlated with renal function (r=0.573 and r=0.53, p<0.001) and negatively with the amount of renal fibrosis. Diffusion parameters in DGF patients did not discriminate between acute rejection and tubular injury. Histological evaluation of the allograft biopsies did not reveal any significant differences between DGF or initial function in the following parameters: leukocyte infiltration (CD4, CD8, CD15, CD20, CD68), CD31 pos. peritubular capillaries or edema (intertubular distance).

Conclusions: Functional MRI with diffusion techniques detects allograft dysfunction early after kidney transplantation correlating with allograft fibrosis. Biopsy is needed to verify rejection.

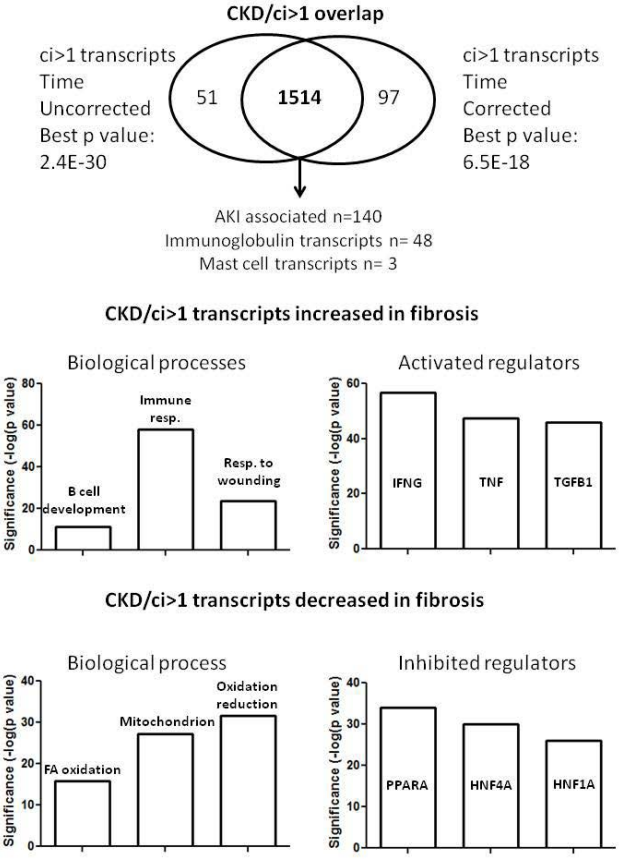
Identification of Common Biological Mechanisms of Fibrosis in Transplanted and Native Kidneys with Chronic Diseases Konrad S. Famulski, Jeffery M. Venner, Jeff Reeve, Philip F. Halloran. *Univ of Alberta, Edmonton, AB, Canada.*

Background: In both primary kidney diseases and in transplants fibrosis is caused by chronic progressive diseases. Hence, we hypothesised that fibrosis has fundamental common biological pathways in native and transplanted kidneys.

Methods: We studied the molecular associations with fibrosis in 703 kidney transplant indication biopsies (bx) 3 days to 35 years post-transplant. The number of bx with fibrosis increased with time post-transplant and most bx with ci>1 (74%) were attributable to time-dependent diseases (ABMR, GN, TG).

Results: By microarrays we compared bx with ci>1 to those with little or no fibrosis (ci£1) and determined the association strength of transcripts (p-value) for ci>1. First we focused on transcripts previously associated with fibrosis: immunoglobulin, mast cells and AKI-associated transcripts. Strongest associations with ci>1 were for immunoglobulin and mast cell transcripts, but not for AKI transcripts. Because time of bx post-transplant is highly correlated with ci, we repeated the comparison of ci>1 vs. ci£1 after correcting for time. This resulted in a massive reduction in association strength for the immunoglobulin and mast cell transcripts (from 10e-27 to 10e-9). However, AKI transcripts were now more strongly associated with fibrosis (from 10e-9 to 10e-18). Thus time correction emphasised the injury-repair response at expense of inflammation. We then analyzed the fibrosis associated transcripts in native kidneys (CKD). 73% of CKD transcripts overlapped with our transcripts.



Ci>1/CKD overlap overrepresented pathways related to immunity, response to wounding and energy metabolism (Figure 1).

Conclusions: Fibrosis in transplants and native CKD is characterized by the same inflammatory compartment, response to injury and loss of metabolism. Some of these processes might be related to the duration of chronic disease.

SA-PO998

DNA Double Strand Breaks Induced Collagen Type VI Secretion of Glomerular Endothelial Cells in Renal Allografts Yuki Matsui, Norifumi Hayashi, Junko Imura, Keiji Fujimoto, Hiroki Adachi, Hideki Yamaya, Hitoshi Yokoyama. *Nephrology, Kanazawa Medical Univ, Uchinada, Japan.*

Background: The relationship between DNA injury and glomerular fibrosis in renal allografts remains unclear.

Methods: We examined renal allograft specimens from 35 patients in which DNA double-strand breaks and glomerular fibrosis were detected by phospho-histone H2A.X (γ-H2AX) expression and collagen (COL) types III, IV, and VI accumulation. We also examined the in vitro relationship between DNA damage and COL accumulation by mitomycin C (MMc)-induced DNA damage in human glomerular endothelial cells (HRGEc).

Results: The γ-H2AX and COL type VI, which mainly accumulated in the subendothelial and mesangial regions, were positively correlated with the duration of the post-renal transplant (RT) period (r=0.691, p<0.01; r=0.760 p<0.01, respectively). In multiple regression analysis, the duration of the post-RT period and cg in the Banff'07 classification were identified as significant predictors of COL type VI accumulation (β value=0.699 p<0.001; 5.558, p=0.035, respectively) and γ-H2AX expression in the glomerular capillaries (β value 0.700,p<0.001; 2.031, p=0.011, respectively). In addition, the γ-H2AX-positive area was also identified as a predictor of glomerular accumulation of COL type VI (β value=0.439, p=0.028). In the immunochemistry examination, γ-H2AX was detected in most cells after 24 hours' MMc treatment, whereas no γ-H2AX expression had been detected before the MMc treatment. Although COL type VI was detected around the nuclei of the HRGEc before the MMc treatment, it was not present there after the MMc treatment. COL type VI was detected in the cytoplasm of the HRGEc, which was secreted into the supernatant after MMc stimulation with γ-H2AX expression. The number of γ-H2AX (-)/COL type VI (+) cells was inversely associated with the number of γ-H2AX (+) /COL type VI (-) cells (r=-0.655, p<0.001) during 24 hours' MMc treatment.

Conclusions: Our findings suggested that over the long term RT may induce DNA double-strand breaks and HRGEc-secreted COL type VI accumulation in the glomerular capillaries, which might progress to intractable glomerular fibrosis.

SA-PO999

Imatinib Improves Interstitial Fibrosis in Deceased Donor Kidney Transplant: A Case Report Ignatius Yun-Sang Tang,[1] Andres M. Acosta,[2] Vishal K. Varma,[2] Suman Setty.[2] *[1]Medicine, Univ of Illinois at Chicago, Chicago, IL; [2]Pathology, Univ of Illinois at Chicago, Chicago, IL.*

Background: Imatinib (IM) is an oral inhibitor of tyrosine kinases. Early short term PDGF inhibition with IM had been shown to prevent interstitial fibrosis and tubular atrophy in pre-clinical kidney transplantation (KT). We assess the effect of long term IM therapy on renal allograft histology in a KT recipient who received IM for gastrointestinal stromal tumor (GIST).

Methods: Patient is a 47 year old female with ESRD due to hypertension, s/p living donor KT in 2007 which failed in 2010. She was then resumed on hemodialysis. A gastric mucosal mass was discovered incidentally in 5/2012. Fine needle aspiration showed c-KIT positive spindle cells consistent with GIST. Patient received deceased donor KT in 7/2012 with Thymoglobulin induction. Maintenance immunosuppression included tacrolimus and mycophenolic acid. Patient was started on IM 100mg daily on day 19 post-KT because of GIST. Post-KT course was complicated by biopsy proven acute tubular necrosis, requiring dialysis in the first month post-KT. Serum creatinine (CR) improved to 1.6mg/dl by 3 months post-KT when she underwent partial gastrectomy. Pathology showed low grade GIST (low mitotic count and low Ki67 labeling index). Surveillance KT biopsy was performed at 6 months, 1 and 2 years post-KT. We compared the 6-month and the 2-year post-KT biopsies for the presence of renal cortical interstitial fibrosis using the Histolab software (Microvision Instruments, France). The core sections stained with Masson trichrome were scanned at high-resolution, and divided into individual images at 200X for quantitative analysis. The software program was then run to quantify fibrosis of the selected areas.

Results: The cortical fibrosis percentage was 20.17% for the 6-month biopsy and 14.35% for the 2-year biopsy. The corresponding serum CR was 1.52mg/dl and 1.17mg/dl, respectively. Trough tacrolimus levels were maintained between 5 and 7ng/ml.

Conclusions: Long term low dose IM reduced cortical interstitial fibrosis in deceased donor KT. The role of long term IM in the prevention of interstitial fibrosis in renal allograft warrants further studies.

SA-PO1000

Factors Associated with Referral, Evaluation and Listing for Kidney Transplant: A Survey of Dialysis Patients Eric Chang, Ming Wang, Fareeha Khalil, Naman Trivedi, Nasrollah Ghahramani. *Penn State Univ College of Medicine, Hershey, PA.*

Background: Kidney transplant (KT) is the treatment of choice for most patients with end stage renal disease (ESRD). Disparities in referral, evaluation, listing and transplantation have been documented. We studied factors associated with the likelihood of referral, evaluation and listing for KT.

Methods: We sent flyers to 1,283 dialysis units. Of 2536 interested participants who fulfilled inclusion criteria, we randomly selected and invited 1400 to complete the questionnaire. Independent variables were demographic factors, location, and modes of education about KT. In multivariate analysis, we calculated odds ratios (OR) and 95% confidence intervals (CI) for the probability of referral, evaluation and listing for KT.

Results: Of 673 participants, 401 had been referred, 361 had been evaluated and 201 were listed. Having received 3 or more modes of education about KT was associated with higher likelihood of referral (OR:5.03;CI:2.76-9.18), evaluation (OR:5.67;CI:3.23-9.96) and listing (OR:2.70;CI:1.43-4.18). Having attended a pre-ESRD class was associated with higher likelihood of referral (OR:2.20;CI:1.44-3.35) and evaluation (OR:2.47;CI:1.63-3.74). If the nephrologist had discussed the option of KT at least twice in previous year there was higher likelihood of referral (OR:2.19;CI:1.44-3.33), evaluation (OR:1.67;CI:1.10-2.53) and listing (OR:1.83;CI:1.19-2.80). A transplant center within 10 miles was associated with higher likelihood of referral (OR:1.64;CI:1.09-2.66) and listing (OR:2.17; CI:1.32-3.57). Age > 60 was associated with lower likelihood of referral (OR:0.51;CI:0.33-0.79), evaluation (OR:0.46;CI:0.30-0.72) and listing (OR:0.28;CI:0.17-0.45).

Conclusions: Many factors influence the decision about KT; a process that begins with referral. Though difficult to change, proximity to a transplant center unsurprisingly improves chances for KT evaluation. Emphasis on educating patients > 60 may improve referral and evaluation. In this study, the quantity and diversity of educational modalities are the most important contributors to the referral, evaluation and subsequent listing.

SA-PO1001

Patient Navigation Program in Kidney Transplant Evaluation: A Randomized Study Mohua Basu, Dawn L. Fletcher, Lisa Petgrave-nelson, Rachel E. Patzer. *Emory Univ, Atlanta, GA.*

Background: We developed a patient navigation program in a kidney transplantation (KTx) clinic to improve KTx evaluation completion for patients deemed "high-risk" of not being placed on the KTx waiting list, based on known disparities in completion of KTx evaluation. We examined whether the addition of patient navigation to standard care was associated with a decrease in the number of days from a patient's referral for KTx evaluation to KTx candidacy decision.

Methods: During evaluation scheduling at a single KTx center, patients answered questions from a risk assessment tool created using existing data; high-risk patients were randomized prior to KTx evaluation to either standard of care (control) or the additional assistance of a patient navigator (intervention). The patient navigator helped guide patients through the KTx process, serving as a point of contact and providing support and education from the time of referral for KTx evaluation through candidacy decision (patient approved for placement on waiting list or deemed "not a candidate").

Results: From January 2013 to October 2014, 394 patients were enrolled in the study. Patient demographics were similar among intervention and control groups (80% Black, 80% Medicare, 50% < age 55). A total of 311 (79%) reached candidacy decision (79% of intervention and 79% of control patients) and were included in preliminary analyses. Intervention patients reached candidacy decision a median of 8 days faster than control patients (119 vs. 127 days). Shorter time to decision for intervention vs. control patients was observed in most examined subgroups, including black (8 days) and white patients (9 days), patients who completed high school (10 days), Medicare patients (15 days), patients with BMI>35 (30 days), married (11 days) and single patients (7 days), and patients < age 55 (19 days).

Conclusions: Preliminary results support the efficacy of a patient navigation program in reducing time from patient KTx referral to candidacy decision in a KTx setting. The use of a similar program in other KTx centers may help patients who require additional assistance during the KTx process complete KTx evaluation more quickly.

Knowledge of Treatment Options in Patients Evaluated for Kidney Transplantation: iChoose Kidney Randomized Trial Mohua Basu,[1] Stephen O. Pastan,[1] Sumit Mohan,[2] John J. Friedewald,[3] Daniela P. Ladner,[3] Rachel E. Patzer.[1] *[1]Emory Univ, Atlanta, GA; [2]Columbia Univ, New York, NY; [3]Northwestern Univ, Chicago, IL.*

Background: Although kidney transplantation (KTx) provides a significant survival advantage over long-term dialysis, many end stage renal disease (ESRD) patients are not educated about KTx options. We developed a clinical decision tool (iChoose Kidney) to provide individualized risk estimates of patient survival on dialysis vs. KTx to evaluate whether use of the decision tool during KTx evaluation improved patient knowledge of the survival benefit of KTx vs. dialysis and of living vs. deceased donor KTx.

Methods: In December 2014, we began enrolling patients from three large KTx centers across the U.S. in a trial, where patients are randomized to usual KTx evaluation (control) or an appointment during which the nephrologist uses iChoose Kidney with the patient (intervention). Pre- and post-nephrology consultation, we surveyed patients on whether they believed their chance of survival was higher, lower, or the same with 1) dialysis vs. KTx and 2) living vs. deceased donor KTx. Improvement in knowledge was defined as a change from incorrect to correct post-nephrology consultation. Health literacy was measured using the Newest Vital Sign and categorized into low/moderate vs. high (0-3 vs. 4-6 correct out of 6, respectively).

Results: To date, 214 patients are enrolled (target enrollment n=450). Among 106 intervention patients, 29% improved their knowledge of the survival benefit of dialysis vs. KTx, vs. 19% of 108 control patients (p=0.07). Among patients with low or moderate literacy, 35% of intervention patients improved vs. 13% of control patients (p=0.01); this difference was not observed among high literacy patients (26% improved in each group). For knowledge of the survival benefit of living vs. deceased donor KTx, 19% of intervention patients improved, vs. 11% of control patients (p=0.17).

Conclusions: Preliminary results show that the use of the iChoose Kidney decision tool in comparing survival estimates for dialysis vs. KTx may improve patient knowledge of treatment outcomes during KTx evaluation, and the tool may be especially effective among a low-literacy population.

Hemodialysis Social Networks Facilitate the Completion of Transplant Testing and Successful Kidney Transplantation Avrum Gillespie,[1,3] Alexey Uversky,[2] Jonathan T. Hunt,[1] Heather Marie Traino,[3] Sarah Bauerle Bass,[3] Teri Browne,[4] Zoran Obradovic.[2] *[1]Nephrology, Hypertension, and Kidney Transplantation, Temple Univ School of Medicine, Philadelphia, PA; [2]Center for Biomedical Informatics, Temple Univ, Philadelphia, PA; [3]School of Public Health, Temple Univ, Philadelphia, PA; [4]School of Social Work, Univ of South Carolina, Columbia, SC.*

Background: Hemodialysis (HD) social networks may promote access to a kidney transplant (KT). We set out to observe the formation of HD social networks and their role in completing the steps of the transplantation process in a newly formed HD clinic.

Methods: Between 8/2012 - 2/2015, 46 patients admitted to a newly formed HD clinic were enrolled, 63% were new to HD. Patients spoke either English (78%) or Spanish (22%). All eligible patients were referred for transplant evaluation and testing. Progression of steps towards KT was tracked. Patients were surveyed on admission and then quarterly using a previously validated questionnaire. Social interactions and seating were recorded, this data was merged with survey data and analyzed in SPSS 21.

Results: Two thirds of patients were observed to participate in social networks. There were no demographic differences among the patients who participated in social networks "social" vs. those who didn't "non-social". More social patients wanted a KT, 100% vs 73.3% (p=0.008). Social patients reported talking to other patients about their health or KT 64.5% vs. 6.7% (p < 0.001). Social patients completed more steps, 2 steps (range 0-6) including 7 transplants vs 0.5 steps (range 0-3) and no transplants in the "non-social" group (p=0.037). In a multivariate regression analysis, only participating in a social network was positively associated with completing more steps (β 1.44 p = 0.028), and vintage was negatively associated (β -0.973, p= 0.029).

Conclusions: In this HD clinic, patients that formed and participated in social networks were more likely to complete the steps and receive a kidney transplant. These findings emphasize the importance of HD social networks and the transfer of health information among patients.

SA-PO1004

Kidney Transplant Referral Among Incident Georgia Dialysis Patients with and without Systemic Lupus Erythematosus: The RaDIANT Community Study Laura Plantinga, Rachel E. Patzer, Sung S. Lim, Cristina Drenkard, Stephen O. Pastan. *Emory Univ, Atlanta, GA.*

Background: Although providers often wait to transplant patients with systemic lupus erythematosus (SLE), shorter overall times to transplant are generally associated with more favorable transplant outcomes in SLE patients. We examined whether referral for evaluation—the first step in the often years-long process of kidney transplantation—is delayed in dialysis patients with SLE, relative to other dialysis patients.

Methods: United States Renal Data System data on a cohort of 18,419 incident (1/1/05-9/30/12) adult (18-69 years) dialysis patients were linked to concurrent referral data from all three Georgia adult transplant centers. SLE was defined by the provider-assigned cause of ESRD. Logistic regression and Cox proportional hazards models were used to examine the associations of assigned cause and patient characteristics with preemptive referral (referral prior to the start of dialysis) and time from start of dialysis to referral [censored for death or last date of follow-up (9/30/12)], respectively.

Results: Of the 352 dialysis patients with SLE, 43 (12.2%) were preemptively referred—50% more often than other ESRD patients [1573/18,067 (8.7%); OR=1.5 (95% CI, 1.1-2.1)]. Adjustment for age rendered this association null [OR=1.1 (95% CI, 0.8-1.6)]. Among the 17,293 dialysis patients not preemptively referred, SLE patients were referred at twice the rate of other dialysis patients in crude analyses [HR=1.9 (95% CI, 1.6-2.2)] but not after adjustment for [HR=1.1 (95% CI, 0.9-1.2)]. Among SLE patients, black vs. white race was associated with lower likelihood of preemptive referral [OR=0.5 (95% CI, 0.2-1.2)] but higher rates of referral after dialysis start [HR=1.8 (95% CI, 1.1-2.9)]. Male vs. female sex was associated with higher rates of referral on dialysis [HR=1.6 (1.1-2.4)].

Conclusions: Referrals for kidney transplant evaluation do not appear to be delayed among dialysis patients with SLE, relative to other dialysis patients of similar age. Efforts to increase kidney transplant access in SLE patients should focus on potential race and sex disparities in referral as well as potential delays in other steps of the kidney transplant process.

SA-PO1005

Association of Kidney Transplantation Referral with Other Indicators of Quality Care Among Incident Georgia Dialysis Patients: The RaDIANT Community Study Laura Plantinga,[1] Stephen O. Pastan,[1] Jenna Krisher,[2] Eric M. Gibney,[3] Laura L. Mulloy,[4] Rachel E. Patzer.[1] *[1]Emory Univ, Atlanta, GA; [2]Southeastern Kidney Council, Inc., Raleigh, NC; [3]Piedmont Transplant Inst, Atlanta, GA; [4]Georgia Regents Univ, Augusta, GA.*

Background: Dialysis facility referral of patients for kidney transplant is a potential indicator of quality care. We examined whether referral within a year of dialysis start (1-year referral) was associated with other quality indicators among incident Georgia dialysis patients.

Methods: We examined a cohort of 14,120 incident (7/1/05-9/30/11; follow-up through 9/30/12) adult (18-69 years) dialysis patients using United States Renal Data System data linked to concurrent referral data from all three adult Georgia kidney transplant centers. Multilevel, multivariable logistic regression was used to examine the association of 1-year referral with dichotomous quality indicators [pre-ESRD nephrology care, dialysis modality, permanent vascular access in place at dialysis start (HD patients only), pre-ESRD erythropoietin use, and transplant information at dialysis start], with adjustment for demographic and clinical variables and accounting for variation across clinics.

Results: Overall, 1-year referral was 24.8% and was higher among patients with other indicators of quality care: 26.0% vs. 23.8%, with vs. without pre-ESRD care (P=0.005); 27.8% vs. 24.6%, PD vs. HD (P=0.03); 28.3% vs. 22.9%, with vs. without a permanent vascular access in place at HD start (P<0.001); and 27.2% vs. 16.5%, informed vs. not informed of transplant options at dialysis start (P<0.001). With adjustment, pre-ESRD care [OR=1.34 (95% CI, 1.22-1.47)], permanent vascular access in place [OR=1.54 (95% CI, 1.41-1.70)], and transplant information at dialysis start [OR=1.63 (95% CI, 1.45-1.85)] remained associated with higher 1-year referral.

Conclusions: These findings suggest that patients who receive quality care in multiple domains are more likely to be referred for kidney transplant evaluation within a year of starting dialysis, independent of demographic and clinical characteristics. Interventions to increase transplant access should be targeted to patients whose care fails to meet other quality indicators.

Feasibility and Sustainability of the RaDIANT Community Study Among Georgia Dialysis Facilities Jennifer C. Gander,[1] Leighann Sauls,[2] Teri Browne,[3] Laura Plantinga,[1] Laura J. McPherson,[1] Eric M. Gibney,[4] Laura L. Mulloy,[5] Stephen O. Pastan,[1] Rachel E. Patzer.[1] *[1]Emory Univ; [2]Southeastern Kidney Council; [3]Univ of South Carolina; [4]Piedmont Hospital; [5]Georgia Regents Univ.*

Background: The Southeastern Kidney Transplant Coalition developed the randomized, dialysis facility-level Reducing Disparities In Access to kidNey Transplantation (RaDIANT) Community Study to address racial disparities and low rates of kidney transplantation (KTx) in Georgia. We aimed to evaluate the feasibility and sustainability of the RaDIANT intervention activities.

Methods: The 67 dialysis facilities that completed a 12-month intervention as part of the RaDIANT study consisted of 12 recommended activities intended to increase KTx referral, such as education and outreach activities targeting the patient, facility staff, and facility policy level. After the intervention, facility staff were asked to complete a 20-item questionnaire on the helpfulness (Likert scale) of each intervention activity and the likelihood (yes/no) of their facility continuing the activity.

Results: A total of 86 staff (51.2% social workers) at the 67 intervention facilities completed the survey. The median number of the 12 intervention activities completed by dialysis facilities was 9 (range 0,11). Most facilities reported discussing the benefits of KTx at a staff orientation (86.6%), attending monthly webinars (80.7%), and developing a referral improvement plan (76.3%) to be helpful or very helpful. The median number of prescribed intervention activities the facilities reported they would continue was 2, with the distribution of educational brochures (41.9%), a staff orientation focused on KTx (41.9%), and a patient and family education session (34.9%) among the most commonly cited.

Conclusions: Dialysis facility staff perceived that RaDIANT intervention activities were feasible to implement, with staff education potentially being the most helpful and sustainable component. Sustainability may be limited to intervention components that were the least expensive and time intensive to implement. Additional ongoing support from ESRD Networks may be necessary to sustain increased KTx referrals observed in the RaDIANT Community Study.

Funding: Other NIH Support - The RaDIANT Community Study is funded in part by NIMHD Award R24MD008077

SA-PO1007

Psychosocial Differences Between Living and Deceased Donor Renal Transplant Recipients Anna Bertram,[1] Selma Pabst,[2] Martina De zwaan,[2] Tanja Zimmermann,[2] Mario Schiffer.[1] *[1]Clinic for Psychosomatics and Psychotherapy, Hannover Medical School, Hannover, Germany; [2]Nephrology and Hypertensiology, Hannover Medical School, Hannover, Germany.*

Background: The specific impact of living donor (LD) as compared to deceased donor (DD) kidney transplants on psychosocial functioning has received surprisingly little attention. The present study aimed to assess whether LD and DD recipients differ in socio-demographic variables, time since transplantation, emotional variables, knowledge about immunosuppressant (IS) intake, and self-reported adherence to IS.

Methods: A questionnaire study was performed among 72 LD and 169 DD recipients who attended the kidney transplant outpatient clinic of Hannover Medical School for a follow-up visit at least 1 year after transplantation. Emotional responses were assessed using the Hospital Anxiety and Depression Scale (HADS) and the Transplant Effect Questionnaire (TxEQ). Patients' knowledge about IS intake was examined with a newly developed test consisting of 8 multiple choice questions, and IS adherence was measured by self-report (BAASIS), physicians' estimates, IS trough level variability, and allograft rejection.

Results: Overall, LD recipients were younger and had a shorter follow-up since transplantation. Our results indicate that LD and DD transplantation may lead to different emotional responses with more feelings of guilt towards the donor and perceived responsibility to do well and with a generally higher anxiety level in LD recipients. LD recipients apparently had more knowledge about IS medication. However, they did not report more adherence to IS. No differences between LD and DD recipients were found for gender, educational level, depression, perceived social support, and allograft rejection.

Conclusions: Feelings of guilt and anxiety may be an important focus for interventions to improve emotional adjustment to transplantation, especially in LD recipients.

SA-PO1008

Physician-Reported Adherence with Immunosuppressants in Renal Transplant Patients: Prevalence, Agreement, and Correlates Anna Bertram,[2] Selma Pabst,[1] Martina De zwaan,[1] Mario Schiffer.[2] *[1]Clinic for Psychosomatics and Psychotherapy, Hannover Medical School, Hannover, Germany; [2]Nephrology and Hypertensiology, Hannover Medical School, Hannover, Germany.*

Background: Assessing adherence to immunosuppressants (IS) is difficult. We investigating (1) the prevalence of non-adherence with IS as estimated by physicians; (2) the agreement between the physicians' estimated and other adherence measures; (3) the difference between adherent and non-adherent patients according to the physicians' estimation with regard to socio-demographic variables, transplant-related variables, and psychological factors.

Methods: All kidney transplant patients attending the outpatient clinic for a follow-up visit from 11/2014 to 02/2015 were screened; 238 patients met inclusion criteria. Adherence with IS was assessed with several measures: 4-item Basel Assessment of Adherence to

Immunosuppressive Medication Scale (BAASIS) and the adherence subscale of the German version of the Transplant Effect Questionnaire (TxEQ) for self-reported adherence; the physicians were asked to estimate patients' adherence to IS on a scale ranging from 1=very good to 5=very poor. Other adherence measures included rejection treatment within the previous 12 months and IS trough level variability in the last 13 months. Psychological variables were assessed with the 14-item Hospital Anxiety and Depression Scale (HADS) and the Questionnaire of Perceived Social Support (FSozU-7).

Results: The physicians rated 9.2% (n=22) of the patients as being non-adherent. There was no agreement between the physicians' estimate of adherence and the patients' self-assessment, IS trough level variability, and allograft rejection. Physicians' ratings were independently related to female sex, non-German native language, higher symptoms of depression and anxiety, and less perceived social support.

Conclusions: Physicians might rely on observable and interactional cues including sex, language, and psychopathology to make inferences about an individual patient's adherence. Also, overestimation of IS adherence may impede physicians's ability to provide high quality care for their renal transplant patients.

SA-PO1009

Evolution Through 20 Years of the Major Kidney Transplant Program from Living Donor in Mexico Edgar Solis,[1] Luis Alberto Evangelista-Carrillo,[1] Enrique Rojas-Campos,[2] Benjamin Gomez-Navarro.[1] *[1]Dept de Nefrologia y Trasplantes, IMSS, Guadalajara, Jalisco, Mexico; [2]Unidad de Investigación Médica en Enfermedades Renales, IMSS, Guadalajara, Jalisco, Mexico.*

Background: According to the National Transplant Center, in 2013 a total of 2707 kidney transplants (KT) were performed in Mexico. Our program performed the highest single center number of transplants with 270 KT, mostly from living donors.

Methods: We use data collected in our registration program at Nephrology and Transplant Unit. All the KT in adult patients performed from January 1994-December 2014 in CMNO were included. We also analized the last 909 kidney recipients and their serum creatinine at the end of first year. Successful KT was defined as a Cr <1.5 mg/dl at 1 year following. Grafts lost were defined as Cr >4.0 mg/dl or replacement therapy initiation.

Results: During this period 3643 KT were performed, 3236 from living donors and 407 from cadaver donor. Of living donors, 2786 were from related donor and 450 were from genetically unrelated donors. The mean age of recipient was 28 years; 65% of our recipients were male. The evolution of the program is shown.

	1994-1999 N=525	2000-2004 N=733	2005-2009 N=1061	2010 – 2014 N = 1323
Recipient Gender N(%)

CSA-MMF-PDN	0	243	246	26
CSA-AZA-PDN	251	222	3	0

Success rate of KT following 1 year was 86.8%. Only female gender and younger donors were statistically significant associated with succesful transplant. Graft lost during the first year was 3.6%. Death was 2.4% during the first year.

Multivariate analysis for succesful transplant			
	OR	**IC 95%**	***p***
Recipient gender	2.56	(1.26-5.13)	0.009
Donor age	1.04	(1.04-1.01)	0.002
Identical HLA	0.21	(0.12-0.21)	0.129
			X^2 =24.50; p <0.001

Conclusions: Each year we are still growing the number of KT. The age of our recipients is diminishing and age of donors is increasing. Months before KT are also increasing lately reflecting the great number of ESRD patients. Recipient age, HLA mismatching, induction therapy use and generic drugs can explain the 13.2% of patients with Cr above 1.5 mg/dl.

SA-PO1010

The Difficult Road for Native Americans in Kidney Transplantation: Decreased Access and Reduced Long-Term Survival Sarah Stith,[1] Kristina Piorkowski,[1] Fidel Barrantes.[2] *[1]Economics, Univ of New Mexico, Albuquerque, NM; [2]Presbyterian Transplant Center, Renal Medicine Associates, Albuquerque, NM.*

Background: Native Americans (NAs) have disproportionately high rates of end-stage renal disease, yet wait listed NAs have lower rates of kidney transplantation than other racial/ethnic groups and worse long-term post-transplant survival outcomes than whites. This study evaluates these disparities across multiple medical and socioeconomic dimensions.

Methods: Using data from the Organ Procurement and Transplantation Network (OPTN), we evaluated wait list removal reasons and post-transplant survival rates from 3/1/95 to 12/31/12. We use a logistic regression model, controlling for patient, donor, match characteristics, and center and year fixed effects, along with a Blinder-Oaxaca decomposition of the results.

Results: Among registered patients removed from the wait list, NAs were less likely to receive a transplant (odds ratio, 0.71 [95% CI, 0.64-0.80]). and more likely to die on the wait list (1.88 [0.89-3.94), compared to whites. NAs are less likely than whites to survive at least two years (odds ratio, 0.80 [95% CI, 0.70-0.92]) and at least three years (0.81 [0.71-0.94]), but these disparities become statistically insignificant with risk adjustment.

Conclusions: NAs experience higher rates of adverse wait list removal reasons than other racial/ethnic groups. Among NAs who do receive transplants, short term survival outcomes are similar to those of whites, but longer term survival outcomes are lower. The decomposition of our results indicates that the disparity in three-year post-transplant survival between NA and whites is driven primarily by the prevalence of lower quality donors among NAs and a greater negative impact from such donor characteristics on survival among NA. NAs also tend to receive transplants at centers associated with worse outcomes and would benefit disproportionately from receiving transplants at better centers.

Estimated GFR for Living Kidney Donor Evaluation Naya Huang,[1] Meredith C. Foster,[1] Krista L. Lentine,[2] Amit X. Garg,[3] Emilio D. Poggio,[4] Bertram L. Kasiske,[5] Lesley Inker,[1] Andrew S. Levey.[1] *[1]Div of Nephrology, Tufts Medical Center, Boston, MA; [2]Div of Nephrology, Saint Louis Univ, MO; [3]Div of Nephrology, Western Univ, London, ON, Canada; [4]Dept of Nephrology and Hypertension, Glickman Urological and Kidney Inst, Cleveland Clinic, OH; [5]Dept of Medicine, Hennepin County Medical Center and Univ of Minnesota, Minneapolis, MN.*

Background: All living kidney donor candidates undergo an evaluation of GFR. Guidelines recommend measured GFR(mGFR) rather than estimated GFR(eGFR), but measurement methods are difficult, time consuming and costly. We questioned whether eGFR using creatinine (eGFRcr) with or without sequential cystatin C (eGFRcr-cys) is sufficiently accurate to identify donor candidates with high probability that mGFR is above or below thresholds for clinical decision making.

Methods: We combined the pre-test probabilities for mGFR thresholds <60, <70, ≥80 and ≥90 mL/min/1.73 m^2 in varying age, sex and race groups estimated from the National Health and Nutrition Examination Survey (NHANES) with test performance of eGFR (categorical likelihood ratios [LRs] determined from the Chronic Kidney Disease Epidemiology Collaboration) to compute post-test probabilities of meeting a given mGFR threshold.

Results: Using NHANES pre-test probabilities,we found that that in some circumstances, eGFRcr and eGFRcr-cys provides high accuracy (post-test probability≥95%) in candidate donors. Using data from the Scientific Registry of Transplant Recipients, we demonstrated that 54% and 82% of recent donors had pre-donation eGFRcr high enough to assure ≥95% probability that pre-donation mGFR was ≥90 and ≥80 ml/min/1.73 m^2 respectively, suggesting a large fraction of donor candidates might not require mGFR.

Conclusions: Implementation strategies could include eGFRcr as a first test and possibly eGFRcr-cys as confirmatory test. If post-test probabilities are of sufficient magnitude, eGFR could be used to accept or reject donors without measurement of GFR. We will provide a web-based application.

SA-PO1012

Change of Physical Activities in Male and Female Recipients in 12 Months After Living Kidney Donor Transplantation Makoto Tsujita. *Transplant Surgery, Nagoya Daini Red Cross Hospital, Japan.*

Background: Since renal dysfunction and immunosuppressive drugs cause muscle degeneration, physical activities decrease in CKD, dialysis patients and transplant recipients. In addition, elderly kidney transplant recipients are increasing in Japan, so improving physical activities and increasing muscle strength and volumes are important to prevent fracture and fall accident.

Methods: Consecutive 58 patients (male 33) older than 40 years were enrolled in this study from 2012. Immunosuppression basically contains steroid, cyclosporine or tacrolimus, and mycophenolatemofetil or everolimus. Hypertension, hyperlipidemia, and osteoporosis were treated as needed. Parameters of physical activities such as hand grip, SMI (skeletal muscle index) and Body fat mass using by DEXA(dual-energy x ray

absorptiometry) , and Body mass index (BMI) were measured and compared at prior, 6, and 12 months after kidney transplantation. Recipients were encouraged to do daily exercise for 30 to 60 minutes everyday.

Results: Mean age (years) were 52.3±10.0 in male, and 53.6±10.4 in female. In male patients, any parameter did not change after transplantation in male patients. In female patients, SMI improved in 12 months ($p<0.005$), and Hand grip also tended to increase without statistically difference.

Figure 1
Results of this study for male and female (mean±SD)

Male (n = 33)	Baseline	6 months after transplantation	12 months after transplantation	P value
BMI (kg/m2)	22.6 ± 3.1	21.8 ± 3.2	22.7 ± 3.2	0.3
Body fat mass (%)	20.4 ± 5.8	20.1 ± 5.5	21.1 ± 5.4	0.59
SMI (kg/m2)	7.1 ± 0.8	7.0 ± 0.8	6.7 ± 1.8	0.12
Hand grip (kgw)	31.6 ± 9.5	32.0 ± 9.1	32.1 ± 8.2	0.56
Female (n = 25)				
BMI (kg/m2)	21.1 ± 3.6	20.2 ± 3.7	21.5 ± 4.2	0.31
Body fat mass (%)	25.4 ± 6.1	27.0 ± 6.8	28.3 ± 7.0	0.03
SMI (kg/m2)	5.4 ± 1.8	5.5 ± 1.5	5.9 ± 0.9	0.005
Hand grip (kgw)	17.7 ± 5.8	19.3 ± 5.1	21.4 ± 5.5	0.17

Physical activities seemed unchanged after transplantion in male patients than before.

Conclusions: In male recipients, physical activities do not seem to recover in 12 months after kidney transplantation. More interventions and more studies are needed to increase physical activities and know the effect of daily exercise clinically.

SA-PO1013

Search for New Data to Predict Kidney Transplant Outcomes in the Organ Procurement and Transplantation Network Database Mohamed A. Sheta,[1] Bertram L. Kasiske,[2] Charles E. Alexander,[3] Joseph Kim.[4] *[1]Univ of Minnesota; [2]Hennepin County Medical Center; [3]Univ Health Network; [4]The Living Legacy Foundation of Maryland.*

Background: The Organ Procurement and Transplantation Network (OPTN) collects data used to monitor transplant program outcomes for quality assurance and regulatory oversight. It is imperative that the variables in the OPTN database used by the Scientific Registry of Transplant Recipients to determine expected outcomes after kidney transplant be reliable,complete,and up-to-date.

Methods: We conducted a systematic review to identify risk factors not included in current OPTN data that predict graft failure or mortality after kidney transplant. We searched for studies with:publication date between Jan 1 2000-May 1 2015; at least 1000 subjects in one or more risk prediction models;multivariate analysis used to select variables predicting patient or graft survival; inclusion in the multivariate model of at least one risk factor collected before or at the time of transplant that is not already collected by OPTN;and English language. For duplicate publications we selected the most recent. For publications with overlapping but distinct cohorts,we selected the one with the largest cohort.We arbitrarily limited the search to studies including 1000 participants in at least one risk-prediction model.Although a small single-center study may convincingly show that a newly described risk factor predicts outcomes at that center,there are likely major barriers to measuring and collecting this risk factor uniformly at every program in the US.

Results: We identified 33 studies that met inclusion criteria; 6 (18%) were single-center, 4 (12%) were multicenter, and 23 (70%) were registry studies. Promising new variables included: myocardial infarction, coronary artery revascularization,atrial fibrillation, congestive heart failure,valvular heart disease,cerebral vascular accident,carotid artery revascularization,aortic aneurysm repair, ischemic leg amputation or revascularization,tobacco abuse, alcohol and illicit drug dependence,ZIP code,and socioeconomic status.

Conclusions: This review provides evidence for the new OPTN Ad Hoc Data Advisory Committee to update the OPTN database.

SA-PO1014

Prevalence of Mineral and Bone Disorders Among Living Kidney Transplant Recipients Essam Mohammed Khedr, Amr Mohab, Haitham Ezzat. *Nephrology Dept, Ain Shams Univ, Cairo, Egypt.*

Background: Mineral and bone disorders (MBD), frequent complications of chronic kidney disease (CKD), occur frequently in kidney transplant recipients.Still, little is known about its prevalence and clinical correlates in transplanted patients.

Methods: We conducted a cross-sectional analysis of 504 stable living kidney allograft recipients. Detailed medical history, demographic data and routine laboratory investigations, including s.creatinine, s.corrected Calcium, s.Phosphorus, serum iPTH and s.Alkaline Phosphatase (ALP) were collected. Estimated GFR was calculated using the abbreviated MDRD formula. Patients were stratified into three groups based on duration of kidney transplantation. Group I:6 months to 1 year, group (II): from 1 to 5 years and group (III): more than 5years.Correlations were done between bone minerals and all laboratory results. We also analyzed the possible relation between various immunosuppressant drugs and bone minerals, serum iPTH and serum ALP.

Results: The mean age was 32±8 years in group I, 45±3.7 years in group II, and 40±5 years in group III, with no significant difference between the three groups ($p>0.05$). There was no significant difference between the studied groups as regards results of laboratory parameters($p>0.05$).115 patients had iPTH levels > 170 ng/dl, while 365 patients (72.4%) had iPTH levels >70 ng/dl. Only 24 patients had hypercalcemia, and 34 patients had hyperphosphatemia. We also found that 68 patients had hypophosphatemia. Serum iPTH and serum ALP levels were higher in group III (156±66 ng/dl, 135±54 IU respectively) when compared to group I (98±33.4 ng/dl,120±33 IU) and group II (138±35 ng/dl,122±60 IU) ($p<0.001$). In group I, iPTH levels were negatively correlated with eGFR (r value= -0.37, $p<0.05$). Both serum ALP and iPTH levels showed significant negative correlation with eGFR in groups II and III ($p<0.05$). In all groups, bone minerals, iPTH and serum Alkaline Phosphatase levels had no statistically significant relation with the immunosuppressant agent used ($p>0.05$).

Conclusions: Disturbances of bone and mineral metabolism after transplantation are prevalent and are strongly correlated with the kidney function and transplantation duration.

SA-PO1015

Risk of Adverse Maternal and Fetal Outcomes During Pregnancy in Living Kidney Donors Jessica B. Kendrick,[1,2] John R. Holmen,[3] Gerard John Smits,[1] Michel Chonchol.[1] *[1]Univ of Colorado Denver, Aurora, CO; [2]Denver Health Medical Center, Denver, CO; [3]Intermountain Health Care, Salt Lake City, UT.*

Background: A frequently asked question by potential kidney donors is risk of nephrectomies on maternal and fetal outcomes in pregnancy. Studies regarding the risks of living kidney donation and pregnancy outcomes are conflicting. The purpose of this study was to determine the risk of adverse maternal and fetal outcomes in donors vs. non-donors.

Methods: Using data from an integrated health care delivery system in Utah from 2000 through 2014, a total of 72 women were living kidney donors that became pregnant after kidney donation. Using a pool of 74,105 women who were not donors, we selected 1223 to use for matches for the living kidney donors. These women were matched 1:3 by age and race. Adverse pregnancy outcomes were defined as preterm delivery, delivery via cesarean section, preeclampsia/eclampsia, length of stay in the hospital and low birth weight (<2,500 g). Logistic regression analysis was used to examine the association between living donation and adverse outcomes.

Results: Of the living kidney donors, the mean (SD) age and mean (SD) gestational age at delivery was 30±5 years and 38±2 weeks, respectively. The mean (SD) length of stay in the hospital was 2.7 ± 2.7 days. Six cases (8%) had a history of chronic hypertension. Living kidney donors did not have a higher risk of preterm delivery (OR 1.82, 95% CI 0.877-3.77), preeclampsia/eclampsia (OR 1.11, 95% CI 0.47-2.65), delivery via cesarean section (OR 1.51, 95% CI 0.85-2.66), length of stay > 3 days (OR 1.29, 95% CI 0.63-2.64) or low birth weight (OR 1.94, 95% CI 0.87-4.35) compared to non-donors.

Conclusions: Living kidney donation is not associated with a higher risk of adverse outcomes in pregnancy.

SA-PO1016

The Quality of Life of Parents of Pediatric Kidney Transplantation Yuko Hamasaki,[1] Miyako Tazaki,[2] Yusuke Takahashi,[1] Seiichirou Shishido,[1] Atsushi Aikawa.[3] *[1]Pediatric Nephrology, Toho Univ Faculty of Medicine, Tokyo, Japan; [2]Psychology, Toho Univ Faculty of Medicine, Tokyo, Japan; [3]Nephrology, Toho Univ Faculty of Medicine, Tokyo, Japan.*

Background: The purpose of the study is to investigate how the Quality of life (QOL) of parents whose child had received kidney transplantation (KT) would change by delivering questionnaires four times; before, one month after, three months after and one year after KT.

Methods: The QOL of thirty-one parents (30 mothers and 1 father) with a mean age of 38.5 years old whose child received KT at Toho University Omori Medical Center from May 2012 to March 2015 was measured using WHO Quality of Life (WHOQOL), Visual Analogue Scale (VAS), and General Health Questionnaire (GHQ). The mean age of the recipients was 5.8 years old (18 boys, 13 girls). Congenital anomalies of the kidney and urinary tract were the most frequent primary diseases (54.8%). Among them, twenty-two children received dialysis before KT, and nine received preemptive KT.

Results: Based on the results, the average WHOQOL scores show the QOL of parents decreased one month after KT (3.15) with a statistical difference compared with before KT ($p=0.042$), but increased at three months (3.40) ($p=0.0073$), and maintained until one year (3.41). The average QOL of the parents of a child with frequent infection was statistically lower than those without any infection ($p=0.448$) at three months after KT and one year after KT ($p=0.0406$). The average QOL scores of nineteen donor parents had a statistically higher QOL before KT then reversed at one month after KT, but became higher again at three months after KT.

Conclusions: The QOL of the parents would decreased one month after KT when infection or other problems often occurred, but increased after three month when the condition of recipients stabilized and maintained until one year after KT, which became as high as before KT.

SA-PO1017

Disparities in Access to Renal Transplant in Puerto Rican Children

Nilka deJesus-Gonzalez,[1] Sonia M. Caraballo,[1] Eduardo J. Santiago-Rodriguez,[2,3] Marta P. Suarez-Rivera,[1] Melvin A. Bonilla-Felix.[1] *[1]Medical School, Pediatric Nephrology Div, Univ of Puerto Rico; [2]Univ Central del Caribe; [3]Puerto Rico Clinical and Translational Research Consortium.*

Background: Disparities in access to renal transplant have been reported in racial minorities living in US. No data is available from children with ESRD living in Puerto Rico (PR), the largest Hispanic group in a single pediatric dialysis unit in US. We describe the pediatric population with ESRD in PR from 2003-2013, the renal transplant rates and possible barriers to receiving a graft.

Methods: Retrospective chart review of patients diagnosed with ESRD in PR from 2003-2013. Incidence, prevalence rates, means/standard deviations (SD), medians/ interquartile range (IQR), frequencies and percentages were calculated and compared to national rates.

Results: From 2003-2013 99 patients, male: 52%, age:13.5yrs (8-16yrs), were diagnosed with ESRD . Congenital anomalies were the primary cause in 40%, and FSGS in 24% . Incidence of ESRD ranged from 3-14 subjects per million population/year, with prevalence per dialysis modality from 7-18 subjects per million population/year. 38% were transplanted in PR (Median age: 14yrs, IQR: 9-16), 23% from living donors. 14.1% received a transplant in the first year (National rate: 38%). 63% of transplanted children had Medicare coverage. None of 9 infants diagnosed with ESRD were transplanted during infancy. 46% of the children who were not transplanted stayed at our unit for a median time of 2 yrs (IQR: 1-3). The rest was transferred to a dialysis unit outside PR (15%) or to an adult facility without being transplanted (39%). 67% of these non-transplanted children were covered by Medicare. The mortality rate during the first year of diagnosis was 3% (National rate: 4%).

Conclusions: Children with ESRD in PR face striking disparities in access to renal transplant. Lack of pediatric transplant surgeons, geographical isolation and minimal living donation are potential barriers. Medicare coverage does not appear to be a factor, as it was similar between transplanted and non-transplanted. Interventions to reduce these inequities are needed.

Funding: Other NIH Support - Supported by grant 2U54MD007587 (RCMI Clinical and Translational Research Award, University of Puerto Rico Medical Sciences Campus) from the National Institute on Minority Health and Health Disparities (NIMHD), a component of the National Institutes of Health (NIH).

SA-PO1018

The Case against Declining Donors with Impaired Fasting Glucose

Robert N. Foley, Naim S. Issa, Danielle M. Berglund, Arthur J. Matas, Hassan N. Ibrahim. *Univ of Minnesota, Mpls, MN.*

Background: The definition of diabetes, impaired fasting glucose (IFG) and impaired glucose tolerance (IGT) have changed over time. IGF was definied in 1997 by fasting glucose 110-125 mg/dL and in 2003 the definition changed to fasting glucose 100-125 mg/dL. With the introduction of this new definition, many potential donors with fasting blood sugar between 100-110 mg/dL have been denied donation. This is highly relevant as many of these are potential donors to family members with type 2 diabetes mellitus.

Methods: We assessed the risk of death, new onset diabetes, hypertension, proteinuria and reduced GFR (<45 and <30 ml/min/1.73m2) in 3783 kidney donors according to fasting blood glucose(FBG) at the time of donation spanning the period between 1963-2013.

Results: 2900 donors had a FBG <100 mg/dL, 550 with 100-109, 205 with 110-125, and 128 donors with FBG > 126 mg/dL. Donors with IFG (100-109 mg/dL) after multivariable adjustment were not more likely to die, develop diabetes, proteinuria, hypertension, eGFR <45 ml/min/1.73m2 or eGFR <30ml/min/1.73m2 as compared to those with FBG <100 mg/dL (Table 1). In contrast, those with FBG between 110-125 mg/dL were more likely to become diabetic and hypertensive but not proteinuric or reduced GFR. Those with FBG ³126 mg/dL were more likely to die, develop DM and HTN but not suffer any adverse renal consequences.

Outcome	Fasting Blood Glucose (mg/dL)		
	100-109	110-125	≥126
Death	1.08 (0.8-1.47	1.41 (0.91-2.18)	**1.57 (1.02-2.41)***
Diabetes	1.19 (0.83-1.69)	**2.07 (1.36-3.14)***	**2.89 (1.8-4.64)***
HTN	1.2 (0.99-1.47)	**1.61 (1.23-2.11)***	**1.76 (1.26-2.44)***
Proteinuria	0.68 (0.44-1.06)	0.76 (0.41-1.41)	1.62 (0.89-2.93)
eGFR <45 ml/min	0.78 (0.43-1.43)	1.26(0.54-2.94)	1.3 (0.52 - 3.27)
eGFR <30 ml/min	0.96 (0.73-1.25)	1.31(0.87-1.96)	1.06(0.66-1.7)

* p-value <0.05 compared to FBG <100 mg/dL

Conclusions: Excluding potential donors with a fasting glucose (100-109 mg/dL) should be revisited as these donors do well in the long-term.

SA-PO1019

Psychosocial Distress and Adherence in Adolescents Post-Kidney Transplant

Jessica L. Stahl,[1] Angela P. Presson,[2] Chong Zhang,[2] Raoul D. Nelson,[1] Matthew M. Grinsell.[1] *[1]Pediatrics, Univ of Utah, Salt Lake City, UT; [2]Study Design and Biostatistics Center, Univ of Utah, Salt Lake City, UT.*

Background: Adolescents who are post-kidney transplant have comorbidities in medical and psychosocial arenas and high risk of non-adherence and graft loss. Limited data exists to describe the relationship between mental health and adherence in this population.

Methods: 22 parent-child dyads with children ages 12-17 were recruited at scheduled post-kidney transplant visits. They completed demographic and standardized Youth Outcomes questionnaires. Adherence was assessed using the standard deviation of the prior 1 year of tacrolimus levels and chart review for hospitalization for non-adherence. Descriptive statistics were used to assess the relationship of adherence to psychiatric diagnosis, psychosocial distress, gender, and time from transplant, as well as differences in parent-child reporting.

Results: Overall, 52% reported a psychiatric diagnosis, which is significant compared to 13% in the general adolescent population (p<0.001), with 38% evidencing elevated levels of psychosocial distress on self-report and 25% elevated per parent report. 68% of adolescents reported a different distress level than estimated by their parent. The psychiatric diagnosis rate was 64% in the non-adherent group and 36% in adherent adolescents. Only 40% of the adherent group reported elevated distress versus 57% of the non-adherent group. There was a gender bias toward male non-adherence in this group with 100% of the non-adherent population being male. The mean time from transplant of non-adherent groups was 6.1 years versus 3.9 years in the adherent group. These differences were not statistically significant except as above.

Conclusions: Our population's rate of psychiatric diagnosis was significantly elevated compared to community norms and also correlated with elevated psychosocial distress and non-adherence. Disagreement in parent and adolescent reporting was common regardless of adherence status. Our sample did demonstrate gender differences in non-adherent behavior as well. Interpretation of these results, as well as statistical significance is limited by the small sample size.

Funding: Other NIH Support - This investigation was supported by the University of Utah Study Design and Biostatistics Center, with funding in part from the National Center for Research Resources and the National Center for Advancing Translational Sciences, National Institutes of Health, through Grant 8UL1TR000105 (formerly UL1RR025764).

SA-PO1020

Post Donation Diabetes and Risk of Death and ESRD

Hassan N. Ibrahim, Robert N. Foley, Scott Reule, Danielle M. Berglund, Aleksandra Kukla, Naim S. Issa, Richard S. Spong, Arthur J. Matas. *Univ of Minnesota, Mpls, MN.*

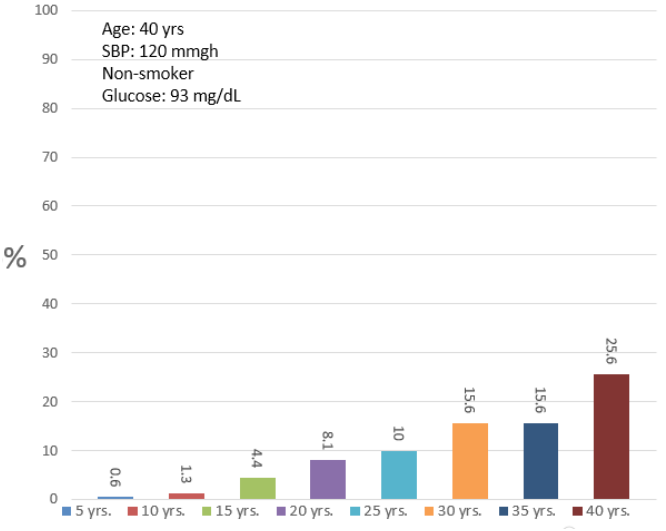
Background: We have previously shown that development of diabetes following live kidney donation does not result in accelerated GFR decline when compared to diabetics with two kidneys. Herein, we report on the development of a risk calculator for new onset DM in donors and address its contribution to mortality and also renal outcomes.

Methods: Donors are followed indefinitely through surveys including development and treatment of diabetes and renal outcomes. Risk factors for post donation diabetes were determined using stepwise proportional hazards regression.

Results: Development of DM was ascertained in 3874 donors with a mean follow-up of 16±12 years. In total, 279 (7%) developed DM. Pre-donation risk factors for development include older age, BMI, tobacco use, and fasting serum glucose at donation, p£0.01 for all (Table 1a). Diabetes following donation was associated with a nearly 5 fold increase in proteinuria and 2 fold increase for eGFR < 30 or ESRD (Table 1b). Coefficients from the regression model were then used to create an individualized risk calculator. This was developed in 1934 donors and validated in the remaining 1934 (C-statistic 0.77). The cumulative risk of developing DM at 5 yearly intervals is shown in figure 1.

Variable	Adjusted Hazard Ratio	p-value
1a) Pre-donation risk factors for DM		
Age	1.01 (1-1.03)	0.01
BMI	1.12 (1.1-1.15)	< 0.001
Tobacco use	1.37 (1.06-1.75)	0.01
Serum glucose	1.01 (1.01-1.02)	< 0.001
1b) Post donation DM, mortality and ESRD		
Death	0.71 (0.46-1.08)	0.11
Proteinuria	4.65 (3.28-6.59)	<0.0001
eGFR <30 or RRT	2.21 (1.32-3.69)	0.0026

Cumulative risk of DM for a typical White kidney donor.



Conclusions: Diabetes can be reasonably predicted in kidney donors using baseline data. Diabetes is a significant contributor to reduced GFR and proteinuria.

SA-PO1021

What Kind of Obesity Does Affect Kidney Function? Survey of Kidney Transplant Donors Mikiko Yoshikawa, Junko Nakano, Kentaro Nakai, Hideki Fujii, Shinichi Nishi. *Div of Nephrology and Kidney Center, Kobe Univ Graduate School of Medicine, Kobe, Japan.*

Background: Currently obesity is a risk for chronic kidney disease. It is also suggested that sarcopenia is the independent risk factor of hypertension. It is unclear whether obesity and body composition affect to kidney function and other prognosis of donors in our country. The aim of this study was to investigate the influence of body composition, the findings of graft biopsy and 1-year after clinical outcome.

Methods: This is a retrospective single center study of 60 living kidney transplant donors from 2009 to 2014. Donors are stratified according to Body Mass Index (BMI³25kg/m^2 is defined as an obesity in Japanese criteria) and skeletal muscle index (SMI) from the appearance of muscle on cross-sectional CT images (L3 SMI, Under 38.5cm2/m^2 for women and 52.4 cm2/m^2 for men are defined as a sarcopenia)(1). We divided donors into four groups; (A) Obesity negative + Sarcopenia negative (ONSN)(B) Obesity positive + Sarcopenia negative (OPSN) (C) Obesity negative + Sarcopenia positive (ONSP) (D) Obesity positive + Sarcopenia positive (OPSP). We evaluated kidney function at donation, baseline kidney graft biopsy findings and clinical course 1 year-after donation.

Results: Seven patients were OPSN (11.7%), 22 patients ONSP (36.7%), and 4 patients OPSP (6.7%). Visceral fat area ³100 m^2 (which is defined as central obesity in Japanese criteria) was significantly higher in OPSP group.S-Cre at donation was significantly lower in OPSN and ONSP groups. In multivariate analysis of graft biopsies, BMI³25kg/m^2 was a significant risk for small artery intimal thickenings and interstitial fibrosis/tubular atrophy. On the contrast, OPSP was an independent risk for global sclerosis. In multivariate analysis, central obesity was significantly correlated with 1-year after proteinuria. In addition, OPSP was a independent risk for 1-year after hypertension.

Conclusions: These results indicate obese donor already has a risk for arterial and interstitial damages at transplantation. In addition, central obesity and sarcopenia contribute to the late graft function and hypertension.[Reference] (1) Prado CM et al. Lancet Oncol 2008; 9: 629–635.

SA-PO1022

Living Donor Remaining Function Measured by CKD-EPI Correlates with Remaining Kidney Volume Asif A. Sharfuddin, Ali Khalil, Muhammad S. Yaqub, Tim E. Taber, Muhammad Ahmad Mujtaba. *Medicine/Neph, Indiana Univ.*

Background: The aim of our study was to evaluate whether preserved kidney volume correlates with donor renal function at 2-years post-donation using the CKD-EPI eGFR equation.

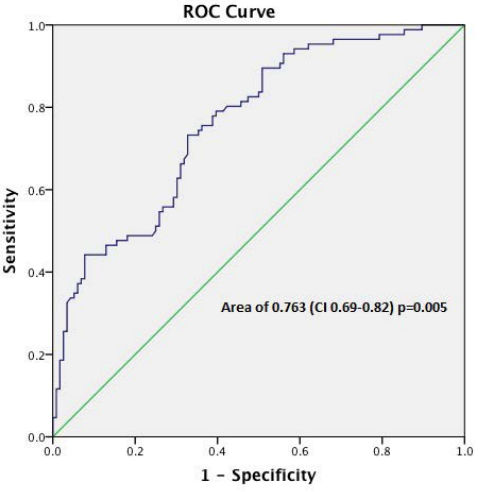
Methods: Demographics and renal function of living donors who underwent living nephrectomy between January 2008 and November 2012 were reviewed. All donors underwent computed tomography with an estimation of kidney volumes. Preserved Kidney Volume (PKV) was adjusted (aPKV) to Body Surface Area.

Results: A total of 208 donors with 2 year follow up data available. Pre-donation eGFR (β Coef. 0.344), age (β Coef.-0.318) and aPKV (β Coef. 0.11) were found to be independent predictors of 2yr eGFR (p<0.001). aPKV was divided into tertiles (low/medium/high) and a 2 year eGFR of <60ml/min was chosen as a cut off for dichotomous analysis as in Table 1.

	2yr eGFR<60	2yr eGFR> 60	Total
Vol Tertile 1 (low)	44(47.8%)	24(20.7%)	68(32.7%)
Vol Tertile 2 (medium)	31(33.7%)	35(30.2%)	66(31.7%)
Vol Tertile 3 (high)	17(18.5%)	57(49.1%)	74(35.6%)
Mean aPKV (ml)	165±29	194±30*	
Mean eGFR (ml/min)	52±6	76±15*	

* p value < 0.001

Mean 2yr eGFR was 57.9±12, 65±16 and 73±17 between the tertile groups (p<0.05). The odds ratio of having a 2yr post-donation eGFR <60 with a cutoff of median aPKV of 194ml was 5.8 (95%CI 2.9-11.6; p<0.0001), while that of 2yr post-donation eGFR <60 with a cutoff of < 25th percentile of aPKV of 159.9 was 5.6 (95%CI 2.7-11.22; p <0.0001). The odds ratio of having an eGFR <60 if the aPKV was above the 75th percentile was 0.13 (95%CI 0.05-0.3) p<0.0001. ROC and AUC for aPKV and eGFR (CKD-EPI) of <60 were 0.763 (CI0.69-0.82) p=0.005 as in Figure 1.



Conclusions: Our study is the first to show using CKD-EPI equation that preservation of residual renal function in living donors needs to take into account remaining kidney volume, when selecting kidneys from healthy donors.

SA-PO1023

Assessing Adherence Barriers in Pediatric Kidney Transplant Recipients Charles D. Varnell,[1] Kristin Loiselle,[2] Ahna Lh Pai,[2] Avani Modi,[2] David K. Hooper.[1] *[1]Div of Nephrology and Hypertension, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]Center for Treatment Adherence and Self-Management, Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Nonadherence in pediatric kidney transplant recipients(KTRs)is associated with poor outcomes and poses a significant financial cost to society. Patient and family reported barriers to taking medications predict nonadherence, rejection, graft failure, and death. Despite their clinical importance and amenability to intervention, barriers to medication adherence are not routinely assessed in pediatric settings.

Methods: From Jan 2015 - May 2015, barriers to immunosuppressant adherence in KTRs were assessed using a standardized checklist of 14 common barriers. For KTRs<10 y.o. the caregiver completed the assessment. For KTRs³10 y.o. both the patient and caregiver, if present, completed the assessment. Assessments were completed during routine outpatient clinic appointments.

Results: 36 pediatric KTRs [M(SD)age=13.14(6.43)years;56.7%male] and 50 primary caregivers completed a barriers assessment. At least one barrier was reported by 47% of KTRs compared to 42% of caregivers. For KTRs the most frequent barriers were forgetting(22%), hating the taste(13.9%) and running out of medicine(8.3%). For caregivers, the most frequently endorsed barriers were forgetting(20%), side effects(6.0%) and patient refuses to take their medication(6.0%). There was excellent concordance(96.2%) in dyads where both KTR and caregiver reported barriers. Assessing for barriers to adherence was easy to perform in practice and required<60 seconds.

Conclusions: Nearly half of all patients report at least one barrier to taking their immunosuppression, and there is generally consistent agreement between patient and caregiver perception of barriers. Standardizing the approach to assessing barriers to immunosuppression adherence in the clinical setting can quickly produce information that might be missed by the provider. Future research should evaluate the effectiveness of interventions delivered as part of routine medical care to overcome identified barriers and prevent known complications associated with nonadherence.

SA-PO1024

A Longitudinal Follow-Up of Hispanic Living Kidney Donors
Clarence E. Foster III,[1] Pinky J. Patel,[2] Hirohito Ichii,[1] Madeleine V. Pahl,[2] Elani Streja,[2] Jonathan R. Lakey,[1] Kamyar Kalantar-Zadeh.[2] *[1]Surgery/ Div of Transplantation, Univ of California, Irvine, Orange, CA; [2]Medicine/ Nephrology, Univ of California, Irvine, Orange, CA.*

Background: This is a long-term follow-up of living kidney donors (LKD) in an ethnically diverse patient population. Hispanics are known to have an increased risk of developing chronic kidney disease, associated with hypertension and obesity. The hypothesis is Hispanic living kidney donors or uninsured living kidney donors would have poorer long-term outcomes secondary to lack of access to health care and secondary to the higher risk factors for developing chronic kidney disease .

Methods: The objectives : measure obesity, hypertension, diabetes, measure CrC, post-donation and compare to the pre-donation CrCl. LKD were contacted & invited to participate & had a questionnaire about their general health & history and physical. Analysis included a CBC, serum chemistry, a 24-hour urine collection to measure creatinine, protein and albumin. A Patient Data Visit Sheet, RAND 35 Health Questionnaire. The IRB approved this study.

Results:

Demographics	(N=42)	Hispanics (23)	Non-Hispanics (19)	
Age @ Donation, Years (range)	36 +/- 12 (18 to 55)	32 +/-11 (18 to 52)	41 +/- 10 (22 to 55)	0.007
Female (%)	57	43	26	NS
U.S. Citizen (%)	55	35	79	<0.0001
Health Insurance (%)	57	26	95	0.0058
Years Post-Donation	3.8 (1.1 to 13.5)	3.6+/- 2.8 (1.2 to 11.8)	4.0 +/- 3.4 (1.1 to 13.5)	NS
Pre-Donation BMI, mean	25.6	27.9	24.7	0.0175
Pre-Donation GFR, ml/ min, mean	122	137	104.5	NS

Pre- and post-donation systolic and diastolic blood pressures were similar between Hispanics and non-Hispanic LKD. Non-Hispanic LKD had a greater decrease in systolic blood pressure post-donation -4.5 mmHg vs. 6 mmHg (p-0.0378). The decrease in CrCl post-donation was the same in Hispanic and Non-Hispanic LKD, 33 ml/min vs. 35 ml/min. None of the LKD in the study had significant proteinuria or micro albuminuria.

Conclusions: Post living donor kidney donation in our ethnically diverse patients are not at a higher risk for developing obesity, HTN, or CKD. Overall, our LKD feel they have a good overall quality of life including both physical and emotional realms.

Predictors of Low Estimated Glomerular Filtration Rate After Living Kidney Donation in a Southeast Asian Population from Singapore
Ru Yu Tan,[1] John C. Allen,[2] Terence Kee Yi Shern,[1] Tazeen H. Jafar.[2] *[1]Dept of Renal Medicine, Singapore General Hospital, Singapore; [2]Duke-NUS Graduate Medical School, Singapore.*

Background: We aim to investigate patterns of change in kidney function and factors associated with low estimated glomerular filtration rate (eGFR) following living kidney donation in Southeast Asian.

Methods: We retrospectively studied living kidney donors with nephrectomy performed at Singapore General Hospital between 1976 and 2012. Quantile regression analysis was performed on pre- to post-nephrectomy percent change in CKD-EPI eGFR levels. Donors were grouped according to elapsed time from donation as short-term (>6 months to <5 years after donation), medium-term (5 to <10 years after donation), and long term (³10 years after donation), and compared on pre-nephrectomy demographic and clinical characteristics. Univariate and multivariate logistic regression were performed to evaluate predictors of low post-donation eGFR. A pre-nephrectomy eGFR cutpoint for prognosticating low post-donation eGFR was obtained using ROC analysis.

Results: 174 donors, predominantly female (63.8%) and of Chinese ethnicity (73%), of average age 40.6 years, were recruited. Median (range) follow-up was 7.8 (0.1–33.8) years during which 30 donors (17%) developed low eGFR, defined as <60 ml/min/1.73m^2. At 5 years post donation, 43.1% of donors recovered to at least 75% of pre-nephrectomy eGFR levels, and 9.8% exhibited 100% recovery to pre-nephrectomy eGFR levels at 19.2 years, on average. High pre-nephrectomy eGFR was protective for risk of low post-donation eGFR, with a 6% reduction in risk for each unit increase in pre-nephrectomy eGFR (OR, 0.94; 95% CI, 0.91–0.97; p=0.002). This relationship was stronger in the short-term than medium to long term (p=0.052). ROC analysis indicated pre-donation eGFR cutpoint of 100 ml/ min/1.73m^2 for prognosticating low post-donation eGFR (sensitivity=0.80, specificity=0.61, PPV=0.30, and NPV=0.95); AUC (95% CI) was 0.75 (0.66–0.84).

Conclusions: In general, kidney function is well preserved following kidney donation in Southeast Asian donors. Pre-nephrectomy eGFR is a good predictor of post-donation eGFR, especially in the short-term.

SA-PO1026

Post-Kidney Transplant Follow-Up in Native American: An Opportunity for Improvement
Fidel Barrantes,[1] Sarah Stith.[2] *[1]Presbyterian Transplant Center, Renal Medicine Associates, Albuquerque, NM; [2]Economics, Univ of New Mexico, Albuquerque, NM.*

Background: Native Americans have been shown to face decreased access to waitlisting and transplantation. We explore the possibility that Native Americans might face decreased access to high quality post-transplant care, especially in the long-run, due to a decreased general access to healthcare, as is faced by many socioeconomically disadvantaged minority populations.

Methods: Using data from the OPTN, we evaluated the quantity and type of post-transplant care received by Native Americans. We compare Native American populations with other ethnic groups from October 1, 1987 to December 31, 2012 using multivariate regression analysis, controlling for time-invariant factors affecting all patients in a given year (year fixed effects) and time-varying factors associated with a specific transplant center (center fixed effects). (Standard errors are clustered at the center level to account for heteroskedasticity and spatial correlation among patients in a given center).

Results: Statistically significant regression results ($p<0.05$) indicate that Native Americans are less likely to receive transplant program-based aftercare than other racial/ ethnic groups (Black, White, Hispanic and Asian/Pacific Islander), opting instead to see other types of specialists. They also are two percentage points more likely to be lost to follow-up (mean=0.15), one percentage point less likely to participate in an immunosuppression-related research study (mean=0.03), and receive 0.3 fewer follow-up visits (mean=2.2) than whites. They face the lowest number of follow-up visits, the lowest probability of participating in a research study, and the highest probability of being lost to follow-up. They are also 13% points less likely to work post-transplant (mean=0.35) than whites.

Conclusions: The results indicate that Native Americans have reduced access to high quality post-transplant care. Further research will explore how much of the disparity in post-transplant care is related to the high correlation between being Native American and poor and between being Native American and living in a rural area, especially on tribal lands.

Medication Adherence Barrier Burden Predicts Subsequent Taking Adherence in Adolescent Kidney Transplant Recipients in the TAKE-IT Trial
Bethany J. Foster,[1] Huaqing Zhao,[2] Ahna Lh Pai,[2] Nataliya Zelikovsky,[2] Crystal D. Holly,[2] Jodi M. Smith,[2] Vikas R. Dharnidharka,[2] Diane Hebert,[2] Douglas G. Matsell,[2] Veronique Phan,[2] Susan L. Furth.[2] *[1]Pediatrics, McGill Univ, Montreal, QC, Canada; [2]TAKE-IT Investigators.*

Background: Longitudinal studies of objectively-measured medication adherence among high-risk adolescent kidney transplant recipients are lacking.

Methods: We aimed to determine whether the burden of perceived barriers to medication adherence predicted taking adherence (proportion of prescribed doses taken) during the subsequent 3 mo., as monitored with a multidose electronic pillbox. We evaluated the 126 participants of TAKE-IT with electronic adherence data available for the 3-mo. run-in period during which no intervention was applied. Participants (11-24 y.; ≥ 3 mo. post-transplant) were followed in 8 transplant centers (Canada and USA). Adherence barriers were assessed at baseline using the Adolescent Medication Barriers Scale (AMBS). A higher score indicates greater barrier burden (possible range 17-85). We used linear regression to estimate the association between baseline AMBS scores (total score and ingestion, disease adaptation, and cognitive/organization subscores) and taking adherence. Models also included sex, age, race, and time since transplant.

Results: 60% were male and 67% were white. Median age at baseline was 15.8 (IQR 13.2-17.4) y. Median time since transplant was 3.1 (0.7-7.5) y. Mean±SD taking adherence for the interval was 87.0%±28.9. Higher barrier burden (median score 38 (IQR 30-44)) was significantly associated with poorer adherence: a 5 unit higher total AMBS score was associated with 1.5% (95% CI 0.04, 3.0) lower taking adherence. Males had 7.5% (0.8, 14.3) lower taking adherence than females. The only subscale score significantly associated with taking adherence was disease adaptation: a 5 unit higher sub-score was associated with 3.3% (0.4, 6.2) lower taking adherence.

Conclusions: While the absolute impact of barrier burden on adherence is small, higher burden of perceived barriers is a significant predictor of poorer adherence. Future analyses of the TAKE-IT data will determine the impact of an intervention targeting individual barriers on objectively-measured adherence.

SA-PO1028

Pre-Procurement Iodinated Contrast Exposure Is Associated with Early and Late Kidney Transplant Outcomes
Fidel Barrantes,[1] Sarah Stith,[2] Abhijit S. Naik,[3] Isaac E. Hall,[4] Mark A. Perazella.[4] *[1]Renal Medicine Associates, Albuquerque, NM; [2]Economics, Univ of New Mexico, Albuquerque, NM; [3]Internal Medicine, Univ of Michigan, Ann Arbor, MI; [4]Internal Medicine, Yale Univ, New Haven, CT.*

Background: Iodinated contrast can cause acute kidney injury. We sought to evaluate the association of iodinated contrast exposure prior to organ procurement in deceased donors with subsequent kidney transplant outcomes.

Methods: Using OPTN data for kidney transplants between May 2000 and December 2012, we performed multivariate regression to model 2 different definitions of delayed graft

function as a function of donor exposure to coronary angiograms, controlling for time-invariant factors affecting all patients in a given year (year fixed effects) and time-varying factors associated with a specific transplant center (center fixed effects with standard errors clustered at the center level to account for heteroskedasticity and spatial correlation among patients in a given center).

Results: Of 93,811 donors listed in study period, 8.5 % (8012)were exposed to coronary angiograms. From this group, 14 628 kidneys were transplanted. Statistically significant regression results ($p<0.01$) indicate that patients receiving organs from donors who received coronary angiograms are 2% points more likely to receive dialysis within the first week of transplant (mean=0.24) and are less likely to experience a >25% decline in serum creatinine in the first week of transplant (mean=0.56). These patients also face a 61 day shorter average graft survival time and a 1% point lower probability of 6-month post-transplant patient survival. At three years recipients from donors with contrast exposure have 2% decrease in survival rate (P=0.005).

Conclusions: This large database analysis provided statistical power to detect an association between donor exposure to iodinated contrast from coronary angiograms before organ procurement and subsequent adverse early as well as later kidney transplant outcomes. Further research into the effects of deceased-donor management strategies is warranted to expand the organ pool while decreasing adverse transplant outcomes.

SA-PO1029

One Year Recovery After Kidney Donation: The Medical and Donor Point of View in a Prospective Cohort Study

Briançon Serge,[1] Lucie Germain,[1] Michele Kessler,[2] Marie-Alice Macher,[3] Marc Soudant,[1] Marie Thuong.[2] *[1]Epidemiologie CIC-EC, CHU de Nancy, Nancy, France; [2]Nephrology, CHU de Nancy, Nancy, France; [3]Transplantation, Agence de la Biomedecine, Paris, France.*

Background: Renal transplantation is the reference treatment for ESRD patients; the living donor kidney has been proven to provide better outcomes to recipients. Recovery of donors has been less studied and understood.

Methods: An exhaustive sample of 500 donors recruited in every French transplantation between October 2009 and January 2012 (T0) were followed at 3 (T1) and 12 months (T2) after surgery. Questionnaires investigating the donation course, quality of life (SF-36 and Euroqol) and recovery were sent home. Medical data were from CRISTAL register. 384 donors participated at 3(85%) and 12months(90%). The exceptional participation rate reflects the high commitment of donors.

Results: Before the donation, the physical health is incredibly high especially for older. On average a 75 year-old donor has the PCS SF36 level of 35 year-old men in the general population Thre months after surgery, all outcomes exhibited decreased health indicators. Three quarters of the donors underwent laparoscopy, associated with less pulmonary complications, kidney failure, high blood pressure, persistent physical pain, better postoperative recovery. More than half the donors have at least one complication of which 8% was severe. The appearance of the scar is one of the dissatisfaction of the donor. One year after the donation, over 10 donors, 9 resumed work, 3 not all completely recovered, three still feel physical pain, .4 have not recovered their PCS pre-donation level, and 5 their MCS level.However their status remains better than that of the general population of the same age and sex. Donors are ready to do it again (98.2%) and recommend the donation (96%).

Conclusions: The experience alters neither the initial impetus nor the meaning attributed to the donation. The recommendations are to pursue the development of laparoscopy, to inform about and manage completely pain, to better prepare the donor to the surgical procedure, its risks and aftermath, including professional ones in younger, to perfectly plan the medical follow up with information to referee physicians.

Discard of Deceased Donor Kidneys in the United States: The Weekend Effect

Sumit Mohan,[1] Karl F.W. Foley,[1] Mariana C. Chiles,[1] Geoffrey K. Dube,[1] Russell J. Crew,[1] Stephen O. Pastan,[2] Rachel E. Patzer,[2] David J. Cohen.[1] *[1]Dept of Medicine, Columbia Univ College of Physicians & Surgeons, New York, NY; [2]Dept of Medicine, Emory Univ School of Medicine, Atlanta, GA.*

Background: The discard rate of deceased donor kidneys (DDK) has slowly increased over time. The underlying reasons remain unclear. The impact of low resource availability over the weekends on the acceptance of DDK for transplantation is currently unknown. We attempt to measure the impact of weekends on organ utilization patterns.

Methods: The majority of DDK (80%) are transplanted over the weekend and are procured on either Friday or Saturday (Fri-Sat). Using data from the Scientific Registry of Transplant Recipients (SRTR), we identified and compared all DDK procured on Fri-Sat to those that were procured on other days of the week. Using logistic regression we estimated the adjusted odds of discard for DDK over the weekend.

Results: Among the available kidneys, the Fri-Sat period was associated with lower procurement (89.5 vs 90.2%, $p<0.001$) and the procured kidneys were older (39.7±17.7 v 39.1±17.6, $p<0.001$) and of lower quality (KDRI 1.33±0.49 v 1.31±0.49, $p<0.001$). Not only were Fri-Sat DDK were more likely to be discarded (18.6 vs 16.4%, $p<0.001$), these kidneys were of higher quality than those discarded during the rest of the week (KDRI 1.82±0.57 vs 1.84±0.56, $p=0.018$). Fri-Sat DDK were more likely to be shared without payback and be transplanted at a large transplant center. After adjusting for KDRI, Fri-Sat DDK were 20% more likely to be discarded than kidneys procured during other times during the week (OR=1.20, $p<0.001$).

Conclusions: DDK procured on Fri-Sat are more likely to be discarded than at other times of the week while those that are transplanted are more likely to be shared with large transplant centers. Our results demonstrate the possibility that low resource availability on the weekends adversely impacts organ procurement, acceptance and transplantation.

SA-PO1031

Medication Adherence Barrier Burden Predicts Subsequent Adherence to Dosing Time Schedule in Adolescent Kidney Transplant Recipients in the TAKE-IT Trial

Bethany J. Foster,[1] Huaqing Zhao,[2] Ahna Lh Pai,[2] Nataliya Zelikovsky,[2] Crystal D. Holly,[2] Jodi M. Smith,[2] Vikas R. Dharnidharka,[2] Diane Hebert,[2] Lorraine E. Bell,[2] Douglas G. Matsell,[2] Veronique Phan,[2] Susan L. Furth.[2] *[1]Pediatrics, McGill Univ; [2]TAKE-IT Investigators.*

Background: Studies of adherence to timing of medication dosing in high-risk adolescent kidney transplant recipients are lacking.

Methods: We aimed to determine whether the burden of perceived barriers to medication adherence predicted timing adherence (proportion of doses taken £1 h. before to £2 h. after the prescribed dosing time) during the subsequent 3 mo., as monitored with a multidose electronic pillbox. We evaluated the 126 participants of TAKE-IT who had electronic adherence data available for the 3-mo. run-in period (no intervention). Participants (11-24 y.; ≥ 3 mo. post-transplant) were followed in 8 centers (Canada and USA). Adherence barriers were assessed at baseline using the Adolescent Medication Barriers Scale (AMBS). A higher score indicates greater barrier burden (possible range 17-85). We used linear regression to estimate the association between baseline AMBS scores (total score and ingestion, disease adaptation, and cognitive/organization subscores) and timing adherence. Models also included sex, age, race, and time since transplant.

Results: 60% were male and 67% were white. Median age at baseline was 15.8 (IQR 13.2-17.4) y. Median time since transplant was 3.1 (0.7-7.5) y. Mean±SD timing adherence for the interval was 82.6%±32.8. Higher barrier burden (median score 38 (IQR 30-44)) was significantly associated with poorer timing adherence: a 5 unit higher total AMBS score was associated with 2.0% (95% CI 0.4, 3.6) lower timing adherence. A 5 unit higher score was associated with 4.3% (1.2, 7.5) lower timing adherence for the disease adaptation sub-scale, and with 5.9 % (0.2, 11.6) lower timing adherence for the cognitive/organization sub-scale. Males had 10% (2.9, 17.6) lower timing adherence than females.

Conclusions: Higher burden of perceived barriers was a significant predictor of poorer timing adherence in this longitudinal study. Future analysis of the TAKE-IT data will determine the impact of an intervention targeting individual barriers on timing adherence.

Deceased Donor Procurement in the U.S.: Measurement of Surgical Damage Inflicted Upon the Procured Organ

Tim E. Taber,[1] Nikole Neidlinger,[2] Muhammad Ahmad Mujtaba,[3] Elling E. Eidbo,[5] Anil S. Paramesh.[4] *[1]Medicine, Indiana Univ School of Medicine / Indiana Donor Network, Indianapolis, IN; [2]Surgery, Donor Network West, Berkley, CA; [3]Medicine, UTMB Galveston, Galveston, TX; [4]Surgery, Tulane Univ School of Medicine, New Orleans, LA; [5]Association of Organ Procurement Organizations, Vienna, VA.*

Background: Deceased organ donation provides healthy allografts for the majority of organ transplants done in this country. While there are many factors involved in determining suitability of allografts for transplantation, one of the most important is careful procurement of the organ.

Methods: In the winter of 2013, the medical directors of the Association of Organ Procurement Organizations (AOPO) agreed upon a standard for organ damage sustained during procurement. Organ damage was classified into three tiers, from 1 – 3 with the latter rendering the organ non-transplantable. For 12 consecutive months starting in January of 2014, 36 of 58 OPOs prospectively submitted quality data regarding organ damage seen on the procured organ. These 36 OPOs recovered 5,401 of the nation's 8,504 deceased donors for calendar year 2014.

Results: A total of 9501 kidneys were procured from this cohort. Organ damage determined at time of procurement was as follows: 156 class 1 (non-clinically relevant damage); 86 class 2 (damage requiring repair prior to transplantation); 43 class 3 (kidneys that were damaged to the extent that they could not be transplanted).

Conclusions: Damage done to the kidney at the time of procurement rendering the allograft non-transplantable occurred at a rate of approximately 0.45%. Smaller organ procurement organizations (measured by total number of donors) were more likely to have higher rates of damage. Class 1 and 2 damage was more frequent than class 3 but did not result in loss of the allograft for transplantation. While damage done to the kidney at the time of procurement was rare, it did exist. Further evaluation of this issue is warranted to maximize the opportunity for organ transplantation.

SA-PO1033

Short-Term Outcomes After Donor Nephrectomy in Individuals with Persistent Asymptomatic Non-Visible Haematuria Ben Talbot,[1] Simon K. Winn,[2] Lubna Rashid,[2] Seema Shrivastava,[2] Peter A. Andrews,[3] Ed Kingdon.[1] *[1]Sussex Kidney Unit, Royal Sussex County Hospital, Brighton, United Kingdom; [2]Renal Unit, St. George's Hospital, London, United Kingdom; [3]Renal Unit, St. Helier Hospital, Epsom, United Kingdom.*

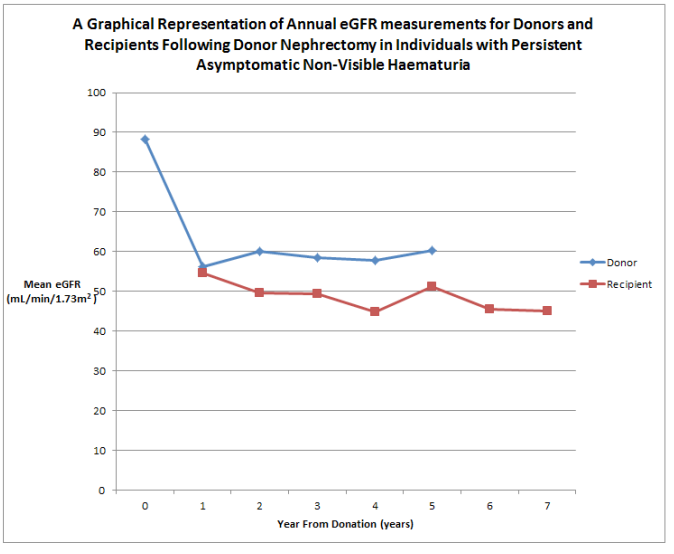
Background: National guidelines in the United Kingdom suggest investigation to exclude urological disease and identify glomerular pathology in potential donors with persistent asymptomatic non-visible haematuria (PANVH). There is currently no guidance on how to proceed where abnormal immunohistochemistry (IHC) is found without proliferative glomerular changes or electron dense deposits (EDD).

Methods: Demographic characteristics, renal function and biopsy details were obtained by retrospective case note review of kidney donors in the South West Thames transplant network who had undergone renal biopsy for PANVH between 2008-13. Light microscopy, IHC and electron microscopy (EM) findings were collected and clinical outcomes analysed for donors and recipients.

Results: Twenty four donors with PANVH proceeded to donation.

Biopsy findings in subjects proceeding to donor nephrectomy (n=24)		
Normal Mesangial Cellularity	24/24	
Focal interstitial fibrosis or tubular atrophy <10%	6/24	
Abnormal glomerular IHC:	15/24	Location:
IgM and C1q	11/24	Mesangial
Isolated IgM	3/24	Mesangial
Isolated C1q	1/24	Mesangial
Thin basement membrane (<250 nm)	7/21	(EM not available in 3 patients)

Mean eGFR before donation 88.2 mL/min/1.73m^2 (69-117) and one year after donation 56.2 mL/min/1.73m^2 (41-77). Five recipients are not followed up locally. The remaining recipients (n=19) had mean eGFR beyond one year 49.9 mL/min/1.73m^2 (24-82), mean follow up 2.9 years (1-7).



Conclusions: Renal biopsy in potential donors with PANVH will identify mesangial proliferation or EDD in a minority of cases. Early outcomes in our small cohort of PANVH donors are favourable. Longer term follow-up of PANVH donors and recipients is being undertaken.

SA-PO1034

Jeevandan: Deceased Donor Transplantation Programme from a Developing Country Swarnalatha Guditi. *Nephrology, NIMS, Hyderabad, Telangana, India.*

Background: In developing country like India the prevalence of end stage organ disease is increasing.Though transplantation has been in practice in India, its been grossly inadequate in terms of actual numbers, due to a shortage of resources and organs. The only solution for the shortage of organs is deceased donor transplantation.

Methods: In India the Human Organs Transplantation Act,was enacted in 1994 with the objective of promoting and regulating the transplantation of human organs like kidney, liver and heart - both live as well as cadaver there was no significant increase in cadaver transplantation over the past two decades for various reasons. India follows "opt in" system and brain death declaration is not mandatory. Andhra Pradesh and Telangana are the two important states in India, situated on the country's southeastern coast. It is India's fourth largest state by area and fifth largest by population. Government of Andhra Pradesh, considering the shortage of organs and burden of end stage organ failure in the state, has come up with a Government Order[6] called **"Jeevandan"** to streamline the procedure for facilitating and regulating the cadaver transplantations on an end-to-end basis.

Results: There were 129 deceased donations in 2 years. Male were 93 and female 36: female to male ratio being 1: 2.58 The mean age was 41 years (range 8 to 79). Most common Blood group was O in 51 (39.5%) donors followed by B in 39 (30.23%), A positive in 29 (22.48%) donors, and AB in 10 (07.75%) donors. Total 593 organs including minor organs were retrieved from 129 deceased donors; 233 kidneys, 126 livers, 7 hearts, 118 heart valves, 103 corneas , 5 lungs and 1 Pancreas.Total deceased donor renal transplantations done during this period were 24.67% . Out of 129 donors, 6.8 % kidneys and 3% livers were not utilized. Mean age of renal recipients was 44.07 years (range 13 to 72). There were 26.8% females and 73.2% males, female to male ratio being 1:2.73. Among deceased donor renal transplant recipients, O blood group was most common, seen in 36.79% followed by B in 32.38%, A in 22.64% and AB in 8.17% patients.

Conclusions: Decease donor transplantation is the solution for organ shortage and increasing demand of organ requirement.

SA-PO1035

Deceased Directed Kidney Donations: A Three-Year Experience at a Single OPO Rebecca Hurst,[1] Michael D. Salvatore,[1] Nikole Neidlinger.[1,2] *[1]Donor Network West, San Ramon, CA; [2]California Pacific Medical Center, San Francisco, CA.*

Background: The UAGA allows for deceased directed organ donations. Our OPO has incorporated the practice of offering the option of directed donations during every donation discussion in response to routine donor family requests. However, facilitating directed donations for donor families remains a controversial topic. Opponents suggest that directing gifts is not only inequitable, but that it may encourage malfeasance in the form of organ solicitation via media or social networking campaigns or by groups who promote discrimination. The purpose of this research effort was to identify how many directed kidney requests were received and honored during a three-year period in order to assess the impact on our allocation scheme.

Methods: We analyzed retrospective data from our OPO for three years from 2012-2014. We evaluated the number of directed kidney donation requests in relation to the overall number of donors, as well as the transplant outcomes or reasons for decline when the request was not honored. Relationship of donors to potential recipients was also assessed.

Results: Over the three year period, 176 of our 1,056 authorized donors had a potential directed donation. Of these, 80% were directed to patients on the kidney waiting list. However, only 16% of the attempted directed kidney donations resulted in a transplant. The data illuminate that incompatibility/mismatch of potential directed kidney recipients is the most common reason that directed kidneys are not transplanted, despite the fact that directed donations are allocated ahead of highly sensitized patients, mandatory shares, multivisceral combinations, and the like.

Conclusions: Facilitating directed donations will continue as part of our routine practice. Each year approximately one in six of our donor families identified potential recipients, but transplants from these requests remained consistently less than 2% of our annual total. Future studies are planned to evaluate recipient outcomes, assess donor family satisfaction with a recipient known to them, as well as to examine our practice in detail in an effort to standardize the language and timing of the directed donation discussions.

SA-PO1036

Optimal Outcomes in Pediatric Renal Transplant Recipients Veronica A. Taylor,[1] Cassie L. Kirby,[1] Jens W. Goebel,[1,2] David K. Hooper.[1,2] *[1]Cincinnati Children's Hospital Medical Center; [2]Dept of Pediatrics, Univ of Cincinnati College of Medicine.*

Background: Pediatric kidney transplant recipients (pKTRs) experience multiple sequelae of their condition, yet comprehensive assessment of these is lacking in the literature. Our objective was to develop a composite outcome measure for pKTRs that considers the most common comorbidities, and to evaluate a population of pKTRs at specific intervals post-transplant.

Methods: We retrospectively reviewed all KTRs at our center from 10/2008 through 2/2015. An optimal outcome composite measure was created consisting of 14 criteria in four domains: allograft function (CKD stage <3, urine protein/creatinine ratio < 0.5, absence of DSAs), histology (no or mild interstitial fibrosis and tubular atrophy, no transplant glomerulopathy, and no history of AMR or ACR), infection (BKV PCR <10,000, CMV PCR£0, no history of PTLD or symptomatic EBV) and cardiovascular (CV) health (triglycerides<500, LDL <130, BP <90th %ile, fasting glucose < 126, and BMI < 85th %ile). Patients were evaluated on these pass/fail criteria at post-transplant yrs 1, 3, 5, and 10. Optimal outcome was defined as passing ³13/14 criteria.

Results: A total of 177 patients and their 282 clinic visits were analyzed. Of 94 patients who completed their 1st year, only 32 patients (34%) achieved an optimal outcome. This was significantly higher than at yrs 3 (8/74, 11%), 5 (13/62, 21%), and 10 (9/52, 17%) ($p < 0.01$). The top two categories in which patients failed at 1 yr were cardiovascular health (which remained relatively stable: ~30% at each time point) and allograft function which decreased from 57/93 (61%) at yr 1 to 24/62 (39%) at yr 3 ($p<0.01$).

Conclusions: Only 1/3 of pKTRs achieved an optimal outcome at 1 year post-transplant, and this fell to 1/6 of patients by 10 years. Cardiovascular health and graft function were the

primary failure modes. Evaluation of all transplant-related outcomes at specific follow-up intervals will allow practitioners to assess the success of kidney transplantation and overall recipient health and focus clinical outcome improvement efforts.

SA-PO1037

Clinical Outcome of Elderly Living Kidney Donors: A Single-Center Study in Japan Jumpei Hasegawa, Kohei Unagami, Masayoshi Okumi, Kazuya Omoto, Hideki Ishida, Kazunari Tanabe. *Urology, Tokyo Women's Medical Univ, Tokyo, Japan.*

Background: Previous studies and current guidelines have suggested that elderly persons can be living kidney donors; however, reports on elderly donors >70 years old are limited. In order to clarify the donor safety and feasibility, we investigate the clinical outcomes of living kidney donors > 70 years old after nephrectomy.

Methods: We conducted a case-series study of living kidney donations involving 48 donors aged >70 years at the time of transplantation. The kidney donations occurred between 2001 and 2014 at Tokyo Women's Medical University in Tokyo, Japan. The primary outcomes were survival or end-stage renal disease (ESRD)-free rate and all crude event-free rates, including cardiovascular-, infection-, ESRD-, or death-free rate. The secondary outcome was serum creatinine level at the end of the follow-up period.

Results: The 48 cases were followed up for a median of 4 years. The survival rate among the donors was 100% until the fifth year, and only two donors died during follow-up. The ESRD-free rate was 100% during the follow-up period. The overall event-free rate was 100% at 1 year, 85.7% at 3 years, and 75.0% at 5 years. The mean serum creatinine level was 1.18 ± 0.24 mg/dL at the time of hospital discharge and did not increase (1.18 mg/dL) at the end of follow-up.

Conclusions: Living kidney donation from elderly donors >70 years old appears to be a safe and acceptable option for patients requiring renal-replacement therapy.

SA-PO1038

Immunosuppressive Medication Adherence following Kidney Transplantation in the Military Healthcare System Dustin J. Little,[1] Matthew Ward,[2] Robert Nee,[1] Christina M. Yuan,[1] Rahul M. Jindal.[2] *[1]Walter Reed National Military Medical Center, Bethesda, MD; [2]Uniformed Services Univ of the Health Sciences, Bethesda, MD.*

Background: Limitations on the amount and duration of Medicare coverage of immunosuppressive medications (ISM) may contribute to ISM non-adherence and allograft failure. ISM adherence has not been reported in US patients who receive these medications at no cost. We therefore designed a prospective cohort to investigate the incidence of ISM non-adherence in Military Healthcare System (MHS) beneficiaries, who receive lifelong post-transplant ISM at no out-of-pocket cost.

Methods: Adult MHS kidney transplant recipients who provided informed consent completed the Immunosuppressive Therapy Adherence Scale (ITAS) and Beck Depression Inventory-II (BDI-II). Chart reviews were performed to obtain demographic and clinical data. Perfectly adherent subjects (P) (ITAS score of 12/12), were compared to not perfectly adherent subjects (NP; ITAS score £11/12) using Student's t-test and Fisher's exact test where appropriate. Exact logistic regression was performed to evaluate for factors associated with P versus NP adherence.

Results: Forty subjects completed survey instruments. 57.5% of subjects were male, 40% were black, 22.5% were aged <65 years, and 45% were >3 years from transplantation. One subject did not complete the ITAS. Mean overall ITAS score was 11.5±0.9, and 69% (27/39) of subjects reported P adherence. BDI-II scores were significantly lower in P vs. NP subjects (6.7±7.2 vs. 13.6±8.8; p=0.014). Exact LR adjusted for race, timing of transplant, sex, and age revealed an OR of 0.61 (0.32-0.98) for P adherence for every 5 point increase in BDI-II score. NP subjects were significantly more likely to have donor specific antibodies (DSA; 6 of 11 vs. 3 of 24; p=0.015).

Conclusions: MHS beneficiaries reported high levels of ISM adherence. Modest increases in BDI score associated with marked reduction in adherence, and subjects with NP adherence were significantly more likely to have DSA. Our results suggest that enhanced ISM coverage as well as prevention, identification, and treatment of depression should be prioritized for future study in order to improve outcomes following renal transplantation.

SA-PO1039

Clinical Impact of Kidney Donor Follow-Up by Nephrologists Hee Jin Kwon, Jin Hae Kim, Jee Eun Park, Subin Hwang, Jung Eun Lee, Wooseong Huh, Yoon-Goo Kim, Dae Joong Kim, Ha Young Oh, Hye Ryoun Jang. *Nephrology Div, Dept of Medicine, Samsung Medical Center, Sungkyunkwan Univ School of Medicine, Seoul, Republic of Korea.*

Background: Compensatory and adaptive mechanisms in the remnant kidney occur immediately after nephrectomy. The adaptability in early postoperative period may affect the renal function of the remaining kidney. Since the introduction of extended criteria living donor system, the numbers of marginal donors with risk of new morbidities are increasing. The aim of this study was to evaluate the clinical impact of kidney donor follow-up by nephrologists at a donor clinic (DC).

Methods: Our study included 427 living kidney donors from January 2010 to December 2014 in Samsung medical center. Nephrologist-run donor clinic was established in January 2013. The study period was divided into pre-DC and post-DC. Primary outcomes were incidence of CKD and renal functional adaptability (%MDRD = post/pre eGFR X100) at 6 months after donation. Secondary outcomes were changes in compliance and incidence of co-morbidities; hyperuricemia and microalbuminuria.

Results: A total of 215 and 172 donors were included in pre-DC and post-DC, respectively. Before donation,age, sex, proportion of hyperuricemia and microalbuminuria were similar. Preoperative eGFR in pre-DC was significantly higher than post-DC (p<.001). After donation, poor renal adaptation (post-donation eGFR at 6 months < 60% of preoperative eGFR) was less frequent in the post-DC period compared to the pre-DC period (p=.026). CKD development tended to be higher in pre-DC period. Donors in the post-DC period had shorter mean outpatient clinic visit intervals (p<.001), more visits within 6 months after donation(p=.001), earlier detection of de-novo hyperuricemia (p<.001). The incidence and detection time of microalbuminuria were similar.

Conclusions: After establishment of kidney donor clinic operated by nephrologists, donors tended to show better renal adaptability andearlier diagnosis and treatment of hyperuricemia. In conclusion, donor clinic may be a good strategy for improvingrenal outcome and detecting potential risk factors of CKD in donors.

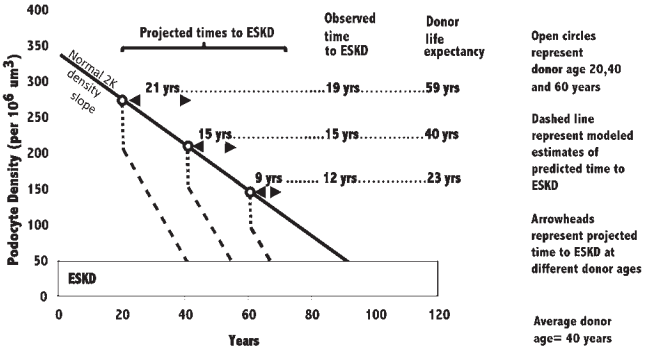
SA-PO1040

Predicting Kidney Allograft Half-Life Using a Podometric Approach Roger C. Wiggins, Abhijit S. Naik, Diane M. Cibrik, Jeffrey B. Hodgin, Farsad Afshinnia, Larysa T. Wickman, Milagros D. Samaniego-Picota. *Univ of Michigan.*

Background: Increasing donor age is a powerful predictor of worse renal allograft outcome. Podocyte depletion is part of the normal aging process (Hodgin, JASN, 2015). Recently we showed that kidney hypertrophy that occurs at time of transition from a 2 kidney to 1 kidney state (transplantation), leads to a 20% reduction in podocyte density and a 6-fold increased rate of podocyte detachment associated with transplant glomerulopathy and allograft failure (Yang, JASN, 2014). To test the hypothesis that podocyte depletion could impact allograft half-life we used a model combining age specific podocyte nuclear density decrease and rate of podocyte attrition after transplantation for comparison with actual allograft outcome data.

Methods: Podocyte density was estimated from immediate post perfusion biopsies from living and deceased donors or from non-diseased nephrectomy specimens. Projected allograft life was predicted based on modeling age-specific podocyte density and the observed attrition of podocytes. Observed data were drawn from the OPTN/UNOS STAR files as of Sept 2014, using all transplants performed between Oct 1987-June 2013. A "conditional" Kaplan Meier analysis using the "period" method was used to calculate observed half-lives at different donor ages.

Results: The podometric projected average half-life for a 40 year old donor is 15.1 years, similar to the observed average allograft half-life (15.1 years). The projected effect of increasing donor age on allograft half-life from podometric measurements is similar to the observed effect of donor age on allograft half-life at all calculated donor ages (p=NS).



Conclusions: Quantitative podometric modeling predicts both shorter-than-expected average renal allograft survival and the donor age effect, compatible with the concept that hypertrophic processes at transplantation significantly impact half-life.

Abstract Withdrawn

SA-PO1042

Prediction of Patient Survival After Kidney Transplantation (Tx): Construction, Validation and Evaluation of Decision Models Using Data Mining Approaches Irina Scheffner,[1] Kaixun Hua,[2] Dan Simovici,[2] Tanja Abeling,[1] Hermann G. Haller,[1] Wilfried Gwinner.[1] *[1]Hannover Medical School, Germany; [2]Univ of Massachusetts.*

Background: Understanding the risk factors that predispose to death is important to deliver the most appropriate therapy to Tx patients (pts). Aim of this study is to build reliable decision models and to identify the relevant risk factors for death using different data mining approaches.

Methods: We analyzed 761 pts transplanted between 2000 and 2007 (follow-up of up to 10 years). Data included biopsy results, clinical & laboratory factors. After conventional statistical feature selection of 28 variables we build Naïve Bayesian (NB), C5.0, RPART and Random Forest (RF) models.

Results: Compared to C5.0 and RPART, NB and RF resulted in models with a higher sensitivity to predict death and a high specificity. Using different partitions for training and test set, NB models had a sensitivity of 62-65% and a specificity of 89-91% to predict death. With RF, sensitivity was 64% and specificity 96%. Because of the imbalance of the outcome groups (13% deceased pts) modeling was repeated with balanced datasets obtained by oversampling. With the balanced data, sensitivity was 82% and specificity 79% with NB. With RF, sensitivity was 83% and specificity of 68%. These models were externally validated with two separate datasets showing sensitivities of 64 and 59% and specificities of 86% and 78% for the NB models and sensitivities of 84 and 61% and specificities of 60 and 65% for the RF models. Highly important variables were recipient age, pre-Tx diabetes mellitus, peripheral arterial and coronary heart disease, cold ischemia time, graft function within the first 6 weeks and annual GFR loss, and post-Tx systolic and diastolic blood pressure, urinary tract infections, and hyperparathyroidism. Modestly important variables included donor age, time on dialysis, HLA DR mismatches, delayed graft function.

Conclusions: The established models permit reliable prediction of death and survival and can be used to identify pts on risk. Moreover, with the identified (modifiable) risk factors pts can be assigned to different treatment strata to offer each patient the optimal therapy.

The Decline of Dialysis in Northern Ireland Kathryn E. Larmour. *Regoinal Nephrology Unit, Belfast City Hospital.*

Background: The first session of haemodialysis in Northern Ireland (NI) was in 1959 for acute kidney injury. There has been an inexorably rise in the prevalent dialysis population in the province since then, with expansion of dialysis facilities to accommodate ever increasing numbers. However, in addition to inferior outcomes compared to transplantation, there are considerable capital and recurrent costs associated with chronic haemodialysis provision. This study considered the impact of an expansion in the living donor (LD) transplant programme on dialysis in NI and the financial implications.

Methods: The prevalence dialysis population from 1999-2014 (inclusive) data were retrieved retrospectively from collected data. The number of LD transplants in NI patients is prospectively recorded. The economic impact of the changes evident in our centre were then evaluated.

Results: In 1999 there were 479 patients in NI receiving maintenance dialysis treatment. This number increased annually until a zenith of 836 in 2009. There were no living donor transplant procedures in 1999, from 2000-2008 there were between 4 and 9 performed annually. There was an expansion of the LD programme thereafter, and for the past four years there have been between 53-60 LD transplants each year (>30 donor pmp). This increase has coincided in an initial plateau and then a decline in the prevalent dialysis population [figure 1]. The cost of maintaining a patient with end-stage renal failure on dialysis is £17,500 ($27,000) per patient per year for a patient on peritoneal dialysis and £35,000 ($54,000) per patient per year for a patient on hospital haemodialysis. The first year of care after a kidney transplant costs around £17,000 ($26,000) and £5,000 ($7,500) for every subsequent year. Live donor costs are approximately £9,000 ($14,000). Transplantation results in a cost benefit in the second and subsequent years of £25,800 ($39,500) per annum. The cost benefit of transplantation compared to dialysis over a period of ten years is £241,000 ($370,000).

Conclusions: A proactive approach to living donor transplantation has benefits not only for individual patients but in reducing the prevalent dialysis population and the healthcare costs associated with renal replacement therapy.

SA-PO1044

Pre-Existing Donor-Related Diabetic Nephropathy Predicts Poor Allograft Survival Steven Salvatore,[1] Mohamad M. Alkadi,[2] Thangamani Muthukumar,[2] Surya V. Seshan.[1] *[1]Pathology, Weill Cornell Med College; [2]Nephrology, Weill Cornell Med College.*

Background: Diabetic nephropathy (DN) is the most common cause of end stage renal disease in the US, and in the transplant setting may play a role in long-term graft dysfunction. In patients without diabetes, finding features of DN in the immediate for-cause post-transplant biopsy may confer increase risk of allograft dysfunction.

Methods: From 2005-2014, 141 biopsies from 120 transplant patients with DN were studied. DN was classified as 1) donor related if present on biopsy <2 yrs from transplant or no diabetes in recipient, 2) recurrent if >2 yrs with history of pre-transplant DN, or 3) de novo in post-transplant diabetes (all >3 yrs). Clinicopathologic parameters were analyzed in 95 patients with adequate clinical history (25 excluded).

Results: Of 95 biopsies with features of DN, 43 were characterized as recurrent, 17 de novo, and 35 donor-related. Biopsies with donor-related DN were done 0.5 yrs (0 days-3.6 yrs) post-transplant and 6 had delayed graft function. Other non-DN related disease was seen, likely prompting biopsy: acute tubular injury (10/35), antibody mediated rejection (4), acute cellular rejection (1), CNI toxicity (3), AIN (4), TMA (1) and BKV (1). Pathologic class of DN were: Class 1-3, Class 2a-21, Class 2b-1, Class 3-10. Class 3 DN lesions are associated with higher proteinuria, Cr, and increased vascular sclerosis. 13/35 donors had known diabetes with mean hemoglobin A1c of 8.5% (range 4.7-14.6%). DN was not listed on any pre-implantation biopsy reports. Mean follow-up times were 3.8 yrs for donor-related, 7.8 for recurrent, and 10.3 for de novo. Despite shorter follow-up, transplants with donor-derived DN had significantly more failure than recurrent DN (49 v 14%, P=.0008) or de novo DN (49 v 18%, P=.024). Recurrent and de novo DN had similar rates of graft loss (P=.64).

Conclusions: Despite careful screening of transplant kidney donors, donor related DN may be missed on pre-surgical biopsy or not effectively reported and leads to renal dysfunction in the early post-transplant period. Donor related DN is a significant contributor to early allograft loss compared to recurrent or de novo DN and predicts poor long term graft survival.

SA-PO1045

Maternal and Fetal Outcomes in Living Kidney Donors in Korea Kyung Don Yoo, Hajeong Lee, Jae Yoon Park, Eunjin Bae, Jung Pyo Lee, Dong Ki Kim, Kwon Wook Joo, Yon Su Kim. *Seoul National Univ College of Medicine.*

Background: Mild elevation of blood pressure was detected after unilateral nephrectomy in kidney donors. Consequently, female kidney donors at risk for complications such as gestational hypertension caused concern. However, the impact of kidney donation on maternal and fetal outcomes had not been well established in Asian kidney donors.

Methods: This study included young female kidney donors under 45years old (YO) at the time of kidney donation in Seoul National University Hospital between 1972 and 2014. In all, 417 female donor participants (≤45YO) were enrolled. A survey of pregnancy experiences was performed by medical chart abstraction and telephone poll. We additionally enrolled 3,608 pregnancies were enrolled as non-donor control. The questionnaires were approved by institutional review board in our institute.

Results: We tried to contact all of 417 female kidney donors. The thirty five donors had no experience of pregnancy, and finally we could have got 253 questionnaires of kidney donors. Donors were compared in the three groups according to pregnancy pre-,post- kidney donation group and non-donor control group. The proportion of predonation pregnancies were 82% (370cases, Mean age 38.8 years), and postdonation pregnancies were 14.0% (56cases, Mean age 27.2 years). In the majority of postdonation pregnancy cases were detected in recent years from 2007 to 2014 (72.3%). There were no differences of fetal outcomes such as incidence of prematurity, low-birth weight and fetal death between the groups. Gestational hypertension were no differences between the postdonation group and non-donor control group (5.4% vs. 5.8%). Donors with pregnancy after donation were more likely to have undergone Cesarean section (40.4%) than those with pregnancy before donation (21.9%).

Conclusions: This study revealed that maternal and fetal outcomes had little difference between the kidney donors and normal control. Further research using matched controls should be warranted.

SA-PO1046

Self-Monitoring Renal Function After Transplantation: A Clinical Trial on Safety and Usability Céline Lianne Van lint,[1] Sandra Van dijk,[1] Wenxin Wang,[2] Mark Neerincx,[2] Ton Rovekamp,[3] Ton J. Rabelink,[1] Paul J. Van der boog,[1] Willem-Paul Brinkman.[2] *[1]Nephrology, Leiden Univ Medical Center, Leiden, Netherlands; [2]Faculty of Computer Science, Delft Technical Univ, Delft, Netherlands; [3]Dept of Technology in Healthcare, Prevention and Health, TNO, Leiden, Netherlands.*

Background: Kidney transplantation requires intensive monitoring which is burdensome for both patient and healthcare. With the availability of an innovative creatinine device, patients are enabled to monitor renal function at home. To investigate safety and usability of self-monitoring during the first year after transplantation an RCT was conducted.

Methods: The intervention group used a Statsensor® Xpress™ to measure creatinine at home during the first year post-transplantation. Measurements were registered in a web-based system using a traffic light analogy to support interpretation of creatinine trends. Differences between groups regarding GFR were assessed at baseline (discharge) and at 1 year. Creatinine trends measured at home were compared to clinically relevant increases (>10%) measured in the hospital laboratory. A subsample of intervention patients was interviewed on self-monitoring experiences.

Results: In total 119 patients were included (intervention n=64; control n=55). GFR did not differ between groups at baseline, nor at 1 year (72.8 and 71.1 ml/min at 1 year for intervention and control group, respectively). For 34 out of 63 laboratory-based creatinine increases, sufficient home-based creatinine measurements were available for trend comparison. In 76% a similar trend was observed. Self-monitoring enhanced early detection of rejection in 3 out of 5 cases, none were missed. Satisfaction was high: 71% of the interviewed patients (n=26) would have liked to extend self-monitoring creatinine beyond 1 year.

Conclusions: Findings suggest that self-monitoring creatinine at home can be used for transplant follow up. With improvement of the detection rate of relevant creatinine increases (e.g. by increasing measurement frequency), self-monitoring creatinine allows number of outpatient visits to be reduced.

SA-PO1047

Comparison of Heart Rate Variability in Kidney Transplantation and End-Stage Renal Disease Patients on Dialysis Lee Heeryong. *Internal Medicine, Bong Seng Memorial Hospital, Busan, Korea; Internal Medicine, Pusan National Univ Hospital, Busan, Korea.*

Background: Heart rate variability (HRV) is a method for evaluation of autonomic nervous system activity by expressing the balance of sympathetic and parasympathetic tones. Some studies of HRV in patients with end-stage renal disease (ESRD) have been performed. However, few have examined kidney transplantation (KT) patients. Therefore, we investigated autonomic nervous system activity by means of HRV in patients with KT due to ESRD.

Methods: We compared the pattern of cardiac sympathetic and parasympathetic activity by time- and frequency-domain analysisof HRV with 24-h Holter monitoring of 23 KT and 56 dialysis patients. Patients underwent KT between January, 2008 and June,2011.

Results: The mean ages of KT and dialysis patients were 54.2 ± 12.3 and 53.7 ± 12.6 years, respectively. The KT group showedincreased time- and frequency-domain HRV (including HRV index), very low frequency (VLF), means and standard deviations ofall normal R-R intervals for all 5-min segments of the entire recording (SDNNi), low frequency (LF), LF in normalized units (LFnorm), and LF to high-frequency power ratio, compared with the dialysis group.

	HD/CAPD	KTP	p value
SDNN(msec)	173.8±700.0	98.0±31.8	0.017
rMSSD(msesc)	447.2±54/5	35.7±53.9	0.424
SDNNi(msec)	34.5±34.1	35.3±35.7	0.048
pNN50(%)	10.4±20.1	7.1±17.6	0.589
HRV index	10.2±5.2	14.0±4.0	0.001

HRV index, intergral of the density distribution divided by the maximum of the density distribution;pNN50, the percentage of adjacent R-R intervals that varied by more than 50msec;rMSSD, root meas square of the difference between the coupling intervals of adjacent R-R intervals;SDNN, standard deviation of all normal sinus R-R intervals over 24h;SDNNi, means and standard deviation of all normal R-R intervals for all 5-min segments of the entire recording.

Conclusions: Autonomic tone in patients with KT is higher than that in patients with ESRD on dialysis.

Physical Capacity and Function Are Associated with Body Composition, Cardiovascular Health and Quality of Life in Renal Transplant Recipients Danielle Richler-Potts, Jill Neale, Maurice Dungey, Patrick Highton, Emma L. Watson, Alice C. Smith. *Leicester Kidney Exercise Team, Dept of Infection, Immunity and Inflammation, Univ of Leicester, Leicester, United Kingdom.*

Background: A renal transplant can transform the life of patients with end stage renal failure but cardiovascular disease remains a major cause of morbidity and mortality. Post-transplant weight gain is common, and physical functioning often fails to improve in line with increased renal function. This study explored associations of physical function and capacity with body composition, cardiovascular status and quality of life (QoL) in renal transplant recipients (RTRs).

Methods: 35 stable RTRs participated (mean age 52 years (range 29-70), 66% male). Self-reported QoL and physical function were measured by EQ5D and Duke Activity Status Index (DASI) questionnaires. Physical capacity was measured by shuttle walk test (SWT), body composition by DXA, cardiac haemodynamic function by bioreactance (NICOM), and systemic inflammation by plasma IL-6 ELISA.

Results: SWT, DASI and EQ5D all showed significant correlations with percentage body fat (SWT: r=-0.63 p<0.001; DASI: r=-0.41 p=0.02, EQ5D r=-0.47, p=0.005) and with IL-6 (r=0.34 p=0.05). On the other hand, fat-free mass showed positive correlation with cardiac output (r=0.79) and stroke volume (r=0.81, both p<0.001), and inverse correlation with total peripheral resistance (r=-0.67 p<0.001).

Conclusions: This study shows that in RTRs, poor physical function and capacity is significantly associated with lower QoL and also with higher percentage body fat and systemic inflammation, both of which are important cardiovascular risk factors. An increase in fat-free mass was significantly associated with superior cardiac function. Taken together, these results suggest that weight loss is desirable for those with excess body fat, and that gaining muscle mass is also important. Optimising body composition through appropriate exercise and nutrition may therefore improve physical function and capacity and enhance quality of life, and also reduce the risk of cardiac-related morbidity and mortality in this vulnerable population.

SA-PO1049

Pregnancy in the Renal Transplant Recipient: Pregnancy Viability and Effects on Graft Function Andre Caires Alvino Lima, Cinthia Montenegro Teixeira, Igor Gouveia Pietrobom, Mayara Ivani de Paula, Geovana Basso, Laila Almeida Viana, Helio Tedesco Silva, J. Medina-Pestana. *Dept of Nephrology, Hospital do Rim - UNIFESP, Sao Paulo, Brazil.*

Background: Fertility in women is recovered few months after kidney transplantation. However, pregnancy viability and maternal complications remain unclear.

Methods: We studied data from patients from a kidney transplant center in Brazil from 2001 to 2012. In this retrospective study, we identified all pregnant kidney transplantat recipient and collected clinical and laboratory data before pregnancy, every quarter and 12 months after delivery. Each pregnancy was considered a single event.

Results: We included 36 subjects and 53 events were found. The average age was 28±5 years. Pregnancy occurred 4,4±3 years after transplantation. Maintenance immunosuppression before pregnancy was prednisone, tacrolimus and azathioprine in 74% of the cases. The frequency of chronic hypertension was 38%, and 8% had preexisting proteinuria greater than 0,5g. 8 (15%) unintended termination of pregnancy (UTP) were observed in the first quarter and 4 (8%) occurred in the second quarter. Delivery was induced by medical conditions in 41% of cases. 9 (22%) premature births and 7 (17%) very premature births were observed. Two (5%) stillbirths and two (5%) neonatal deaths occurred. Maternal complications were proteinuria de novo (60%), urinary tract infection (23%), preeclampsia (9%) and high blood pressure (9%). During the follow-up period, two (6%) acute rejection and one (2%) graft loss occurred. Average baseline creatinine was compared with third quarter and 12 months follow-up creatinine and significant increase (1,17 vs. 1,46 vs. 1,59mg/dL, p<0,001) was found.

Conclusions: Although the sample is limited, the number of UTP was higher than the general population, with high rates of maternal complications. Besides, diagnosis of preeclampsia may be challenging because of the high frequency of hypertension and preexisting proteinuria. The sustained increase in creatinine suggests higher risk of long-term graft loss. Further research regarding the issue of pregnancy and kidney transplantation is required, in order to improve maternal safety and preserve graft function.

Outcomes of Twin, Triplet and Quadruplet Pregnancies in Kidney Transplant Recipients Serban Constantinescu,[1,2] Lisa Coscia,[2] Dawn Armenti,[2] Michael J. Moritz.[2,3] *[1]Medicine, Temple Univ School of Medicine, Philadelphia, PA; [2]National Transplantation Pregnancy Registry (NTPR), Gift of Life Inst, Philadelphia, PA; [3]Transplantation, Lehigh Valley Health Network, Allentown, PA.*

Background: The purpose of this study is to analyze multiple gestation pregnancy outcomes reported to the National Transplantation Pregnancy Registry (NTPR) in 50 kidney transplant recipients.

Methods: Data were collected via questionnaires, telephone interviews, and hospital records.

Results: Of 986 kidney recipients (1802 pregnancy outcomes) participating in the NTPR, there were 50 who reported 52 multiple gestations with 112 pregnancy outcomes (45 sets of twins, 6 sets of triplets, and 1 set of quadruplets). There were 94 live births, 11 miscarriages, 6 stillbirths, and 1 reduction (triplet to twin pregnancy). Pregnancy occurred after 1st kidney transplant in 47, after a 2nd in 4, and after 3rd in 1 recipient; 14 recipients had a prior post-transplant live birth and 2 recipients had 2 multiple birth pregnancies. Use of reproductive assistance was reported for 16 conceptions (medication 5, intrauterine insemination 5, *in vitro* fertilization 4, and unspecified 2). There were no reports of rejection during pregnancy or postpartum (PP). Mean serum creatinine (mg/dL) was pre-pregnancy 1.4±0.6, during pregnancy 1.4±0.5, and PP 1.4±0.5. There were 4 graft losses within 2 yrs PP. Mean gestational age was 32.1±4.1 wks (range 23-37.4 wks) and mean birthweight was 1680±652 g (range 454-3551 g). There were 11 neonatal deaths including all of the infants in the quadruplet pregnancy. There were 5 birth defects reported: soft cleft palate, hypospadias, unilateral kidney, undescended testicle, and Tetralogy of Fallot. Overall, the majority of the children were reported healthy and developing well at last follow-up.

Conclusions: Female kidney transplant recipients can successfully maintain a pregnancy with multiple gestations. Given the increase in multiple gestations with the use of assisted reproductive techniques and the greater risks to the resulting fetuses, heightened surveillance in the transplant recipient population is warranted.

Kidney Transplantation for End-Stage Kidney Disease After Hematopoietic Stem Cell Transplantation Akihiro Tsuchimoto,[1] Kosuke Masutani,[1] Kei Kurihara,[2] Hidehisa Kitada,[2] Takehiro Nishiki,[3] Morihito Ota,[3] Masayoshi Okumi,[4] Tomokazu Shimizu,[4] Hideki Ishida,[4] Kazunari Tanabe,[4] Kazuhiko Tsuruya,[1] Takanari Kitazono.[1] *[1]Medicine and Clinical Science, Kyushu Univ, Fukuoka, Japan; [2]Surgery and Oncology, Kyushu Univ, Fukuoka, Japan; [3]Sugery, Tomishiro Central Hospital, Okinawa, Japan; [4]Urology, Tokyo Women's Medical Univ, Tokyo, Japan.*

Background: Hematopoietic stem cell transplantation (HSCT) is associated with various kidney diseases. The safety of kidney transplantation (KT) for end-stage kidney disease (ESKD) after HSCT has not been established. In this retrospective multicenter study, we investigated the immunological background, immunosuppressive regimens, and outcome in the KT patients after HSCT.

Methods: We report our experience with 5 KT patients following HSCT: 4 patients received bone marrow transplantation and 1 received umbilical cord blood transplantation. Median age at the time of HSCT was 29 years old (ranged 13-54 years old), and ESKD developed after 119 months (67-307 months). The median duration of pre-transplant dialysis therapy was 18 months (7-69 months). In one patient, bone marrow and kidney were from the same donor.

Results: Median observational period was 18 (5-60) months. All patients were treated antibody-induction with basiliximab followed by triple immunosuppression consists of tacrolimus, mycophenolate mofetil and methylprednisolone. In one patient with positive complement dependent cytotoxicity cross match, we added rituximab, splenectomy and plasmapheresis. In another one patient who received KT and BMT from the same donor, we temporary gave immunosuppressive drugs. After KT, only one patient experienced subclinical acute T-cell mediated rejection and bacterial pneumonia, and the other 4 patients have not experienced acute rejection or severe infectious complications.

Conclusions: Previous studies of KT patients after HSCT suggested low incidence of rejection and stable graft function, but high mortality caused by infections, whereas the patients in our file revealed rare infectious complications as well as mild allograft rejection. Current pre- and post-transplant management contributes favorable outcome of KT patients after HSCT.

SA-PO1052

The Risk Factors of Chronic Kidney Disease Occurrence in Patients Received Liver Transplantation Li Yuehong. *Nephrology, Tsinghua Changgung Hospital, Medical Center, Tsinghua Univ, Beijing, China.*

Background: Analysis the risk factors of chronic kidney disease (CKD) occurrence in patients with liver transplantation.

Methods: 190 patients received liver transplantation followed up during 2001 to 2013 were analyzed retrospectively. 40 patients developed CKD. The observation items included patients' gender, age, primary diseases, surgical approach, preoperative complications, laboratory examinations (hemoglobin, albumin, creatinine, glomerular filtration rate), intraoperative blood loss and blood transfusion volume, postoperative complications and average serum calcineurin concentration (from liver transplantation to the onset of CKD). Clinical data of CKD occurence group were compared with the non-CKD group. Chi square test, t test, and logistic regression analysis were used.

Results: The incidence of CKD in patients with liver transplantation was 21.1%. Renal pathology included IgA nephropathy, hepatitis B virus associated nephropathy, membranous proliferative glomerulonephritis, focal segmental glomerular sclerosis and cryoglobulinemia associated renal injury. 85.7% patients had tubulointerstitial damage. Univariate analysis showed that preoperative renal function, hemoglobin, intraoperative blood loss and transfusion volume, postoperative acute kidney injury, average calcineurin concentration and hypertension were risk factors of CKD in patients with liver transplantation. Logistic regression analysis showed that preoperative glomerular filtration rate (OR=0.980, P=0.041), hemoglobin (OR=0.972, P=0.034), calcineurin concentration (OR=1.364,P=0.015) and postoperative hypertension (OR=4.833, P=0.048) were independent risk factors of CKD occurrence .

Items	B	OR	95%CI	P
eGFR	-0.020	0.980	0.962-0.999	0.041
Hemoglobin	-0.029	0.972	0.946-0.998	0.034
calcineurin concentration	0.311	1.364	1.063-1.751	0.015
postoperative hypertension	1.575	4.833	1.014-23.027	0.048

Risk factors of CKD occurence in patients with liver transplatation by logistic regression analysis.

Conclusions: The incidence of CKD in patients with liver transplantation was higher. Independent risk factors included preoperative glomerular filtration rate, hemoglobin, postoperative average calcineurin concentration and hypertension.

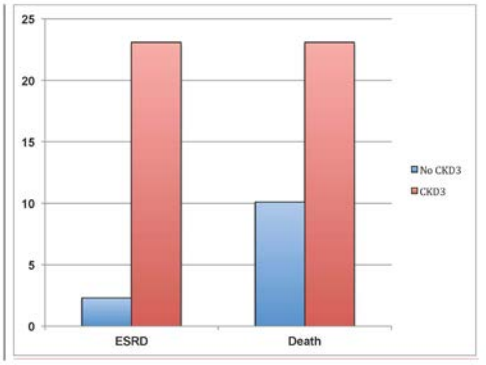
SA-PO1053

Pre-Transplant CKD, but Not AKI, Impacts Survival in Liver Transplant Recipients Yorg Al Azzi, Girish N. Nadkarni, Vinay Nair, Thomas Schiano, Madhav C. Menon. *Medicine, Icahn School of Medicine, New York, NY.*

Background: Chronic kidney disease (CKD) stage and duration of RRT pre-liver transplant (OLT) have been associated with increased risk of progression to ESRD in OLT recipients. Currently, allocation of dual organ transplantation (liver/kidney) is limited to CKD stage 4 and/or RRT > 4 weeks. The data regarding the associations of less severe pre-OLT AKI (RRT<4 weeks) and, of CKD stage 3, with ESRD post-OLT is unclear. We examined the renal outcomes of OLT recipients at our center.

Methods: We reviewed charts of OLT recipients at Mount Sinai for clinical, demographic, laboratory and outcome data from the medical record. We utilized multivariable logistic regression for analysis.

Results: We had data on 115 OLT recipients from 2008-14 (mean age 57.7 years, 66% male). 55/115(47%) patients developed AKI pre-transplant, most often from HRS (47%). Pre-existing CKD-3 was present in 26/115 patients. Pre-OLT AKI developed in 23/26 CKD-3 patients. RRT was required in 8/26 CKD-3 patients. Mean eGFR at 1- and 2-yr follow-up in the CKD-3 group compared to non-CKD group were 37.4 ± 16.6 vs. 33.3 ± 23.1($p<0.01$) and 59.8 ± 20.8 vs. 62.7 ± 22.3($p<0.01$) respectively. At a mean follow up of 1.4 years post OLT, proportion of patients developing ESRD was higher in CKD3 vs. non CKD group (23.1% vs. 2.3%;$p<0.01$) Although, AKI was a significant predictor of ESRD (adjusting for age, sex, race, diabetes), its effect was attenuated after adjusting for CKD. CKD3 was the strongest predictor of ESRD (aOR 8.34; 95% CI 1.25-55.7;p=0.02) (figure 1). Overall, patient survival at a mean of 2.4 years of follow-up was lower in CKD3 vs. non-CKD3 groups (76.9%vs. 91%;p=0.08).



Conclusions: Although limited by small sample size and low event rate, our analysis suggest that pre-OLT CKD3 may have an effect on development of ESRD post-OLT. These effects if generalizable in larger cohorts are important for organ allocation.

SA-PO1054

Can Acute-On-Chronic Liver Failure Classification Predict Post-Liver Transplant and Liver Kidney Transplant Outcomes? Giselle Guerra,[1] Panagiotis Tryphonopoulos,[2] Kalyan Bhamidimarri,[2] Ian Thomas,[1] Rodrigo Vianna.[2] *[1]Div of Nephrology, Miami Transplant Inst, Miami, FL; [2]Divison of Transplantation, Miami Transplant Istitute, Miami, FL.*

Background: Recent evidence suggests that acute on chronic liver failure (ACLF) stratification is more accurate than other methods in predicting short term mortality rates pre-transplant. There is no evidence of ACLF stratification as predictor of post- transplant outcomes. We analyzed if ACLF could predict patient and allograft survival in liver transplant recipients (LTR) or simultaneous liver kidney transplant recipients (SLKTR) especially if hepatorenal syndrome (HRS) is present.

Methods: A retrospective analysis was performed on 86 adult patients, 77 LTR and 9 SLKTR transplanted in 2013. Patients were classified into different ACLF grades (0-3) based on their pre-transplant parameters:MELD labs (total bilirubin, serum creatinine, INR), hepatic encephalopathy, ventilator dependence and the presence of shock. Patient and allograft survival, and kidney function (serum creatinine < 1.5 mg/dL) were analyzed at 6 & 12 months post-transplant between LTR and SLKTR. A further analysis between recipients with HRS receiving either LT or SLKT was made. SLKTR received kidney transplants based on current International Club of Ascites (ICA) guidelines.

Results: Demographics of LTR and SLKTR cohorts: mean age of 58 and 59 years; males 63% and 56%; mean MELD of 21 and 33 respectively. Recipients with HRS pre-transplant had mean MELDof 38 vs. 30 in the LTR and SLKTR groups respectively. 27% of LTR had ACLF 0-1, 11% SLKTR had ACLF 0-1; 73% of LTR had ACLF 2-3; 89% of SLKTR had ACLF 2-3. LTR with HRS had 100% with ACLF 2-3; SLKTR with HRS had 83% with ACLF 2-3. One year post transplant outcomes: Patient Survival – 92% LTR, 66.7% SLKTR; Graft Survival – 89.6% LTR, 66.7% SLKTR; Kidney Function good – 81.8% LTR, 33.3% SLKTR. In patients with HRS both patient and graft survival are 83.3% SLKTR and 75% LTR, but kidney function trended to be better in LTR (50%)vs SLKTR (33.4%).

Conclusions: Patient/graft survival and kidney function appear to trend better overall in LTR vs. SLKTR. However, HRS patients faired the opposite favoring SLKTR vs LTR.

SA-PO1055

C3 Alone Is Not a Prognostic Indicator of Patient or Graft Survival in Post-Transplant Glomerulonephritis Amber Hertz-Tang, Arjang Djamali, Brad C. Astor, Sarah E. Panzer, Weixiong Zhong, Maha A. Mohamed, Didier A. Mandelbrot, Sandesh Parajuli. *Nephrology, Univ of Wisconsin Hospital and Clinics, Madison, WI.*

Background: The prognostic implications of glomerular C3 in the post-transplant setting are not well characterized.

Methods: We examined patient and graft outcomes in 71 kidney transplant recipients diagnosed with glomerulonephritis(GN). Biopsies were studied by immunofluorescence(IF) for glomerular C3 staining and divided into two categories, C3-positive or C3-negative. Primary outcomes were graft and patient survival at 3, 12, and 36 months and at last follow-up. Serum creatinine(Cr) at last follow-up was a secondary outcome.

Results: Thirty three(46%) patients were C3-positive and 38(54%) were C3-negative. Mean follow up was 103 months for positive C3 and 117 months for negative C3 groups. There were no significant differences among groups by age, gender, type of donor, or prevalence of hypertension, diabetes, and hepatitis B or C. A total of 57% of C3-positive patients had a functioning graft at 36 months post-transplant, compared to 75.1% of C3-negative (p=0.16). A total of 88.2% of C3 positive patients were alive at 36 months post-transplant, compared to 85.7% of C3 negative (p=0.9). The mean serum Cr for C3 positive patients at 36 months was 1.59mg/dl compared to 1.71mg/dl for C3 negative (p=0.55). There were no significant differences in graft and patient survival between two groups.

Conclusions: There was no significant difference in patient or graft survival, or in serum Cr between patients with GN and C3-positive IF compared to patients with C3-negative IF. This suggests that the presence of C3 alone is not a prognostic indicator of patient or graft survival in post-transplant GN.

	Positive C3(%)	Negative C3(%)	P
Graft survival at 3 months	96.8	91.8	0.39
Graft survival at 12 months	74.2	80.7	0.58
Graft survival at 36 months	56.8	75.1	0.16
Graft survival at last follow up	27.3	44.7(17)	0.19
Mean serum Cr at last follow up	2.00(0.67)	2.06 ±1.30	0.88
Patient survival at 3 months	100	100	-
Patient survival at 12 months	92.6	97.2	0.41
Patient survival at 36 months	88.2	85.7	0.90
Patient survival at last follow up	75.7	65.7(25)	0.36

SA-PO1056

Pretransplant Hepatitis B Viral Infection Increased Risk of Death After Kidney Transplantation: A Multicenter Cohort Study in Korea Jin Ho Hwang,[1] Jeonghwan Lee,[2] Jang-Hee Cho,[3] Jung Nam An,[4] Chan-Duck Kim,[3] Curie Ahn,[5] Chun Soo Lim,[4] Yon Su Kim,[5] Young Hoon Kim,[6] Jung Pyo Lee.[4] *[1]Internal Medicine, Chung-Ang Univ Hospital, Seoul, Republic of Korea; [2]Internal Medicine, Hallym Univ Hangang Sacred Heart Hospital, Seoul, Republic of Korea; [3]Internal Medicine, Kyungpook National Univ Hospital, Daegu, Republic of Korea; [4]Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul, Republic of Korea; [5]Internal Medicine, Seoul National Univ College of Medicine, Seoul, Republic of Korea; [6]Surgery, Ulsan Univ Seoul Asan Medical Center, Seoul, Republic of Korea.*

Background: Outcomes in kidney transplant recipients (KTRs) with hepatitis B virus (HBV) have not been well evaluated. Here, we aimed to investigate the recent posttransplant clinical outcomes of KTRs with HBV comparing with those with hepatitis C virus (HCV) or seronegative patients.

Methods: Among 3885 kidney recipients from Apr. 1999 to Dec. 2011, 3490 patients were enrolled whose viral hepatitis serology data was available. Numbers of patients with HBV and hepatitis C virus (HCV) were 166 (4.8%) and 55 (1.6%).We analyzed the overall mortality and graft failure (GF) among patients who had taken KT.

Results: Patients with HBV showed poorer patient survival (P=0.030, adjusted HR=2.296, 95% CI 1.084-4.864) than KTRs without HBV. However HCV did not affect patient survival (P=0.763). Patients with chronic hepatitis C showed increased incidence of GF (P=0.015, adjusted HR=2.330, 95% CI 1.178-4.606). However, the GF of patients with chronic hepatitis B (CHB) was not different (P=0.066). Among causes of mortality of KTRs with HBV, hepatic failure was predominant (44.4%). The KTRs with HCV had increased incidence of acute rejection (log-rank P=0.005; crude HR=2.147, 95% CI 1.344-3.432, P=0.001). Among KTRs with HBV, mortality was significantly correlated with higher grade of inflammation in pretransplant liver biopsy (P=0.007) and lower rate of prophylactic antiviral treatment (P=0.019).

Conclusions: The KTRs with CHB could show poor survival due to post transplantation hepatic complications. Continuous close monitoring and antiviral management of KTRs with CHB patients will be needed, even if liver function is within normal range.

SA-PO1057

Does Hepatitis B Virus Impact the Outcomes in Kidney Transplant Recipients? Analysis by Phases of Infection Bhavna Chopra, Swati Arora, Richard J. Marcus, Sabiha M. Hussain, Khaled Nashar, Tina Y. Ko, Kalathil K. Sureshkumar. *Allegheny General Hospital, Pittsburgh, PA.*

Background: In kidney transplant recipients (KTRs) with hepatitis B virus (HBV) infection, immunosuppression may increase the risk for the progression of liver disease. HBV may contribute to allograft disease and anti-HBV therapy can have nephrotoxic potential. All these factors could adversely influence graft/patient outcomes. We aimed to analyze the impact of different phases of HBV infection on the outcomes in KTRs.

Methods: Using OPTN/UNOS database, we selected adult KTRs from 2001 - 2011 who received peri-operative antibody induction followed by calcineurine inhibitor/mycophenolate mofetil maintenance along with/without steroid. The cohort was divided into 4 groups based on the presence/absence of hepatitis B surface antigen(HBsAg) and core antibody (HBcAb) at the time of transplantation: HBsAg+/HBcAb-(acute infection); HBsAg+/HBcAb+ (developing immune response); HBsAg-/HBcAb+ (resolving infection) and HBsAg-/HBcAb- (HBV naive). Graft and patient survivals were compared among the groups as shown in the table by using multivariate Cox model. Donor, recipient and transplant related confounders including lamivudine therapy were adjusted in the model.

Results: Adjusted graft and patient survival comparisons are shown in the table.

	HBsAg+/HBcAb- (n=1098) vs. HBsAg+/HBcAb+ (n=467)		HBsAg+/ HBcAb+(n=467) vs. HBsAg-/HBcAb+ (n=6117)		HBsAg-/HBcAb+ (n=6117) vs. HBsAg-/HBcAb- (n=81968)	
Outcomes	**HR (95%CI)**	**p**	**HR (95%CI)**	**p**	**HR (95%CI)**	**p**
Death-censored graft suvival	0.83 (0.71-0.98)	0.02	0.80 (0.71-0.91)	0.002	0.97 (0.9-1.0)	0.05
Patient survival	1.06 (0.93-1.25)	0.40	1.11(1.0-1.25)	0.10	0.97 (0.91-1.11)	0.10

Conclusions: Our findings favor delaying kidney transplantation in HBV infected patients until they start to develop an immune response to the virus (HBsAg+/HBcAb+ sero-status) and preferably till HBV infection begins to resolve (HBsAg-/HBcAb+ sero-status) in order to optimize graft outcomes. With the availability of newer anti-viral agents, transplant outcomes are likely to improve further in KTRs with HBV infection.

SA-PO1058

Incidence of Hepatitis B Viral Reactivation After Kidney Transplantation with Rituximab Administration Kosuke Masutani,[1] Kazuya Omoto,[2] Masayoshi Okumi,[2] Hidehisa Kitada,[3] Tomokazu Shimizu,[2] Hideki Ishida,[2] Kazunari Tanabe,[2] Kazuhiko Tsuruya,[1] Takanari Kitazono.[1] *[1]Medicine and Clinical Science, Kyushu Univ, Fukuoka, Japan; [2]Urology, Tokyo Women's Medical Univ, Tokyo, Japan; [3]Surgery and Oncology, Kyushu Univ, Fukuoka, Japan.*

Background: The efficacy of antiviral prophylaxis for rituximab (RIT)-associated hepatitis B virus (HBV) reactivation in patients with malignant lymphoma has been reported. However, the effect of single-dose RIT on HBV reactivation in kidney transplant patients with hepatitis B surface antigen-negative (HBsAg-) and hepatitis B core antigen antibody-positive (HBcAb+) results is unclear, and there is no evidence for the necessity of prophylaxis in those patients.

Methods: From 2001 through 2014, 1021 patients underwent kidney transplantation (KTx) at Kyushu University and Tokyo Women's Medical University, of whom 76 (7.4%) had HBsAg-/HBcAb+ results. Those patients showed hepatitis C virus (HCV)-RNA-negative, hepatitis B surface antibody-positive (HBsAb+), and HBV-DNA-negative. A RIT dose of 200mg/body was administered to 49 patients, and 45 patients did not receive prophylaxis. We monitored HBV-DNA and alanine transaminase levels every 1-3 months after KTx. HBV reactivation was defined as an elevation of serum HBV-DNA level ³2.1 log copies/mL.

Results: HBV reactivation was found in 1 of 45 patients (2.2%) without prophylaxis. In the patient with HBV reactivation, serum HBV-DNA was detected at 6 weeks after KTx, and the minimum and maximum HBV-DNA levels were 2.1 and 2.6 log copies/mL, respectively. Although the patient was not treated with antiviral therapy, the HBV-DNA disappeared at 8 months after KTx. HBV reactivation was not found in the patients without RIT, and in the 4 patients who received both RIT and prophylaxis. Four (8.9%) of the 45 patients developed acute rejection, and 1 patient (2.2%) died of sepsis during the observation period.

Conclusions: The incidence of RIT-associated HBV reactivation in the HBsAg-/HBcAb+ patients without prophylaxis was less than 5%, suggesting that low-dose RIT might be associated with low incidence of HBV reactivation. However, sequential monitoring of HBV-DNA is necessary to prevent severe *de novo* hepatitis.

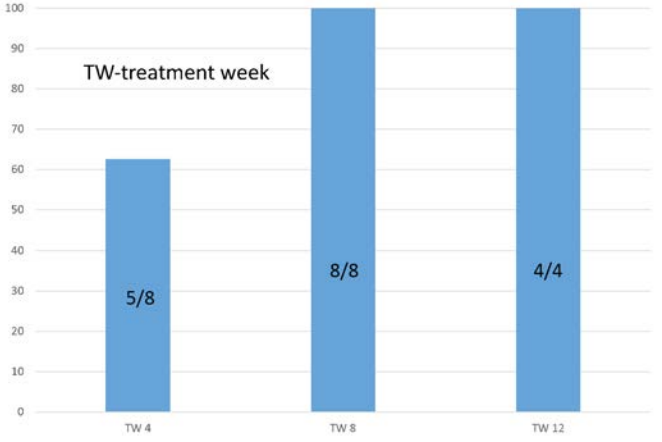
SA-PO1059

Direct Acting Antiviral Agents for HCV-Infected Patients Transplanted with a Kidney from a HCV Positive Donor David Roth, Michael J. Goldstein, Warren L. Kupin, Giselle Guerra, Linda J. Chen, Adela D. Mattiazzi, Gaetano Ciancio, Paul Martin, George William Burke, Kalyan Bhamidimarri. *Medicine, Univ of Miami Miller School of Medicine, Miami, FL.*

Background: The availability of direct acting antivirals (DAAs) has changed the treatment of hepatitis C virus (HCV) infection. The decision to treat a HCV (+) patient (pt) before or after transplant has important ramifications. The current study reports outcomes in HCV-infected pts who received a kidney from a HCV (+) donor followed by early post-transplant treatment with DAAs.

Methods: HCV RNA (+) pts on the waiting list were consented to receive a kidney from a HCV (+) donor. Induction immunosuppression (IS) included thymoglobulin and simulect followed by maintenance IS with tacrolimus and mycophenolate mofetil. At 3 months post-transplant sofosbuvir combined with either ledipasvir, simeprevir and/or ribavirin for 12 or 24 weeks was initiated.

Results: Ten pts have started DAA therapy (5 others pending); 6 blacks and 4 hispanics with a mean age of 49.4 yrs. No pts were HIV or HBV co-infected. All pts were treatment naïve, genotype 1 and non-cirrhotic. Median wait time was 30 days after consenting to accept a HCV (+) kidney. Viral clearance rates are shown in figure1.



No viral relapses have occurred. Ribavarin was lowered or stopped in 2/3 pts for anemia. Two pts had ABMR after attaining viral clearance. Tacrolimus dose required upwards titration in 6 pts. from 17-400%.

Conclusions: This report describes the use of DAAs in HCV infected kidney recipients who received a kidney from a HCV (+) donor. Accepting a HCV (+) kidney significantly shortened wait time. Response to DAAs appears similar to that being reported for pts without kidney disease however IS dosing must be carefully monitored. This treatment strategy should be considered for non-cirrhotic HCV-infected pts awaiting deceased donor kidney transplantation.

SA-PO1060

Impact of Treatment of HCV Infection on Renal Transplant Outcome Sanjay K. Agarwal, Soumita Bagchi, Dipankar M. Bhowmik, Sandeep Mahajan, Akansha Agrawal. *Nephrology, All India Inst of Medical Sciences, New Delhi, Delhi, India.*

Background: Impact of HCV treatment on post renal transplant outcome has not been reported adequately. This retrospective study was done to evaluate impact of HCV treatment on the post renal transplant outcome.

Methods: Adult patients on dialysis with HCV infection treated with pegylated interferon and subjected to renal transplant (RT) formed the study group. Untreated patients subjected to RT during same period served as controls. Primary end points were patient's and graft survival and secondary end points were serious infections and NODAT. Factors which affect the outcome like age, gender, diabetes as basic disease, dialysis vintage, HBV co-infection, HCV genotype, viral load, liver biopsy grade and stage, induction and baseline immunosuppression were considered for analysis.

Results: At the time of study, 2010 RT were done in department of which 133 had HCV infection. 30 were treated with 68% SVR and 103 were untreated. In untreated group, there were more males (92% Vs 77%), less dialysis number (137 Vs 211), less HBV co-infection (0.9% Vs 10%), less use of Tacrolimus (13.6% Vs 30%). There was no difference in terms of age, diabetes, HCV genotype, viral load, liver biopsy grade and stage, use of induction, Mycophenolate mofetyl and duration of follow-up in two groups. With mean follow-up of 59 ± 22 months (range 12- 105), there was no statistically significant difference in term of acute rejection (23% vs. 15%), NODAT (10% vs. 16.7%) and overall serious infections (23% vs. 15%) between two groups. However, there were 11 deaths in untreated group (8 sepsis related, 3 liver failure and 1 coronary artery disease) while only one death related to sepsis in treated group. Patients survival (97% vs. 89%) and graft survival (97% vs. 84%) was significantly better ($p<0.05$) in treated group as compared to untreated group.

Conclusions: Treatment of HCV with pegylated interferon during dialysis results in significant improvement of patients and graft survival following transplantation as compared to untreated patients. There is also trend of decrease in serious infection in treated patients. Sepsis and liver failure are two most common cause of mortality in untreated patients.

SA-PO1061

Prospective Study of Urinary Tract Infection in Renal Allograft Recipients in India: Single Center Study Sanjay K. Agarwal, Muthu kumar B, Soumita Bagchi. *Nephrology, All India Inst of Medical Sciences, New Delhi, India.*

Background: Urinary tract infection (UTI) is common in renal transplant (RT) and in addition to morbidity, presumed to affects graft outcome also. Still it is least studied infection in RT. There is no data from India. We looked for incidence, risk factors and pattern of UTI in first 6 months after RT and its impact on graft function.

Methods: All RT between Dec 2013 and March 2015 were followed with urine exam and C/S at day 3, 7, 14, 21, 28 and then every two week till 3 months then monthly for another 3 months. Patients with asymptomatic bacteuria (ASB) were randomized into treatment and no treatment group. Treatment was done for 7-10 days as per C/S. Study was approved by institute review board and informed consent was taken from each subject.

Results: During the study period 180 RT were done, (4 died, 2 nephrectomy, 1 graft failed, 4 lost to FU); 169 were analysed. Mean age of patients was 31.4 ± 10.4 (14-56) yrs and 81.6% were males. Diabetes was in 3.5%, renal stone in 3.5% and 3.5% had history of pre-RT recurrent UTI. All were on tacrolimus, MMF and steroid. 53% received induction. None got anti-reflux surgery. All were on cotrimoxazol for 6 months. 49 (29%) patients had at least one episode of UTI; 23 symptomatic and 26 ASB. Most common UTI was seen at 21 days followed by 14 days post surgery. 50-60% of these were symptomatic. Following RT, with time, frequency of UTI went on decreasing. Of the 84 UTI episodes, 47 (56%) were caused by E.coli followed by Klebisella (16.7%), Enterococci (12%) and Pseudomonas (8.3%). Of the patients who had UTI, there were more females (33% vs. 13%), more stone disease (8.2% vs. 1.7%) and more post-operative surgical complications (24.5% vs. 11.7%). Of the 26 ASB, 11 were treated and 15 untreated. Of the 15 untreated ASB, none developed symptomatic UTI or rejection. There was no difference in serum creatinine between treated and untreated ASB on last follow-up.

Conclusions: In conclusion, symptomatic UTI in RT in our setting is seen in 13.6% patients, mostly in first month with E.coli as causative organism in half of patient. Untreated asymptomatic UTI does not affect graft outcome and does not lead to symptomatic UTI.

SA-PO1062

High Dose Steroid Therapy in BK Viremia Adversely Affected Long Term Graft Function in Kidney Transplantation Hyosang Kim, Chung Hee Baek, Su-Kil Park. *Div of Nephrology, Dept of Internal Medicine, Asan Medical Center, Univ of Ulsan College of Medicine, Seoul, Republic of Korea.*

Background: High dose steroid therapy has been tried for the management of confusing cases of BK nephropathy (±mixed cellular rejection). However, the eventual fate of renal allograft after steroid therapy in the long term is still unknown. Therefore we investigated the graft survival and the change of BK viral load after steroid therapy in patients with BK viremia.

Methods: The study population comprised 144 kidney transplant recipients with BK viremia (serum BK viral load>$1x10^4$ copies/mL) consecutively detected at least two times, followed by steroid pulse treatment between July 2004 and March 2013. Patients were divided into two groups based on the amount of steroid: low dose (steroid 0-2g) or high dose (steroid>2g).

Results: A total of 123 patients belonged to low dose group and 21 patients were in high dose group. There were no differences in baseline characteristics, including age, gender, and the rates of biopsy-proven BK nephropathy and acute rejection. Serum BK viral loads at the time of steroid pulse therapy were 5.38±1.10 log copies/mL in low dose group and 6.00±0.98 in high dose group (p=0.054). They were changed into 5.25±1.05 and 6.14±1.45 in each group one month after steroid treatment (p=0.03) and 4.92±1.25 and 5.86±1.74 at two months (p=0.133), respectively. From three months to one year, serum BK viral loads were not different from each group. Kaplan Meier analyses demonstrated that the incidences of further 50% decline in renal function assessed by estimated GFR and graft failure were significantly higher in the high dose group (p=0.004 and p=0.04, respectively). In multivariate regression analysis, high dose steroid treatment (p=0.002, HR 9.61, 95% CI 2.25-40.99) and log serum BK viral load at two months after high dose steroid administration (p=0.027, HR 1.72, 95% CI 1.06-2.78) were important risk factors of further 50% decline in renal function.

Conclusions: In kidney transplant recipients with BK viremia, high dose steroid therapy induced BK viral activation and subsequently resulted in poor long term graft function and early graft failure.

SA-PO1063

Donor Seroreactivity Strongly Correlates with Recipient BKV-Viremia and Nephropathy Herman F. Wunderink,[1] Els Meijden van der,[1] Caroline van der Blij-de Brouwer,[1] Antoine Touze,[2] Marko Mallat,[1] Geert Haasnoot,[1] Erik Van zwet,[1] Eric Claas,[1] Johan W. De Fijter,[1] Aloys Kroes,[1] Frans Claas,[1] Joris I. Rotmans,[1] Mariet Feltkamp.[1] *[1]Leiden Univ Medical Center, Netherlands; [2]Univ François Rabelais, France.*

Background: Incidence and severity of reactivating latent infections in kidney transplant (KTx) recipients are difficult to predict. In case of BK polyomavirus (BKV)-induced nephropathy, donor origin of infection is likely. Since BKV-seroreactivity reflects BKV-(re)activity, we hypothesized that donor BKV-seroreactivity correlates with infectivity and predicts BKV infection of recipients.

Methods: In a retrospective cohort of 407 living donor-recipient pairs transplanted between 2003 and 2013 at LUMC, pre-KTx sera from donors and recipients were tested for presence and intensity of BKV IgG-seroresponses. Measured seroresponses were compared with recipient BKV-loads (viremia) determined post-KTx and compared with other potential risk factors for BKV-infection.

Results: Within one year after KTx, BKV-viremia was observed in 27% of recipients. Baseline BKV-seroprevalence among donors (96%) and recipients (95%) was high and not correlated with viremia. However, a strong association was observed between the strength of donor BKV-seroreactivity and occurrence of both viremia and PVAN ($p<0.001$). Baseline recipient BKV-seroreactivity as such was not associated. The hazard ratio of viremia was almost 10-fold higher in recipients of high compared to low seroreactive donors. In multivariate analysis, donor seroreactivity was the strongest baseline factor associated with viremia and nephropathy post-KTx ($p<0.001$), outcompeting other described risk factors.

Conclusions: The strong association between donor BKV-seroresponse and recipient BKV-infection points directly to the donated kidney as the source of BKV-induced disease and possibly reflects the BKV allograft load. Our findings warrant further research into the usefulness of BKV-serological testing prior to transplantation.

SA-PO1064

The Role of BK Viral Subtypes in BK Viral Infection After Renal Transplantation Anke Schwarz,[1] Silvia Linnenweber-Held,[1] Hermann G. Haller,[1] Corinna Schmitt.[2] *[1]Nephrology, Hannover Medical School, Hannover, Germany; [2]Virology, Hannover Medical School, Hannover, Germany.*

Background: Risk factors for developing BK virus (BKV) infection after renal transplantation are unresolved, including the role of BKV subtypes.

Methods: We report on 146 patients with viral replication in urine tested by quantitative PCR (Cepheid-Affigene Kit) before transplantation (29 donors and 11 recipients, spontaneous replication in urine) and after transplantation (106 infected recipients, routine recipient BKV testing). Genotyping of BKV DNA subtypes was performed. Patients with post-transplant BKV nephropathy or high viremia of >10000 copies/mL (n=32, group 1) were compared to post-transplant recipients with viruria alone or with low viremia of <10000 copies/mL (n=43, group 2) and with donors and recipients before transplantation (n=40, group 3).

Results: BKV subtype Ib-1 was seen in 14 /146 (10%), subtype Ib-2 in 92/146 (63%), subtype II in 9/146 (6%), subtype III in 1/146 (2%), and subtype IV in 30/146 (21%) of all patients. Thus, subtype Ib-2 was the first and subtype IV the second in frequency of subtypes in all patients. Comparing the 3 groups (group 1 vs group 2 vs group 3), there was no stat. sign. difference in the prevalence of subtype Ib-1 (8 vs 12 vs 10%), subtype Ib-2 (60 vs 70 vs 60%), subtype II (3 vs 7 vs 10%), subtype III (2 vs 0 vs 0%), and subtype IV (27 vs 12 vs 20%). However, after transplantation, subgroup IV had a trend to be less prevalent in patients with viruria/ low viremia (group 2) compared to patients with BKV nephropathy or high viremia of >10000 copies/mL (group 1) (5/43 vs 17/63, p=0.054).

Conclusions: BKV subtype Ib-2 is the most frequent subtype in all patients of the three groups. In the situation after renal transplantation, patients being infected with BKV subtype IV could be more likely to develop BKV nephropathy or high viremia than patients being infected with other subtypes. This has to be investigated in larger patient groups.

SA-PO1065

Inflammation and Reconstitution Injury in Resolving Polyomavirus Nephropathy: Good or Bad? Insights from a Protocol Biopsy Based Prospective Study Harsharan Kaur Singh, A. Gasim, Volker Nickeleit. *Div of Nephropathology, The Univ of North Carolina, Chapel Hill, NC.*

Background: Polyomavirus nephropathy (PVN) has been extensively studied at time of disease onset and in index biopsies. In contrast, little is known about acute and chronic changes occurring during PVN resolution under low dose maintenance immunosuppression. **Aim**: Enhance understanding of resolving PVN.

Methods: From 1/2009-9/2014 423 adult renal transplants with an 8.5% incidence of PVN (n=37) were prospectively followed at UNC. PVN patients were monitored with the urinary PV-Haufen test and protocol biopsies collected in 9/37 patients when the test turned from positive to negative as marker for PVN resolution. Histology in index PVN (n=9) versus corresponding protocol biopsies (n=9) was compared; clinical, treatment and long-term outcome data were obtained from electronic medical records.

Results: Serum creatinine and Banff scores at time of PVN index biopsy and follow-up protocol biopsy in Table 1.

	Serum Creatinine (median) mg/dl	BANFF Scores (mean)			
		Tubulitis - t	Interstitial inflamma-tion-i	Scarring – ci	Tubular atrophy-ct
A] Index Biopsy at time of PVN diagnosis	1.78	1.4	1.3	0.7	0.9
B] Follow-up Protocol Biopsy at time of PVN resolution	2.7	2.4	2.0	1.2	1.3
C] 12 month follow-up post protocol biopsy	1.75				

Index biopsy: 5/9 cases with PVN grade 1 and 4/9 grade 2. *Treatment:* reduction tacrolimus and/or MMF. *Protocol biopsy* (median 6 weeks post index, range: 4-60): 5/9 cases resolved PVN, 4/9 residual minimal PVN; 1/9 recurrent MPGN, 3/9 acute ABMR or Banff type 2 definitive rejection. Anti-rejection therapy 6/9 cases with decrease in S-Cr in 4/6 and deterioration in 2/6; function stable in 3/9. *Further 12-month follow-up*: Serum creatinine 1.75 mg/dl (median), no graft losses.

Conclusions: Resolving PVN under 'low-dose' immunosuppression shows significant increases in Banff acute inflammation scores and S-Cr. "Bad"inflammation is in part secondary to acute rejection and responds to anti-rejection therapy. "Good" self limiting reconstitution inflammation can be postulated in 1/9 cases (10%) of resolving PVN. PVN results in only mild increases in chronic tissue injury.

SA-PO1066

Effectiveness of Simeprevir and Sofosbuvir in the Treatment of Hepatitis C Virus in Genotype 1 Post-Kidney Transplant Recipients Karolyn S. Horn,[1] Michelle T. Martin,[1] Ignatius Yun-Sang Tang.[2] *[1]Pharmacy Practice, Univ of Illinois at Chicago; [2]Medicine, Univ of Illinois at Chicago.*

Background: The 2014 American Association for the Study of Liver Diseases (AASLD) guidelines recommended the use of simeprevir (SMV) + sofosbuvir (SOF) for the treatment of liver transplant recipients with genotype (GT) 1 hepatitis C virus (HCV). There is a paucity of data on the treatment of other solid organ recipients. We conducted a retrospective, single-center analysis of kidney transplant recipients (KTRs) who received HCV treatment.

Methods: All KTRs who received HCV treatment with 12 weeks of SMV + SOF between January and November 2014 were evaluated. The primary endpoint was the sustained virologic response at 12 weeks after the end of treatment (SVR12). Secondary outcomes included HCV PCR levels, serum creatinine, urine protein/creatinine ratio, trough calcineurin inhibitor (CNI) levels and dose changes, and AST to platelet ratio index (APRI) at week 4, end of treatment (EOT), and 12 weeks post-treatment.

Results: Twelve patients met inclusion criteria: mean age of 60+5.3, 11 males, 8 African American, 6 GT 1a and 6 GT 1b. There were 6 liver-kidney, 4 kidney, and 2 pancreas-kidney transplant recipients. All but 1 patient recieved tacrolimus as their CNI. Ten of 12 patients (83.3%) achieved SVR12. Mean tacrolimus levels increased significantly by 1.5 ng/mL between week 0 and 4 (p=0.041). Five (41.7%) required a mean tacrolimus dose decrease of 2 mg during treatment. Nine (75%) required a mean dose increase of 2 mg between EOT and SVR12. The APRI scores decreased from 0.64 to 0.17 between baseline and 12 weeks of treatment, but this is not statistically significant (p=0.216). Both serum creatinine and urine protein/creatinine ratio remained stable pre- and post-treatment (p=0.260 and p=0.973, respectively).

Conclusions: SVR12 was achieved in 83.3% of KTRs treated with SMV + SOF. Renal allograft function was stable during and after HCV therapy. Treatment with SMV + SOF increased CNI levels during treatment. CNI dose adjustment is needed to maintain therapeutic levels after SMV + SOF therapy.

SA-PO1067

25-Hydroxyvitamin D Insufficiency Is Associated with Higher Risk of BK Virus Re-Activation After Kidney Transplantation Nissreen Elfadawy, Stuart M. Flechner, Emilio D. Poggio, Brian R. Stephany, Richard A. Fatica, Jesse D. Schold, Sherif B. Mossad. *Cleveland Clinic.*

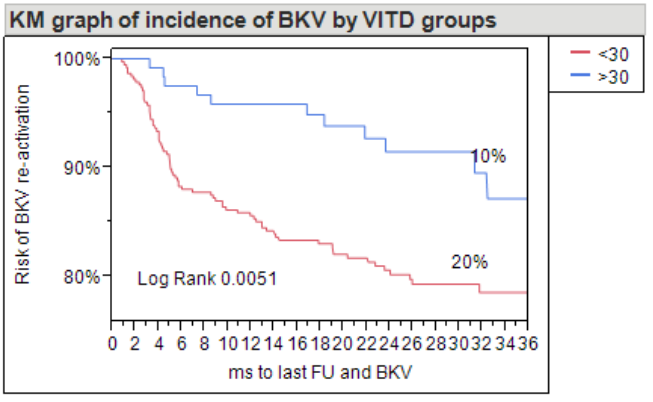
Background: The past decade has seen increased interest in vitD, because new data suggest that it plays a role in the immune system. The purpose of this study was to evaluate the association of 25-hydroxyvitD level (25[OH]D) after kidney transplant with the risk of BK virus reactivation.

Methods: We identified 498 kidney transplant recipients (2007-2011) who had serum levels of (25[OH]D), and PTH. We evaluated the relationship between the average levels of 25(OH)D and PTH and BKV reactivation in blood.

Results: VitD insufficiency (25[OH]D <30 ng/mL, defined by The Endocrine Society Clinical Practice 2011) was observed in 377 (75%)of 498 kidney recipients after transplant. The VitD insufficient and sufficient groups were comparable in terms of gender, age, BMI, race, and immunosuppressio. VitD insuffiency was more frequent in recipients of cadaveric allografts (P=0.009, Fisher test). By multivariable Cox regression analysis, vitD insuffiency was an independent risk factor for BKV reactivation after kidney transplantation (HR=2.4, 95% CI 1.3-4.7, P=0.002). Moreover, vitD insuffiency was associated with significantly earlier onset of BKV reactivation (9 compared to 16 months, P 0.01). ROC analysis using logistic regression showed that 25[OH]D < 24ng/mL was predictive of BKV

reactivation(OR:82.9, 95% CI: 17.2–744.6, P < 0.001, AUC 0.7). VitD insufficiency was not associated with higher risk of CMV reactivation (17 vs 19% resp, p 0.5). The positive BKV group had significantly higher PTH compared to the negative group (196 vs 148 resp, P 0.01). No significant associations of 25[OH]D with clinical outcomes were observed in time-dependent or fixed-covariate Cox models.

Conclusions: Vitamin D insufficiency is a risk factor for BKV reactivation after kidney transplantation. D3 supplementation may help reduce BKV reactivation.



SA-PO1068

Different Types of Cytomegalovirus DNAemia and Long-Term Outcomes After Renal Transplantation Tomas Reischig,[1] Martin Kacer,[1] Ondrej Hes,[2] Daniel Lysak,[3] Mirko Bouda.[1] *[1]Internal Medicine I, Biomedical Center, Charles Univ Medical School and Teaching Hospital, Pilsen, Czech Republic; [2]Pathology, Biomedical Center, Charles Univ Medical School and Teaching Hospital, Pilsen, Czech Republic; [3]Hematooncology, Biomedical Center, Charles Univ Medical School and Teaching Hospital, Pilsen, Czech Republic.*

Background: Although occurring very often the role of cytomegalovirus (CMV) DNAemia in patients managed by preemptive therapy or by universal antiviral prophylaxis is not established. The aim of the study was to determine the impact of different types of CMV DNAemia during 4 years after transplantation.

Methods: A total of 180 consecutive renal transplant recipients at risk for CMV (donor and/or recipient CMV seropositive) were included and followed prospectively. Universal prophylaxis for 3 months was given to 132 (high-dose valacyclovir, n=87; valganciclovir n=45) patients, 48 patients were managed by preemptive therapy. Based on CMV DNAemia status during the first year after transplantation patients were stratified to 1) no DNAemia, 2) early-onset (<3 months) DNAemia, late-onset (³3 months) DNAemia, and 4) combined early+late-onset DNAemia groups, respectively.

Results: Early-onset, late-onset, and combined early+late-onset CMV DNAemia occurred in 18%, 25%, and 13% of the patients being asymptomatic in majority (91%) of cases. Graft survival at 4 years was inferior in patients with late-onset CMV DNAemia compared to patients without CMV DNAemia (73% vs. 94%, P=0.002) while no significant differences were observed in patients with early-onset (85%, P=0.139) or combined early+late-onset CMV DNAemia (96%, P=0.682). Patient survival was comparable in all groups. Moderate to severe interstitial fibrosis and tubular atrophy assessed by protocol biopsy at 36 months was not increased in early-onset (15%, P=0.05), late-onset (21%, P=0.180), and combined (29%, P=0.609) CMV DNAemia compared to no CMV DNAemia group (36%). Likewise, renal function was not different at 36 months.

Conclusions: Late-onset CMV DNAemia is a risk factor for graft loss after renal transplantation.

Funding: Government Support - Non-U.S.

SA-PO1069

Assessment of Cytomegalovirus-Specific Cell-Mediated Immunity for the Prediction of Cytomegalovirus Spontaneous Clearance in High-Risk Kidney Transplant Recipients with Cytomegalovirus Viremia Marine Lochouarn,[1] Sylvia Benzaken,[2] Laetitia Albano,[1] Elisabeth Cassuto,[1] Ahmed Jeribi,[1] Anne Caramella,[3] Valerie Giordanengo,[3] Ghislaine Bernard,[2] Vincent L.M. Esnault,[1] Barbara Seitz-Polski.[1,2] *[1]Nephrology and Kidney Transplantation Dept, Univ Hospital, Nice, France, Metropolitan; [2]Laboratory of Immunology, Univ Hospital, Nice, France, Metropolitan; [3]Laboratory of Virology, Univ Hospital, Nice, France, Metropolitan.*

Background: Cytomegalovirus (CMV) is the most common virus pathogen in kidney transplant recipients (KTR) and CMV disease impacts patient and graft survival. CMV-specific CD8 T cell-mediated immunity (CMI) kinetics may help to assess the risk of CMV disease and to adapt preventive treatment strategies.

Methods: High risk KTR with CMV seropositive donor/seronegative recipient (D+/R-), were longitudinally monitored after CMV prophylaxis discontinuation and during the first year post-transplant for CMV viremia (WHO standardization) and CMI (QuantiFERON®-CMV). We analyzed the ability of the CMI-test to predict subsequent spontaneous viral clearance in case of asymptomatic viremia after prophylaxis discontinuation or CMV disease recurrence after curative treatment.

Results: We enrolled 12 consecutive (D+/R-) KTR. Eleven patients developed viremia during follow-up. Spontaneous viral clearance occurred in 7 of 11 (63.6%) patients and 4 of 11 (36.4%) developed CMV disease. At viremia onset, 6 of 11 (54,5%) patients had a positive CMI-test. In those patients, the incidence of subsequent spontaneous viral clearance was 6 of 6 (100%) compared with only 1 of 5 (20%) among patients displaying a nonreactive CMI ($p = 0.02$). This latter patient revealed a positive CMI-test one month later. In the 4 patients who developed CMV disease, persistence of a nonreactive CMI after treatment in one patient was associated with disease recurrence, while patients whose CMI-test became positive under treatment showed no recurrence.

Conclusions: We show for the first time that D+/R- KTR with asymptomatic viremia attested by WHO standardized CMV viral load monitoring after prophylaxis discontinuation may benefit from QuantiFERON®-CMV to predict spontaneous viral clearance or CMV disease.

Prevalence of Double Stranded DNA (dsDNA) Viral Infections Among Kidney Transplant Recipients Essy Mozaffari,[1] Jay Lin,[2] Melissa Lingohr-Smith.[2] *[1]Chimerix Inc., Mendham, NJ; [2]Novosys Health, Green Brook, NJ.*

Background: Management of immunosuppression following solid organ transplant is a delicate balance between preventing graft rejection and minimizing the risk of infection. Antimicrobial prophylaxis can decrease the risk of infection, while increased immunosuppression can increase these same risks. Our objective was to estimate the occurrence of opportunistic infections, specifically dsDNA viral infections, in kidney transplant recipients.

Methods: Patients who received a kidney transplant between January 2009 and September 2013 were identified from the Premier Hospital database using ICD-9-CM codes. The first transplant procedure was defined as the index event. The frequencies of opportunistic infections, documented by diagnostic codes, were evaluated during the first 12 months after kidney transplant.

Results: Of patients who received kidney transplant (n=5,402; mean age: 50.8 years) 61% were male. Most patients received transplant in urban (98%), large (≥600 beds: 61%), teaching hospitals (84%). During the 12 month post kidney transplant, 33% (1,800 patients) had a diagnostic code for ³1 opportunistic infection, and among these 25% (n=448) had at least one dsDNA viral infection. Among the 448 dsDNA viral infections, 81% (n=365) were cytomegalovirus (CMV), 8% (n=36) BK virus, and 16% (n=70) other dsDNA viral infections (HSV, VZV, HHV, HPV, EBV).

Conclusions: Opportunistic infections frequently result from the immunosuppression required following kidney transplantation. In our study, one-third of the kidney transplant recipients had a discharge diagnosis for at least one opportunistic infection. One of four opportunistic infections were classified as dsDNA viral infections, with the majority caused by human herpesviruses including CMV despite the common use of anti-CMV agents. Our study also highlights the rate of BKV-related complications, which represent an unmet need given the absence of therapeutic options for this dsDNA virus and the known association with BK-associated nephropathy.

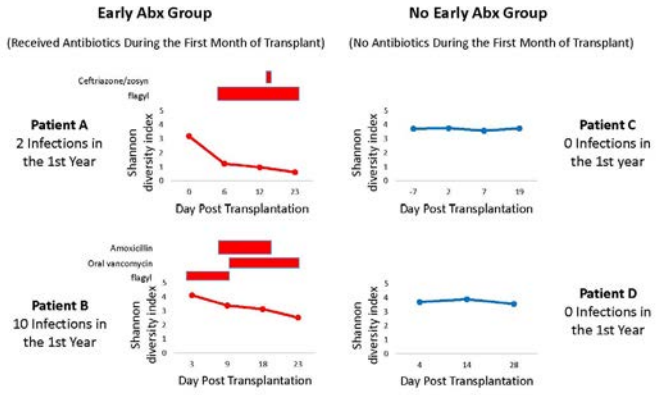
Antibiotics, Gut Microbial Diversity, and Infectious Complications in Kidney Transplant Recipients Anjali Masand,[1] John R. Lee,[1] Thangamani Muthukumar,[1] Darshana Dadhania,[1] Lilan Ling,[2] Eric Pamer,[2] Manikkam Suthanthiran.[1] *[1]Medicine, Weill Cornell Medical College, NY, NY; [2]Medicine, Memorial Sloan Kettering Cancer Center, NY, NY.*

Background: Emerging data suggests that antibiotic usage can decrease gut microbial diversity and predispose patients to future bacterial complications.

Methods: We profiled serial fecal specimens by 16S rRNA deep sequencing in 26 kidney transplant recipients. Microbial diversity was assessed using the Shannon diversity index in subjects exposed to antibiotics in the 1st post-transplant month and in subjects not exposed. Based on a higher number of infections in antibiotic-exposed subjects, we conducted a retrospective study of 301 consecutive kidney transplant recipients and evaluated antibiotic usage in the 1st month of transplantation and development of bacterial complications in post-transplant months 2-12.

Results: Subjects exposed to antibiotics during the 1st month of transplant had decreased gut microbial diversity and an increased number of infections in the 1st year of transplant.



In 301 transplant recipients, the most common infections (N=255) were UTIs (61%) and pneumonia (9%). 74 kidney transplant recipients received antibiotics during the first month of transplantation (Early Abx Group) and 227 did not (No Early Abx Group). The Early Abx Group had a significantly higher number of infections during post-transplant months 2-12 than the No Early Abx Group (1.2±0.2 vs. 0.3±0.1, P<0.001, Wilcoxon rank-sum test). Within the Early Abx Group, subjects who received anaerobic coverage had a significantly higher number of infections during post-transplant months 2-12 than subjects who did not (1.8±0.5 vs. 0.9±0.2,P=0.050).

Conclusions: Early antibiotic usage was associated with increased future bacterial infections in kidney transplant recipients. A decrease in gut microbial diversity is a biologically plausible pathogenic mechanism.

SA-PO1072

Successful Treatment of Hepatitis C in Renal Transplant Recipients with Directly Acting Antiviral Agents

Michelle L. Lubetzky, Enver Akalin, Paul Gaglio, Graciela De Boccardo. *Transplantation, Montefiore Medical Center, Bronx, NY.*

Background: Hepatitis C infection (HCV) in kidney transplant (KTx) recipients has been shown to be an independent risk factor for decreased patient and allograft survival. Historically treatment of HCV has been interferon-alpha based, which is associated with acute rejection in KTx patients. With the development of new, oral, interferon-free directly acting antiviral (DAA) medications, treatment of HCV in renal transplant recipients is possible, but limited data exists on its safety and efficacy.

Methods: We performed a retrospective review of all KTx patients at our center with HCV started on DAA for treatment of HCV. Any patient with at least 30 days of follow up was included in the analysis (n=10). Clinical data including graft function, survival, and response to therapy was collected.

Results: Patient demographics are in Table 1. At a median of 92 days of follow up (range 33, 438), all patients have undetectable viral load. Median time from KTx to treatment was 781 days (range 173,10404). At most recent follow up, mean creatinine is 1.48±0.51 mg/dl and mean proteinuria is 0.47±1.07 g/day with no adverse side effects reported. No patients have lost their grafts or developed acute rejection, but 2 patients had detectable CMV. For the 8 patients on tacrolimus (Tac), there was a drop in 12-hr trough level during therapy (mean 6.3±2.1 ng/mL pre-treatment, and mean of 4.9±2.1ng/mL after 6 weeks of treatment); during treatment 3 patients had a level < 4 ng/mL. All patients with level <4 ng/mL had dose increase and repeat level was in normal range.

Characteristics	N=10
Age (median, range)	61.6 (42, 74)
Sex	7 Male
Race	5 Hispanic 3 Black/African American
Type of Transplant	8 DDRT 2 Dual Organ (combined liver-kidney)
Cause of ESRD	4DM 1 HCV
Induction Immunosupression	5 Anti-Thymocyte Globulin
Maintenance Immunosupression	7 Prednisone, Tacrolimus, Mycophenolate
HCV Genotype	8 type 1 2 type 2
Prior Therapy	8 treatment naïve
Mean Viral Load at start of therapy	3460819±3823258
Mean Creatinine at start of therapy	1.3±0.4
Proteinuria at start of therapy	0.9±0.6
Treatment regimen	5 ledipasvir/sofosbuvir 4 sofosbuvir/ribavirin 1 ledipasvir/sofosbuvir/ribavirin

Conclusions: Our data demonstrates that DAAs can be used safely and effectively in patients after KTx. Tac levels should be monitored closely during therapy. Longer follow up of KTx recipients treated for HCV is needed determine the effects treatment has on graft and patient survival.

SA-PO1073

A Systematic Review and Meta-Analysis of Cytomegalovirus Infection in Renal Transplant Recipients Receiving Alemtuzumab versus Anti-Thymocyte Globulin for Induction Therapy

Payvand Milani, Nasrollah Ghahramani. *Medicine, Pennsylvania State Univ College of Medicine, Hershey, PA.*

Background: Use of antibody induction for kidney transplant has improved patient outcomes over the past decade. One common induction agent is rabbit anti-thymocyte globulin (ATG), a polyclonal anti-human T-cell antibody. Alemtuzumab, a humanized monoclonal anti-CD52 antibody with stronger lympho-depleting properties, has been used as an induction agent in steroid-sparing or steroid-minimizing protocols. Like all immunosuppressive agents, these agents are associated with opportunistic infections, including cytomegalovirus (CMV). Our aim was to compare the relative risk of CMV infection between the two induction regimens.

Methods: We used five comprehensive search themes (CMV, ATG, alemtuzumab, transplant, and induction) to search electronic databases from 1980 to 2014 using PubMed and The Cochrane Library while also manually reviewing recent abstracts from the American Society of Nephrology and the American Transplant Congress meetings. Studies reporting the number of cases of CMV infection in patients receiving one of the two agents were included. The outcome was the pooled relative risk (RR) of CMV infection in the alemtuzumab group compared to that in the ATG group.

Results: A total of 73 studies were identified and reviewed, 64 of which were excluded upon initial screening. Analysis of the 9 studies (8 complete articles and 1 abstract; 1,735 patients) showed a RR of 0.58 (95% CI: 0.31-1.07) for incidence of CMV infection in patients receiving alemtuzumab versus ATG. Other reported adverse effects in both induction groups (infections, post-transplant lymphoproliferative disorder (PTLD) and/or malignancy, decrease in estimated glomerular filtration rate , and post-transplant diabetes mellitus) were similar in both groups.

Conclusions: This study suggests that for induction therapy in kidney transplant, the incidence of CMV infection associated with alemtuzumab is not significantly different than that associated with ATG.

SA-PO1074

Occurrence and Determinants of Antibiotic Resistance in Bacteriuria After Kidney Transplantation

Habib Mawad, Alexandre Tavares-Brum, Claude Lemieux, Alain Duclos, Azemi Barama, Heloise Cardinal. *Nephrology, Centre Hospitalier de l'Univ de Montréal.*

Background: Asymptomatic bacteriuria is often treated after kidney transplantation, which can result in the development of antibiotic resistance. Our aim was to assess the antibiotic resistance profile of gram-negative bacteriuria in our kidney transplant population, and to determine the factors associated with antibiotic resistance.

Methods: We performed a single center, retrospective cohort study in patients who received a kidney allograft at our center between January 1st, 2008 and June 1st, 2013. Through chart review, information on all bacteriuric episodes involving gram negative bacilli was collected during follow-up, which ended on June 1st, 2014. Bacteriuria was defined as growth exceeding 10^4 CFU/ml. Multivariable logistic regression using a generalized estimating equation (GEE) procedure was performed to identify the factors associated with resistance to antibiotics.

Results: Amongst the 318 patients studied, 629 bacteriuric episodes involving gram negative bacilli occurred in 143 patients. Resistance to TMP-SMX occurred in 336 episodes (53%), resistance to ciprofloxacin in 142 episodes (23%) and extended beta-lactamase production occurred in 30 episodes (5%). An increased risk of resistance to ciprofloxacin and/or extended spectrum beta lactamase production was statistically associated with the number of previously treated bacteriuric episodes (compared to no prior treatment, 2-4 previous treatments (odds ratio (OR):2.29, 95%confidence interval (CI):1.16-4.52), and ≥5 previous treatments (OR:3.05, 95%CI:1.28-7.26))), diabetes (OR:2.57, 95%CI:1.01-6.55), caucasian race (OR:0.38, 95%CI:0.16-0.91) and a longer time elapsed between bacteriuria and transplantation (OR:0.32, 95%CI 0.15-0.66, for episodes supervening >1 year post transplant versus ≤ 1 year).

Conclusions: Elevated resistance rates to TMP-SMX and ciprofloxacin were observed in our kidney transplant population, which can reduce the usefulness of prophylaxis with TMP-SMX and argue against treating asymptomatic bacteriuria, given the association we observed between the number of previous treatment of bacteriuric episodes and resistance to ciprofloxacin/ESBL production.

Carbapenem-Sparing Antibiotic Regimens for the Treatment of Extended-Spectrum Beta-Lactamase Producing Enterobacteriacea Infections: A Comparative Study

Tiffany Ebony Bias,[1] Gregory Malat, PharmD,[1] Akshay Sharma,[2] Dong Heun Lee,[3] Alden Michael Doyle.[2] *[1]Pharmacy, Hahnemann Univ Hospital, Philadelphia, PA; [2]Surgery, Drexel Univ, College of Medicine, Philadelphia, PA; [3]Infectious Diseases and HIV Medicine, Drexel Univ, College of Medicine, Philadelphia, PA.*

Background: Extended spectrum beta lactamase producing Enterobactericaea (ESBL-PE) has been recognized as a significant cause of mortality in solid organ transplant recipients. Carbapenems are considered the drug of choice for the treatment of ESBL-PE infections. However, antibiotic selective pressure associated with carbapenem use may

contribute to resistance, further stressing hospital epidemiology. Our study sought to compare the effectiveness of carbapenem sparing regimens to carbapenem containing regimens on clinical outcomes in transplant patients with ESBL-PE infections.

Methods: A retrospective, observational cohort study was conducted to evaluate adult patients who underwent a successful kidney transplant (defined as graft survival >30 days) prior to August 2014 with a ESBL-PE infection post-transplant. Patients were stratified into 2 cohorts according to antibiotic regimens: carbapenem-containing and carbapenem-sparing. The outcomes of clinical cure, 30-day mortality, and recurrence were assessed.

Results: Fifty-two kidney transplant patients were included in our analysis: 29 in the carbapenem-sparing group and 23 in the carbapenem-containing group. Majority of infections were caused by Escherichia coli (46%) and Klebsiella pneumoniae (44%). The most common infection type was urinary tract infections (46%) followed by bloodstream infections (23%) and nosocomial pneumonias (15%). There was no statistically significant difference in clinical cure rates (91% vs. 76%, p=0.268) and 30-day mortality (24% vs. 9%, p=0.268) in the carbapenem sparing and carbapenem containing groups respectively.

Conclusions: ESBL-PE infections pose a serious threat to transplant recipients. Carbapenem sparing regimens may be adequate for the treatment of ESBL-PE infections, while offering advantages against minimizing selective pressure.

SA-PO1076

Clinical Recurrence of Primary Glomerular Disease in Kidney Transplantation Saul Enrique Pampa, Ana M. Fernandez Rodriguez, Sara Jimenez Alvaro, Fernando Caravaca-Fontan, Estefania Yerovi, Maria Delgado Yagüe, Maite Rivera, Cristina Galeano, Sandra Elias, Fernando Liano. *Nephrology, Hospital Ramón y Cajal. UAH, Madrid.*

Background: Recurrence of primary glomerular disease (PGN) in renal transplantation (RT) is a major cause of failure and renal allograft lost which determines the prognosis of the patient. We analyzed the prevalence, clinical course and survival of graft in this group of patients.

Methods: We conducted a retrospective analysis of 1513 renal transplants between January 1980 and December 2013, included in our database, medical records and biopsy register, collecting all patients who presented recurrence of PGN. We excluded from the study patients with secondary GN and those without biopsy study. Renal biopsy was indicated according the following criteria: impairment of renal function, proteinura>1g/day and/or microhematuria. The analisis stadistic was SPSS version 18.

Results: 414 of 1513 RT (27%) had chronic GN as underlying disease. 317 patients (260 man;57 woman) were primary GN (21%). The most frequent primary GN was IgA nephropaty (IgAGN) n=122(38,4 %); Membranoproliferative GN (MPGN), n:90(28 %); Focal segmental GN(FSGS), n: 58(15,1 %); membranous GN(MGN), n: 33(10,4 %) and rapidly progressive GN (RPGN), n:14(4,4%). Forty(12.6%) patients with primary GN recurred. IgA GN (5%), FSGS (20%), MPGN (17%), MNGN(12%) and GRNP (12%). Three MPGN patients recurred in the second RT. The mean time of recurrence was: 48.18, 33.2, 18 and 33.2 months respectively Patients with graft loss due to GN recurrence were: IgAGN (n=10;75%), MPGN (n=14;93%), FGSG(n=10,75%), MNGN(n=3,70%). No significant difference was observed between GN types(p=0,15) and graft survival. In the Kaplan Meier analysis and COX test, recurrence primary GN had low survival at 10 years (p: 0.002). No significant differences was observed at 20 years(p: 0.15).

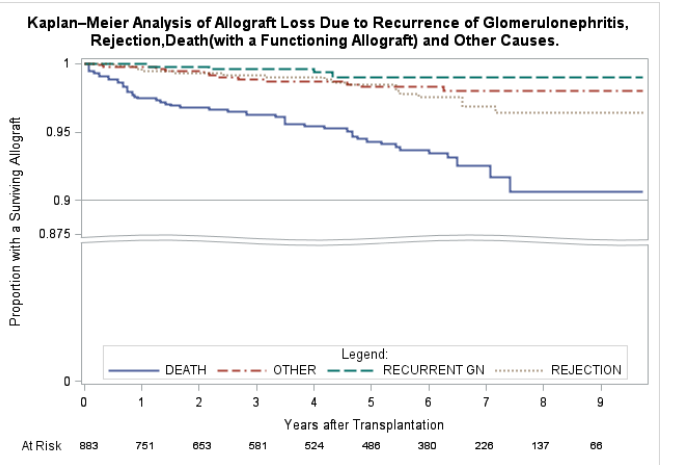
Conclusions: Clinical Recurrence of primary GN is an important cause of graft loss. GN with most recurrence was GSF and graft lost was MPGN. We didn't observe differences in graft survival between tipe of primary glomerular disease. Graft survival was higher in the group without recurrence at 10 years and no differences at 20 years.

SA-PO1077

Glomerular Diseases following Prednisolone Free Transplant with Low Dose Rituximab and ATG Induction and Protocol Biopsies Vivek Pathak. *Nephrology, Kovai Medical Center and Hospital, Coimbatore, Tamil-Nadu, India.*

Background: The purpose of this study is to document the incidence of post transplant glomerulonephritis in a steroid free protocol and other recurrent renal diseases leading to graft loss.

Methods: 883 patients, who underwent renal transplantation at our institute in nine years and eight months since July 2005 till March 2015 were studied.Thymoglobulin was used for induction at a dose of 1.5mg/kgm 3 doses.Rituximab 200 mg was given before transplant to those patients who were considered to be at high risk for rejection.Maintenance immunosuppression was Tacrolimus and Mycophenolate mofetil. Prednisolone was rapidly discontinued by fifth post operative day. All patients underwent protocol biopsies at 3 months , 1 year and 5 years and indicated biopsies whenever required. The total number of biopsies was 2928. Discussion Our results show only 1% graft loss due to cumulative recurrent Glomerulonephritis at nearly 10 years.Our figures could be low due to Thymoglobulin induction therapy.We could prevent graft loss due to recurrent FSGS by achieving complete or partial remission by using Rituximab in 15/19(79%) patients.



Results: The number in glomerulonephritis group was 412 of which 158 were biospy proven and others suspected on clinical grounds The histologically confirmed recurrent IgA was seen in 23 patients and 3 lost the graft. Prednisolone was added to this group. Recurrent FSGS was observed in 21 patients of which 3 lost the graft.We saw 1 case each of recurrent DDS, DHA crystallopathy,de novo anti GBM disease and post infectious glomerulonephritis.

Conclusions: Our aggressive biopsy policy detected recurrence at a stage of urinary abnormalities.We use Rituximab to treat FSGS to reduce the graft loss.Unique induction policy probably had a protective effect and thus recurrent glomerulonephritis is lower then published literature.

SA-PO1078

Post-Transplant Focal Segmental Glomerulosclerosis Recurrence Among Patients with Native Kidney Collapsing Variant: A Single-Center Retrospective Cohort Study Panupong Hansrivijit,[1,2] Katherine D. Westreich,[1] Jonathan Alexander Miles,[1] Evan Zeitler,[1] Maria E. Ferris,[1] Randal K. Detwiler.[1] *[1]Univ of North Carolina, Chapel Hill, NC; [2]Chulalongkorn Univ, Bangkok, Thailand.*

Background: Focal segmental glomerulosclerosis (FSGS) is one of the most common causes of end-stage kidney disease (ESKD), and is known to recur in renal transplant grafts. The collapsing variant of FSGS (CvFSGS) is clinically distinct from other variants: it has a stronger association with African-American race, more severe proteinuria, and rapid progression to ESKD. The impact of native FSGS subtype on post-transplant FSGS recurrence rate and subtype is not known.

Methods: Clinical and pathological records were reviewed for renal transplant recipients at UNC between 2000 and 2014 with FSGS as the cause of ESKD. Native FSGS subtype was dichotomized into CvFSGS and FSGS-Other. Baseline demographics (sex, age, and race), and rates and subtypes of post-transplant FSGS recurrence were compared between the two groups.

Results: Of 879 patients reviewed, FSGS was the cause of ESKD in 101. Among this subgroup, mean age at time of transplant was 45±17 years; 62% male; 50% non-Hispanic black, 45% non-Hispanic white, and 5% Hispanic. Ten patients (10%) had CvFSGS as the native lesion. Over a mean follow-up time of 2.4 years, the overall rate of recurrent FSGS was 34%. Compared to those with native FSGS-Other, patients with native CvFSGS had a higher rate of post-transplant FSGS of any type (50% vs 31%, RR 1.6), and were also more likely to have collapsing variant as the recurrent lesion (60% vs 11%, RR 5.5).

Native lesion (n)	Recurrence n (%)	Recurrent lesion n (%)	
		CvFSGS	FSGS-Other
CvFSGS (10)	5 (50%)	3 (60%)	2 (40%)
FSGS-Other (91)	28 (31%)	3 (11%)	25 (89%)
Total (101)	33 (34%)	6 (18%)	27 (82%)

Conclusions: In a population of predominantly black and Hispanic patients in the Southeastern US, native CvFSGS predicts a 60% higher post-transplant FSGS recurrence rate, and the recurrent lesion is likely to be CvFSGS. However, 11% of patients with native FSGS-Other developed de novo CvFSGS post-transplant. Further study of this cohort will determine the predictive power of native and recurrent CvFSGS with regard to clinical outcomes.

SA-PO1079

Pre-Transplant Rituximab in Recurrent Focal Segmental Glomerulosclerosis John Manllo,[1] Dany Matar,[1] Sami Alasfar,[1] Jochen Reiser,[2] Nada Alachkar.[1] *[1]Johns Hopkins Univ; [2]Rush Univ.*

Background: Focal segmental glomerulosclerosis (FSGS) recurs in 30-40% of patients after kidney transplant (Tx). Rituximab was suggested to have cross-reactivity with podocyte sphingomyelin-phosphodiesterase-acid-like-3b (SMPDL-3b), which was found

to be reduced in post perfusion biopsies of kidney Tx recipients who later on developed recurrent (r)FSGS. However, the use of rituximab to prevent rFSGS remains controversial. In this study, we assessed the efficacy of pre-Tx rituximab in preventing or delaying the recurrence of FSGS.

Methods: We enrolled 56 adult patients, 50 with biopsy proven FSGS and 6 with a pre-Tx course highly suggestive of FSGS. Patients underwent kidney transplant between 2008-2014. We compared FSGS recurrence and allograft survival between recipients who received rituximab and those who did not.

Results: Mean time of follow-up was 28.6 months. 24 patients received rituximab (table 1). 35 patients developed rFSGS, 17 (48%) of them received rituximab. Of the 21 who did not develop recurrence, 7 patients (33%) received rituximab. This difference was not statistically different (p=0.26). The time from Tx to rFSGS in the patients who received rituximab was 9.4 ±3.4 vs 8.7 ±3.7 months in patients who did not receive rituximab (p=0.7). The mean and standard deviation (SD) of eGFR at the most recent follow-up in the patients with rFSGS who received rituximab was 42 ±28 versus 39 ±21 mL/min/1.73m^2 in those who did not received it, respectively (p=0.74). There was no difference in allograft survival in the two groups.

Conclusions: Our data showed that pre-transplant rituximab did not decrease the incidence or delayed the development of recurrent FSGS, and did not improve allograft survival.

	Pre-Tx rituximab (n=24)	No-rituximab (n=32)	P-value
Mean Age at Diagnosis (SD), yrs	28.5 (±18)	33.2 (±15)	0.33
Mean Time from Dx to RRT (SD), yrs	4.8 (±5.6)	10.1 (±11.5)	0.03
Mean of cumulative dialysis duration (SD), yrs	4.8 (±3.8)	2.9 (±3.7)	0.07
Mean Age at current tx (SD), yrs	43 (±13)	44.8 (±13)	0.62
Male, n (%)	12 (50%)	16 (50%)	1
Prior tx, n (%)	13 (54%)	6 (18%)	0.006
ABO Incompatible Tx, n (%)	5 (20%)	3 (9%)	0.22
Allograft failure, n (%)	3(12%)	3(9%)	0.91

SA-PO1080

Role of Plasmapheresis in Post-Transplant Focal Segmental Glomerulosclerosis Sami Alasfar,[1] Dany Matar,[2] John Manllo,[1] Jochen Reiser,[3] Nada Alachkar.[1] *[1]Johns Hopkins Univ, Baltimore, MD; [2]McKinsey & Company, Washington, DC; [3]Rush Univ, Chicago, IL.*

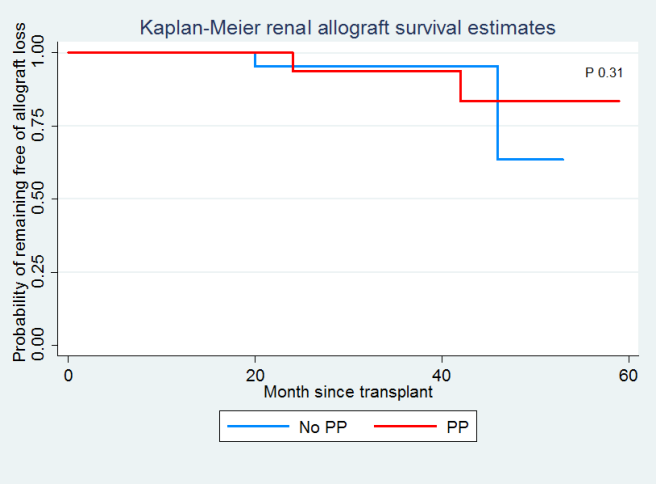
Background: Focal segmental glomerulosclerosis (FSGS) commonly recurs after kidney transplant(Tx). This is attributed to the presence of a circulating permeability factor that may be removed or diminished by plasmapheresis (PP). In this study, we assessed the efficacy of PP in prevention and treatment of post-Tx (r)FSGS.

Methods: We prospectively enrolled 56 Tx-patients with biopsy proven FSGS(50) or de novo FSGS with a pre-Tx course suggestive of FSGS(6); patients were transplanted between 2008-2014. We compared between the preventive and non-preventive PP groups.

Results: Mean time of follow-up was 28 months. Differences between the 2 groups are as following:

	Preventive PP(n26)	No PP(n30)	P
Male(n)	15	13	0.2
White(n)	17	14	0.23
Time from FSGS diagnosis to renal replacement initiation,y(SD)	6.1(8.6)	10.1(9.1)	0.04
Prior Tx(n)	11	8	0.21
Living donor(n)	21	12	0.008
Induction with rATG(n)	25	26	0.23
rFSGS (n)	19	16	0.12
Time to rFSGS, month(SD)	7.7(3.7)	10.5(3.5)	0.6
Mean of most recent UPC, g/g(SD)	2.7(0.5)	0.2(0.1)	0.001

rFSGS developed in 35 patients (62%); of whom preventive PP was performed in 19. Out of the 21 cases that did not develop rFSGS, 7 received PP (P=0.1). Patients who received preventive PP had a shorter time from FSGS diagnosis to ESRD compared to those who did not [(6.1±8.6 yr vs 10.1±9.1 yr (p 0.047)]. 33 out of the 35 patients (95%) with rFSGS received therapeutic PP, and 24 also received anti-CD20 therapy. Only 5(15%) did not respond; 2 lost their grafts. Of the 28 who responded, 14 (50%) subsequently relapsed. 71% of the relapses responded to a second course of PP; only 4 lost their grafts. Kaplan-Meier allograft survival in both groups is shown in figure 1.



Conclusions: Preventive PP does not reduce the incidence or delay the development of rFSGS. However, PP remains an effective therapy for post-transplant FSGS.

SA-PO1081

Post-Transplant Thrombotic Microangiopathy: A Single Center Experience Cinthia Montenegro Teixeira,[1] Igor Gouveia Pietrobom,[1] Andre Caires Alvino Lima,[1] Gianna Mastroianni-kirsztajn,[1,2] Laila Almeida Viana,[1] J. Medina-Pestana,[1,2] Helio Tedesco Silva.[1,2] *[1]Hospital do Rim- Fundação Oswaldo Ramos, Sao Paulo, Brazil; [2]Univ Federal de Sao Paulo, Sao Paulo, Brazil.*

Background: Thrombotic microangiopathy (TMA) occurs in 1-15% of kidney transplant allografts and predicts poor outcomes.

Methods: We reviewed 35 cases of TMA in the kidney allograft diagnosed at our institution between 2011-2015.

Results: The mean age was 39±14 years with 18 (51%) women. Three (9%) patients were recipients of simultaneous pancreas-kidney transplant. Among the recipients of kidney transplant alone, 21 (66%) received deceased donor grafts. The cause of end stage renal disease was unknown (37%), chronic glomerulonephritis (31%), obstructive uropathy (11%), diabetes (9%), hemolytic uremic syndrome (3%) or others (9%). Induction with thymoglobulin or basiliximab was performed in 24 (63%) patients. Maintenance immunosuppression was prednisone (PRED), tacrolimus (TAC), and azathioprine in 15 (43%), PRED, TAC and mycophenolate sodium in 12 (37%) and PRED, TAC and everolimus in 3 (9%) patients. Patients were diagnosed with TMA at a median of 71 days (range: 5-1645) from transplant, wherein 37% patients developed TMA within 1 month of transplantation and 31% after 1 year. Mean serum creatinine was 4.5±3.3 mg/dL and 13 (47%) patients needed renal replacement therapy after TMA diagnosis. TMA was renal-limited in 23 (66%) patients. Concomitant acute rejection was present in 12 (34%) cases and cellular rejection was the most common (92%) type of rejection related to TMA. Cytomegalovirus infection occurred in 5 (14%) and other infections were present in 19 (54%) patients. Following diagnosis of TMA, calcineurin inhibitor (CNI) withdrawal was the first step in the management of 22 (63%) patients and 8 (23%) also received fresh frozen plasma (FFP) and/or plasmapheresis. The mean follow-up was 375 days (range: 2-4840); 22 (62%) patients had improvement or stabilization of renal function and 11 patients (31%) had allograft failure.

Conclusions: High clinical suspicion is essential for early diagnosis of TMA after kidney transplant. Withdrawal of CNI and treatment of concomitant rejections and infections contribute to renal function maintenance.

SA-PO1082

Outcome After Eculizumab Therapy to Prevent Recurrence of Atypical Hemolytic Uremic Syndrome: Experience in Eleven Renal Transplant Recipients Charlene Levi,[1,2] Veronique Fremeaux-bacchi,[3,2] Anne Scemla,[1] Julien Zuber,[1,2] Christophe M. Legendre,[1,2] Rebecca Sberro-Soussan.[1] *[1]Dept of Renal Transplantation, Assistance Publique-Hôpitaux de Paris, Hôpital Necker, Paris, France; [2]Medicine Faculty, Paris Descartes Univ, Paris, France; [3]Dept of Immunology, Assistance Publique-Hôpitaux de Paris, Hôpital Georges Pompidou, Paris, France.*

Background: Atypical hemolytic uremic syndrome (aHUS) is a rare disease with a high recurrence rate after kidney transplantation. aHUS is associated with histological lesions of thrombotic microangiopathy (TMA) that mainly leads to graft loss. The successful use of Eculizumab (Ecu) to prevent or to treat post-transplantation aHUS recurrence has been scarcely reported. In this study, we describe 11 patients who received a renal transplantation for aHUS and who were treated by Ecu after renal transplantation.

Methods: Eleven renal transplants recipients, with aHUS on their native kidney, received Ecu at our center between 2010 and 2015. Nine patients received prophylactic

Ecu at day 0. Two were treated at time of recurrence (day 6 and 25) . We reviewed clinical, genetic testing and histological data, and posttransplant course. Mean follow-up was 21,6±19 months.

Results: Five patients had at least one previous transplantation that failed secondary to recurrent aHUS. A genetic mutation was identified in ten patients (H factor (4) ; I factor (2), CFH-CFHR1 hybrid gene (1) ; C3 (1), CFHR1 deletion and anti-H-factor antibody (2)). There was no graft loss and mean serum creatinine was 135± 60mmol/l at last follow-up. No patient experienced biological TMA recurrence under treatment. We found transient histological lesions in the 2 patients with later Ecu introduction. Three antibody mediated rejections (AMR) occurred during treatment including one associated with TMA lesions.

Conclusions: These data confirm that Ecu is highly effective to prevent post-transplantation aHUS recurrence, without graft loss and with a good renal function. However, Ecu doesn't prevent AMR. The best treatment duration remains to be defined.

SA-PO1083

Recurrence of Scleroderma Renal Crisis After Renal Transplant Is Associated with Decreased Rates of Graft Survival and Earlier Graft Failure Andrew A. Collins, Donald A. Molony. *Internal Medicine, UT Health Houston, Houston, TX.*

Background: The recurrence of Scleroderma Renal Crisis (SRC) after renal transplant has been previously described though its effects on outcomes and allograft survival are uncertain. Prior estimates suggest a recurrence rate of 20-50% (Pham et al, American Journal of Transplantation 2005, 5:2565-2569). Such rates of recurrence if leading to graft failure will have important implications. This study was conducted to better define the probability of recurrence and understand its impact on allograft and patient survival.

Methods: We identified all cases of renal transplantation for patients with SRC and all cases of disease recurrence in the UNOS database from 1987 to 2014. We analyzed the impact of recurrence on graft survival and compared this to outcomes of patients with other renal diseases: SLE, FSGS, and HUS.

Results: 492 patients were identified as having SRC as their primary diagnosis. Of those, 5.28% (26) had documented disease recurrence, which was similar to those with SLE (2.59%), FSGS (7.38%), and HUS (8.71%). Graft failure for any reason excluding death occurred in 80.8% (21) of patients with recurrence, compared to 24.5% (114) of those without recurrence ($p = 0.00$). Recurrent disease accounted for 11.9% (16) of graft failures in SRC, compared to 6.10% in patients with SLE as the cause of ESRD, 16.4% with FSGS, and 20.9% with HUS. The 5 year graft survival rates were similar: 68.7%, 63.2%, 67.8%, and 57.1% for SRC, SLE, FSGS, and HUS, respectively. SRC recurrence was associated with earlier graft loss; graft failure occurred an average of 628 days sooner in the recurrence group compared to non-recurrence, 1072 days versus 1700 ($p = 0.021$). Age, gender, and ethnicity were not associated with an increased risk of recurrence.

Conclusions: Identification of disease recurrence after renal transplantation holds prognostic significance. Both the rate and timing of kidney transplant failure is made more severe by recurrence. Post-transplant recurrence rates for SRC appear to be similar to those observed with SLE, FSGS, and HUS. Monitoring for recurrence of disease in these patients should be part of routine measures to reduce risk of allograft failure.

Clinical Characteristics of Recurrent IgA Nephropathy within the First Year After Renal Transplantation: Single Center Study Yasuhiro Otsuka, Daijo Inaguma, Yoshihiko Watarai, Asami Takeda. *Kidney Center, Nagoya Daini Red Cross Hospital, Nagoya, Japan.*

Background: There are a few studies showing that the long-term allograft survival of patients with IgA nephropathy (IgAN) is lower than that of non-IgAN, indicating that the cause of lower graft survival is recurrence of IgAN. There have been no large, prospective studies defining the risk factors contributing to the development of recurrent IgAN, and preventive therapy for recurrent IgAN is unknown.

Methods: Retrospective data was collected from 2008 to 2013 on 61 consecutive biopsy-proven IgAN patients who underwent renal transplantation (RTx) in a single center, excluding one case of medication nonadherence. Protocol biopsies were obtained one hour, three weeks, six months and one year after RTx. Recurrent IgAN (rIgAN) is defined as positive for IgA in mesangial area and previously negative for IgA in immunofluorescence study.

Results: Of 61 patients,7 had rIgAN within the first year after renal transplantation. There were no significant differences between rIgAN group and NOT rIgAN group in recipient age (mean±SD) (39.1±18.6, 41.8±12.3)years, sex (6M;1F, 31M;23F), donor age (55.0±8.5, 56.3±9.8)years, diabetes mellitus (2, 8)cases, PEKT (3, 23)cases, living-related donor kidney (5, 33)cases, immunosuppressants, tonsillectomy before transplantation (4, 11) cases, ABO incompatible (0, 18)cases, HLA matching, HLA alleles in recipient including HLA-B35, DR4, B8, DR3, serum IgA concentration (263.0±66.4, 254.4±105.0)mg/dL, and urinary protein (0.57±1.29, 0.07±0.13)g/day. Duration of dialysis before transplantation (months) was significantly shorter in rIgAN group (11.1±20.3 vs 34.9±54.9, $p=0.0383$, Fisher's exact test). Urine occult blood was also significantly higher in rIgAN group ($p=0.000841$, Mann-Whitney U test).

Conclusions: Albeit PEKT was not risk factor for recurrence of IgAN in this study, short-duration dialysis before transplantation could be novel risk factor for recurrence of IgAN. Further analysis is needed to determine risk factors for rIgAN and to establish preventive therapy for rIgAN for better graft survival.

SA-PO1085

An Investigation of 13 Cases of Membranous Nephropathy of the Donor Origin Accidentally Detected by 0-h Renal Biopsy During Kidney Transplantation Kohei Unagami,[1] Masayoshi Okumi,[2] Anri Sawada,[1] Daisuke Toki,[2] Taichi Kanzawa,[2] Yasuyuki Sato,[1] Jumpei Hasegawa,[3] Kazuya Omoto,[2] Hidetoshi Ishigooka,[2] Kazuma Tsujimura,[2] Tomokazu Shimizu,[2] Masashi Inui,[2] Hideki Ishida,[2] Kazunari Tanabe,[2] Kosaku Nitta.[2] *[1]Nephrology, Tokyo Women's Medical Univ; [2]Urology, Tokyo Women's Medical Univ; [3]Nephrology, Ohkubo Hospital.*

Background: Membranous Nephropathy (MN) is a type of glomerulonephritis characterized by thickening of the glomerular basement membrane with immunoglobulin deposition. Proteinuria is a primary symptom, and the condition may sometimes present as nephrotic syndrome. MN is usually diagnosed by a renal biopsy. Therefore, without symptoms, such as proteinuria, hematuria or renal dysfunction, MN is rarely suspected. Here we describe 13 cases of MN of donor origin that were accidentally detected by 0-h renal biopsy, which is routinely performed at the time of kidney transplantion in our hospital.

Methods: During the period between January 1995 and April 2015, 13 cases of MN of donor origin were accidentally detected by 0-h renal biopsy during kidney transplantation. We evaluated the histopathological characteristics of these cases and the clinical course of donors and recipients.

Results: MN view was disappeared in 7 recipients by transplanted renal biopsy at 1035.1 ± 776.2 days after transplantation. Three donors have past histories such as hepatitis B past infection, prostatic cancer, or the internal past taking of thiamazole, all of which are well known causes of secondary MN. In the pre-transplantation evaluation, two donors had hematuria, however, all donors were negative for proteinuria and had normal kidney function (serum Cr 0.92 ± 0.25mg/dl, eGFR 70.1 ± 20.2ml/min/1.73m2). After follow-up of 972.3 ± 916.5 days after operation, significant proteinuria, hematuria and decreased kidney function (serum Cre 1.17 ± 0.44mg/dl, eGFR 50.0 ± 20.0 ml/min/1.73m2) were not observed. In terms of maliginancies, one donor had undergone a prostatectomy for prostatic cancer before transplantation.

Conclusions: Among cases of MN of the donated kidney accidentally detected in the 0-h renal biopsy, several donors did not have symptoms such as proteinuria and hematuria.

SA-PO1086

The Occurrence of Post-Transplant Malignancies Among Kidney Transplant Recipients Is Not Associated with the Level of Tacrolimus Exposure Over Time Shelly Lichtenberg, Ruth Rahamimov, Avry Chagnac, Benaya Rozen-zvi. *Nephrology, Rabin Medical Center, Petah Tikva, Israel.*

Background: Immunosuppressive therapy plays a major role in the development of post-transplant cancer. In this case-control study of kidney transplant recipients, we investigated whether the occurrence of post-transplant cancer is associated with the level of tacrolimus exposure over time.

Methods: We screened the Rabin Medical Center registry data base for adults who received kidney transplants during the years 2001 to 2014, and developed post- transplant nonskin cancer. Those patients were matched with controls by sex, age, type of induction therapy, time of transplantation and length of follow-up. All patients included in the study received a maintenance immunosuppression with tacrolimus, micophenolate mofetil and corticosteroids. Exposure to tacrolimus was estimated using all blood level values of tacrolimus measured until time of cancer diagnosis. The time-averaged value of tacrolimus blood levels was calculated as the area under the curve divided by time at 1, 6 and 12 months after transplantation, and at the time of cancer diagnosis.

Results: 32 patients who met the inclusion criteria developed nonskin cancer. They were matched with 64 controls. The time-averaged tacrolimus blood level at time of cancer diagnosis was 7.97±1.37 ng/mL in the cancer group and 7.9±1.32 ng/mL in the control group ($p=0.8$). The time-averaged tacrolimus blood levels at 1, 6 and 12 months were 9.86±1.94 ng/mL in the cancer and 9.98±1.9 ng/mL in the control groups ($p=0.97$), 9.85±2.3 ng/mL in the cancer and 9.97±1.14 ng/mL in the control groups ($p=0.75$) and 8.95±2.03 ng/mL in the cancer and 8.96±1.04 ng/mL in the control groups ($p=0.97$), respectively. By multiple logistic regression, only smoking status was associated with cancer. The time-averaged tacrolimus blood level at time of cancer diagnosis was not significantly associated with cancer after adjustment for this variable (Hazard ratio=1.08 per ng/mL, 95% confidence interval - 0.78 to 1.5, $p=0.65$).

Conclusions: The development of de novo nonskin cancer after kidney transplantation was not associated with the level of tacrolimus exposure over time.

SA-PO1087

Renal Cell Carcinoma Post Renal Transplant: The Case for Post-Transplant Ultrasound Surveillance William M. Bennett, Alison M. Garre, Thomas D. Batiuk, Kevin M. Mcevoy, Erica Simonich. *Legacy Transplant Services, Legacy Good Samaritan Medical Center, Portland, OR.*

Background: Following successful renal transplantation, there is an increased relative risk of renal cell carcinoma in retained native kidneys. Stimulated by a case of widespread metastatic cancer nine months after transplant with a normal pre-transplant ultrasound, we began routine 6-18 month post-transplant surveillance on all recipients except those with known autosomal dominant polycystic kidney disease.

Methods: 128 consecutive patients were entered into the study. At 6-12 months post-transplant.

Results: 16 suspicious masses were detected (12.5%). Of these only 9 had evidence of acquired cystic disease (ACD) (four or more cysts) pre-transplant. The remainder had normal pre-transplant scans showing only small contracted kidneys or less than the required number of cysts to make a diagnosis of acquired cystic disease. We are following 14 of these patients with scans every 6-12 months to detect growth in newly discovered, less than 1 cm solid lesions. We have found 2 patients in which frank renal cell cancers were discovered. We have now adopted an annual screening process for all post-transplant patients at their one-year post-transplant visit.

Conclusions: Routine screening of native kidneys post-transplant appears critical to detect renal cell carcinoma at a stage early enough to achieve a cure by nephrectomy.

SA-PO1088

Non-Melanoma Skin Cancer Mortality in Kidney Transplant Recipients
Michael Thomas Burke,[1] Annie-Claire Nadeau-Fredette,[1] Carmel M. Hawley,[1] Elaine M. Pascoe,[4] Stephen P. McDonald,[2] Sunil V. Badve,[1] David W. Johnson,[1] Adele Green,[3] Robert Peter Carroll,[2] Nicole Isbel.[1] *[1]Dept of Renal Medicine, The Univ of Queensland, Princess Alexandra Hospital, Brisbane; [2]Central Northern Adelaide Renal and Transplantation Services, Adelaide; [3]Cancer and Population Studies Group, Queensland Inst of Medical Research, Brisbane; [4]School of Medicine, The Univ of Queensland, Brisbane.*

Background: Non-melanoma skin cancer (NMSC) frequently occurs in kidney transplant recipients (KTRs). However, the frequency of, and risk factors for NMSC mortality in KTRs are poorly characterised.

Methods: Aims: To determine the proportion and predictors of fatal NMSC in KTRs. This cohort study included all KTRs transplanted in Australia and New Zealand between 1980 and 2013, using Australia and New Zealand Dialysis and Transplant (ANZDATA) Registry data. A multivariable competing-risk survival analysis was used to calculate risk factors for fatal NMSC in KTRs.

Results: During the study, 21875 transplant episodes occurred in 19344 patients. Of the 6780 patients who subsequently died, 231 (3.4%) died from NMSC. Of these, 172 (74%) were male, 226 (98%) were Caucasian, 219 (95%) were first graft recipients and 213 (92%) died with a functioning graft. Amongst first graft KTRs who died from NMSC, the mean age at transplantation was 48.8 +/- 13.7 years and the mean age at death was 61.8 +/- 11.1 years. Male sex (HR 2.0, 95% CI, 1.48 -2.74); Caucasian ethnicity (HR 5.31, 95% CI, 2.15-13.11) and pre-transplant skin cancer (HR 3.79, 95% CI, 2.38-6.04) were associated with NMSC mortality. Age at transplantation and multiple kidney transplants had time-dependent associations for NMSC mortality with the 5-year post-transplant HR 1.08 per year (95% CI, 1.06-1.1) and 2.90 (95% CI, 1.39-6.05); and the 15-year post transplant HR 1.03 per year (95% CI, 1.02-1.04) and 1.29 (95% CI, 0.66-2.55) respectively.

Conclusions: NMSC is an important contributor to mortality in KTRs. Risk factors for mortality from NMSC include male sex, Caucasian ethnicity, pre-transplant skin cancer, multiple kidney transplants and older age at transplantation.

SA-PO1089

NFAT-Regulated Gene Expression in Patients Developing Non-Melanoma Skin Cancer
Claudia Sommerer,[1] Thomas Giese,[2] Janina Brocke,[1] Stefan Meuer,[2] Martin G. Zeier.[1] *[1]Nephrology, Univ Hospital, Heidelberg, Germany; [2]Immunology, Univ Hospital, Heidelberg, Germany.*

Background: After transplantation the risk of non-melanoma skin cancer (NMSC) is significantly increased. Immunosuppression with calcineurin-inhibitors (CNIs) is associated with the development of NMSC. Association to the individual immunosuppressive loads of CNIs assessed by residual NFAT-regulated gene expression was investigated in renal allograft recipients.

Methods: Renal allograft recipients from the Department of Nephrology, University Hospital Heidelberg, Germany, were included. All patients had a regular annual skin examination. Residual expression of NFAT-regulated genes (IL-2, IFNγ, GM-CSF) in PMA/ionomycin-stimulated peripheral blood was measured by quantitative real-time PCR at predose and 2h after Ciclosporin A (CsA) intake.

Results: 258 renal allograft recipients were enrolled (160 male, age 51±14y). Of these patients 75 allograft recipients developed NMSCs after renal transplantation (29.1%). The following NMSCs were histologically confirmed: 36 basal cell carcinoma, 34 squamous cell carcinoma, 33 actinic keratosis, 27 Bowen disease, 8 kerato-acanthoma. As risk factors to develop NMSC were identified: age 60 years, skin type (Fitzpatrick 1 and 2), and load of immunosuppression. NFAT-regulated gene expression was significantly lower in patients who developed NMSCs compared to patients without NMSCs (8.3±6.5 vs. 12.7±12.8%, p<0.001). Squamous cell carcinoma and actinic keratosis were significantly associated with a high inhibition of IL-2 and IFNγ. Patients with basal cell carcinoma and Bowen disease showed a general low expression of NFAT-regulated gene expression. However, in patients with kerato-acanthoma no significant inhibition of NFAT-regulated gene expression could be detected.

Conclusions: The immunosuppressive load contributed to the risk of NMSCs. NFAT-regulated gene expression was significantly inhibited in patients developing NMSCs. Monitoring of NFAT-regulated gene expression in CNI treated transplant recipients provides an individual profile of response to CNIs and is a useful tool for an individual immunosuppression with respect to safety and toxicity.

SA-PO1090

T Cell Immunosenescence Is a Stable and Strongly Performing Predictor of Recurrent Squamous Cell Carcinoma in High-Risk Renal Transplant Recipients
Matthew James Bottomley,[1,2] Paul N. Harden,[2] Kathryn J. Wood.[1] *[1]Nuffield Dept of Surgical Sciences, Univ of Oxford, Oxford, Oxfordshire, United Kingdom; [2]Oxford Kidney Unit, Oxford Univ Hospitals NHS Trust, Oxford, Oxfordshire, United Kingdom.*

Background: Cutaneous squamous cell carcinoma (SCC) is a major cause of morbidity in renal transplant recipients (RTR). 50% of RTR develop recurrent SCC, but current methods to stratify this risk are limited. Screening thus represents a major healthcare burden. We hypothesised RTR demonstrating increased immunosenescence, associated with ageing and increased infection risk, would be at high risk of recurrent SCC.

Methods: RTR at high clinical risk of SCC were recruited. Predictive value of previously published risk equations, clinical phenotype and immunosenescence (assessed by CD57 expression on CD8+ T cells, using FACS) for SCC development were compared using Cox regression. CMV serology was assessed at enrolment.

Results: 117 RTR participated. Half had a history of previous SCC. Median follow-up was 594 days. CD57 expression on CD8+ T cells correlated with other established markers of immunosenescence. RTR who developed SCC during follow-up and had >50% CD57-expressing CD8+ T cells (CD57hi) were 2.6 (95% CI: 1.0 – 6.7, p=0.04) times more likely to develop a further SCC (median time between SCC: 449 days in CD57hi cohort, not reached in CD57lo). Previously defined clinical risk scores provided no predictive value for SCC in this cohort when adjusted for age at enrolment. CD8+ T cells from CD57hi RTR displayed normal cytotoxic and cytokine-secreting function. CD57hi phenotype was not associated with greater CD4+ Treg number in peripheral blood. CMV IgG titres correlated with CD57 percentage but CMV seropositivity was not, in itself, a predictor of SCC development. CD57 expression was stable over a one year period and with SCC development.

Conclusions: Immunosenescence, partly driven by CMV and identified by the CD57hi phenotype, is a stronger predictor of SCC in high-risk RTR than previously identified clinical scores. Quantifying CD57 expression on CD8+ T cells may enable stratification of RTR at increased risk of recurrent SCC, who may benefit from increased screening and early reduction of immunosuppression.

PUB001

Role of Toll-Like Receptors in Aristolochic Acid Nephrotoxicity

Gem Batuman,[1] Altaf-M Khan,[1] Madlin Alzoubi,[1] Vecihi Batuman.[1,2] *[1]Dept of Medicine, Section of Nephrology & Hypertension, Tulane Univ School of Medicine, New Orleans, LA; [2]Dept of Veterans Affairs, SLVHCS, New Orleans, LA.*

Background: Studies demonstrated that aristolochic acid (AA) is toxic to renal tubular epithelium and carcinogenic to urethral epithelium. Although the exact extent of AA nephropathy (AAN) is unknown, case series have been reported in throughout the world and it has been implicated in the etiology of Balkan endemic nephritis (BEN) suggesting that this is a global health problem. The precise mechanisms of AA nephrotoxicity are not known. We investigated the role of Toll-like receptors (TLRs) in the pathophysiology of AAN using human renal proximal tubule epithelial cells (RPTECs).

Methods: Confluent RPTECs were exposed to AA (30 μM – 480 μM) for 24 – 48 hr and cytotoxicity was measured using lactate dehydrogenase (LDH) assay. RNA and protein were isolated from AA-exposed and unexposed RPTECs. Real time RT-PCR was performed for various gene primers to evaluate the role of innate immunity in AAN development.

Results: At 240 μM after 48 hr exposure, AA induced significant toxicity in RPTECs as measured by LDH release in the culture medium and significant cell injury was observed morphologically. AA significantly increased mRNA expression of acute kidney injury (AKI) biomarker neutrophil gelatinase-associated lipocalin (NGAL), but at the same time significantly decreased the expression of another AKI biomarker kidney injury molecule 1 (KIM-1). AA also significantly upregulated the expression of prominent AKI-related TLRs (TLR2, TLR4 and TLR6) and their adaptor molecules (MyD88 and TICAM-1) followed by the activation of pro-inflammatory cytokines (IL-6 and TNF-α) and the tumor suppressor protein and a biomarker for apoptosis, p53, in the down-stream signaling pathways of TLRs. AA also significantly upregulated expression of multi drug resistant family gene MDR1 in RPTECs.

Conclusions: AA is toxic to RPTECs and restricts cell growth. NGAL but not KIM-1 could be a diagnostic biomarker for AAN. AKI prominent TLR2 and TLR4 could be potential candidates for therapeutic target in developing new strategies for AAN and BEN treatment.

PUB002

A Case of Severe Symptomatic Iatrogenic Hypermagnesemia

Rohan V. Mehta,[1] Vandana Niyyar,[1] Rahul Mehta.[2] *[1]Renal Medicine, Emory, Atlanta, GA; [2]Hospital Medicine, UVA, Charlottesville, VA.*

Background: Hypermagnesemia is an uncommon but a potentially life threatening condition. Symptoms may develop in patients with acute kidney injury (AKI) or chronic kidney disease with the administration of pharmacologic dose of magnesium (Mg), and with use of oral laxatives or magnesium containing enemas.

Methods: A 30-year-old African American man with baseline Cr of 1, admitted for management of multiple fractures, subdural hemorrhage and traumatic brain injury sustained in a motor vehicle accident, suddenly became hypotensive and developed AKI. UOP declined from 2-3L/ day on admission to 700 ml over the next 24 hours. He became areflexic and developed ARDS, with increasing FiO2 requirements. Repeat laboratory data showed Cr 3.9, hemoglobin 6.9 and Mg 9.5 mg/dl. Review of his chart revealed he had received a total of 8.75g of magnesium citrate through enemas on the previous day. Aggressive resuscitation was started, including IV calcium, but he continued to require multiple pressors. Hypermagnesemia was presumed to be the cause of his ongoing hemodynamic instability. Intermittent hemodialysis was initiated for 2 hours to rapidly remove magnesium and he was then switched to CVVHD for continuous magnesium removal. Within 12 hours of RRT, pressor requirements decreased, UOP improved to 50-60 ml/hr and Mg levels ranged between 2-3 mg/dl. CVVHD was discontinued after 72 hrs and the patient had complete renal recovery to his baseline Cr of 1.

Results: Severe symptomatic hypermagnesemia can develop even with small doses of Mg containing laxatives. It prevents presynaptic acetylcholine release resulting in blockade of neuromuscular transmission. Clinical features of Mg toxicity range from delayed deep tendon reflexes, flaccid paralysis, respiratory failure, to hypotension, bradycardia, complete heart block and cardiac arrest. Management includes rapid supportive measures, fluids, IV calcium, loop diuretics. Urgent hemodialysis can rapidly reverse shock and respiratory failure preventing significant morbidity and mortality.

Conclusions: In summary, we report a case of severe hypermagnesmia, in the setting of AKI, presenting with shock and respiratory failure, requiring RRT.

PUB003

Ischemic and Non-Ischemic Acute Kidney Injury Cause Gut Damage

Tao Jiang Li, Chen Yu. *Nephrology Dept, Shanghai Tongji Univ, Tongji Hospital, Shanghai, China; Nephrology Dept, Shanghai Tongji Univ, Tongji Hospital, Shanghai, China.*

Background: Chronic uremia induced gut injury has been well documented in a number of studies. However, remote effects of acute kidney injury(AKI) on the intestine are far less investigated. Here we studied whether the gut also suffers damage during induction of renal ischemia–reperfusion in rats and compared this to bilateral nephrectomy.

Methods: To test our hypothesis, six groups of SD rats (n=6 in each group) were studied: 1) sham operation for 6h; 2) ischemic AKI for 6h (60 min of renal pedicle clamping and then reperfusion for 6h); 3) bilateral nephrectomy for 6h; 4) sham operation for 24h; 5) ischemic AKI for 24h(60 min of renal pedicle clamping and then reperfusion for 24h); 6) bilateral nephrectomy for 24h. Ilium and blood were collected. The damage of gut mucosa was assessed by histological staining. Malondialdehyde(MDA) and apoptosis of the ilium were measured to determine the underlying mechanism of the AKI-induced gut injury.

Results: We found histological evidence of ilium injury following both ischemia and bilateral nephrectomy. MDA, an index of lipid peroxidation, increased in both the renal ischemia and nephrectomy groups, suggesting activation of oxidative stress. Ilium apoptosis,which was quantified by histone-associated DNA fragmentation enzyme-linked immunosorbent assay, were increased after 6 and 24 h of renal ischemia or nephrectomy .

Figure 1. The comparison of damage parameters between different groups

	Sham 6h	RIR 6h	Bilat.neph 6h	Sham 24h	RIR 24h	Bilat.neph 24h
BUN(mg/dl)	23±7.2	70±14.2*	72±16.2*	22±6.2	70±14.2#	170±44.2#
Scr(mg/dl)	0.5±0.1	1.5±0.3*	1.6±0.4*	0.65±0.1	3.6±0.93#	5.0±0.1#
Ileum MDA(mmol/g pto)	0.3±0.11	1.1±0.12*	1.3±0.13*	0.35±0.12	1.15±0.1#	1.2±1.15#
histone-associated DNA fragmentation(absorbance units/15ug pto)	0.35±0.06	0.6±0.15*	0.65±0.12*	0.35±0.07	0.71±0.06#	0.73±0.08#

*p<0.05 compared with sham 6h;#p<0.05 compared with sham 24h

Conclusions: Our study shows that acute kidney ischemia or renal failure activates oxidative stress and promotes apoptosis, and tissue damage in gut . Whether the AKI induced-gut injury by itself is sufficient to provoke systemic inflammatory response need further investigation.

PUB004

Serum from Rats with Acute Kidney Injury Contains Reactive Oxygen Species Generating Activity That Causes Oxidative Stress *In Vitro*

Jon D. Ahlstrom,[1] Zhuma Hu,[1] Nicole Molin,[1] Christof Westenfelder.[2] *[1]Medicine, Univ of Utah and VA Medical Centers, Salt Lake City, UT; [2]Physiology, Univ of Utah and VA Medical Centers, Salt Lake City, UT.*

Background: The uremic state that is induced by Acute Kidney Injury (AKI) adversely affects multiple organ systems by mechanisms that are still poorly characterized, including through reactive oxygen species (ROS).

Methods: Serum was obtained from rats 24 hrs post ischemia/reperfusion-AKI (50 min bilateral pedicle clamp, AKI serum), and control sera was obtained from rats 24 hrs following SHAM surgery (SHAM serum), or from rats 24 hrs post bilateral nephrectomy (NPHX serum). Serum samples were evaluated for ROS activity with the sensitive Amplex Red H_2O_2 assay. For in vitro assays, NRK cells (normal rat kidney cells, proximal tubular) or rat mesenchymal stem cells (MSC) were cultured in rat serum for 48 hours, and then assayed for gene expression, GSH levels, and oxidative stress markers.

Results: Compared to SHAM or NPHX serum, serum from rats with AKI had increased amplex red activity compared to SHAM and NPHX serum controls. Adding catalase to rat serum reduced—but did not eliminate--the ROS activity of AKI serum in a dose-dependent manner. The ROS generating properties of AKI serum were completely destroyed with strong (90°C for 1 hr) but not mild (45°C for 30 min) heat inactivation. Culturing normal rat kidney cells (NRK, proximal tubular) or rat mesenchymal stem cells (MSC) in 10% AKI serum (compared to SHAM or NPHX serum) resulted in increased oxidative stress, including increased anti-oxidant gene expression (HO-1, catalase), increased GSH levels, and increased cellular ROS activity (CMH_2DCFDA and mitosox).

Conclusions: At comparable levels of azotemia (AKI vs. NPHX), AKI serum contains ROS generating activity that is heat labile, but that is not blocked by catalase incubation. These results suggest that the injured kidney releases heat-sensitive factors into the blood stream (likely proteins) that generate ROS and may adversely affect renal tissue and distant organs. The Amplex Red H_2O_2 assay provides a useful tool for the determination and mechanistic dissection of the ROS activity found in AKI serum.

PUB005

Properdin Deficiency Enhances Renal Ischemia Reperfusion Injury in Mice

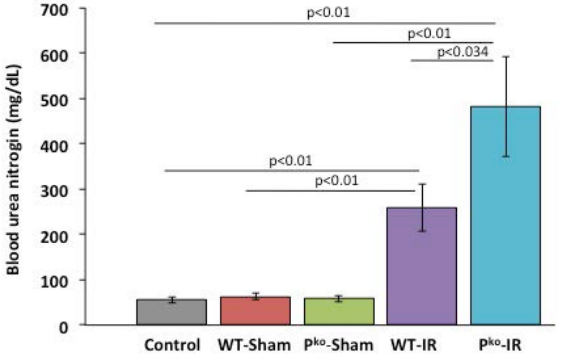
Zinah Dheyaa Zwaini,[1,3] Nigel J. Brunskill,[1] Hans-Wilhelm Schwaeble,[1] Cordula M. Stover,[1] Bin Yang.[1,2,4,5] *[1]Infection, Immunity and Inflammation, Univ of Leicester; [2]Renal Group, Univ Hospitals of Leicester; [3]College of Medicine, Univ of Kufa, Iraq; [4]Basic Medical Research Centre, Medical school of Nantong Univ, China; [5]Nephrology, Affiliated Hospital of Nantong Univ, China.*

Background: Properdin is the only positive regulator of the alternative pathway of complement activation via stabilizing C3bBb convertase. Properdin has been detected on proximal tubular epithelial cells associating with proteinuric renal damage. Previous studies showed that mice with combined deficiencies of properdin (P^{ko}), DAF and CD59, the negative regulators of complement activation, had less renal ischemia reperfusion injury (IRI) in 24 hours.

Methods: P^{ko} mice (n=9) and their wildtype (WT) littermates (n=7) were used to assess the role of properdin in renal IRI. Ischaemia was induced by bilateral clamping of the renal pedicle for 30 minutes followed by 72-hour reperfusion using normal (n=2) and sham operated mice (n=4 or 5) as controls.

Results: Renal IRI was successfully induced in the WT and P^{ko} mice with more prominent injury in P^{ko} mice as evidenced in renal function. Serum creatinine was significantly increased after IRI compared with the sham groups, which was further increased

in P^{ko} in relation to WT mice (1.78±0.29 vs.1.19±0.18, *P*=0.046) post IRI. Similarly, blood urea nitrogen in IRI mice was higher than the sham animals, with significant increase in P^{ko} in comparison with WT mice .



This difference was supported by histological examination, in which P^{ko} mice showed a worse score of tubulointerstitial damage than WT (2.67±0.26 vs. 1.94±0.22, *P*=0.025) post IRI.

Conclusions: This study shows, for the first time, that properdin deficiency alone enhances IRI shown by worsened renal function and histology. The underlying mechanisms for these unexpected phenotype are under present investigation.

Neurogenic Function of Neurons with Renal Afferents Is Altered by Lipopolysaccharides -LPS

Kristina Rodionova,[1] Martin Ziemer,[1] Tilmann Ditting,[1] Stefan Karl,[1] Sonja Heinlein,[1] Peter Linz,[1] Peter Reeh,[3] Kerstin U. Amann,[2] Roland Veelken.[1] *[1]Dept of Medicine 4 - Nephrology and Hypertension, Universitaetsklinikum Erlangen-Nuernberg, Erlangen, Bavaria, Germany; [2]Dept of Nephropathology, Universitätsklinikum Erlangen-Nuernberg, Erlangen, Bavaria, Germany; [3]Dept of Physiology and Pathophysiology, FAU Erlangen-Nuernberg, Erlangen, Bavaria, Germany.*

Background: Renal afferent nerves (RNs) exert complex neurogenic sympathomodulatory and paracrine effects. Recently, we could demonstrate that lipopolycaccharide (LPS) sensitized TRPV1 receptors and increased the release of CGRP from afferent axons in kidney. Hence,we wanted to test the hypothesis that LPS alters firing patterns and acid induced inward currents in cultured neuron sample.

Methods: Dorsal root ganglion neurons (Th11-L2) of rats were incubated with LPS (E.coli O127/B8,20mg/l) 12h before patch clamp recordings. Inward currents were assessed during stimulation of TRPV1 and ASICs with protons (pH6,9 and 5,0). Current clamp mode was performed at physiological conditions and after 12h of LPS-incubation.Neurons were characterized as tonic,i.e. sustained AP firing or phasic, i.e.<5 APs in response to current injections.

Results: Firing patterns and currents induced by acidic superfusion were studied in 246 neurons.Renal neurons (RNs) exhibited in 59% tonic firing pattern under control conditions. The number of neurons with tonic response was significantly reduced by exposure to LPS (59%vs.42%,p<0,05).Under control conditions 70,8% of RNs exhibited both sustained and transient inward current, whereas 29,2% showed sustained current. LPS exposure significantly increased sustained,i. e. TRPV1 induced current (-793,18+/-66pA vs.-1224+/-200pA,p<0,05) and transient, i. e. ASICs induced inward current even under subthreshold proton stimulation (pH6,9) and could not be enhanced further by pH5,0.

Conclusions: LPS altered the properties of neurons with renal axons in a complex way: while the ease of AP production was significantly deceased, the responsiveness to acidic milieu was increased. In how far these alterations subserve different effects (e.g. decreased sympathetic control, altered peptide release) in experimental sepsis needs further research.

Protective Effect of Nitric Oxide in Aristolochic Acid-Induced Toxic Acute Kidney Injury

Inès Jadot,[1] Anne-Emilie Decleves,[2] Vanessa Colombaro,[1] Blanche Martin,[1] Isabelle Habsch,[1] Eric De Prez,[2] Joelle L. Nortier,[2] Nathalie Caron.[1] *[1]Molecular Physiology Research Unit - URPHYM, Faculty of Medecine, Univ of Namur, Namur, Belgium; [2]Laboratory of Experimental Nephrology, Faculty of Medicine, Univ Libre de Bruxelles, Bruxelles, Belgium.*

Background: Aristolochic Acid (AA) nephropathy is a pertinent example of tubulo-interstitial (TI) nephritis characterized by an early phase of acute kidney injury (AKI) leading to progressive fibrosis and chronic kidney disease (CKD). Nitric oxide (NO) has been shown to play a critical role in the AKI-to-CKD transition. Here, the AAN model was used to determine the role of NO in this process, focusing on the acute phase.

Methods: C57BL/6J male mice were randomly subjected to daily i.p. injection of control solution or AAI (3,5mg/kg) for 4 days and L-Arginine (L-Arg; substrate for NO synthesis) was supplemented in drinking water (5%) until mice were euthanized, 5 days after the beginning of AAI injections.

Results: At day 5, AA-treated mice displayed polyuria, increased plasma creatinine level and proteinuria. In addition, histological analyses revealed severe proximal tubular cell necrosis, renal inflammation and increased oxidative stress in AA-treated mice. These changes were associated with a significant reduction of NO bioavailability, as attested by urinary NOx and cGMP levels. L-Arg supplementation in AA-treated mice significantly improved kidney function, as reported by a significant reduction in urine volume, plasma creatinine level and proteinuria. Moreover, L-Arg treatment resulted in a significant reduction of tubular cell necrosis, renal inflammation and oxidative stress. These were concomitant to normalized NO levels.

Conclusions: Our findings demonstrated that sustaining NO bioavailability due to L-Arg supplementation improve the renal outcome of AA-induced AKI phase. Further investigations are ongoing to determine whether increasing NO bioavailability can also prevent chronic injuries in the AAN model.

PUB008

The Study of Curcumin-Loaded Nanoparticles against Renal Ischemia-Reperfusion Injury Function and Mechanism

Yong Xu, Lili Zhong. *Dept of Nephrology, Huaian Second Hospital, Huaian, Jiang Su, China.*

Background: To study the effects of curcumin-loaded nanoparticles against ischemia-reperfusion renal injury, and to investigate its mechanism.

Methods: Synthetize controlled releasing curcumin-loaded nanoparticles by amphilic mPEG-PCL block copolymers and cultivated renal tubular epithelial cell (cell line HK-2) in vitro. HK-2 cells were divided into four groups: Control group; Ischenmia reperfusion injurygroup(IRI group); Curcumin group(Cur group); Curcumin nanoparticle group(CurNP group). In each group, HK-2 cells viability was assessed by dimethylthiazol-diphenyltetrazoliumbromide (MTT) tests. Apoptotic Cells were measured by Flow Cytometry. H2DCF-DA was used to detect intracellular generation of ROS. BCA were used to detect SOD activation and the Concentration of MDA. Protein levels of procaspase-3 were analyzed by Western Blot.

Results: Successfullyconstructed curcumin-loaded nanoparticles by amphilicmPEG-PCL block copolymers. We found the differences between four groups. In IRI group, cells viability reduced gradually, cells apoptosis was obvious, SOD activity declined, the level of ROS and MDA activation increased significantly, the expression of Caspase-3 was increased.In Cur group and CurNP group,cells viability was improved.A great reduction in the level of apoptosis was observed.SOD activity was improved.The level of ROS and MDA activation were inhibited, the expression of Caspase-3 was decreased. Compared with Cur group,it also showed a marked improvement in CurNP group. Difference Had Statistics Meaning(P<0.05).

Conclusions: 1. Efficiently produce controlled releasing Curcumin-loaded nanoparticles by amphilic mPEG-PCL block copolymers.Drug loading content(DLS) and encapsulation efficiency(EE) were more than other peports.Data indicated that incorporated Cur could be slow released from the core–shellstructureof polymericnanoparticles. 2. CurNP can ameliorate ischemia-reperfusionrenal injury in vitro. 3. The protective effects of Cur-NP against ischemia-reperfusion renal injurywere involved in the suppression of oxidative stress reaction.

PUB009

Disruption of Polyamine Catabolism Reduces the Severity of Cisplatin Nephrotoxicity

Kamyar A. Zahedi,[1,2] Sharon L. Barone,[1,2] Marybeth Brooks,[1] Jie Xu,[1] Manoocher Soleimani.[1,2] *[1]Dept of Internal Medicine, Univ of Cincinnati, Cincinnati, OH; [2]Research Services, Veterans Affairs Medical Center, Cincinnati, OH.*

Background: Platinum-based drugs (e.g. cisplatin) are used for treatment of many types of solid organ tumors. Cisplatin crosslinks the DNA, interferes with mitosis, activates the DNA repair response and leads to apoptosis when repair proves impossible. The latter is the primary anti-tumor mechanism of cisplatin. Platinum-based drugs also cause oxidative cell injury, which may mediate their general toxic effects. Acute kidney injury (AKI), due to oxidative damage, is a major side effect of cisplatin that necessitates dose reduction or withdrawal from treatment thereby reducing the effectiveness of cancer therapy. We hypothesized that treatments that reduce the oxidative tissue damage caused by cisplatin lessen the severity of AKI without interfering with its anti-proliferative DNA damaging effects and obviate the need for dose reduction or drug withdrawal.

Methods: Cisplatin-AKI was compared in wild type and SSAT-KO mice using functional and molecular parameters. Mechanism of polyamine catabolism mediated-cell injury were assessed in cultured cells.

Results: The expression of polyamine catabolic enzymes, spermidine spermine-N1-acetyl transferase (SSAT) and spermine oxidase (SMO) increase in the kidneys of cisplatin-treated mice. SSAT-KO mice are protected against tissue damage and renal dysfunction caused by cisplatin. Using cultured cells capable of inducible expression of SSAT, the effect of SSAT on the induction of endoplasmic reticulum stress and unfolded protein response (ERS/UPR). Our results indicate that up-regulation of polyamine catabolism in general, and enhanced production of SSAT in particular, activated the ERS/UPR.

Conclusions: These studies suggest that polyamine catabolism is involved in the mediation of cisplatin-AKI. These and our previous results indicate that the activation of polyamine catabolism causes cell injury through both genotoxic response and ERS/UPR pathways. Our studies suggest that short-circuiting or neutralization of toxic products of polyamine catabolism can be novel therapies that reduce the severity of cisplatin nephrotoxicity.

PUB010

Renoprotective Effect of NADPH Oxidase 4 Inhibition in Contrast Induced Nephropathy Se-Hee Yoon,[1] Won Min Hwang,[1] Sung-Ro Yun,[1] Sukyung Lee,[2] Hee-Yeon Jung,[2] Ji-Young Choi,[2] Sun-Hee Park,[2] Chan-Duck Kim,[2] Yong-Lim Kim.[2] *[1]Internal Medicine, Konyang Univ, Deajeon, Korea; [2]Internal Medicine, Kyungpook National Univ School of Medicine, Daegu, Korea.*

Background: The objective of this study was to investigate the renoprotective effect of NADPH oxidase 4(Nox4) inhibition in contrast induced nephropathy.

Methods: HK-2 cells were incubated with iohexol (nonionic low-osmolar radiocontrast agent) at a concentration of 75 mg I/ml, 150mg I/ml for 2 h. Cells were pre-exposed to GKT137831, a selective Nox1&4 inhibitor (Genkyotex,Switzerland), for 30 min before exposure to iohexol. Cell viability was measured at 0, 3 and 22 h after removal of iohexol by ATPlite assay. Apoptosis was investigated by caspase 3/7 activity assay. Reactive oxygen species (ROS) production was assessed by DHE assay, NADPH oxidase activity by the lucigenin-enhanced chemiluminescence method, and Nox4 expression by western blot and real time PCR.

Results: Nox4 protein expression significantly increased at 30 min after iohexol exposure. GKT137831 pre-exposure showed significantly less cytotoxicity at 3h after removal of iohexol. Caspase 3/7 activity was significantly lower in GKT137831 pre-exposed cells than only iohexol exposed cells at 22 h after removal of iohexol. ROS generation was higher with only iohexol exposed cells compared to GKT137831 pre-exposed cells.

Conclusions: A selective Nox4 inhibition induced fewer cytotoxic effects on cultured HK-2 cells than iohexol along with a lower induction of Nox4-dependent ROS generation. This enzyme may represent a potential therapeutic target to prevent iodinated radiocontrast media related oxidative stress.

PUB011

Autophagy Increased in the Early Stage of Rat Acute Kidney Injury Model Junyi Lin,[1] Xing Mao,[2] Yiwen Shen,[1] Huijuan Wu,[2] Aimin Xue.[1] *[1]Deparment of Forensic Medicine, Shanghai Medical College, Fudan Unviersity, Shanghai, China; [2]Deparment of Pathology, Shanghai Medical College, Fudan Unviersity, Shanghai, China.*

Background: Acute kidney injury (AKI) is a major kidney disease without effective therapies, and thus associated with a high mortality. The pathogenesis of AKI is very complex and still unclear. Recently, researches have shown the induction of autophagy in proximal tubular cells and kidneys during AKI.In the present study, we investigated the role of autophagy in the pathogenesis of rat renal ischemia-reperfusion (I/R) model which causes AKI.

Methods: All male Sprague-Dawley rats were subjected to clamping of bilateral renal artery only for 25 min except sham group, and then they were randomly divided into four groups depended on different reperfusion time point, including 3h, 6h, 12h and 24h. The Sham group underwent surgical procedures without ischemia was as the control.

Results: The level of blood urea nitrogen (BUN) and serum creatinine were increased from 3h after I/R. By H&E staining, protein casts were found at 3h after I/R, which kept increasing at 6h and 12h after I/R. At 24h after I/R, we found some necrotic proximal tubules. Immunoblotting showed the protein level of Beclin-1 and Vps34 and the ratio of LC3 II/I was increased from 3h after I/R, which was confirmed by electron microscopy showing the formation of autophagic vacuoles in proximal tubule cells. Moreover, immunohistochemical staining clearly showed an increasing positive staining of Vps34 and LC3 at 3h after I/R compared to the control.

Conclusions: Taken together, our results demonstrate the occurrence of autophagy in the very early stage of rats AKI model.

The Previous Cardio Exercise (Exe) Normalizes Renal Function of Wistar Rats Subjected to Acute Kidney Injury by Ischemia, and Reperfusion Weslei Vicente Lima, Waldemar S. Almeida, Nestor Schor. *Nephrology, Federal Univ of Sao Paulo, São Paulo, Brazil.*

Background: The acute kidney injury (AKI) is characterized by acute reduction of renal function and has a high mortality rate in hospitalized patients and in severe cases may progress to chronic kidney disease (CKD). The AKI by ischemia and reperfusion (I/R) causes tubular damage mainly in the proximal convoluted tubule, reducing mitochondrial activity in renal cell and increasing the reactive oxygen species (ROS). It is known that aerobic Exe lower blood pressure (BP), slows the heart rate (HR), improves muscle aerobic capacity, increases both the number and size of muscle mitochondria, however little is known about the effects of the previous Exe in AKI. We suspect that aerobic Exe may be a non-pharmacological resource in the prevention of AKI. Thus, we investigated the effect of previous aerobic Exe on renal injury resulting from I/R. To evaluate the effects of the previous aerobic Exe on renal function in Wistar rats subjected to I/R.

Methods: We used male Wistar rats with 10 week of life and they were separated into two groups Sham clamp (SC) and trained control clamp (TC), moreover the TC were subjected to a prior physical training protocol for four weeks. After completed 14 weeks each group were underwent acute kidney injury surgery by I/R, the rast recovering for 24 hours after that they were placed in metabolic cages for 24 hours. We evaluate renal function (serum creatinina and proteinuria). Then they will be realized: renal morphological study by light microscopy and mitochondrial (number and size) by electron microscopy. Finally, we will evaluate apoptosis through caspases 3 activity.

Results: The SC group increased weight compared to the TC group (399±5vs365±5g, P<0.05), Proteinuria was significantly different in SC vs. TC group (25.62±4.93vs14.54±1.65 mg/24h, P<0.05). Now the creatinina serum showed significant difference in SC vs TC group (0.30±0.8vs0.67±0.6 mg/dL; P<0.05). We evidenced that SC group had a damage renal function after 48 hours recovery.

Conclusions: The results of this study are preliminary in nature, but suggest that the previous aerobic Exe can be renoprotective in the model I/R.

PUB013

Angiogenin Mediates a Non-Cell Autonomous Response to Endoplasmic Reticulum Stress in the Kidney Nicolas Pallet,[1] Dany Anglicheau,[3] Eric Thervet,[2] Iadh Mami.[1] *[1]INSERM U1147, Paris, France; [2]Nephrology, Georges Pompidou European Hospital, Paris, France; [3]Nephrology, Necker Hospital, Paris, France.*

Background: Endoplasmic Reticulum (ER) stress is involved in the pathophysiology of kidney diseases, but the molecular basis of its biological outputs remain to be established. Angiogenin (ANG), a secreted ribonuclease, is a previously unappreciated component of the mammalian stress response that acts both in cell-autonomous and non-cell autonomous fashions to promote tissue adaptation to injury. Whether ANG signaling is a genuine component of the ER stress response is currently unknown.

Methods: In the present study, we explored the molecular mechanisms by which ANG is secreted under ER stress, and determined how it contributes to the modulation of the inflammatory microenvironment.

Results: Our results indicate that i) ANG secretion is specifically induced during ER stress and ii) this mechanism is under the selective control of IRE1a signaling. We demonstrate that ANG canonical secretion is induced upon ER stress, similar to the proinflammatory cytokine IL-6, and as such might play an instrumental role in macrophage activation. These data are relevant to human disease since we identified ANG as a urinary marker of immune-mediated acute kidney injury.

Conclusions: Collectively, our data identify ANG as a key mediator of ER stress-dependent inflammatory response in kidney diseases, and is a potential non-invasive biomarker of acute kidney injury.

PUB014

Sustained Infiltration of Th17 Cells Is Associated with Pulmonary Fibrosis in Rats with Salt Induced CKD Secondary to Renal Ischemia Purvi Mehrotra, Jason Andrieu Collett, David P. Basile. *Dept of Cellular and Intergrative Physiology, Indiana Univ of Medicine, Indianapolis, IN.*

Background: Acute kidney injury (AKI) is associated with high mortality rates and is a leading cause of prolonged hospitalizations. The high risk of death is due in part to distant organ damage (e.g., lungs, heart, brain). It is well established that experimental AKI induced by renal ischemia and reperfusion (I/R) induces an increase in pulmonary infiltration of various immune cells like T cells as early as 24 hours post surgery, which may alter endothelial barrier function in the lung. However, the long-term effect of kidney injury induced pulmonary inflammation on lung function and structure and function is not known. We hypothesize that T cells infiltrate into the lung post kidney injury with potential effects on pulmonary structure.

Methods: SD rats were subjected to a model of AKI-to-CKD in which rats are allowed to recover from unilateral I/R (40 min ischemia) for 5 weeks on standard salt diet (0.4% NaCl) and then subjected to contralateral UNX and 4% NaCl diet for 4 additional weeks.

Results: Consistent with prior reports, infiltration of CD4+ T cells were detected as early as 24 hours post surgery in the BAL fluid, and these were shown to be predominantly of Th17 phenotype (63%±10.1, p^3 0.05). Interestingly, Th17 cells persisted in the lungs even after 5 weeks of post surgery after resolution of kidney injury ($2.3X10^4$±0.1, $p^3$0.05), when compared to sham ($0.53X10^4$±0.0.3). Exposure of rats to high salt diet to hasten CKD further increased the number of Th17 cells in the lungs ($4.1X10^4$±0.23, $p^3$0.05). There was a corresponding increase in pulmonary fibrosis in post-AKI rats on high salt relative to sham-controls.

Conclusions: Taken together, these data suggest that AKI leading to CKD is associated with pulmonary fibrosis, an activity that may be due in part to the infiltration of Th17 cells into the lung and influenced by dietary salt.

PUB015

Endothelial-to-Mesenchymal Transition and Endothelial Cilia in EPC-Mediated Postischemic Kidney Protection Daniel Patschan, Susann Patschan, Gerhard A. Mueller. *Clinic of Nephrology and Rheumatology, Dept of Internal Medicine, Göttingen, Nierdersachsen, Germany.*

Background: AKI increases the risk for CKD. Ischemia induces peritubular capillary rarefication and interstitial fibrosis with the latter partly resulting from mesenchymal transition of endothelial cells (EndoMT). Endothelial cilia are mechanosensory organelles responsible for transmitting forces of the blood flow into the cell. Early Endothelial Progenitor Cells (eEPCs) have reproducibly been shown to protect mice from AKI in the short-term. Aim of the study was to analyze mid-term consequences of eEPC treatment of murine AKI. Our special interest focused on dynamics of endothelial cilia and EndoMT.

Methods: Male, 8-12 weeks old C57/Bl6N mice were subjected to unilateral renal ischemia (40) post-uninephrectomy. Syngeneic murine eEPCs (0.5×10^6) were injected once at the time of reperfusion. Animals were investigated 1, 4, and 6 weeks later (renal function,

fibrosis, EndoMT, endothelial alpha-Tubulin). Cultured mature endothelial cells (ECs) were exposed to a variable flow with versus without treatment with eEPC supernatant. Later (24 h) cells were investigated for the presence of cilia, alpha-Tubulin, and EndoMT, respectively.

Results: Systemically injected eEPCs significantly improved postischemic kidney function at week 1 (35 and 45 minutes) and 4 (45 minutes). Interstitial fibrosis was significantly diminished by cell treatment at all time points as well, EndoMT was less pronounced at week 4 (35 minutes) and 6 (45 minutes). eEPC supernatant reduced aSMA expression and alpha-tubulin abundances in flow-treated cultured mature endothelial cells while percentages of cilium+ cells increased. The loss of peritubular capillaries was prevented by eEPCs. Intrarenal endothelial alpha-tubulin decreased postischemia and was further reduced after eEPCs. The latter effect exclusively occurred in the 35 minutes groups.

Conclusions: We conclude that eEPCs are capable of reorganizing the endothelial cytoskeleton in an indirect manner, ultimately resulting in stabilization of the endothelial ciliom. The investigation indicates an anti-mesenchymal role of endothelial cilia in the process of postischemic tissue fibrosis / EndoMT.

PUB016

Mediators of Kidney Recovery following Ischemia-Reperfusion Injury Casper Lassen, Marie Louise Vindvad Kristensen, Henrik Birn, Bente Jespersen, Rikke Norregaard. *Dept of Clinical Medicine, Aarhus Univ.*

Background: Ischemia-reperfusion injury (IRI) is a major cause of acute kidney injury. Remote ischemic conditioning (rIC) performed as brief episodes of intermittent ischemia and reperfusion in a distant tissue may protect the kidney against IRI. We investigated the renal effects of rIC applied either prior to or during ischemic kidney injury.

Methods: One week after uninephrectomy Wistar rats were randomly divided into 4 groups; sham (n=7), IR (n=10), IR+rIPC (n=10), and IR+rIPerC (n=10). rIC consisted of 4 episodes of 5 min clamping of the infrarenal aorta and 5 min of release either before (rIPC) or during (rIPerC) 37 min of left renal artery clamping (IRI). Urine and blood were sampled prior to ischemia or sham operation as well as 3 and 7 days after reperfusion. At day 7 the kidney was harvested for purification of mRNA and protein.

Results: Three days after IRI the decline in creatinine clearance (CrCl) from baseline values was similar comparing the IR group (Δ:-1.59 ml/min/kg [-2.55;-0.64]) to both the IR+rIPC group (Δ:-1.19 ml/min/kg [-2.22;-0.15], p>0.99) and the IR+rIPerC group (Δ:-1.48 ml/min/kg [-2.17;-0.79], p>0.99). At day 7 all groups exposed to IRI recovered to baseline CrCl. This was associated with a significant up-regulation of mediators of kidney recovery including phosphorylated Akt, ERK1/2 and HSP27 in all 3 groups. rIC was not associated with any significant differences in the expression of tubular damage markers, inflammatory or fibrosis markers, as well as anti-oxidant enzymes following IRI (see table).

Conclusions: In our study rIC did not protect the kidney against IRI. However, from day 3 to day 7 after IRI all groups recovered full renal function. This was associated with an up-regulation of *p*Akt, *p*ERK1/2 and *p*HSP27 at day 7.

PUB017

Effect of Double Genes Transfected Adipose-Derived Stem Cells on Cisplatin-induced Renal Tubular Epithelial Cells Injury Nanmei Liu. *Jimin Hospital of Shanghai.*

Background: To observe the effects of adipose-derived stem cells (ADSCs) transfected with CXCR4 and EPO gene on renal tubular epithelial cells (HKC) injury.

Methods: To construct lentivirus expression system consisting of CXCR4 and EPO genes and transfected the system to adipose-derived stem cells (ADSCs), which co-culture with the cisplatin-induced HKC for 48 and 72 hrs. CCK8 detected cell proliferation of HKC. Electron microscope observed the ultrastructure of HKC cells and ADSCs migration was assayed. Western blot detected the expression of apoptosis proteins in HKC. ELISA detected the expression of inflammatory cytokines in culture medium.

Results: No significant changes were observed in the morphology of ADSCs after gene transfection, and the multiple differentiation ability were not affected. After co-culture the inhibitory effect of cisplatin on HKC cell proliferation was alleviated. Compared with the control group, the migration index of ADSCs was increased after co-culturing with cisplatin-induced HKC, and the gene transfection group were increased significantly as the extension of the culture time, indicating that the target gene transfection can promote the ADSCs migration to the damaged parts. Incubation with cisplatin, HKC cells EPO-R protein expression decreased. After co-culturing with ADSCs, the EPO-R expression increased. After incubated with cisplatin, the expression of Caspase-3, Bax expression in HKC cells increased significantly, which mediates the apoptosis. After co-cultured with ADSCs, the protein expression decreased, and the transfection groups decreased more obviously. After incubated with cisplatin, bcl-2 expression of HKC cells decreased obviously and the expression increased when ADSCs were cultured, and co-transfection group was more obviously. After incubated with cisplatin, IL-6 and RANTES were significantly increased in the cisplatin group. The inflammatory factor content decreased when ADSCs were cultured, and decreased more obviously in gene transfection group.

Conclusions: EPO has the protective effects on the damaged cells and CXCR4 could promote the migration of stem cells to damage sites. Double genes transfected to ADSCs may enhance the protective effect on HKC cells injury.

PUB018

The Role of Endosialin in Renal Ischemia-Reperfusion Injury Chia-Hao Liu,[1] Fang Ling Liao,[1] Shun-Yang Cheng,[1] Shuei-Liong Lin.[1,2] *[1]Physiology, National Taiwan Univ College of Medicine, Taipei, Taiwan; [2]Internal Medicine, National Taiwan Univ Hospital, Taipei, Taiwan.*

Background: Many studies reported that Endosialin deficiency can attenuate the inflammation, fibrosis or growth, invasion and metastasis of tumors. It is highly expressed during embryonic development, but largely absent in adult tissue except kidney and uterus. We are intrigued by the role of endosialin in the acute kidney injury.

Methods: We performed unilateral nephrectomy and then ischemia-reperfusion injury to induce acute kidney injury in the endosialin-deficiency (lacZ knock-in) and littermate wild type mice. Plasma levels of blood urea nitrogen and creatinine were analyzed at day 2,5 and 10 after injury. We analyzed the cells expressing endosialin, tubulointerstitial injury, and specific cells by X-Gal staining, Periodic acid-Schiff staining and immunohistochemistry respectively.

Results: Positive X-Gal staining was shown in the glomeruli, small arteries and interstitial cells of the kidney. The capillary density determined by CD31 staining did not show significant difference between endosialin-deficiency and wild type mice. Nephrectomy and ischemia-reperfusion injury led to marked elevation of plasma blood urea nitrogen and creatinine in wild type mice, however the elevation of plasma blood urea nitrogen and creatinine was less in endosialin-deficiency mice at day 2 after injury. Interestingly the protective property of endosialin deficiency was lost since day5 after injury.

Conclusions: Endosialin-deficiency can attenuate acute kidney injury induced by ischemia-reperfusion injury, but the protective property is lost during the repair/regenerative phase after acute injury. The protective property of endosialin deficiency is not related to capillary density which has been shown increased in previous study. Further study needs to delineate the mechanism underlying the protective property of endosialin deficiency and why the protective property is lost during repair/regenerative phase.

PUB019

The Mechanism of β2-Adrenergic Receptor /Protein Kinase A Signal Transduction Pathway in Restoration of Acute Kidney Injury by Endothelial Progenitor Cells Ying Zhou, Chen Yu. *Dept of Nephrology, Tongji Hospital, Tongji Univ, Shanghai, China.*

Background: Endothelial progenitor cells (EPCs) could improve renal microenvironment, stimulate endothelial repair and angiogenesis, and promote AKI restoration. However, the molecular mechanism has not been elucidated. In this study we investigated the role of β2-adrenergic receptor (β2 -AR) and its downstream factors (protein kinase A, protein kinase B, protein kinase C) in restoration of acute kidney injury by EPCs.

Methods: The model of ischemia-reperfusion acute kidney injury (I-R AKI) was used in vivo, while sham operation was performed in control group. Renal tissue was got after 7 days. Renal histology was measured by HE staining. The expression of β2-AR was examined using Q-PCR and immunofluorescence staining. The specific antigens on surface of EPCs(CD34,CD133 and VEGFR-2) were examined by Q-PCR; while VEGFR-2 was examined using immunofluorescence staining too. The downstream factors (PKA, PKB, PKC) were measured by Q-PCR and Western blotting.

Results: Renal histology suggested acute tubular necrosis, and β2-AR was positive by immunofluorescence staining in I-R AKI group; while neither appeared in control group. The mRNA levels of CD34,VEGFR-2,β2-AR and PKA were significantly up-regulated in I-R AKI group than in control group($p<0.05$). The protein level of PKA was significantly higher expressed in I-R AKI group than in control group($p=0.04$); while the protein levels of PKB and PKC were not.According to Pearson's correlation analysis, there were significant positive-correlations between VEGFR-2 and CD34($p=0.005$), VEGFR-2 and β2-AR($p<0.05$), CD34 and β2-AR($p<0.05$), β2-AR and PKA($p<0.05$).

Conclusions: When I-R AKI occurred, the mRNA levels of specific antigens on surface of EPCs(CD34 and VEGFR-2) were significantly up-regulated, which suggested that I-R AKI might induce EPCs homing to kidney. At the same time, the mRNA levels of β2-AR and PKA were significantly up-regulated, and most of them were positive-correlated, which suggested that β2-AR/PKA pathway may play a role in the restoration of AKI by EPCs.

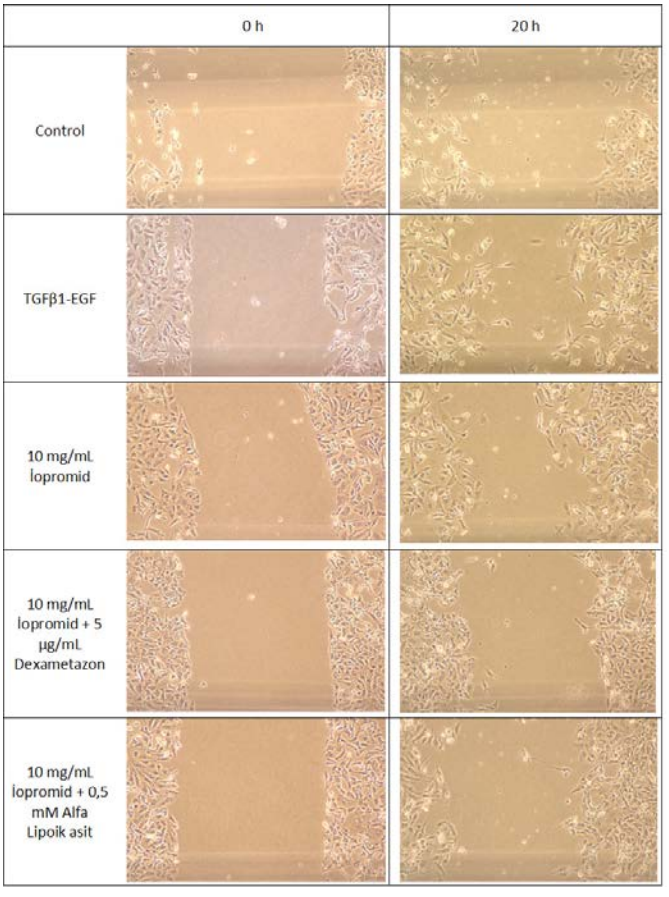
PUB020

Alpha Lipoic Acid and Dexamethasone Counteract Contrast Media-Induced Proximal Tubule Cell Dysfunction Hayriye Sayarlioglu,[1] Ali Okuyucu,[2] Abdulkerim Bedir,[2] Osman Salis,[2] Eser Yenen.[2] *[1]Dept of Nephrology, Ondokuz Mayis Univ Medical Faculty, Samsun, Turkey; [2]Dept of Medical Biochemistry, Ondokuz Mayis Univ Medical Faculty, Samsun, Turkey.*

Background: Contrast medium induced nephropathy (CIN) is one of the most common cause of hospital-acquired acute renal failure. But its pathogenesis is unclear. In this study, we observed the effect of iopromide, low osmolar contrast medium, on tubular cells in HK-2 cell line.

Methods: We observed the effect of iopromide, low osmolar contrast medium, on tubular cells in HK-2 cell line. First, we examined the effects of different doses of iopromide (10, 20, 40 and 80 mg/mL iodine) on proliferation of HK-2 cells by the real time cell analyser (RTCA). According to the results of RTCA we examined whether the non-toxic doses of iopromide (10 and 20 mg/mL iodine) is causing of the EMT by scratch assay for 20 h. We also observed whether alpha lipoic acid (0,5 mM) and dexamethasone (5 µg/mL) is preventing to EMT in this assay.

Results: We observed whether alpha lipoic acid (0,5 mM) and dexamethasone (5 µg/mL) is preventing to EMT in this assay. Although cytotoxic effect was observed for iopromide with concentration of 80 mg/ml iodine, the iopromide with lower doses did not show any effects for HK-2 cells. In scratch assay, we observed that the non-toxic doses of iopromide (10 and 20 mg/mL iodine) is causing of the cell migration which an indicator of EMT and lipoic acid and dexamethasone prevent the cell migration



Conclusions: In conclusions, the EMT caused by contrast medium is prevented or reduced by dexamethasone and lipoic acid in HK-2 cells. This result suggest that dexamethasone and lipoic acid may be a potential treatment to prevent the development of CIN in individuals with high-risk.

PUB021

Contribution of Proliferating Endothelial Cells for Endothelial Repair After Site Specific Endothelial Injury of the Mouse Kidney Jan Sradnick, Anika Luedemann, Vladimir T. Todorov, Christian Hugo, Bernd Hohenstein. *Div of Nephrology, Dept of Internal Medicine III, Univ Hospital CGC, Dresden, Germany.*

Background: Our previous studies have shown that renal endothelial cell regeneration occurs exclusively via local mechanism. To further dissect the relevance of local mechanisms for endothelial repair. we now investigated the contribution of local endothelial cell proliferation in the kidney in our model of site selective endothelial injury (ECI).

Methods: Selective ECI was induced in 9 out of 15 mice by renal arterial perfusion with ConcanavalinA (ConA)/anti-ConA, while 6 mice served as sham operated controls. Edu (15µg/g), a marker of proliferation, was injected starting 24hours after ECI every 12hours intraperitoneally. Kidneys were harvested on day 7 and Edu+ cells were analyzed using flow cytometry and histology. Endothelial cells were stained using CD31, CD105, CD34 and CD146 and hematopoietic cells were detected as CD45+. Inflammatory cells (macrophages, dendritic cells and neutrophils) were analyzed via GR1, CD11c, CD11b and F4/80 positivity. By histology, proliferating EC were detected as anti-ERG/EdU double positive cells.

Results: Significantly more EdU+ cells could be detected after ECI on day 7 (sh: 1.2%±0.7; ECI: 7.6%±4.8). Most of those EdU+ cells were positive for CD45 (65%±8) and 5% (sh) up to 7% (ECI) were positive for EC surface markers. In diseased kidneys more endothelial cells were found (sh: 5.5%±0.7; ECI: 7.3±0.5; $p<0.01$). A larger amount of EdU+ EC was found in injured kidney (sh: 1.5%±0.8 Ø160 cells; d7: 5%±1.5 Ø630 cells $p<0.01$). Histological analysis supported these findings. Glomeruli of ECI kidneys had more ERG/EdU+ cells (Ø sh: 0.23±0.16; d7: 1.22±0.6; $p<0.01$). Inflammatory cells in injured kidneys were slightly increased. Many macrophages (21%±13), neutrophils (38%±17) and dendritic cells (19%±13) were EdU+.

Conclusions: Enhanced endothelial proliferation was detected following ECI. Thereforey EC proliferation reflects an relevant repair mechanism following site selective ECI. The further investigation of EC repair will have to dissect the contribution of the proliferative response by adult local EC from other contributors such as local progenitor cells.

PUB022

Injury of Proximal Tubular Cells in Neonate Rats with Hypoxic-Ischemia Brain Damage Dong Li,[1] Mei Han.[2] *[1]Pediatric Dept, The Second Affilliated Hospital od Dalian Medical Univ, Dalian, Liaoning Province, China; [2]Pediatric Internal Medicine Dept, Dalian Children's Hospital, Dalian, Liaoning Province, China.*

Background: Proximal tubular cells play a critical role in renal injury. To investigate the consequence of mitochondria in renal proximal tubular cells after hypoxic-ischemia brain damage (HIBD) in rats and the apoptosis in it.

Methods: Neonatal (7 days old) Sprague Dawley rats were randomly divided into 2groups: sham group and operation group (n=5 per group). The Rice method was used for establishment of HIBD model, proximal tubular cells Mitochondria pathology and histology were examined under electron microscope at 1 day, 7days, 14days and 21days after the hypoxic-ischemic treatment, and apoptosis was analyzed by TUNEL.

Results: After the HIBD, the mitochondria of proximal tubular cells were showed damage under EM, some membrane and ridges were broken, the mitochondria bodies were swelling, and partial crista fragmentation were observed from the 1day till 21days after. And the 21days was the most worst for mitochondria under EM. For the TUNEL, after HIBD, it showed significant increased for 1day, 7days, 14days and 21days groups comparing with sham group. ($p<0.05$).

Conclusions: After the hypoxic and ischemic brain injury of neonate rats, the mitochondria were damaged in proximal tubular cells, even in 21days after HIBD. And the apoptosis maybe one of the causes of this damage.

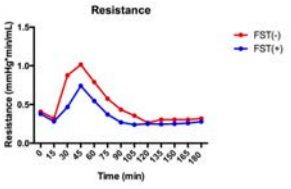
PUB023

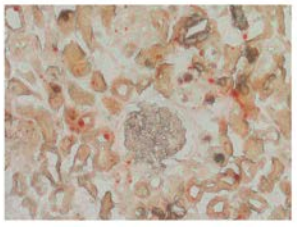
Ex-Vivo Normothermic Perfusion (EVNP) to Repair Monoethylene Glycol Toxicity in Human Kidneys Ivonne Palma,[1] Sasha Karan Narayan,[1] Ivania Palma,[1] Rajendra Ramsamooj,[2] Junichiro Sageshima,[1] Jakub Woloszyn,[1] Nam Tran,[2] Chandrashankar Santhanakrishnan,[1] Richard V. Perez.[1] *[1]Surgery, Univ of California-Davis, Sacramento, CA; [2]Pathology and Laboratory Medicine, Univ of California-Davis, Sacramento, CA.*

Background: Monoethylene glycol (MeG), a component of radiator fluids, results in crystal-induced acute kidney injury, hypocalcemia and often death, if ingested. Utilization of kidneys from deceased donors with MeG poisoning may not be suitable for transplant. EVNP may be utilized to potentially assess/repair high-risk kidneys in this setting.

Methods: A pair of transplantable human kidneys from a brain dead 38 year old female suicide victim from MeG poisoning were discarded due extensive intratubular crystal deposition. The kidneys were placed on 3 hours of EVNP with leukocyte depleted packed red blood cells at 37°C. Oxygenation via a hollow fiber membrane oxygenator supplemented with parenteral nutrition/insulin. One kidney was given Furosemide (10 mg) at the beginning to induce diuresis and assess acute kidney injury. Hemodynamic pump parameters and urine output were monitored. Blood and urine samples were collected at the start and every 30 minutes and analyzed for pH, oxygen, electrolytes, creatinine, and lactate. Wedge biopsies were collected pre & post perfusion & stained with alizarin red to measure calcium oxylate tubular deposition.

Results: Blood flow and resistance improved over time in both kidneys. EVNP reduced calcium deposits compared to baseline wedge biopsies. Kidney treated with furosemide showed slightly better hemodynamic profile and fewer crystals after EVNP.





Fourosemide Positive Pre-Perfusion
10x, Alizarin Red Stain

Fourosemide Positive Post-Perfusion
10x, Alizarin Red Stain

Conclusions: EVNP may have the potential to repair MeG acutely injured kidneys rendering them suitable for transplantation. Ex vivo administration of furosemide may be a useful tool to assess injured deceased donor kidneys being considered for transplantation.

Transfusion of Red Blood Cell as Predictor of Acute Kidney Injury in Patients Undergoing Cardiac Surgery Eduesley Santana-Santos, Luiz Aparecido Bortolotto, Ludhmila Abrahão Hajjar. *ICU-Cardiac Surgery Postoperative Care, Heart Inst (InCor) Inst do Coração do Hospital das Clínicas da Faculdade de Medicina da Univ de São Paulo, São Paulo, Brazil.*

Background: The red blood cell transfusion in the perioperative period of cardiac surgery have been associated with acute kidney injury. Our purpose was to analyze the influence of transfusion of red blood cell in the incidence of acute kidney injury after cardiac surgery.

Methods: We performed a prospective cohort study carried out in a tertiary hospital specialized in Cardiology. Adult patients who had undergone elective myocardial revascularization surgery, valvular and aortic surgery and who had agreed to participate in the study were included. The primary endpoint was acute kidney injury defined by KDIGO criterion. Secondary outcomes was serious clinical complications defined according to the guidelines of the Society of Thoracic Surgeons.

Results: According to KDIGO criterion, the incidence of AKI was 46.5%. The mean age was 60±12 years old in the AKI group and 58±13 in the no AKI group (p=0 .145), and mostly male (56%). The surgical risk assessed by EuroSCORE was greater in the AKI Group 5 (1-25) when compared to the no AKI group 4 (2-10), (p=0.047). There were no differences between the groups for the secondary outcomes. The use of red blood cells in the perioperative period (OR=3.166, p=0.001) and the presence of prior chronic kidney disease (CKD) (OR=2.027, p=0.036) was associated with AKI postoperatively.

Variable	OR	CI (95%)	p (value)
Age, years	1.486	0,990 – 1,043	0,223
Cardiac Heart Failure	2,549	0,116 – 1,247	0,110
Male gender	0,661	0,395 – 1,469	0,416
Chronic Kidney Disease	2,027	1,406 – 3,052	0,036
Red Blood Cell Trasnfusion	3,166	1.572 – 6.380	0,001
Use of Cardiopulmonary Bypass	0,841	0,308 – 2,296	0,736

During the period of hospitalization the mortality rate was 6.9%. When we compare the mortality rate between the groups it was 4.3% in the no AKI Group and 10% in the AKI Group (p=0.229).

Conclusions: In our study the use of perioperative red blood cells influenced the primary outcome. Patients who had used red blood cells had 3 times more risk of AKI.

PUB026

A Picture Is Worth a Thousand Words: Simultaneous ATN, AIN, and Post Infectious GN Ankur Shah,[1] Rachel Criner,[1] Jean Lee.[2] *[1]Internal Medicine, Temple Univ Hospital, Philadelphia, PA; [2]Nephrology, Temple Univ Hospital, Philadelphia, PA.*

Background: The differential diagnosis of hospital acquired acute kidney injury in its most general terms often is described as pre-renal, intrinsic ,or post-obstructive. Further differentiating the intrisnsic causes of AKI, we are given the differential of Acute Tubular Necrosis, Acute Interstitial Nephritis, and Glomerulonephritis. We present a case of a patient who presented with sepsis and developed acute kidney injury whose biopsy revealed a plethora of pathology.

Methods: We present a case of a 54 y/o male with a pmhx of only HTN and DJD who presented with leg pain and weakness for 2 weeks and hematuria found to be bacteremic with MSSA with L spine epidural abscess and bilateral psoas muscle abscesses. He developed acute kidney injury thought clinically and based on microscopy to be secondary to hypotensive acute tubular necrosis and was started on hemodialysis on HD6**.** He was being treated with cefazolin and over weeks had minimal return of renal function, the differential diagnosis was revisited and concern for AIN from the penicillin agent was raised, the patient was switched to Daptomycin, but remained RRT dependent. After 25 days on hemodialysis, a biopsy was obtained which revealed diffuse interstitial inflammation with eosinophils, focal mild-moderate tubular injury with vacuolization, as well as by electron microscopy, subepithelial deposits but not subendothelial deposits,most of which are largely absorbed, including in “notch” areas. These findings are consistent with an acute post-infectious glomerulonephritis, resolving stage; drug induced acute interstitial inflammation, as well as mild-moderate focal tubular injury.

Conclusions: This case demonstrates a variety of the potential causes of AKI. The patients course was long and provided multiple opportunities for re-evaluation and a return to the differential diagnosis process. This is an excellent case for the teaching of the fundamentals of medicine, as the differential diagnosis is truly the instrument of the master clinician. This patients aberrance from the expected course prompted reevaluation and his pathology was staggering.

PUB027

Monitoring and Follow-Up of Acute Kidney Injury Post-Discharge: Retrospective Case Review Series Kosmas Papailiadis,[1] Judith H. Veis.[2] *[1]Medicine, Washington Hospital Center, Washington, DC; [2]Nephrology, Washington Hospital Center, Washington, DC.*

Background: AKI during hospitalization increases risk of progression to CKD and death upon discharge. Recent KDIGO guidelines suggest patients should be evaluated 3 months after AKI for resolution, new onset, or worsening of pre-existing CKD. We determined factors associated with whether patients with AKI had kidney function assessed 3 months post-discharge.

Methods: Restrospective chart review of hospitalizations in 2013 complicated by AKI, who had follow-up in Ambulatory Medical Clinic to assess discharge communication; serum Cr, urine protein:Cr at 3 and 4-9 months; 1 year outcomes including progression to CKD, death and referral to nephrology.

Results: 77 inpatients with AKI (48(66%) stage 1, 9(12%) stage 2, 20(26%) stage 3; and 6(8%) requiring RRT) had a post-discharge visit. Of these, 51(66%) had serum Cr and 16(21%) had urine protein:Cr checked by 3 months. For 4-9 months, 13(17%) had serum Cr and 5(6%) had urine protein:Cr checked; 3(4%) were deceased by 1 year. 26(34%) had normal kidney function pre-AKI and of this group, 10(38%) had CKD by 1 year. Of these 26, only 5(19%) were referred to nephrology. For documentation, 54(77%) had AKI as a problem in the inpatient hospital summary, 42(54%) had AKI documented in the brief outpatient hospital summary and 29(41%) had AKI addressed in the follow-up visit. There was no significant association between AKI severity, need for RRT, or documentation with checking kidney function by 3 months nor between AKI inpatient documentation and addressing AKI at follow-up ($p<0.05$). There were significant associations between addressing AKI at follow-up and checking kidney function; p=0.043 and between AKI stage and addressing AKI at follow-up; p=0.022 and between AKI outpatient summary and addressing AKI at follow-up; p=0.004.

Conclusions: Outpatient follow-up of inpatient AKI is inconsistent despite evidence of poorer outcomes and recent guidelines which suggest the need for closer monitoring. Improving transitions of care through more effective documentation and streamlined EMRs, as well as increasing primary care physician awareness could reduce the risk of progression to CKD and death.

PUB028

Late Recovery of Renal Function in Atypical Hemolytic Uremic Syndrome (aHUS) After Eculizumab Therapy Jeffrey D. Clement, Delin Wang, Maoyin Pang, Tanmay Sahai, Keith R. Bartolomei. *Roger Williams Hospital.*

Methods: A 33-year-old woman with hypertension and left renal agenesis presented with fever and acute kidney injury with serum creatinine of 2.1 mg/dL. Initially, hemoglobin was 11.3 mg/dL and platelets 193,000/ul. Over the next three days platelets dropped to 55,000/ul and LDH rose to 770 U/L; renal function worsened. Thrombotic microangiopathy was suspected. Stool culture was negative. Urine protein was 6.8 g per 24 hours. Serologic assessment, including C3, C4, ANA, ANCA, HIV, cryoglobulins, dsDNA, lupus anticoagulant, anticardiolipin antibodies, and β-2-glycoprotein I antibodies, was unremarkable. The patient was treated with cryo-poor plasma exchange and steroids. Hemodialysis was started for uremia. ADAMTS13 was 67% of normal. Renal biopsy

showed acute thrombotic microangiopathy, acute tubular injury, and moderate interstitial fibrosis. The presentation suggested the diagnosis of aHUS. Eculizumab, an anti-C5 antibody, was initiated at 900 mg weekly for four weeks followed by 1200 mg every two weeks. Eculizumab therapy resulted in resolution of hemolysis. Dialysis was continued thrice weekly. Eculizumab was continued every two weeks, and LDH and platelet counts remained normal. Twelve months after initial presentation urine output improved and interdialytic weight gains were negligible. Pre-dialysis serum creatinine was 3.9 mg/dL, and a urine collection showed creatinine clearance of 30 ml/minute. She has remained off dialysis for twenty weeks, and latest serum creatinine is 3.4 mg/dL. Screening for complement genetic defects has been negative.

Conclusions: Experience with eculizumab is ongoing. Most patients with aHUS have a rapid hematologic response. If they need dialysis, then recovery of renal function is usually prompt; late recovery is rare. We hypothesize that sustained control of complement activation has eliminated the microangiopathy and allowed for vascular remodeling and tubular regeneration, even months later. Patients are at risk for relapse if they stop treatment. This case points out that the presumed genetic defect may require lifelong treatment, and that late recovery of renal function is possible with complement inhibition and supportive care.

PUB029

The Effectiveness of Theophylline in Preventing Cisplatin Related Nephrotoxicity in Patients with Cancer Ismail Kocyigit,[1] Derya Karademir,[1] Fatma Dogruel,[1] Cevat Yazici,[2] Aydin Unal,[1] Murat H. Sipahioglu,[1] Oktay Oymak,[1] Bulent Tokgoz.[1] *[1]Nephrology, Erciyes Univ Medical School, Kayseri, Turkey; [2]Biochemistry, Erciyes Univ Medical School, Kayseri, Turkey.*

Background: Cisplatin is a potent antineoplastic agent used in treatment of many solid tumors. The major limiting side effect of cisplatin is nephrotoxicity. Theophylline is a competitive antagonist of adenosine which has antiinflammatuar activity. In this study, early detection of acute kidney injury with biomarkers such as neutrophil gelatinase associated lipocalin (NGAL) and cystatin C and investigation of the potential nephron-protective effects of theophylline were aimed.

Methods: Sixty patients who are planned administration of cisplatin for the first time were included in the study. Patients were divided into two groups as group 1 (n=30) (standard treatment arm) and group II (n=30) (theophylline arm). Glomerular filtration rate (GFR), NGAL, cystatin C were measured at 5th day in all of the patients. Also, these parameters were repeated measured after the administration of cisplatin, at 2nd hour, 5th and 20th days.

Results: In both groups after the administration of cisplatin, glomerular filtration rate (GFR) showed a significant decrease within time (p=0.006). In creatinine, in spite of the decline in GFR, no significant difference was observed between groups and within time. After 2 hours of cisplatin administration, in spite of the decline in GFR, a significant decline was detected in serum cystatin C (p<0.001). Urine NGAL was significantly high after 2 hours of cisplatin administration (p<0.001). No significant difference was observed between groups. However, when the time*group effects were considered together, higher NGAL was detected in the group not receiving theophylline (p=0.025). After 5 days of cisplatin administration, urine protein levels were significantly higher in both groups (p<0.001).

Conclusions: Results showed that urine NGAL level is a superior biomarker compared to creatinine and cystatin C in the detection of early acute kidney injury. Theophylline was found not to bring a complete protection for the kidneys, but less nephrotoxicity was developed when compared to the group not receiving theophylline.

PUB030

IgA Nephropathy Presenting as RPGN After G-CSF Administration: An Interesting Case Talal A. Khan,[1] Ahmad Hassan,[2] Agha Syed Shabbir Ali,[2] Hafiz Armaghan Saeed,[2] Abdul Mateen Nagaria,[1] Azka Arif.[1] *[1]Freeman Health System; [2]Rawalpindi Medical College.*

Background: IgA nephropathy is the most common form of primary glomerulonephritis & a major cause of ESRD in the world, its pathogenesis involves lymphocyte infiltration within renal interstitium as well as glomerulus. Selectins are adhesion molecules that play very important role in leukocytes to endothelial cell attraction. G–CSF is commonly used to induce neutrophil production .It induces E-selectin expression on endothelial cells & E selectin ligand on leukocytes. We present an interesting case of IgA nephropathy presenting as RPGN after G-CSF administration.

Methods: 66-year-old male with past medical history significant for T-cell leukemia on Cyclophosphamide(CYC) who presented with epistaxis was found to have acute agranulocytosis, he was admitted for further evaluation and management ,his CYC was held & on the day of discharge he was given 1 dose of G–CSF. He presented in 2 days with acute renal failure, gross hematuria & rash in his lower extremities, his creatinine went up from 1.3 to 5.1mg/dl. He was evaluated by nephrology service, and emergent renal biopsy was performed which showed rapidly progressive glomerulonephritis (RPGN) with IgA deposition in mesangium. Glomeruli showed diffuse mesangial hypercellularity and matrix increase with focal nodule formation. 3/17 Glomeruli had epithelial crescents & focal necrosis with fibrin deposits. The sections were stained for IgG, IgM, IgA, C3, C4, C1q, albumin, fibrinogen, & kappa and lambda light chains. There were mesangial granular deposits with IgA (3+), C3 (1+), lambda (1+); kappa was negative. The remaining stains showed no significant deposits. Patient underwent induction with CYC and pulse steroids, his creatinine improved to 1.4mg/dl.

Conclusions: The pathogenesis of IgA nephropathy involves E selectin interactions, which are induced by G-CSF administration. In our case development of RPGN with IgA nephropathy might be linked to G-CSF administration especially with the timeline of presentation. IgA nephropathy has not been linked to G-CSF administration before in adults, we suggest underlying complex genetic predisposition.

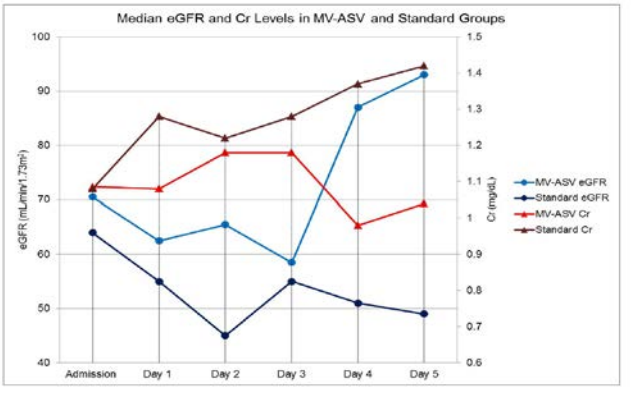
PUB031

Minute Ventilation-Targeted Adaptive Servo Ventilation Protects Renal Function in Acute Decompensated Heart Failure Patients Matt Kawahara,[2] Trenton Gluck,[2] Elizabeth Lee,[2] Boris Arbit,[1] Kathleen Sarmiento,[3] Atul Malhotra,[3] Alan S. Maisel.[1] *[1]Div of Cardiovascular Medicine, Univ of California, San Diego, La Jolla, CA; [2]Cardiac Research, VA San Diego Healthcare System, La Jolla, CA; [3]Div of Pulmonary and Critical Care Medicine, Univ of California, San Diego, La Jolla, CA.*

Background: Acute kidney injury (AKI) in patients admitted for acute decompensated heart failure (ADHF) carries a poor prognosis. Minute ventilation-targeted adaptive servo ventilation (MV-ASV) therapy relieves apneas and renal hypoxia. Serum creatinine (Cr) and estimated glomerular filtration rate (eGFR) are markers that signal kidney injury and improvement of kidney function. MV-ASV may mitigate kidney injury and improve renal function in patients admitted with ADHF compared to standard therapy.

Methods: This is a study where twenty-one patients with ADHF were randomized to receive either MV-ASV therapy (S9 VPAP Adapt, ResMed Corp.) with standard care, or standard care alone. MV-ASV therapy was administered for a minimum of six hours per day for up to 5 days, or until discharge. Cr was measured daily and used to calculate eGFR.

Results: The median baseline Cr levels in the MV-ASV and standard groups were 1.09mg/dL and 1.08mg/dL, respectively. After therapy, Cr levels were unchanged in the MV-ASV group and increased by 0.34 mg/dL (31.5%) in the standard care group. The median baseline eGFR levels in the MV-ASV and standard groups were 70.5mg/dL and 64mg/dL, respectively. Upon completion of therapy, the eGFR levels in the treatment group increased by 22.5mg/dL (32%) and decreased in the control group by 15mg/dL (23%).



Conclusions: MV-ASV therapy in patients with ADHF stabilizes Cr levels during a period of aggressive diuresis. MV-ASV may be a valuable for renal protection and could improve kidney function in patients with ADHF.

Evaluation of Acute Kidney Injury in Patients Continued on Renin-Angiotensin System Blockers During Hospitalization Numan Alabdan,[1] Elvira Gosmanova,[1,2] Carrie Oliphant,[1,2] Joyce E. Broyles,[1,2] Pan Hu,[2] Quynh Tran,[2] Joanna Hudson.[1,2] *[1]Methodist Univ Hospital, Memphis, TN; [2]Univ of Tennessee Health Science Center, Memphis, TN.*

Background: Acute kidney injury (AKI) occurs in over 20% of hospitalized patients and is associated with adverse outcomes. Whether continuation of angiotensin converting enzyme inhibitors (ACEIs) or angiotensin receptor blockers (ARBs) during hospitalization increases the risk of AKI has not been fully assessed. We evaluated the development of AKI and its associated risk factors in patients continued on ACEIs/ARBs in the inpatient setting.

Methods: This was a retrospective cohort study that included adult patients who were continued on ACEIs/ARBs within 24 hours of hospitalization. Patients who developed AKI within 48 hours of admission or received cancer treatment were excluded. AKI was defined using KDIGO criteria. Risk factors for AKI were compared between the AKI and non-AKI groups.

Results: Among the 184 patients included, 92 patients developed AKI (age 66±13 yrs (mean±SD), 52% male, 54% Black). Patients with AKI had a higher baseline serum creatinine (1.2±0.4 vs. 1±0.4 mg/dL, p<0.001), a lower eGFR (54±10 vs. 56±7mL/min/1.73m^2, p=0.03), and were more likely to have a diagnosis of CKD (40% vs.14%, p<0.001), an ICU stay (44% vs. 17%, p<0.001), a surgical procedure (34% vs. 14%, p<0.001), hypotension (24% vs. 2%, p<0.001), and concomitant loop diuretic therapy (52% vs. 36%, p=0.03). The AKI group had a longer length of stay (14±11 vs. 8±3 days, p<0.001) and a higher rate of all cause hospital mortality (8% vs. 1%, p=0.03). Factors associated with a significant increase in risk of AKI in the multivariable analysis were CKD (OR=4.3, 95% CI 1.6-9.3, p<0.001), hypotension (OR=14.2, 95% CI 3.1-65.0, p<0.001), and surgical procedures (OR=3.5, 95% CI 1.6-7.9, p<0.001).

Conclusions: Continuation of ACEIs/ARBs during hospitalization may increase the risk of AKI in select patients. Temporary discontinuation of ACEIs/ARBs may be warranted during hospitalization in patients with CKD, hypotension, or planned surgical procedures.

PUB033

Serum Neutrophil Gelatinase-Associated Lipocalin: A Novel Biomarker for Prediction of AKI Development in Critically Ill Patients

Magdy M. Elsharkawy, Abdel Rahman Khedr, Amr Mohab, Haitham Ezzat. *Nephrology, Ain Shams Univ, Cairo, Egypt.*

Background: Acute kidney injury (AKI) is a frequent complication in critically ill patients and is associated with high morbidity and mortality; therefore, its prophylaxis, diagnosis and intervention positively impact patient evolution.Neutrophil gelatinase-associated lipocalin (NGAL) is thought to be a novel biomarker of AKI of several etiologies and is increased in both serum and urine before the increase of serum creatinine.

Methods: A prospective cohort study was conducted on 100 critically ill patients in ICU. Patients were stratified into 2 groups based on AKI development. Group I which included 50 patients who did not develop AKI, and group II which included 50 patients who developed AKI. AKI was defined based on acute kidney injury network (AKIN) classification.The Sequential Organ Failure Assessment (SOFA) scores were also calculated for all patients. Detailed medical history, demographic data and routine laboratory investigations were done. Serum NGAL was measured upon admission to ICU and upon AKI development.

Results: 60 males and 40 females were included in the study with mean age 37.52 years. As regards risks of AKI development, 9% of patients had sepsis, 15% were dehydrated, 11% had contrast exposure, 12% had rhabdomyolysis, 29% had shock and 24% had history of NSAID intake recently. On admission, there were no significant differences between the patients as regards s.creatinine, hemoglobin level and other laboratory parameters ($p > 0.05$). Serum levels of NGAL were significantly higher in group II, before AKI development, with mean value 958.5 ng/ml, when compared with group I, mean value 272.17 ng/ml ($p<0.01$). Serum NGAL levels were significantly higher in group II after AKI development when compared with the levels before AKI development in the same group (1660.35 ng/ml) ($p<0.01$). There was no significant correlation between NGAL levels and AKIN classification stages.

Conclusions: In the absence of diagnostic increases in serum creatinine, NGAL detects patients with likely subclinical AKI who have an increased risk of adverse outcomes. Reassessment of AKI classification and stages should be considered.

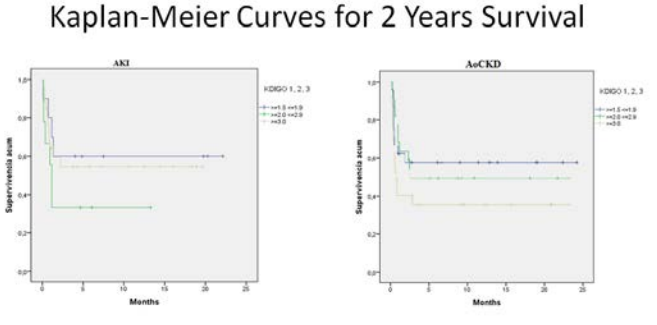
PUB034

Does Previous CKD Affect Renal Recovery After Acute Kidney Injury?

Maria Isabel Acosta-Ochoa, Josefina Martin, Alicia Mendiluce. *Nephrology, Hospital Clinico Univ, Valladolid, Spain.*

Background: AKI definition includes a sharp increase of serum creatinine (SCr), essentially reversible. There is a lack of consensus of a standard definition of Renal Recovery (RR). The exact course of the repair process is subject of thorough investigation. Few studies have engaged in comparing rates of RR in patients with previous impaired vs. normal renal function.

Methods: Retrospective cohorts study, 12-months period. We defined RR as discharge SCr with maximum increment £25% over basal value, and non recovery as ³26%, HD persistence, and death. We studied 2 groups: AKI and Acute on Chronic Kidney Disease (AoCKD). We tested epidemiological features, Charlson Index (ChaI), and KDIGO stage. We plotted a Kapplan-Meier survival curve 24 moths post-discharge.



Results: 270 patients, AKI=125, AoCKD=145, clinical features and KDIGO stages: see table 1.

Features	AKI (N=125)	AoCKD (N=145)	P Value
Male (%)	77 (62)	98(68)	0,30
Age (SD)	66.9 ± 15	**75.4 ± 11.9**	**<0.001**
HT (%)	96 (77)	**131 (90)**	**<0.001**
DM (%)	44 (35)	**70 (48)**	**0.003**
ChI (SD)	3.8 ± 2.5	**4.4 ± 2.3**	**<0.001**
KDIGO			
Stage1 (%)	43 (34)	47 (32)	0,19
Stage2 (%)	17 (14)	16 (11)	0,52
Stage3 (%)	65 (52)	82 (57)	0,45
Results			
RR (%)	44 (35)	51 (35)	0,99
HD Dependence (%)	1 (1)	**7 (5)**	**0.05**
Mortality (%)	21 (17)	38 (26)	0,06

65% were males, AoCKD were older 66,9y, worst ChaI 4,4. In AKI group 35% met RR criteria, 1% were HD dependent and 17% died. AoCKD group 35% recovered, 26% died, 5% were HD dependent at discharge P=0.05. Kaplan-Meier curves show a worst survival in the KDIGO Stage 2 for AKI and Stage 3 in the AoCKD group.

Conclusions: In spite of older age and worst ChaI AoCKD cohort recovered similarly with the AKI group, except for HD dependence at discharge. The finding that KDIGO Stage 2 means worst medium term survival for the AKI group needs further study.

PUB035

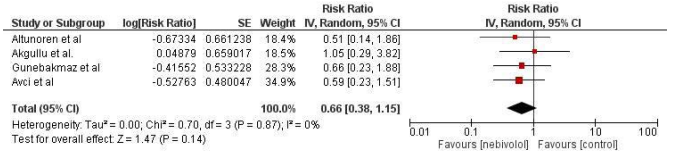
The Effect of Nebivolol on Contrast-Induced Acute Kidney Injury: A Meta-Analysis

Natanong Thamcharoen,[1] Charat Thongprayoon,[1] Wisit Cheungpasitporn.[2] *[1]Dept of Medicine, Bassett Medical Center and Columbia Univ College of Physicians and Surgeons, Cooperstown, NY; [2]Div of Nephrology and Hypertension, Dept of Internal Medicine, Mayo Clinic, Rochester, MN.*

Background: Nebivolol provides protective effect on contrast-induced acute kidney injury (CIAKI) in animal models. However, the reports on the efficacy of nebivolol for the prevention of CIAKI in human remain unclear. The objective of this meta-analysis was to assess the effect of nebivolol for the prevention of CIAKI.

Methods: Comprehensive literature searches were performed using MEDLINE, EMBASE, and Cochrane Database from inception through February 2015. Studies that reported relative risks, odd ratios or hazard ratios comparing the risk of CIAKI in patients who received nebivolol versus those who did not were included. Pooled risk ratios (RR) and 95% confidence interval (CI) were calculated using a random-effect, generic inverse variance method.

Results: Four studies (2 RCT and 2 cohort studies) with 543 patients were included in our analysis to assess the risk of CIAKI and the use of nebivolol. Of 543 patients with contrast exposures, 30 patients (5.32%) had CIAKI. Patients in the nebivolol group had an overall lower incidence of CIAKI (14.35%) compared to the control group (17.43%). The pooled RR of CIAKI in patients receiving nebivolol was 0.66 (95% CI, 0.38-1.1.15, $I^2 = 0$).



When meta-analysis was limited only to RCTs, the pooled RR of CIAKI in patients receiving nebivolol was 0.79 (95% CI, 0.35-1.79, I^2=0%).

Conclusions: Despite no statistical significance, there was a trend toward reduced CIAKI risk in patients receiving nebivolol. This finding suggests the need of further studies on the use of nebivolol in addition to standard IV crystalloid hydration in the prevention of CIAKI.

PUB036

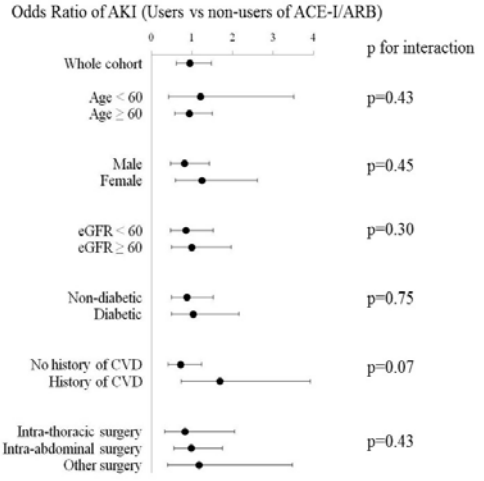
Patients with Cardiovascular Diseases Are Susceptible to Acute Kidney Injury After Non-Cardiac Surgery Under Preoperative Use of Angiotensin Converting Enzyme Inhibitors or Angiotensin Receptor Blockers

Miho Tagawa,[1] Takayuki Hamano,[2] Masaru Matsui,[1] Katsuhiko Morimoto,[1] Ken-ichi Samejima,[1] Yasuhiro Akai,[1] Yoshihiko Saito.[1] *[1]Nara Medical Univ, Nara, Japan; [2]Osaka Univ, Osaka, Japan.*

Background: It is unknown in which subgroups of patients the preoperative use of angiotensin converting enzyme inhibitors(ACE-I) or angiotensin receptor blockers(ARB) is a predictor for acute kidney injury(AKI) after non-cardiac surgery.

Methods: This is a retrospective cohort study on patients who underwent non-cardiac surgery from 2007 to 2009. After exclusion of urological surgery, missing creatinine values, and preoperative dialysis, the data for 2,725 patients were available. The exposure of interest was preoperative use of ACE-I/ARB. Primary outcome was postoperative AKI(AKIN criteria). The odds ratio(OR) of postoperative AKI among ACE-I/ARB users compared to non-users was analyzed using multivariable logistic regression models, adjusted for the logit of propensity score for ACE-I/ARB use. $P<0.1$ was considered statistically significant for interaction.

Results: Mean(SD) age was 61(16) and estimated glomerular filtration rate was 81(24) ml/min/1.73m^2. There were 40/460(8.7%) cases of postoperative AKI in ACE-I/ARB users and 97/2,265 (4.3%) in non-users. The addjusted OR of AKI were shown.



History of cardiovascular diseases(CVD) (either coronary artery disease, stroke, peripheral arterial disease, atrial fibrillation, or left ventricular ejection fraction<40%) was a significant effect modifier for the association of ACE-I/ARB and AKI (p for interaction 0.07). The OR(95% CI) of AKI among ACE-I/ARB users was 1.70(0.73-3.93) and 0.72(0.42-1.24) in patients with CVD and without CVD, respectively.

Conclusions: ACE-I/ARB use was associated with higher OR of AKI in patients with prior CVD compared to patients without, suggesting that patients with CVD are more prone to AKI with the use of ACE-I/ARB.

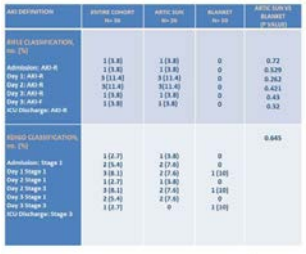
PUB037

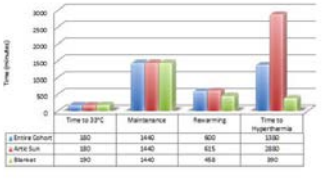
Whole Ischemia-Reperfusion Injury: The Effect of Whole-Body Cooling on Renal Function Silvia De Rosa,[1] Zaccaria Ricci,[3] Salvador Roberto Lopez,[1] Jose Luis Salas,[1] Stefano Marcante,[1] Sara Samoni,[1] Massimo de Cal,[1] Silvia Maria Pulitano,[2] Massimo Antonelli,[2] Raffaele Bonato,[1] Claudio Ronco.[1] *[1]IRRIV; [2]Intensive Care Unit, UCSC, Rome; [3]Paediatric Cardiac Intensive Care Unit, OBG, Rome.*

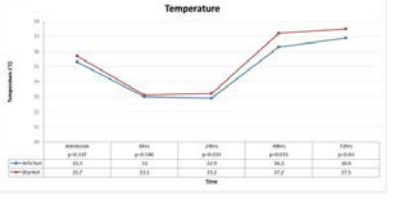
Background: Hypothermia is able to reduce the risk of renal failure after renal ischemia-reperfusion injury in animals.In humans,Cardiac Arrest(CA),a whole-body ischemia-reperfusion syndrome,causes warm renal ischemia-reperfusion injury,similar to animal models of ischemic acute kidney injury(AKI).Induced hypothermia(IH)is a treatment potentially efficacious for post-ischemic injury.It is unclear what effect could have on renal function.The aim of the study was to investigate the development of AKI during the IH.

Methods: Between Jan2013-Mar2015,we performed a prospective observational study of 36comatose pts resuscitated from CA and treated with IH performed with 2differents surface cooling devices:1)Arctic Sun Temperature Management System(Medivance,LouisvilleCO);2)Blanket.Temperature rate and trend,and the development of AKI during induction(0-6hrs),maintainance(24hrs),rewarming(48hrs)and normothermia(72hrs)was assessed with RIFLEandKDIGO criteria.

Results: Pts were enrolled and followed for the development of AKI during intensive care unit stay.In the induction and maintaince phases,the rate and the target temperature was similar;conversely,the rewarming phase was shorter with a target temperature higher in Blanket than in ArticSun group(458 minvs615 min;37.2°Cvs36.3).The trend and the rate of temperature,but also the development of AKI is showed in figure 1.







Conclusions: IH could be associated with development of AKI in the rewarming phase(rate 0.25 to 0.5 °C).The optimal rewarming rate is unknown.Randomized controlled trials are needed to determine the real effect of temperature on kidney,the optimal rewarming strategy and applications of this treatment for kidney in other settings.

PUB038

Decongestion-Associated Worsening Renal Function Does Not Increase Mortality of Patients with Acute Heart Failure Girish Singhania, Kawther Farouk Alquadan, Amir Kazory. *Nephrology, Univ of Florida, Gainesville, FL.*

Background: A significant subset of patients admitted for acute decompensated heart failure (ADHF) develop worsening renal function (WRF). While there is consistent data regarding the negative impact of baseline renal dysfunction on the outcomes of these patients, the evidence on the prognostic implication of WRF during admission for decongestion is less well-understood. The aim of this study is to provide a reappraisal of the effect of decongestion on the prognostic value of WRF in patients admitted for ADHF.

Methods: Articles cited in PubMed database from 1995 to 2015 using key words"congestion", "heart failure", "worsening renal function", and "hemoconcentration" were searched. Those studies evaluating the relationship between decongestion, renal function, and ADHF in patients treated with diuretic-based conventional therapies were selected. Ultrafiltration trials were excluded. Relevant data including change in renal function, diuretic dose, change in weight, and mortality were extracted and compared.

Results: A total of 12,843 patients from 13 trials (9 retrospective and 4 prospective) with data pertaining to decongestion in ADHF patients were included in this study. The mean age of the patients was 67.1 years with follow up periods ranging from 60 days to 5.3 years. Eleven studies reported development of WRF following decongestion. The incidence of WRF was reported to be 10 to 50.1% with weight reduction ranging from 2 to 5.4 kg. Twelve studies did not observe any negative impact for WRF on the mortality of patients with ADHF unless associated with markers of persistent congestion such as lack of hemoconcentration.

Conclusions: Decongestion is associated with markers of fluid removal and WRF in the setting of ADHF. Currently available data suggest that decongestion-associated WRF does not result in increased mortality whereas persistent congestion is likely to be the driving factor for adverse outcomes in these patients. Randomized controlled trials are needed to confirm these findings as they could portend significant therapeutic implications in cardiorenal syndrome.

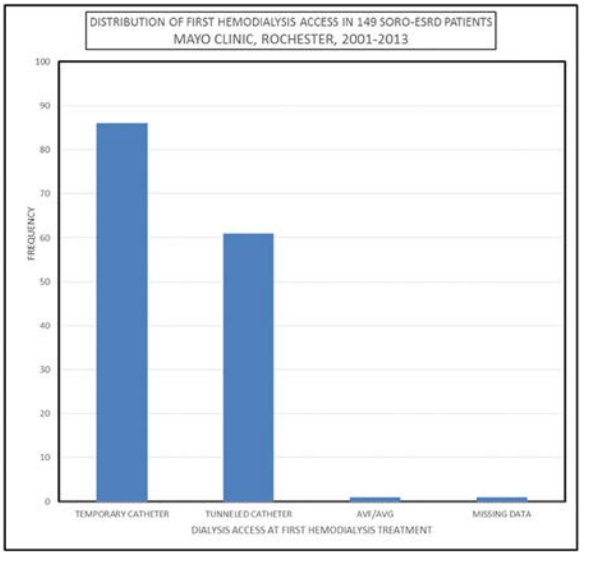
PUB039

A 13-Year Mayo Clinic Retrospective Study of the Syndrome of Rapid Onset End Stage Renal Disease (SORO-ESRD) in an Incident Hemodialysis Cohort Macaulay A. Onuigbo,[1,2] Nneoma Agbasi,[1] LaTonya J. Hickson.[3] *[1]Medicine, Mayo Clinic College of Medicine, Rochester, MN; [2]Nephrology, Mayo Clinic Health System, Eau Claire, WI; [3]Psychiatry Nursing, North East London NHS Foundation Trust, London, United Kingdom.*

Background: We first described the syndrome of rapid onset end stage renal disease (SORO-ESRD) in 2010 - acute yet irreversible ESRD after AKI. However, its overall impact on ESRD outcomes in the general US ESRD population remains speculative.

Methods: A retrospective examination of SORO-ESRD among the incident Mayo Clinic ESRD population, 2001-2013 was completed in November 2014.

Results: 149 of 1461 (10%) incident ESRD patients had SORO-ESRD – M:F = 76:73, mean age 62 years (19-95), 139 (93%) native kidneys, 10 (7%) kidney transplant recipients (RTRs). Ninety-nine percent of SORO-ESRD patients' initial vascular access was a dialysis catheter. Kidney biopsy - the commonest pathologic diagnoses were acute tubular necrosis (ATN) in 3 (25%) KTRs and in 7 (21%) native kidneys. Cardiac arrest was the leading cause of death in SORO-ESRD.



Conclusions: Among 1461 incident ESRD patients seen at Mayo Clinic Dialysis Services, Rochester, 2001-2013, 149 (10%) had SORO-ESRD. There was no gender nor age disparity between SORO-ESRD patients and the general ESRD cohort. Ninety-nine percent (99%) SORO-ESRD patients' initial vascular access was a dialysis catheter. ATN was the leading pathologic diagnoses for AKI among KTRs and in native kidneys. Cardiac arrest was the leading cause of death in SORO-ESRD, similar to the general ESRD population. We conclude that SORO-ESRD contributes significantly to incident ESRD here in the USA both among KTRs and in native kidneys. Furthermore, it negatively impacts on the success of AVF-First Programs. Efforts to mitigate AKI in CKD patients must be given more attention and priority by practicing nephrologists in particular, and by physicians in general.

PUB040

Saline-Induced, Diuretics-Responsive Acute Renal Failure (ARF): Evidence that Anasarca Is Nephrotoxic and Diuresis Is Therapeutic

Grant Meltzer,[1] Kai Lau.[1,2] *[1]Nephrology, Univ of Oklahoma Health Sciences Center, Oklahoma City, OK; [2]Medicine, VA Medical Center, Oklahoma City, OK.*

Background: Recent studies showed the association of fluid overload in ARDS & surgical patients and increased ventilator dependency, ICU & hospital stays, short-term mortalities, & incidence of ARF. But a cause-and-effect relationship was unproven in cross-sectional observations. In grossly edematous in-patients with unexplained ARF, we tested the hypothesis that anasarca caused the renal failure & diuresis induced recovery.

Methods: Entry criteria were fully evaluable patients, ³3 kg weight or ³3 L fluid gain, ≥50% acute loss of estimated creatinine clearance (CrCl) or ≥ 2 x rise in serum creatinine (Scre) without identifiable causes. All data were reviewed, recorded, tabulated & statistically analyzed, notably vital signs, weight, intake, output & lab. 36 qualified patients were diuresed by IV furosemide at rates keeping normotension off anti-hypertensives. Serial volume markers & renal responses were noted. Palliative care & hepatorenal syndrome were excluded.

Results: Fluid overload was due to heart failure (40%), liver failure (22%), CKD (16%), proteinuria (9%) & iatrogenic factors (10%). During 42 ARF episodes, mean weight was up 12.5 kg in 13.7d. Scre rose (4.41 vs. 1.27mg%) & CrCl fell (25 vs. 76 ml/min). Decrements in CrCl correlated with edema weight gain ($p<0.02$). Over 11.9 d, 15.2 kg of fluid were diuresed. Renal function greatly improved in 33 patients & unchanged in 3 despite >4 kg diuresis. As an entire group, Scre fell to 1.45 mg% & CrCl rose to 67 ml/min. Increments of CrCl also correlated with diuresis volume ($p<0.04$). At a diuretic rate of 1.5 kg/d, no adverse events occurred.

Conclusions: 1. Our data support the hypothesis for the entity of Saline-Induced, Diuretics-Responsive Acute Renal Failure. 2. Likely mediated by reduced cardiac output, venous congestion, renal interstitial edema &/or abdominal hypertension, it is analogous to congestive kidney failure. 3. Preventable & treatable, it could cause or aggravate ARF from other etiologies. 4. Diuresis in cohorts at rates & monitored as ours should be safe & efficacious.

PUB041

Is RIFLE Classiifcation a Good Shot for Staging Acute on Chronic Kidney Disease?

Maria Isabel Acosta-Ochoa, Josefina Martin, Alicia Mendiluce. *Nephrology, Hospital Clinico Univ, Valladolid, Spain.*

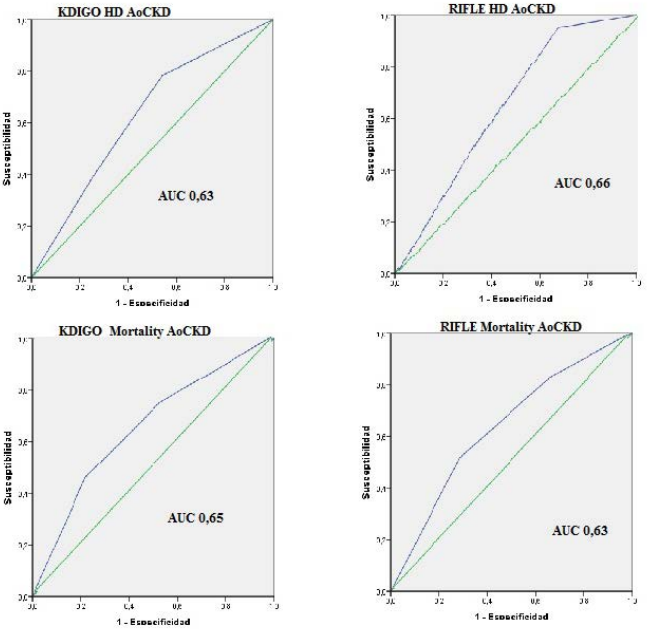
Background: 8-16% of worlds population may have CKD, which is a risk factor and promoter of AKI. We tested the performance of RIFLE and KDIGO classifications in staging severity and predicting outcomes in Acute on CKD (AoCKD) individuals. KDIGO with a 0,3mg/dL SCr increase includes patients in stage 1 category, and includes automatically in stage 3 patients with peak SCr ≥4.0 mg/dL.

Methods: Retrospective cohorts study. Patients were divided in 2 groups: AKI and AoCKD. We collected clinical data, and classified AKI severity contrasting distribution strata between groups by RIFLE and KDIGO criteria. And tested the ability of both classifications for pred¡cting need for HD and in hospital mortality with a AUC ROC analysis.

Results: 270 patients were included, AKI=125, AoCKD=145. Clinical features and RIFLE and KDIGO stages are listed in table 1.

FEATURES	AKI (N=125)	AoCKD (N=145)	P Value
Male (%)	77 (62)	98(68)	0,30
Age (SD)	66.9 ± 15	**75.4 ± 11.9**	**<0.001**
HT (%)	96 (77)	**131 (90)**	**<0.001**
DM (%)	44 (35)	**70 (48)**	**0.003**
ChI (SD)	3.8 ± 2.5	**4.4 ± 2.3**	**<0.001**
RIFLE			
No AKI (%)	21 (17)	23 (16)	0,83
Risk (%)	22 (17)	35 (24)	0,18
Injury (%)	17 (14)	**44 (30)**	**0,001**
Failure (%)	**65 (52)**	43 (30)	**<0.001**
KDIGO			
Stage1 (%)	43 (34)	47 (32)	0,19
Stage2 (%)	17 (14)	16 (11)	0,52
Stage3 (%)	65 (52)	82 (57)	0,45

65% males, AoCKD individuals were older 66,9y, and had worst Charlson Index (ChaI) 4,4. In figure 1 are shown AUC ROC curves for adverse outcomes.



Conclusions: With the KDIGO staging criteria we obtain more homogeneous distribution strata. With the ROC analysis neither classification performs better in predicting adverse outcomes. We found no practical advantage when using neither classification. In the noAKI (by RIFLE) stratum no adverse event was present, so by including a 0,3mg/dL SCr increase augments sensibility, but may be not especificity.

PUB042

Incidence of Acute Kidney Injury, Risk Factors for Acute Kidney Injury and Absence of Renal Recovery in Patients on Aminoglycosides

Francois Paquette,[1] Amelie Bernier-Jean,[1] Veronique Brunette,[1] Vincent Pichette,[2] Helene Ammann,[1] Stephan Troyanov,[1] Josee Bouchard.[1] *[1]Hopital du Sacre-Coeur de Montreal, Canada; [2]Hôpital Maisonneuve-Rosemont, Canada.*

Background: The KDIGO guidelines recommended to avoid aminoglycosides (AG) in patients at risk or with acute kidney injury (AKI). We determined the frequency of administration, incidence of AKI, and risk factors for AKI and absence of renal recovery in patients receiving AG over the last decade.

Methods: We performed a retrospective cohort study on AG administration in two university-affiliated centers, and then performed a nested case-control study, pairing AG-AKI cases to 2 controls for age and gender. AKI was defined by a 50% increase in creatinine after ≥5 days of AG up until 7 days after cessation of AG, and renal recovery, by a decrease in creatinine to within 50% of baseline creatinine over 3 weeks after cessation of AG.

Results: Between 2001 and 2015, the frequency of AG administration and drug dosing progressively declined. Out of 562 patients, sixty-five developed AKI attributed to AG (12%). In the case-control study (n=195), age was 71 (IQR 58-81) and 46% were male. The duration of AG administration was 10.0 (IQR 7.0-15.0) days, excluding days after AKI diagnosis in AKI patients. Maximal AKI stage was 1 for 55.3%, 2 for 29.2% and 3 for 15.4% of patients. Independent risk factors associated with AKI were concomitant vancomycin administration, high trough levels, heart failure, and site of infection (endocarditis and febrile neutropenia vs. other). Only fifty-one percent (50.8%; 33/65) of patients recovered their kidney function. These patients had an AKI duration of 7.0 (IQR 4.0-11.5) days. Heart failure was associated with a lower likelihood of renal recovery, while cancer patients more likely recovered their kidney function.

Conclusions: Over the last decade, the frequency of AG administration and dosing have progressively decreased but the incidence of AKI remained unchanged. In our cohort, vancomycin administration, high trough levels, heart failure, and site of infection were independent risk factors associated with AKI. Almost half of patients did not recover their kidney function, which was more often seen in patients with heart failure.

PUB043

Prairie Continuous Renal Replacement Therapy (CRRT) Study – Outcomes of CRRT in a Single Canadian Tertiary Centre Bhanu Prasad,[1] Michelle Urbanski,[2] Erwin Karreman.[3] *[1]Nephrology, Regina Qu Appelle Health Region, Regina, SK, Canada; [2]College of Medicine, Univ of Saskatchewan, Regina, SK, Canada; [3]Research and Performance Support, Regina Qu Appelle Health Region, Regina, SK, Canada.*

Background: Patients with stage III Acute Kidney Injury (AKI) requiring Renal Replacement Therapy (RRT) have the highest short-term and long-term mortality of any group with AKI. Our study aimed to prospectively follow patients with stage III AKI on Continuous Renal Replacement Therapy(CRRT) during their hospitalization in our tertiary care centre from April 2013 to September 2014.

Methods: We prospectively gathered the following: date and time of hospital admission, transfer to ICU, and starting CRRT, creatinine at admission and at CRRT initiation, weight on admission and at CRRT initiation.Duration of oliguria and anuria, exposures (sepsis,critical illness, circulatory shock, trauma, cardiac surgery, major non cardiac surgery, nephrotoxic medications, and radio contrast agents) and susceptibilities (dehydration, >65 years of age, female,pre existing CKD), APACHE score II, Inotrope support, FiO2, ECMO. Survival on CRRT, in ICU and hospital survival and renal recovery was documented.

Results: Of the 2634 patients:(2201/2634)83.6% had no AKI, and (269/2634)10.2% had stage III AKI of whom 106/269 (40%) were started on CRRT. 8/106 died in ICU whilst on CRRT, 58 died after CRRT was discontinued in ICU and 4 died on the ward. Mean(± SD) were: Creatinine(mmol/L) 337.2 (±260.1), Norepinephrine dose 22.5 (±19.6), APACHE II scores 34.8 (±9.0). The prescribed CRRT dose was 35 mls/minute and the mean delivered dose was 34.6±2.6(SD). Survivors were younger (years)(54.5± 15.6 vs. 62.0 ±15.4), had lower Norepinephrine dose (mcg/minute) (16.95±13.58 vs. 26.09±21.18), and had a shorter stay in ICU prior to starting CRRT (6:06 hours vs. 12:26 hours). Stage III AKI needing CRRT was associated with 62% mortality in hospital. 17/106 died within 24 hours of initiating therapy. 5/106 patients recovered within 24 hours.

Conclusions: AKI is associated with 62% in centre mortality.16% died within 24 hours of initiating CRRT. This raises a clinical concern of the benefit vs futility of initiating CRRT in specific settings.

PUB044

Urinary Liver Fatty Acid Binding Protein Predicts Acute Kidney Injury Associated with Abdominal Aortic Repair Daisuke Ichikawa,[1] Atsuko Ikemori,[1] Takeshi Sugaya,[1] Kenjiro Kimura,[2] Yugo Shibagaki.[1] *[1]Nephrology and Hypertension, St. Marianna Univ School of Medicine, Kawasaki, Kanagawa, Japan; [2]Internal Medicine, Tokyo Takanawa Hospital, Tokyo, Japan.*

Background: Acute kidney injury (AKI) is common problem after cardiovascular surgery. AKI is usually diagnosed on the basis serum creatinine (SCr) and urinary output. However, SCr is of low sensitivity in patients with poor renal function. Because urinary liver-type fatty acid binding protein (L-FABP) reflects renal tubular injury, we evaluated whether perioperative changes in urinary L-FABP can predict AKI.

Methods: Subjects were 68 patients who underwent EVAR and 32 patients who underwent open repair. We obtained urine samples before surgery, after anesthesia induction, upon stent placement, at the end of surgery, 4 hours after surgery, and on postoperative day (POD) 1, 2, and 3 for measurement of urinary L-FABP and urinary albumin in the EVAR patients. We obtained urine samples before surgery, after anesthesia induction, before aortic cross clamping (AXC), 1 and 2 hours after AXC, at the end of surgery, and on PODs 1, 2, and 3 for measurement of urinary L-FABP and urinary albumin in the open repair patients. We obtained serum samples before surgery, immediately after surgery, and on POD 1, 2, and 3 for measurement of SCr.

Results: AKI developed in 5 (7.4%) EVAR patients and in 9 (28.1%) open repair patients. With EVAR,, urinary L-FABP was increased 4 hour after the procedure (P = 0.002), and it decreased but remained elevated for 3 POD (P = 0.003). With AKI, SCr increased (P = 0.004) and eGFR decreased (P = 0.003) by POD2. SCr and eGFR did not change in patients in whom AKI did not develop. With open repair, urinary L-FABP increased significantly to its maximum by 2 h after AXC (P = 0.008) and then decreased gradually over the 3 PODs (P = 0.038). The increase in urinary L-FABP was greater with open repair than with EVAR. ROC analysis showed urinary L-FABP to be more sensitive than SCr, eGFR, and urinary albumin for early detection of AKI.

Conclusions: Urinary L-FABP appears to be a sensitive biomarker of AKI in patients undergoing abdominal aortic surgery, especially those treated by EVAR.

PUB045

Plasma Neutrophil Gelaninase-Associated Lipocalin (NGAL) as a Biomarker for Acute Kidney Injury in Patients with Chronic Kidney Disease Ha yeon Kim, Eun Hui Bae, Soo Wan Kim, Seong Kwon Ma. *Internal Medicine, Chonnam National Univ Medical School, Gwangju, Korea.*

Background: The aim of this study was to evaluate plasma NGAL levels as a predictor of early AKI in patients with with/without chronic kidney disease (CKD) and to assess whether plasma NGAL level could represent a useful marker of recovery in patients undergoing continuous renal replacement therapy (CRRT).

Methods: This single center retrospective observational study included 343 patients with AKI or CKD. The patients were classified into 3 groups: AKI (N=69), AKI on CKD (N=162), CKD (N=112). The cut-off values of NGAL was 200 ng/ml and those of cystatin-C was 1.0 mg/L. **Study II:** The retrospective observational study included 404 patients treated with CRRT. The patients were divide into 2 groups: renal recovery (N=120) vs. renal non-recovery (N=284) and survivor (N=193) vs. non-survivor (N=211).

Results: The prevalence of abnormal NGAL values was 69.0 % in AKI group, 94.5 % in AKI on CKD group and 91.8 % in CKD group. The value of NGAL was positively correlated with eGFR (r = 0.41, $p < 0.001$), and cystatin-C (r=0.45, $p = 0.021$). The mean values of follow-up NGAL were 475.9 ± 435.9 ng/ml in AKI group, 773.2 ± 370.6 ng/ml in AKI on CKD group, 709.4 ± 401.6 ng/ml in CKD group ($p < 0.001$). In AKI group, the difference of NGAL (baseline NGAL – follow-up NGAL) was the highest (110.8 ± 325.0 ng/ml in AKI group, 35.7 ± 205.2 ng/ml in AKI on CKD group, 14.1 ± 201.3 ng/ml in CKD group, $p < 0.001$). In comparisons between renal recovery group and non-recovery group and survivors and non-survivors in CRRT patients, both baseline NGAL and follow-up NGAL were not different, but the difference of NGAL (baseline NGAL – follow-up NGAL) was increased significantly in a renal recovery and survivors group (90.6 ± 82.9 ng/ml in renal recovery group vs. 33.8 ± 53.7 ng/ml in renal non-recovery group, 129.8 ± 182.4 ng/ml in survivor group vs.- 98.5 ± 162.6 in non-survivor group, $p < 0.001$, respectively).

Conclusions: The value of serum NGAL per se has a limitation on diagnosis of AKI in patients with underlying CKD. In patients treated with CRRT, hourly urine output and follow up of serum NGAL value may predict renal recovery and survival.

PUB046

C3 Glomerulopathy: A Pediatric Case Luis A. Ortiz,[1] Daniel Kleven,[2] Harika Gorti.[3] *[1]Ped. Nephrology, Georgia Regents Univ, Augusta, GA; [2]Pathology, Georgia Regents Univ, Augusta, GA; [3]MCG, Georgia Regents Univ, Augusta, GA.*

Background: C3 glomerulopathy (C3G) is characterized by C3 deposit in the glomeruli with minimal Ig deposition. C3G is described as an unregulated activation of the alternative complement pathway due to a genetic mutations in Factor H or I, or acquired factors such as C3 nephritic factor, an IgG autoantibody stabilizing C3 convertase. The pattern of the injury varies from mesangio-proliferative, membranoproliferative, to endocapillary proliferative glomerulopathy. EM finding demonstrate hump shaped sub epithelial deposits, characteristic of acute post-infectious glomerulonephritis (PIGN). We present a pediatric case that met the initial criteria for PIGN, but was diagnosed as C3G according the pathology.

Methods: 15 y/o AA/M with Thin Basement D., HTN, asthma presented with one Hx of sore throat, gross hematuria, facial swelling, no distal edema. Initial oliguria and high Cr. PE revealed periorbital edema, no pharyngeal erythema, lung clear, abdomen with no ascites. On admission, Hb 11.6 g, Cr:3.26mg, Albumin:2.5 gr, UA20-50 RBC, UOP: 0.37 ml/k/hr. Despite treatment with methylprednisolone, albumin and furosemide, his Cr. increased to 6.48, ASO 654 UI, aDNAseB normal., CRP 12.6. Group A strep was negative for growth. Kidney biopsy: glomeruli w/segmental sclerosis, endocapillary infiltration of neutrophils, IF: extensive C3 staining with scant IgG and small fibrin deposition (focal necrosis). EM: large subepitelial deposits. Worsening kidney function required hemodialysis. After 6 months, he continues on Hemodialysis.

Conclusions: Kidney biopsy with C3 dominant on IF, large subepithelial deposits on EM, hypocomplementemia and clinical of gross hematuria preceded by URI suggested acute PIGN, but this overlaps with the histological presentation of C3G of C3 dominant staining with scant IG deposition, subepitelial deposits and low serum C3. No resolution of AKI after 8 weeks of presentation was unusual for PIGN, steering diagnosis towards C3G. Clinicians should note the high overlap between the clinical and histology of PIGN and C3G. it is impeprative to conduct further studies to accurately diagnose and treat patient with C3G.

PUB047

Predictors of End Stage Renal Disease in Scleroderma Renal Crisis – A Single Center Experience Sumedha Dhar, Cybele Ghossein. *Div of Nephrology, Northwestern Univ - Feinberg School of Medicine, Chicago, IL.*

Background: Scleroderma renal crisis (SRC) is one of the most acute and life-threatening complications of systemic sclerosis (SSc). It is typically characterized by accelerated hypertension and acute kidney injury (AKI). Angiotensin converting enzyme inhibitors (ACEI) are currently the treatment of choice for this disease. Despite use of ACEI, 50% of patients with SRC develop end stage renal disease (ESRD) which is associated with poor long term outcomes. Our aim was to define the clinical characteristics and outcomes of SRC patients admitted to our institution.

Methods: This was a retrospective chart review of all patients admitted with SRC to Northwestern Memorial Hospital (NMH) between the years of 1/1994 to 4/2015. ESRD was defined as the need for chronic dialysis during admission for SRC.

Results: There were 23 patients with a diagnosis of SRC made either clinically or by renal biopsy during this time period. Mean time to SRC was 1.3 years after diagnosis of SSc. 47% of patients developed ESRD during the same admission. Development of ESRD was not associated with age, gender, race, anti-RNA polymerase III test positivity, intensive care unit (ICU) admission, prior ACEI or angiotensin receptor blocker (ARB) use, or creatinine on admission. ESRD was significantly associated with time to control blood pressure.

	Not requiring HD N = 12 (%)	Requiring HD N = 11 (%)	P value
Mean Age (yr)	57	57.36	0.95
Gender Female Male	11 (91) 1 (8)	8 (72) 3 (27)	0.32
Race White Afro-American Other	8 (66) 3 (25) 1(8)	7 (63) 2 (18) 2 (18)	0.87
anti-RNA polymerase III	3 (25)	5 (45)	0.39
ICU initial admission	6 (50)	2 (18)	0.19
ACEI/ARB on admission	3 (25)	7 (63)	0.09
Mean days to start ACEI	0.9	1	0.88
Mean days to control BP	3.1 (N = 11)	5.83 (N = 6)	0.03
Normotensive on admission	2 (16)	4 (36)	0.37
Mortality	2 (16)	2 (18)	1.00
Mean Creatinine on admission (mg/dl)	2.04	2.95	0.07

Conclusions: SRC is a serious kidney and life threatening complication of SSc. Delay in blood pressure control increases risk of ESRD in SRC patients.

PUB048

Acute Kidney Injury Risk Assessment at the Hospital Front Door: What Is the Best Measure of Risk? Aled O. Phillips,[1] Dafydd Phillips,[1] Mohamed Hassan,[5] John Geen,[2] Vikas Lodhi,[6] Hemanth Bolusani,[4] Gareth Roberts.[3] *[1]Nephrology, Cardiff Univ School of Medicine, Cardiff, Wales, United Kingdom; [2]Dept of Clinical Biochemistry, Univ of South Wales, Wales, United Kingdom; [3]Dept of Medicine, Royal Gwent Hospital, Newport, Wales, United Kingdom; [4]Dept of Medicine, Univ Hospital of Wales, Cardiff, Wales, United Kingdom; [5]Dept of Medicine, Prince Charles Hospital, Merthyr Tydfil, Wales, United Kingdom; [6]Dept of Medicine, Univ Hosptial Llandough, Cardiff, Wales, United Kingdom.*

Background: We examined the prevalence of AKI-risk factors in the emergency medical unit, generated a modified risk assessment tool and tested its ability to predict AKI.

Methods: 1196 patients admitted to medical admissions units were assessed for patient associated AKI-risk factors. Subsequently, 898 patients were assessed for a limited number of fixed risk factors with the addition of hypotension and sepsis. This was correlated to AKI episodes.

Results: In the first cohort the prevalence of AKI risk factors was 2.1±2.0 per patient, with a positive relationship between age and the number of risk factors and a higher number of risk factors in patients ≥65yrs. In the second cohort 12.3% presented with or developed AKI. Patients with AKI were older and had a higher number of AKI risk factors. In the AKI cohort 72% of the patients had ³2 AKI risk factors compared to 43% of the cohort with no AKI. When age ≥65 yrs was added as an independent risk factor 84% of those with AKI had ³2 AKI risk factors compared with 55% of those with no AKI.ROC analysis suggest that use of common patient associated known AKI risk factors performs no better than age alone as a predictor of AKI.

Conclusions: Detailed assessment of well established patient associated AKI-risk factors may not facilitate clinicians to apportion risk. This suggests that additional work is required to develop a more sensitive validated AKI predictive tool which would be useful in this clinical setting.

PUB049

Acute Kidney Injury, Requiring Renal Replacement Therapy – Incidence, Causes and Outcomes: One Center Experience Elena Zakharova. *Nephrology, City Clinical Hospital n.a. s.P. Botkin, Moscow, Russian Federation.*

Background: Acute Kidney Injury (AKI) is complex condition, associated with high mortality and morbidity. We aimed to evaluate AKI incidence, causes, risk factors and outcomes in patients, managed in nephrology unit of general hospital and urgently requiring Renal Replacement Therapy (RRT).

Methods: Using electronic database for 2010-2014 (4531 admissions, 2257 patients), we searched 604 cases which met KDIGO AKI definition, and selected patients, required RRT.

Results: Study group included 115 patients (19% of all AKI cases), 51 (44%) male, 64 (56%) female, median age 61 [22; 89] years. In 102 (89%) cases AKI was community acquired. Median serum creatinine prior to start of RRT was 981 [242; 2665] µmol/l, 37 (32%) patients had known CKD. Causes and susceptibilities for AKI are shown in table.

Cause/exposure	n of patients	%
Decreased kidney perfusion	33	29
Vasculitis	8	7
Thrombotic microangiopathy	2	2
Interstitial nephritis	8	7
Sepsis	10	9
Critical illness	7	6
Circulatory shock	3	3
Nephrotoxic drugs	6	5
Radiocontrast agents	1	1
Poisoning	2	2
Hantavirus infection	2	2
Hemolysis	2	2
Rhabdomyolysis	9	8
Cast-nephropathy	8	7
Urinary tract obstruction	14	12
Underlying conditions		
Chronic kidney disease	37	32
Dehydration/volume depletion	33	29
Diabetes	9	8
Chronic heart, lung or liver disease	22	19
Multiple myeloma/lymphoma	13	11
Systemic amyloidosis	7	6
Cancer	10	9
Age over 75	18	16

76 (66%) patients partially or completely recovered kidney function, 27 (23%) were still dialysis-dependent after 3 month of follow-up, and 12 (10%) patients died

Conclusions: In our cohort incidence of AKI was 27%, proportion of patients requiring RRT constituted 19% of AKI cases. Vast majority had community acquired AKI, 1/3 developed AKI on the top of pre-existing CKD, 16% were elder than 75 years. Main trigger for RRT-requiring AKI in 29% of cases was initially considered as decreased kidney perfusion, with volume-unresponsiveness due to severe underlying conditions, such as CKD, chronic heart and liver diseases, multiple myeloma, cancer, diabetes and amyloidosis. Other most frequent causes of AKI were sepsis, rhabdomyolysis, vasculitis, and interstitial nephritis. Mortality rate was 10%, ESRD developed in 23% of cases.

PUB050

Renal Manifestations in Paroxysmal Nocturnal Haemoglobinuria Ram R,[1] Dakshinamurty Kv,[2] Krishna Parasd A.[3] *[1]Nephrology, Sri Venkateswara Inst of Medical Sciences, Tirupati, AP, India; [2]Nephrology, Mahatma Sri Ramchandra Centenary Memorial Hospital, Hyderabad, Telengana, India; [3]General Medicine, NIMS, Hyderabad, India.*

Background: Paroxysmal nocturnal haemoglobinuria (PNH) is an acquired chronic disorder characterized by a triad of clinical features- haemolytic anaemia, pancytopenia, and thrombosis. Not many reports of renal involvement in PNH are available in literature.

Methods: We present a case series of PNH with renal involvement. We present the data of PNH patients attended to departments of General Medicine and Nephrology at a government run tertiary care institute in South India. The diagnosis of PNH in these patients during initial phase, between 1998 and 2004 was based on sucrose lysis and Ham's test. After 2004, the diagnosis was based on flow cytometry to detect CD59 (MIRL), a glycoprotein, and CD55 (DAF) in regulation of complement action. The patient data was collected from 1998 to 2014.

Results: There were 13 patients of paroxysmal nocturnal haemoglobinuria in this period. The mean age was 37 years and the range was 16 to 68 years. There were 7 females. Acute renal failure was noted in 5 patients. Dialysis was performed in three of them. The mean serum creatinine and urea at the initiation of dialysis was 5.4 ± 0.6 mg/dL and 64.1 ± 6.1 mg/dL respectively. The median number of haemodialysis sessions done was four. Renal biopsy was done in four patients. The indication for the biopsy was acute renal failure of more than four weeks. The median number of glomeruli was 9. The tubules showed prominent brown granular pigment within the epithelial cells. It was confirmed as hemosiderin with the Perls' Prussian blue reaction. A few deposits of hemosiderin were also seen within the tubular lumina. The pathological diagnosis in these four patients was acute tubular necrosis secondary to hemosiderin deposition. In three patients the urinalysis and serum chemistry was suggestive of Fanconi syndrome.

Conclusions: In our patients, three renal manifestations of PNH were identified. They were acute renal failure, renal vessel thrombosis and Fanconi syndrome. Chronic renal failure was not identified.

PUB051

Filling the Gaps in Acute Kidney Injury Epidemiology: A Multicenter Prospective Study in Amazon Fernando de Assis Ferreira Melo,[1,2] Waledya Araujo lopes de Melo,[2] Tarcisio Andrade Souza,[2] Natali Mendes,[2] Luis Yu,[3] Emmanuel A. Burdmann,[3] Dirce M T Zanetta.[1] *[1]Epidemiology, Univ of Sao Paulo, São Paulo, Brazil; [2]Medicine, Federal Univ of Acre, Rio Branco, Acre, Brazil; [3]Medicine, Univ of Sao Paulo, São Paulo, Brazil.*

Background: In some areas of developing countries, infectious tropical diseases or animal venoms may be important causes of Acute Kidney Injury (AKI). Epidemiological studies of AKI incidence in these areas are scanty and prospective population-based studies are even scarcer.

Methods: Prospective data on all adult patients admitted in all intensive care units (ICU) of the Western Amazon region (600 square kilometers and 800,000 inhabitants) were collected for 6 months in 2014. Patients with chronic kidney disease stage 5, kidney transplant or ICU stay < 48 hours were excluded. AKI was diagnosed by KDIGO and mortality was assessed 30 days after ICU discharge. Data are presented as mean±SD or percent.

Results: 367 patients aged 57.8 ± 19.2 years and with 39% white were evaluated. Main reasons for ICU admission were postoperative (34%), hemodynamic instability (22%) and respiratory failure (13%), with only 1% with tropical diseases. AKI incidence was 38%, but was lower in postoperative patients (28% vs 43% in non-postoperative, p = 0.005). Mortality was higher in AKI patients (53% vs 30% in non-AKI, p <0.001). Postoperative patients who developed AKI had similar mortality to those non-operative (46% vs 56%, p=0.302).

Conclusions: AKI has a high incidence in ICU patients of the Western Amazon area. The causes of ICU admission did not differ from those seen in developed countries. The few number of patients with the typical tropical diseases of Amazon may be due to poor access to health care. The peculiar social geographical region characteristics, with rivers that are not navigable most of the year, long rain period that difficult access to larger cities and the lack of health services in diverse areas, may be associated to the present findings.

Funding: Government Support - Non-U.S.

PUB052

Uncovering Complement Mediated Thrombotic Microangiopathy: Use of a Real Time Genetic Assay in the Diagnosis of Atypical Hemolytic Uremic Syndrome Jan C. Hofmann. *Dept of Medicine, California Pacific Medical Center, San Francisco, CA.*

Background: Improved diagnostic tests and greater understanding of pathophysiology of thrombotic microangiopathy (TMA) have led to more rapid differentiation of various types of TMAs. While ability to rapidly diagnose TTP (ADAMTS13 activity <5-10%) has improved, atypical HUS (aHUS) remains diagnosis of exclusion due to poor sensitivity, high cost, and long turnaround time (TAT) of aHUS genetic assays. We describe a patient (pt) with hypothyroidism and renal insufficiency diagnosed with aHUS, using appropriate clinical algorithms for TMA, including "real-time" aHUS genetic assay (TAT 2-5 days).

Methods: 59 y.o. female with 1-2 week (wk) history of fatigue, anemia, thrombocytopenia, renal insufficiency, and recent diagnosis of hypothyroidism with changes in CBC and creatinine (Cr) over 3 wks: hemoglobin (hgb) 13.9 to 7.1 g/dl, platelet count (plt ct) 241 to 68 X 10^9/L, and Cr 0.71 to 1.41 mg/dl (baseline Cr 0.56, BMI 19.5). Pt's CNS status normal; no other signs/symptoms of systemic thrombosis noted. Additional labs: haptoglobin <9 mg/dl, LDH 1942 U/L (312-618 U/L), direct coombs negative, PT/INR/PTT/fibrinogen normal, 5-6 schistocytes/high power field, ADAMTS13 activity 79% (40-130%) ruling out TTP.

Results: Pt received 11 plasma exchange (PE) treatments (txs) (hospital day [HD] 3-21). By day 4 of PE (HD 7), plt ct 197 X 10^9/L; despite 11 PE txs, LDH remained elevated (886-2123) and Cr rose to 2.72 (3.8-4.9X higher than baseline). aHUS genetic panel (sent HD 10, results on HD 17) revealed: positive variant in CFI gene (predicted to be significant, but not previously described) and heterozygous mutations for 3 CFH polymorphisms. Pt clinically diagnosed with aHUS, received meningococcal vaccine (HD 20), and ciprofloxacin (2 wk course). Induction eculizumab started and PE stopped (HD 21). After 2^+ months of eculizumab, pt's Cr normalized.

Conclusions: With development of improved genetic testing (ie, increased sensitivity and speed), aHUS genetic assays may represent "real-time" diagnostic tools enabling more rapid assessment of selected TMA cases leading to more targeted treatment.

PUB053

Oral Hydration: The Way Forward in the Prevention of Contrast-Induced Nephropathy Hsu pheen Chong, Matthew L p Howse. *Nephrology, Royal Liverpool Univ Hospital, United Kingdom.*

Background: : Contrast induced nephropathy is defined as increased serum creatinine of 0.5 mg/dL (44.2 mol/L), or a 25% increase of creatinine from baseline levels checked 48 hours after exposure to iodinated contrast medium. Studies have suggested the use of intravenous fluids such as sodium chloride 24 hours prior to contrast exposure. However, this step would require the patient to be admitted prior to contrast medium exposure and incur extra cost for this hospital. This audit explores the use of oral hydration in the prevention of contrast induced nephropathy.

Methods: Using the ICE computer system, all patients who were diagnosed with Type 2 Diabetes Mellitus and taking metformin were identified from the time period of January 2008 until January 2014. They were then advised to stop their metformin prior to contrast exposure. Recommended regime for contrast prophylaxis was given which was 2 litres of oral fluids before and after the procedure. Patients were also given advice to get their renal function checked, 48 – 72 hours after contrast exposure. Their renal function pre and post contrast exposure was documented and any patients with a reduction of their eGFR more than 20% were then referred to the nephrology department for follow up.

Results: A total of 277 patients were included in this audit. The mean eGFR was 47 ml/min/1.73m². 79% of patients had their renal function checked within 48 – 72 hours, 15% of patients had their renal function checked after that time period and 6% of patients did not have their renal function rechecked at all. Only 0.7% of patients had deterioration of their renal function that met the criteria above. However it was important to note that, these patients had also other multiple co-morbidities and the exposure to contrast was not the sole cause to the deterioration of their renal function.

Conclusions: Oral hydration should be considered as part of the protocol for the prevention of contrast-induced nephropathy. This regime has reduced the need for patients to be admitted into hospital admission for intravenous fluids, thus reducing waiting times for imaging and as well as reducing hospital cost.

PUB054

Gemcitabine-Mediated Thrombotic Microangiopathy – A Rare Cause of Hemolytic Uremic Syndrome Natalie M. Ertz-Archambault,[1] Ibrahim Qaqish,[2] Leslie F. Thomas.[2] *[1]Internal Medicine, Mayo Clinic Arizona; [2]Nephrology and Hypertension, Mayo Clinic Arizona.*

Background: Thrombotic microangiopathy (TMA) is a pathological diagnosis of endothelial cell injury and microvascular thrombosis. TMA has been categorized in the present era as one of three distinct disease processes: 1) classical hemolytic uremic syndrome, 2) atypical hemolytic uremic syndrome (aHUS), and 3) thrombotic thrombocytopenic purpura. Our focus, aHUS, reflects an underlying aberrancy in regulation of the alternative complement cascade. Several genetic defects have been identified leading to an affinity to develop uncontrolled activation of this cascade which may commence after exposure to a trigger. Gemcitabine is one rare trigger described in the literature.

Methods: A 66 year-old female with locally advanced, unresectable pancreatic cancer who had completed 12 cycles of gemcitabine-abraxane therapy with no major oncologic progression of disease was hospitalized with acute kidney injury. Two months prior to admission, she developed hypertension, nausea, and profound cytopenias requiring platelet and red cell transfusion. She endured a progressive decline in renal function with a nadir eGFR 19 mg/mL/1.73 m². One month prior to admission, her urinalysis reflected active sediment. Admission labs demonstrated microangiopathic anemia with thrombocytopenia. ADAMTS13 activity was normal (88%), consistent with aHUS. Renal biopsy confirmed subacute changes consistent with TMA. Despite discontinuation of the gemcitabine-abraxane therapy, she continued to demonstrate progressive anemia and thrombocytopenia in addition to persistent proteinuria, hematuria, and impaired eGFR. The patient was subsequently initiated on eculizumab therapy.

Conclusions: Gemcitabine-mediated aHUS is rare and associated with a 75% mortality rate at four months. Previous attempts at therapy have included apheresis. However, current guidelines discourage apheresis in this patient population. To date, six cases of gemcitabine-mediated aHUS have reported the successful use of eculizumab, a terminal complement inhibitor.

PUB055

Intravenous Contrast Material Administration Increases Mortality in Patients with Acute Kidney Injury Requiring Renal Replacement Therapy Katsuhito Ihara, Atsuki Ohashi, Yoshito Iida, Makiko Kobayashi, Hitomi Tanaka, Seiji Inoshita. *Internal Medicine, Tokyo Metropolitan Bokutoh Hospital, Japan.*

Background: Contrast material exposure is well known to induce acute kidney injury (AKI); however, it is yet unclear whether contrast material administration is related to the prognosis of AKI. We hypothesized that intravenous contrast material administration might be a poor prognostic factor for short-term mortality in AKI requiring renal placement therapy (RRT).

Methods: We enrolled AKI patients in our hospital, who have been prescribed RRT for the first time, from January 2012 to December 2013 and collected the baseline information and data. Patients already initiated on continuous hemodialysis or peritoneal dialysis, patients almost reaching end-stage kidney disease with vascular access, and patients admitted to our hospital with cardiopulmonary arrest were excluded. The primary outcome was 28 days mortality from initiation of RRT. We divided the patients into two groups, either with or without exposure to contrast material after admission to our hospital. The effect of contract material exposure was evaluated by univariate and multivariate cox proportional hazard ratio.

Results: One hundred and seventy patients were eligible. Seventy one percent was male, and mean age was 65.3 ± 14.9 years old. Mean serum creatinine was 5.5 ± 5.0 mg/dL, and mean urine output for six hours was 2.64 ± 2.93 mL/kg. Contrast material was administered in 50.6 % of the patients. Each the exposure group and non-exposure groupincluded 86 and 84 patients, respectively, and the 28 day mortalities of each group were 55.8 % and 36.9 %,respectively. The hazard ratio in theexposure group was 2.666 [95 % Confidence Interval (C.I.) 1.573-4.517] (p = 0.000) by univariate analysis. After adjustment by hypertension, sepsis, ischemia, and diuretics usage, which were the significantly different cofounders between the two groups, the hazard ratio was 1.987 [95% C.I. 1.093-3.610] (p = 0.024).

Conclusions: Our results demonstrated that intravenous contrast material administration is an independent risk factor for mortality in patients with AKI requiring RRT.

PUB056

Dabigatran Induced Acute Kidney Injury and Management with Hemodialysis Darren W. Grabe,[1,2] Syed S. Haqqie.[2] *[1]Dept of Pharmacy Practice, Albany College of Pharmacy and Health Sciences, Albany, NY; [2]Dept of Medicine, Div of Nephrology and Hypertension, Albany Medical College, Albany, NY.*

Background: A 55-year-old man with a history of A Fib, cirrhosis, portal HTN, esophageal varices arrives in the ED, transferred from an outside hospital following initial presentation with multiple episodes of hematemesis and melena. Medication regimen recently changed with a switch from warfarin to dabigatran 8 months prior to admission in order to avoid frequent INR checks.

Methods: On admission, initial blood work was obtained and revealed: Hg 6.3 g/dL, INR 6.9, SCr 15.6 mg/dL and BUN 189 mg/dL. Patient was admitted to the intensive care unit for management of acute blood loss and AKI. On physical exam shows a pulse of 95 bpm and BP of 111/75 mmHg and mild hepatosplenomegaly, the physical exam was unremarkable. Dabigatran was discontinued and patient was transfused with packed red blood cells and fresh frozen plasma and administered vitamin K. Hemodialysis was initiated and continued throughout the hospital course. Kidney biopsy was performed and was consistent with ATN, chronic tubulointerstitial nephritis, and IgA Nephropathy (HAAS class I).

Results: Serum dabigatran concentration (conc) drawn on admission was 860 ng/mL. Following the initial emergent hemodialysis (HD) procedure, subsequent dabigratan conc. were determined during the second HD procedure. Predialysis and postdialysis dabigatran conc. were 130 ng/mL and 30 ng/mL, respectively. Pharmacokinetic parameters were calculated and shown in the table.

Dabigatran pharmacokinetics while on hemodialysis		
K_D (h^{-1})	t 1/2 (hrs)	Cl_D (mL/min)
0.489	1.4	571
k=elimination rate constant; t½= half-life; D =dialytic		

Over the hospital course, patient required regular HD, Hg stabilized following transfusion and vitamin K. Patient was stable on discharge with a serum creatinine of 5.9 mg/dL and remained on dialysis.

Conclusions: Dabigatran induced AKI is rare. The mechanism of the insult in this case was unclear but acute blood loss leading to prolonged ischemic insult was largely contributive. Hemodialysis was successful in removing the offending agent with resolution of bleeding but patient remains dialysis dependent.

PUB057

Relation Between BNP And NGAL, with Bioelectrical Cardiothoracic Impedance Hemodynamics Parameters in Patients with Cardiorenal or Renocardiac Syndrome Francisco Javier Lavilla, Maria Jose Molina Higueras, Nuria Garcia-Fernandez, Paloma L. Martin Moreno, Diana Lopez espinosa, Pelayo Moiron Fdez-Felechosa, Pedro Errasti. *Nephrology, Clinica Univ de Navarra, Pamplona, Navarra, Spain.*

Background: Evaluate the aplication of cardiothoracic bioelectrical impedance (CTBIA) in the classification of patients with cardiorenal or renocardiac syndrome.

Methods: We use a cohort with 18 patients (mean age 72 years SD 2.6, males 77 %) with cardiorenal or renocardiac syndrome. We evaluate hemodynamic parameters (cardiac output –CO-, cardiac output index –COI-, left ventricular work index –LVWI- and systemic vascular resistance index –SVRI-) with BNP (pg/ml, limits 0-100) andNGAL (ng/ml, limits 0-149).

Results: Mean levels of BNP were 545.71 (SD 128.8) and mean levels of NGAL were 500.11 (SD 96.25). Only vascular resistance index was associated with NGAL (r=-0.461, p=0.054). Not found associations with BNP. However we classificate patients in four groups: Group 1 (BNP high, NGAL normal) (n=7), Group 2 (BNP high, NGAL high) (n=1), Group 3 (BNP normal, NGAL high) (n=7) and Group 4 (BNP normal, NGAL normal) (n=3).

The associations indicate that in Group 1 are patients with cardiac dysfunction (cardiorenal) and higher BNP (BNP>NGAL), with lower cardiac output and higher vascular resistance, and in group 3 are patients with renal dysfunction (renocardiac) and higher NGAL (NGAL>BNP, with higher cardiac output and lower vascular resistance.

Table 1.

Group	mean/ Sd	BNP pg/ml	NGAL ng/ml	CO l/min	COI l/ min/m2	LVWI Kg m/m2	SVRI dyn s cm-5 m2
1		1068 185.9	252 36.3	4.3 0.47	2.56 0.23	2.5 0.25	2338 245.3

	p	0.001	0.005	0.01	0.008	0.085	0.001

CO: CARDIAC OUTPUT. COI: CARDIAC OUTPUT INDEX. LVWI: LEFT VENTRICULAR WORK INDEX.
SVRI: SYSTEMIC VASCULAR RESISTANCE INDEX.

Conclusions: The use of CTBIA is usseful to evaluate and classify patients with cardiorenal or renocardiac syndrome. There are association between vascular resistance and renal tubular necrosis.

PUB058

Recovery of Renal Function After Removal of Functional Causes of Advanced Renal Failure Maria-Eleni Roumelioti,[1] Faraz khan Luni,[2] Sandeep Vetteth,[2] Darlene Melinda Vigil,[1,3] Kavitha Ganta,[1,3] Deepak K. Malhotra,[2] Antonios Tzamaloukas.[1,3] *[1]Univ of New Mexico; [2]Univ of Toledo; [3]Raymond G. Murphy VA Medical Center.*

Background: It is important to predict whether renal function recovers completely, early in the course of functional azotemia.We hypothesized that the level of renal function can be predicted from the early change in serum creatinine concentration ([Cr]) during treatment of functional azotemia.

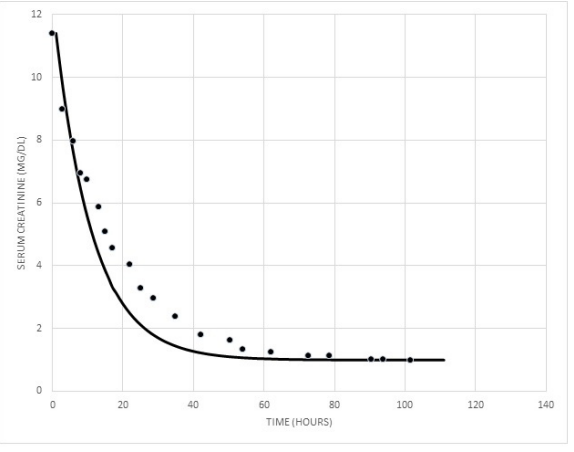
Methods: Taking into account the changes in the body pool of Cr at diagnosis and Cr production during treatment, we calculated the Cr clearance (C_{Cr}) between the [Cr] levels in the blood sample obtained at presentation ($[Cr]_0$) and in the first blood sample after the initiation of non-dialytic treatment ($[Cr]_1$) in 6 pts, 5 men with urinary retention and a woman with prerenal azotemia. The calculated C_{Cr} value was used to predict [Cr] levels corresponding to times of subsequent [Cr] measurements. We compared the predicted [Cr] levels to the corresponding measured ones.

Results: The table shows $[Cr]_0$ and $[Cr]_1$ levels, calculated C_{Cr} values, predicted and measured [Cr] levels at steady state after correction of the azotemia ($[Cr]_{SS}$. Predicted and measured $[Cr]_{SS}$ values were close.

Patient	1	2	3	4	5	6
$[Cr]_0$, mg/dL	42.70	17.67	11.35	35.23	8.10	6.86
$[Cr]_1$, mg/dL	34.70	5.58	8.97	8.11	7.77	5.16
$[Cr]_0$ to $[Cr]_1$ hours	3.6	14.7	2.9	12.3	3.2	5.4
C_{Cr} mL/min	45	56	59	88	34	39
Predicted $[Cr]_{SS}$, mg/dL	1.97	1.24	0.99	0.99	2.41	1.48
Measured $[Cr]_{SS}$, mg/dL	1.60	1.52*	1.18	0.87	2.17	1.41

***Patient 2 died while [Cr] was decreasing**

A modeling of the decline in [Cr] of patient 3 is presented in figure



(solid line: exponential decline of the [Cr] predicted by the C_{Cr} full circles: measured [Cr] levels)

Conclusions: Computation of early C_{Cr} after removal of the cause of functional azotemia may provide estimates of post-treatment [Cr] levels reasonably close to the measured levels. More observations are needed.

PUB059

Relation of Cardiothoracic Bioelectrical Impedance Hemodynamics and Volemics Parameters with Acute Kidney Injury Prognosis Francisco Javier Lavilla, Nuria Garcia-Fernandez, Diana Lopez Espinosa, Paloma L. Martin Moreno, Maria Jose Molina Higueras, Pelayo Moiron Fdez-Felechosa, Pedro Errasti. *Nephrology, Clínica Univ de Navarra, Pamplona, Navarra, Spain.*

Background: Evaluate the relation of hemodynamics and volemic parameters with cardiothoracic bioimpedance (CTBIA) and Acute Kidney Injury (AKI) prognosis.

Methods: We use a cohort of 21 patients (mean age 69 years SD 2.8, 76.2% males) with AKI We evaluate hemodynamic parameters (cardiac output –CO-, cardiac output index –COI-, left ventricular work index –LVWI- and systemic vascular resistance index –SVRI-) and thoracic volemic parameters (Thoracic fluid volumen -TFV-, Thoracic fluid volumen index –TFVI- and systolic volumen –SV-) with clinical index prognosis (severity individual index –ISI), analytical parameters (c-reactive protein –CRP-, prealbumin –PRALB, albumin –ALB-) and chronic health index (Karnofsky –K-).

Results: Patients with lower vascular resistance and higher cardiac work have worse prognosis, associated with inflammatory state and thoracic hypovolemia, oliguria and higher renal replacement therapy requeriments. But patients with higher thoracic volumen have higher risk of respiratoy failure.

Table 1.

Conclusions: CTBIA can be used to evaluate prognosis and theraphy of higher risk AKI, as a patients with vasoplegic state (with inflammatory origen and higher multiorgan failure risk) or thoracic hypervolemia (with higher respiratoy failure and intubation risk).

Abruptio Placenta as a Complement Amplifying Condition for Atypical Hemolytic Uremic Syndrome Syed S. Haqqie, Amro Elshoury, Daniel Sedhom, Arif Asif. *Albany Medical College, Albany, NY.*

Background: Endothelial injury resulting in microvascular thrombosis is the underlying pathology leading to target organ injury in aHUS. The syndrome is characterized by microangiopathic hemolytic anemia, thrombocytopenia, and ischemic injury to multiple organs including the kidney. Complement amplifying conditions often lead to the activation of complement cascade involved in the pathogenesis of atypical HUS. In this report, we present 33-year-old Hispanic women with abruptio placenta at 33 weeks of gestation and fetal death who underwent cesarean section. Post procedure, patient developed microangiopathic hemolytic anemia (6.7 mg/dl), thrombocytopenia (39,000/ µL) and renal failure necessitating initiation of hemodialysis. Fibrinogen (267 mg/dl), PT, PTT were normal while LDH was markedly elevated at 2670 IU/L haptoglobin was severely reduced at 5.8 mg/dl. Market schistocytosis was observed on peripheral smear. ADAMTS 13 was ordered and plasma exchange was initiated. Five sessions failed to show any improvement and ADAMTS 13 activity returned at 56%. Plasma therapy was discontinued and Eculizumab (monoclonal antibody directed against complement C5) was initiated for the diagnosis of aHUS. At a follow-up of two weeks patient is off dialysis with a serum creatinine of 3.4 mg/dl, hemoglobin of 8.8 mg/dl and platelet count of 147,000/ µL. We believe that abruptio placenta acted as a complement amplifying condition in this case. However, pregnancy, fetal loss and caesarean section can all serve as complement amplifying conditions for aHUS.

Methods: Clinical Case Report

Results: Successful outcome with Eculizumab therapy.

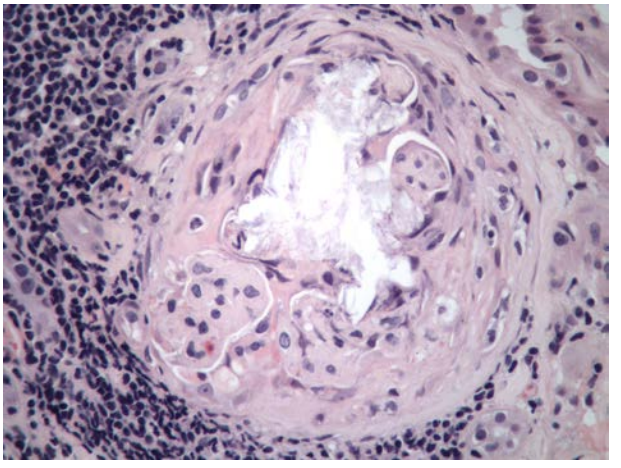
Conclusions: aHUS responding to Eculizumab therapy.

PUB061

Foscarnet Crystal-Induced Nephropathy in a Patient with Diminished Native Renal Capacity Sadiq Ahmed,[2] Patrick J. Hensley,[1] Virgilius Cornea.[1] *[1]Pathology, Univ of Kentucky; [2]Nephrology, Univ of Kentucky.*

Background: Drug-induced crystalline nephropathies are characterized by glomerular, tubular or interstitial injuries with rising creatinine, hematuria and low grade proteinuria. Foscarnet is a pyrophosphate analog that inhibits DNA polymerase in ganciclovir-resistant CMV. Tubular-interstitial damage due to Foscarnet is common but reports of crystalline-induced nephrotoxicity are rare. We report this unique case of Foscarnet crystal-induced nephropathy in a patient with lymphoma and solitary functioning kidney.

Methods: A 56 year old female with history of solitary functioning left kidney with remote history of right kidney atrophy due to obstructive uropathy was diagnosed with stage IV mantel cell lymphoma. Renal function was normal prior to chemotherapy and stem cell transplant. This was complicated by CMV infection requiring IV Foscarnet for 8 weeks. She developed AKI with nephrotic range proteinuria and hematuria. The patient was initiated on hemodialysis. Renal biopsy showed deposition of calcium crystals in the mesangium and interstitium characterized by short sticks with angular edges and birefringence on polarized light microscopy.



Conclusions: Foscarnet crystal-induced nephropathy has been reported in a limited number of immunosuppressed states resulting in CMV infection, including AIDS and solid organ transplantation. Foscarnet is solely eliminated by glomerular filtration and renal injury is typically characterized by reversible tubular necrosis. Foscarnet chelates metallic ions and frequently complexes with ionized calcium to form a highly insoluble salt that cannot be filtered by the kidney. This patient's pre-treatment renal function was adequate despite history of a solitary functioning kidney. Altered renal hemodynamics in the solitary kidney may have enhanced precipitation of Foscarnet-calcium salts despite adequate hydration.

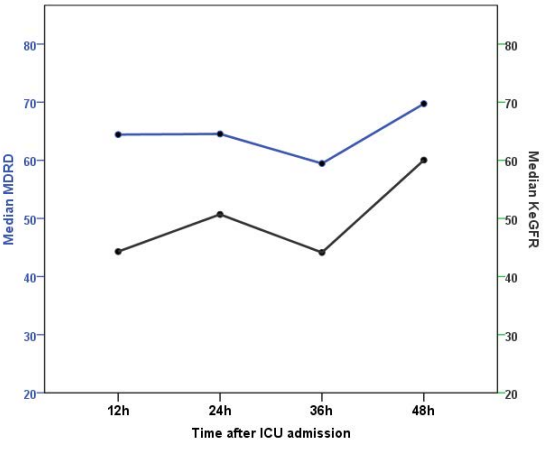
PUB062

Comparison of Estimated Glomerular Filtration Rate (eGFR) and Kinetic eGFR (KeGFR) in Critically Ill Intensive Care Unit (ICU) Patients Rakesh Malhotra,[1] Etienne Macedo,[2] Josee Bouchard,[3] Ravindra L. Mehta.[2] *[1]VUMC; [2]UCSD; [3]Univ de Montréal.*

Background: Estimation of kidney function in critically ill patients is important for appropriate drug dosing and therapeutic strategies. However, current GFR equations are not applicable when plasma serum creatinine (sCR) is rapidly changing. Chen et al (JASN 2013) has recently proposed KeGFR formula to calculate GFR from fluctuating sCR values. The aim of this study was to compare KeGFR values with eGFR using the Modification of Diet in Renal Disease (MDRD).

Methods: We analyzed data from a cohort of 735 ICU patients screened in a prospective observational study on the incidence of AKI from Jun06 to Dec08 at an academic center. Demographic data, co-morbidities, clinical course, and laboratory parameters were recorded from ICU admission. We estimated KeGFR and eGFR for each patient during the first 48 hr of ICU stay. We defined KeGFR = (SSPcr × CrCL/ Mean Pcr) × (1 - 24 × Δ Pcr / Δ Time (h) × Max Δ Pcr/Day) and MDRD eGFR = $175 \times (S_{cr})^{-1.154} \times (Age)^{-0.203} \times (0.742$ if female) × (1.212 if African American). We compared estimated GFR assessed by kinetic formula and MDRD GFR equation.

Results: Thirty-two patients with only one time sCR measurements were excluded from the analysis. In remaining 703 patients for analysis, the median age was 55 (IQR 23) years; 62% (n=436) were men and 53% (n=373) were white. In total, 4329 eGFR and KeGFR measurements were performed. Estimated GFR predicted by kinetic formula declined earlier and remained diminished as compared to eGFR till steady state was achieved.



Conclusions: Our study highlights the overestimation of renal function by MDRD equation in critically ill patients with acute kidney injury (AKI). KeGFR may be more accurate in tracking renal function changes in AKI. Further studies are needed to confirm these findings.

PUB063

Contrast Induced Nephropathy Among Hospitalized South Africans – Impact of Serum Albumin Justor Banda,[1] Saraladevi Naicker.[1] *[1]Faculty of Health Sciences, Univ of the Witwatersrand, Johannesburg, Gauteng, South Africa; [2]Faculty of Health Sciences, Univ of the Witwatersrand, Johannesburg, Gauteng, South Africa.*

Background: Despite ranking 3rd as cause of hospital acquired acute kidney injury in hospitalized patients, contrast induced nephropathy (CIN) causes significant morbidity, mortality and high hospital costs. In sub-Saharan Africa, information on rates of CIN is lacking. This study investigated the rates of CIN and influence of serum albumin on CIN.

Methods: This is an on-going prospective case controlled study conducted at Charlotte Maxeke Johannesburg Academic Hospital, in South Africa. In-patients undergoing contrast media administration in the Divisions of Radiology and Cardiology were consecutively recruited to the study. Ethical approval was obtained from the Human Research Ethics Committee of the University of the Witwatersrand. CIN was defined as serum Creatinine >25%µmol/l or >44µmol/l from baseline over a 48-72 hours post exposure to contrast media. Creatinine clearance was calculated using the CKD-EPI. The following were exclusion criteria; age below 18years, evidence of AKI (clinical or laboratory), ESRD and prior contrast media administration.

Results: Among 285 recruited hospitalized patients, a rate of CIN was 16.9%. Serum albumin below 35d/dl positively predicted development of CIN (RR 2.3, 95% CI 1.14-4.64, p=0.020). The mean album was 28.4±4.6 SD and 41±2.39 SD in the CIN and non CIN groups respectively. An eGFR <60ml/min was associated with a 6 fold risk of developing CIN (P<0.00001).

Conclusions: Rates of CIN is significantly higher in developing countries and the presence of hypoalbuminemia, a traditional bio-maker is significantly associated with development of CIN.

PUB064

A Curious Case of Evans Syndrome Sagar R. Patel, Imara Dissanayake. *Internal Medicine, Albert Einstein Medical Center, Philadelphia, PA.*

Background: Evans syndrome is a rare autoimmune condition in which antibodies attack their own RBC and platelets resulting in an hemolytic anemia (AIHA) and ITP in the absence of a known etiology. Both of these can occur simultaneously or sequentially. Although many cases are idiopathic in origin, ES has been associated with other conditions in half of the cases, including infections and lymphoproliferative disorders.

Methods: . A 45 year old African American male seen in ED with a Hgb of 6.4 and asymptomatic. The patient has a history of autoimmune hemolytic anemia (AIHA), immune thrombocytopenic anemia (ITP), anti-phospholipid syndrome (APS) with a previous DVT/PE and non-compliant with warfarin. labs On admission Hgb 6.4, Plts 114,T Bil 1.3, D Bil 0.4, LDH 346, Haptoglobin <8. He had AKI (Cr 0.9), with new onset nephrotic range proteinuria. Renal US showed medical renal disease. ANA 1:160, double stranded DNA was negative. Anti MPO, P-ANCA, C- ANCA, antiproteinase 3, atypical P-ANCA and glomerular basement membrane antibody were negative. CH 50,C3 and C4 were all low. No cryoglobulins were detected in the blood assay. Urine Electrophoresis was negative for monoclonal light chains. Renal biopsy was performed and showed findings consistent with lupus nephritis stage 4/5. The patient was treated with PRBCs and given pulse dose steroids for 3 days after which his hemoglobin remained stable.

Results: ES is diagnosed in only 0.8% to 3.7% of all patients with either ITP or AIHA at onset. Since it is thought to be secondary to immune dysfunction, a high clinical suspicion should be maintained for underlying autoimmune disease. However this patient was unique, he did not meet the standard criteria for SLE but demonstrated lupus nephritis on biopsy. This has a significant implication in management, and should be treated for his underlying SLE which could help in reducing recurrence of Evans syndrome. He responded well to first line therapy with corticosteroids and did not require further acute therapy such as IVIG. He was started on hydroxychloroquine for SLE and referred to renal clinic for cellcept.

Conclusions: This case reflects that we should have a high suspicion for SLE and lymphoproliferative diseases even in asymptomatic patients with Evans Syndrome.

PUB065

Anticoagulation-Free Continuous Renal Replacement Therapy: A Single Center Observation Akshatha Rao, Ziauddin Ahmed. *Div of Nephrology, Drexel Univ.*

Background: Renal failure in the ICU setting is associated with 40-60% mortality. Continuous renal replacement therapy (CRRT) is used for volume and electrolyte management in critical care units. To avoid clotting of hemofilters, patients are routinely started on anticoagulation. In literature, anticoagulation has been associated with complications of increased risk of bleeding and metabolic or electrolyte disturbances based on type of anticoagulation used. We aimed to investigate the length of cartridge use and the association of anticoagulation.

Methods: We conducted a retrospective review of 20 ICU patients who were started on CRRT over a course of two months for acute renal failure. We looked at the number of cartridges used per day. Prescription for CRRT was dialysate flow rate of 25-35 ml/kg/hr and blood flow rate of 250 ml/hr. No anticoagulation was ordered initially due to bleeding risks in this cohort. All patients were ordered 100 ml of normal saline flushes every 4 hours.

Results: For 70% of the patients, the hemofilter cartridge lasted >24 hours. 30% of the patients required more than 1 filter per day, of which only 1 patient was started on a heparin drip for anticoagulation due to multiple filter changes. We used predilution replacement fluid to reduce the blood viscosity and hemoconcentration for the patients requiring > 2 filter changes per day. Decreased requirement of filter change was noted after these changes were made. Among the patients with increased filter clotting, 33% had femoral non-tunneled dialysis catheters and 50 % had internal jugular tunneled dialysis catheters. Longer duration of dialysis was associated with increased cartridge use per pearson correlation 0.818 (p=0.000). No documentation was made in the nursing notes to distinguish between vascular access problems versus filter clotting.

Conclusions: Recurrent filter clotting leads to interruption of RRT. Frequent filter changes is not cost effective. However anticoagulation in critical care settings poses multiple potential problems. There was an association between permcatheters and increased cartridge use.

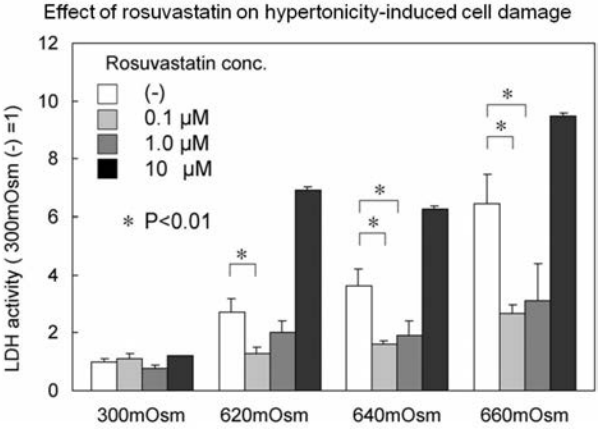
PUB066

Rosuvastatin Has a Protective Effect against Hypertonicity-Induced Cell Damage Miku Sato, Masaru Horio. *Functional Diagnostic Science, Osaka Univ Graduate School of Medicine, Suita, Japan.*

Background: Contrast-induced nephropathy (CIN) is one of the causes of acute kidney injury. Some studies raised a concern that statins have protective effect against CIN. Hypertonic stress in renal tubular cell is a possible factor inducing cell damage in CIN. Reactive oxygen species (ROS) can induce apoptosis. We studied the effect of rosuvastatin on hypertonicity induced cell damage in MDCK cells.

Methods: Hypertonic medium was made by addition of NaCl. Rosuvastatin was added 24 hours before the hypertonic exposure. Cell damage was assessed by LDH activity in culture medium. Apoptosis was evaluated by caspase-3 activity. Content of cellular glutathione (GSH), an important antioxidant, was measured.

Results: Hypertonicity more than 600 mOsm showed significant cytotoxic effect in MDCK cells. LDH activity in culture medium of 620, 640 and 660mOsm cells increased in osmolality dependent manner (Figure). Low concentration (0.1 and 1.0 µM) of rosuvastatin had a protective effect against the hypertonicity-induced cell damage. On the other hand, 10 µM rosuvastatin that had no significant cytotoxic effect in 300mOsm condition, stimulated hypertonicity induced cell damage.



Caspase-3 activity in 660mOsm cells was 13 fold higher compared with 300mOsm cells. Rosuvastatin (1µM) inhibited the increase of caspase-3 activity about 50%. Cellular GSH contents in 300mOsm, 660mOsm and 660mOsm with rosuvastatin after 8h were not significantly different (35.7±11, 33.0±8.1 and 34.2±19.2 nmoles/mg protein, respectively). Mevalonolactone (100µM)inhibited the protective effect of rosuvastatin, suggesting the inhibition of HMG-CoA reductase by rosuvastatin plays an important role of the protective effect against hypertonicity induced cell damage.

Conclusions: Low concentration of rosuvastatin has a protective effect on hypertonicity-induced cell damage in MDCK cells.

PUB067

Transcription Factor SRF Promotes Renal Fibrosis in IgA Nephropathy Lijie He, Shiren Sun. *Dept of Nephrology, Xijing Hospital, Xi'an, Shaanxi, China.*

Background: The role of transcription factors SRF, which regulate CArG element contained genes, in IgA nephropathy is unknown.

Methods: Here we performed expression of SRF in human IgA nephropathy tissues from ItoV stage and the cultured proximal tubular cells (HK-2) under hypoxia or induced by TGF-bcompared with control conditions.

Results: we performed SRF expression from formalin-fixed, paraffin-embedded tissues from renal biopsies diagnosis as IgA nephropathy. We noted the greatest change in SRF expression, which was significantly higher in IgAV stage compared with early presenters, like IgA Ior IIstage. Furthermore, in individual biopsies, high expression of SRF correlated with tubulointerstitial fibrosis and low estimated GFR. Next, in vitro, we identified overexpression of SRF was observed in hypoxia-induced HK-2 cells. Treatment of HK-2 with TGF-bincreased SRF expression. Lower expression of SRF suppressed expression of the CArG element snail1, thereby opposing TGF-β-mediated downregulation of E-cadherin.

Conclusions: In summary, high expression of SRF associates with increased fibrosis and decreased estimated GFR in IgA nephropathy in vivo, perhaps by enhancing TGF-β-mediated downregulation of snail and E-cadherin in HK-2.

PUB068

Increased Erythrocyte Reactive Oxygen Species Production Induced by Indoxyl Sulfate Precedes Red Blood Cell Death Gabriela Ferreira Dias,[1] Viktoriya Kuntsevich,[2] Lia S. Nakao,[3] Fellype C. Barreto,[1] Stephan Thijssen,[4] Peter Kotanko,[2,4] Roberto Pecoits-Filho,[1] Andrea Novais Moreno-Amaral.[1] *[1]Pontifícia Univ Católica do Paraná, Brazil; [2]Icahn School of Medicine at Mount Sinai, New York; [3]Univ Federal do Paraná, Brazil; [4]Renal Research Inst, New York.*

Background: The uremic toxin indoxyl sulfate (IS) triggers eryptosis, an event characterized by phosphatidylserine (PS) exposure on red blood cell (RBC). The aim of the present study was to evaluate whether increase in RBC reactive oxygen species (ROS) induced by IS precedes eryptosis.

Methods: RBC from healthy controls (HC) were incubated for 4, 12 or 24h with IS (free concentration 4.5 mg/L) in the presence or absence of free radicals scavenger N-acetylcysteine (NAC 0.5mM). Flow cytometry was employed to assess eryptosis (annexin-V+ binding) and ROS (DCFH-DA).

Results: Incubation of HC-RBC with IS over 4h did not trigger significant eryptosis compared to control cells incubated without IS (4.5±1.2% vs 3.4±0.2%). However, 12h and 24h incubation with IS increased levels of eryptosis in a time-dependent manner (10.4±3.4% and 16.6±6.1, respectively). This IS-induced PS exposure on HC-RBC was inhibited in the presence of NAC (6.0±1.3% and 6.5±1.4%, respectively). On the other hand, ROS production by HC-RBC was increased even after only 4h of incubation with IS in a time-dependent manner (14±4.2%, 22.1±5.3 and 34.8±15.8% for 4h, 12h and 24h respectively) when compared to control cells (4.6±2.3%, 4.2±0.5% and 5.2±8%, respectively). ROS production was inhibited in the presence of NAC (6.6±3.4%, 6,3±2% and 13.4±10.5%) demonstrating the ability of an antioxidant to reverse the oxidative stress induced by IS.

Conclusions: Taken together our results suggest that IS in a high free concentration, which is in accordance with reported free toxin concentration in patients, induces ROS production in HC-RBC that precedes PS exposure. Thus, imbalance of RBC redox status induced by IS appears to be an important mechanism of elevated eryptosis observed in CKD that consequently may contribute to renal anemia.

PUB069

Impact of Constitutive C-MIP Expression on Mouse T-Cell Proteome Mario Ollero,[1] Pauline Vachin,[1] Cerina Chhuon,[2] Kélhia Sendeyo,[1] Melanie Mangier,[1] Ida Chiara Guerrera,[2] André Pawlak,[1] Djillali Sahali.[1] *[1]INSERM, U955 (Eq. 21), Créteil, France; [2]Plateau Protéomes Necker, Paris, France.*

Background: The protein c-mip is overexpressed in lymphocytes and podocytes of MCNS patients. In order to dissect its role in INS pathogenesis, we generated a transgenic mouse expressing c-mip in peripheral mature T-cells. We aimed to evaluate the impact of c-mip expression on T-cell proteome in basal and stimulating conditions.

Methods: T-cells from transgenic (Tg) and control (Wt) mice (n=3) were purified by negative immunoselection, and subjected to anti-CD3 and anti-CD28 stimulation, to mimic activation by antigen presenting cells. At 0 and 60 min post-activation, total proteins were extracted, trypsin digested, and peptides analyzed by nano-RSLCC Q Exactive Plus MS. Protein quantification was performed by a label-free approach using MaxQuant and Perseus softwares on three parallel technical replicates per sample.

Results: The expression levels of 2660 proteins were compared in the four conditions. As a result, 46 proteins were found differentially expressed between Tg and Wt as a function of T-cell activation (two-way ANOVA interaction, $p<0.05$). Among these, GO annotation showed a significant enrichment in proteins bearing ATPase activity. Hierarchical clustering by K-means algorithm displayed, most remarkably, a cluster of 14 proteins upregulated upon T-cell activation in Wt mice but depleted in Tg mice in the same conditions - including KEGG annotations for tight junction, Wnt signaling, TLR signaling, RIG-I-like receptor signaling, Notch signaling, spliceosome, riboflavin metabolism, and DNA replication-, and a cluster of 11 proteins depleted in Wt and augmented or unchanged in Tg after activation – involved in aminoacid and nicotinamide metabolism, proteasome, and regulation of actin cytoskeleton-. Studies are underway to explore the mechanisms involved.

Conclusions: c-mip overexpression exerts profound alterations in the protein expression pattern following T-cell activation in mice, involving diverse signaling, metabolic pathways and cellular functions. These results, along with other preliminary data obtained from the same mouse model, point at a defect in T-cell activation associated with c-mip expression.

PUB070

An Investigation into the Prognosis of Nephrotic Syndrome and Regulatory T Cells in Elderly People Tetsuhiko Yasuno. *Internal Medicine, Fukuoka Univ, Fukuoka, Japan.*

Background: Peripheral blood flow cytometry analysis of nephrotic syndrome (NS) in children has been performed, and among T cells, regulatory T cells (Tregs) are involved in NS. In adults, there are reports about Tregs and ANCA-associated glomerulonephritis, and the nephritic inhibitory effect of Tregs has become clear. As there has been no investigation focusing only on NS in elderly people, we conducted the analysis in this study.

Methods: In this investigation, we examined 7 patients aged 65 years or older who had NS. Regarding the primary disease, 3 of these patients had membranous nephropathy, 1 had minimal change, 1 had immunotactoidglomerulopathy (ITG), 1 had diabetic nephropathy, and 1 had Lupus nephritis. Flow cytometry using peripheral blood was conducted, and among T cells, the percentage of Th1, Th2, Treg, and Th17 was examined.

Results: The average value of Th1 cells was 31.8%, Th2 was 4.2%, Treg was 9.3%, and Th17 was 2.6%. The patient with ITG had a higher percentage of Treg (19.9%), but this patient achieved complete remission after 2 years owing to the administration of a steroid and mizoribine. For the other patients, there were no distinctive features for the 2-year prognosis.

Conclusions: The Treg value was higher for the patient with ITG. However, as only 1 such patient was examined, it is unclear whether this was because of a disease or was a unique phenomenon for this patient. It is possible that peculiar T cell actions could be involved in elderly people, so various ailments of NS should be further investigated by using flow cytometry.

PUB071

Antibodies against Linear Epitopes on a3(IV)NC1 in Patients with Antineutrophil Cytoplasmic Antibodies Associated Vasculitis Xiaoyu Jia,[1] Juntao Yu,[2] Zhao Cui,[1] Minghui Zhao.[1,3] *[1]Renal Division, Peking Univ First Hospital, Beijing, China; [2]Academy for Advanced Interdisciplinary Studies, Peking Univ, Beijing, China; [3]Peking-Tsinghua Center for Life Sciences, China.*

Background: In a substantial number of patients with crescentic glomerulonephritis, both anti-glomerular basement membrane (GBM) antibodies and antineutrophil cytoplasmic antibodies (ANCA) are detected simultaneously. ANCA is presumed to be the initial event leading to the production of anti-GBM antibodies. In the present study, we investigated the antibodies against linear epitopes on a3 chain of type IV collagen (a3(IV)NC1) in patients with ANCA associated vasculitis who had no classical anti-GBM antibodies, aiming to reveal the mechanisms of the coexistence of the two kinds of autoantibodies.

Methods: Twenty-four overlapping linear peptides were synthesized across the whole sequence of a3(IV)NC1 and antibodies were detected by ELISA.

Results: We found 25/31 (80.6%) ANCA associated vasculitis patients possessing antibodies against linear peptides on a3(IV)NC1. These antibodies were detected from 50% of patients with normal renal function (Scr£133mmol/L), 70% of patients with moderate renal dysfunction (133mmol/L<Scr≤600mmol/L), and 94% of patients with renal failure (Scr>600mmol/L). Patients with more aggravated renal damage had higher frequency of peptide recognition (P=0.032). The highest recognition frequencies were found for peptides P4 (51.6%), P14 (54.8%) and P24 (54.8%), which contained the sequences that constitute the epitopes E_A (P3) and E_B (P14 and P24) on a3(IV)NC1. The level of anti-P4 antibodies was positively correlated with the percentage of crescents in glomeruli (r=0.764, P=0.027). Patients with anti-P24 antibodies had a significantly higher prevalence of renal dysfunction on diagnosis (88.2% vs. 42.9%, P=0.018).

Conclusions: In conclusion, antibodies against linear peptides on a3(IV)NC1 could be detected in patients with ANCA associated vasculitis who had no classical anti-GBM antibodies and were associated with clinical features.

PUB072

Urine suPAR and CD80 Levels in Patients with Focal Segmental Glomerulosclerosis and Minimal Change Nephrotic Syndrome Chang-Yien Chan, Yaochun Zhang, Wee Song Yeo, Isaac Liu, Hui Kim Yap. *Pediatrics, National Univ of Singapore, Singapore.*

Background: Recent studies suggested soluble urokinase-type plasminogen activator receptor (suPAR) as the plausible circulating factor in the pathogenesis of focal segmental glomerulosclerosis (FSGS) while patients with minimal change nephrotic syndrome (MCNS) were reported to have increased CD80 levels in the urine. This study aimed to determine the value of urine suPAR and CD80 levels in distinguishing between FSGS and MCNS in patients with nephrotic relapse.

Methods: Plasma and urine suPAR and CD80 levels were analyzed in 51 primary nephrotic patients in relapse with urine protein:creatinine ratio of >0.2g/mmol (26 MCNS, 25 FSGS) and 24 healthy controls, using Quantikine Human uPAR Immunoassay (R&D Systems) and Human sCD80 Elisa kit (eBioscience). Urine were concentrated using centrifugal filter units with molecular weight cut-offs at 3kDa (Amicon) before quantification of sCD80. Urine levels of suPAR and CD80 were normalised with urine creatinine. Results were expressed as mean±SEM. Statistical analysis was done using Mann-Whitney test.

Results: Plasma suPAR levels in patients with FSGS (3216.8±295.2pg/ml) were significantly higher than controls (2330.8±207.2pg/ml) and MCNS patients in relapse (2178.9±196.7pg/ml) ($p<0.02$). Urine levels of suPAR were significantly higher in both MCNS (351.8±52.3pg/µmol, p=0.02) and FSGS (381.6±52.9pg/µmol, p=0.012) compared to control (210.4±20.2pg/µmol). There was modest correlation between suPAR levels in plasma and urine (Spearman's $\rho=0.509$, $p<0.001$). We were unable to detect CD80 levels in plasma samples even after removal of high-abundance proteins in the plasma samples with the combinatorial peptide ligand library beads (ProteoMiner). Urine CD80 levels were 2.5-fold higher in MCNS (0.31±0.13ng/µmol) compared to controls (0.13±0.03ng/µmol, p=0.19) and 1.6-fold compared to FSGS (0.19±0.49ng/µmol, p=0.44).

Conclusions: Our study suggested that neither urine suPAR levels nor the CD80 levels are useful to distinguish patients with FSGS or MCNS.

PUB073

Effects of 1,25-Dihydroxy Vitamin D_3 on Treg cells, Interleukin -17, RORgt in Rats with IgA Nephropathy Hui Guo. *Div of Nephrology, 2nd Affiliated Hospital of Shanxi Medical Univ, Taiyuan, Shanxi, China; Div of Rheumatology, 2nd Affiliated Hospital of Shanxi Medical Univ, Taiyuan, Shanxi, China.*

Background: To investigate the relationship between Treg cells, RORgt, IL-17 and rats with IgA nephropathy; to explore the intervention effect of $1,25(OH)_2D_3$ on Treg cells, RORgt, IL-17 expression in rats with IgA nephropathy.

Methods: We choosed Wister 52 rats, with witch 8 rats were choosed in control group (group E) in random, while other 44 rats were established the IgA nephropathy model by mucosal immune with bovine serum albumin and were divided into model group,$1,25(OH)_2D_3$ treated group, prednisone treatment group and prednisone +$1,25(OH)_2D_3$ treatment group. The change of 24 hours of urinary protein, red blood cells in urine, creatinine and blood calcium of rats were detected. Foxp3, RORgt and IL-17 levels were detected by using RT-PCR, Immunohistochemistry and Westernblot.

Results: The level of RORgt, IL-17 in model groups were higher than prednisone treatment group, prednisone+$1,25(OH)_2D_3$ treatment group,$1,25(OH)_2D_3$ treatment group and control group ($p<0.05$). After treatment the expression of RORgt, IL-17 of each group were declined significantly ($p<0.05$). The prednisone+$1,25(OH)_2D_3$ treatment group declined significantly compare to prednisone treatment group and $1,25(OH)_2D_3$ treatment group ($p<0.05$). **The expression of Foxp3 decreased significantly in IgAN group. After treatment with $1,25(OH)_2D_3$, the level of Foxp3 increased significantly.**

Conclusions: Treg cells, IL-17 and RORgt may participate in the occurrence/development of IgAN; $1,25(OH)_2D_3$ may play a role in immune regulation by regulating the expression of Treg cells ,IL-17 and RORgt directly or indirectly.

PUB074

MGRS, Complement and C3 Glomerulopathy Yuzhou Zhang,[1] Fernando C. Fervenza,[2] Christopher D. Blosser,[3] Peter M. Fitzpatrick,[4] Dingwu Shao,[1] Niamh Kieran,[3] Carla M. Nester,[1] Sanjeev Sethi,[2] Nicolae Leca,[3] Richard J. Smith.[1] *[1]Carver College of Medicine, Univ of Iowa, Iowa City, IA; [2]Mayo Clinic, Rochester, MN; [3]Univ of Washington Medical Center, Seattle, WA; [4]Mayo Clinic, Jacksonville, FL.*

Background: Monoclonal gammopathy of renal significance (MGRS) implies a causal relationship between clonal B cell proliferation and renal disease. By definition, these patients do not meet criteria for overt multiple myeloma/B-cell proliferation, however their hematologic disorder is not of undetermined significance. Rather, it is associated with high morbidity secondary to renal compromise induced by circulating monoclonal immunoglobulins (MIg). Recently, a subset of MGRS with dominant glomerular C3 deposition or MGRS-C3 glomerulopathy (C3G) has been reported.

Methods: Factor H (FH) autoantibodies, free light chains against FH and factor B (FB) autoantibodies were detected by ELISA. C3 nephritic factors were detected using ELISA and hemolytic-based assays.

Results: Six patients developed MGRS-C3G triggered by four different mechanisms of action. The first mechanism of action, identified in three patients, was an IgG form of MIg to FH. These FH autoantibodies compromised function of FH, the only fluid-phase negative regulator of the alternative pathway (AP) of complement. The second mechanism, identified in one patient, was a free light chain (FLC) form of MGRS against FH. The FLCs acted as mini autoantibodies against the N-terminus of FH and impaired cofactor activity. The third mechanism, also identified in one patient, was an IgG form of MIg to FB as FB autoantibodies, resulting in increased activity of C3 convertase (C3bBb). The final mechanism, identified in one patient, was an IgG form of MIg, as a C3 nephritic factor that bound to and stabilized C3bBb.

Conclusions: These findings highlight the variability in autoantibodies associated with MGRS-C3G, thus mandating a comprehensive and detailed analysis of the alternative pathway in these patients. Acknowledgment: We gratefully acknowledge both the clinicians across North America who allow us to study their patients, and the patients, whose participation enhances our understanding of rare complex renal diseases.

PUB075

Elucidation of Tubulo-Interstitial Injury in Chronic Kidney Ischemia by Use of Novel Renal Artery Coiling Model Kentaro Fujii, Kazutoshi Miyashita, Hiroyuki Inoue, Aika Hagiwara, Masanori Tamaki, Masaaki Sato, Hiroshi Itoh. *Internal Medicine, School of Medicine, Keio Univ, Tokyo, Japan.*

Background: Recent studies emphasize an essential role for tubulointerstitial hypoperfusion in the progression of chronic kidney disease (CKD) as a common pathway to end stage renal disease (ESRD). However, the mechanism of renal injury needs further to be elucidated.

Methods: Most previous animal models which aimed to simulate renal ischemia have been ischemic-reperfusion injury model, which shows major characteristics of acute kidney injury. To elucidate the progression of kidney dysfunction with chronic ischemia, we developed novel renal ischemia model by setting a coil around a left renal artery of right hemi-nephrectomized mice and reducing the kidney bloodstream for 80 %. The coil was made of the titanium and the inside diameter is from 0.17 to 0.28 mm.

Results: After transient decline in renal function until post-operative day 14, slowly progressive renal dysfunction and elevation of N-acetyl-β-D-glucosaminidase (NAD) in urine were observed in the chronic renal ischemia model from post-operative day 14 to 84. A histological observation of the ischemic kidney on post-operative day 7 revealed no remarkable changes from control kidneys and there are no findings of tissue injury and infiltration of inflammatory cells. However, the progression of tubulointerstitial fibrosis and the increase in the markers for apoptosis and oxidative stress were significant from post-operative day 28 to 84. Real-time quantitative PCR analysis in ischemic kidney revealed the progressive changes of the hypoxia-responsive gene expressions such as pyruvate dehydrogenase kinases.

Conclusions: These data suggests that the novel chronic renal ischemia model by coiling renal artery is an appropriate animal model for CKD, which shows a slowly progressive tubulointerstitial injury.

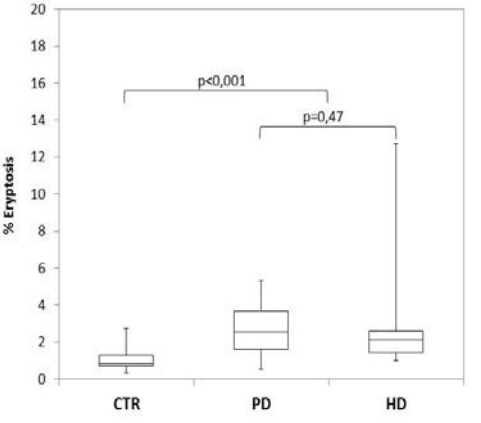
Dialysis Induces Morphological Changes and Eryptosis in Erythrocytes Grazia Maria Virzì, Sabrina Milan Manani, Anna Clementi, Alessandra Brocca, Massimo de Cal, Claudio Ronco. *IRRIV and Dept Nephrology Vicenza.*

Background: Suicidal death of erythrocytes (eryptosis) is characterized by cell shrinkage, membrane blebbing, activation of proteases, and phosphatidylserine (PS) externalization. Exposed PS is recognized by macrophages that engulf and degrade affected cells. Eryptosis is a physiological mechanism under complex regulation. During their daily life, erythrocytes (RBCs) are exposed to several stress stressors, such as oxidative stress, osmotic shock, energy depletion. Eryptosis is observed in a wide range of clinical conditions, such as CKD, malignancy, diabetes and sepsis. The aim of this study was analysed cell volume and PS abundance at the RBC surface in peritoneal dialysis (PD) and hemodialysis (HD).

Methods: 40 PD patients, 30 HD patients and 17 healthy subjects (CTR) were included in the study. All measurements were made in isolated RBCs. RBC volume and morphology was estimated from forward scatter, PS exposure at the cell surface was estimated from FITC-AnnexinV binding using flow cytometric analyses.

Results: We observed that the RBCs of PD and HD patients are indeed rather dramatically deranged in their morphology. Furthermore, the PS externalization on the RBC surface was significantly higher in these groups than in CTR (PD patients: 2.6%; IQR 1.6-3.7, HD patients: 2.2%; IQR 1.2-4.1 versus CTR: 0.8%; IQR 0.7-1.3; p=0.000001). We did not find significant differences in PS exposure between the PD and HD patients (p=0.47).



Conclusions: In conclusion, the percentage of eryptosis has indeed been shown to be significantly higher in patients on dialysis than CTR. Our data suggest that dialysis may induce morphological changes in erythrocytes and may lead to a significant increase in eryptosis, but no differences in its level were observed between PD and HD. Additional efforts will be required to define major eryptosis-inducing components in uremic, PD and patients.

PUB077

Toll Like Receptor 2, 4 and 9 Expression Is Enhanced in Kidneys of Patients with Anti Neutrophil Cytoplasmic Antibody Associated Vasculitis (AAV) Kim M. O'Sullivan,[1] Anthony Longano,[3] A. Richard Kitching,[1,2] Stephen R. Holdsworth.[1,2] *[1]Dept of Medicine, Monash Univ, Clayton, Victoria, Australia; [2]Dept of Nephrology, Monash Health, Clayton, Victoria, Australia; [3]Pathology Dept, Monash Health, Clayton, Victoria, Australia.*

Background: Toll like receptors (TLRs) may be the possible link between infection and autoimmunity. This study investigates the distribution of TLR2, 4 and 9 in human kidney biopsies from patients with AAV (40), lupus (8) and controls (with non proliferative glomerular lesions, minimal change and thin membrane disease, 10).

Methods: Biopsies were examined by confocal microscopy with immunofluorescent staining in serial sections for the cellular distribution of TLR2, 4 and 9. Mean fluorescent intensity (MFI) was measured by imaging software (Image J) and was correlated with histopathological parameters.

Results: TLR2, 4 and 9 in the AAV group, (for both MPO and PR3 patients) had significantly stronger staining than controls in glomeruli (1.5 vs 13.3AU; 0.25 vs 32.0AU; 0.7 vs 36.2AU, all $P<0.05$, respectively) and the interstitium (7.4 vs 63.0AU; 0.41 vs 53.8AU; 1.6 vs 59.6 AU, all $P<0.05$, respectively). The lupus patients also had higher

expression of TLR2 (4.8AU), 4 (12.6AU) and 9 (7.3AU, P<0.05) compared with controls, but their staining was significantly less than that of the AAV group for all TLRs (P<0.05). Cellular infiltrates contained intense staining for TLR2, 4 and 9 on macrophages and neutrophils in both glomeruli and interstitium. TLR2 and TLR4 staining was prominent on both endothelial cells and podocytes, although TLR9 was particularly evident on podocytes. In AAV glomerular TLR4 expression correlated with the % of normal glomeruli,(r=0.48, P<0.05) suggesting TLR4 prominence occurs in early glomerular lesions. Glomerular TLR2 and 9 were present concurrently in more severely affected glomeruli (r=0.71, P=0.0001). TLR2, 4 and 9 were prominent in all crescentic glomeruli of AAV and lupus patients.

Conclusions: This study demonstrates that TLR expression is most prominent in AAV. Significant expression of TLRs was evident on leukocytes and intrinsic glomerular cells. TLR4 is prominent in early glomerular lesions, while TLR2 and 9 correlate with severe glomerular lesions.

Podocyte CD40 Expression in Patients with Post-Transplant FSGS Recurrence Rutger J. Maas,[1] Brigith Willemsen,[2] Henry Dijkman,[2] Jeroen Deegens,[1] Jack F. Wetzels.[1] *[1]Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands; [2]Pathology, Radboud Univ Medical Center, Nijmegen, Netherlands.*

Background: antibodies against CD40 were recently reported to predict post-transplant recurrent FSGS (rFSGS) with 78% accuracy (Delville et al. Sci Transl Med 2014). Using immunohistochemistry, the authors reported strong focal podocyte CD40 expression in glomerular lesions of two patients with rFSGS. We sought to validate this novel finding of podocyte CD40 expression as a potential marker of rFSGS.

Methods: we used formalin-fixed, paraffin embedded kidney tissue from five patients with rFSGS. Two samples were obtained from nephrectomy specimens, and three were needle biopsy specimens. All patients had nephrotic range proteinuria at the time of tissue sampling. A human tonsil was used as a positive control. For immunohistochemistry, four mm slides were cut and deparaffinised. After endogenous peroxidase block, antigen retrieval was performed by boiling in a microwave with EDTA buffer (pH 9.0). Slides were incubated with primary antibody mouse anti CD40 (clone 11E9, Abcam ab50849) diluted in PBS with 1% BSA overnight at 4°C. Detection was done with Brightvision biotin-free goat anti rat/rabbit/mouse poly HRP (Immunologic) and DAB as substrate.

Results: specificity and adequacy of the staining was confirmed by strong CD40 expression in tonsillar germinal centers (Figure, panel A). In kidney samples from patients with rFSGS, CD40 staining was found in areas of interstitial cellular infiltration, and some tubular epithelial cells (Figure, panel B). However, no glomerular CD40 was detected in any of the rFSGS samples.

Conclusions: we could not confirm glomerular CD40 staining in rFSGS with immunohistochemistry. The role of CD40 antibodies in rFSGS pathogenesis needs further study and validation.

Increased Cellular Microchimerism in Women with Systemic Lupus Erythematosus Suzanne Wilhelmus,[1] Malu Zandbergen,[1] Emilie Rijnink,[1] Juan D. Diaz de Pool,[2] Mathilde M.M. Almekinders,[1] Hans J. Baelde,[1] Jan A. Bruijn,[1] Ingeborg M. Bajema.[1] *[1]Pathology, Leiden Univ Medical Center, Leiden, Netherlands; [2]Gynaecology, Leiden Univ Medical Center, Leiden, Netherlands.*

Background: Microchimerism (Mc) has been suggested to play a role in the development of systemic lupus erythematosus (SLE). We previously showed that Mc occurs twice as often in kidney biopsies of patients with lupus nephritis as in controls. Recently, it was demonstrated that the amount of Mc in lupus nephritis is associated with renal function (Arthritis Research & Therapy, 2015). Because in previous studies the Y chromosome was used to detect Mc, these studies were limited to detecting male Mc and the origin of the chimeric cells remained largely unknown. The aim of the present study was to determine the frequency, amount and origin of chimeric cells in SLE patients and controls, by using insertion-deletion polymorphisms and null alleles for the detection of Mc.

Methods: We included 11 SLE patients and 22 controls, as well as their children and mothers. A quantitative PCR for insertion-deletion polymorphisms and null alleles was used to detect Mc in peripheral blood mononuclear cells and granulocytes. The relationship between the presence of Mc and disease onset, disease activity and accumulated damage since disease onset was investigated.

Results: Mc was detected more often in SLE patients than in controls (54.4% vs 13.6%, p=0.03), and was fetal in origin in almost all cases. The median total number of fetal chimeric cells was significantly higher in patients than in controls ($5/10^6$ versus $2.5/10^6$, p=0.048). In 50% of SLE patients with Mc, Mc originated from multiple relatives whereas in controls Mc was derived from only one relative. We found no relationship between Mc and clinical or laboratory parameters.

Conclusions: SLE patients had Mc in peripheral blood more often than controls, and at higher levels. We showed that Mc was mostly fetal in origin and, in SLE patients, could be derived from multiple relatives. Our findings substantiate the role for Mc in autoimmune diseases such as SLE.

An Oxalate-Induced Mouse Model of CKD That Displays Common CKD Complications Hans J. Anders,[1] Shrikant R. Mulay,[1] Jonathan Nicodemos Eberhard,[1] Victoria Pfann,[2] Julian A. Marschner,[1] Simone Romoli,[1] Jyaysi Desai,[1] Santhosh Kumar Vr,[1] Peter S. Aronson,[3] Felix Knauf.[2] *[1]Univ of Munich; [2]Univ of Erlangen-Nürnberg; [3]Yale Univ School of Medicine.*

Background: Chronic kidney disease (CKD) research is limited by the lack of a convenient inducible C57BL/6 mouse model mimicking relevant human CKD complications. We have reported a high soluble oxalate diet (50 µmoles/g sodium oxalate mixed with virtually calcium free diet) that induces a progressive decline in glomerular filtration rate (GFR) reflected by increasing creatinine as well as blood urea nitrogen levels in C57BL/6 mice.

Methods: All in vivo experiments were approved by the local government authorities. Computed tomography, ultrasound and MRI were used for imaging.IHC, RT-PCR were used for data analysis. GFR was measured using single i.v. bolus injection of FITC sinistrin in conscious mice.

Results: We now demonstrate that mice fed this high soluble oxalate diet develop typical CKD complications such as sustained hypertension, normochromic anemia, metabolic acidosis, hyperphosphatemia, hyperparaphyroidism, and hyperkalemia. Renal histology is characterized by calcium-oxalate crystal plugs in the tubular lumen, tubular atrophy, interstitial fibrosis, and atubular glomeruli. This pathophysiology of CKD resembles that of primary hyperoxaluria type I, also in terms of renal ultrasound, computed tomography, and magnetic resonance imaging. The duration of feeding a high soluble oxalate diet determines the amount of nephron loss, interstitial fibrosis, and impaired GFR equivalent to different stages of CKD. This can be used to produce various levels of stable impaired baseline GFR, a useful way to study, for example, AKI on precedent CKD.

Conclusions: We conclude that feeding a high soluble oxalate diet is a convenient way to induce progressive and stable CKD with clinically established complications in C57BL/6 mice. This model should serve to be useful for many areas of CKD research and avoid surgery to induce nephron loss or renal fibrosis.

PUB081

Cyclosporine A Reduces Renal Injury Through Protecting Glomerular Charge Barrier in Passive Heymann Nephritis Zilong Li, Juan Wang, Lining Wang. *Dept of Nephrology, First Affiliated Hospital of China Medical Univ, Shenyang, Liaoning, China.*

Background: Cyclosporine A (CsA) has been reported to reduce proteinuria in several kinds of kidney diseases. Glomerular charge barrier plays an important role in preventing urinary protein loss. The aim of this study was to elucidate the effects of CsA on glomerular charge barrier in passive Heymann nephritis (PHN).

Methods: Wistar rat PHN model was established by injecting antiserum against renal tubular epithelial antigens (anti-Fx1A) following pre-immunization. The experiment included Group 1: PHN control, Group 2: PHN plus CsA treatment before anti-FxlA injection, Group 3: PHN plus CsA treatment for the first 7 days after injection, and Group 4: PHN plus CsA treatment from the 8th day after injection. Serum creatinine (sCr) and urinary protein (uPro) were measured at the 7th and/or the 14th day. Kidney tissues were obtained at the 14th day and labeled with a cation tracer polyethyleneimine (PEI) to study the distribution of negative charges on glomerular basement membrane (GBM). Kidney pathological changes were investigated.

Results: PHN model was established showing proteinuria and kidney injury of thickened GBM, a mass deposition of immune complex (IC), and decreased density and disturbed distribution of negative charges along the GBM. sCr was not increased in all of groups. With CsA treatment, uPro was significantly declined in Group 2 and 3 at 7th day, and in Group 2 and 4 at 14th day. In Group 2, it showed little pathological changes in kidney with less IC deposition and negative charges distributed evenly. In Group 3 and 4, the deposition of IC was reduced, and the negative charges distribution was repaired showing stronger density compared to Group 1, while less regularly arranged compared to Group 2.

Conclusions: Using a rat model of PHN, CsA was able to protect glomerular charge barrier, which might benefit from the regulation of Ca^{2+} influx and reduction of IC deposition, thus minimizing proteinuria and renal injury.

PUB082

Absence of Caspase-1 Attenuates Adriamycin-Induced Nephropathy
Jinghui Luo,[1] Yingbao Yang,[1] J. Michelle Kahlenberg,[2] Tamra J. Reed,[2] Stephanie Wylie,[1] Christopher Lund O'Connor,[3] Jeffrey B. Hodgin.[1] *[1]Pathology, Univ of Michigan, Ann Arbor, MI; [2]Rheumatology, Univ of Michigan, Ann Arbor, MI; [3]Univ of Michigan, Ann Arbor, MI.*

Background: Recent studies have demonstrated a pathogenic role of caspase-1 in mediating proteinuria-associated renal injury. As a chronic proteinuric renal disease model, adriamycin (ADR)-induced nephropathy (AIN) has been characterized by podocyte injury followed by glomerulosclerosis (GS), tubulointerstitial inflammation and fibrosis, but the mechanisms underlying it remain poorly understood. Based on the evidence that oxidative stress stimulates inflammasome activation which subsequently contributes to renal injury, we hypothesize that abolishing caspase-1 expression in the kidney may be protective.

Methods: Male caspase-1 knockout (KO) and wildtype (WT) mice on the BALB/c background were injected with ADR (10.5 mg/kg) or saline at 8-10 weeks of age. Twenty four-hour-urine was collected and the mice were sacrificed 14 days post the injection. Creatinine (Cr), triglycerides, and total cholesterol (TCH) were determined in serum, and histological analyses, western blot, and RT-qPCR were performed in kidney tissue.

Results: ADR triggered overexpression of caspase-1 and IL-1β in kidney tissue of WT mice, but not in that of KO mice. ADR induced albuminuria and GS, which was accompanied with decreased kidney weight/body weight ratio (Kw/Bw), and increased Cr and TCH levels in both KO and WT mice. Compared with WT animals, KO mice showed significantly lower ACR, reduced GS scores, increased Kw/Bw, and attenuated Cr levels ($P<0.05$ each). Meanwhile, elevated expression of TNF-α and INF-γ, augmented 12-LO, and decreased PPAR-α, SDHA, and SOD2 levels were observed in ADR-treated kidneys, and all these changes were shown to be significantly ameliorated in KO mice. In addition, positive correlation between Cr and TCH was recognized in both KO and WT ADR-treated mice.

Conclusions: Cytokine-mediated inflammatory cascade, hyperlipidemic injury, and impaired mitochondrial function are all responsible for ADR-induced kidney injury. Caspase-1 might be a potential therapeutic target in proteinuric renal disease.

Glomerular HO-1 Expression Control by Hemin: Role of Hemopexin
Maria Detsika,[1] Vasileios Atsaves,[1] Emanuela Tolosano,[3] Pu Duann,[2] Elias A. Lianos.[1,2] *[1]Medicine, Univ of Athens, Greece; [2]Medicine, Rutgers Biomedical and Health Sciences, NJ; [3]Molecular Biotechnology Center, Univ of Torino, Italy.*

Background: Hemopexin (HPX) maintains low free heme levels in serum thus mitigating heme-associated cell injury. HO-1 induction also minimizes injury by degrading heme to CO and bile pigments. In hemolytic disorders, heme scavenging by HPX is overwhelmed and glomeruli may be exposed to high free heme, exceeding 200 μM. However, while HO-1 prominently increases in tubules, it is barely detectable in glomeruli. We hypothesized that this is due to presence of a HO-1 expression "threshold" above which HO-1 induction in glomeruli is not sustainable.

Methods: *hmox1*$^{+/-}$ rats were generated by Zinc Finger Nuclease (ZFN)-mediated HO-1 gene disruption and rats with GEC targeted HO-1 overexpression (GEC^{HO-1}) by Sleeping Beauty Transposon mediated transgenesis using a nephrin promoter. Glomeruli from wild type (WT) or *hmox1*$^{+/-}$ or GEC^{HO-1} rats were incubated for 18 h with 10% HPX replete (HPX^{+}) or HPX-deficient (HPX^{-}) serum obtained from HPX knock-out mice. Exogenous heme was added at concentrations encountered in hemolytic disorders (100-400 μM). HO-1 protein levels were assessed by western blot.

Results: HO-1 protein was reduced by 70% in *hmox1*$^{+/-}$ and increased by 2-fold in GEC^{HO-1} glomeruli. HO-1 protein levels were no different between 10% HPX^{+} serum vs serum-free media. In incubations with varying dilutions of HPX^{-} serum (1.25, 2.5, 5, 10%) HO-1 levels in WT glomeruli progressively increased and were 2.5-fold higher with 10% HPX^{-} serum compared to 10% HPX^{+} serum. Co-incubation with 10% HPX^{-} serum and heme (200, 400 μM) markedly reduced HO-1. This reduction was attenuated in incubations with higher dilutions (2.5 %) of HPX^{-} serum or with 10% HPX^{+} serum. The effect of heme on HO-1 levels in glomeruli incubated with HPX^{-} serum was recapitulated in GEC^{HO-1} glomeruli. In contrast, heme further increased HO-1 in *hmox1*$^{+/-}$ glomeruli.

Conclusions: Heme-mediated HO-1 induction in glomeruli is limited by HO-1 expression levels attained. This may serve to limit level of HO activity thereby preventing excessive heme-derived Fe^{++} in hemolytic disorders.

GEC-Targeted HO-1 Over Expression: Protective Effects in Secondary but Not Primary GEC Injury
Vasileios Atsaves, Maria Detsika, Elias A. Lianos. *Medicine, Univ of Athens, Athens, Greece; Medicine, Rutgers Biomedical and Health Sciences, N. Brunswick, NJ.*

Background: In contrast to tubular epithelial cells, induction of the cytoprotective enzyme, Heme Oxygenase (HO-1), in response to injury in glomerular epithelial cells (GEC) is limited or absent and this may increase their vulnerability to injury. We, therefore, explored whether targeted HO-1 over expression in GEC can protect against primary injury induced by puromycin aminonucleoside (PAN) or secondary injury resulting from anti-GBM Ab induced glomerulonephritis (GN).

Methods: HO-1 over expression in GEC of Sprague-Dawley (SD) rats was achieved by targeting a FLAG-human(h)HO-1 sequence under the control of a murine nephrin promoter using transposon-mediated gene-trap insertional mutagenesis based on a *Sleeping Beauty*(SB) transposon system (SB rats). GEC-targeted over expression was validated by FLAG immunolocalization and by western blot. PAN-mediated GEC injury was induced in SD rats by a single intraperitoneal injection. GN was induced by a single intravenous injection of a rabbit anti-rat GBM Ab. At defined points following PAN or anti-GBM Ab injection, albuminuria (Ualb/Ucreat) was assessed and glomeruli were isolated to determine changes in HO-1 and nephrin expression (GEC integrity marker).

Results: In glomeruli from SB rats HO-1 levels (protein) increasedcompared to Wild type (Wt). Administration of either PAN or anti-GBM to Wt rats increased glomerular HO-1. In SB rats receiving PAN, HO-1 markedly decreased compared to Wt. In contrast, HO-1 was preserved following anti-GBM Ab. Nephrin expression was markedly decreased in glomeruli from SB rats treated with PAN. In contrast, nephrin was preserved in glomeruli from SB rats treated with anti-GBM Ab. Ualb/Ucreat was significantly higher in WT compared to SB rats treated with anti GBM Ab. In contrast, there was no difference in Ualb/Ucreat between Wt and SB rats receiving PAN.

Conclusions: Augmentation of HO-1 expression in primary GEC injury is impaired. This could be yet another mechanism contributing to GEC vulnerability in primary podocytopathies.

PUB085

Comparative Evaluation of Cellular Injury Models Based on Conditionally Immortalized and Primary Podocytes
Vivek C. Abraham,[1] Loan N. Miller,[1] Caton Brent Putman,[1] Laura Kim,[2] Steve Pratt,[2] Sujatha M. Gopalakrishnan,[2] Andrew J. King.[1] *[1]Renal Discovery, AbbVie, North Chicago, IL; [2]High Throughput Screening, AbbVie, North Chicago, IL.*

Background: Podocyte injury is a hallmark of proteinuric chronic kidney disease. The response of podocytes to injury includes cytoskeletal reorganization, oxidative stress, de-differentiation & detachment. The purpose of this study was to compare commonly used conditionally immortalized podocytes with primary podocytes, by measuring podocyte markers and responses to injury.

Methods: Primary human podocytes were isolated and cultured from a healthy human donor kidney and compared to 1) a subclone (C5) of conditionally immortalized human podocytes (selected based on podocyte specific gene expression) and 2) conditionally immortalized mouse podocytes. Cellular phenotypes and gene expression were measured using high content screening (HCS), qPCR and western blots. For assessment of diabetic serum as a stressor, serum was pooled from db/db and control mice. Differential cytotoxicity of db/db sera was measured by quantifying cytoskeletal integrity, cell morphology, heme oxygenase-1 expression and cell adhesion.

Results: C5 podocytes were benchmarked to primary human podocytes using 1) expression of WT-1, podocin, synaptopodin and a-smooth muscle actin and 2) cytoskeletal and cell cycle phenotypes. C5 cells were also evaluated by comparing gene expression profiles in response to TGF-b treatment. C5 podocytes were judged to be similar to primary human podocytes based on these analyses. Current cellular models of podocyte protection often use the stressors puromycin aminonucleoside and TGF-b. We demonstrate cytoprotection by multiple reference compounds with these insults. We have also increased the disease relevance of stressors by showing that serum isolated from proteinuric db/db mice differentially elicits podocyte injury across multiple parameters.

Conclusions: Our results validate the use of conditionally immortalized C5 podocytes by benchmarking against primary human podocytes. We have also enhanced the pathologic relevance of models of podocyte injury by incorporating key disease-relevant stressors and readouts.

Hypoxia Stimulates the Expression of Tissue Factor in Human Podocytes in Culture
Ikuyo Narita,[1] Michiko Shimada,[1] Reiichi Murakami,[1] Masayuki Nakamura,[1] Norio Nakamura,[1] Moin Saleem,[2] Peter W. Mathieson,[3] Hideaki Yamabe,[1] Ken Okumura.[1] *[1]Nephrology, Hirosaki Univ, Hirosaki, Japan; [2]Renal Academic Unit, Univ of Bristol, Bristol, United Kingdom; [3]Univ of Hong Kong, Hong Kong, China.*

Background: Hypoxia contributes to tubulointerestitial injury, however, the effect on podocytes and its underlying mechanisms are less well understood. Tissue factor (TF) is the initiator of extrinsic coagulation pathways and is also related to various biologic effects such as proliferation, inflammation, and cell motilities. In this study, we tested the expressions of TF and tissue factor pathway inhibitor (TFPI) in the hypoxic conditions. We further tested the roles of known transcription factors of TF such as, nuclear factor-κB (NF-κB) and early growth response gene-1 (Egr-1), as well as hypoxia-inducible factor-1α (HIF-1α) which regulates numerous changes in hypoxia.

Methods: Conditionally immortalized human podocytes were grown at 33°C and differentiated at 37°C. The cells were treated in normoxic or hypoxic conditions. mRNA expressions of TF and TFPI were analyzed by quantitative RT-PCR, and protein levels of TF in the cell lysate and TFPI in the supernatant were tested by ELISA. The expression of TF and HIF-1α were demonstrated by immunofluorescent staining. We used siRNA for the temporal knockdown of HIF-1α and Egr-1, and pyrrolidine dithiocarbamate (PDTC) for the inhibition of NF-κB.

Results: Hypoxia increased mRNA expression of TF (6h: 2.3±0.05 fold, $p<0.001$, 24h: 5.6±2.4 fold, $p<0.05$) and suppressed TFPI (6h: 0.54±0.04 fold, $p<0.05$, 24h: 0.24±0.06 fold, $p<0.001$) compared with normoxia. The protein levels of TF in the cell lysate were increased and TFPI in the supernatant were decreased. The TF staining was enhanced in

the cytoplasm of podocyte. As expected, HIF-1α was strongly stained in the nuclei of podocytes exposed to hypoxia for 6h. The expression of TF was not affected by HIF-1α siRNA, and neither Egr-1 siRNA. Whereas, PDTC reduced the induction of TF by hypoxia.

Conclusions: Hypoxia upregulated the expression of TF in human podocyte NF-κB dependently, and HIF-1α and Egr-1 independently. These changes may be related to the podocyte disorders and lead to proteinuria in the hypoxic condition.

PUB087

Integrity of the Mature APOL1 Protein Is Indispensable for Its Toxicity Xiqian Lan,[1] Hongxiu Wen,[1] Ashwani Malhotra,[1] Karl Leon Skorecki,[2] Pravin C. Singhal.[1] *[1]Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY; [2]Medicine, Rambam Health Care Campus, Haifa, Israel.*

Background: Several clinical reports have demonstrated that the development of higher rates of non-diabetic glomerulosclerosis (GS) amongst African Americans can be attributed to two coding sequence variants (G1 and G2) in the APOL1 gene. Recent studies indicate that the gene products of these APOL1 risk variants have augmented toxicity in kidney cells. The APOL1 protein is composed of several functional domains, including signal peptide (SP), pore forming domain (PFD), membrane address domain (MAD), and SRA-interacting domain. However, it is not clear, which domain contributes to APOL1 induced cellular toxicity. In case, specific domain is contributing to APOL1-induced cellular toxicity, it will suggest us to design therapeutic strategy to target the specific domain.

Methods: To investigate the relative contribution of each domain to cell injury, we constructed serial of expression vectors to delete each domain, we transfected these vectors into the human embryonic kidney cell line 293T, and then compared the cytotoxicity. In addition, we conducted studies in which APOL1 wild type (G0) was co-transfected in combination with G1 or G2 to see whether G0 could counteract the toxicity of the risk variants.

Results: The results showed that deleting the SP did not abolish the toxicity of APOL1, though deletion of 26 amino acid residues at the N-terminal partially decreased the toxicity. Deleting PFD or MAD or SRA-interacting domain abolished toxicity, while, overexpressing each domain alone could not cause toxicity to the host cells. Deletion of the G2 sites while retaining G1 sites in the risk state resulted in persistent toxicity. Either deletion or exchanging the BH3 domain in the PFD led to complete loss of the toxicity in this experimental platform. Adding G0 to either G1 or G2 did not attenuate the toxicity of the either moiety.

Conclusions: These findings indicate that the integrity of the mature APOL1 protein is critical for its toxicity.

PUB088

Human Podocyte Depletion: The Effects of Aging and Hypertension Victor G. Puelles,[1] Luise A. Cullen-McEwen,[1] Jinhua Li,[1] Peter G. Kerr,[2] Wendy E. Hoy,[3] John F. Bertram.[1] *[1]Dept of Anatomy and Developmental Biology, Monash Univ, Melbourne, Victoria, Australia; [2]Dept of Nephrology, Monash Medical Centre, Melbourne, Victoria, Australia; [3]Centre for Chronic Disease, The Univ of Queensland, Brisbane, Queensland, Australia.*

Background: Podocyte depletion plays a major role in the development and progression of glomerulosclerosis. Many kidney diseases are more common in older age, and usually coexist with the presence of hypertension. We hypothesize that podocyte depletion develops with aging and is exacerbated by the presence of hypertension.

Methods: Kidneys from 21 adult Caucasian American males without overt renal disease were collected at autopsy in Mississippi, USA. Subjects were categorized based only on age as young adults, middle-aged adults and older adults. Subjects were also categorized based on age and hypertension as young normotensives, older normotensives, and older hypertensives. Demographic data were collected from available medical records. Design-based stereology was used to estimate individual glomerular volume (IGV), podocyte number and podocyte density. Data are presented as mean±SD.

Results: Glomeruli from young adults (22.0±2.7 years; n=6) were small (1.72±0.50 $x10^6 mm^3$), and contained 457±97 podocytes and 278±66 podocytes per $10^6 mm^3$ of glomerular tissue. Glomeruli from older adults (60.0±8.6 years; n=7) were larger (2.94±1.41 $x10^6 mm^3$; P<0.001), contained fewer podocytes (390±105; P<0.05) and had lower podocyte density (156±65 podocytes per $10^6 mm^3$; P<0.0001). Among normotensives, older age was associated with a 15% increase in IGV (P=0.28), a 12% decrease in podocyte number (P=0.06) and a 17% decrease in podocyte density (P<0.01). Glomeruli from hypertensives and normotensives contained similar numbers of podocytes, but hypertensives had larger glomeruli (P<0.0001) and a markedly lower podocyte density (P<0.001).

Conclusions: These findings demonstrate that both aging and hypertension are independent and additive contributors to podocyte depletion in this cohort of white American men without overt kidney disease.

PUB089

Alport Nephropathy Progression Involves Altered Glomerular Mechanical Properties and Activation of the Unfolded Protein Response Addie Embry,[1] Liping Liu,[1] Leslie A. Bruggeman,[2] Paul A. Janmey,[3] R. Tyler Miller.[1] *[1]Medicine, UTSW, Dallas, TX; [2]Medicine, CWRU, Cleveland, OH.*

Background: Tissue and cell mechanics are important factors in the development and maintenance of tissues but are not well defined in renal disease. We determined the biophysical properties of glomeruli over the course of disease in the Col4a3-/- (Alport) mouse.

Methods: Glomerulur EMod was measured with microindentation, gene transcript levels with qRT-PCR and immunofluorescence, and kidney structure with histology.

Results: $Col4a3^{-/-}$ kidneys have normal histology, no proteinuria, and a normal glomerular E_{Mod} (2,200Pa) through 2 mo of age. At approximately 4 mo, early interstitial and glomerular fibrosis and proteinuria appear, and the glomerular E_{Mod} decreases (~1400Pa). Glomerular softening is characteristic of injured glomeruli, is associated with injured podocytes, and could lead to capillary injury even with normal hemodynamics. By 6 mo, the glomeruli regain their original E_{Mod} (~ 2,200 Pa) but with increased proteinuria and more severe glomerular and interstitial fibrosis. By 7-8 mo, the glomerular E_{Mod} increases (~ 2,600 Pa) with further increases in proteinuria and glomerular and interstitial fibrosis. At 2 mo, glomerular transcripts for matrix and fibrotic factors (CTGF, a-SMA, filamin, lysyl oxidase) are increased and remain so, demonstrating early responses of cells to alter their mechanical environment. Transcripts associated with UPR activation (BiP, CHOP, grp94) are elevated, suggesting that loss of the Col4a3 chain leads to activation of the UPR. Tunicamycin-treated glomeruli demonstrated a markedly reduced E_{Mod} (~1100Pa), suggesting that UPR activation causes glomerular injury.

Conclusions: Biophysical abnormalities occur early in the course of this Alport model, suggest that the reduced E_{Mod} of glomeruli (increased deformability) may lead to mechanical injury of capillaries even with normal hemodynamic force, that cells of glomeruli respond by producing proteins that will reduce deformability, and that glomerular or podocyte injury may be attributable to activation of the UPR.

PUB090

A New Assay to Study Podocyte (De)Differentiation Frances Kindt, Karlhans Endlich, Nicole Endlich. *Anatomy and Cell Biology, Univ Medicine Greifswald, Greifswald, Germany.*

Background: Podocytes play an essential role in the formation and maintenance of the glomerular filtration barrier. Glomerular disease is associated with podocyte damage, frequently resulting in podocyte dedifferentiation. The loss of podocyte differentiation is poorly understood. Moreover, there are no drugs available that could halt or even reverse podocyte dedifferentiation. Since podocytes of isolated glomeruli have long been known to spontaneously loose their highly differentiated state over time, we established an assay to follow dedifferentiation of living podocyte in isolated glomeruli over time.

Methods: Using magnetic separation with dynabeads, glomeruli were isolated from transgenic mice that express cyan fluorescence protein (CFP) under control of a nephrin promoter fragment (Cui et al., <em style=”font-family: ‘Times New Roman’; font-size: 16px;”>J. Am. Soc. Nephrol.[/italic] 16: 3247-55, 2005).

Results: Isolated glomeruli were mostly free of Bowman’s capsule, exhibited minimal cell damage as assessed by propidium iodide, showed intact immunostaining for nephrin, and possessed intact interdigitating foot processes as judged by scanning electron microscopy. Isolated glomeruli were cultured for up to 9 d in RPMI containing 10% FBS. To quantify CFP fluorescence as a measure of differentiation, we recorded z-stacks of several glomeruli by confocal laser scanning microscopy on each day. Mean total fluorescence intensity per glomerulus (MFG) was calculated from z-stacks after background correction. MFG remained stable for 5 d. Thereafter, MFG gradually decreased to 10% of the initial value on day 9. Dedifferentiation of podocytes could be accelerated by treatment of isolated glomeruli with doxorubicin, strongly decreasing MFG within the first three days.

Conclusions: In summary, we established a new assay to study podocyte (de) differentiation. This assay may help to understand the molecular mechanisms of the loss of podocyte differentiation, and may allow to screen for compounds that stabilize podocyte differentiation.

PUB091

Methods to Selectively Remove Murine Endothelial Glycocalyx *In Vivo* Using Glycosaminoglycan Digesting Enzymes without Causing Non-Target Effects Karen L. Onions, Anjiola Onifade, Chris R. Neal, Monica Gamez, Gavin Iain Welsh, Andy Salmon, Simon C. Satchell, Rebecca R. Foster. *Academic Renal Unit, Univ of Bristol, Bristol, United Kingdom.*

Background: The endothelial glycocalyx (e-GLX) is an important component of the glomerular filtration barrier (GFB), damage to which increases vascular permeability and microalbuminuria. Jeansson and Haraldsson previously used glycosaminoglycan (GAG) digesting enzymes to study the role of the e-GLX in glomerular permeability. However, e-GLX removal was not directly quantified. The aim of this research was to confirm removal of systemic e-GLX and identify any non-targeted effects in the glomerular or coronary microcirculation.

Methods: Mice were injected I.V with chondroitinase (Ch) and hyaluronidase (Hy) at a high (Ch: 87 mU/g, Hy: 15U/g or low (Ch: 0.087 mU/g, Hy: 15 mU/g) dose. Mice

were whole body (cardiac) perfusion fixed with gluteraldehyde containing Alcian blue to stain the e-GLX. Transmission electron microscopy (TEM) was used to image the ultrastructure of the heart and glomerular microcirculation, which was quantified using defined parameters in ImageJ.

Results: In the heart, the low dose significantly reduced glycocalyx coverage to 62% compared to sham (84%) and high (87%) dose groups (p=0.0227 one way ANOVA). The high dose caused an increase in vesicle number within the endothelial basement membrane (3.3/um) compared to controls (1.2/um) (p = 0.0328 t-test). Within the parameters of this analysis there were no structural changes to other components of the GFB or coronary circulation at either enzyme concentration.

Conclusions: These results indicate that a low dose of GAG digesting enzymes targets systemic e-GLX loss and does not cause any non-target effects. This technique will be utilised to study the role of the e-GLX in glomerular permeability. Increasing understanding in this area will identify how e-GLX contributes to glomerular albumin permeability in different pathological scenarios and may highlight new therapeutic targets. This work was funded by the British Heart Foundation (FS/13/9/29957).

PUB092

Dietary Salt Restriction Induces New, Single Mesenchymal Stem Cell-Derived Progenies in the Glomerulus and Proximal Tubule Donna Ralph, Kengo Kidokoro, Anne Riquier-Brison, Janos Peti-Peterdi. *Physiology & Biophysics, Univ of Southern California, Los Angeles, CA.*

Background: Salt restriction is known to slow down the progression of chronic kidney disease (CKD) and improve albuminuria via blood pressure-independent structural changes in the glomerulus, however the underlying mechanisms have been elusive. We aimed to track the migration and fate of individually identified resident mesenchymal stem/progenitor cells in the renal cortex in intact mouse kidneys.

Methods: In vivo serial multiphoton microscopy (MPM) of the same glomeruli over several days, and genetic cell fate tracking using histology in tamoxifen-induced NG2CreERT2-Confetti mice expressing either CFP/GFP/YFP/RFP were performed during salt deficient diet+ACE inhibition for 10 days.

Results: At baseline, a few cells belonging to the NG2 lineage (NG2+) were observed in a scattered pattern throughout the renal interstitium. Serial MPM showed that in response to salt deprivation, monochromatic (either blue/green/yellow or red) multi-cellular tracing units appeared at the glomerular vascular pole, mesangium, Bowman's capsule, and in the proximal tubule within 10 days. Subsequent histology of NG2-Confetti mouse kidneys found that the highest density of NG2+ cells was in the outer medulla, and confirmed the presence of 3-10 cells-containing monochromatic (clonal) tracing units along the cortical vasculature, afferent arteriole, and within the glomerulus (including mesangial and parietal epithelial cells, and a very few podocytes) and the proximal tubule. Spherical or stellate-shaped NG2+ cells were observed in the Bowman's space and in the proximal tubule lumen suggesting cell migration.

Conclusions: In summary, our data are consistent with highly dynamic cellular remodeling of the renal interstitium, vasculature, glomerulus, and the proximal tubule by single progenitor cells. These results also suggest the presence of a complex nephron repair program which is augmented in response to salt deprivation.

PUB093

Beraprost Ameliorates Renal Function and Reduce Uremic Toxin in GBM Nephropathy in Rat and in Humans (Small Number Study) Yasuno Mukaiyama, Yuki Oba, Koichi Kikuchi, Hisato Shima, Eikan Mishima, Yasutoshi Akiyama, Takehiro Suzuki, Daisuke Saigusa, Sadayoshi Ito, Takaaki Abe. *Tohoku Univ Graduate School of Medicine.*

Background: In CKD patients, the accumulation of uremic toxins exacerbates renal damage. Beraprost sodium (BPS) is prostacyclin analogue and is mainly used to treat atherosclerotic obliterans. Recently, Several reports show that BPS reduced progression of renal damages in CKD. To identify the reno-protective effect of BPS, we measured uremic solutes by capillary electrophoresis with mass spectrometry (CE-MS) in anti-GBM Glomerular Nephropathy(GN) rat model as well as 4 CKD patients before and 5 month after BPS administration.

Methods: A comprehensive and quantitative analysis of charged metabolites by CE-MS was performed. We obtained serum from (1) Normal rats, GBM GN rats and BPS-administered GBM GN rats and (2) 4 CKD patients treated with BPS. We performed CE-MS and a comprehensive and quantitative analysis of charged metabolites. All the experiments were performed under Animal and Ethical Committee approval.

Results: Among 500 organic anions and cations, 16 anionic solutes and 42 cationic solutes were further examined. Among the anionic solute that increased in GN rats, the concentration of 2 anionic solutes(Gluconate and Citrate) are ameliorated by BPS treatment. Among the cationic solute that increased in GN rats, the concentration of 10 cationic solutes (N,N-Dimetylglycine, Creatinine, Uridine, Citrulline, Creatine, Hydroxyproline, Alanine, Arginine, Glycine, Cystathionine) also increased in GN and all of them are reduced by BPS treatment. Conversely, the concentration of 8 metabolites were decreased in GN rats, and by BPS treatment, the reduced concentration of tryptophan recovered to the normal level. Well-known uremic toxins such as ADMA, SDMA and 1-metyladenosine are also reduced by BPS in GN rats. In addition, in humans, the serum concentration of creatinine and Indoxyl sulfate are reduced by BPS after 6 month administration.

Conclusions: BPS reduced uremic toxins in CKD rats and ameliorates renal dysfunction and the serum level of indoxyl sulfate in CKD patients. These results suggest that BPS has a potential to prevent the progression of CKD.

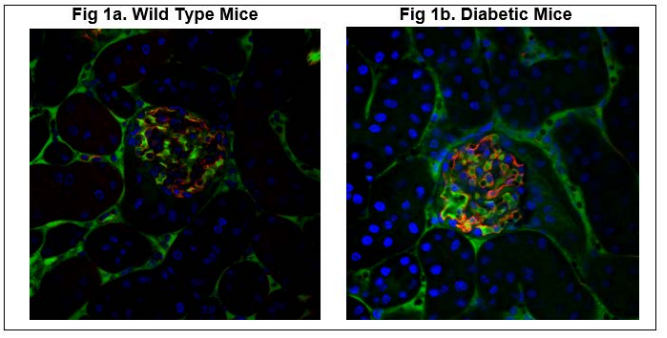
PUB094

A Novel Method to Measure Glomerular Permeability Jin Wei, Shaohui Wang, Lei Wang, Gensheng Zhang, Jie Zhang, Byeong Cha, Kay-Pong D. Yip, Ruisheng Liu. *Molecular Pharmacology & Physiology, Univ of South Florida, Tampa, FL.*

Background: Glomerular capillaries are relatively impermeable to proteins, but in certain kidney diseases, such as diabetic nephropathy, the glomerular permeability (GP) is increased and some of the lower molecular weight (LMW) proteins, especially albumin, are filtered through the glomerular barrier into the Bowman's space. Increased GP is a hallmark for many kidney diseases. Proteinuria is often implicated for impaired GP. However, since LMW proteins can be reabsorbed by proximal tubules, proteinuria is detected only when the GP is significantly increased. Recently, real-time quantification of GP can be visualized by two-photon microscopy, but it can only be applied to superficial nephrons, where laser can penetrate, in Munich-Wistar rats. We developed a novel method to monitor GP in C57/BL6 mice by using florescent lysine-fixable dextran conjugates without these limitations.

Methods: 100µl Tomato Lectin 594 (endothelial cell marker) plus 50µl 40 KD lysine-fixable dextran 488 (fluid phase marker) were injected intravenously. The kidneys were removed 1 min later and put into liquid nitrogen immediately for 10 minutes followed by fixation with 10% Formalin on ice overnight. Then 100µm thick sections were prepared using a vibratome and the florescent images were collected with two-photon microscopy. The ratio of florescent intensity in bowman's space over that in glomerular capillary lumen was used as an index of GP.

Results: In WT mice, the GP is extremely low with a ratio of 0.16±0.08%, N=6 **(figure1)**. In contrast, in diabetic mice induced by alloxan for 8 weeks, the GP is significantly increased with a ratio of 5.9±1.3%, N=6 .



Conclusions: In summary, we developed a novel and sensitive method to monitor changes in GP using two-photon microscopy, which can be used for rodents and bigger animals.

PUB095

Vasopressin Regulates the Uptake of Extracellular Vesicles by Kidney Collecting Duct Cells Wilna Oosthuyzen,[1] Jessica R. Ivy,[1] Jonathan Street,[2] Andrea Caporali,[1] David J. Webb,[1] Chris Gregory,[3] Matthew A. Bailey,[1] James W. Dear.[1] *[1]Centre for Cardiovascular Science, Univ of Edinburgh, United Kingdom; [2]National Inst of Diabetes and Digestive and Kidney Diseases, National Insts of Health; [3]MRC/Univ of Edinburgh Centre for Inflammation Research, Univ of Edinburgh, United Kingdom.*

Background: Urine contains extracellular vesicles (ECVs) originating from the circulation and all cells lining the urinary tract. ECVs are a route of inter-cellular communication along the nephron able to transfer protein and RNA. It is not known whether this is a regulated process analogous to other cell-to-cell signalling systems.

Methods: Kidney cortical collecting duct cells (CCDs) were stimulated with desmopressin, a vasopressin analogue, and uptake of fluorescently-loaded or microRNA-loaded ECVs was measured. In mice, fluorescently-loaded ECVs were intravenously injected before and after administration of the V2 antagonist, tolvaptan, and urinary ECV excretion was measured. By combining antibodies to nephron segment-specific proteins with nanoparticle tracking analysis we measured human urinary ECV excretion in central diabetes insipidus (DI) and after radiocontrast exposure (n=37).

Results: Desmopressin stimulated ECV uptake into CCDs via V2 receptor stimulation. Intra-cellular uptake of ECVs was confirmed by microRNA specific mRNA down-regulation. Mechanistically, ECV uptake in response to desmopressin required cyclic AMP production, was mediated by clathrin-dependent endocytosis and was selective for ECVs from kidney tubular cells. In mice, basally, 2.5% of injected ECVs were recovered in urine; tolvaptan treatment resulted in a 5-fold increase. In DI, desmopressin reduced the excretion of ECVs derived from upstream glomerular and proximal tubule cells. In patients exposed to radiocontrast, urinary ECVs from the glomerulus were positively correlated with the tubular injury markers KIM-1 and NGAL.

Conclusions: Tubular ECV uptake is a specific, hormonally regulated process that is reduced with injury. Physiologically, ECVs are a mechanism of inter-cellular communication; therapeutically, ECVs represent a novel vehicle by which RNA therapy could be targeted for the treatment of kidney disease.

PUB096

Systemic Hypothermia and Pro-Inflammatory Cytokines Massimo de Cal,[1] Grazia Maria Virzì,[1] Alessandra Brocca,[1] Salvador Roberto Lopez,[1] Jose Luis Salas,[1] Stefano Marcante,[2] Silvia De Rosa,[1] Claudio Ronco.[1] *[1]Nephrology, S.Bortolo Hospital, Vicenza, Italy; [2]ICU, S.Bortolo Hospital, Vicenza, Italy.*

Background: Cytokines produced by renal tubular epithelial cells are critical factors in inflammatory processes of renal ischemia-reperfusion injury. Increased levels of cytokines have been reported after resuscitation from cardiac arrest. Pro-inflammatory cytokines, such as IL-1β, IL-6 and IL-18, produced in the kidney during ischemia-reperfusion injury, are able to contribute to the renal damage. The purpose of this investigation was to define the proinflammatory cytokines response after resuscitation and during extended observation following therapeutic hypothermia phases.

Methods: We performed a prospective observational study in 36 post-cardiac arrest patients treated with Induced Hypothermia (IH) with two different cooling device:1)Artic Sun; 2)Blanket. On Admission time and at 12, 24, and 72 hours after the start of treatment, blood and urine samples were collected. Plasma cytokines were measured by ELISA.

Results: During IH, we observed a decrease of IL-6, IL-1β and IL-18u levels in both groups, and an increase of inflammatory during rewarming phase. The results are showed in table.

Variable		Artic Sun (26 pts)	Blanket (10 pts)	*p* value
IL-1β	Adm	18 (12-20)	27 (9-43)	0.227
	12hrs	17 (13-18)	17 (9-18)	0.841
	24hrs	19 (13-21)	28 (10-51)	0.179
	72hrs	20 (12-24)	35 (13-53)	0.089
IL-6	Adm	102 (40-121)	79 (29-104)	0.136
	12hrs	100 (28-148)	72 (12-138)	0.194
	24hrs	57 (33-77)	63 (20-112)	0.406
	72hrs	59 (34-61)	67 (30-84)	0.713
IL-18u	Adm	412 (363-978)	847 (189-1071)	0.749
	12hrs	327 (326-365)	265 (201-327)	0.028
	24hrs	348 (290-371)	140 (42-295)	0.0005
	72hrs	505 (332-538)	264 (44-337)	0.048

Conclusions: Optimal rewarming rate is unknown. Adverse effects from suboptimal rewarming could diminish a protective effect from hypothermia. These biomarkers may serve as indicator of an individual patient's place in the injury-repair continuum. Further investigations are needed.

PUB097

Impact of Different I.V. Iron Preparations on Monocyte Function and Differentiation Adam M. Zawada,[1] Lisa H. Fell,[1] Sarah Seiler,[1] Martina Sester,[2] Danilo Fliser,[1] Gunnar H. Heine.[1] *[1]Internal Medicine IV, Saarland Univ Medical Center, Homburg, Saarland, Germany; [2]Dept of Transplant and Infection Immunology, Saarland Univ Medical Center, Homburg, Saarland, Germany.*

Background: Treatment of iron deficiency with intravenous (i.v.) iron is a first-line strategy to improve anemia and quality of life in patients with chronic kidney disease (CKD). However, in vitro experiments demonstrated that certain i.v. iron preparations may have immunological side-effects. In the present study we now investigated substance-specific impacts of different i.v. iron preparations on monocytic function and differentiation.

Methods: We in vitro stimulated monocytes with different concentrations (0.133 mg/ml, 0.266 mg/ml, 0.533 mg/ml) of iron sucrose (IS), sodium ferric gluconate (SFG), ferric carboxymaltose (FCM), and iron isomaltoside 1000 (IIM) and assessed monocytic adhesion and transmigration capacity. Monocyte differentiation into M1 and M2 macrophages and dendritic cells (DCs) was flow-cytometrically analyzed, and functional characteristics of monocyte derived cells were tested. Finally, we performed ultra-deep miRNA sequencing to characterize dysregulated signaling pathways in iron stimulated monocyte derived cells.

Results: IS and SFG increased monocytic adhesion, while transmigration was not affected by any preparation. The expression of M1 (CD40) and M2 (CD16, CD206) markers as well as the phagocytosis capacity were significantly reduced in IS and SFG stimulated macrophages. IS and SFG down-regulated CD1c and CD86 in DCs and up-regulated CD141 and HLA-DR. FCM affected macrophage and DC phenotype and function to a lesser degree, and IIM had no measurable immunological effects. In miRNA expression analysis we found IS to strongly dysregulate miRNAs which are linked to TLR and MAPK signaling pathways (e.g. miR-146b-5p, miR-155-5p).

Conclusions: Our findings demonstrate that less stable i.v. iron preparations like IS and SFG substance-specifically affect monocyte function and differentiation into macrophages and DCs in vitro. Future clinical trials should delineate in how far these observations will lead to clinically relevant changes in immune responses and thus affect the infection risk in CKD patients.

PUB098

The Involvement of p38 MAPK in Neutrophil Bactericidal Dysfunction of Hemodialysis Patients Yasutaka Kamikawa, Shinji Kitajima, Akinori Hara, Norihiko Sakai, Miho Shimizu, Kengo Furuichi, Yasunori Iwata, Takashi Wada. *Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Japan.*

Background: Mortality from infection has been reported to be higher in hemodialysis (HD) patients than that in healthy subjects. However, the precise mechanism causing it remains to be investigated. Neutrophils play crucial roles in host defenses against bacterial infection. Therefore, we investigated the impact of neutrophil inflammatory signal on bactericidal function in HD patients.

Methods: Four HD patients and six healthy subjects were recruited for this study. None of HD patients had diabetes, cardiovascular disease and cancer. Neutrophils were isolated from peripheral blood by density gradient centrifugation. The purity was tested by flow cytometry after lactoferrin staining. Microarray analysis was performed to assess global gene expression in leukocytes. Neutrophil bactericidal function was evaluated by the growth rate of *Staphylococcus aureus* (*S.aureus*) after co-culture of it with neutrophils obtained from HD patients or healthy subjects. Reactive oxygen species (ROS) production and myeloperoxidase (MPO) activity were analyzed by fluorescence intensity.

Results: Microarray analysis showed the impairment of p38 mitogen activated protein kinase (MAPK) signal in neutrophils from HD patients. The growth rate of *S.aureus* was higher in HD patients than that in healthy subjects (490.1±147.1%, 144.5±49.4%, respectively; $p<0.01$) suggesting that neutrophil anti-bacterial killing function was dysregulated in HD patients. The levels of ROS from neutrophils after co-culture with *S.aureus* were lower in HD patients than those in healthy subjects (14.6±8.3, 32.4±15.4, respectively; $p<0.01$). On the other hand, there was no difference of MPO activity between both groups. To confirm the importance of p38 MAPK, we examined the effect of the selective pharmacological p38 MAPK inhibitor SB202190 on neutrophil bactericidal function. The treatment with SB202190 suppressed anti-bacterial killing function as well as ROS production in neutrophils.

Conclusions: Impaired of p38MAPK signaling pathway might contribute to the suppression of neutrophil bactericidal function in HD patients through the dysregulation of ROS production.

PUB099

Detached c-Abl from Nephrin Contributes to Cytoskeleton Remodeling in Podocytes Yiqiong Ma, Qian Yang, Zhentong Zhong, Zhilong Ren, Wei Liang, Cheng Chen, Huiming Wang, Guohua Ding. *Div of Nephrology, Renmin Hospital of Wuhan Univ, China.*

Background: Previous studies showed that nephrin is required for cytoskeleton remodeling in podocytes. However, its specific mechanism remains incompletely understood. c-Abl is a non-receptor tyrosine kinase involved in cytoskeleton regulation, which is a candidate of signaling proteins interacting with SH2/SH3 domains of nephrin. The present study evaluated whether c-Abl contributes to nephrin-dependent cytoskeleton remodeling of podocytes.

Methods: Colocalized expression of nephrin and c-Abl was evaluated in glomeruli of patients with nephrotic syndrome (NS) by double immunolabeling assays. In *vitro*, AngII was used to promote cytoskeleton remodeling of podocyte. Differentiated murine podocytes were exposed to Ang II (10^{-7}M) for 24h. Cytoskeleton configuration was evaluated by FITC-phalloidin staining. Western blotting was performed to evaluate the expression and phosphorylation of nephrin and c-Abl. Colocalization of nephrin and c-Abl was determined by confocal microscopy and co-immunoprecipitation analysis. Co-immunoprecipitation was conducted in COS7 cells co-transfected with CD16-CD7-nephrin and SH2/SH3-defective c-Abl vectors to identify the domain of c-Abl binding with nephrin.

Results: The glomerular staining of nephrin and c-Abl indicated that the colocalization in patients with NS was decreased compared with that in control patients. In cultured podocytes, AngII treatment induced dephosphorylation of nephrin and diminished the interaction between nephrin and c-Abl. In addition, F-actin disruption was aggravated by treatment of both AngII and overexpression of c-Abl. Furthermore, the disorganized cytoskeleton stimulated by cytochalasin D in COS7 cells was restored by cotransfection with phosphorylated CD16-CD7-nephrin and c-Abl full-length constructs. Co-immunoprecipitation showed that phosphorylated CD16-CD7-nephrin interacted with wild type c-Abl, not with SH2/SH3-defective c-Abl.

Conclusions: These results indicate that phosphorylated nephrin is able to recruit c-Abl in a SH2/SH3-dependent manner and detached c-Abl from nephrin contributed to cytoskeleton remodeling in podocyte.

Nrf2 and NF-κB mRNA Expression in Chronic Kidney Disease: A Focus on Non-Dialysis Patients Denise Mafra,[1] Viviane Oliveira Leal,[2] Juliana Saldanha,[1] Milena Barcza Stockler-Pinto,[3] Ludmila Fmf Cardozo,[3] Felipe Rizzetto Santos,[4] Alex Sandro Duarte Albuquerque,[4] Maurilo Leite.[4] *[1]Graduate Program in Medical Sciences, Federal Univ Fluminense, Rio de Janeiro, Brazil; [2]Pedro Ernesto Univ Hospital, State Univ of Rio de Janeiro (UERJ), Rio de Janeiro, Brazil; [3]Graduate Program in Cardiovascular Sciences, Federal Univ Fluminense, Rio de Janeiro, Brazil; [4]Div of Nephrology, Federal Univ of Rio de Janeiro (UFRJ), Rio de Janeiro, Brazil.*

Background: Nuclear factor erythroid 2-related factor 2 (Nrf2), a regulator of genes encoding antioxidant and detoxifying enzymes appear to be downregulated in chronic kidney disease patients undergoing hemodialysis (HD). However, data regarding the expression of Nrf2 in non-dialysis patients are scanty. Thus, the aim of this study was to evaluate Nrf2 and nuclear factor kappa-B (NF-κB) mRNA expression in non-dialysis patients, comparing with data from HD patients.

Methods: 20 non-dialysis patients, 20 HD patients and 11 healthy subjects were enrolled. The peripheral blood mononuclear cells were isolated and processed for the evaluation of NF-κB and Nrf2 expression by quantitative real-time polymerase chain reaction.

Results: Nrf2 mRNA was significantly higher in non-dialysis when compared to HD patients but similar to healthy individuals. Inversely, NF-κB mRNA was lower in non-dialysis when compared to HD patients and also similar to healthy individuals i.e.

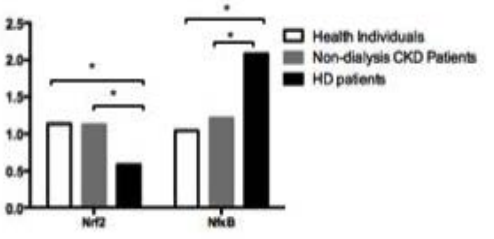

Figure 1. Nrf2 and NF-κB mRNA expression health individuals, non-dialysis and HD patients.

Nrf2 mRNA was positively correlated with NF-κB mRNA in non-dialysis patients and healthy individuals . By contrast, Nrf2 mRNA was inversely correlated with NF-κB mRNA in HD patients.

Conclusions: Non-dialysis patients may conserve regular homeostatic balance between Nrf2 and NF-κB expressions, being comparable to healthy individuals. As renal disease progresses to more advanced stages, an impaired Nrf2/NF-κB balance can be observed, as in HD patients.

PUB101

ERK 1/2 and ERK 5 Signaling Pathways via Renin Angiotensin System Activation Play Differential Regulatory Roles During the Progression of Glomerulonephritis Takashi Nagai,[1] Maki Urushihara,[1] Shuji Kondo,[1] Toshiaki Tamaki,[2] Shoji Kagami.[1] *[1]Dept of Pediatrics, Inst of Biomedical Sciences, Tokushima Univ Graduate School, Tokushima, Japan; [2]Dept of Pharmacology, Inst of Biomedical Sciences, Tokushima Univ Graduate School, Tokushima, Japan.*

Background: Although extracellular signal regulated kinase (ERK)1/2 and ERK5 are key kinases of signaling pathway involved in various cellular functions in kidney injury, the mechanism between those kinase and renin-angiotensin system (RAS) activation in glomerulonephritis (GN) have not been fully elucidated. This study was performed to clarify the potential role of ERK1/2 and ERK5 via RAS activation in the pathogenesis of GN.

Methods: We examined the expression of ERK1/2 and ERK5 in rat progressive model of GN induced by anti-glomerular basement membrane antibodies in Wistar Kyoto rats. In addition, the signal transduction pathway in angiotensin II (Ang II)-induced glomerular pathologic alterations were investigated in primary cultured mesangial cells (MCs).

Results: GN rat developed typical cellular crescent in glomeruli on day 7 and severe fibrocellular crescent and glomerulosclerosis were found on day 28. Immuno-staining of kidneys revealed that strong expression of phospho-ERK1/2 was observed on day 7 and phospho-ERK5 expression was markedly increased on day 28 of GN. Ang II type 1 receptor blocker (ARB) suppressed those augmentations. Macrophage infiltration and PCNA positive cells were seen on day 7 and collagen type 1 expression was enhanced on day 28, and ARB treatment reduced these expressions. Next, cultured MCs stimulated by Ang II showed significantly increases in MCP-1 and collagen type 1 expression, and cell proliferation. While optimized PD98059 that inhibited ERK1/2 phosphorylation abolished the elevation of MCP-1 expression ($P<0.01$) and cell proliferation ($P<0.01$), optimized BIX02189 that inhibited ERK5 phosphorylation abolished the elevation of collagen type 1 expression ($P<0.01$). ARB treatment attenuated these augmentations.

Conclusions: These data suggest that ERK1/2 regulates acute inflammatory reactions and ERK5 induces the development of chronic glomerular fibrosis during RAS activation in GN.

PUB102

Chinese Herbal Medicine for IgA Nephropathy, ShenPing Decoction, Blocks Platelet-Derived Growth Factor Signaling Pathway Activated by IgA1-Containing Immune Complexes in Human Mesangial Cells Xianwen Zhang,[1,2] Zhi qiang Huang,[2] Stacy D. Hall,[2] Lin Wang,[1] Yueyi Deng,[1] Bruce A. Julian,[2] Yiping Chen,[1] Jan Novak.[2] *[1]Longhua Hospital, Shanghai Univ of Traditional Chinese Medicine, Shanghai, China; [2]Univ of Alabama at Birmingham, Birmingham, AL.*

Background: IgA nephropathy (IgAN) is characterized by mesangial immunodeposits containing galactose-deficient IgA1 (Gd-IgA1) usually associated with mesangial proliferation and matrix expansion. There is no disease-specific therapy of IgAN, although a herbal medicinal prescription, ShenPing decoction (SP), has been used in China for decades to effectively treat IgAN. Mesangial cell proliferation in IgAN is likely induced by Gd-IgA1-containing immune complexes (CIC) and this process may involve activation of platelet-derived growth factor (PDGF) signaling pathway. We have shown previously that SP blocks the activation of PDGF pathway induced by PDGF. In this study, we investigated the effect of CIC on PDGF signaling pathway in human mesangial cells (hMC) and assessed the effects of SP on this pathway.

Methods: CIC were isolated from sera of IgAN patients using size-exclusion chromatography. Primary hMCs were incubated with PDGF or CIC for 15 min or 24 h with or without SP. Cellular proliferation was measured with Syto60. PDGF signaling was evaluated by SDS-PAGE and Western blotting.

Results: 24-h incubation with CIC increased MC proliferation and SP inhibited this effect. Stimulation of hMC with CIC increased phosphorylation of PDGFR and ERK1/2 after 15 min and 24 h. PDGFR degradation was not observed in CIC-treated group, which is different from PDGF. SP inhibited CIC- and PDGF-induced phosphorylation and degradation of PDGFR.

Conclusions: CIC induced cellular proliferation of hMC and activation of PDGF pathway without degradation of PDGFR, a normal negative feedback observed for PDGF. CIC possibly caused persistent activation of PDGF pathway. SP inhibited these effects. These findings indicate that SP likely contains component(s) targeting the PDGF/PDGFR system that may play a role in the mesangial injury of IgAN.

PUB103

Effects of Fluorofenidone on the Expression of Thioredoxin-Inter-Acting Protein and Thioredoxin of Human Peritoneal Mesothelial Cell in High Glucose and Lipopolysaccharide Yichen Chen, Jianfei Ma. *Nephrology, The First Affiliated Hospital of China Medical Univ, Shenyang, China.*

Background: Peritoneal dialysis is one of an important alternative therapies for end-stage kidney disease, But the occurrence of peritoneal dialysis correlation peritonitis has brought great resistance for the development of peritoneal dialysis.Significance of oxidative stress in peritoneal dialysis related peritonitis has been paid more and more attention.In cells that did not receive stimulation, Txnip combined with thioredoxin, when the elevated ROS concentration inside the cell, the formation of the compounds are separated. After dissociation Trx play its functions to remove ROS, whereas Txnip participation NLRP3 activation. Objective:To observe the effects of Fluorofenidone on the Expression of Txnip,Trx of HPMCs in High Glucose and Lipopolysaccharide.

Methods: The expression of Txnip and Trx mRNA was measured by real time-PCR,The level of Trx,Txnip,IL-6,TGF-b1 in the supernatants of HPMCs(HMrSV5) were measured by ELISA. Experimental groups:Control group;High glucose and LPS for different concentrations and different times group;Fluorofenidone intervene group.

Results: Compared with the normal control, high glucose and LPS can significantly increase the expression of Txnip,Trx,IL-6 and TGF-b1 in a concentration and time dependent manner, all have statistically significant($P<0.05$).Compared with 2.5% glucose and 10mg/L LPS group, Fluorofenidone can reduce the expression of Txnip,IL-6 and TGF-b1, increase the expression of Trx, all have statistically significant ($P<0.05$).

Conclusions: High glucose and LPS up-regulate the expression of Txnip,Trx,in the protein and gene levels,and increase the expression of IL-6 and TGF-b1 .Fluorofenidone could reduce the increase of Txnip, IL-6 and TGF-b1, and increase the express of Trx in HPMCs that have been pre-treated with high glucose and LPS. Fluorofenidone have the effect of anti-oxidant and anti-fibrosis.

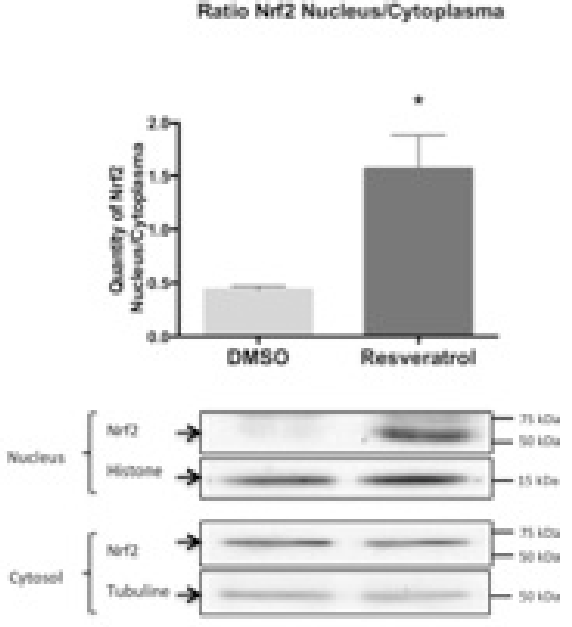
PUB104

Effects of Resveratrol on NRF2 Expression in Raw 264.7 Macrophages Cells and Non-Dialyzed CKD Patients Denise Mafra,[1] Juliana Saldanha,[1] Milena Barcza Stockler-Pinto,[2] Viviane Oliveira Leal,[3] Denis Fouque,[4] Christophe O. Soulage.[5] *[1]Pos-Graduate Program in Medical Sciences, Fluminense Federal Univ (UFF), Niterói, Rio de Janeiro, Brazil; [2]Pos-Graduate Program in Cardiovascular Sciences, Fluminense Federal Univ (UFF), Niterói, Rio de Janeiro, Brazil; [3]Div of Nutrition, Pedro Ernesto Univ Hospital, State Univ of Rio de Janeiro (UERJ), Rio de Janeiro, Brazil; [4]Dept of Nephrology, Centre Hospitalier Lyon Sud, Univ de Lyon, Pierre Bénite, France; [5]INSA de Lyon, CarMeN, INSERM U1060, Univ de Lyon, Villeurbanne, France.*

Background: Oxidative stress and inflammation are common in CKD. Bioactive compounds as resveratrol may modulate the Nrf2 expression, a transcription factor that could up-regulate cellular antioxidant systems. The aim of this study was observe Nrf2 expression in macrophages cells and in non-dialyzed CKD patients treated with resveratrol.

Methods: Mouse RAW 264.7 macrophages cells were treated with 50μM of resveratrol in DMSO 1% (v/v). Nucleus and cytoplasm were separated. Western Blot (WB) was performed to quantify Nrf2. qRT-PCR was performed to evaluate Nrf2 expression. 7 non-dialyzed CKD patients (5 women; 64.0±6.5 years; GFR 37.9±10.4mL/min) received 500mg of resveratrol/day for 4 weeks. qRT-PCR to evaluate Nrf2 expression was performed in PBMC before and after supplementation.

Results: Cells treated with resveratrol showed a significant activation of Nrf2 with an increase in the ratio nucleus/cytoplasm compared to control cells i.e.



p=0.02). The same was observed in qRT-PCR (p=0.02). In patients, we observed a trend to increase Nrf2 expression with resveratrol supplementation (p=0.06).

Conclusions: We concluded that both cells and patients treated with resveratrol increased Nrf2 expression. So, we suppose that supplementation with resveratrol can lead to an increase in oxidative stress and inflammatory status among CKD patients.

PUB105

Mitochondrial Implications of Glycolate Metabolism in Primary Hyperoxaluria Sonia Fargue, Tanecia Mitchell, John Knight, Ross P. Holmes. *Urology, Univ of Alabama at Birmingham, Birmingham, AL.*

Background: The primary hyperoxalurias (PH) are rare but severe inherited diseases characterized by an increased endogenous production of oxalate and calcium oxalate kidney stones in patients. Deficiency in alanine glyoxylate aminotransferase (AGT, deficient in PH1) or glyoxylate reductase (GR, deficient in PH2) have repercussions on the metabolism of the oxalate precursors glyoxylate and glycolate. Excessive amounts of glycolate are characteristic of PH1, through glyoxylate to glycolate cycling in the presence of glycolate oxidase (GO) and GR. Perturbations in glycolate metabolism may affect mitochondrial function in PH patients. The objective of this study is to assess how over-expression of these enzymes regulates glycolate and glyoxylate generation and mitochondrial function.

Methods: An established transformed CHO cells model was used in which cells express GO ± AGT or GR. Cells were incubated with glycolate or glyoxylate and the extracellular concentrations of oxalate and glyoxylate, and the induction of oxidative stress were analyzed. Cellular bioenergetics were assessed with a Seahorse XF-96 extracellular flux analyzer.

Results: The metabolism of glycolate by GO generated glyoxylate, oxalate and H_2O_2. Intracellular ROS were produced and cell viability was reduced. Mitochondrial respiration and the cellular bioenergetic reserve capacity were decreased following glycolate oxidation. The expression of AGT or GR reduced the untoward effects of glycolate metabolism to glyoxylate and oxalate.

Conclusions: The disruption of normal glycolate metabolism by GO, AGT and GR in a cell model causes the production of stress related metabolites and mitochondrial dysfunction. Limiting mitochondrial dysfunction might be a therapeutic approach in treating PH patients.

PUB106

Effect of Fasudil on Response Oxidative Stress in High Glucose and Lipopolysaccharide Induced Human Peritoneal Mesothelial Cells Ye Hu, Jianfei Ma. *Nephrology, The First Affiliated Hopital of ChinaMedical Univ, Shenyang, Liaoning Province, China.*

Background: Peritoneal fibrosis is a common cause of chronic peritoneal dialysis patients withdrew from peritoneal dialysis.Research shows that, there are oxidative stress exists in peritoneal dialysis patients.Rho/Rho kinase signaling pathway is involved in the regulation of multiple biological process, including inflammation,oxidative stress and fibrosis.The transcription factor NFE2 relatedfactor is a central regulator of cellular antioxidant responses.Rho kinase inhibitor fasudil is a Rock inhibitor which currently used in clinic and experiment,it can regulate cell proliferation,migration,adhesion and movement at the cellular level,it also can regulate a variety of factors in inflammation,thrombogenes is,oxidation and fibrosis at the molecular level.

Methods: By using the method of Real Time-PCR to detect the expression of RhoA,Rock1,Nrf2 and HO-1 mRNA;Western Blot to detect the expression of RhoA,Rock1,Nrf2 and HO-1 protein;.chemistry fluorescence test to detect the expression of ROS protein;chemical colorimetry to detect the expression of GSH-PX protein;ELISA detect the expression of TGF-b1 protein in the human peritoneal mesothelial cell.Experimental groups:Control group;High glucose and LPS for different concentrations group;Fasudil intervene group.

Results: Compared with the normal control, high glucose and LPS can significantly increase the expression of RhoA, Rock-1, ROS and TGF-b1,reduce the expression of Nrf2, HO-1 and GSH-PX in a concentration dependent manner, all have statistically significant($P<0.05$).Compared with 2.5% glucose and 10mg/L LPS group, fasudil can reduce the expression of RhoA, Rock-1, ROS and TGF-b1, increase the expression of Nrf2, HO-1 and GSH-PX, all have statistically significant ($P<0.05$).

Conclusions: High glucose and LPS up-regulate the expression of RhoA and Rock1 but reduce Nrf2 in the protein and gene levels,and increase the expression of ROS and TGF-b1 but reduce the expression of HO-1 and GSH-PX.Fasudil could reverse the increase of RhoA and Rock1 and the reduce of Nrf2 in HPMCs that have been pre-treated with high glucose and LPS,play the role of anti-oxidant and anti-fibrosis.

PUB107

Glucose Induces Mitochondrial Reactive Oxygen Species Through Carbonyl Stress and Respiratory Chain in Rat Peritoneal Mesothelial Cells Satoshi Shimada,[1] Takefumi Mori,[1] Yusuke Ohsaki,[2] Ikuko Oba,[1] Shinichi Sato,[1] Kenji Koizumi,[1] Sadayoshi Ito.[1] *[1]Nephrology, Endocrinologyand Vascular Medicine, Graduate School for Medicine, Tohoku Univ, Sendai, Miyagi, Japan; [2]Div of Integrative Renal Replacement Therapy, Graduate School of Medicine, Tohoku Univ.*

Background: Glucose and its degradation products (GDPs) play a major role in the peritoneal injury and affect peritoneal dialysis vintage. Peritoneal mesothelial cell dysfunction has been demonstrated to involve in peritoneal injury by glucose and GDPs. GDPs induced carbonyl stress has been demonstrated to induce mitochondrial dysfunction in several cell types. The present study was designed to determine the role of GDPs and respiratory chain in glucose induced mitochondrial ROS in peritoneal mesothelial cells.

Methods: Primary rat peritoneal mesothelial cells (RPMC) were isolated from Wister rats. Real-time mitochondrial superoxide was monitored using a specific fluorescent indicator Mito SOX red under fluorescence microscope equipped with temperature controlled chamber. RPMC was stimulated with 90 mmol/L of glucose and compared to those of vehicle. In separate experiments, RPMC was pre-incubated with a mitochondrial specific superoxide dismutase mimetic mitoTEMPO, respiratory chain inhibitor rotenone or carbonyl stress inhibitor pyridoxamine to determine the mechanism of glucose induced mitochondrial ROS production.

Results: 90 mmol/L glucose significantly increased mitochondrial superoxide production within 200 seconds in primary cultured RPMC (0.21±0.07 AU, n=8, $P<0.05$ vs vehicle). These responses were abolished when RPMC was pre-incubated with mitoTEMPO (-0.04±0.15 AU, n=5, P=0.34 vs vehicle), rotenone (0.00±0.06 AU, n=6, P=0.42 vs vehicle) and pyridoxamine (-0.34±0.34 AU, n=5, P=0.26 vs vehicle), indicating that mitochondrial superoxide production through respiratory chain and GDP.

Conclusions: The results in the present study indicate that glucose and GDP present in the PD effluent is responsible for oxidative stress in the peritoneal mesothelial cells by stimulation of mitochondrial ROS production, which could play a role in peritoneal function and injury during PD.

PUB108

Renal Cell Carcinoma Models: Effect of Chemopreventative Agents on the Carcinogenic Potential of Potassium Bromate in Human Renal Epithelial Cells Ismael Obaidi, Tara McMorrow. *School of Biomolecular and Biomedical Science, Conway Inst, Univ College Dublin, Ireland.*

Background: Renal Cell Carcinoma (RCC) is a leading cause of renal cancer worldwide. The cause of RCC remains unknown, with many chemicals implicated in its development. We have developed an in vitro model of RCC using the carcinogen, potassium bromate, to investigate potential prevention and possible treatment options of RCC. Chemoprevention is the use of different chemicals, natural or synthetic, to halt, block or reverse the process of carcinogenesis. It is one of the novel approaches that is being used to control cancer and it is a good alternative to the conventional therapies that are associated with a long list of side effects and limitations. These agents have antioxidant, anti-inflammatory, antiangiogenic effects and induce phase II enzymes, apoptosis, cell cycle arrest, and differentiation. They antagonize hormones and growth factor- induced tumor proliferation. The aim of this study was to examine the functional and mechanistic effects of chemopreventative agents on chemically induced RCC using human (RPTEC/ TERT1) renal cells and cancerous (ACHN) renal cell lines.

Methods: Morphological changes, viability and cytotoxicity assays were used to assess the toxicity of both the chemopreventatives and the carcinogen when RPTEC/ TERT1 cells were exposed to them individually and in combinations. Oxidative stress was also

assessed by measuring the intracellular concentration of H2O2. Oxidative stress-induced DNA damage was estimated quantitatively by measuring 8-OHdG concentrations. Western blot analysis was used to detect the changes in particular oxidative stress- induced proteins.

Results: The carcinogenic effects induced by potassium bromate were reduced by the co-administration with all of the chemopreventative agents used. Oxidative stress markers, H2O2 and DNA adduct formation, were reduced.

Conclusions: The results suggest that these chemopreventative agents show significant potential against KBrO3-induced carcinogenicity. Further analysis is being carried out to understand the functional mechanisms of this chemoprevention on the cells, in particular on the genetic and epigenetic mechanisms involved.

The Podocyte as a Target for the Actions of Levamisole in Nephrotic Syndrome

Lulu Jiang,[1] Charles Colin Thomas Hindmarch,[1] Mark Rogers,[1] Peter W. Mathieson,[2] Gavin Iain Welsh.[1] *[1]School of Clinical Sciences, Univ of Bristol; [2]Univ of Hong Kong.*

Background: Levamisole is an antihelminthic agent that has also been shown to be effective as a second line treatment for steroid-dependent or frequently-relapsing nephrotic syndrome (SD/FRNS) in children. Levamisole is able to decrease steroid dosages and reduce the relapse frequency and severity. We have recently reported the effectiveness of levamisole in a small cohort of adult patients and provided evidence which suggests that levamisole's mode of action in SSNS is attributable to its direct effects on podocytes.

Methods: To further clarify its therapeutic effectiveness and identify the therapeutic targets of this drug, we have employed RNA-sequencing technology to profile transcriptome changes of human podocytes in response to levamisole.

Results: We have identified a number of genes which are differentially expressed in podocytes in reponse to levamisole. These include genes linked to the cellular interferon response pathways and a number which overlap with those regulated by dexamethasone in podocytes. These have been validated in vitro and are now being studied in animal models of nephrotic syndrome.

Conclusions: Together, our molecular evidence strongly supports the promising use of levamisole in treating nephrotic syndrome.

PUB110

The PRIMAVERA Study: A Prospective, Randomized, Multicenter Trial Assessing the Effect of Continuous Erythropoiesis Receptor Activator (C.E.R.A.) on Renal Function in Non-Anemic Patients with Chronic Kidney Disease (CKD)

Danilo Fliser,[1] Frank Dellanna,[2] Michael Koch,[3] Jochen Seufert,[4] Oliver Witzke,[5] Alfons Wiggenhauser,[6] Ingeborg A. Hauser.[7] *[1]Saarland Univ Medical Center, Homburg/Saar, Germany; [2]DaVita Renal Center, Düsseldorf, Germany; [3]Center of Nephrology, Mettmann, Germany; [4]Univ Hospital of Freiburg, Freiburg, Germany; [5]Univ Hospital Essen, Essen, Germany; [6]Roche Pharma AG, Grenzach-Wyhlen, Germany; [7]Frankfurt Univ Medical Center, Frankfurt, Germany.*

Background: Erythropoiesis stimulating agents (ESAs) are the mainstay of renal anemia management. ESAs may provide a beneficial non-hematopoietic effect on deterioration of kidney function in CKD, but such an effect has not been examined in a prospective controlled trial. PRIMAVERA is the first randomized study to assess whether low-dose ESA therapy can slow CKD progression in patients with near-normal hemoglobin levels (11–14g/dL) (NCT01194154).

Methods: PRIMAVERA was a single-blind, 2-year, multicenter trial which enrolled patients with type 2 diabetes or recipients of a kidney transplant, all with CKD stage 3, urinary albumin to creatinine ratio <3000mg/g or total urine protein <3000mg/24h. Patients were randomized in a 1:1 ratio to placebo or once-monthly low-dose C.E.R.A. (30-75µg per dose). The primary efficacy endpoint was annual change in estimated GFR using the abbreviated MDRD formula. Secondary efficacy endpoints were the changes from baseline in urinary albumin to creatinine ratio, serum cystatin C and serum creatinine. Safety endpoints included adverse events and discontinuation due to pre-specified adverse events.

Results: 241 patients were randomized: (139 type 2 diabetes, 102 kidney transplant recipients). The 2-year study was completed by 159 patients (66%).

Conclusions: The PRIMAVERA study provides the first prospective examination of a potential effect for low-dose ESA therapy in ameliorating kidney function decline in CKD patients. Analysis of the study data is planned shortly.

A New Approach to Phosphate and FGF23 Lowering: Design of the COMBINE Trial

Joachim H. Ix,[1] Tamara Isakova,[2] Stuart M. Sprague,[9] Kalani L. Raphael,[3] Jennifer J. Gassman,[5] Linda F. Fried,[4] Dominic S. Raj,[6] Alfred K. Cheung,[3] Andrew N. Hoofnagle,[10] John W. Kusek,[7] Michael F. Flessner,[7] Geoffrey A. Block,[8] Myles S. Wolf,[2] The pilot clinical trials in Ckd study group.[7] *[1]UCSD; [2]Northwestern; [3]U of Utah; [4]U of Pittsburgh; [5]Cleveland Clinic; [6]George Washington U; [7]NIDDK; [8]Denver Nephrology; [9]Northshore; [10]U Washington.*

Background: Elevated serum phosphate and FGF23 are associated with CVD, CKD progression, and mortality in CKD. Phosphate binders inconsistently reduce phosphate and FGF23 levels. Nicotinamide (vitamin B3) decreases active phosphate transport by down regulating NaPi2b in the gut. Whether nicotinamide alone or in combination with binders can safely and tolerably lower phosphate and FGF23 levels in CKD is unknown.

Methods: We designed a 4 arm parallel group randomized double blind trial comparing lanthanum carbonate (1000mg tid), nicotinamide (750mg bid), neither, or both. Supported by the NIDDK CKD Pilot Clinical Trials U01, 200 participants with eGFR 20-45 ml/min/1.72m^2 recruited from 7 centers across the US will be randomized 1:1:1:1 and treated for 12 months. Main exclusions include phosphate < 2.8mg/dL, liver disease, anemia, and thrombocytopenia. The dual primary efficacy endpoints are change in phosphate and FGF23. Secondary endpoints are change in LV mass and renal fibrosis by MRI. Enrollment began in March 2015.

Results: To date, 45 persons were screened, 33 were eligible, 26 entered run-in, and 18 were randomized. Baseline characteristics of randomized participants are shown in the table. Updated data will be available at presentation.

Randomized Patients (n)	18
Age±SD	65±14
Male, n(%)	12 (67%)
Black, n(%)	5 (28%)
Diabetes, n(%)	7(44%)
eGFR±SD	30±9
Urine ACR mg/g, median (IQR)	505 (48, 905)
Serum Phosphate±SD	3.9±0.6
Serum Calcium±SD	9.5±0.4
Intact PTH, median (IQR)	104 (71, 133)

Conclusions: Simultaneous blockade of NaPi2b and intestinal phosphate binding using nicotinamide and binders provides a new strategy for phosphate and FGF23 lowering in CKD, but efficacy, safety, and tolerability are uncertain. The COMBINE trial will inform us about combined therapy compared to either therapy alone, and to dual placebo in CKD 3b-4.

Funding: NIDDK Support

PUB112

Sofosbuvir plus Ribavirin Combination Therapy for Hepatitis C Virus Infection in Hemodialyzed Patients: New Simpler, Shorter and Safer but Costly Option

Achour Laradi,[1] Christian Pilette,[2] Francois Babinet,[1] Stephanie Lanoiselee,[1] Guillaume Seret,[1] Jean baptiste Pain,[3] Laurent Martin,[4] Gilles Peytavin.[3] *[1]Néphrologie-Dialyse, ECHO-CMCM -Pôle Santé Sud, Le Mans, France; [2]Gastro-enterologie, Centre Hospitalier du Mans, Le Mans, France; [3]Laboratoire de Pharmaco-Toxicologie, Hôpital Bichat-Claude Bernard, Paris, France; [4]Biologie, Labomaine Pôle Santé Sud, Le Mans, France.*

Background: Hepatitis C virus (HCV) infection is a serious issue in hemodialyzed patients (HD pts) and treatment is complex and rapidly evolving with the advent of newer direct-acting antivirals.

Methods: We evaluated SOF given with RBV in an 86 years old male HD pt , 90 kg, on HD since 7 years for a diabetes- related ESRD and infected by a nosocomial transmission of HCV genotype 2 overseas . SOF was given at a dose of 400 mg three times a week after dialysis session and RBV given 200 mg daily during 12 weeks.Plasma HCV RNA values were measured with the COBAS Taqman HCV Test , Roche diagnostics.Safety, efficacy and pharmacokinetics issues were studied as well as standard laboratory tests.Sustained virologic response(SVR) is evaluated six months after treatment.

Results: HCV infection was associated with cirrhosis with Fibroscan staging score of 10.3 KPa. HCV viral load at diagnosis was 7.52 log.The viral decline was < 1.18 log only 3 weeks after treatment and négative after 1 month therapy. SVR with a value of HCV NRA <1.18 log occured six months after. Side effects are mainly anemia and thrombocytopenia. No life threatening adverse event was noticed .Mean Plasma SOF values before and after HD session was < 1 ng /mL in accordance to the dose given.Mean Plasma value of métabolite 007 before HD session was 2394 ng/mL and falled to 938 ng/mL after HD.

Conclusions: Treatment for 12 weeks with all-oral combination of Sofosbuvir and Ribavirin of our old age HD pt with HCV genotype 2 hépatitis resulted in a high degree of antiviral efficacy with an excellent tolerability and safety profile with a dose recommandation of 400 mg 3 times a week.But the very high cost (41000 euros) make access extremely limited.A reduction of the costs is mandatory to make theses new therapies accessible to the majority of the patients in the world who are left untreated.

PUB113

The Rationale for and Design of TREVI TR02: A Multicenter Randomized, Double-Blind, Placebo-Controlled Trial of Nalbuphine ER for the Treatment of Uremic Pruritus in Hemodiaysis Patients Vandana S. Mathur,[1] Michael J. Germain,[2] Roberta Duncan,[3] Thomas Sciascia.[3] *[1]MathurConsulting, Woodside, CA; [2]Western New England Renal & Transplant Associates, PC, Hamden, MA; [3]Trevi Therapeutics, New Haven, CT.*

Background: Uremic pruritus (UP) is common in hemodialysis patients, but there are no FDA-approved treatments or "regulatory roadmap" for the development of new drugs. Nevertheless, the significant quality of life (QOL) burden of chronic itching underscores need for treatments. The striking bilateral, non-dermatomal distribution of itching and perception of non-pruritogenic skin stimuli as itch suggest that UP is centrally mediated, like neuropathic pain. Reduction in endogenous κ/μ opioid ligand ratio is hypothesized to be a mechanism. Our goal was to evaluate nalbuphine ER tablet (NAL), a κ-agonist and μ-antagonist as a treatment for UP.

Methods: The study was powered for an $\alpha = 0.05$, $\beta = 0.9$ for a group difference of 1.5 (SD = 3.5) in worst itching numerical rating scale (NRS, 0-10): N = 120/arm (NAL 120 mg BID, NAL 60 mg BID, and placebo BID). Patients with NRS ≥ 4.5 (moderate to severe pruritus) were enrolled at ~45 US and 6 EU sites.

Results:

Key Scientific or Logistical Consideration	Study Design Solution
1. Itch is subjectively perceived. Itching intensity and QOL were relevant endpoints.	Used patient-reported outcomes previously validated in UP patients including NRS and Skindex-10 (1° and 2° endpoints)
2. Opioid drugs require titration to minimize opioid side effects	To perform a blinded opioid titration with a self-administered oral drug, we used blister cards that were labeled for each study day
3. Long enough duration to demonstrate durability and lack of tolerance but short enough to avoid excessive dropouts due to background comorbidities.	Used an 8-week blinded treatment duration
4. Post-treatment safety	Added a 2-week washout period after the blinded treatment period
5. Day-to-day variability in NRS was expected	The mean of 2 weeks of measurements at baseline and on treatment (Wks 7 and 8) were used for the calculation of the 1° endpoint.

Conclusions: The trial design overcame the challenges. Unblinded results will be presented.

PUB114

The Rationale and Design of Trevi TR02 Extension: A Multi-Center Open Label Extension Study of the Safety and Anti-Pruritic Efficacy of Nalbuphine HCl Extended Release Tablets in Uremic Pruritus Patients on Hemodialysis Thomas Sciascia,[1] Howard Hait,[2] Amale Hawi,[3] Roberta Duncan,[1] Vandana S. Mathur.[4] *[1]Trevi Therapeutics, Inc., New Haven, CT; [2]Edenridge Associates LLC, Wilmington, DE; [3]Hawi Consulting, Ridgefield, CT; [4]Mathur Consulting, Woodside, CA.*

Background: Nalbuphine HCl is a mu antagonist/kappa agonist being investigated for the treatment of pruritus in hemodialysis patients (UP). The safety and long-term benefits of Nalbuphine ER in the treatment of uremic pruritus is being investigated in this ongoing open-label extension study.

Methods: TR02ext is a 26-week multicenter open-label extension study of a double-blind placebo controlled study in which UP patients with a baseline NRS ≥4.5 were treated with Nalbuphine ER or placebo for 8 weeks followed by a 2-week washout period. At the end of study, patients that opt to roll over into the extension study, and have an NRS > 2 enrolled in a 26-week Treatment Period (TP), while patients with an NRS £2 entered a 13-week Observation Period (OP). If a patient's itch worsened (NRS > 2) within the OP, they entered the TP for the remainder of the study.

All patients on treatment were titrated between 30 mg QD-120 mg BID over a 3-4 week period based on reported tolerability and efficacy and then maintained their dose until end of study. Patients whose itch intensity failed to improve during the TP were discontinued from treatment.

Key Scientific Considerations	Study Design Solution
1. Characterize the time course of worsened itch intensity following 8 weeks on blinded study drug or placebo followed by a 2-week wash-out period	Separate subjects into TP and OP
2. Dose distribution of flexible dosing to optimize efficacy and safety	Individualized titration to understand preferred doses
3. Individualized titration to maximize drug efficacy with tolerable side effects	Up to 26 weeks of treatment with discontinuation of subjects who do not respond to treatment

Conclusions: Approximately 70% of the eligible patients who completed the blinded controlled study, enrolled in the extension study. Final study data will be presented once the study is complete.

Funding: Pharmaceutical Company Support - Trevi Therapeutics

PUB115

Assessing Treatment Safety and Efficacy of a New Patient-Centered Hemodialysis System Luis Alvarez,[1] Geoffrey A. Block,[2] May L. Yau,[3] Glenn Matthew Chertow.[4] *[1]Palo Alto Medical Foundation, Palo Alto, CA; [2]Denver Nephrology, Denver, CO; [3]Outset Medical, San Jose, CA; [4]Stanford School of Medicine, Stanford, CA.*

Background: Many studies designed and conducted for the evaluation of new technologies utilized in hemodialysis have been small, observational studies. These studies may have underestimated the rate of clinical symptoms yielding biased safety results.

Methods: We designed a prospective, multicenter, open-label, non-randomized, cross-over study where patients serve as their own control. The study was designed with novel approaches to ensuring accuracy of clinical symptom reporting both in the home and clinic settting. Up to 50 patients will be enrolled in the study for 19 weeks and will use the Tablo™ Hemodialysis System for treatments 4 times/week.

Phase	Description
Run-in	clinic staff administered in-center hemodialysis treatment for 1 week.
In-Center treatment	clinic staff administered hemodialysis treatment for 8 weeks in-center.
In-Home transition	device training, perform self-care dialysis for approximately 2 weeks (1 week in-center and 1 week in-home), and assessment for stability in the home environment.
In-Home treatment	self-care dialysis treatment for 8 weeks at home.

During each study phase, patients will record inter- and intra-dialytic symptoms for each treatment via questionnaire. Research staff will review all responses weekly to determine if an adverse event (AE) has occurred. In addition, research staff will conduct weekly visits to the dialysis clinic and to home to educate patients on AEs and to collect questionnaires. Patients will also be assessed to determine if a standardized weekly Kt/V of 2.1 has been achieved.

Results: Study enrollment is expected to begin in 2015 with results expected in 2016.

Conclusions: By utilizing patients to collect AE data both in-center and at home, we should more accurately capture AE rates due to the uniformity of the reporting mechanism. In terms of the clinical efficacy endpoint of the study, modelled clearance data suggests the majority of patients will achieve the weekly standard Kt/V target. Actual clearance data will be forthcoming at the completion of the trial.

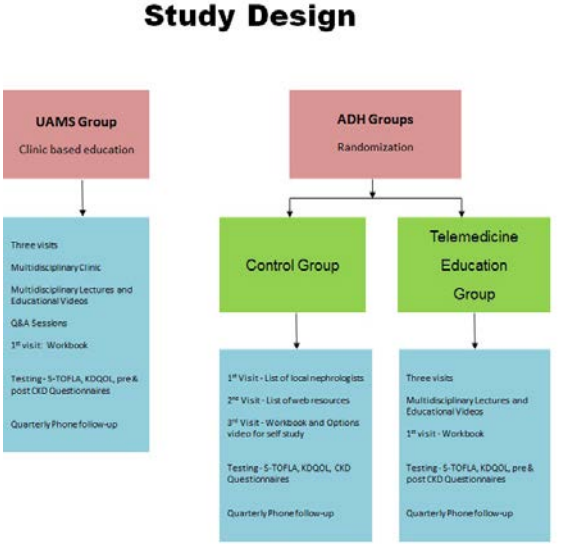
PUB116

Interim Analysis of Comprehensive CKD Education Modality Choice Outcomes Andrea K. Easom,[1] Dumitru Rotaru,[1] Fahd Syed,[1] Manisha Singh,[1] Ashutosh M. Shukla,[2] Sudhir V. Shah.[1] *[1]Univ of Arkansas for Medical Sciences; [2]Unversity of Florida.*

Background: Preliminary data from a study comparing telemedicine vs conventional CKD education is presented here. The primary aim is to see if patients are able to make a modality choice by the end of the third visit.

Methods: Patients are enrolled in three groups as shown in the pilot study design.



Each group attends 3 sessions and are given handouts or an 82 page workbook designed specifically for the study. They are asked about their modality choice pre-education and at the end of each session.

Results: To date 80 subjects have been enrolled and 32 have completed all sessions. After 3 sessions, 38% chose peritoneal dialysis (PD), 28% chose home hemodialysis (HHD), 28% chose in center hemodialysis (ICHD), 3% chose no dialysis (ND), 3% could not make a choice (NC) and 84% chose transplant. On enrollment, 47% made a modality choice with 40% choosing home modalities. At the end of 3 session, 97% were able to make a modality choice with 66% choosing home modalities. Of the 6 subjects who have completed 3 visits and started renal replacement therapy (RRT), 5 started PD and 1 had a pre-emptive transplant. Additionally, 4 subjects did not complete all visits: 3 started ICHD (2 with AVFs) and 1 died. Enrollment in the telemedicine arm has been slower than expected. Strategies to involve community leaders and local providers were developed and are being implemented. Communities interested in the program have been added as telemedicine sites.

Conclusions: This preliminary data shows that at the end of 3 education sessions there is a significant increase in subjects being able to make a RRT choice (97% vs. 47%) and most chose home dialysis(66% vs. 40%). Community engagement is key to a successful outreach of this state-wide CKD education program. Further strategies are being developed to improve local involvement.

PUB117

Determination of Oxidative Stress and Inflammation Index in Patients with Different Dialysis Modalities and Analysis of Related Factors Linshan Jiao, Jianfei Ma. *Nephrology, The First Affiliated Hospital of China Medcial Univ, Shenyang, Liaoning, China.*

Background: This study through the determination of serum AOPPs, GSH-PX, PTX-3, IL-6 level in ESRD patients with different treatment groups,to explore the changes and influence factors of oxidative stress and inflammation in dialysis patients.

Methods: 70 cases of ESRD patients divided into three groups: 26 cases of PD patients,26 cases of MHD patients,18 cases of CKD5 patients.Select 14 normal persons as control group.Age,gender and other data of the four groups were matched.Get Serum of each group of subjects,using ELISA for determination of serum AOPPs, GSH-PX, PTX-3, IL-6 content in each group.

Results: 1.The concentration of AOPPs:PD Group(25.04±12.18) ng/ml, MHD group(18.46±10.47)ng/ml, CKD5 group(17.96±9.81)ng/ml,healthy group(15.73±6.68) ng/ml.PD group was statistically significant different with other groups ($p<0.05$).2.The concentration of GSH-PX:PD group(188.54±112.04)U/ml, MHD group(157.12± 82.47) U/ml,CKD5 group(133.59±65.59)U/ml,healthy group(176.03±98.25)U/ml. There was no significant difference between the groups.3.The concentration of PTX-3:PD Group(9.85±5.13)ng/ml, MHD group(7.54±4.07)ng/ml, CKD5 group (6.69±3.12)ng/ml, healthy control group(6.08±2.49)ng/ml. The PD group was statistically significant different with other groups($p<0.05$).4.The concentration of IL-6:PD group(123.69±84.46) ng/L, MHD group(81.17±72.48) ng/L, CKD5 group(64.92±36.92)ng/L,healthy control group(59.08±19.27)ng/L. The PD group was statistically significant different with other groups($p<0.05$).5.Through Correlation analysis in PD group($P<0.05$): AOPPs was positively correlated with PTX-3 ($R=0.956$, $P=0.000$),AOPPs was positively correlated with IL-6 ($R=0.934$, $P=0.000$), PTX-3 and IL-6 levels were positively correlated ($R=0.939$, $P=0.000$).

Conclusions: Determination of serum AOPPs, GSH-PX, PTX-3, IL-6 content in Experience group is significantly increased compared with the control group.The PD patients compared with patients in other treatment groups has more severe oxidative stress and microinflammation state.Oxidative stress is closely related to the state of inflammation in PD patients.

PUB118

Impact of Type of Referral and Dialysis Start on Clinical Outcomes and Final Renal Replacement Therapy in a Multicenter Integrated Care Setting Belen Marron,[1] Janusz Ostrowski,[2] Marietta Torok,[3] Delia Timofte,[4] Jose C. Divino-Filho.[1] *[1]Diaverum Home Therapies. Medical Office, Diaverum, Munich, Germany; [2]Wloclawek Diaverum Clinic, Diaverum, Wloclawek, Poland; [3]Szeged Diaverum Clinic, Diaverum, Szeged, Hungary; [4]Sema Diaverum Clinic, Diaverum, Bucharest, Romania.*

Background: Early referral, choice of RRT modality and planned start increase patient survival, however international reports show disparities between desirable patterns and practice. Objectives**:** To analyze the effects of Integrated Care and education on dialysis start (planned vs. non-planned) and RRT modality choice.

Methods: Retrospective analysis of 547 incident patients starting dialysis in 23 HD/PD clinics from PL, HU and RO during 2012. Scheduled initiation of dialysis with a permanent vascular or peritoneal access was considered as planned start.

Results: Population: 30% DM, mean age 64 years, 84% with previous medical care of renal disease, 49 % late referral, 58 % unplanned start, 92% on HD as modality.37% of those with unplanned start had previous Nephrology follow-up. Patients (n=332) with GFR <30 ml/min were followed up mainly by "general nephrologists" (68%) and 29% in structured predialysis units Modality information (80% of all patients) and general renal education (87%) were more frequent ($p<0.001$) in planned start. Half of patients were involved in therapy choice whereas informed and dialysis start consents were signed by 57% and 77%. The median time from information to dialysis start was 2 months. Unplanned start (p£0.05) correlated with nephropathy of uncertain origin, worse clinical status, shorter time from information to RRT start and less PD. Patient non-compliance (36%) and unexpected GFR loss (19%) contributed to unplanned start. "Optimal care" defined as combination of Nephrology follow-up (> 3 months), modality information and planned start occurred in 22% of the patients.

Conclusions: Despite the high rate of late referral, information and education were widely provided. Unplanned start was frequent and may underlie the low frequency of PD choice. Measures such as implementation of structured predialysis units may facilitate better and timely referral and improve well-being and planning of RRT start as well as increased PD use.

PUB119

ATHENA: A Natural History Study to Observe Disease Progression, Standard of Care, and Investigate Biomarkers in Alport Syndrome Patients Jacqui Blem,[1] Paul C. Grint,[1] Victoria Pratola,[1] James F. Simon.[2] *[1]Regulus Therapeutics Inc., San Diego, CA; [2]Cleveland Clinic, Cleveland, OH.*

Background: Alport syndrome (AS) is a rare genetic disorder caused by mutations in genes coding for type IV collagen (COL4) α3, α4 and α5 proteins leading to hematuria, renal failure, hearing loss and eye involvement in affected patients. Patients with COL4α5 mutations develop end stage renal disease (ESRD). While there are currently no approved therapies for AS, ACE-inhibitors have been shown to delay the onset of ESRD. A better understanding of the decline of kidney function in AS is necessary to design clinical trials to enable the development of new therapeutics.

Methods: Regulus' Natural History of Disease Study, ATHENA, is an international multi-center observational study designed to characterize the progression of renal dysfunction in up to 120 subjects that have been clinically or genetically diagnosed with AS with a measured GFR (mGFR) between 30-75cc/min/1.75m^2. Genetic mutation analysis is performed at enrollment. mGFR (iohexol), 24 hour urine protein excretion and serum creatinine levels are measured every 3-6 months. Serum and urine biomarkers of renal stress (microRNAs, ADMA, TGFβ, CTGF and NGAL) will also be collected.

Results: 48 subjects with clinically or genetically diagnosed Alport syndrome have been enrolled to date. The population has an age range of 20 to 67 years of age and 29% are male. Average baseline mGFR was 54.8 cc/min/1.75m^2. Ethnicity is reported at 91% Caucasian, 2% Hispanic or Latino, 2% African American and 5% Asian.

Conclusions: Data gathered from the ATHENA study will investigate links between genetic mutations, biomarkers of renal stress and disease progression in AS patients. The correlative data collected from the ATHENA study will provide clinically important basis for the design of the Phase 2 clinical proof of concept study to determine efficacy of RG-012 (an anti-miR targeting microRNA-21) on the decline in renal function and time to end-stage renal disease in Alport syndrome patients.

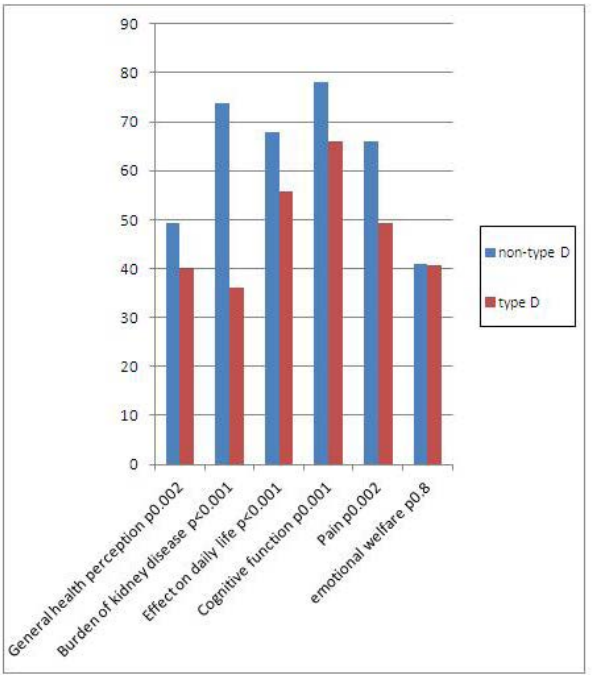
PUB120

Health-Related Quality of Life in Dialysis Patients: Effect of Type D Personality Christopher Susanto,[1] Constantijn Konings,[2] Jeroen Kooman.[3] *[1]Nephrology, Elkerliek Hospital, Helmond, Netherlands; [2]Nephrology, Catharina Hospital, Eindhoven, Netherlands; [3]Nephrology, Maastricht Univ Medical Centre, Maastricht, Netherlands.*

Background: Measurement of HRQoL is a useful tool to describe the burden of illness and the impact of treatment. These information's could be essential to develop a personal care. Type D (distressed) personality is defined as a tendency to experience both negative affectivity (NA) and social inhibition (SI). The prevalence of this personality and his effect on HRQoL in dialysis patients are assessed.

Methods: Participants were from outpatient clinic. DS 14 was used. A score of ³10 on both NA and SI subscales indicates that the person has a type D personality. HRQOL was measured using the Dutch version of the Kidney Disease Quality of Life. Six components of the KDQOL were the primary end points (general health perceptions, burden of kidney disease, effect on daily life, cognitive function, pain, emotional welfare).

Results: 147 patients with mean age of 71.2 (±11.7). Mean time on dialysis 37 months. The prevalence of type D personality was 30%. HRQoL in patients with type D personality was lower compared with non type D. It was statistically significant in all components except for emotional welfare.



NA was significantly related to all components except for emotional welfare. SI was found to be significantly correlated esspecially with effect on daily life

	NA		SI	
	r	p-value	r	p-value
Age	-O.20	0.02	-0.13	0.11
Duration of RRT	-0.09	0.3	-0.07	0.43
General health perception	-0.28	0.001	-0.20	0.02
Burden of kidney disease	-0.47	<0.001	-0.27	0.001
Effect on daily life	-0.36	<0.001	-0.30	<0.001
Cognitive	-0.40	<0.001	-0.26	0.002
Pain	-0.29	<0.001	-0.16	0.006
Emotional welfare	0.15	0.07	-0.03	0.7

Conclusions: Type D personality may be an important determinant of individual differences in HRQoL and should be an important consideration in a personal care of dialysis patients.

PUB121

Sleep Disorder and mRNA Expression Profile of Sleep-Related Gene in Peripheral Blood Cells in Patients with CKD Shinji Kitajima, Yasunori Iwata, Yasuyuki Shinozaki, Norihiko Sakai, Miho Shimizu, Kengo Furuichi, Takashi Wada. *Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Japan.*

Background: Although uremic substances would be candidates involved in sleep disorder, detailed mechanisms remain unclear so far. we performed polysomnographic analysis in CKD patients and used PBCs to examine the expression of genes related to sleep and wakefulness states.

Methods: Polysomnographic analysis was performed in 9 CKD patients and 6 healthy controls. Genes related to sleep and wakefulness were evaluated by RNA microarray in 19 subjects, including CKD patients and control subjects.

Results: Polysomnographic analysis revealed that the duration of the rapid eye movement (REM)/non-REM phases during total sleep time was different between CKD patients and healthy controls. In mRNA microarray evaluation, hierarchial clustering analysis showed the different pattern of sleep related gene expression in the patients with HD. The mRNA expression levels of GABA receptor, noradrenaline receptor, dopamine receptor and histamine receptor showed an inverse correlation with renal function. Moreover, orexin and its receptor mRNA expression also showed an inverse correlation with renal function.

Conclusions: These data raise the possibility that sleep related gene expression on PBC in CKD/HD patients may be associated with sleep disorder.

PUB122

Potential Link Between Iron, Inflammation and FGF23 in Patients with Early Stages of Chronic Kidney Disease Ewelina Lukaszyk,[1] Mateusz Lukaszyk,[2] Jolanta Malyszko.[1] *[1]2nd Dept of Nephrology and Hypertension with Dialystis Unit, Medical Univ of Bialystok, Bialystok, Poland; [2]Dept of Allergology and Internal Medicine, Medical Univ of Bialystok, Bialystok, Poland.*

Background: Fibroblast growth factor 23 (FGF23) is a hormone commonly increased in patients witch chronic kidney disease and alike inflammation and iron deficiency is a known risk factor of cardiovascular outcomes and death in patients with chronic kidney disease (CKD). The aim of the study was to evaluate the potential link between FGF23 concentration, novel iron status and inflammatory parameters among patients with early stages of CKD.

Methods: 96 patients with early stage of CKD and 54 with normal renal function were enrolled in the study. Standard laboratory methods were used to measure serum hemoglobin, fibrinogen, creatinine, iron, total iron binding capacity (TIBC) and ferritin. Intact FGF23, hepcidin-25, sTfR (soluble transferrin receptor), GDF-15 (growth differentiation factor-15), IL-6 (interleukin 6) and hsCRP (high sensitivity C-reactive protein) were measured using commercially available kits. Data was analyzed in different group of patients according to iron status (absolute and functional iron deficiency and normal iron levels).

Results: There was no difference of FGF23 concentration regarding to iron status. Significant correlations in patients with CKD are presented in Table.

	iFGF23
eGFR	-0.49
hepcidin-25	-0.21
IL-6	0.22
GDF-15	0.31

There were no statistically significant associations between FGF23 and TSAT, ferritin and hsCRP. We revealed significantly higher concentrations of FGF23 in patients with type 2 diabetes (mean logFGF23: 4±0.5 vs 3.8±0.5, *P*=0.03) and with heart failure (mean logFGF23: 4±0.6 vs 3.8±0.5, *P*=0.04) in comparison to those without these diagnoses.

Conclusions: Kidney function, inflammation and iron status were the parameters affecting FGF23 in the early stages of CKD. Our data are paving the way for further studies on the role of FGF23 in cardiorenal anemia-iron deficiency syndrome, in particular in the early stages of CKD.

PUB123

Echocardiography and Cardiovascular Risk: What's the Relationship in the Renal Transplant Recipient? Miguel Goncalves,[1] Micaela Neto,[2] Pedro Vieira,[1] Luis Resende,[1] Nuno Rosa,[1] Susana Gomes,[2] Jose Duraes,[1] Jose Alves Teixeira,[1] Gil Silva.[1] *[1]Nephrology, Hospital Dr. Nélio Mendonça, Funchal, Portugal; [2]Cardiology, Hospital Dr. Nélio Mendonça, Funchal, Portugal.*

Background: Cardiovascular (CV) disease is the major cause of death among renal transplant recipients (RTR). Unlike end stage renal disease, it is unknown whether echocardiographic abnormalities are useful to identify RTR with high cardiovascular and risk of death.

Methods: Retrospective review of 107 RTR with a functioning and stable graft for longer than 12 months and an echocardiography performed in the last year. Risk of MACE and death using a CV risk calculator specific for RTR and all echocardiographic parameters were reviewed and analyzed.

Results: Among 107 patients (57,9% males, 50,4±13,9 years old), 7-years risk for MACE was >10% in 30,9% of patients and 7-years risk for death >10% in 56,1%. Left ventricular hypertrophy (LVH) was found in 55.1%, diastolic dysfunction in 39,3%, dilated left atrium (LA) in 53,3%, high pulmonary artery systolic pressure (PASP) in 29,0%, valvular calcifications in 22,4% and moderate to severe mitral regurgitation in 3,7%. Mean Ejection Fraction was 68.36±6.87%. Univariate analysis showed with statistical significance an increased risk of MACE in patients with LVH, diastolic dysfunction, dilated LA, high PASP, valvular calcifications and mitral regurgitation. Univariate analysis also showed statistical relationship on increased risk of death in patients with LVH, diastolic dysfunction, dilated LA, high PASP, valvular calcifications and mitral regurgitation. Multivariate analysis identified an independent association between the risk of MACE >10% and valvular calcifications [OR 3.499 (1.115-10.982, P=0.032)] and high PASP [OR 7.954 (2.412-26.238, p=0.001)]. Risk for death >10% in multivariate analysis had an independent association with diastolic dysfunction [OR 3.909 (1.261-12.115, p=0.018)] and with high PASP [OR 4.319 (1.201-15.535, p=0.025)].

Conclusions: Echocardiographic abnormalities identify RTR at increased risk of MACE and death. Valvular calcifications and high PASP are significant predictors of MACE whereas diastolic dysfunction and high PASP are significant predictors of death.

PUB124

Hemodynamic Determinants of Glomerular Filtration Rate in Pulmonary Hypertension: A Prospective Cohort Analysis Laurent Bitker,[1] Cecile Payet,[3] Florence Sens,[1,4] Turquier Segolene,[2] Antoine Duclos,[3,4] Vincent Cottin,[2,4] Laurent Juillard.[1,4] *[1]Nephrology, Hospices Civils de Lyon, Lyon, France; [2]Pneumology, Hospices Civils de Lyon, Lyon, France; [3]Medical Research and Statistics Dept, Hospices Civils de Lyon, Lyon, France; [4]Univ of Lyon, Lyon, France.*

Background: Up to date, renal dysfunction incidence and determinants remain unevaluated in pulmonary hypertension (PHT). We aim to assess hemodynamic and demographic factors associated with a decrease in glomerular filtration rate (GFR) in the context of PHT.

Methods: The regional competence center for PHT of Lyon (France) prospectively compiles demographic, hemodynamic and biological variables among newly diagnosed patients. We retrospectively analyzed data for patients with pulmonary arterial hypertension (PAH, group 1 of PHT classification) after exclusion of the following causes of PHT: thromboembolic, lung diseases and/or hypoxia and left heart disease. Hemodynamic variables from the right heart catheterization and estimated GFR (eGFR, CKD-EPI formula) were assessed at PAH diagnosis time.

Results: 209 patients (mean age 59.1±17.1, 63.2% women) were included from October 1998 to July 2012. 40.2% presented with systemic arterial hypertension (HT) and 12.9% with diabetes. Mean eGFR was 83.9±27.1 ml/min/1.73m^2 (eGFR inferior to 60 ml/min/1.73m^2 in 18.5% of cases). Mean values of mPAP, right atrial pressure (RAP) and cardiac index (CI) were 43.5±12.6 mmHg, 7.8±5.3 mmHg and 2.6±0.9 L/min/1.73m^2. In multivariate analysis, age, male gender, HT, anorectic-related PAH and a CI inferior to 2.5 L/min/1.73m^2 were associated with a significant decrease in eGFR of 1.0 ml/min/1.73m^2/year, (95% confidence interval, 0.8 to 1.2), 11.8 ml/min/1.73m^2 (5.8 to 17.8), 6.6 ml/min/1.73m^2 (0.1 to 13.2), 13.4 ml/min/1.73m^2 (2.3 to 24.5) and 10.1 ml/min/1.73m^2 (4.4 to 15.9). RAP were not statistically related to eGFR levels.

Conclusions: Renal dysfunction is frequent from diagnosis among PAH patients. A low CI is associated with a significant decrease in eGFR, whereas RAP seem unrelated. Equally, male gender, HT and anorectic-related PAH are correlated with a significant decrease in eGFR. These results should incite renal prevention in PAH patients presenting these risk factors.

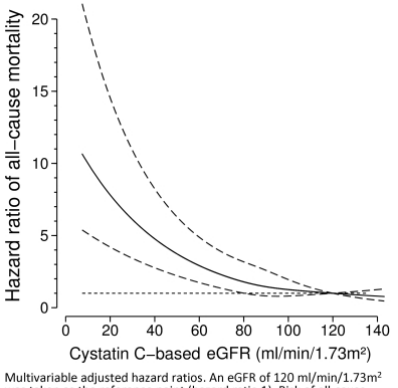
PUB125

Kidney Function and Cause-Specific Mortality in Drug-Treated Older Cardiac Patients: A 10-Year Follow-Up Study Ellen K. Hoogeveen,[1] Johanna M. Geleijnse,[2] Daan Kromhout,[2] Theo Stijnen,[3] Erik Giltay.[4] *[1]Nephrology, LUMC, Leiden, Netherlands; [2]Human Nutrition, WU, Wageningen, Netherlands; [3]Medical Statistics and Bioinformatics, LUMC, Leiden, Netherlands; [4]Psychiatry, LUMC, Leiden, Netherlands.*

Background: Chronic kidney disease (CKD) is highly prevalent among older (>60y) cardiac patients. The relation between CKD and cause-specific mortality among older cardiac patients who are treated with state-of-the-art pharmacotherapy is unclear.

Methods: From 2002-2006, 60-80 years old Dutch post-myocardial infarction patients were enrolled in the Alpha Omega Trial and followed until death or January 2012. We estimated Glomerular Filtration Rate (eGFR) with serum cystatin C (cysC) and creatinine using the CKD-EPI equations. Kidney function was available in 4,561 (94.3%) participants and analyzed in relation to major causes of death using Cox models and four-knot restricted cubic splines.

Results: At baseline mean age was 69y, 79% were men, 21% had diabetes, 90% used antihypertensive drugs, 85% used statins. Patients were divided into four categories of $eGFR_{cysC}$: ≥90 (33%; reference), 60-89 (47%), 30-59 (18%), and <30 (2%) ml/min/1.73m^2. Median follow-up was 6.4y. During follow-up, 873 (19%) patients died, of which 370 (42%) from cardiovascular causes, 309 (35%) from cancer, and 194 (22%) from other causes. The hazard ratios (95%-CI) for any death according to $eGFR_{cysC}$ category, after adjustment for major risk factors, were: 1 (reference), 1.4 (1.1-1.7), 2.9 (2.3-3.6) and 4.4 (3.0-6.4). For cardiovascular mortality the corresponding figures were 1.6, 3.6 and 6.0, for cancer 1.2, 2.1 and 1.6, and for other causes 1.4, 3.1 and 6.7. Similar, but weaker, results were obtained with creatinine-based eGFR.



Multivariable adjusted hazard ratios. An eGFR of 120 ml/min/1.73m^2 was taken as the reference point (hazard ratio 1). Risk of all-cause mortality increased significantly below an eGFR of 80 ml/min/1.73m^2.

Conclusions: We found a strong inverse graded relation between kidney function and mortality in drug-treated older cardiac patients, in particular due to cardiovascular and non-cardiovascular-non-cancer causes.

The Association Between Serum Uric Acid and Incidence of Non-Fatal Stroke in a Community-Based Population: A Longitudinal Survey of a Nationwide Cohort in Japan Keita Kamei,[1] Kazunobu Ichikawa,[1] Tsuneo Konta,[1] Shouichi Fujimoto,[2] Kunitoshi Iseki,[2] Toshiki Moriyama,[2] Kunihiro Yamagata,[2] Kazuhiko Tsuruya,[2] Kenjiro Kimura,[2] Ichiei Narita,[2] Masahide Kondo,[2] Koichi Asahi,[2] Tsuyoshi Watanabe.[2] *[1]Dept of Cardiology, Pulmonology, and Nephrology, Yamagata Univ School of Medicine, Yamagata, Japan; [2]Steering Committee of Research on Design of the Comprehensive Health Care System for Chronic Kidney Disease (CKD) Based on the Individual Risk Assessment by Specific Health Checkup, Japan.*

Background: Hyperuricemia is a risk for adverse renal outcomes in chronic kidney disease. This study investigated the effect of uric acid on incidence of non-fatal strokein a community-based population.

Methods: We used a nationwide database of 160,164 subjects (aged 29–74, male 39%), participated in an annual health check, "The Specific Health Check and Guidance in Japan" between 2008–2010, and examined the relationship between the gender-specific quintiles of serum uric acid level at baseline and the 2-year incidence of non-fatal stroke.

Results: During the follow-up period 2,081 non-fatal stroke occurred (1.3%). The incidence of non-fatal stroke showed a significant J-shaped association with the increase in serum uric acid levels (P for trend <0.001, lowest [1.2%] in the 3rd quintile of uric acid [Q3: males 5.7–6.2 mg/dL, females 4.4–4.8 mg/dL] and highest [1.6%] in the 5th quintile [Q5: males ≥7.1 mg/dL, females ≥5.5 mg/dL]). After adjusting for possible confounders, the odds ratio for incident stroke was significantly higher in Q5, compared with Q3 (OR 1.21, 95%CI 1.05–1.39, P = 0.007). The odds ratio of hyperuricemia (serum uric acid ≥7 mg/dL) for incident stroke was significantly increased in total subjects (OR 1.22, 95%CI 1.07–1.39), especially in females (OR 1.46, 95%CI 1.04–1.99) and non-hypertensive subjects (OR 1.34, 95%CI 1.04–1.70). In contrast, the association between serum uric acid levels and incident stroke was not significant in subjects with diabetes, proteinuria and renal insufficiency.

Conclusions: This study showed that serum uric acid level is significantly associated with incident non-fatal stroke and that hyperuricemia might be an independent risk for non-fatal stroke in the general population.

PUB127

The Association Between Serum Calcium and Mortality in a Community-Based Population: The Takahata Study Sayumi Watanabe, Keita Kamei, Kazunobu Ichikawa, Tsuneo Konta, Isao Kubota. *Dept of Cardiology, Pulmonology, and Nephrology, Yamagata Univ School of Medicine, Yamagata, Japan.*

Background: The low intake of calcium is a risk for cardiovascular events. This study investigated the association between serum calcium and mortality in a community-based population.

Methods: This study included 1,314 participants (aged 40–87, males 45%) at local health checkup in Takahata, Japan. We divided them into 3 groups according to the tertiles of serum calcium at baseline and compared the mortality during 8-year follow-up period. Serum calcium was corrected for serum albumin.

Results: At baseline serum calcium level was 9.8 ± 0.4 mg/dL (mean ± SD). In the multivariate linear regression analysis serum calcium was positively associated with serum sodium, potassium, phosphorus, albumin, uric acid and total cholesterol, and was negatively associated with serum chloride and HDL-cholesterol, and urinary beta2-microglobulin. During the follow-up period 62 deaths, including 14 cardiovascular deaths occurred. In Kaplan-Meier analysis all-cause mortality was significantly increased along with the decrease in serum calcium (Log-rank P = 0.03). In Cox proportional hazard analysis adjusted for confounders including age, gender, smoking and drinking habits, comorbidities and other serum electrolytes, the association of serum calcium was of borderline significance with all-cause mortality (HR 2.09, 95%CI [0.94–4.75], P = 0.07, low tertile [≤ 9.6 mg/dL] vs. high tertile [≥ 10.0 mg/dL]) and was significant with cardiovascular mortality (HR 6.33, 95%CI [1.13–43.7], P = 0.04, low tertile vs. high tertile). In addition, there was a significant interaction between serum calcium and sodium on all-cause mortality (P = 0.03) and the association of serum calcium with the mortality was significant in the subjects with low serum sodium (≤ 150 mEq/L), but not high sodium.

Conclusions: This study showed that serum calcium was significantly associated with various environmental factors and low serum calcium was an independent predictor for the mortality in the general Japanese population.

Funding: Government Support - Non-U.S.

PUB128

Endothelial Dysfunction According to Classification of Serum Phosphorus Level within Normal Range in Chronic Kidney Disease Shina Lee, Jung-hwa Ryu, Seung-Jung Kim, Dong-Ryeol Ryu, Duk-Hee Kang, Kyu Bok Choi. *Dept of Internal Medicine, Ewha Womans Univ Mok Dong Hospital, Seoul.*

Background: Hyperphosphatemia is a important problem because of its affect on endothelial dysfunction as well as homeostasis of bone. Chronic kidney disease(CKD) patients tend to have higher serum phosphorus values than those in healthy population due to their positive balance of phosphorus in kidney. There are a few studies which reported that serum phosphorus level was correlated with endothelial function. Recently it has been reported the patients with higher serum phosphorus level related to the worse endothelial function in healthy population. Thus, the following study was carried out in an effort to redefine the relationship between serum phosphorus level and endothelial dysfunction to those on chronic kidney disease.

Methods: This is a cross-sectional study and the enrolled 85 CKD patients with exception of CKD stage 5 or receiving renal replacement therapy. They were subjected to the measurement with laser doppler flowmetry with iontophoresis, reactive hyperemia peripheral arterial tonometry(RH-PAT) and ankle brachial index, which represented endothelial function assessment.The average serum phosphorus level in patients was measured for the last three months including examination month. The Pearson's correlation coefficient analysis and multiple regression analysis were performed to define the association of serum phosphorus and endothelial function.

Results: When participants were divided into four groups according to estimated GFR, serum phosphorus level had significant higher values in CKD stage 4. From univariate analysis, phosphorus level was associated with RH-PAT values(r=0.296, p=0.008). Multivariate analysis showed serum parathyroid hormone was independent predictor for endothelial dysfunction assessed with RH-PAT.

Conclusions: This study showed that serum phosphorus level may associate with endothelial function even in CKD. Furthermore, it is required a prospective study of larger population to identify the relationship between phosphorus and endothelial function and to establish optimal reference range of phosphorus level for protection from endothelial dysfunction.

PUB129

Coronary Artery Calcification in Predialysis Diabetic and Nondiabetic CKD Patients Sonoo Mizuiri,[1] Yoshiko Nishizawa,[1] Kazuomi Yamashita,[1] Kyoka Ono,[1] Mariko Asai,[1] Masahiro Ishine,[2] Shigehiro Doi,[3] Takao Masaki,[3] Kenichiro Shigemoto,[1] Satoru Harada.[1] *[1]Nephrology, Iciyokai Harada Hospital, Hiroshima, Japan; [2]Radiology, Iciyokai Harada Hospital, Hiroshima, Japan; [3]Hiroshima Univ Hospital, Hiroshima, Japan.*

Background: Risk factors for coronary artery calcification may include low vertebral bone mineral density (BMD), and may differ in diabetic and nondiabetic CKD patients.

Methods: We examined Agatston coronary artery calcium score (CACS), BMD of T8 vertebra using MDCT, age, sex, presence of diabetes, hypertension, smoking history, statin administration, BMI, eGFR, urinary protein, blood urea, glucose, serum iron, calcium, phosphate, uric acid, alkaline phosphatase, albumin, LDL-cholesterol, and triglyceride in 128 predialysis CKD patients, 82 nondiabetics, and 46 diabetics. Factors related to CACS were assessed by multivariate regression and logistic regression analyses using all of the above independent variables.

Results: Coronary artery calcification was present in 106 (82.8%) patients. Significant associations between CACS≥400H and age, diabetes, and statin administration were observed, and odds ratios were 1.1, 3.4, and 3.7, respectively, in all subjects (P<0.05). Log CACS showed a significant association with age, diabetes, statin administration, serum phosphate, and iron in all subjects (P<0.05). Mean age and eGFR were 70±14 vs. 70±9 years (ns) and 37±20 vs. 30±19 ml/min/1.73m^2 (P<0.05), in nondiabetics and diabetics, respectively. Serum phosphate levels were not significantly different in the both groups. CACS (H) was 239±411 in nondiabetics and 942±1258 in diabetics (P<0.001). Significant associations were observed between Log CACS and age (P<0.0001, β:0.42), statin administration (P<0.01, β:0.31), and serum phosphate (P<0.05, β:0.20) in nondiabetics, and between Log CACS and blood urea (P<0.01, β:0.55), serum iron (P<0.01, β:-0.41), age (P<0.01, β:0.41), BMI (P<0.05, β:0.29) and smoking history (P<0.05, β:0.29) in diabetics. BMD showed no association with CACS.

Conclusions: Hyperphosphatemia is a risk factor for coronary artery calcification in nondiabetic but not diabetic CKD patients, and an association between CACS and BMD of T8 vertebra was not observed.

Association of APOL1 Risk Variants with Cardiovascular Events Among HIV-Infected Individuals Tessa Kimberly Novick, Michael J. Choi, Michelle M. Estrella, Mohamed G. Atta, Derek M. Fine. *Nephrology, Johns Hopins Hospital, Baltimore, MD.*

Background: HIV+ individuals have higher risk of cardiovascular disease versus HIV- individuals. Recently, the APOL1 risk variants that are associated with CKD among African Americans were also associated with adverse cardiovascular events (CVE). Given the potential interaction between HIV and APOL1 variants, we examined the association between the APOL1 risk variants and CVE in HIV+ adults.

Methods: We conducted a cohort study among HIV+ African Americans who underwent clinically indicated kidney biopsies from 1996-2011 and were successfully genotyped for the APOL1 G1 and G2 alleles. Multivariable logistic regression was used to compare the high-risk (2 copies) vs. the low-risk (0/1 copy) genotype and the odds of CVE (diagnosis of acute myocardial infarction, percutaneous cardiac intervention, CABG or stroke).

Results: Of 203 individuals, 64% were male with mean age of 46 years, eGFR of 38.4 ml/min/1.73m^2, and urine protein-to-creatinine ratio (UPCR) of 4.1g/g. Mean CD4 count was 259 cells/mm^3; only 29% had HIV RNA levels <400 cps/mL. During follow-up, 12% had CVE and 40% died from all causes. Individuals with the high-risk vs. low-risk genotype had similar odds of CVE, adjusting for age, CVD risk factors, statin and aspirin use, eGFR and proteinuria (OR 1.13, 95% CI: 0.34 – 3.81). Similarly, APOL1 risk genotype was not associated with the composite outcome of CVE and death from all causes, adjusting for age, CVD risk factors, statin and aspirin use, and viral suppression status (OR 1.17; 95% CI: 0.58-2.34).

Conclusions: There is no clear relationship between the APOL1 risk variants and CVE or death from all causes in adults with advanced CKD and HIV.

PUB131

Proteinuria: Is It a Therapeutic Target or Only a Cardiovascular Risk Marker? Jafar Al-Said. *Internal Medicine and Nephrology, Bahrain.*

Background: Studies published over the last decade had illustrated that despite the successful reduction in proteinuria there were either no benefit or a negative impact on renal and cardiovascular outcomes.

Methods: Review recent published trials, which have shown an evidence of decreased proteinuria and have renal and cardiovascular outcome.

Results: The following studies were identified: The IDNT; The final outcome revealed that although Irbisartan succeeded in lowering doubling of S. Creatinine as well as proteinuria, it failed to show a significant difference in CV mortality, non-fatal MI, heart failure, or stroke. The DIAB-HYCAR; the result confirmed a successful reduction in albuminuria by 14%. However, no significant difference was found on CV outcome, including death, non-fatal MI, stroke or heart failure. The ONTARGET, in a sub analysis; looking at renal outcome, including doubling S. Cr., dialysis and death, it revealed that although the ACE Inh. and the ARB combination had successfully reduced proteinuria, but it resulted in worse renal outcome. The TRANSCEND; by looking specifically at the renal outcome, including dialysis and doubling serum Cr., it was found that GFR had decreased. The AASK trial; the results did not show a positive solid endpoint associated with lowering proteinuria, no statistical difference was encountered. The ROADMAP; the result revealed that decreasing miroalbuminuria as well as blood pressure in the Olmisartan subgroup was not reflected in decreased cardiovascular death. The Altitude trial; decreased proteinuria did not show a significant evidence in the primary renal or cardiovascular composite endpoints. Moreover, the study was terminated prematurely because of severe decline in eGFR, hyperkalemia and hypotension. The *VA-NEPHRON-D;* The final outcome was not statistically different. The study was stopped prematurely because of more acute renal injury and hyperkalemia in the combination arm.

Conclusions: Decreased proteinuria was associated with negative cardiac and renal outcomes. This could be due to the effect of RAAS combination, but we have to admit that these repeated observations carries an evidence, at least to question our standard belief, and that proteinuria might not be more than a cardiac risk factor indicator.

PUB132

Prevalence of Hematuria and Associations with All-Cause and Cardiovascular Mortality in China Jinwei Wang, Fang Wang, Luxia Zhang, Ming Hui Zhao. *Renal Div, Dept of Medicine, Peking Univ First Hospital, Beijing, China.*

Background: Hematuria is one of the indicators of kidney damage. We aimed to estimate the prevalence of hematuria in China and evaluate its association with mortality and cardiovascular adverse outcome.

Methods: A nationally representative sample of 47,204 Chinese adults was obtained during the survey conducted between January 2009, and December 2012. Each participant's survival status was identified through Dec 31, 2013. Causes of death in ICD code I00-I99 were classified as cardiovascular disease. Hematuria was defined as ³3 red cells per high-power field in microscopic examination. Subjects with pyuria and women undergoing menstruation were excluded from the analysis. The associations between hematuria and all-cause and cardiovascular mortality were studied by using the Cox regression model.

Results: The mean age of the population at baseline was 49.6±15.2 years, and 42.7% of the participants were male. Altogether, 2126(4.5%) of the population was detected with hematuria. The all-cause and cardiovascular mortality for participants with hematuria were 3.8 and 2.6 per 1000 person-years, while those for participants without hematuria were 3.4 and 1.3 per 1000 person-years. Hematuria was found to be significantly associated with increased risk of cardiovascular mortality with the multivariable adjusted hazard ratio of 1.7 (95% confidence interval: 1.1-2.7), compared with those without hematuria. However, no significant associations were found between hematuria and all-cause mortality.

Table 1. Mortality risk estimation and hazard ratios for mortality according to hematuria status			
Hematuria	% Events	Events per 1000 person-years	Fully adjusted hazard ratio (95% confidence interval)
All-cause mortality			
No	1.8%(805/45078)	3.4	Reference
Yes	2.0%(43/2126)	3.8	0.9(0.6,1.3)
Cardiovascular mortality			
No	0.6%(285/45078)	1.3	Reference
Yes	0.9%(20/2126)	2.6	1.7(1.1,2.7)

Conclusions: Mortality, especially due to cardiovascular diseases, was greater among the Chinese patients with hematuria. These results suggest the possible effect of hematuria on cardiovascular mortality.

PUB133

Glomerular Filtration Rate Is a Predictor of Subclinical Left Ventricular Diastolic Dysfunction in Patients with Rheumatoid Arthritis

Suad Ma Hannawi, Kashif Naeem, Issa AL Salmi. *Medicine, MOH, United Arab Emirates; Medicine, MOH, United Arab Emirates; Medicine, The Royal Hospital, Oman.*

Background: Rheumatoid arthritis(RA)is a systemic disease effecting primarily joints with subclinical kidney involvement. Subclinical cardiovascular disease(CVD)is a leading cause of morbidity& mortality in RA& chronic kidney disease(CKD) at early stages. Left ventricular diastolic dysfunction(LVDD) is a principal pathophysiologic mechanism& essential diagnostic indexes of HF with preserved ejection fraction(HFPEF).

Methods: Renal parameters correlated with echocardiographic findings in patients with RA& eGFR,as estimated(MDRD equation). Doppler echocardiography was performed by pulse wave Doppler with sample volume at tip of mitral valve in apical 4-chambers view. Peak early(E)&late(A)diastolic velocities were measured as indicator of LVED pressure. Assessment of peak early(E')& late(A)diastolic mitral annular velocity was performed by pulsed wave tissue Doppler imaging(TDI)of lateral wall in apical 4-chamber view &to diagnose LVDD(E/E'>8).

Results: Interim analysis:29(3M,26F) with RA diagnosed(ACR1988), aged46±12year&GFR 130±36 ml/min. Univariate regression showed a negative linear relationship of GFR&age(p<0.001,CI-2.77,-1.03),age@RA onset(p=0.001,CI-2.32,-0.65),age@RA diagnosis(p=0.002,CI-02.55, -0.66),SBP(p=0.032,CI-1.51,-0.07),ESR(p=0.005,CI-1.09,-0.21),ferritin level(p=0.008,CI-0.45,-0.08),EE'(p=0.005, CI-20.76,-4.26). Multiple regression maintained a negative relationship between GFR& each of age (p=0.004,CI-2.59,-0.57)&EE(p0.04,-15.25, -0.011)&R2 was 0.54.

Conclusions: RA patient have subclinical CKD and cardiac dysfunction &eGFR independently & negatively correlated to LVDD with moderate correlation(0.54). E/E' increased with decreasing GFR& higher than in patients GFR≥90. LVDD influenced by increase LV preload due CKD progression& it's a pre-clinical predictor of future HF& mortality. However, milder form of LVDD may stabilize or improve& subset of patients may, over time, be at risk for functional deterioration. Inflammation as a major pathological key in RA may be underlying cause for increased subclinical kidney& VD.

PUB134

The Association Between Creatinine versus Cystatin-C-Based eGFR and Cardiovascular Risk Factors in Children with Chronic Kidney Disease

Sheena Sharma,[1] Ji Young Kim,[2] Susan L. Furth.[1] *[1]Nephrology, Children's Hospital of Philadelphia, Philadelphia, PA; [2]Biostatistics Core, Clinical and Translational Research Center, Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: Chronic kidney disease (CKD) is an independent risk factor for cardiovascular events (e.g. stroke, myocardial infarction) in adults. Children with mild-moderate CKD have a high prevalence of cardiovascular risk factors (CRF). Higher levels of cystatin-C demonstrate a stronger predictive value for cardiovascular events compared with creatinine-based eGFR in adults. However, whether similar associations exist in children and young adults has yet to be determined. We hypothesize that cystatin-C-based eGFR will demonstrate a stronger association with CRF compared with creatinine-based eGFR in children and young adults.

Methods: We used cross-sectional data of 93 subjects aged 8-25 years with CKD and 70 healthy controls. eGFR was calculated using age appropriate creatinine and cystatin-C based formulas. The CRF included were anemia (hemoglobin < 2 standard deviations below the mean), hypertriglyceridemia (>130mg/dL) and proteinuria (urine protein/ creatinine >0.2mg/dL or urine albumin/creatinine >30mcg/g). Multivariate analysis assessed the association between creatinine and cystatin based eGFR and each risk factor after adjusting for age, gender and race.

Results:

CRF	eGFR creatinine estimate [95% CI]	eGFR cystatin-C estimate [95% CI]
Hemoglobin (g/dL)	0.22 [0.15, 0.3]	0.23 [0.16, 0.31]
Triglycerides (mg/dL)	-5.08 [-7.83, -2.34]	-6.23 [-8.89, -3.58]
Urine protein/creatinine (mg/dL)	-0.18 [-0.26, -0.09]	-0.20 [-0.28, -0.11]
Urine albumin/creatinine (mcg/g)	-53.03 [-69.93, -36.13]	-56.45 [-72.84, -40.06]

Conclusions: These results suggest that creatinine and cystatin-based eGFR have similar associations with CRF.

PUB135

The Influence of Selected Demographics and Clinical Factors on Left Ventricular Function Presented by Echocardiographic Study in Patients Treated with Peritoneal Dialysis

Maria Wanic-Kossowska, Krzysztof Pawlaczyk, Krzysztof Schwermer, Krzysztof Hoppe. *Dept of Nephrology, Transplantology and Internal Medicine, Poznan Univ of Medical Sciences, Poznan, Poland.*

Background: The purpose of the study was to perform a cross-sectional analysis between the selected demographics including age, sex, BMI as well as peritoneal dialysis treatment vintage, volume of residual diuresis, presence of arterial hypertension, anemia, inflammatory states, malnutrition, mass of the left ventricle, problems with the contractile function of the left ventricle as well as decreased relaxation of the left ventricle in the group of patients treated with peritoneal dialysis with regard to survival prognosis.

Methods: The study was conducted on 105 patients (49 men, 56 women) treated with peritoneal dialysis with the average time of 36.1±23.7 months. The control group consisted of 30 healthy volunteers (20 women, 10 men, mean age 55.0±23.8 years). Based on general known vascular and cardiac risk factors the patients were divided into subgroups: elderly patients (>65 years of age), male, patients treated on peritoneal dialysis over 3 years, daily diuresis <500 ml, Kt/V<2.1, arterial hypertension, anemia, inflammatory states, malnutrition.

Results: Analyzing the frequency of vascular and cardiac risk factors resulting in inadequate echocardiogram results showed the inflammatory states were the most common reason for increased left ventricular mass, diastolic dysfunction of the left ventricle as well as decreased ejection fraction. In the model of logistical regression taking into account age, sex, dialysis vintage, concentration of CRP, ejection fraction of the left ventricle, left ventricle mass, and factoring E/A from the echocardiogram study only advanced age of the patient treated on peritoneal dialysis decreased survival rate.

Conclusions: Chronic low-grade inflammation and advanced age seem to be two most common negative prognostic factors decreasing life expectancy. Further research is necessary to verify the intricate relationships between demographic factors and prognosis in the group of patients undergoing peritoneal dialysis.

PUB136

Ankle Brachial Index and Exertional Leg Pain Among Hemodialysis Patients without a Clinical Diagnosis of Peripheral Arterial Disease

Pranav S. Garimella,[1] Lucia Kwak,[2] Kunihiro Matsushita,[2] Esther D. Kim,[3] Michelle M. Estrella,[2] Stephen M. Sozio,[3] Lucy A. Meoni,[2] Rulan S. Parekh,[4] Bernard G. Jaar.[2] *[1]Tufts Medical Center; [2]Johns Hospkins Univ; [3]Univ of Toronto.*

Background: Exertional leg pain is considered pathognomonic for diagnosing peripheral artery disease (PAD). However, patients on dialysis may have multiple comorbidities causing or masking leg pain, potentially precluding its use to diagnose PAD. Furthermore, the utility of the ankle-brachial index (ABI) to diagnose PAD in this population is questionable due to the presence of arterial calcification. In this context, there are no data on the association of leg symptoms with ABI in dialysis patients despite them having an extremely high burden of PAD.

Methods: We evaluated the cross-sectional association of exertional leg symptoms with the spectrum of ABI in 247 incident hemodialysis patients without clinical diagnosis of PAD enrolled in the Predictors of Arrhythmia and Cardiovascular Events (PACE) study. The presence of exertional leg pain was based on questionnaire and ABI was categorized as low (<0.90), borderline (0.90-<1.00), normal (1.00-1.39) and high (³1.4). We used logistic regression analysis to report odds of exertional leg pain.

Results: Mean age was 54 years, 76% were black and 51% had diabetes. The prevalence ofexertional leg pain was lowest in the normal ABI category and increased towards both ends of the spectrum. Compared to normal ABI, low ABI was associated with 2.8 fold higher odds of exertional leg pain, although it did not reach significance. After adjusting for age, gender and race this association was attenuated to 2.5 fold odds. Borderline and high ABI were also similarly associated with exertional leg pain.

ABI	Proportion without exertional leg pain, (%)	Unadjusted OR (95% CI)	P value
<0 .9	6/12 (50%)	2.80 (0.85 - 9.18)	0.09
0.9 ≤ to < 1.0	7/21 (33%)	1.40 (0.53 - 3.72)	0.50
1.0 ≤ to < 1.4	39/148 (26%)	ref	--
≥ 1.4	22/66 (33%)	1.40 (0.74 - 2.62)	0.30

Conclusions: Low ABI tended to be associated with higher risk of exertional leg pain. A low ABI value may be useful to identify ischemic etiology of leg pain even among dialysis patients with high prevalence of leg symptoms due to various conditions.

PUB137

Chronic Kidney Disease Is Highly Prevalent at Emergency Department and Associated with Cardiovascular Comorbidity Jolanta Malyszko,[1] Anita Swietochowska.[2] *[1]Nephrology, Medical Univ, Bialystok, Podlaskie, Poland; [2]Emergency, Regional Hospital, Lomza, Poland.*

Background: Different stages of CKD affects more than 10% of the population, while in high-risk patients, the incidence of 30-50% is reported. The aim of this work was to evaluate the prevalence of CKD in patients admitted to the non-surgical emergency department in one year, the impact of CKD risk factors, rate of hospitalization and mortality.

Methods: From 10500 patients admitted to ED, the group of patients with serum creatinine measured, i.e. 3835 (40%) patients over 18 years was selected, including 2095 (55%) subjects over 70 years. Gender, age, medical history of hypertension, heart failure, ischemic heart disease, acute coronary symptoms (ACS), diabetes, inflammation, current medications, physical examination, laboratory results: creatinine, C-reactive protein (CRP), leukocyte count, hemoglobin, the alcohol level in serum, urinalysis were analyzed.

Results: 2179 patients were hospitalized (57%) mainly for cardiovascular reasons, remaining were discharged home. 561 (15%) were admitted to the ED more than once. Abnormal serum creatinine was found in 27%,while 19% have CKD stage 3 and 5% stage 4. Active urine sediment was present in 20% of studied patients. Patients and physicians were unaware of this finding.A small percentage of patients were under nephrology care. Accumulation of risk factors such as gender, age, hypertension, diabetes, results in an increased prevalence of CKD. Prevalence of hypertension in the population of patients with CKD is high (59% vs 29% in non-CKD, p<0.001), similarly to prevalence of CAD (24%), DM (15%) and CHF (16%). In CKD, 30% of patients have anemia.In-hospital mortality was 6%. Analysis of mortality of patients admitted to the emergency department and then hospitalized showed that the majority of patients were over 70, with CKD (64%), CHF (75%), DM (35%), ACS (25%) and anemia (56%). Deaths were mainly from cardiovascular causes.

Conclusions: Prevalence of CKD is high in patients admitted to ED, and associated with mainly cardiovascular disease. Education is of utmost importance to diagnose and treat CKD in a timely manner and decreased cardiovascular morbidity and mortality in this population.

Funding: Government Support - Non-U.S.

PUB138

Predictors of In-Hospital Mortality of CKD4-6 Patients with Takotsubo Cardiomyopathy Fernando Rodrigo Aguilar, Mark Abi Nader, Wen Shen, Serban A. Dragoi, Alex Montero, Ping Li. *Internal Medicine, Div of Nephrology, Medstar Georgetown Univ Hospital, Washington, DC.*

Background: The pathophysiology of Takotsubo cardiomyopathy (TTC) remains poorly understood and little is known about the factors predicting mortality in these patients among those with chronic kidney disease. We aimed to study the epidemiology of TTC and predictors of mortality in these patients.

Methods: All patients with CKD 4 to CKD 6 (ICD9 585.4-585.6) diagnosed with TTC (ICD9 429.83), in the Nationwide Inpatient Sample database between 2007 and 2012, were compared to CKD4 -CKD6 patients without TTC. Capturing only cases undergoing left heart catheterization (ICD9 procedure code 32.22) and excluding those recieving stent (ICD9 procedure code 00.66; 36.01 - 07;00.45-00.48) as a main treatment. Both groups were matched, using propensity matching score for chronic conditions including diabetes mellitus, hypertension, hyperlipidemia, coronary artery disease, obesity, alcohol use, smoking, heart failure and ventricular arrhythmias. Non-cardiovascular conditions were also used to match individual cases. Multivariable logistic regression analysis was performed.

Results: 143 cases of TTC were diagnosed from 2007-2012 in patients having CKD4-6. Were 138 cases were matched (n to 1) and posteriorly analyzed. Among to control group, CKD 4-6 patients with TTC was more commonly diagnosed in Women (86.23% vs 13.77 p=1.0). Alcohol, older, smoking and anxiety, were significantly more prevalent in TTC group. In-hospital mortality rate was not different among both groups even after multivariable regression analysis. Contrary to epidemiologic studies in the general population, Age, Race Stress, anxiety, smoker, Obesity and HTN did not predict mortality with TTC.

Conclusions: In CKD4-6 patients, TTC does not carrya higher mortality outcome compared to the general CKD4-6 patients. Older CKD4-6 females, with anxiety disorder and smokers are at higher risk to develop TTC.

PUB139

The Importance of Evaluating Coronary Artery Disease by Multi-Director Row Computed Tomography in Advanced CKD Masataka Hasegawa,[1] Daiki Kobayashi,[2] Masahiko Nagahama,[1] Takuya Fujimaru,[1] Yuki Heath,[1] Fumika Taki,[1] Miyuki Futatsuyama,[1] Yasuhiro Komatsu.[1] *[1]Nephrology, St. Luke's International Hospital, Tokyo, Japan; [2]General Internal Medicine, St. Luke's International Hospital, Tokyo, Japan.*

Background: There is a growing body of evidence that CKD contributes to the severity of coronary artery disease (CAD). Although Multi-director row computed tomography (MDCT) provides valuable information about CAD, its use for patients with CKD is difficult due to the risk of contrast induced nephropathy (CIN). To our knowledge, there have been no studies to explore the association of CAD and advanced CKD. The objectives of this study are to assess the severity of CAD in advanced CKD patients by MDCT and clarify the association between CAD and renal function.

Methods: We retrospectively collected the data from 168 advanced CKD patients, stage 3b to 5, who underwent MDCT angiography at St Luke's international hospital between 2011 and 2014. We assessed CAD by coronary artery calcification score (CASC), coronary plaque characteristics and number of vessel disease. Risk factors for CAD were sought using univariate and multivariate logistic regression.

Results: Among the 168 patients (56 females, age 60.0±17.0), 108 patients were CKD stage 3b, 42 patients were stage 4, and 18 patients were stage 5. No patient developed CIN by MDCT. On univariate analysis, patients with CASC³100 were older (P=0.003), male sex (P=0.011), diabetic (P=0.045), and more likely to be a smoker (P=0.014). Multivariate logistic regression analysis identified age (hazard ratio = 1.08, P<0.01), male sex (hazard ratio = 2.97, P=0.013), and CKD stage (hazard ratio = 2.58, P=0.041) as independent risk factors for CASC³100.

Conclusions: Coronary artery calcification is worsened significantly with decreasing renal function in advanced CKD. Given the high morbidity and mortality of cardiovascular disease in CKD, our study underscores the importance of evaluating CAD in advanced CKD.

PUB140

Cardiovascular Biomarkers and Coronary Calcification in CKD Patients Joaquin Manrique,[1] Diana Izquierdo,[1] Patricia Restituto,[2] Nuria Garcia-Fernandez,[3] Maria Fernanda Slon,[1] Diana Lopez Espinosa,[3] Maria Jose Molina Higueras,[3] Nerea Varo.[2] *[1]Servicio de Nefrologia, Complejo Hospital de Navarra, Pamplona, Spain; [2]Servicio de Bioquimica, Clinica Univ de Navarra, Pamplona, Spain; [3]Servicio de Nefrologia, Clinica Univ de Navarra, Pamplona, Spain.*

Background: Cardiovascular calcification and mortality are highly prevalent in patients with CKD. Biomarkers can help to an early diagnose, like Osteoprotegerin (OPG) a glycoprotein from TNF family that has been associated with cardiovascular (CV) disease. FGF-23, a phosphaturic protein has been linked to vascular calcification, ventricular hypertrophy and mortality. Coronary artery calcification (CAC) measured with Agatston score (AS) by CT is associated to CV disease in CKD patients.We hypothesized that OPG and FGF-23 are abnormally elevated in CKD and are associated CAC measured with AS.

Methods: An observational study including 138 CKD 3-5patients, and 20 control subjects were included. Serum FGF-23 and OPG levels were measured by ELISA and CAC was determined by multi-detector computed tomography (AS). Biochemical regular labs (sCr, Ca, P and PTHi) were measured.

Results: Compared with control subjects, CKD patients exhibited significantly augmented serum FGF-23 (16.2 vs 304.8pg/mL; p<0.001) and OPG levels (157.0 vs 1711.7pmol/L; r2=0.58; p<0.001), and increased proportionally to CKD stage. FGF-23 and OPG were correlated to PTHi and P (p<0.001) and OPG correlated with renal function (sCr) in non-dialysis patients(p<0.05). CKD 5 patients showed significantly higher coronary calcification (AS: 1344.3) compared with CKD 3 (144.3;p<0.05) or CKD 4 (527.7; p<0.05). FGF-23 and OPG were associated with AS (r2=0.24; p<0.05 and r2=0.37;p<0.001, respectively). Among CKD patients, high CAC (AS>800) compared to low CAC patients (AS levels<150) showed higher FGF-23 (374.9 vs 156.1; p<0.05) and OPG levels (2121.2 vs 1305.2; p<0.001).

Conclusions: CKD is related to high coronary artery calcification levels. FGF-23 and OPG are higher in CKD patients and are significantly associated to coronary artery calcification. Further investigations are needed to determine if they could promptly assess increased cardiovascular risk in CKD patients.

PUB141

Rate of Kidney Function Decline and Risk of Hospitalizations Yan Xie,[1] Benjamin Charles Bowe,[1] Sumitra Balasubramanian,[1] Ziyad Al-Aly.[1,2] *[1]Research and Development, VA Saint Louis Health Care System, Saint Louis, MO; [2]Medicine, VA Saint Louis Health Care System, Saint Louis, MO.*

Background: Risk of hospitalizations is increased in patients with chronic kidney disease (CKD). We sought to examine the association between rate of kidney function decline and risk of hospitalization in a cohort of patients with early CKD.

Methods: We built a cohort of 241,274 United States veterans with an estimated glomerular filtration rate (eGFR) between 60 and 45 ml/min on October 1, 1999 and who had at least 1 additional eGFR measurement between October 2003 and September 2004. Patients were followed longitudinally from October 2004 until September 2013. We built

survival models to examine the association between rate of kidney function decline and risk of hospitalization, and readmission. We built linear regression models to estimate the length of hospital stay.

Results: Over a median follow up of 9 years (IQR 5.42 – 9.00), compared to patients who experienced mild eGFR decline, patients with moderate and severe eGFR decline exhibited an increased risk of hospitalizations HR=1.10 (CI:1.07-1.12), and HR=1.29 (CI:1.26-1.32); respectively. The number of hospitalizations modified the association between rate of decline and risk of hospitalizations in that the risk was increasingly more pronounced with increased number of hospitalizations (p value for interaction <0.0001). Compared to patients with mild decline in kidney function, patients with moderate and severe kidney function decline had increased risk of future readmission, HR=1.16 (CI:1.10-1.21), and HR=1.47 (CI:1.39-1.55); respectively. Among patients with severe kidney function decline, the risk of readmission was increasingly stronger with increased number of readmissions (p value for interaction < 0.0001). Compared to patients with mild decline in kidney function, patients with moderate and severe decline experienced an additional length of stay of 0.91 (CI: 0.58-1.25) and 2.82 (CI: 2.43-3.20) day/year; respectively.

Conclusions: Our findings suggest that rate of kidney function decline is associated with future risk of increased health care utilization.

PUB142

Racial Influences on the Association of Albumin and Hemoglobin in Chronic Kidney Disease Divya Shankaranarayanan, Avaneesh Jakkoju, Goutham Gudavalli, Ziad Maurice Ashkar. *Dept of Internal Medicine, Louisiana State Univ, Lafayette, LA.*

Background: In CKD, anemia is associated with reduced kidney function, female gender, diabetes, older age, African-American race(AA), iron deficiency, low albumin , renin-angiotensin blockade, and chronic inflammation. There is a paucity of studies evaluating relationship of albumin and hemoglobin(Hb) in CKD among racial groups.

Methods: Retrospective cross section design of 196 patients with CKD stages 2-5, in a community clinic over a 7 months period. Averages of hemoglobin, albumin, body mass index (bmi), and glomerular filtration rate(GFR) were obtained for each individual patient. Patients on dialysis and on erythropoesis-stimulating agents were excluded. Multi-linear regression analysis (MLR) was then done between serum albumin and hemoglobin adjusting for age, sex, diabetic status, GFR, bmi ,and Ace inhibitors/angiotensin receptors blockers intake (ACEi) among African-Americans(AA) and Caucasians(W).

Results: 51% were AA. 49% were diabetics. Mean Hb was 11.7 in AA compared to 12.3 in Caucasians . Mean serum albumin was also lower (3.5 AA versus 3.8 in W). Bmi and GFR were higher in AA (36.4 and 42.8 in AA vs 32.3 and 39.9 in W respectively). Using MLR , there was a statistically significant positive association between GFR(coefficient=0.02,p<0.001) , albumin (coefficient=0.77,p=0.002),and hemoglobin. AA race was negatively related to hemoglobin(coefficient= -0.68,p=0.02). When MLR was done separately among racial groups, there was a persistent positive relationship between albumin and hemoglobin among AA (coef=0.95, p=0.001). In Caucasians however there was no association between albumin and hemoglobin (p=0.181).

Conclusions: In CKD2-5, using multilinear regression analysis, there was a positive association between serum albumin and hemoglobin. This relationship occurs only in AA and disappears among Caucasians. It is of interest that in our sample AA had higher baseline bmi and GFR and lower serum albumin and hemoglobin. More needs to be done to understand the interplay between bmi , albumin and markers of inflammation and nutrition among African Americans with chronic kidney disease and their relationships to hemoglobin levels.

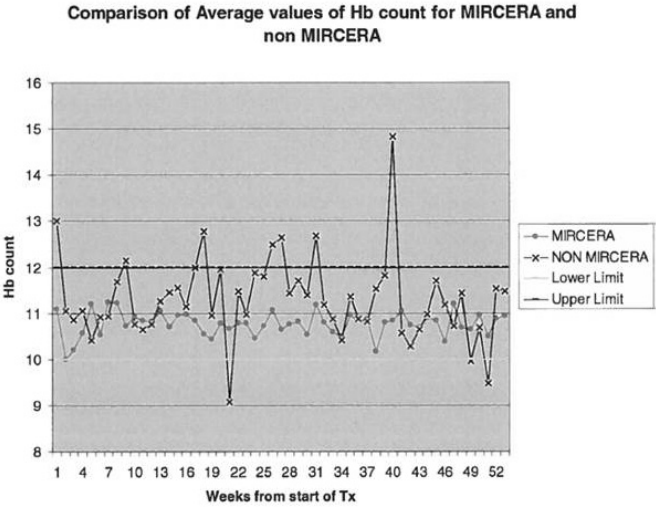
PUB143

Mircera Use in Chronic Kidney Disease Patients with Symptomatic Renal Anemia: The Real Life Setting Sai Krishna Duraisingham, Suzanne H. Forbes, Muhammad M. Yaqoob. *Renal and Transplantation Medicine, Barts Health NHS Trust on behalf of the Mircera Audit Consortium, London, United Kingdom.*

Background: Randomized controlled trials have confirmed non inferiority of Mircera in the management of renal anemia when compared to other erythropoietin stimulating agents (ESAs). Many of these trials had strict exclusion criteria which perhaps confounded any benefit that may be seen in an unselected cohort of patients. This multicenter audit assessed the outcomes of Mircera use in the real life setting.

Methods: A prospective audit was conducted by 6 UK Renal Centers between 2009 and 2011. Demographic data, as well as hematological and biochemical parameters were longitudinally collected from 1000 adult patients requiring ESAs, over a 1 year period. A cohort of 500 patients were switched from previous ESAs to Mircera and 500 patients remained on their existing ESA therapy. Patients with hemoglobinopathies or malignancies were excluded. Achievement of target hemoglobin (Hb) as per the National Institute of Clinical Excellence (NICE) guidelines was ascertained as the primary objective. Hb variability was reviewed as a secondary objective.

Results: Demographic data confirmed both cohorts were comparable. Only 11% of Mircera treated patients had their Hb maintained within range (10-12g/dl) over the entire 1 year versus 4% in the non-Mircera group (p<0.05). (If an Hb recording was out of range the patient was classified as 'not maintained'). Parameters such as B12, folate and iron were similar in both cohorts. Hb was less variable in the Mircera group



Conclusions: The results of this audit confirm that Mircera use in the correction of anemia associated with CKD is equally efficacious as other ESA therapies in this real life setting.Over a year period, Hb variability was noted to be reduced in the Mircera treated cohort suggesting a role for its use in patients with fluctuant Hb levels.

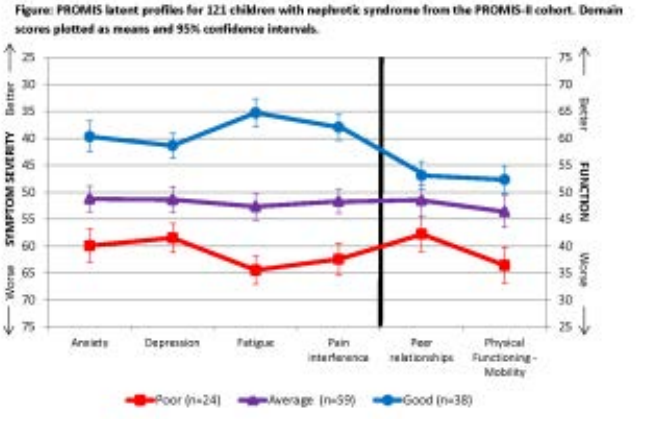
Latent Profiles of Patient Reported Outcomes in Nephrotic Syndrome Patients Jonathan P. Troost,[1] Debbie S. Gipson,[1] Bryce B. Reeve,[2] Patrick H. Nachman,[2] Rasheed A. Gbadegesin,[3] Jichuan Wang,[4] Frank Modersitzki,[5] Susan F. Massengill,[6] John D. Mahan,[7] Howard Trachtman,[5] David T. Selewski.[1] *[1]Univ of MI; [2]Univ of NC; [3]Duke Univ Medical Center; [4]George Washington Univ; [5]New York Univ; [6]Levine Children's Hospital; [7]The Ohio State Univ.*

Background: Nephrotic syndrome (NS) can significantly impair the quality of life in children and adults. The purpose of this study was to demonstrate the feasibility and utility in using a latent profile analysis (LPA), a type of cluster analysis, to identify subgroups of patients based on their patient reported outcomes using the Patient Reported Outcomes Measurement Information System® (PROMIS®) measures as well as identifying significant predictors of those subgroups.

Methods: Prospective data were collected on 121 children with NS from the PROMIS-II study. Data from 55 children and 254 adults with biopsy confirmed NS from the NEPTUNE cohort were used as validation. LPA was used to identify patterns and subgroups of patients based on PROMIS domain scores. Classification was assessed using entropy statistics. Generalized multinomial logit models were used to identify predictors of profile membership as well as transitions between profiles over time.

Results: We identified three patient reported outcome profiles (figure1) in the PROMIS-II cohort with strong indicators of membership classification (entropy>0.86).



Initial subgroups derived from the PROMIS-II cohort were also present in NEPTUNE. Reaching complete proteinuria remission, reduction in symptom number, increase in serum albumin, and shorter disease duration were significant predictors of better quality of life over time.

Conclusions: LPA may be an effective tool in stratifying NS patients by quality of life. Profile membership changed in response to changes in disease status over time.

Sex Hormone Status in Women with Chronic Kidney Disease: A Survey of Nephrologists Sharanya Ramesh,[1] Ellen Wells Seely,[2] Matthew T. James,[1,3] Jayna M. Holroyd-Leduc,[3] Stephen B. Wilton,[3,4] Sofia B. Ahmed.[1,3,4] *[1]Medicine, Cumming School of Medicine; [2]Brigham and Women's Hospital; [3]Community of Health Sciences, Univ of Calgary; [4]Libin Cardiovascular Inst of Alberta.*

Background: Chronic kidney disease (CKD) in women is often accompanied by menstrual and fertility disorders due to kidney-mediated endocrine disturbances. Whether this issue is recognized by nephrologists and discussed by them with their patients is unknown.

Methods: We electronically surveyed 111 nephrologists in Canada, identified via Canadian Society of Nephrology membership (39% response rate), regarding their impressions of sex hormone status, menstrual cycle, fertility and the role of postmenopausal hormone therapy (HT) in women with CKD. Responses were stratified by kidney transplant nephrologist status.

Results: Fourteen percent of respondents were transplant nephrologists. There were no differences in age or sex between transplant and non-transplant nephrologists. Ninety-three percent of respondents agreed that kidney function has an important impact on regulation of sex hormones. However, only 35% reported discussing fertility, and even fewer (14%) reported discussing menstrual irregularities with their patients. Only 40% of respondents advised their patients to address these concerns with their family physician or an endocrinologist or gynecologist. Most of the of nephrologists responded that they do not know if there is a role for hormone replacement therapy in patients with CKD (48%), 23% of nephrologists disagreed with the statement. Nephrologists did not know whether the potential benefits of postmenopausal hormone therapy outweighed the risks in CKD (51%) or if the formulation (44%), route of administration (46%), and time of HRT initiation (50%) play a role in the actions of postmenopausal hormone therapy.

Conclusions: While nephrologists recognize the impact of CKD on sex hormone status in women, few address fertility and menstrual disorders with their patients. Our survey highlight existing uncertainties of nephrologists about how to manage disturbances of sex hormones in people with CKD.

Clinical and Pathological Analysis of Elderly Hospitalized Patients with Chronic Kidney Disease Fu-You Liu, Yinghong Liu. *Inst of Nephrology, the Secongd Xiangya Hospital, Central South Univ, Changsha, Hunan, China.*

Background: To investigate the primary disease and to examine the pathological patterns of renal in elderly patients with CKD.

Methods: Medical histories,laboratory test results and renal biopsy datum were collected and retrospectively analyzed from 967 elderly patients with CKD.

Results: (1)The average age of 967 cases of elderly patients was 68.27 ±6.41 years old.The leading cause of CKD was primary glomerular diseases(37.33%),followed by diabetes nephropathy (23.27%) and hypertensive nephropathy (19.75%). (2) The left kidney was larger than the right,and kidney of male patients was larger than the female($P<0.05$). There was a positive correlation between eGFR and the left kidney width, depth, and the right kidney width, depth. (3)In 75 patients who underwent renal biopsy,the most common renal histopathology in primary glomerular disease was membranous nephropathy (MN) (48.08%). In patients with MN, 88.00% presented as nephrotic syndrome. (4)The prevalence of hypertension was 80.66%.eGFR was negatively correlated with systolic blood pressure levels. (5)The anemia rate of elderly patients with CKD was77.97%.eGFR and hemoglobin levels were positively correlated (6) There was a positive correlation between eGFR and HDL-C, LDL-C, total cholesterol and triglyeride respectively . (7) Calcium-phosphorus metabolism were mainly hypocalcemia (27.92%) and hyperphosphatemia (54.91%) .eGFR was negatively related to the level of blood phosphorus and intact parathyroid hormone(iPTH),and positively related to blood calcium levels.

Conclusions: (1)This study shows that primary glomerular disease is still the leading causes of elderly patients aged 60 and above with CKD,followed by diabetes nephropathy and hypertensive nephropathy. (2)In elderly patients receiving renal biopsy,the most common renal histopathology pattern was MN in primary glomerular disease. (3)It indicated that high systolic blood pressure, renal atrophy,anemia,low HDL-C,hyperphosphatemia and secondary hyperparathyroidism may be associated with deterioration of renal function level.

Measurement of Breath Ammonia for Detection of Patients with Chronic Kidney Disease Sebastjan Bevc,[1] Evelina Mohorko,[2] Mitja Kolar,[2] Polonca Brglez,[3] Andrej Holobar,[3] Daniela Kniepeiss,[4] Matej Podbregar,[5] Nina Hojs,[1] Masa Knehtl,[1] Robert Ekart,[1] Radovan Hojs.[1] *[1]Univ Clinical Centre Maribor, Slovenia; [2]Faculty of Chemistry and Chemical Engineering Maribor, Slovenia; [3]ECHO d.o.o. Slovenske Konjice, Slovenia; [4]Medical Univ Graz, Austria; [5]Univ Clinical Centre Ljubljana, Slovenia.*

Background: In a healthy individual, ammonia is converted to urea in the liver through urea and citric acid cycles. Urea is then transported through the bloodstream to be excreted into the urine by the kidneys. In patients with chronic kidney disease (CKD) an equilibrium concentration of ammonia and urea becomes imbalanced, concentrations exceeding physiological values and breath ammonia can be used for detecting increased nitrogen-bearing wastes in the body. In our pilot study, the electrochemical sensor was used to measure and analyze breath ammonia in healthy volunteers and CKD patients.

Methods: Six CKD patients and eight healthy volunteers were enrolled. The mean age of CKD patients was 47.2 years, mean age of healthy volunteers 61.3 years. One controlled breath sample was given from each participant. Immediately after the sample was collected gas analyzer (BA-NH3, Echo, d.o.o.) was used for measuring breath ammonia in our participants. BA-NH3 detects breath ammonia in parts per million (ppm) and measures the electric current in milliamperes (mA). BA-NH3 was validated with reference gas concentrations prepared with a precise accredited gas mixing device (M4-1-S-220, Echo, d.o.o.) using calibrated mass flow controllers controlled with computer software.

Results: Mean serum creatinine in CKD patients was 455.17±294.12 µmol/L and 62.13±7.5 µmol/L in healthy volunteers. BA-NH3 detected more ppm of ammonia in breath of CKD patients (mean ppm 3.32±2.19; range 1.26-6.33) comparing to healthy volunteers (mean ppm 0.49±0.08; range 0.38-0.64 ppm) ($p=0.003$) and measured higher electric current from breath samples of CKD patients (mean mA 4.33±0.25; range 4.10-4.67 mA) comparing to healthy volunteers (mean mA 4.01±0.01; range 4.00-4.03 mA) ($p=0.003$).

Conclusions: Results of our pilot study show that breath monitoring of ammonia can be an useful simple, fast and noninvasive tool for detection of kidney impairment.

PUB148

Use of Urine Biomarker-derived Clusters to Predict CKD Risk and All-Cause Mortality in HIV+ Women Rebecca Scherzer,[1] Heather Thiessen Philbrook,[2] Chirag R. Parikh,[3] Michael R. Bennett,[4] Mardge H. Cohen,[5] Anjali Sharma,[6] Mary A. Young,[7] Phyllis Tien,[1] Vasantha Jotwani,[1] Michael Shlipak.[1] *[1]UCSF; [2]London Health Sciences Centre; [3]Yale; [4]Cincinnati Children's Hospital; [5]Rush; [6]Albert Einstein; [7]Georgetown.*

Background: Individual urine biomarkers are associated with CKD incidence and all-cause mortality in the setting of HIV infection, but their combined utility for prediction remains unknown.

Methods: We measured 8 urine biomarkers in 902 HIV+ women: NAG, KIM-1, alpha 1 microglobulin (a1m), IL-18, NGAL, ACR, L-FABP, and AAG. A novel cluster method classified each participant into 3 groups using the three most distinguishing markers (NAG, KIM-1, and a1m). We evaluated associations of each cluster with incident CKD and all-cause mortality, adjusting for traditional and HIV-related risk factors.

Results: Over 8 years of follow-up, 177 CKD events and 128 deaths occurred. As shown in the Table, incidence of CKD and mortality increased incrementally across the 3 clusters. After multivariable adjustment, cluster 3 remained associated with a nearly 3-fold risk of both outcomes compared with cluster 1. Addition of the clusters to the multivariable model improved discrimination for CKD (c-statistic=0.72 to 0.76, $p=0.0029$), but only modestly for mortality (c=0.79 to 0.80, $p=0.099$). Clusters derived with all 8 markers were no better for discrimination than the 3-biomarker clusters.

Conclusions: Among HIV+ women, clusters developed from 3 urine biomarkers moderately improved discrimination for CKD risk, but not for all-cause mortality.

Association of biomarker-derived cluster* with incident CKD and all-cause mortality in HIV+ women

Incident CKD	**Cluster 1 n=289**	**Cluster 2 n=435**	**Cluster 3 n=94**
Event rate	13%	21%	50%
Unadjusted Risk Ratio (95%CI)	Ref	1.7 (1.2, 2.4)	3.9 (2.7, 5.6)
Adjusted Risk Ratio (95%CI)	Ref	1.6 (1.1, 2.3)	2.9 (2.0, 4.3)
All-cause mortality	**Cluster 1 n=301**	**Cluster 2 n=470**	**Cluster 3 n=131**
Event rate	7%	13%	34%
Unadjusted Hazard Ratio (95%CI)	Ref	1.9 (1.1, 3.0)	5.4 (3.2, 9.0)
Adjusted Hazard Ratio (95%CI)	Ref	1.5 (0.9, 2.5)	2.8 (1.6, 4.8)

* Clusters were derived using NAG, α1m, and KIM-1. Adjusted models control for traditional kidney risk factors and HIV-related risk factors.

Minimizing Erythropoietin Stimulating Agents Requirement by Comprehensive Clinical Care Rachita Singh Dhull, Rossana Baracco, Melissa J. Gregory, Tej K. Mattoo. *Pediatric Nephrology, Children's Hospital of Michigan, Detroit, MI.*

Background: Anemia is a common problem in children with chronic kidney disease (CKD). The objective of the study was to evaluate prevalence of anemia, use of iron supplement and erythropoietin stimulating agents (ESA) in children with CKD stage 2-4, and compare the same with previous pediatric studies.

Methods: This is a retrospective chart review of children with CKD stage 2-4 (defined per KDOQI), aged between 1-18 years followed at Children's Hospital of Michigan (CHM) in 2013. Data on transferrin saturation, hemoglobin level, use of iron supplements and ESA was collected.

Results: Total number of patients were 62. The mean age was 10.12 ± 5.52 years and 27.4% were female. The main causes of CKD were renal dysplasia (20%), obstructive uropathy (18%), reflux nephropathy (14.5%), cystic dysplasia (13%), glomerular pathology (11.2%) and others (23.3%). In our cohort, 27% patients had anemia compared to 44% in CkiD study and 43.5% in study by Wong et al. Also, only 6.5% of CKD patients were on ESA, compared to 18% in Ckid study and 19.5% in study by Wong et al. Results are elaborated in the table below.

	CKiD STUDY (2008)	Wong et al (2006)	**CHM DATA**			
CKD STAGE	Pateints(%) with anemia[a]/n[b]	Patients(%) with anemia[c]/n[b]	Patients (%)with anemia[a]/ n[b]	Transferrin saturation >=20%	On iron supplement	on ESA
2	21/39	28.57/106	7.7/13	7(53.8%)	9(69.2%)	0
3	39/217	65.8/38	27/37	24(64.8%)	21(56.7%)	0
4	73/82	93.3/15d	50/12	8(66.6%)	9(75%)	4(33.3%)
TOTAL	45/338	43.5/159	27.4/62	39(63%)	39(63%)	4(6,45%)

[a]Anemia as defined by hemoglobin (Hb) level < 5th percentile for age and sex according to NHANES III data.
[b]n= number of children with CKD in that group.
[c]Anemia as defined by Hb <12 g/dl or on medical management for anemia.
[d]includes children with stage 4 and 5 CKD .

Conclusions: Our CKD patients had a lower prevalence of anemia and lower use of ESA compared to other pediatric studies. We maintain adequate iron stores by using iron supplements even in children with normal hemoglobins. The administration of supplemental iron prior to the development of anemia in children with CKD decreases the need for ESA.

PUB150

Validation of Urinary Biomarkers for the Diagnosis of Urothelial Carcinoma in Patients with Chronic Kidney Disease Chiu-Ching Huang,[1] Che-yi Chou,[1] Chao-Jung Chen.[2] *[1]Kidney Inst, China Medical Univ and Hospitals, Taichung, Taiwan; [2]Proteomics Core Laboratory, Dept of Medical Research, China Medical Univ, Taichung, Taiwan.*

Background: Many urine biomarkers for diagnosis of urothelial carcinoma(UC) have been published. CKD patients are prone to have UC. Most of the studies are tested in healthy controls and UC patients. Whether these biomarkers are specific to diagnose UC in CKD patients have not been studied before. **AIMS:** To investigate if current urinary biomarkers are specific to diagnose UC in CKD patients.

Methods: This is a multicenter prospective case-control study, carried out at 7 tertiary medical centers in Taiwan (Taiwan UC Consortium). Subjects were healthy adults (healthy controls), patients with CKD but without UC (disease controls) and patients with ongoing UC.Urine was collected from each patient and frozen immediately after collection. We measured 9 urinary UC biomarkers : BLCA-1.HAI-1.HtrA1, NMP22, CYFRA21-1, TSCSTD2, BLCA-4, BTA and Midkine. Mann-Whitney Rank Sum Test was used for statistical analyses.

Results: A total of 47 UC cases, 288 CKD patients and 20 healthy controls were recruited. We selected 47 CKD control patients who were age, sex and CKD-staging best matched with 47 UC patients. Among the 9 biomarkers tested, six biomarkers,e.g.NMP22, CYFRA21-1, TSCSTD2, BLCA-4, BTA and Midkine showed significant increase of urinary concentrations in UC patients when compared to healthy controls. Nevertheless, only Midkine and CYFRA 21-1 had significantly increased concentrations in UC patients when compared to CKD controls.The other 4 UC biomarkers did not show significant higher concentrations in UC patients than CKD controls.

	P value		
Urine biomarker	Healthy controls vs. CKD controls	CKD controls vs. ongoing UC	Healthy controls vs. ongoing UC
BTA	0.023	0.420	0.175
Blca-4	0.002	0.379	<0.001
NMP22	<0.001	0.486	0.007
TACSTD2	0.005	0.265	0.001
Midkine	0.027	0.050	<0.001
CYFRA21-1	0.676	0.003	0.007

Conclusions: Among 9 urine biomarkers tested, only two showed statistically significant higher urinary concentrations in UC patients than matched CKD patients. Our findings would raise caution of interpreting urinary biomarkers for UC diagnosis in CKD patients.

PUB151

Predictors for 30-Day Hospital Readmission in a Nephrology Ward Carla S. Moreira,[1] Ligia Bessa,[2] Vanda Guardado,[2] Jorge Malheiro,[1] Josefina S. Lascasas,[1] António Cabrita.[1] *[1]Nephrology, Centro Hospitalar do Porto, Porto, Portugal; [2]Nephrology, Hospital Militar de Luanda, Luanda, Angola.*

Background: Rehospitalization, particularly 30-day hospital readmission is a growing concern in health care services. In this study we searched for predictors of 30-day readmissions (including emergency department visits) and 12-months hospitalization rate in patients admitted to a nephrology ward.

Methods: A group of 144 patients admitted to our nephrology ward from 2012 to 2013 were randomly selected. Their medical records regarding demographic and clinical-laboratorial data were collected. The statistical analysis was performed using univariate and multivariate logistic regression, and poisson regression.

Results: Median age was 66yo (IQ 56-81), with 63% of male patients. The majority of the patients had an emergent admission (63%) and regular hospital follow-up (55%). The median length of hospital stay was 7 days. The readmission rate was 23% and the median length until readmission was 13 days. The prevalence of chronic kidney disease was 89%, with 30% of these patients undergoing chronic intermittent hemodialysis and 11% peritoneal dialysis. The median Charlson Comorbidity Index (CCI) was 7 points (IQ 4-11). In the univariate analysis we found a statistical significant association between diabetes mellitus (OR =2.45, p=0.04), lower (<3.5g/dL vs ≥ 3.5g/dL) albumin level (OR=8.73, p=0.006), higher (<8 vs ≥ 8) CCI score (OR=2.94, p=0.02) and 30-day hospital readmission. In the binary logistic regression only albumin level kept its significant association (OR=7.9, p=0.01), with diabetes mellitus maintaining a tendency for significance (OR=2.97, p=0.09). The rate of rehospitalizations at the first year adjusted for gender was 2.6 vs 6.4 rehospitalizations/100 patients-month in the lower and higher CCI score groups, respectively (p=0.01). The rate of emergency department episodes adjusted for gender was 29 versus 75 episodes/100 patient-month in the lower and higher CCI score groups, respectively (p<0.001).

Conclusions: The Charlson Comorbidity Index and albumin level may be valuable predictors of hospital readmission risk in patients from a nephrology ward.

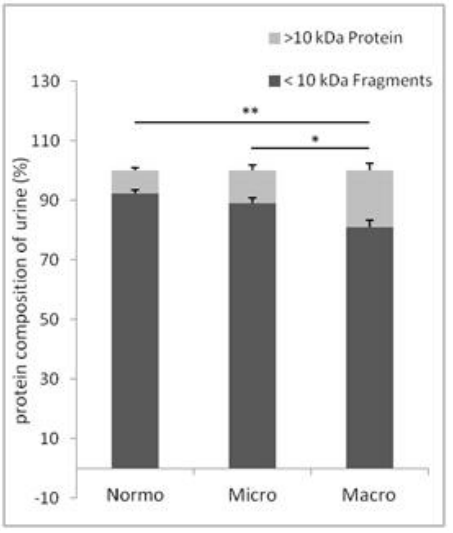
PUB152

Urine Protein Fragment Excretion in Diabetic Patients with Chronic Kidney Disease Michele V. Clarke,[1] Elif Ekinci,[1,2] Nicholas J. Radcliffe,[1,2] Richard J. MacIsaac,[3] George Jerums,[1] Wayne Comper.[4] *[1]Austin Health, Melbourne; [2]Univ of Melbourne, Melbourne; [3]St. Vincent's Hospital, Melbourne; [4]Sal Aqua Diagnostics, New York.*

Background: Albuminuria is an established marker for the development of diabetic nephropathy. Normal renal handling of albumin involves endocytosis by proximal tubule cells through a lysosomal pathway. This returns small albumin fragments, undetectable by standard clinical assays, to the tubular lumen. Albuminuria has been shown in patients with type 1 diabetes to be associated with an impaired degradation pathway, and urinary peptides have been shown to be reduced in patients with macroproteinuria. However, urine peptide excretion studies have not controlled for changes in estimated glomerular filtration rate (eGFR) in patients with diabetes.

Methods: Patients with diabetes and eGFR <60ml/min were stratified into normo- (<20mg/min, n=9), micro- (20-200mg/min, n=12) or macroalbuminuric (>200mg/min, n=9) groups. 24 hr urines were passed through a 10kDa protein filter, and the <10kDa and >10kDa fractions were assayed separately using the BCA protein assay to detect peptide bonds.

Results: Macroalbuminuric patients had a reduced proportion of peptide fragment excretion (<10kDa) compared to micro- and normoalbuminuric patients (81.1% vs 89.0%, p<0.05 & 96.8%, p<0.001 respectively); however there was no difference between micro- and normoalbuminuric groups (Figure 1). Mean fragment concentrations were lower in micro- and macro- groups compared to normoalbuminuric patients, (3389µg/ml and 3480µg/ml vs 4396µg/ml) but did not reach statistical significance.



Conclusions: In patients with diabetes and reduced renal function, we have demonstrated a reduction in peptide fragment proportional excretion in macroalbuminuric patients. These findings are consistent with the hypothesis that albuminuria is linked to defects in the renal tubule resorption and fragmentation pathways.

PUB153

Chronic Kidney Disease of Uncertain Etiology: A Systematic Review Joseph Lunyera, Dinushika Mohottige, Megan Von Isenburg, Uptal D. Patel, Marc A. Jeuland, John W. Stanifer. *Duke Univ.*

Background: Epidemics of chronic kidney disease of uncertain etiology (CKDu) are emerging around the world. Highlighting common risk factors for CKDu across various regions and populations may be important for health policy and public health responses.

Methods: We conducted a systematic review of the PubMed, Embase, Scopus and Web of Science databases to identify published studies on CKDu. Two independent authors reviewed all abstracts for inclusion, assessed each study for quality, and extracted the data. We used a vote-counting method to evaluate the exposures across all studies.

Results: We identified 2535 articles of which 25 met inclusion criteria. Eighteen (72%) were conducted in CKDu-endemic countries: Sri Lanka (40%), Nicaragua (20%) and El Salvador (12%). The other studies were from India, Japan, Australia, Mexico, Sweden, Tunisia and the United States. Risk factors most frequently measured were agricultural occupation (48%), age (48%), gender (44%), and agrochemical use (40%). Heavy metals, heat stress and dietary exposures were reported in studies across all geographical regions. In South Asia, family history, agrochemical use, and heavy metal exposures were reported most frequently while altitude and temperature were reported only in studies from Central America. Across all regions, CKDu was most frequently associated with a family history of CKDu, farming occupation, male gender, middle-age, snake bites and heavy metal exposures. Among high risk populations, CKDu prevalence was reported to be 7.3%-14.9% in South Asia and 13%-25.9% in Central America.

Conclusions: Studies examining etiologies of CKDu have reported many potential exposures that are heterogeneous and vary by region. It remains unknown whether the regional variation in CKDu risk factors reflects inconsistencies in measurement across studies or complexity in the interactions between global exposures and local factors such as environment, genetics, and lifestyle. Thus, to identify the causative factors of CKDu, one important approach could be to design consistent and comparative multi-site studies in high-risk populations that would provide insights into the importance of region-specific versus global risk factors.

PUB154

Understanding the Socio-Demographic Status of Patients Receiving Care at Sonar Bangla Foundation Dialysis Centers in Bangladesh: A Cross-Sectional Pilot Study Tamanna M. Noyon,[1] Mahmood Hussain,[1,2] Imtiaz M. Islam,[1,3] Akm Monoarul Islam,[1,4] Abu hena M. Kamal.[1] *[1]Sonar Bangla Foundation, Santa Clara, CA; [2]Marketing, San Francisco State Univ, San Francisco, CA; [3]Nephrology, Good Samaritan Specialists, Kearney, NE; [4]Nephrology, Rajshahi Medical College & Hospital, Rajshahi, Bangladesh.*

Background: This study constitutes an exploratory investigation to understand the socio-demographic status of patients receiving care at the nine dialysis centers operated by Sonar Bangla Foundation (SBF) in Bangladesh. SBF is a leading non-profit organization, exclusively dedicated to the care of patients suffering from End-Stage Kidney Disease (ESKD). Although ESKD is very common, there is little to no data addressing prevalence of ESKD in Bangladesh. Without understanding its prevalence and the socio-demographic status of patients, little can be done to increase effectiveness and quantity of dialysis centers throughout Bangladesh. This study was launched in April 2015 and will continue throughout the dialysis centers' operations.

Methods: A one-time survey is being conducted to obtain clinical and demographical information on all existing and new patients at SBF centers.

Results: Currently, the study reveals a large gender disparity amongst dialysis recipients, 1 out of 4 patients is female (n=101). The average age of male patients is 44.7 years (SD ±12.7), while the average age of female patients is 45.3 years (SD ±14.2). Furthermore, patients from at least 20 different districts receive dialysis at the centers. The study also finds a significant positive correlation between education level and the frequency of dialysis received.

Conclusions: Data collected throughout this study will be incorporated into an expanding database, first of its kind in Bangladesh**.** ESKD is a devastating disease that forces patients to become dependent on a machine. By understanding the education level, financial status, distance traveled and other factors in relation to the frequency of dialysis received, services provided by SBF centers could be greatly improved. The study aims to change the quality of kidney care in Bangladesh.

PUB155

Clinical and Pathological Features of Idiopathic Membranous Nephropathy in Young Adults Chenni Gao, Jing Xu, Wen Zhang, Xiaoxia Pan, Xiao Li, Nan Chen. *Nephrology, Ruijin Hospital, Shanghai Jiaotong Univ, Shanghai, China.*

Background: Membranous nephropathy (MN) is a common pathological types in elderly nephrotic syndrome (NS) patients. Few researches focus on the young idiopathic MN population.

Methods: 583 patients hospitalized between Jan 2009 and Dec 2014 in our department, with biopsy-proved MN eliminating secondary causes, are enrolled. All patients were divided into 3 groups: 150 patients (25.1%) in young adults group (≤44 yrs), 202 (34.7%) in middle-aged group (45-59 yrs) and 231 (39.6%) in elderly group (≥60 yrs). We collected and compared their clinical and pathological data as well as therapy regimes.

Results: 310 male and 273 female enrolled. The young adults group had a lower rate of NS (P=0.022), higher serum albumin (P<0.01), estimated-GFR (P<0.01) and hemoglobin level (P<0.01), and lower fast blood glucose level (P<0.01).

	young adults group (n=150)	middle-aged group (n=202)	elderly group (n=231)	*P* value
proteinuria(g/24h)	4.7±3.8	4.6±3.9	5.1±3.4	0.271
serum albumin(g/L)	23.8±7.8	23.9±6.9	21.2±6.0	<0.01
nephrotic syndrome	73	105	143	0.022
fast blood glucose (mmol/L)	4.5±0.9	4.8±0.9	4.9±1.1	<0.01
serum creatnine(μmol/L)	64.2±175	71.0±24.8	85.2±40.5	<0.01
eGFR(ml/min/1.73m²)	124.4±31.2	102.2±29.3	83.8±25.3	<0.01
hemoglobin(g/L)	135.4±18.1	132.8±18.1	123.2±17.4	<0.01

Table 1. Clinical features in three groups

There's no significant difference in the disease staging or immunofluorescences staining. However, the young adult patients had fewer mesangial, interstitial, tubular and arteriole lesions, and fewer inflammatory cells infiltration as well (P<0.01). For the therapy, the number of ACEI/ARB regime applied in the three groups was 72/95/75, while corticoid associated with immunosuppressive agents regime was 66/92/140 (P<0.01).

Conclusions: About a quarter of all IMN patients are young adults. They had fewer cardiovascular risk factors, higher serum albumin level and better renal function. Their pathological lesions were milder. ACEI/ARB regime is more widely applied in young adults patients.

PUB156

Effect of Glycemic Control on Estimated Glomerular Filtration Rate by Cystatin C Masaru Horio,[1] Enyu Imai,[2] Yoshinari Yasuda,[3] Tsuyoshi Watanabe,[4] Hitoshi Yokoyama,[5] Hirofumi Makino,[6] Seiichi Matsuo.[3] *[1]Osaka Univ Graduate School of Medicine, Suita, Japan; [2]Nakayamadera Imai Clinic, Takarazuka, Japan; [3]Nagoya Univ Graduate School of Medicine, Nagoya, Japan; [4]Fukushima Medical Univ, Fukushima, Japan; [5]Kanazawa Medical Univ School of Medicine, Kanazawa, Japan; [6]Okayama Univ Graduate School of Medicine, Okayama, Japan.*

Background: Cystatin C has been proposed as an alternative marker for estimating glomerular filtration rate (GFR). But, some factors other than GFR affect the accuracy of estimated GFR (eGFR). Some studies raised a concern that poor glycemic controlmay cause inaccuracy of estimation of GFR. We studied the effect of glycemic control on eGFR based on serum cystatin C (eGFRcys).

Methods: GFR was measured by inulin clearance (Cin). Estimated GFRs were calculated by CKD-EPI equation (CKD-EPI) and Japanese GFR equation (J-Eq) based on standardized cystatin C. Glycemic control was evaluated by serum glycated albumin (GA). Three hundred and forty five Subjects with normal GA (12.4-16.3%) and 126 subjects with high GA (>16.3%) were included. Effects of age, gender, BMI, GA and serum albumin on eGFRcys / Cin ratio was analyzed by multiple regression analysis.

Results: Cin, eGFRcys(J-Eq) and eGFRcys (CKD-EPI) in normal GA were 57.9±34.0, 56.1±31.7 and 57.9±33.9 ml/min/1.73m², respectively. Cin, eGFR(J-Eq) and eGFR (CKD-EPI) in high GA were 36.2±28.9, 36.71±27.5 and 36.7±28.5 ml/min/1.73m², respectively. There was no significant difference among Cin, eGFRcys (J-Eq) and eGFRcys (CKD-EPI) in both subjects. Slopes (95%CI) of the regression lines with zero intercepts in subjects

with high GA were 0.989 (0.944-1.033) in J-Eq and 0.965 (0.922-1.009) in CKD-EPI. The slopes were not significantly different from 1.0, suggesting that eGFRcys performed well in subjects with high GA. Multiple regression analysis showed that age, gender, BMI, GA and serum albumin were not significant factors affecting both eGFRcys(CKD-EPI) /Cin and eGFRcys(J-Eq) /Cin.

Conclusions: Estimated GFR based on cystatin C performed well in subjects with high GA.

PUB157

Renal Hyperfiltration and Outcome in HIV-Infected Subjects

Gianni Cappelli,[1] Elisabetta Ascione,[1] Giovanni Guaraldi,[2] Andrea Malagoli,[2] Elisabetta Rubbiani,[1] Antonio Bellasi.[3] *[1]Univ Hospital of Modena, Nephrology Dialysis and Renal Transplantation Unit, Modena, Italy; [2]Univ Hospital of Modena, Metabolic Clinic, Infectious and Tropical Diseases Unit, Modena, Italy; [3]Azienda Ospedaliera S. Anna, Como; Dept of Health Sciences, Univ of Milan, Nephrology and Dialysis Unit, Como, Italy.*

Background: Although highly active antiretroviral therapy (HAART) improves life expectancy of HIV-infected subjects, it is also associated with numerous comorbidities. Evidence suggests that renal hyperfiltration (RHF) is associated with various lifestyles, clinical conditions and portends poor prognosis in the general population. We sought at determining prevalence of RHF and its associations with traditional and HIV-related risk factors as well as all-cause mortality in a large cohort of HIV-infected subjects.

Methods: Retrospective study of 3875 HIV-infected patients attending at the "Modena Metabolic HIV Clinic". The Chronic Kidney Disease Epidemiology Collaboration equation (CKD-EPI) was used to estimate glomerular filtration rate (eGFR). Linear regression was used to model eGFR against age and sex. RHF was defined as eGFR with residuals above the 95th percentile. Anova, Chi-square, logist regression and survival analyses were used to identify factors and the risks associated with RHF.

Results: Overall, we investigated middle-age (44.5+7.5 years) men and women (male 65.1%) with preserved renal function (eGFR 94.5+17.1 ml/min/1.73 m^2). RHF was inversely associated with age (Odds Ratio 0.93), hemoglobin (OR 0.8), WBCs (OR 0.9) and positively associated with HIV-infection (OR 1.07). Of interest, no association with HAART was noted. Over mean follow-up of 7 years, 75 persons died. RHF was associated with all-cause mortality independently of potential confounders (Hazard ratio: 4.17, 95%CI: 1.81 - 9.6; p<0.001).

Conclusions: RHF is influenced by HIV infection duration independently of established factors and isrelated with the risk of all-cause of death. Future efforts are needed to clarify what are the mechanisms that link RHF with poor prognosis and if RHF modulation improves survival in HIV-infected subjects.

PUB158

Bioelectrical Impedance Analysis as a Screening Tool for Chronic Kidney Disease

Anita Saxena, Amit Gupta. *Nephrology, Sanjay Gandhi Post Graduate Inst of Medical Sciences, Lucknow, UP, India.*

Background: Chronic Kidney Disease (CKD) has a latent period during which the disease is present but asymptomatic. With increasing incidence of hypertension and diabetes, incidence and prevalenceof CKD is on increase. Bioelectric impedance analysis (BIA) a noninvasive method for estimation of body composition in clinical setting but it has not been used for CKD screening. Purpose: To evaluate applicability of BIA as a screening tool for presence of kidney disease in general population with creatinine clearance and glomerular filtration rate (GFR).

Methods: A pilot-cross-sectional CKD screening study on randomly selected 52 subjects from general population. Maltron BIOSCAN analyzer 915/916 was validated with Hume etal's equation for estimation of total body water. BIA derived GFR was validated with ^{99m}Tec-DTPA nuclear scan derived GFR, a study done on voluntary healthy kidney donors.

Results: There was no significant difference between total body water estimated with BIA and Hume etal's equation and BIA derived GFR and DTPA nuclear scan GFR. Mean serum creatinine for males was 0.94 ± 0.14mg% and 0.91± 0.84mg% for females. BIA derived creatinine clearance was 97.39± 28.98 in males and107.60± 34.03 in females, GFR was 74.1±25.98 ml/min/1.73 m^{2}in males and 65.17 ±21.14 ml/min1.73 m^2 in females. Based on GFR subjects were classified into CKD. Out of 52 subjects 8 were in CKD stage 1 (15.5%), 23 (44.2%) were in CKD stage 2, 18 (34.6%) were in CKD stage 3 , 1 (1.9%/1.9%) each in CKD stage 4 and CKD stage 5 respectively. Incidentally, 13.5% were diabetic. and 65.8% were hypertensive. Mean blood pressure was 133.99 ±40.89/82.76 ±27.79 mmHG in males and 132.10 ±16.20/ 83.46± 7.85mmHG in females. Based on American Heart Association classification for hypertension, 19 (36%) patients had normal blood pressure, 8 (15.5%) were in prehypertensive stage, 16 (30.7%) patients were in hypertension stage 1, 6 (11.5%) were in hypertension stage 2 and 2 had crisis hypertension.

Conclusions: Population-based CKD screening programs can identify people with renal injury for early intervention. BIA can be used for screening CKD in general population. It can also be a routine test as ^{99m}Tec-DTPA scan for estimation of GFR.

PUB159

Design and Implementation of a Chronic Kidney Disease Prevalence Study in Rivas, Nicaragua

Kailey Minnings,[1] Martha Mosco,[2] Madeline M. Fiore,[3] Eric S. Kerns,[4] Juan Jose Amador,[5] Rulan S. Parekh,[6] Louis D. Fiore.[5] *[1]Faculty of Medicine, Univ of Toronto, Toronto, ON, Canada; [2]Lowering Poverty and Disease, Boston, MA; [3]Tulane Univ, New Orleans, LA; [4]Warren Alpert Medical School, Brown Univ, Providence, RI; [5]School of Public Health, Boston Univ, Boston, MA; [6]Hospital for Sick Children, Toronto, ON, Canada.*

Background: High rates of chronic kidney disease of unknown etiology (CKDu) have been noted in certain populations along the Pacific coast of Central America. CKDu is unlike traditional CKD in that the usual underlying risk factors are not present. CKDu in Nicaragua has been noted to affect mainly sugarcane workers although there is a paucity of data for the general population.

Methods: A population based cross sectional study using a random sampling of 32 communities was carried out in the department of Rivas in Nicaragua. Visits were conducted in Spanish in 2012 for screening and in 2014 for repeat evaluations. Participants were consented and completed a baseline questionnaire. Serum creatinine was initially screened using a finger stick creatinine measurement device. Repeat measurements to confirm CKD were performed centrally at the Centro Nacional de Diagnostico y Referencia in Managua using the Cobas Integra Jaffe Generation 2 assay, which has been standardized to the IDMS method.

Results: The study sample consisted of 1240 individuals representing 75% of adults living in the 533 homes visited. The refusal rate was 9.3%. The median age was 36.4 years, 57% were female, 6.6% reported DM, and 27% reported HTN. The study cohort is slightly enriched for women, while young people are slightly underrepresented when compared to census data. Repeat measurement was done in 320 with elevated creatinine to confirm CKD over 2 years. The re-contact rate was 85%.

Conclusions: This cross sectional study population is representative of the general population of the department of Rivas in Nicaragua. Establishment of this study population will allow investigators to determine the prevalence of CKD in a random selection of the general population in both urban and rural areas of Nicaragua not previously studied.

PUB160

Validation of the Lund Model Combining Simultaneous Cystatin C and Creatinine-Based eGFR

Emil Den bakker, Arend Bokenkamp. *Pediatric Nephrology, VU Univ Medical Center, Amsterdam, Netherlands.*

Background: Estimated GFR (eGFR) based on serum creatinine (crea) and/or cystatin C (cys) is used to monitor GFR. Based on known limitations of either marker (muscle wasting for crea, corticosteroids for cys) Grubb et al have proposed the "Lund model" to identify such patients by calculating the difference between crea and cys-based eGFR (Scand J Clin Lab Invest 70 (2010): 65-70). If the difference is below a certain cut-off, the mean of eGFRcrea and eGFRcys is used. Otherwise a choice is made for one or the other as a more accurate estimate based on patient history. The aim of this study was to test the "Lund model" using eGFR equations from the CKiD study (Kidney Int 82 (2012): 445-53).

Methods: Retrospective analysis of 449 single injection inuline clearance (mGFR) studies, in which serum crea, cys and urea had been measured simultaneously. Calculation of eGFR using crea (CKiD1), cys (CkiD2) or crea+cys+urea (CKiD3) as well as the average of CKiD1 and CKiD2 (avCKiD1-2). For the Lund approach, the relative difference (ΔCKiD1-2) between CKiD1 and CKiD2 was calculated as percentage of avCKiD1-2 and categorized as >40%, 30-40%, 20-30%. If ΔCKiD1-2 was > 40%, a choice was made for CKiD1 (corticosteroid) or CkiD2 (neuromuscular disease, wasting, malignancy). The performance of the different approaches was studied using bias (mGFR minus eGFR in ml/min/1.73m2) and accuracy (% of measurements within ±30% of mGFR).

Results: CKiD1, CKiD2 and CKiD3 had a bias of 4.6, 14.2 and 2.8 and an accuracy of 81.7, 80.6 and 90.4, respectively. avCKiD1-2 had a bias of 9.4 and an accuracy of 88.9. ΔCKiD1-2 was >40% in 11.4%, 30-40% in 18.9% and 20-30% in 33.9% of the studies. The Lund model was applied in 51 studies with ΔCKiD1-2 >40%. In 42/51 studies, a choice could be made based on history (CKiD1 n=16, CKiD2 n=26). This resulted in a bias of 10.5 and an accuracy of 86.4.

Conclusions: The various CKiD equations performed comparably to the original publication. The arithmetic mean between creatinine-based and cystatin C-based eGFR yielded similar results to the complex CKiD3 equation while the Lund model did not improve the diagnostic performance. This may be due to the higher bias of CKiD2.

PUB161

Evaluation of Chronic Kidney Disease Epidemiology Collaboration Equation (CKD-EPI), Modification of Diet in Renal Disease (MDRD) and Cockcroft-Gault (CG) Equations to Assess Glomerular Filtration Rate (GFR) in Kidney Cancer Patients Veronica T. Costa e Silva,[1] Celso Marialva,[2] George Augusto Monteiro Lins de albuquerque,[3] Renato Antunes Caires,[1] Giuliano Betoni Guglielmetti,[3] Maurício Dener Cordeiro,[3] Rafael Ferreira Coelho,[3] Elerson Costalonga,[1] Eduardo J. D. de Sa Carneiro Filho,[1] Emmanuel A. Burdmann,[1] William C. Nahas.[3] *[1]Cancer Inst of Sao Paulo, Univ of São Paulo School of Medicine, Sao Paulo, Brazil; [2]Urology, Garcia de Orta Hospital, Lisboa, Portugal; [3]Urology, Univ of Sao Paulo School of Medicine, Sao Paulo, Brazil.*

Background: Equations used to estimate GFR were not validated in kidney cancer patients. The aim of this study was to assess the performance of CKD-EPI, abbreviated (a) MDRD and CG equation in these patients.

Methods: Prospective evaluation of 124 outpatients with kidney cancer admitted to treatment at São Paulo State Cancer Institute between September 2012 and February 2015. Estimated (e) GFR was calculated using CG, aMDRD and CKD-EPI equations and compared to ^{51}Cr-EDTA radioisotopic (r) clearance. The bias was given as the mean difference between the eGFR and rGFR values and the precision as the SD of the differences. Accuracy was described as the number of eGFR studies within 10 and 30% of the rGFR values.

Results: Patients were 59.0 ± 10.3 years old, 50.2% were women. rGFR (ml/min/1.73 m^2) was 78.7 ± 24.6 and eGFRs (ml/min/1.73 m^2) using the CKD-EPI, aMDRD and CG (ml/min) equations were respectively 80.7 ± 22.1, 83.4 ± 25.3 and 87.8 ± 26.5. Equations bias is detailed on table 1.

Mean bias of differences

	CKD-EPI	aMDRD	CG
Mean Bias (mL/min)	2.0	4.7	9.1
SD	21.5	21.5	24.1
p	0.306	0.017	<0.001

The accuracy of eGFR equations within 10% of rGFR were 31.4%, 27.4% and 19.4% with CKD-EPI, aMDRD and CG, respectively. Within 30% of rGFR, the accuracy of eGFR equations were 75.8%, 78.2% and 68.5% with CKD-EPI, aMDRD and CG, respectively.

Conclusions: CKD-EPI equation showed smaller bias and satisfatory accuracy when compared with the GFR assessed by ^{51}Cr-EDTA in this group of kidney cancer patients.

PUB162

Correlation Between Equation for Estimating Glomerular Filtration Rate : CKD -EPI, Cockcroft-Gault -CG- and MDRD in Colombia Carlos H. Mejia. *Nephrology, Cuenta de Alto Costo, Bogota, Cundimarca, Colombia.*

Background: The determination of the GFR has been recommended the calculation from different equation , mainly Cockcroft- Gault (CG) or the Modification of Diet and Renal Disease (MDRD) and Chronic Kidney Disease Epidemiology Collaboration (CKD -EPI); we have found differences of over and underestimation of renal function by these equation.

Methods: Between July 1 2013 and June 30 2014 3,055,568 patients diagnosed with hypertension, diabetes mellitus and chronic kidney disease of all members of the general social security system in health in Colombia were reported. The inclusion criteria for this analysis was older than 18 years. Quantitative variables were described by their mean and standard deviation and qualitative variables using frequency distribution. They were compared equation pairs of CG -MDRD4, CG-CKD-EPI and CKD-EPI-MDRD by calculating and plotting, prediction limits for differences between pairs and the values of the correlation coefficients Lin-matching.

Results: 1,348,214 patients were included, 832. 129 women (61.7%). The mean age was 64.3 years (standard deviation (SD) 13.2), 50% of patients are 60 - 74 yo. 94% had diagnosis of HTA and 26% had diagnosis of DM. The mean creatinine was 0.95 mg/dl for population. The correlation coefficient between interclase (ICC)CG and MDRD is 0.704 IC95%(0.703, 0.705) and limits of agreement of Bland and Altman from -31.65 to 43.83; ICC being CG and CKD-EPI is 0.728 CI 95% (0729-0730) and limits of agreement of Bland and Altman from -37.26 to 40.62 and the correlation coefficient being intraclase CKD-EPI and MDRD is 0.855 IC 95%(0.855, 0.856) and limits of agreement of Bland and Altman between -25.61 and 21.89.

Conclusions: General population studies have reported a good correlation comparison between MDRD and CKD -EPI, our results show a good correlation between them, rather than between CKD -EPI and CG .A higher GFR greater are the limits of agreement, both the overall analysis and analysis stages, similar findings have been observed in other reports. Despite some limitations MDRD4 and CKD -EPI remain the most comparable and used to estimate kidney function.

PUB163

Family Caregivers in Chronic Kidney Disease: A Missed Opportunity to Improve Overall Care Jason Christopher George,[1] Andrea Lynn Berger,[2] Christina Yule,[3] Jamie Alton Green.[2,4] *[1]Dept of Medicine, Geisinger Medical Center, Danville, PA; [2]Center for Health Research, Geisinger Medical Center, Danville, PA; [3]Center for Clinical Innovation, Geisinger Medical Center, Danville, PA; [4]Dept of Nephrology, Geisinger Medical Center, Danville, PA.*

Background: Many patients with chronic illness rely on the assistance of loved ones to adequately manage their disease. While there is increased recognition of the role of family caregivers in end-stage renal disease, little attention has been given to this role among patients with chronic kidney disease (CKD) not on dialysis. The aim of this study was to assess CKD patients' degree of dependency on non-professional caregivers for their self-management needs.

Methods: We conducted a survey-based study of 208 patients with non-dialysis dependent CKD stages 3-5 to identify 1) whether they receive help from an informal caregiver to perform health-related activities and 2) the nature of this relationship. We excluded patients residing in a nursing facility as well as those with an assigned formal caregiver, since their self-management needs are different.

Results: Mean age of participants was 72, 57% were male, 98% were white, and 53% had a high school or lower level of education. Overall, 65% (133/205) of patients reported receiving help from another individual with at least one health-related task. Help with activities included medical decision making (51%), medication management (32%), scheduling medical appointments (30%), attending office visits (43%), understanding medical providers (23%), and activities of daily living (13%). The majority stated that the main person who helped them was their spouse (70%) or adult child (16%) vs. other family members (6%). Nearly half (46%) reported that another individual had access to their electronic health information through the online health portal to assist with their care.

Conclusions: A significant number of independently functioning CKD patients rely on the help of family members to navigate their care. Efforts are needed to acknowledge and support these informal caregivers in the medical management of complex patients with kidney disease in order to provide optimal care.

PUB164

Impacts of Chronic Kidney Disease on Other Non-Communicable Chronic Diseases – The Burden in the Health System of China Luxia Zhang, Jinwei Wang, Ming Hui Zhao. *Renal Div, Dept of Medicine, Peking Univ First Hospital, Beijing, China.*

Background: The spread of non-communicable diseases (NCDs) presents a global crisis, and accumulating evidence based on individual disease reveals that major NCDs including heart disease and stroke have a worse prognosis in the presence of chronic kidney disease (CKD). However, there is neither large-scale study quantitatively evaluating the burden of CKD on various NCDs, nor study comparing the burden of CKD with other NCDs, especially among low- and middle-income countries like China.

Methods: A national in-patient database involving 19.5 million patient-records was used. Diagnoses of CKD and other major NCDs, including hypertension, coronary heart disease, stroke, chronic obstructive pulmonary diseases, and cancer, were extracted from International Classification of Diseases-10 codes of the discharge diagnoses. The effect of CKD on costs, length-of-stay, and in-hospital mortality were analyzed for each NCD. Then the effect of CKD on those outcomes was compared with other major NCDs.

Results: For each NCD, the presence of CKD was associated with increased length-of-stay and in-hospital mortality. And the costs were also increased by 0.1-20.3%, except for coronary heart disease and diabetes. Among those NCDs, CKD was associated with the highest length-of-stay, and with in-hospital mortality only lower than that of cancer.

Conclusions: Using database with large sample size and broad geographic coverage in China, we found that the presence of CKD was associated with substantial increased healthcare resources utilization and increased risk of in-hospital mortality.

PUB165

Patient Empowerment in a Multi-Disciplinary Chronic Kidney Disease (CKD) Clinic Therese T. Adamowski, Jonathan H. Segal, Julie A. Wright Nunes. *Internal Medicine, Univ of Michigan, Ann Arbor, MI.*

Background: Existing research shows economic and health gains associated with multi-disciplinary CKD care, but there is little data examining associations with patient-centric measures. We collected patient-centric measures on perceptions related to care in a multi-disciplinary CKD clinic.

Methods: Our multi-disciplinary CKD clinic includes a pharmacist, physician assistant, social worker, dietician and RN educator-with oversight by a medical doctor. Patients see each provider during visits. Most patients have an eGFR ≤ 40 ml/min/1.73m^2. As part of assessing quality patients were asked to: 1. Report their level of comfort asking questions ("please circle the number that indicates how comfortable you feel asking your doctor questions about kidney disease: 1=not at all comfortable to 6=very comfortable"), and 2. Rate perceived confidence and empowerment in kidney care (ten questions with responses, 1 =not confident to 5 =confident, averaged as a summary measure of confidence / empowerment).

Results: Data were available on 51 patients. The mean (SD) age was 62 (15) years. 53% were male, 65% Caucasian, and 33% African American. Patients reported being comfortable asking their doctor questions, mean (SD) 5.5 (0.97). The mean (SD) of the confidence / empowerment measure was 4.3 (0.74). In univariate analysis, higher ratings

of comfort asking questions was associated with higher confidence / empowerment, β 0.23 CI (0.04, 0.45); p=0.02. Multivariate analysis adjusted for age, sex, race and comfort asking questions revealed comfort asking questions was independently associated with higher confidence / empowerment, β 0.31 (0.09, 0.53); p=0.007. Our 10-item confidence / empowerment measure showed excellent internal reliability (Cronbach alpha =0.89).

Conclusions: Patients in a multi-disciplinary CKD clinic reported being comfortable asking their doctor questions and rated confidence and empowerment as high. Comfort asking the doctor questions was positively associated with patient confidence and empowerment in care. More work is needed to compare patient-centric quality measures across care models and assess changes over time.

PUB166

Factors Affect Use of Healthcare Services Among Different Ethnicities

Enchi K. Chang,[1] Li-Li Hsiao.[2] *[1]Harvard College, Cambridge, MA; [2]Renal, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Background: Use of healthcare services by medically underserved minority populations varies by ethnicity and cultural factors. Healthcare providers may address ethnicity-specific barriers to healthcare service usage to decrease disparities in healthcare use. Through free community health screenings provided by the Kidney Disease Screening and Awareness Program (KDSAP), we seek to elucidate ethnicity-specific differences and sociocultural barriers to healthcare service use.

Methods: A questionnaire available in English, Chinese, and Spanish was administered to KDSAP participants in Massachusetts, New Jersey, and Toronto from 2012 to 2014. Participants were asked to provide their ethnicity, health insurance, primary care physician, and difficulties and alternatives to receiving care.

Results: 330 Asian, 190 African-American, 82 Hispanic, and 50 Caucasian participants were surveyed. Participants lacking health insurance comprised 29.1% of Asian and 45.1% of Hispanic participants, compared with 17.3% of African-American and 8% of Caucasian participants. 25% of Asian and Hispanic participants reported language barriers with their healthcare professional, compared with 6% of African-American and Caucasian respondents. 50% of Asian and Hispanic participants were prevented from seeking care due to lack of insurance, and as an alternative, 51% of Asian participants would ignore the problem. African American participants without insurance primarily reported seeking emergency care (51%), and Hispanic participants reported seeking free clinics (40.5%) or emergency care (37.8%).

Conclusions: Culture and ethnicity-specific barriers to receiving care affect use of healthcare resources for medically underserved populations. Asian and Hispanic populations experience greater difficulty accessing healthcare services and are less likely to have health insurance compared to African-American and Caucasian populations, suggestive of linguistic and sociocultural barriers to healthcare for immigrant populations. Healthcare services targeting medically underserved populations must address ethnicity-specific sociocultural differences to reduce healthcare disparities between ethnic populations.

PUB167

Trends in Access to Care in Adults with Kidney Disease, United States 2002-2011

Mukoso N. Ozieh,[1] Kinfe Gebreegziabher Bishu,[2] Rebekah J. Walker,[2] Leonard Egede.[2] *[1]Nephrology, MUSC; [2]Center for Health Disparities Research, Internal Medicine, MUSC, Charleston, SC.*

Background: Access to healthcare is essential in other to attain health equity in the US. Studies on access to healthcare in kidney disease (KD) are scant and there are no studies on national trends in access to healthcare in people with KD. This study aims to evaluate trends in access to healthcare, prescription medication and factors associated with access to healthcare in people with KD.

Methods: Data on 4,399 adults with KD aged ³18 from the Medical Expenditure Panel Survey were analyzed. Individuals with KD were identified with Clinical Classification Codes: 156 - nephritis, nephrosis, renal sclerosis; 157-acute/unspecified renal failure; 158-chronic renal failure; 160-calculus and; 161-other diseases of kidney and ureters. Access to healthcare was defined as having a usual provider, ability to get necessary medical care and no delay in getting medical care. Assess to prescription medications was defined as ability to get necessary prescription and no delay in getting prescription. We used unadjusted and adjusted logistic regression to examine factors associated with access to care overtime. Covariates included demographics and comorbidities.

Results: Of the 4,399 adults with KD, 81% and 97% reported having access to medical care and prescription medications respectively. Access to medical care was stable while access to prescription improved over time in people with KD. Factors associated with increased access to medical care were age ≥45, gender, high income and comorbidity–hypertension while marital status, being uninsured, residential region and comorbidity–joint pain were associated with decreased access to medical care. Factors associated with increased access to prescription were Hispanic race, age ≥65 and ³college degree while being uninsured, residential region and comorbidities – diabetes and joint pain were associated with decreased access to prescription medication.

Conclusions: Access to medical care has remained stable and access to prescription medication in people with KD has improved over time. Further studies on access to healthcare in people with KD compared to the overall US population are needed.

PUB168

Patient-Centered Care in United States Adults with Kidney Disease

Mukoso N. Ozieh,[1] Kinfe Gebreegziabher Bishu,[2] Rebekah J. Walker,[2] Leonard Egede.[2] *[1]Nephrology, MUSC; [2]Center for Health Disparities Research, Internal Medicine, MUSC, Charleston, SC.*

Background: Patient-centered care is a quality of personal, professional, and organizational relationships. There no studies on factors associated with patient-centered care in patients with kidney disease (KD). This study examines trends in and factors associated with patient-centered care (PCC) in people with KD.

Methods: Data on 3,868 adults with KD aged ³18 from the Medical Expenditure Panel Survey (MEPS) Household Component were analyzed. Individuals with KD were identified with Clinical Classification Codes: 156 - nephritis, nephrosis, renal sclerosis; 157 - acute and unspecified renal failure; 158 - chronic renal failure; 160 - calculus or urinary tract and; 161 - other diseases of kidney and ureters. Patient-centered care was ascertained if the usual care provider asked about prescription medications and treatments other doctors may give them; showed respect for medical, traditional and alternative treatments that the person is happy with; asked the person to help make decisions between a choice of treatments; presented and explained all options to the person; and spoke the persons language or provided translator services if person is uncomfortable speaking in English. We used unadjusted and adjusted poison regression to examine the association of patient-centered care overtime. Covariates included demographics and comorbidities.

Results: Of the 3,868 adults with KD, 3%, 7%, 22%, 63% and 4% reported a positive response to 1, 2, 3, 4, and 5 out 5 questions on patient-centered care respectively. Patient-centered care was significantly reported in 2010/2011. Hispanic race was significantly associated with increased while residence in the west was associated with decreased patient-centered care. Compared to 2002/2003, year 2004/2005 and 2010/2011 were significantly associated with increased patient-centered care in the poison regression analysis.

Conclusions: Patient-centered care in people with kidney disease has improved in recent years. Prospective studies examining the impact of patient-centered care on kidney disease outcomes especially end stage renal disease is imperative.

PUB169

Hypertension and Correlating Factors in a Minority-Rich Population

Andrew A. Lin,[1] Jennie Kuo,[2] Li-Li Hsiao.[2] *[1]Harvard College, Cambridge, MA; [2]Renal, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Background: Analysis of demographic variations in hypertension (HTN) in minority-specific populations presents a major opportunity for understanding the factors that influence chronic kidney disease (CKD). This study analyzes the influence of various factors in BP control in a minority-rich population.

Methods: Data from 417 participants from minority populations in the Boston area (38.4% Asian, 37.6% Black, 8.2% Hispanic, 10.8% White, and 5.0% other races) was sampled via Kidney Disease Screening and Awareness Program screenings from 2012-2014. Participants were assessed via questionnaire for awareness of their BP, healthcare/insurance, and an assessment of their own health as well as their race, gender, age, & education. Participants then had their systolic (SBP) & diastolic (DBP) blood pressure measured, which was in turn classified according to American Heart Association guidelines & analyzed via T-tests & one-way ANOVA.

Results: Of the 417 participants,28.8% had normal BP, 47.2% were pre-HTN (130-140/80-90), 18.5% had stage I HTN (140-160/90-100), & 5.5% had stage II HTN (>160/100). Participants aware of their HTN had higher SBP ($p<0.0001$) & DBP ($p=0.007$) than those who self-reported no HTN. Men had significantly higher SBP & DBP than women ($p=0.002$, $p=0.0003$, respectively), & individuals with little/no education had higher SBP than those with college ($p=0.005$) or post-graduate degrees ($p<0.0001$). Younger age groups (below 30 years: mean BP 125/76) had significantly lower BP than older age groups (60-69+ years: mean BP 136/81); $p<0.0001$ & $p=0.037$ for SBP & DBP. Notably, no significant differences in SBP among ethnicities emerged.

Conclusions: Our results revealed that awareness of HTN status, gender, education level & age influence BP variations in minority-rich communities. Services tailored to these factors may help reduce HTN prevalence among minorities.

Veterans Affairs (VA) eKidneyClinic: A Freely-Available Online Tool to Help Close the Chronic Kidney Disease (CKD) Patient Education Gap

Devasmita Choudhury,[1] R. Brooks Robey,[2] Rosemary M. Pries,[3] Dorian R. Schatell,[4] Susan T. Crowley.[5] *[1]Medicine, Salem Veterans Affairs Medical Center, Salem, VA; [2]Medicine, White River Junction Veterans Affairs Medical Center, White River Junction, VT; [3]Veterans Health Education & Information Program, Veterans Health Administration, Durham, NC; [4]MEI INC., Madison, WI; [5]Medicine, Veterans Affairs Connecticut Health Care System, West Haven, CT.*

Background: Patient education remains an important tool in the management of CKD and end stage renal disease (ESRD)- diseases with significant patient and economic burden. Patient knowledge and understanding of CKD are dismal, particularly amongst highly-affected populations (e.g. African Americans). For Veterans with CKD, limited health literacy, and varied, fragmented presentation of patient education materials (PEMs) compound the gap in understanding CKD.

Methods: To address these deficiencies, VA developed a comprehensive web tutorial, VA eKidneyClinic (http://ckd.vacloud.us). This freely-available, Veteran-centered, virtual

PEM details at 5th grade reading level (using Flesch-Kincaid formula), basic disease process, nutritional, laboratory, social, pharmacy, and treatment aspects of all stages of CKD in written and graphical format, supplemented by video narrative vignettes. Pre- and post-tutorial questions engage, test, and reinforce understanding through action planning. Links to additional Internet resources allow for further knowledge acquisition.

Results: Despite the absence of a national marketing campaign, annual web traffic on VA health portals featuring eKidneyClinic has tripled from 5,374 (~15/d; 01 Apr 2013 to 31 Mar 2014) to 16,730 views (~46/d; 01 Apr 2014 to 31 Mar 2015) over the past 2 y.

Conclusions: VA eKidneyClinic provides a novel, patient-centered, readily accessible Internet resource to remedy knowledge gaps in Veteran CKD education. Use of VA online resources has progressively increased over the past 2 y. Better metrics of use and targeted research correlating use with clinical outcomes are needed to fully validate the utility of this education tool and its impact on organizational health literacy.

PUB171

Should All Patients with Diabetic Nephropathy Be Treated in a Joint Renal Diabetic Clinic? Jonathan P. Wong, Tara Lee, Tracy Maryan, Jocelyn Berdeprado, Suresh Mathavakkannan. *Lister Renal Unit, United Kingdom.*

Background: The natural history of diabetic nephropathy is variable. Some patients have rapidly declining kidney function and would benefit from close monitoring in a joint renal-diabetic clinic, however joint renal-diabetic clinics are not widely available in the UK health system. We studied outpatient attendance patterns, rate of eGFR decline and other clinical parameters in patients with diabetic nephropathy to determine potential need for development of a joint renal-diabetic clinic at our unit.

Methods: A cross-sectional survey of all patients with CKD and diabetes mellitus (DM) at our unit was performed. Demographic, diabetic clinic attendance and clinical parameters including HbA1c, BP, urine protein:creatinine ratio (uPCR) and eGFR for the previous 5years were collected. Patients who had a rate of decline in eGFR³2ml/min/1.73m^2 were defined as having progressive CKD.

Results: 630 CKD patients with DM attending CKD clinic at our trust were identified. 195/630 (31%) of patients had diabetic nephropathy. 54.6% (100/195) had progressive CKD, but only 37% (37/100) of these patients attended a diabetic clinic. Conversely, 45.4% did not have progressive CKD, potentially representing a group of patients who could be safely monitored by general physicians. Patients with progressive diabetic nephropathy were more proteinuric than those with stable CKD (161 vs 46mg/mmol, p=0.004) but did not significantly differ in terms of age, weight, glycemic control or BP. 9.2% (58/630) were lost to follow-up from nephrology services, 31% (18/58) of this subset of patients continued to attend the diabetic clinics and 69% (40/58) were lost to follow-up from both diabetic and renal services.

Conclusions: Not all patients with diabetic nephropathy develop progressive CKD. Identifying patients (e.g. low-level proteinuria) who could be safely monitored by general physicians may relieve pressure on CKD clinic and reduce hospital visits for patients. However, many patients with progressive CKD were not being monitored in a diabetic clinic, potentially missing out on specialist interventions. Development of a joint diabetic-renal clinic could streamline care and improve management for these patients.

PUB172

Leveraging Predictive Modeling to Improve the Participant Identification Process for Transition to Dialysis Support Programs Meghan Martin Cockrell, Yanting Dong, Huyi Hines, Gilbert Haugh, Vipin Gopal, Roy Beveridge, Todd Prewitt. *Humana, Louisville, KY.*

Background: Evidence demonstrates that renal care management is beneficial to patients suffering from late-stage chronic kidney disease (CKD) and end-stage renal disease (ESRD), especially around the time of transition to dialysis. Integrated care management solutions provide assessment, education, and care coordination. Engagement in these programs improves health outcomes, including compliance with dialysis schedules and vascular access, and also reduces costs.

Methods: Traditionally, patients are identified for renal care management programs via a qualified estimated glomerular filtration rate (eGFR) lab value of <20mL/min/1.73 m2. However, since eGFR is not always available, there may be a gap in identifying people who could benefit from this type of support. A predictive model (PM) was developed to identify candidates for a transition to dialysis program. The PM identifies individuals with CKD over the prior 12 months and determines their likelihood of starting dialysis within the subsequent 12 months. It is based on claims, demographics, and lab and consumer data. To assess the effectiveness of the PM, a random portion of individuals scored in the top 2% most likely to transition to dialysis were referred directly to the program for

Results: Thirteen percent of people referred by the PM ultimately transitioned to dialysis and all were invited into a renal care management program. Seventeen percent of the people identified by the PM and observed to see if they would be referred by the current standard process ultimately transitioned to dialysis, but 27% (n=68) were never identified for the renal care management program. Hence, the model is effective in identifying those that will not get identified via the standard referral process.

Conclusions: Application of advanced predictive modeling permitted identification of participants who may not have otherwise had the opportunity to benefit from renal care management.

PUB173

Does the Kidney "Age" with Time? Umbar Ghaffar, Page Casey Moore. *Nephrology, UAMS, Little Rock, AR.*

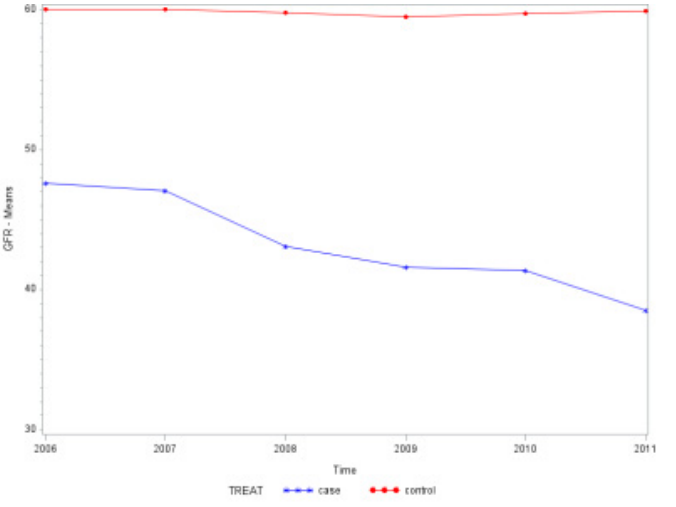
Background: Studies show that eGFR declines with advancing age but it is unclear if this is related to co-morbidities or aging per se.The objective was to study predictors of eGFR decline in elderly individuals with and without pre-existing CKD.

Methods: Chart review for patients >65 years of age with and without CKD at baseline was done over 5 years.Data regarding risk factors like proteinuria, medications, contrast use was obtained.Repeated measures models were used to test difference in GFR between CKD cases versus controls.Semi-partial correlations were used to determine factors with largest contribution to GFR decline.

Results: CKD cases were more likely to have DM, HTN and receiving drugs like diuretics and antibiotics.Age, proteinuria and IV contrast exposure were identifed as the most significant predictors of eGFR decline.In the CKD group, rate of GFR decline was 1.7% to 10 % per year. In the group without preexisting CKD, GFR did not decline over 5 years.

	CKD cases		Controls[b]	
Year	**eGFR means**	**% change in eGFR**	**eGFR means[a]**	**% change in eGFR**
2006	53.166	-	72.481	-
2007	51.104	2006-2007 3.88%	72.543	2006-2007 -0.08%
2008	50.224	2007-2008 1.72%	67.368	2007-2008 7.13%
2009	47.449	2008-2009 5.43%	61.982	2008-2009 8.00%
2010	47.651	2009-2010 -0.32%	67.539	2009-2010 -8.97%
2011	42.846	2010-2011 10.08%	71.864	2010-2011 -6.4%
Net change in eGFR		**2006-2011 19.41%**		**2006-2011 0.85%**

Table 1. Adjusted rate of decline in GFR across time
[a] LS means based on repeated measures model with the following independent variables: treatment, time, treatment*time, age, Sex, HTN, DM, AKI, AKI type, NSAIDs, contrast and proteinuria.
[b] GFR values 60 or greater were reported as ≥60 in lab reports.



Conclusions: Results suggest that GFR decline may not be attributed to aging only. Each episode of AKI related to contrast or nephrotoxic drugs increases risk for CKD progression/GFR decline in elderly.Preexisting CKD is a strong predictor of GFR decline after adjustment for other co-morbidities.

PUB174

Oxidative Stress: Dual Pathway Induction in CKD Pathogenesis Grazia Maria Virzì, Alessandra Brocca, Massimo de Cal, Claudio Ronco. *Nephrology Dept-IRRIV, San Bortolo Hospital, Vicenza, Italy.*

Background: Oxidative stress is defined as the imbalance between excess formation and insufficient removal of highly reactive molecules (Reactive Oxygen Species-ROS and Reactive Nitrogen Species-RNS) that attack DNA, protein and lipids, either denaturing or altering their structure. The variations and the correlation of inflammation and oxidative stress in CKD have not been thoroughly understood. In this study, we examined the putative role of ROS and RNS in the pathogenesis of CKD and the interaction with inflammation.

Methods: 25 patients with CKD(5 for each stage) and 18 healthy subjects (CTR) were included in the study. Determinations for IL6, Myeloperoxidase (MPO), Nitric Oxide (NO) and Endogenous Peroxidase Activity (EPA) were performed by ELISA. A p-value of <0.05 was considered statistically significant.

Results: CKD patients displayed significant augmentation in circulating ROS and RNS, as well as expression of inflammatory cytokines, as IL6 (all, p<0.01).

	CKD	CTR
EPA U/L	1963.6 (1081.0-2728.6)	5,9 (2.6-9.9)
MPO pg/mL	5987.0 (3989.6-11469.8)	10.2 (6.0-19.3)
NO μM	710.1 (575.6-781.6)	13.4 (12.8-14.7)
IL6 pg/ml	59.8 (45.6-104.3)	5.9 (3.4-7.6)

There is a positive correlation between IL6 and all oxidative stress markers and an inversely correlation with eGFR (all, p<0.05). We divided CKD patients in CKD1-2 (n=10) and CKD3-5 (n=15): a significant higher level of oxidative stress was observed in CKD3-5 (p=0.008).

Conclusions: CKD is characterized by ROS and RNS disequilibrium and inflammation that promote additional damage to the kidney and to distal tissues with development and progression of concomitant diseases. This pilot study demonstrates the significantly heightened presence of dual oxidative stress pathway induction in CKD patients that increase with the progression of CKD: each stage of CKD could be characterized by differing levels of ROS/RNS disequilibrium. Our findings indicate that oxidative stress is a potential therapeutic target, as it promotes inflammation by ROS/RNS-linked pathogenesis. Future research should focus on interventions that aim to reduce oxidative stress and inflammation in patients with various stages of CKD and slow the progression of CKD during its early stages.

PUB175

Comparative Biomarker Analysis Reveals Serum and Urine sTNFR1 Correlate with eGFR and Albuminuria in Man Diana L. Donnelly-Roberts, Marian T. Namovic, Mark T. Houser, Murali Gopalakrishnan, Timothy A. Esbenshade. *Renal Discovery, Abbvie, North Chicago, IL.*

Background: It has been demonstrated that soluble tumor necrosis factor receptors (sTNFR1 & sTNFR2) are elevated in serum of patient cohorts with various renal disease etiologies with a strong association to early renal decline with or without proteinuria. The current study was designed to gain further insight into the relationship of renal function to sTNFR1 and other biomarkers (BMs) from a recently completed clinical study in high-risk subjects undergoing non-cardiac surgery. A subset of baseline serum and urine samples from patients with and without CKD (mean age of 70, 64% male, mean eGFR of 58 ml/min/1.73 m^2, and mean total urinary protein concentration 70 g/l) were evaluated to assess sTNFR1 and other select BMs reflective of progression of DN, CV risk, inflammation, fibrosis or renal injury.

Methods: Samples were selected based on medical history (DM, DN, other CKD, or no renal disease) and stratified for analysis based on eGFR values**.** All samples examined were from baseline/pre-dose collections prior to drug administration or surgery and analyzed in a blinded manner.

Results: In serum, several BMs correlated with eGFR with sTNFR1 (P <0.0001) and uromodulin (P=0.0004) being significant but moderate for FGF-23 (P<0.01), and ADMA (P<0.01). In urine, results revealed that several BMs correlated with eGFR with a strong significance for sTNFR1 (P <0.001) as well as for complement C9 (P=0.011) and iC3b (P=0.013). Significant correlations were also observed for qualified biomarkers such as NGAL (P<0.01), albumin (P<0.01), and cystatin C (P=0.05). sTNFR1 in urine also strongly correlated with albuminuria (P=0.0002) and UACR (P=<0.0001).

Conclusions: Our studies demonstrate that sTNFR1 correlates with renal functional decline across a wide eGFR range (22 to 116 ml/min/1.73 m^2) regardless of renal disease, which was assessed in both serum and urine. Limitations of this preliminary study are small sample size and use of static eGFR values. Additional correlation analyses in longitudinal cohorts can shed further light into the relationships of sTNFR1 and other BMs to CKD.

PUB176

The Association of Plasma Uric Acid with Renal Vascular Lesions and Interstitial Fibrosis in Biopsy-Confirmed Kidney Disease Anand Srivastava,[1] Venkata Sabbisetti,[1] Isaac Ely Stillman,[3] Helmut G. Rennke,[2] Sushrut S. Waikar.[1] *[1]Renal Div, Brigham & Women's Hospital, Boston, MA; [2]Dept of Pathology, Brigham & Women's Hospital, Boston, MA; [3]Dept of Pathology, Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Elevations in plasma uric acid (PUA) have been hypothesized to play a pathogenic role in the development of chronic kidney disease (CKD) through multiple mechanisms, including mitochondrial dysfunction, oxidative stress, endothelial dysfunction, vascular smooth muscle proliferation, and intra-renal inflammation.

Methods: We measured PUA in plasma samples obtained from 272 patients on the day of native kidney biopsy at three tertiary care hospitals in Boston, MA. We compared PUA against measures of kidney function and pathology, including estimated glomerular filtration rate (eGFR) and adjudicated semi-quantitated measures of kidney pathology using Spearman correlation coefficients. Arterial and arteriolar sclerosis/hyalinosis were classified as none (1), mild (2), moderate (3), or severe (4). Fibrosis was classified as 0% (1), 1-10% (2), 11-25% (3), 26-50% (4), and > 50% (5) of cortical volume.

Results: The primary indications for kidney biopsy were proteinuria in 61%, hematuria in 33%, abnormal eGFR in 35%, and nephrotic syndrome in 14% (sum exceeds 100% due to multiple indications). Mean age was 51.2 + 16.0 yrs, 53% were women, 18% were black, and median eGFR was 50 (IQR, 30–83) ml/min/1.73m^2. Median PUA was 6.3 [IQR 5.1-7.5] mg/dl, and was inversely correlated with eGFR (r=-0.43) and positively correlated with arterial sclerosis (r=0.21), arteriolar hyalinosis (r=0.23), and interstitial fibrosis (r=0.28) (P for all < 0.001). The associations between PUA and kidney pathology were attenuated and no longer statistically significant after adjustment for eGFR. Findings were generally consistent in subgroup analyses of those with diabetes, glomerulonephritis, vascular disease, and tubulointerstitial disease.

Conclusions: We found no independent associations between PUA and semi-quantitated measures of kidney pathology. The cross-sectional associations of PUA with renal vascular lesions and interstitial fibrosis appear to be confounded by eGFR.

PUB177

Association of Plasma Sphingomyelins and Ceramides with Chronic Kidney Disease and Glomerular Filtration Rate Maria Lourdes Gonzalez Suarez,[1] Vesna D. Garovic,[1] Norman James Haughey,[2,3] Veera Venkata Ratnam Bandaru,[2] Susan Resnick,[4] Luigi Ferrucci,[4] Michelle M. Mielke.[5] *[1]Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Dept of Neurology, Johns Hopkins Univ School of Medicine, Baltimore, MD; [3]Dept of Psychiatry, Johns Hopkins Univ School of Medicine, Baltimore, MD; [4]Intramural Research Program, NIA/NIH, Baltimore, MD; [5]Dept of Health Sciences Research, Mayo Clinic, Rochester, MN.*

Background: Sphingolipids are a class of bioactive lipids linked to insulin resistance and diabetes. Ceramides have been implicated in acute renal failure and diabetic nephropathy. We cross-sectionally examined the associations of plasma ceramides and sphingomyelins (SM) with glomerular filtration rate (GFR) and Chronic Kidney Disease (CKD).

Methods: Baltimore Longitudinal Study of Aging participants (N=486) with plasma ceramides, SM and GFR were included (median age 63, 58% men); 23 had CKD defined as GFR<60 ml/min. Ceramides and SM were quantitatively measured using a HPLC-coupled electrospray ionization tandem mass spectrometer. Logistic regression was used to determine the association between the log transformed sphingolipids and odds of CKD, adjusting for age, sex, and race. Among participants without CKD, linear regression was used to examine the association between the sphingolipids and GFR adjusting for age, sex, race, BMI, and hypertension.

Results: Higher levels of all SM were associated with increased odds of CKD: each log unit increase in SM C18:1 was associated with six-fold increased odds of CKD (OR=6.92, p=0.002). Among individuals without CKD, higher SM were also associated with lower GFR. This association was most pronounced among the 290 individuals without diabetes or pre-diabetes: each log unit increase in SM C18:1 was associated with lower GFR (b=-8.40, p=0.002).

Conclusions: These results suggest that elevated plasma SM are associated with CKD. Likewise, among those without CKD, elevated SM are associated with lower GFR.The cross-sectional study design limits specific conclusions on the mechanisms and temporality of these associations but suggests that further research is warranted.

PUB178

Clinical and Pathologic Predictors of Progression to End Stage Renal Disease following Renal Biopsy Andrew S. Allegretti,[1] Ivy A. Rosales,[2] A. Bernard Collins,[2] Nina E. Tolkoff-Rubin,[2] Robert B. Colvin,[2] Ishir Bhan,[1] Julia Beth Wenger, Joshua Wibecan, Rex Neal Smith. *[1]Div of Nephrology, MGH, Boston, MA; [2]Dept of Pathology, MGH, Boston, MA.*

Background: The value of renal biopsy in prognosis of chronic kidney disease remains unclear. Irreversible, chronic changes such as interstitial fibrosis and glomerulosclerosis are thought to provide prognostic information. We sought to define the relative prognostic value of biopsy pathology and clinical factors for predicting progression to end stage renal disease (ESRD).

Methods: Retrospective, single center review of renal biopsies performed between 2004-2014 in four kidney diseases. Cox regression was used to evaluate nine pathologic findings on light microscopy and 21 clinical variables as potential predictors of progression to ESRD.

Results: 231 cases were reviewed (34% IgA nephropathy, 29% focal segmental glomerulosclerosis, 19% tubulointersitial disease, 18% diabetic nephropathy). 83/231 (36%) subjects progressed to ESRD within 5 years follow-up. Median estimated glomerular filtration rate (eGFR) at time of biopsy was 32 [IQR: 18, 54] mL/min. Median percent interstitial fibrosis was 20% [IQR: 10%, 40%]. In multivariable Cox regression adjusting for pathologic diagnosis and eGFR at the time of biopsy, independent predictors of progression to ESRD within 5 years of biopsy were: interstitial fibrosis > 20% (HR 1.94 [95% CI 1.09, 3.44]; p = 0.02), presence of endocapillary inflammation (HR 2.35 [1.22, 4.53]; p = 0.01), presence of arteriosclerosis (HR 2.03 [1.01, 4.05]; p = 0.05), history of liver disease (HR 1.55 [0.95, 2.53]; p = 0.08) and congestive heart failure (HR 1.85 [0.99, 3.49]; p = 0.06).

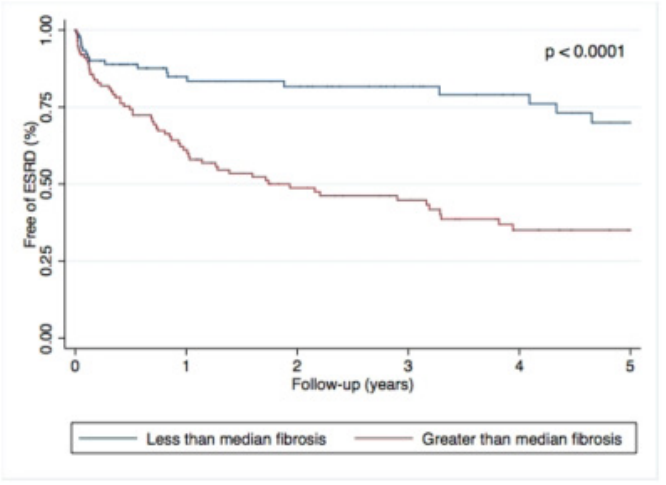

Figure: Kaplan Meier curve depicting time to end stage renal disease (ESRD) by above or below median percent interstitial fibrosis.

Conclusions: Pathologic findings of interstitial fibrosis greater than 20%, endocapillary inflammation, and arteriosclerosis as well as a clinical history of congestive heart failure and liver disease were the strongest predictors of progression to ESRD.

PUB179

The Influence of Mutagenic Lactobacilli on Concentration of IS in Blood and the Renal Expression of Renal Fibrosis Related Factors Yafen Jiang,[1] Yunhuan Bai,[2] Fang Wang,[3] Yunsheng Jiang,[1] Fuyou Liu.[1] *[1]Nephrology Inst, Central South Univ, Changsha, Hunan, China; [2]Div of Nephrology, Xuzhou Central Hospital; [3]Ningbo Medical Treatment Center Lihuili Hospital.*

Background: to observe the concentration changes of Indoxyl Sulfate(IS)in blood and the renal expression of renal fibrosis related factors(transforming growth factor-beta (TGF-beta 1) and Fibronectin(FN)after administration of mutagenic lactobacilli by oral.

Methods: 60 male SD rats aged 6 weeks were divided into 3 groups randomly: normal control group (Sham group, n = 20) who received SHAM operation of just incision of skin without kidney removed. The other two groups of rats were all renal failure models selected from survivals of the other 40 rats who received real operation with 5/6 of the kidney removed.Then 35 rats finally got were randomly divided into 2 groups:pathological control group(Model group)(n = 17) , administrated of 2ml Sterile Saline Solution once a day by gavage ,Experimental group (LB group)(n = 18) administrated of 2ml mutagenic lactobacilli (1.5 x108 cfu/ml) once a day by gavage.8 weeks later ,blood specimens were taken to test the concentration of IS by High performance liquid chromatography- fluorescence detection (HPLC – FLU)and urea and creatinine by automatic biochemical analyzer,while the rats were killed to get kidney tissues for pathological examination.

Results: the concentration of IS in the experimental group were 3.18 + / - 1.39 ug/ml ,while 3.67 + / - 2.13 ug/ml in the Model group.two groups were significantly different($P < 0.05$).And also Blood urea and creatinine levels were statistically dtifferent between two groups($P < 0.05$). Both the level of renal tubular damage and renal interstitial fibrosis were both lessen in the experimental group whencomparing with the Model group ($P < 0.05$);TGF - beta 1 and FN expression in renal tissues were also decreased.

Conclusions: Mutagenic lactobacilli can not only reduce serum concentration of IS, urea and creatinine in renal failure rats, but also lowering the expression of TGF - beta 1 and FN in renal tissue.

PUB180

Lower Dietary Intake of Magnesium Is Associated with Faster Decline in Kidney Function: The Healthy Aging in Neighborhoods of Diversity Across the Life Span Study Adrienne Tin,[1] Casey Rebholz,[1] Yang Liu,[1] Alan B. Zonderman,[2] Marie Kuczmarski,[3] Deidra C. Crews.[1] *[1]Johns Hopkins Univ; [2]National Inst on Aging; [3]Univ of Delaware.*

Background: Lower dietary magnesium intake has been associated with higher prevalence of chronic kidney disease (CKD). We hypothesized lower dietary magnesium intake would be associated with more rapid decline in kidney function.

Methods: Participants with estimated glomerular filtration rate (eGFR) ≥ 60mL/min/1.73 m^2 at baseline (2004-2008) of the population-based, Healthy Aging in Neighborhoods of Diversity across the Life Span (HANDLS) study were followed for a median of 4.7 years. Baseline dietary magnesium intake was calculated from two 24-hour dietary recalls. eGFR was calculated from serum creatinine using the CKD-EPI equation. We defined rapid decline as eGFR decline ³3% per year. The association between dietary magnesium intake and eGFR decline was evaluated using Cox regression.

Results: Among 1,326 participants, those with lower dietary magnesium intake (tertile 1 vs. 3) were significantly younger (mean age of 46 vs. 49 years), more likely to be African-American (67% vs. 48%) and male (45% vs. 31%); had lower mean body mass index (BMI, 29 vs. 30 kg/m^2), higher mean baseline eGFR (99 vs. 94 mL/min/1.73 m^2) and lower prevalent diabetes (10% vs. 18%); $p<0.05$ for all. In the overall study population, eGFR was stable without any decline (mean change: 0.1 mL/min/1.73 m^2), while 189 participants experienced an eGFR decline ³3% per year. Lower dietary magnesium intake was associated with higher risk of eGFR decline ³3% per year (tertile 1 vs. 3, hazard ratio 1.9, 95% confidence interval: 1.1, 3.3) adjusted for socio-demographics, baseline eGFR, prevalent diabetes and hypertension status, BMI, serum magnesium, total energy intake, and dietary intake of calcium, potassium, and phorsphous.

Conclusions: Among persons with preserved eGFR, we detected a significant association between lower dietary Mg intake and increased risk of rapid kidney function decline independent of traditional CKD risk factors. These results highlight the importance of magnesium intake in the overall diet for the preservation of kidney function.

Renin-Angiotensin System: A Possible Mechanism for AKI-CKD Continuum Shun-Yang Cheng, Shuei-Liong Lin, Ching-Chin Yang, Yu-Hsiang Chou, Fang Ling Liao, Ming-Hsuan Tsai. *Graduate Inst of Physiology, National Taiwan Univ.*

Background: Based on many clinical observations and studies, acute kidney injury (AKI) was now regarded as an important risky factor causing chronic kidney disease (CKD). Not only does CKD lead to end-stage renal disease (ESRD), but also increases the risk of cardiovascular disease or even death. Clinical studies often disclose that the higher the AKI severity of a patient is, the more likely her/his kidneys progress into CKD. To this day, the mechanism underlying the progression of kidneys into CKD after AKI remains illusive. Since the higher severity of the AKI leads to more reduction of nephron numbers, we propose that activation of renin-angiotensin system (RAS) may be involved in the progression to CKD after recovery from AKI.

Methods: Severe AKI was induced in male adult CD-1 mice by right uni-nephrectomy (Nx)followed by ischemia-reperfusion injury of left kidney 2 weeks later. Drinking water with or without type 1 angiotensin II receptor blocker losartan or direct vasodilator hydralazine was administered to mice from 4 weeks after surgery. Mice with Nx only were served as the control. Blood pressure, urinary albumin-creatinine ratio (ACR)and plasma levels of creatinine were evaluated.

Results: Compared to Nx group, AKI mice showed acute rise of plasma creatinine levels on day 2 after Nx+IRI surgery, which decreased to baseline on day 7. Moreover, elevated systolic blood pressure and increased urinary ACR were noted since 4 weeks after Nx+IRI. During the 4-month experimental period, progressive increase of urinary ACR and plasma levels of creatinine were noted. On the contrary, systolic blood pressure, urinary ACR and plasma creatinine level were normalized in mice administered with losartan since 4 weeks after Nx+IRI surgery. However the increase of urinary ACR and plasma creatinine level were not prevented in mice administered with hydralazine despite similar normalization in blood pressure.

Conclusions: These data suggest that RAS activation may underlie the mechanism for development of CKD in mice after recovery from AKI. Future studies are needed to explore the effect of RAS blockade in prevention of CKD and its pression in patients recovered from AKI.

The Renal Effects of Neprilysin Inhibition in Heart Failure and Hypertension Girish Singhania, Abhilash Koratala, Amir Kazory. *Nephrology, Univ of Florida, Gainesville, FL.*

Background: Neprilysin inhibitors (NEPi) represent an emerging therapeutic option for treatment of hypertension (HTN)) and heart failure (HF) through enhancement of natriuresis. While these agents have shown promising results with regards to lowering blood pressure (BP) and HF events, their impact on the kidney remains largely unknown. The aim of this study is to evaluate the currently available evidence on the effect of NEPi use on kidney-related parameters in patients with HTN or HF.

Methods: A search of articles cited in PubMed database from 1995 to 2015 using key words “neprilysin”, “heart failure” and “hypertension” found 237 articles. Animal studies were excluded. Those studies containing kidney-related parameters such as serum creatinine, glomerular filtration rate (GFR), or BP were selected. Relevant data including changes in renal function, blood pressure and mortality were extracted and compared.

Results: A total of 42,487 patients from 12 randomized controlled trials with data pertaining to NEPi use were included (8 in HTN and 4 in HF). Seven studies used NEPi combined with ACE-i, 4 with ARB, and 1 with endothelin converting enzyme inhibitors. The follow up periods ranged between 7 days and 27 months. All studies in HTN (including 27,401 patients) reported significantly better BP lowering effect for NEPi compared to control group, while 94% of the patients in the HF studies presented with improvement in HF events or mortality. Although change in renal function was not the primary endpoint, all HF studies (including 15,086 patients) showed less frequent renal impairment (expressed as an adverse event, incidence of worsening renal function, change in GFR, or serum creatinine) compared to the control group. In contrast, only 3 HTN studies (including 466 patients) explored the impact on renal function and reported no significant benefit.

Conclusions: Current evidence suggests that in patients with HF, NEPi can lower HF-related events and mortality while portending favorable impact on renal function. In patients with HTN, although NEPi have been shown to reduce BP, there is no conclusive evidence of their role in improvement of renal function in this setting.

PUB183

The Differences of Renal Protective Effect by Hyperuricemia Treatment Using Febuxostat in Various CKD Subgroups Akinori Yamaguchi, Makoto Harada, Yosuke Yamada, Koji Hashimoto, Makoto Higuchi, Yuji Kamijo. *Dept of Nephrology, Shinshu Univ, Mtsumoto, Nagano, Japan.*

Background: We often experience the CKD cases exhibiting the attenuation of eGFR decline by hyperuricemia treatment using febuxostat. However, renal protective effect by the hyperuricemia treatment has not yet been established. We hypothesize that the therapeutic response of febuxostat treatment might differ among various subgroups of CKD patients.

Methods: To investigate the difference of the therapeutic response in CKD patients, 272 outpatients with hyperuricemia who were treated by febuxostat from May 2011 to March 2015 were enrolled. Patients undergoing hemodialysis and/or peritoneal dialysis treatment, and patients lacking essential clinical data were excluded. Finally, 178 patients were analyzed. Correlation coefficient between the average of serum uric acid level and the eGFR variation during 6 months after the treatment were statistically investigated in various clinical subgroups.

Results: In all patients, significant correlation between the average of serum uric acid levels and the eGFR variation was detected (spearman's correlation coefficient: r=-0.163, p=0.019). This significant correlation was also detected in each patient groups as follows: male patients (n=121, r=-0.211, p=0.020), non-elderly (below 70 years old) patients (n=107, r=-0.261, p=0.007), patients whose systolic blood pressure were below 130 mmHg (n=72, r=-0.238, p=0.044), patients without dyslipidemia (n=133, r=-0.316, p=0.005) and non-diabetic-nephropathy patients (n=133, r=0.184, p=0.034). However, the significant correlation was not detected in each opposite subgroups.

Conclusions: The current study suggest that therapeutic response of febuxostat treatment might be well in each CKD subgroups, including male, non-elderly, non-hypertention, non-dyslipidemia and non-diabetic-nephropathy. It is possible that various risk factors of atherosclerosis conceal the beneficial renal protective effects of hyperuricemia treatment using febuxostat.

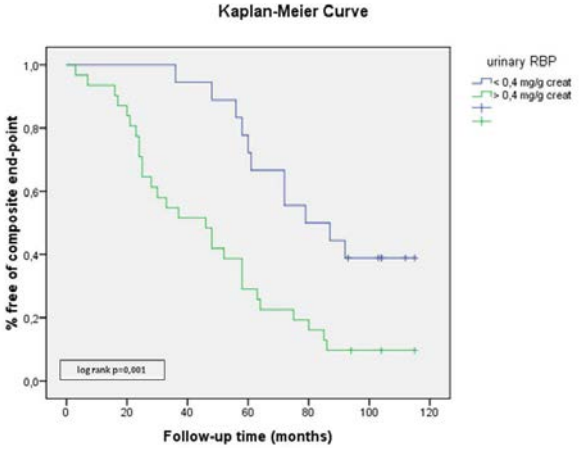
PUB184

Urinary RBP as an Independent Predictor of "Hard Composite Outcome" in Albuminuric Diabetic Nephropathy Gesiane Fernandes Tavares, Roberto Zatz, Silvia M. Titan. *Renal Div, Dep. Clinical Medicine, Faculty of Medicine, Univ of Sao Paulo, Sao Paulo, Brazil.*

Background: The current search for new biomarkers in CKD is intense, with particular emphasis on hard end-points, such as ESRD, creatinine duplication and cardiovascular and overall mortality. In this analysis, we sought to evaluate which baseline clinical and laboratorial variables were related to ESRD/mortality in 56 patients with albuminuric diabetic nephropathy after mean follow-up time of 5 years.

Methods: Baseline clinical and laboratorial data of 56 participants of a clinical trial were evaluated as predictors of major outcomes (primary outcome, PO: ESRD, creatinine duplication or mortality). Mann-Whitney and chi-square tests were used for univariate analyses. Several univariate and multivariate COX regression models were built on the risk of PO. Kaplan-Meier curve and LOG rank test were also performed.

Results: PO occurred in 39 participants after a mean follow-up time of 5 years (70%). In univariate analyses, sex, creatinine clearance, 24h proteinuria, uRBP, urinary VEGF and serum TGF-beta were related to the event group. In univariate COX regression models, sex, proteinuria, creatinine clearance, VLDL-cholesterol, ferritin, PTH, RBP and uMCP-1, uVEGF and uTGF-beta were significantly associated to the risk of the PO. However, after adjustments for creatinine clearance and proteinuria, only uRBP and uMCP-1, uTGF-beta and uVEGF remained significantly associated to PO. In a stepwise model, only creatinine clearance (HR 0,98, 95%CI 0,97 - 1,00, P=0,06) and uRBP (HR 1,13, 95%CI 1,07 - 1,20, P<0,0001) were left as independent predictors of PO in this population. KM curve for uRBP is shown in figure 1.



Conclusions: Urinary RBP is an independent predictor of PO in albuminuric diabetic nephropathy. Its role as a risk biomarker should be further explored in larger studies of CKD patients.

Funding: Government Support - Non-U.S.

PUB185

Association Between Urinary RBP and Renal and Cardiovascular Risk Factors in a Population with CKD: The Progredir Study Maria Alice Muniz Domingos,[1] Alessandra C. Goulart,[2] Paulo Lotufo,[2] Isabela M. Bensenor,[2] Silvia M. Titan.[1] *[1]Renal Div, Dep. Clinical Medicine, Faculty of Medicine, Univ of Sao Paulo, Sao Paulo, Brazil; [2]Clinical Research Center, Univ Hospital, Sao Paulo Univ, Sao Paulo, Brazil.*

Background: Urinary RBP (uRBP) has been related to the risk of ESRD in glomerulonephritis and renal transplant. However, its role in CKD is not well established.

Methods: Baseline clinical and laboratorial data on 454 participants of the Progredir Study was analysed. uRBP was measured by an immunoenzymatic assay with monoclonal antibody. Descriptive data is presented according to tertiles of uRBP, and correlation coefficients were calculated. Several univariate and multivariate linear regression models were built. Lastly, binary regression models were built on the risk of presenting more advanced CKD (class IV+V versus class II+III).

Results: In the descriptive data, the tertiles of uRBP were significantly related to sex, diabetes, renal function, SBP, glycated hemoglobin, HDL, proteinuria, WHR, phosphorus, acidosis, albumin, pulse-wave velocity (PWV), left atrium diameter (LAD), systolic and diastolic left ventricular diameters and ejection fraction. These results were confirmed by correlation. In the univariate regression models, diabetes, SBP, WHR, renal function, proteinuria, phosphorus, albumin, lipids, glycated hemoglobin, PWV and echographyc variables remained related to uRBP. However, after adjustments, only renal function, proteinuria, SBP, bicarbonate and LAD remained associated to uRBP.

Table1: Stepwise multivariate linear regression models on log of urinary RBP.

Model	B	Std. Error	95,0% IC		p
24H proteinuria	,303	,033	,238	,369	<0,001
24H proteinuria	,235	,033	,170	,299	<0,001
eGFR-MDRD	-,021	,003	-,027	-,015	<0,001
24H proteinuria	,209	,033	,145	,274	<0,001
eGFR-MDRD	-,021	,003	-,027	-,015	<0,001
SBP	,006	,002	,003	,010	<0,001
24H proteinuria	,219	,032	,155	,282	<0,001
eGFR-MDRD	-,021	,003	-,027	-,015	<0,001
SBP	,006	,002	,003	,009	<0,001
LAD	-,026	,007	-,039	-,012	<0,001
24H proteinuria	,210	,032	,146	,273	<0,001
eGFR-MDRD	-,019	,003	-,025	-,014	<0,001
SBP	,007	,002	,003	,010	<0,001
LAD	-,023	,007	-,037	-,009	,001
Bicarbonate	-,027	,013	-,053	-,001	,041

*eGFR-MDRD: estimated glomerular filtration rate using MDRD; SBP: systolic blood pressure; LAD- left atrium diameter.

Lastly, uRBP was associated to an increased risk of class IV+V CKD (OR 1,16, 95%CI 1,08 - 1,25, p<0,0001), even after adjustments for age, sex, diabetes, proteinuria and SBP.

Conclusions: uRBP is independently related to cardiovascular risk factors in the CKD population. Its role as a biomarker of hard clinical end-points should be further explored.

PUB186

Treatment of Subclinical Hypothyroidism and the Progression of Chronic Kidney Disease Padmavathi Mali,[1] Sudheer Muduganti.[2] *[1]Internal Medicine, Marshfield Clinic, Marshfield, WI; [2]Nephrology, Univ of Wisconsin Hospitals and Clinics, Madison, WI.*

Background: Evidence suggests that treatment of subclinical hypothyroidism may slow the progression of chronic kidney disease (CKD) and delay or prevent development of end stage renal disease (ESRD).The goal of this study was to provide additional evidence regarding the same.

Methods: Patients with subclinical hypothyroidism and CKD stages 3 or 4 were identified by retrospective chart review over a period of 6 years. Subjects were grouped based on L-thyroxine treatment. Subjects treated with L-thyroxine before first elevated thyroid stimulating hormone (TSH) were excluded. Index date was defined as the date of first L-thyroxine for treated patients. Index dates for untreated patients were assigned by random sampling of dates for treated patients. TSH and serum creatinine values were captured from the electronic medical record. Change in eGFR (glomerular filtration rate) over time in treated and untreated patients was assessed using a linear random coefficients model in the subset with two or more eGFR results spanning a period of at least 6 months, both before and after the index date.

Results: A total of 258 patients meeting inclusion criteria were identified; 181 were treated with L-thyroxine and 77 were not. Treatment initiation began after the first elevated TSH in the study period for 110/181 subjects. Upon analysis, before the index date, eGFR showed a significantly decreasing trend (p<0.001) that was not significantly different

between treated and untreated patients (p = 0.593). After the index date, the rate of eGFR change showed a significant positive change (p<0.001) toward a gradual increase, but again this was not significantly different between groups (p = 0.522).

Conclusions: The similar results in the two groups, regardless of L-thyroxine treatment status, provides no evidence that treatment of subclinical hypothyroidism influences progression of CKD in individuals with stage 3 or 4 disease. Although previous studies have suggested that treatment of subclinical hypothyroidism in this population may delay or prevent the progression of ESRD, our results do not support the hypothesized treatment benefits.

PUB187

Effect of Hyperuricemia on the Blood Pressure-Dependent Proteinuria in Non-Nephrotic Chronic Kidney Disease Kentaro Kohagura,[1,2] Ryo Zamami,[2] Tsuyoshi Miyagi,[2] Masako Kochi,[2] Yusuke Ohya.[2] *[1]Dialysis Unit, Univ Hospital of the Ryukyus, Nishihara-cho, Okinawa, Japan; [2]Cardiovascular Medicine, Nephrology and Neurology, Univ of the Ryukyus, Nishihara-cho, Okinawa, Japan.*

Background: Patients with chronic kidney disease (CKD) are suggested to be highly susceptible for hypertensive renal damage due to disrupted autoregulation system in afferent arteriole. We reported that hyperuricemia was associated with renal arteriolar hyalinosis in the CKD patients. However, effect of hyperuricemia on a relationship between blood pressure (BP) and proteinuria is unknown inCKD patients.

Methods: A total of 208 consecutive patients who underwent renal biopsy at our department between 2003 and 2007 were considered for the study. We excluded patients receiving renin angiotensin inhibitor and nephrotic CKD patients defined as serum albumin equal or more than 3 g/gCr, leaving us with 117 patients (57 men and 60 women) for analysis.Arteriolar hyalinosis were assessed by semi quantitative grading for arterioles. We compared the relationship between systolic BP and logarithm-transformed urine protein (g/gCr) in the patients with or without hyperuricemia.

Results: The mean ± standard deviation values for age, BP, estimated glomerular filtration rate (eGFR), and urine protein were as follows: 40± 18 years, 126 ± 20/75 ± 12 mmHg, and 84 ± 37 ml/min/1.73 m^2, and 0.9±0.8 g/gCr, respectively. In the patients with hyperuricemia (n=63), systolic BP was significantly correlated with log-transformed urine protein (r=0.43, p=0.004). In contrast, there was no significant correlation between them in the patients without hyperuricemia (n=53, r=0.07, p=0.60). In the multiple regression model (R^2=0.25, p=0.01), systolic BP was significantly correlated with logarithm-transformed urine protein (β=0.33, p=0.02) independent of age, sex and classical risk factors in the patients with hyperuricemia. However, its statistical significance was disappeared after additional adjustment with arteriolar hyalinosis.

Conclusions: These results suggested that hyperuricemia might potentiate the susceptibility for hypertensive glomerular damage via disrupted autoregulation in non-nephrotic CKD patients.

PUB188

HCV Independently Affects Kidney Function Among HIV Co-Infected Individuals Maya Balamane,[1] Richard A. Teran,[1] Joseph G. Timpone,[1] Jason G. Umans,[2,3] Princy N. Kumar,[1] Seble Kassaye.[1] *[1]Georgetown Univ Medical Center, Washington, DC; [2]Georgetown Howard Univs Center for Clinical & Translational Science, Washington, DC; [3]MedStar Health Research Inst, Hyattsville, MD.*

Background: Predictors of chronic kidney disease (CKD) include increasing age, hypertension and diabetes. Hepatitis C (HCV) infection has also been associated with increased risk for CKD. We sought to determine the relative contribution of HCV vs other co-morbidities on kidney dysfunction among individuals with HIV.

Methods: We analysed data from HIV-positive patients enrolled in the DC HIV Clinical Cohort study at Georgetown University Hospital (2011-2014). Estimated glomerular filtration rate (eGFR) was calculated using the CKD-EPI formula. Analyses were conducted stratified by HCV status. Chi square, Cochran–Mantel–Haenszel and Breslow Day Test statistics were performed to determine factors associated with normal kidney function (eGFR > 90 ml/min/1.73^2), compared with participants with decreased kidney function, stage 2 and 3 (³30 eGFR ≤89) usingSAS ν9.4.

Results: Among 771 participants, median age was 48, 73.4% male, 50.3% black, median CD4+ T cell count 546.5 cells/µL, and HIV-RNA <20 copies/mL. 93 (12.1%) had HCV co-infection. There was significantly higher prevalence of stage 2-3 kidney dysfunction with HIV/HCV co-infection than HIV mono-infection (35% vs. 19%, p=0.0016; OR, (95% CI) 2.2 (1.3-3.6)). Prevalence of hypertension, diabetes, hyperlipidemia and chronic Hepatitis B was similar between HIV and HIV/HCV co-infected groups. Presence of these co-morbidities was not a confounder in the increased risk for CKD with HIV/HCV, (Mantel-Haenszel chi-square OR, (95% CI) of 2.2 (1.3-3.6) for hypertension, 2.18 (1.3-3.6) diabetes and 2.2 (1.3-3.6) hyperlipidemia (Breslow Day test p values<.05 for each co-morbidity.

Conclusions: We identified a strong association between HIV/HCV co-infection and reduced kidney function independent of co-morbidities usually associated with kidney dysfunction in this group with well controlled HIV. Further investigation is needed to study the mechanisms by which HCV affects kidney function.

PUB189

Vitamin D Deficiency Is a Cause and a Result of Renal Dysfunction in Rheumatoid Arthritis Suad Ma Hannawi, Issa AL Salmi. *Medicine, Ministry of Health, Duabi, United Arab Emirates.*

Background: Asymptomatic kidney dysfunction is common in RA. Low vitamin D(VD) increases susceptibility to development of RA& disease activity. Sequential hydroxylations occurs in liver & kidney to form active1,25-VD & patients with kidney failure are often resistant to VD & suffer from 2nd hyperparathyroidism & renal osteodystrophy. In addition to its role in maintaining Ca&PO4 homeostasis, VD is important for maintaining maximum muscle strength & prevention of chronic diseases. Our objective is to evaluate eGFR & VD status in RA.

Methods: RA diagnosed by ACR 1988 criteria. 25-VD level obtained & GFR calculated by MDRD at Rheumatology clinic visit. Univariate linear regression analysis carried out to determine the relation between 25-VD and eGFR, other renal parameters & RA inflammatory markers.

Results: Interim analysis of 52 RA(47F,5M) with mean age 46±13 year(F46±12, M45±21). 25-VD level is 40±29 nmol/l(NR50-80)&GFR is 134±49 ml/min/m2. Univariate linear regression showed a negative relationship between 25-VD level & GFR(p=0.041,CI-0.23,-0.01), micro-albuminuria(p=0.046,CI -0.63,-0.01), CRP (p=0.01,CI -1.16,-0.16), neutrophil count (p= 0.03,CI -1.67,-0.11) . A positive linear relationship between GFR &weight (p=0.03,CI 0.06,1.04), BSA(p=0.02, CI 11, 119)& BMI(p=0.009,CI 0.65-4.05), Ca(p=0.0.03, CI 7.24, 133.12 mmol/l).

Conclusions: Negative relationship between eGFR &25-VD, indicating a higher 25-VD as failure to convert to active form as GFR decreases. Extra-renal formation of active VD requires high level of 25-VD >78 nmol/L(30 ng/mL)& is necessary for maximal extra-renal production of 1,25VD. 1,25-VD is one of the most potent regulators of cellular growth & very effective modulator of the immune system. VD receptors are present in most cells & tissues in the body including activated T and B lymphocytes. Surveillance for VD deficiency, should be part of follow-up as it may be linked to underlying kidney dysfunction in RA. On the other hand, reduced VD might worsen RA & hence, increase the possibility of renal deterioration. VD supplementation may be needed early in management for prevention of kidney dysfunction & to reduce RA severity.

PUB190

Associations Between the Progression of Chronic Kidney Disease and Patient Demographics Danqing Xu,[1] Mark Stuart,[3] Barbara Cannon,[3] Chad Sowers,[3] John W. Larkin,[2] Sophia Rosen,[2] Carly R. Van Zandt,[4] Len A. Usvyat,[2] Yuedong Wang,[1] Terry Ketchersid,[2] Dugan Maddux,[2] Franklin W. Maddux.[2] *[1]Univ of California, Santa Barbara; [2]Fresenius Medical Care North America; [3]Acumen Physician Solutions; [4]Frenova Renal Research.*

Background: It is not well known if demographic factors are related to the progression of chronic kidney disease (CKD). We aimed to investigate whether age, sex, race, marital status and geography are associated with significant changes in kidney function determined by linear slopes of mean annual glomerular filtration rate (GFR).

Methods: We analyzed data from 90,240 CKD patients (Pts), who had significant declines in GFR, in the Fresenius Medical Care CKD Data Registry. Annual average decline in GFR was estimated on a per pt basis using linear regression with time as the predictor and GFR as the outcome variable. Univariate linear models were fitted for age groups (15-30, 31-45, 46-60, 61-75, and 76-90 years old), sex (female or male), race (African American, Caucasian, or other), marital status (married, unmarried) and geography (10 divisions of zip codes); a multiple linear regression model was utilized to investigate associations in mean annual GFR slope and demographics.

Results: This analysis identifies significant associations between mean annual GFR slope and Pt demographics. CKD Pts age 15-30 years old were found to decline faster in GFR versus older Pts in all other age groups (p<0.001). Males were observed to decline slower in GFR versus females (p<0.001). Pts with a race of "other" were seen to decline slower in GFR versus Pts of African American or Caucasian race (p<0.001). The geographical location of Pts by zip code was observed to be associated with differences in GFR slope (p<0.001). The marital status of Pts was not found to be related to differences in slopes of GFR (p=0.218).

Conclusions: This study identifies that during the progression of CKD, younger Pts tend to have faster declines in GFR, as compared to older Pts; males have slower declines in GFR, as compared to females; Pts with a race of "other" have slower declines in GFR, as compared to Pts of African American or Caucasian race; and declines in GFR are related to Pt geography.

PUB191

Correlation of Increased Th17 to Treg Cell Ratio with Endoplasmic Reticulum Stress in Chronic Kidney Disease Ou Yan. *Kidney Dept, Second Affiliated Hospital of Xi'an Jitong Univ, Xi'an, Shaanxi Province.*

Background: The study aimed to investigate the relationship between the regulatory immune network and endoplasmic reticulum stress (ERS) in patients with different stages of chronic kidney disease (CKD).

Methods: A total of 91 patients diagnosed with CKD were divided into different groups according to the stage of disease. Routine blood and biochemical tests were performed in patients and in healthy controls (n = 20). The frequencies of T helper type 17 (Th17) and regulatory T (Treg) cells in the overall T cell population was measured by flow cytometric analysis. Levels of Th17 cell (IL-17) and Treg cell (IL-10) cytokines and the ERS markers

CHOP and GRP78were measured by ELISAin serum samples collected from controls and patients in the different CKD groups. Correlations between each parameter and serum creatinine, an indicator of renal function, were analyzed by Spearman's rank correlation and regression test.

Results: CKD stage showed a positive correlation with serum creatinine level, and increased and decreased percentages of Th17 and Treg cells, respectively, reflected in an increased Th17/Treg cell ratio. Consistent with this, CKD stagewas positively correlated with serum concentrations of IL-17and negatively correlated with serum IL-10 levels. Moreover, serum levels of CHOP and GRP78 increased with advancing CKD stage. These correlations were most pronounced in patients in the CKD5 group, who also had the poorest response to hemodialysis and peritoneal dialysis treatment, compared with CKD5 patients in the non-dialysis group.Correlation analysis showed that serum levels of CHOP and GRP78 were independently and positively correlated with the ratio of Th17/Treg cells.

Conclusions: We have found that an increased Th17/Treg cell ratio and increased serum levels of ERS markers correlate with the progression of CKD. Our results indicate that the interplay between regulation of the immune network and management of ERS is closely associated with the pathogenesis of CKD. Although hemodialysis and peritoneal dialysis treatment manage chronic kidney conditions and prevent further deterioration of renal function, they have limited effects on improving the immune disorder and relieving ERS.

PUB192

Metabolic Phenotyping in Thin Basement Membrane Nephropathy

Claire Boulange,[1] Manuja Kaluarachchi,[1] Elaine Holmes,[1,2] John C. Lindon,[1,2] Joram Matthias Posma,[2] Konstantinos Voskarides,[3] Isavella Savva,[3] Alkis Mikis Pierides,[3] Constantinos Deltas.[3] *[1]Metabometrix Ltd, London, United Kingdom; [2]CSM, Dep of Surgery & Cancer, Imperial College London, London, United Kingdom; [3]MMRC, Dep of Biological Sciences, Univ of Cyprus, Nicosia, Cyprus.*

Background: Thin basement membrane nephropathy (TBMN) is the commonest cause of familial microscopic hematuria in children and adults, usually associated with benign clinical conditions i.e minimal proteinuria and normal renal function. In a Greek-Cypriot cohort of TBMN patients, 35% of patients were shown to develop ESRD by age 70-years while ~50% of patients over 50-years developed CKD of variable degree. 40% of TBMN patients inherit heterozygous mutations in the COL4A3/A4 genes. What predisposes these TBMN patients to an adverse outcome and chronic kidney function decline during aging is presently unclear. Using Metabolic phenotyping techniques (NMR and mass spectrometry) our study should provide new biological insights in the development of extreme conditions in adult TBMN patients.

Methods: Spot urine samples from 81 patients with the same founder mutation, COL4A3-G1334E. Patients were classed; Severe (S) (n= 55): proteinuria > *500 mg/day* and CKD, irrespective of age. Mild (M) (n=26): normal kidney function with no proteinuria, regardless of age. It is expected that some will proceed to CKD on follow-up. Samples were analysed by 600 MHz ^{1}H NMR spectroscopy (detecting predominantly small molecules >1μM) and UPLC-MS (detecting water-soluble molecules > 0.05 nM). Multivariate analysis (MVA) was used to elucidate class differences.

Results: MVA of M vs S samples revealed significant metabolic differences between the groups. From the UPLC-MS 15 MS features discriminate M and S. Among the discriminating metabolites discovered using NMR; citrate, glycine and creatinine were negatively correlated with S. Metabolite identification is ongoing, as well as application of additional metabolic profiling technologies.

Conclusions: Urine metabolic profiling may prove useful to classify renal disorders such as the M and S cases of TBMN by their specific renal metabolite signatures and lead to the discovery of novel molecular disease biomarker profile patterns.

Funding: Other NIH Support - The research leading to these results has received funding from the European Union's Seventh Framework Programme (FP7/2007-2013) under grant agreement no. 305608 (EURenOmics)

Uric Acid and Its Association with Glomerular Filtration Decline Rate in an Incident Pre-Dialysis Population

Pedro Vieira, Miguel Goncalves, Gil Silva. *Nefrologia, Hospital Central do Funchal, Funchal, RAM, Portugal.*

Background: Hyperuricemia is highly prevalent and there is cumulative evidence based on experimental models of its' likely detrimental role in multiple pathologies, namely hypertension, vascular and renal diseases. Given hyperuricemia's high occurrence on chronic kidney disease patients, we have tried to assess the association between uric acid basal levels (UABL) in an incident pre-dialysis population with renal function decline rate.

Methods: We have randomly selected incident patients with chronic kidney disease stages IV-V, referred to low clearance nephrology assessment from 2010 to 2014. We kept follow up until dialysis initiation, death or lost of follow-up.

Results: Sixty-six patients were selected with mean UABL of 8,15 (±2,10) mg/dl and a mean glomerular filtration decline rate of -4,00 (±10,81) ml/min/1,73m^2/year. Of notice that by each unit increase in UABL an added variation of -1,41 ml/min/1,73m^2/year on glomerular filtration decline rate was perceived (CI 95%, p= .039). Adopting a linear mixed model analysis on UABL' impact on glomerular filtration decline rate, despite adjustment for multiple demographic confounders and comorbilities, statistical significance (p=.006) was conserved.

Conclusions: High UABL were associated, with statistical significance, to enhanced deterioration of kidney function.

PUB194

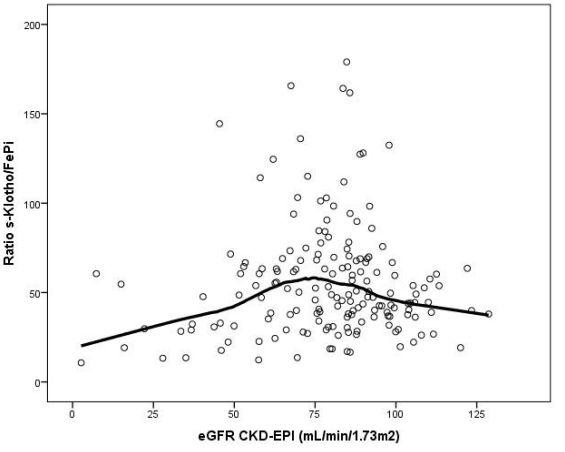
Soluble α-Klotho in HIV-Infected Patients and Kidney Dysfunction

Clara Dias,[1] Sara Maia,[1] Fernando G. Pereira,[2] Pedro Pereira Campos,[2] Ana Luisa Papoila,[3] Alberto Ortiz,[4,5,6,7] Sofia Pereira,[1] Karina Soto.[2,3] *[1]Centro de Estudos de Doenças Crónicas, NOVA Medical School/Faculdade de Ciências Médicas; [2]Nephrology, Hospital Fernando Fonseca; [3]Centro de Estatística e Aplicações, Univ de Lisboa (CEAUL), Portugal; [4]Nephrology, IIS-Fundacion Jimenez Diaz, Madrid, Spain; REDinREN, Madrid, Spain; [5]REDinREN, Madrid, Spain; [6]Univ Autonoma de Madrid, Madrid, Spain; [7]IRSIN, Madrid, Spain.*

Background: Kidney disease is common among HIV-infected patients. Klotho is a new endocrine protein that exerts modulation of kidney solute transport and nephroprotection in AKI and CKD. We aim to explore whether levels of serum soluble α-Klotho are related with CKD progression in HIV-population.

Methods: As a part of an on-going prospective study of HIV-infected patients, a cross-sectional analysis was performed. Glomerular filtration rate (eGFR) was estimated by CKD-EPI equation being Early Kidney Disease (EKD) when <90 mL/min/1.73m^2. Fractional excretion of phosphate (FePi) was also assessed and serum soluble α-Klotho was quantified by ELISA.

Results: A total of 169 HIV$^+$ patients were included, 66% men, 75% non-Black, 55yo (48-62). Median values Klotho: 957 pg/mL (717-1213) and FePi: 21% (14-25). Klotho/FePi ratio was negatively correlated with eGFR when ≥75 mL/min/1.73m^2 (*Spearman* r=-0.213, p=0.024); while the correlation was positive if eGFR<75 (*Spearman* r=0.410, p=0.002)



No direct relation between Klotho and eGFR was found, while FePi was only related with eGFR<75 (*Spearman* r=-0.396, p=0.002).

Conclusions: In HIV-infected patients, the association between Klotho and CKD progression has only significance when normalized by FePi levels. This association differed in opposite directions between patients with EKD and with normal kidney function, or in very early CKD stages. Of note, Klotho/FePi ratio seems to be better biomarker of EKD than Klotho itself.

PUB195

Association of hsCRP and Kidney Damage Indicators in 5667 Adults Receiving Physical Examination

Hao Zhang, Juan Mao, Bin Yi, Guo Xu, Wei Li. *The Third Xiangya Hospital of Central South Univ.*

Background: Chronic kidney disease and cardiovascular disease share many risk factors. Injury to the vascular endothelium, measured by elevated levels of serum high-sensitivity C-reactive protein (hsCRP), may play a role in kidney disease. We therefore examined the association of hsCRP with kidney damage indicators (uACR,eGFR) among 5667 participates receiving physical examination in the Third Xiangya Hospital.

Methods: We conducted a cross-sectional analysis of 5667 adults who received healthy physical examinationin in 2014. Spearman correlation analysis, multiple linear regression and multivariable logistic regression analysis were used to analyze the correlation between hsCRP with uACR, eGFR. ROC curves was drawing to explore the statistically significant intercept point of hsCRP in predicting the occurrence of albuminuria and declining in eGFR. Multivariable logistic regression analysis was used to calculate the ORs for albuminuria, declining in eGFR according to the quartile of hsCRP levels and other risk factors.

Results: Spearman correlation analysis showed that uACR was positively correlated with serum hsCRP (r=0.233,p<0.01). While eGFR showed negative correlation with hsCRP(r=-0.135,p<0.01). Multiple linear regression analysis showed that hsCRP was independently correlated with uACR(B=0.205,β=0.156, P<0.01). While hsCRP did't enter the multivariate linear regression model of eGFR. Multivariable logistic regression analysis showed that male, central obesity, hypertension, diabetes and high hsCRP levels were independent risk factors for albuminuria. Based on the ROC curve, the 0.85mg/L of hsCRP was the best numerical value to predict the risk of albuminuria. Multivariable logistic regression analysis showed that the risk of albuminuria significantly increased in male, central obesity, hypertension, or diabetes combined with high hsCRP levels.

Conclusions: HsCRP was correlated with kidney damage indicators, and hsCRP was an independent risk factor of albuminuria. The 0.85mg/L of hsCRP was the best numerical value to predict the risk of albuminuria. Male, central obesity, hypertension, diabetes accompanying high serum hsCRP levels are more likely to have albuminuria.

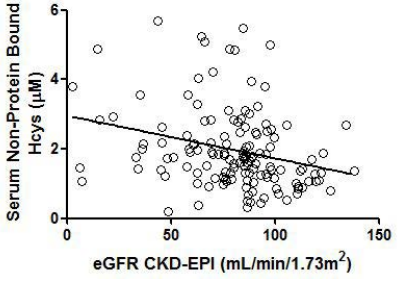
PUB196

Serum Non-Protein Bound Homocysteine Levels Are Related with Chronic Kidney Disease Progression in HIV-Infected Patients Clara Dias,[1] Nelson Casimiro,[1] Nuno Coelho,[1] Ana R. Lemos,[1] Pedro Pereira Campos,[3] Ana Luisa Papoila,[2] Sara Maia,[1] Karina Soto,[1,3] Sofia Pereira.[1] *[1]Centro de Estudos de Doenças Crónicas, NOVA Medical School/Faculdade de Ciências Médicas (NMS/FCM), Univ Nova de Lisboa; [2]Centro de Estatística e Aplicações da Univ de Lisboa (CEAUL), NOVA Medical School/Faculdade de Ciências Médicas, Univ Nova de Lisboa; [3]Nephrology, Hospital Fernando Fonseca, Lisbon, Portugal.*

Background: Homocysteine (Hcys) is present in serum in two major forms: disulfide protein-bound (PB) (70-80%, mostly albumin) and non-protein bound (NPB) (20-30% combined thiol dimers + 1% thiol free). Only the NPB-fraction of Hcys is able to enter into the cell and accumulatesIn both kidney failure and HIV-infected patients, hyperhomocysteinemia is a common feature. The present study was aimed to explore the relation of Hcys NPB-fraction and chronic kidney disease (CKD) progression in HIV-infected patients.

Methods: As a part of an on-going prospective study of HIV$^+$ population, a cross-sectional analysis was performed in a cohort of HIV-infected patients under combined antiretroviral therapy. Serum NPB-fraction of Hcys was quantified by HPLC with fluorescence detection. Glomerular filtration rate (eGFR) was estimated by CKD-EPI equation. The fractional excretion of phosphate (FePi) was also assessed.

Results: A total of 141 HIV-infected patients were included, 65% men, 73% non-Black, and 55 years old (IQR44-63). Median values of eGFR and FePi were 85 ml/min/1.73m^2 (66-95) and 19% (13-25) respectively. Univariable analysis was performed for eGFR, FePi and age. Only eGFR remained in the multivariable model (r=-0.332, p<0.0001).



Conclusions: Serum NPB-Hcys fraction was independently related with kidney dysfunction. The present data suggest that monitoring this sub-fraction of Hcys could be a tool for early kidney dysfunction detection in HIV-infected patients.

PUB197

Diabetic Foot Ulcers and Acute Kidney Injury Are Associated with a Decline in Renal Function Huda Mahmoud,[1] Maarten W. Taal,[1,3] Frances Game,[1,3] Laura M. Proctor,[1] Heather Sherriff,[1] Christina Udani Peter,[1] Hana Baig,[1] Faaiza Asma,[1] Emma J. Lincoln,[1] Nicholas M. Selby.[1,3] *[1]Renal Medicine, Royal Derby Hospital, Derby, United Kingdom; [2]Diabetes, Royal Derby Hospital, United Kingdom; [3]Div of Medical Sciences and Graduate Entry Medicine, Univ of Nottingham, United Kingdom.*

Background: There is an increased incidence of foot ulcers in patients with diabetes in the period immediately prior to the initiation of chronic dialysis; this may be explained if chronic foot ulcers accelerate a decline in renal function. We sought to examine this further by describing changes in renal function associated with hospitalisation for diabetic foot ulcer management.

Methods: All patients admitted to our centre during 2013 with ICD10 coding for diabetes and a primary diagnosis of foot ulcer (L97x) were identified. Data were manually extracted for those with a relevant clinical episode and sufficient biochemical results from routine clinical care. Patients undergoing amputation were excluded. Absolute creatinine and eGFR (CKD-EPI) values were collected from 6 months (+/- 1 month) pre and post hospital admission.

Results: 95 patients were included. 67 men, median age 68 years (range 31-96). Renal function was worse after an admission with an active diabetic ulcer; 6 months prior to hospital admission the mean eGFR was 72 +/- 25 SD ml/min/1.73m^{2}compared to 67+/- 27 SD ml/min/1.73m^2 6 months after admission, p=0.01. 27% of the admissions were associated with acute kidney injury (AKI stage 1, 2, 3: 19, 6, 1 patients respectively). Patients who sustained AKI during the admission had larger changes in eGFR than those patients without; median decline of -2ml/min/1.73m^2/year(IQR 6,-11) versus -5 ml/min/1.73m^2/year(IQR 2,-28), p=0.008.

Conclusions: These data add strength to the hypothesis that an active diabetic foot ulcer may contribute to a decline in renal function, particularly when associated with an episode of AKI. This decline may also be under-estimated due to loss of muscle mass and subsequent over-estimation of eGFR in the post hospitalisation period. These results support additional prospective epidemiological and mechanistic studies to further explore the relationship between diabetic foot ulcers, AKI and CKD progression.

PUB198

Gender – An Additional Cardiovascular and Chronic Kidney Disease Risk Factor in an Apparently Healthy Population Attilio Di Benedetto,[1] Annalisa Ciotola,[1] Fabrizio Cerino,[1] Annamaria Colao,[2] Daniele Marcelli,[3] Bernard J. Canaud.[3] *[1]NephroCare Italy, Naples, Italy; [2]Medicina Clinica e Chirurgia, Univ Federico II, Naples, Italy; [3]Fresenius Medical Care, Bad Homburg, Germany.*

Background: Cardiovascular disease (CVD) is on the rise, presenting significant societal and economic burden. Early detection of CVD and chronic kidney disease (CKD) risk factors may prevent related complications. We report results of a CVD and CKD risk factor screening program in an apparently healthy population.

Methods: Participants and spectators of the "Prevention Races" held in 2013/2014 in Naples/Salerno (Italy) were screened for CVD and CKD risk factors by different specialists, including nephrologists. Parameters assessed were: systolic blood pressure (SBP), diastolic blood pressure (DBP), weight, height, waist circumference, BMI, and body composition. Lean (LTI) and Fat (FTI) tissue indexes and overhydration were evaluated by Body Composition Monitor (Fresenius Medical Care, Bad Homburg, Germany) using multi-frequency bioimpedance spectroscopy at 50 different frequencies.

Results: 701 subjects (38.5% m; 61.5% f) were evaluated. Mean age was 54.54 + 15.6 (m) and 50.06 +15.2 (f). 3.7% m and 6.8% f had dyslipidemia; 5.9% m and 3.0% f were diabetic; 18.6% m and 11.4% f were hypertensive; 2.2% m and 0.7% f had heart disease; 0% m and 3.5% f had hypothyroidism; 1.5% m and 1.2% f had CKD. Gender differences in SBP, DBP, overhydration, FTI, LTI and BMI are shown (Table).

GENDER	SBP (mmHg)	DBP (mmHg)	Overhydration (% of ideal BW)			FTI (%)			LTI (%)			BMI (%)			
			<-1.0 L	>-1.0 <1.0 L	>1.0 L	low	normal	high	low	normal	high	<20 kg/m^2	20 – 24 kg/m^2	25 – 29 kg/m^2	>30 kg/m^2
Male	135.39 ± 18.4	79.97 ± 10.9	8.7%	43.6%	47.7%	1.5%	80.3%	18.2%	28.0%	67.4%	4.5%	0.7%	25.7%	49.1%	24.5%
Female	121.85 ± 18.0	75.28 ± 10.0	15.3%	50.7%	34.0%	3.5%	79.7%	16.7%	21.5%	72.9%	5.7%	4.4%	41.7%	31.2%	22.6%

Waist circumference was higher than normal (i.e. ≥88 cm for f and ³102 cm for m) in 38.4% (m) and 51.6% (f).

Conclusions: In a large sample of apparently healthy persons, males had more CVD and CKD risk factors than females, such as SBP, overhydration, and FTI. In association with other CVD risk factors, these increase morbidity and mortality. Evaluation of body composition is important in the general population for identification of CVD and CKD risk.

PUB199

Potential Effect of Treatment of Metabolic Acidosis on Reducing the Risk of End Stage Renal Disease in Chronic Kidney Disease Solomon Dalezman, Candace D. Grant, Vladimir Liberman, Alejandro Pepen Romero, Shayan Shirazian, Nobuyuki (Bill) Miyawaki, Joseph Mattana. *Medicine, Winthrop-Univ Hospital, Mineola, NY.*

Background: There is increasing evidence that low serum bicarbonate levels impact adversely on the progression of chronic kidney disease (CKD) to end stage renal disease (ESRD). It is plausible that treatment could result in a significant reduction in ESRD incidence though the potential impact in a CKD population and number needed to treat (NNT) are incompletely understood. We carried out the present study to estimate the potential impact of treatment of metabolic acidosis on the incidence of ESRD in a population of CKD patients.

Methods: We evaluated a cross section of 623 Stage 3 and 4 CKD patients at our institution. Their risk of developing ESRD at 2 and 5 years was estimated using the method of Tangri et al (*JAMA* 2011;305:1553-1559) which incorporates age, gender, eGFR, urine albumin to creatinine ratio, calcium, phosphorus, albumin, and bicarbonate. ESRD risk was then recalculated after assuming correction of all serum bicarbonate levels to 28 mEq/L.

Results: The population had a mean serum bicarbonate level of 24.3 mEq/L, with 79.5% having levels below 28 mEq/L. When ESRD risk was calculated following correction of low serum bicarbonate levels to 28 mEq/L, 16 fewer patients were predicted to develop ESRD at 2 years and 27 fewer at 5 years (relative risk reductions of 0.31 and 0.23 respectively). This effect was greatest for patients with CKD stage 4, accounting for 13 fewer ESRD patients predicted at 2 years and 20 fewer at 5 years. For the population as a whole, the NNT to prevent one case of progression from CKD to ESRD was 40 and 23 at 2 and 5 years respectively, while for those with CKD stage 4 the NNT was only 16 and 11.

Conclusions: Our findings suggest that in a population of CKD patients correction of metabolic acidosis could potentially result in a substantial reduction in the number who reach ESRD given the large numbers of patients with low serum bicarbonate levels. Prospective studies are needed to determine whether sodium bicarbonate therapy in populations of CKD patients could prevent many cases of ESRD.

PUB200

The Impact of Vascular Disease on Risk of Development of End Stage Renal Disease in Patients with Chronic Kidney Disease Vladimir Liberman, Sairah Sharif, Candace D. Grant, Alejandro Pepen Romero, Shanza Mujeeb, Nobuyuki (Bill) Miyawaki, Shayan Shirazian, Joseph Mattana. *Medicine, Winthrop-Univ Hospital, Mineola, NY.*

Background: Patients with chronic kidney disease (CKD) are not only at higher risk for development of end stage renal disease (ESRD) but also suffer disproportionately from vascular disease (VD), with associated high cardiovascular mortality. VD can plausibly impact progression of CKD and increase the risk of ESRD. However, VD also shortens survival, and may therefore reduce the risk of ESRD by increasing the competing risk of death. In the present study we evaluated the relationship between VD and the risk of development of ESRD in patients with CKD.

Methods: We carried out a retrospective cross sectional study of 623 CKD patients and recorded demographic, clinical and laboratory variables. We divided them in two groups based on presence or absence of VD and stratified them into different age groups. We estimated the risk of ESRD progression using the method of Tangri et al (*JAMA* 2011;305:1553-1559) and compared the risk levels between each group.

Results: Out of 623 patients with CKD 285 had VD (coronary artery disease and or peripheral vascular disease) documented in the record. Patients with VD were significantly older than patients with no VD (76 vs 70 years), had lower serum albumin (4.0 vs 4.1 g/dL) and lower eGFR (33.8 vs 36.4ml/min/1.73 m^2). We found that older patients with VD had significantly higher risk of developing ESRD. For the 70 to 79 year age group the 2 year risk was 2.45 vs 1.50 (p=0.029) and 5 year risk was 6.80 vs 4.31 (p=0.03) in patients with and without VD. For patients ≥80 years the 2 year risk of developing ESRD was 2.18 vs 1.35 (p=0.029) and 5 year risk of developing ESRD was 6.80 vs 4.31 (p=0.03).

Conclusions: Our findings suggest that older patients with VD may be at increased risk for the development of ESRD despite the higher competing risk of death. This may be partly due to shared pathophysiological mechanisms between atherosclerosis and CKD progression. If validated in an ongoing prospective study this finding would suggest that VD should be considered a risk factor predisposing to an increased risk of developing ESRD.

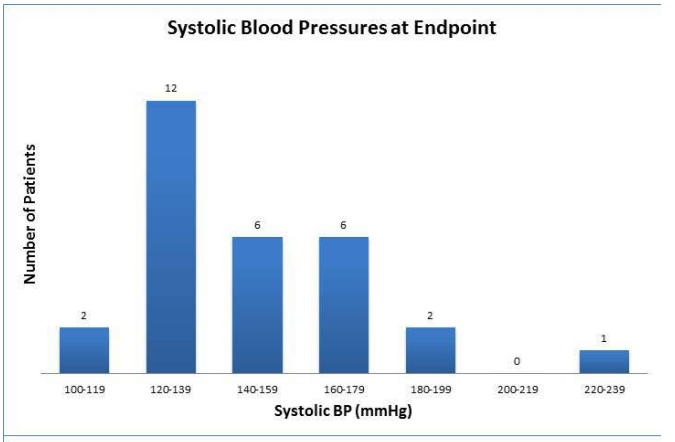
PUB201

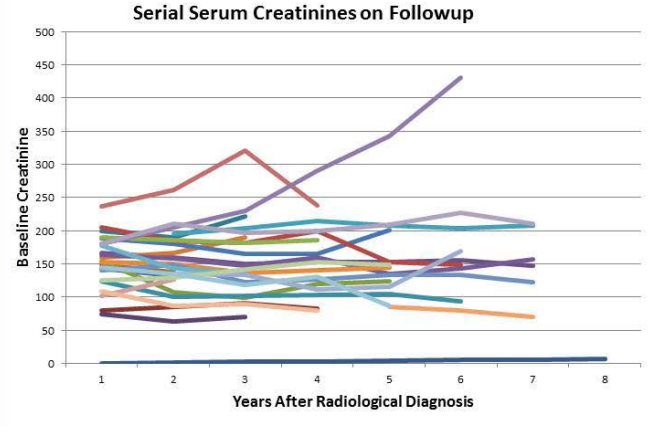
Management of Renal Artery Stenosis Post-ASTRAL and CORAL: Outcome of Patients with Radiologically Confirmed Atherosclerotic Renal Artery Stenosis Treated Conservatively Moheen Mohammed Ahmed,[1] Nicholas John Railton,[2] Abdelgalil Abdelrahman Ali,[1] Anthony Chan.[1] *[1]Renal Medicine, Mid Essex NHS Trust, Chelmsford, United Kingdom; [2]Radiology, Mid Essex NHS Trust, Chelmsford, United Kingdom.*

Background: Following the publications of ASTRAL and CORAL trials, the use of percutaneous renal artery angioplasty and stenting (PRAS) in the treatment of atherosclerotic renal artery stenosis (ARAS) has fallen dramatically. We report the outcomes of patients with radiologically confirmed diagnosis of ARAS who did not undergo PRAS and were managed medically.

Methods: Retrospective review of all patients undergoing CT/MRI angiography for suspected ARAS from 2008-2014 in Broomfield Hospital, Essex. Patients with more than >50% stenosis in a renal artery who were medically managed and did not undergo PRAS were included in analysis. They were followed for blood pressure control, renal events and mortality.

Results: 29 patients were identified, all Caucasians with a median age of 78 (49-85 years) of which 59% were males. None underwent PRAS.They were followed up from diagnosis till December 2014 or date of death with a mean period of 51 months. Systolic BP at end of study was <140 mmHg in 48%, 140-200 in 48% and >200 in 4% of patients. 69% were on 3 or more antihypertensives with 34% on renin angiotensin system blockade. 20 patients were CKD 3 and 8 with CKD 4 at baseline, with 3 patients progressing from stage 3 to 4 and 1 to stage 5 CKD, requiring dialysis.





13 out of 29 patients were dead at the end of study.

Conclusions: From this study of patients with ARAS not indicated for PRAS, only a small number progressed to higher grades of CKD. Blood pressure control appeared adequate in a significant proportion of patients. This is in keeping with the findings from ASTRAL/CORAL trials and may be of significant benifit in terms of cost and reducing patient morbidity.

PUB202

Clinical, Laboratorial and Immunological Characteristics of Membranous Nephropathy in Kidney Transplantation Patients Artur Quintiliano Silva, Juliana Busato Mansur, Marisa Petrucelli Doher, Gianna Mastroianni-kirsztajn. *Dept of Nephrology, UNIFESP, Sao Paolo, Brazil.*

Background: Membranous nephropathy (MN) is one of the more common causes of nephrotic syndrome in the adult population and may occur in the transplanted kidney. The goal of this study was to describe clinical and laboratorial characteristics of membranous nephropathy in kidney transplantation patients. A total of 41 patients was studied. The first proteinuria was with 48 months and time at diagnosis was 57.9 months. Eleven patients had a secondary cause of MN. Independently of the immunosuppressive regimen occurred MN.

Methods: The characteristics evaluated were graft survival, time to onset of symptoms, patient profiles, treatment evolution , time from onset of symptoms to graft loss, immunosuppression used before and after the diagnosis of membranous nephropathhy post transplant (MNPT), blockers of the renin-angiotensin-aldosterone system, proteinuria levels and time of biopsy x beginning of the onset of symptoms with disease progression.

Results: The mean age of the receptor was 49.4 years and 58.5% were males. The most common comorbidities were HBP (96.7%), dyslipidemia(22%), neoplasia (12.2%), diabetes (9,1%), SLE (7.3%) and hepatitis (7.3%). Induction therapy to prevent acute rejection during the early post transplant period was used in 9 (21.9%) patients (8 antithymocyte and 1 basiliximab) followed up by initial imunossuppression with PRED+CNI+AZA (56.1%) and PRED+CNI+MPA (34.1%).The end imunossuppression was Pred+CNI+AZA (29.2%), Pred+CNI+MPA (41.1%).Secondary MN causes had a more benign course (graft function) than the primary causes. Death censored graft survival in 10 years was 58.6%.

Conclusions: About 50% of grafts which develop de novo MGN eventually fail. This rather poor outcome may not represent the natural history of de novo MGN per se but rather the consequences of associated chronic rejection. Evidence is presented that many of the cases of so-called de novo MGN may be a complication of transplant glomerulopathy rather than being caused by mechanisms totally independent from rejection. The beneficial effects of immunosuppression agents have not been validated.

PUB203

Factors Influencing Initiation and Choice of Immunosuppressive Therapy in Primary FSGS Louis-Philippe Laurin,[1] Bethany J. Foster,[4] A. Gasim,[2] Caroline J. Poulton,[3] J. Charles Jennette,[2] Ronald J. Falk,[3] Patrick H. Nachman.[3] *[1]Div of Nephrology, Hôpital Maisonneuve-Rosemont, Montreal, QC, Canada; [2]Dept of Pathology and Laboratory Medicine, Univ of North Carolina at Chapel Hill, Chapel Hill, NC; [3]Div of Nephrology and Hypertension, Univ of North Carolina at Chapel Hill, Chapel Hill, NC; [4]Div of Nephrology, McGill Univ Health Center, Montreal, QC, Canada.*

Background: The treatment of patients with primary focal segmental glomerulosclerosis (FSGS) may include immunosuppressive therapy in patients not responding to conservative treatment or considered at high risk of progression to renal failure. We sought to determine the patient and disease characteristics associated with choice of therapy early in disease course.

Methods: Inception cohort of biopsy-proven patients with primary FSGS diagnosed between 1980 and 2012. Factors influencing choice of therapy were identified using multiple logistic regression; we report odds ratios (OR) with 95% confidence interval (CI).

Results: 458 patients were studied (183 on no immunosuppressives; 173 treated with glucocorticoids [GC] alone; 90 with calcineurin inhibitors [CNIs] ± GC; 12 with other immunomodulatory agents).

	No immunosuppression N=183	Immunosuppression N=275
Median age (yr)	48 (32-63)	36 (18-55)
Female sex (%)	48.1	49.1
Black race (%)	45.1	45.9
Median eGFR (mL/min/1.73m^2)	43.8 (27.2-69.9)	62.8 (41.7-85.7)
Median proteinuria (g/d)	3.8 (2.4-6.6)	6.0 (3.5-12.0)

Tip lesion variant (OR 3.00; 95% CI 1.23-7.32), eGFR ³30 mL/min/1.73m^2 (OR 1.89; 95% CI 1.01-3.45) and hypoalbuminemia (OR 2.22 per g/dL lower; 95% CI 1.59-3.13) were associated with a higher likelihood of any immunosuppressive treatment. Only tip lesion was associated with choice of GC alone vs. CNIs (OR 0.17; 95% CI 0.05-0.53).

Conclusions: Presence of tip lesion, preserved renal function at baseline and more severe hypoalbuminemia are associated with immunosuppressive therapy in primary FSGS, but only tip variant appears to influence choice of GC alone over CNIs.

PUB204

A Performance-Enhancing Drug and Its Depressing Effects Wajdi Bader. *Internal Medicine, John Stroger Hospital of Cook County, Chicago, IL.*

Background: Anabolic steroid use is a habit with a global 3.3% lifetime prevalence rate and is well known for its adverse effects on the renal, endocrine, hepatic, and hematologic systems. We bring a case of focal segmental glomerular sclerosis (FSGS) in a known user of anabolic steroids.

Methods: A previously healthy 28 year old male had presented to our hospital after being told he had kidney damage during a recent routine check up. On presentation, he complained of generalized weakness of one month's duration; the social history was significant for use of Mutant Plexx, a bodybuilding supplement that contained an anabolic steroid, methylstebolone. On admission, his vitals were pertinent for a blood pressure of 189/109 and a heart rate of 82. His physical exam noted a muscular male with normal cardiovascular, respiratory, and abdominal exams. On labs the patient had a BUN of 59, a creatinine of 5.6, and a hemoglobin of 13.1. A urinalysis showed 1 WBC, 2 RBCs, and 1+ protein. Nephrology team was consulted for further workup. Urine microscopy was performed and showed no dysmorphic RBCs. Spot urine protein/creatinine ratio was 2.2 grams. HIV was negative; HBsAg, HBsAb, and hepatitis C antibody were negative. Three days into his admission, the patient had an ultrasound guided kidney biopsy. On biopsy, half of the glomeruli had segmental scars, some with collapsing features. The interstitium had areas of fibrosis and the arteries showed mild sclerosis and arterioles with hyalinosis. The patient was diagnosed with collapsing FSGS secondary to anabolic steroid use; he was educated on control of hypertension and was advised to stop using anabolic steroids.

Conclusions: FSGS, the third most common cause of nephrotic syndrome after minimal change and membranous nephropathy, is usually attributed to HIV or obesity. The pathophysiologic cause of FSGS secondary to anabolic steroids is thought to be due to intraglomerular hypertension. In addition, high protein diets are known to cause an elevation in glomerular pressure. Collapsing FSGS is most common variant in anabolic steroid users, and is associated with the poorest prognosis. The treatment is discontinuation of steroid use and control of hypertension, preferably with an ACEi or ARB.

PUB205

Uric Acid Is Independet Risk Factor for Progression of Renal Dysfunction in IgA Nephropathy Female Patients Yasuyuki Nagasawa,[1] Ryohei Yamamoto,[2] Maki Shinzawa,[2] Sayuri Kawada,[1] Katsuyuki Nagatoya,[3] Aritoshi Kida,[1] Tatsuya Shoji,[4] Yukiko Hasuike,[1] Terumasa Hayashi,[4] Takahiro Kuragano,[1] Atsushi Yamauchi,[3] Yoshitaka Isaka,[2] Takeshi Nakanishi.[1] *[1]Dept of Internal Medicine, Div of Kidney and Dialysis, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan; [2]Dept of Nephrology and Geriatric Medicine, Osaka Univ, Suita, Osaka, Japan; [3]Dept of Internal Medicine, Osaka Rousai Hospital, Sakai, Osaka, Japan; [4]Dept of Nephrology, Osaka General Hospital, Osaka, Japan.*

Background: Ig A nephropathy is one of common primary glomerulonephritis. Hyperuricemia could be caused by reduced renal function. Therefore, it was difficult to distinguish hyperuicemia from the factors which promote renal dysfunction. Recently, several reports indicated that hyperuricemia might be independent risk factor for renal worsening, but there was little information about the effect of hyperuricemia itself upon progression of kidney diseases, especially in IgA nephropathy patients. Aim is to reveal effect of uric acid upon renal prognosis in IgA nephropathy patients.

Methods: This study is retrospective cohort study. Subjects were 923 IgA nephropathy patients who had not been treated uric acid lowering drugs, from 1001 IgA nephropathy patients who were diagnosed by renal biopsy, and over 15 years old in Osaka University Hospital, Osaka general medical center, Osaka Rosaki Hospital. Outcome was 1.5 times of serum creatinine. Exposure is uric acid at renal biopsy. Explanatory variables included sex, age, BMI, blood pressure, baseline eGFR, proteinuria, smoking status.

Results: Mean age was 34[23-46] years, proteinuria was 0.40[0.18-0.89] g/day. Uric acid was 6.5+-1.3mg/dl in male patients, and 4.8+-1.3mg/dl in female patients. Multivariate Poissaon regression analysis revealed that uric acid was significant risk for progression of renal disease [Hazard Ratio 1.30[1.01-1.65] UA per 1mg/dl] in female patients along with proteinuria(g/day) [HR 1.27[1.08-1.47],p<0.001], Creatinine (mg/dl) [HR 2.73[1.84-3.74]]. In male patients, uric acid was not independent risk factor.

Conclusions: Hyperuricemia is independent risk for progression of kidney disease in female IgA nephropathy patients.

PUB206

Long-term H.P. Acthar® Gel Treatment of Relapsing Idiopathic Membranous Glomerulopathy: A Case Study Firas Marayati. *Southwest Kidney Inst, Gilbert, AZ.*

Background: Long-term treatment with H.P. Acthar® Gel (repository corticotropin injection, Questcor Pharmaceuticals, Inc., Hayward, CA), an FDA-approved treatment for remission of proteinuria associated with nephrotic syndrome, was examined in a patient with biopsy-confirmed idiopathic membranous glomerulopathy (iMN).

Methods: A retrospective clinical record review examined Acthar Gel treatment over 2 years and 8 months in a patient with iMN who received prescription-based treatment in a clinical practice. Outcomes included proteinuria level (mg/g), serum creatinine (SCr), serum albumin and treatment-related side effects. Complete remission was defined as proteinuria <500 mg/g. Partial remission was defined as ≥50% reduction in proteinuria from baseline and proteinuria 500-3500 mg/g.

Results: The 54-year-old Vietnamese patient with iMN was treated over 7 years. At diagnosis, the patient's proteinuria was 8000 mg/g, SCr 0.7 mg/dL, and serum albumin 2.1 g/dL. Initial treatment included prednisone, cyclosporine, mycophenolate mofetil, tacrolimus, and rituximab over 4.5 years. The patient showed partial or complete remissions followed by relapse. At Acthar Gel initiation, proteinuria was 3400 mg/g, SCr 0.6 mg/dL, and serum albumin 4.2 g/dL. The patient did not tolerate 80 U twice weekly but did tolerate 40 U twice weekly. At 4 months, she showed complete remission (proteinuria <150 mg/g). Dose reduction to 20 U twice weekly resulted in relapse 7 months later (proteinuria 2300 mg/g). Dose increase to 40 U twice weekly led to complete remission 4 months after that. Loss of insurance and cessation of Acthar Gel for 4 months led to relapse (proteinuria 7700 mg/g). Acthar Gel was re-started at 32 U twice weekly followed by 24 U twice weekly. Partial remission occurred 4 months later (proteinuria 2100 mg/g) with greater improvement at 10 months (proteinuria 800 mg/g). The patient has maintained partial remission (proteinuria 970 mg/g) 4 months post-therapy. Side effects over the course of Acthar Gel therapy included fatigue, myalgia, hyperglycemia, and weight gain.

Conclusions: Long-term treatment with H.P. Acthar Gel may help meet an important treatment need in patients with treatment-resistant and frequently-relapsing iMN.

PUB207

Outcome of Steroid Dependent (SDNS) and Frequent Relapsing Nephrotic Syndrome (FRNS) in Children Isabel Roberti, Shefali Vyas. *Children's Kidney Center, Saint Barnabas Medical Center, Livingston, NJ.*

Background: Management of SDNS and FRNS in children can be frustrating. With the goal of minimizing steroid toxicity while achieving a sustained remission multiple regimens have been used with variable resullts. We reviewed our cases of SDNS/FRNS who had kidney biopsy (Bx) after failing MMF, for the past 12 yrs.

Methods: Charts of children **with Bx due to SDNS or FRNS** (after failure of MMF) were reviewed. Congenital and secondary causes of NS were excluded. Demographics, medications, side effects and response to therapy were studied. IV cytoxan (CYP) was considered in non-FSGS cases with suspected non-adherence (800 mg/m2/dose monthly

x 3). Others received tacrolimus (TAC) (0.1mg/kg BID; trough up to 6 ng/ml). Rituximab (7o5mg/m2 x 2 doses IV) was given if child became TAC dependent or resistant. Response to therapy was classified as: complete remission (CR), partial remission (PR), infrequent relapse (IR)(<2/yr), failure (F).

Results: 32 children had **kidney biopsy (Bx) for primary SDND/FRNS**. 14 females; 14 H, 10 AA, 6 C, 2 other race. **Age at presentation**: 2-14 yrs (median= 3 yrs). **Bx**: 15 MCNS (4 diagnosed later with FSGS), 9 IgMN, 5 FSGS, 3 C1QN, 1 idiopathic immune mediated GN. All children had normal GFR at the time of the bx. **24 children received TAC**: 21 CR (13 became TAC dependent with IR), 2 PR, 1 F; **15 received CYP**: 6 CR, 9 F (4 had initial diagnosis MCNS but later bx had FSGS); **7 received rituximab**: all had CR (5 IR). The rates of CR were significantly higher for TAC (87.5%) and rituxan (100%) as CYP had a failure rate 60% ($p<0.01$), including 4 cases with MCNS. However, those who had CR from CYP didn't have further relapses. Rate of IR among those who initially had CR was similar between rituximab and TAC. **Follow-up time**: 2-12 yrs (median= 4 yrs), including 6 discharged due to stable CR and 3 ESRD (all with FSGS). **Side effects**: 4 AKI with TAC (reversible), 2 respiratory distress/allergy in rituximab group (IV D/C). Late TAC resistance was seen in 3 patients.

Conclusions: Children with SDND/FRNS despite failure to respond to MMF had an excellent outcome. Some required sequencial use of tacrolimus and rituximab after failure of CYP with a rate of CR/IR >88% with minimal side effects.

PUB208

Granulomatosis with Polyangiitis (GPA) versus Sarcoidosis Sruthi Jinna,[1] Sami S. Zarouk.[2] *[1]Internal Medicine, Beaumont Health, Royal Oak, MI; [2]Nephrology, Beaumont Health, Royal Oak, MI.*

Background: An African American male was diagnosed at age 18 with GPA by kidney biopsy with negative serology. He was treated with intravenous cyclophosphamide and steroids. Four months post treatment a repeat kidney biopsy showed focal segmental glomerulosclerosis (FSGS). At age 25, he presented with fever, fatigue and cough for few weeks, chronic postnasal drip with bloody secretions, nausea, vomiting, and 40-pound weight loss in the last two months.

Methods: His BUN was 18 mg/dl, and creatinine 1.33 mg/dl. Urinalysis showed 3+ blood, 2+ protein, over 100 RBCs, 10 WBCs. Serology for Hepatitis B and C, HIV, EBV and CMV were negative. Antinuclear antibody, anti-neutrophil cytoplasmic antibody, anti dsDNA antibody, smith antibody, RNP antibody, myeloperoxidase antibody, proteinase 3 autoantibody, anti SSA antibody, anti SSB antibody, and complement levels were negative. An angiotensin converting enzyme (ACE) level was 81 U/L (8-52). A chest Computed Tomography scan showed mediastinal, hilar lymphadenopathy, and multiple pulmonary nodules.

Results: Suspicion for relapsing GPA prompted renal biopsy. It showed 3 out of 13 glomeruli with pauci-immune crescentic glomerulonephritis. There were extensive non-caseating granulomas in the interstitium with interstitial fibrosis and associated tubular atrophy. No microorganisms were noted on AFB and PAS stained sections. Nasal septum biopsy showed non-necrotizing granulomatous inflammation. Mediastinal lymph node biopsy showed necrotizing granulomatous lymphadenitis. These 3 biopsy sites were consistent with sarcoidosis.

Conclusions: This case highlights the difficulty in differentiating between ANCA negative GPA versus sarcoidosis as both can cause granulomatous lesions. Glomerular involvement in sarcoidosis can show membranous glomerulonephritis, FSGS and rarely a crescentic glomerulonephritis. In our opinion, high ACE level combined with extensive presence of non-caseating granulomas in the nasal septum, mediastinal nodes and renal interstitium are more characteristic of sarcoidosis. He responded well to steroids and his urine sediment became inactive, which is in favor of sarcoidosis and not GPA.

PUB209

Epidemiology of Glomerulonephritis in Southern Arizona Benjamin Kwesi Sarsah, Irfan K. Moinuddin, Bijin Thajudeen, Amy Nicole Sussman, Pradeep V. Kadambi. *Nephrology, Univ of Arizona, Tucson, AZ.*

Background: Knowledge about the incidence and prevalence of GN and its regional trends are mandatory for health care planners to adopt measures for preventing patients with glomerular disease from progression to dialysis. The aim of the study was to look at the patterns of biopsy proven non-diabetic glomerulopathy in Southern Arizona.

Methods: Renal biopsy specimens from adult patients above the age of 18 years with glomerular renal disease were included. Renal transplant biopsies showing glomerulonephritis and biopsies showing co-existing diabetic nephropathies were excluded. Histological diagnoses were grouped into one of the following 8 categories: minimal change disease, FSGS, membranous nephropathy,membrane-proliferative glomerulonephritis, pauci-immune glomerulonephritis, IgA nephropathy, lupus nephritis and others. Demographic parameters were systematically collected from the medical records archive.

Results: The most common histopathological diagnosis was FSGS followed by membranous nephropathy and IgA nephropathy. There was male preponderance in all histological variants except IgA nephropathy, lupus nephritis and pauci-immune glomerulonephritis. The race distribution was uneven, and all histological variants except minimal change disease and lupus nephritis were more commonly seen in whites. In separate analysis of the histological pattern in Hispanics, lupus nephritis was found to be the most common pathology followed by FSGS. In American Indian population the most common pathology was IgA nephropathy followed by FSGS. Bar diagram represents frequency of each glomerular disease

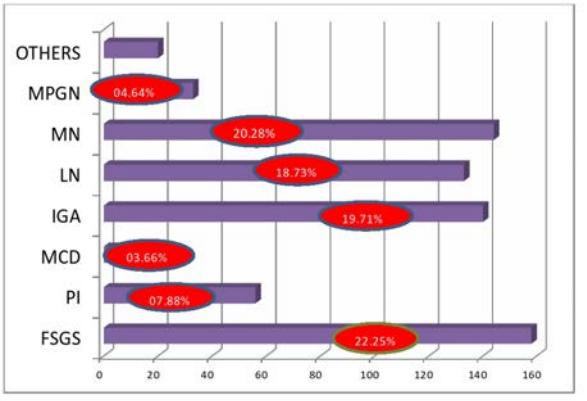

Figure 1: Bar diagram showing frequency of glomerular diseases

MPGN: membranoproliferative glomerulonephritis; MN: membranous nephropathy; LN: lupus nephritis; IGA: IgA nephropathy; MCD: minimal change disease; PI: pauci-immune glomerulonephritis; FSGS: focal segmental glomerulosclerosis.

Conclusions: This survey highlights the histopathological patterns of glomerular disease in southern Arizona. The data suggest regional and ethnic variations in glomerular disease that may suggest genetic or environmental influence in the pathogenesis of glomerular diseases.

PUB210

Use of Rituximab to Induce Remission in Frequently Relapsing Pediatric Nephrotic Patients Jason Peter Thomas,[1] Teri L. Crumb,[2] Alejandro Quiroga.[2] *[1]Pediatrics, Helen DeVos Children's Hospital, Grand Rapids, MI; [2]Pediatric Nephrology, Helen DeVos Children's Hospital, Grand Rapids, MI.*

Background: Rituximab has been shown to be effective in patients with frequent relapsing nephrotic syndrome (NS) with a reported 82% response rate. We evaluated the clinical response of pediatric nephrotic patients for induction of remission following one dose of rituximab.

Methods: This is an IRB approved, prospective clinical research trial. Informed consent was obtained from each family. Four pediatric patients with NS were enrolled prior to their clinically indicated rituximab infusion. Urine Protein/Creatinine ratio and albumin blood levels were collected.

Results: Urine Protein/Creatinine ratios obtained post infusion of rituximab decreased between 37-93% from pre infusion levels. 50% of patients identified had resolved edema noted on physical exam post infusion.

Conclusions: Rituximab may be an effective agent for inducing remission for pediatric patients with frequently replapsing nephrotic syndrome. 50% of patients had clinical response on physical exam post infusion and 100% of our patients had a decrease in the amount of protein excreted in their urine. The use of rituximab for the induction of remission is a novel and innovative treatment option for children with frequently relapsing nephrotic syndrome, warranting further investigation.

PUB211

Lupus Nephritis: An Exploration of Management Style Abhishek Nandan, Huzaefah J. Syed, Christen Vagts, Jason M. Kidd. *Internal Medicine, Virginia Commonwealth Univ Medical Center, Richmond, VA.*

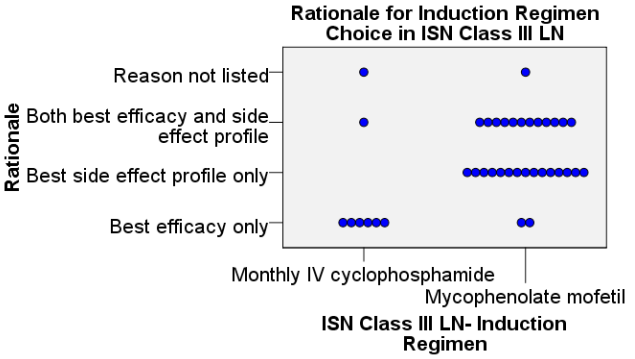
Background: We aim to evaluate the differences and rationale behind the diagnostic and therapeutic approaches to proliferative lupus nephritis (LN) among nephrologists and rheumatologists.

Methods: A de-identified, multiple-choice survey was distributed to nephrologists and rheumatologists. The survey consisted of a demographic questionnaire and two case vignettes exploring the decision of when to biopsy, management of ISN Class III LN, and management of refractory ISN Class IV LN.

Results: There were 38 respondents to our survey: 12 rheumatologists and 26 nephrologists. Work setting: 81% academic, 19% non-academic. Management of abnormal UA findings in an asymptomatic lupus patient: 33% of rheumatologists versus 76% of nephrologists chose to biopsy. Induction regimen of ISN Class III LN: 79% of all providers chose MMF and 21% chose IV cyclophosphamide.

Choice of Induction Regimen in ISN Class III LN per Specialty

	Mycophenolate Mofetil	IV Cyclophosphamide	Total
Nephrology	18	8	26
Rheumatology	12	0	12
Total	30	8	38



Maintenance regimen of ISN Class III LN: all surveyed rheumatologists chose MMF as a sole maintenance agent compared to 32% of nephrologists who elected the addition of low-dose corticosteroids to MMF. Choice of an adjunctive agent in refractory ISN Class IV LN: 68% of providers chose rituximab, 14% chose tacrolimus, 5% chose CTLA-4 IgG, and 14% elected not to add any agents listed.

Conclusions: The results of this survey suggest a significant difference among rheumatologists and nephrologists on the decision to perform initial kidney biopsy and management of ISN Class III LN. The results suggest that perception of side effect profiles play an important role in the choice of therapeutics. This study emphasizes the need for a multi-disciplinary approach toward renal disease in lupus patients. We continue to recruit subjects to complete this survey.

PUB212

Maintenance of Proteinuria Treatment Response to H.P. Acthar Gel® in Patients with Nephrotic Syndrome: A Follow-Up Case Series Anupa Khastgir,[1] Geoffrey S. Teehan.[2] *[1]Nephrology Practice, Oklahoma City, OK; [2]Lankenau Medical Center, Wynnewood, PA.*

Background: The duration of proteinuria response to H.P. Acthar® Gel (repository corticotropin injection, Mallinckrodt Brand Pharmaceuticals, Inc., Hazelwood, MO) treatment is not yet known. The current case series examined maintenance of proteinuria response in 7 patients who were included in a previously presented case series of Acthar Gel treatment of treatment-resistant NS in clinical practice.

Methods: Five patients with partial remission (500-3500 mg/d proteinuria and ≥50% reduction from baseline), 1 patient with clinical response (³30% reduction without meeting remission criteria), and 1 patient with clinical response and ongoing treatment following initial prescription-based Acthar Gel treatment for NS, and who had follow-up clinical care, were included. Medical charts were reviewed for proteinuria levels. Follow-up ranged from 2 to 19 months.

Results: Biopsy-confirmed NS etiological diagnoses included focal segmental glomerulosclerosis (FSGS, n=3), membranous lupus nephritis (MLN, class V, n=2), membranoproliferative glomerulonephritis (MPGN, n=1), and diabetic nephropathy (DN, n=1). 5/5 patients (2 FSGS, 2 MLN, 1 MPGN) with initial partial remission maintained partial remission during the follow-up period from a minimum of 2 months up to 19 months post-Acthar Gel treatment. The patient with MPGN and 1 with FSGS showed increased proteinuria with relapse at 12 months and 19 months post-treatment, respectively. The patient with DN received ongoing Acthar Gel treatment and maintained a proteinuria clinical response during the 11-month follow-up period. The patient reported fatigue but did not require cessation of Acthar Gel treatment. The patient with FSGS who showed an initial clinical response had further improved proteinuria at 2 months post-Acthar Gel treatment and showed partial remission at 12 months post-therapy without intervening immunosuppressive medications.

Conclusions: These follow-up proteinuria outcomes in 7 patients treated with H.P. Acthar® Gel for varied etiology NS suggest the proteinuria treatment response can be maintained long-term in some patients during treatment and beyond treatment cessation.

PUB213

Pauciimmune Glomerulonephritis with Immune Deposits: A Clinicopathologic Outcome Study Benjamin Kwesi Sarsah, Irfan K. Moinuddin, Bijin Thajudeen, Amy Nicole Sussman, Pradeep V. Kadambi. *Nephrology, Univ of Arizona, Tucson, AZ.*

Background: The clinical impact of the immune complexes in pauciimmune GN remains unclear. The objective of this study is to compare the clinical outcome of patients with pauci-immune GN and positive ANCA in the presence and absence of immune deposits on immunofluorescence.

Methods: Cases of pauci-immune GN were identified retrospectively from the archives of native renal biopsies. For inclusion in the study the cases have to meet the following criteria 1) should have full spectrum of histopathological analysis 2) complete follow up information in the chart 3) ANCA positivity 4) negative serologies 5) EM showing absent or scant immune deposits 6) absence of comorbidities 7) absence of co-existing histopathological diagnosis 8) less than 25% glomerulosclerosis. Patients' medical records were reviewed for age, race, gender, parameters of renal function, treatment, and outcome.

Results: Two groups- group which had immune deposits (group 1) and group with no immune deposits(group 2).All patients in group 2 had complete or partial improvement in renal function. None of them were dialysis dependent at any stage of their treatment. On the contrary in group 1, four patients required hemodialysis. (36% vs 0%, p value =0.0001). The group with immune deposits presented with higher mean creatinine (5.10±3.27 mg/dl vs 3.67±1.03 mg/dl, p value 0.195). Relevant demographic,lab and histologic variables are represented in table 1.

Variable	Positive immune deposits N=11 (group 1)	Negative immune deposits N=8 (group 2)	P value
Age (mean±SD) (years)	54.82±21.27	57.75±19.54	0.76
Gender (M/F)	4/7	2/6	0.12
Race (W/H)	6/5	7/1	0.0001
Initial creatinine mg/dl	5.11±3.27	3.67±1.03	0.19
ANCA(P/C)	9/2	7/1	0.33
Crescents (>50/<50)	4/7	3/5	0.88
TIF(mild/mod-severe)	6/5	2/6	0.0001
Type of crescents (C/CF,F)	7/4	1/7	0.0001

Conclusions: Pauciimmune GN with immune deposits has poorer prognosis compared to those without immune deposits. Pauciimmune GN with immune deposits likely represent patients with severe immune complex deposition and partial clearance of immune complex. These are patients who might benefit from plasmapheresis in addition to standard treatment.

PUB214

Eosinophilic Pneumonia with Renal Involvement Gabrielle Goldet,[1] Rachel Hung,[1] Michael Sheaff.[2] *[1]Basildon and Thurrock Univ Hospital; [2]Pathology, Barts and the London School of Medicine.*

Background: Eosinophilic pulmonary renal syndromes are well established and can be either vasculitic or infectious in aetiology. We describe a novel case of a patient whose presentation could not be fitted into either category.

Methods: A fifty year old male presented with increasing weight loss, night sweats and shortness of breath of 3 months duration. Additionally he noted some swelling of his lower limbs and frothy urine. He was extensively investigated with urinalysis, blood tests, imaging and histopathology till a novel diagnosis was made.

Results: The patient was found to have nephrotic range proteinuria with stable renal function, He had multifocal consolidation on computed tomography of the lungs and eosiniphilic infiltrates on lung histology. A kidney biopsy revealed dense subcapsular inflammatory cell infiltrate including eosinophils with possible subendothelial depostits on light microscopy. A vasculitic screen excluded vasculitis as the underlying pathology and no signs of vasculitis were seen on either the lung or kidney biopsies. Additionally filiarisis was excluded with negative serology. The patient was treated with steroids and his pulmonary and systemic symptoms resolved. Unfortunately, he has been found to relapse when an attempt at a steroid wean was made and is thus maintained on a low dose of prednisone.

Conclusions: We describe a novel pulmonary-renal syndrome and provide an approach to its investigation and management. This case opens the way for further research into eosinophilic pulmonary-renal syndromes.

PUB215

Role of Remission of in Idiopathic Membranous Nephropathy on Long Term Renal Function Outcome Abdulkareem Alsuwaida,[1] Hala M. KFoury,[2] Sufia Husain,[2] Tariq Aljohani,[2] Saad S. Alobaili,[1] Mohammed A. Al-Ghonaim,[1] Jamal S. Al Wakeel.[1] *[1]College of Medicine, King Saud Univ, Riyadh, Saudi Arabia; [2]College of Medicine, King Saud Univ, Riyadh, Saudi Arabia.*

Background: Heavy proteinuria is considered a poor prognostic marker among patients with idiopathic Membranous Nephropathy (iMN). However, the impact of the remission status on the renal out come in patients with iMN is not well studied. The purpose of this study was to evaluate the long-term prognosis after achieving a complete or partial remission among patients with iMN presenting with heavy proteinuria.

Methods: In this study, 25 patients with IMN with heavy proteinuria defined as ≥ 6 gm per day were evaluated for the effect of a partial remission (50% reduction in baseline proteinuria to ≤ 3 g/d and ≤ 25% increase in baseline creatinine) and complete remission (proteinuria ≤ 0.5 g/d and serum creatinine £123 µmol/l) on renal outcomes compared with patients who did not attain a remission. Worse renal outcomewas defined as doubling of the baseline serum creatinine value or development of end-stage renal disease at the last follow up.

Results: The cohort consisted of 20 men and 5 women. The median proteinuria at presentation was 9.4 gm per day (IQR: 6.7-12.1 gm per day) and the median of follow up duration was 7.0 years. The median base line creatinine was 91µmol/l (IQR: 74-98 µmol/l). A complete remission was attained in 7 (28%) patients, a partial remission in 12 (48%) patients, and no remission in 6 (24%) patients. The worse renal outcome was not observed in all patients who achieved complete remission, but it was seen in 16.7% of the partial remission group and in 66.7% of the no remission group (*P* value 0.14).

Conclusions: Achieving a complete or partial remission compared to no remission in patients with iMN is associated with a significantly better renal outcome.

PUB216

Comparison of Short- and Long-Term IgA Nephropathy Clinical Remission Rates Between Tonsillectomy plus Consecutive and Intermittent Steroid Pulse Therapies Kazuhiro Yoshikawa, Izaya Nakaya, Karen Kato, Yuta Tezuka, Satoshi Kumakura, Jun Soma. *Div of Nephrology, Iwate Prefectural Central Hospital, Morioka, Iwate, Japan.*

Background: Tonsillectomy (Tx) plus steroid pulse therapy (TSP) is widely performed across Japan for clinical remission (CR) of IgA nephropathy (IgAN) but treatment protocol lacks consensus. We used both TSP (methylprednisolone at 0.5 g/day iv for 3 days*) thrice/3 consecutive weeks (TSP-C) and intermittent pulse (*) thrice/6 months (TSP-I). Oral prednisolone (oPSL) between pulse therapies began at 0.5 mg/kg on alternate days. After the third pulse, oPSL was tapered over 1 and 0.5 years in TSP-C and TSP-I groups, respectively. Tx was performed before or during steroid therapies. We compared the effects of two regimens for CR.

Methods: This is a retrospective cohort study of 169 patients newly diagnosed with IgAN during January 2007 to December 2013 in our institute. We enrolled 90 patients we could follow to oPSL cessation and compared short- and long-term CR rates in both groups. CR was defined as urine protein < 0.3 g/gCr and urinary red blood cells < 5/high-power field.

Results: Before treatments, there were no significant clinical [TSP-C (n = 57) vs. TPS-I (n = 33): age, 31.0 ± 11.2 vs. 34.0 ± 11.9 years; male:female, 17:40 vs. 12:21; eGFR, 82.2 ± 29.9 vs. 77.4 ± 28.7 mL/min; blood pressure, 121 ± 17/72 ± 12 vs. 120 ± 17/76 ± 13 mmHg; urinary protein, 0.41 (0.18, 1.19) vs. 0.79 (0.20,1.08) g/gCr; and positive occult blood, 91.2 vs. 90.9%] and histological grade stratification differences between the groups. At oPSL cessation, short-term CR rates were equivalent between the groups [TSP-C vs. TPS-I: 68.4 vs. 61.0%]. Long-term CR rates at 1, 2, and 3 years after oPSL cessation were equivalent between the groups [TSP-C vs. TPS-I: 1 year, 64.1 (n = 39) vs. 59.1% (n = 22); 2 years, 64.0 (n = 25) vs. 80.0% (n = 10); 3 years, 73.7 (n = 19) vs. 66.7% (n = 6)]. CR continuation rates by Kaplan–Meier method also revealed no significant differences between the groups.

Conclusions: Tx plus either consecutive or intermittent steroid pulse therapies may be equally beneficial for short- and long-term IgAN CR. IgAN patients can flexibly choose therapies.

PUB217

Clinical Characteristics of Multiple Myeloma Patients Diagnosed by Nephrologist Byoung Geun Han, Jae seok Kim, Hyeon-Cheol Park, Shinhan Song, Jae Won Yang, Seung-Ok Choi. *Internal Medicine, Yonsei Wonju College of Medicine, Wonju, Korea.*

Background: Early diagnosis of multiple myeloma (MM) that is in early phase or has atypical presentation may be difficult. Even though MM is a hematologic malignancy, clinicians in different departments can make a diagnosis with a suspicious eye. In our department, we routinely performed protein electrophoresis in the patients with renal failure for the early diagnosis of MM.

Methods: We reviewed the medical records of 151 patients and examined the data of 117 patients diagnosed with MM in our hospital between January, 2003 and December, 2014. The patients were divided into three groups: group I presented to nephrologist prior to diagnosis (n=31), group II presented to hemato-oncologist directly (n=53), and group III presented to the other departments of our institute. The age, sex, initial symptoms, hematologic and biochemical parameters, and survival data were retrospectively analyzed.

Results: The main findings were anemia (n=30), renal failure (n=25), back pain (n=17), paraproteinemia (n=10), rib pain (n=7), mass (n=7), proteinuria (n=7), fracture (n=5), infection (n=4), bleeding (n=3), etc. Osteolytic bone lesion, survival rate, % of plasma cell in bone marrow study, Hb, platelet, CRP, serum albumin and calcium were not significantly different between three groups. 24 hours urine study (amount of proteinuria, protein-albumin ratio, protein-creatinine ratio) did not show any differences. Beta-2 microglobulin and serum uric acid were significantly higher in group I than those in the other groups ($p<0.05$). Immunoglobulin G, total protein, globulin, and amount of serum M protein were significantly lower in group I than those in the other groups ($p<0.05$). Distribution of BJ protein positive patients in group I was higher ($p<0.05$). ISS score was also higher in group I ($p<0.05$).

Conclusions: Multiple myeloma patients diagnosed by nephrologist did not show typical features of disease. Low levels of total protein and globulin in the patients with renal failure could be a cause of delayed diagnosis of MM. We recommend the protein electrophoresis should be routinely performed in the patients with renal failure.

PUB218

Screening for Renal Involvement in Newly Diagnosed ANCA-Associated Vasculitis Patients in Clinical Practice – Differences Between Hospital Departments Eline Houben,[1] Willem A. Bax,[1] Bastiaan Van Dam,[1] Walentina A. Slieker,[2] Gideon Verhave,[1] Fenneke C.P. Frerichs,[1] Erik Lars Penne.[1] *[1]Dept of Nephrology, MCA-Gemini Group, Alkmaar, Netherlands; [2]Laboratory of Clinical Chemistry, Hematology and Immunology, MCA-Gemini Group, Alkmaar, Netherlands.*

Background: Kidney involvement occurs in a majority of ANCA-associated vasculitis (AAV) patients and requires early and aggressive immunosuppressive therapy. The aim of the present study was to evaluate screening procedures for renal involvement in newly diagnosed AAV patients and to identify differences between hospital departments.

Methods: All AAV patients with a positive ANCA (PR3 and/or MPO) between 2005 and 2015 in a secondary care hospital in the Netherlands were included. Patient demographic data and the department making the diagnosis were recorded, as well as whether or not a complete screening for renal involvement had been made. The latter was defined as assessment of serum creatinine, analysis for erythrocyturia and proteinuria within two weeks before or after the diagnosis AAV.

Results: We included 110 newly diagnosed AAV patients (age 62± 14 years (mean±SD); 63% male). 81 patients (68%) had renal involvement (defined as: rise in creatinine >30%, ^{3}10 RBC/hpf and/or proteinuria ≥500mg/24h). Complete screening was performed in 90 patients (82%), depending on department: Nephrology 100% (21 of 21), Internal Medicine 88% (29 of 33), Pulmonology 68% (15 of 22), Ear Nose Throat 62% (8 of 13), other departments 81% (17 of 21). Of the 20 patients with incomplete screening, assessment of proteinuria was missing in 100% (20 of 20), erythrocyturia in 55% (11 of 20) and serum creatinine in 5% (1 of 20). Serum creatinine was higher in patients with complete renal screening (72 versus 109 µmol/l, p=0.01). Screening was completed within 2 months (n=12), 4 years (n=3), or never (n=5). One patient was found to have erythrocyturia 6 weeks after the diagnosis, but had not been treated accordingly.

Conclusions: In a substantial amount of newly diagnosed AAV patients, screening for renal involvement was incomplete, especially in patients with a normal creatinine level outside the renal department. Incomplete screening may have led to suboptimal treatment in some patients.

PUB219

A Case Series on the Treatment of Nephrotic Syndrome with Natural Adrenocorticotropic Hormone Gel in an Office Setting Marco A. Bonilla, Xavier F. Parada, Mario A. Henriquez. *Nephrology, Bronx Nephrology-Hypertension, Bronx, NY.*

Background: ACTH is a promising treatment for the nephrotic syndrome, associated with significant improvement in proteinuria and relatively few adverse effects. We present our experience using natural ACTH gel for nephrotic syndrome in patients with diverse diagnosis.

Methods: Retrospective case series of 7 Adults patients with nephrotic syndrome, treated with ACTH gel. Data was gathered by chart review, from the clinic EMR and paper based records. ACTH was given in the form of ACTHAR gel 80 USP units/ml SC twice a week for 6 months. Complete remission defined as stable or improved renal function with final proteinuria of <500 mg/day; partial remission as stable or improved renal function with ≥50% reduction in proteinuria and final proteinuria 500 to 3500 mg/day. Failure to meet this criteria was classified as treatment failure.

Results: Table 1. Outcomes

Patient	Age	Gender	Race	Diagnosis	Previous immunosupresion	eGFR (ml/min/1.73 m^2)	Proteinuria pre-ACTH (mg/g)	Proteinuria post-ACTH (mg/g)	Outcome
1	52	M	Hispanic	IgA nephropathy	None	20	1031.2	871	Failure
2	52	M	Hispanic	MGN	Prednisone, MMF	104	1001	290	Failure
3	62	F	Black	MGN	Prednisone	20	1010.4	295.4	Complete

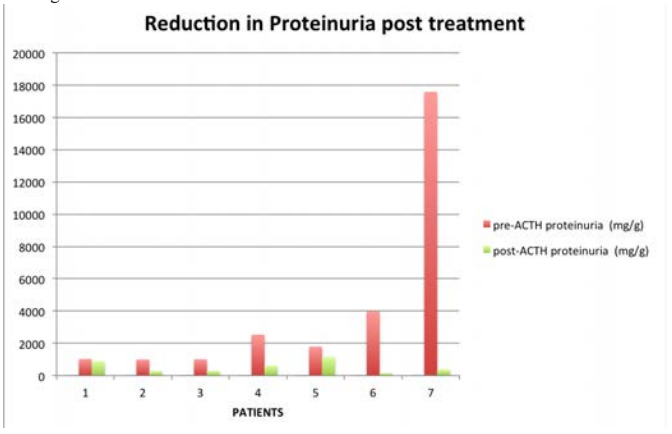
Figure 1.



Conclusions: ACTH gel is an effective therapy in patients with nephrotic syndrome, as significant reductions in proteinuria were seen in the majority of patients, it was not only patients with membranous nephropathy who responded to treatment with ACTH but also patients who were nephrotic due to other diagnosis such as IgA nephropathy; this data highlights a need of further studies on natural ACTH gel in the treatment of nephrotic syndrome.

PUB220

Efficacy of Rituximab in Severe Lupus Nephritis in Children: A Case Series Julien Hogan, Véronique Baudouin, Georges Deschenes. *Pediatric Nephrology, Robert Debré Hospital, Paris, France.*

Background: The association of cyclophosphamide or Mycophenolate Mofetil (MMF) with prednisolone is the treatment of reference of lupus nephritis(LN), both in adults and children but is associated with major side effects. Rituximab (RTX) failed to demonstrate an improvement of patient outcome when associate with MMF and prednisolone. However, recent data suggest that it might allow to spare prednisolone. We report our experience of the use of RTX in first LN flair in children.

Methods: We included patients treated by RTX for a first flair of LN class III to V between 2006 and 2014. Treatment associated methylprednisolone (500mg/m2) followed by RTX (1000mg/1.73m2) at day one and 15 and MMF 1200mg/m2/day. Tapered down and withdrawal of prednisolone was left to each physician appreciation. Complete remission (CR) was defined as a proteinuria over creatininuria ratio (Pu/creat) <50mg/mmol and normal serum creatinine and partial remission (PR) as a Pu/creat<300mg/mmol and no raise of creatininemia over 15% of baseline.

Results: Seven patients were included with a median follow-up of 14.0months [6.0-69.1]. They presented with proteinuria (median 0.24g/mmol [0.05-0.71]), hematuria and 4 out of 7 had impaired renal function (mean GFR 78.4mL/min/1.73m2 [62.6-133.6]).Three had a LN stage IV, three a class IV+V and one a class III+V. Median CD20 depletion time was 10.0 [6-25] months. Prednisolone was rapidly tapered down, the median dose were 0.2, 0.11, 0.05 mg/kg at 3, 6 and 12 month respectively. At 3 months, two patients achieved CR and three PR. Patients without remission had a nephrotic range proteinuria and no renal failure and had LN stage III+V and IV+V. At 6 and 12 months all patients achieved remission. No patient experienced renal relapse, two had an infectious complication and one presented a mild pancreatitis.

Conclusions: A treatment combining RTX, MMF with a rapid decrease of prednisolone seems efficient in severe lupus nephritis. Such protocol may be of major interest in children, since steroids are known to have major side effects in this population. More studies are needed to assess the safety and the efficacy of this treatment and to evaluate the amount of steroids that can be spared through this strategy.

PUB221

Clinical Prognosis of Anti-Neutrophil Cytoplasmic Antibody (ANCA) Negative Pauci-Immune Necrotizing Crescentic Glomerulonephritis: A Retrospective Cohort Study in Korea Sung Woo Lee, Seon Ha Baek, Shin-Young Ahn, Sejoong Kim, Ki Young Na, Dong-Wan Chae, Ho Jun Chin. *Seoul Nation Univ Bundang Hospital.*

Background: Very few studies have reported on the prognosis of anti-neutrophil cytoplasmic antibody (ANCA) negative pauci-immune necrotizing crescentic glomerulonephritis (piNCGN).

Methods: Between July 2003 and December 2013, 48 patients were diagnosed with piNCGN. The ANCA status was tested using indirect immunofluorescence and enzyme-linked immunosorbent assay. The primary and secondary outcomes were 1-year renal and patient survival, respectively.

Results: Among the 48 patients, 6 (12.5%) had ANCA negative piNCGN, while 42 (87.5%) had ANCA positive piNCGN. All ANCA negative piNCGN patients were male and showed high proportion of protein ³3 positive with dipstick test. No significant differences in renal pathology, clinical manifestation, or treatment were noted between the groups. The trend of 1-year end stage renal disease was higher for ANCA negative than ANCA positive piNCGN (66.7% vs. 23.8%; p=0.052). In Kaplan-Meier estimation, ANCA negative piNCGN showed poorer 1-year renal survival than ANCA positive piNCGN [median (95% CI) 9 (0.0-51.0) vs. mean (95% CI) 287.5 (244.8-330.2) days; log-rank p = 0.010]. In Cox-proportional hazard analysis, ANCA negativity was found to be an independent factor for 1-year renal survival with a hazard ratio (95% CI) of 10.93 (1.03-115.94) compared to ANCA positivity (p=0.047). In contrast, the 1-year all-cause mortality and patient survival did not differ depending on ANCA status.

Conclusions: Although the proportion of ANCA negative piNCGN was not high in our study population, poor 1-year renal survival was noted among these patients. We believe that particular caution should be exercised while treating ANCA negative piNCGN.

PUB222

Clinical Implication of Serum Free Light Chain in Patients with IgA Nephropathy Woo Jin Jung,[1] Sang Heon Song,[1] Su Min Park,[1] Jong Man Park,[1] Il Young Kim,[1] Dong Won Lee,[1] Soo Bong Lee,[1] Harin Rhee,[1] Eun Young Seong,[1] Ihm Soo Kwak,[1] Min Jung Kim,[1] Joo Hui Kim.[1] *[1]Dept of Internal Medicine, Pusan National Univ School of Medicine, Busan, Republic of Korea; [2]Dept of Internal Medicine, Pusan National Univ School of Medicine, Busan, Yangsan, Republic of Korea.*

Background: Free light chains (FLCs) are produced in excess during immunoglobulin synthesis by plasma cells and other cells of the B-cell lineage. Recent studies demonstrated that elevated polyclonal FLCs are associated with increased mortality in chronic kidneys disease. But little is known about the clinical implication of FLCs in patients with IgA nephropathy which is caused by the overproduction of an aberrant form of IgA1 and the activation of B-cells responding to mucosal infection. Therefore, we investigated the relationship between the serum levels of combined FLCs (cFLCs) and prognostic markers in IgA nephropathy.

Methods: This retrospective study analyzed consecutive 42 patients with biopsy-proven IgA nephropathy without renal function impairment (estimated glomerular filtration rate (eGFR) $\geq$ 60 ml/min/1.73m^2) at the Pusan National University Hospital from January 2010 to December 2013. cFLCs was defined as a sum of kappa and lambda FLCs and clinical and laboratory data were collected by medical records reviewing.

Results: The mean (±SD) age were 41.4 (±14.9) years and the median (inter-quartile range) of cFLC and urinary protein-to-creatinine ratio (uPCR) were 40.5 (32.6 – 47.8) mg/L and 666.3 (364.8 – 1306), respectively. In correlation analyses, log-transformed cFLCs was positively related to age, serum cystatin C, IgG and log-transformed uPCR, and negatively associated with serum albumin and hemoglobin levels. In multivariate regression models, increased cFLCs was significantly associated with higher log-transformed uPCR(β(SE)=0.0124(0.006), p=0.045) after adjusting confounding factors. However, no significant association of cFLCs with pathologic classification was observed.

Conclusions: The cFLC level was independently correlated with the magnitude of proteinuria in patients with IgA nephropathy. Further longitudinal studies are needed to clarify the role of cFLC as a prognostic maker in IgA nephropathy.

PUB223

Long Term Renal Outcomes in Lupus Nephritis in a Multi-Racial Asian Population: A Retrospective Study Hui Zhuan Tan, Cynthia Ciwei Lim, Jason Choo Chon Jun, Chan Choong Meng. *Dept of Renal Medicine, Singapore General Hospital, Singapore, Singapore.*

Background: Lupus nephritis causes significant morbidity with racial predilection affecting prognosis and treatment responses. We aimed to evaluate risk factors for progressive CKD in lupus nephritis (LN) in a multi-racial Southeast Asian population.

Methods: We retrospectively reviewed 113 consecutive patients with newly diagnosed biopsy-proven LN diagnosed between 10 May 2001 to 30 May 2009. Demographics, indices of renal function and disease activity, histopathological data and pharmacotherapy were evaluated. Primary endpoint was progressive chronic kidney disease (CKD) defined by doubling of serum creatinine or end stage renal failure.

Results: Median age was 41.6 (IQR 29.2, 51.6) years, predominantly Chinese (76.1%) and female (81.4%). Twelve patients (10.6%) had Class I or II LN, 13 (11.5%) Class III LN, 62 (54.9%) Class IV LN and 25 (22.1%) isolated Class V LN. Eight patients (7.1%) had mixed proliferative and membranous LN. Most patients received either angiotensin converting enzyme (ACE) inhibitors or angiotensin II receptor blocker (100 patients, 88.5%). Induction immunosuppressants included glucocorticosteroids in 109 patients (96.5%), cyclophosphamide 26 (23.0%), mycophenolate mofetil or mycophenolate sodium 51 (45.1%), cyclosporine 9 (8.0%), and azathioprine 14 (12.4%). Median follow up was 79.0 (61.5, 104.0) months. One hundred and eight patients (95.6%) achieved remission, with complete remission in 89 patients. Among patients who achieved remission, 61 patients had disease relapse. Thirteen patients had progressive CKD at last clinic visit, with ESRD occurring in 5 patients at median 12.0 (1.0, 59.5) months from biopsy. Patients with progressive CKD tended to be non-Chinese (53.8% vs. 20.0%, p=0.01), with higher serum complements [median C3 0.66 (IQR 0.48, 0.87) vs. 0.38 (0.29, 0.60), p=0.04 and C4 0.17 (0.12, 0.22) vs. 0.06 (0.05, 0.12), p=0.004], fewer remissions (69.2% vs. 99.0%, p=0.001) and more relapses (100% vs. 52.5%, p=0.005).

Conclusions: In this multi-racial Asian cohort, race, higher serum complement levels, failure to achieve remission and relapses were associated with poor renal outcomes in lupus nephritis.

PUB224

The Clinical Predictors for Outcome of Antineutrophil Cytoplasmic Autoantibody-Associated Vasculitis Patients with Renal Involvement

Pu Lei, Guisen Li, Li Wang. *Nephrology, Sichuan Academy of Medical Sciences & Sichuan Provincial People's Hospital, Chengdu, Sichuan, China.*

Background: Primary anti-neutrophil cytoplasmic antibody(ANCA)-associated vasculitis(AAV) are chronic multisystem autoimmune diseases and result in dysfunctions of multisystem. Renal involvement is the most common manifestation and is closely associated with the outcome of patients with vasculitis. We investigated the clinical determinants of the early mortality of patients with vasculitis-related renal injury followed up 2 years in a single west Chinese center to study the factors associated with patient outcome.

Methods: A total of 123 consecutive patients with AAV-related renal injury diagnosed in our center were recruited. Clinical and laboratory data were collected retrospectively. All the patients were followed up for 2 years after diagnosis. The predictive values of variables associated with mortality were analyzed.

Results: During 2 years follow up duration, 54 (43.9%) died, of whom 41 diedwithin the first 12 months after diagnosis. Compared with surviving patients, the deceased patients had higher BVAS scores and higher incidence of pulmonary hemorrhage. They also had higher serum creatinine and ESR, lower hemaglobin and complement C3, more patients accepting renal replacement therapy than surviving patients during hospitalization,. Higher BVAS scores and serum creatinine>400umol/L were the predictors of death in patient with AAV-related renal injury independently.

Conclusions: the incidence of early mortality in patients with AAV-related renal injury was higher. Prudent monitoring and therapy should be given to patients with active vasculitis and serious renal dysfunction to reduce adverse events.

PUB225

Significance of Resistive Index in Renal Arterial Ultrasonography as a Clinical Parameter for Tubulo-Interstitial Nephropathy

Minoru Hatano,[1] Kaori Takayanagi,[1,2] Taisuke Shimizu,[1] Hiroaki Hara,[1] Nobuyuki Onizawa,[1] Koki Ogawa,[1] Yuka Tanaka,[1] Kunihiko Yasuda,[1] Tomonari Ogawa,[1] Akihiko Matsuda,[1] Hajime Hasegawa.[1] *[1]Nephrology and Hypertension, Saitama Medical center, Saitama Medical Univ, Kawagoe, Saitama, Japan; [2]Ishikawa Kinenkai Kawagoe Ekimae Clinic, Kawagoe, Saitama, Japan.*

Background: Renal arterial ultrasonography (RA-US) has been principally applied to evaluate the stenosis of the renal artery and the indication of catheter intervention by the measurement of peak systolic velocity (PSV). Resistive index (RI) is calculated as (PSV-EDV)/PSV, where EDV indicates end-diastolic velocity, and is reported to be related to the renal function. In this study, we aimed to investigate the possible clinical benefit of RI for the assessment of tubulo-interstitial nephropathy (TIN).

Methods: We studied 51 patients (51.6±2.3 years old) who underwent RA-US and sufficient laboratory tests for the analysis in the past 10 years in our hospital. PSV and RI were measured at both main renal arteries (RA-measurement) and intra-renal arteries roughly corresponding to the inter-lobular arteries (IRA-measurement). NAG index (urine excretion ratio of N-acetylglucosaminidase (NAG) to creatinine) was used as a conventional clinical parameter for the assessment of TIN.

Results: Stratified analysis by median value of RI (0.69) showed significant difference in eGFR in the RA-measurement (43.4±4.7 vs 60.3±4.2), but not in the IAR-measurement. In contrast, the analysis showed significant difference in NAG index in the IRA-measurement (median: 11.6 vs 5.4), but not in RA-measurement. When the patients showing NAG index ≥ 15, indicating advanced renal insufficiency, would be excluded from the analysis, NAG index significantly correlated with RI of IRA-measurement (R=0.50, p<0.05), but not RA-measurement. In addition, ROC analysis revealed that the cut-off value of RI to NAG index was 0.65.

Conclusions: In addition to the previous report showing the relevance of RI to the histological severity, the present study demonstrated the correlation of RI with the conventional parameter of TIN, NAG index. Particularly, for the assessment of TIN, RI value measured at intra-renal artery would be more beneficial.

PUB226

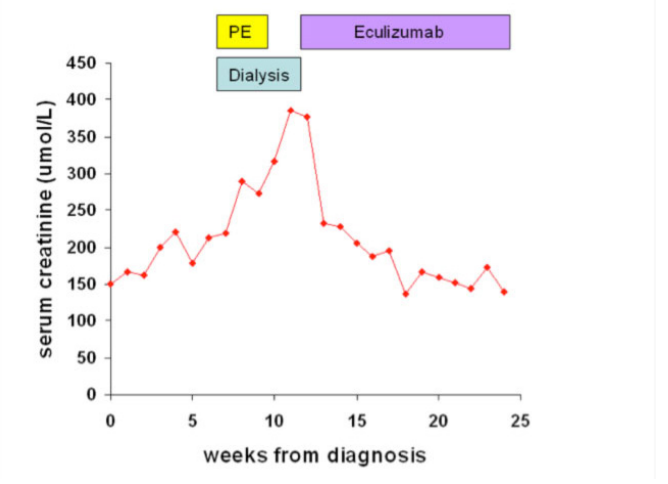
Recovery of Renal Function with Eculizumab in a Girl with Dense Deposit Disease and Normal Soluble C5b-9 Levels

Martin Kömhoff,[1] Arjan Diepstra,[2] Marc Maj Seelen,[3] Coen A. Stegeman,[3] Valentina Gracchi.[1] *[1]Pediatrics, UMCG, Groningen, Netherlands; [2]Pathology, UMCG, Netherlands; [3]Nephrology, UMCG, Netherlands.*

Background: Dense Deposit Disease (DDD) is a rare glomerulopathy characterized by electron-dense deposits in the glomerular basement membrane (GBM) and glomerular complement deposition. 50% of patients progress to ESRD and have recurrences after kidney transplantation. Dysregulation of the alternative complement pathway plays a key role in the pathogenesis. Increased soluble C5b-9 in blood is considered to predict response to eculizumab, an anti-C5 monoclonal antibody.

Methods: We report the case of a previously healthy 15-year-old girl who presented with acute kidney injury, hypertension, nephrotic syndrome (10.8 gr protein /24 hours) and microscopic hematuria.

Results: Biochemical (C3 &4, sC5b-9, factors H & I, C3 nephritic factor and anti-FH) and genetic workup of the complement system (CFI, CFB, C3 and MCP) showed normal results, except for a slightly increased C3d and a risk allele in the CFH gene. Renal biopsy showed cellular crescents and electron-dense deposits in the GBM. Glomerular C3 and C5b-9 immunofluorescence staining was positive. Despite escalating therapy, including methylprednisolone pulses followed by oral prednisolone, cyclophosphamide and plasma exchange (PE), the renal function further deteriorated and hemodialysis was started. Eculizumab was administered. This led to a rapid improvement of renal function (discontinuation of dialysis and increase of endogenous creatinine clearance from 11 to 53 ml/min/1.73m^2). Three months later the girl is in a good clinical condition but proteinuria is still in the nephrotic range (3.6 gr/24 hours). Treatment with eculizumab is ongoing. Up to now no side effects have been observed.



Conclusions: Response to eculizumab in DDD cannot be predicted merely on the basis of levels of sC5b-9 in blood.

PUB227

Ten-Year Experience of IgA Nephropathy in the South East of Ireland

Heather Martha Gunning, Sean F. Leavey, Vivian Elizabeth Abernethy, Catherine M. Brown. *Nephrology, Univ Hospital Waterford, Waterford, Ireland.*

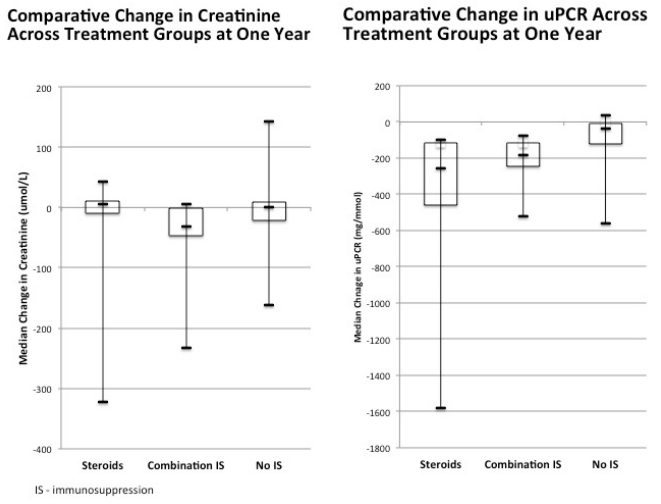
Background: Worldwide IgA nephropathy (IgAN) is the most common non-infectious glomerulonephritis[1]. Its presentation varies widely from asymptomatic urinalysis abnormalities to nephrotic syndrome and renal failure. There are few randomised controlled trials to guide its best management and many patients continue to be treated on 'best opinion'[1].

Methods: All renal biopsies undertaken in our institution between January 2005 and December 2014 were retrospectively reviewed and those diagnostic of IgAN were identified. Data collected included patient characteristics, presentation, treatment and disease course, serum creatinine and urinary protein creatinine (uPCR) ratio at six months and one year.

Results: 426 native renal biopsies were reviewed. IgAN was diagnosed in 65 (15%); 51 (78%) male and 14 (22%) female. At time of biopsy median age was 39 years (IQR 19), median creatinine was 139umol/L (IQR 146) and median uPCR was 234mg/mmol (IQR 334). Presenting features are detailed in table 1.

	Patient number (n = 65)	Percentage (%)
Vasculitic rash	7	11
Frank haematuria	17	26
Nephrotic range proteinuria	25	38
Hypertension	44	68
Creatinine ≥ 200umol/L	19	29
Creatinine ≥ 300umol/L	11	17

56 (86%) received renin-angiotenisin blockade. 31 (48%) received immunosuppressive therapy; 19 (29%) steroids, 9 (14%) combination immunosuppression and 3 (5%) mycophenolate. Follow-up data at one year was available in 58 (89%), 6 were receiving renal replacement therapy. Median changes in creatinine and uPCR at one year are detailed in figure 1.



Conclusions: Manifestations of IgAN vary widely. The mainstay of therapy consists of supportive measures, which the majority of our cohort received. Immunosuppressive regimens are reserved for a select group, and in our cohort both mycophenolate and steroid based regimens yielded a reduction in proteinuria.

PUB228

Effect of Rituximab on Immunoglobulin Levels and Infection Risk in ANCA Associated Vasculitis Shivani Shah,[1] M-Hafizur Rahman,[2] Duvuru Geetha.[1] *[1]Div of Nephrology, Dept of Medicine, Johns Hopkins Hospital, Baltimore, MD; [2]Bloomberg School of Public Health, Johns Hopkins Univ, Baltimore, MD.*

Background: Rituximab (RTX), a B cell depleting anti-CD20 monoclonal antibody, is approved for treatment of ANCA associated vasculitis (AAV). Low immunoglobulin (Ig) levels are a consequence of RTX treatment. The association between the degree of Ig deficiency and infection risk is unclear in AAV patients.

Methods: AAV patients treated with RTX in a single center with available serum Ig measurements were included. The rates and types of infection after RTX administration were correlated with Ig level using correlation matrix and logistic regression analysis.

Results: Our cohort of 27 patients had a median age of 68 years, eight males, 15 GPA patients, and 17 with a new diagnosis of AAV. Twenty five received four doses of RTX 375 mg/m^2 weekly and two received RTX 1000 mg biweekly for two doses. Nine received concomitant cyclophosphamide. Twenty three patients had low serum IgG levels (<751 mg/dL) greater than one month following RTX treatment. Ten out of these 23 developed infections over the median follow up time of 338 days. Pneumonia was the most common infection. The odds of having an infection with IgG level ≤500 mg/dL is 3 times higher than with IgG level between 501-750 mg/dL, though p= 0.26. There is a significant association between infection and IgM level £20 mg/dL (p = 0.047).

	Odds Ratio	SE	Z	p-Value	95% CI
IgM (normal ≥ 46 mg/dL, reference ≥ 46 mg/dL)					
21-45 mg/dL	1.16	1.33	0.13	0.89	0.12-10.99
≤20 mg/dL	8.17	8.64	1.99	0.047	1.103-64.94
IgG (normal ≥ 751 mg/dL, reference 501-750 mg/dL)					
≤500 mg/dL	3	2.93	1.13	0.26	0.44-20.31

Conclusions: Severely low Ig levels due to RTX therapy may increase the risk of infection in AAV patients, and these patients may benefit from IVIG therapy. Further investigation is warranted given our study is limited by small sample size, concomitant cyclophosphamide use, and variable timing of Ig measurement.

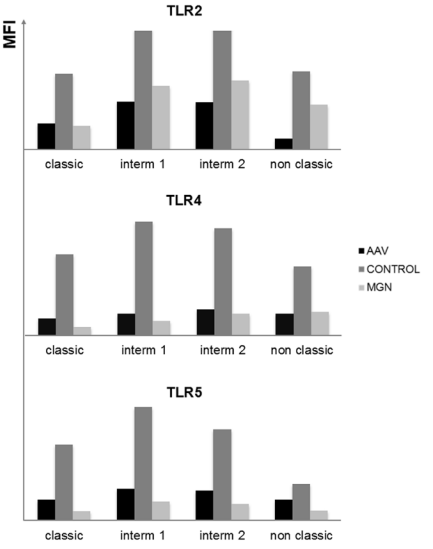
PUB229

Monocyte Subpopulations of Patients with Different Forms of Glomerulonephritis Exhibit Distinct Changes of Toll Like Receptor Expression Leon Brian Schubert,[1] Florian Gunnar Scurt,[1] Noemi Rose emma Doll,[1] Marius Früh,[1] Tobias Hölscher,[2] Andreas Jeron,[2] Dunja Bruder,[2] Peter R. Mertens,[1] Christos D. Chatzikyrkou.[1] *[1]Nephrology, Hypertension, Diabetes and Endocrinology, Otto-von-Guericke Univ Magdeburg; [2]Inst of Microbiology, Otto von Guericke Univ Magdeburg.*

Background: We are still in need for more reliable markers to monitor disease activity in primary glomerulonephritis.

Methods: In patients with active primary glomerulonephritis monocyte subpopulations were first differentiated by flow cytometry withthe use of the surface markers CD 14, CD 16 CCR2 and CxCR3. The expression of different proteins reflecting antigen presentation or activation status as well as scavenger receptor and toll like receptor functions was then quantified. Blood samples of healthy individuals were used as controls. Preliminary results regarding toll like receptors 2, 4 and 5 in a patient with treatment naïve MPO positive vasculitis, a patient with treatment naïve membranous glomerulonephritis and a control are presented here.

Results: The expression of the toll like receptors 2, 4 and 5 was lower in patients with primary glomerulonephritis compared to the controls.



This was the case in all monocyte subpopulations: classical (CD14++CD16-CCR2highCXCR1-), intermediate type 1 (CD14++CD16+CCR2highCXCR1-) non-classical (CD14+CD16++CCR2lowCXCR1high) and intermediate type 2 (CD14+CD16+CCR2lowCXCR1high).

Conclusions: Toll like receptors seem to be down regulated in monocytes of patients with primary untreated glomerulonephritis during the active phase. The pathophysiological significance of these findings is unclear and remains to be elucidated.

PUB230

Lipoprotein Glomerulopathy Hostensia M. Beng, Basema I. Dibas, Hsiao Ling Lai, Guillermo Hidalgo. *Pediatrics, ECU, Greenville, NC.*

Background: Lipoprotein glomerulopathy has been associated with mutations in the Apolipoprotein E (APOE) gene. The average age of reported cases is 32 years and the youngest patient described to date is 4yrs old.Here we present the first case of a 3 years old AA male with right hemihypertrophy, malignant hypertension, severe proteinuria & lipoprotein glomerulopathy,with a heterozygous mutation on APO E2 gene.

Methods: 3 year old African American male presented to pediatrician complaining of hemihypertrophy, short stature, polydipsia &hypertension. physical examination remarkable for right leg soft tissue hemi hypertrophy. Echocardiogram revealed left ventricular hypertrophy likely secondary to chronic hypertension. Hypertension and proteinuria persisted despite adequate treatment. Renal US showed persistent echogenic kidneys. Kidney biopsy showed Lipid vacuolization of podocytes, endothelial cells, tubular epithelial cells, and glomerular capillary lumens. Labs & imaging studies AFP and abdominal US have been normal with exception of proteinuria and increased lipid profile. Patient currently on a trial treatment with fibric acid and dietary modification.

Results: eGFR is stable at 60 ml/min/1.73 m2, proteinuria has improved from a ratio of 2.1 to 0.8 mg/mg and lipid profile has significantly improved.

Conclusions: APOE is an important LDL in transporting cholesterol to the liver for processing. Four main alleles of the APOE gene located on chromosome 19 have been described and different alleles have been associated with various medical conditions. Mutations of near the LDL bind domain of the APOE gene coexist and may be associated with certain kidney diseases. Renal biopsy shows lipid deposits and thrombi which results in glomerular damage and glomerular sclerosis. No effective preventative or curative treatments have been identified for apolipoprotein glomerulopathy. In our patient a trial of fibrates to lower cholesterol,Gemfibrozil and effective management of hypertension has resulted in some improvement but it is uncertain if these medication can effectively lower lipid and prevent long term progression of kidney disease. More research to find more effective treatment and management strategies of this disease in children.

PUB231

Proliferative Lupus Nephritis (LN) – 60 Month Evolution of an Argentinian Cohort Gabriel Pedro Alvarez,[1] Marcelo Alejandro De Rosa,[2] Luis Alberto Touceda.[1] *[1]Hospital San Martin. La Plata, Buenos Aires; [2]Univ of Buenos Aires, Argentina.*

Background: Remission of proteinuria predicts good evolution in many glomerular diseases; we describe the behavior of the proteinuria, renal function and flare up in a group of patients with proliferative LN in a 60 month period.

Methods: Data from 55 patients were obtained. Proteinuria and Creatinine were shown at 0 (time of the biopsy), 6 and 60 months; renal biopsies were classified using ISN-RPS 2003. All patients received an induction with at least 6 gr. of cyclophosphamide plus prednisone and a maintenance treatment with sodium mycophenolate 1440 mg/d and low doses of prednisone for at least 3 years. Flares was considered in case of 50% proteinuria increase or an active urinary sediment.

Results: Results are in table

Table 1

N	55	%		
Age (mean)	31,2		range 18-64	
Sex f/m	52/3			
Bx class II	1	2		
Bx class III	7	12		
Bx class IV	40	72		
Bx class V	1	2		
Bx class V+ III/IV	7	12		
	T0	6m	60m.	p
Proteinuria gr/d (median)	3,04 (0,2-28)	1,2 (0,1-16,6)	0,2 (0,1-3,8)	‹ 0,05
Creatinine mg/ dl (median)	0,94 (0,5-4,23)	0,9 (0,6-4,22)	0,91 (0,55-7,22)	NS
Flares up			17/ 32%	
Treatment months			36 (30-60)	

Conclusions: We observed a sustained decline in proteinuria and a preservation of renal function in most of patients; Treatment was well tolerated and flares up were in a high number of patients.

PUB232

A Case Study Comparing Cyclophosphamide plus Methylprednisolone versus Cyclophosphamide Alone in Idiopathic Membranous Nephropathy

Basel Jaafar Alhayki. *Dept of Nephrology and Renal Transplant, Salmaniya Medical Complex, Manama, Bahrain.*

Background: In the treatment of high risk idiopathic membranous nephropathy the modified Ponticelli protocol with the use of alternative month Cyclophosphamide and steroid is the most used treatment protocol. The scientific bases for the use of intermittent alternating month Cyclophosphamide and Methylprednisolone versus Cyclophosphamide alone in the treatment protocol is not well established and in many studies showed that steroid alone has limited role in the treatment of idiopathic membranous nephropathy. Weather this intermittent use of Cyclophosphamide and Methylprednisolone lead to a fluctuating response to therapy and prolong the recovery or not need to be investigated.

Methods: This is a case study of a 26 years old male with idiopathic membranous nephropathy and a positive AntiPLA2R antibody who needed to be started on Modified Ponticelli protocol with alternative month Cyclophosphamide and Methylprednisolone for a persistent massive Proteinuria of 16 gram per day and who failed cyclosporine in the past .Initially the patient was given the six month the modified Ponticelli protocol but he failed to reach a complete or a partial remission with persistent Proteinuria of more than 6 gram per day and high Anti-PLA2R antibody titer and later he was given an extra three months of Cyclophosphamide alone .

Results: There was a fluctuating in antibody titer during the course of therapy with increase Anti-PLA2R antibody titer at the end of the Methylprednisolone month and reduce level after the month of Cyclophosphamide use. After the start of the extra three months of continues Cyclophosphamide the anti-PLA2R antibody titer was reducing in each month and at the end of the extra three months it disappeared completely with a remission of the Proteinuria.

Conclusions: This case shows that the use of Cyclophosphamide is more effective in the treatment of idiopathic membranous nephropathy than Methylprednisolone and it might provide a better control of the disease activity. Future study to evaluate this with the use of novel biomarker like Anti-PLA2 R antibody is recommended.

PUB233

Plasma Cytokines and Chemokines Profile in Patients with Systemic Lupus Erythematosus: Its Potential Use as Biomarkers of Kidney Damage

Gustavo Aroca Martinez,[1,2] Lisandro Pacheco,[1] Elkin Navarro Navarro,[1] Yirys Diaz,[1] Henry J. Gonzalez torres,[1] Gloria Garavito,[3] Eduardo Egea bermejo,[3] Eduardo I. Navarro,[1] Lisneth Almendrales,[1] Antonio De jesus Iglesias-Gamarra.[4] *[1]Medicine, Univ Simón Bolívar, Barranquilla, Atlántico, Colombia; [2]Nephrology, Clínica de la Costa, Barranquilla, Atlántico, Colombia; [3]Medicine, Univ del Norte, Barranquilla, Atlántico, Colombia; [4]Medicine, Univ Nacional de Colombia, Bogotá DC, Cundinamarca, Colombia.*

Background: Systemic lupus erythematosus is an autoimmune disease in which the innate and adaptive response plays a significant roll, mainly mediated by cytokines. Lupus nephritis-LN-is the most severe complication associated with SLE. **Objective**: To identify differential expression of cytokines profiles and circulating chemokines in plasma of SLE patients with different degrees of Caribbean region.

Methods: This was a case- control study. Plasma samples from 10 patients with NL class-II 10 patients with NL class-III, and 30 patients with NL class-IV were analyzed. As a control plasma from 30 SLE patients without nephritis were used. Plasma samples were analyzed using the Luminex technology of 38 analytes (EGF, Eotaxin, FGF-2, Flt-3 ligand, Fractalkine, G- CSF, GM-CSF, GRO, IFN-a2, IFN -γ, IL-10, IL-12 (p40), IL 12(p70), IL-13, IL-15, IL-17, IL-1Rα, IL-1α, IL-1β, IL-2, IL 3, IL4, IL-5, IL-6, IL-7, IL-8, IL-9, IP-10, MCP-1, MCP-3, MDC (CCL22), MIP-1α, MIP-1β, TGF-α, TNF-α, TNF-β, VEGF, sCD40L, RIL-2Ra) using MILLIPLEX®-MAP-Human Cytokine/Chemokine-Magnetic-Bead-Panel-Premixed 39 Plex.

Results: Significant differences($p<0.05$) was between concentrations of cytokines EGF, G-CSF, GM-CSF, GRO, IFN, IL4, IL8, IP10, MCP, MDC, MIP.1a, sIL2Ra,TNFb when SLE-patients with LN vs SLE-patients without LN were compared.

Conclusions: These preliminary data suggest that there are differences in the LN plasma patients level of some chemokines and proinflamatory cytokines. Results support the hypothesis that circulating levels in plasma samples of these molecules may be considered.

PUB234

Clinical Outcomes of IgA Nephropathy with Necrotizing and Crescentic Lesions in Inner City Hospital

Ambarish Athavale, Amit J. Joshi, Kalyani Perumal, Albert M. Osei, Peter D. Hart, Taha Iqbal. *Nephrology, John H Stroger Jr. Hospital of Cook County, Chicago, IL.*

Background: IgA nephropathy is the most common cause of glomerular disease worldwide. Segmental necrosis and crescents are seen only in small subset of patients and literature regarding their clinical outcomes is sparse.

Methods: Retrospective analysis of cases with primary IgA nephropathy from Stroger Renal biopsy database from January 2005 to May 2015 was performed. Demographic and clinical information was obtained from medical charts. Study was approved by IRB.

Results: Of 66 cases of IgA nephropathy, 10 (15%) had lesions with segmental necrosis and/or crescents. These patients responded well to cyclophosphamide based therapy with improvement in creatinine and proteinuria after a mean follow up of 4.6 years. However, patients without vasculitic lesions had a progressive decline in renal function despite immunosuppressive therapy. This group had longer follow up period (mean 7.1 yrs) and 21% required dialysis.

	With necrotizing/ crescentic lesions (n=10)	Without necrotizing/ crescentic lesions (n=56)	P value
Age (in years)	44.6	46.2	
Gender (M:F %)	30:70	54:46	
Ethnicity Hispanic or Latino Non Hispanic/Latino	 5 5	 27 29	
S. creatinine (mg/dl) at biopsy	1.4	1.7	0.26
Estimated proteinuria at biopsy (g/g of Cr)	3.5	2.7	0.21
Prednisone(%)	90	34	
Immunosuppressants(%) Cyclophosphamide based Others	80 70 30	23 1 99	
ACEI/ARB (%)	80	81	
Length of follow up (in years)	4.6	7.1	0.001
Last S. creatinine (mg/dl)	1.0	1.8	0.65
Last estimated proteinuria (g/g of Cr)	1.2	2.3	0.47
Biopsy			
Mesangial hypercellularity (%)	80	73	
Endocapillary proliferation (%)	50	5	
Segmental sclerosis (%)	70	66	
Tubular atrophy T0<25% T1>25% T2 >50%	 50 30 0	 34 37 28	

Conclusions: Patients with vasculitic lesions (necrosis and crescents) carry a favorable prognosis when treated with Cyclophosphamide based therapy. When applying MEST criteria among patients with and without vasculitic lesions, only tubular atrophy was predictive of future decline in renal function (p=0.007). In this cohort, 21% reached ESRD within a mean follow up of 7 yrs which highlights the aggressive nature of this disease in ethnic minorities.

PUB235

Acute Tubulo-Interstitial Nephritis (ATIN): Predicting Long Term Outcomes Victoria C. Robins,[1] Aravind Cherukuri,[2] Padmini Prasad,[1] Richard J. Baker.[1] *[1]SJUH; [2]Pittsburgh.*

Background: ATIN is a relatively common potentially reversible cause of acute kidney injury.It has become clear over the last 2 decades that the disease is not always reversible,particularly in the elderly.We present a large contemporary single centre retrospective series concentrating on factors that predict poor outcomes.

Methods: 62 cases retrospectively diagnosed histologically via patholgy records as primarily ATIN were included.An experienced histopathologist,blinded to outcomes,graded biopsies according to the presence,absence and degree of 8 different parameters: Interstitial inflammation,tubular atrophy,eosinophilia,plasma cell infiltration,chronic vascular lesions,hyalinosis,granulomas + oedema.Patients were classified as a poor outcome if eGFR(4 variable MDRD) after 12 months was less than 30ml/min/1.73m^2 or they died.

Results: 62 patients with biopsy proven ATIN were identified.15 had a poor outcome. Baseline demographics are presented in Table 1.

	Good (eGFR>30)	Poor (eGFR<30)	p value
n	47	15	
age	56.2+/-16.8	56.6+/-19	Not significant(-)
Sex M/F	19/28	6/9	-
Creatinine:diagnosis	366+/-245	545+/-334	0.02
Creatinine:6 months	130+/-40	220+/-90	<0.0001
PCR:diagnosis	103+/-72	126+/-90	-
Treatment: prednisolone	87%	80%	-
Serum eosinophil count	0.4+/-1.0	0.4+/-0.5	-
Biopsy degree of:interstitial Inflammation	2.1+/-0.8	2.1+/-0.7	-
tubular atrophy	1.2+/-0.4	1.3+/-0.6	-
eosinophilia	0.9+/-0.8	1.3+/- 1.0	-
plasma cell infiltation	2.0+/-0.9	2.0+/-0.8	0.03
chronic vascular lesions	1.3+/-0.5	1.6+/-0.5	-
hyalinosis	0.6+/-0.7	0.6+/-0.7	-
granulomas	0.3+/-0.6	0.9+/-1.1	0.03
oedema	0.3+/-0.5	0.5+/-0.8	-

Aetiology was difficult to definitely ascertain but consisted of drug induced, infectious, sarcoid or sjogrens. Parameters significantly associated with poor outcomes include higher creatinine at presentation & 6 months,presence of granulomas and chronic vascular lesions on biopsy at diagnosis.The effect of steroid treatment was difficult to assess since most patients were treated at the outset.

Conclusions: ATIN usually carries a good prognosis but some patients experience poor outcomes.Poor renal function at diagnosis and the presence of granulomas and chronic vascular lesions are predictive of poorer outcomes.

PUB236

Cotreatment of Olmesartan and Caterpillar Fungus Attenuate Albuminuria in Patients with Glomerulonephritis Hua Zhou, Ye Zhang, Ya Li, Hairong Tang, Congcong Jiao, Lining Wang. *Nephrology Dept, 1st Hospital of China Medical Univ, Shenyang, China.*

Background: Angiotensin II receptor blockers (ARBs) were demonstrated to reduce proteinuria since a decade ago. However, proteinuria still remains as the top of clinical symptoms in glomerulonephritis (GN). We aim to investigate the effect of cotreatment with olmesartan (Olm), an ARB and caterpillar fungus capsule (CF) on proteinuria in patients with GN.

Methods: 491 patients with GN were retrospectively studied. GN was diagnosed by moderate albuminuria and/or dysmorphic hematuria. Patients were divided into seven groups by treatment: 1) CF alone, 2) Olm alone, 3) other ARBs defined as non Olm ARBs, 4) all ARBs include Olm and other ARBs, 5) CF + Olm, 6) CF + other ARBs, and 7) CR + all ARBs. High blood pressure is not necessary indication for ARBs treatment. Urinary albumin concentration (uAlb, mg/L) were examined before and 1, 2, and 3 months of the treatment.

Results: uAlb was significantly attenuated in the groups with Olm alone, all ARBs, CF + Olm, and CF + all ARBs at 1 and 2 months after the treatment compared to pretreament (Olm alone 343±82vs 483±77, p=0.009, n=92; all ARBs 351±68vs 494±68, p=0.004, n=125; CF+Olm 509±81vs 853±105, P=0.0002, n=118; CF+all ARBs 544±81 vs 836±92,P=0.0006, n=138 at 1 month. Olm alone 264±54 vs 466±107, p=0.006, n=35; all ARBs 295±50 vs 606±117, p=0.0003, n=58; CF+Olm 395±92 vs 814±157, P=0.001, n=60; CF+all ARBs 438±80 vs 902±135,P<0.0001, n=77 at 2 months). At 3 months after the treatment, the significant reduction of uAlb was only seen in cotreatment with CF and Olm/all ARBs (CF+Olm 357±141 vs 559±112, P=0.026, n=28; CF+all ARBs 368±102 vs 631±119,P<0.019, n=41). The decrease of uAlb was not found in groups of CF alone, other ARBs, and CR+other ARBs (numbers of patients received other ARBs are 33, 13, 8 and received CF+other ARBs are 21, 9, 7 at 1, 2, and 3 months, quite smaller than Olm). The cotreatment with CF showed an increased statistical p value.

Conclusions: Cotreatment of Olmesartan and caterpillar fungus significantly attenuated albuminuria in patients with GN. caterpillar fungus might be a promising agent to treat glomerular proteinuria via synergizing the effect of ARBs in glomerulonephritis.

PUB237

Tubulointerstitial Involvement in Lupus Nephritis Angela Pakozdi,[1] Dev Pyne,[1] Michael Sheaff,[2] Ravindra Rajakariar.[3] *[1]Rheumatology, Barts Health NHS Trust, London, United Kingdom; [2]Histopathology, Barts Health NHS Trust, London, United Kingdom; [3]Nephrology, Barts Health NHS Trust, United Kingdom.*

Background: Tubulointerstitial disease is frequent in lupus nephritis (LN), and interstitial infiltration, tubular atrophy and interstitial fibrosis are all independent risk factors for LN renal outcome. We aimed to analyze tubulointerstitial changes on a series of repeat renal biopsies (RB) and identify correlations with clinical variables.

Methods: Histopathological changes of 39 LN patients were analysed using the revised Austin's semi-quantitative grading system of 0 to 3 (0, normal; 1, mild <25%, 2, moderate 26-50%; 3, severe >50% of the interstitium affected). Spearman's rank-order correlation was run to determine relationship between clinical variables and histological findings.

Results: We found a progression in both tubular atrophy (p=0.001) and interstitial scarring (p<0.001), but not in inflammatory cell infiltration by the time of RB. The mean total tubulointerstitial score (± SD) has progressed from 2.69 ± 2.03 to 3.78 ± 2.03 (p=0.001). There was a positive correlation between serum creatinine and the severity of tubular atrophy at time of both reference biopsy (r=0.33, p=0.048) and RB (r=0.56, p<0.001). Serum creatinine at time of RB showed a strong correlation with interstitial scarring (r=0.60, p<0.001). A trend was identified between the severity of interstitial inflammation on reference biopsy and the amount of tubular atrophy and interstitial scaring on RB (r=0.349, p=0.19; r=0.385, p=0.009). Chronicity indices (CI) also progressed by the time of RBs. Patients with proliferative histopathology on initial biopsy had higher CI at both the reference biopsy (p=0.047) and RBs (p=0.019). Treatment decisions did not seem to be influenced by the progression of CI (p=0.982).

Conclusions: Tubulointerstitial lesions show progression in time illustrated by our study using RBs, and serum creatinine level showed good correlation with the severity. Interstitial inflammation on reference biopsies correlated with the severity of tubular atrophy and interstitial scaring on repeat biopsies, suggesting a possible predictive role for damage.

PUB238

Seasonal Variations of Renal ANCA Associated Vasculitis Juliana Bordignon Draibe, Joan Torras, Xavier Fulladosa. *Nefrology, Hospital Univ de Bellvitge, Barcelona, Spain.*

Background: Filling the gaps in the genetic research of etiological factors related with ANCA associated vasculitis (AAV) is a major challenge in the current investigation. Descriptive and analytical epidemiological studies may improve our understanding of environmental influences on the disease. Seasonal variations in AAV have been previously described, mainly related to Wegener's disease, showing an increased number of cases during the winter months. It has been hypothesized tha infection could be the underlyig factor for these observations. Our goal is to study seasonal variations of AAV diagnosed in the city of Barcelona.

Methods: Our study included 209 AAV patients diagnosed between 2001 and 2013 in 5 different University Hospitals of Barcelona. We analyzed their medical records, including the date of diagnosis and the approximate date of the first symptoms in 194 patients. We have also analyzed data related to ANCA subtypes in each patient.

Results: Of the 209 patients, 160 (76.5%) were MPO-positive, 28 (13.3%) were PR3 positive and 21 (10%) were ANCA negative. Regarding the onset of symptoms, we have found a greater number of cases in the months of January, February and March, compared with the rest of the year.This data correlates positively with the higher incidence of flu symptoms in Barcelona between 2009 and 2013.

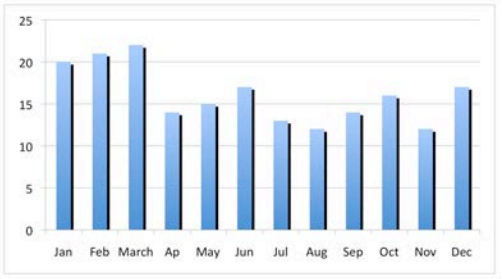

Figure 1

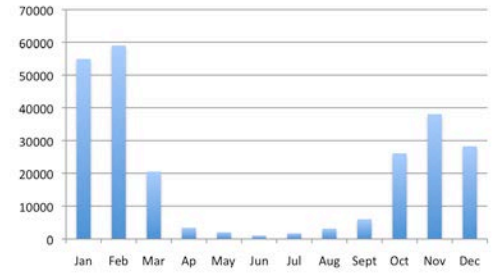

Figure 2

Considering the date of diagnosis we found a greater number of cases in two periods of the year; the months of May, June and July, and the months of October, November and December.

Conclusions: In our population, predominantly ANCA MPO-positive related vasculitis, we found a higher incidence of the disease in the winter months, being diagnosed more frequently in May, June and July or October, November and December. One potential environmental factor,influenza disease,may explain this finding.

PUB239

Mycophenolate Mofetil for the Treatment of Idiopathic Nephrotic Syndrome: A Meta-Analysis of Randomized Controlled Trials Bin Zhu, Yongjun Wang. *Nephrology, Hangzhou Hospital of Traditional Chinese Medicine (Guangxing Hospital) Affiliated to Zhejiang Chinese Medical Univ, Hangzhou, Zhejiang, China.*

Background: This meta-analysis was performed to investigate the efficacy and safety of mycophenolate mofetil (MMF) in treating idiopathic nephrotic syndrome.

Methods: We searched MEDLINE, EMBASE, the Cochrane Library database, the Database for Chinese Technical Periodicals, Wanfang, Chinese National Knowledge Infrastructure and the Chinese Database of Biology and Medicine for randomized controlled trials compared MMF with the other immunosuppressive agents for the treatment of idiopathic nephrotic syndrome. Weighted mean difference (WMD) and summary estimates of relative risk (RR) reductions with 95% CIs were calculated.

Results: We identified 36 trials that included 2007 patients, mainly on membranous nephropathy (MN), focal segmental glomerulosclerosis (FSGS) and refractory nephrotic syndrome without clearly pathological diagnosis (RNS). Overall, MMF therapy significantly reduced proteinuria (WMD:-462.31mg/d, CI: -219.69 to -704.92 $P<0.001$), increased the likelihood of complete remission (RR: 1.25, CI: 1.11 to 1.41, $P<0.001$), complete or partial remission (RR: 1.15, CI: 1.09 to 1.22, $P<0.001$) compared with the other immunosuppressors. The subgroup analyses shown that MMF was superior to cyclophosphamide in the RNS patients in reducing proteinuria, serum creatinine, relapse, and increasing the remission rate. In the MN patients, MMF therapy was better than cyclophosphamide in reducing proteinuria, increasing remission rate, whereas it was poorer than chloramubucil in lowering proteinuria. MMF therapy also significantly decreased proteinuria in FSGS compared with cyclophosphamide. MMF was safer than most of the other agents, particularly than cyclophosphamide.

Conclusions: MMF seems superior to the other immunosuppressive regimens for the treatment of idiopathic nephrotic syndrome with mild adverse effects, particularly in MN, FSGS and RNS. High-quality large-sample trials are still required to reliably define the balance of efficacy and safety.

PUB240

A Retrospective Analysis of Acute Kidney Injury in Adult-Onset Minimal Change Disease Yosuke Nakagawa, Takuya Isegawa, Masahiro Koizumi, Masafumi Fukagawa. *Div of Nephrology, Endocrinology and Metabolism, Tokai Univ School of Medicine, Isehara, Kanagawa, Japan.*

Background: Minimal change disease (MCD) is a major cause of primary nephrotic syndrome in adults, accounting for 10 to 25 percent of cases. In terms of treatment, steroid therapy is very effective, however in some cases an acute onset of moderate to severe decline in kidney function is seen, occasionally requiring transient dialysis. To the best of our knowledge, the risk factor for acute kidney injury (AKI) and clinical course of cases with AKI had not been fully elucidated.

Methods: This study isa single center, retrospective observational study. The clinical records of adult (older than 18 years old) who had biopsy-proven MCD and were followed at Tokai University Hospital from 2000 to 2015 were retrospectively reviewed. The diagnosis of AKI was based on KDIGO criteria, namely, serum creatinine changes ≥ 1.5 times baseline within 7 days and a 0.3 mg/dl increase in serum creatinine within 48 hours.

Results: 57 patients were enrolled, and AKI occurred in 24 patients at presentation or subsequently, among whom five patients underwent hemodialysis. Patients with AKI showed lower level of serum albumin and higher rates of use of diuretics, renin-aldosterone system (RAS) inhibitors, and NSAIDs. Logistic-regression analysis showed that use of these drugs before presentation at our institution could predict the development of AKI (odds ratio, 2.8; 95% CI, 2.2 to 3.2). Furthermore, use of these drugs could determine the time to remission (Hazard ratio, 2.4, 95% CI, 1.8 to 3.0), as well as the initial serum creatinine. All cases were initially treated with steroid, and there was no difference in the time to remission between oral and parenteral administration of steroid.

Conclusions: There is a high incidence of AKI in adult-onset MCD. The use of several drugs such as diuretics could influence the onset of AKI and clinical course of MCD.

PUB241

Expression of HLA-G Molecule in Crescentic Glomerulonephritis and Its Clinical Significance Guisen Li, Li Wang. *Nephrology, Sichuan Academy of Medical Sciences & Sichuan Provincial People's Hospital, Chengdu, Sichuan, China.*

Background: In recent years, human leukocyte antigen-G (HLA-G) was found to be an important immune-regulatory molecular. Our purpose of this study is to assay the concentrations of serum soluble HLA-G(sHLA-G)in patients with CGN and to analyze its clinical significance.

Methods: 48 patients with CGN from 2009 to 2014 were involved in this study. The clinical data were collected, include demographic characteristics, laboratory parameters, pathological examinations, prognostic information and immunosuppressive therapy. Analyze if oliguria or anuria, serum creatinine levels, the crescent formation ratio and therapy would affect the prognosis of patients.22 patients with CGN, 15 patients with MCD, and 30 healthy adults in control group were enrolled with serum levels of sHLA-G measured by ELISA. The relationship between the clinical or pathological features and sHLA-G was studied and the value of the HLA-G in crescentic glomerulonephritis was analyzed.

Results: 3-years kidney survival rate was only 38% with one case of death. Cox regression analysis showed higher serum creatinine was associated with the patients with a poor prognosis(HR=4.04,95%Cl:1.548-10.544, $P=0.004$).Serum level of sHLA-G in CGN was significantly higher than in healthy control(2198.81 ± 1924.17pg/ml *vs*.1311.86 ± 448.84pg/ml, $P=0.0408$), while higher than in MCD, (2198.81 ± 1924.17 pg/ml *vs.* 1181.33 ± 320.10 pg/ml, $P=0.023$).Kaplan Meier survival analysis showed elevated levels of HLA-G was associated with poorer patients.

Conclusions: High serum creatinine level(>5mg/dl) at admission is an independent risk factor for the development to be ESRD. sHLA-G was significantly elevated in the serum of patients with CGN, and the level of sHLA-G had relationship with the prognosis of the patients with CGN. sHLA-G may be used as a new biomarker in CGN with clinical value in the early diagnosis and prognosis.

PUB242

A Treatment of Nutcracker Syndrome Leads to a Resolution of Unexplained Proteinuria Badamkhand Baatarkhuu, Raymond Raut, Winston Y. Shih, Panupong Lisawat. *Nephrology and Hypertension, WCHN Danbury Hospital, Danbury, CT.*

Background: The nutcracker syndrome is rare and can be a cause of unexplained proteinuria. We report a case of nutcracker syndrome related proteinuria and resolution of the proteinuria is observed after the entrapment was surgically corrected.

Methods: This is a 22-year-old male with a history of unexplained proteinuria since he was 17 years old. He has moved to a new location and presented to our clinic with proteinuria. The patient's initial work up at an outside hospital revealed 1.4g proteinuria per 24 hours. A left kidney biopsy showed mesangial hypercelluarity and preserved foot processes. The patient at that time was treated with prednisone, cyclosporine and lisinopril. His proteinuria decreased to 196 mg per 24 hours. Due to intolerance, lisinopril was stopped and urine protein subsequently rose. At the time of evaluation, the patient's 24 hour urine protein was 700 mg and the autoimmune and infectious work up was negative. Upon reviewing the medical record from 2 years ago, he had inferior venacavagram as a part of varicocele treatment. It showed compression of the left renal vein between the aorta and superior mesenteric artery. Nutcracker syndrome was suspected. Subsequently, he was referred to vascular surgery, and underwent an open reconstructive surgery. Postoperatively the patient remained off lisinopril and repeated 24 hour urine protein was down to 102 mg.

Conclusions: Nutcracker syndrome can cause significant proteinuria. Although it is rare, an early recognition could lead to a definitive treatment, help avoid unnecessary medications and invasive procedure such as a kidney biopsy.

PUB243

Parvovirus B19 Immune Complex Glomerulonephritis Beth Lynne Braunhut, Erika R. Bracamonte. *Pathology, Univ of Arizona College of Medicine, Tucson, AZ.*

Background: A 14 year old girl underwent a cadaveric renal transplant due to end-stage renal disease from obstructive uropathy and developed parvovirus B19 viremia and graft dysfunction. Renal biopsy showed de novo immune complex glomerulonephritis with parvovirus B19 DNA detected in renal tissue by PCR. We herein review of B19-associated glomerular disease.

Methods: A search of the English-language medical literature was conducted. PubMed, Medline, and Google scholar were used. Adult and pediatric cases were included. Sources included case reports and series, including prior reviews. Articles were evaluated for demographic data, clinical findings, laboratory data, and renal biopsy results.

Results: 67 cases were identified. 51 involved native kidneys and 16 transplants. 66 of 67 cases had serologic evidence of B19 infection (98.5%). B19 DNA testing by PCR of various samples was positive in 82.9% of cases. Biopsy results were reported in 52 cases. Of native cases, 92.5% reported a proliferative glomerulonephritis. Allografts most commonly showed TMA (66.7%). IF showed C3 in 84.4%, IgM in 68.8%, IgG in 62.5% and IgA in 40.6%. IF was negative in all transplant cases, save for our patient who showed IgG, IgM, C1q and C4d. EM results were reported in 24 cases with subendothelial deposits being most common (91.7%).

Conclusions: The findings in B19-associated glomerular disease are different in the native kidney versus transplant setting. In a native kidney, proliferative immune complex glomerulonephritis is most common. In the transplant setting, most cases showed TMA. The pathogenesis of this discrepancy remains unclear. To our knowledge, this is the first report of B19 immune complex glomerulonephritis in a renal transplant patient. Our patient showed findings more commonly seen in native-kidney B19 disease. We believe this discrepancy may be explained by insufficient immunosuppression in our patient, as evidenced by concurrent AMR. B19 infection in a transplant patient has practical implications. B19 glomerular disease represents a largely reversible form of renal injury. But, adverse outcomes have been reported. Management may require a balancing act with the risk of rejection on one hand and B19 disease on the other.

PUB244

A Case of ANA-Negative Systemic Lupus Erythematosis Ankur Shah,[1] Rachel Criner,[1] Jean Lee.[2] *[1]Internal Medicine, Temple Univ Hospital, Philadelphia, PA; [2]Nephrology, Temple Univ Hospital, Philadelphia, PA.*

Background: Systemic Lupus Erythematosis is a chronic autoimmunse disorder hallmarked by several autoantibodies targeting intracellular antigens. The most sensitive of these antibodies is the anti-nuclear antibody. Various studies show that this antibody is present in 95-98% of individuals with the disorder. As methodology improves, the incidence of ANA-negative Lupus has been decreasing.

Methods: We report a case of a 53 year old female whose known past medical history included only hypertension who presented to the outpatient clinic with arthralgias, pancytopenia, alopecia, proteinuria and skin rash whose labwork to this point included an elevated ESR of 115, negative ANA, neg HIV, Hep B, and Hep C serology. She was then lost to followup until presenting to the hospital with anisarca and acute kidney injury. Her further workup confirmed a negative ANA but also revealed positive Anti-SSa, and anti-DsDNA as well as low titer Anti-Phospholipid. Her C3 and C4 were decreased at 43 and 66 respectively. She had a renal biopsy performed revealing focal proliferative and membranous lupus nephritis, Class III/V. The patient was started on mycophenolate, plaquenil, and prednisone.

Conclusions: Once a byproduct of a technically variable laboratory test, the entity of ANA negative Lupus has been decreasing in its frequency. The adoption of the human epithelial substrate has brought standardization to this assay and also increased its sensitivity. Nonetheless, the entity still exists, and has been described before. The majority of ANA-Negative Lupus cases will present with antibodies to cytoplasmic components – SSA or SSB, as did our case. ANA negative cases of SLE have been shown to have a decreased incidence of renal manifestations, with our case being an interesting exception. Our case serves as a reminder that the entity of systemic lupus erythematosis remains a clinical one, and that while the ACR criteria do include immunologic studies, the absence of the hallmark antibody does not rule out the disorder.

PUB245

Patients with Combined Membranous Nephropathy and Focal Segmental Glomerulosclerosis Have Comparable Clinical and Autoantibody Profiles with Primary Membranous Nephropathy Qiu-hua Gu, Zhao Cui, Jing Huang, Gang Liu, Minghui Zhao. *Renal Div, Peking Univ First Hospital, Inst of Nephrology, Peking Univ, Beijing, China.*

Background: Patients with combined membranous nephropathy (MN) and focal segmental glomerulosclerosis (FSGS) have been reported with different clinical significance. Investigation on the possible mechanisms of the combined glomerular lesions is necessary but scarce.

Methods: 20 patients with both MN and FSGS lesions were enrolled, 29 patients with primary MN and 27 patients with primary FSGS were used as disease controls. Clinical data were collected on renal biopsy and during follow-up. Circulating anti-phospholipase A2 receptor (PLA2R) antibody, glomerular PLA2R expression and IgG4 deposition, and soluble urokinase receptor (suPAR) levels were detected.

Results: We found that patients with combined lesions presented with elder age, less proteinuria, higher serum albumin, better renal function on biopsy, more complete remission after treatments and better renal outcome during follow-up. These were comparable to the patients with primary MN, but different from the patients with primary FSGS. Patients with combined lesions showed higher stages of MN, no cellular variant on FSGS classification and more common (100%) tubulointerstitial injury than both primary MN and primary FSGS patients. In the patients with combined lesions, 80% had circulating anti-PLA2R antibody and 68.4% had IgG4 predominant deposition in glomeruli, which were comparable to primary MN. No circulating antibody or IgG4 deposition was detected in primary FSGS patients. The patients with combined lesions had significantly lower urinary suPAR concentration, compared to the primary FSGS patients (315.6±302.0 vs. 691.3±1223.5pg/umol, P=0.014), but similar to the primary MN patients (275.7±253.4pg/mmol).

Conclusions: We conclude that patients with combined MN and FSGS may share the same underlying pathogenesis with primary MN. The FSGS lesion might be secondary to primary MN.

Funding: Government Support - Non-U.S.

PUB246

Glomerulosclerosis Is Prevalent but Not Associated with Kidney Function in Healthy Japanese Elderly Koji Sato, Tsukasa Naganuma, Daisuke Ichikawa, Sayuri Shirai, Yugo Shibagaki. *Div of Nephrology and Hypertension, St. Marianna Univ, Kawasaki, Kanagawa, Japan.*

Background: Previous western studies have shown that global glomerulosclerosis (GS) is common in healthy elderly but is not associated with kidney function. We here conducted a study to determine whether healthy Japanese elderly, whose glomerular filtration rate (GFR) are much lower than that of western counterparts, have also same relationship among kidney function and prevalence of GS.

Methods: We analyzed 81 kidney biopsy specimens from Japanese living donors obtained at donor nephrectomy between 2009 and 2014. Using the 2007 Banff classification system, GS, tubular atrophy (TA), interstitial fibrosis (IF), and arteriosclerosis (AS) on kidney samples were evaluated. Donor characteristics such as age, serum creatinine (sCr), Cr-based estimated GFR (eGFR), proteinuria, and the prevalence of hypertension, were also evaluated. Data were expressed as mean ± standard deviation or median and interquartile range (IQR). We performed univariate and multivariate analyses to identify the relationship between the parameters.

Results: Average age was 59.5 ± 9.1 years, male accounted for 38 (46.9%), with sCr 0.68 ± 0.15 mg/dl (eGFR 80.0 ± 12.9 ml/min/1.73m^2), proteinuria 125.5 ± 61.0 mg/gCr, and hypertensive 28 (34.6%). Each kidney sample had the average of 16 glomeruli (IQR, 12 to 23) and 1 GS (IQR, 0 to 2), so the proportion of GS among total glomeruli was 6.25% (IQR, 0 to 14.3). The prevalence of any GS was 65.4%, any TA, 51.9%, IF greater than 5%, 48.1%, and any AS, 91.4%. Statistical analyses revealed that donor age was the only independent factor related to GS, and also to TA, IF, and AS. Among kidney biopsies of our 53 normotensive donors, 5 (9.4%) had more GS than the 95th percentile of the number of GS in western studies.

Conclusions: Although Japanese healthy adults had lower GFR and a higher number of GS than western counterparts, GS was still not associated with kidney function. Pathological significance of GS in otherwise healthy Japanese is not supported as in western counterparts.

PUB247

241 Case of Monoclonal Gammopathy with Renal Biopsy Analysis Yuqing Chen, Beini Lv, Yan Wang, Yu Xiaojuan, Ming Hui Zhao. *Renal Devision, Dept of Medicine, Peking Univ Frist Hospital, Beijing, China.*

Background: Patients with monoclonal gammopathy can accompany various renal lesions related or unrelated to the monoclonal gammopathy. We aim to describe the renal lesions with monoclonal gammopathy in china.

Methods: Data of renal biopsy and clinical presentation of patients with monoclonal gammopathy on serum and/or urine immunofixation electrophoresis in our center from 1999 to 2014 were collected.

Results: 241 patients met the inclusion criteria and were classified as renal disease related to multiple myeloma (MM) (n=18, 7.5%), monoclonal gammopathy of renal significance (MGRS) (n=85, 34.9%) and monoclonal gammopathy of undetermined significance (MGUS) (n=138, 57.4%). Among patients with MGRS, Amyloidosis (n=69, 28.6%) is the most common diagnosis, followed by Light Chain Deposition Disease (LCDD) (n=7, 2.9%), Cryoglobulinemic glomerulonephritis (n=6, 2.5%), and 56 cases (40.6%) received clone-responsible treatment. Among patients with MGUS, a variety of renal lesions were found, including membranous nephropathy (n=48, 20.2 %), IgA nephropathy (IgAN) (n=17, 7.05%), interstitial nephritis (n=13, 5.4%), membranous proliferative glomerulonephritis (MPGN) (n=9, 3.3%) and so on.

Conclusions: We analyzed the data of monoclonal gammopathy with renal biopsy in china for the first time. A growing number of renal diseases were found to be associated with monoclonal gammopathy. MGUS is the most common diagnosis of patients with monoclonal gammopathy, while membranous nephropathy and IgAN are most common among MGUS. Further work are in need to determine whether some MGUS are truly underdetermined or with renal significance and whether or not early treatment is in need for these patients.

PUB248

Urine Microscopy in a Case of Acute Kidney Injury: A Report of an Interesting Case Azka Arif,[1] Ahmad Hassan,[2] Muhammad Awais Arif,[2] Hafiz Armaghan Saeed,[2] Agha Syed Shabbir Ali,[2] Abdul Mateen Nagaria,[1] Talal A. Khan.[1] *[1]Freeman Health System; [2]Rawalpindi Medical College.*

Background: RBCs casts are usually present in the urine of patients presenting with AKI secondary to RPPGN. They are sometimes seen in patients with AIN. A single RBC cast seen in urine is enough to consider glomerulonephritis as underlying pathology. We report a case of biopsy proven Myoglobinuric AKI with urine RBC casts.

Methods: 68-year-old male presented with AMS and was found to have AKI with BUN of 106 mg/dL. & creatinine of 28.6 mg/dL. , He had severe hyperkalemia.His urine analysis showed 20-30 RBCs and 3+ Blood. His urine microscopy was done which revealed RBC casts, pigmented casts and renal tubular epithelial cells as reviewed by nephrologist on call, based on such acute presentation and positive RBC cast, glomerulonephritis was considered as possible etiology in addition to acute tubular necrosis and rhamdomyolysis. He underwent emergent hemodialysis for severe hyperkalemia and uremia, he was started on pulse steroids and underwent CT guided kidney biopsy.It showed extensive myoglobinuric ATN, with no evidence of any glomerulonephritis. His ANCA serology, complements levels, Anti GBM antibodies & ANA were negative. He required hemodialysis for few days and then recovered with residual CKD.

Conclusions: RBC casts are important component of rapid and early diagnosis of RPGN.RBCs in a cast are almost always pathological and marker of acute glomerular injury. Our case represents an unusual finding of RBC casts in myoglobinuric ATN.We purpose extensive renal glomerular injury secondary to severe rhabdomyolysis as possible etiological factor.Renal tubular epithelial cells are marker for acute tubular necrosis and pigmented casts are usually found in rhabdomyolysis which were seen in urine microscopy in our case. Urine microscopy though less commonly used provides a vital & faster way of diagnosing etiology of AKI and it should be considered in our evaluation of acute kidney injury.

PUB249

Acute Renal Failure in Thrombotic Microangiopathy and C3 Glomerulopathy? Tiziana Stellato,[1] Paolo Fabbrini,[1] Sonia Sirtori,[2] Andrea Stella.[1,2] *[1]Dept of Nephrology, San Gerardo Hospital, Monza, Italy; [2]Univ of Milano Bicicca, Milan, Italy.*

Background: Thrombotic microangiopathy is a rare disease characterized by arteriolar and capillary thrombosis with endothelial damage. Clinical manifestations include renal involvement such as acute renal failure associated with haematuria and proteinuria .

Methods: We report a case of a 75 years old man without past medical history that referred to us with oliguric acute renal failure dialysis-dipendent. Laboratory work up revealed creatinine of 7.5 mg/dl, prolonged activated *partial thromboplastin time* (aPTT) in order to 2.2 Ratio, normal *Prothrombin* time (PT), reduced C3 (65 mg/dl) with normal C4, VES augmented, positive low title anti-cardiolipine and anti-beta2 glicoprotein1 antibodies, positive LAC screening. Urinalysis showed microhaematuria and proteinuria 2.5 g/24 h, ANA, ANCA, antiDNA are negative. A renal biopsy was performed and showed mesangial proliferative glomerulonephritis associated to thrombotic microangiopathy with sub-endothelial and mesangial C3 deposits. Considering the clinical history, the laboristic tests and the biopsy result, suggestive of antiphospholipid syndrome (APS), we start treatment with plasma-exchange (total 4 sessions) with plasma sostitution and corticosteroids (500 mg IV methylprednisolone for 3 days, followed by 0.5 mg/Kg/die oral prednisone). So we obtained rapidly recovery of diuresis that resulted in a progressive recovery of renal function till serum creatinine 1.4 mg/dl. The post-bioptic course was complicated by macrohaematuria and a formation of a pseudoaneurysm immediatly treated with selective embolization. Because of this complication we waited start oral anticoagulant till 7 days after missing macrohaematuria.

Conclusions: Acute renal failure is a reversible kidney damage that can revert with a specific diagnosis and treatment. Kidney biopsy was always gold standard and a combination treatment with multiple sessions of plasma exchange and oral and corticosteroids, even in presence of contrasting data in literature, may be useful in case of thrombotic micro-angiopathy.

PUB250

Differences Between Clinical Parameters at Diagnosis and After Treatment in Membranous Nephropathy Sanjana Gupta,[1] Horia Stanescu,[1] Kieran Mccafferty,[2] Alan D. Salama,[1] Stephen H. Powis,[1] John Connolly,[1] Neil Ashman,[2] Muhammad M. Yaqoob,[2] Robert Kleta,[1] Stephen B. Walsh.[1] *[1]UCL Centre for Nephrology; [2]Royal London Hospital.*

Background: Membranous Nephropathy is the leading cause of nephrotic syndrome in adults. Idiopathic (IMN) and secondary (SMN) forms exist. Clinical parameters such as serum creatinine (sCr), serum albumin (sAlb) and urine protein creatinine ratio (PCR) are important to make a diagnosis, and are used as surrogate markers for evidence of remission from disease.

Methods: We performed a retrospective analysis of all patients with biopsy proven IMN at the Royal London and Royal Free Hospitals that were under follow between 1995 - 2015. Clinical data was collected using renal databases.

Results: We identified 240 patients with biopsy proven MN. 171 patients still had native renal function. 69 reached end stage renal failure (ESRF). 188 had IMN, 52 had SMN. There was no significant difference in age between IMN and SMN (56.8 ± 1.5 vs. 52.6 ± 1.9 years respectively). At the time of diagnosis, there was no difference between IMN and SMN in PCR (924 ± 73 vs 863 ± 154, ns) or sCr (116 ± 12 vs 101 ± 10 µmol/L, ns). At presentation the sAlb was significantly lower in IMN (24.9 ± 0.8 vs 28 ± 1.2 mmol/L, p=0.02). In IMN, treatment significantly improved the PCR (924 ± 73 to 337 ± 57, p<0.0001) and sAlb (24.9 ± 0.8 to 39.7 ± 0.6 mmol/L, p<0.0001), but sCr significantly worsened (116 ± 12 to 123 ± 7.2 µmol/L, p=0.017). In SMN, treatment again significantly improved the PCR (863 ± 154 to 221 ± 36, p=0.001) and sAlb (28 ± 1.2 to 39 ± 0.8 mmol/L, p<0.0001), but sCr significantly worsened over the treatment period (101 ± 10 to 126 ± 12 µmol/L, p=0.0045). Of the MN patients who reached ESRF, the sCr was significantly worse on presentation (235 ± 42 vs 111 ± 8 µmol/L, p<0.0001). These patients had significantly higher sAlb (30.8 ± 1.4 vs 26 ± 0.6 mmol/L, p=0.001) and accordingly PCR tended to be lower at presentation, but this difference failed to reach significance (628 ± 79 vs 901 ± 78, p=0.06).

Conclusions: In our cohort of patients with membranous nephropathy, sAlb is lower in IMN compared to SMN. Treatment improves proteinuria and albumin but does not prevent a decline in serum creatinine.

PUB251

An Unusual Case of Seronegative Lupus Nephritis with ANCA-Positive Serology Amibahen Gandhi, Varun Malhotra, Shani C. Kotadia, Medha Joshi. *Conemaugh Memorial Medical Center, Johnstown, PA.*

Background: Seronegative lupus nephritis is a condition with renal histology typical for lupus nephritis without clinical and serologic evidence of systemic lupus nephritis (SLE).

Methods: Here, we report an unusual presentation of seronegative SLE diagnosed with kidney biopsy who does not meet any other diagnostic criteria for SLE established by American Rheumatism Association. Our patient was 60- year-old woman with past medical history of only hypothyroidism, presented with new onset of acute kidney injury and hypertension. Laboratory data showed BUN and creatinine of 74mg/dl and 10.3mg/dl respectively, hypocomplementemia and nephrotic range proteinuria and hematuria. Serology tests including serum ANA, anti ds DNA, anti-smith and smooth muscle antibodies, anticardiolipin IgG and IgM titers, C1Q binding assay were negative. HIV, hepatitis B and C viruses serologies were negative too. C-ANCA (0.7 U) and P-ANCA (1.5U) were positive. Renal biopsy showed proliferative crescentic and membranous glomerulonephritis with a full house immuno-fluorescence pattern with extra-glomerular tubular basement deposits suggestive of Lupus like glomerulonephritis. Patient required hemodialysis for her renal failure and was treated with oral cyclophophamide and corticosteroids. Seven months into treatment, patient still requires twice a week hemodialysis with only minimal recovery of renal function and has not yet experienced any clinical symptoms of SLE.

Conclusions: In conclusion, we present an unusual case of ANCA positive, ANA negative full house nephropathy. ANA negative lupus nephritis is very rare presentation with incidence rate of 1-5%. At this point we are not sure if in the future patient will develop further clinical or serological evidence of SLE and then be diagnosed as "SLE with positive immunological response to ANCA". ANCA vasculitis is pauci-immune and hence it would be extremely unlikely and rare if it turns out that she has ANCA vasculitis with full house on renal immuno-florescence. The treatment and prognosis of renal-limited lupus-like glomerulonephritis remains unclear, although limited data suggest a poor prognosis.

PUB252

Pathological and Clinical Analysis of the Kidney Puncturation Biopsy in 1,551 Cases Mei Li,[1] Qiong-li Yin,[1] Zhenda Zheng,[2] Cai-Lian Cheng,[3] Xun Liu,[3] Cheng-gang Shi.[3] *[1]VIP Healthcare Center, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou; [2]Cardiovascular Dept, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou; [3]Nephrology Dept, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, China.*

Background: To summarize all the renal biopsy cases in the Past ten years in the Third Affiliated Hospital of Sun Yat-sen University;analyze the pathological type distribution,and their relationship with clinical manifestations.

Methods: Pathological and clinical data in 1, 551 cases with renal biopsy with complete clinical data were analyzed retrospectively from January 2005 to December 2014.

Results: Among 1, 551 cases, age 6-83 (34.81±14.28 years). including primary glomerular disease (63.8%) , secondary glomerular diseases(33.5%). The first third pathological types of primary glomerulonephritis are IgA nephropathy(38.6%), glomerular minor lesion(25.9%) and membranous nephropathy(MN) (19.3%). The first third pathological types of secondary glomerulonephritis are lupus nephritis(LN)(65.2%), diabetic nephropathy(DN)(8.5%) and hepatitis B virus associated glomerulonephritis(HBV-GN)(7.3%). Acute and chronic rejection are the most common pathological type of renal transplantation in 26 cases. Chronic nephritis syndrome and nephrotic syndrome are the most common clinical manifestations. For male versus female, the ratio is 1.32:1 in the primary glomerulonephrtis,while 0.73:1 in the secondary glomerulonephrtis.

Conclusions: Primary glomerulonephritis is still the most common form of renal disease,and almost in male. IgA nephropathy is the most common pathological type of primary glomerulonephritis followed by glomerular minor lesion.While for the secondary glomerulonephritis,female is more than male,and LN is the most common pathological type followed by DN. And Chronic nephritis syndrome is the most common clinical manifestations of renal biopsy.

PUB253

Iodine-123 MIBG Imaging of Renal Cell Carcinoma with Pathological Correlation Ken Hiratsuka,[1] Isao Kurihara,[1] Sayuri Suzuki,[1] Shintaro Yamaguchi,[1] Toshiaki Monkawa,[1] Koichi Suzuki,[2] Hiroshi Itoh.[1] *[1]Dept of Internal Medicine, Keio Univ School of Medicine, Japan; [2]Dept of Mycobacteriology, Leprosy Research Center, National Inst of Infectious Diseases, Japan.*

Background: The incidence of renal cell carcinoma has continuously increased during the last fifty years. Despite the increase in number, the five year survival rate has been reduced by the advances in renal imaging. Chromophobe renal cell carcinoma (ChRCC) is an uncommon variant of RCC, accounting for approximately 5% of renal cancer. Although its prognosis is usually favorable, preoperative diagnosis is difficult because there is no marker for this variant. Here, we reported a novel method to distinguish ChRCC from othter RCC(especially, clear cell carcinoma).

Methods: We experienced a case of ChRCC with adrenal pheochromocytoma in a 69-year-old Japanese female. We noticed that iodine-123 MIBG scintigraphy showed uptake in ChRCC in addition to pheochromocytoma; uptake was not observed in othter cases of clear cell carcinoma. As a candidate transporter that mediate iodine-123 uptake in ChRCC, we determined the expression of pendrin, a Cl^-/HCO^{3-} exchanger expressed in the kidney cortex. The pendrin messenger RNA (mRNA) expressions, and protein expressions were analyzed in 4 cases of ChRCC and 3 cases of clear cell carcinoma.

Results: The protein expression of pendrin, the candidate transporter, which related to iodine-123 uptake, was highly detected in ChRCC compared with clear cell carcinoma. Moreover, the mRNA expression was also exclusively increased in ChRCC.

Conclusions: We identified specific transporter, pendrin, which is highly expressed in ChRCC. Our results indicates that iodine-123 MIBG scintigraphy may be a useful tool for the diagnosisof ChRCC and represents a substantial advance in the diagnosis of ChRCC.

PUB254

Clinical Significance of Glomerular IgG Deposits in IgA Nephropathy Anthony Alvarado,[1] Nicole K. Andeen,[2] Sergey V. Brodsky,[3] Alice Hinton,[4] Tibor Nadasdy,[3] Charles E. Alpers,[2] Christopher D. Blosser,[5] Behzad Najafian,[2] Brad H. Rovin.[1] *[1]Faculty of Medicine, Nephrology Div, The Ohio State Univ, Columbus, OH; [2]Pathology Dept, Univ of Washington, Seattle, WA; [3]Pathology Dept, The Ohio State Univ, Columbus, OH; [4]Div of Biostatistics, College of Public Health, The Ohio State Univ, Columbus, OH; [5]Faculty of Medicine, Nephrology Div, Univ of Washington, Seattle, WA.*

Background: IgAN is characterized by IgA dominant or IgA-IgG co-dominant mesangial immune deposits. It is not clear whether the presence of IgG in IgAN affects disease prognosis. We evaluated the significance of IgG co-deposits in IgAN.

Methods: Consecutive IgAN biopsies (n=80) from Ohio State University and University of Washington (2001-2013) were retrospectively classified into IgA only and IgA+IgG (IgG > trace). The presence or absence of IgG was correlated to the combined primary outcome of renal replacement therapy, death, OR doubling of serum creatinine (SCr). The change in estimated GFR (eGFR) was also assessed. Covariates were age, sex, race, SCr and proteinuria at biopsy, length of follow-up, treatment, Oxford score, and presence of crescents.

Results: This cohort was 64% male, 69% Caucasian and 14% Asian. IgA+IgG deposits were seen in 25 of the patients. There was no difference between IgA and IgA+IgG with respect to any of the covariates or between initial and follow-up proteinuria. There was a tendency for more endocapillary hypercellularity to be seen in IgA+IgG biopsies (p=0.08). The primary outcome was reached in 24 patients, 16 with IgA and 8 with IgA+IgG (p=0.82). Using multivariate modeling the change in eGFR over time was not different between IgA and IgA+IgG.

Conclusions: In this cohort of IgAN patients the presence of IgG co-deposits in the mesangium did not affect clinical outcomes.

PUB255

Idiopathic Cryoglobulinemic Crescenteric Glomerulonephritis – A Rare and Atypical Case Pedram Joseph Kohan,[1] Akshatha Rao,[2] Sandeep Aggarwal.[2] *[1]Internal Medicine, Drexel College of Medicine/Hahnemann Univ Hospital, Philadelphia, PA; [2]Nephrology, Drexel College of Medicine/Hahnemann Univ Hospital, Philadelphia, PA.*

Background: Cryoglobulinemic Glomerulonephritis is an rare entity, manifesting in middle-aged females, We report an atypical case of cryoglobulinemic cresenteric glomerulonephritis in an 18-year-old African American Male without an identifiable viral, autoimmune or lymphoproliferative etiology.

Methods: Our case is an 18 y/o AAM with no significant PMH who presented for an incidental hematuria and proteinuria. Patient did not complain of edema, recent illness, joint pains, rash, night sweats or weight loss. No history of IVDA. BP was 114/72, without significant physical exam findings. **Urine microscopy**: cellular casts and dysmorphic RBCs. Serum creatinine was 1.27 mg/dL.

Renal Biopsy

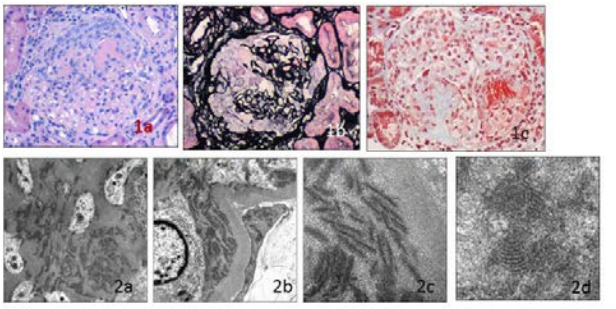

Figure 1. (1a). H&E Crescenteric GN (1b) Jones Silver: MPGN with Crescents. Trichrome staining (1c) reveals eosinophilic intra-glomerular deposits with collagen deposition and obliteration of Bowman's space. Substantial mesangial (2a; 30000x) and subendothelial (2b; 30000x) electron dense deposits of randomly arranged, slightly curved microtubular/ fibrillary structures of approximately 20-25nm in diameter (2c; 120000x), and fingerprinting (2c: 30000x)

LM: crescents and endocapillary proliferation. EM showed subendothelial, subepithelial and paramesangium 20.5-25nm microtubular fibrils. **IF:** only C1q 2-3+ granular GBM and mesangial deposits. **Labs**: UPCR: 2.1 grams/day, ESR and CRP levels were markedly elevated. Viral hepatitis/HIV PCR, ANA, anti-DsDNA, anti-RNP,anti-smith, SSA/SSB, anti SM and Rh factor/CCP, C3, C4, ASO, cryocrit, SPEP/UPEP/free light chains/ Immunofixation , peripheral flow cytometrywere negative. Patient was treated with IV methylprednisolone pulse and rituximab with improvement of renal function and proteinuria.

Conclusions: The uniqueness of this case is underscored by a variety of factors; clinical presentation, laboratory, serologies, and pathology. Laboratory and serological studies in cryoglobulinemia generally follow a characteristic pattern, detection of circulating cryoglobulins, low levels of complement, viral, autoimmune or lymphoproliferative etiology- yet a limited number of cases have presented with normal serological results, similar to the case presented here.

PUB256

Development of a Clinicopathologic Kidney Biopsy Database Using Billing and Diagnosis Codes: A Descriptive Study Nosayaba Enofe,[1] Anju A. Oommen,[1] Jason Cobb,[1] Jose E. Navarrete,[1] Demilade Adedinsewo,[2] Oluwatobiloba A. Osikoya,[3] Helene B. Fevrier,[4] Frederic F. Rahbari-Oskoui,[1] Alton Brad Farris,[5] Laura Plantinga,[1] Titilayo O. Ilori.[1] *[1]Dept of Nephrology, Emory Univ School of Medicine, Atlanta, GA; [2]Morehouse School of Medicine, Atlanta, GA; [3]Lee Univ, Cleveland, TN; [4]Dept of Epidemiology, Rollins School of Public Health, Emory Univ, Atlanta, GA; [5]Dept of Pathology and Laboratory Medicine, Emory Univ School of Medicine, Atlanta, GA.*

Background: A growing kidney disease population coupled with expanded use of electronic medical records (eMR) presents a unique opportunity for regional translational clinical research. We developed a comprehensive registry of all native renal biopsies at a major hospital in Southeastern US and described the pattern of glomerular diseases.

Methods: We identified all native percutaneous renal biopsies (n=2,245) performed on adults (>18) between 2000 and 2011 using CPT and ICD-9 billing codes (50200 and 55.23).Transplant biopsies (V42.0) and cytopathology were excluded. Renal pathology reports were reviewed by at least two independent clinical nephrologists. Clinical, laboratory and demographic data were extracted and validated by independent chart review. A clinicopathologic diagnosis was subsequently entered. Descriptive and bivariate statistics were used to analyze patient characteristics at biopsy.

Results: Patients in the registry had a mean age of 44.2 years; approximately half were male and majority were African American (40.7%). Overall, lupus nephritis (n=278, 12.4%) was the most prevalent renal clinicopathologic diagnosis. Among primary glomerular diseases, FSGS (136, 9.2%) was the most prevalent, followed by IgA nephropathy (123, 8.3%), membranous glomerulonephritis (GN) (69, 4.6%), membranoproliferative GN (24, 1.6%) and minimal change disease (27, 1.8%). Diabetic nephropathy was the second most common secondary GN (97, 6.5%) followed by ANCA-associated vasculitis (31, 2.1%). Other diagnoses were all less than 2%.

Conclusions: We successfully established a kidney biopsy registry at our center, which will be instrumental to studying outcomes in this rare group of diseases**,** the most prevalent of which were lupus nephritis and FSGS.

PUB257

Is There Clinical Significance of IgM and Complement Staining in Idiopathic Focal Segmental Glomerulosclerosis Vasantha M. Muthuppalaniappan,[1] Kieran Mccafferty,[1] Michael Sheaff,[2] Muhammad M. Yaqoob.[1] *[1]Nephrology, Barts & The London NHS Trust, London, United Kingdom; [2]Pathology, Barts & The London NHS Trust, London, United Kingdom.*

Background: Experimental evidence suggest that focal segmental glomerulosclerosis with complement deposits is associated with poor outcome. Whether this is transferable or relevant in human disease is unclear.

Methods: We performed a proof-of-concept observational study on all patients with a diagnosis of idiopathic focal segmental glomerulosclerosis (iFSGS) on native renal biopsies from January 2004 to December 2014. A total of 40 renal biopsies were identified. Clinical outcome data were obtained to seek an association with complement deposits (CD) and outcomes. Immunosuppression administered was according to the local trust policy which included prednisolone and cyclophophamide or calcineurin inhibitor.

Results: See Table 1

	No CD (n= 21)	CD (n= 19)	P
Age	43 (35-50)	39 (30.5-54.5)	0.6
Sex Male	11 (52)	7 (27)	0.35
Race Black/Asian/White	6 / 9 / 6	8 / 5 / 6	0.39
Type of lesion : Tip/Collapsing/NOS	2 / 2 / 17	3 / 0 / 16	0.34
IgM	0 (0)	18 (95)	<0.0001
Immunosuppression	12 (57)	12 (63)	0.75
Baseline urine protein creatinine ratio (UPCR)	540 (330-1000)	1000 (560-1200)	0.07
Baseline albumin	29 (24-38)	26 (21-36)	0.47
Baseline eGFR	49 (25-71)	60 (48-81)	0.26
Change in UPCR	- 370 [-700 - (-140)]	- 430 [-790- (-260)]	0.7
Change in serum albumin	8.5 (2.3-13)	4 (0-17)	0.55
Change in eGFR	4.5 (-5.5 - 21)	4 (-15-11)	0.44

CD was present in approximately 50% of the biopsies, but there was no significant association between CD and baseline clinical or demographic characteristics, furthermore, there are no association between CD and markers of disease progression (change in proteinuria, serum albumin or GFR between baseline and 1 year follow up). IgM staining was strongly co-associated with CD.

Conclusions: Our results indicate that, unlike animal models of iFSGS; IgM and complement deposition does not alter outcomes. However, these findings will need to be confirmed in a larger study.

PUB258

A Case of Intra-Ocular Lucentis (Ranibizumab) Induced Minimal Change Disease Ashwin Reddy Ganta. *Dept of Nephrology, Archbold Memorial Hospital, Thomasville, GA.*

Background: Intrvitreal Monoclonal antibodies like Lucentis (Ranizibumab) , Eylea and Avastin are being increasingly used for the treatment of Wet Age related Macular Degeneration (wAMD) and Diabetic Macular Edema (DME) of the eye. Though the systemic toxicity of these VEGF inhibitors is well known, not much is known about the renal toxicity profile of these agents when administered intravitreally.

Methods: A 78 y/o WM presented with worsening shortness of breath and anasarca. His PMH was significant for Afib, h/o Lung Cancer s/p RLL resection 8 years ago and he was receiving Lucentis intravitreal shots for his AMD and had just had his 5th monthly dose a few days ago. His urine showed 3 + protein with some RBCs and we were consulted for worsening renal function with a Scr of 2.4 mg/dl , up from a baseline of 1.0 mg/dl. Given his h/o cancer with almost 3 gms of proteinuria, MCD (Minimal Change Disease) was high in the differential. Serology for HIV, SPEP, Hep C, SIEP, ANA and ANCA was negative . His Scr continued to worsen and reached a peak of 4.6 and he had to undergo Dialysis for volume overload . Renal Biopsy performed showed 9 glomeruli with no evidence of IC mediated injury and MCD pattern confirmed on EM. He was started on high dose steroids and discharged with a diagnosis of MCD 2/2 Lucentis. He was taken off HD after he started showing signs of renal recovery in a few weeks and he was gradually tapered of Steroids over the next 4 months. His proteinuria has completely subsided and his Scr is back to his baseline .

Conclusions: Systemic use VEGF inhibitors and their renal toxicity is well documented. Now , they are currently being to treat wAMD and DME. However, there is some evidence that intravitreal use may result in systemic absorption, with the potential for AKI. We report the first case to our knowledge of a patient who developed severe AKI needing HD with MCD pattern of injury after 5 intravitreal injections of ranibizumab that was successfully treated with cessation of Lucentis and Steroids. Because of the increasing use of these agents, ophthalmologists and nephrologists should be aware of the associated risks.

PUB259

Eculizumab in a Patient with Lupus Nephritis and Thrombotic Microangiopathy: Outcome After One Year Maria Izabel Neves de Holanda Barbosa,[1] Lilian M. Pereira,[2] Alicia Imada,[1] Luiz Fernando Christiani.[1] *[1]Nephrology and Kidney Transplant, Hospital Federal de Bonsucesso, Rio de Janeiro, Brazil; [2]Pediatrics Nephrology, Univ Estadual de Campinas, Campinas, São Paulo, Brazil.*

Background: Lupus Nephritis is a severe disease and when is associated with Thrombotic microangipathy the prognosis is worst.

Methods: This is a cse report of a female patient, 18 years old, with no past history of disease, started fever, abdominal pain and dysuria treated initially as UTI. She evolved with skin rash and a few days later, oligoanuria, nausea and vomiting. She was admitted and started hemodialysis on the same day. Initial exams showed thrombocytopenia, anemia, High LDH, schistocytes on blood smear, direct Coombs test negative, urinalysis with hematuria and proteinuria. ANA and anti DNAds were positive, ADAMST13 96%, C3 and C4low. SLE was diagnosed and she received standard therapy with metilprednisolone and cyclophosphamide.She needed RBC transfusions at least twice a week. After 55 days of treatment, she still presented over hemolysis and anuria in hemodyalisis.

Results: We decided to start eculizumab and after one week, platelet count increased allowing for a renal biopsy that showed lupus nephritis class IV with thrombotic microangiopathy. After the third dose of eculizumab, there was improvement of anemia and she started to present diuresis. She was discharged from hospital one week later with creatinine of 2.3 mg/dL and off dialysis. After one year, she is on maintenance eculizumab every two weeks with low dose prednisone and mycophenolate mofetil 1per day.Creatinine is 1.7 mg/dL, hemoglobin 11 g/dL, normal platelet count and LDH.

Conclusions: This is a successful case of eculizumab in a patient with Lupus nephritis and thrombotic microangiopathy refractory to classical treatment. A putative explanation is that autoantibodies may have primed the endothelium, unmasking a complement defect that was successfully controlled by terminal complement blockade. A genetic analysis may reveal a mutation in regulator factors of the alternative complement pathway or auto-antibodies against Factor H or I. Eculizumab may be an option for the treatment of refractory lupus nephritis with thrombotic microangiopathy.

PUB260

Diagnostic Items for Renal and Hepatic Cyst Infection – A Delphi Survey Marten A. Lantinga,[1] Alexander J.M. Darding,[1] Rudolphe De Sevaux,[1] Ron T. Gansevoort,[2] Marie C. Torres,[3] Joost P.H. Drenth.[1] *[1]Radboudumc; [2]UMCG; [3]Mayo Clinic; [4]McGill; [5]Legacy Health; [6]AMU; [7]Emory Med; [8]CHRU; [9]CU Med; [10]Dr Preset Hosp; [11]UCL Saint-Luc; [12]UAB; [13]UZ Leuven; [14]Univ São Paulo; [15]SNUH; [16]U of T; [17]San Luigi Gonzaga Hosp; [18]WMI; [19]LUMC; [20]IIB Sant Pau; [21]Hopkins Med; [22]ULg CHU; [23]Toranomon Hosp.*

Background: Diagnosis of renal and hepatic cyst infection is made on the presence of a positive cyst aspirate culture. If that is absent, diagnosis is made on a mix of clinical, biochemical, and imaging findings. The weight of these diagnostic items is uncertain, hence our aim to establish a set of items for cyst infection diagnosis.

Methods: We used a Delphi survey among acknowledged experts to achieve consensus on diagnostic items. We retrieved items from literature and physician/patient interviews. Items were rated on a nine-point scale in a three-round online survey. We categorized items by median rating (£3.4=inappropriate; 3.5-6.4=uncertain; ≥6.5=appropriate).

Results: Of 58 invited experts, 35 (60%) responded to round one (round two: 91% n=32; round three: 86% n=30). The final panel included 23 nephrologists, five hepatologists, a nuclear medicine specialist, and an infectiologist from 11 countries (male 67%, age 47±11yrs, median clinical experience 21yrs). We identified 59 items and rated each for renal and hepatic cyst infection. Majority was derived from literature (n=46). Ultimately, 26 renal and 22 hepatic items were rated as appropriate. Remaining items were rated inappropriate (renal n=18; hepatic n=12) or uncertain (renal n=15; hepatic n=25).

Conclusions: We identified diagnostic items for renal and hepatic cyst infection and on this basis we developed a diagnostic algorithm.

PUB261

The Use of Multiplex Ligation-Dependent Probe Amplification Technology for Genetic Analysis of the Entire PKD1 Gene and PKD2 Gene Tetsuhiko Yasuno. *Fukuoka Univ, Fukuoka, Japan.*

Background: In common cases of autosomal dominant polycystic kidney disease (ADPKD), diagnosis is relatively simple using a combination of diagnostic imaging of the kidney and analysis of ADPKD in the patient's family history. Therefore, in most patients with ADPKD, genetic testing for ADPKD is not necessary for diagnosis. However, in ADPKD cases where a definitive diagnosis is not obtained by imaging or living relative related donor is identified for kidney transplantation, genetic testing may be necessary.

Methods: Multiplex ligation-dependent probe amplification (MLPA) kits have been developed for genetic analysis by MRC-Holland using proprietary MLPA technology. We obtained informed consent from nine patients (mean age, 45 years) and collected 8 mL of blood from each patient for analysis of genetic mutations in PKD1 and PKD2 genes using the MLPA method.

Results: In case 1 (a 39-year-old man), we found deletions in exons 3 and 39 of the PKD1 gene. The kidney was extracted due to enlargement and cyst infection. Dialysis was initiated when the patient was 39 years of age. The kidney capacity was 5013 mL. In case 2 (a 32-year-old woman), we found a deletion in exon 3 of the PKD1 gene. Renal function was maintained, and the serum creatinine level was 0.7 mg/dL.She has hope of the delivery. Tolvaptan does not have the safety about the dosage to a pregnant woman. Tolvaptan was administered after delivery.

No mutations were identified in the other subjects.

Conclusions: Genetic screening of the PKD1 and PKD2 genes using the MLPA method may decrease cost and labor. Indeed, the MLPA method was especially useful in cases exhibiting juvenile onset and rapid kidney enlargement.

PUB262

Short-Term Effects of Tolvaptan to a Body Water Balance in Patients with ADPKD

Minoru Makita, Saori Nishio, Junya Yamamoto, Tasuku Nakagaki, Tatsuya Atsumi. *Internal Medicine 2, Hokkaido Univ, Sapporo City, Hokkaido, Japan.*

Background: In the clinical trials of Tolyaptan, reversible serum creatinine elevation and adverse events related to increased aquaresis were reported in some patients with autosomal dominant polycystic kidney disease (ADPKD). To clarify the mechanism of those adverse events, we preliminarily evaluated a volume statusbefore and after administration of tolvaptan in ADPKD patients by analysing body composition with multiple-frequency bioelectrical impedance analyser (InBody720®) and associating with renal function.

Methods: Nineteen ADPKD patients who started administration of tolvaptan were examined. Body weight and renal function were measured before (baseline) and 2 days (day2) after initial tolvaptan administration. Height-corrected total kidney volume (htTKV) were measured at baseline. Total body water (TBW), intracellular water (ICW) and extracellular water (ECW) [whole body, limbs and trunk, respectively], were measured using InBody720® at baseline and day2.

Results: The administration of tolvaptan significantly reduced body weight, eGFR, TBW, ICW and ECW in whole body and TBW in limbs. However, TBW in trunk were sustained (Table).

	baseline	day2	p-value
Body weight(kg)	64.0±12.5	62.1±11.8	<0.001
eGFR(ml/min/1.73m^2)	53.9±27.2	51.4±24.8	0.013
TBW whole(kg)	38.2±8.1	36.0±7.4	<0.001
ECW whole(kg)	14.8±2.9	13.9±2.7	<0.001
ICW whole(kg)	23.3±5.2	22.2±4.8	<0.001
TBW trunk(kg)	16.8±3.7	16.5±3.5	0.75
ICW trunk(kg)	10.3±2.4	10.2±2.2	0.58
TBW limbs(kg)	16.9±4.3	15.7±4.1	<0.001

HtTKV at baseline correlated with rate of ICW in trunk and TBW in whole at baseline (r=0.39, p=0.049). There were no significant correlation between eGFR decrease and rate of change in body weight (r=0.02, p=0.46). Rate of TBW in limbs and TBW in whole at baseline correlated with rate of change in eGFR (r=0.45, p=0.028). These results suggest that cyst fluid might be measured as ICW by InBody720®. TBW in limbs can predict eGFR decline.

Conclusions: Measuring body water balance by InBody720® could be useful as predictors of htTKV and eGFR decline in short term after administration of tolvaptan in ADPKD patients.

A Rare Presentation of Acute Kidney Injury: Have a Look at the Skin

Alper Alp,[1] Sarenur Esener,[2] Didar Gursoy.[3] *[1]Nephrology, Van Education and Research Hospital, Van, Turkey; [2]Dermatology, Van Education and Research Hospital, Van, Turkey; [3]Pathology, Van Education and Research Hospital, Van, Turkey.*

Background: Tuberous sclerosis(TS) is a multisystem,rare,genetic disorder of autosomal dominant inheritance which can involve different organs.Most commonly involved organ system is skin.We describe a case presented with periungual fibromas,multiple renal cysts and Shagreen patch without other features of TS.

Methods: A 33 yo woman presented with fatigue and renal failure.On physical examination,she had multiple non traumatic periungual fibromas in both hands and feet. Also Shagreen patch was seen in the right lumbosacral region.

On admission biochemical tests;urea 132 mg/dl,creatinine 4,7 mg/dl,potassium 4,7 mmol/L,pH 7,32,HCO3 18,4.Urinary output was satisfactory,no uremic symptoms were present.Renal ultrasonography revealed bilateral renal cysts with normal size and parenchymal thickness.Histopathology of the Shagreen patch revealed dense collagen bundles in the dermis.Due to the skin lesions and renal cysts the patient was diagnosed as TS.Other manifestations of TS were not present.Renal biopsy was suggested but she did not accept the procedure.

Conclusions: As stated in diagnostic criterias,physical examination has a strong impact on diagnosis of TS.Hypomelanotic macules(>3),Shagreen patch,forehead plaque,non traumatic periungual fibromas,adenoma sebaceum,facial angiofibromas should remind the physicians TS.Kidneys are involved in almost 50-80% of the adult patients.Most frequent renal lesions in TS are angiomyolipomas.Bilateral and multiple characteristics of angiomyolipomas are pathognomonic.They may progress to end stage renal disease. However in some rare cases frank renal lesions may be absent.With a detailed inspection it is possible to recognize these specific dermatological signs,making the Tuberous sclerosis diagnosis and taking these patients under nephrological follow up.

PUB265

Use of Antidepressant Medications During the HALT-PKD Randomized Trials

Vicente E. Torres,[1] Kaleab Z. Abebe,[2] Theodore I. Steinman,[3] Charity G. Moore,[2] Ronald D. Perrone,[4] Arlene B. Chapman,[5] Robert W. Schrier,[6] Alan S.L. Yu,[7] William E. Braun,[8] Kyongtae Ty Bae,[2] Peter C. Harris,[1] Charity G. Moore,[2] Michael F. Flessner,[9] The HALT PKD Investigators.[10] *[1]Mayo; [2]U. Pittsburgh; [3]BIDMC; [4]Tufts U.; [5]U. Chicago; [6]U. Colorado; [7]KS U. Med. Ctr.; [8]Cleveland Clinic; [9]NIH; [10]Multi-Ctr.*

Background: Depression occurs in CKD more commonly than in the general population and is associated with poor outcomes. The use of antidepressants (ADs) has been associated with inappropriate release of vasopressin and hyponatremia. Since vasopressin is thought to aggravate the progression of ADPKD, AD use could be deleterious.

Methods: Examine the use of ADs in the participants of the HALT-PKD randomized clinical trials (RCTs) and whether their administration is associated with faster disease progression. Post-hoc analysis of two HALT-PKD RCTs (A and B) studying the effect of rigorous vs standard BP control (A) and of ACE inhibitor alone vs ACE inhibitor/ARB combination (A and B) on rates of change of TKV (A) and eGFR (A and B) in ADPKD patients with eGFR >60 (A) or 25-60 (B) ml/min/1.73 m2.

Results: Female used ADs more frequently than male participants (39.7% of 526 vs 20.4% of the 518, P<0.0001). Study A used ADs as frequently as study B participants (31.7% and 28.4%, respectively). Participants with *PKD2* mutations used ADs (42.4%) more frequently than those with *PKD1* mutations (27.9%, P=0.0009) despite having milder disease. Ages of those using or not using ADs were similar. To assess the effect of ADs on disease progression we divided the participants into three groups, no exposure to ADs, exposure for less £30% and exposure for >30% of the time:

Study	AD Use	S. Sodium* (mEq/L)	Ucr/Pcr*	U. Sodium* (mEq/24 hrs)	LnTKV change (% per yr)	eGFR change (ml/min/1.73m2/yr)
A	None (N=381)	138.7	65.1	178.3	6.32	-2.85
A	>30% (N=128)	138.4	65.9	175.1	5.81	-3.32
P-value		0.031	0.89	0.37	0.22	0.07
B	None (N=348)	139.3	30.5	168.2	-	-3.81
B	>30% (N=112)	138.8	31.9	151.6	-	-3.82
P-value		0.06	0.46	0.005	-	0.98
*Average of measurements for each participant during the trial						

Conclusions: AD use, defined as >30% use, does not affect the progression of ADPKD. Whether a particular AD class has an effect is under evaluation.

Dysregulation of miR-378a-3p and ADAMTS1 Gene in *cpk* Mice: A Model of ARPKD Masashi Sato,[1] Koichi Nakanishi,[1] Taketsugu Hama,[1] Hironobu Mukaiyama,[1] Hiroko Togawa,[1] Yuko Shima,[1] Masayasu Miyajima,[2] Kandai Nozu,[3] Shizuko Nagao,[4] Hisahide Takahashi,[4] Kazumoto Iijima,[3] Norishige Yoshikawa.[5] *[1]Pediatrics, Wakayama Medical Univ, Wakayama, Japan; [2]Laboratory Animal Center, Laboratory Animal Center, Wakayama, Japan; [3]Pediatrics, Kobe Univ, Kobe, Japan; [4]Education and Research Center of Animal Model for Human Disease, Fujita Health Univ, Aichi, Japan; [5]National Center for Child Health and Development, Tokyo, Japan.*

Background: The pathophysiology of cystic epithelia in PKD is characterized by altered proliferative activity, a secretory rather than absorptive function, and an abnormal matrix microenvironment. miRNAs are clarified to be involved in PKD. However, the detail has not been fully investigated. We reported that *cpk* cystic epithelia partially share cell pathophysiology with colorectal carcinoma (JASN 25:414A, 2014). Recently, dysregulation of miR-378a-3p/ADAMTS1 axis was reported in colorectal carcinoma (Kara, et al. Gene, in press). ADAMTS1 is one of the ADAMTS (A Disintegrin And Metalloproteinase with ThromboSpondin motifs) metalloproteinase family. Elevated ADAMTS1 promotes pro-tumorigenic changes such as increased tumor cell proliferation and altered extra cell matrix environment.

Methods: To identify miRNAs that are differentially expressed between *cpk* and control kidneys, we performed miRNA microarrays, and assessed the target molecule gene and its product expression using real-time PCR and western blotting.

Results: miRNA microarray analysis revealed that 22 (up 4, down 18) miRNAs were differentially expressed (more than 4-fold) in *cpk* (day 21, n=7) kidneys. Of 22 miRNAs, miR-378a-3p was significantly downregulated in *cpk* (5.1-fold). Real-time PCR confirmed that miR-378a-3p was significantly downregulated in *cpk* (day 14, n=14, 5.0-fold, p=0.002; day 21, n=12, 9.1-fold, p<0.0001) and that one of the target molecules of miR-378a-3p, ADAMTS1 mRNA was significantly upregulated in *cpk* (day 14, n=20, 1.4-fold, p=0.01; day 21, n=12, 3.5-fold, p=0.0002). Western blotting showed that ADAMTS1 was increased in *cpk* (day 21, n=6, 1.8-fold, p=0.03) kidneys.

Conclusions: Results suggest that miR-378a-3p/ADAMTS1 axis is involved in *cpk*. In conclusion, this axis may be a therapeutic target in PKD.

PUB267

Identifying and Integrating Consumer Perspectives in Clinical Practice Guidelines on Autosomal Dominant Polycystic Kidney Disease David J. Tunnicliffe,[1] Allison Tong,[1] Pamela Andrea Lopez-Vargas,[1] Jonathan C. Craig,[1] Gopala K. Rangan.[2,3] *[1]The Univ of Sydney, Australia; [2]Westmead Millennium Inst, Australia; [3]Westmead Hospital, Australia.*

Background: Integration of consumer perspectives into clinical practice guidelines is widely advocated as it ensures that recommendations are relevant to all stakeholders. We aimed to identify consumer perspectives on topics and outcomes to include in clinical practice guidelines on autosomal polycystic kidney disease (ADPKD).

Methods: A workshop involving three concurrent focus groups with consumers was convened. Guideline topics, interventions and outcomes were identified, and integrated into guideline development. Thematic analysis was used to analyze the reasons for their choices.

Results: Eighteen consumers (patients with ADPKD [n=15], caregivers [n=3]) participated and 22 priority topics (including interventions) were identified, with most focused on non-pharmacological management (diet, fluid intake, physical activity, complementary medicine), pain management, and psychosocial care (mental health, counseling, cognitive and behavioral training, education, support groups). They also identified 27 outcomes including quality of life, progression of kidney disease, kidney function, cyst growth, and nephrotoxicity. Almost all topics/outcomes had already been identified by health professionals in the guideline working group with the exception of five topics/outcomes (surgical management of cysts, patient education about end-stage kidney disease, psychosocial impact of diagnosis, need for dialysis, knowledge). Many more topics (33) and outcomes (44) were identified as priorities by health professionals than consumers. Six themes reflected reasons for consumer choices: clarifying ambiguities, resolving debilitating pain, concern for family, preparedness for the future, taking control, and significance of impact.

Conclusions: Although there was considerable concordance between the priority topics and outcomes of health professionals and consumers for guidelines of ADPKD, there was also important discordance with consumers focused on fewer issues but particularly on lifestyle, psychosocial support, pain management, and quality of life and renal outcomes.

PUB268

Urine AQP2 Is One of the Candidates for a Surrogate Maker in the Treatment of ADPKD Patients by Tolvaptan Kenichi Akiyama, Toshio Mochizuki, Miki Nishida, Masayo Sato, Hiroshi Kataoka, Hidekazu Sugiura, Ken Tsuchiya, Kosaku Nitta. *Medicine IV, Tokyo Women's Medical Univ, Shinjyuku, Tokyo, Japan.*

Background: Tolvaptan, arginine vasopressin (AVP) V2 receptor antagonist is accepted for autosomal dominant polycystic kidney disease (ADPKD) patients in Japan since 2014. TEMPO study showed tolvaptan from 60 to 120 mg per day slowed renal cyst expansion and renal function decline. Tolvaptan dose is decided by preliminary study (TEMPO$^2_4$) which showed the maximum dose that meet both urinary osmolality (Uosm) under 300 mOsm/kg and patient's tolerance. So that adequate dose for individual patient has not been suggested. Moreover, tolvaptan cause polyuria, thirsty, polydipsia due to aquaresis. Thus, it is necessary to find surrogate markers for determine the maximum effects and minimum side effects for long-term administration.

Methods: Seventeen ADPKD patients initiated tolvaptan of 60 mg were investigated. Physical data, plasma osmolality (Posm), Uosm, AVP, urine cyclic AMP (UcAMP), and urine AQP2 (UAQP2) were assessed. UcAMP was measured by radioimmunoassay (Yamasa corp.) and UAQP2 was measured by a sandwich enzyme-linked immunosorbent assay method (Otsuka Pharmaceutical Co. Ltd.).

Results: After initiation of tolvaptan, average urine volume was 8621 ml/day and delta body weight was -1.42 kg/day on day1. One month after, AVP increased from 3±3 to 7.3±11.2 pg/mL (p= 0.001), Uosm decreased from 367±349 to 243±436 mOsm/kg (p<0.001). Posm and UcAMP were not statistically associated. UAQP2 decreased from 0.029±0.068 to 0.012±0.028 pmoL/mgCr (p<0.001). In our preliminary data (n=5), the serum copeptin, a precursor of vasopressin, was shown to be no consistent level.

Conclusions: It has been reported that 3% of total production of AQP2 excreted into the urine, it reflected directly the intracellular action of AVP. Thus, UAQP2 is likely to be one of surrogate markers of tolvaptan effect, moreover it could provide additional information of determination of individual dosage and monitoring for long-term usage.

PUB269

Abnormalities in the Radius of Patients with Autosomal Dominant Polycystic Kidney Disease Measured by High-Resolution Peripheral Quantitative Computed-Tomography Imaging Danielle Diarra,[1] Janina M. Patsch,[2] Claudia Schueller-Weidekamm,[2] Michael Weber,[2] Arastoo Nia,[3] Gere Sunder-Plassmann.[1] *[1]Dept of Medicine III, Medical Univ of Vienna, Austria; [2]Dept of Radiology, Medical Univ of Vienna, Austria; [3]Dept of Medicine II, St. Vincent Hospital, Medical Univ of Vienna, Austria.*

Background: ADPKD is a multi-organ disorder and the most common of all cystic kidney diseases. Mutation of the *PKD1* or *-2* gene causes epi- and endothelial ciliopathies, which lead to the dysfunction of various organs. Animal studies show that primary cilia are present in osteoblasts of mice and point mutation of the osteoblastic *PKD1* gene induces osteopenia.

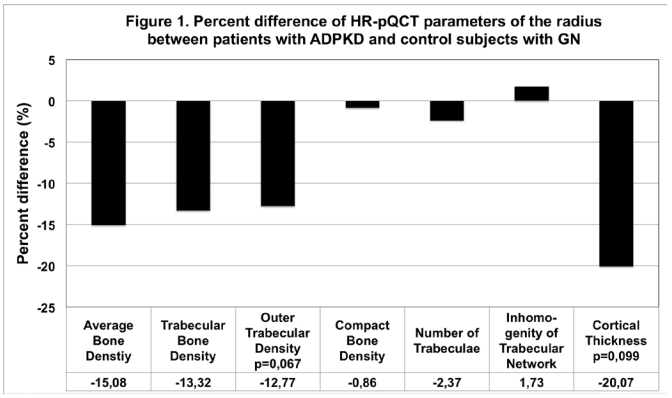
Methods: In this pilot-study, we examined the bone structure in 6 ADPKD patients in comparison to 6 matched patients with glomerular disease (GD), both in CKD stages I-II, by HR-pQCT of the radius and the tibia. The aim of the study was to identify microarchitectural target parameters for a subsequent larger study in patients with ADPKD.

Results: Demographic data see Table 1.

Table 1.

Parameter	GD Patients (controls)	ADPKD Patients
Patient number	6	6
Gender (male)	3	3
Age (years)	27±6,4	26±7,6
Serum creatinine (mg/dl)	0,81±0,17	0,83±0,19
eGFR (ml/min per 1.73 m^2)	109±18	108±23

We found reduced cortical and trabecular microstructural parameters by HR-pQCT, mainly affecting the radius. The outer trabecular density, the cortical thickness and the total density of the radius showed the biggest differences between the two groups, see Figure 1.



The total density of the radius was the best parameter to distinguish between the bone structure of ADPKD- in comparison to GD patients (AUC=0,861).

Conclusions: We provide evidence of microstructural bone deterioration of the radius in patients with ADPKD. We thus hypothesize that ADPKD is associated with microstructure bone changes in men.

PUB270

An Accurate Formula for a Quick Estimate of Total Liver Volume in Polycystic Liver Disease Patients Hedwig M.A. D'Agnolo,[1] Wietske Kievit,[2] Melissa Chrispijn,[1] Joost P.H. Drenth.[1] *[1]Gastroenterology and Hepatology, Radboud Univ Medical Center, Nijmegen, Netherlands; [2]Radboud Inst for Health Sciences, Radboud Univ Medical Center, Nijmegen, Netherlands.*

Background: Polycystic liver disease (PLD) appears in two disorders; autosomal dominant polycystic kidney disease (ADPKD) and autosomal dominant polycystic liver disease (ADPLD). The primary aim of treatment of PLD is reduction of total liver volume (TLV) as patients often suffer from hepatomegaly. The gold standard to assess TLV is CT volumetry which involves manual delineating of the liver outline. Unfortunately this is a time-consuming method (45-60 minutes per CT scan) and requires a certain level of expertise. An easily accessible and fast method to estimate TLV in routine clinical practice is needed. Therefore we aimed to develop an accurate formula for quick estimation of TLV.

Methods: We collected a cohort of PLD patients in whom CT scans were available. Manual delineation of TLV served as gold standard. PLD patients were distributed in 2 cohorts, a development cohort (N=80) and a replication cohort (N=50). We measured anterior-posterior (AP), transverse (T) and cranial-caudal (CC) distance (in meters) of the liver on CT. TLVs were logarithmically transformed as data were not normally distributed. R^2 was measured as it indicates the goodness of fit of the prediction model. The prediction model was tested in a replication cohort.

Results: Median liver volumes in the development and replication cohort were 4749mL [1084-14816] and 4684mL [1287-16746] respectively. All three diameters significantly correlated with TLV ($p < 0.0001$). Linear regression analysis resulted in the following formula: Logarithm of TLV = 5.240 + T*5.608+ CC*2.522+AP*6.041. Our model predicted TLV accurately in the development cohort (R^2= 0.898). The correlation in the development cohort was 0.948 and validation in the replication cohort resulted in a correlation of 0.937.

Conclusions: Our model accurately and quickly (< 2 minutes) predicts TLV in PLD patients based on three liver dimensions.

PUB271

Clinical Significance of Urine NAG and L-FABP Excretion for the Assessment of ADPKD-Progression Yoshimi Okada,[1] Mai Aoyagi,[1] Kaori Takayanagi,[1,2] Takatsugu Iwashita,[1] Tota Kiba,[1] Tatsuro Sano,[1] Kento Hirose,[1] Yuichiro Kawai,[1] Ryo Yamamoto,[1] Yuya Shioda,[1] Yosuke Tayama,[1] Hajime Hasegawa.[1] *[1]Nephrology and Hypertension, Saitama Medical Center, Saitama Medical Univ, Kawagoe, Saitama, Japan; [2]Ishikawa Kinenkai Kawagoe Ekimae Clinic, Kawagoe, Saitama, Japan.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) shows various renal prognosis. Because the progression of renal damage in ADPKD is principally caused by tubulo-interstitial nephropathy (TIN), the present study focused to study the relationship between TIN-related clinical parameters and progression of ADPKD.

Methods: In this study, 59 ADPKD cases with consents were retrospectively analyzed. Average age, duration of the observation, median values of kidney volume (KV) and kidney growth rate (KGR), average estimated GFR (eGFR) were 50.5 yeas old, 3.4 yeas, 1423 mL and 1.74% growth/year, respectively. KV was calculated by using the ellipsoid formula.

Results: In all cases, KV and eGFR showed exponential correlation (R=0.47). We focused kidney volume (KV), kidney growth rate (KGR), eGFR, and urine excretion ratio of N-acetylglucosaminidase (NAG) to Cr (NAG index) for the clinical assessment of TIN. We stratified patients by the average or median value of the parameters mentioned above, and analyzed their differences in each stratified group. KV, eGFR and KGR showed significant difference only in the eGFR-, KV- and eGFR-stratified group. However, NAG index showed significant difference in both KV-stratified (median: 7.42 vs 6.09 U/mgCr) and eGFR-stratified (8.00±5.98 vs 3.93 U/mgCr) groups. Additionally, urine liver type fatty acid binding protein (L-FABP), as a biomarker of the tubular ischemia, showed significant difference in all stratified groups (KV: 7.29±9.98 vs 1.76±1.68, eGFR: 4.15±7.76 vs 2.45±2.34, KGR: 4.46±7.68 vs 2.09±2.30, NAG index: 4.33±7.20 vs 1.88±2.10).

Conclusions: Progression of ADPKD has been primarily assessed by the kidney volume. However, the present study may show that the assessment of TIN might be more helpful to evaluate the severity and prognosis of ADPKD. It might be suggested that TIN-related markers such as NAG index or L-FABP index should be actively utilize in the clinical management of patients with ADPKD.

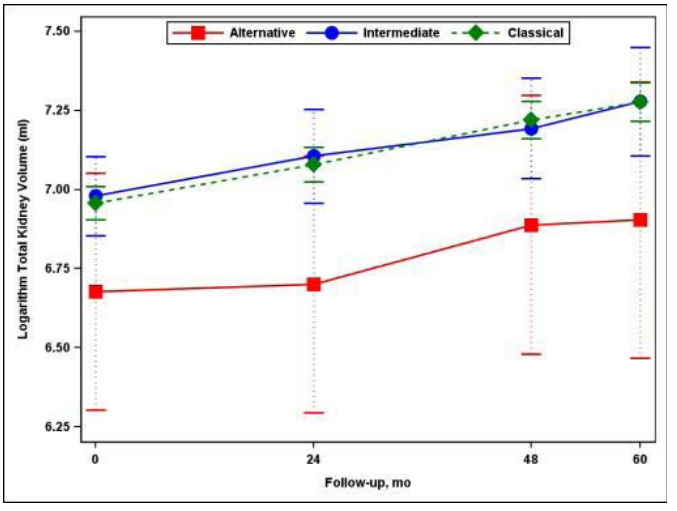
PUB272

Classic and Alternative Criteria for the Diagnosis of Autosomal Dominant Polycystic Kidney Disease: Genetics and Disease Progression in HALT-PKD William E. Braun,[1] Kaleab Z. Abebe,[2] Arlene B. Chapman,[3] Peter C. Harris,[4] Godela M. Brosnahan,[5] Peter G. Czarnecki,[6] Kyongtae Ty Bae,[2] Charity G. Moore,[2] Robert W. Schrier.[5] *[1]Cleveland Clinic; [2]Univ of Pittsburgh; [3]Univ of Chicago; [4]Mayo Clinic; [5]Univ of Colorado; [6]Brigham & Women's Hospital.*

Background: The HALT-PKD trials based the diagnosis of ADPKD on classic criteria (CC) as well as on alternative criteria (AC) with no ADPKD family history(–FH). Patients with AC and genetically no mutation detected (NMD) were analyzed as a distinct subset (AC-NMD).

Methods: Of 959 HALT-PKD patients with genetic testing 835 (87.1%) had CC, and 124 (12.9%) had AC**.** Three groups: **Alternative** (AC-NMD), **Classical** (CC-PKD1/PKD2 mutation),and **Intermediate** (combined CC-NMD + AC-PKD1/PKD2 mutation) were compared for annual change in total kidney volume (TKV, htTKV) in early ADPKD (n=17, 410, 81, respectively),and eGFR in early/late ADPKD (n=17/8, 414/375, 81/64,respectively).

Results: TKV baselines were not significantly different (P=0.66). The TKV annual increase was 4.21% in **Alternative** (AC-NMD) compared to 6.39% in **Classical** (CC-PKD1/PKD2),and 6.68% in **Intermediate** (CC-NMD + AC-PKD1/PKD2) (lnTKV P=0.0346; lnhtTKV P=0.0355)and was not affected by BP level.



NMD patients were 20.2% of AC but just 5.5% of CC patients which was true in both early (P<.0001) and late ADPKD (P=0.0066). Annual eGFR change in early and late ADPKD was not significantly different in the 3 groups, and Low vs Standard BP, or lisinopril+telmisartan vs lisinopril+placebo, did not alter that.

Conclusions: AC-NMD (**Alternative**) patients with early ADPKD have a significantly lower annual increase in TKV/htTKV. The –FH factor in AC appears to be the clinical portal to a genetically complex population enriched 3.7-fold for NMD. Patients with AC-NMD might have mosaicism, atypical mutations, or even polycystic kidney disease(s) other than ADPKD.

Lifestyle Counseling in Polycystic Kidney Disease Patients Wen-Ching Tran, Jonathan Chan, Chi-yuan Hsu, Meyeon Park. *UCSF.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is a common cause of end-stage kidney disease worldwide, affecting all ethnicities. Although there is no cure for this condition, dietary modification and water intake may attenuate progression of disease, yet lifestyle counseling is not consistently implemented by providers. Furthermore, cardiovascular risk is high in this group, and exercise may benefit cardiovascular health. Patients with ADPKD often express a desire to be able to "do anything" to modify their disease. We designed this study to determine the prevalence of lifestyle counseling in nephrology clinic visits with individuals with ADPKD.

Methods: We performed a systematic chart review. Using our electronic medical record system, we identified patients with ADPKD whose most recent visit at UCSF with a nephrologist occurred during the previous six months. We reviewed the notes associated with these visits to assess for nephrologists' discussion of dietary advice, water drinking parameters, and exercise recommendations based on documentation in clinic notes.

Results: We identified 56 unique patient visits in the previous six months. Mean age was 44.6 (+/- 14.9) years. 29 (52%) were women. 28 patients had documentation of dietary discussions; 26 received water intake recommendations; and 8 received exercise advice. Only 5 patients received counseling on all 3 parameters.

Number of patients receiving counseling on X of 3 parameters (Diet, Water intake, Exercise)				
0 of 3	1 of 3	2 of 3	3 of 3	Total
21	13	17	5	56

Conclusions: Prevalence of lifestyle counseling was moderate as ascertained by chart review of our electronic medical record. Discussion of exercise recommendations was low. Nephrologists could consider focusing more attention on offering lifestyle counseling to individuals with ADPKD.

Lipid Alterations in Murine Models of Polycystic Kidney Disease Christine Podrini,[1,2] Isaline Rowe,[2] Marco Chiaravalli,[2] Alessandra Boletta.[2] *[1]Univ Vita-Salute San Raffaele, Milan, Italy; [2]Dibit San Raffaele Scientific Inst, Milan, Italy.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is a common genetic disorder characterized by massive bilateral renal cyst formation. ADPKD results from mutation in the *PKD1* or *PKD2* genes, encoding Polycystin-1 (PC-1) and 2 (PC-2) proteins respectively. Previous studies have suggested that the mTORC1 cascade might play an important role in PKD. Further, mTORC1 regulates the activity of SREBP which regulate the expression of genes required for the synthesis of fatty acids and cholesterol. However, the regulation of fat synthesis in ADPKD remains poorly understood. In this study, we seek to understand the relationship between fatty acid regulation and defective PKD1 function.

Methods: We analyzed newborn kidneys of *Ksp*-Cre;*Pkd1*$^{flox/-}$ mice and detected an increased expression of SREPB1 and its target genes including fatty acid synthase (FAS) and stearoyl-CoA desaturase (SCD) when compared to control, non-cystic kidneys (*Ksp*-Cre;*Pkd1*$^{flox/+}$ or *Pkd1*$^{flox/+}$).

Results: As expected the increased expression of SREPB1 also correlated with increased transcript levels of SREPB2 concomitant with an increased transcript levels for sterol biosynthesis mevolonate kinase (MVK) and acetyl-CoA synthetase (ACSL). Next, we performed a lipidomic profiling of *Ksp*-Cre; *Pkd1*$^{flox/-}$ kidneys compared to controls *Ksp*-Cre; *Pkd1*$^{flox/+}$ collected at P4 using shotgun lipidomics technology. The profiles confirmed the alteration of some lipid classes, particularly sphingolipids and sterol esters (cholesterol). Of interest both have been implicated in regulating membranes trafficking and they may cross-talk to mTORC1 in response to altered nutrient/fatty acid signals. Notably, some of the lipid alterations that we observed appear to be gender-specific.

Conclusions: We are currently characterizing this aspect further and trying to determine which lipid alterations might be dependent and/or independent of mTORC1 upregulation.

PUB275

Reactive Hyperaemic Index in Early Disease Stages of Autosomal Dominant Polycystic Kidney Disease Adebowale Olayinka Adekoya,[1] Andrew J. Streets,[1] Albert C. Ong.[1] *[1]Academic Nephrology Unit, The Medical School, Univ of Sheffield, Sheffield, South Yorkshire, United Kingdom; [2]MRC Centre for Developmental and Biomedical Genetics, Univ of Sheffield, Sheffield, South Yorkshire, United Kingdom.*

Background: ADPKD is the commonest inheritable cause of ESKD. Cardiovascular complications are the commonest cause of death in ADPKD. Endothelial dysfunction (ED) has been reported to precede CV events. In our pilot study of sixty ADPKD patients in the late stages of disease (CKD 3 and above), ADMA and 8 isoprostane were found to be increased suggesting ED. The aim of this study is to investigate ED in the ADPKD patients in early stages of the disease (CKD 1 and 2) and to identify factors associated with its severity.

Methods: This is a single centre cross sectional study of ADPKD patients in the early stages of disease. Individuals with HBP, DM, eGFR< 60ml/min/1.73m^2 and sokers were excluded. 23 patients and 26 age, sex and eGFR matched controls were recruited. 24hr urine was collected for creatinine clearance and protein. Reactive hyperaemic index (RHI) was measured using endoPAT 2000.

Results: The mean±SD age of the patients was 40.80±14.18 years. M:F was 1:2.3. Patients' mean±SD eGFR was 81.87± 18.02ml/min/1.73^2, creatinine clearance was 125.75± 55.69 while SBP was 129.35 ± 7.47 mmHg.There was no significant difference in RHI between patients and control. Furthermore, there was no significant difference in cholesterol, C reactive protein, uric acid, calcium phosphate product and homocysteine between patients and controls (p>0.05) Conversely, there was a significant difference in the level of proteinuria between the patients and controls. Proteinuria and homocyteinemia correlate with RHI on univariate and multivariate analysis.

Conclusions: Pulse arterial tonometry as measured by RHI was not significantly reduced in ADPKD patients in the early stages of disease. However, increased proteinuria and hyperhomocysteinemia were detectable in ADPKD patients with preserved kidney function suggesting more subtle changes in endothelial function which may not be detected by RHI.

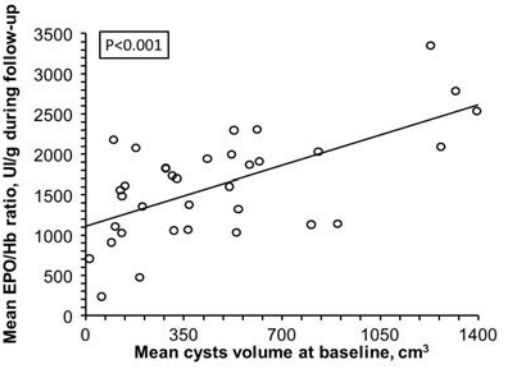
PUB276

Baseline Renal Cysts Diameter Predicts the Erithropoietin Requirement in Autosomal Dominant Polycystic Kidney Disease Paolo Lentini,[1] Luca Zanoli,[2] Massimo de Cal,[1] Stefania Rastelli,[2] Andrea Contestabile,[1] Antonio Granata,[3] Roberto Dell'Aquila.[1] *[1]Nephrology, St. Bassiano Hospital, Bassano Del Grappa, Italy; [2]Internal Medicine, Univ of Catania, Catania, Italy; [3]Nephrology, St. Giovanni Di Dio Hospital, Agrigento, Italy.*

Background: Subjects with autosomal dominant polycystic kidney disease (ADPKD) require classically low recombinant human erythropoietin (EPO) to reach haemoglobin target levels. We hypothesize that EPO requirement in subjects with ADPKD is more dependent to the enlargement of the cysts than the reduction of glomerular filtration rate. Aim: To evaluate the role of renal cyst and kidney size on EPO requirement in severe chronic kidney disease (stage 4-5).

Methods: A total of 35 pts with ADPKD and anaemia treated with EPO were enrolled (14 pts with CKD Stage 4 and 21 pts Stage 5), the mean volume (V) and diameter (D) of the four largest cysts and the mean antero-posterior renal diameter (AP) were prospectively followed-up for 18 months with computer tomography.

Results: The overall mean age was 65±14 years, male sex 57%. At baseline, AP was 19.7±2.2cm, D 4.6±1. cm, V 749±641 cm^3. During the 18 months follow-up, rHu-EPO dose was 8543±6626 UI/week, and EPO/haemoglobin ratio (E/H) was 1983±1039. In a multivariate linear regression model, adjusted for age and sex, at baseline both AP and V were significantly associated with E/H; after 18 months, only V remains significantly associated with E/H. Baseline V (100cm^3 increase: β=115UI/g week, 95%CI 65-164, P<0.001) was also associated with mean E/H during follow-up and explain 42% of E/H variability.



Conclusions: The Cysts volume is useful to predict propectively the EPO requirement in ADPKD in stage 4-5 CKD.

PUB277

A Novel Method to Determine Glomerular Volume Distribution from Few Serial Sections on a Single Slide Mohan C. Abraham,[1] Rishi Singh,[2] Krishnamurthy P. Gudehithlu,[2] Jose A.L. Arruda,[1,2,3] Ashok K. Singh.[1,2,3] *[1]Div of Nephrology, John H Stroger Hospital, Chicago, IL; [2]Hektoen Research Inst, Chicago, IL; [3]Section of Nephrology, Univ of Illinois at Chicago, Chicago, IL.*

Background: Estimating glomerular volumes is important in understanding pathogenesis of glomerular diseases. Some methods are convenient but give a single mean volume for the entire kidney and do not provide volume profiles. Methods for volume profiling are too laborious for routine use. We describe here a new method to obtain glomerular volume profiles from few serial sections. The method uses the formula, $\mathbf{R^2 = r_1^2 + [(r_1^2 - r_2^2 - h^2)/2h]^2}$, where **R** is the radius of a sphere and $\mathbf{r_1}$ and $\mathbf{r_2}$ are the radii of two parallel circular planes cut across the sphere **h** distance apart.

Methods: To validate our method we compared glomerular volumes between normal (n=5) and STZ diabetic rats (n=4) by measuring 100 random glomeruli from each group. Three (or four) serial sections each 5μM apart were obtained on the same slide. Sections were stained with H&E and glomerular diameter was measured at four points to arrive at a mean diameter and radius $\mathbf{r_1}$. The same glomerulus was identified on the third (h = 10 μM) (or fourth; h = 15 μM) serial section to similarly determine $\mathbf{r_2}$. R was calculated by the formula to obtain the glomerular volume $\mathbf{(4/3\ \pi\ R^3)}$.

Results: The mean glomerular volume (10^6 μM^3) of normal rats was 1.04 ± 0.06, a value very close to that determined by MRI recently (Heilmann et al 2012). The mean glomerular volume of diabetic rats was 1.48 ± 0.06, which was 45% higher (P<0.05) than normal, confirming glomerular hypertrophy. While the volume distribution in normal rats was Gaussian, the distribution of glomerular volumes in diabetic rats was skewed towards higher volumes (42% glomeruli >1.4 X 10^6μM^3 compared to 12% in normals), suggesting that not all glomeruli but only a population of glomeruli hypertrophied in diabetic rats.

Conclusions: Precise glomerular volumes can be conveniently determined by our method using a few serial sections of the kidney, making it possible to obtain glomerular volume distribution from experimental as well as human kidney biopsies.

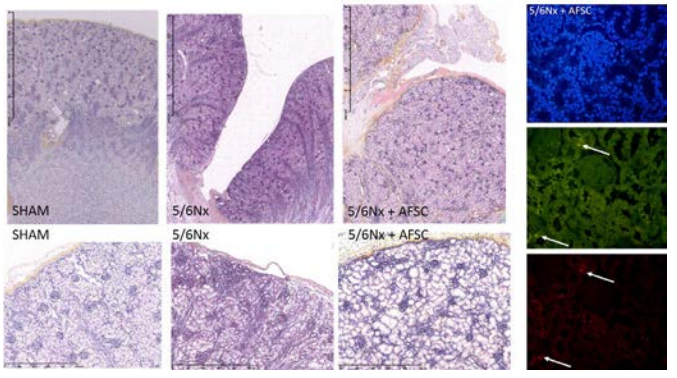
Amniotic Fluid Stem Cells Transplantation in Fetal Kidney to Regenerate Nephrons Loss Kathleen Laborde,[1] Sebastien Sammut,[2] Mehrak Hekmati,[2] Agnieszka Anna Ksiazek,[3] Benedikt Weber,[3] Luc Behr.[2] *[1]Necker Hôpital-Paris5 Univ, Paris, France; [2]IMMR, Paris, France; [3]Swiss Center for Regenerative Medecine, Univ Hospital, Zurich, Switzerland.*

Background: Amniotic fluid stem cells (AFSC) harbour the potential to differentiate toward renal lineages and contribute to the development of primordial kidney structures. To investigate whether AFSC can improve prenatal renal compensatory growth, cells were transplanted in a model of subtotal nephrectomy (5/6NX) in the fetal sheep.

Methods: Ovine AFSC labelled with GFP were selected using c-kit. In absence of LIF, AFS formed embryonic bodies which cultured in an optimized medium generated a renal epithelial progenitor population (oAFSCd), expressing PAX-2. 5/6NX was performed at 70 days of gestation in 10 fetal lambs; 5 were injected with oAFSCd in the kidney poles. Sham-operated did not received oAFSCd (SHAM, n=8). At 134 days of gestation, fetuses were euthanized, kidneys removed and processed.

Results: Body weight did not differ significantly among the groups and no morphologic abnormalities were observed, in spite of a severe reduction in amniotic fluid in 5/6NX+oAFSCd. Compensatory renal growth of the remaining kidney was observed in all 5/6NX, but in spite of oAFSd injection, catch-up kidney growth was similar in both 5/6NX groups: SHAM: 3.2±0.6;5/6NX:4.6±2.4;5/6NX+oAFSCd:5.5±1.4 KW/BW. Glomeruli number/section was similar in all groups: SHAM:2711±237;5/6NX:2155±694;5/6NX+o AFSCd:1962±199. In 5/6NX+oAFSCd, GFP cells were present in renal proximal tubes, and proximal tubule hypertrophy was observed.



No striking changes were observed in PAX2, WT1 or PCNA expression.

Conclusions: Transplantation of oAFSCd predifferentiated toward renal epithelial progenitor cells during nephrogenesis increases proximal tubule mass but has no effect on the number of glomeruli in the 5/6NX and do not restore fully kidney damage.

Low Birth Weight Impairs Renal Development and Function Christina M. Barnett, Michael S. Shen, Kunzah Aleem Syed, Joseph A. Zullo, David L. Payne, Oluwadara Nnoli, Wasan Abdulmahdi, Amy R. Patel, Tala F. Azar, May M. Rabadi, Brian B. Ratliff. *New York Medical College.*

Background: Low birth weight (LBW) results in a significant risk to the newborn, with many of these babies developing acute kidney failure and dying soon after birth due to underdeveloped vascular and renal systems. Surviving LBW neonates are also susceptible to a variety of health problems later in life during adulthood including hypertension, diabetes and chronic kidney disease with an associated 70% increased risk of end-stage kidney failure.

Methods: Using a maternal malnourished mouse model, we examined the causes of vascular and renal underdevelopment and impaired function in the LBW neonate. Parameters measured in the LBW offspring included nephron development, stem cell levels, apoptosis, gene expression, circulating cyto-/chemokines, renal blood flow and renal function.

Results: Within 24 hours after birth, LBW male offspring had 40% reduced weight, while only 49% of LBW neonates survived the first week after birth. Within the first week after birth, LBW neonates had an up to 40% reduction in renal blood flow and elevation of serum creatinine up to 3.0 mg/dL. Nephrogenesis was impaired in the LBW neonates with a 75% reduction in renal vesicle formation and a significant downregulation of Wnt9B (which induces differentiation of progenitor cells into tubular epithelia) at day E17.5, which ultimately resulted in a 30% reduction in glomeruli at the conclusion of nephrogenesis. During nephrogenesis, six2-positive nephron progenitor cells were reduced by up to 70% in the LBW embryonic kidney, which was accompanied by 6-fold increase in apoptosis. At birth, the LBW neonate had significantly elevated circulating levels of proinflammatory IL-1beta. Using explanted embryonic kidneys, we observed IL-1beta dramatically reduces six2+ cell populations and their ability to aggregate and form renal vesicles during kidney development.

Conclusions: LBW impairs vascular and renal function due to undeveloped renal and vascular systems that result from enhanced IL-1beta, increased apoptosis, altered Wnt9b expression, and reduced six2 nephron progenitor cells in the embryonic and neonate kidney.

PUB280

Increasing Podocyte Number in Neonatal Kidney Reduced Renal Injury in Adulthood Jianyong Zhong,[1,2] Ji Ma,[2] Taiji Matsusaka,[3] Agnes B. Fogo,[1] Valentina Kon,[2] Haichun Yang.[1] *[1]Pathology, Microbiology and Immunology, Vanderbilt Univ, Nashville, TN; [2]Pediatric Nephrology, Vanderbilt Univ, Nashville, TN; [3]Dept of Molecular Life Science, Inst of Medical Science, Tokai Univ School of Medicine, Isehara-shi, Kanagawa, Japan.*

Background: Preterm birth increases the risk of hypertension and renal disease, which have been linked to decreased nephron number. We previously found that puromycin injection in mice at birth impairs glomerular maturation, and has renal pathology phenotype which is similar to that observed in human preterm births. In the present study, we tested the hypothesis that increasing podocyte number during glomerular maturation can rescue glomerular loss and thus reduce renal injury in adulthood.

Methods: We mated podocin-rtTA with TRE-SV40T mice to generate double-transgenic mice (RS), in which podocyte proliferation can be activated by doxycycline (Dox). rtTA mice (R) served as controls. After a single puromycin injection, doxycycline was given at P1 until P8. At 12 weeks of age, mice underwent uninephrectomy (UNx) and were started on a high salt diet. At 14 weeks of age, angiotensin II (Ang II) was given by minipump for the next 8 weeks. All mice were sacrificed at week 22.

Results: At week 3, there were more WT1 positive glomerular cells in RS than R mice (RS 10.34±0.41 vs. R 8.15±0.58 $X10^{-3}/\mu m^2$, $p<0.05$), while glomeruli in superficial cortex were less mature (RS 2.13±0.05 vs. R 2.32±0.06, maturity scale 1-3, $P<0.05$). At week 6, glomerular number increased in RS (RS 9039.2±644.2 vs. R: 6932.1±244.7/ kidney, $P<0.05$). Glomerular volume and albuminuria did not differ between groups at week 3 and 6. At week 22, after UNx, high salt and Ang II, blood pressure, albuminuria and glomerular number were similar in RS and R. However, RS mice had lower KW/BW ratio (RS 0.976±0.143 vs. R 1.263±0.041, $p<0.05$) and less mesangial expansion (0-4 scale) (RS 0.72±0.10 vs. R 1.14±0.14, $p<0.05$).

Conclusions: We conclude that increasing podocyte number in developing kidney rescues puromycin-induced impairment of glomerular growth, which in turn reduces renal injury following a second hit in adulthood.

PUB281

Exploring Ciliopathies – Cep164 Tissue Expression in a Murine Model Simon Ramsbottom, Shalabh Srivastava, Colin Miles, John Andrew Sayer. *Inst of Genetic Medicine, Newcastle upon Tyne, United Kingdom.*

Background: Nephronophthisis (NPHP) is the major cause of paediatric renal failure, yet the disease remains poorly understood, partly due to the lack of appropriate animal models. Joubert Syndrome (JBTS) is an inherited ciliopathy giving rise to NPHP and neurodevelopmental abnormalities and mutations in *CEP164* are one of the known genetic causes. Clinical phenotypes of patients with *CEP164* mutations include NPHP with retinal degeneration and cerebellar vermis aplasia. In cultured cells CEP164 localises to centrosomes as well TIP-60 postive nuclear foci, and CEP164 has an established role in DNA damage response signalling. However, there has been no previous documentation of *CEP164* spatial expression during development.

Methods: We have recently acquired heterozygous *Cep164* mice from the International Mouse Phenotyping Consortium (MRC/Harwell) (B6NTac;B6N-Cep164$^{tm1a(EUCOMM)Wtsi/H}$). We used these animals for tissue expression studies, including X-gal staining from heterozygote adults and whole embryos. Homozygoyte *Cep164* animals had 100% perinatal lethality.

Results: In heterozygote *Cep164* animals, specific X-gal staining representative of *Cep164* expression was observed in all tissues examined. This included the brain (olfactory bulbs and cerebellum); the eyes (within the retina layers); the testis and renal tissues. In E13.5 embryos, staining was observed globally at a low level. Stronger staining can be seen in discrete regions including the developing eyes and limbs, areas undergoing high levels of proliferation and apoptosis, further indicating a role for Cep164 in these processes.

Conclusions: These data support a role for Cep164 in multiple organs throughout development and explain the wide phenotypic spectrum of JBTS mutations in man.

PUB282

Specific Deletion of Early B Cell Factor 1 from Podocytes Does Not Recapitulate the Developmental Defects Observed in the Globally Deficient Animals but Does Provide Protection from Injury Jackie A. Fretz, Tracy Nelson, Li Li. *Orthopaedics and Rehabilitation, Yale School of Medicine, New Haven, CT.*

Background: Globally deficient mice lacking the transcription factor Ebf1 (Ebf1 KO) are extremely sick owing to the multiple functions of Ebf1 across the body. We recently described a novel function of Ebf1 as an essential component of the latest stages of metanephric development. Mice globally deficient in Ebf1 have impaired formation of peripheral glomeruli and a thinned cortex. Within the kidney Ebf1 is present within multiple cell types including distinct tubular epithelium, interstitial pericytes, glomerular mesanguim, and podocytes. This investigation aimed to identify if the actions of Ebf1 in the podocyte were driving the developmental defects present in the global knockout.

Methods: In this study we made a specific deletion of Ebf1 within the podocytes using the podocin-driven cre mouse. These were mated with mice where the 3rd exon of Ebf1 (encoding part of the DNA-binding domain) is flanked by flox sites. This is the same genetic region that is excised in the global deletion model. BSA overload injury was also performed on 3 month old animals (100mg/kg, IP daily for 4 weeks).

Results: Restricted deletion of Ebf1 from podocytes did not result in any observable developmental changes as assessed at the functional and histological level. Renal mass, glomerular number, and glomerular development were unchanged regardless of genotype. The mice were followed for up to 6 months. During this time renal function did not decline in the mice with podocyte-specific deletion of Ebf1, and in fact baseline proteinuria was reduced in Podocin-cre+, Ebf1-fl/fl animals compared to littermate controls. To examine if Ebf1-deficient podocytes harbored differential response to injury 3 month old animals were subjected to BSA-overload and exhibited reduced proteinuria.

Conclusions: Taken together these results suggest that Ebf1 regulates metanephric development through other cell types than the podocyte. While Ebf1 does not control glomerular development through its actions in the podocyte, it appears to participate in proper damage response by podocytes as its removal appears to be protective.

Remote Ischemic Pre Conditioning and Pharmacological Treatment in Prevention of Renal Damage in Experimental Diabetes

Marcelo Rodrigues Bacci, David Feder, Fernando Luiz Affonso Fonseca, Matheus Polly, Jaqueline Victoria Ciancaglini, Giuliana Petri, Guilherme Zaremba. *ABC Medical School, Brazil.*

Background: The main features of diabetic nephropathy are glomerular hypertrophy,thickening of the basal membrane,tubular atrophy,interstitial fibrosis and nodular and focal glomerulosclerosis.Remote ischemic preconditioning(RIPC)is a procedure that generates a brief period of ischemia followed by reperfusion.Its role in preventing glomerular and tubular changes is still under debate.The aim of the study was to evaluate the nephroprotective effect of RIPC in a diabetic rat model.

Methods: Five groups of 10 Wistar male rats were formed:control without diabetes;untreated diabetes;diabetes treated with pharmacological treatment(PT);diabetes with RIPC and diabetes with RIPC and PT.For the induction of diabetes,alloxane was infused intraperitoneally at a dose of 160mg/kg.PT consisted of daily use of metformin(250mg/kg),sitagliptin(8mg/kg)and valsartan(30mg/kg).RIPC was performed with an external tourniquet placed on the back leg for three 5-minute rounds alternated with the same rounds of reperfusion,resulting in a total duration of 30 minutes.This was performed every week on all mice in RIPC groups.All mice were kept in a biological cage with controlled temperature and humidity and routine feeding.Blood and urine samples were collected weekly to evaluate serum glucose,creatinine and urine glucose levels and albumin/creatinine urine ratio(ACR).At the end of the observation period,animals were sacrificed and their kidneys were biopsied for microscopic analysis.

Results: Animals subjected exclusively to PT showed a significant reduction in serum and urine glucose levels but these reductions were not greater in the group that underwent RIPC in addition to PT.There were no significant differences in creatinine level between any of the groups but ACR was significantly reduced in all treated animals compared to controls. Tubular atrophy was observed in all diabetic rats and was greatest in the untreated group.

Conclusions: PT was more effective at reducing ACR and tubular atrophy than RIPC. RIPC alone or in combination with PT did not cause the expected effect of preventing histological and urinary abnormalities.

Cross Talk Between TLR4 Signaling and Angiotensin II Induces Pathophysiological Changes in Human Tubular Epithelial Cells Under High Glucose Conditions

Jinlei Lv,[1] Guohua Ding.[2] *[1]Nephrology, The First Affiliated Hospital of NanChang Univ, NanChang, Jiangxi, China; [2]Nephrology, Renmin Hospital of WuHan Univ, WuHan, China.*

Background: To investigate the cross talk between TLR4 and angiotensin II by observe the expression of TLR4 in tubular epithelial cells under high glucose conditions, and observe the changes of fibrogenic and inflamamatory factors in human renal tubular epithelial cells, revealing the innate immune pathogenesis in diabetic nephropathy.

Methods: Cells were divided into five groups after cultivated with normal glucose medium: 1. normal-glucose group 2. mannitol group 3. AngII group 4. high-glucose group(25mmol/L) 5. high-glucose+Irbesartan group, extract total RNA and total protein after 24 hours. Real time PCR was used to analyze the expressions of TLR4, MyD88, HSP47 mRNA, western blot was used to observe the expressions of TLR4, MyD88, NF-κB, CoIV, HSP47 protein, analyse the effect of high-glucose and AngII to TLR4 / MyD88 / NF-κB signaling pathway.

Results: Compared with normal group, TLR4, Myd88, HSP47 mRNA and TLR4, Myd88, NF-κB, CoIV, HSP47 protein were highly expressed under high glucose condition and after AngII stimulate (p<0.01) . The expression of IL-6 and MCP-1 also increased (p<0.01). Compared with HG group, the expresssion of TLR4, MyD88, HSP47 mRNA and TLR4, MyD88, NF-κB, CoIV, HSP47 in the high-glucose+Irbesartan group were significantly reduced (p<0.01) . The difference of above indicators between the negative transfected group and high-glucose group and AngII group were statistically significant(p>0.05). the expression of IL-6 and MCP-1 in the group that cells were transfected with TLR4-siRNA also reduce(p<0.01).

Conclusions: Cross talk between angiotensin II and TLR4 can up-regulate the expression of inflammatory factors and fibrogenic factors in HK-2 cells. Irbesartan can block the activation of TLR4 signaling pathway induced by high glucose and angiotensin II. TLR4 signaling pathway is the major pathway induce the release of inflammatory and fibrogenic factors in tubular epithelial cells under high glucose conditions.

Possible Renoprotective Effects of Acetazolamide Administration in Obese Diabetic Mice with Nephropathy

Yushi Nakayama, Koji Eguchi, Terumasa Nakagawa, Tomoaki Onoue, Yuichiro Izumi, Hideki Inoue, Yutaka Kakizoe, Takashige Kuwabara, Masashi Mukoyama. *Dept of Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan.*

Background: Administration of carbonic anhydrase inhibitors (CAI) is thought to decrease glomerular filtration rate (GFR) by activation of the tubuloglomerular feedback (TGF) system. Acetazolamide (ACZ), a major CAI, has been shown to decrease urinary albumin excretion in the patients of type 1 diabetes with nephropathy. Previously, we showed that ACZ treatment in mice could ameliorate the onset of diabetic nephropathy due to the reduction of intraglomerular pressure by activating the TGF system.

Methods: In the current study, we treated obese diabetic mice (KK-Ay/TaJcl) with ACZ for 14 weeks, and evaluated the long-term effects on urinary albumin excretion and glomerular hyperfiltration.

Results: The blood glucose levels were significantly higher in KK-Ay/TaJcl mice compared to the control mice (BALB/cAJc1) at 14 weeks. The blood glucose levels were significantly reduced in KK-Ay/TaJcl mice treated with ACZ (547±37 vs 250±75 mg/dL). Interestingly, urinary glucose excretion levels in the ACZ group were not significantly different compared to the non-treated group. Creatinine clearance was higher in KK-Ay mice, which was not changed by ACZ (0.73±0.07 vs 0.69±0.15ml/min) (Figure A). Urinary albumin excretion was reduced with ACZ treatment by 29% (Figure B). The plasma renin activity was not reduced by ACZ in this model.

Conclusions: These results suggest that the long-term oral treatment with ACZ may exert renoprotective effects in obese diabetic models with nephropathy, not due to activation of the TGF system but to better glycemic control.

Inhibition of miR-34a Reduces Podocyte Apoptosis by Targeting Bcl-2 and Autophagy

Yang Liu,[1] Ruixi Li,[1] Wai Han Yiu,[1] Hao-Jia Wu,[1] Dickson W.L. Wong,[1] Joseph C K Leung,[1] Loretta Y.Y. Chan,[1] Kar Neng Lai,[1] Moin Saleem,[2] Peter W. Mathieson,[1,2] Sydney C.W. Tang.[1] *[1]Dept of Medicine, The Univ of Hong Kong, Queen Mary Hospital, Hong Kong, China; [2]Academic and Children's Renal Unit, Univ of Bristol, Bristol, United Kingdom.*

Background: Podocyte apoptosis is a key event in the pathogenesis of diabetic nephropathy. MiR-34a has been reported to be involved in cell proliferation and apoptosis, but its potential roles in podocytes under the diabetic condition remains unknown.

Methods: Type 2 diabetic nephropathy was established by uninephrectomy (Unx) in nine-week-old *db/db* mice. In cultured immortalized human podocytes, miR-34a was over-expressed or knocked down by transfection with miR-34a precursor (pre-34a) or inhibitor (anti-34a), respectively. Podocytes were exposed to glycated human serum albumin (AGEs) and then examined for the expression of apoptosis and autophagy markers. The expression of miR-34a in mouse renal cortex and cultured podocytes were determined by quantitative PCR (Q-PCR) using specific Taqman miRNA assay.

Results: Compared with control group, Unx *db/db* mice(n=7) showed significantly higher expression level of miR-34a in renal cortex. In cultured human podocytes, exposure to AGEs also markedly increased miR-34a expression. The anti-apoptosis genes Bcl-2 and survivin, podocyte cytoskeleton molecule synaptopodin, tight junction protein ZO-1, as well as autophagy marker LC3-II, were all reduced after AGE treatment. Moreover, inhibition of miR-34a by transfection with anti-34a in podocytes prevented AGE-induced apoptosis by rescue of Bcl-2 and LC3-II expression.

Conclusions: Our data demonstrated that miR-34a is involved in podocyte injury under diabetic conditions. Inhibition of miR-34a in podocytes attenuates apoptosis induced by AGEs via enhancing expression of Bcl-2 and regulating autophagy. These results indicate that targeting miR-34a might be a potential therapeutic strategy for diabetic nephropathy. *This study is supported by the National Basic Research Program of China 973 program no. 2012CB517600 (no. 2012CB517606), Small Project Funding (project code 201309176123) from The University of Hong Kong, and Hong Kong Society of Nephrology Research Grant 2014.*

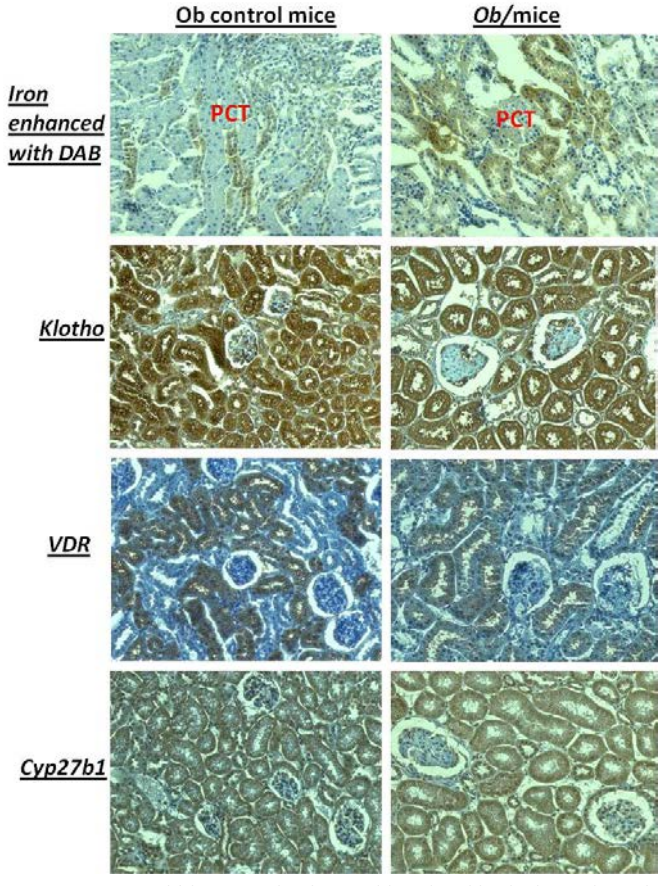
Increased Iron Deposition Is Associated with Decreased α-Klotho and Vitamin D Receptor Expression in the Renal Proximal Tubules in Ob/Ob Mice

Farid M. Nakhoul,[1] Deb Dilip,[1] Inbal Dahan,[2] Lei Li,[1] Yan Chun Li.[1]
[1]Dept of Medicine, Biological Sciences Div, Univ of Chicago, IL; [2]Diabetic Nephropathy Lab, Baruch Padeh Poriya M Ctr, Lower Galilee, Israel.

Background: Diabetic nephropathy is the most common renal complication of diabetes. Diabetes increases oxidative stress and promotes iron deposition in proximal convolute tubules (PCT) of the kidney, leading to renal damage. Mutations in the *LEP* (*ob*) gene product lead to sever obesity and type 2 diabetes, and ob/ob mice in BTBR background develop severe diabetic nephropathy. Klotho and vitamin D receptor (VDR) have been shown to involve in renal protection against diabetic injury. The goal of this study is to assess the relationship between iron deposition and klotho and VDR expression in the kidney of ob/ob mice.

Methods: One- and three-month old ob/ob BTBR mice and ob/+ control mice were studied in parallel. After sacrifice, the kidneys were harvested. The expression of a-klotho, VDR and Cyp27b1 was examined by immunohistochemistry, Western blotting and qRT-PCR, and iron deposition was assessed by staining with Perl's enhanced with Dab.

Results: Compared with ob/+ mice, ob/ob BTBR mice showed increased iron deposition in the PCT and decreased expression of a-klotho, VDR and Cyp27b1 in the renal PCT and kidney lysates.



Conclusions: In ob/ob BTBR mice, increased iron deposition in the renal PCT is associated with a decrease in klotho expression, vitamin D hormone synthesis and VDR signaling in the PCT . These changes together contribute to the progression of diabetic renal injury in these mutant mice, and future treatments.

Erythropietin Protects Endothelial Cells from High Glucose Induced Injury

Haruka Yasuda,[1] Yasunori Iwata,[2,3] Kengo Furuichi,[3,4] Takashi Wada.[1,3]
[1]Dept of Laboratory Medicine, Kanazawa Univ, Kanazawa, Japan; [2]Div of Infection Control, Kanazawa Univ, Kanazawa, Japan; [3]Div of Nephrology, Kanazawa Univ, Kanazawa, Japan; [4]Div of Blood Purification, Kanazawa Univ, Kanazawa, Japan.

Background: Diabetic nephropathy (DN) is a major cause of end stage kidney disease and a strong risk factor for cardiovascular diseases. High glucose induces endothelial injury in vasculature, resulting in tissue injury in diabetic condition. Chronic inflammation has been reported to play an important role for the progression of high glucose induced cell injury. Growing data showed that erythropoietin (EPO) protect the tissues from some kind of injury, such as hypoxia and mechanical stress. However, the contribution of EPO to high glucose induced the aberrant immune balance remains to be explored. Therefore, we hypothesized that EPO modulates endothelial cells from high glucose (HG) induced injury via the regulation of inflammatory and anti-inflammatory balance.

Methods: To explore this possibility, we performed genome-wide transcriptome profiling in human umbilical vein endothelial cells (HUVEC), which were stimulated by high glucose (HG) with/without EPO treatment and detected the expression of inflammation associated genes.

Results: Hieralchial clustering and principal component analysis showed the different pattern of mRNA expression in HG stimulated HUVEC with/without EPO. While inflammatory cytokines/chemokines mRNA expression were increased by the HG stimulation in HUVEC, Th2 related cytokine receptors and intracellular signaling molecules showed the reduced mRNA expression levels. EPO treatment reduced inflammatory cytokines/chemokines mRNA expression and increased Th2 related cytokine mRNA expression levels. Real-time PCR analysis confirmed the increased expression of inflammatory related genes, those were decreased in HG stimulated HUVEC with EPO treatment. Moreover, EPO stimulation increased mRNA expression of EPO receptor and b-common receptor. EPO signaling affect neither cell proliferation nor cell death.

Conclusions: Taken together, EPO signaling might protect high glucose induced cell injury by the regulation of immune balance.

PUB289

The Possible Mechanisms of Ameliorating Diabetic Mice Renal Insulin Resistance by NF-κB Inhibitor Parthenolide

Xuemei Li, Baobao Wang.
Nephrology, Peking Union Medical College Hospital, China.

Background: Diabetic nephropathy (DN) was the severe complication of Diabetes Mellitus (DM). The treatment of DN was limited. Insulin resistance(IR)was associated with diabetic complications. The concrete forms of insulin resistance in diabetic renal tissue lacked research. AS160 could regulate the transportation of many transporters including glucose transporters. In kidney, AS160 was found can regulate sodium and water channel protein, while its role on glucose transporters has not been reported. Glucose transporter 4 (GLUT4) was an important effector of insulin signaling, which related to insulin resistance closely. Sodium glucose transporter 2 (SGLT2) and sodium glucose transporter 1(SGLT1) were important to promote renal tubular glucose re-absorption and were the new target of anti-diabetic drug. Our previous results showed NF-κB inhibitor Parthenolide (PTN) could improve db/db mice systemic insulin resistance and renal tissues injury. The aim of the study was to study the expression of AS160 and GLUT4 in diabetic kidney tissue and correlation between AS160 with GLUT4 and SGLT2/SGLT1.To explore whether PTN could improve renal IR and the possible mechanisms.

Methods: Set up db/m mice as control group, the db/db mice as diabetic nephropathy model group and db/db mice with PTN intervention as treatment group. The mice were sacrificed at week 8, 12, 16 and 20 and using blood, urine and kidney specimens for the study.

Results: 1) The db/db mice showed increased body weight, blood cholesterol, blood glucose and insulin, as well as glomerular hypertrophy and the increased mesangial matrix. PTN could improve the systemic insulin resistance and renal pathological changes of db/db mice. 2) AS160 and p-AS160, GLUT4 were all mainly expressed in renal tubules.3) The expression of p-AS160 and GLUT4 reduced gradually in db/db mice kidney with the increase of weeks.4) p-AS160 showed co-expression with part of GLUT4, but no significant co-expression with SGLT2/SGLT1.

Conclusions: The diabetic kidney tissue may have insulin resistance resulted from abnormal glucose transport by AS160 and GLUT4. The NF-κB inhibitor improved kidney insulin resistance may by increasing the expression of p-AS160 and GLUT4.

Hypertension Results in Moderate Diabetic Nephropathy in a Mouse Model of Metabolic Syndrome

Reinout Stoop,[1] Arianne van Koppen,[1,2] Roel Goldschmeding.[2]
[1]MHR, TNO, Leiden, Netherlands; [2]Pathology, UMCU, Utrecht, Netherlands.

Background: Diabetic nephropathy (DN) is a major complication in metabolic syndrome/diabetes patients. We have developed a metabolic syndrome mouse model characterized by non-alcoholic steatohepatitis and atherosclerosis upon high fat diet feeding. These animals show mild renal changes, but don't progress to moderate DN. Therefore, we investigate whether inducing hypertension on top of metabolic syndrome leads to progression of DN.

Methods: Male LDLr-/- mice (8 wk old) received high fat (45%) + high salt (6%) diet for 6 wk. To induce hypertension, combinations of several pro-hypertensive components were used (uninephrectomy (UNX), angiotensin II (ANGII), DOCA and a vasoconstrictor) for an additional 10 wk. At regular intervals, systolic blood pressure (SBP), 24h diuresis and albumin/creatinine ratio (UACR) were assessed. 17 wk after start diet, mice were terminated and renal injury was scored. We used age-matched chow fed animals as controls.

Results: Cholesterol and diuresis were significantly elevated in all groups vs chow from wk 5 onwards. ANGII induced a 20 mmHg increase in SBP at wk 13 vs. chow. At wk 8, UACR was significantly increased by ANGII in combination with HFD+HS (264±303µg/mg) and UNX+HFD+HS (438±781µg/mg) vs chow (62±24µg/mg). At wk 13, ANGII further elevated UACR in HFD+HS (593±737µg/mg) but decreased it in UNX+HFD+HS (287±263µg/mg). Combining ANGII, DOCA and L-NNA strongly induced albuminuria (717 ±585µg/mg) at wk 5 but also caused fatal thoracic bleedings. This group was terminated at wk 11. Renal injury score showed glomerular hypertrophy, mesangium expansion, nodular glomerulosclerosis, mild hyalinosis and micro-aneurisms.

Conclusions: We show that exposure of LDLr-/- mice to HFD+HS and ANGII induces hypertension and mild progressive DN, in addition to NASH and atherosclerosis in a single

model providing broad coverage of metabolic syndrome complications. Administration of additional hypertensive compounds (DOCA and L-NNA) further aggravated the model but also led to early fatal thoracic bleedings thus precluding further studies.

PUB291

Autophagy Activation in Proximal Tubular Epithelial Cells in Diabetic Nephropathy Acts as a Renoprotective Role Ying Xu,[1] Lei Liu,[2] Wei Xin,[2] Xu Zhao,[2] Liyong Chen,[2] Qiang Wan.[3] *[1]Renal Div, Shandong Provincial Hospital Affiliated to Shandong Univ, Jinan, Shandong, China; [2]Shandong Provincial Hospital Affiliated to Shandong Univ, Jinan, Shandong, China; [3]Shandong Provincial Qianfoshan Hospital Affiliated to Shandong Univ, Jinan, Shandong, China.*

Background: Previous studies revealed that lipotoxicity participated in epithelial-to-mesenchymal transition (EMT) of proximal tubular epithelial cells (PTECs) under diabetic conditions. Based on evidences that autophagy and lipid metabolism are closely related, the aim of the present study was to investigate autophagy under diabetic conditions and its role in lipotoxicity and EMT.

Methods: HK-2 cells were cultured in normal (5.5 mmol/L glucose) and high glucose medium (30 mmol/L glucose). At 6h, 24h, 48h, and 96h, autophagy activity was evaluated by western blot of LC3I/II, Beclin1 and p62. Next, the inhibition of autophagy was achieved by chloroquine diphosphate (CQ), 3-methyladenine (3-MA), or *Atg5* knockdown using siRNA transfection. Rapamycin, which is a mammalian target of rapamycin (mTOR) receptor specific inhibitor and a known autophagy activator, was used to induce autophagy in HK-2 cells. Lipid accumulation was detected by Oil-Red O staining; EMT was estimated by western blot of vimentin and E-cadherin.

Results: In high glucose cultured HK-2 cells, Beclin1 and LC3-II were elevated, while p62 was decreased. These results indicate that autophagy activity was elevated under diabetic conditions. Autophagy deficiency induced by autophagy inhibitors, CQ and 3-MA, or by *Atg5* siRNA transfection exacerbated lipid accumulation and EMT. Treatment of rapamycin attenuated high glucose induced lipid accumulation and EMT. The *Atg5* silence counteracted the protective effect of rapamycin.

Conclusions: In conclusion, these results demonstrate that autophagy activity in PTECs is elevated under diabetic conditions and the elevated autophagy activity acts as a renoprotective response.

Insulin Sensitivity Before and Six Months After Kidney Transplantation Morten Buus Jørgensen,[1] Mads Hornum,[1] Gerrit van Hall,[2] Claus Bistrup,[3] Jesper Hansen,[4] Bo Feldt-Rasmussen.[1] *[1]Dept of Nephrology, Rigshospitalet, Denmark; [2]Clinical Metabolomics Core Facility, Rigshospitalet, Denmark; [3]Dept of Nephrology, Odense Univ Hospital, Denmark; [4]Dept of Nephrology, Herlev Univ Hospital, Denmark.*

Background: Severe uraemia is a known cause of insulin resistance. We aimed to investigate the effect of kidney transplantation (Tx) on peripheral and central insulin sensitivity.

Methods: Nine non-diabetic patients awaiting living related kidney Tx were examined prior to Tx (Pre-Tx) with an oral glucose tolerance test (OGTT) and a 3h hyperinsulinaemic euglycaemic clamp. The clamp was repeated six months after Tx (Post-Tx). Nine age, gender and BMI matched individuals with normal kidney function were examined once with an OGTT and clamp serving as controls (Ctrl). Endogenous glucose production (EGP, N = 6), glucose rate of disappearance (Gd, N = 6) and lipolysis (glycerol rate of appearance, N = 5) were measured in a subgroup of patients with corresponding controls using stable isotope tracer technique. Results are in mean mmol/kg/min [95% confidence interval] during the clamp.

Results: Two patients had pre-Tx prediabetes whereas all other had both normal fasting plasma glucose and normal glucose tolerance. The amount of glucose utilized during clamp was non-significantly lower in patients before Tx (Pre-Tx: 15.1 [11.2–19.0], Ctrl: 20.2 [13.4–27.0], P = 0.17) but significantly reduced after Tx (Post-Tx: 9.8 [6.7–12.9], P = 0.01). The suppression of EGP were comparable before Tx (Pre-Tx: 7.0 [5.4–8.5], Ctrl: 7.0 [1.3–12.7], P = 0.99) but was significantly impaired after Tx (Post-Tx: 9.4 [7.8–11.1], P = 0.04). Gd were comparable both prior to and after Tx (Pre-Tx: 18.1 [13.6–22.5], Ctrl: 22.3 [15.1–29.5], Post-Tx: 17.1 [13.4–20.8], P > 0.22). The suppression of glycerol rate of appearance were comparable before Tx (Pre-Tx: 1.1 [0.9–1.4], Ctrl: 1.1 [0.6–2.1], P = 0.96) but significantly impaired after Tx (Post-Tx: 2.0 [1.0–3.8], P = 0.04).

Conclusions: The reduced insulin sensitivity after kidney Tx is characterized by a central insulin resistance with impaired suppression of endogenous glucose production, impaired suppression of lipolysis and comparable peripheral insulin sensitivity.

Renal Functional and Morphological Changes Related to Obesity and Hyperglycemia in Göttingen Minipigs Rikke Lindgaard Thomsen,[1] Berit Østergaard Christoffersen,[2] Trine P. Ludvigsen,[2] Rikke Kaae Kirk,[2] Jonas Kildegaard,[2] Lisa Tidman Fuchs,[1] Pall Leifsson,[1] Henrik D. Pedersen,[2] Lisbeth Høier Olsen.[1] *[1]Dept of Veterinary Disease Biology, Univ of Copenhagen, Frederiksberg, Denmark; [2]Novo Nordisk A/S, Maaloev, Denmark.*

Background: Obesity and diabetes, two major health problems worldwide, both lead to renal functional and morphological changes; with diabetic nephropathy being the leading cause of end-stage renal failure. A large animal model displaying human-like features of obesity-related and diabetic nephropathy would be very valuable to study pathogenesis and effects of new drug candidates on these syndromes. The aim of the present study was to evaluate renal function and morphology in diet-fed obese, atherosclerotic Göttingen minipigs with or without mild diabetes.

Methods: Male castrated Göttingen minipigs, aged 8 weeks at study start, were fed normal chow (n=6) or high-fat, high-cholesterol diet (n=16) for 43 weeks. Mild diabetes was induced in 11 pigs after 18 (n=6) and 25 (n=5) weeks of diet-feeding, using streptozotocin (125 mg/kg IV) preceded by nicotinamide (67 mg/kg IV). The study included two cohorts. Parameters of interest were: Body fat percentage (BF) estimated by dual-energy X-ray absorptiometry, inulin clearance (IC), kidney resistive index (RI), plasma fructosamine reflecting plasma glucose (FRA), plasma urea, plasma creatinine (PCr), plasma total cholesterol (TC), urinary protein excretion (protein (UPCr) and albumin (UACr) adjusted for creatinine). Glomerulus area and number of nuclei/glomerulus area were estimated post mortem. Influence of BF, TC and FRA on in vivo kidney function and post mortem kidney changes was evaluated using ANOVA with cohort as fixed covariate.

Results: BF was positively associated with urea (P<0.01), IC (P<0.05), Glomerulus area (P<0.001) and UPCr (P=0.05), and negatively with PCr (P<0.001). FRA was positively associated with UACr (P<0.05) and number of nuclei/glomerulus area (P<0.05). RI was not associated with BF, TC or FRA.

Conclusions: In conclusion, functional and histological renal changes were found in diet-fed obese, atherosclerotic Göttingen minipigs with and without mild diabetes. The changes were associated with obesity and hyperglycemia.

PUB294

Activation of Toll-Like Receptors Through Fetuin-A Leads to an Inflammatory Response in Podocytes and Exacerbates Palmitic Acid-Induced Cell Death Jana Orellana,[1] Kapil Dev Kampe,[1] Andreas Werner Jehle.[1] *[1]Dept of Biomedicine, Univ Hospital Basel, Basel, Switzerland; [2]Dept of Biomedicine, Univ Hospital Basel, Basel, Switzerland; [3]Dept of Biomedicine, Univ Hospital Basel, Basel, Switzerland.*

Background: Inflammation participates in the pathogenesis of type 2 diabetes and contributes to diabetic nephropathy (DN). There is growing evidence that chronic elevated free fatty acids (FFAs) contribute to this chronic inflammatory milieu. Studies in pancreatic β-cells suggest that the inflammatory response mediated by FFAs depends on toll-like receptor (TLR) 4 and Il-1 receptor (Il-1R). The signaling pathways of TLRs and Il-1R involve activation of the transcription factor nuclear factor-κB (NF- κB) which induces a wide range of cytokines/chemokines including monocyte-chemoattractant protein-1 (MCP-1), and Il-1β. Here, we addressed whether fetuin-A together with FFAs leads to an inflammatory response in podocytes and whether this exacerbates palmitic acid-induced podocyte death.

Methods: Conditionally immortalized murine podocytes were used. Murine and bovine fetuin-A were used alone or in combination with palmitic acid complex to BSA. MCP-1 was measured by ELISA. Podocyte death was determined by flow cytometry (annexin V and propidium iodide staining).

Results: Palmitic acid alone did not, but fetuin-A induced MCP-1 in podocytes and this was further increased by palmitic acid. The MCP-1 release was prevented by ClO95 (TLR4 blocker). Fetuin-A or LPS exacerbated palmitic acid induced podocyte death, and CLI095 as well as the IL1 receptor antagonist anakinra or an anti IL1β antibody attenuated cell death.

Conclusions: Fetuin-A alone and in combination with palmitic acid leads to an inflammatory response in podocytes and promotes palmitic acid induced podocyte death. As inhibition of TLR4 as well as Il1 β prevents these effects, both pathways are promising targets to attenuate the progression of DN.

IL-1β Mediates the High Glucose Induced Endothelial-to-Mesenchymal Transition in Human Aortic Endothelial Cells Dongdong Zhu, Ri-ning Tang, Kun Ling Ma, Bi-Cheng Liu. *Zhong Da Hospital, Southeast Univ Medical School, Nanjing, Jiangsu.*

Background: Studies have shown that endothelial-to-mesenchymal transition (EndMT) induced by high glucose(HG) contributed to cardiac fibrosis.Additionally, proinflammatory cytokine interleukin-1β (IL-1β) has been implicated as one of the dominant players in the development of fibrosis and diabetic heart. In vitro studies , retinal endothelial cells(ECs), human intestinal ECs and human dermal ECs have been reported to undergo EndMT by

IL-1β stimulation.Interestinly, most IL-1β immunoreactivity is localized to endothelial cells and interstitial macrophages in an animal model of cardiac hypertrophy .However, the potential role of IL-1β in high glucose induced EndMT remain unknown. Here, we hypothesize that IL-1β might mediate the process.

Methods: Primary human aortic endothelial cells (HAECs) were divided into three groups: a normal glucose (NG) group, HG group, and anti- interleukin1β antibody treated (HG+Anti-IL-1β) group. The concentration of IL-1β in the supernatant was detected by Elisa. Pathological changes were investigated using fluorescence microscopy and electron microscopy. Immunofluorescence staining was performed to detect the co-expression of CD31 and FSP1. The expressions of FSP1 and a-SMA were detected by RT-PCR and Western blot.

Results: The treatment of HAECs in the HG group resulted in significant increases in the expressions of FSP1 , aSMA and IL-1β in dose-and time-dependent manners. The incubation of HAECs exposure to HG resulted in a fibroblast-like phenotype, wherein increased microfilamentation and a roughened endoplasmic reticulum structure were observed in the cytoplasm. The expressions of FSP1 and a-SMA were significantly increased in the HG group, and these changes were inhibited by anti interleukin1antibody or Il-1bsiRNA treatment ($P < 0.05$). Double staining of the HAECs indicated a colocalization of CD31 and FSP1, while treatment with anti-interleukin1bantibody or Il-1β siRNA attenuated the expression of EndMT ($P < 0.05$).

Conclusions: These findings suggest that IL-1β mediates the HG induced EndMT, which was inhibited by anti- interleukin1bantibody orIL-1β siRNA treatment.

PUB296

Serum Bilirubin and Asparagine Aminotransferase Concentrations Predict Loss of Renal Function in Type 2 Diabetes Kevin M. Wheelock,[1] Gudeta D. Fufaa,[1] William Knowler,[1] Madhumita Sinha,[1] Frank C. Brosius,[2] Robert G. Nelson.[1] *[1]NIDDK, Phoenix, AZ; [2]Univ of Michigan, Ann Arbor, MI.*

Background: Higher serum bilirubin concentration is reported to slow the progression of nephropathy in type 2 diabetes. We examined associations of serum bilirubin and asparagine aminotransferase (AST) concentrations with renal function loss (RFL) in a post-hoc analysis of a clinical trial of renoprotection with losartan in Pima Indians with type 2 diabetes (ClinicalTrials.gov number, NCT00340678).

Methods: Serum bilirubin and AST were measured at baseline in 168 subjects who underwent annual measurement of GFR by the urinary clearance of iothalamate. RFL was defined by ≥40% decline in GFR from baseline. Cox regression was used to compute hazard ratios (HRs) for the association of a 1 standard deviation (SD) increment in bilirubin and AST concentrations with RFL adjusted for age, sex, treatment group, HbA1c, GFR, and urinary albumin/creatinine ratio (ACR). The sum of standardized AST and bilirubin was standardized to create a liver index variable with mean=0, SD=1.

Results: Participants (73% female, mean age 42±11 years, bilirubin 0.6±0.2 mg/dL, HbA1c 9.3±2.2%, GFR 163±43 ml/min, and median AST 19 U/L (IQR=13.0-31.5 U/L), ACR 31 mg/g (IQR=12-77 mg/g)) were followed for a median of 7.0 years (IQR=4.5-9.9 years); 73 subjects (43%) developed RFL. After multivariable adjustment, serum bilirubin (HR=1.33) and serum AST (HR=1.39) predicted RFL. The combination of these liver function tests provided the strongest prediction (HR=1.52).

	Renal Function Loss (95% CI), P-value	
Variable	Univariate	Multivariate
Log AST (per SD)	1.34 (1.04-1.74), *P*=0.025	1.39 (1.07-1.80), *P*=0.015
Bilirubin (per SD)	1.30 (1.05-1.62), *P*=0.016	1.33 (1.05-1.67), *P*=0.017
Liver index (per SD)	1.43 (1.13-1.81), *P*=0.003	1.52 (1.18-1.95), *P*=0.001

Conclusions: Higher serum bilirubin and AST concentrations predict loss of renal function in Pima Indians with type 2 diabetes.

Baseline Data from the Multinational Prospective Cohort Study in Patients with Type 2 Diabetes for Validation of Biomarkers (PROVALID) Gert J. Mayer,[1] Susanne Eder,[1] Laszlo Rosivall,[2] Peter Voros,[3] Hiddo Jan Lambers Heerspink,[3] Dick de Zeeuw,[3] Beata Czerwienska,[4] Andrzej Wiecek,[4] Dianne Z. Hillyard,[5] Patrick B. Mark,[5] Georg Heinze,[6] Peter Rossing.[7] *[1]Internal Medicine IV, Medical Univ Innsbruck, Innsbruck, Austria; [2]Inst of Pathophysiology, Semmelweis Univ, Budapest, Hungary; [3]Egyesitett Szent Istvan es Szent Laszlo Korhaz, Budapest, Hungary; [4]Dept Clinical Pharmacy and Pharmcology, Univ Medical Center Groningen, Groningen, Netherlands; [5]Dept of Nephrology, Transplantation and Internal Medicine, Medical Univ Silesia, Katowice, Poland; [6]Inst of Cardiovascular and Medical Sciences, Univ of Glasgow, Glasgow, United Kingdom; [7]Section for Clinical Biometrics, Medical Univ Vienna, Vienna, Austria; [8]STENO Diabetes Center, Gentofte, Denmark.*

Background: We recruited 4065 subjects at the primary healthcare level in Austria, Hungary, Netherlands, Poland and Scotland, who will be treated according to local practise and followed for 4 years to compare the incidence and progression of renal and cardiovascular disease between the countries. Additionally extensive biobanking is performed.

Methods: We will determine the cumulative incidence of progression of albuminuria, doubling of creatinine, end stage renal disease as well as fatal and not fatal cardiovascular events. Exclusion criteria are active malignancy and age <18 years.

Results: The mean age of the population was 62 years, mean duration of diabetes as 9.9 years. 9% of the patients had eGFR values <45 and 22% <60 ml/min/1.73m^2. Baseline data

	"lowest" country	"highest" country
SBP (mmHg)	134±15	140±19
DBP (mmHg)	78±9	84±12
HbA1c (%)	6.7±1.1	7.3±1.4
eGFR<45 (%)	4	12
albuminuria (mg/day)	8 (5,26)	15 (6,40)
microalbuminuria (%)	10	26
LDL cholesterol (mg%)	91±34	118±39

We observed marked variability in treatment pattern between the countries (use of metformin 49-74, RAS blocking agents 59-77, β-blockers 28-59, statins 21-81%).

Conclusions: We conclude that health care practices in patients with type 2 diabetes at the primary level of care vary widely between European countries. Whether these differences affect outcome remains to be established.

PUB298

FGF-23 and Magnesium Are Independent Risk Factors for an Increased Albumin-to-Creatinine Ratio in Type 2 Diabetics with Chronic Kidney Disease Filipa Brito Mendes,[1] Ana Paula Silva,[1,2] André Fragoso,[1] Nélio Santos,[1] Teresa M. Jeronimo,[1] Ana Pocinho Pimentel,[1] Pedro L. Neves.[1,2] *[1]Centro Hospitalar do Algarve- Hospital de Faro, Portugal; [2]Univ do Algarve, Portugal.*

Background: Microalbuminuria is the earliest sign of glomerular involvement in diabetes mellitus. The multiple physiopathological mechanisms involved are complex and not completely understood. Recently, it appeared that fibroblast growth factor- 23 (FGF-23) and magnesium play a role in the emergence and maintenance of albuminuria in type 2 diabetics. The aim of this study is to investigate the role of FGF-23 and magnesium in relation to the urine albumin-to-creatinine ratio in type 2 diabetics with chronic kidney disease (CKD) stages 2-4.

Methods: In a cross-sectional study we included all eligible type 2 diabetic patients with CKD stages 2-4, followed in our outpatient Diabetic Kidney clinic. We included 150 patients, f=53 m=97, with a mean age of 66.6±9.7 years (40-85) and a mean follow-up of 76 months. We used descriptive statistics, the Student's test, ANOVA and the chi-square test. We divided our population according to the urine albumin-to-creatinine ratio (GI=30-300 mg/g and G2³300 mg/g) and compared these groups regarding the several biological and laboratorial parameters analyzed. We employed a multiple regression model to identify risk factors of increased urine albumin-to-creatinine ratio. In this model we used the urine albumin-to-creatinine ratio as the dependent variable and as independent ones age, duration of diabetes, systolic blood pressure, HgA1c, eGFR, HOMA-IR, manonaldehyde, hs-CRP and $1,25(OH)_2D3$ levels.

Results: The patients in G2 displayed a lower eGFR (p=0.0001) and magnesium (p=0.004) levels, as well as higher levels of FGF-23 (p=0.043) compared to patients in G1. In the multivariate linear regression model we found that FGF-23 (β=0.562, P=0.0001) and the magnesium (β=-8.916,p=0.0001) are independent risk factors for increasing the urine albumin-to-creatinine ratio.

Conclusions: The present study shows that a dysregulation of mineral metabolism, reflected by altered levels of magnesium and FGF-23, correlates with an increased urine albumin-to-creatinine ratio in type 2 diabetic patients with CKD stages 2-4.

PUB299

FGF-23 and Klotho Influence the Pulse Pressure in Diabetic Patients with Nephropathy Ana Paula Silva,[1,2] Filipa Brito Mendes,[1] André Fragoso,[1] Teresa M. Jeronimo,[1] Ana Pocinho Pimentel,[1] Nélio Santos,[1] Pedro L. Neves.[1,2] *[1]Nephrology, Centro Hospitalar do Algarve, Faro, Portugal; [2]Dept of Biomedical Sciences and Medicine, Univ of Algarve, Faro, Portugal.*

Background: The last decade have shown that FGF23 and Klotho may have relevant independent actions on the renal and CV systems. They interfere with vascular functions and may play a role in vascular calcification, atherosclerosis and arteriolosclerosis. Their interactive activities may also have direct and indirect effects on interdependent renal and CV pathophysiology. The aim of this study is to investigate the relationship between FGF-23 and Klotho with pulse pressure in type 2 diabetic with chronic kidney disease (CKD) stages 2-3.

Methods: In a cross-sectional study we included 107 type 2 diabetic patients (67 males, 62,6%), a mean age of 66.6 ±9.7 years and CKD stage 2-3.We used descriptive statistics, the Student´s t and the chi-square tests. We also divided our population according to the pulse pressure (G I <50 mmHg and G2 ≥ 50 mmHg), and compared these groups regarding the several biological and laboratorial parameters analyzed. We employed a multiple regression model to identify risk factors of increased pulse pressure (PP). In this model we used as dependent variable the pulse pressure, and as independent ones age, metabolism mineral, urine albumin-to-creatinine ratio, insulin resistance, oxidative stress and eGFR.

Results: We found that G2 patients showed higher age (p=0.017), phosphorus (p=0.0001), iPTH (p=0.0001), urine albumin-to-creatinine ratio (p=0.001), Homa-IR (p=0.001), FGF-23 (p=0.0001) and OxLDL (p=0.0001) and lower levels of eGFR (p=0.0001), Klotho (p=0.0001) and 1.25(OH)2D3 (p=0.0001). In the multivariate linear regression model we found that FGF-23 (β=0.377, P=0.047) and the Klotho (β= - 0.567, p=0.023) are independent risk factors for increasing the pulse pressure.

Conclusions: In conclusion, in a population of type 2 diabetic with chronic kidney disease stages 2-3, the Klotho and FGF-23 levels are independently associated with PP. Further studies with more patients are warranted to confirm whether an increase in Klotho and a decrease in FGF-23 would reduce the PP and consequently the cardiovascular risk of our patients.

Prediction of Renal Outcome in Type 2 Diabetic Dephropathy by Estimating GFR from a Combination of Serum Creatinine and Cystatin C

Yu Pan, Song Jiang, Dandan Qiu, Yu An, Yongchun Ge, Honglang Xie, Zhihong Liu. *National Clinical Research Center of Kidney Diseases, Research Inst of Nephrology, Jinling Hospital, Nanjing, Jiangsu, China.*

Background: Serum cystatin C is an alternative to serum creatinine for estimating glomerular filtration rate (GFR), however, the utility of estimated GFR from combination of serum creatinine and cystatin C as marker to predict long-term renal outcome is uncertain, particularly in the Type 2 diabetic nephropathy (DN).

Methods: A total of 501 patients (The National Clinical Research Center of Kidney Diseases, 2003-2011) were recruited in prospective cohort study. Follow-up was 5-year. Renal outcome was defined by eGFRcre-cys<15 ml/min per 1.73m^2 or renal replacement therapy.

Results: The distributions of standardized serum cystatin C with eGFRcre and eGFRcre-cys are shown in. Kaplan-Meier curves showed significantly increased renal end points with higher quartile of cystatin C (p <0.001) and lower eGFRcre-cys (p <0.001). The highest AUROCs was eGFRcre-cys in predicting the renal endpoint compared with eGFRcre or eGFRcys.The best cut-off value for predicting the renal endpoint was 29.28% decline in the 24-month, which value showed 79.6% sensitivity and 82.6% specificity. Cox regression models with restricted cubic splines were shows a change of -30% in eGFRcre-cys was associated with adjusted HRs for ESRD of 27.92 (95%CI, 3.95-197.48) over 2-year.

Conclusions: eGFRcre-cys was a precision, and accuracy marker in the predicting of the renal outcome and 30% decline of eGFRcre-cys over 2 years was strongly associated with the risk of ESRD, suggesting it could be used as an alternative end point in T2DN.

Prevalence and Prognostic Role of Uncontrolled Risk Factors in Diabetic CKD (DM-CKD) Treated in Nephrology Clinics

Roberto Minutolo,[1] Michele Provenzano,[1] Paolo Chiodini,[2] Giuseppe Conte,[1] Luca De Nicola.[1] *[1]Nephrology, Second Univ, Naples, Italy; [2]Med Stat, Second Univ, Naples, Italy.*

Background: Knowledge of prognosis of DM-CKD mainly derives from RCTs and cohorts followed in the diabetology setting. Epidemiologic features are less defined in patients with overt disease managed in renal clinics.

Methods: We studied 763 DM-CKD patients derived from 3 prospective cohorts that in 2000-2010 enrolled 2,488 CKD patients stage III-V under stable care from ≥6 months in 40 Italian renal clinics. Endpoints were ESRD (chronic dialysis-transplant) and first major cardiovascular (CV) events (fatal and non fatal) assessed through 12/2014. Uncontrolled risk factors were defined as high blood pressure (BP>140/90 or >130/80 if proteinuria >0.150 g/24h), HbA1c >7.5%, hemoglobin <10.5 g/dL, serum phosphorus (P) >4.5 mg/dL, LDL-C ³100 or 70 mg/dL according to ESC 2012 guidelines, proteinuria (Uprot) >0.5 g/24h.

Results: HbA1c was 6.9%, (IQR 6.2-7.8), Uprot 0.5 g/24h (IQR 0.1-1.4), P 3.9±0.8 mg/dL, Hb 12.3±1.7 g/dL and BP 142±19/78±11 mmHg. During follow-up (43 months, IQR 21-56), 171 ESRD and 170 CV events occurred (incidence rate 6.4 and 6.9/100 pts/y). Multivariable Cox analyses for ESRD and CV risks (HR, 95% CI) stratified by cohort are in the Table.

	Descriptive	ESRD	CV
Age, years	70±10	**0.98 (0.96-0.99)**	**1.03 (1.02-1.05)**
Males, %	57.9	**1.93 (1.36-2.72)**	1.36 (0.97-1.91)
Smokers, %	9.7	1.07 (0.62-1.87)	1.06 (0.60-1.88)
CV disease, %	46.7	**1.56 (1.13-2.15)**	**1.77 (1.29-2.43)**
BMI, Kg/m^2	29.3±5.3	1.00 (0.97-1.03)	1.00 (0.97-1.03)
GFR-EPI, ml/min/1.73m^2	31.2±14.1	**0.90 (0.88-0.92)**	**0.97 (0.96-0.99)**
High BP, %	53.1	1.30 (0.91-1.88)	**1.60 (1.13-2.26)**
HbA1c>7.5, %	33.0	0.78 (0.55-1.10)	**1.45 (1.06-1.99)**
Hemoglobin<10.5, %	13.8	**1.58 (1.09-2.28)**	1.43 (0.94-2.18)
LDL-C≥100-70, %	83.6	1.01 (0.66-1.56)	1.03 (0.65-1.62)
Uprot>0.5, %	49.8	**1.95 (1.26-3.00)**	1.07 (0.74-1.54)
P>4.5, %	18.1	**1.49 (1.05-2.12)**	0.92 (0.60-1.41)
Anti-RAS, %	78.6	0.98 (0.67-1.44)	1.04 (0.71-1.54)

Similar results were obtained when testing continuous variables.

Conclusions: Epidemiologic peculiarities emerge in DM-CKD patients treated in renal clinics. This information can be helpful to optimize risk stratification and adequately design RCTs.

PUB302

Serum NGAL and Cystatin C Accuracy in Early Detection of Kidney Dysfunction in Type 2 Diabetes

Marcelo Rodrigues Bacci, Fernando Luiz affonso Fonseca, Livia Yadoya Vasconcelos, Mariana Rigolo, Ross Rozier-Alves, Beatriz Alves. *General Practice, ABC Medical School, Brazil.*

Background: Diabetic nephropathy is associated with specific histological changes. An early detection of depletion of glomerular and tubular function can be done with biomarkers of diabetic disease.The aim of this study is to evaluate the accuracy of early kidney dysfunction biomarkers in diabetes.

Methods: Patients with diabetes were splited according to their levels of glycated hemoglobin(GHb):greater than 7% or below this value.Urine samples were taken to measure cystatin C(uCYS),uNGAL,beta-trace protein(uBTP) and albuminuria(ACR).In blood,sCYS sNGAL,creatinine.Patients with end stage renal disease or in dialysis were not included. ROC curve was used to evaluate the accuracy of the markers relative to renal dysfunction according to their simplified MDRD estimated glomerular filtration rate(eGFR).Spearman's correlation and regression models were built to evaluate the markers.

Results: Ninety patients with diabetes were recruited.The mean eGFR was 79.1ml/min/1.73m and 76.7 in GHb> 7% group.sCYS was positively correlated with creatinine(p<0.001),eGFR(p<0.001) and uBTP(p=0.01).The ROC curve showed value of 0.635 for sCYS,0621 to sNGAL and 0.660 for ACR.Urine had lower values for CYS(0.569),0.526 for NGAL and 0.567 for uBTP.The crude logistics regression model observed a positive association between sCYS(p=0.01) and sNGAL(p<0.001).The linear regression model showed positive association with sCYS and creatinine and eGFR(p<0.001) but not with GHb(p=0.892).ACR showed the same parameters(p=0.005 for creatinine and 0.018 to eGFR).

Conclusions: In this study,a comparative panel of tubular and glomerular dysfunction markers was built in diabetics with eGFR>60.There was a worse performance of the markers in urine except for ACR that had the best value in ROC analysis.The sCYS and sNGAL presented the best association with worse GFR and glicemic control.In another study of our group uBTP had better performance to distinguish early kidney disfunction between diabetics and non diabetics.Finally,with worse eGFR, sNGAL, sCYS and ACR performed better in diabetics.A worse glycemic control was positively associated with sCYS and sNGAL.

PUB303

Comparison of Renal Outcome Between "Chronic Kidney Disease due to Diabetes" and "Chronic Kidney Disease with Diabetes" in Gonryo Study

Toshiki Iwai,[2] Mariko Miyazaki,[1] Gen Yamada,[1] Tae Yamamoto,[1] Hiroshi Sato,[2] Masaaki Nakayama,[3] Sadayoshi Ito.[1] *[1]Nephrology, Hypertension, and Endocrinology, Tohoku Univ Deparment of Pharmacology, Sendai, Miyagi, Japan; [2]Clinical Pharamacology and Therapeutics, Graduate School of Pharmaceutical Sciences, Tohoku Univ, Sendai, Japan; [3]Kidney and Hypertension, Fukushima Medical Univ, Fukushima, Japan.*

Background: Diabetic nephropathy (DN) is defined as chronic kidney disease (CKD) due to diabetes mellitus (DM) in a narrow sense. The difference is not unclear between DN and CKD patients of other cause but complicated DM (CKD with DM) in clinical outcome. This study mentioned the clinical difference and renal outcome of DN, CKD with DM, and CKD without DM.

Methods: This is a part of Gonryo CKD study. It is the multicenter prospective observational survey for 5 years. From May 2006, 4,015 patients were registered. We include 2,484 of them into this analysis who could classify to DN (n=249), CKD with DM(n=448), and CKD without DM (n=1,787). The classification was performed at registration by clinical finding and history of other diabetic complication such as retinopathy if case without kidney biopsy.

Results: The characteristics of age, gender, systolic blood pressure (SBP), and dyslipidemia in "DN"(66.6 y.o., male 67.9%, sBP 136.6mmHg, dyslipidemia 50.1%) and "CKD with DM"(58.7 y.o. male 58.7%, sBP 132.3mmHg dyslipidemia 54.4%) were similar compared with "CKD without DM"(50.5 y.o, male 50.5%, 129.8 mmHg, 40.1%) . For renal outcome analysis of each CKD stage was performed. The hazard ratio of "DN" was significantly higher than "CKD without DN" for end stage kidney disease (ESKD) in G3b 7.10(2.46-20.49 95% CI), G4 2.31(1.35-3.94), G5 1.67(1.16-2.42). On the other hand, that of "CKD with DM" didn't elevate in G3b 0.89(0.19-4.24 95% CI), G4 1.21(0.66-2.23), G5 1.36(0.74-2.51) compared with "CKD without DM" . Kaplan-Meier analysis revealed G3b and G4 in "DN" showed significantly poor outcome. The evaluation of annual decline of eGFR revealed stage G3b in DN was the largest. (-3.7 ml/min/1.73m^2/year).

Conclusions: Renal risk between "CKD with DM" and "DN" was completely different. G3b was most important critical point in renal prognosis of DN.

PUB304

Prevalence of Proteinuria, Albuminuria and Associated Factors in Obese Patients Undergoing Bariatric Surgery Max R. Pommier, Gaurang P. Mavani, Maria V. DeVita, Michael F. Michelis, Jordan L. Rosenstock. *Dept of Medicine Div of Nephrology, Lenox Hill Hospital Northshore/ LIJ, NYC, NY.*

Background: Obesity is associated with proteinuria. But the exact prevalence of proteinuria or albuminuria with and without additional risk factors in obese patients is unclear.

Methods: Consecutive patients undergoing bariatric surgery were included in study. Participating patients had a urine sample for protein creatinine ratio and albumin creatinine ratio prior to their surgery. We defined a positive protein to creatinine ratio as greater than or equal 300 mg and a positive albumin to creatinine ratio as greater than or equal to 30 mg. Associated factors such diabetes mellitus (DM), hypertension (HTN), body mass index (BMI), and ACEi/ ARB use were collected.

Results: One hundred forty-three patients were included. The mean age was 43 years +/- 11. Twenty five percent of the patients had DM, 50% had HTN, and the mean BMI was 44 +/- 9. The prevalence of proteinuria and albuminuria was 8.5% (95% CI 4.5- 14.4%) and 21% (95% CI 14- 30%) respectively. Sixty six percent of the patients with proteinuria had DM as did 43% of the patients with albuminuria. Eighty three percent of patients with proteinuria had either DM or HTN. Seventy eight percent of patients with albuminuria had either DM or HTN. Of patients with neither DM nor HTN (n=58), only 3.4% and 8.6% had proteinuria and albuminuria respectively. In contrast to patients who did not have proteinuria, the mean BMI was higher in those with proteinuria (44 vs. 40). However, the BMI did not differ between those with and without albuminuria. The BMI for diabetics did not differ from non-diabetics. The use of ACEI/ ARB was 33% and 30% in patients with proteinuria and albuminuria and 25% and 20% in those without.

Conclusions: The majority of patients with proteinuria and albuminuria had diabetes and/or hypertension and there was a much lower prevalence of proteinuria/albuminuria in patients without these risk factors. Patients who had proteinuria had a higher BMI than patients who did not have proteinuria, though for albuminuria the BMI did not differ.

Plasma Uric Acid and Cardio-Renal Function in Adolescents with Type 1 Diabetes Yuliya Lytvyn,[1] Farid H. Mahmud,[2] Livia Deda,[2] David B. Dunger,[3] John Eric Deanfield,[4] Yesmino Elia,[2] Ronnie Lok-Hang Har,[1] Timothy J. Bradley,[5] Rahim Moineddin,[6] Heather N. Reich,[1] James W. Scholey,[1] Luc Mertens,[5] Etienne Bertrand Sochett,[2] David Cherney.[1] *[1]Nephrology, Univ Health Network, Univ of Toronto; [2]Endocrinology, The Hospital for Sick Children, Univ of Toronto; [3]Pediatrics, Univ of Cambridge, Cambridge, United Kingdom; [4]Univ College Hospital, London, United Kingdom; [5]Cardiology, The Hospital for Sick Children, Univ of Toronto; [6]Family and Community Medicine, Univ of Toronto.*

Background: Plasma uric acid (PUA) correlates with higher blood pressure (BP), lower GFR and lower renal blood flow in adults with type 1 diabetes (T1D). Our overall aim was to determine if similar relationships exist in adolescents with T1D, analyzed on the basis of low-, middle- or high- albumin to creatinine ratio (ACR) tertile within the normal range, compared to healthy controls (HC). We hypothesized that PUA within the normal range would be associated with lower GFR and higher values for BP and arterial stiffness in T1D adolescents but not HC.

Methods: PUA, BP, $GFR_{cystatin\ C}$ and carotid-femoral pulse wave velocity (Car-Fem PWV) were measured in 65 HC, 64 low-, 74 middle- and 50 high-tertile T1D participants from the Adolescent Type 1 Diabetes Cardio-Renal Intervention Trial (AdDIT).

Results: PUA was lower in T1D vs. HC (242±55 vs. 306±74mmol/L, $p<0.0001$). There were no differences in PUA between the 3 ACR tertiles. Higher PUA correlated with lower GFR in T1D after correcting for age, gender, HbA1C, BMI z-score, BP z-score, T1D duration and plasma HDL ($p<0.0001$). This association was not seen in HC. In the T1D group, PUA did not correlate with BP z-score before or after correcting for HbA1C, T1D duration and plasma HDL. Higher PUA correlated with higher Car-Fem PWV ($r=0.18$, $p=0.018$) in T1D, but not in HC. This association in T1D was abolished after correcting for age, gender, HbA1c, BMI z-score, T1D duration and HDL.

Conclusions: PUA correlates with lower GFR in T1D adolescents and may also be associated with increased arterial stiffness, despite lower PUA in T1D vs. HC. The presence of T1D may potentiate the hemodynamic impact of PUA, thereby modifying future cardio-renal risk.

PUB306

Risk Factors for Renal and Cardiovascular Events in Type 2 Diabetic Patients with Biopsy-Proven Nephropathy in Japan Akinori Hara,[1] Kengo Furuichi,[1] Miho Shimizu,[1] Yukio Yuzawa,[2] Hiroshi Kitamura,[3] Hiroshi Sato,[4] Takashi Wada.[1] *[1]Div of Nephrology, Kanazawa Univ Hospital, Japan; [2]Dept of Nephrology, Fujita Health Univ Hospital, Japan; [3]Dept of Pathology, Clinical Research Center, National Hospital Organization Chiba East National Hospital, Japan; [4]Clinical Pharmacology and Therapeutics, Tohoku Univ Graduate School of Pharmaceutical Sciences.*

Background: Standardized pathological classification is an essential tool in the evaluation of disease progression and/or efficacy of clinical management. In this nation-wide, multicenter, retrospective study, we examined pathological findings as risk factors for renal and cardiovascular events in Japanese patients with type 2 diabetes.

Methods: Renal biopsy and clinical data were retrospectively collected from 356 patients with type 2 diabetes in 13 centers in Japan. The mean observation period was 76.3 months and the observation period was 2264 person-year in total. Nine glomerular lesions, two interstitial lesions, and two vascular lesions were classified and evaluated as pathological predictors.

Results: One hundred sixty nine composite renal events (dialysis and doubling of serum creatinine or half of estimated glomerular filtration rate (eGFR)), 94 kidney deaths (dialysis), 34 cardiovascular events, and 30 deaths occurred. Specific pathological risk factors were detected for composite renal end points, renal death, and cardiovascular events in normo- to microalbuminuria and preserved eGFR group (G1-3a, A1-2). Among them, the presence of double contour of the glomerular basement membrane/subendothelial space widening (SubendW) and advanced interstitial cell infiltration (ICell) were particular risk factors for composite renal events, and glomerulomegaly (GMeg) was a risk factor for cardiovascular events.

Conclusions: This study revealed that specific pathological parameters (presence of SubendW, ICell, and GMeg) were predictors for renal and cardiovascular events in patients with preserved eGFR and normo- to microalbuminuria.

The Effect of Carbohydrate – Blood Glucose Feedback Method with Basic Carbohydrate Counting for Glycemic Control in Diabetic Dialysis Patients Toru Hyodo. *Dialysis Center, Eijin Clinic and Kurata Hospital, Hiratsuka, Kanagawa, Japan.*

Background: Basic carbohydrate counting (BCC), a method used in the dietary management of diabetes, is based on the concept that the postprandial rise in blood glucose levels is primarily affected by ingested carbohydrates. In this method, patients are instructed to eat a consistent amount of carbohydrates across their three daily meals to minimize fluctuations in postprandial blood glucose levels. We applied the carbohydrate glucose feedback method (CBGFM) with BCC for the diabetic dialysis patient whose HbA1c levels did not keep each favorable level only by BCC. CBGFM is to measure the predialysis blood glucose and show the results to patients in every dialysis session. Patients can estimate their carbohydrate intake balance and doses. The effect of CBGFM with BCC is reported in this study.

Methods: Eight diabetic patients undergoing maintenance hemodialysis (6 men and 2 women; mean age, 64.4 ± 11.9 years; mean dialysis period, 4.0 ± 5.0 years; 2 insulin users, 6 nonusers) were instructed in CBGFM with BCC and followed for 3 months to assess changes in their predialysis blood glucose (BG), hemoglobin A1c (HbA1c), Hemoglobin (Hb), triglycerides (TG), Potassium (K), Phosphorus (P), albumin (Alb), total cholesterol (T-Cho), high-density lipoprotein-Cho (HDL-Cho), low-density lipoprotein-Cho (LDL-Cho), protein catabolic rate (PCR), dry weight (DW), body mass index (BMI), and the Geriatric Nutritional Risk Index (GNRI).

Results: HbA1c levels were significantly decreased from the pre-instruction values ($P=0.0054$), The GA and BG showed the tendency toward decrease, but no marked changes were observed for the other parameters. Pre BG: 173.1± 50.9 mg/dL Pre HbA1c: 7.0±0.4 % Pre GA: 19.2±4.5, 3M BG: 131.5±29.5 ($P=0.066$), 3M: HbA1c: 6.1±0.6 ($P=0.0054$), 3M GA: 17.7±2.3($P=0.111$).

Conclusions: The results demonstrated that the CBGFM with BCC is a useful method of dietary management for glycemic control that can be applied independently of, but concurrently with, the control of potassium and phosphorus intake in dietary therapy for dialysis patients.

PUB308

The Clinical Effects of Renoprotection with DPP-4 Inhibitors Koichi Kanozawa, Saeko Sato, Yoshimi Okada, Hiroaki Hara, Minoru Hatano, Nobuyuki Onizawa, Takatsugu Iwashita, Tomonari Ogawa, Hajime Hasegawa. *Nephrology and Hypertension, Saitama Medical Center, Saitama Medical Univ, Kawagoe, Saitama, Japan.*

Background: Recently, not only animal models of diabetic nephropathy, but also non-diabetic nephropathy models, DPP-4 inhibitors(DPP-4i)was reported to have the renoprotective effects that improve albuminuria or tissue damage, through inhibition of oxidative stress, inflammation, and fibrosis. The aim of study is to clarify the mechanisms of renoprotective effect by DPP-4i in human diabetic nephropathy (DMN), clinically.

Methods: We gave DPP-4i (either of vildagliptin 50-100mg, alogliptin 25mg, teneligliptin 20-40mg) for Japanese Type 2 diabetes patients with nephronpathy. We were compared surrogate marker of oxidative stressandrenal injury, before and afterthree months.

Results: The administration of the DPP-4i, HbA1c was improved from 6.9±0.4 to 6.3±0.3% ($p<0.01$), either 1,5-anhydro-d-glucitol (1,5AG) was increased from 11.0±6.4 to 15.3±6.9% ($p<0.01$). Although eGFRcreat was no change ($p=0.05$), but eGFRcys was significantly increased from 92.1±23.8 to 96.7±21.7 ml/min/1.73m^2 ($p=0.03$). MDA-LDL is an oxidative stress marker, was decreased from 128±39 to 110±34 mU/L ($p<0.01$), urinary 8OHdG was reduced from 10.8±5.3 to 8.1±4.5 ng/mgCr ($p<0.01$). Although log urinary albumin to creatinine ratio(UACR) was reduced from 1.52±0.63 to 1.36±0.64 ($p<0.01$), and urinary liver-type fatty acid binding protein(L-FABP) was improved from 8.1±8.3 to 4.5±4.6 mg/gCr ($p=0.02$), but NAG and urinary b2-microglobrin(MG) were no change ($p=0.65$, 0.47). In inflammation, or fibrosis, log urinay MCP-1 was decreased from 2.41±0.53 to 2.12±0.32 ($p<0.01$), and urinary collgen IV was from 5.2±3.3 to 3.9±2.4 mg/gCr ($p<0.01$). In the context of blood glucose change, strong association was observed between the change rate of 1,5AG and urinary 8OHdG ($p<0.01$), also was also associated with the change rate of UACR ($p=0.03$). On the other hand, HbA1c and these were not associated ($p=0.31$, 0.14).

Conclusions: In DMN, DPP-4i have oxidative stress relief and renoprotective effect, by the improvement of short-term blood sugar fluctuations, also by oxidative stress reduction which independently of the improving glycemic control.

PUB309

Fibrinogen: A Potential Predictive Factor for the Progress of Diabetic Kidney Disease Wenbo Zhao, Hui-qun Li, Zhenda Zheng. *The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong.*

Background: To evaluate the potential of fibrinogen as a predictor of the progress of proteinuria in diabetic kidney disease.

Methods: For a Cross-Sectional Study, collecting 1121 type 2 diabete patients without or with microalbuminuria or massive proteinuria were treated during January 2008 to January 2013. Proteinuria was negative in 755 cases, 285 cases i with microalbuminuria, and 171 cases with massive proteinuria;We analyzed the correlation factors of the negative protein urine group and the microalbuminuria group; the correlation factors of the microalbuminuria group and the massive proteinuria group. Fibrinogen levels were compared between three groups.

Results: Retinopathy, hypertension grading, SBP, Fibrinogen levels, serum albumin, serum cystatin were the related progress factors of Microalbuminuria; Diabetes course, retinopathy, waist to hip ratio, Fibrinogen levels, serum albumin levels, serum cystatin C, serum creatinine were the related progress factors of the massive proteinuria; Except fibrinogen, other factors had been known relating to the progress of diabetic kidney disease. There were differences in the levels of three groups of fibrinogen ($P < 0.05$), which were 3.43 + 0.91 g/L, 4.15 + 1.31 g/L, 5.16 + 1.44 g/L.

Conclusions: Fibrinogen was a potential predictive factor for the development of diabetic kidney disease. The conclusion needs to be confirmed by further study.

PUB310

Interaction of HDLc, Iron, and Diabetes on Kidney Function Baqiyyah Conway,[1] Tina Costacou,[2] John M. Arthur.[3] *[1]Epidemiology, West Virginia Univ; [2]Epidemiology, Univ of Pittsburgh; [3]Univ of Arkansas for Medical Sciences.*

Background: The effect of HDL cholesterol (HDLc) on kidney function has recently received attention, partly due to the finding of increased hemoglobin (hb) inside of the HDL protein in persons with high risk haptoglobin (hp) genotypes. Such hb w/in the HDL protein may lead to iron induced lipid peroxidation products. These lipid peroxidation products may lead to iron-induced kidney damage. We have recently shown an interaction between HDLc and iron w/ kidney function (eGFR) in persons with diabetes such that after controlling for hb, higher serum iron levels were associated w/ reduced eGFR but only in those w/ HDLc levels above the median for the population. Because of the diabetes-specific association of increased hb inside the HDL protein in those w/ high risk hp genotypes, we hypothesize that this interaction between HDLc and iron w/ kidney function varies by diabetes status. To test this hypothesis, we examined the inter-relationship between HDLc, iron, and diabetes status w/ eGFR in approximately 55,000 individuals in West Virginia and Ohio.

Methods: Data on adults aged ³20 years were obtained from the C8 Health Project. eGFR was estimated using the CKD-EPI formula. Linear regression analysis was used to test the relationship between HDLc, serum iron, and diabetes status, and their interactions, with eGFR.

Results: Mean age was 57.8 in those w/ diabetes and 45.1 in those w/out diabetes. In multivariable analyses controlling for age and sex, iron was positive related w/ eGFR in those w/ ($p=0.03$) and inversely in those w/out diabetes (<0.0001), while HDLc was positively associated w/ eGFR only in those w/out diabetes ($p=0.97$ in diabetes; $p<0.001$ in those w/o diabetes). As previously reported, an interaction existed between HDLc and iron in diabetes ($p=0.04$). Here we report that this relationship was even stronger in those w/out diabetes (interaction $p=0.0008$). A significant 3-way interaction existed between HDLc, serum iron, and diabetes status w/ eGFR ($p=0.008$). Controlling for hb, the interaction between iron and HDLc disappeared in those w/ diabetes but remained robust in those w/out diabetes.

Conclusions: The divergent relationship between iron and HDL on the eGFR by diabetes status needs further investigation.

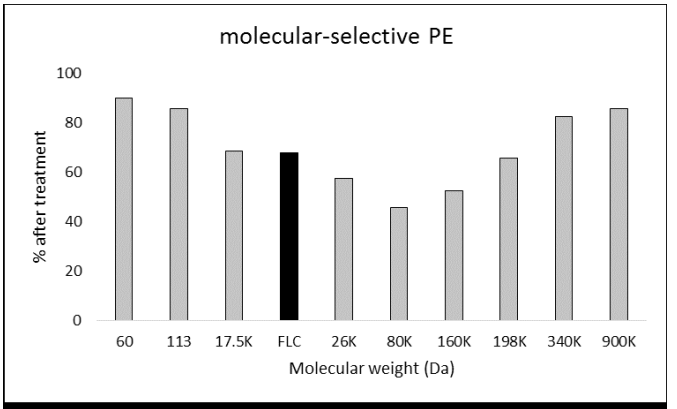
PUB311

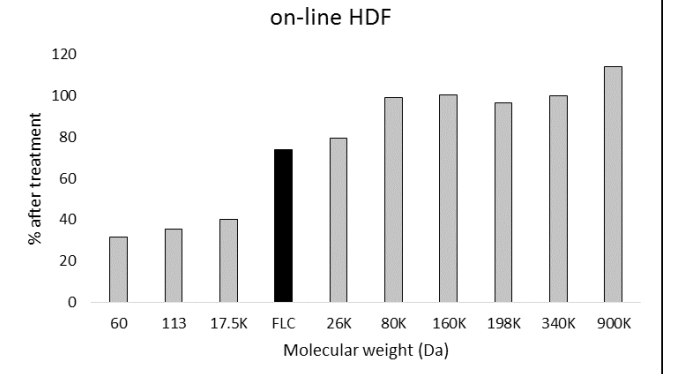
Molecular-Selective Plasma Exchange in Acute Kidney Injury due to Multiple Myeloma Manabu Kanda, Satoru Sanada, Shinichi Mizuno, Shu Yamakage, Mitsuhiro Sato, Yoshio Taguma, Toshinobu Sato. *Nephrology, Japan Community Health Care Organization Sendai Hospital, Sendai, Miyagi, Japan.*

Background: Benefit of plasma exchange in overall survival of patients with multiple myeloma (MM) remains to be determined, however, it is evident that lowering free light chain (FLC) reverses renal function in acute kidney injury (AKI) due to MM. High cut-off hemodialysis is recommended to remove FLC as an initial treatment for MM related AKI, which is different from traditional plasma exchange (PE) in preventing loss of large size molecules. As another option, we show the effect of molecular-selective plasma exchange to remove FLC, which enables target size removal without losing other size molecules.

Methods: A 49 year male with Bence-Jones type M protein was admitted with AKI; serum creatinine rose from 3.8 to 7.9mg/dL in 1 month. Past history included bone fracture and anemia. Serum FLC lambda was elevated to 29800 mg/dL. MM was confirmed by plasma cells in the bone marrow. The patient was treated with sequential molecular-selective plasma exchange (Evacure) and on-line HDF every other day combined with Bortezomib.

Results: PE was performed 6 times and removed 43.1% of FLC each on average without losing small and large size molecules.





On-line HDF removed 11.6% on average. Few, if any, rebounds were found in the FLC concentration between the treatments. Serum FLC level decreased to 411mg/dL after a series of treatments (day 14) and serum creatinine reversed to 2.7mg/dL at day 21.

Conclusions: A molecular-selective plasma separator is designed to limit the loss of high molecular weight substances. Using this machine, FLC can be removed effectively while preserving large size molecules. Moreover, the use of plasma substitute fluid can be reduced compared to that of conventional PE. We conclude that molecular-selective plasma exchange could be an effective treatment option for MM associated AKI.

PUB312

Preliminary Evaluation of a New CRRT Machine: Kibou™ Mauro Neri, Francesco Garzotto, Anna Lorenzin, Silvia Guggia, Alessandra Brendolan, Federico Nalesso, Monica Zanella, Claudio Ronco. *IRRIV and San Bortolo Hospital, Vicenza, Italy.*

Background: Kibou™ (Asahi Kasei Medical Co., Tokyo, Japan) is a new multifunctional automatic machine for Continuous Renal Replacement Therapy (CRRT) system (figure 1).

CRRT TREATMENT	REPLACEMENT			DIALYSATE		ADULT		PEDIATRIC	
	PRE	POST	PRE & POST	CO-CURRENT	COUNTER-CURRENT	HEPARIN	CALCIUM-CITRATE	HEPARIN	CALCIUM-CITRATE
SCUF	-	-	-	-	-	x	x	x	-
CVVH	x	x	x	-	-	x	x	x	-
CVVHD	-	-	-	x	x	x	x	x	-
CVVHDF	-	x	-	x	x	x	x	x	-
TPE	-	-	-	-	-	x	x	x	-

Kibou can perform different CRRT therapies with the possibility to use only a single platform; in particular, modalities for both adults and pediatrics, counter-current and co-current configuration, the use of heparin or citrate-calcium anticoagulation therapies and plasma exchange can be delivered(figure 1).

Methods: Based on the traditional experience of International Renal Research Institute of Vicenza (IRRIV), *in vitro* and α test evaluations of Kibou and related disposables have

been conducted. 12 treatments were performed. Machine's usability and accuracy has been evaluated by the staff through scores table. The measurement of fluid balance accuracy was even performed.

Results: Based on score given by the staff (engineers, nurses and physicians), the machine hardware results compact and well organized, with 3 well separated compartments (dialysate/replacement, blood and effluent) that facilitate the preparation phase. Auto-priming function allows short priming time. The interface is user friendly in all the modalities (SCUF, CVVH, CVVHD, CVVHDF, TPE both for adults and pediatrics). The measured fluid balance error was always lower than 0.3%. On the contrary CVVHDF pre-infusion and pre+post infusion are not performable. For pediatric treatment the continuity of the flow of blood pump need to be maintained and improved.

Conclusions: Kibou is a promising CRRT machine that can perform multiple continuous therapies with just one platform. In particular, we evaluated a highly accurate gravimetric fluid balance control system and a user friendly interface. Kibou is one of the first machines of the new frontier of CRRT devices: the fourth generation of CRRT machines.

PUB313

The Effect of MySleeve on Fluid Restriction Adherence in Hemodialysis Patients Idowu B.I Ayoola,[1] Marijke J.E. Dekker,[2] Marc Schonck,[2] Jeroen Kooman,[3] Erik Korsten,[1,2] Wei Chen,[1] Constantijn Konings,[2] Loe M. Feijs.[1] *[1]Industrial Design, Technology Univ Eindhoven, Eindhoven, Netherlands; [2]Medicine, Div of Nephrology, Catharina Hospital Eindhoven, Eindhoven, Netherlands; [3]Medicine, Div of Nephrology, Maastricht Univ Medical Center, Maastricht, Netherlands.*

Background: In hemodialysis patients, non-adherence to fluid restriction is associated with high interdialytic weight gain (IDWG) and adverse outcomes. Monitoring drinking behaviour and direct feedback to the patient can lead to better adherence. We developed the MySleeve, a device that can be wrapped around a drinking glass to monitor fluid intake throughout the day. The MySleeve will also provide a subtle vibration on the glass when the amount drunk exceeds target. The information about drinking behaviour can be found in the accompanying application on a mobile phone. In this study, we investigate the effect of direct feedback and information to the patient on fluid restriction adherence, measured by the IDWG.

Methods: We will include 40 prevalent, anuric hemodialysis patients from the Catharina Hospital Eindhoven, The Netherlands in a randomised controlled trail. Patients in the intervention group are provided a MySleeve device, a mobile phone and an activity tracker. BCM measurements are performed weekly and IDWG will be calculated before every dialysis session. The patients in the control group will continue with regular hemodialysis.

Results: We expect that by providing patients insight in fluid intake, there will be an increase in fluid restriction adherence and an increase in activity levels and better quality of sleep. Due to less IDWG, patients will experience less discomfort of fluid overload.

Conclusions: Introducing a MySleeve device to provide direct insight into drinking behavior will help the patients to adhere to their fluid restriction, leading to less IDWG and better quality of life measured by daily activity and better sleep.

A Time and Motion Study of Erythropoiesis Stimulating Agent Administration in United States Dialysis Centers Mark Stephens,[1] Larry C. Emerson,[2] Leslie A. Spry,[2] John P. Caloyeras,[3] Ernest R. Anderson,[4] John Reitan,[4] Akhtar Ashfaq.[3] *[1]Prima Health Analytics; [2]Dialysis Center of Lincoln; [3]Amgen, Inc.; [4]RJM Group.*

Background: Previous research suggests that ESA administration in dialysis is a time-consuming task and switching to less frequently dosed ESAs may offer opportunities for more efficient and effective patient care. This study estimated the time required for activities involved in the ESA process at US dialysis centers using epoetin alfa (EPO) or darbepoetin alfa (DPO), and examined potential time savings of switching from EPO to DPO.

Methods: Time and motion study conducted from 10/2014 to 1/2015 to assess activities involved and staff time required to prepare, administer and document ESA doses. A sample of 11 dialysis centers using either 3 times-per-week (TIW) EPO or once-weekly (QW) DPO were selected in pairs (one EPO, one DPO), where possible, from the same organization or nephrology practice to help control for anemia management protocols and staffing patterns. ESA-related tasks were timed by trained nurse observers. Time savings expected from switching from TIW EPO to QW DPO were estimated. Staff were interviewed about alternate patient-focused activities that could be accomplished if time were saved in the ESA process.

Results: 200 administrations were observed (81 DPO, 119 EPO). A mean of 2.3 (95% CI: 2.1-2.5) minutes per dose were required for ESA-related activities. RNs performed 95% of tasks; LPNs 5%. ESA process time did not vary significantly between EPO and DPO (>p=0.83). Staff time savings would accrue due to fewer ESA administrations using QW DPO: 10-20 minutes per nurse/day. For an average facility, the total monthly nurse time that could be re-purposed was 24 hours. Patient education, fulfillment of care plans and more frequent review of labs were identified as opportunities for improved care processes that could be implemented after conversion.

Conclusions: Switching from TIW EPO to QW DPO for anemia management in dialysis patients can result in time savings and opportunities to redirect nurse time towards activities aimed at improving patient care while still offering the ability to respond to changing clinical circumstances to effectively manage anemia.

PUB315

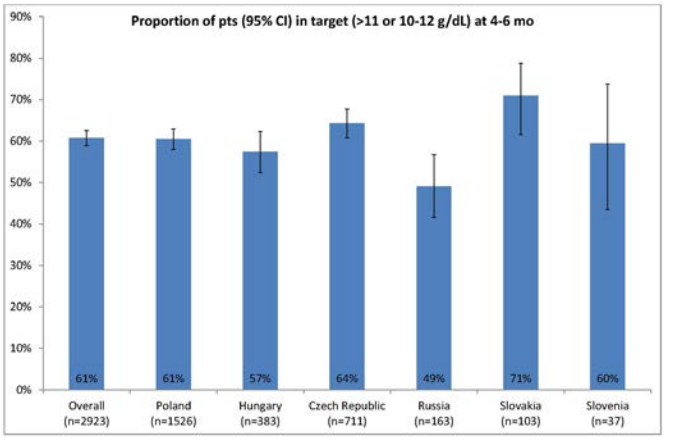
Observational Study on the Use of Darbepoetin Alfa in Hemodialysis Patients in Central Eastern Europe – ANREG Final Analysis Tomasz Jerzy Irzyniec,[1] Alena Parikova,[2] Alexander Selyutin,[3] Botond Csiky,[4] Jaroslav Rosenberger,[5] Igor Rus,[6] Kinga Jedynasty.[7] *[1]Dept of Nephrology/ENDO, MSW Hospital, Katowice, Poland; [2]Dept of Nephrology, Inst for Clinical and Experimental Medicine, Prague, Czech Republic; [3]B. Braun Atvium, Orenburg, Russian Federation; [4]FMC Dialysis Center, Pécs, Hungary; [5]Nephrology and Dialysis Center Fresenius, Kosice, Slovakia (Slovak Republic); [6]Dept of Hemodialysis/ Nephrology, General Hospital Jesenice, Jesenice, Slovenia; [7]CEE Headoffice, Amgen GmbH, Vienna, Austria.*

Background: This study observed anemia treatment patterns in HD patients (pts) treated with darbepoetin alfa (DA) in clinical practice in CEE.

Methods: Multicenter observational study in HD pts treated with DA. From 2007 to 2014, 14 cohorts were observed for 6 months (mo) each. Primary outcome: % pts maintaining an average Hb at >11 (cohorts 1/2 enrolled prior to label change in 02/2008) or 10-12 g/dL (cohorts 3-12) during mo 4-6. Secondary: conversion versus *de novo* pts, Hb trends, ESA and iron use, adverse drug reactions (ADR).

Results: Of 2923 enrolled pts (n=1101 *de novo*; n=1822 converted from other ESAs), 2647 (91%) completed 6 mo of DA, 276 (9%) discontinued (155 [5%] due to death). At baseline (BL) 83% received iron.

	all	*de novo*	conversion
Median Hb at BL, g/dL	10.2	9.5	10.5
Median Hb at 6 mo, g/dL	11.2	11.3	11.2
% with Hb >11 or 1012 g/dL at 4-6 mo	61	61	61
% with Hb 11-12 g/dL at 4-6 mo	36	36	36



The median DA dose was 10.6 mcg/wk at mo 1 and mo 6. Approx 75% received DA i.v. and once weekly (84% at mo 1, 75% at mo 6). 12 ADR were reported (8 serious, 3 fatal: intracranial hemorrhage; myocardial infarction, death).

Conclusions: Hb increased substantially in *de novo* and conversion pts after DA initiation; >60% reached target by mo 4-6 with some variation between countries.

PUB316

Dysutilization of Iron for Erythropoiesis Is a Significant Predictor for Adverse Events and Survival in Maintenance Hemodialysis Patients Takahiro Kuragano, Takeshi Nakanishi. *Dept of Internal Medicine Div of Kidney and Dialysis, Hyogo College of Medicine, Nisinomiya, Hyogo, Japan.*

Background: Patient with high serum ferritin and low transferrin saturation (TSAT) levels could be considered as dysutilization of iron for erythropoiesis. Long-term safety iron administration to these patients has not been well studied.

Methods: Study design was the observational multicenter study for period of 3 years. In 805 patients with maintenance hemodialysis (MHD), we evaluated Hb, ferritin, TSAT levels in every 3 months, and high sensitive C reactive protein (hsCRP) and b2microglbulin (MG) levels every 6 months. We defined dysutilization of iron for erythropoiesis as the patients with lower TSAT (<20%) and higher ferritin (³100 ng/mL) levels. The association between dysutilization of iron for erythropoiesis and adverse event was investigated with the time dependent cox hazard model.

Results: Compared with low TSAT (≤ 20%) level, patient with normal TSAT (20-30%) was significantly lower risk for cerebrovascular and cardiovascular disease (CCVD) (HR:0.25, P=0.04), and patients with higher TSAT (³30%) were significantly lower risk for death (HR:0.12, P=0.01). In multivariate logistic regression analysis, male, younger patients, without diabetes, low hsCRP, and low b2MG were selected as significant predictors of high TSAT, but iron administration or ferritin were not. Compared with low ferritin (<100 ng/mL) and high TSAT (³20%), patients with high ferritin (³100ng/mL) and low TSAT (<20%)

(HR: 4.5, p<0.001), and with high ferritin and high TSAT (HR: 2.9, p<0.001, respectively) had a significantly higher risk of CCVD. Moreover, patients with high ferritin and low TSAT had a significantly higher risk of death (HR:5.8, p<0.001) compared with those with low ferritin and high TSAT.

Conclusions: Although patients with low TSAT had a significantly higher risk of CCVD or death, higher TSAT was not associated with iron administration or iron storages. Patients with high ferritin and low TSAT who were suspected as dysutilization of iron for erythropoiesis had a higher risk of CCVD and death. From these results, the administration of iron should be cautious to the patients with dysutilization of iron for erythropoiesis.

PUB317

Inflammatory and Metabolic Syndrome Biomarkers Analysis of Vascular Outcomes in End-Stage Renal Disease Vinod K. Bansal,[1] Patrick Sweigert,[2] Debra Hoppensteadt,[2] Jennifer Saluk,[2] Daneyal Syed,[2] Jawed Fareed.[2] *[1]Nephrology, Loyola Univ Medical Center, Maywood, IL; [2]Pathology, Loyola Univ Medical Center, Maywood, IL.*

Background: The relevance of some biomarkers of inflammation and metabolic syndrome to vascular outcomes in end stage renal disease (ESRD) is not clear. To study these relationships, biochip array technology method was used to profile the complex plasma biomarkers in the setting of various comorbid outcomes such as Stroke or Transient Ischemic Attack (TIA), Acute Coronary Syndrome (ACS), Congestive Heart Failure (CHF), and Coronary Artery Disease (CAD).

Methods: Plasma samples were collected from 83 ESRD patients (mean age 65) prior to hemodialysis and were profiled using biochips for metabolic and inflammatory biomarker levels. Inflammatory cytokine and Metabolic Syndrome arrays were used to profile C peptide, ferritin, insulin, leptin, resistin, TNFa, PAI-1, IL1a, IL1b, IL2, IL4, IL6, IL8, IL10, VEGF, EGF, IFNG, and MCP1. Retrospective review was performed to group patients based on history of Stroke or TIA, ACS, CHF, and CAD.

Results: Of the 83 ESRD patients, 25 (30.1%) were found to have history of Stroke/TIA, 14 (16.9%) were found to have history of ACS, 30 (36.1%) were found to have history of CHF, and 39 (47.0%) were found to have history of CAD. Stroke/TIA patients were found to have decreased plasma IFNG levels (p=0.042) and elevated plasma resistin, IL1a, and leptin levels (p=0.008, 0.021, 0.026; respectively) when compared to patients without Stroke/TIA. ACS patients had elevated plasma IL6 levels (p=0.040) when compared to those without ACS. CHF patients had decreased plasma leptin levels (p=0.031) and elevated plasma IL1b levels (p=0.042) when compared to patients without CHF. CAD patients had elevated plasma IL1a levels (p=0.049) when compared to ESRD patients without CAD.

Conclusions: Profiling of multiple inflammatory and metabolic syndrome biomarkers may aid in the risk stratification of ESRD patients for cerebrovascular and cardiovascular disorders. These studies demonstrate that biomarker profiling of vascular comorbidities in ESRD may provide useful diagnostic and prognostic information in the management of ESRD patients.

PUB318

Individualized Anemia Management in Pediatric Nephrology Patients Adam E. Gaweda,[1] Jason Misurac,[2] Michael E. Brier,[1] Jeffrey D. Leiser.[2] *[1]Medicine, Univ of Louisville, Louisville, KY; [2]Nephrology, Riley Hospital for Children at Indiana Univ, Indianapolis, IN.*

Background: Anemia management in pediatric patients on dialysis poses a great challenge to the nephrologist. In this study, we tested the hypothesis that individualized approach anemia management, previously demonstrated successfully in adult patients, improves hemoglobin maintenance within target range in pediatric dialysis patients.

Methods: We performed prospective evaluation of Clinical Decision Support System "Smart Anemia Manager" (SAM) in pediatric dialysis patients at Riley Hospital for Children at Indiana University. SAM was implemented as a stand-alone software on a desktop computer used by the nurse anemia manager and connected to a database containing Hemoglobin (Hgb) and ESA dose data. The anemia manager was allowed to override dose recommendations from the system and each override was documented. The followup period was 10 months, including 4 month washout period. We compared the hemoglobin distribution within 9-12 g/dL range during 6 months immediately before SAM implementation and 6 months after the washout period. Only patients who received ESA and had at least 4 Hgb values within each period were included in the analysis.

Results: 13 patients satisfied the inclusion/exclusion criteria. The percentage of monthly Hgb within target range varied between 82% and 92% in 6 months prior to deployment of SAM and between 69% and 100% during 6 months after SAM deployment. Quarterly Hgb distribution varied between 86% to 87% prior to SAM deployment and 87% to 95% after. There was a significant decrease in low Hgb numbers after SAM deployment, but no change in high Hgb levels, compared to the period before SAM deployment.

	Quarter	Month	< 9 g/dL	9 - 12 g/dL	> 12 g/dL	N
Pre-SAM	Q1	Nov-13	18%	82%	0%	11
	86%	Dec-13	9%	91%	0%	11
		Jan-14	15%	85%	0%	13
	Q2	Feb-14	0%	92%	8%	13
	87%	Mar-14	8%	85%	8%	13
		Apr-14	15%	85%	0%	13
SAM	Q3	Sep-14	8%	92%	0%	13
	95%	Oct-14	0%	100%	0%	13
		Nov-14	8%	92%	0%	13
	Q4	Dec-14	0%	100%	0%	13
	87%	Jan-15	8%	92%	0%	13
		Feb-15	23%	69%	8%	13

Conclusions: Individualized anemia management in pediatric patients improves distribution of Hgb within the target range, compared to a standard population-based protocol approach.

PUB319

Extracorporeal Ultrafiltration Therapy for Acute Decompensated Heart Failure Negiin Pourafshar, Ashkan Karimi, Amir Kazory. *Medicine, Univ of Florida, Gainesville, FL.*

Background: There has been a renewed interest in the use of ultrafiltration (UF) for management of patients with acute decompensated heart failure (ADHF). While a number of studies reported on the efficacy of this therapy and lack of any significant adverse impact, the more recent trials have challenged its safety. The aim of this study is to provide a reappraisal of the current evidence on the use of UF in ADHF.

Methods: Articles cited in PubMed database from 2000 to 2015 using key words"ultrafiltration" and "heart failure" were searched. Those randomized and non-randomized trials using recent portable devices dedicated for UF were selected. Case reports, and case series were excluded. Relevant data such as renal function, cardiac status, and weight change were extracted and compared.

Results: A total 940 patients from 15 trials (7 randomized and 8 non-randomized) that used dedicated UF devices were included. Eleven studies reported either no change or non-significant decrease in serum creatinine, while 4 found worsening renal function after UF therapy; these studies had included patients with more severe renal dysfunction at baseline. Concerning weight, a reduction of 2 to 9 Kg was reported that was similar to conventional therapies in 9 studies but was significantly lower with UF in 6 trials. Length of stay was evaluated in 5 studies, 2 of which showed a significant reduction. Three studies showed fewer re-hospitalizations in the UF group at 30 days, 90 days, and 1 year follow ups. None of the studies evaluated long-term outcomes of patients undergoing UF therapy.

Conclusions: Based on the currently available data, UF is efficient for management of volume overload in ADHF. However, these studies do not support any beneficial impact for this therapy on renal function, and suggest that it might be associated with suboptimal renal outcomes if used for patients with more severe renal dysfunction at baseline. Currently there is no data on the effect of UF on long-term outcomes of patients with ADHF. Whether this would translate into a lack of effect for UF on these outcomes needs to be elucidated by future studies.

PUB320

Ultra-Sensitive Troponin I Predictive Value in Remote Ischemic Pre Conditioning in Hemodialysis: A Randomized Double Blinded Clinical Trial Marcelo Rodrigues Bacci, Livia Yadoya Vasconcelos, Felipe R. Bruniera, Felipe Moreira Ferreira, Neif Murad, Antonio Carlos palandri Chagas, Fernando Luiz affonso Fonseca. *ABC Medical School, Brazil.*

Background: Remote ischemic cardiac preconditioning(RIPC)is a procedure that generates a brief period of ischemia followed by reperfusion.Areas submitted to RIPC in the experimental ischemia models have less occurrence of necrosis.RIPC role in protecting myocardial ischemia during hemodialysis is not stablished yet.The aim of the study was to evaluate RIPC as myocardial protection evaluated by ultra sensitive I troponin in hemodialysis outpatients.

Methods: It is a double blind randomised trial with two groups:intervention;submitted to RIPC with external compression in the right arm with sphygmomanometer with 200mm/Hg of pressure with three-5 minute rounds alternating with deflation totalling 30 minutes and control group;without RIPC.Intervention group received RIPC in three consecutive hemodialysis sessions.Blood samples were taken before and after each session. Randomization was made by a software stratified by sex and age.BUN for calculation of single pool Kt/v and ultra sensitive I troponin were measured to evaluate dialysis adequacy and myocardial injury.

Results: A total of 47 patients were randomized.About 60.8% were men and 54% diabetic.The mean single pool Kt/v was 1.51 in the intervention group and 1.49 in control.

There was a trend to higher mortality in the control group(26%,p=0.09).The ultra sensitive troponin I measured no significant change from the time of collection:before or after dialysis,however it showed a high negative predictive value in all models tested.

Conclusions: The RIPC applied in 3 consecutive sessions did not demonstrate superiority to control therefore another study tested RIPC in 12 consecutive sessions with a positive result in myocardial protection with RIPC.In our study more than half of the patients were diabetic.Diabetic patients have a trend to show a lower response to RIPC because of the greater presence of collateral coronary circulation.In summary,in this model there was no interference of RIPC in ultra sensitive troponin I values but troponin had a high negative predictive value for myocardial infarction in all tested models.

PUB321

Racial Differences in the Evolution of Subclinical Cardiovascular Disease from CKD to ESRD: The CRIC Study Nisha Bansal,[1] Jason Roy,[2] Hsiang-Yu Chen,[2] Alan S. Go,[3] Martin Keane,[4] Rajat Deo,[2] Elyse Foster,[5] Sankar D. Navaneethan,[6] Jiang He,[7] Mahboob Rahman,[8] Mirela A. Dobre,[8] John W. Kusek,[9] Michael J. Fischer,[10] Emile Mohler,[2] Chi-yuan Hsu.[5] *[1]UW; [2]UPenn; [3]KPNC; [4]Temple; [5]UCSF; [6]Case Western; [7]Tulane; [8]UH; [9]NIDDK; [10]UIC.*

Background: Studies have reported that black incident dialysis patients have better survival compared with white dialysis patients, even after accounting for adverse profile of comorbidities among blacks. We hypothesized that differences in subclinical cardiovascular disease (CVD) may explain this paradox.

Methods: We studied incident dialysis patients in the CRIC study who had a research echocardiogram performed before and after the initiation of dialysis. Left ventricular mass index (LVMI) and ejection fraction (LVEF) were measured at CKD (mean eGFR 24 ml/min/1.73 m^2) and at dialysis initiation (median time after initiation 7.9 months).

Results: Of 316 participants, 74% were black and 26% were white. After initiation of dialysis, there were 88 deaths. In multivariable models, black (vs. white) race was independently associated with a 38% (95% CI: 1%, 61%) lower risk of mortality. From CKD to incident dialysis, mean LVEF worsened in whites (51±10% to 47±11%; p-value for change <0.0001) and blacks (52±9% to 48±10%; p <0.0001). LVMI trended worse in whites (54±16 g/$m^{2.7}$ to 57 ±15 g/$m^{2.7}$; p=0.1) and significantly improved in blacks (61±16 g/$m^{2.7}$ to 58±13 g/$m^{2.7}$; p=0.004). Adjusting for LVMI, change in LVMI, LVEF and change in LVEF did not change the association between black race and lower risk of death.

Association of race for risk of mortality after initiation of dialysis

	Model 1*	Model 1 + LVMI at incident ESRD	Model 1 + change in LVMI from CKD to ESRD	Model 1 + LVEF at incident ESRD	Model 1 + change in LVEF from CKD to ESRD
White	ref	ref	ref	ref	ref
Black	0.62 (0.39, 0.99)	0.55 (0.32, 0.94)	0.57 (0.32, 1.0)	0.57 (0.35, 0.94)	0.60 (0.36, 0.99)

*adjusted for gender, age, tobacco use, systolic blood pressure, body mass index, diabetes, and history of cardiovascular disease

Conclusions: In CRIC, black dialysis patients had better survival than whites. This association was not explained by differences in subclinical CVD at incident dialysis or by differences in the evolution of CVD from CKD to ESRD. Further studies are needed to understand mechanisms underlying the differential survival by race among dialysis patients.

Funding: NIDDK Support

PUB322

Study Design and Baseline Characteristics in the "Outcome Study of Lanthanum Carbonate (LC) Compared with Calcium Carbonate (CC) in Hemodialysis (HD) Patients (LANDMARK) Study" Hiroaki Ogata,[1] Masafumi Fukagawa,[2] Hideki N. Hirakata,[3] Tatsuo Kagimura,[4] Tadao Akizawa.[1] *[1]Div of Nephrology, Dept of Medicine, Showa Univ School of Medicine, Tokyo, Japan; [2]Div of Nephrology, Endocrinology, and Metabolism, Tokai Univ School of Medicine, Isehara, Japan; [3]Div of Nephrology and Dialysis Center, Japanese Red Cross Fukuoka Hospital, Fukuoka, Japan; [4]Translational Research Informatics Center, Kobe, Japan.*

Background: The LANDMARK study is planned to elucidate whether a non-calcium (Ca)-based phosphate (P) binder, LC treatment reduces cardiovascular (CV) mortality and morbidity compared with a Ca-based P binder, CC treatment in HD patients.

Methods: This is a multicenter, randomized, open-label, parallel comparative study between LC and CC (NCT01578200/UMIN000006815). Adult HD patients who had at least one of following criteria; age>65 yrs, postmenopausal women, or type 2 diabetes mellitus) with intact parathyroid hormone (iPTH) £240pg/mL and life expectancy ³1 years, were eligible. In LC group, patients initially received LC of 750mg/day or previous used dose and were titrated up to a maximum of 2250mg/day to achieve serum P levels of 3.5-6.0mg/dL. In CC group, patients received CC of 3g/day or previously used dose, and were titrated to achieve same P range as LC group. If serum P level was not achieved within the target with maximum tolerated dose, non-Ca-based P binders (other than LC) could be also added in CC group. The primary endpoint is the CV events (CV death, non-fetal myocardial infarction and stroke, unstable angina, hospitalization for heart failure and ventricular arrhythmia) free survival time.

Results: 2309 patients were allocated to LC (N=1154) or CC group (N=1155). At baseline, mean age was 68.7 yrs, 40.6% were female and 51.7% were diabetes. 13.4% had a history of ischemic heart disease, and 13.3% had cerebrovascular disease. 8.0% had undergone coronary intervention procedure. Mean serum Ca, P and iPTH concentrations were 8.9mg/dL, 5.4mg/dL, and 122.4pg/mL, respectively. Baseline characteristics were well balanced between the two groups.

Conclusions: The LANDMARK study will determine whether a non-Ca-based P binder, LC, reduce CV mortality and morbidity in HD patients.

PUB323

The Relationship Between Prescription of Ultrafiltration in Hemodialysis and Intradialytic Hypotension: A Retrospective Study of Chinese Hemodialysis Patients Fei Deng, Daqing Hong, Guisen Li, Li Wang. *Nephrology, Sichuan Academy of Medical Sciences & Sichuan Provincial People's Hospital, Chengdu, Sichuan, China.*

Background: Our study aims to explore the relationship between prescribed ultrafiltration and intradialytic hypotension (IDH)and, to demonstrate risk factors of intradialytic hypotension in order to reduce the incidence of relevant complications and improve patient prognosis.

Methods: 312 patients maintenance hemodialysis patients in our dialysis center were enrolled with 33224 HD/HDF treatment sessions recorded. Hypotension was defined as a decrease of systolic blood pressure >20mmHg or mean arterial pressure declination³10 mmHg whether presence of hypotensive symptoms or not. ROC curve was applied to study the cut-off point of UF/Wt (ultrafiltration/weight) ratio for the presence of hypotension. Pearson analysis and logistic regression was used to study the risk factor associated with hypotension.

Results: The prevalence of intradialysis hypotension was 38.7%. Decrease of SBP and MAP positively correlated with UF/Wt and age, and negatively correlated with blood flow. The cut-off point of UF/Wt was 4% for all patients, diabetes and non-diabetic patients with AUCs of 0.575, 0.570, and 0.622 respectively. The AUC for diabetic patients was higher than that of non-diabetic patients (P<0.001). Multivariate logistic regression showed that age (OR=1.005, 95%CI: 1.004-1.007), diabetes (OR=1.209, 95%CI: 1.122-1.303), and UF/Wt>4%(OR=1.605, 95%CI:1.532-1.682) was associated with hypotension.

Conclusions: Asymptomatic intradialytic hypotension is prevalent. Increased intradialytic SBP/MAP variability is associated with greater UF and UF/Wt, but is not associated with greater blood flow. To Chinese hemodialysis patients, UF/Wt>4% is sensitive and specific in predicting intradialysis hypotension, especially in patients with diabetes mellitus. UF/Wt>4%, diabetes mellitus and age are independent risk factors for asymptomatic intradialytic hypotension.

PUB324

Whole Blood Viscosity at Low Shear Rate Is Associated with Cardiovascular Mortality in Patients with Hemodialysis Jong-Hwan Jung,[1] Dong Hwan Lee,[2] Young I. Cho,[3] Kyung Pyo Kang,[1] Sik Lee,[1] Sung Kwang Park,[1] Won Kim.[1] *[1]Internal Medicine, Chonbuk National Univ Medical School, Jeonju, Republic of Korea; [2]Dept of Mechanical Design Engineering, Engineering College, Chonbuk National Univ, Jeonju, Republic of Korea; [3]Dept of Mechanical Eng. and Mechanics, Drexel Univ, Philadelphia, PA.*

Background: The change of whole blood viscosity (WBV) may increase risk of major atherosclerotic events, including congestive heart failure, myocardial infarction, and stroke. However, there is few report about the relationship between WBV and mortality rate due to atherosclerotic vascular disease. The objective of the present study was to investigate correlation between values of WBV at shear rates of 1, and 5 S^{-1} before and after hemodialysis in patients with end-stage renal disease (ESRD) and mortality; especially cardiovascular or cerebrovascular mortality.

Methods: Forty three patients with ESRD receiving maintenance hemodialysis had initially participated in this study. In a prospective observational study, we examined the effect of WBV in pre- or post-dialysis on cardiovascular or cerebrovascular mortality in dialysis patients for approximately 5.8 years.

Results: Twenty seven patients among total 43 patients died and 2 patients had received transplantation of kidney within period of this study.Cardiovascular deaths occured in 8 patients among 27 patients, and cerebrovascular deaths occurred in 5 patients among the 27 patients.The hazard ratios for overall survival in the patient with hemodialysis according to increase of predialytic diastolic WBV at low shear rate of 1 S^{-1} in an univariate Cox proportional analysis were 1.585 (95% CI, P=0.382) in the group of moderate blood viscosity and 2.351 (95% CI, P=0.128) in the group of high blood viscosity. However, pre-DBV1 was not still statistically significant after adjustment for covariates. In addition, the HRs for overall survival according to increase of pre-DBV5 were 1.527 and 1.930 in each moderate and high blood viscosity group. In Kaplan-Meier's survival analysis, when pre-DBV1 increased, cumulative mortality relatively showed rising tendency, but, unfortunately there was no statistical significance.

Conclusions: These results suggest that the diastolic low-shear WBV may impact on cardiovascular or cerebrovascular mortality in hemodialysis patients. New prospective and large-scaled studies to more exactly evaluate the correlation between WBV and mortality will be needed in the future.

PUB325

Survival of Patients Over 75 Years Old in a Chronic Hemodialysis Program
Adriano Luiz Ammirati, Maria C.C. Andreoli, Fabiana Dias Carneiro, Thais Nemoto Matsui, Nadia Guimaraes- Souza, Bento C. Santos. *Dialysis, Albert Einstein Hospital, São Paulo, Brazil.*

Background: The intensity of medical care for people over 75 years of age has increased over the past decade. In this surrounding context is increasing the number of individuals with this profile that has clinical indication starting renal replacement therapy. Published data have shown a varied patient survival after initiation of hemodialysis (HD) according to the presence of comorbidities.The aim of this study was to evaluate the survival of elderly patients with chronic kidney disease on regular HD.

Methods: From analysis of medical records was assessed the rate of survival of incident patients in a chronic HD program from 2000 to 2010. Demographic and clinical data were also collected. It was made a comparison, based on these data, among the elderly (over 75 years old) and non-elderly groups who died.

Results: During the study period, 158 patients started HD program, 69% male and 46% were older than 75 years. The overall mortality rates at 6 and 12 months were, respectively, 7.5% and 17%. Considering only the elderly, mortality rates at 6 and 12 months were respectively 14 and 27%. The median survival of these patients was 33 months. Considering only patients younger than 75 years mortality rates at 6 and 12 months were, respectively, 2% and 8%. Comparing elderly patients with non-elderly, we observed that the first group had a higher proportion of diabetic and hypertensive patients and with a history of cardiovascular disease and cancer. Considering only the patients who died, there were no important significant differences in the presence and score of comorbidities, when the elderly was compared with the non-elderly.

Conclusions: Patients over 75 years in HD had a mortality rate two times higher than younger patients and the presence of comorbidities may be a contributing factor to the age to explain this data.

PUB326

The Difference of Cognitive Function and Brain Magnetic Resonance Findings Between Chronic Hemodialysis and Peritoneal Dialysis Patients
Ke Zheng, Haiyun Wang, Xuemei Li. *Nephrology Dept, Peking Union Medical College Hospital, Beijing, China.*

Background: Cognition decline and cerebrovascular lesions has been gradually realized by clinicians nowadays. But It is still not clear whether there are some difference in cognitive function and cerebrovascular disease between chronic hemodialysis (HD) and peritoneal dialysis (PD) patients.

Methods: This is a cross-sectional study in a single center. 124 HD patients and 74 PD patients were recruited. Cognitive function was evaluated with Chinese-MMSE and Chinese-MoCA .MR images and MR Angiography were assessed.Demographic informations, Clinical features, laboratory data were collected. Results were analyzed with SPSS.

Results: (1) Age, gender and educational level were comparative between HD and PD patient. Average age was 56.2±13.2 yrs and 56.6±16.1 yrs, respectively in HD and PD groups.(2)Average dialysis voltage was longer in HD than PD group, 70.0±60.6 months v.s. 40.7±35.7 months. Average blood pressure was 136.7/79.6±19.5/11.3 v.s.138.4/76.7±21.4/11.8mmHg, Hgb was 110.9±13.7 v.s. 114.0±13.6 g/L, SCr 961.1±251.2 v.s. 857.0±276.6 umol/L, Alb39.6±3.9 v.s. 35.4±3.8 g/L,respectively in HD and PD groups. SCr and Alb level was higher in HD group(P<0.05). (4) In cognitive function evaluation, HD compared with PD groups, MMSE score was 28.0±2.5 v.s.29.6±3.1(p=0.84), MoCA score was 22.7±4.4 v.s 21.1±5.7(p=0.108), respectively. (5) For the brain MR results, in severity of brain artery stenosis, number of cortical infarcts, lacunar infarcts,microbleeds,chronic hematoma and Fazeka score of brain white matter lesions, only artery stenosis is more severe in PD groups (P<0.05). For the two kinds of bleeding lesions, there was a more severe tendency in HD group, but there was a more severe tendency of two kinds of ischemic lesions in PD group. (5) MoCA Score was relative to SCr,and Alb, negative relative with age,artery stenosis,lacunar infarcts and WMLs.

Conclusions: Compared with HD patients, there was a tendency of more severecognitive function decline in PD patients. Also we found a tendency of more brain bleeds lesions in HD patients, on the contrary, a tendency of more ischemic lesion in PD patients. But we need a larger sample size to prove those.

Paucity of Evidence for Use of Postmenopausal Hormone Therapy for Cardiovascular Prevention in Women with Chronic Kidney Disease: A Systematic Review
Sharanya Ramesh,[1] Michelle C. Mann,[1] Matthew T. James,[1,2] Stephen B. Wilton,[2,3] Jayna M. Holroyd-Leduc,[2] Sofia B. Ahmed.[1,2,3] *[1]Medicine, Cumming School of Medicine; [2]Community Health Sciences, Univ of Calgary; [3]Libin Cardiovascular Inst of Alberta.*

Background: Women with chronic kidney disease (CKD) have low sex hormone levels due to kidney-mediated endocrine disturbances, and are at increased risk of cardiovascular adverse events. Whether postmenopausal hormone therapy (PHT) alters cardiovascular risk in this population is unknown. We aimed to summarize current knowledge about the association between use of PHT and (1) cardiovascular outcomes, and (2) established cardiovascular risk factors, in women with CKD.

Methods: Setting and population: Adult women with CKD (eGFR≤90 mL/min/1.73m^2) **Selection Criteria for Studies:** Randomized control trials and observational studies, studying PHT with either placebo or untreated control groups. **Outcome measures:** All-cause and cardiovascular mortality, non-fatal cardiovascular event (myocardial infarction, stroke), and surrogate measures of cardiovascular risk (blood pressure, serum lipids).

We searched electronic bibliographic databases (MEDLINE, EMBASE, Cochrane Central Register of Controlled Trials) (inception to 2014 September), relevant conference proceedings, tables of contents of journals and review articles.

Results: Of 2928 references retrieved, 4 RCTs (N=142 patients) were identified. No studies reported on cardiovascular outcomes or mortality. Three studies examined the effect of PHT on lipid profile (mean age 60 years, all patients end-stage kidney disease on dialysis). Compared with placebo, PHT led to increased high density lipoprotein cholesterol (weighted mean difference (WMD) 0.82 mmol/L 95% CI: 0.47, 1.17), but no difference in low density lipoprotein (WMD -0.39 mmol/L 95% CI: -0.85, 0.07) or total cholesterol levels (WMD 0.11 mmol/L 95% CI: -0.23, 0.45. One study examined the effect of PHT on blood pressure, with PHT causing no change in blood pressure.

Conclusions: Studies examining the effect of PHT on cardiovascular outcomes in women with CKD are lacking. Further prospective study of the role of PHT in improving cardiovascular outcomes in this high-risk group is required.

PUB328

Prevalence of Abnormal Ankle – Brachial Index in Haemodialysis Patients in Mexico and Its Association with Other Cardiovascular Risk Factors
Laura E. Izguerra Ochoa, Heriberto Reyes López. *Nefrología, Regional General Hospital #46, Guadalajara, Jalisco, Mexico.*

Background: Abnormal Anckle-Brachial index (ABI), defined as ≤ 0.9 or ³1.3, is considered an independent predictor of mortality in hemodialysis patients, in other countries abnormal ABI is found between 35% and 80 % of hemodialysis patients. In Mexico the prevalence of abnormal ABI has not been reported. The aim of the study was to determine the frequency of abnormal ABI and its association with other cardiovascular risk factors.

Methods: Prevalent hemodialysis patients over 16 years old were included; data were obtained from medical records and interviews. ABI was measured by oscillometry (Model HEM-705CPINT) and classified as a normal result between 0.91 - 1.3 (NABI), ≤ 0.9 (LABI) or ³1.3 (HABI). NAVI was considered as the control group and the data were analyzed using descriptive and inferential statistics, using T Student and Chi2.

Results: Of the 119 patients analyzed abnormal ABI was present in 36 (30%); 10 (8.4%) with LABI and 26 (21.9%) with HABI. The mean age was 44.9 years, 68% were male, duration of dialysis of 7.1 years. In univariate analysis LABI was significantly associated with older age (p=0.03), smoking history (p <0.001), diabetes mellitus (DM) (p=0.04), lower creatinine (p <0.001) and albumin (p <0.001) and higher calcium (p <0.001); HABI was significantly associated with lower age (p=0.01), smoking history (p=0.05), lower systolic blood pressure (SBP) (p=0.02), high levels of sodium (p=0.04) and calcium (p=0.001). No association was found between abnormal ABI and history of hypertension, dyslipidemia, heart disease, stroke; there were no differences with the dose of calcium carbonate or calcitriol, the value of Kt / V, the type of vascular access and serum phosphorus.

Conclusions: Abnormal ABI was less prevalent than in other populations, among these HABI is the most common. LABI was associated with older age, DM, smoking history, high calcium and low creatinine and albumin (probably associated with poor nutritional status). HABI patients were younger, with smoking history, lower SBP, high serum sodium and calcium levels.

PUB329

A Lower Serum Uric Acid Is Associated Not Only with All-Cause Mortality but Also Cardiovascular Mortality Among Patients Receiving Hemodialysis in Japan
Naoki Sugano,[1] Yukio Maruyama,[1] Keitaro Yokoyama,[1] Koki Takane,[1] Yasuhito Takahashi,[1] Chisa Kobayashi,[1] Shinichiro Nishio,[1] Daisuke Takahashi,[1] Satoshi Kidoguchi,[1] Kosuke Honda,[1] Norihiko Morisawa,[1] Gorou Tokudome,[1] Iwao Ohno,[1] Tatsuo Hosoya,[1] Takashi Yokoo,[1] Takashi Shigematsu,[2] Kunitoshi Iseki,[2] Ikuto Masakane.[2] *[1]Div of Nephrology and Hypertension, Dept of Internal Medicine, The Jikei Univ School of Medicine, Tokyo, Japan; [2]Committee of Renal Data Registry, Japanese Society for Dialysis Therapy, Tokyo, Japan.*

Background: High level of serum uric acid is prevalent in chronic kidney disease (CKD), however it has a controversy whether high or low serum uric acid level appears to be a risk factor of cardiovascular event and mortality in the patients of receiving renal replacement therapy.

Methods: We collected the baseline data of 222,434 patients receiving HD thrice weekly (males: 63.0%, 66 ±12 years, median HD vintage of 60 months, females: 68 ±13 years, median HD vintage of 72months) extracted from a nationwide dialysis registry at the end of 2011 in Japan. Then we evaluated the patient survival and development of complication using the registry at the end of 2012.

Results: During one-year follow-up, 18775 (8.4%) died of all causes including 8094 (3.6%) cardiovascular death. All-cause mortality, and cardiovascular mortality were lower in line with the increase of baseline uric acid. In a multivariable logistic regression analysis, patients of the highest quartile of uric acid had lower all-cause, and cardiovascular mortality compared with those of the lowest quartile (males: OR, 0.745; 95% CI, 0.6753 to 0.8207, females: OR, 0.8333; 95% CI, 0.7206 to 0.9636, and males: OR, 0.7202; 95% CI, 0.6266 to 0.8278, females: OR, 0.8575; 95% CI, 0.7029 to 1.0462, respectively).

Conclusions: In this large observational cohort study, lower levels of serum uric acid were independently associated not only with all-cause mortality but also cardiovascular mortality among Japanese HD patients. Close monitoring of serum uric acid is thought to be necessary for the management of HD patients.

PUB330

Post Stroke Disability Deterioration and Mortality of Hospital Onset Stroke in Patients with and without End-Stage Renal Disease Tomoko Usui,[1] Norio Hanafusa,[1] Hideo Yasunaga,[2] Masaomi Nangaku.[1] *[1]Dept of Hemodialysis and Apheresis, The Univ of Tokyo Hospital, Japan; [2]Dept of Clinical Epidemiology and Health Economics, School of Public Health, the Univ of Tokyo, Japan.*

Background: Increasing evidence suggests that end-stage renal disease is associated with higher risk and severity of cerebrovascular disease. However, the risk factors for post stroke disability and mortality is not clear. We examined the association between risk factors including dialysis treatment and disability deterioration and mortality during the hospital stay of hospital onset stroke.

Methods: The Japanese Diagnosis Procedure Combination database includes administrative claims and discharge abstract data of about 50% of all acute-care inpatients in Japan. Using this database, we extracted data of inpatients age ³20 years old, hospital-onset stroke between July 2010 and March 2013. Disability level was divided into modified Rankin Scale (mRS) 0-1, 2-3, 4-5, and 6 (death). Deterioration of disability was defined as an increase in disability level. The odds ratio (OR) for in-hospital deterioration of disability and mortality was calculated using a logistic regression model.

Results: Out of 26,834 patients, 593 (2.2%) had dialysis therapy. The median length of stay was 39 and 33 days for patients with and without dialysis, respectively. During the hospital stay, there were 7,655 (28.5%) disability deterioration and 3,851 (14.4%) death. The patients with dialysis had higher disability deterioration (47.0%) and mortality rate (31.3%) compared to those without. After adjustment with age, gender, BMI, mRS, Activities of Daily Living, smoking habits, hypertension, diabetes, dyslipidemia, atrial fibrillation, coronary heart disease, heart failure, peripheral arterial disease, cerebrovascular complications, antiplatelet, anticoagulant, and thrombolytic medications, multivariate-adjusted ORs of dialysis for disability deterioration was 2.88 (95%CI 2.40-3.45), and in-hospital mortality was 3.57 (95%CI 2.94-4.33).

Conclusions: Dialysis treatment was an independent risk factor for in-hospital disability deterioration and mortality of hospital onset stroke.

PUB331

Role of Bioimpedance as Tool for Fluid Management in Hemodialysis Patients Maria Cecilia Recalde,[1] Manuela Bello,[1] Cecilia Arruabarrena,[1] Alvaro Herou,[1] Fabian Cano,[2] Laura Sola.[1,2] *[1]Hemodialysis Unit, CASMU, Uruguay; [2]Preventive Medicine, Univ of the Republic, Uruguay.*

Background: Fluid management in hemodialysis patients is difficult, hypertension and fluid overload is frequent as well as hypotensive episodes leading to cerebral and cardiac injury and increased mortality risk. The objective of the study is to evaluate if bioimpedance could be a tool to optimize fluid management in hemodialysis patients.

Methods: Patients were included after giving informed consent when fulfilled inclusion and exclusion criteria. Were recorded age, gender, diabetes status, dialysis vintage, body mass index (BMI) estimated dry weight, and mean in previous month: systolic blood pressure (SBP), diastolic blood pressure (DBP), interdialytic weight gain, ultrafiltration volume (UF VOL), hypotensive episodes and use of antihypertensive drugs. A multi-frequency bioimpedance device (BCM Fresenius Medical Care) was used to evaluate fluid overload. Patients were categorized according post dialysis fluid overload and analyzed regarding SBP, DBP, hypotensive episodes and drugs. Data were analyzed in free software (epi info 7). Quantitative data were expressed as mean ± standard deviation and compared by t test, and categorical variables were compare by chi square. Were considered significant differences when $p < 0.05$.

Results: Fifty patients were included, 32 (64%) men, age 66.1± 13.1 years, 14 (28%) diabetics, and BMI 30.9 ± 9.5. Mean SBP 128 ± 13, DPB 72 ±8.0, interdialytic weight gain 2.1 ± 0.1 kg, and UF VOL 2.0 ± 0.9 lts. Of them 26 patients (52%) had hypotensive episodes, and 29 (58%) were on antihypertensive drugs. Only 5 patients had mean SPB³140, of which 4 were overhydrated postdialysis. None had DPB≥90. The 22 (44%) patients with weight below the estimated by BMC presented more frequent hypotensive episodes during dialysis ($p<0.05$), and had significant higher mean BMI (33.9 vs 27.5), UF VOL (2.3 vs 1.7 l) and weight gain (2.4 vs 1.7). No association was found between interdialytic weight gain and SPB≥ 140.

Conclusions: Obtaining tight SBP and DBP was accompanied with reduced total body water and frequent hypotensive episodes. Adjusting dry weight according BMC estimation could improve dialysis tolerance.

PUB332

Effect of Renin Angiotensin Aldosterone System Blockade on Clinical Outcomes in Patients with End-Stage Renal Disease: A Prospective Cohort Study in Korea Kyung Don Yoo,[1] Jung Pyo Lee,[1] Jung Nam An,[1] Yun Kyu Oh,[1] Shin-Wook Kang,[2] Chul Woo Yang,[3] Yong-Lim Kim,[4] Chun Soo Lim,[1] Yon Su Kim.[1] *[1]Seoul National Univ College of Medicine; [2]Yonsei Univ College of Medicine; [3]The Catholic Univ of Korea College of Medicine; [4]Kyungpook National Univ School of Medicine.*

Background: Adequate blood pressure control plays a key role in the management of patients with end-stage renal disease (ESRD). Although renin angiotensin aldosterone system (RAAS) blockade is known as the best treatment option for chronic kidney disease with hypertension, there is debate in the ESRD patients maintaining dialysis.

Methods: A total of 5,223 patients in the Clinical Research Center for ESRD (CRC for ESRD) prospective observation cohort from Aug 2008 to Dec 2014 were enrolled to this study. We compare overall survival and major cardiovascular event (MACE)-free survival between RAAS group and control group for using 1:1 propensity score matching (PSM) analysis. We defined the RAAS group as using ACE inhibitor or angiotensin receptor blocker more than 3month.

Results: Before matching, the RAAS group was younger; however, had more comorbidities such as diabetes and cardiovascular disease. The RAAS group had higher systolic blood pressure and was prescribed more number of other antihypertensive drugs than control group. After matching, there were no differences in age, sex, dialysis modalities, comorbidities and number of other antihypertensive medications. Before PSM, patient survival was significantly better in the RAAS group using the Gehan-Wilcoxon test (P=0.001), however, this difference disappeared after matching (P=0.450). Cardiovascular event-free survival was not different between RAAS group and control group before and after PSM analysis.

Conclusions: RAAS blockade did not affect all-cause mortality and MACE-free survival in the Korean ESRD patients. Further researches such as randomized control study will be needed.

PUB333

Lipidemic Profile and Sleep Apnea Syndrome in Hemodialysis Patients Olga Nikitidou,[1] Vassilios Liakopoulos,[1] Aikaterini A. Papagianni,[2] Euphemia Daskalopoulou,[3] Nicholas V. Dombros.[1] *[1]Div of Nephrology and Hypertension, 1st Dept of Internal Medicine, AHEPA Hospital, Aristotle Univ of Thessaloniki, Thessaloniki, Greece; [2]Dept of Nephrology, Hippokration Hospital, Aristotle Univ of Thessaloniki, Thessaloniki, Greece; [3]Sleep Laboratory, "Aghios Pavlos" General Hospital, Thessaloniki, Greece.*

Background: Dyslipidemia, characterized by low high density lipoprotein-HDL, high triglyceride-TG levels and normal levels of low density lipoprotein-LDL, is one of the traditional cardiovascular risk factors in hemodialysis-HD patients. On the other hand, sleep apnea syndrome-SAS, which is very common in this population, is one of the newest non-traditional cardiovascular risk factors. We investigated the impact of SAS and nocturnal hypoxia on the lipidemic profile of HD patients.

Methods: 37 HD patients (23 males) participated in the study. The night between two consecutive midweek HD sessions, they underwent an overnight polysomnography study. The following morning fasting blood samples were obtained and serum levels of total cholesterol-TC, TG, LDL, HDL, apolipoprotein A-apo A, apolipoprotein B-apo B and lipoprotein α-Lp (α) were measured.

Results: We investigated the correlation of the patients' lipidemic profile with their characteristics [age, Body mass index-BMI, duration of HD] and their sleep parameters [Apnea/Hypopnea Index-AHI, Respiratory Disturbance Index-RDI, Desaturation Index-DI, mean and minimum SpO_2, percentage of sleep time with SpO_2<90%and total sleep time) and found that: 1) TC correlated negatively with minimum SpO_2 (r=-0.454, p=0.005), 2) TG correlated positively with BMI (r=0.490, p=0.002) and RDI (r=0.438, p=0.007), 3) HDL correlated negatively with duration of HD (r=-0.350, p= 0.037) and BMI (r=-0.391, p=0.02), 4) apo A correlated negatively with duration of HD (r=-0.344, p=0.046), 5) Lp (α) correlated negatively with minimum SpO_2 (r=-0.364, p=0.034) and 6) LDL and apo B showed no correlation.

Conclusions: The results of the present study indicate that in HD patients with SAS the severity of the syndrome and the nocturnal hypoxia correlates with many parameters of their lipidemic profile which might contribute in the augmented cardiovascular risk in this population.

PUB334

Hemodynamic Changes in Maintenance Hemodialysis Patients with Intradialytic Hypotension Meijuan Meng, Hong Ye, Junwei Yang. *Center for Kidney Disease, Second Affiliated Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: Intradialytic hypotension (IDH) is a common complication in patients undergoing maintance hemodialysis (MHD) which leads to high mortality. This study is to explore the hemodynamic changes in MHD patients with IDH.

Methods: Thirty-seven patients were included in our study. IHD were defined as a decrease of systolic blood pressure (SBP)>20mmHg or the lowest SBP below 90 mmHg during dialysis. Twenty-three patients were diagnosed with IDH. Among them, 13 were

asymptomatic while the other had the hypotensive symptoms, such as abdominal discomfort, sighing, nausea, vomiting, muscle cramps and restlessness. All of them underwent a noninvasive hemodynamic evaluations before, during and after dialysis.

Results: Compared to the patients without IDH, the dialysis age was longer and the prevalence of diabetes was higher in the patients with IDH. There were no difference in age, amount of ultrafiltration, pre-dialysis cardiac index (CI), systemic vascular resistance index (SVRI) and thoracic fluid capacity (TFC) between these two groups. During dialysis, CI decreased while SVRI increased gradually especially in patients with IDH. At the end of dialysis, ΔCI was markedly higher in patients with IDH. However, there was no significant difference in the change of CI, SVRI and TFC ten minutes before and after hemodialysis between these two groups. Meanwhile, the hemodynamic changes were analyzed in IHD patients with or without symptoms. It was found that there were no difference of change values and absolute values of CI and SVRI in these subgroups.

Conclusions: It was found that CI decreased while SVRI increased during hemodialysis. In the mid and later period, the CI decreased much more in patients with IDH. It was suggested that CI might be an indicator of IDH.

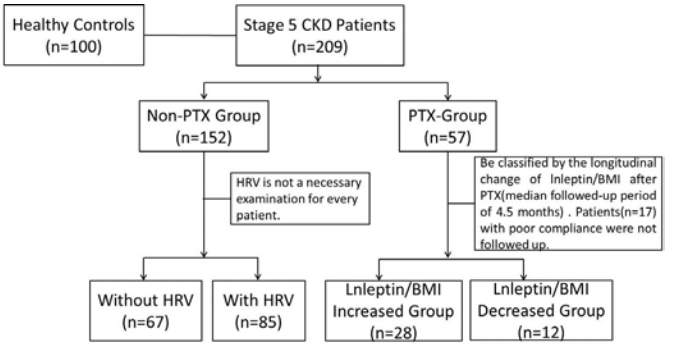
PUB335

Dual Relationships of Serum Leptin on Heart Rate Variability in Patients with Stage 5 Chronic Kidney Disease Ningning Wang, Yao Jiang, Jingjing Zhang, Changying Xing. *Nephrology, First Affiliated Hospital of Nanjing Medical Univ, Nanjing, China.*

Background: Leptin regulates nutrition, bone metabolism and cardiovascular function. Lower heart rate variability(HRV) in chronic kidney disease(CKD) predicts higher risk of cardiovascular disease(CVD).Relationships between leptin and HRV in CKD is obscure.

Methods: This included cross-sectional observation and longitudinal followed-up on parathyroidectomy(PTX) patients.



Serum leptin/BMI is transformed using natural logarithm(lnleptin/BMI).

Results: lnleptin/BMI showed no difference between stage 5 CKD and controls. However, quartile 2 of lnleptin/BMI level in CKD patients prone to have higher HRV indices

Lnleptin/BMI in PTX group is correlated with serum Ca, P and PTH. Compared with lnleptin/BMI decreased group, lnleptin/BMI increased group has higher serum PTH before PTX and their HRV indices were significantly elevated after PTX.

Conclusions: Serum leptin has dual relationships with HRV and keeping its proper level contributes to reduce CVD in stage 5 CKD. PTX can reverse above disorders in severe SHPT patients.

PUB336

Association of Geriatric Nutritional Risk Index and Responsiveness to Erythropoiesis-Stimulating Agent in Mortality of Chronic Hemodialysis Patients Kosaku Nitta, Ken Tsuchiya. *Dept of Medicine, Tokyo Women's Medical Univ, Shinjuku-ku, Tokyo, Japan.*

Background: Responsiveness to erythropoiesis-stimulating agent (ESA) may be associated with mortality in hemodialysis (HD) patients. The aim of the present study was to assess the effects of geriatric nutritional risk index (GNRI) and responsiveness to ESA in outcome in HD patients.

Methods: The ESA resistance index (ERI) was determined as the weekly weight-adjusted dose of ESA divided by hemoglobin concentration. Patients were divided into four groups by quartiles of ERI. Odds ratios were estimated using a Cox proportional model for the association between GNRI and ERI and mortality, adjusting for potential confounders. Patients were divided into four groups by quartiles of ERI.

Results: Of the 298 subjects enrolled, 51 died with 31 cardiovascular deaths during the follow-up period of 34.6 ± 6.1 months. The ERI was inversely correlated with the GNRI ($r = 0.287$, $p < 0.0001$). Age, gender, serum total cholesterol, phosphorus levels, transferrin saturation and GNRI were independent predictors of ERI. Older age, female gender, serum total cholesterol, transferrin saturation and GNRI were independent predictors for ESA hyporesponsiveness. Receiver operating curve analyses indicated the cut off values of GNRI and ERI for mortality were 94.9, 13.5, respectively. When subjects were stratified by ERI and GNRI value into four groups, those who had low GNRI and high ERI were associated with the highest risk of mortality among the four groups (log-rank $p < 0.001$).

Conclusions: high ERI and low GNRI were associated with an increased risk of all-cause mortality.

PUB337

A Multidisciplinary Approach Is Required to Reduce Hospitalizations for Cardiovascular Disease in Maintenance Hemodialysis Patients David L. Epstein,[1,2] Thomas Parker,[1,2] Daniel Levine,[1,2] Jeffrey I. Silberzweig.[1,2] *[1]Medicine, The Rogosin Inst, New York, NY; [2]Medicine, Weill Cornell Medical College, New York, NY.*

Background: Patients receiving maintenance hemodialysis have hospital admissions rates significantly greater than patients with other chronic diseases[1]. Approximately 40% of the hospital admissions are related to cardiovascular disease including both acute events and pulmonary edema[1]. We sought to assess the contribution of fluid weight gains to hospital admissions.

Methods: We compared inter-dialytic weight gains as a percentage of target weight and changes in blood pressure for the approximately 1200 patients receiving maintenance hemodialysis in our seven dialysis clinics in New York City between January and April 2015. We compared these data to total and cardiovascular hospital admissions using t- tests.

Results: Greater relative weight gains were significantly associated with pre-treatment systolic blood pressure (2.7 mmHg increase in BP per 1% increase in weight; $p < 0.0001$) and hospitalizations for cardiovascular complications ($p=0.03$). In contrast, neither greater relative weight gain nor pre-treatment systolic blood pressure was significantly associated with all-cause hospitalization ($p>0.5$). The clinic with both the greatest relative weight gains and the highest rate of hospitalization for cardiovascular disease was without a full-time dietitian for the months of the study.

Conclusions: In our population of maintenance hemodialysis patients, we report a statistically significant association between relative weight gains, hypertension and hospitalization for cardiovascular disease. We suggest that this relationship may be related to the absence of a full-time dietitian leading to a lack of a true multidisciplinary team approach to fluid management in these patients. **References:** 1. Acute Effects of Cinacalcet on Arterial Stiffness and Ventricular Function in Hemodialysis Patients Mohsen Agharazii, Karine Marquis, Catherine Fortier, Sacha A. De Serres, Fabrice Mac-Way. *CHU de Quebec Research Center, Hotel-Dieu de Quebec Hospital, Québec, QC, Canada.*

Background: Ionized calcium concentrations are crucial for vascular smooth muscle tone and myocardial contractility. The aim of the present study was to investigate whether a reduction in serum calcium concentration by the calcimimetic cinacalcet can reduce aortic stiffness and improve diastolic dysfunction.

Methods: This is a randomized, double blinded, cross-over study comparing the effects of 30 mg/d of cinacalcet for 7 days to 7 days of placebo. Aortic stiffness was measured by determination of carotid-femoral pulse wave velocity (cf-PWV), central aortic pressure wave form was performed by radial tonometry using generalized transfer function, and cardiac function was evaluated by an echocardiogramme. Linear mixed model with fixed effects including period, treatment and sequence, while a random effect for the patients nested in sequence was used.

Results: 21 patients were enrolled. After administration of cinacalcet the total serum calcium decreased (2.28 ± 0.18 versus 2.15 ± 0.14 mmol/L, $p<0.001$), with a significant reduction of PTH levels as expected (558 ± 293 to 306 ± 333 ng/l, $p<0.001$). There were no significant differences in central pulse wave profile. Taking into account changes in the mean blood pressure, sequence, carryover and treatment effect, there was a numerically lower cf-PWV under cinacalcet that was not statistically significant (0.35, 95% CI -0.13 – 0.83

m/s, p=0.139). In 14 subjects, who underwent echocardiogramme, there were no significant changes in cardiac output, stroke volume and ejection fraction. However, left ventricular end-systolic volume (52 ± 22 versus 57 ± 25 ml (p=0.20) and end-diastolic volumes (92 ± 35 versus 97 ± 17, p=0.08). were numerically higher under cinacalcet, but not statistically significant. There were no significant changes in the parameters of diastolic dysfunction.

Conclusions: In this short term study, there were no detectable effects of cinacalcet on aortic stiffness and diastolic dysfunction despite the expected reduction in serum calcium concentration. The numerically higher left ventricular volumes with cinacalcet, may need to be investigated. Clinical trials: NCT01250405.

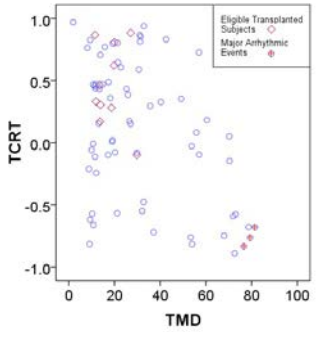
Kidney Transplantation and Cardiac Repolarization Descriptors

Dimitrios J. Poulikakos,[1] Debasish Banerjee,[2] Marek Malik.[3] *[1]Renal, Salford Royal, United Kingdom; [2]St. George's Univ of London, United Kingdom; [3]Imperial College, London, United Kingdom.*

Background: Selected descriptors of cardiac repolarization derived from the computerized analysis of electrocardiogram (ECG) can predict cardiac risk in hemodialysis (HD) patients. Kidney transplantation improves cardiovascular survival. The aim of the study was to investigate the impact of kidney transplantation on these descriptors.

Methods: The study was conducted in two phases. In phase 1, Holter ECGs were obtained during HD sessions and repeated 5 times at 2-weeks intervals in stable HD patients. The repolarisation descriptors QRS-to-T angle (TCRT) and T wave morphology dispersion (TMD)) were calculated in overlapping 10 second ECG segments and averaged over the first hour of recordings. In phase 2, continuous 1-hour ECG recordings were obtained in patients who received a kidney transplant minimum three months after transplantation and if they were stable with EGFR>30 ml/min/1.73m2. Average values of post transplant repolarisation descriptors were compared with average values over the first hour of HD using Wilcoxon test and t-test was used for baseline comparisons.

Results: In 80 HD patients in phase 1 both descriptors showed intrasubject stability and exhibited extreme values in subjects that suffered major arrhythmic events. During a period of 35.9 ±3 months 10 eligible transplanted subjects were recorded and although TMD and TCRT improved 7 months following kidney transplantation (see table) the difference did not reach statistical significance (p>0.05). However these subjects had better baseline TCRT and TMD values compared to the study population (TCRT 0.463 vs 0.078 p < 0.05 and TMD 17.9 vs 32.4 p<0.05) .



Characteristics of eligible transplanted subjects (n=10)	
Age	47 (range 27-73)
Females	50% (n=5)
Diabetes	20% (n=2)
Months from last HD recording to transplantation	7.5 (range 2-25)
Months from transplantation to post transplantation recording	7 (range 3-8)
QRS-T angle (TCRT) before transplantation	0.349±0.423
QRS-T angle (TCRT) post transplantation	0.438±0.331
TMD pre-transplantation	17.4±7.1
TMD post transplantation	15.2 ±5.7

Conclusions: In transplant recipients with healthier baseline repolarization profiles the improvement did not reach statistical significance in the early post transplant period. Larger studies with longer follow up are needed.

PUB340

Prognostic Significance of Cardiopulmonary Exercise Test and 6-Minute Walk Test in Chronic Dialysis Patients

Wioletta Dziubek,[1] K. Bulinska,[1] B. Ochman,[2] Ukasz Rogowski,[3] Mariusz Kusztal,[4] Tomasz Golebiowski,[4] D. Markowska,[1] A. Zembron-Lacny,[5] Marian Klinger,[4] M. Wozniewski.[1] *[1]Dept of Physiotherapy, Univ School of Physical Education, Wroclaw, Poland; [2]Dept of Physical Education, Univ School of Physical Education, Wroclaw, Poland; [3]Non-Public Medical College of Wroclaw, College, Wroclaw, Poland; [4]Nephrology and Transplantation Medicine, Wroclaw Medical Univ, Wroclaw, Poland; [5]Physical Education, Univ of Zielona Gora, Zielona Góra, Poland.*

Background: Dialysis patients (pts) are burdened by significant morbidity and mortality from cardiovascular causes. Identifying patients with an increased risk of ominous prognosis is of essential clinical relevance.The aim of the study was to evaluate prognostic value of cardiopulmonary exercise test (spiroergometry) and 6-minute walk test (6MWT) in chronic dialysis pts.

Methods: In prospective study 90 pts receiving high-flux dialysis (12h/week) were examined by means 6MWT and spiroergometry (VO2max,VE,VCO2, METS). After 3 years of follow-up data were evaluated in term to assess prognostic value of physical performance tests. Patients were divided into 2 groups: survivors and non-survivors (died within 3 years).

Results: Mortality at 3 years was 22.2% (20 pts) – non-survivors. They showed significantly lower values in cardiopulmonary exercise test and achieved shorter distance in 6 MWT compared to survivors – table. In multivariable analyses controlling for age, and sex lowed distance in 6 MWT was significantly correlated with all lower measures of spiroergometry (r 0.5-0.6). VO2max and 6 MWT were independently (from age) associated with death within 3 years.

	Non-survivors; n=20 (median)	Survivors; n=70 (median)	P (U Mann Whitney)
Age [y]	67	62	0,008332

Adaptive Servo-Ventilator Therapy Improves the Cardiac Dysfunction in Hemodialysis (HD) Patients with Sleep-Disordered Breathing

Fumiko Fukuuchi,[1] Ken Tsuchiya,[2] Kosaku Nitta.[2] *[1]Nephrology, Komagome Kyouritsu Clinic, Bunkyo-ku, Tokyo, Japan; [2]Medicine IV, Tokyo Women's Medical Univ, Shinjyuku-ku, Tokyo, Japan.*

Background: Cardiac dysfunction is a very serious problem in HD patients. Sleep Disordered Breathing (SDB) is considered to cause cardiac dysfunction. Dialysis patients have a disordered respiratory center and a high prevalence of central apnea. Adaptive Servo-Ventilator (ASV) is automated modality used to treat heart failure patients with SDB, especially central apnea. The aim of this study is to explore the relationship between sleep apnea and cardiac dysfunction, and to evaluate the effects of ASV therapy in HD patients.

Methods: Sleep study was performed using a portable sleep test device (Sleeptester LS-300, Fukuda Denshi Co., Ltd, Japan). We measured the variables of cardiac function by echocardiogram. The relation between apnea index and the echocardiogram indicates was evaluated. We also collected baseline information on demographics, laboratory values, plasma BNP level, medications, and clinical conditions. ASV therapy was used in the patients diagnosed with severe SDB and/or central apnea. The cardiac function variables were evaluated in comparison to the previous year.

Results: The 27 dialysis patients (sixteen diabetics, eleven non-diabetics) are included in this study. Out of them, echocardiogram, SDB indications showed a connection. The obstructive apnea hypopnea index was related to the left ventricular posterior wall thickness (LVPWT) (r=0.49, *p*=0.02). Seven patients received ASV therapy. There has been improvement of overall of their cardiac function with significant increase of ejection fraction (*p*=0.02) 1 year after ASV introduction.

Conclusions: In this study, we demonstrated the efficacy of ASV therapy in hemodialysis patients with SDB. Near future, ASV is possible to be one of attractive devises for HD patients, with aging, several complications, to improve their poor prognosis.

PUB342

Endovascular Renal Denervation: Effects on Dyslipidaemia and Vascular Inflammation in Dialysis Patients

Neil A. Hoye,[1] J. Christopher Baldi,[1] David L. Jardine,[2] John B.W. Schollum,[1] Gerard T. Wilkins,[1] Luke C. Wilson,[1] Robert J. Walker.[1] *[1]Dunedin School of Medicine, Univ of Otago; [2]Christchurch School of Medicine and Health Sciences, Univ of Otago.*

Background: Endovascular renal denervation (RDN) reduces afferent and efferent sympathetic nerve activity. Its effects on vascular inflammation and cholesterol levels in dialysis patients are unknown. We hypothesized RDN would reduce sympathetic activity, resulting in improvement in biomarkers of vascular inflammation and dyslipidaemia.

Methods: Nine dialysis patients with uncontrolled office BP (>140/90mmHg despite two or more agents at maximal tolerated dosages) were recruited into this feasibility study. Office and ambulatory BP monitoring (ABPM) were performed at baseline, one and three months post RDN, along with supine muscle sympathetic nerve activity (MSNA) and venepuncture. Bilateral RDN was undertaken with an EnligHTN™ catheter.

Results: Similar to previous, office systolic BP reduced and the effect on ABPM was attenuated. MSNA did not change, a novel finding. Despite lack of change in MSNA, total cholesterol:HDL ratio increased along with a falling trend in CRP and rising trend in albumin, all novel findings.

	Baseline	1 Month	3 Months	P value
Office Systolic BP (mmHg)	179±28	156±24	152±25	**<0.05**
Office Diastolic BP (mmHg)	90±17	76±13	82±12	0.137
Mean Systolic ABPM (mmHg)	173±19	173±23	166±24	0.544
Mean Diastolic ABPM (mmHg)	92±11	89±13	88±11	0.906
MSNA Burst Frequency (n=6) (bursts/min)	59±12	59±15	59±13	0.872
Albumin (g/L)	38±5.0	39±6.3	41±4.6	0.068
Total Protein (g/L)	66±6.1	68±8.2	69±5.9	0.282
CRP (mg/L)	27±28	20±20	15±18	0.056
Chol (mmol/L)	4.1±0.9	4.1±1.0	4.4±1.2	0.228
HDL Chol (mmol/L)	1.2±0.3	1.2±0.2	1.1±0.2	0.388
Chol:HDL Ratio	3.6±1.1	3.5±0.9	4.1±1.1	**<0.05**
LDL Chol (mmol/L)	2.2±0.7	2.4±0.9	2.5±1.0	0.071
Triglycerides (mmol/L)	1.4±0.8	1.2±0.6	1.6±0.7	0.160

Conclusions: RDN in dialysis patients improves office systolic BP, impacts uraemic dyslipidaemia and possibly reduces vascular inflammation. Further controlled studies are warranted.

PUB343

Comparative Study of Non Survivors and Survivors Among Twice Weekly Hemodialysis Patients in India Topoti Mukherjee, Naksha Jagannath Anchan, Geetha S, Gayathri Devi R.G., Avinash Ignatius, Tanmay Pandya, Vidyashankar Panchangam, Sylvia Paz B. Ramirez, Suresh Sankarasubbaiyan. *Nephrology, Davita Care India Private Limited, Chennai, Tamilnadu, India.*

Background: Hemodialysis practice varies based on health system, payer practice, patient choice and socioeconomic environment. We analyzed the practice pattern and characteristics of non survivors and survivors among twice weekly hemodialysis patients across 9 centers in India.

Methods: Retrospective study of patients on HD between July 1, 2013 to Dec 31, 2014. Inclusion criteria: > 30 days of HD & 1.8 - 2.3 HD sessions/week. Demographic characteristics, comorbidites, hospitalizations, cumulative follow up, hemoglobin, Albumin,Calcium and Phosphorus were compared among non survivors and survivors . We compared mean and proportion using Student T test and chi- square test respectively.

Results: N=255; 63.9% males. Non survivors 61 , survivors 194. Data presented as non survivors vs survivors: Hospitalizations: 42.6% vs 25.8% (<0.01), DM: 63.2% vs 34.5%, (<.01)CAD: 17.5% VS 6.4% (<.05),CVA: 1.8% vs 2.3%; HCV: 1.8% vs 10.9% (p< 0.05), HBV: 7% vs 1.1 % (< 0.05), HIV: 5.3% vs 3.4%

	Non survivors (n-61)	Survivors (n-194)	
Age	59.5 (12.5)	51.6 (14.3)	<.01
Cumualtive follow up (pt yrs)	41.3pt yrs	186.8 pt yrs	
Median follow up (days)	209	385	
Total sessions	83.6(59)	118(74.6)	<.01
Avg HD /week	1.9(0.2)	1.9(0.2)	ns
S. Hb (G%)	8.9 (1.7)	9.5 (1.6)	<.05
URR (%)	68.8 (5.5)	67.9 (7.9)	ns
Std Kt/V	1.6 (0.30	1.7 (0.4)	ns
S. Alb (g%)	3.5 (0.9)	4.0 (1.4)	<.01
S. Ca (mg%)	8.4 (0.8)	8.4 (0.9)	ns
S. Ph (mg%)	5.6 (1.3)	5.7 (1.6)	ns
S. K (mEq/L)	5.2 (0.8)	5.3 (0.7)	ns
Pre HD MAP standing	100.9(9.9)	103.4(13.5)	ns
Post HD MAP standing	99.7(8.7)	103.6(28.3)	ns
IDWG	3.8(1.4)	3.9(1.5)	ns
UF rate	0.6(0.2)	0.6(0.2)	ns
Mean hospitlalization/patient	0.6(0.9)	0.3(0.7)	ns
No of hospitalizations	37	69	

Non survivors were significantly older, had lower number of total sessions, lower albumin and Hb.

Conclusions: Non survivors were characterized by older age, higher prevalence of diabetes, CAD, lower Hb & Albumin. But dialysis adequacy and UF were comparable. Short duration of follow up may limit the ability to study other factors influencing outcomes.

PUB344

New Anticoagulant Free Strategy for Non Valvular Atrial Fibrillation in Hemodialysis Patients Teresa Arcidiacono, Patrizio Mazzone, Marco Simonini, Donatella Spotti, Maria Teresa Sciarrone Alibrandi, Rita Quartagno, Marco Melandri, Stefano Tentori, Giorgio Slaviero. *San Raffaele Scientific Inst, Italy.*

Background: Vascular calcification in patients with CKD-5 is associated with increased cardiovascular morbidity and mortality. An excessive calcification of coronary arteries and of aortic valve has been reported during Warfarin treatment. In addition use of oral anticoagulation (OAC) seems to be an important risk factor for calciphylaxis. Atrial fibrillation (AF) is the most frequent reason for OAC use in CKD patients.

Methods: An alternative to OAC could be the percutaneous Left Atrial Appendage (LAA) closure. With this technique an implantable component is permanently fixed in the LAA to prevent thrombus embolization. Different studies demonstrated that this procedure is not inferior to systemic anticoagulation with OAC in prevention of thromboembolic risk. We reported our clinical experience with the use of this technique in haemodialysis patients with non valvolar AF.

Results: In the last few months seven (7) haemodialysis patients were treated with percutaneous LAA closure. Bleeding and stroke risks were evaluated by HAS-BLED score and CHA2DS2-VASc score: HAS-BLED score was 4.5±0.58 (equal to 9%±0.11 yearly risk of major bleeding) and CHA2DA2-VASc was 4±0.81 (equal to 4.47%±1.5 yearly risk of stroke). This procedure was well tolerated by each patient. OAC treatment was interrupted after the procedure and doubled antiplatelet therapy was introduced for a month. At this moment median of 9 months of follow-up was archived [IQR 3-12]; no adverse events has been assessed.

Conclusions: To the best of our knowledge this is the first consecutive series of LAA closures in haemodialysis patients. This procedure represents a real clinical alternative to the use of coumarin derivated drugs. Our experience leads the way to the possible routinary use of this procedure in CKD-5D patients. As well as this procedure could be used in those patients with contraindications to OAC, even more this treatment should be used in haemodialysis population, in which the use of OAC should be avoided for both increased risk of life-threatening bleeding events and well known negative cardiovascular effects.

PUB345

Management of Subclinical Thyroid Dysfunction Can Reduce Cardiovascular Events in Patients with End-Stage Renal Disease on Hemodialysis Hong Joo Lee. *Dept of Nephrology, Seoul Red Cross Hospital, Seoul, Republic of Korea.*

Background: Normal thyroid function influences basal metabolic rate and general body metabolism and thyroid dysfunction is often associated with dyslipidemia and increased cardiovascular risk in general polulation. It is known that about 25% of patients with end-stage renal disease(ESRD) on hemodialysis had subclinical thyroid dysfunction. We investigated that subclinical hypothyroid dysfunction associate with dyslipidemia and cardiovascular event in hemodialysis patients. Hence, we conducted our study to elucidate whether subclinical thyroid dysfunction treated or not in ESRD patients.

Methods: All hemodialysis patients in Red Cross Hospital within a period of one year were included in the study. Thyroxine-3 (T3), free thyroxine-4 fT4, Thyroid Stimulating Hormone (TSH) and lipid profiles in the serum were estimated and death from all causes and CV events served as outcome variables over a median follow-up period of 12 months. Participants were divided into groups based on the thyroid function. Statistical analysis was carried out by using SPSS.

Results: Among the 92 cases, 28.2% of the patients were having thyroid disorder. In which 2.1% were of hypothyroid, 13.7% were of subclinical hypothyroid, and 0.8% were of hyperthyroid, 11.6% were of subclinical hyperthyroid. We observed negative correlation between TC & fT3. Total cholesterol was raised in hypothyroidism in comparison to euthyroid ESRD patients. However, thyoroid function didn't have significant association with lipid profiles. Cardiovascular disease significantly often occurred in subclinical thyroidism patients than other group.

Conclusions: Our results show that the blood thyroid hormone level isn't affected by dyslipidemia but affected by occurrence of CVD. Therefore, the management of subclinical hypothyroidism in hemodialysis patients should be considered.

PUB346

Effect of Altitude on All-Cause Mortality in End-Stage Kidney Disease Patients Ongoing Hemodialysis in Peru Katia Bravo-Jaimes,[1] Viky Y. Suncion,[2] Jose Ernesto Rojas,[3] Christian R. Mejia,[4] Sandra C. Schult.[5] *[1]Medicine, Univ of Rochester Medical Center, Rochester, NY; [2]Medicine, Jackson Memorial Hospital, Miami, FL; [3]Inst de Investigaciones de Altura, Univ Peruana Cayetano Heredia, Lima, Peru; [4]Asociación Médica de Investigación y Servicios en Salud, Lima, Peru; [5]Pediatrics, Inst Nacional de Salud del Niño, Lima, Peru.*

Background: Worlwide, end-stage kidney disease (ESKD) prevalence has tremendously risen. Previous studies suggested that receiving hemodialysis (HD) at high altitude confers mortality benefits; however this effect has not been proved above 2000 m or in developing countries.

Methods: This historical cohort study analized medical records from six HD centers of the Peruvian Social Security System. Adult ESKD patients who started HD between 2000 and 2010 were included. Patients were classifed into two strata (< 2000 and > 2000 m). The outcome variable was death from any cause. Cox proportional hazards models were built for the time from first dialysis to death from any cause, stratifying by year and censoring patients at 5 years after first dialysis; loss to follow-up; transference to another HD center out of the city; renal transplantation or migration to peritoneal dialysis during follow-up.

Results: 723 patients were enrolled, including 248 women (38.2%). The mean age was 52.8 ±16.9 years. 166 patients lived > 2000 m (22%). In first years after follow-up, survival rates were lower in the group > 2000 m, however after 8 years of follow-up this trend reversed . Age and gender were not significantly associated to mortality at altitude levels > 2000 m. Patients with diabetes had higher mortality rates at > 2000 m (p=0.003), independently of age.

Conclusions: In Peru, patients receiving HD at high altitude do not experience mortality benefits. In fact, diabetics have higher mortality rates at > 2000 m.

End-Stage Renal Disease in North Region of Oman/Epidemiology, Incidence, and Aetiology Ruqiya Khamis Al-Za'abi,[1,2] Elizabeth P. Tolmie,[1] Ann marie Rice,[1] Nabil Mohsin,[2] Ahmed Said Al-Busaidi.[2] *[1]Nursing and Health Care, Univ of Glasgow, Glasgow, United Kingdom; [2]Nursing Education, Ministry of Health, Muscat, Sohar, Oman.*

Background: The epidemiology of renal failure in Oman is scarce. There is a paucity of information on the size and burden of renal failure in Oman. Therefore, our research was conducted to measure the prevalence, incidence and death rate (epidemiology) among patients who have renal failure and undergo renal dialysis in four dialysis centers in the North of Oman; and to provide a description of the major characteristics of the studied patients.

Methods: A cross-sectional study was conducted. A proportional sample (n = 341) patients from four Renal Dialysis Centres (RDC) were interviewed face to face or via telephone using a structured questionnaire. Data collection took place between October and November, 2014. The incidence, prevalence and death rate are under collection until the end of December, 2015.

Results: Over the period January 1st, 2014 to December 31st, 2014, a total of 96 new patients started dialysis in the four observed RDCs. The overall incidence rate was 13 patients per 100,000. The period prevalence for the patients undergoing renal dialysis was 52 patients per 100, 000. The mortality rate for the same period of time was four patients per 100,000. Demographic data are summarized in table1.

	N	%
Subjects	380	100
Included	341	89.7
Excluded	39	10.3

Secondary Education	58	17
College Degree	18	5.3
Post-College	3	0.9
Employment Status		
Unemployed	292	85.6
Employed	49	14.4

Conclusions: Renal failure is a burden on patients, and the health and social systems of Oman. The expenditure on these 380 patients in 2014 was 6.5 million dollars. However, to determine the size of the burden, we need a comprehensive study covering the whole country of Oman and we need to receive data from neighbouring countries to compare with.

PUB348

Low Potassium Bath Protocol Experience in Hemodialysis Patients in Qatar Abdullah Hamad, Fadwa S. Al-Ali, Eiman Mohamed Hamid, Shaza Yousif Elsanoosi, Mohamed Yahya Mohamed, Hany Ezzat Ismail. *Nephrology, Fahad Bin Jassim, Hamad General Hospital, Doha, Qatar.*

Background: Hyperkalemia is a major problem in hemodialysis (HD) patients affecting there morbidity and mortality. HD patients receiving low potassium (K) bath for hyperkalemia have double the risk of sudden cardiac death. We noticed high rate of use of low K dialysate due to high prevalence of hyperkalemia in our dialysis unit. We are studying this phenomenon.

Methods: Our study was done in the biggest out-patient HD facility in Qatar (306 patients). We identified patients who required low K bath (based on an existing rigorous protocol, any K over 5.5 will be started on low K bath 1 mmol/L with checking K level every HD treatment till corrected) in 6 months period from 10/1/2014 to 3/31/2015. We collected background data in these patients and their potassium levels during that period.

Results: 62 out of 306 hemodialysis patients required low K bath continuously (5 patients) or intermittently (57 patients). Mean age was 59.9 +/- 15 years. There were 36 females on low K bath out of total 137 females versus 26 males out of 169 (p Value 0.014) . 39 out of 62 were Qatari (62% versus 65% in patients not on low K bath). Table 1 summarize number of patients on low K bath and number of low k bath HD treatments on monthly base versus average temperature in Doha, Qatar.

	October	November	Decem-ber	January	Febru-ary	March
number of patients on low K bath	35	34	28	17	9	27
number of HD treatments done with low K bath	349	362	178	79	65	160
average temperature in Doha, Qatar (degree centigrade)	35	29	25	22	25	27

Conclusions: In a study of using low K bath in a major HD clinic in Qatar we found a statistically significant higher number of female patients who required low K bath than males. This might be attributed to dietery habits based on our dietititions experience and vascular access issues but further study is needed to explain these findings. There was a significant decrease in need for low k bath in January and February compared to other months both in the number of patients and HD treatments . We attributed that to combination of cooler weather and seasonal change in dietery habits. Further study again is needed to evaluate that prosepectively.

PUB349

Co-Morbidity Rather Than Clinical Practice Patterns Determines Mortality in an Aged Dialysis Population An Vanacker,[1] Bert Bammens,[2] Bart De Moor,[3] Bart D. Maes.[1] *[1]Nephrology, AZ Delta, Roeselare, Belgium; [2]Nephrology, Univ Hospitals, Leuven, Belgium; [3]Nephrology, Jessa Hospital, Hasselt, Belgium.*

Background: Hemodiafiltration (HDF), by adding convective to diffusive transport, is more effective in removing larger uremic retention solutes than hemodialysis (HD). As these solutes are thought to have a role in the accelerated cardiovascular disease of dialysis patients, HDF might result in lower mortality compared to HD.

Methods: All patients treated with thrice weekly HD (high-flux) or online HDF at 3 Belgian dialysis centers for ≥ six and < 42 months were included in July 2008. Hospitalized patients or patients with access-related problems were excluded. The effect of HDF versus HD on all-cause mortality at 6 years was evaluated. Multi-variate analysis taking into account all relevant baseline variables was performed to determine independent predictors of outcome.

Results: 242 patients were included (142 male, mean age 70,9 ± 11,8 years): 84 treated with HD, 158 with HDF. After 6 years, the incidence of all-cause mortality was significantly higher in HD than in HDF: 54 of 84 patients in HD-group (64,3%), 70 of 158 patients in HDF-group (55,7%) (P = 0,04). Based on univariate associations with survival (*) and/or significant association with center or HD/HDF variable, following parameters were introduced in multivariate analysis: HD/HDF*, vintage, age*, weight, CCI*, use of calcium(Ca)-based and non-Ca-based phosphate (P) binders, dialysis hours/week, Qb, Qd, dialysate Ca concentration*, vascular access*, mean P*, Ca-P product*, hemoglobin, albumin*, interdialytic weight gain and center. The final multivariate model is shown in the table below.

Variable	HR	95% CI	p-value
Age	1,03	1,01 – 1, 06	0,003
Charlson Comorbidity Index CCI	1,30	1,16 – 1,45	< 0,0001
Weight	0,98	0,97 – 0,99	0,02
Calcium concentration of dialysate	3,60	1,06 - 12,24	0,04
Vascular access	1,43	1,19 - 1,72	0,0002
Interdialytic weight gain	1,31	1,07 - 1,61	0,009
Albumin	0,38	0,39 - 0,97	0,04

Conclusions: In an aged Western dialysis population, treatment with HDF did not improve all-cause mortality compared to high-flux HD. Mortality seems to be determined by comorbidity rather than by clinical practice patterns.

PUB350

Depression Is Associated with Frailty and Malnutrition but Not Comorbidity Load in Chinese Peritoneal Dialysis Patients Cheuk-Chun Szeto,[1] Shin Man Choy.[2] *[1]Dept of Medicine & Therapeutics, The Chinese Univ of Hong Kong, Shatin, Hong Kong; [2]Dept of Medicine & Therapeutics, Prince of Wales Hospital, Shatin, Hong Kong.*

Background: Depression is common amongst patients with chronic kidney disease and is associated with excessive mortality in dialysis patients. This study determines the prevalence and risk factors of depression in Chinese peritoneal dialysis (PD) patients.

Methods: We studied 178 prevalence PD patients (103 males). Depression was screened by the 15-item self-reported Geriatric Depression Scale (GDS). We also determined patients' comorbidity load, dialysis adequacy, residual renal function, nutritional status, and degree of frailty.

Results: The mean age was 60.7 ± 11.7 years; vintage of dialysis 42.5 ± 44.1 months. Average GDS score was 4.9 ± 4.4. GDS score is closely associated with the frailty score ($r = 0.692$, $p < 0.0001$), malnutrition inflammation score ($r = 0.406$, $p < 0.0001$), and subjective global assessment score ($r = -0.386$, $p < 0.0001$). GDS score also has a modest but significant correlation with Charlson's comorbidity index ($r = 0.164$, $p = 0.028$) and serum albumin level ($r = -0.192$, $p = 0.019$), but not with patient age, vintage of PD, dialysis adequacy, or residual renal function. When defined as a GDS score ≥8, 50 patients (28.1%) had depression.

Conclusions: Depression is common amongst Chinese PD patients. Frailty and malnutrition are the major risk factors of depression in our cohort, while comorbidity load and dialysis adequacy have little effect.

PUB351

Trends in Anemia Management with Darbepoetin Alfa in Patients on Maintenance Hemodialysis Robert H. Yenchek,[1] Anne C. Beaubrun,[2] Jeffrey Petersen,[2] David G. Dalpias,[1] Alfred K. Cheung.[1] *[1]Univ of Utah, Salt Lake City, UT; [2]Amgen, Inc., Thousand Oaks, CA.*

Background: In the US, darbepoetin alfa (DA) is primarily used to treat anemia in patients receiving treatment in hospital-based dialysis centers. Epoetin alfa (EA) doses and hemoglobin (Hb) levels declined in response to recent regulatory and reimbursement events but little is known about trends in anemia management with DA in the US maintenance hemodialysis (HD) population receiving treatment in free-standing dialysis centers (FSDCs). We describe herein anemia management in FSDCs within the University of Utah (UU) Dialysis Program who switched from the use of EA to DA program-wide in 2005.

Methods: We included ~650 adults (age ³18 yrs) with 1+ months on HD between 2008-2013 in 18 FSDCs within the UU Dialysis Program. We summarized quarterly intravenous DA and iron use and dose, Hb, and serum transferrin saturation (TSAT) and ferritin levels.

Results: 70-78% of patients received DA over the study period. Mean Hb levels among patients who received DA fell from 12.2 g/dL in 2008 before leveling around 10.3 g/dL from Q4 2011 to 2013 (Figure). The mean monthly DA dose was 209 mcg in Q1 2008, reached a peak of 256 mcg in Q1 2010, and decreased to ~105 mcg in 2013. Quarterly iron use rose from 52% in 2008 to 67% of patients in 2013. Iron dose also rose from 129 mg in Q4 2008 to 194 mg in Q4 2010, but declined to 163 mg in Q4 2013. Mean serum TSAT levels remained relatively constant at ~30% between 2008-2013 but serum ferritin levels increased from 449 ng/mL in Q1 2008 to 770 ng/mL in Q4 2013.

Conclusions: Trends in anemia management parameters among patients on HD treated with DA within FSDCs in the UU Dialysis program were consistent with national reports of patients treated with EA.

Figure. Mean DA dose (per 30 OP days), IV iron dose (per 30 OP Days), hemoglobin (among DA recipients), TSAT, and ferritin levels, 2008-2013

PUB352

Shorter Dialysis Session Time Was Associated with Higher Risk of Hospitalization and Death in Maintenance Hemodialysis Patients Takahiro Kuragano, Takeshi Nakanishi. *Dept of International Medicine, Div of Kidney and Dialysis, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan.*

Background: Recently, dialysis efficiency was dramatically improved by using super flux dialysis membrane. However, in the condition of the common use of high flux dialysis, it has not been well studied the relationship between treatment time and adverse events or survivals of maintenance hemodialysis (MHD) patients.

Methods: Subject: 805 patients undergoing MHD. Study design: Prospective, observational multi-center study of 3 years. We measured serum levels of urea nitrogen (UN), creatinine (Cr), b2microgroblin (MG), total protein, albumin, prealbumin, high sensitive C reactive protein (hCRP) every 3month. We also evaluated body mass index (BMI), and Kt/V. The associations between dialysis intensity and adverse events or death were investigated with the cox proportional hazards model for time-dependent variables.

Results: Although there was no significant correlation between pre-dialysis levels of b2MG or UN and adverse event or survival, high pre-dialysis Cr level was associated with lower risk of hospitalization (HR:0.89, P=0.003) and death (HR:0.71, P=0.002). Moreover, high Kt/V was also associated with lower risk for cerebrovascular and cardiovascular

disease (CCVD) (HR:0.37, P=0.039) and hospitalization (HR:0.55, P=0.026). There was no significant difference in serum levels of prealbumin, albumin, Cr, Kt/V and hCRP levels among 3 groups of treatment time (<4hours(h), 4-5h, >5h). On the other hand, BMI in the patients treated with >5h was significantly (p=0.012) higher than those of patients treated with <4h. In time dependent cox hazard model, the risk of hospitalization (HR:0.43, P=0.001) and death (HR:0.49, P=0.013) of patients treated with 4-5h were significantly lower than that of patients treated with <4h. Moreover, the risk of death in patients treated with >5h was significantly (HR:0.45, P=0.024) lower than that of treated with <4h.

Conclusions: Higher Kt/V was associated with lower risk of CCVD and hospitalization of MHD patients, but not pre-dialysis level of b2MG levels. Shorter dialysis session time was associated with higher risk of hospitalization or death than that of longer treatment time.

PUB353

A Randomized, Factorial Pilot Study to Evaluate the Feasibility of an Intradialytic Exercise Intervention (*DIALY-SIZE!*) Stephanie E. Thompson,[1] Scott Klarenbach,[1] Anita Molzahn,[1] Mark Haykowsky,[1] Anita Lloyd,[1] Marcello Tonelli.[2] *[1]Univ of Alberta, Edmonton, AL, Canada; [2]Univ of Calgary, Calgary, AB, Canada.*

Background: Intradialytic exercise (IDE) is associated with improved dialysis adequacy and amelioration of dialysis-related symptoms. However, the uptake of IDE is limited by knowledge gaps on efficacy—what type of exercise to prescribe to optimize outcomes, and on feasibility. The results of this pilot will inform the design of a full-scale efficacy study evaluating two types of IDE (aerobic and resistance) and will also provide research users with practical information on IDE.

Methods: In this single center, randomized, factorial (2 x 2) study, chronic adult hemodialysis patients were randomized to one of four IDE groups: cycling, resistance, cycling and resistance, or stretching (an attention control). Exercise was semi-supervised by a kinesiologist. Outcomes focused on a priori feasibility criteria: recruitment, fidelity to the protocol, and participant and unit staff response to IDE. As a secondary outcome, we evaluated the main effect of cycling and weights each compared with control on quality of life and physical performance at baseline and 12-weeks. To better understand feasibility, we conducted interviews with users.

Results: We exceeded targeted accrual of 28 people over 12 weeks. Of 100 patients screened, 31 were enrolled (36 did not meet inclusion criteria, 33 declined participation); 16% dropped out after randomization. Fidelity to the intervention was high: of 1,039 training sessions offered, 87% were delivered. Participant response to the intervention was favorable: 92% of participants continued exercising after the trial. There were no crossovers and no reported contamination. Dialysis staff were not consistently available to assist with implementation, so study staff were necessary to deliver IDE. Secondary outcomes were not statistically significant.

Conclusions: This pilot study demonstrated feasibility of recruitment, high patient acceptability, and low risk of contamination. However, IDE will not be feasible in the long term unless dialysis staff assist with implementation. This will need to be addressed before executing a definitive trial.

PUB354

A Prospective Study of Routine Heparin-Free Hemodialysis (HFD) with Streamline® Bloodlines (SL) in a Large Tertiary Acute Care Inpatient Practice Sami Safadi,[1] Mary Ann Ryan,[2] Amanda L. Severson,[2] Fares Alahdab,[3] John J. Dillon,[1] Robert C. Albright,[1] Amy W. Williams,[1] Marie C. Hogan.[1] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Nursing, Mayo Clinic; [3]KSP Unit, Mayo Clinic.*

Background: Extracorporeal circuit (EC) anticoagulation (AC) with heparin was a key advancement in hemodialysis (HD). However, AC in patients at risk of bleeding remains a frequently encountered problem. SL bloodlines eliminate blood-air contact, and reduce turbulence in HD circuit. Small studies suggest that SL reduces heparin use and improves HD efficiency. We prospectively evaluated EC clotting rates, impact on dialysis efficiency, and associated risk factors in our inpatient practice.

Methods: In this complete study, we followed acute care inpatients requiring HD without routine EC heparin. Patients could be on ACs for other non-HD indications. All sessions were performed using SL and Fresenius 2008K. HD sessions were observed for clotting events (CE) defined as interruption of HD session, loss of HD circuit, or inability to return blood.

Results: 1200 HD runs were performed. Demographics & HD session characteristics are summarized in table 1. Overall CE rate was 5.2%. Determinants for CE were temporary HD catheters (OR=2.8, p<0.01), transfusions (OR=2.3, p=0.05), systemic AC (OR=0.2, p<0.01), & antiplatelets (OR=0.4, p<0.01). CE were associated with a lower delivered KT/V (diff-0.39, p<0.01). Most CE during transfusions (71%) occurred when blood products were given by the HD circuit.

Conclusions: We successfully adopted HFD with SL as our standard inpatient protocol. This protocol is feasible and safe in acute care inpatient HD. CE risk is low, and is associated with temporary HD catheters and transfusions. Use of antiplatelets and systemic AC is protective.

Patterns of Oral Disease in Adults with Chronic Kidney Disease Treated with Long-Term Haemodialysis: A Multinational Ecological Study Giovanni F.M. Strippoli.[1,2,3,4] *[1]On behalf of the ORAL-D Study Investigators*; [2]Diaverum Medical Scientific Office; [3]Univ of Bari; [4]Univ of Sydney.*

Background: Oral disease is a potentially treatable risk factor for premature death and impaired quality of life. However, the oral disease burden and candidate preventative strategies are uncertain in the dialysis setting.

Methods: ORALD was a prospective study in 4726 adults treated with hemodialysis in Europe and Argentina recruited from a convenience sample of 80 dialysis clinics within a treatment network. Oral disease was assessed using standardized WHO methods. Participants self-reported oral health practices and symptoms. Socio-demographic and clinical factors associated with oral diseases were assessed within nation states.

Results: Of 4726 eligible adults from 80 dialysis units, 4205 (88.9%) participated. Overall, 20.6% were edentulous (95% CI, 19.4-21.8). Participants had on average 22 (21.7-22.2) decayed, missing or filled teeth while moderate to severe periodontitis affected 40.6% (38.9-42.3). Oral disease patterns varied markedly across countries. Participants in Spain, Poland, Italy and Hungary had the highest mean adjusted odds of edentulousness (2.31, 1.90, 1.90, and 1.54) whilst those in Poland, Hungary, Spain and Argentina had highest odds of ³14 decayed, missing, and filled teeth (23.2, 12.5, 8.14, 5.23). National levels of tobacco consumption (R^2=0.79), diabetes (R^2=0.49), and child poverty (R^2=0.66), were associated with edentulousness within countries.

Conclusions: Oral disease in adults on hemodialysis is very common, frequently severe, and highly variable among countries, with much of the variability unexplained by participant characteristics or oral practices. Given the substantial variation among countries and high burden of disease, strategies to improve oral health in hemodialysis patients will require national strategies. *List of ORAL-D Investigators: S Palmer, M Ruospo, G Wong, JC Craig, M Petruzzi, M De Benedittis, P Ford, DW Johnson, M Tonelli, P Natale, V Saglimbene, F Pellegrini, E Celia, R Gelfman, MR Leal, M Torok, A Bednarek-Skublewska, J Dulawa, P Stroumza, L Frantzen, D del Castillo, AG Bernat, J Hegbrant, C Wollheim, L Gargano, CP Bots and GFM Strippoli.

Low Serum Albumin Is a Risk Factor for In-Hospital Mortality Among Hemodialysis Patients Hospitalized with Infectious Diseases: A Multicenter Retrospective Cohort Study in Japan Shun Minatoguchi,[1,2] Hideaki Shimizu,[1,2] Takaya Ozeki,[2] Daisuke Uchida,[2] Hiroo Kawarazaki,[2] Hiroki Nishiwaki,[2] Takahiro Imaizumi,[2] Yoshiro Fujita,[1,2] Yugo Shibagaki.[2] *[1]Nephrology, Chubu Rosai Hospital, Nagoya, Aichi, Japan; [2]TOMEI Nephrology Group for Clinical Research, Japan.*

Background: Serum albumin is the known marker of nourishment and inflammation. Several studies in the past have shown the relationship between low serum albumin and long-term mortality among dialysis patients. However, There is insufficient data on the

relationship between serum albumin levels and short-term mortality among chronic dialysis patients who are hospitalized with infectious diseases. This multicenter retrospective cohort study in Japan evaluated if serum albumin levels at the occurrence of infection is a risk factor for in-hospital mortality among hemodialysis patients.

Methods: From June 2011 to July 2013, a total of 418 hemodialysis patients who took blood cultures were reviewed retrospectively in five tertiary dialysis units participating the "TOMEI Nephrology Group for Clinical Research" study. After exclusion of 232 patients diagnosed with non-infectious diseases, 186 patients diagnosed with infections were analyzed. Patients were divided into two groups according to the serum albumin level at hospitalization; low serum albumin (Serum albumin<3.5g/dL) or not. Outcome measure was in-hospital mortality. For statistical analysis, cox proportional hazard model was used.

Results: Among 186 patients with infectious diseases, there were 117 patients (62.9%) in low albumin group, and 69 patients (37.1%) in normal albumin group. During hospitalization (median 19 days, interquartile range 10-37), 29 patients (15.5%) died; 25 of 117 (21.4%) in low albumin group, and 4 of 69 (5.8%) in normal albumin group. The cox proportional hazard model verified that low serum albumin and bacteremia were associated with in-hospital mortality. The hazard ratio of in-hospital mortality among low albumin group was 4.293 (95% CI: 1.36-13.55).

Conclusions: Although low serum albumin is a known risk factor for long-term mortality, this study showed that low serum albumin strongly predicts short-term mortality among hemodialysis patients hospitalized with infectious diseases.

PUB357

Usefulness of High-Frequency Wave-Length Ultrasonography as a Diagnostic Tool for Carpal Tunnel Syndrome in Hemodialysis Patients

Tadashi Yamazaki,[2] Tokie Hayasaka,[2] Tetsuo Saito,[2] Shuichi Tsuruoka.[1]
[1]Nephrology, Nippon Medical School, Tokyo, Japan; [2]Dialysis Unit, Moka Hospital, Moka, Tochigi, Japan.

Background: Carpal tunnel syndrome (CTS) is a common complication in dialysis-induced amyloidosis. In orthopedics, high-frequency wave-length ultrasonography (US) with improved resolution is recently used for diagnosing disorders of the upper extremities. We aimed to determine the value of US for diagnosing CTS in hemodialysis (HD) patients, through a cross-sectional analysis.

Methods: All maintenance HD patients (N = 150) at our hospital were recruited after providing written informed consent. Patients with apparent paralysis or pain in the upper extremities due to causes other than CTS were excluded. Longitudinal scan of the median nerve around the carpal tunnel area was performed with US (Toshiba Viamo TM, 12-MHz probe) during HD, and the compression rate (CR) of the nerve was calculated as (1 - shortest diameter/longest diameter of the nerve around the carpal tunnel area). The CTS symptoms were evaluated with the visual-analogue scale (VAS) of pain around the index finger area and the quick form of the Disabilities of the Arm, Shoulder and Hand (Quick-DASH) questionnaire. Pinch strength was also measured. Serum C-reactive protein (CRP) and b2-Mg concentrations, and medical histories related to CTS or dialysis-induced amyloidosis were extracted from the patients' record.

Results: Total 250 wrists from 125 patients (Mean age = 65.6±10.6 years) were studied. The mean CR was 11.8±0.7% and the cut-off values of CR from ROC curve for history of carpal tunnel release was 25.7% (sensitivity 0.80, specificity 0.91). Multivariate analysis revealed that CR was significantly positively correlated with dialysis career , VAS and Quick-DASH scale, positive Tinnel's sign, and serum CRP and b2-Mg concentrations, whereas it showed a significantly negative correlation with pinch strength. Especially, patients with >4 years of HD and serum b2-Mg concentrations >20 mg/L showed significantly high CRs.

Conclusions: Measurement of CR with US is an easy and reproducible method for diagnosing dialysis-related CTS. The CR significantly correlated with symptoms and factors associated with dialysis-induced CTS.

Technique Failure in Korean Incident Dialysis Patients: A National Population-Based Study

Shina Lee,[1] Hyunwook Kim,[2] Seung-Jung Kim,[1] Duk-Hee Kang,[1] Kyu Bok Choi,[1] Dong-Ryeol Ryu.[1] *[1]Dept of Internal Medicine, School of Medicine, Ewha Womans Univ Mokdong Hospital, Seoul, Republic of Korea; [2]Dept of Internal Medicine, Wonkwang Univ College of Medicine Sanbon Hospital, Gunpo, Republic of Korea.*

Background: Technique failure is an important issue for dialysis patients. In this study, we aimed to analyze a detailed technique failure rate and to determine the predictors for technique failure in Korea.

Methods: We identified all patients who had started dialysis between January 1, 2005 and December 31, 2008 in Korea, using the Korean Health Insurance Review and Assessment Service database. A total of 32,357 eligible patients [24,743 hemodialysis (HD) patients and 7,614 peritoneal dialysis (PD) patients] were included, and the median follow-up was 26.4 months.

Results: The crude incidence rates of technique failure among HD patients and PD patients were 3.4 and 54.1 per 1000 patient-years, respectively. When comparing technique survival rate between HD and PD in both Kaplan-Meyer analysis and competing risks analysis, it was significantly higher in patients on HD than in those on PD. However, the gap of technique failure incidence between HD and PD was exaggerated in Kaplan-Meier analysis compared to competing risks analysis. In multivariate analyses, diabetes mellitus and Medical aid as a crude reflection of low socioeconomic status were independent risk factors in both Cox proportional hazard model and Fine and Gray subdistribution model. In addition, cancer was independently associated with a lower risk of technique failure in Fine and Gray model.

Conclusions: Technique failure in PD is higher than that in HD, and it is major concern in patients initiating dialysis in Korea. The results of our study offer a basis for risk stratification and customized care for technique failure.

PUB359

Frequency of Not Achieving Target Weight in Hemodialysis Patients and the Reasons Behind It

Line Malha,[1,2] Frank Modersitzki,[1] Lada Beara Lasic.[1,2]
[1]Internal Medicine, Div of Nephrology, New York School of Medicine, New York, NY; [2]Internal Medicine, Div of Nephrology, New York Harbor VA Healthcare System, New York, NY.

Background: Volume overload and volume depletion have both been associated with morbidity and mortality in patients with end stage kidney disease (ESKD) on hemodialysis (HD). A recent study demonstrated an increased mortality risk when post HD weight is more than 2kg above or below the prescribed estimated dry weight (EDW) for >30% of HD sessions. Our aim was to determine the frequency of sessions with weight difference (WD)>±2kg, determine the prevalence of patients WD>±2kg for >30% of sessions and identify the possible reasons in our outpatient chronic HD population.

Methods: 32 outpatients on chronic HD at the New York Harbor VA Healthcare System in Manhattan were monitored for 2 months. Data for 631 sessions was obtained. Charts and HD nursing notes were reviewed every 2-4 weeks for: weight, prescribed EDW, ultrafiltration (UF) rate, intradialytic complications (hypotension with systolic BP<90, dizziness, cramping, administration of intravenous fluids). Sessions with a missing documented EDW or post HD weight were excluded. 502 sessions were used in the analysis.

Results: The mean WD for all sessions was 0.67±1.64 kg with a majority (83.7%) of HD sessions ending with post HD weight within 2kg of EDW which is consistent with the literature. 6 out of 31 (19.3%) patients had WD>±2kg for >30% of the evaluated sessions. The inability to achieve post HD weight within 2 kg of EDW was most commonly (51.2%) associated with an elevated UF rate (defined as >875ml/hour). Possible reasons for not achieving EDW also included cramps (4.9%) and hypotension (2.4%).

Conclusions: Failing to achieve EDW within 2kg range is most commonly associated with high UF rates, indicating high weight gains between treatments. Proposed strategies to continue aiming at achieving EDW while compensating for the constraints of elevated UF include: decreasing intradialytic weight gain, increasing treatment frequency or treatment time. Further studies identifying the best strategies to achieve this goal are needed.

PUB360

Comparative Effectiveness of Dialyzers: A Longitudinal Propensity Score-Matched Study

Scott Sibbel,[1] Abigail Hunt,[1] Suzanne Laplante,[2] Werner Beck,[2] Mary Gellens,[2] John Alan Laich,[1] Steven M. Brunelli.[1] *[1]DaVita Clinical Research, Minneapolis, MN; [2]Baxter Healthcare Corporation, Deerfield, IL.*

Background: Differences in dialyzer design may affect systemic inflammation and extracorporeal blood sequestration and thereby impact anemia management and control. We evaluated the comparative effectiveness of commonly used dialyzers with respect to longitudinal hemoglobin (Hb) levels, and ESA and IV iron utilization.

Methods: Patients included in the analysis received hemodialysis between 01 Jan 2009 and 31 Dec 2013 and were new users of Revaclear, Optiflux 160, or Optiflux 180 dialyzers. Patients were followed for 1 year or until end of study or censoring for dialyzer switch, modality change, or loss to follow up. For each comparison, eligible patients were propensity score-matched 1:1 on a range of demographic, comorbidity history, and baseline laboratory parameters. Outcomes were assessed using generalized linear mixed models including fixed effects for dialyzer type, time, and their interaction term.

Results: Matched patient pairs (21,551 for Revaclear-Optiflux 160 comparison; 21,008 for Revaclear-Optiflux 180 comparison) were assessed. ESA doses evolved differently over time among Revaclear patients versus both Optiflux 160 and Optiflux 180 patients (p interaction<0.001 for both). Differences in ESA dose were significant from month 3 for Revaclear versus Optiflux 160 (range, 173-483 U/treatment) and at all time points for Revaclear versus Optiflux 180 (range, 120-392 U/treatment). Hb levels were equivalent between Revaclear and Optiflux patients at all times. IV iron dosing was lower for Revaclear patients than Optiflux 160 and 180 patients (p<0.001 for each) but differences were small (1-5 mg/month).

Conclusions: Use of Revaclear versus Optiflux dialyzers was associated with lower ESA doses, modestly lower IV iron doses, and equivalent Hb concentrations.

PUB361

Lack of Leukocytic Response to Infections in End Stage Renal Disease

Deepa Amberker,[1] Ritesh J. Rampure,[1] Mary C. Naglak,[1] Harold D. Stein.[2] *[1]Internal Medicine, Abington Jefferson Health, Abington, PA; [2]Hypertenson Nephrology Associates, Abington Jefferson Health, PA.*

Background: Patients with end stage renal disease (ESRD) on dialysis are at increased risk of infection resulting from a relatively immunosuppressed state. Dysfunctional immunity may be the result of uremia, dialyzer membrane interactions, poor nutritional status and impaired leukocyte responsiveness. Abnormal leukocytic response in such situations may result in missed diagnosis in the clinical setting as well as increased morbidity and mortality. The nature and magnitude of the leukocytic response to infection in this population has not been well characterized. This study is an attempt to assess the degree of leukocytosis in ESRD patients and compare it with the general population in the presence of an infection.

Methods: This was a retrospective study wherein all patients with ESRD on hemodialysis admitted to our hospital between December 2011 and December 2014 with any kind of infection were taken as the ESRD group and compared to others without ESRD or significant chronic kidney disease. Analysis of total WBC as well as percentage of Bandemia were compared and analyzed for statistical significance. Patients were excluded if on steroids, less than 18 years of age, presence of cancer, HIV, pregnancy, CKD stages 3-5 or if sent from dialysis unit.

Results: After reviewing the medical records of approximately 600 patients admitted for infection, 201 patients were studied based on selection criteria, of which 100 had ESRD and 101 did not. Pneumonia followed by sepsis were the most common infections in both groups. The variables studied were as shown in following table:

	ESRD group	Comparison group	P-Value
Average WBC count per microliter	10, 800	15, 700	< 0.0005
No. of patients with leukocytosis (>11000 WBC/mcl)	32 %	87 %	< 0.005
No. of patients with Bandemia (>700 bands/mcl)	26 %	41 %	0.03
Mean neutrophil percent	78.6 %	81. 9 %	0.018

Conclusions: The results of this study demonstrate impaired leukocytic response in ESRD patients on dialysis with infection. Leukocytic response in this population is not a reliable infectious biomarker and if used clinically may lead to diagnostic error and potentially adverse outcomes.

PUB362

Fluid Overload Predicts Mortality Risk in Maintenance Hemodialysis Patients

Carlo Donadio, Valentina Vigo. *Clinical and Experimental Medicine, Univ of Pisa, Pisa, Italy.*

Background: Maintenance hemodialysis (MHD) patients have a high mortality rate, mainly due to cardiovascular disease and malnutrition. The aim of this study was to evaluate the efficacy of the analysis of body composition by bioimpedance (BIA) to predict the mortality risk in hemodialysis patients.

Methods: Observational longitudinal study lasting six years on 78 prevalent MHD patients (68% male, mean age 65 ± 14 years; dialysis vintage 7 ± 7 years). Every two years, starting from the baseline, we collected clinical, laboratory and BIA data, including vectorial analysis (BIVA) and hydration scale, that is the hydration as percentage of lean body mass. We compared the BIA data of patients dead during the study period (n = 45; 65%) with those of survivors (n = 24; 35%). The significance of the differences between the mean values of the two groups at the baseline was evaluated.

Results: Nine patients moved to another hemodialysis facility. The patients dead at different times during the six years had significantly higher values of BMI (28 ± 6 vs 24.8 ± 3.1 kg /m^2, p <0.01) and fat mass index (11.2 ± 4.1 vs 8.4 ± 2.8 kg /m^2, p <0.003) compared to the survivors, while there were no significant differences for body cell mass (BCM) index (7.1 ± 1.7 vs 7.9 ± 1.8 kg / m^2) and serum albumin (4.1 ± 0.4 vs 4.1 ± 0.1 mg/dl). Furthermore, deceased patients had lower values of reactance (53.5 ± 11.7 vs 67.3 ± 13.7 Ohm, p <0.000003), phase angle (5.1 ± 0.9 vs 5.9 ± 0.8 degrees, p <0.00003) and the percentage of extracellular water was higher (50.6 ± 5.2 vs 46.1 ± 3.6 %, p <0.00003). Finally the BIVA analysis confirmed that the hydration was significantly higher in the deceased (73.3 ± 1.8 vs 71.2 ± 3.3 %, p <0.00006). In summary survivors had normal values of BMI and fat mass, a smaller reduction in BCM and less fluid overload than deceased patients.

Conclusions: The survival of HD patients is influenced by the nutritional status. In particular, fluid overload and decrease in muscle mass play a decisive role on survival. Fluid overload, low values of electrical resistance and phase angle predict mortality risk in MHD patients.

A Single Center 2-Year Experience with Haemodialysis Care in Nigeria

Bala Waziri,[1] Isah Alhaji Umar.[2] *[1]Dept of Medicine, IBB Specialist Hospital, Minna, Niger State, Nigeria; [2]Dept of Medicine, IBB Specialist Hospital, Minna, Niger, Nigeria.*

Background: In Nigeria, sustaining maintenance haemodialysis while awaiting renal transplantation is largely being hampered by high cost of care. Furthermore, the scarcity of dialysis units, lack of government funding or subsidy on haemodialysis have made survival very difficult for patients with End Stage Renal Disease in Nigeria Thus the aim of this study was to share our experience with the challenges of providing maintenance haemodialysis in a developing country.

Methods: We retrospectively reviewed records of all the patients with ESRD who had haemodialysis at our dialysis facility over a period of 24 months. Data on their demographic characteristics, etiology of Chronic Kidney Disease, types of vascular access for dialysis, frequency of haemodialysis, history of blood transfusion and patient outcomes were collected.

Results: This study included 64 patients on maintenance haemodialysis. The mean age was 43.9±18.1 years, and there were 39 males (60.9%) and 25 females (39.1%). The underlying presumed etiology of Chronic Kidney Disease were hypertension (73.4%), diabetes mellitus (3.1 %) chronic glomerulonephritis (1.6%) and (21.0%) was unknown. Their mean haemoglobin level at the time of commencing dialysis was 7.2±2.2g/dl , with 37.5 % receiving 3-4 pints of blood transfusion.The mean systolic and diastolic blood pressure were 169.1±37.6mmHg and 103.3±15.5mmHg respectively. A significant inverse correlation between haemoglobin level and serum creatinine was observed (r= □0.413, p<0.001). A predominant proportion of the patients 60(93. 8%) were dialyzed via femoral cannulation, while 3 (4.7%) and 1(1.6%) received dialysis through tunneled internal jugular catheter and A-V fistula respectively.Majority of the patients 43 (67.2%) had less than thrice weekly dialysis. At the time of review, more than half of the study population 37 (57.8%) had died, while 23 (35.9 %) are alive and 3(4.7 %)have had kidney transplant.

Conclusions: The high mortality in this study, is likely due to a combination of inadequate dialysis with other predictors of cardiovascular events such as anaemia and uncontrolled hypertension as demonstrated in our results.

PUB364

Characteristics and Patient Survival in Nursing Home Residents on Maintenance Dialysis

Robert Nee,[1] Lawrence Agodoa,[2] Kevin C. Abbott.[1] *[1]Nephrology, Walter Reed National Military Medical Center, Bethesda, MD; [2]NIDDK, National Insts of Health, Bethesda, MD.*

Background: There is limited data on the growing nursing home (NH) population with end-stage renal disease (ESRD) in the United States. We evaluated the characteristics and predictors of mortality of NH patients on dialysis.

Methods: In this retrospective cohort study using the United States Renal Data System database, we identified 782,161 patients initiated on maintenance dialysis from January 1, 2007 through December 31, 2013, followed until 31 May 2014. Covariates include age, gender, race, dialysis modality, body mass index, serum albumin, indicators

of poor functional capacity and other co-morbid conditions from the Medical Evidence Form 2728. We conducted both Kaplan-Meier and adjusted Cox regression analyses with death as the outcome variable.

Results: 56,194 (7.18%) were identified as nursing home residents upon initiation of dialysis. Among NH patients, 50.53% were female, 69.92% were white, and 99.49% were on hemodialysis and the mean age was 71.1 ± 12.1 years. The overall incidence rates of death of NH vs. non-NH patients were 51.8/100 and 17.6/100 patient-years, respectively ($p<0.001$). The unadjusted 1-year mortality was 50% in NH patients (vs. 20% in non-NH patients, $p<0.001$). Adjusted Cox analysis showed that NH patients were at significantly higher risk of death compared to non-NH patients (adjusted hazard ratio [AHR] 1.37; 95% confidence interval 1.35-1.38). Within this NH cohort, age (AHR 1.02; 95% CI 1.02-1.02), inability to transfer (AHR 1.25; 95% CI 1.22-1.29), inability to ambulate (AHR 1.08; 95% CI 1.05-1.11), cancer (AHR 1.15; 95% CI 1.12-1.19) and other co-morbid conditions were significantly associated with death.

Conclusions: NH patients on dialysis have a high mortality rate, even when compared to the broader ESRD population. Further studies on modifiable risk factors of mortality in this particularly high-risk ESRD population are warranted. [Disclaimer: The views expressed in this paper are those of the authors and do not reflect the official policy of the Department of the Army, the Department of the Navy, the Department of Defense, or the United States government].

PUB365

Bicarbonate as Nutrition Marker in Hemodialysis Patient Louis-Michael Pellerin, Robert Zoel Bell, Jean-Philippe Lafrance, Vincent Pichette, Michel Vallee. *Nephrology, Hopital Maisoneuve-Rosemont, Montreal, QC, Canada.*

Background: Protein-energy malnutrition (PEM) is prevalent in the hemodialysis (HD) population and is associated with a high morbidity-mortality burden. Metabolic acidosis and PEM are closely related. Protein intake, which constitutes an acid load, is an important factor of pH regulation in end-stage renal disease patients. Therefore, could a higher bicarbonate serum level be the result of insufficient protein intake and be a useful marker of malnutrition?

Methods: We conducted a retrospective study in our HD service using a computer database with measurements obtained simultaneously for all 342 patients. Correlation between pre-HD session bicarbonate, albumine, prealbumine and normalized protein catabolic rate (nPCR) was assessed by the use of Pearson's and Spearman's correlation test. Subgroup analysis were realised for patients with negative C-Reactive Protein (CRP < 5) and patients classified as clinically stable.

Results: We found a significant, negative and moderate, correlation between bicarbonate and nPCR, (spearman's p :-0.27, p<.0001). Subgroup analysis showed similar results, (spearman's p : -0.28, p<.0001)for198clinically stable patient and (spearman's p : -0.24, p<.003) for 144 patients with a negative CRP. There was no association between albumin (spearman's p :-0.06, p=0.1511) or prealbumin (spearman's p :-0.08, p=0.1511) and bicarbonate in any group.

Conclusions: A higher serum level of bicarbonate is associated with a lower nPCR, reflecting of poor protein intake, but not with a malnutrition state define by albumin or prealbumin criteria. These patients are at risk to develop a clinically apparent malnutrition state after a prolonged period.

PUB366

Scope and Consistency of Outcomes Reported in Randomized Trials of Hemodialysis Gabrielle J. Williams, Allison Tong, Jonathan C. Craig. *School of Public Health, Univ of Sydney, Sydney, NSW, Australia.*

Background: Inconsistent outcome selection and reporting in clinical trials may limit their capacity to inform evidence-based decision making and the ability to combine findings in systematic reviews. **Aim:** We aimed to assess the scope and consistency of outcome selection and reporting in trials included in systematic reviews of interventions for patients on hemodialysis (HD).

Methods: The Cochrane Database of Systematic Reviews was searched from 1999 to January 2015 for published systematic reviews of interventions for patients on chronic HD. The description and frequency of outcomes reported within the source randomized controlled trials were assessed.

Results: The 18 systematic reviews included 282 trials that reported over 518 outcomes. There was considerable heterogeneity among the outcomes reported. Across all trials, 320 outcomes occurred only once, and 198 outcomes were identified twice. The five most common outcome domains were mortality (50 trials, 18%), blood pressure (46 trials, 16%), calcium (44 trials, 16%), parathyroid hormone (41 trials, 15%) and quality of life (39 trials [14 %]). There was considerable variation in how the domains were measured, the time at which they were measured, and the units and threshold changes that defined an outcome. For example, blood pressure was reported as pre-dialysis, post-dialysis, maximum, difference in pre and post dialysis, ambulatory, resting, rise, and time to restore.

Conclusions: A wide array of outcomes are reported in trials of interventions in HD, with large heterogeneity in timing of measurements, units of measure, and threshold changes that define an outcome. This highlights the need for a well-defined set of standardized core outcomes to improve the comparability of trial findings in meta-analysis and to provide greater confidence around treatment decisions for patients undergoing HD.

PUB367

Blood Pressure and Cognitive Decline in Hemodialysis Patients Sarah M. Duncan,[1] Hocine Tighiouart,[1] David A. Drew,[1] Tammy Scott,[1,2] Daniel E. Weiner,[1] Mark J. Sarnak.[1] *[1]Tufts Medical Center, Boston, MA; [2]Tufts Univ, Boston, MA.*

Background: Cognitive impairment is common in hemodialysis (HD) patients; however, the relationship between measures of blood pressure (BP) and longitudinal decline in cognitive function is unknown in this population.

Methods: 314 participants in the Cognition and Dialysis Study underwent an annual comprehensive battery of cognitive tests. Using principal components analysis (PCA), we reduced individual test results to two domain scores representing memory and executive function. Adjusted joint mixed models accounting for death, transplant, and drop-out were used to explore the association of blood pressure [systolic (SBP), diastolic (DBP) and pulse pressure (PP)] with change in cognitive function over time.

Results: Mean (SD) age was 63 (16) years, 47% were women, 22% were African American, and 44% had cardiovascular disease (CVD). Mean (SD) SBP, DBP, and PP were 141 (21), 73 (12) and 68 (15) mmHg, respectively. Median follow up time was 1.8 years (IQR 1.0-3.4). Mean slopes of PCA memory and executive were 0.03 (95% CI -0.01, 0.07) and -0.11 (95% CI -0.15, -0.06) per year, respectively. Lower DBP and higher PP were associated with decline in measures of both memory and executive function. There was no association between SBP and cognitive decline.

Changes in Slopes of Test Scores per Year (with 95% CI)*

	Test	Slope: per 1SD ↑ SBP	Slope: per 1 SD ↑DBP	Slope: per 1 SD ↑ PP
	PCA Memory	0.00 (-0.04, 0.04)	0.03 (-0.01, 0.06)	-0.03 (-0.07, 0.01)
	PCA Executive	0.00 (-0.03, 0.04)	**0.05 (0.01, 0.08)**	**-0.05 (-0.09, -0.01)**
Contribute to PCA Memory	Recall total	-0.04 (-0.33, 0.25)	0.23 (-0.02, 0.49)	**-0.34 (-0.64, -0.04)**
	Delayed Recall	0.07 (-0.04, 0.18)	**0.15 (0.06, 0.25)**	-0.09 (-0.20, 0.03)
	Short Delay Recall	-0.02 (-0.12, 0.09)	0.03 (-0.06, 0.13)	-0.06 (-0.18, 0.05)
Contribute to PCA Executive	Digit Symbol	0.25 (-0.27, 0.76)	**0.85 (0.43, 1.27)**	**-0.77 (-1.33, -0.21)**
	Trails A	1.75 (-1.48, 4.98)	-2.34 (-5.27, 0.59)	**5.28 (1.99, 8.57)**
	Trails B	0.37 (-2.96, 3.71)	**-3.41 (-6.19, -0.63)**	**4.91 (1.38, 8.45)**
	Blocks	0.34 (0.00, 0.68)	**0.53 (0.23, 0.82)**	**-0.14 (-0.51, 0.23)**

*Adjusted for baseline BP measure, age, sex, race, education, vascular access and CVD. Negative coefficients are associated with worse scores except on Trails Tests. Bold results are significant.

Conclusions: Lower DBP and higher PP are associated with faster rate of cognitive decline, in particular that related to executive function. Because impairment in executive function is a manifestation of vascular disease and lower DBP and higher PP are associated with CVD in HD patients, our results suggest that cognitive decline may be mediated by vascular disease in this population.

High Ferritin Levels Achieved with Ferric Citrate as a Phosphate Binder Do Not Associate with Adverse Events Udayan Y. Bhatt,[1] Kausik Umanath,[2] Mohammed Sika,[3] Mark Koury,[3] Robert M. Niecestro,[4] Barbara A. Greco,[5] Dana G. Negoi,[6] Ingrid J. Chang,[7] Tom Greene,[8] Stephen Z. Fadem,[9] Molly Mcfadden,[8] Julia Lewis,[3] Jamie P. Dwyer,[3] The Collaborative study group.[4] *[1]Ohio State; [2]Henry Ford Hosp; [3]Vanderbilt; [4]CSG; [5]Baystate Med Ctr; [6]U of VT; [7]Western Neph; [8]U of Utah; [9]Baylor College of Med.*

Background: Ferric citrate (FC) as a phosphate binder increases Fe stores and reduces IV iron/ESA use while maintaining hemoglobin. This analysis compares effects of higher achieved ferritin levels in subjects on FC to those in subjects on sevelemer carbonate and/or calcium acetate (active control, AC).

Methods: Data were obtained from the 52-wk active control period of the FC pivotal trial. Subjects with a baseline ferritin ³1000ng/mL or TSAT≥50% were excluded from the trial. We randomized 292 subjects to FC and 149 to AC. Any subjects who developed ferritin level ³1500ng/mL at any time over 52wks were identified. CV, ID, and dialysis access related adverse events (AE) occurring at any time over the 52-week period were tabulated.

Results: 57 subjects (19.8%) in the FC group and 14 subjects (9.5%) in the AC group had at least a single ferritin³1500ng/mL (p=0.012) during the 52 wks. CV events including MI, CHF, and arrhythmias, occurred in 12.3% of the FC group compared to 21.4% AC. ID AEs occurred in 42.1% FC and 50% AC. Dialysis access related AE occurred in 15.7% FC and 42.9% AC. IV iron administration was statistically lower (p=0.003) in the FC group (2.95±3.57mg/wk) than the AC group (6.20±3.64mg/week), consistent with the full FC cohort that saw a significant reduction in IV iron use. Cumulative ESA dosing was 1016±906 Units/wk FC and 1781±1756 Units/wk AC (p=0.256).

Conclusions: This study in the subset who developed ferritin ³1500ng/mL shows that fewer subjects experienced a CV, ID, or dialysis access related AE in those receiving FC vs AC. IV iron use was statistically lower and ESA dosing was numerically lower. As previously reported the majority of ferritin³1500ng/mL resolved and 90.1% were adjudicated to be related to IV iron and/or inflammatory AEs. This analysis, although limited by small sample size, supports the contention that FC is clinically useful and safe vs traditional binders.

PUB369

Association Between Employment Status and KDQOL Scores in Dialysis Patients

Duane V. Dunn,[1] Deborah S. Evans,[1] Elizabeth I. Jones,[1] Caroline Hann,[1] Rich Mutell,[2] Allen R. Nissenson,[1] Deborah A. Benner.[1] *[1]DaVita HealthCare Partners Inc, Denver, CO; [2]Apex Health Innovations, Simi Valley, CA.*

Background: Studies have shown that unemployment negatively impacts dialysis patients' quality of life (QOL).[1-3] QOL can be quantified and low scores on the Kidney Disease Quality of Life (KDQOL) survey are associated with poor outcomes.[4] Our study examines employment/unemployment status and KDQOL scores.

Methods: We collected employment status data on 122,166 adult patients at a large dialysis organization from Nov 2014-Apr 2015. Patients were grouped as either employed (received pay or in training), unemployed (including retirees and those on long- or short-term disability or Workers Compensation) or other (involved in work/activity but not paid). Data were matched with patients' most recent KDQOL scores.

Results: The employed group (n=16,216) had the highest KDQOL scores in all categories, followed by the other (n=7936) and unemployed groups (n=98,014) [Table]. A clinically meaningful difference (6.8) in Physical Component Score was found between the employed (42.0) and unemployed (35.2) groups. This difference was greater (~10 points) between full-time employed and Workers Compensation patients, who scored lowest in all categories.

Table: Employment Status Among Adult Dialysis Patients at a Large Dialysis Organization and KDQOL Scores

Employment Status	n (%)	KDQOL Scores (Mean)					Age, yr (Mean)	Vintage, yr (Mean)
		PCS Score	MCS Score	Effects Score	Burden Score	Symptoms Score

Reduction of Pruritus in Hemodialysis Patients by Adjustment of Serum B-Type Natriuretic Peptide

Yoshio Shimizu,[1] Nao Nohara,[2] Eri Nomura,[2] Kaori Yamada,[2] Mayumi Matsumoto,[2] Toshiki Kano,[2] Yasuhiko Tomino.[2] *[1]Juntendo Univ Shizuoka Hospital, Izunokuni, Japan; [2]Juntendo Univ, Tokyo, Japan.*

Background: Pruritus reduces the quality of life (QOL) and worsens the prognosis in hemodialysis patients. It was reported that the neuropeptide natriuretic polypeptide B (Nppb; alias BNP) is a neurotransmitter of pruritus. We reported that serum BNP was a factor that contributed to the exacerbation of pruritus in hemodialysis patients. We determined whether pruritus could be reduced by controlling serum BNP.

Methods: Forty-eight patients participated in this study. (Test 1) Serum BNP was measured with common laboratory tests and visual analogue scale (VAS) in a single hemodialysis session. The factors influencing the changes of VAS during the dialysis session were analyzed. (Test 2) The fluid volume was strictly managed to decrease serum BNP level by reporting the weight gain during each dialysis session. Patients who gained more than 5% of the target dry weight were warned with a document and the session was extended until they reached the target dry weight. VAS, DLQI (Dermatology Life Quality Index) and an inventory survey using the KDQOL (the kidney disease quality of life short form, Ver.1.3) were examined once a month.

Results: (Test 1) VAS decreased significantly after dialysis. Similarly, a significant decrease was found in BNP. Using univariate analysis, a significant correlation was found in the change in serum BNP, urea nitrogen, iron and ferritin. In multivariate analysis the BNP change and serum iron were extracted as factors that influenced a decrease of the VAS. (Test 2) BNP reduced the overall mean. Monthly VAS did not decrease for the first two months, but after three months, a significant decrease was observed (p=0.031). DLQI did not correlate with the BNP at the beginning of the study, but one month later, a significant correlation was found between DLQI and BNP. No improvements in either a renal disease-specific standard or the comprehensive standard in KDQOL were observed as a result of the intervention.

Conclusions: It was suggested that the adjustment of serum BNP by strictly managing the weight reduced pruritus in hemodialysis patients but it was difficult to improve long-term QOL.

The Mechanisms Study on Neointimal Hyperplasis of Autogenous Arteriovenous Fistula in Maintenance Hemodialysis Patients

Nanmei Liu. *Jimin Hospital of Shanghai.*

Background: To evaluate the influence and the possible mechanism about neointimal hyperplasis of autogenous internal arteriovenous fistula in hypertensive nephropathy and diabetic nephropathy patients which was going maintenance hemodialysis and provide possible theory about how to prevent from intimal hyperplasia, extend the life of AVF in clinic.

Methods: Collecting cephalic vein when the hemodialysis patients had the surgey of AVF angioplasty and reconstruction.Vascular tissues were divided into chronic glomerulonephritis group,hypertensive nephropathy group and diabetic nephropathy group. Immunohistochemistry was used to detect the expression of vascular smooth muscle actin (a-SMA). Selecting the control group and fistula vascular tissue which the useful life was 12-18 months, basic fibroblast growth factor (bFGF), insulin-like growth factor 1(IGF-1),matrix metalloproteinase2 (MMP2) and matrix metalloproteinase9 (MMP9) were to detect expression change by immunohistochemical staining.

Results: Compared with chronic glomerulonephritis group, intima thickness of hypertensive nephropathy and diabetic nephropathy were significantly increased and the increase was more significant in diabetic nephropathy. Hyperplasia intima was eccentric thickening and the hyperplasia intima showed obvious inflammatory cells infiltration and vacuolar degeneration. Immunohistochemical staining showed that compared with the group of chronic glomerulonephritis, hypertensive nephropathy and diabetic nephropathy groups's a-SMA, bFGF, IGF-1 and MMP9 expression levels were significantly increased, expression of VEGF was significantly reduced, MMP2 was no significant change (P>0.05). Univariate regression analysis revealed that the expression levels of a-SMA was positively correlated with bFGF, IGF-1 and MMP9,negatively correlated with the VEGF. AVF intimal hyperplasia mainly dominated by the vascular smooth muscle cells (VSMC) proliferation.

Conclusions: Hypertension and diabetes can accelerate the process of intimal hyperplasia, shorten the life of fistula and diabetes promote intimal hyperplasia more significant. This study provides a theory and therapeutic targets for the prevention and treatment on intimal hyperplasia of AVF in dialysis patients.

PUB372

Association of Nutritional Status with Depression and Sleep Disorders in Elderly Hemodialysis Patients

Avsin Ibis,[1] Emre Tutal.[2] *[1]Nephrology, Afyonkarahisar State Hospital, Afyonkarahisar, Turkey; [2]Nephrology, Baskent Univ Hospital, Ankara, Turkey.*

Background: The relationship between depression, sleep quality, and malnutrition in an elderly population in maintenance hemodialysis is very complex and not yet fully understood. We aimed to determine the association between nutritional status and psychological factors such as depression and sleep disturbance in elderly dialysis patients.

Methods: Seventy three dialysis patients (41 female, 32 male; aged, 72.5±6.0 years) older than 65 years of age, were enrolled in the study. Nutritional status was determined by Subjective Global assesment (SGA). Beck Depression Inventory (BDI) questionnaire was used to measure presence and degree of depression. Quality of sleep was measured using the Pittsburgh Sleep Quality Index (PSQI). Demographic and biochemical parameters and Charlson Comorbidity Index and frequency of infection in previous year period of all patients were recorded.

Results: In our elderly patients 15 (%20.5) had sleep disorder and 24 (%32.9) had mild to moderate depression and 11 (%15.1) had moderate to severe depression. According to SGA 48 (%65.8) patients were well-nourished and 25 (%34.2) patients had mild-moderate and severe malnutrition. When the well-nourished and malnourished patients were compared, well-nourished group had higher albumin levels (4.28±0.25 g/dL vs 3.50±0.36 g/dL), lower CRP levels (7.51±4.23 vs 16.02±19.45), better quality of sleep (3.50±0.82 vs 5.56±1.73) and better depression scores (8.68±2.75 vs 16.28 ±4.56) than malnourished group. By multivariate analysis when factors affecting nutritonal status were taken into account BDI (p=0.001; OR=1.79; CI, 1.26-2.56) and PSQI (p=0.022; OR=4.33; CI, 1.23-15.2) was associated with SGA.

Conclusions: Depression and sleep disorders are important factors influencing the nutritional status and could be an independent risk factors for malnutrition in elderly patients receiving maintenance dialysis. Psychological assessment should be mandatory in the follow up of these patients to identify depression and sleep disturbance because many of them are reversible.

PUB373

Predialysis Hyponatremia and Mortality in Elderly Patients with Incident Maintenance Renal Replacement Seon Ha Baek, Sung Woo Lee, Shin-Young Ahn, Sejoong Kim, Ki Young Na, Dong-Wan Chae, Ho Jun Chin. *Internal Medicine, Seoul National Univ Bundang Hospital, Republic of Korea.*

Background: Predialysis hyponatremia recently have been reported to be associated with mortality in incident hemodialysis patients. However, little is known about whether predialysis hyponatremia is associated with unfavorable outcomes in elderly patients.

Methods: We retrospectively assessed mortality in 397 (mean age 73.0 year, male/female 226/171) patients aged ≥65 years with non-diabetic end-stage renal disease (ESRD) who initiated renal replacement therapy (RRT) at a tertiary university hospital between 2000 and 2010. 1 year all-cause mortality (ACM) was analyzed in relation to predialysis serum sodium (sNa). We divided subjects into 3 groups according to sNa: Group1, < sNa 125; Group 2, sNa 125-134, Group 3, sNa ≥ 135 mEq/L. Patients with sNa levels >145mEq/L were excluded.

Results: The median value of sNa was 137 mEq/L (interquartile range 133-140 mEq/L). Chronic cormobidities including congestive heart failure (r = -0.215, P<0.001) and liver cirrhosis (r = -0.174, P <0.001), late referral (r = 0.230, P <0.001), use of thiazide (r = -0.160, P = 0.001), lower estimated glomerular filtration rate (r = 0.152, P = 0.005) and albumin (r = 1.296, P = 0.002), higher white blood cell count (r = -0.136, P = 0.006) were associated with lower sNa levels in elderly patients after fully adjustment. One hundred and five (26.4%) patients had died at the 1-year follow up. Higher sNa level was associated with lower adjusted ACM in a continuous model (HR 0.433, 95% CI 0.261-0.718, P = 0.001). Group 1 had a higher mortality than normonatremia group in a categorical model (reference group 3, HR 5.048, P = 0.018) and mortality difference was not observed between group 2-3 (reference group3, HR 1.511, P=0.161).

Conclusions: Predialysis hyponatremia was associated with increased 1-year mortality in elderly ESRD patients who initiated RRT. However, the higher mortality was only observed in elderly patients with severe hyponatremia (sNa < 125mEq/L). These finding suggested that compared to adults <65 years, other cormobidites or factors rather than sNa may affect mortality in elderly.

PUB374

Observation of the Correlation Between the Uremic Toxins with Clinical Feature in Uremia Patients Mei Li,[1] Qiong-Li Yin,[1] Zhenda Zheng,[2] Cai-Lian Cheng,[3] Xun Liu,[3] Cheng-Gang Shi.[3] *[1]VIP Healthcare Center, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, China; [2]Cardiovascular Dept, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, China; [3]Nephrology Dept, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, China.*

Background: To investigate the correlation between the uremic toxins with age, dialysis duration, and the different blood purification techniques on removal uremic toxins with hemodialysis (HD) and hemodiafiltration (HDF).

Methods: 72 cases of maintenance hemodialysis patients were observed, age 28~80years(59.75±13.86), dialysis duration 4~192months (34.46±39.15), HD group (n = 50), HDF group (n = 22)(once 1~2 weeks).Before each conventional HD and HDF therapy, blood was sampled for small molecule water-soluble toxins BUN with automatic biochemical analyze, Middle molecular and macromolecular toxins (MMS) with Ultraviolet spectrophotometry, pentosidine(PENT) with enzyme-linked immunosorbent assay method(from ADL Company, USA), Protein-bound toxins, indoxyl sulfate(IS) with high performance liquid chromatography method.

Results: For HDF versus HD, there was no significant differences between BUN,MMS, pentosidine and IS.There was low positive correlation between MMS, PENT, IS and the age of the patients (r being 0.322, 0.263 resp**ectively**, *P*<0.05). MMS, PENT and IS were positively related with dialysis months (r being 0.406, 0.427, 0.742 respectively, *P*<0.05).

Conclusions: HD and HDF therapy maybe not good enough in clearing middle molecular toxins and protein-bound toxins, which results in their accumulation in patient's body with the increase of dialysis course. It is recommended that better dialysis methods be adopted for patients who have received hemodialysis for a long time.

PUB375

Parathyroid Hormone Response in Chronic Hemodialysis Patients Converted from Intravenous Doxercalciferol to Oral Calcitriol Three Times a Week Anna Jeanette Jovanovich,[1,3] Annegret Howe,[2] Morgan E. Marcuccilli,[3] Michel Chonchol.[3] *[1]Denver VA Medical Center; [2]Fresenius Medical Care; [3]Univ of Colorado Denver.*

Background: The purpose of this study was to characterize serum calcium, phosphorus and intact parathyroid hormone (iPTH) level response during the initial 24 weeks following conversion from intravenous doxercalciferol to oral calcitriol three times a week in a real-world setting.

Methods: Data was collected by a retrospective chart audit of end stage renal disease patients on hemodialysis in an outpatient chronic dialysis unit. We identified 33 chronic hemodialysis patients that had a record of treatment with intravenous doxercalciferol (6 months) and conversion to oral calcitriol three times a week (6 months) between June 2014 and May 2015 following a conversion algorithm. The change in serum calcium, phosphorus, and iPTH between treatment periods (intravenous doxercalciferol vs. oral calcitriol) was analyzed.

Results: Patient characteristics were as follows: mean age, 63±16 years; 39% women; and 55% black. The mean (SD) for serum calcium and phosphorus and median (IQR) serum iPTH during the 6 months of intravenous doxercalciferol were 8.8±0.7 mg/dL, 4.5±1.3 mg/dL and 643 (384 to 908) pg/mL, respectively. The corresponding values after 6 months of oral calcitriol were 8.8±0.6 mg/dL, 4.5±1.2 mg/dL and 545 (368-812) pg/mL. None of the comparisons achieved statistical significance (p > 0.43 for all). 48% of participants were on cinacalcet during each of the treatment periods. The median (IQR) change in iPTH increased slightly among those patients receiving oral calcitriol and sevelamer (34 (-132 to 147)) pg/mL while iPTH decreased among patients receiving oral calcitriol and other non-sevelamer binders (-102 (-294 to 155 pg/mL; p=0.17)).

Conclusions: This small retrospective study suggests that conversion from intravenous doxercalciferol to oral calcitriol using a conversion algorithm maintains iPTH within KDIGO recommended targets and does not appear to cause hypercalcemia or hyperphosphatemia. The clinical significance of higher iPTH values among those treated with oral calcitriol and sevelamer needs further study.

PUB376

Pregnancy and Dialysis in Chronic Kidney Disease – A Case Study Morgan E. Lindsay, Syed S. Haqqie, Arif Asif. *Albany Medical College.*

Background: For women with underlying renal disease, pregnancy remains high risk. Case series have provided guidance on the interdisciplinary management of these patients. Herein, we report one institution's management of five patients requiring dialysis in pregnancy. The present case series includes patients with chronic kidney disease secondary to lupus nephritis (n=2), cystinosis (n=1), malignant hypertension (n=1), and diabetic nephropathy (n=1) . All five patients, one of whom was on dialysis prior to pregnancy and the rest were CKD 5 were placed on six-times weekly dialysis upon the presentation with pregnancy. Three of the patients, two with Lupus and one with Malignant HTN delivered infants with whom they were able to discharge home after NICU stays, two patients one with cystinosis and one with DM delivered infants who subsequently died in the NICU secondary to prematurity. All 5 patients post-delivery continued on maintenance hemodialysis. Although improving, maternal and fetal outcomes in those with chronic kidney disease remain variable. Our experience adds to the growing literature on dialysis for chronic kidney disease in pregnancy.

Methods: Restrospective study of patients at one institution.

Results: Out of five pregnancies three had successful outcome with intensive dialysis.

Conclusions: Pregnancy is rare in dialysis patients and outcomes are generally poor. There are improved results with intensive dialysis and multidisciplnary approach to the management.

PUB377

When Shall the Advanced Chronic Kidney Disease Patients Start Dialysis? Lee Ying Yeoh, Sri Fairuz baizuri Saifful, Bek Choon How, Yan Lun Allen Liu, Milind Nikam. *Medicine, Khoo Teck Puat Hospital, Singapore.*

Background: Recent guidelines suggest dialysis should be initiated when estimated glomerular filtration rate (eGFR) drops below 10-12ml/min. The aim of the present study was to analyse outcomes of those initiating dialysis at very low eGFRs.

Methods: A single center, prospective study of new ESRD patients who were initiated on dialysis between 2012 –2014 and dialysis was performed for >90 days. The patients were categorized into 2 groups according to eGFR ≤ 5 and > 5ml/min upon initiation. The patients with incomplete data, and those who underwent transplantation were excluded.

Results: A total of 251 patients were included with mean age of 59.0 ± 11.9 years, mean eGFR of 5.4 ± 2.9ml/min; 57% were males and 51.4% were Chinese. Majority started on hemodialysis (81.7%) and 69.7% were unplanned. The survival rate till May, 31 2015 was 88.4%; 61% were initiated when eGFR ≤ 5 (mean 3.6±1.1 ml/min) and 39% with eGFR > 5 (mean 8.3 ± 2.6 ml/min). Dialysis vintage was shorter in the group with eGFR ≤ 5 (18.5 ± 9.5 vs. 21.7 ± 11.1 months). The patients with eGFR ≤ 5 had lower Charlson Comorbidity Index (4.0 ± 1.3 vs. 4.7 ± 1.2), and hemodialysis was preferred (90.9% vs. 67%). The disease burden was significantly lower in the group with eGFR ≤ 5, including diabetes mellitus (72.1 vs. 88.7%), ischemic heart disease (23.4% vs. 37.1%) and peripheral arterial disease (4.5 vs. 12.4%). However, there were trends showing that these patients were younger, had higher serum albumin and shorter hospitalization for index admission. Underlying diabetes, ischemic heart disease, modality selection and dialysis vintage remained significant after adjusted. Mean survival for both groups were comparable (36.3 months, 95% CI: 34.4-38.2 vs. 34.5 months, 95% CI: 32.0-37.0). Among the patients who survived, 97.7% remained on their initial modality.

Conclusions: Our study suggests that the ESRD patients without significant morbidities may be able to delay dialysis initiation without significant short term adverse outcomes. Further studies are required.

PUB378

The Incidence and Type of Cancer in Patients with End-Stage Renal Disease: A Prospective Cohort Study for End-Stage Renal Disease in Korea
Kyung Don Yoo,[1] Hajeong Lee,[1] Jung Pyo Lee,[1] Dong Ki Kim,[1] Shin-Wook Kang,[2] Chul Woo Yang,[3] Yong-Lim Kim,[4] Chun Soo Lim,[1] Kwon Wook Joo,[1] Yon Su Kim.[1] *[1]Seoul National Univ; [2]Yonsei Univ; [3]The Catholic Univ; [4]Kyungpook National Univ.*

Background: In patients with end-stage renal disease, urinary tract kidney cancer is known to be higher than in the general population. However, the incidence and type of cancer is affected by variable factor such as age, gender, ethnic differences. Moreover, the causality of dialysis and cancer incidence in certain type of cancer is still needed to be clarified.

Methods: A total of 5,225 patients in the clinical research center for ESRD cohort were enrolled from Aug 2008 to Dec 2014. The primary outcome is to compare the cancer incidence rate of ESRD patients with the general population. We obtained cancer incidence data from National Cancer Information Center Registry in healthy counterpart.

Results: A total of 2,200 incident and 3,035 prevalent dialysis patients was included the analysis. The mean follow up duration was 25.6 ± 16.2 months, and 116 (2.2%) patients were diagnosis with cancer during the observation periods. ESRD with cancer group was significantly older, longer dialysis duration and more comorbidity than control group. The incident rate of cancer in prevalent dialysis patients was higher than those in incident dialysis patients (2.5% vs.1.3%, p=0.002). The proportion of primary organ was highest in digestive organ (33.6%) including stomach, colon. The mean time to discovery of cancer from dialysis initiation was 58.6 months in digestive cancer, 52.0 months in urinary tract cancer. The standardized incidence ratio (SIR) of overall cancer was 0.94 [95% CI: 0.72 –1.19]. Urinary tract cancer showed the highest SIR [SIR: 4.7, 95% CI: 4.42–8.19] and had the second highest frequency (16.1%). Interestingly, the highest frequency (33.3%) of digestive organ cancer showed no difference in the incidence of cancer compare to the general population [SIR : 0.607, 95% CI: 0.36–0.94].

Conclusions: Further research was needed to compare the organ-specific cancer incidence of ESRD patients with the general population. The screening test could be necessary for digestive and urinary tract cancer.

PUB379

The Role of Social Support in Hemodialysis Patients Gun Woo Kang. *Internal Medicine, Catholic Univ of Daegu School of Medicine, Daegu, Korea.*

Background: A number of patients with End-Stage Renal Disease (ESRD) have significant impairment in social support. Especially, the limited function of patients with hemodialysis (HD) prevents them from social activities and even makes them social withdrawal. There are few studies of the factors affecting the social support in HD patients. The aim of the current study was to identify the clinical and psychosocial factors including quality of life related to impaired social support in HD patients.

Methods: The 101 participants on HD from the Daegu Catholic University Medical Center were assessed from September in 2013 to September in 2014. Patients on HD for acute kidney injury were excluded from this study. Multidimensional Scale of Perceived Social support(MSPSS) was used for evaluating patients' social support. Psychosocial factors including quality of life, anxiety, depression and sleep disorder were evaluated. Laboratory and clinical information including hemoglobin, vitamin D (25(OH)D, $1,25(OH)_2D_3$), albumin, Kt/V, normalized protein catabolic rate, ferritin, bone mass index, duration of HD were assessed. Stepwise multivariate logistic regression with backward selection was performed.

Results: The mean of MSPSS (social support) score was 36.8±9.3. In subgroups of social support, the MSPSS-family, MSPSS-friend, and MSPSS-medical team scores were 14.79±4.28, 10.44±4.76, and 10.74±4.39, respectively. The variables showed significant association with social support were quality of life (r=0.332, p=0.001), depression (r=-0.290, p=0.003), anxiety (r=-0.372, p<0.001), and serum creatinine (r=-0.270, p=0.007). Multiple regression showed that quality of life (95% CI; 0.615~19.799, p=0.037) and serum creatinine (95% CI; -1.543~-0.319, p=0.003) were independent predictors of impaired social support.

Conclusions: This study explored the determinants of high susceptibility to the impaired social support in HD patients. We found that the impaired social support is associated with the quality of life and serum creatinine. Further study will be needed because of the possibility of different results depending on culture and ethnicity. As well as, we should consider the psychosocial interventions to improve the impaired social support.

PUB380

Use of Portable Fundoscopic Photography to Screen for Diabetic Retinopathy in the Hemodialysis Unit Beckie Michael,[1] Yasmin G. Brahmbhatt,[2] Nika Bagheri,[3] Laura T. Pizzi,[4] Benjamin Leiby,[4] Anne P. Murchison.[3] *[1]Marlton Nephrology and Hypertension; [2]Thomas Jefferson Univ; [3]Wills Eye Hospital.*

Background: Over 40% of dialysis patients have diabetes, yet only 25% get annual eye exams. Due to the frequency and duration of visits to dialysis centers, patients on dialysis likely have increased barriers to receiving eye exams and other recommended preventive care. This study evaluated the need for ophthalmic care, barriers to care, and prevalence of diabetic retinopathy (DR) in this population.

Methods: Prospective cohort study at two dialysis centers (1 urban, 1 suburban). A patient survey (measuring eye care utilization, barriers to eye care, and self-reported visual functioning) and eye screening (visual acuity test and non-mydriatic fundus photos) was completed for diabetics who consented to the study. Other variables were obtained from medical records and included demographics, duration of diabetes, co-morbidities, and insurance type. Descriptive analyses examined barriers to eye care and presence of DR. Qualitative data on satisfaction with eye screening were also obtained from both staff and patients.

Results: 58 patients (79.5% of diabetics at the two sites) were screened. Of the readable fundus photos, 50% had DR and only 10% had no ocular abnormalities. The majority (64%) knew diabetes can cause severe eye problems. Only 11% of patients reported that getting an annual eye exam is a priority. The most commonly reported barriers to eye care were cost (89%) and transportation difficulty (82%). Qualitative data indicated that staff and patients were overall very satisfied with the program.

Conclusions: There is a significant unmet need for ophthalmic care among diabetics receiving dialysis. Since cost and transportation were reported as main barriers to eye exams, providing the screening at dialysis centers could improve adherence to eye care thereby improving ophthalmic and other health outcomes.

PUB381

Recent Dialysis Beginning Is a Mortality Predictor for In-Patients Treatment Nadia Guimaraes- Souza, Ana C M S Ramos, Thais Nemoto Matsui, Adriano Luiz Ammirati, Maria C.C. Andreoli, Fabiana Dias Carneiro, Marisa Petrucelli Doher, Bento C. Santos. *Dialysis Center, Hospital Israelita Albert Einstein, Brazil.*

Background: Acute kidney failure occurs in 5% of hospital admitted patients. Dialysis need during patients stay in hospital is associated with higher mortality risk. The main objective was to evaluate patients profile in our dialysis center and the impact in the outcomes.

Methods: Prospective observational study. A check list was applied for every patient originating from intensive care or in clinics who need hemodialysis section in our dialysis center from 2010 to 2014. Patients were older than 18 y. o. and signed a consentient term. For analysis purpose patients were assigned as undergoing previously dialysis (PD) or patients that initiated dialysis in this hospital stay (ND). The possible outcomes were: kidney recovering function (KRF), kidney transplantation (KT), mortality (M) and maintained dialysis (MD). 437 patients were included. 231 (53%) were patients PD, 47% of ND.

Results: From all patients in our follow-up 27% were from kidney transplant program (KTP) and 33% were from liver transplantation program (LTP). 15 % started dialysis with arterial-venous fistula, 14% tunneled cuffed catheter and 51% with non-tunneled cuffed catheter. PD groups had more hypertension and were more likely came from KTP ($p<0.01$). ND group had significantly more C hepatitis ($p<0.01$) and came from LTP. In the outcomes we observed ND patients had higher mortality (25% vs 13%; $p<0.01$) and also significantly higher KRF (63% vs 10%; $p<0.01$). MD outcome was more prevalent in PD group (47% vs 11%; $p<0.01$) as expected. When risk factors for our outcomes were analyzed patients coming from KTP, LTP and positives for C hepatitis had significantly higher KRF. Mortality were similar among the groups. Hypertensive patients had worse outcomes. Recovery time in days was shorter in ND group (56±140 vs 148±283;$p<0.01$).

Conclusions: It's well known that patients treated with chronic dialysis have an increased risk of death. Surprisingly we observed a higher mortality rate on the ND group. Hypertension is a risk factor for worse outcomes. Check list is an important tool for analyzing and follow patients undergoing dialysis.

PUB382

Awareness and Beliefs Towards Organ Donation in Chronic Kidney Disease Patients in Western India Manish Ramesh Balwani. *Nephrology, IKDRC, Ahmedabad, Gujarat, India.*

Background: In India, there seems to be paucity of information and awareness regarding organ donation in general population. The study was conducted to see the awareness and beliefs towards organ donation programme in chronic kidney disease patients in western india.

Methods: The author conducted a cross sectional study among 85 CKD patients to evaluate the knowledge about and attitude towards organ donation at a large tertiary academic hospital in western india. The author used a questionnaire that included items on knowledge, attitude and demographics.

Results: Age of respondents participated in study ranged from 15 to 75years. Around 2/3rd participants were males. About eighty-two percent belonged to hindu religion. All were aware of term organ donation and cadaver donation. About 47% of people heard about organ donation through hospital or from doctor. The audiovisual media such as television (21%) followed by newspaper/magazines (14%) were the major source of information about organ donation. Strikingly, radio was not the source of information to any of the respondents who participated in this study, despite radio being one of the most common medium of mass communication in india. Fourteen percent of people heard about organ donation through a friend or colleague. Almost 1/3 rd of patients were unaware about any legislation regarding organ donation. All respondents felt that the organs should go to the needy irrespective of their religion. About 70% feel that medical colleges/government institutions should make decisions about organ donation in case of unclaimed dead bodies. About 64.70% believe that there is a danger that donated organs could be misused, abused or misappropriated.

Conclusions: The study shows about 64% of our participants believe that there is a danger that donated organs could be misused, abused or misappropriated.There seems to be paucity of information and awareness regarding organ donation among CKD patients. Mass media, religious and political leaders may be involved to maximize awareness about organ donation.

PUB383

Enhancing Patient Engagement in Future Clinical Trials – The Effects of Age and Ethnicity Territa Santhakumaran, Kieran Mccafferty. *Renal, Royal London Hospital, London, United Kingdom.*

Background: Increasing patient engagement from ethnic minority populations is crucial to the widespread applicability of research findings, but this represents a challenge in nephrology clinical research. Ethnicity, socio-cultural and language barriers along with a lack of understanding and awareness of clinical trials are potential factors that affect patient involvement in clinical trials.

Methods: We developed a patient survey in English, Urdu and Bengali to represent our ethnically diverse population in East London to explore the attitudes and understanding of clinical research using a 1-7 scoring system to rate various statements about research. The surveys were offered to all patients attending the haemodialysis and renal outpatients department over a 2 week period.

Results: 151 forms were completed, 143 in English, 7 in Bengali and 1 in Urdu. 41% of forms were from patients who attended transplant clinic and 31% from patients who attended for haemodialysis. Overall there was a strong message that patients wanted more trials in nephrology and felt that taking part in trials would help them take a more active role in their health. They also felt there was a lack of information on how to access research opportunities. Of those who completed the survey there was no significant ethnicity differences in their attitudes and understanding of clinical research, however transplant patients who identified themselves as White British were significantly more likely to take part in the survey ($p<0.02$). Patients who identified themselves as Black British were significantly less likely to take part in the survey ($p<0.02$). In the dialysis cohort, patients who identified themselves as White British were significantly more likely to take part in the survey ($p<0.02$). Whereas patients who identified themselves as Bangladeshi were significantly less likely to take part in the survey ($p<0.04$). Age did not appear to have an effect on patients' perception and understanding of clinical trials.

Conclusions: From our work it is clear that there is a patient led demand for greater engagement in translational research. However, challenges remain in engaging ethnic minority cohorts in clinical research.

PUB384

Deferred Educational App Personalization Increases Registration Completion Daniel Schwartz,[1] Chan Kruse.[2] *[1]Faculty of Medicine, Univ of British Columbia, Vancouver, BC, Canada; [2]QxMD, Vancouver, BC, Canada.*

Background: 'Read by QxMD' (http://qxmd.com/read) is an app that curates the nephrology literature and personalizes reading recommendations based on a clinician's or researcher's interests. In order to provide highly accurate recommendations, the app must collect content preferences such as preferred journals and topics. In addition, it must collect email address and personal identifiers in order to complete registration and offer CME. When the registration process is too onerous, mobile app users may not complete registration. If the registration process fails to collect necessary user data, this may negatively impact the educational value of the app. We hypothesized that allowing users to delay providing personal information until after they set their preferences would increase registration completion.

Methods: We randomly assigned all users registering on the Android version of Read to two different registration processes. In version 1, "upfront personalization", users are asked to provide personal identifiers prior to setting their preferences, while in version 2, "deferred personalization", users set preferences first and after this has been completed are asked for personal identifiers. The Leanplum SDK was used to implement and automate the randomization of alternate registration pathways. The primary outcome was completion of registration.

Results: Between April 6, 2015 and June 1, 2015, a total of 5660 users who registered using the Android version of 'Read' were randomized with 2824 users randomized to upfront personalization and 2836 to deferred personalization. Upfront personalization yielded a 47.4% (95% CI 46.0 to 48.8) registration completion rate versus 50.7% (95% CI 49.0 to 52.4) with deferred personalization ($p < .05$).

Conclusions: A strategy of deferred collection of personal identifiers yielded slightly higher completion rates. To maximize user registration when onboarding users to educational medical apps, consider deferring the collection of personal information until user preferences have been provided. Further research is required to maximize app registration when data requested is extensive as in 'Read'.

PUB385

Onconephrology Abstracts Trends in ASN Kidney Week 2012-2014 Jyotsana Thakkar, Rimda Wanchoo, Kenar D. Jhaveri. *Nephrology, Hofstra NSLIJ School of Medicine.*

Background: Onconephrology is an emerging new specialty of nephrology. The ASN created a forum dedicated to the field of Onconephrology in 2011 to improve collaborative care for cancer patients with kidney disease. One of the aims was to allow for collaborative research strategies in the field of onconephrology. However, the number of onconephrology related abstracts accepted to be presented at ASN Kidney Week (ASN-KW) 2012-2014 is not known.

Methods: We reviewed the abstracts presented in the ASN-KW over past 3 years from 2012-2014 which were related to Onconephrology. Search terms used to identify abstracts included cancer, myeloma, chemotherapy, tumor lysis, paraneoplastic syndrome and hypercalcemia. They were then categorized into: basic science, chemotherapy, myeloma, epidemiology, electrolyte disorders, AKI, tumor lysis, GN, paraneoplastic syndromes and obstructive uropathy. Abstracts were also categorized based on study design.

Results:

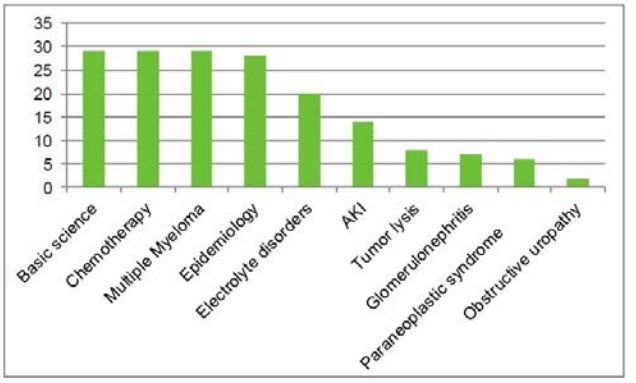

Figure above breaks down the total number(n) of abstracts(Y axis) in the last 3 years presented at ASN-KW by category. There has been an increase in the number of onconephrology abstracts over last 3 years. A total of 175 abstracts were reviewed. In 2012, there were 50 onconephrology related abstracts, increased to 54 in 2013 and 71 in 2014. Abstracts related to basic science(16%), chemotherapy toxicities(16%), myeloma(16%) and epidemiology (16%) dominated most of the accepted abstracts. Of the clinical abstracts, > 50% were case reports, 41% were retrospective studies, 4.5% database studies and <1% RCT.

Conclusions: Over the last 3 years, we have seen a growing trend in the number of abstracts submitted in the ASN-KW related to the field of onconephrology. We suggest creating a separate section dedicated to onconephrology in the ASN meetings to allow for collaborative research and greater understanding of cancer related nephrology, leading to improved patient outcomes.

PUB386

Patients-Initiated Educational Research in a Digital Age Chayakrit Krittanawong,[1] Zhen Wang,[2] Sakkarin Chirapongsathorn,[3,4] Hua Ann Jenny Lu.[5] *[1]Div of Cardiovascular Disease, Mayo Clinic, Rochester, MN; [2]Dept of Healthcare Policy and Research, Mayo Clinic, Rochester, MN; [3]Div of Gastroenterology and Hepatology, Mayo Clinic, Rochester, MN; [4]Div of Gastroenterology, Dept of Medicine, Phramongkutklao Hospital and College of Medicine, Royal Thai Army, Bangkok, Thailand; [5]Div of Nephrology, Massachusetts General Hospital and Harvard Medical School, Boston, MA.*

Background: The emergence of web-based technology in the digital age has become popular in the healthcare industry, particularly in the educational research field. A web-based technology can bridge the educational gap between researchers and patients.

Methods: We aimed to develop a user-friendly interface between a virtual community that can be used by patients and researchers and a preliminary knowledge-building activity. Wikiheart is a web research environment that creates a real-time community between researchers and patients without geographical restrictions.

Results: Once patients have registered for free, the system allows these users to write their own articles or to edit other articles, which often leads to thought provoking medical research questions. Wikiheart also demonstrates a novel approach to population science that is based on huge databases with multiple cloud servers that reach the web research community. Nowadays Wikiheart has more than one million visitors, and serves as an educational web technology that provides its users with both a variety of learning methods, and several areas of research focus.

Conclusions: Wikiheart is an innovative web-based program for conducting educational research in the digital community. It is an excellent tool for researchers and patients to generate new hypotheses via the scientific method in an online environment.

PUB387

Detailed Subject Lines Increase Engagement with Educational Emails Daniel Schwartz,[1] Chan Kruse,[2] Stephane Boyer.[2] *[1]Faculty of Medicine, Univ of British Columbia, Vancouver, BC, Canada; [2]QxMD, Vancouver, BC, Canada.*

Background: 'Read by QxMD' (http://qxmd.com/read) is an educational service and mobile app that curates the nephrology/medical literature and personalizes reading recommendations based on a clinician's or researcher's interests. Each week, registrants receive an email alert that highlights the most popular medical articles in the reader's clinical or research area of specialty. The content of email subject lines have been shown to have a significant impact on whether email is read or deleted prior to being read. We hypothesized that providing more details in the subject line would result in greater engagement with the email content.

Methods: We randomly assigned all emails sent containing the "Most Read" articles of the week to either a generic/consistent email subject line or a subject line that included the title of the most commonly read article of the week (detailed/variable). SendGrid, an email delivery service provider, was utilized for email delivery and to automate the subject line randomization. The primary outcome was email open rate. Secondary outcome was email click through rate.

Results: Between January 7, 2014 and May 1, 2015, a total of 1,287,442 emails were sent. 643,475 were generic/consistent and 643,967 were specific/variable. A specific/variable email subject line yielded a 70.76% (95% CI 70.68 to 70.84) open rate versus 48.85% (95% CI 48.76 to 48.94) with an email subject line that was generic ($p < .01$). A detailed/variable subject line did not increase click through rate as compared to a generic/consistent subject line, 9.87% (95% CI 9.82 to 9.92) vs 9.85% (95% CI 9.8 to 9.9) $p > 0.05$.

Conclusions: Including details about the content of an educational email in the subject line resulted in a greater email open rate but did not increase the click through rate. Further research is required to increase engagement with the content of educational emails provided by the 'Read' educational service.

PUB388

Teaching Ethics and EBM in the Medical School: Case Discussion as a Teaching Tool on End-of-Life Issues – Dialysis or Palliative Treatment in a 92 Year Old Patient? Giorgina B. Piccoli,[1] Laura Sacchetti,[2] Laura Verze,[2] Franco Cavallo.[2] *[1]SS Nephrology, Clinical and Biological Sciences, Univ of Torino, Italy; [2]Course of EBM and Ethics, Univ of Torino, Italy.*

Background: History of Nephrology follows and influences the development of Bioethics and offers insights for teaching: the first Ethics Committee (the "God's Committee"), brain death, the sale of organs, the limitation of resources, up to the global needs (as in the 0-by-25 project). Case discussion within the Medical school may be a useful tool to acquire bioethical skills and analytical tools.

Methods: Discussion of a clinical case: patient in his nineties, high comorbidity, good cognitive status (writer), GFR 10 mL / min. The case raises questions about the choice diet-dialysis-palliation. 50 medical students of the curricular course of ethics and EBM are tutored for an academic year through the collection of information from databases (Pubmed), web, talk with experts, tutors and teachers. The analysis is performed according to the 4 main ethical principles (beneficium, non maleficum, justice, autonomy) to a narrative approach.

Results: The students produces a text, here summarized: from a clinical standpoint, beneficium and non-maleficium suggest to postpone dialysis (intent-to-defer) with the start of low-protein diet (equal to or greater survival, minimal damage, favorable context). Distributive justice favors less expensive therapies (diet, palliation); in the context of individual justice, the start of dialysis, if necessary, has a role in life support. The patient, by consulting more doctors, has expressed his desire for autonomy. Considering the chronic disease, the intellectual level, a doctor-patient relationship of "shared decision making" is advisable. Sharing the choice improves results, reduces dropout rate of dialysis, if undertaken. Since the four principles of bioethics take on different priorities depending on the socio-cultural context, the approach to the patient will be modulated in a narrative than his views or religious beliefs.

Conclusions: Nephrology offers suggestions for bioethical discussion. Conversely, bioethics offers analytical tools for the analysis of complex decisions such as dialysis in the "very old".

PUB389

SLIT2 Is Upregulated in Proximal Tubules and Urine following Folic Acid Induced Kidney Injury Jonathan Street, Ana C. Souza, Xuzhen Hu, Yuning George Huang, Peter S.T. Yuen, Robert A. Star. *NIDDK, Bethesda, MD.*

Background: SLIT2, signaling via ROBO receptors, was originally described for its role in neuronal guidance, and has since been linked with leukocyte chemotaxis and angiogenesis. As both processes might be involved in kidney injury and repair, we tested whether SLIT2 signaling is involved in folic acid induced kidney injury.

Methods: Eight-week old male CD-1 mice were injected i.p. with 250 mg/kg folic acid. Groups were euthanized 0-7, or 14 days later. Expression levels were determined by RT-qPCR and western blot of whole kidney lysates. Localization was determined by immuno-histochemistry. In a second experiment mice received folic acid and then 70 mg/kg i.p. recombinant human SLIT2 or vehicle on days 2, 4, and 6. On day 14 GFR was measured in conscious mice by transcutaneous fluorescence monitoring of FITC-Sinistrin elimination.

Results: Following folic acid injection, whole kidney SLIT2 mRNA and protein levels decreased two-fold by day 3, whereas SLIT2 protein increased in proximal tubule cells by immunohistochemistry on day 3. Expression of SLIT2 protein was observed in the proximal tubule derived HK-2 cell line, and urinary SLIT2 protein was increased by 2-fold 2 to 7 days after folic acid injection, supporting tubules as a site of SLIT2 synthesis. In a separate experiment mice were given folic acid, then recombinant human SLIT2 i.p. on days 2, 4, and 6. Kidney function measured directly as GFR or indirectly via BUN 14 days after injection was not significantly improved by SLIT2 treatment.

Conclusions: Folic acid induced injury increased expression of SLIT2 in proximal tubule cells followed by detection of SLIT2 in the urine, which points to SLIT2 as a candidate urine biomarker for tubular injury. Amelioration of injury with systemic SLIT2 treatment was not observed, suggesting better utility as a marker than a mediator.

Urinary Trefoil Factor 3 Is Significantly Associated with Renal Tissue Fibrosis in Patients with Tubulointerstitial Nephritis Keiko Tanaka, Hitoshi Sugiyama, Toshio Yamanari, Ayu Akiyama, Akifumi Onishi, Masashi Kitagawa, Hiroshi Morinaga, Yoko Kikumoto, Tatsuyuki Inoue, Jun Wada. *Dept of Medicine and Clinical Science, Okayama Univ Graduate School, Okayama, Japan.*

Background: Trefoil factor 3 (TFF3) is a small peptide involved in mucosal protection. TFF3 is widely expressed in multiple tissues including kidney. Previous studies have suggested that serum and urinary TFF3 significantly increases in patients with chronic kidney disease and that urinary TFF3 level decreases in rats with acute kidney injury. However, it is unclear whether serum or urinary TFF3 is associated with human renal tissue injury. The aim of this study is to elucidate the relationship between serum and urinary TFF3 levels and the degree of renal tubulointerstitial injury.

Methods: The total study population included 52 patients (tubulointerstitial nephritis: 31, minor glomerular abnormalities and thin basement membrane disease as controls; 21) who underwent renal biopsy. The serum and urinary TFF3 concentrations were determined by a specific ELISA. The degrees of tubulointerstitial cell infiltration and fibrosis were semiquantitatively graded in biopsy specimens and defined by the inflammation score and the fibrosis score, respectively. An immunohistochemical analysis was performed to reveal the localization of the TFF3 protein.

Results: The median serum and urinary TFF3 levels of the disease group were significantly higher than those of the controls ($p=0.002$ and $p=0.008$, respectively). A statistically significant positive correlation was observed between the urinary TFF3 levels and the renal fibrosis score in the disease group. However, there was no correlation between the serum or urinary TFF3 level and the renal inflammation score in disease group. TFF3-positive cells were observed in the renal tubular epithelium.

Conclusions: The data indicate that serum and urinary TFF3 levels are significantly increased and, in particular, that urinary TFF3 could reflect renal tissue fibrosis in patients with tubulointerstitial nephritis. Further studies are required to elucidate the precise distribution of renal TFF3 protein and mRNA, and the mechanism underlying the contribution of TFF3 to renal fibrosis.

PUB391

Induction of Epithelial-to-Mesenchymal Transition and Fibrosis Signals via AKT and Peroxisome Proliferator-Activated Receptor Pathway in Renal Tubular Cells Induced by a Plasticizer Di(2-ethylhexyl) Phthalate Shing-Hwa Liu,[1] Li-Chen Huang,[1] Bo-Lin Chen,[1] Chih-Kang Chiang.[1,2] *[1]Inst of Toxicology, College of Medicine, National Taiwan Univ, Taipei, Taiwan; [2]DIDT, NTUH, Taipei, Taiwan.*

Background: Di(2-ethylhexyl)phthalate (DEHP) is a plasticizer and a probable endocrine disruptor. More than two million tons of DEHP were used each year worldwide. Recent studies have suggested that DEHP has potential adverse effects on the liver, kidney, and reproductive system. It could also cause carcinogenicity and developmental toxicity. DEHP exposure might exacerbate kidney progression. Tubular epithelial-to-mesenchymal transition (EMT) is recognized to play pivotal role in the process of renal fibrosis. However, the mechanisms of nephrotoxicity induced by DEHP remain unclear. Here, we investigated whether DEHP could induce renal fibrosis via EMT process.

Methods: A rat renal proximal tubular cell model (NRK-52E cells) was used to evaluate EMT and fibrosis signaling. Cell morphology was observed by microscope. Cell viability evaluated by MTT assay. The molecule signals of EMT and fibrosis were analyzed by flow cytometry, confocal laser scanning microscopy, immunocytochemistry, and Western blotting.

Results: Treatment with DEHP (5-25 μM) for 72h caused the change in renal tubular cell morphology shifting to spindle-like shape. DEHP did not induce cell apoptosis, but significantly induced G2/M cell cycle arrest. Moreover, the expressions of vimentin, α-SMA, and CTGF, which are the markers of the mesenchymal phenotype, were significantly increased. The expressions of E-cadherin, a maker of epithelial cells, was significantly decreased by DEHP. DEHP could also inhibit the expression of peroxisome proliferator-activated receptor (PPAR)α and γ. The phosphorylation of Akt and Smad 2/3 was also significantly increased by DEHP. Notably, treatment with MK2206 (an Akt inhibitor) significantly inhibited DEHP-induced phosphorylation of Akt and EMT. Further investigation revealed that MK2206 suppressed the expression of Akt downstream proteins (NF-κB and GSK3).

Conclusions: These findings suggest that DEHP is capable of inducing the EMT process through AKT and PPAR signaling pathway, which may lead to renal fibrosis.

PUB392

Src Kinase Is a Potential Therapeutic Target in Renal Fibrosis Yanli Yan,[1,2] Murugavel Ponnusamy,[2] Evelyn Tolbert,[2] George P. Bayliss,[2] Shougang Zhuang.[2] *[1]Dept of Emergency Medicine, Shanghai East Hospital, Tongji Univ School of Medicine, Shanghai, China; [2]Dept of Medicine, Rhode Island Hospital and Alpert Medical School, Brown Univ, Providence, RI.*

Background: Increased activity of Src, a non-receptor tyrosine kinase, has been associated with the pathogenesis of renal tumors and some glomerular diseases, but its role in renal interstitial fibrosis remains elusive.

Methods: In this study,we investigated the effect of Src inhibition on renal interstitial fibroblast activation in vitro and renal fibrogenesis in a murine model of unilateral ureteral obstruction and the mechanisms involved.

Results: Exposure of cultured renal interstitial fibroblasts (NRK-49F) to PP1, a selective inhibitor of Src, resulted in decreased expression of α-smooth muscle actin (α-SMA), and fibronectin and collagen I, in response to serum- or transforming growth factor-b1(TGF-b1). Silencing Src with siRNA also inhibited expression of those proteins. Furthermore, inhibition of Src activity blocked renal fibroblast proliferation as indicated by a dose-dependent down-regulation of cyclin D, cyclin E and PCNA (proliferating cell nuclear antigen), three proteins involved in cell cycle progression and up-regulation of p21 and p27, two major cell cycle inhibitors. In a murine model of renal interstitial fibrosis induced by unilateral ureteral obstruction (UUO), the active form of Src (phopsho-Src Tyr416) was upregulated in the fibrotic kidney, and its inactivation with PP1 reduced renal fibroblast activation and attenuated extracellular matrix protein deposition. Src inhibition also suppressed expression of TGF-bR1, activation of Smad3 and STAT3, and phosphorylation of epidermal growth factor receptor. Finally, PP1 treatment reduced renal epithelial cells arrested at G2M phase of cell cycle, a phenotype that produces profibrotic growth factors/cytokines, after UUO injury.

Conclusions: Our results demonstrate the importance of Src in mediating renal interstitial fibroblast activation and renal fibrogenesis and suggest Src as a potential therapeutic target for treatment of chronic renal fibrosis.

PUB393

MiRNAs as Novel Biomarkers and Therapeutic Target in Chronic Kidney Disease Laura Martín-Gómez,[1] Elia Aguado fraile,[1] Edurne Ramos,[1] Elisa Conde,[1] Esperanza Macarena Rodriguez serrano,[1] Sara Gimenez-Moyano,[1] Sara Jimenez alvaro,[2] Fernando Liano,[2] Maria Laura Garcia-Bermejo.[1] *[1]Biomarkers and Therapeutic Targets Unit, IRYCIS, Madrid, Spain; [2]Nephrology, Ramon y Cajal Hospital, Madrid, Spain.*

Background: Statistical meta-analysis demonstrates that episodes of Acute Kidney Injury(AKI) eventually promote development of chronic renal damage(CKD).So far,there aren´t quantifiable and accurate biomarkers to predict the evolution of AKI to CKD,what would enable clinicians to monitor these patients.Our group has validated a combination of serum miRNAs as AKI biomarkers, including:miR-127,miR-101,miR-210,miR-126,miR-146a,miR-26b,miR-29a,miR-10a,miR-93 and miR-27a. Here we have identified some of this miRNAs as novel biomarkers for CKD and potential new therapeutic targets for renal fibrosis.

Methods: For this purpose,in vitro experimental model of proximal tubular epithelial cells under TGFb treatment as pro-fibrotic stimulus and human samples from patients with established CKD(stage 1-5)have been used.

Results: We characterize in vitro model by estimation of:loss of E-cadherin expression,increase of α-SMA expression, expression of collagen I and fibronectin and activation of metalloproteinase(MMP-2 and MMP-9),by qRT-PCR and zymogram. Furthermore, we have modulated miR-127 in TGFb treated cells, pre-miRs and anti-miRs transfection, finding that miR-127 overexpression maintains epithelial phenotype and miR-127 blockage induces epithelia-mesenchymal transition(EMT), estimated as mentioned above. In addition, we have determined the expression of miRNAs combination in the serum of CKD patients by qRT-PCR and statistical correlations with clinical data indicate:1) miR-127 is downregulated along CKD development;2) miR-126 and miR-26b are significant in diabetic nephropathy;3) miR-146 discriminates patients exhibiting dyslipidemia.

Conclusions: In summary we have identified miRNAs involved in renal fibrosis development as well as miRNAs correlated with CKD features,suggesting that miRNAs could have a potential clinical use for CKD patient's management and they can be point out as novel therapeutic target in this clinical context.

Clofarabine Induced Acute Kidney Injury Sameer Gupta, Ramapriya Sinnakirouchenan, Kamlesh Reddy Kurre. *Nephrology, Medical College of Wisconsin, Milwaukee, WI.*

Introduction: Clofarabine induced acute kidney injury (AKI) has been documented but the mechanism leading to AKI has not been well understood. Here we describe a case of clofarabine treated relapsing ALL leading to anuric AKI and death.

Case Description: A 30 year old male with relapsing ALL was admitted to the hospital for AKI. His creatinine was 1.2mg/dl 2 weeks prior to admission. He received his first cycle of clofarabine at 40mg/m^2 for 5 days one month ago. On the fifth day of cycle 2 he was admitted for AKI with creatinine of 2.5 mg/dl. Nephrology was consulted next day for oliguria and creatinine elevation up to 3.3 mg/dl. Urine microscopy revealed acute tubular necrosis (ATN). His hospital stay was complicated by anuria and septic shock necessitating continuous renal replacement therapy. Proteinuria could not be assessed due to anuric AKI. After a prolonged and complicated hospital course patient expressed his wishes for comfort care.

Discussion: Clofarabine is approved for the treatment of relapsed or refractory ALL in children but is also used out of label in adults. It acts by inhibiting DNA synthesis, the enzyme ribonucleotide reductase and repair and activation of mitochondrial repair processes. It is postulated based on animal studies and its mechanism of action that collapsing glomerulopathy or tubular injury alone or in combination may be the etiology. In our case, there is a temporal relationship between clofarabine use and AKI.

The risk factors for clofarabine-associated AKI include older age, higher AUC (area under the curve) and, lower baseline GFR. While the current recommendation is a 50% dose reduction for renal impairment, this only applies to patients with a baseline creatinine clearance of 30–60 mL/min. There are currently no guidelines for those patients with ostensibly "normal" creatinine clearance values.

We suggest that dosing based on baseline GFR even among patients with apparently normal serum creatinine deserves consideration in the future use of clofarabine. Careful monitoring for renal toxicity and minimizing other renal insults in older patients and those with lower baseline GFRs should help prevent this adverse effect.

PUB395

Orthostatic Hypotension as the Presenting Feature of Primary Systemic Amyloid Light-Chain (AL) Amyloidosis Scherly Leon,[1] Farouk Talakshi,[1] Rajiv A. Perinbasekar,[1] Gary R. Briefel,[2] Moro O. Salifu.[1] *[1]Medicine, Renal Div, Downstate Medical Center, Brooklyn, NY; [2]Medicine, Renal Div, Kings County Hospital Center, Brooklyn, NY.*

Introduction: Orthostatic hypotension is a common disorder among the elderly, often associated with hypovolemia, adrenal insufficiency, and autonomic neuropathies. Primary systemic amyloid light-chain (AL) amyloidosis is a rare acquired plasma cell disorder. Morbidity results from extracellular depositions of amyloid fibrils in vital organs. Deposition of amyloid protein in the nervous system leads to autonomic neuropathy, resulting in orthostatic hypotension,early satiety, erectile dysfunction and intestinal motility dysfunction. We report a case of primary systemic amyloidosis, presenting initially as orthostatic hypotension.

Case Description: A 61-year-old man was admitted for orthostatic hypotension with syncopal episodes and proteinuria. He was well until six months prior to admission, when he began experiencing severe recurrent orthostatic lightheadedness, anorexia, and dysgeusia. He reported weight loss and periumbilical paresthesias. He had been admitted to an outside hospital and underwent extensive evaluation including a chest CT which revealed lung and liver granulomas. Fludrocortisone was started for hypotension. He noted no improvement and stopped fludrocortisone two weeks prior to presentation to our hospital.

Extensive evaluation of his orthostasis, including an adrenocorticotropic hormone stimulation study was normal. Cardiac and endocrine evaluation revealed no abnormalities. Laboratory exam showed serum creatinine of 0.74 mg/dL, Hgb of 10 g/dL, MCV of 90fL, total protein 6.4 g/dl and albumin 2.5 g/dl. A 24-hour urine protein excretion was 5g. Free kappa (436 mg/L) and lambda light chains (6.5 mg/L) with a ratio of 67. A monoclonal spike was noted on serum protein electrophoresis. Additional rheumatologic workup was negative. Bone marrow biopsy was consistent with multiple myeloma and congo red stain was positive for amyloidosis.

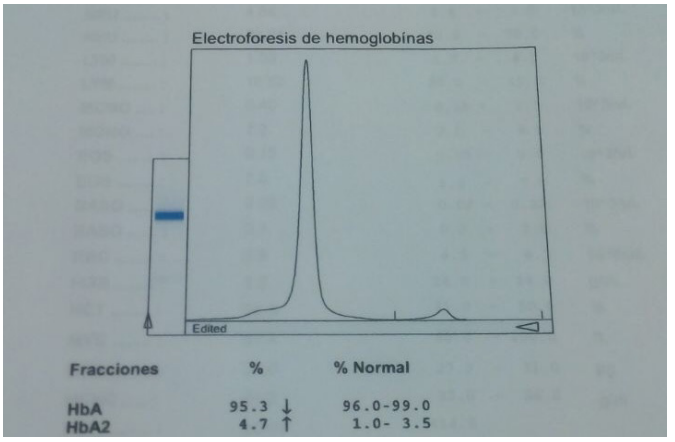
Discussion: The finding of heavy proteinuria in conjunction with orthostatic hypotension should lead one to consider the diagnosis of primary systemic (AL) amyloidosis in the differential diagnosis.

PUB396

Refractory Anemia Secondary to B Thalassemia in a Patient with CKD: Case Report Lilia Maria Rizo Topete, Giovanna Y. Arteaga Muller, Jesus Cruz Valdez, Elisa Maria Guerrero Gonzalez, Concepcion Sanchez Martinez. *Nephrology, Univ Autonoma de Nuevo Leon, Monterrey, Nuevo Leon, Mexico.*

Introduction: We present a case of a Male patient, 28 years old, Mexican, diagnosed with CKD of unknown etiology.

Case Description: He denies chronic diseases. Mother with SLE, Sd. Evans and DM.The renal sonogram showed small kidneys . Viral panel negative as immunological tests. The patient comes as ERC G5 with uremic syndrome. RRT starts with PD, 3 months after an episode of peritonitis for candida and HD was initiated. He presented hemoglobin of 7.5 g/dl, microcytichypochromic anemia, treated with erythropoietin 12 000 IU a week, oral Iron and folic acid. Months later the patient came up with anemic syndrome and hemoglobin of 6.6 mg/dl, 2 units of blood were transfused. He presented 3 similar episodes , so 6 more units were transfused. Erythropoietin exchanged for darbepoetinand. Direct Coombs test was negative. He did not respond to treatment, iron test was performed and IV iron therapy was initiated. Hematology reported aspiration and biopsy Bone marrow normal, with megakaryocytes, M:E ratio 2:1m without blastas. Biopsy reported hypocellular . Abdominal US reported normal. Hemoglobin electrophoresis was performed which reported increased A2 hemoglobin



Discussion: The B Thalassemia is a hereditary disorder of hemoglobin synthesis in the B-globin gene that present clinically with microcytic hypochromic anemia, erythropoiesis ineffective, normal reticulocyte counts or slightly elevated and high levels of A2 hemoglobin. In the kidneys can cause tubular injury and GFR decline. Developing glomerulosclerosis and fibrosis. We can not rule out that CKD is secondary to B-thalassemia, a genetic study would be necessary. It is an uncommon diagnosis in Latin America, but should be considered in patients with CKD and microcytic hypochromic anemia refractory to convecional treatment.

PUB397

Empirical Antifungals in Peritoneal Dialysis Patients with Bowel Obstruction: Time to Reconsider? Ravinder Pal S. Bhatti, Elwaleed Elnagar, Dumitru Rotaru. *Nephrology, Univ of Arkansas for Medical Sciences, Little Rock, AR.*

Introduction: Intestinal obstruction, even without perforation or ischemia, predisposes patients on peritoneal dialysis (PD) to peritonitis by gut commensals including fungi. Fungal peritonitis (FP), with (Secondary) or without (Primary) prior antibiotic use, is associated with increased mortality and technique failure. This raises the question of empirical antifungal use in PD patients with bowel obstruction. We present our experience with such a patient.

Case Description: A 74 year old male who had been on Continuous Cycling Peritoneal Dialysis for the past four years with his prescription being 5 exchanges of 2 liters of 1.5% and 2.5% dianeal with a last fill of 2 liters of icodextrin, presented with worsening abdominal pain. His dialysate was clear and had just 3 leucocytes. His CT abdomen showed small bowel obstruction (SBO) with conservative management pursued. Over the next few days, the SBO resolved and dialysate cell counts remained unremarkable. On day 5, he became hypotensive. Examination was notable for increased abdominal tenderness and a cloudy dialysate. Repeat dialysate studies were sent and intraperitoneal vancomycin and cefepime were started. Imaging suggested SBO. He responded appropriately to the antibiotics over the next three days with no growth on any cultures thus far. However, the dialysate grew yeast the next day. Fluconazole was started, later being switched to micafungin with the yeast identified as *Candida cruzei*. His Tenckhoff catheter was removed and hemodialysis (HD) was initiated. He completed 4 weeks of micafungin and opted to continue on HD.

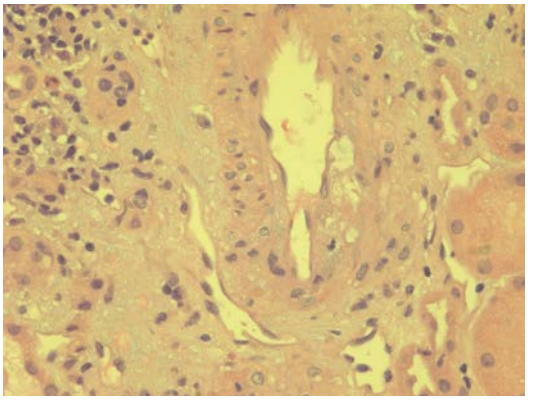
Discussion: Evidence on antifungal prophylaxis while treating PD related bacterial peritonitis has been mixed, with the decision being individualized on a per-center basis. Additionally, no clear role has been defined for prophylactic antimicrobials in PD patients with bowel obstruction. With a high risk for both primary and secondary FP, these patient present a conundrum. Our case highlights this while also suggesting a role for prophylactic antifungals even when antibiotic exposure is brief. We conclude that it may prudent to provide empirical antifungal coverage in PD patients with SBO.

PUB398

Leukocytosis and Peripheral Blood Eosinophilia Are Early Signs of Acute Cellular Rejection of a Transplanred Kidney Elwaleed Elnagar, Ravinder Pal S. Bhatti, Aziz Bakhous. *Nephrology, UAMS, Little Rock, AR.*

Introduction: Leukocytosis and peripheral blood eosinophilia were well described in acute rejection of transplanted livers and pancreas rejection This labaratory abnormality was not well evaluated in kidney allograft rejection. In this case report, we explore leukocytosis and peripheral blood eosinophilia as possible labaratory abnormalities preceeding ACR.

Case Description: We are presenting a 65 years old woman with a history of ESRD due to ADPKD, who had a DDKT in 2012. Her medications included Prednisone, Tacrolimus, and Mycophenolate Mofetil. She maintained a stable allograft function, with a creatinine of 1-1.2. She was found to have leukocytosis and peripheral blood eosinophilia. Evaluation for infections and malignancy was negative. 6 weeks later she was noted to have AKI. She complained of mild lower extremities swelling. Physical examination was unremarkable. Labs evaluation revealed a creatinine of 2 mg/dl, WBCs count of 15.9 k/uL, and eosinophilia. Renal biopsy however, showed ACR (figure1). There were abundant infiltrates with neutrophils and eosinophils. She was treated for ACR with return of creatinine to baseline.



Discussion: Several reports have evaluated the predictive value of peripheral blood eosinophilia as a simple noninvasive diagnostic marker for ACR of transplanted livers and of acute pancreatic rejection. However, peripheral blood eosinophilia was not evaluated as a possible test predicting renal ACR. In a case report, Baradhin et al, described the etiology of AKI following treatment with armodafinil for narcolepsy. They indicated that both (AIN and ACR) has similar biopsy characteristics. However, our patient had no clinical features to suggest AIN, including no new medications. We conclude that leukocytosis and peripheral blood eosinophilia could represent signs of impending acute cellular rejection of transplanted kidneys.

PUB399

A Case of IgA Nephropathy in an HIV-Positive Patient Hermes Garcia-Sanchez, Vandana Niyyar, Thomas E. Rogers. *Nephrology, Emory Univ, Atlanta, GA.*

Introduction: IgA nephropathy has been described in patients infected with HIV. Though IgA levels are commonly elevated in HIV, these patients may also develop IgA antibodies against specific HIV antigens. Renal lesions may result from HIV antigen-specific immune complexes that are derived from the circulation and from in-situ complex formation.

Case Description: We present a case of a patient with HIV/AIDS, on highly active antiretroviral therapy (HAART), who was evaluated for microscopic hematuria and worsening renal function. The patient's only complaint was early morning peri-orbital edema. On examination, BP was 103/72 mm Hg with a BMI 23 kg/m2. Labs showed normal electrolytes, serum creatinine 1.7 mg/dL (baseline 0.7mg/dL), urine protein/creatinine ratio of 2.5 grams/dl. Other serologies were negative. HIV VL was undetectable, and CD4 count was 183. Renal US showed bilateral enlarged, echogenic kidneys.

Renal biopsy revealed sclerosing glomerulopathy with IgA immune type deposits on immunofluorescence. The patient was initiated on an ACE inhibitor and a low salt and protein diet, with resolution of his proteinuria to 0.7 Grams/dL. His renal function stabilized, with a creatinine of 1.6 mg/dL.

Discussion: In conclusion, IgA glomerular disease arising in HIV positive patients has clinical and pathologic aspects similar to idiopathic IgA nephropathy. IgA nephropathy should be suspected in patients with HIV presenting with unexplained hematuria, and renal biopsy should be performed as soon as possible for early diagnosis and therapy. Current management recommendations are similar to those with idiopathic IgA, including ACE inhibitors or ARB for control of proteinuria (>1 g / day) or hypertension.

PUB400

Calcium Channel Blocker Toxicity: Management Strategies and Considerations Sreesh G. Iyengar, Mark I.C. Hong, Seyed-Ali Sadjadi. *Nephrology, Loma Linda Univ, Loma Linda, CA.*

Introduction: Calcium channel blocker overdose is rare but carries a high mortality due to cardiovascular complications. Generally the management is supportive with use of vasopressors, IV fluids, cardiac pacing, and insulin therapy. There are reports of CVVHDF, hemodialysis or hemofiltration alone and charcoal hemoperfusion for the treatment of CCB overdose. Effective management strategies are needed to improve outcomes.

Case Description: Here we describe a patient who presented to the ER after a suicide attempt with ingestion of Norvasc. On arrival to the ER he was awake but later he was intubated. The patient developed acute kidney injury and became anuric. Patient was started on CVVHD that lasted 48 hours. Unfortunately after two days the patient continued to decompensate and expired.

Discussion: Amlodipine is a CCB of the dihydropyridine group acting primarily on vessel walls whereas the non-dihydropyridines act more on cardiac muscle and pacer cells. In our case it was clear Norvasc selectively took its effect on the vasculature with profound hypotension with preserved systolic function and no arrhythmia. The case was complicated with ARDS related to diffuse pulmonary edema, a well known complication with CCB overdose. In our case renal failure was likely related to severe hypoperfusion leading to ischemia. There was development combined respiratory and metabolic acidosis. The metabolic acidosis was attributed to renal failure but it is possible that CCB induced inhibition of insulin secretion leading to ketoacidosis may also have contributed. In terms of management of CCB overdose, if recent ingestion then GI decontamination is reasonable with activated charcoal or whole bowel irrigation. The use of high dose insulin therapy has been tried and its role may include increasing ionized calcium levels, improvement of hyperglycemic acidosis, and improved myocardial function. Most case reports, though

few, have shown little benefit from hemofiltration or hemodialysis theoretically due to high protein binding, high tissue distribution and rapid metabolism of the drug. One case report did show some promise when multiple therapies were used including IV lipid emulsion, CVVHDF and charcoal hemoperfusion.

PUB401

A Rare Case of IgG1-Heavy Chain Deposition Disease Using Oral Prednisone and Therapeutic Plasmapheresis Sacha Baldeosingh, Madhu Kandarpa. *Internal Medicine, Kettering Medical Center.*

Introduction: Heavy chain deposition disease (HCDD) is rare, especially without light chain deposition and when causing non-amyloid tissue deposits.

Case Description: A 75-year-old male with chronic kidney disease (CKD) stage 3 (baseline creatinine 2.3mg/dL) and right single lung transplant for idiopathic pulmonary fibrosis in 2008 presented with extremity edema and decreased urine output. He has no history of diabetes or uncontrolled hypertension. Admission labs showed BUN 77 mg/dL, creatinine 4.37 mg/dL, and subtherapeutic tacrolimus levels at 3.9 ng/mL. Urine protein/creatinine ratio was 6.6. A 24-hr urine protein collection revealed 5822 mg/24hr. Serum protein electrophoresis showed hypoalbuminemia, but no monoclonal proteins were identified. Urine protein electrophoresis was negative for Bence Jones proteins or monoclonal proteins. Urine protein concentration was 713 mg/dL, consisting of 57.8% albumin and 42.2% globulins. C3 and C4 complement levels were low at 46.5 mg/dL and 8.92 mg/dL respectively. Antinuclear antibodies (ANA), anti-streptolysin O (ASO), anti-neutrophil cytoplasmic antibodies (C-ANCA and P-ANCA), and cryoglobulins were negative. Renal ultrasound showed multiple renal cysts without hydronephrosis. Renal biopsy revealed nodular sclerosing glomerulopathy and IgG1-heavy chain deposition disease. Bone marrow biopsy was negative for multiple myeloma. The patient was placed on oral prednisone and therapeutic plasmapheresis in an effort to prevent further renal damage and delay hemodialysis. The patient underwent eight plasmapheresis treatments, however still required hemodialysis for fluid overload.

Discussion: HCDD is a monoclonal plasma cell proliferative disorder characterized by tissue deposits of heavy chain fragments which can lead to renal disease. In HCDD, deposits do not have a fibrillar structure and do not stain positive with Congo red such as with heavy-chain amyloidosis. The rarity of the disease and limited data on evidence-based guidelines for treatment make HCDD challenging to treat. We describe a rare case of IgG1-HCDD with no plasma cell dyscrasia. To our knowledge, no cases have been described using oral prednisone and therapeutic plasmapheresis to treat HCDD renal dysfunction.

PUB402

Cocaine-Induced Vasculitis David Agyapong. *Nephrology, Univ of New Mexico, Albuquerque, NM.*

Introduction: An increasing number of cases of Cocaine -induced vasculitis are being found among cocaine users in the United States which is due to the use of Levamisole laced cocaine. It is estimated that about 70% of the cocaine used here in the US is contaminated with Levamisole.

Case Description: We describe a 65 year old male, with a 20 year history of cocaine abuse, who presented with a 1 month history of a progressively worsening, non-healing and painful rash on his trunk and extremities. He denied fever, weight loss and myalgias but admitted to itchiness. Examination revealed multiple tender, erythematous and violaceous plaques with central necrosis on the trunk and extremities. These plaques were found to be in different stages of healing with their size ranging from 1cm-7 cms. Lab investigations revealed an elevated creatinine of 2.9 mg/dL, an elevated ESR, a low C3, presence of Myeloperoxidase (MPO) antibody and perinuclear Anti Neutrophil Cytoplasmic Antibody (p- ANCA), and an absence of Antinuclear Antibody (ANA) and Anti Proteinase 3 (PR-3) antibody. Urine drug screen was positive for cocaine and urine microscopy showed dysmorphic RBCs. Skin biopsy showed thrombotic vasculopathy with overlying re-epithelialization. Kidney biopsy revealed focal endocapillary proliferative glomerulonephritis with crescents involving 10 % of glomeruli and interstitial fibrosis and tubular atrophy involving approximately 70% of the specimen.

•Treatment is mainly abstinence and supportive. •The clinical course of patients is difficult to assess due to the fact that few patients are able to abstain from cocaine use. •Our patient was able to abstain from cocaine use for about 30 days ,and that almost resulted in clinical resolution after 30 days of being cocaine-free (Fig 3.) •Although ,in the setting of worsening skin lesions and ongoing cocaine use ,some patients have been treated with anticoagulation or thrombotic vasculopathy , immunosuppresion and corticosteroids with varying degrees of success , robust evidence lacking.

Discussion: •With more than 2 million Americans using cocaine , occurrences of levamisole –induced vasculitis will increase Levamisole exposure should be included in the differential of patients with purpuric vasculitis , neutropenia and cocaine.

Morbidity Associated with Uremic Ascites Among Emergent Dialysis Patients Shobana Sivan, Rajeev Raghavan. *Nephrology, Baylor College of Medicine.*

Introduction: Patients with end-stage renal disease(ESRD) on emergent dialysis often develop complications of inadequate dialysis such as pleural effusion, ascites and pericardial effusion. Uremic ascites is characterized by exudative ascites with SAAG usually <1.1 and is diagnosed after excluding liver, cardiac, infectious and malignant causes. The incidence of uremic ascites in standard dialysis population was described as 0.7-20%. We believe that emergent dialysis patients with uremic ascites have higher morbidity and mortality.

Case Description: Total of 463 emergent dialysis patients, who were initiated on dialysis between July 2010 and April 2015 were analyzed. Among 36 patients with Ascites of any cause, 12 patients were included in the study group of uremic ascites. A cohort of 36 patients without ascites was randomly selected for comparison. Two groups were compared based on demographics and morbidity indicators.

The mean age was 50 years with predominance of Hispanic male in both groups. The serum albumin in the uremic ascites group and the cohort group was 2.6±0.4 and 3.29±0.2 respectively. The mean emergency center(EC) visits and hospital admissions in uremic ascites and cohort group were 79.6, 9 and 63.4, 5.2 respectively. Volume overload and abdomen pain were the major reasons for admissions in the study group. They underwent paracentesis and frequent dialysis during the hospital course.

	Cohort Group(36)	Study Group(12)
Age	50.7±3.9	50.1±
Sex	31M/5F	9M/3F
Ethnicity	91.6%(33)Hispanic	80%(10)Hispanic
Serum Albumin (g/dl)	3.3±0.2	2.6±0.4
EC Visits/Year	63.4	79.6
Hospital Admissions/Year	5.2	9

Discussion: The Emergency room visits and hospital admissions are more in emergent dialysis patients with the complication of uremic ascites. The serum albumin, a marker for increased cardio-vascular events and death is lower in these patients. We conclude that uremic ascites increase the morbidity and mortality in emergent dialysis population with ESRD. The modalities such as Continuous ambulatory peritoneal dialysis, scheduled outpatient dialysis and kidney transplant may prove beneficial.

PUB404

A Case of Multiple Vertebral Compression Fractures due to Glucocorticoid-Induced Osteoporosis in a Pediatric Patient with Nephrotic Syndrome Akihiko Shirasu,[1] Akira Ashida,[1] Yuko Fujii,[1] Hideki Matsumura,[1] Hyogo Nkakura,[1] Motoshi Hattori,[2] Hiroshi Tamai.[1] *[1]Dept of Pediatrics, Osaka Medical College, Takatsuki, Osaka, Japan; [2]Dept of Pediatric Nephrology, Tokyo Women's Medical Univ, Tokyo, Japan.*

Introduction: Glucocorticoid therapy has a number of adverse effects, among which osteoporosis and bone fracture are major complications. However, there are few reports of this condition in pediatric patients. Here we describe a pediatric case of multiple vertebral compression fractures due to glucocorticoid-induced osteoporosis during treatment for steroid-dependent nephrotic syndrome in a child.

Case Description: A 12-year-old boy was referred to our hospital for treatment of nephrotic syndrome with massive proteinuria and generalized edema. He was treated with the standard corticosteroid regimen stipulated by the International Study of Kidney Disease in Children (ISKDC). Although he achieved complete remission, he suffered two relapses of nephrotic syndrome during administration of prednisolone on alternative days. In the second relapse, the disease became resistant to the steroid therapy, and therefore he received two courses of steroid pulse therapy followed by steroid tapering concomitant with cyclosporine administration. Two months after the diagnosis of steroid-resistant nephrotic syndrome, the patient complained of back pain. Magnetic resonance imaging demonstrated compression fractures from the sixth thoracic vertebra to the first lumbar vertebra. Therefore, the steroid dosage was rapidly reduced and then withdrawn because he was able to maintain remission under cyclosporine therapy.

Discussion: It is necessary to evaluate the state of bone particularly the bone mineral density of the lumbar spine, at an early stage of treatment for nephrotic syndrome in children, even though the incidence of glucocorticoid-related vertebral fracture is low in this patient population.

PUB405

First Use of Lixelle Beta 2-Microglobulin Apheresis Column (Lixelle Column) for Dialysis Related Amyloidosis in the United States Vesh Srivatana,[1] Anjali Masand,[1] Jeffrey I. Silberzweig.[2] *[1]Dept of Nephrology and Hypertension, NYP- Weill Cornell Medical Center, New York, NY; [2]Dept of Nephrology, The Rogosin Inst, New York, NY.*

Introduction: Dialysis related amyloidosis (DRA) is a debilitating complication of long-term hemodialysis characterized by excess accumulation of Beta 2-microglobulin, which deposits as amyloid fibrils in the bones, joints, and organs of affected patients. The Lixelle Beta 2-microglobulin apheresis column (Lixelle column) is a recently FDA approved medical device that contains specialized beads that selectively remove Beta 2-microglobulin from the blood. This device has been used successfully in Japan to relieve symptoms and prevent progression of DRA. We describe the anticipated first use of this device in the United States.

Case Description: The patient is a 65 year-old man diagnosed with end-stage renal disease of unknown etiology in 1968. A deceased donor renal transplant in 1969 failed within 6 months, and a second transplant in 1970 functioned for 3 years. He has been

treated by maintenance hemodialysis since 1973. In 1995, biopsies documented beta 2-microglobulin amyloid deposits in his tongue, consistent with a diagnosis of DRA. Over time, it has progressed to involve his shoulders bilaterally, his hips, knees, wrists and most recently his colon. He has undergone bilateral total hip replacements and carpal tunnel release procedures. Given his extensive disease burden as a result of DRA despite adequate dialysis, we intend to enroll him in a post-approval study using the Lixelle column. Measures of disease burden will include pre- and post- treatment Beta 2-microglobulin levels, presence of bone cysts, and quality of life (QOL) scores.

Discussion: The Lixelle Beta 2-microglobulin apheresis column appears to increase the Beta 2-microglobulin reduction rate in a single dialysis session, and therefore may be an effective treatment option to improve symptoms and quality of life for patients with dialysis related amyloidosis.

PUB406

An Unusual Case of Anticoagulant-Like Nephropathy in a Non-Anticoagulated Patient

Elyas Safar, Apurv Khanna. *Internal Medicine, Div of Nephrology, SUNY Upstate Medical Univ, Syracuse, NY.*

Introduction: Anticoagulant-related nephropathy is a well-known cause for Acute Kidney Injury (AKI), which was first described in Coumadin anti-coagulated patients, usually with excessive anticoagulation (INR >4). It was also reported to be associated with other Anticoagulants such as direct thrombin inhibitor Dabigatran. We report a case of Anticoagulant-related Like Nephropathy in a Non-anticoagulated patient.

Case Description: A 71-year-old male was admitted to the VA medical center for shortness of breath and hemoptysis. Past medical history was significant for Non Small cell Lung Cancer, cryptogenic liver cirrhosis and COPD. CT chest, showed no pulmonary emboli. He was treated with Vancomycin and Zosyn for Pneumonia. The patient reported gross hematuria initially, which resolved spontaneously. His admission creatinine was 1.1 mg/dl, (baseline 0.6 mg/dl), and went up to 2.4 mg/dl. The patient had another episode of gross hematuria and his creatinine went up to 3.5 mg/dl. The patient remained non-oliguric throughout the course of his AKI. Kidney biopsy showed Tubular epithelial cells injury with red cell casts, but no inflammatory changes and no Immune complexes by Immunofluorescence. The histopathologic pattern shown by the kidney biopsy was consistent with Anticoagulant-related nephropathy. However, the patient was not anticoagulated with Coumadin, Heparin, or any other anticoagulants. His Pro-thrombin time (PT) was 13.1 seconds (normal 9-12 seconds) and INR 1.2. His PTT was 20.1 seconds (normal 25-34 seconds). He had a low platelets count between 55-100K/mm3, due to liver cirrhosis.

The findings in this case, suggest a role for Thrombocytopenia in liver cirrhosis, in causing anticoagulant like intra-glomerular hemorrhage, which may result in an AKI.

Discussion: Thrombocytopenia and likely Platelets dysfunction in Liver cirrhosis can cause intra-glomerular Hemorrhage and results in Anticoagulant-like Nephropathy, even in the absence of excessive coagulopathy as evidenced by a normal PTT & near normal INR. To our knowledge, there has not been a reported case of Anticoagulant-like Nephropathy in Non-Anticoagulated patients.

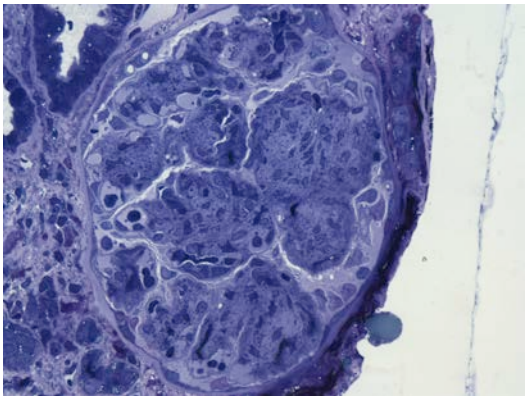
PUB407

Smoking Related Idiopathic Nodular Glomerulosclerosis with Crescents

Tahir Zaman,[1] Frederic Clayton,[2] Josephine Abraham.[1] *[1]Nephrology, Univ of Utah, Salt Lake City, UT; [2]Pathology, Univ of Utah, Salt Lake City, UT.*

Introduction: Idiopathic nodular glomerulosclerosis (ING) is a rare but important cause of nephrotic syndrome. There have been case series reported in the literature regarding the association of ING and smoking.

Case Description: A 37-year-old female with a history of rheumatoid arthritis (RA) presented to the hospital with cough and hemoptysis. Her RA treatment consisted of leflunomide, prednisone and folic acid. Her social history is pertinent for a history of smoking (20 pack-years). Urine analysis was with dysmorphic hematuria and proteinuria (spot protein/creatinine ratio 3.2gms). Serologic workup was unremarkable. Renal biopsy revealed nodular glomerulosclerosis with sparse crescents. Due to sparse crescents, hemoptysis, and AKI the patient was started on high dose steroids which exacerbated patient's nephrotic syndrome. Ultimately steroids were discontinued which lead to an improvement in proteinuria. Smoking cessation was encouraged.



Discussion: ING with crescents has not been described in the literature. In a case series reported by Markowitz et al, patients with ING had renal failure with a mean sCr of 2.4 mg/dL and proteinuria. The main clinical predictors of progression included lack of angiotensin II blockade and continued smoking.[1] In retrospect, it is likely the severity of her intra-glomerular pressures which lead to proteinuria was exacerbated with steroid treatment and resolved with discontinuation.

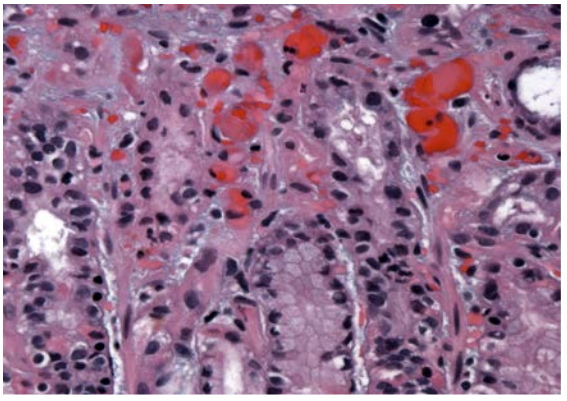
PUB408

Thrombotic Microangiopathy Secondary to Hepatocellular Carcinoma

Tahir Zaman,[1] Frederic Clayton,[2] Josephine Abraham.[1] *[1]Nephrology, Univ of Utah, Salt Lake City, UT; [2]Pathology, Univ of Utah, Salt Lake City, UT.*

Introduction: Thrombotic microangiopathy (TMA) is a microvascular occlusive disorder characterized by microangiopathic hemolytic anemia, thrombocytopenia and end organ damage. We report a case of malignancy associated TMA.

Case Description: 65-year-old female presented with diarrhea and was noted to be in acute renal failure with microangiopathic hemolytic anemia and thrombocytopenia. Therapeutic plasma exchange was discontinued after ADAMST 13 activity was normal. Patient underwent colonoscopy and EGD with evidence of microthrombi in bowel wall concerning for TMA.



Serologies were remarkable for negative APS, SLE, ANCA-vasculitis but Ca-125 was 753. Stool Shiga toxin was negative. Patient was treated for atypical hemolytic uremic syndrome (aHUS) with weekly eculizumab. Diagnostic laparoscopy on HD 24 with peritoneal washings were negative for malignancy. The patient died on hospital day 25 from septic shock secondary to bowel perforation. Autopsy revealed 2.5 x 2.0 x 2.0 cm lesion within the liver consistent with hepatocellular carcinoma (HCC).

Discussion: TMA occurring in older patients who fail to respond to TPE should increase suspicion of malignancy-associated TMA.[1] HCC is a rare but known cause of malignancy-associated TMA as noted in the literature. HCC-associated TMA is quite severe leading to rapid progression to a fatal outcome.[2] 1. George, J. N. Systemic malignancies as a cause of unexpected microangiopathic hemolytic anemia and thrombocytopenia. *Oncology* **25,** 908–14 (2011). 2. Seo, D. W. *et al.* Hepatocellular carcinoma associated hemolytic uremic syndrome unrelated to chemotherapy. *J. Korean Med. Sci.* **9,** 254–8 (1994).

Charcot Foot Syndrome in a Nondiabetic Hemodialysis Patient

Werner Kleophas,[1,2] Sebahat Sat,[1] Barbara Klein,[1] Andreas Westhoff,[1,2] Frank Dellanna,[1,2] Gerd R. Hetzel.[1,2] *[1]MVZ Davita Karlstrasse, Duesseldorf, Germany; [2]Heinrich-Heine Univ, Duesseldorf, Germany.*

Introduction: The prognosis is very poor for diabetic hemodialysis (HD) patients with foot lesions. Foot lesions are associated with risk of systemic inflammation and cardiovascular (CV) morbidity. Severe cases of diabetic foot with neuropathic arthropathy, microvascular changes from mediasclerosis, and alteration of foot architecture are known as Charcot Foot Syndrome (CFS). Since diabetic and nondiabetic HD patients may experience changes in calcium and phosphate metabolism and secondary hyperparathyroidism, the question arises whether CFS can occur in HD patients in the absence of diabetes.

Case Description: Presented is a decade-long case study of a male HD patient (DOB 1961) who was treated since Dec 1999 for biopsy-proven nephrotic syndrome due to glomerulosclerosis. The patient began thrice weekly HD in Sept 2005 without prior treatment for diabetes mellitus (A1C 4.9%). In Apr 2012 he presented with a painless inflammatory acute foot syndrome, then presented in Apr 2013 with a planar ulceration. After conservative wound management, prophylactic shoes were prescribed. In clinical examination he showed signs of chronic CFS and arthropathic changes in ossa metatarsalia 2 and 3 with osteolysis and luxation of tarsometatarsal joints. Lab results indicate secondary hyperparathyroidism: parathyroid hormone 465 pg/mL, phosphate 6 mg/dL, and calcium 2.2 mg/dL.

Discussion: We believe this is the first description of chronic CFS in a nondiabetic HD patient. Acute CFS diagnosis is important because its symptoms (red warm skin, foot edema) are similar to those of phlegmon and osteomyelitis, and thus may be considered a differential diagnosis. Further investigations are necessary to determine whether this is an authentic entity of a foot syndrome, and if it's associated with CV morbidity.

PUB410

Crescentic Glomerulonephritis (GN) in a Lupus Patient with Normal Serum Creatinine – A Treatment Challenge Venkata Buddharaju, Rishikesh Morey, Rudrick V. Ledesma, Savneek S. Chugh, Praveen N. Chander. *Nephrology, Westchester Medical Center, Elmsford, NY.*

Introduction: Crescentic GN is usually manifested by features of active glomerular disease in the urine and by progressive rapid loss of significant renal function. SLE can present as predominantly crescentic GN often as Class III or IV lupus nephritis (LN) usually resulting in rapid deterioration of renal function requiring RRT.

Case Description: 18 y/o female recently diagnosed with SLE, on Plaquenil presented to ER with nausea, vomiting and epigastric pain after consuming "tiny tea" and was found to have serum creatinine (SCr) 4.5 mg/DL, which further increased to 4.74 with 3+ protein (2.5g/day), 3+ blood and RBC casts on urinalysis. Other relevant lab data: ANA 1:600, negative dsDNA, positive RNP, anti-SM Ab and normal complements. She was initiated on IV fluids and SCr normalized within 2 days.Renal biopsy showed Pauci immune Crescentic GN, class IV-S (A/C) with minimal IF staining. The clinical course was complicated by seizures; the diagnostic considerations included lupus cerebritis vs. PRESS. She was put on valproate to be started on immunosuppression as outpatient. She was admitted a week later with acute liver failure due to valproate and Tylenol at which time she was pulsed with IV Solu-Medrol and discharged on oral steroids with a plan to start MMF after normalization of LFTs.

Discussion: Crescentic and focally necrotizing GN can be infrequently present in the spectrum of diffuse proliferative LN. Such cases are generally ANCA negative. Normalization of SCr after hydration in this case suggest pre renal as the likely etiology which poses a treatment dilemma for biopsy proven crescentic GN. While there isnot much literature available regarding the treatment of lupus with crescentic GN and normal SCr, a retrospective case series reported that even <50% crescents portend a significant renal risk despite clinically evident preserved renal function. We believe that intense immunosuppression should be used in patients with crescentic GN and preserved renal function, despite the absence of any controlled studies. Our patient was started on MMF and prednisone with improvement in proteinuria from 2.6 gm to 150 mg with normal SCr.

PUB411

Anti-Thymocyte Globulin Induced Non Cardiogenic Pulmonary Edema Jaya Kala, Amit Lahoti. *Nephrology, Univ of Texas MD Anderson Cancer Center, Houston, TX.*

Introduction: Anti-Thymocyte globulin (ATG) is used in treatment of hematologic malignancies and solid organ transplantation. Immediate local and systemic reactions are known. There has been only one reported case of non cardiogenic pulmonary edema (NCPE) caused by ATG.

Case Description: Our patient was a 59-year-old man with Marginal Zone Lymphoma which had progressed to diffuse large B cell lymphoma. Despite Hyper CVAD and Rituximab his disease continued to progress. He received Matched Unrelated Bone marrow transplantation after conditioning with ATG and rituximab. The next day he was admitted to the ICU with respiratory distress and bilateral lung infiltrates initially thought to be pulmonary edema. He was started on Lasix drip but did not improve. His CVP was 5, and his echocardiogram showed normal ejection fraction. Based on these findings he was diagnosed to have NCPE. Bronchoscopy revealed pulmonary hemorrhage. His condition worsened and he was intubated and started on Continuous Renal replacement therapy. He was given additional doses of steroids but without improvement. His died due to respiratory failure after two days of ICU stay.

Discussion: Non cardiogenic pulmonary edema is a clinical syndrome characterized by presence of severe hypoxemia, bilateral alveolar infiltrates on chest radiograph without evidence of left atrial hypertension, fluid overload or congestive heart failure. Drug related NCPE is usually diagnosed after other causes of pulmonary infiltrates such as gastric aspiration, sepsis and pneumonia are excluded. The presence of normal echocardiogram and pulmonary hemorrhage within a day of administration of ATG, pulmonary infiltrates which did not resolve after intense attempts of volume removal indicated that the patient had NCPE. ATG is known to cause acute respiratory distress syndrome, alveolar hemorrhage and rapidly progressive interstitial fibrosis likely secondary to Cytokine release syndrome. Providers need to be aware of such complications as even though rare these cause increased morbidity and mortality. It is beneficial to give ATG infusions slowly and accompanied by high dose systemic steroids.

PUB412

Hypomagnesemia After Treatment with Pertuzumab Lilian Saro-Nunez,[1] Tiffany A. Traina,[2] Karen A. Cadoo,[3] Teresa Gilewski,[2] Ilya Glezerman.[4] *[1]Nephrology, NYP-Weill Cornell Medical Center, New York, NY; [2]Breast Medicine Service, Memorial Sloan Kettering Cancer Center, New York, NY; [3]Gynecologic Oncology Service, Memorial Sloan Kettering Cancer Center, New York, NY; [4]Renal Service, Memorial Sloan Kettering Cancer Center, New York, NY.*

Introduction: Hypomagnesemia is a known side effect of epidermal growth factor receptor (EGFR) inhibitors such as cetuximab and panitumumab. Pertuzumab blocks HER (human epidermal growth factor receptor) 2 dimerization with HER3 and EGFR, and is used in HER2+ breast cancer. We present two cases of hypomagnesemia with pertuzumab use.

Case Description: Case 1 58 year-old woman with history of breast cancer treated with trastuzumab (T), docetaxel, pertuzumab (2 doses of 840mg and one dose of 420mg) and carboplatin (AUC6). Patient developed hypomagnesemia with serum magnesium (Mg^{2+}) 0.7 (1.7-2.6)mg/dl and symptomatic hypocalcemia of 5.9 (8.5-10.5)mg/dl. Since initiation of chemotherapy she experienced diarrhea controlled with loperamide. Fractional excretion of magnesium (FeMg) was 2%. Parathyroid hormone (PTH) was 309.2 (12-88)pg/ml. Pertuzumab and carboplatin were stopped. Mild hypomagnesemia persisted 6 months later.

Case 2 56 year-old woman with history of breast cancer on treatment with T, paclitaxel and pertuzumab (one dose of 840mg and 2 doses of 420mg) was admitted with Mg^{2+} of 0.3 (1.4-2.2) mEq/L and corrected calcium of 6.1mg/dl. She complained of chronic diarrhea which improved with loperamide and was receiving proton pump inhibitor (PPI). FeMg was 3%. PTH was 16.1 (12-88)pg/ml. PPI was stopped but patient received another dose of pertuzumab (840mg). She remained hypomagnesemic and required IV supplementation until her death from progression of disease 22 months later.

Discussion: Although there were other confounding factors that could have caused hypomagnesemia including diarrhea, PPI and carboplatin, hypocalcemia (a manifestation of hypomagnesemia) did not develop until patients were started on pertuzumab. Carboplatin has been associated with hypomagnesemia but not with the degree of hypomagnesemia seen in these two patients. We postulate that pertuzumab may interfere with reabsorption of Mg^{2+} similar to EGFR inhibitors.

PUB413

Acute Renal Infarction: Case Series Yelda Deligoz bildaci,[1] Rumeyza Kazancioglu.[2] *[1]Nephrology, Bezmialem Vakif Univ, Istanbul, Turkey; [2]Nephrology, Bezmialem Vakif Univ, Istanbul, Turkey.*

Introduction: Acute renal infarction (ARI) occurs from interruption of kidney's blood supply either partially or totally. Causes of renal infarction include; thromboembolism (usually from injured or replaced heart valves, congenital heart defects etc.) vasculitic disorders, trauma to the kidneys or hypercoagulable state. We present five cases of ARI with different etiologies.

Case Description: Description of Cases : Two female, three male, mean age 52 (range 26-72) patients presented to the emergency department between 2013 and 2015 in a university based hospital setting. Presenting complaint was severe flank pain lasting between 2 to 5 days for all of them. At initial examination all patients had costo-vertebral angle tenderness at the effected side. Contrast enhanced abdominal tomography was useful for showing renal artery occlusion and also renal infarction. Trans thoracic echocardiography were all normal and were not adequate in identifying patients having had heart defects, trans esophageal echocardiography was obviously superior in finding cases with possible paradoxical embolism. All patients were treated with enoxaprin therapy. During follow-up there was neither further complication nor kidney damage.

	Age	Gender	History of Hypertension	trans thoracic echocardiography	trans esophageal echocardiography	Initial creatine levels before treatment	Follow up creatine levels
CASE 1	26	FEMALE	NEGATIVE	NORMAL	PATENT DUCTUS ARTERIOSUS	0,8	0,7
CASE 2	72	MALE	POSITIVE	NORMAL	-	4,2	3,8
CASE 3	69	MALE	POSITIVE	NORMAL	-	0,8	0,8
CASE 4	38	MALE	NEGATIVE	NORMAL	-	0,8	0,9
CASE 5	56	FEMALE	POSITIVE	NORMAL	PATENT DUCTUS ARTERIOSUS	0,8	0,8

Discussion: ARI usually is a hidden disease, which can easily be missed without any spesific suspicion for patients presenting with flank pain. It should be kept in mind that there is no specific biochemical test for ARI and diagnosis process must involve evaluation of cardiac pathologies preferably with trans esophageal echocardiography.

PUB414

Disseminated Cryptococcal Infection in a 24-Year-Old Man with Primary Focal Segmental Glomerulosclerosis Judith J. Wilber,[1,2,3] Caitlin Dugdale,[1,2,3] George P. Bayliss.[1,2,3] *[1]Rhode Island Hospital, Providence, RI; [2]Miriam Hospital, Providence, RI; [3]Alpert Medical School, Providence, RI.*

Introduction: Focal segmental glomerulosclerosis (FSGS) is commonly treated with high doses of corticosteroids and calcineurin inhibitors to induce remission of proteinuria, however immunosuppression carries with it the risk of infection. We present here the case of a 24-year-old African American man following seven months of intermittent treatment for biopsy-proven FSGS with high-dose prednisone and cyclosporine.

Case Description: Our patient initially responded to prednisone 80 mg daily with proteinuria reduced to 37 mg/g from 3.5 g/g, but then suffered frequent hospitalizations for infection necessitating interruption of immunosuppression, now with decreased responsiveness to prednisone. Cyclosporine was added but interrupted after he developed skin findings concerning for necrotizing fasciitis. A surgical wound became infected, and he developed Clostridium difficile diarrhea. He was placed on ethacrynic acid and atovaquone because of a sulfa allergy. His albumin remained < 1.5 mg/dL. Renal function worsened, now with ascites requiring paracenteses and subsequently developed E coli peritonitis. He was admitted to our medical ICU with hypoxia seven months after initial presentation. Chest xray at this time demonstrated pulmonary edema versus multilobar pneumonia. White blood cell count was 18.5, and increased to 30.0 after beginning prednisone taper. Broad-spectrum antibiotics and hemodialysis were initiated with no improvement. Head CT after seizure demonstrated diffuse hemorrhaging. Fungal cultures were sent, and patient was started on empiric voriconazole. Cultures returned after he expired positive for Cryptococcus. Autopsy showed disseminated Cryptococcus with cause of death attributed to cryptococcal pneumonia.

Discussion: This case demonstrates the infectious risk of high dose immunosuppression in treating resistant focal segmental glomerulosclerosis and the need to balance efficacy of treatment against these risks.

PUB415

A Rare Case of Kidney Amyloidosis Caused by Heroin Abuse Ravina Patel, Nilson D. Feliz, Roberto L. Collazo-Maldonado. *Nephrology, Dallas Methodist Medical Center, Dallas, TX.*

Introduction: Secondary(AA)Amyloidosis nephropathy is a rare manifestation of IVDA.Is a condition characterized by deposition of insoluble fibrils in various organs; most commonly the liver and kidneys.Occurs as a result of chronic inflammatory states such as RA, IBD, chronic osteomyelitis,or familial Mediterranean fever.Kidney involvement in amyloidosis is a significant source of morbidity as it can progress to CKD.

Case Description: A 40 y/o AA man with no past medical history just 20 years of IV heroin abuse presented to the ED with the CC: Worsening lower extremity edema and a weight gained of 20 lbs. in the past few months.Patient denied any other medical problems or complains.On PE, afebrile, normotensive, with clear lungs, normal heart at auscultation and benign abdominal findings,but with 3+lower extremity edema.Multiple skin popping in upper and lower extremities with scaring,and no evidence of active infection.Creatinine 0.8 mg/dL on arrival.The UA showed,>600mg/dL of protein and no hematuria.A 24 hour urine collection showed 35 gm of proteinuria and serum albumin 2.1g/dL. Cholesterol 232mg/dL,LDL192 mg/dL and Trig.189mg/dL.LFT's were normal and the rest of serologic workup including HIV,Hep B and C were negative.A biopsy showed a nodular increase in mesangial matrix material that was congophilic and stained positive with both amyloid A and P, consistent with AA amyloidosis.The EM, showed the presence of nonbranching fibrils that measure 7 and 12 nm in size.The mainstay treatment for secondary renal amyloidosis consists of tackling the underlying cause.In this case of heroin induced amyloidosis, the patient was counseled extensively about heroin cessation.Per the literature, not many other treatment options exist. We started him on colchicine as there are studies indicating its efficacy on disrupting the amyloid fibrils and decreasing progression of disease.He was also started on anti-coagulation and diuretics, but we were unable to start him on ACEI's/ARB's due to low blood pressure.

Discussion: AA kidney amyloidosis is a rare manifestation of IVDA, especially after a prolonged exposure.We should always considered this diagnosis in chronic heroin users presenting with proteinuria.

PUB416

Addressing Fertility and Management of a Patient with PCOS and C1q Nephropathy Monica Sircar,[1] Ivy A. Rosales,[2] Rex Neal Smith,[2] A. Bernard Collins,[1] Robert B. Colvin,[2] Ravi I. Thadhani,[1] Andrew L. Lundquist.[1] *[1]Nephrology, MGH, Boston, MA; [2]Pathology, MGH, Boston, MA.*

Introduction: C1q nephropathy is a rare disease that can present in a variety of ways. We present the case of a 26 year-old female with PCOS and borderline diabetes who developed non-nephrotic-range proteinuria with preserved renal function who wished to become pregnant.

Case Description: Her serologic workup was unrevealing. She did not have any classical symptoms of SLE and her ANA was only mildly positive at 1:40. Biopsy of the kidney revealed predominant immunofluorescent staining for IgG and C1q with mesangial deposits of C1q. There was no clear evidence of focal segmental glomerulosclerosis to portend a worse prognosis. Her decision to pursue pregnancy prompted further inquiry into the effects of pregnancy on her renal disease.

Review of existing literature, limited as it may be, suggested that C1q autoimmunogenicity may be associated with normal placental growth and development in the context of hormonal changes.

Discussion: Therefore, interpretation of typical parameters, including urinary protein excretion alone, may not be sufficient in determining disease status. This case demonstrates the importance of renal biopsy in defining the underlying pathology in young women with evidence of glomerular disease who wish to become pregnant as it can help guide prognosis.

PUB417

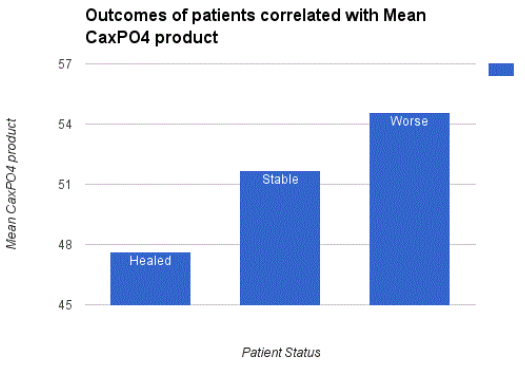
Outcomes of Calcific Uremic Arteriolopathy (CUA) Management: An Inner City Tertiary Center Experience Marwan M. Abu Minshar, Nanette S. Chua, Sahrish Ilyas, Najibah Rehman, Nashat Burhan Imran, Zeenat Yousuf Bhat, Yahya M. Osman Malik. *Nephrology, Wayne State Univ S.O.M, Detroit, MI.*

Introduction: CUA is a rare, necrotizing skin condition caused by medial calcification of sub/cutaneous arterioles leading to tissue ischemia and eventual necrosis. It predominantly occurs in patients with chronic kidney disease, associated with high morbidity, mortality and variable outcomes-- posing a difficulty in management.

Case Description: We conducted a retrospective chart review from 2010-15. 17 patients were diagnosed and treated for CUA in a tertiary university center. Diagnostic methods and multi-disciplinary treatment included parathyroidectomy, medical management of bone mineral disease, standard wound care, and sodium thiosulfate. We classified outcomes as No Improvement, Stable, and Improvement of Lesions related to the mean Calcium-Phosphate product (CaXPhos). Table 1 shows patient characteristics.

Characteristics	Subjects N=17	Range (min-max)		
Gender			**Comorbidities**	
Female	13(76.4%)	—	**CAD**	7 (41.17%)
Male	4 (23.5%)	—	**CVA**	3 (17.64%)
Ethnicity		—	**PAD**	8(47.05%)
African American	16 (94.1%)	—	**DM**	13(76.4%)
White	1 (5.9%)	—	**HTN**	17 (100%)
Mean Age	56.68	28-81	**DVT/PE**	7 (41.2%)
Mean PTH	1244.68	35-9262	**ESRD**	16(94.1%)
Mean Calcium	8.95	7.6-10.3	**HD**	15(93.8%)
Mean PO4	5.75	3.5-8.7	**PD**	1(6.2%)
CaXPO4 product	51.3	29.1-78.2	**Renal Transplant**	1(5.9%)
Mean Ferritin	829.7	98-1640	**Biopsy Proven Dx**	10(58.8%)
Mean Transferrin Sat%	29%	7-51.6	**Outcome**	
Cincalcet use	10(58.8%)	—	**Healing**	5(29.4%)
Parathyroidectomy	1 (5.8%)	—	**Stable**	4(23.5%)
Wound Care Consult	14(82.4%)	—	**Worsening**	8(47.1%)
Sodium thiosulfate	17(100%)	—		

Figure 1 shows mean CaXPhos product was higher in patients with no response vs. those that remained stable or improved.



Discussion: CUA management still remains multi-faceted, with unpredictable responses, and no definitive cure.

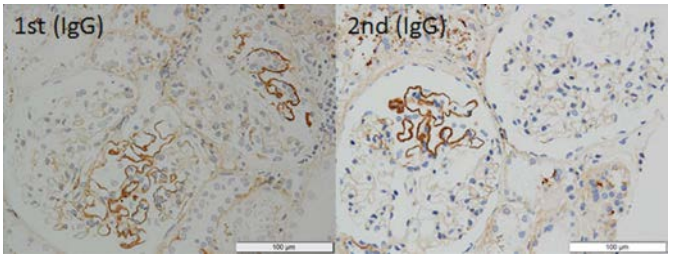
PUB418

A Case of Adult-Onset Segmental Membranous Glomerulonephritis

Mao Watanabe, Toshiyuki Imasawa, Takehiko Kawaguchi, Takafumi Yamakawa, Maiko Nagata, Moritoshi Kadomura, Hiroshi Kitamura. *Internal Medicine, National Hospital Organization Chiba East Hospital, Chiba, Japan.*

Introduction: Generally, adult-onset membranous glomerulonephritis (MN) has diffuse and global glomerular changes. We experienced a rare case of segmental MN (SMN).

Case Description: A 66 years old Japanese male was firstly noted proteinuria in an annual health check-up. Serum creatinine was 0.76 mg/dl, urine protein excretion was 2.1 g/gCr, and 10-19 red blood cells/high-power field were observed in the urine sediment. A percutaneous renal biopsy revealed segmental spike formation on the glomerular basement membrane (GBM) and segmental subepithelial deposits in all glomeruli. Granular deposits of IgG, IgM, IgA, C3, C1q were segmentally positive with granular patterns at the same regions. In electron microscopy, electron dense deposits were also found segmentally. The glomerular tufts with deposits included inflammatory cells (mainly macrophages). Any autoimmune disease, malignancies, and infections were detected by further examinations. Because urine protein decreased less than 1g/gCr during the hospitalization, only temocapril hydrochloride has been prescribed from 67 years old. He has never taken immunosuppressive drugs. In 68 years old, because urine protein increased to 3g/gCr, the second renal biopsy was performed. Similarly to the first biopsy, segmental spike formation on GBM and segmental staining of immunoglobulins and complements were observed. The percentage of glomeruli with subepithelial deposits decreased to 60% (6/10) compared with 100% (20/20) at the first biopsy.



Discussion: Adult-onset SMN was rarely reported in spite of 30% of MN cases in childhood. Here, we firstly reported the sequential pathological changes of adult-onset SMN without any immunosuppressive therapy. We will also discuss about the pathogenesis about SMN.

PUB419

Hyporeninemic Hypaldosteronism with Hypokalemia: A Rare Association

Julia Brown, Shankho Shuvro Ganguli, David J. Leehey, Kavitha Vellanki. *Dept of Nephrology, Loyola Univ Medical Center, Maywood, IL.*

Introduction: Hyporeninemic hypoaldosteronism is characterized by diminished renin and aldosterone secretion, with hyperkalemia and mild hyperchloremic metabolic acidosis being the hallmark clinical manifestations. It is often seen in diabetic patients with mild to moderate renal insufficiency or in patients taking calcineurin inhibitors. Here, we describe a rare case of hyporeninemic hypoaldosteronism in the setting of severe hypokalemia.

Case Description: A 19 year old male with a liver transplant due to cryptogenic fulminant liver failure presented to our institute with nausea, emesis, and fevers. He was 3 months post-transplant and taking tacrolimus, mycophenolate, and prednisone for immunosuppression. During the hospital stay, he developed hyponatremia, hypokalemia, and severe orthostatic hypotension (table 1). While hyponatremia improved with hydration and hypokalemia with aggressive potassium supplementation, orthostatic hypotension persisted despite volume repletion and high dose corticosteroids. Further work up revealed a normal morning cortisol level of 13.8 ug/dl but very low renin and aldosterone levels (table 1). He was started on fludrocortisone 0.1 mg daily, which was subsequently increased to 0.1 mg twice daily. His serum potassium levels improved and remained stable without potassium supplementation. The etiology of his hyporeninemic hypoaldosteronism was thought to be calcineurin inhibitor use, with hypokalemia caused by persistent nausea, emesis, and poor oral intake.

Discussion: In conclusion, hypokalemia should not exclude work up for hyporeninemic hypoaldosteronism in the appropriate clinical setting.

Time	Admission	Day 9	Day 17	Day 23

PUB420

A Case of Hydronephrosis due to Bilateral Retroperitoneal Fibrosis

Zachary Freestone, Akram M. Shaaban, Josephine Abraham. *Nephrology, Univ of Utah, Salt Lake City, UT.*

Introduction: Retroperitoneal fibrosis is characterized by inflammatory and fibrous retroperitoneal tissue. It is believed to be due to an exaggerated inflammatory reaction to aortic atherosclerosis resulting from an immunologic trigger. Retroperitoneal fibrosis can be classified as primary or secondary. Secondary causes include medications, malignancy, infection, radiotherapy, and trauma. Patients diagnosed with retroperitoneal fibrosis should undergo thorough evaluation for infectious causes and malignancy.

Case Description: A 55 year old male presented to the clinic with a chief complaint of left side flank and groin pain. He had additional symptoms of night sweats, left leg edema, and weight loss. He was referred to our clinic after initially presenting to the emergency department and receiving a CT scan of the abdomen identifying left side hydronephrosis and a retroperitoneal mass. His past medical history included melanoma 4 years prior and cutaneous follicular lymphoma of the right mandible one year prior. Repeat ultrasound prior to initiation of therapy showed new right sided hydronephrosis. The patient was started on monotherapy with prednisone 1 mg/kg/day. Imaging after initiation of therapy showed improvement in fibrosis with resolution of ureteral obstruction. The patient's serum creatinine improved from 1.93 to 1.2 after initiation of therapy. No secondary causes of retroperitoneal fibrosis was identified.

Discussion: Retroperitoneal fibrosis can present as obstruction of the ureters. It is often idiopathic, but secondary causes should be ruled out. Secondary causes include malignancy, infection, and medications. Recommended therapy includes decompression of obstruction if renal function is compromised. If the cause of the disease is idiopathic, then immunosuppressive therapy is recommended. If the disease is due to secondary causes, the underlying cause should be immediately addressed.

PUB421

BK Virus-Associated Uropathy: A Culprit Mimicking Mechanical Post-Renal Obstruction in Early Post-Kidney Transplantation

Ekamol Tantisattamo, Aneesha A. Shetty, Bing Ho, Mohammed Javeed Ansari. *Nephrology and Hypertension, Northwestern Univ.*

Introduction: BK virus has a predilection towards infecting the uroepithelial cells and is a known but rare cause of ureteral obstruction of kidney allografts.

Case Description: A 26-year-old woman with ESRD underwent renal transplantation. Maintenance immunosuppression included tacrolimus(FK) and mycophenolic acid(MPA). FK and MPA levels were 8-16ng/mL and 2-5mg/L, respectively. Three months posttransplant,

she developed new onset BK viruria. One month later, she had a new onset BK viremia and worsening BK viruria up to 3 million and 67.5 billion copies/mL, respectively(Figure1). Concurrently, she had AKI with a serum creatinine(SCr) of 4mg/dL from a baseline of 1.4mg/dL. Ultrasound showed moderate hydronephrosis(Figure 2). Allograft biopsy revealed acute tubular injury with negative SV40. A percutaneous nephrostomy (PCN) tube was placed and antegrade nephrostogram showed high-grade ureteral stricture(Figure3). A ureteral stent was placed. FK and MPA target levels were decreased to 5-7ng/mL and 2-4mg/L, respectively. One week later, a repeat nephrostogram showed no obstruction and PCN tube was removed. SCr trended down to 1.2mg/dL. Ureteral stent was removed 6 weeks later. BK viremia became undetectable 6 months posttransplant with low-level BK viruria. The high-level BK viremia but negative SV40 in the kidney biopsy in the context of ureteric obstruction suggested that there was extensive BK replication within the urothelium leading to ureteral stricture and mechanical obstruction. The obstruction improved with resolution of BK viremia following reduction in immunosuppression.

Discussion: Medical management of BK virus with lowering immunosuppression can be an effective treatment to reverse ureteral obstruction due to BK virus infection, while surgical intervention is used to temporarily relieve obstruction.

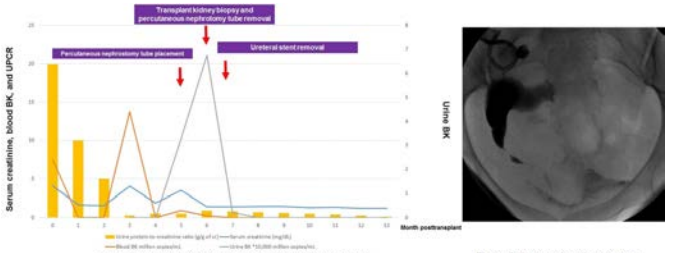

Figure 1: *Clinical course after living-related renal transplantation*

Figure 3: Antegrad nephrostogram demonstrated high-grade mid and distal ureteral stricture.

Figure 2: Transplant renal ultrasound (longitudinal) showed markedly dilated collecting system.

PUB422

Impact of Cannulation Technique on Access-Related Complications in Hemodialysis Patients Shriharsha Kallahalli Jayaramu, Abhilash Koratala, Amir Kazory. *UFL; UFL; Div of Nephrology, Univ of Florida.*

Introduction: There is growing interest in home hemodialysis therapy leading to increased involvement of patients in their own care. Buttonhole cannulation technique (BHCT) is considered a practical option for self-cannulating patients due to perceived lower incidence of access-related complications such as pain. The aim of this study is to provide a reappraisal of the current evidence on the complications of BHCT and conventional rope-ladder cannulation technique (RLCT) in hemodialysis patients.

Case Description: Articles cited in PubMed database from 2000 to 2015 using key words "hemodialysis", "cannulation", and "buttonhole" were searched. Original articles evaluating hemodialysis access cannulation techniques were reviewed; randomized controlled trials (RCT) were selected.Relevant data including primary outcomes and access-related complications (i.e. pain, infection, bleeding, and aneurysm) were extracted and compared.

A total of 70 articles were found, of which 6 RCT were reviewed and 5 were included in this study (1 duplication). There were a total of 472 patients (BHCT 227 and RLCT 245) with follow up periods ranging from 2 to 12 months. Two studies reported more pain with RLCT while it was similar in 2 studies and one found more pain with BHCT. Importantly, there was a significant tendency for infection with BHCT compared to RLCT in all 4 studies that could evaluate this complication and included 73% of the patients; the overall rate of infection being too low in one trial to be conclusive. Bleeding complications were similar in 4 studies while 1 found higher risk with BHCT. Only 2 studies reported higher tendency for increase in the size of the access in the RLCT group while 3 did not evaluate this complication.

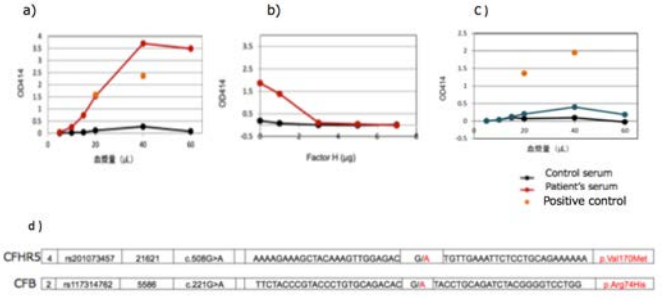
Discussion: BHCT is associated with only a modest favorable impact on access-related pain in hemodialysis patients while it portends a significant increased risk of infection. There is inconclusive data regarding the impact of cannulation technique on bleeding complications and aneurysmal changes. Based on the findings of the currently available RCT, routine use of BHCT cannot be recommended for hemodialysis patients.

PUB423

A Case of Lupus Nephritis Accompanied with Long-Term Thrombotic Microangiopathy Kazuhito Fukuoka,[1] Shinya Kaname,[1] Yoko Yoshida,[2] Hideki Kato,[2] Masaomi Nangaku,[2] Yoshihiro Arimura.[1] *[1]1st Dept of Internal Medicine, Div of Nephrology and Collagen Disease, Kyorin Univ School of Medicine, Mitaka, Tokyo, Japan; [2]Dept of Nephrology and Endocrinology, The Univ of Tokyo School of Medicine, Bunkyo-ku, Tokyo, Japan.*

Introduction: Although TMA is sometimes complicated in collagen disease, the features and its cause are still unclear.

A 39-year-old woman with a history of lupus nephritis (class V) for 19 years was admitted to our hospital due to complicated microangiopathic hemolytic anemia (MHA). Coombs test and anti-phospholipid antibodies were both negative. Considering that SLE played some roles, we reinforced immunosuppressive treatment and plasma exchange, which was only partially effective. MHA fluctuated, and seven years later renal function began to decline gradually, with an exacerbation of MHA. TMA was suspected, but ADAMTS13 activity showed within normal ranges without anti-ADAMTS13 antibody, thus TTP was neglected. Serum C3 levels proved low, thus we considered the possible involvement of complement activation, and performed hemolysis test for sheep RBCs using the patient's plasma



(a). The results showed that hemolysis was observed with recovery by adding complement factor H, suggesting that complement system was activated(b). Based on these results, she was diagnosed as atypical HUS. Despite intensive treatment, she finally progressed to maintenance HD, but the findings of TMA were gradually improved. Two months later, we examined the hemolysis test again, showing the negative results. Sequence analysis of the aHUS-related genes revealed two SNPs, none of which have been reported before.

Discussion: Our case report shows that a SLE patient can complicate TMA caused by complement-mediated HUS, which may be reversed during the treatment course, suggesting the possible involvement of genetic predisposition and some triggering factors/conditions.

PUB424

Glomerulonephritis Crescentic Pauci-Immune ANCA Related IgA – A Case Report Maria C. Piraciaba, Precil Diego Miranda de Menezes Neves, Cristiane B. Dias, Luis Yu, Leonardo Abreu Testagrossa, Denise M. Malheiros, Viktoria Woronik, Irene L. Noronha, Lectícia Jorge. *Univ de São Paulo.*

Introduction: The pauci-immune crescentic glomerulonephritis (PICG) are mostly related to antineutrophil cytoplasmic antibodies (ANCA). IgG is detected in 80-90% of cases. PICG reports related to ANCA IgA are rare due to low suspicion and research of IgA ANCA. We report a case of PICG ANCA related IgA.

Case Description: Pacient female with 83 years, asthenia and abdominal pain for 4 months and 10 days ago emergence of purpuric lesions in upper and lower limbs and trunk. Biopsy of purpuric lesion showed leukocytoclastic vasculitis with granular IgA deposits in the vessels of the papillary dermis. After diagnosis of Henoch-Schonlein, prescribed treatment with prednisone 1 mg / kg for two weeks, with drug weaning. The skin lesions disappeared, but the patient evolves with important asthenia. Renal biopsy, 15 glomeruli, 7 completely sclerotic, 3 with increasing cell and 3 with increasing focal fibroblast. Positive immunofluorescence for Fibrinogen + 2 / + 3 in the growing, being the framework compatible with glomerulonephritis crescentic pauci-immune, mixed form. By previous cutaneous involvement with IgA deposits, requested assessment of ANCA IgA by immunofluorescence. As the result was positive, the patient was treated with methylprednisolone and mycophenolate sódico, with recovery of renal function.

Discussion: The ANCA IgA evaluation should be considered in cases where there PICG increased serum IgA levels.

PUB425

Acute Interstitial Nephritis Associated with Probiotic Use Sandar Win, Gaurang P. Mavani, Joshua A. Schwimmer. *Div of Nephrology, Lenox Hill Hospital of the North Shore-LIJ Health System, New York, NY.*

Introduction: Acute interstitial nephritis (AIN) is associated with a variety of etiologies, including infections, autoimmune conditions, and medications. Probiotics are over-the-counter microorganisms used for their potential health benefits, and studies show probiotics may have immunostimulatory and immunomodulatory effects. We report the first potential case of AIN associated with the use of probiotics.

Case Description: A healthy 44-year-old man was found to have a stable baseline Cr of 1.16 mg/dL with a measured CrCl in the normal range. 42 d later, to treat infrequent loose bowel movements (2x/wk), he consumed a probiotic regimen of 10 billion cells of Lactobacillus GG bid for 14 d. There was no diarrhea, fevers, rash, blood in the stool, or exposure to NSAIDs, antibiotics, herbs, or other medications. 11 d after probiotics use, during a routine physical, he was found to have an increase in his Cr to 1.66 mg/dL (an increase of .5 mg/dL in 52 d). There was no proteinuria or hematuria, and an ANA was negative. A renal sonogram revealed echogenic, normal-sized kidneys. His Cr remained 1.4-1.6 mg/dL and did not return to baseline. 135 d after exposure to probiotics, a renal biopsy was performed. The biopsy revealed patchy tubular atrophy and interstitial fibrosis affecting 10% of the cortical area with a few mononuclear inflammatory cells and focal mild lymphocytic tubulitis, consistent with resolving AIN.

Discussion: In this case, the temporal association between the use of probiotics with kidney injury and the absence of other causes of AIN implicates the probiotic Lactobacillus GG as the etiologic agent. The mechanisms by which probiotics could potentially cause AIN include manipulation of intestinal microbial communities, immunomodulation, alteration of

responsiveness of intestinal epithelial and immune cells, and altering the immunogenicity of degraded enteric antigens. Given the frequent over-the-counter use of probiotics, multiple potential coexisting etiologies for AIN, the often indolent nature of this disease, the rarity of this association, and the need for a renal biopsy to establish the diagnosis, the association between probiotics and AIN may be under-recognized.

PUB426

Decision-Making for the Critically Ill Un-Befriended Patient Aprajita Mattoo, Jennifer S. Scherer. *Nephrology, NYU School of Medicine, New York, NY.*

Introduction: The "un-befriended" patient is one that lacks decision-making capacity & a surrogate decision-maker (SDM). Nephrologists encounter un-befriended patients often, yet limited literature exists to guide decision-making for these vulnerable patients. This case describes an organized approach to caring for a critically ill un-befriended patient.

Case Description: Mr. S was a 74 year old wheelchair bound nursing home (NH) resident who underwent an urgent right hemicolectomy for a perforated colon. His post-operative course was complicated by septic shock & multi-organ failure including AKI due to ATN. During this time his serum Cr increased from 0.8 to 3.6 mg/dl, with a urine output of <50cc/day. Mr. S was obtunded & had diffuse anasarca. He lacked advance directives & any SDM. The primary service believed that dialysis (HD) should be withheld given his overall poor prognosis. The consulting renal service utilized the four-topic approach to ethical decision-making to guide their recommendations. An estranged sister was asked to partake in an inter-disciplinary team (IDT) family meeting with renal, palliative care, bioethics, & the primary service to explore Mr. S's values. It was established that Mr. S cherished his life in the NH & would have appreciated time there even if on HD. Given this information, the IDT decided that a time-limited trial of HD would be reasonable. Before HD was needed however, Mr. S decompensated due to fungemia. The IDT agreed that death was imminent, even with HD. Under provisions of the NY State Family Health Care Decisions Act (FHCDA), it was determined to be ethically appropriate to withhold HD & transition Mr. S to comfort care.

Discussion: Utilizing the four-topic approach to decision-making, established legal policies, & an IDT, nephrologists can manage un-befriended patients within an organized, legally sound, & ethically sensitive framework.

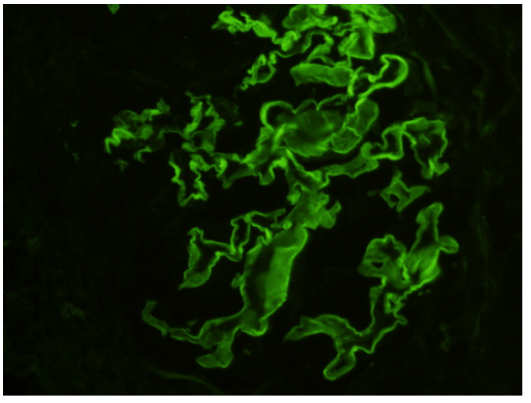
MEDICAL INDICATIONS *Beneficence and Non-maleficence*	PATIENT'S PREFERENCES *Respect for Patient Autonomy*
Medical Problems: Acute renal failure due to septic shock with resolved surgical and infectious complications. **Prognosis:** Uncertain, but likely weeks to months. Patient's AKI is acute and potentially reversible. He would likely tolerate HD. However, given his frail state and co-morbid medical conditions (HTN, wheelchair bound, recent emergent surgery) his long term prognosis is likely limited. **Goal of Treatment:** Life extension (continued dialysis so that he may return to his NH). Conflict of quantity versus quality given the high likelihood of complications.	**Does The Patient Have Capacity?:** The patient is without capacity. **If Incapacitated, Who is the Appropriate Surrogate?:** The patient's next of kin is an estranged sister who is unwilling to act as a SDM. **Has the Patient Expressed Prior Preference?:** The patient is without advanced directives.
QUALITY OF LIFE *Beneficence, Non-maleficence, and Respect for Patient Autonomy*	CONTEXTUAL FEATURES *Loyalty and Fairness*
What Are The Prospects W/WO Treatment For The Patient Returning To A Normal Life?: Patient has a potentially reversible kidney injury and may be able to return to NH stable on dialysis for the remainder of his lifespan. **Is The Patient's Present Condition Such That His Continued Life May Be Judged As Undesirable?** Patient has limited mobility at baseline. Patient had expressed that he loved his NH at his current QOL. This implied he would be happy there, even on HD. **Is There A Potential For Provider Bias About His Quality Of Life?** The SICU team was very worried about the possibility of chronic critical illness, complications, and a life marked by several hospitalizations.	**Are There Religious Or Cultural Preferences?:** Patient is not religious. No cultural preferences were highlighted by his sister. **How Does The Law Effect Treatment Decisions?:** The NY FHCDA provides the following guidance: -If the patient has no surrogate, then the hospital must identify, to the best extent possible, the patient's wishes and preferences for health care decisions. -In an unbefriended patient, a decision to withhold or withdraw life sustaining treatment can be made if the patient is imminantly dying even if treatment is provided, and the provision of the treatment would violate accepted medical standards. https://www.nysba.org/FHCDA/

PUB427

Persistent Kidney and Alveolar Damage in Patients with Goodpasture's Disease and Negative Anti-GBM Antibodies Giovanna Y. Arteaga Muller,[1] Lilia Maria Rizo Topete,[1] Elisa Maria Guerrero Gonzalez,[1] Concepcion Sanchez Martinez,[1] Jesus Cruz Valdez,[1] Gabriela Alarcón-Galván.[2] *[1]Nephrology, Univ Hospital José E. González UANL, Monterrey, Mexico; [2]Anatomic Pathology, Univ Hospital José E. González UANL, Monterrey, Mexico.*

Introduction: Goodpasture's disease is characterized by the presence of basement membrane antibodies which act against type 4 collagen in the glomerular basement membrane (GBM) and alveoli, it represents 20% of all crescentic glomerulonephritis.

Case Description: 21 year old woman, with anemic syndrome presenting Hb 4.33g/dl, Cr 0.8mg/dl, receiving a red cell transfusion. Is readmitted 15 days later Hb 2.7g/dl and Cr 1.9 mg/dl, whereby three globular packages were transfused and she was referred to our hospital. On admission, the patient was hypertension, lower limb edema and gross hematuria, Hb 11g/dl, Cr 1.7mg/dl, negative ANA's and ANCA'S and positive anti-GBM antibodies. Renal biopsy showed crescentic glomerulonephritis and linear staining deposits of IgG in GBM (4+).



Direct immunoflourescence technique (400X). Linear glomerular basement membrane staining for IgG.

Immunosuppresive therapy begins with methylprednisolone and CYCLOPS protocol.Later hemoptysis which improves with plamasferesis, negative control anti-GBM antibodies. After presented sudden hypoxemia, bronchoscopy with abundant hemosiderin-laden macrophages, whereby plasmapheresis is performed again together with methylprednisolone, cyclophosphamide and rituximab. Currently the patient is in chronic hemodialysis, with negative anti-GBM antibodies.

Discussion: In patients with positive anti-GBM antibodies renal involvement may occur alone or associated with pulmonary hemorrhage, our patient despite having negative anti-GBM antibodies presented pulmonary hemorrhage. The literature recommends confirm the sustained absence of anti-GBM antibodies and signs of recurrence every 6 months.

PUB428

Gitelman Syndrome: Use of Dual Potassium-Sparing Agents in Refractory Hypokalemia Maria Bernadette Yballe, Sandeep Aggarwal. *Div of Nephrology, Drexel Univ, Philadelphia, PA.*

Introduction: Hypokalemia is one of the most frequently encountered electrolyte disturbances. Chronic hypokalemia with hypomagnesemia should prompt further investigation to include rare genetic disorders such as Gitelman syndrome. Despite the appropriate diagnosis, treatment can be challenging.

Case Description: We present a case of a 49 year-old non-hypertensive Caucasian female who presented to our outpatient clinic for an evaluation of her polyuria, chronic hypokalemia and hypomagnesemia. Her polyuria started in the first trimester of her first pregnancy in her 20s. She has one sibling with similar complaints, sparing her parents and her daughter. She complained of paresthesia and lower extremity weakness. She reports no diuretic use, OTC weight loss regimen, and no diarrhea. She has been on potassium and magnesium supplements with spironolactone without a definitive diagnosis. Despite these interventions, electrolytes remained abnormal with a potassium of 2.8, magnesium of <1.0, and a serum creatinine of 0.5 mg/dL with a renin activity of 1.78 ng/dL and aldosterone level of 36 ng/dL (ARR 20.2). A 24-hour urine study revealed a low urine calcium of <5.0 mg/day consistent with Gitelman syndrome. Genetic testing revealed two distinct heterozygous missense autosomal recessive mutations of the SLC12A3 gene from Athena Diagnostics: c. 1315G>A; p.Gly439Ser and c. 2221G; p.Gly741Arg. She was continued on spironolactone along with potassium and magnesium supplements. Despite supplementation, she often required hospital visits which prompted magnesium and potassium infusions. Addition of amiloride improved her electrolyte levels, decreasing the need for hospitalizations and supplementations.

Discussion: Gitelman syndrome occurs in only ~1% of the Caucasian population which presents as chronic, sometimes severe and symptomatic hypokalemia, hypomagnesemia, hypocalciuria, and normotensive aldosteronism. The existence of 2 unique recessive alleles inherited by two siblings makes this case even more of a rarity. Our case also demonstrates the effective addition of a second potassium-sparing agent such as amiloride in ameliorating the need for more supplementation.

PUB429

Cerebral Ethylene Glycol Toxicity Despite Prompt Renal Replacement Therapy Maria Bernadette Yballe, Sandeep Aggarwal. *Div of Nephrology, Drexel Univ, Philadelphia, PA.*

Introduction: Acute cerebral edema is a rare consequence of ethylene glycol toxicity. Despite prompt initiation of therapy with fomepizole and renal replacement therapy, rare case reports of central hypodensities on CT imaging with neurologic abnormalities have been reported.

Case Description: We present a case of a 38 year-old female with PMH of HTN and anxiety who was brought in for agitation. One hour later, the patient became obtunded with significant respiratory distress requiring intubation. Home medications included bupropion. It was unclear if she ingested any toxins but the patient did have a history of marijuana use. On physical examination, the patient was hypertensive 210/114 mm Hg with reactive pupils. She was found to have high anion gap metabolic acidosis with a pH of 6.808, a serum bicarbonate of 4, an osmolal gap of 68, and a lactic acid of 5.6. Levels of ethanol, acetaminophen, phenobarbital, salicylate, and valproic acid levels were undetectable while urine drug screen was only positive for THC. Head CT did not reveal any acute

pathology. Urine microscopy revealed multiple ovoid colorless crystals in rosette formation consistent with monohydrate calcium oxalate crystals. Fomepizole was immediately started and intermittent dialysis initiated promptly within 10 hours of ingestion. However, due to hemodynamic instability, RRT had to be converted to a continuous veno-venous hemodialysis. After 2 days, patient then experienced an acute hypertensive episode with a BP of 27/120 mm Hg from a radial arterial line with pinpoint pupils and a repeat head CT revealing cerebral hypodensities in the basal ganglia, thalami, and brainstem along with transtentorial and tonsillar herniation. On day 5, patient met criteria for brain death and was assessed for organ donation.

Discussion: Despite prompt initiation of dialysis, rare case reports of acute cerebral edema from ethylene glycol toxicity have been reported. It is unknown whether these abnormalities are due to direct cellular toxicity or deposition of crystals in the cerebral vasculature causing ischemia and subsequent edema and inflammation. Our case demonstrates a rare neurologic sequela of ethylene glycol toxicity despite appropriate and prompt treatment.

PUB430

Encapsulating Peritoneal Sclerosis – Case Reports André Luiz De Andrade Araújo, Maria Alina G.M. Cavalcante, Amadeu Marinho, Teg Marcos Veiga, Luis H.B.C. Sette, Lucila Maria Valente. *Nephrology, Univ Federal de Pernambuco, Recife, Pernambuco, Brazil.*

Introduction: Encapsulating Peritoneal Sclerosis (EPS) is a rare but serious and potencially lethal complication in peritoneal dialysis (PD), first described in 1980. Intestinal obstruction, serious malnutrition and sepsis are the causes of death. This uncommom condition is the result of chronic abdominal inflammation of multifactorial origin. High risk patients include PD for more than 8 years and with frequent peritonitis (two-hits theory). The exact incidence is unknown.

Case Description: We described outcomes of 6 cases followed in a referral service of PD between 2010 and 2015.

Case	Gender/ Age (years)	CKD ethiology	Time on PD (years)	EPS related infectious agent	Previous Peritonitis (number)	Clinical Features	Radiologic Finds	Peritoneal Biopsy	Outcome
1	F / 47	SAH	8	*Candida sp / Staphylococcus aureus*	6	Acute abdominal obstruction + Bloody effluent	Loculated ascites + Peritoneal thickening and calcifications	Chronic peritonitis + Peritoneal thickening + Fibrin depositions	HD since 2010
2	F / 47	SAH	4	*Pseudomonas aeruginosa*	3	Partial bowel obstruction + Bloody effluent	Loculated ascites + bowel thickening	--	HD at 08 months
3	F / 18	PIGN	10	*Staphylococcus coagulase negative*	5	Partial bowel obstruction + pain	Moderate ascites + Peritoneal/Bowel calcification.	--	HD since 2013
4	M / 68	T2DM	2,5	*Escherichia coli / Klebsiella oxycata.*	2	Partial bowel obstruction + pain	High volume loculated ascites + bowel tethering	--	HD since 2012
5	F / 39	SLE	8	*Enterococcus sp*	1	Bowel obstruction + Severe malnutrition + Chronic abdominal pain + Bloody effluent	Peritoneal calcification + bowel distention + high volume ascites	--	Death for sepsis after 8 months
6	M / 53	T2DM	2,5	*Streptococcus viridans*	2	Abdominal distension + pain	High volume unique peritoneal collection + intestinal coccon	--	HD since 2014

SAH: Sistemic Arterial Hypertension; SLE: Sistemic Lupus Eritematous; T2DM: Type 2 Diabetes Mellitus; PIGN: Post Infectious Glomerulonephritis;CKD: Chronic Kidney Disease.

Discussion: EPS is a severe event related a long term on peritoneal dialysis or severe cases of peritonitis.

PUB431

AM Tolvaptan to Avert Hyponatremic Seizures in a Patient with Primary Polydipsia and New Mildly Impaired Free Water Excretion Amit N. Shah, Adam G. Winkler, Claude Bassil, Bassem H. Rouphael, Jacques A. Durr. *Div of Nephrology, Univ of South Florida, Tampa, FL.*

Introduction: A former pilot with a history of primary polydipsia PP (past urines >6 l/day) complained of confusion. Plasma (P_{Na}) and urine sodium were 123 and 37 mEq/l, and plasma (P_{osm}) and urine osmolalities, 251 and 207 mOsmol/kg H_2O . With cessation of Prozac and advised fluid restriction (FR) P_{Na} corrected. Interim P_{osm} was 286 mOsmol/kg and urine SG 1.005. Following multiple surgeries (decompressive laparotomy, subtotal colectomy, ileostomy, feeding gastrostomy, for compartment syndrome/pancreatitis), she had a first hyponatremic seizure (HS). No cause for impaired free water excretion (iFWE) was found. Her PP made FR difficult, as she was thirsty at P_{Na} <125 mEq/l, and caused repeat HSs.

Case Description: After her 4th seizure, we replaced FR and salt tablets with AM tolvaptan. This normalized PNa, abolished her recurrent HSs, and was tailored to her new dreadful PP-SIADH combination.

Indeed, since thirst is constant in DI but only diurnal in PP, the AM tolvaptan-induced daytime DI allowed her to quench her thirst without fear of HSs, since iFWE recurred only by hs, when the drug effect wore off, and her PP abided. She was reluctant giving up this diurnal/nocturnal PP-DI/SIADH, for fear of seizures.

Discussion: Given the high capacity for FWE, a syndrome of inappropriate antidiuresis (SIAD) or impaired diuresis-aquaresis (SIDA), due or not to ADH (SIAD/H or SIDA/H) must coexist in PP, for HS to occur; conversely some PP or other source of free H_2O must exist in the 'SIAD/H – SIDA/H' spectrum of iFWE to cause HS, since FR alone increases the low P_{Na}, and prevents HS during depot ADH in man, or chronic dDAVP infusion in rats. This is the first report of successful compassionate off label use of AM tolvaptan, instead of FR, to prevent HS in a patient where PP is the culprit. However FR instead of vaptans is the first line treatment of low P_{Na} in SIADH, yet here ADH is the culprit. The fact that PP and SIAD/H (or iFWE state) must coexist to cause HS, and that ADH, as assessed by sensitive assays is rarely totally suppressed, resolves this paradox.

PUB432

Atypical Presentation of Calcium Oxalate Nephropathy Young-Soo Song,[1] Joel M. Henderson,[2] David J. Salant,[1] Sandeep Ghai.[1] *[1]Renal Medicine, Boston Univ Medical Center, Boston, MA; [2]Pathology and Laboratory Medicine, Boston Univ Medical Center, Boston, MA.*

Introduction: Ethylene glycol ingestion can cause multi-organ dysfunction including acute kidney injury (AKI) and death. The diagnosis can be made based on history, a high anion gap metabolic acidosis with an elevated osmolar gap, oxalate crystalluria and an elevated ethylene glycol level. The diagnosis may be challenging with the concurrent use of other substances such as cocaine as it causes vasomotor AKI or ANCA vasculitis. To elucidate the diagnosis, a renal biopsy may be required. Herein, we present a patient with biopsy proven calcium oxalate nephropathy who presented with unexplained AKI likely related to unintentional low dose regular ethylene glycol use. She did not have any symptoms or classic biochemical features of ethylene glycol intoxication.

Case Description: A 57-year-old homeless woman with a history of rheumatoid arthritis, COPD presented with a productive cough and dysgeusia and was found to have a Cr of 8.9 mg/dl, elevated from a recent baseline of 0.9 mg/dL. Her anion gap was 17, with no other electrolyte abnormalities. Toxicology was negative for ethanol or salicylates. Her BP was 157/77 mm Hg and physical exam was unremarkable. Her last use of cocaine was 3 days prior to admission. She was initially given normal saline and maintained an adequate urine output, but her Cr continued to rise to 13.0 mg/dL. Urine sediment showed a few isomorphic RBCs only. A renal ultrasound revealed normal sized kidneys. Serological tests for autoimmune, post-infectious and dysproteinemic causes of AKI were normal or negative. Renal biopsy revealed acute tubular injury with calcium oxalate deposition. An in depth history did not reveal a high oxalate diet nor a medical history predisposing her to hyperoxaluria, however she admitted to the regular ingestion of "juiced" street alcohol. She did not require dialysis. Her follow-up Cr was 1.8 mg/dl two months later.

Discussion: In conclusion, a thorough history is required when encountering unknown AKI in patients with a history of drug abuse or homelessness, while keeping a high index of suspicion for drug intoxications including ethylene glycol.

PUB433

Thrombotic Microangiopathy (Hemolytic-Uremic Syndrome) Induced Acute Kidney Injury Associated with Brucella Infection Thomas E. Craig, Jonathan G. Owen. *Dept of Medicine, Section of Nephrology and Hypertnesion, LSUHSC, New Orleans, LA.*

Introduction: Thrombotic microangiopathies (HUS, TTP and DIC) have been associated with a host of infectious agents. Its association with Brucellosis is uncommon. We present a case of a patient who developed TMA associated with a case of Brucellosis.

Case Description: 52 year-old woman with minimal past medial history presented to the hospital with abdominal pain, fevers/chills and generalized body aches. History was significant for intermittent bloody diarrhea approximately 2 weeks prior to ED presentation. Physical examination revealed epigastric and right upper quadrant tenderness to palpation and patient was started on broad-spectrum, empiric IV antibiotic therapy with

Vancomycin, Piperacillin/Tazobactam, and Ciprofloxacin. Shortly thereafter, her clinical status deteriorated resulting in acute respiratory failure requiring intubation and mechanical ventilation. CBC was notable for a white blood cell count of 27,000, hemoglobin of 7.3 g/dL and a platelet count 80,000. Other labs were notable for total bilirubin 2.3 mg/dL, LDH 509 U/L, haptoglobin less than 10 , lactic acid 5.7 mmol/L and elevated transaminases. Peripheral Smear was notable to be positive for numeours schistocytes. Patients was anuric and Nephrology consultated to begin CRRT in setting of sepsis requiring three vasopressors. Patient had a rapid improvment in symptoms after initiation of sepsis protocol and was weaned off all vassopressors by 72 hours. Initial workup including abdominal imaging and blood cultures were negative for a source of infection. Patient had remarkable spontaneous clinical recovery and was later found to be positive for Brucellosis by immunoglobluin assay.

Discussion: Brucella infection has uncommonly been associated with the development of Hemolytic Uremic Syndrome. In addition, clinical course is widely variable, ranging from spontaneous recovery, as occurred with this patient, to disease requiring long-term renal replacement therapy.

PUB434

Patient with Clinical Diagnosis of Scleroderma Presenting with Sjögrens' Associated Renal Disease Aala Jaberi, Jasvinder S. Bhatia. *Nephrology, Boston Medical Center, Boston, MA.*

Introduction: Overlap rhematologic syndromes can occur in a substantial number of patients with renal disease. The clinical manifestations often favor one diagnosis over another, which can make diagnosing and treating the renal disease very challenging.

Case Description: 69-year-old female with no known history of previous rheumatologic disease presented with cough, fever and AKI and was diagnosed with multifocal pneumonia. Initial laboratory tests revealed a creatinine level of 2.2mg/dl, and persistent non anion- gap metabolic acidosis. On further history, she complained of long standing heartburn and Raynaud's symptoms in her fingers. Her physical exam disclosed telangiectasia on palms and skin thickening of the face and PIP joint. These features were consistent with systemic scleroderma, which prompted a rheumatologic work-up. Serologies were significant for a positive ANA and SSA antibody as well as hypocomplementemia. Urine sediment revealed many WBCs with no casts and some non-dysmorphic RBCs. A decision was made to proceed with kidney biopsy to identify the cause of her renal disease since the sediment was not supportive of Scleroderma associated renal disease. Kidney pathology showed acute interstitial nephritis with mild chronic changes which, when combined with the serologic tests, was highly suggestive of Sjögrens syndrome-associated renal disease. She was commenced on corticosteroid therapy and two months post-initiation, her renal function has stabilized.

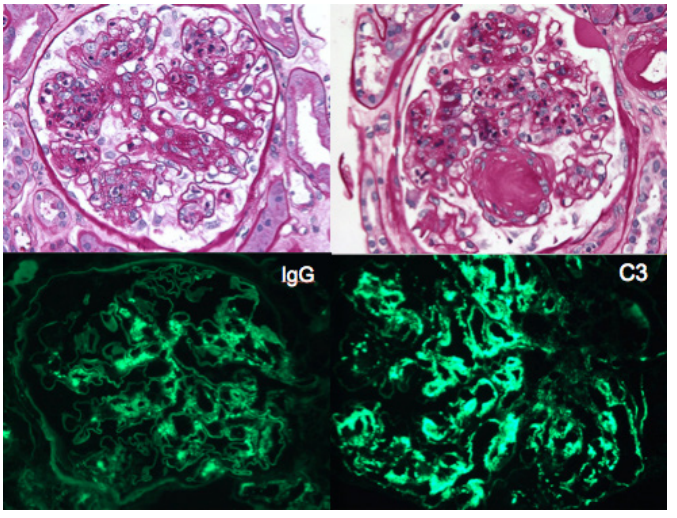
Discussion: This case demonstrated the importance of kidney biopsy in elucidating a diagnosis in a challenging case of overlap syndrome. The rapid diagnosis of interstitial nephritis was particularly important in this patient since most cases of renal associated Sjögrens' go unrecognized until significant renal dysfunction has occurred. It has been proposed to consider kidney biopsy findings of tubulointerstitial disease as additional supportive criteria in the classification of Primary Sjögren's syndrome, which is a sentiment we also support.

PUB435

More Than Just Diabetic Glomerulosclerosis – "A Challenge to the Epidemiological Paradigm" Juan Antonio Medaura, Jeffrey D. Wallach. *Nephrology, Harlem Hospital Center, New York, NY.*

Introduction: Acute post infectious glomerulonephritis (APIGN) most frequently affects children and is relatively uncommon in adults. The incidence has declined sharply in industrialized countries over the last 50 years. Adults with an immune compromised background, especially due to alcoholism and/or diabetes are at higher risk for developing the disease.

Case Description: A 61 year old Hispanic male with medical history of uncontrolled diabetes, Hypertension and chronic alcohol abuse presented to the emergency department due to shortness of breath and swelling of his legs since one week. Patient was afebrile, blood pressure 200/102 mm Hg. On exam he had clear signs of fluid overload. Pitting edema was seen over the lower extremities bilaterally, up to the shins. He also had an oval ulcer on his right leg anteriorly measuring 2 cm discharging pus. The remainder of the physical exam was grossly normal. Relevant laboratory results potassium of 6.4 meq/L, BUN 51 mg/dl, Creatinine 1.7 mg/dl (Baseline unknown) and Albumin 2.8 gr/dl. Urinalysis: protein 300 mg/dl, blood MOD, WBC 61/hpf, RBC 87/hpf, Hyaline casts 7/hpf. Urine eosinophils present. Urine 24 Hr Protein: 6.7 gr. Wound cultures positive for Beta Hemolytic Streptococcus Group A. Complement C3: 19 Ch50: <10, C4:34 Antistreptolysin O:400 [<200 IU/ml] Anti DNAse B Titre: 967. Kidney biopsy results: acute post-infectious glomerulonephritis superimposed on background changes of moderate nodular diabetic glomerulosclerosis.



Discussion: Most children with APIGN recover completely, but there is general agreement that the prognosis is more guarded in adults. Full recovery of renal function can be expected in just over half of patients, and prognosis is dismal in those with underlying diabetic glomerulosclerosis.

PUB436

Two Cases of Kidney Injury Induced by Anti-VEGF Therapy for Carcinoma Yudai Isozaki, Yosuke Nakagawa, Takuya Isegawa, Masahiro Koizumi, Masafumi Fukagawa. *Div of Nephrology, Endocrinology and Metabolism, Tokai Univ School of Medicine, Isehara, Kanagawa, Japan.*

Introduction: Anti-vascular endothelial growth factor (VEGF) agents have been widely used in the treatment of various types of advanced-stage malignant tumor, including lung carcinoma and renal cell carcinoma. Although these agents are generally well tolerated, there are increasing reports of renal adverse events, especially proteinuri.

Case Description: Case 1: A 69 year-old male started chemotherapy including bevacizumab (monoclonal antibody of VEGF) with a diagnosis of advanced lung adenocarcinoma of left upper lobe. The completion of four-course chemotherapy resulted in reduction of tumor volume, and then converted to bevacizumab monotherapy. At one year after the start of therapy, proteinuria with renal insufficiency developed. He was referred to our service for further evaluation and management. Renal biopsy demonstrated microthrombi in the loop wall with duplication of GBM, which was consistent with thrombotic microangiopathy (TMA). Thereafter, with cessation of anti-VEGF agent, proteinuria was gradually ameliorated to less than 1.0 g/day and renal function returned to normal range. **Case 2**: A 56 year-old male with renal cell carcinoma, who had undergone nephrectomy with three years before, subsequently proved to have metastatic lesion in lumbar vertebra. He started treatment with sunitinib, a tyrosine kinase inhibitor which blocks the intracellular domain of the VEGF receptor. This patient had baseline renal insufficiency due to nephrectomy and diabetes. After the introduction of therapy, he exhibited progression of kidney disease with nephrotic-range proteinuria in a short time. In addition to the cessation of sunitinib, hemodialysis was initiated because of fluid overload. After several times of dialysis, urine output was gradually increased and renal function returned to the baseline level.

Discussion: The renal adverse effects of anti-VEGF agents are supposed to arise from inhibition of podocyte-endothelial VEGF signaling pathway. VEGF signaling pathway plays an essential part in glomerular development and endothelial maintenance. We need to pay attention to renal adverse effects with anti-VEGF therapy.

PUB437

Concurrent Development of Eculizumab (ECU) (Anti-C5 Antibody)-Responsive Atypical Hemolytic Uremic Syndrome (aHUS) and Siltuximab (SLT) (Anti-IL-6 Antibody)-Sensitive Multicentric Castleman Disease (MCD): Evidence for the Pathogenic Role of Inflammatory Cytokines Joe Ghata,[1] Abdulmawla Albirini,[1] Kai Lau.[1,2] *[1]Nephrology, Univ of Oklahoma, Oklahoma City, OK; [2]Medicine, VA Medical Center, Oklahoma City, OK.*

Introduction: The literature has a few cases on the association of MCD with thrombotic microangiopathy (TMA), but the pathogenesis & therapy are unknown.

Case Description: We describe a 29-year-old previously healthy man initially presented with non-specific symptoms of what later proved to be MCD. Diagnosis was delayed due to explosive full-blown systemic & biopsy-proven renal TMA, producing dialysis-dependent ARF, severe thrombocytopenia & transfusion-dependent hemolytic anemia till eculizumab (ECU). The appearance of diffuse lymphadenopathy 8 weeks after acute renal failure (ARF) led to node-biopsy proven MCD diagnosis & therapy with SLT. We postulate MCD was the trigger for TMA & full resolution needs both ECU & SLT directed at the etiology.

10 d before ARF, patient had abdominal pain, treated as cholecystitis by cholecystectomy. Mild splenomegaly & trace ascites were overlooked. Day 7 after ARF, bilateral pleural & pericardial effusion & moderate ascites emerged but overlooked as serum creatinine rose

from 0.9 to 11.3 mg% by day 33. At this point, Hgb fell to 6 g%, platelet to 45 k/mm^3, LDH peaked at 760, C3 down to 50 & C4 to <0.8. aHUS was diganosed by normal (nl) ADAMTS13 level, absent Ab & negative Shigatoxin. After 4 doses of ECU, by day 50 all features of TMA improved. Negative were ANA, ANCA, cryo, antiphosplipid Ab, hepatitis profile, SPEP, HHV 6, 8, & HIV. On day 54, diffuse large lymphadenopathy appeared on CT of chest & abdomen with 18.8 cm spleen & generalized anasarca & polyserositis. HS-CRP was up 25 x nl. [IL-6] & [VEGF] were 2-12 fold nl. Lymphadenopathy regressed 50% after 4 & >75% after 8 doses doses of SLT. Edema fully resolved after 2 doses.

Discussion: We conclude that intense cytokine activation due to MCD played a pathogenic role in his aHUS, as evidenced by the precedence of splenomegaly & anasarca to his TMA & by the dependency of anti-IL-6 Ab for full resolution of his MCD.

PUB438

Severe Hypercalcemia Presenting During Recovery Phase of Ischemic Acute Kidney Injury Buthayna A. Dinary,[1] Fazel Dinary,[2] Lavinia A. Negrea.[1] *[1]Nephrology and Hypertension, Univ Hospitals Case Medical Center, Cleveland, OH; [2]Internal Medicine, SVCMC/CWRU, Cleveland, OH.*

Introduction: AKI is frequently complicated by multiple electrolyte abnormalities, including hyperkalemia, hyperphosphatemia, and hypo/hypercalcemia. Hypercalcemia is often seen in the recovery phase of rhabdomyolysis associated AKI, can be severe and life-threatening. Several etiologies for delayed hypercalcemia have been proposed, including mobilization of calcium deposits out of the recovering muscles, secondary hyperparathyroidism, increase in calcitriol, and resolution of hyperphosphatemia.

Case Description: A 31 yo Caucasian male with recently diagnosed Type I DM. Admitted for DKA complicated by cardiac arrhythmia, cardiac arrest, respiratory failure, septic shock, and oligouric AKI requiring a prolonged period of renal replacement therapy Ultimately renal function recovered and patient was taken off dialysis. There was no evidence of rhabdomyolysis clinically or biochemically at any time during his hospitalization. He was hypocalcemic during the oliguric phase of AKI but during the diuretic phase he developed severe symptomatic hypercalcemia. Improved with volume replacement and administration of calcitonin. Hypercalcemia reached a peak of 14.1 mg/dL, corrected for serum albumin and urine output was as high as 3.5 liters daily. Hypercalcemia lasted for 3 weeks and then calcium returned back to normal levels. Plasma levels of 25-OH and 1-25(OH)2 vitamin D were not elevated, intact parathyroid hormone level was appropriately suppressed, and 24-hour urine calcium was 520 mg. Immobilization hypercalcemia as well as mobilization of calcium from calcium deposited in various tissues seems to account for hypercalcemia and hypercalciuria in this case.

Discussion: Hypercalcemia is uncommon during the recovery phase of non-rhabdomyolysis associated ATN. Unattended, it can cause severe morbidity. Fluid administration, calcitonin, and bisphosphonates are some of the methods used for its treatment.

PUB439

A Case of Hyponatremia from Adrenal Insufficiency Mimicking Siadh Pradeep Reddy Thodima, Rasib Raja, Siddhesh R. Lotlikar, Imara Dissanayake, Eric J. Bloom. *Nephrology, Albert Einstein Medical Center, Philadelphia, PA; Nephrology, Albert Einstein Medical Center, Philadelphia, PA; Nephrology, Albert Einstein Medical Center, Philadelphia, PA; Nephrology, Albert Einstein Medical Center, Philadelphia, PA; Nephrology, Albert Einstein Medical Center, Philadelphia, PA.*

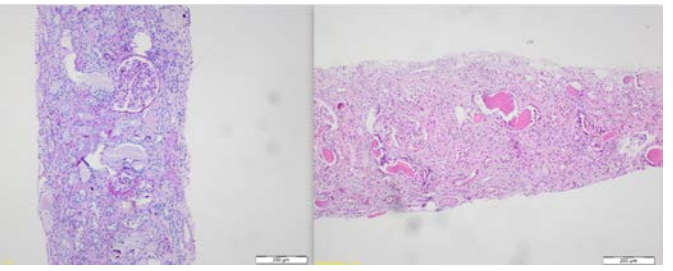
Introduction: A 40 yr old male with a diagnosis of nasopharyngeal carcinoma was admitted for dysphagia and decreased oral intake. He had severe hyponatremia with serum Na 126 meq/l, other labs including K -4.2, Cl- 94, HC03-26. He was euvolemic and normotensive. A urine panel showed Na - 122 meq/l and Uosm of 932 osm/l. He was deemed to have euvolemic hyponatremia from SIADH and started on fluid restriction. There was no improvement in hyponatremia and Una increased to 235 meq/l. He was diagnosed with adrenal insufficiency with a co-syntropin test. Imaging studies did not demonstrate pituitary invasion by nasopharyngeal carcinoma. He was started on high doses of hydrocortisone with rapid improvement of hyponatremia and Una dropped to 35meq/l. Hyponatremia with high Una (280 meq/l) recurred during hydrocortisone taper. He required prolonged high doses of hydrocortisone to maintain normal serum sodium level. Although there have been many case reports of hyponatremia with adrenal insufficiency, to the best of our knowledge there has been no reports of hyponatremia with very high Urine sodium (> 200 meq/l). This case highlights that euvolemic hyponatremia can occur with adrenal insufficiency with clinical and biochemical manifestations mimicking SIADH. Adrenal insufficency should be considered in all cases of hyponatemia especially with very high urine sodium.

PUB440

Acute Tubulointerstitial Nephritis Preceding the Diagnosis of Multiple Myeloma Alper Alp,[1] Hakan Akdam,[2] Aysegul Ormeci,[3] Ibrahim Meteoglu,[3] Harun Akar,[4] Yavuz Yenicerioglu.[2] *[1]Nephrology, Van Region Education and Research Hospital, Van, Turkey; [2]Nephrology, Adnan Menderes Univ, School of Medicine, Aydin, Turkey; [3]Pathology, Adnan Menderes Univ, School of Medicine, Aydin, Turkey; [4]Internal Medicine, Nephrology, Tepecik Education and Research Hospital, Izmir, Turkey.*

Introduction: Multiple myeloma(MM) is characterized by a neoplastic proliferation of monoclonal plasma cells-usually-originating in the bone marrow.Atypical presentations of MM is not seldom in clinical practice.The hidden signs of the disease may cause late diagnosis and clinicians should be suspicious and aware for this entity.However in some rare cases these signs may really be invisible.

Case Description: A 55 yo woman presented with confusion,oliguria and elevated creatinine level of 18.2 mg/dl.Hemodialysis was started acutely.Renal ultrasonography revealed normal size kidneys without hydronephrosis.Renal biopsy was compatible with acute tubulointerstitial nephritis.



Kappa and lambda light chain staining was negative.1 mg/kg metilprednisolone therapy was initiated and given for 1 month.No regression was observed and hemodialysis therapy was continued.After 2 months steroid therapy was reinitiated again but there was no clinical and biochemical response.On follow-up,after 7 months from renal biopsy hypercalcemia,anemia,high sedimentation rate,hyperglobulinemia and lytic bone lesions were detected.16% monoclonal plasma cells were present in bone marrow.With further examinations MM diagnosis was made.

Discussion: Renal biopsies revealing acute tubulointerstitial nephritis pattern which are unresponsive to steroid therapy should always be deeply investigated for alternative diagnoses.MM may have obscure presentations.

PUB441

Sleep Disturbances in an ESRD Patient Soon After Initiation on Hemodialysis: An Atypical Presentation of ESRD-Related Sleep Disorders Desiree Garcia Anton, Franco H. Cabeza Rivera, Alexandre Abreu, Marco A. LadinoAvellaneda. *Nephrology, Univ of Miami, Miami, FL.*

Introduction: Sleep disorders including obstructive sleep apnea (OSA), restless leg syndrome (RLS) and insomnia are highly prevalent in ESRD patients undergoing dialysis, however, these remain stable or tend to improve after initiation of dialysis. There is scarce evidence of new-onset sleep complaints or disorders after initiation of dialysis.

Case Description: We present a case of a 64 year-old male with HTN, DM, ESRD and no previous sleep problems who developed insomnia, RLS, sleepwalking and other sleep disturbances within a month after initiation of continuous hemodialysis. He presented to the primary care clinic with secondary complications from uncontrolled diabetes (neuropathy, retinopathy and nephropathy); he had been followed by the nephrology service for 4 years before requiring dialysis for uremia and volume overload. Intermittent HD was well tolerated during first month of treatment, achieving good metabolic clearance and volume control; his KT/V was 1.16, phosphorus was controlled at 4.6 mg/dl and his anemia improved to a hemoglobin of 9.6 mg/dL; iron was 36 mcg/dl, ferritin 135 ng/ml, and transferrin saturation 15%. Despite clinical and laboratory improvement, disabling sleep symptoms were reported and he was referred to the Sleep clinic for further evaluation. On his initial actigraphy, a bedtime or rise time pattern was unable to be determined as it showed continuous movements 24 hours per day for the 14 days monitored. Overnight Polysomnography (PSG) revealed severe OSA and periodic limb movements (PLM); there was also evidence of insomnia with severely reduced sleep efficiency.

Discussion: New-onset sleep problems after initiation of dialysis in patients who previously had no sleep complaints are an atypical presentation. The role of RRT on sleep disturbances in the ESRD population is unknown. We propose PSG pre and post dialysis initiation on advanced CKD patients to assess for differences and identify how RRT may be a cause of sleep disturbances.

PUB442

Reduced Serum Anion Gap due to Lithium Overdose Tanmay Sahai,[1] Josef Bautista.[2] *[1]Internal Medicine, Roger Williams Medical Center, Providence, RI; [2]Nephrology, Brown Univ/Rhode Island Hospital, Providence, RI.*

Introduction: This case demonstrates the clinical presentation and corresponding laboratory results of lithium overdose as well as further discuss management of overdose with intermittent hemodialysis.

Case Description: A 32-year-old man with a history of bipolar disorder came to the hospital with altered mental status and worsening lethargy. He was subsequently intubated for airway protection. Patient's lithium level was > 20 mmol/L. CT head showed no injury. The rest of the toxicology screen was negative. His basic metabolic panel (including calcium and albumin) was within normal limits however his bicarbonate was 32 mmol/L and creatinine was elevated to 1.5 mg/dL. Calculated anion gap was 1 mmol/L. Serum osmolality was not measured at time of presentation. Patient was hemodynamically stable. Vigorous hydration with isotonic saline was initiated. Intermittent hemodialysis with high blood pump speed was initiated. Serum lithium level was checked 24 hours later and it fell to 2mmol/L. Intermittent hemodialysis was discontinued 24 hours later as patient was awake, alert and arousable with dramatic improvement in mental status. Creatinine also trended down to 0.9 after 48 hours. Patient was extubated 48 hours after initial presentation.

Discussion: Lithium has a narrow therapeutic window and therefore in cases of overdose or toxicity have many symptoms including altered levels of consciousness as seen in this patient. Low anion gap is a diagnostic clue to lithium intoxication however other causes include hyperkalemia, hypermagnesemia, and monoclonal gammopathies. Although serum osmolalilty was not measured in our patient, this can also be a helpful indicator noted in previous case reports. Elevated osmolar gaps with low anion gaps are useful in diagnosing lithium overdose. The standard management for lithium overdose is intermittent hemodialysis and maintaining water balance. The theory behind using intermittent hemodialysis versus continuous venovenous hemodiafiltration is that higher clearance of lithium can be achieved from faster blood flow rates in intermittent hemodialysis if it can be tolerated hemodynamically.

PUB443

Episodes of Hypertensive Crises in a Tetraplegic Dialysis Patient due to Catheter-Associated Endocarditis Martin Russwurm, Joachim Hoyer, Ivica Grgic. *Dept of Internal Medicine and Nephrology, Philipps-Univ Marburg, Marburg, Germany.*

Introduction: Hypertensive emergencies are a life-threatening condition associated with organ damage including acute heart failure, seizures and coma. Pre-existing arterial hypertension and non-adherence to anti-hypertensive treatment as well as volume overload particularly in dialysis patients are considered major triggers of HC. ESRD patients have a high prevalence (>70%) for hypertension and are at high risk for the development of cardiovascular disease and related complications. Early assessment and treatment of hypertensive states including HC is therefore imperative.

Case Description: Here, we report a case of a 34-year-old patient with sudden onset of repeated episodes of hypertensive emergencies on dialysis. The first episodes of spiking blood pressures of >240/120 mmHg occurred several weeks prior to admission and had become increasingly difficult to manage forcing early termination of dialysis sessions. The patient had been on hemodialysis, via tunneled catheter, for one year. Laboratory findings showed elevated inflammation parameters. Blood cultures were positive for gram-negative rods which were later identified as Pseudomonas aeruginosa (P.a.). We performed transesophageal echocardiography which showed echodense masses at the tip of the catheter and right cardiac atrium. Hemodialysis via an alternative vascular access instantly resulted in normal blood pressures during dialysis. Subsequently, the patient underwent heart surgery. The tunneled catheter and a large (5.2 x 3.5cm), P.a-infected thrombus were removed from the right atrium and the patient put on a targeted antibiotics. Following recovery, a forearm fistula was created and used without major complications.

Discussion: To our knowledge, there is no report in the current literature of hypertensive crises in direct association with CVC infection. We speculate that initiation of dialysis via the infected catheter may have led to transient bacteremia triggering hyptertensive episodes via an unclear mechanism. This case demonstrates that catheter-associated infections should be included in the differentials of causes and triggers of HC.

Adypsic Nephrogenic Diabetes Insipidus a Possibility? Nivin Haroon, Zeenat Yousuf Bhat. *Dept Nephrology, Wayne State Univ, Detroit, MI.*

Introduction: Adypsic diabetes insipidus (DI) is a rare syndrome where the patient has central DI and lack of thirst response due to presence of central lesion. We describe a patient who developed nephrogenic DI following a contrast exposure and acute kidney injury (AKI).

Case Description: The patient is a 47 yr old African American female with significant past medical history of mild diabetes mellitus. Her baseline kidney function was stable with creatinine (Cr) < 1 and non proteinuric. She had left sided progressive inflammatory breast cancer. She completed 2 cycles of paclitaxel and doxorubicin and cyclophosphamide. During this time she was admitted to the hospital following incision and drainage of a rectal abscess and treated with vancomycin and zosyn. Patient had received contrast exposure from computed tomography imaging for the abscess. Two days later the patient started to have rise in Cr with level going from 0.7 to 1.5. Nephrology was consulted for the same. There was no overt septic shock or blood pressure fluctuation. Urine microscopy was bland and ultrasound showed no pathology. Acute kidney injury was possible from the contrast exposure due to the time line of Cr bump within 48 to 72 hour period and lack of other overt evidence. Along with the AKI patient was found to have rise in sodium levels. She was having increased urine output in the range of over 4 Liters every day. Sodium was going up from baseline 140 up to 152. Interestingly patient was not having increased thirst response. She was given desmopressin (DDAVP) challenge test with no change in the urine output. An MRI imaging of brain was negative for pathology. She was instructed to drink water to match her urine out even if not thirsty. Initially the sodium leveled off and later trended down along with AKI.

Discussion: The case is very unique as the contrast injury resulted in nephrogenic DI. The patients lack of thirst response and rise in sodium was even more peculiar as the DI was clearly nephrogenic due to lack of response to DDAVP. It is still unclear why the thirst response in this patient was affected. More studies in future will unravel the complex relation between thirst response and osmolarity.

PUB445

Frailty Modifies the Association Between Age and Dysnatremia in Community-Dwelling Adults Amanda Jean Miller,[1] Susan E. Howlett,[2] Kenneth John Rockwood,[2] Karthik K. Tennankore.[1] *[1]Nephrology, Dalhousie Univ, Halifax, NS, Canada; [2]Geriatrics, Dalhousie Univ, Halifax, NS, Canada.*

Background: Frailty represents a state of increased risk to adverse health outcomes, reflecting some combination of increased damage and compromised repair processes. Dysnatremia is more common with age and can occur in many settings, suggesting that it may reflect not simply a specific renal problem, but a more general imbalance in damage and repair. The aims of this study were to establish whether frailty severity is associated with a higher rate of dysnatremia and to determine whether frailty explains the previously established association between age and dysnatremia.

Methods: The relationship between age, frailty severity and dysnatremia was investigated across the adult life course in 8898 respondents from the 2003-2004 and 2005-2006 cross-sectional National Health and Nutrition Examination Survey (NHANES) datasets. Respondents were assigned a frailty index (FI) and assessed for dysnatremia (a deviation of serum sodium from the 135-144 mmol/L normal range). The coefficient of variation in serum sodium was used as a systems measure of the response repertoire.

Results: In the overall population, there was a significant positive association between increasing frailty severity and the proportion of patients with dysnatremia (chi-square trend $p < 0.001$). Increasing frailty severity was also associated with more variability in serum sodium. There was a significant association between advancing age and dysnatremia ($p < 0.001$); however after stratifying by frailty (FI <0.100, 0.100-0.199, 0.200-0.299, 0.300-0.399, >=0.400), the association between increasing age and dysnatremia became non-significant in all categories.

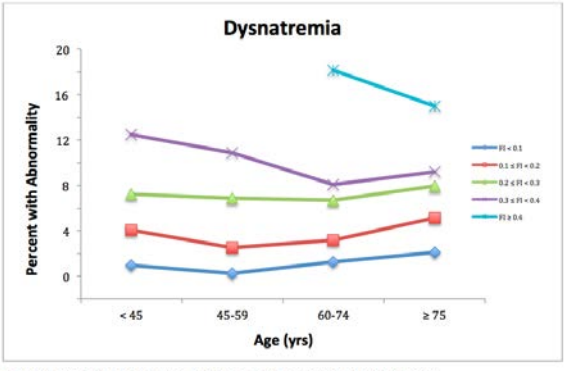

Figure 1: Proportion of dysnatremia with increasing age, stratified by frailty index

Conclusions: Increasing frailty severity is associated with dysnatremia and greater variability in serum sodium. Furthermore, frailty appears to modify the earlier association between age and dysnatremia.

PUB446

Approach to Hyponatremia in Congestive Heart Failure: A Survey of Canadian Physicians and Trainees Amanda Jean Miller,[1] Bonnie Kuehl,[2] Karthik K. Tennankore.[1] *[1]Nephrology, Dalhousie Univ, Halifax, NS, Canada; [2]Research, Scientific Insights Consulting Group Inc., Mississauga, ON, Canada.*

Background: Hyponatremia is a complication of congestive heart failure (CHF) and is associated with reduced survival, however there are no consensus guidelines for the treatment of hyponatremia in CHF. The aim of this study was to determine the approach to hyponatremia in CHF amongst Canadian healthcare practitioners and trainees.

Methods: Respondents completed 15 multiple-choice style questions surrounding three cases of hyponatremia complicating CHF using an online survey on UKidney.com between December 2012-May 2013. Results were summarized as the proportion of correct/incorrect responses among Canadian Nephrologists, Cardiologists, Internists and trainees in each of two domains; pathophysiology and management. Management topics included use of diuretic therapy, hypertonic saline, oral urea tablets, vasopressin receptor antagonists (vaptans) and rate of sodium correction. Correct answers were determined by an expert panel of Canadian Nephrologists and Cardiologists.

Results: There were 1097 responses to survey questions among 455 Canadian respondents. Pathophysiology governing hyponatremia in CHF was correctly identified in 68.7% of responses (n = 380). Overall, hyponatremia was managed inappropriately in 43.6% of responses (n = 759). The proportion of incorrect responses among specialists and trainees is depicted in Figure 1. Importantly, an incorrect rate for sodium correction was selected 61.1% of the time (n = 211).

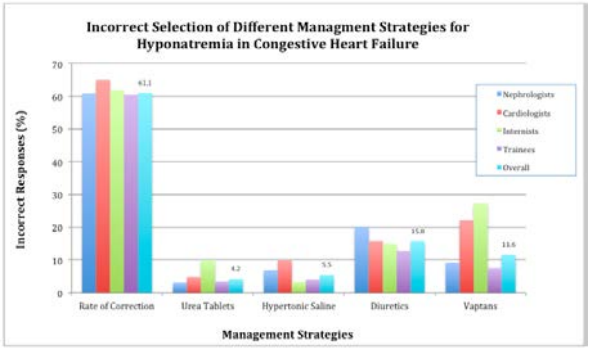

Figure 1: Proportion of Select Specialists and Trainees Choosing Incorrect Management Strategies for Hyponatremia in CHF

Conclusions: This study highlights knowledge gaps regarding pathophysiology and management of hyponatremia in CHF amongst Canadian specialist physicians and trainees. There is a need for further education to improve the management of hyponatremia in CHF at a national level.

PUB447

Sorafenib Induced Hyponatremia Elan Gorshein,[1] Catherine K. Wei,[1] Jasmeet S. Bajaj.[2] *[1]Internal Medicine, Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ; [2]Critical Care Unit, Univ Medical Center of Princeton at Plainsboro, Plainsboro, NJ.*

Background: Sorafenib treats unresectable hepatocellular carcinoma (HCC). It is a multi-targeted tyrosine kinase inhibitor (TKI), which prevents tumor cell proliferation. For those with inoperable disease, it prolonged median survival. Nevertheless, adverse reactions may limit its use. Sorafenib has been associated with hyponatremia, which may be related to the syndrome of inappropriate antidiuretic hormone (SIADH) secretion. We present a case of sorafenib induced hyponatremia.

Methods: A 58 year-old female presented with lethargy and edema. Patient was diagnosed with HCC 6 months earlier. She underwent transcatheter arterial chemoembolization and was noted on repeat imaging to have metastatic disease. Patient began sorafenib two weeks prior to admission, with a dose of 200 mg daily. A week later, the dose was increased to 200 mg twice daily. Three days later, the patient increased her dose to 400 mg in the AM and 200 mg in the PM. A day thereafter, patient became lethargic, with generalized swelling. The serum sodium was 106 mmol/L, with a baseline of 134 mmol/L three weeks prior to admission. Urine osmolality was 542 mOsm/kg, and the urine random sodium was less than 25 mEq/L. Patient's TSH was 6.82, with a normal FT4. AM cortisol was measured at 20.2. Her total protein and lipid profile were normal.

Conclusions: TKI agents have improved median survival in advanced HCC disease. Their use, however, has been limited by adverse events. Hyponatremia has been reported with a rate of up to 11% in patients treated for HCC. The pathophysiology may be related to SIADH. TKI agents may enhance the effects or increase the action of ADH. Time to onset of hyponatremia may be within ten days. Our patient took sorafenib for two weeks. Upon admission, her serum sodium was 106. With hypertonic saline and fluid restriction, her sodium reached 128. Other etiologies of hyponatremia were excluded. Sorafenib was discontinued, and attempts at patient follow-up have been unsuccessful. However, this report highlights that while sorafenib has had favorable impact on advanced HCC outcomes, clinicians should be mindful of its adverse effects.

PUB448

Current Trends in Etiologic Factors Responsible for the Development of Hyponatremia in Hospitalized Patients Sandar Win,[1] Maria V. DeVita,[1] Diana Dreyer,[2] Samuel J. Wahl,[2] Michael F. Michelis.[1] *[1]Nephrology, NSLIJ/Lenox Hill Hospital, New York, NY; [2]Pathology, NSLIJ/Lenox Hill Hospital, New York, NY.*

Background: Hyponatremia remains the most common electrolyte disorder seen in hospitalized patients. The prevalence has been reported to vary from 5% to 15% and to be as high as 29.6% depending on the hospital setting.

Methods: New data were obtained on 2 separate days to evaluate the prevalence and etiologies of hyponatremia in hospitalized patients in a large metropolitan hospital. Hyponatremia was defined as less than 135mmol/L.

Results: Hyponatremia was recognized in 41 of 879 patients (4.6%). The mean serum sodium level in the hyponatremia group was 132.0+/-3.2 mmol/L. Eighty-five percent of the patients exhibited a serum sodium level of >130 mmol/L. Individuals aged 65 years old or greater made up 58.5% of the patients. Etiologic factors identified in the total number of hyponatremic patients included 9.7% with ESRD, 4.8% post op, 14.6% dehydration, 24.3% with pulmonary disorders, 26.8% with a diagnosis of cancer. The majority of patients were noted, however, to be receiving related drug therapies 63.4%. They were distributed between diuretic therapy (36.6%) and psychiatric drug therapy (26.8%).

Percent Distribution of Drug Therapies

Diuretics (36.6%)		CNS Drugs (26.8%)	
Diuretics Alone (17.1%)	Diuretics + CHF (19.5%)	SSRIs (17.1%)	Others (9.7%)

Conclusions: This study suggests that hyponatremia often is mild, is commonly associated with drug therapy, affects a significant number of younger patients, and now includes novel conditions such as patients receiving renal replacement therapy.

PUB449

Development of Metabolic Acidosis After Neobladder Replacement in Korea Shina Lee, Dong-Ryeol Ryu, Kyu Bok Choi, Duk-Hee Kang, Seung-Jung Kim. *Dept of Internal Medicine, School of Medicine, Ewha Womans Univ, Seoul, Republic of Korea.*

Background: Metabolic acidosis frequently develops in patients after neobladder replacement. However, the incidence of metabolic acidosis in patients with neobladder and the factors associated with the development of metabolic acidosis have not been well elucidated. We aimed to investigate the incidence and the potential predictors for the development of metabolic acidosis after neobladder replacement with intestinal segment.

Methods: We included all patients who underwent neobladder replacement using intestinal segment at Mokdong Hospital between January 1, 2005 and December 31, 2014. Metabolic acidosis was defined as serum tCO2 below 22 mEq/L at any visit during the follow up period. Patients' biologic data was presented using x^2 test and student t test. Subgroups according to the time of metabolic acidosis occurance was further analyzed in order to characterize predictors for metabolic acidosis by ANOVA tests and multiple regression.

Results: Metabolic acidosis was encountered in 79.4% of patients with neobladder during follow up period. When patients were divided into 2 groups according to anion gap(AG), total CO2(18.9±2.1mEq/L *vs.* 20.0±1.3mEq/L, p=0.001) and chloride(106.6±4.9mE/L *vs.* 109.4±3.6mEq/L; p<0.001) were significant different between groups with AG>12 and AG£12 respectively. Furthermore, when patients were divided into 3 groups; patients with metabolic acidosis at post operative day 1; within a 14days; after 14days, there was significant difference of postoperative laboratory findings among the those subgroups.

Conclusions: Our study showed the rate of development of metabolic acidosis in patients underwent neobladder replacement and the difference between patients with metabolic acidosis and those without metabolic acidosis after neobladder replacement for the first time in Korea. In the future, well designed prospective study will be needed to prevent metabolic acidosis after neobladder replacement.

PUB450

Potassium Abnormalities and Acute Kidney Injury Are Common Complications After Colectomy Lindsay M. Smith,[1] Robert M. Perkins,[2] Andrea Lynn Berger,[1] H. Lester Kirchner,[1] Morgan Grams,[3] Alex R. Chang.[1] *[1]Geisinger Health System; [2]Bayer Healthcare; [3]Johns Hopkins Bloomberg School of Public Health.*

Background: Patients undergoing colectomy may be predisposed to disturbed potassium homeostasis, since the colon has a role in potassium excretion, and volume depletion due to diarrhea occurs frequently after colectomy.

Methods: We examined the frequency of incident mild (>5 mmol/L) and severe hyperkalemia (>6 mmol/L), mild (<3.5 mmol/L) and severe (<2.5 mmol/L) hypokalemia, and inpatient AKI, stratified by estimated glomerular filtration rate (eGFR) using creatinine (inpatient only) and potassium (inpatient/outpatient) data from 1,762 patients who underwent colectomy surgery at Geisinger Health System between 2004-2013.

Results: Median age was 66 and mean baseline eGFR was 79 ml/min/1.73m^2. Colonic conditions included inflammatory bowel disease (8%), bowel obstruction (8%), ischemic bowel (2%), diverticulitis (23%), and colorectal cancer (20%). During the surgery hospitalization, post-operative AKI occurred in 32% of patients ; mild and severe hyperkalemia occurred in 18% and 3% of patients. Over a median of 4.0 years post-discharge after colectomy, mild and severe hyperkalemia occurred at a rate of 13.4 events/100 person-years and 1.8 events/100 person-years; mild hypokalemia and severe hypokalemia occurred at a rate of 15.4 events/100 person-years and 0.7 events per person-years. Rates of inpatient AKI after discharge were high (9.1 events/100 person-years). Risks for AKI, mild and severe hyperkalemia increased as eGFR declined (p values<0.001; Table).

Conclusions: Patients who undergo colectomy are at high risk for hyperkalemia, hypokalemia, and AKI, particularly when eGFR is decreased. Comparison to a control group is needed to determine whether the high incidence of hyperkalemia is related to removal of the colon or frequent AKI episodes.

Table. Event Rates for Hyperkalemia, Hypokalemia, and AKI Events after Colectomy by Baseline eGFR Category

	Number of Events per 100 person-years				
	K>5	K>6	K<3.5	K<2.5	AKI
Baseline eGFR >=90 (n= 614)	9.9	1.1	13.6	1.0	7.3
Baseline eGFR 60-89 (n= 755)	11.6	1.5	15.0	0.6	8.3
Baseline eGFR 45-59 (n= 233)	26.7	2.7	17.6	0.6	13.6
Baseline eGFR 30-44 (n= 117)	32.0	4.4	22.0	0.8	16.0
Baseline eGFR < 30 (n= 43)	63.4	14.3	55.3	0	22.7

Identify the Causes of Chronic Hypokalemia: Importance of Urinary Sodium and Chloride Excretion Chih-chien Sung,[1,2] Kun-Lin Wu,[1,3] Chih-Jen Cheng,[1] Yu-Juei Hsu,[1] Sung-Sen Yang,[1,2] Shih-Hua P. Lin.[1] *[1]Div of Nephrology, Dept of Medicine, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan; [2]Graduate Inst of Medical Science, National Defense Medical Center, Taipei, Taiwan; [3]Dept of Medicine, Armed Forces Taoyuan General Hospital, Taoyuan, Taiwan.*

Background: Chronic hypokalemia with potassium (K^+) wasting from kidney or gut is etiologically diverse. However, the correct diagnosis of the underlying causes is still fraught with challenge. To identify clinical and laboratory parameters helpful for the differential diagnosis of chronic hypokalemia.

Methods: The patients referred for evaluation of chronic hypokalemia in a medical center were enrolled prospectively for five years.

Results: Ninety-nine patients with chronic hypokalemia (serum K^+ 2.8 ± 0.4 mmol/L, duration 4.1 ± 0.9 years) were enrolled. The major presentations were dizziness, fatigue, palpitation, abdominal fullness and muscle weakness/tetany. The plasma renin activities were increased in all patients along with normal-high serum aldosterone level. The main imaging findings were nephrocalcinosis/renal stones (n=25). Although Gitelman's/Bartter's syndrome (n=32/13) and renal tubular acidosis (n=10) were major renal tubular disorders, forty-four patients were identified with anorexia/bulimia nervosa (n=24), surreptitious use of laxatives (n=10) and diuretics (n=10). The urinary K^+ excretion rates in patients with renal versus non-renal tubular disorders were significantly overlapped for making the diagnosis alone. Of note, unparalleled urinary sodium (Na^+) and chloride (Cl^-) excretion with urinary Na^+/Cl^- ratio are unique to non-renal tubular disorders. Furthermore, body mass index, serum bicarbonate and magnesium levels, and urine pH were also helpful for the differential diagnosis.

Conclusions: Chronic hypokalemia due to non-renal tubular disorders is emerging and often clinically indistinguishable from those with renal tubular disorders. The integrative interpretation of urine electrolytes excretion rates, especially Na^+ versus Cl^-, is important to make a prompt and accurate diagnosis.

PTHrP Induced Severe Hypercalcemia Secondary to Metatstatic Neuroendocrine Tumor: A Case Report Azka Arif,[1] Ahmad Hassan,[2] Muhammad Awais Arif,[2] Agha syed Shabbir Ali,[2] Hafiz Armaghan Saeed,[2] Abdul Mateen Nagaria,[1] Talal A. Khan.[1] *[1]Freeman Health System; [2]Rawalpindi Medical College.*

Background: Hypercalcemia is a common clinical problem. Most common etiology is hyperparathyroidism followed by malignancy. We report an interesting case of PTHrP induced severe hypercalcemia secondary to metatstatic neuroendocrine tumor.

Methods: 49-year-old female with history of metastatic neuroendocrine tumor presented to the hospital with worsening mental status. On initial evaluation she was found to be severely hypercalcemic with serum calcium (Ca) of 19.6 mg/dL. Her ionized Ca was 2.45 mmol/liter. Her initial PTH level was 8.4 pg per mL. Her TSH level was 3.63 miu/ml & CK level was 66 U/L. She was not on Lithium, Thiazide diuretics. She had normal renal function. She was aggressively hydrated & started on intra muscular calcitonin. She was also given a dose of Intravenous bisphosphonates .Her serum calcium came down appropriately to 8.9 mg/dL, later her serum PTHRP was reported as 78 pg per mL. Her 25-hydroxy vitamin D level was low at 11 pg /mL, and her 1 25-hydroxy vitamin D level was 11 pg /mL. Her ACE level was 21 U/L. She was eventually transferred to hospice.

Conclusions: PTHrP is a normal gene product expressed in variety of neuroendocrine tumors .Gastrointestinal neuroendocrine tumors rarely excrete PTHrP. our case represents a severe form of malignant hypercalcemia secondary to hyper-secretion of PTHrP.Literature review showed that it was amongst the highest serum calcium reported,we did not proceed with renal replacement therapy initially as per family meeting. Hypercalcemia secondary to PTHrP production significantly increases mortality and morbidity.

PUB454

Carboplatin Induced Severe Hypomagnesemia and Concurrent Hypocalcemia: A Report of an Interesting Case to Elaborate Evaluation and Management of Hypomagnesemia: "The Forgotten Electrolyte" Azka Arif,[1] Ahmad Hassan,[2] Muhammad Awais Arif,[2] Agha syed Shabbir Ali,[2] Hafiz Armaghan Saeed,[2] Abdul Mateen Nagaria,[1] Talal A. Khan.[1] *[1]Freeman Health System; [2]Rawalpindi Medical College.*

Background: Hypomagnesemia is commonly encountered in hospitalized patients. Renal wasting secondary to use of diuretics and persistent diarrhea are most important causes. It is one of the "forgotten" electrolytes .Many clinicians have limited awareness of how to accurately evaluate and manage hypomagnesemia.We report an interesting case of severe hypomagnesemia and hypocalcaemia secondary to carboplatin administration with a view point of elaborating diagnostic approach to hypomagnesemia.

Methods: 62-year-old female with history of adenocarcinoma of the lung, developed severe hypomagnesemia with serum magnesium (Mg) levels reported as low as 0.5 mg/dL. She had concurrent severe hypocalcaemia with serum calcium (Ca) of 5.1 mg/dL. Aggressive repletion was started & further workup was done. Her urine spot Mg level was reported as 381 mg, her fractional excretion of Mg was calculated & it was **9%.** She received 3 cycles of carboplatin before hospitalization She was not on any diuretics, PPIs & Aminoglycosides. She did not receive cetuximab as well;Urine calcium was less than 150mg, it was thought that she had carboplatin-induced distal nephron Mg wasting . Her serum PTH level was 245.5 pg/ml. Her hypercalcemia was thought to be secondary to PTH resistance mediated by severe hypomagnesaemia. After aggressive repletion her serum Mg & Ca level normalized.

Conclusions: Hypomagnesemia can be due to multiple causes,Initial step in evaluation involves calculating FeMg,if less than 2.5%,it is likley secondary to GI loss.If FeMg is>2.5% then we measure 24hour urine calcium,if its more than 250mg it is likely due to TAL-Mg wasting which can be secondary to loop diuretics,nephrotoxins(Aminoglycosides) or Familial hypomagnesemia with hypercalciuria.If less than 150mg then it is likley due to distal nephron Mg wasting which can be secondary to thiazides & Gitleman's syndrome. Our case represents an interesting concurrent presentation of severe hypomagnesemia and hypocalcaemia, which was successively treated.

PUB455

Effect of Arterial PH and Bicarbonate Level on Survival of Lactic Acidosis Patients Treated with Sodium Bicarbonate Dongyeol Lee,[1] Hansae Kim,[1] Eu Gene Jeong,[3] Su Mi Lee,[3] Sung Hyun Son,[2] Yong Ki Park,[1] Young Ki Son,[3] Seong Eun Kim,[3] Won Suk An.[3] *[1]Internal Medicine, Bong Seng Hospital, Busan, Korea; [2]Internal Medicine, Han Seo Hospital, Busan, Korea; [3]Internal Medicine, Dong-A Univ, Busan, Korea.*

Background: Patients with lactic acidosis have high mortality rate, and higher lactate level is poor prognostic indicator. The correction of lactic acidosis with sodium bicarbonate is potentially harmful when sodium bicarbonate inappropriately was used. Therefore, we evaluated whether starting pH of sodium bicarbonate affect on the survival in lactic acidosis patients treated with sodium bicarbonate.

Methods: We conducted a single center analysis from May 2011 through April 2014. We retrospectively analyzed 230 patients with lactic acidosis treated with sodium bicarbonate. Patients were divided four groups according to starting arterial pH of sodium bicarbonate. We analyzed arterial blood gas analysis, lactate level about 6, 12, 24, 48 hours after using sodium bicarbonate.

Results: The mean age of patients was 62.8 ± 15.0 years, 174 patients (75.7 %) were died. The non-survivals had lower albumin, hemoglobin, and CRP ($P < 0.001$, $P = 0.001$, $P = 0.003$), higher SOFA and APACHE II scores ($P < 0.001$, $P < 0.001$), and higher blood lactate level at 6, 24, 48 hours, and maximum after checking the initial lactic acid levels ($P < 0.001$, $P < 0.001$, $P < 0.001$, $P < 0.001$). Patients with increased second lactate level showed high mortality (84.4 %). The mortality rate was 90 % in patients with sustained high lactate level at 48 hours. The mortality rate was not different according to starting point of sodium bicarbonate. In survival group, arterial bicarbonate level was slowly increased without fluctuation. However, arterial bicarbonate level showed fluctuation in non-survival group. The mortality rate was independently associated with arterial pH at 12 hours after sodium bicarbonate infusion.

Conclusions: Stably increased arterial bicarbonate without fluctuation and recovering arterial pH at 12 hours are important factors in patients survival treated with sodium bicarbonate. Therefore arterial pH and sodium bicarbonate level should be closely monitored especially till 48 hours, if sodium bicarbonate treatment with lactic acidosis.

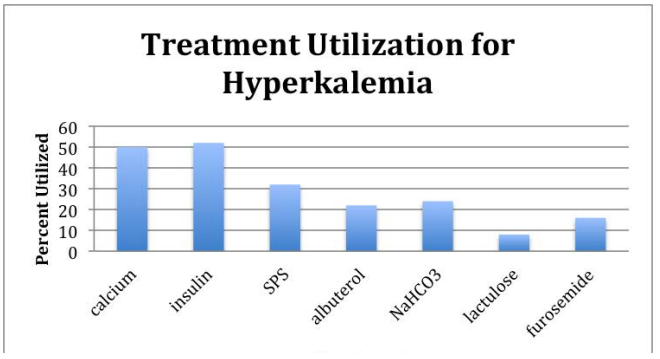
PUB456

Evaluation and Management of Hyperkalemia in an Academic Medical Center Jason K. Law,[1] Gaurav Ghosh,[2] Daniel Edmonston,[1] Saif A. Muhsin,[1] Yasin Hussain,[3] Miriam Chung,[1,2,4] Jeffrey I. Silberzweig.[1,2,4] *[1]Dept of Medicine, New York-Presbyterian Hospital, New York, NY; [2]Weill Cornell Medical College, New York, NY; [3]Weill Cornell Medical College, Qatar, Doha, Qatar; [4]Rogosin Inst, New York, NY.*

Background: Hyperkalemia ($K > 6.0$ mmol/L) is common among hospitalized patients but the approach to evaluation and management is highly varied. Patients are not routinely evaluated for clinical effects. Decisions regarding whether and how to treat are often based on individual physician judgments since few evidence-based guidelines exist. Since both hyperkalemia and its treatments can be associated with serious adverse consequences, we sought to evaluate the management in our institution.

Methods: Electronic medical records were reviewed for patients in our institution with potassium levels greater than 6.0 mmol/L between January 1, 2012 and December 31, 2014. Records were extracted for hyperkalemia associated symptoms and ECG findings, as well as interventions and outcomes.

Results: Only 2% of patients had clinical findings consistent with hyperkalemia. One-third of patients had ECGs performed and only 20% of those had findings consistent with hyperkalemia. Of patients with ECG findings consistent with hyperkalemia, only 15% had repeat tracings performed after treatment. At least 50% of patients were treated with insulin and dextrose and/or calcium. One-third of patients were treated with sodium polystyrene sulfonate (SPS), 25% with sodium bicarbonate and 10-15% were treated with lactulose or furosemide. Only 25% of patients had repeat potassium levels measured within six hours of treatment.



Conclusions: Management of hyperkalemia in our institution is far from systematic. Most patients receive treatment without evaluation for clinical effects of hyperkalemia. There is no standard treatment regimen and follow up measurements of potassium and ECGs were rarely done.

PUB457

Treatment of Hyperkalemia with Kayexalate in an Academic Medical Center Gaurav Ghosh,[2] Yasin Hussain,[3] Jason K. Law,[1] Daniel Edmonston,[1] Saif A. Muhsin,[1] Miriam Chung,[1,2,4] Jeffrey I. Silberzweig.[1,2,4] *[1]Dept of Medicine, New York-Presbyterian Hospital, New York, NY; [2]Weill Cornell Medical College, New York, NY; [3]Weill Cornell Medical College, Qatar, Doha, Qatar; [4]The Rogosin Inst, New York, NY.*

Background: Hyperkalemia (K > 6.0 mmol/L) is a potentially life-threatening condition; standard treatment has included sodium polystyrene sulfonate (Kayexalate) since its introduction in 1958. Recent literature has questioned the benefits of this treatment because of the lack of proven efficacy and the risk of serious adverse effects. We evaluated the effectiveness of Kayexalate for treatment of patients with hyperkalemia in our institution.

Methods: Electronic medical records were reviewed for all patients in our institution with potassium levels > 6.0 mmol/L between January 1, 2012 and December 31, 2014. Records were extracted for hyperkalemia treatment and outcomes. Hyperkalemia treatments included albuterol, diuretics, insulin, lactulose, sodium bicarbonate, and Kayexalate. Comparisons between hyperkalemia treatments with Kayexalate and without Kayexalate were made using t-tests.

Results: One-third of patients diagnosed with hyperkalemia were treated with Kayexalate. Post-treatment potassium values decreased by 14.8% in treatment with Kayexalate, compared to 17.4% reduction in treatment combinations without Kayexalate (p = 0.46). No patients suffered serious adverse effects from Kayexalate treatment.

Conclusions: In our population, treatment of hyperkalemia with Kayexalate was common. While no adverse events of treatment were noted, there was no significant difference in reduction of potassium levels with it. We conclude that there is insufficient evidence to support routine use of Kayexalate in our population.

PUB458

The Impact of Hyponatremia on Children: Prevalence and Consequences During Hospitalization Zachary Sartor, Poonam Thakore, Tetyana L. Vasylyeva. *Pediatrics, Texas Tech Univ Health Sciences Center, Amarillo, TX.*

Background: Hyponatremia in adults is associated with increased morbidity and mortality, but this association has not been explored in pediatrics. The aim of this study is to characterize the prevalence of hyponatremia and assess its impact on the course of hospitalization in pediatric patients.

Methods: Patients who were admitted to the TTUHSC pediatric service at Northwest Texas Hospital in Amarillo, TX from January through December 2012 were considered for retrospective chart review. Patients were divided into 3 diagnosis groups: bronchiolitis, asthma exacerbation, and gastroenteritis. Other diagnoses and patients without serum chemistries were excluded. Age, sex, and serum sodium levels were documented. The number of days admitted were also recorded. Hyponatremia was defined as mild if the sodium was 130-135 mEq/L, moderate if 125-129 mEq/L, or severe if <125 mEq/L. Prevalence was calculated. Prevalence was determined to be statistically significance by comparing sodium levels between patients with hyponatremia and those with normal sodium levels. All patients were then grouped together, and length-of-stay (LOS) was compared between those with hyponatremia and those with normal sodium. The analysis for prevalence and LOS was performed using a two-tailed, unpaired t-test with a p <0.05 used for significance.

Results: Overall, 416 patients were admitted to the inpatient service during the study period. After exclusion,128 patients with bronchiolitis, 137 patients with asthma exacerbation, and 69 patients with gastroenteritis were available for analysis. There were 24 cases of hyponatremia in the bronchiolitis group (18.75% prevalence),8 cases in the asthma exacerbation group (5.84% prevalence), and 18 cases in the gastroenteritis group (26.09% prevalence). There was one case of moderate hyponatremia in the bronchiolitis group, otherwise all other cases involved mild levels of hyponatremia. LOS was increased for patients with hyponatremia (2.33±0.11 days versus 4.26±0.71 days, p=0.01).

Conclusions: Hyponatremia was prevalent at an overall rate of 15% during the study period. Hyponatremia was associated with increased hospitalization at a statistically significant level.

PUB459

Disorders of Plasma Sodium in Hospitalized Patients and Effect of Total Plasma Protein Concentration on Its Measurement Pedro J. Labrador, Silvia Gonzalez S, Santiago Polanco Candelario, Elena Davin Carrero, Jesús P. Marin, Ines Castellano, Juan R. Gomez-Martino. *Nephrology, San Pedro de Alcantara Hospital, Caceres, Spain.*

Background: The aim of the study was analysed the prevalence of hyponatremia in hospitalized patients, and the effect of total plasma protein (TPP)concentration on plasma sodium (Na) measurements.

Methods: We registered all biochemical analysis from in-hospital patients during one year. Data from age, sex, and department was recorded. Plasma Na was measured by an indirect ion selective electrode measuring system (Cobas 8000 analyzer, Roche Diagnostics). Hyponatremia was considered when plasma Na was lower than 135 mmol/L. Hyponatremia was classified based on plasma Na concentration. Mild hyponatremia was defined as 130-134 mmol/L, moderate as 125-129 mmol/L and profound as lower than 125 mmol/L. When TPP was measured, plasma Na concentration was corrected according to: a) Plasma Na = indirect Na x 93 /(99.1 – (0.7 x TPP concentration)); and b) Plasma Na= indirect Na + 0.7 x (TPP concentration – 10).

Results: Our hospital is a 520 in-hospital beds. Plasma Na was measured in 26.904 biochemical analytics from 6.873 patients. Median age was 67 (IQR 50-79). 55.9% were men. Median plasma Na measurements was 5 (IQR 2-11). Hyponatremia was present in 1.514 patients (22%), mild hyponatremia 1.114 (16.2%), moderate 287 (4.2%) and profound 113 (1.6%). Plasma Na could be corrected to TPP in 3.122 patients, using the first formula hyponatremia was present in 29.4% (mild 19.6%, moderate 6.8% and profound 3%) while using the second one, 27.9% (mild 18.7%, moderate 6.4% and profound 2.8%). Kappa index for hyponatremia diagnostic between measured plasma Na and corrected to TPP was 0.7 and 0.74 (p<0.001). Hyponatremia prevalence was increased in Onco-Haematology (49.7%), General surgery (42%), Nephrology (37.1), Pulmonary (35.1%), Urology (34.2%), Neonatology (32.8%), Digestology (32%), Orthopedic surgery (30.3%), and Internal medicine (28.4%).

Conclusions: Hyponatremia is present in one fifth of in-hospital patients. Correction of plasma Na concentration according to TPP concentration increase hyponatremia diagnostic up to 25%.

PUB460

An Unusual Cause of Hypokalemia Mohamad A. Hanouneh,[1] James F. Simon.[2] *[1]Internal Medicine, Cleveland Clinic, Cleveland, OH; [2]Glickman Urologic and Kidney Inst, Cleveland Clinic, Cleveland, OH.*

Methods: A 59-year-old woman presented as a self-referral for a second opinion regarding hypokalemia.She had long-standing resistant hypertension currently treated with metoprolol, lisinopril and amlodipine. Four weeks ago she began experiencing hypotension. She claimed a history of edema treated with diuretics, including metolazone stopped one month prior and amiloride which was stopped one week prior.She denied taking any furosemide in the past 2 years.She complained of occasional orthostatic symptoms.Physical examination revealed orthostatic hypotension and no edema.Work-up revealed normal free serum cortisol, elevated plasma renin activity of 36.5 ug/L/hr (0.8-5.8 ug/L/hr) and serum aldosterone level of 76. ng/dL (3.1-35.4 ng/dL). Adrenal glands appeared normal on CT.24-hour urine studies suggested renal potassium wasting (sodium 310 mmol/24 hour without a sodium load, potassium 38 mmol/24 hour, chloride 269 mmol/24 hour).Repeat chemistry done at the same time showed a serum creatinine of 2.2 mg/dL compared to 1 mg/dL 4 weeks prior, potassium level of 3.1 mmol/L.She was admitted for acute kidney injury. After receiving 2 liters of 0.9% saline IV, blood pressure stabilized and creatinine returned to 1mg/dL.She remained hypokalemic.Repeat labs after IVF showed plasma renin activity of 5.3 ug/L/hr and aldosterone of 15.0 ng/dL.Urine diuretic screen drawn while admitted was positive for furosemide, consistent with diuretic abuse .This patient's initial complaint of difficult to control hypertension and hypokalemia suggested a primary disorder of the renin-angiotensin system.However, hypotension upon presentation conflicted with this and was more consistent with a tubular wasting disorder such as Bartters or Gitelman syndrome or diuretic abuse, the last of which was most likely in this clinical situation.Suppression of both renin and aldosterone secretion after IVF confirmed the initial abnormalities were due to volume depletion.

Conclusions: Diuretic abuse should be considered when patients present with hypotension and hypokalemia. This case provides a rare insight into physiologic response of the renin-angiotensin system to diuretic abuse and volume resuscitation.

PUB461

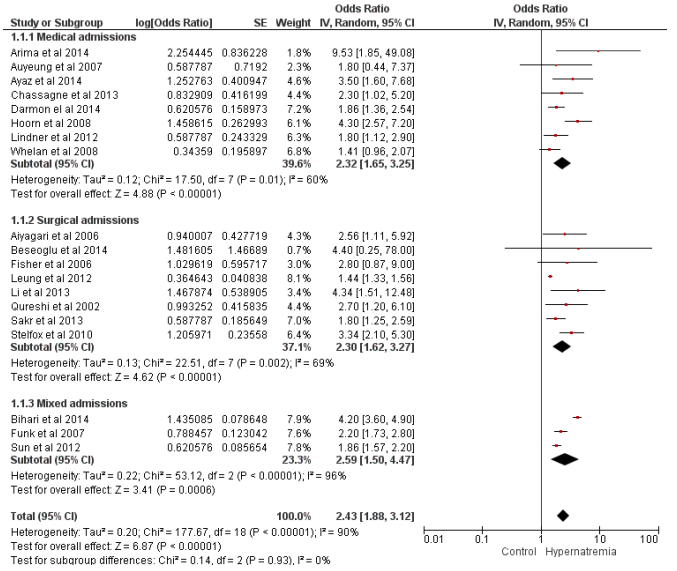
Hypernatremia During Hospitalization Is Associated with Increased Risk of Death: A Systematic Review and Meta Analysis Yorg Al Azzi, Rabi Yacoub, Samira S. Farouk, Ioannis Konstantinidis, Girish N. Nadkarni, Steven G. Coca. *Icahn School of Medicine at Mount Sinai, NY.*

Background: While hyponatremia is the more common dysnatremia compared to hypernatremia, and hyponatremia has been independently associated with mortality in several studies, some analyses have suggested that hypernatremia portends a worse prognosis. Robust estimates regarding the excess hospital mortality associated with hypernatremia across different inpatient settings are lacking. We sought to quantitatively synthesize the available evidence.

Methods: We systematically searched PubMed, EMBASE and Cochrane Central through May 2015, and selected studies using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) checklist. We analyzed studies reporting risk for

mortality adjusted for patients' characteristics and co-morbid conditions. We used random effects meta-analysis to derive pooled estimates of effect in medical, surgical and mixed admission settings.

Results: We evaluated 135 full text publications from 10,215 reviewed abstracts, of which 32 studies met the inclusion criteria (19, 13, and 5 reported aOR, proportion and both respectively). Patients with hypernatremia were at increased risk of hospital mortality (OR=2.59, 95% CI 1.5-4.47, P<0.001).



There was no difference in mortality risk between medical, surgical and mixed admission (P=0.9). Comparison of studies based on severity of hypernatremia revealed a small dose effect [(OR=2.23, 95% CI 1.64-3.04, P<0.001 for Na³145) and (OR=2.84, 95% CI 2.02-4, P<0.001 for ³150 mg/dl]. Analysis of proportion revealed higher odds of mortality (OR=5.48, 95% CI 3.66-8.21, P<0.001).

Conclusions: Admission with serum Na of ³145 mg/dl is significantly associated with twice the odds of hospital mortality. Protocols towards increasing awareness of hypernatremia and studies evaluating the efficacy of early intervention are warranted.

Clinical Features of Reported Ethylene Glycol Exposures in the United States Meghan A. Jobson,[1] Susan L. Hogan,[1] Yichun Hu,[1] Gerald A. Hladik,[1] Ronald J. Falk,[1] Michael C. Beuhler,[2] William Franklin Pendergraft.[1] *[1]Div of Nephrology and Hypertension, Dept of Medicine, UNC Kidney Center, Chapel Hill, NC; [2]Carolinas Poison Center, Carolinas Medical Center, Charlotte, NC.*

Background: Ethylene glycol is highly toxic and represents an important cause of poisonings worldwide. Toxicity can result in central nervous system dysfunction, cardiovascular compromise, elevated anion gap metabolic acidosis and acute kidney injury. Many states have passed laws requiring addition of the bittering agent, denatonium benzoate, to ethylene glycol solutions to reduce severity of exposures. The objectives of this study were to identify differences between unintentional and intentional exposures and to evaluate the utility of denatonium benzoate as a deterrent.

Methods: Using the National Poison Data System, we performed a retrospective analysis of reported cases of ethylene glycol exposures from January 2006 to December 2013. Outcome classification was summed for intentionality and used as a basis for comparison of effect groups.

Results: There were 45,097 cases of ethylene glycol exposures resulting in 154 deaths. Individuals more likely to experience major effects or death were older, male, and presented with more severe symptoms requiring higher levels of care. Latitude and season did not correlate with increased exposures; however, there were more exposures in rural areas. Denatonium benzoate use appeared to have no effect on exposure severity or number.

Conclusions: Deaths due to ethylene glycol exposure were uncommon; however, there were major clinical effects and more exposures in rural areas. Addition of denatonium benzoate was not associated with a reduction in exposures. Alternative means to deter ingestion are needed. These findings suggest the need to consider replacing ethylene glycol with alternative and less toxic agents.

PUB463

OTC Medication Leading to Chronic Salicylate Toxicity Muhammad Deen, Roohi Khan. *Nephrology, CHI St. Luke's Health, Houston, TX.*

Background: OTC medication containing salicylate leading to intoxication.

Methods: 60 YO F with PMH significant for chronic migraines, PUD s/p partial gastrectomy, presented to the ED with complains of nausea, vomiting, AMS, confusion and lethargy along with headaches, tinnitus and decreased bilateral hearing. Patient was found to be tachypnic, diaphoretic with respiratory alkalosis and anion gap metabolic acidosis with normal renal function.

Vitals: BP 114/67mmHg, Pulse 90/min, Temp 97.6 °F, RR 22/min and SpO2 100%.

Examination: Unremarkable examination except AMS.

Labs: Na 133mEq/L, K 3.1 mEq/L, Cl 103 mEq/L, C02 12 mEq/L, BUN 10 mg/dl, Cr 0.8 mg/dl, venous lactate 8 mg/dl and ethanol <10 mg/dl. VBG: pH 7.5, pCO2 13 mmHg and pO2 49mmHg and HCO3 11 mmHg.

Imaging: CT head -NAF. Review of medication: Unremarkable for toxic medication. On further discussion with family, it was found that patient had been taking BC powder for her chronic headaches. Hence salicylate levels were drawn and found to be 75 mg/dl thus leading to the diagnoses of chronic salicylate toxicity.

Treatment:Medical management was initiated with IV fluid containing bicarb. In the following days patient's condition gradually improved and labs revealed salicylate level < 8.

Conclusions: Chronic salicylate intoxication is most common in the elderly. Increased toxicity in older patient often appears due to inadvertent over dosage. Dual prescribing or additional use of non prescription OTC salicylates are some causes of unwitting long term toxicity. Chronic intoxication often poses a diagnostic dilemma with atypical presentation mimicking other disease states. The diagnosis of salicylate intoxication should be borne in mind when an older patient presents with recent deterioration in ADL with no known cause. Plasma salicylate concentration should be measured if salicylate toxication is suspected, even if there is no documented history of salicylate ingestion. Chronic toxicity, which can occur even with marginally high salicylate concentrations is treated with drug withdrawal and supportive therapy. It can be averted by prescription of conservative doses of drugs, avoidance of concomitant use of different salicylate preparations, and therapeutic monitoring to guide dosage.

PUB464

Diagnostic Workup of Hyponatremia in Hospitalized Patients: Does Education Have an Impact? Faraj Kargoli, Ladan Golestaneh. *Dept of Nephrology, Montefiore Medical Center, Bronx, NY.*

Background: Hyponatremia is associated with poor outcomes. Studies show that hospitalized hyponatremic patients seldom get adequate diagnostic workups. This study tests the effects of a CME activity on physician's behavior in the diagnostic workup of hyponatremia.

Methods: This is a cross sectional analysis of patients admitted to the Internal medicine department at Montefiore Medical Center between 05/01/2014 and 12/01/2014. Demographic and clinical data were collected retrospectively. Patients were included if they were admitted under the service of 24 hospitalist attendings. These attendings were chosen based on their participation in a CME activity (lecture based). This activity was implemented to improve hyponatremia workup as defined by the frequency of the following orders: serum osmolality, urine osmolality, and urine sodium. Hyponatermia was defined as the earliest serum sodium less than 135 meq/dL. There was further subclassification into three groups based on the severity: mild: 130-135 meq/dL, moderate: 125-130 meq/dL and severe: less than 125 meq/dL. Frequency of the diagnostic orders was stratified to before and after the activity.

Results: There were 358 patients with hyponatremia: 176 hyponatremia admissions occurred before the live lectures and 182 occurred after. Average age was 63yrs ±17, average length of stay was 5.2 days ± 2.9. The severity of hyponatremia was 82%, 14% and 3.4% for mild, moderate and severe, respectively. Forty eight percent of all patients who had hyponatremia at admission were discharged with hyponatremia. There was an increase in serum sodium between admission and discharge with a mean difference of 3.06 (95%CI, 2.6-3.5mg d/L), (P<0.0001). The frequency of all 3 orders was 3.2%, 19% and 50% in the cohorts, (p value <0.001). This frequency was 6% in the pre-activity cohort versus 8% post. More of the severely hyponatremic patients were discharged with hyponatremia than the mild or moderate (p<0.005).

Conclusions: Hyponatremia was underinvestigated in our cohort despite a formal educational exercise addressing better diagnostic workup. Further research is warranted to investigate the effect of CME activity on the treating physician behavior and patients outcomes.

Characteristics and Initial Outcomes of a Multidisciplinary Renal Genetics Clinic (RGC) Andrew John Mallett,[1,2,3] Helen G. Healy,[1,2,3] Julie M. Mcgaughran,[2,3,4] Melissa H. Little,[3,5,6] Chirag Patel.[2,3,4] *[1]Kidney Health Service & Conjoint Kidney Research Laboratory, Royal Brisbane & Women's Hospital, Brisbane, QLD, Australia; [2]School of Medicine, The Univ of Queensland, Brisbane, QLD, Australia; [3]Inst for Molecular Bioscience, UQ, Brisbane, QLD, Australia; [4]Genetic Health Queensland, RBWH, Brisbane, QLD, Australia; [5]Murdoch Children's Research Inst, Melbourne, VIC, Australia.*

Background: Genetic Renal Disease (GRD) accounts for 10% of adults and 50% of children with end stage kidney disease. Advances in molecular genetic diagnostic testing and multidisciplinary renal clinic models suggest opportunities for clinical redesign. Here we describe the initial characteristics, experience and outcomes of the first Australian multidisciplinary RGC.

Methods: A retrospective audit was undertaken of the RBWH Adult Conjoint RGC (1st year of operation; Aug'13-Jul'14). Each encounter involved a nephrologist, clinical geneticist and genetic counselor.

Results: 27/48 patients (56%) encountered had a known GRD, 9/48 (19%) had a suspected GRD and 12/48 (25%) had an unknown GRD with positive family history (FHx). Patients were most commonly referred by nephrologists (66%).The most common GRD category & diagnosis were cystic kidney disease (49%) and Autosomal Dominant Tubulointerstitial Kidney Disease (25%). Extra-renal features were associated with GRD in 26/48 (54%). During consultations differential diagnoses were explored (54%), management

advice provided (83%) and genetic counseling undertaken (79%). A genetic test was requested in 58.3%, most commonly being indicated for combined diagnostic and genetic counseling reasons (78.6%). Of 12 returned genetic test results, 7 were positive and 1 was a variant of uncertain significance. Two negative results have prompted additional genetic testing. Of 27 patients referred with a known GRD, 6 now have a new suspected GRD. The majority of those referred with either a suspected (6/9) or unknown GRD diagnosis (10/12) now have a new suspected or confirmed GRD.

Conclusions: These findings demonstrate the early successful operation of this RGC model including diagnostic and genetic counseling benefit. Future assessment of clinical outcomes and expansion to telehealth and paediatric settings is anticipated.

Characteristics and Clinicopathological Analysis of Japanese Nephronophthisis Patients

Keisuke Sugimoto,[1] Tomoki Miyazawa,[1] Takuji Enya,[1] Hitomi Nishi,[1] Kohei Miyazaki,[1] Hidehiko Yanagida,[2] Mitsuru Okada,[1] Tsukasa Takemura.[1] *[1]Pediatrics, Kindai Univ Faculty of Medicine, Osakasayama, Osaka, Japan; [2]Pediatrics, Sakai Hospital, Kindai Univ Faculty of Medicine, Sakai, Osaka, Japan.*

Background: Nephronophthisis (NPHP) accounts for 4 to 5% of end-stage renal disease (ESRD) occurring in childhood. Disease subtypes include infantile NPH, which progresses to ESRD around the age of 5 years. juvenile NPH, which develops from early childhood to school age and usually progresses to ESRD by an age of about 13 or 14 years; and adolescent NPH, with development of ESRD at an average age of 19 years. Juvenile NPH is reported to be the most common subtype.

Methods: We investigated clinical, histologic, and genetic features in 35 Japanese patients clinically and histologically suspected to have NPHP, aiming to promote early diagnosis. We studied many exons as many as 13 NPHP genes. Since such genetic analysis involves significant cost and time, we also screened biopsy specimens by immunohistologic methods employing antibodies against relevant peptides.

Results: NPHP occurred fairly uniformly throughout Japan irrespective of region or gender. In 3 families, NPHP affected siblings. The median age of patients was 12.5 years. Renal abnormalities attributable to NPHP discovered through mass screening, such as urine tests in school. However, NPHP accounted for less than 50% of children with abnormal findings, including incidentally discovered renal dysfunction during evaluation of extrarenal symptoms or during routine check-ups. Typical extrarenal manifestations leaded to discovery including anemia and delayed physical development. The urine often showed low gravity specific density and low-molecular-weight proteinuria. Frequent renal histologic findings included cystic dilation of tubules, mainly in the medulla, and irregularity of tubular basement membranes. Genetically abnormalities of *NPHP1* were not common, with large deletions frequently noted. Compound heterozygotes showing single abnormalities in each of *NPHP1*, *NPHP3*, *NPHP4* were observed.

Conclusions: Our findings resemble those reported in Western populations.

PUB467

The Functional Role of the ARHGAP32 L405V Mutation on Cytoskeleton

Guisen Li, Li Wang. *Nephrology, Sichuan Academy of Medical Sciences & Sichuan Provincial People's Hospital, Chengdu, China.*

Background: A site-directed mutagenesis for ARHGAP32 was developed to whether the mutation of ARHGAP32 has the effect on the related factors of cytoskeleton in vitro and to understand the functional role of ARHGAP32 in FSGS.

Methods: 1. (1) Blood DNA of 110 FSGS patients proved by renal biopsy were sequenced and screened for the mutation of ARHGAP32. (2) Total exons sequencing were performed in 28 DNA samples to find out whether mutation of ARHGAP32and other genes were existed. 2. (1) site-directed mutagenesis primers of ARHGAP32 was designed and amplified by PCR, obtainding the mutations of ARHGAP32 plasmids. (2) Transform the wild type and mutant plasmids of ARHGAP32 into Escherichia Coli respectively, sequenced the plasmids to identify whether the site-directed mutagenesis of ARHGAP32 was successful constructed. (3) Transfected the mutated plasmid of ARHGAP32 into 293T cells and thenverified by western blot and realtime RT-PCR. 3. (1) Detected the expression of ARHGAP32 in FSGS, IgAN, MN, minimal change disease and diabetic disease by IHC. (2) Detected the expression of CDC42 andβ-catenin by realtime RT-PCR and western blot in 293T cells which were transfected with the wild type and mutated plasmids of ARHGAP32. (3) Observed the expression of F-actin by immunofluorescence in the wild plasmid of ARHGAP32 and mutant type in COS7 cells.

Results: 1. (1) No mutation of ARHGAP32 was detected while 6 candidate genes were selected by sequencing all exons. 2. (1) ARHGAP32 gene was expressed mainly in glomerular in kidney tissue in all different pathologic types by IHC. (2) The expression of CDC42 andβ-catenin by realtime RT-PCR and western blot were no significant differences between the wild plasmid of ARHGAP32 and mutant type in 293T cells. (3) The distribution of F-actin was more significant in the wild type than that in mutant plasmid of ARHGAP32. It spreaded all the directions in wild type, while the distribution was scattered in mutant type.

Conclusions: 1 No mutation was detected in sporadic FSGS currently. 2 The mutation of ARHGAP32 had effect on the distribution of cytoskeletal protein of F-actin.

PUB468

Hyponatraemia and Fractured Neck of Femurs in a Geriatric Population: A Retrospective Analysis

Tamer Rezk, Krish Patel, Ashish Karir, Sashinie Tennekoon Jayasundera, Christine Sarah Catley, Abdelgalil Abdelrahman Ali, Sumith Abeygunasekara. *MEHT, United Kingdom.*

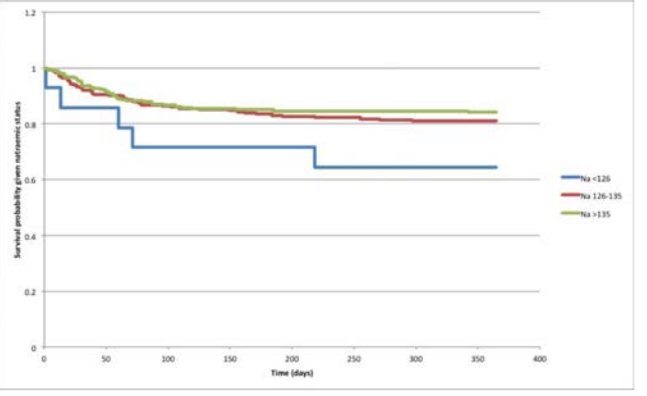
Background: Hyponatraemia is the commonest electrolyte abnormality found in elderly hospitalized patients defined as a serum sodium concentration <135 mmol/L with a mean prevalence of 5%. (NDT 2003; 18: 2486). It is a risk factor for fractures due to unsteady gait as well as osteoporosis and bone fragility. Fractured necks of femurs (NOF) are a significant cause of morbidity and mortality in the elderly with an estimated 24% mortality at 1 year (JAMA 2001; 285: 2736).

Methods: Retrospective analysis of 501 patients from fractured NOF database from 1/1/2014 to 31/12/2014 to identify the incidence and severity of hyponatraemia, Chronic Kidney Disease(CKD) Stage and mortality at 30 days and 1 year.

Results: Mean age was 83 years and M:F ratio of 1:3. Mild-moderate hyponatraemia was found in 48% of patients (serum sodium of 126-134mmol/L) with only 3% suffering with severe hyponatraemia (< 126mmol/L). 31% of patients had CKD Stage 3, 5% Stage 4 and 2% Stage 5. 30-day and 1-year mortality was 7% and 18% respectively. Patients were separated into 3 groups based on natraemic status

Natraemic status (mmol/L)	1 year survival (%)
<126 (severe)	0.643
126-134 (mild-moderate)	0.809
≥135 (normal)	0.841

Kaplan-Meier survival functions were calculated looking at 1-year mortality.



Those with hyponatraemia at the time of presentation appeared to have a worse 1-year survival. Log-rank test was performed. Using a chi-squared value of 3.521, a p value of 0.172 was obtained (not significant).

Conclusions: From our analysis it is clear that nearly half of patients on admission with fractured NOF have at least mild hyponatraemia with evidence to suggest reduction in 1-year survival. We propose more rigorous investigation of this subtle electrolyte disturbance in primary care which carries with it a significant morbidity and mortality.

PUB469

The Effect of Age on Mitochondrial Protein Levels in Rat Kidney Cortex and Medulla

Marianna J. Zamlauski-Tucker, Natalya Mezenina, Cameron M. Behringer. *Physiology & Health Science, Ball State Univ, Muncie, IN.*

Background: The present study was undertaken to determine the effect of rat age on total protein levels in mitochondria from kidney cortex and medulla.

Methods: Young (3 months of age) and Old (22 months of age) female Lewis rats were used. The kidneys were harvested from anesthetized rats after being perfused with isotonic saline via a catheter in the abdominal aorta. The kidneys were separated into cortical and medullary sections and homogenized in isotonic saline. Differential centrifugation was used to isolate the mitochondrial pellet. The mitochondrial pellet was dissolved in distilled water and spun again at 10,000 rpm to isolate the mitochondrial protein pellet. The mitochondrial protein pellet was dissolved in 1 ml of 0.1 M sodium hydroxide. The protein concentration of the sodium hydroxide solution was measured using the Lowry Protein Assay. The protein concentration was expressed as mg protein/g kidney wet weight. Differences were evaluated using a Student's t test.

Results: A significant decrease in the total mitochondrial protein level was observed in kidney cortex from Old rats. The total mitochondrial protein level in kidney medulla from Old rats was not significantly decreased.

		Young (n=5)	Old (n=5)
Mitochondrial Protein	Cortex	2.02 ± 0.42	0.59 ±0.30 *
mg/g kidney wet wt	Medulla	2.43 ±0.42	1.11 ±0.40

All data expressed as X ± SEM; * Significantly different from the Young

Conclusions: Total mitochondrial protein levels decrease in the cortex but not in the medulla of the rat kidney with age.

PUB470

Intradialytic Hemodynamic Stability and Functional Status Zubin T. Lathara, Aniko Szabo, Alexis Visotcky, Dawn F. Wolfgram. *Nephrology, Medical College of Wisconsin, Milwaukee, WI.*

Background: Prior research suggests that functional status in ESRD patients declines after initiation of dialysis, implicating the dialysis process in contributing to functional decline. We evaluated a dialysis-specific risk factor of intradialytic change in blood pressure (BP) in relation to changes in physical performance, a component of functional status.

Methods: We enrolled 29 dialysis patients age ≥ 50 years. Participants completed a 4m timed walk to measure gait speed both pre and post dialysis and a Falls Efficacy Survey, a measure of concern for falls. Dialytic variables included BP measurements from pre, post and during dialysis along with ultrafiltration rate. Demographics and comorbid data was collected. Analysis evaluated for association between dialytic BP variables and change in gait speed and score on Falls Survey. Multivariate analysis was done to adjust for age, race, sex, diabetes and congestive heart failure.

Results: 28 participants completed the study. The mean age was 62.7 (12.3) years. The majority were male (70.4%) and hypertensive (86.2%). Diabetes was present in 55.2%. The mean (SD) change in gait speed from pre to post dialysis was -0.1(0.1) m/s. The mean (SD) change in systolic and diastolic BP from pre to post dialysis was -10.6(25.8) mmHg and -4.6(10.5) mmHg, respectively. Participants with diabetes had greater intradialytic hemodynamic changes with mean (SD) change of SBP + DBP of -26.9(23.5) and -7.9(11.3) respectively. Univariate analysis showed that every 10mmHg decrease in systolic BP and every 5mmHg decrease in diastolic BP was associated with a change in gait speed of -0.01m/s ($p = 0.02$) and -0.02m/s ($p = 0.01$), respectively. This association was no longer significant in multivariate analysis, likely due to correlation of change in BP with diabetes status. There was no association between BP change and Falls Survey score.

Conclusions: Decline in physical performance, as measured by gait speed, can be seen post dialysis and is associated with hemodynamic changes during dialysis. Patients with diabetes may be most susceptible to hemodynamic changes. Improving dialytic hemodynamic stability may be a way to reduce the significant functional impairment that occurs post-dialysis.

PUB471

Sirtuin1 Expression in Kidney Tissue Specimens in Patients with IgA Nephropathy Cetin Ozener,[2] Izzet Hakki Arikan,[2] Ceren Ozcan,[1] Derya Guler,[2] Serhan Tuglular,[2] Deniz Filinte.[3] *[1]Internal Medicine, Marmara Univ Hospital, Istanbul, Turkey; [2]Nephrology, Marmara Univ Hospital, Istanbul, Turkey; [3]Pathology, Marmara Univ Hospital, Istanbul, Turkey.*

Background: SIRT 1 immunexpression in renalbiyopsy samples of the patients with IgA nephropathy were evaluated to identify the possible role of SIRT 1 on the pathogenesis of SIRT 1 in IgA nephropathy.

Methods: Twenty eight patients 28 patients (16 women, mean age 37±13.8 years) were included. Biopsy specimens of the patients were reevaluated according to Oxford Classification.Immunoexpression of SIRT 1, TNF-α, IL-10 and TGF-β were evaluated on kidney tissue specimens byimmunohistochemical staining.

Results: Older age, and higher serum creatinine and uric acid levelswere the predictors of a greater decline of the kidney function. There was a positive correlation between mesangialhypercellularity and uric acid levels. TGF-β (nuclear) and IL-10 (cytoplasmic) expressions were shown in 20 (%71.4) and 25 (%89.3) of the patients, respectively. Expression of the IL-10 was higher in patients who had a high average mesangialscore. Tubular and weak (1+) SIRT 1 expression was present only in 7 patients.

Age	37 ∓ 14
Gender(female/male)	16/12
BMI(kg/m2)	23.6 ∓ 2.6
Creatinine(mg/dl)	1.6 ∓ 1.5
Albumin(g/dl)	4.0 ∓ 0.6
Uric acid(mg/dl)	6.0 ∓ 2.2
Proteinuria(g/day)	2.4 ∓ 1.9
GFR(CKD-EPI)(ml/min)	74.6 ∓ 41.2
Hypertension,n(%)	13(46.6)
Macroscopic hematuria,n(%)	11(39.3)
Microscopic hematuria,n((%)	23(82.1)
Previous immunosuppressive therapy,n(%)	3(10.7)
Follow-up time (years)	4.8 ∓ 2.7

Table 1. Baseline demographic and laboratory data of thepatients (n=28)

Conclusions: A positive correlation was shown between mesangial hypercellularity with serum uric acid levels in the first time. These results suggest that SIRT 1does not play a direct role in the pathogenesis of IgAnephropathy.

Response of Human Primary Renal Proximal Tubular Epithelial Cells to Different LPS Strains Hong Wang, Margaret M. O'Neill, Carine Boustany, Steven S. Pullen. *CardioMetabolic Diseases Research, Boehringer Ingelheim Pharmaceuticals, Ridgefield, CT.*

Background: Toll-like receptors are expressed on leukocytes and renal tubular epithelial cells where they regulate immune responses. Recent evidence has implicated renal TLR4 signaling in the pro-inflammatory response in diabetic nephropathy. Ligands for TLR4 include lipopolysaccharide (LPS) and HMGB1. We sought to explore the response of renal proximal tubular epithelial cells (PTEC) to different strains of LPS and HMGB1 as well as modulation by TLR4 antagonists.

Methods: The HK-2 human proximal tubular cell line was stimulated with 3 strains of LPS (S. minnesota, E. coli K12, E. coli 0111:B4) and HMGB1. Primary human PTEC were stimulated with 5 strains of LPS (S. minnesota, E. coli 0111:B4, E. coli 055:B5, E. coli K12, S. typhosa)and HMGB1. Supernatants were harvested and IL-1β, IL-6, IL-8, TNFα, and MCP-1 were detected.TLR4 antagonists EX 76233 and EX 76824 were tested for the ability to modulate cytokine production induced by LPS stimulation.

Results: In HK-2 cells, LPS from E. coli 0111:B4 induced IL-6 and IL-8 production, whereas, S. minnesota and E. coli K12 did not stimulate cytokine production. In PTEC, IL-6 and IL-8 production increased upon S. typhosa, and S. minnesota stimulation. Other strains of LPS did not stimulate production of IL-6 and IL-8 in PTEC. There was little detectable production of IL-1β, TNFα or MCP-1 under the conditions tested in both PTEC and HK-2 cells. HMGB1 induced IL-8 production in PTEC whereas HK-2 cells did not produce of any of the cytokines or chemokines tested upon HMGB1 stimulation. The TLR4 antagonists EX 76824 and EX 76233 blocked cytokine production stimulated by S. typhosa in PTEC. EX 76824 inhibited IL-6 and IL-8 production stimulated by E. coli 0111:B4 in HK-2 cells.

Conclusions: Primary PTEC have unique responses to different strains of LPS, and this response profile differs from that of the HK-2 cell line. HMGB1 induced IL-8 production in PTEC, whereas HK-2 cells did not respond to HMGB1 stimulation. These results highlight a limitation of using the HK-2 cell line in lieu of primary PTEC for interrogating the role of TLR4 in renal inflammation.

PUB473

Assessment of Serum Transforming Growth Factor-Beta 1 in Patients with Diabetic Nephropathy Om Prakash Kalra,[1] Avanish Shukla,[1] Ashok Kumar Tripathi,[2] Alpana Raizada.[1] *[1]Medicine, UCMS & GTB Hospital, Delhi, India; [2]Biochemistry, UCMS & GTB Hospital, Delhi, India.*

Background: Diabetes mellitus is the leading cause of chronic kidney disease (CKD) worldwide. The pathogenesis and initial molecular events leading to diabetic nephropathy are still elusive. Chronic low grade inflammation plays an important role in pathogenesis of diabetic nephropathy. Ubiquitous cytokines like transforming growth factor-beta (TGF-β) function in an autocrine or paracrine fashion to elicit extra cellular matrix (ECM) accumulation and cellular hypertrophy in several cell types. TGF-β may play an important role in the pathogenesis of diabetic nephropathy by influencing ECM accumulation.

Methods: This was a case control, cross sectional study. 75 subjects aged 30– 65 years of either sex were recruited and divided into three groups: Group I: healthy controls (n=25), Group II: patients of T2DM without nephropathy (n=25), Group III: patients of T2DM with nephropathy(n=25). Detailed history, complete physical examination, routine investigations, urine albumin creatinine ratio (ACR) estimation was done. Serum levels of hs-CRP and TGF-b1 were estimated by ELISA.

Results: A statistically significant difference in serum TGF-b1 and hs-CRP levels was observed between all the 3 groups ($p<0.001$), where highest levels were found in group III and lowest in group I. A positive correlation was observed between serum TGF-b1 and duration of diabetes, FBS, PPBS, HbA_1c levels, serum creatinine, urinary ACR and serum hs-CRP. Similarly serum hs-CRP levels positively correlated with the duration of diabetes, FBS, PPBS, HbA_1c levels, serum creatinine, and urinary ACR. Serum TGF-b1 and serum hs-CRP showed negative correlation with eGFR.

Conclusions: Overall, TGF-b1 and hs-CRP levels were significantly higher in diabetics as compared to non-diabetic subjects. They were higher in diabetic subjects with nephropathy as compared to those without nephropathy. Serum TGF-b1 and hs-CRP levels in diabetic subjects appear to be dependent on duration of diabetes, glycemic control and degree of renal dysfunction. Thus cytokines like TGF-β may play a role in the etiopathogenesis of diabetic nephropathy.

PUB474

Daptomycin Antibiotic Lock Therapy for Hemodialysis Patients with Gram-Positive Bloodstream Infections following Use of Tunneled, Cuffed Hemodialysis Catheters. Retrospective Single Center Analysis

Hung-Wen Yen, Szu-yuan Li. *Dept of Medicine, Div of Nephrology, Dept of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan.*

Background: Catheter-related blood stream infection (CRBSI) is a major complication in hemodialysis patients. We assessed the efficacy of systemic daptomycin (DPT) plus DPT antibiotic lock therapy (DPT-ALT) for catheter-salvage in patients with Gram-positive CRBSIs.

Methods: Study Design: Retrospective study of hemodialysis patients with tunneled, cuffed hemodialysis catheters. **Setting** & **Participants:** All patients were from a single institution in Taipei and received systemic DPT plus DPT-ALT for treatment of Gram-positive CRBSI. **Outcome:** Successful resolution of CRBSI. **Measurements:** Resolution of fever within 48 h, negative result of repeated blood cultures after resolution of fever, no clinical evidence of CRBSI relapse, and no need for catheter removal.

Results: Fifteenhemodialysis patients received DPT-ALT for CRBSI, 9 with coagulase-negative *Staphylococcus* (CONS), 2 with methicillin-resistant *Staphylococcus aureus* (MRSA), 3 with methicillin-sensitive *Staphylococcus aureus* (MSSA), and 1 with polymicrobial infections. Systemic DPT plus DPT-ALT cured 11 patients (73.3%). Treatment failed in all 3 MRSA cases (2 with MRSA and 1 with MRSA + *Enterococcus faecalis*).

Fever	15 (100.0%)
Microorganisms	
CONS	9 (60.0%)
MRSA	2 (13.3%)
MSSA	3 (20.0%)
Polymicrobial infection	1 (6.7%)
Outcome	
Success	11 (73.3%)
Relapse	0 (0%)
Failure	4 (26.7%)
Infection attributable mortality	4 (26.7%)
Success in Subgroup Analysis	
CONS	8 (88.9%)
MRSA	0 (0%)
MSSA	3 (100%)

Conclusions: Systemic DPT plus DPT-ALT appears to be a promising treatment for CRBSI from CONS and MSSA, but not for MRSA CRBSI. Systemic DPT plus DPT- ALT should be considered for patients with CRBSIs caused by certain species.

PUB475

The Association of the Type of Vascular Access and Erythropoitin Dose in Maintenance Hemodialysis Patients with Targeted Hemoglobin Level

Fangping Lu.[1] *[1]Nephrology, First Hospital of Tsinghua Univ, Beijing, China; [2]Blood Purification, Beijing Chaoyang Hospital, Beijing, China; [3]Nephrology, The Third Hospital of Beijing Hospital, Beijing, China.*

Background: Both patients with central venous catheter(CVC) and higher doses of erythropoitin(EPO) are at increased risk of mortality in hemodialysis patients, but very limited studies involved the relationship. The present retrospective study aimed to investigate the association between the type of vascular access and EPO dose in MHD patients with targeted hemoglobin level.

Methods: We selected sixty-one patients among 711 MHD patients met inclusion criteria from January 2014 to June 2014 from three hospitals in Beijing, China and compared the difference of EPO dose between arteriovenous fistula(AVF) and CVC group. Inclusion criteria: MHD treatment for >6 months with 3 sessions per week, at least 18 years of age, no malignant disease or obvious infection or active immunological disease, no gastrointestinal bleeding, no severe iron depletion, no blood transfusions within 3 months before inclusion, stable hemoglobin level(100-120g/L for consecutive 3 times within 6 months), and unchanged vascular access and EPO adjustment for 6 months.

Results: There were 32 AVF and 29 CVC patients. There were no difference of KT/V,serum ferritin, albumin, iPTH and CRP level between AVF and CVC patients . The mean total EPO dose (8793.10±2664.31vs 7039.06±3651.79 iu/week,p=0.035).Standerised mean EPO dosage (IU/kg body weight/week)were significant higher in CVC patients compared with AVF patients(160.30±58.89 vs 118.02±70.06,p=0.013. It had been associated with increase in total weekly erythropoietin dose by 24.9% in CVC patients.

Conclusions: The findings of this study suggest that CVC patients need more EPO dose compared with AVF patients within targeted hemoglobin level. It is to further illustrate the importance of priority of AVF .

Trans Radial Access for Percutaneous Treatment of Arteriovenous Fistula Thrombus – 2 Cases

Cinthia Sobral Vieira,[1] Enio Ziemiecki Junior,[2] Eduardo Ferreira Medronha,[2] Heloísa Maria Chagas Rego,[2] Maurício Da Silva Telles.[1] *[1]Hemodialysis Unit, Hospital Ernesto Dornelles, Porto Alegre, RS, Brazil; [2]Intervention Radiology Service, Hospital Ernesto Dornelles, Porto Alegre, RS, Brazil.*

Background: Arteriovenous Fistula (AVF) is considered to be the preferential access for patients needing hemodialysis. It is called the "line of life" for these patients. Complications may occur even in autologous AVF or grafts (PTFE). Stenosis is the most frequent complication. Therefore thrombosis is the medical urgency. They are responsible for high morbidity, mortality, hospitalizations, interruption of the treatment and access loss. The patient must go to angiography study immediately. We want to show that endovascular percutaneous technique with transluminal angioplasty through trans radial access (TRA),results in quick recovery, particularly in AVF thrombus.

Methods: case 1: a 62 y.o. man with right medium radial AVF, for 3 y, started having AVF ache and missed the fistula thrill 48 h after dialysis. It took 45min. to realize the exam. **Case 2**: a 81 y.o man, with a left brachiocephalic AVF, for 5 m. visited the ER with gastroenteritis, dehydration and loss of fistula fremitus (less than 24 h).

Results: In these cases, TRA were used with implant of a 6Fr with high compliant ballon angioplasty (Conquest,Bard Peripheral Company). The AVF was recovered without early or later complications.

Conclusions: Besides the small number of subjects and a follow up of 4 months with AVF patency, the TRA technique shows to be a good alternative, promising and very useful for AVF recovery, even without fibrinolytics in south Brazil. Contraindications must be observed like: intra cardiac shunt R/L, pulmonary hypertension, infected access, surgery in the last 30 days. The most traditional techniques use thrombolysis by accessing directly the occluded vein, angioplasty or mechanical thrombectomy which demands more time of Rx and contrast exposition, higher costs and hospitalization. This procedure does not need hospitalization. The success is dependent of early diagnosis of AVF thrombus, by the Nephrology staff. There must be a close relationship between the staffs: Nephrology and Intervention Radiology.

PUB477

Incidence and Risk Factors for Catheter Related Infections (CRI) and Their Antibiograms in Haemodialysis Patients – A South Indian Study

Shefali Gupta,[1] Shrikara P. Mallya.[2] *[1]Microbiology, SGPGIMS, Lucknow, India; [2]Microbiology, KMC, Mangalore, India.*

Background: Bacterial infections particularly *Staphylococcus* species often complicate the vascular access in dialysis patients. This study was aimed to determine the incidence and associated risk factors for catheter related infections in patients on maintenance hemodialysis in a tertiary Hospital in South India.

Methods: Eighty-seven hemodialysis patients (56 M; 31 F) were enrolled in the study. After insertion of dual lumen catheter, patients were followed up till its removal. Nasal swabs were also collected before insertion. At each dialysis session, catheters were examined for any evidence of local infection or sepsis. In case of suspicion, local pus swab, blood culture samples and the catheter tip were sent to microbiology laboratory and patients were empirically administered vancomycin. Data obtained was examined for relationship of CRI with clinical and socio-demographic risk factors.

Results: Fifty–three catheters (61%) showed colonization(>15 CFU). Twenty four (45.2%) catheter tips were found to be colonized by *S. aureus*, 9 (17%) by *P. aeruginosa*, 5 (9%) by *Acinetobacter*, 4 (7.5%) by *Enterobacter*, 3 (5.6%) by *Klebsiella*, 2 (3.7%) each by *E. coli* and *Citrobacter* spp and one (1.9%) each by *S. epidermidis*, *S. maltophilia* , *S. marcescens* and *C. albicans*. Bacteremia was positive in 18(20.7%) patients and *P. aeruginosa* was the organism isolated in 7(38.8%) episodes. Staphylococcal nasal carriage was seen in 60 (69%) patients, and 36(41.4%) of these isolates were MRSA. Positive Statistically significant factors associated with CRI included history of bacteremia, presence of diabetes mellitus, long duration (>15 days) of catheterization and antibiotic use within 3 months ($p < 0.05$ for all). However, the age, gender and staphylococcal nasal carriage did not correlate with increased risk of infection.

Conclusions: *P. aeruginosa* is the most common organism in catheter related bacteremia which may have a bearing on our current antibiotic policy. Also, early initiation of hemodialysis through fistula may help reduce the CRI rate.

PUB478

Analysis of Risk Factors of Death in Patients of Maintenance Hemodialysis with Tunneled Cuffed Venous Catheter Li Zhou, Min Shi, Ping Fu. *Nephrology/Medicine, West China Hospital of Sichuan Univ, Chengdu, Sichuan, China.*

Background: To analyze the causes of death in patients of maintenance hemodialysis with tunneled cuffed catheter,and explore the risk factors of death.

Methods: All patients of maintenance hemodialysis with tunneled cuffed venous catheter starting hemodialysis from January 1,2009 to December 1,2014 in West China hospital were included and observed till June 1,2015.The patients were divided into observation(death) and control group (survival).Multivariate logistic regression analysis was used.

Results: In total 94 hemodialysis patients who met the inclusion criteria, 24 cases died in the study period.The median age of dead patients was 73.4 years (51.5~96.4). The median time of hemodialysis was 19.20 months (3.17~56.27).Just 1 case replaced tunneled cuffed catheter for once. The main primary causes of renal disease were: diabetic kieney disease (DKD) 50.0%, chronic glomerulonephritis (CGN) 25.0%, hypertensive renal damage (HTN)12.5%. The main causes of death were as following: infection 29.2%, cardiovascular diseases (CVD) 25.0% , cerebrovascular diseases 12.5%. The median age of survival patients was 64.9 years (20.8~95.4). Nineteen cases replaced tunneled cuffed catheter for twenty three times in total. The main primary causes of renal disease were: CGN 54.3%, DKD 25.7%, HTN 4.3%, polycystic kidney disease 4.3%. Multivariate logistic regression analysis showed that elder age, infection, low serum albumin were risk factors of death. Replacement of tunneled cuffed catheter was not the risk factors for death.

Conclusions: The main causes of death of patients with maintenance hemodialysis by tunneled cuffed venous catheter were cardiovascular and cerebrovascular diseases and infection.Elder age, infection, lower level of serum albumin were risk factors of death in patients of maintenance hemodialysis with tunneled cuffed venous catheter. Replacement of tunneled cuffed catheter was not the risk factors for death. Funds: the National Key Technology R&D Program of China (No. 2011BAI10B08), ,Cost and Evaluation System Study on payment revolution for patient in chronic hemodialysis with insurance of Chengdu City (Chengdu Municipal Medical Insurance Bureau).

PUB479

Analysis of Vascular Access of Maintenance Hemodialysis Patients: A Single Center Retrospective Study Yuan Luo, Hong Ye. *Center for Kidney Disease, Second Affiliated Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: Vascular access is life line for maintenance hemodialysis patients. The main options for vascular access for hemodialysis patients are arteriovenous fistulas (AVFs), arteriovenous grafts(AVGs), and tunneled cuffed central venous catheters. Proper vascular access is associated with lower complications and costs, which could improve the survival rate. The aim of our study is to analysis the characteristics of vascular accesses of maintenance hemodialysis patients in our hemodialysis center.

Methods: Patients underwent maintenance hemodialysis in the blood purification center of our hospital from January 2010 to December 2014 were enrolled in this study. The demographic characteristics, duration of dialysis, types of vascular access and blood flow volume, as well as the patency rate of AVFs of these patients were collected and analyzed.

Results: Sixty percent of the maintenance hemodialysis patients were male and the mean age was 57.89±14.27 years old. More than 60% patients' initial vascular access was non-tunneled central venous catheters, only 20% applied AVFs as their initial vascular access. Vascular access types was as follows, 87.0% for AVFs, 3.5% for AVGs and 9.5% for tunneled cuffed central venous catheter. The cumulative patency rate of AVFs was 86.6%. The duration of primary patency was 29.00 (12.00, 68.00) months and the duration of the cumulative patency was 37.00 (12.75, 95.25) months. Fourteen patients applied AVG as their vascular access, of whom thromboembolism was the main complication. AVG thrombosis of three patients were treated using percutaneous interventions. Among the 294 patients applying non-tunneled central venous catheters, 5.4% have their catheters changed for more than 2 times and 66.7% have their catheters on the right internal jugular vein.

Conclusions: AVF is the leading type of vascular access in our dialysis center. The usage of tunnel cuffed central catheters is under 10%, while the usage rate of AVGs is increased. Non-tunneled central venous catheter is the main option for initial dialysis patients and the percentage of patients who prepared their AVFs ready before dialysis is still low.

Funding: Government Support - Non-U.S.

PUB480

Exchange Technique Using Over the Guidewire from Tunneled to Tunneled Hemodialysis Catheter Can Be Performed without Increasing Infection and Compromising Catheter Long Term Patency Hoon Suk Park, Min Seok Choi, Woo Jeong Kim, Sung Jun Kim, Byung Ha Chung, Hyung Wook Kim, Bum Soon Choi, Cheol Whee Park, Chul Woo Yang, Dong-Chan Jin. *Div of Nephrology, Dept of Internal Medicine, College of Medicine, The Catholic Univ, Korea.*

Background: Exchange over the guidewire technique does not require time for hemostatsis after removal and the temporary insertion of femoral HD catheter. It can also avoid additional new venipuncture that may be associated with the development of central vein stenosis later. However, some concerns of the increased risk of infection and bleeding after procedure cause to follow the de novo placement of the new tunneled catheter rather than exchanging over the guidewire.

Methods: From March in 2009 to March in 2013, 46 cases where the exchange from tunneled to tunneled catheter and 310 cases with de novo catheter placement were respectively assigned to exchange and de novo placement groups and these 2 groups were compared.

Results: Compared with the de novo placement group, the exchange group over the guidewire had a higher hemoglobin level (10.6 ± 1.7 g/dl vs. 9.5 ± 1.6 g/dl; $p < 0.001$), more females (69.6% vs. 48.1%; $p = 0.006$), more ESRD rather than AKI as a cause of catheter insertion (95.7% vs. 74.8%; $p = 0.002$). Both immediate complication rate including suturing at exit site for bleeding control (19.6% vs. 8.7%; $p = 0.02$) and late one including infection and catheter dysfunction (37.0% vs. 21.6%; $p = 0.02$) were higher in the exchange group. However, the catheter survival rates between two groups were comparable ($p = 0.58$) and multivariate Cox regression analysis for catheter survival showed the development of late complication was the only risk factor (odds ratio [OR] 1.391, 95% confidence interval [CI]: 1.017–1.901; $p = 0.039$) rather than the exchange procedure was not a risk factor (OR 0.878, 95% CI: 0.554–1.393; $p = 0.582$).

Conclusions: The exchange over the guidewire from a previous tunneled catheter to a new one should be positively considered and performed when the new tunneled catheter placement is required.

PUB481

The Exchange Technique Using Previous Venotomy Site Over the Guidewire from Non-Tunneled to Tunneled Hemodialysis Catheter Can Be Performed without Compromising Catheter Long Term Patency Woo Jeong Kim, Min Seok Choi, Hoon Suk Park, Sung Jun Kim, Byung Ha Chung, Hyung Wook Kim, Bum Soon Choi, Cheol Whee Park, Chul Woo Yang, Dong-Chan Jin. *Div of Nephrology, Dept of Internal Medicine, College of Medicine, The Catholic Univ, Korea.*

Background: The exchange from non-tunneled HD catheter to tunneled one over the guidewire using previous venotomy does not require time for hemostasis for a new tunneled catheter insertion after its removal. It also does not require a new venipuncture so that it can prevent additional vessel wall injury. However, some concerns that it may be associated with the increased risk of infection and bleeding after procedure prevent its application.

Methods: From March in 2009 to March in 2013, 47 cases where the exchange from non-tunneled to tunneled catheter and 310 cases with de novo catheter placement were respectively assigned to exchange and de novo placement groups and these 2 groups were compared.

Results: Compared with the de novo placement group, the exchange group over the guidewire were younger (61 ± 16 years vs. 66 ± 14 years; $p = 0.04$), had a lower platelet count (171478 ± 115942 mm^{-3} vs. 207896 ± 100929 mm^{-3}; $p = 0.03$), the lower incidence of DM (38.3% vs. 58.4%; $p = 0.01$), more AKI rather than ESRD as a cause of catheter insertion (42.6% vs. 25.2%; $p = 0.02$). The immediate complication rate including suturing at exit site for bleeding control was higher in the exchange group (19.1% vs. 8.7%; $p = 0.03$), but the late complication rate including infection and catheter dysfunction was higher in the de novo placement group (21.6% vs. 8.5%; $p = 0.04$). The catheter survival rates between two groups were comparable ($p = 0.35$). Multivariate Cox regression analysis for catheter survival showed the development of late complication was the only risk factor (odds ratio [OR] 1.495, 95% confidence interval [CI]: 1.045–2.139; $p = 0.028$) rather than the exchange procedure (OR 1.715, 95% CI: 0.991–2.968; $p = 0.054$).

Conclusions: The exchange over the guidewire from non-tunneled to tunneled catheter should be positively considered and performed when the catheter replacement of non-tunneled catheter with tunneled one is required.

PUB482

Analysis of Deep Venous Catheter-Related Infections in Hemodialysis Patients Yuan Zhang, Fei Deng, Daqing Hong, Li Wang. *Nephrology, Sichuan Academy of Medical Sciences & Sichuan Provincial People's Hospital, Chengdu, Sichuan, China.*

Background: Catheter-related infections are an ever-present risk in patients undergoing hemodialysis, and reports from Western countries have indicated their high prevalence. To analyze catheter-related infection rates in patients undergoing hemodialysis at the East Department of Sichuan Academy of Medical Science, Sichuan Provincial People's Hospital, Sichuan, China.

Methods: We cultured blood samples drawn from the catheters of 464 patients undergoing hemodialysis with deep venous catheters at our dialysis center between April 2011 and August 2013. We determined the type of pathogen, if present, and performed antimicrobial susceptibility tests. Data are presented as means ± standard deviation (SD). To analyze differences between two groups, we performed the c2 test. $P < 0.05$ was considered significant.

Results: Overall, 47 patients had catheter-related infections, including 41 patients with femoral venous catheters (9.9% of all patients with femoral venous catheters), and 6 had jugular venous catheters (12.0% of all patients with jugular venous catheters). There was no significant difference in infection rates between the two groups. Catheter blood cultures revealed 38 infections caused by Gram-positive bacteria, seven infections caused by Gram-negative bacteria, and two fungal infections. Three infections were caused by methicillin-resistant Staphylococcus aureus. Antimicrobial sensitivity tests revealed that Gram-positive bacteria were most sensitive to vancomycin, whereas Gram-negative bacteria were most sensitive to meropenem or imipenem.

Conclusions: The infection rates of patients with deep venous catheters undergoing hemodialysis were relatively high. Venous catheterization should be performed under strict sterile conditions, and arteriovenous fistulas should be established as early as possible.

PUB483

Utility of Arterio-Venous Fistula Flow and Doppler Ultrasound in the Prevention of Thrombosis of the Vascular Access Milagros Fernandez-Lucas, Fernando Caravaca-Fontan, Estefania Yerovi, Maria Delgado yagüe, Saul Enrique Pampa, Jose L. Teruel, Fernando Liano. *Nephrology, Hospital Univ Ramon y Cajal, Madrid, Spain.*

Background: A Multidisciplinary Unit for attention to the vascular access was established in our hospital in December 2010. The main role of the nephrologist consists in monitoring the functioning of the vascular access by determining the artery-venous flow (AVF) and undertaking the doppler ultrasound. The objectives for initiating this program were to reduce the thrombosis rate by diagnosis and treatment of a non clinically detected pathology and to decrease the percentage of patients with a tunnelled catheter.

Methods: The prevalence of haemodialysis patients on 31st December 2014 was 65 patients in the Hospital Unit and 90 patients in the Dialysis Center. In the Hospital Unit we supervise the functioning of the vascular access by measuring the AVF flow and we perform a Doppler ultrasound study if the flow is less than 500 ml/min, if there are significant decreases in comparison with previous controls or if there is any clinical dysfunction. The Dialysis Center uses first generation methods for monitoring (increase in venous pressure, pump flow decrease, recirculation) and requests the Hospital Unit to undertake a Doppler ultrasound study whenever there is any type of dysfunction.

Results: We have observed differences in the results between both centers: 1º Incidence of patients with a tunnelled catheter was lower in the Hospital Unit (14 vs 22%). 2º Thrombosis rate was 40% lower in the Hospital Unit (7,9 vs 12/100 patients-year). 3º Doppler ultrasound detected 25 patients with haemodynamically significant stenosis, confirmed by radiologic study, which were successfully treated.

Conclusions: The combined use of AVF flow measuring and Doppler ultrasound studies for monitoring the vascular access is an efficient method for reducing the rates of thrombosis and the number of tunnelled catheters due to the early detection of stenosis and its preventive treatment.

PUB484

Females Have Less Arteriovenous Fistula and More Grafts Compared to Men: Data from the Slovenian Renal Replacement Therapy Registry Jadranka Buturovic-Ponikvar, Jakob Gubensek, Vanja Persic, Rafael Ponikvar. *Dept of Nephrology, Univ Medical Centre Ljubljana, Ljubljana, Slovenia.*

Background: The aim of our study was to compare prevalence of arteriovenous fistula (AVF) and graft in female and male chronic hemodialysis (HD) patients.

Methods: Data on vascular access in prevalent HD patients on December 31, from 2009-2013, were analyzed, in addition to sex, age, dry body weight and blood flow (QB) during HD, from database of the Slovenian Renal Replacement Therapy Registry. The use of preoperative ultrasonography mapping before AVF and graft construction in standard practice in the country.

Results:

Year	2013	2012	2011	2010	2009
All HD (No)	1375	1361	1346	1375	1397
Males No	831	837	824	818	827
Males age (years)	64±14	64±14	63±14	63±14	63±14
Males % AVF	82.8	81.8	83.5	85.0	84.6
Males % grafts	7.0	7.1	5.0	5.5	4.5
QB (ml/min)	287±35	287±39	290±39	290±44	295±44
Females No	544	524	522	557	570
Females age (years)	67±16	67±15	67±15	66±15	65±15
Females % AVF	72.1	72.3	72.4	76.5	75.1
Females % grafts	9.2	7.9	7.5	7.5	7.7
QB (ml/min)	273±35	274±38	275±38	271±40	277±41

The difference between percentage of AVF comparing females and males is persistent and highly significant during the observation period ($p<0.001$), with females having less AVF. Females had persistently slightly more grafts. Males had higher mean dry body weight (77.1±16 kg vs. 64.7±14.7 kg, end of 2013, $p<0.001$). Although absolute blood flow during HD was higher in males, females had higher blood flow when standardised to body weight (4.41±1.05 vs. 3.83±0.83 ml/min/kg, $p<0.001$, end of 2013).

Conclusions: Female chronic HD patients have significantly less arteriovenous fistula and slightly more grafts compared to males, with the difference being persistent during five years. Blood flow during HD, when standardised to body weight, was significanly higher in females than in males. Potential clinical consequence of higher blood flow during HD in females should be explored. Strategies to increase arteriovenous fistula prevalence in females should be explored, including potential acceptance of AVF providing lower blood flow during HD.

PUB485

Analysis of Early Arteriovenous Fistula/Graft Management and Coexistence of Dual Hemodialysis Accesses: Etiology and Clinical Implications of Waiting Too Long to Intervene Neena Jube, Peter J. Mattingly, Syed S. Haqqie, Arif Asif. *Albany Medical College, Albany, NY.*

Background: A number of patients with newly created arteriovenous fistulae (AVF) require tunneled dialysis catheter (TDC) for dialysis until their AVF is deemed mature. Although data have emphasized that the AVF maturation period is 4-6 weeks long, providers often wait up to 6 months hoping the AVF will eventually mature. During this maturation period if dialysis is required, patients frequently use TDC and can experience complications associated with these devices. This retrospective study evaluated 43 ESRD patients with a maturing AVF who were dialyzing with a coexisting TDC placed within 3 months of AVF creation. The patient population was divided based on dual access (DA) duration: DA <42 days (n=10), DA=42-90 days (n=13), and DA>90 days (n=20). An analysis of DA duration and follow-up visits were performed. All patients had surgical follow up at least once within the first 42 days of AVF placement regardless of DA duration. Additionally, patients with DA duration greater than 90 days were evaluated consistently by a surgeon during this period suggesting that prolonged DA is not due to lack of surveillance. Despite this, patient with DA period of greater than 42 days had increasing propensity to undergo avoidable exposure to the risks of prolonged TDC use ($p<0.01$). Specifically patients with DA<42 days, DA=42-90 days, and DA>90 days were unnecessarily exposed to the risks of dual access for an additional 2.5, 11.7, and 46 days, respectively ($p<0.01$). This discrepancy between regular surveillance and delayed TDC removal raises concerns that there is a lack of timely intervention after assessment. A more thorough documentation of reasons for prolonged TDC use and analysis of such data are required to verify this hypothesis and get a better idea of etiology of delayed TDC removal.

Methods: Retrospective collection of data from outpatient dialysis units on patients who have AVF/Graft and TDC.

Results: The delayed TDC removal in patients with AVF/Graft raises the risk of infection in these patients with both devices.

Conclusions: TDC should be removed at an appropriate period once AVF/Graft are mature enough to be used.

PUB486

Gene Methylation Profile of Human Vein Tissues Taken at the Time of Surgery: Correlation with AVF Maturation Begoña Campos, Sonia Bhati, Nikhil Grandhi, Mario Medvedovic, Amy Pflum, Timmy C. Lee, Rino Munda, Prabir Roy-Chaudhury. *Univ of Cincinnati.*

Background: Early arteriovenous fistula (AVF) failure remains an important cause of hemodialysis vascular access dysfunction and a major impediment to the Fistula First initiative. Despite the magnitude of the clinical problem, there are currently no effective therapeutic interventions for early AVF failure. In order to better understand the cellular and molecular mechanisms involved in early AVF failure we have evaluated the gene methylation profile of venous segment tissue samples obtained at the time of AVF creation. DNA methylation of CpG islands (regions of the genome that are rich in cytosine and guanine sequences), influences gene expression (turns off the gene). An increasing number of diverse factors are now known to epigenetically regulate genes, including stress, inflammation, nutrition, metabolism, drugs and infection (all of which are prominent in the biological milieu of patients with CKD and ESRD). In this study we compare the overall methylation profiles of non-maturing AVFs at 6 months as compared to AVFs that are able to support dialysis.

Methods: gDNA was isolated from venous segments collected at the time of AVF creation. Deep sequencing technologies were used to identify genes with the greatest differences in methylation between the two groups. Gene networks focused on inflammation, oxidative stress and endothelial dysfunction were evaluated. Standard bioinformatic techniques were used to identify/interrogate both the gene list and the network analyses.

Results: We were able to identify approximately 300 genes that were significantly different in the overall methylation profiles of non-maturing AVFs at 6 months as compared to AVFs that were able to support dialysis.

Conclusions: Our results suggest that epigenetic regulation (DNA methylation) could play an important role in AVF maturation, and also in the identification of novel druggable targets. This latter point could result in the development of novel therapies for dialysis vascular access dysfunction as a whole.

PUB487

Development of a Uremic Pig Model of Arteriovenous Fistula Stenosis (AVF): A Surgical Approach Begoña Campos,[1] Yang Wang,[1] Carissa Nicole Lester,[1] Krishnanath Gaitonde,[3] Keith Louis Saum,[1] Sanjay Misra,[2] Prabir Roy-Chaudhury.[1,3] *[1]Univ of Cincinnati; [2]Mayo Clinic; [3]Cincinnati VA Medical Center.*

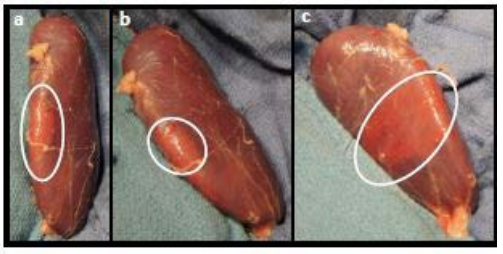
Background: AVF stenosis remains an important cause of hemodialysis vascular access dysfunction for which there are no truly effective therapies. We and others have previously described well characterized large animal models of AVF stenosis. An important flaw in these models is the lack of uremia, which increasingly has been shown to play an important role in the pathogenesis of AVF stenosis.

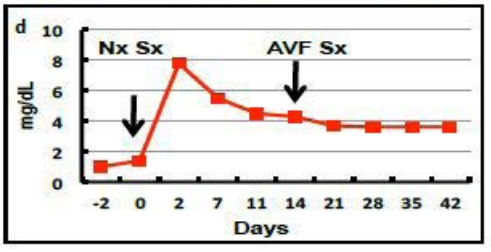
Methods: Chronic renal insufficiency was created by initially removing one of the kidneys through a midline incision. Following this the contralateral kidney underwent a dissection of the pelvis in order to expose the primary, secondary and if possible tertiary branches of the renal vasculature. A selective ligation of the renal vasculature in the pelvis,

which allowed for the viability of less than 20% of the renal mass on one side was then performed (upper figure = a, b and c). Of note the differential blanching/mottling of the kidney following ligature of vessels in the renal pelvis, allows us to perform a real time assessment in terms of the amount of viable renal tissue. BUN and creatinine estimations were then made biweekly for 6 weeks.

Results: The described surgical technique has allowed us to achieve a stable creatinine of 4 mg/dL over a four week period (lower figure = d). This stable period of uremia will allow us test out the impact of "downstream uremic vascular biology" on AVF maturation.

Conclusions: We have developed a unique, innovative and surgically created pig model of uremia with potential logistic and financial benefits. The availability of this animal model will put us in a unique position to be able to tease out the relative contributions of hemodynamics and uremia to AVF stenosis both in our experimental pig model and also in CKD and ESRD patients.





PUB488

Multimedia Education Tools for Dialysis Vascular Access Monitoring Tushar J. Vachharajani,[1] Claudia L. Poole,[2] Victoria L. Cash,[2] Joseph A. Vassalotti.[3] *[1]Nephrology, W. G. (Bill) Hefner VAMC, Salisbury, NC; [2]Fistula First Catheter Last Workgroup Coalition, ESRD National Coordinating Center; [3]Nephrology, Icahn School of Medicine at Mount Sinai & National Kidney Foundation, NY.*

Background: From 2005 to 2012, the Fistula First Breakthrough Initiative (FFBI) of the Centers for Medicare & Medicaid Services focused on improving the arteriovenous fistula (AVF) rate in the hemodialysis (HD) patients. Since the transition to Fistula First Catheter Last (FFCL) in 2013, the workgroup has created multimedia tools to help dialysis facilities and clinicians reduce the use of central venous catheters (CVCs) and further increase AVF use. The key focus for FFCL remains access planning, access monitoring, and prevention of access infection. Access monitoring involves use of physical examination (PE) and interpreting the findings whereas access surveillance involves measuring access blood flow or venous pressure.

Methods: Why access monitoring? PE is cheap, reproducible and easy to perform and implement before each HD treatment. Evidence supports PE as an effective tool to accurately detect access dysfunction and infection. However, in practice, PE is underutilized due to inadequate training and perception of it being a labor-intensive evaluation method. Access monitoring tools: FFCL tools are created to educate the patient and the multidisciplinary dialysis care team (DCT) with the ultimate goal of maintaining a functional access.

Results: Two separate toolkits available on the FFCL website (http://esrdncc.org/ffcl/) highlight patient-level and DCT-level education.Practical teaching guides to implement the evidenced-based PE include "Check Before You Connect" for CVC and "One Minute Check" for AV access, which target the DCT and patients. The multimedia toolkits focus on a "look, listen and feel" concept, are interactive and are easily accessible from any mobile device. Poster/handout formats are also available. The impact of these educational tools will be evaluated once these resources are widely utilized in clinical practice.

Conclusions: The purpose of this presentation is to achieve wider dissemination of these tools to narrow the gap between evidence and clinical practice.

PUB489

Multimedia Access Planning Tools to Attain Catheter Freedom Tushar J. Vachharajani,[1] Claudia L. Poole,[2] Victoria L. Cash,[2] Joseph A. Vassalotti.[3] *[1]W. G (Bill) Hefner VAMC, Salisbury, NC; [2]Fistula First Catheter Last Workgroup Coalition, ESRD National Coordinating Center; [3]Icahn School of Medicine at Mount Sinai & National Kidney Foundation, NY.*

Background: From 2005 to 2012, the Fistula First Breakthrough Initiative (FFBI) of the Centers for Medicare & Medicaid Services focused on improving the arteriovenous fistula (AVF) rate in hemodialysis (HD) patients. Since the transition to Fistula First Catheter Last (FFCL) in 2013, the workgroup has created multimedia tools to help dialysis facilities and clinicians reduce the use of central venous catheters (CVCs) and further increase AVF use. The key focus for FFCL remains access planning, access monitoring (physical examination) and prevention of access infection.

Methods: Why the need for change? FFBI Change Concepts over the past decade resulted in an increase in the AVF rate in the prevalent HD population from 23% to 61% of eligible patients. The impact on the incident HD population has remained suboptimal, with >78% HD patients initiating dialysis with a tunneled CVC. Moreover, the percentage of patients in the prevalent HD population with CVCs in use for 90 days or longer has remained stagnant. Access planning tools: FFCL tools are created to educate the patient and the multidisciplinary dialysis care team (DCT) with the ultimate goal of achieving freedom from CVC. Two separate toolkits available on the FFCL website (http://esrdncc.org/ffcl/) highlight patient-level and DCT-level education.

Results: The multimedia toolkits are interactive and easily accessible from any mobile device. Conventional handout/poster formats are also available. The impact of these educational tools will be evaluated once these resources are widely utilized in clinical practice. The primary goal is to develop and disseminate tools to educate and create awareness to increase AV fistula utilization to 68% of appropriate patients, decrease the use of long term catheters (≥90 days) to <10%. FFCL is currently collecting metrics on professionals that are aware and using these tools.

Conclusions: The purpose of this presentation is to achieve wider dissemination of these tools and increase awareness among patients/professionals.

PUB490

Cardiac Implantable Electronic Device Infection and Ipsilateral Arteriovenous Fistula in End Stage Renal Disease: Avoidance and Management of Complications Stephanie Lanoiselee,[1] Francois Babinet,[1] Guillaume Seret,[1] Helene Loubiere,[3] Achour Laradi.[1] *[1]Centre ECHO Nephrologie Dialyse, Le Mans, France; [2]Chirurgie Vasculaire, CH Le Mans, Le Mans, France.*

Background: Cardiovascular implantable electronic devices(CIEDs) are frequently utilized for management of cardiac dysrhytmias in patients(pts) with End Stage Renal disease(ESRD) and are associated with central venous stenosis resulting in adverse effects for existing or future arteriovenous fistula(AVF) with an increase risk of infection of both (CIEDs and AVF).We report the case of a pt with ESRD who experienced a potentially life-threatening complication related to his ipsilateral AVF and CIEDs.

Methods: We report the case of a 80 years-old male pt who developed a symptomatic unilateral left arm edema with skin lesions.He has past history of CIEDs four years ago and the ipsilateral implementation of a AVF 2 years after the CIEDS.He experienced 3 angioplasies on his AVF and a repeated surgery with a persistant post-anastomotic anastomosis with flow reduction of 180 ml/mn. A left side chest blood collateral circulation was also present.A deep veinous thrombosis related to the implementation of CIEDs was investiguated and a left subclavian venous thrombosis was confirmed.On the meantime infection of the CIEDs was suspected but non confirmed. An attempt of a venous recanalization was unsuccessful.A closure of AVF with a plug of 14mm diameter leading to a complete occlusion of AVF.

Results: After the occlusion of AVF we noticed a complete régressionof the huge left arm edema and a total recovery of the skin lésions.The pt underwent antiobiotics therapy for life for the CIEDs infection with succesful results two years after initiation of treatment.

Conclusions: Although the CIEDs can provide life-savings benefits, device associated complications needs careful mangement and should be placed by the epicardial approach as a first option for pts with ESRD.It remind us that the AVF is still the Achille's heel of dialysis.

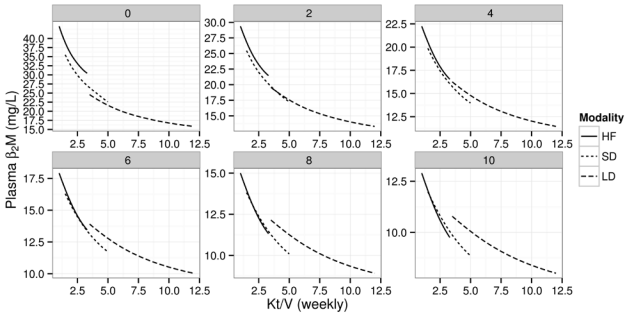
PUB491

Weekly Beta 2 Microglobulin (B2M) Kt/V, Residual Renal Function and Middle Molecule Levels in Daily Dialysis Christos Argyropoulos, Maria-Eleni Roumelioti, Mark L. Unruh. *Internal Medicine, Div of Nephrology, UNM-HSC, Albuquerque, NM.*

Background: B2M and residual renal function (RRF) are predictors of cardiovascular morbidity, mortality and LVH in ESRD. Daily dialysis leads to higher B2M removal and has been associated with improvements in LVH and mortality in randomized trials. It is not known whether kinetic measures of middle molecule adequacy are applicable to daily dialysis.

Methods: We adopted a population kinetic model (PKM) for the intraindividual variability in generation, distribution and extrarenal removal of B2M (ASN 2014,SA-PO969). We used the PKM to simulate B2M concentrations in 10000 patients dialyzed with HF membranes. We examined the intervention protocols for Short (SD), Long Daily (LD) and thrice weekly HF dialysis utilized in the FHN trials. Weekly B2M Kt/V was calculated as the sum of the Kt/V in each session. The impact of Kt/V relative to residual renal function (RRF) on B2M was examined across the three dialysis modalities averaging over the intra-individual variability of kinetic parameters and dialysis prescription.

Results: B2M was lower in SD and LD relative to HF irrespective of RRF. Given the variability in dialysis prescriptions there was a substantial overlap in the average Kt/V values between HF and SD.



There was a steep relationship between weekly Kt/V and B2M in all three modalities. The steepness of this relationship was similar between HF and SD across RRF values, but differed for RRF>4ml/min in LD. At any given level of Kt/V the B2M level depended on RRF and dialysis modality.

Conclusions: Weekly B2M Kt/V, a simple measure of middle molecule dialysis adequacy, tracks middle molecule exposure in conventional and daily dialysis. The interpretation of a given Kt/V value requires knowledge of RRF in all dialysis modalities. Future studies should determine whether RRF, dialytic Kt/V or both are predictors of survival in daily dialysis.

PUB492

A Test Battery to Establish Changes in Physical Performance and Protein Energy Wasting in Nocturnal Hemodialysis: The DiapriFIT Study Manouk Dam,[1] Floor Neelemaat,[1] Caroline E Douma,[3] Brigit C. van Jaarsveld.[2] *[1]Nutrition and Dietetics, VU Univ Medical Center, Amsterdam, Netherlands; [2]Nephrology, VU Univ Medical Center, Amsterdam, Netherlands; [3]Nephrology, Spaarne Gasthuis, Hoofddorp, Netherlands.*

Background: Nocturnal hemodialysis (NHD) improves volume control and phosphate and middle molecule removal. Observational data show increases in body weight and protein intake upon switching to NHD. Other aspects of protein energy wasting (PEW) remain underexposed and also little is known about functional outcomes, such as physical performance and muscle strength. Therefore, the aim of this study is to investigate whether physical performance improves and PEW decreases in patients who change from conventional hemodialysis (CHD) to NHD, compared to patients who continue their treatment on CHD.

Methods: The DiapriFIT study plans to include 25 patients on CHD (2-4x/wk, 3-4 hours) and 25 patients on CHD who switch to NHD (3-4x/wk, 8 hours) with 1-year physical performance and PEW as endpoints. They were submitted to a Visual Appetite Score (VAS), Handgrip Strength (HGS), upper arm circumference (UAC), Short Physical Performance Battery (SPPB) and 6 minute walk test (6MWT), baseline results are reported here. As in NHD weight increases, we tested associations of the outcome parameters with dry weight.

Results: At present, 23 patients were included, aged 58.3±16.0 years, 30.4% males, with a dry weight of 87.6±17.2 in males and 74.3±17.2 in females. Mean VAS was 7.3±2.3, HGS 22.7±9.8 kg, UAC 31.9±5.6 cm, SPPB 8.0±1.96 and 6MWT 576±328 meters. Only HGS and UAC were correlated with HD dry weight (r 0.43, p<0.05 for HGS, r 0.79, p<0.001 for UAC).

Conclusions: The DiapriFIT Study measures a great variety of parameters regarding physical performance and PEW. As some, but not all parameters correlate with HD dry weight, we expect them to differentiate between CHD and NHD during follow-up of the study. Other results of physical performance and PEW, such as subjective global assessment, physical activity-, sleep-, and QOL-questionnaires, activity monitoring, body composition measurement, nutritional diary, DEXA and lab tests will provide additional information on these patient-relevant outcomes of NHD.

Anti-Thymocyte Serum Nephritis Rats Develops Augmented Circadian Rhythm of the Intrarenal Renin-Angiotensin System Shinsuke Isobe, Naro Ohashi, Sayaka Ishigaki, Hideo Yasuda. *Internal Medicine 1, Hamamatsu Univ School of Medicine, Hamamatsu, Shizuoka, Japan.*

Background: We reported the disturbed circadian rhythm of urinary angiotensinogen (AGT) excretion levels might lead to renal damage, hypertension and diurnal BP variation. Our purpose is to clarify the circadian rhythm of intrarenal renin-angiotensin system (RAS) components and its contribution to renal damage, hypertension and BP variation and to evaluate whether administration of RAS dependent or independent antihypertensive drug contributes to circadian rhythm of intrarenal RAS components.

Methods: Anti-thymocyte serum (ATS) nephritis rats were made as chronic progressive glomerulonephritis models (A group) and compared with control rats (C group). Other rats with ATS nephritis received olmesartan [angiotensin II (AngII) type 1 receptor (AT1R) blocker] (AO group) or hydralazine (vasodilatory drug) (AH group), respectively. Rats were sacrificed every 6 hour and the levels of the intrarenal RAS components were evaluated.

Results: The protein expression levels of intrarenal AGT, AngII and AT1R were increased in A group and peaked at the same time point as the peak of BP and urinary protein excretion during the rest phase. The amplitude of circadian fluctuation of these proteins was increased in A group compared with C group and attenuated in AO and AH group (Peak to trough ratio of AGT in C: 1.13, A 1.47, AO 1.24, AH 1.17, AngII in C: 1.03, A: 1.26, AO: 1.14, AH: 1.17 and AT1R in C: 1.36, A: 1.51, AO: 1.37, AH: 1.26). However, renal function, proteinuria and augmentation of intrarenal RAS components were attenuated only in AO group. The protein expression levels of intrarenal renin and prorenin were the same tendency as AGT, AngII and AT1R, though fluctuation of them was augmented in AO group. The protein expression levels and fluctuation of angiotensin converting enzyme and (pro)renin receptor were not different among groups.

Conclusions: Intrarenal AGT, AngII and AT1R proteins were increased and the amplitude of oscillations of these proteins was augmented in ATS nephritis rats. Furthermore, renal damage may be linked to the activation of the intrarenal RAS independent of amplitude of its oscillation and BP.

PUB494

Do KCNQ1 Channels Contribute to Control of Arterial Vascular Tone? Dmitry Tsvetkov,[1] Lan Chen,[1,2] Mario Kassmann,[1] Jean-Yves Tano,[1] Johanna Schleifenbaum,[1] Jakob Völkl,[3] Florian C. Lang,[3] Yu Huang,[4] Maik Gollasch.[1] *[1]Experimental and Clinical Research Center (ECRC), a Joint Cooperation between the Charité Medical Faculty and the Max Delbrück Center for Molecular Medicine (MDC), Berlin, Germany; [2]Xiamen Zhongshan Hospital, Xiamen Univ, Xiamen, Fujian Province, China; [3]Dept of Physiology, Univ of Tübingen, Tübingen, Germany; [4]School of Biomedical Sciences, Lo Kwee-Seong Integrated Biomedical Sciences Building, Area 39, Chinese Univ of Hong Kong, Hong Kong, Hong Kong.*

Background: Recent data suggest that the KCNQ family of voltage activated K^+ (K_v7) channels represents a new therapeutic target in cardiovascular disease. We used *Kcnq1*-/- mice to determine whether KCNQ1 ($K_v7.1$) play a role in the regulation of arterial tone.

Methods: Wire-myography, pharmacology approach and patch-clamp technics were used.

Results: We found that R-L3 produces similar concentration-dependent relaxations (EC_{50} ~1,4 µM) in wild-type (*Kcnq1*+/+) and *Kcnq1*-/- arteries pre-contracted with either phenylephrine or 60 mM KCl. This relaxation was not affected by 10 µM chromanol-B293, 10 µM HMR1556, 30 µM XE991 or 500 µM 4-aminopyridine. Chromanol-B293 and HMR1556 did not affect the anti-contractile effects of perivascular adipose tissue (PVAT). The anti-contractile effects of PVAT were normal in *Kcnq1*-/- arteries. Whole-cell recordings showed normal peak K_v currents, capacity and their blockade by XE991 in *Kcnq1* -/- VSMCs. The pan KCNQ2-5 opener retigabine lead to a similar relaxations in *Kcnq1*-/- and wild-type vessels.

Conclusions: We conclude that KCNQ1 channels are apparently not involved in the control of arterial tone by $alpha_1$ adrenergic vasoconstrictors and PVAT. R-L3 is aninappropriate pharmacological tool for studying the function of native vascular KCNQ1 channels in mice.

PUB495

The Role of Renal AT1 Receptor-Associated Protein in Salt-Sensitive Blood Pressure Regulation Hiromichi Wakui,[1] Kouichi Tamura,[1] Ryu Kobayashi,[1] Kazushi Uneda,[1] Masato Ohsawa,[1] Toru Dejima,[1] Akinobu Maeda,[1] Yoshiyuki Toya,[1] Kotaro Haruhara,[2] Satoshi Umemura.[1] *[1]The Dept of Medical Science and Cardiorenal Medicine, Yokohama City Univ Graduate School of Medicine, Yokohamah, Japan; [2]Div of Nephrology and Hypertension, Dept of Internal Medicine, Jikei Univ School of Medicine, Tokyo, Japan.*

Background: The intrarenal renin-angiotensin system plays a role in the regulation of renal hemodynamics and the maintenance of water electrolyte balance, and is also involved in the pathophysiology of hypertension and target organ damages. We previously identified an angiotensin II type 1 receptor-associated protein (ATRAP). which interacts with the C-terminal domain of angiotensin II type 1 receptor (AT1R) and attenuates AT1R-mediated pathological responses. The present study was designed to investigate the putative functional role of ATRAP in the blood pressure regulation by high salt loading in vivo.

Methods: We generated transgenic mice expressing ATRAP dominantly in renal tubules on a C57BL/6J background. Renal ATRAP transgenic mice and their wild-type littermate mice on a normal salt diet at baseline were subjected to dietary high salt loading for 7 days.

Results: In renal ATRAP transgenic mice, the development of high blood pressure in response to high salt loading was suppressed, concomitant with a significant increase in urinary sodium excretion, as compared to wild-type mice.

Conclusions: These results demonstrate that renal tubule-dominant overexpression of ATRAP suppresses the salt-sensitive blood pressure elevation provoked by high salt loading, thereby suggesting ATRAP to be an interesting target in hypertension.

PUB496

Carbonic Anhydrase II Inactivation Confers Salt Appetite and Elicits Salt Sensitive Hypertension Mujan Varasteh kia,[1] Sharon L. Barone,[2] Saeed Alshahrani,[1] Marybeth Brooks,[1] Kamyar A. Zahedi,[1,2] Jie Xu,[1] Manoocher Soleimani.[1,2] *[1]Center on Genetics of Transport, Dept of Medicine, Univ of Cincinnati, Cincinnati, OH; [2]Research Services, VA Medical Center, Cincinnati, OH.*

Background: Salt appetite or salt intake in excess of physiological needs is a major health problem and a risk factor in the pathogenesis of hypertension, which consequently can lead to heart disease and stroke. Few genetic factors are implicated in the pathogenesis of salt appetite.

Methods: Wild-type and CAII null mice were given a choice of regular water or 140mM NaCl dissolved in their drinking water. Balance studies were performed and blood pressure was measured via the CODA tail cuff system. Western blots and Northern Hybridizations were performed.

Results: Our results indicate that CAII null mice display significant salt appetite as judged by their preference for salted water (140 mM NaCl) over regular water, when both options are provided. In age and gender matched mice (n=4 per each group), daily salted water intake was 2.89 ml in WT vs. 5.71 ml in CAII null mice, while daily regular water intake was 5.05 ml in WT and 3.6 ml in CAII null mice. Kidney renin expression and blood creatinine concentration were comparable in WT and CAII null mice. When given only salted water, CAII null animals showed a robust increase in their daily salt intake (12.21ml in CAII null vs. 7.80ml in WT mice) and urine volume (4.62ml/day in CAII null vs. 2.62ml/day in WT mice). Expression of sodium and water absorbing channels, ENaC and AQP-2, increased by ~100 to 200% in both cortex and medulla in CAII null vs. WT mice in response to salt intake for 10 days. Consequently, CAII null mice developed hypertension (systolic BP of 155 +/- 3.9 in CAII null vs. 138 +/- 3.2 in WT, $p<0.003$). The protein expression levels of ENaC in taste buds were not different between the two genotypes. Male CAII null mice exhibited a remarkable propensity toward salted water intake vs. regular water intake as compared to female null mice.

Conclusions: We propose that CAII plays an important role in regulating salt intake and its inactivation can cause salt appetite, specifically in male animals, and provoke salt sensitive hypertension.

PUB497

Ambulatory Blood Pressure in Chronic Kidney Disease: An International Collaborative Study Paul E. Drawz,[1] Luca De Nicola,[2] Naohiko Fujii,[3] Francis B. Gabbai,[4] Jennifer J. Gassman,[4] Satoshi Iimuro,[3] Roberto Minutolo,[2] Robert A. Phillips,[4] Luis M. Ruilope,[5] Raymond R. Townsend,[6] Mahboob Rahman.[6] *[1]Div of Renal Diseases & Hypertension, Univ of Minnesota; [2]Italian Cohort; [3]CKD-JAC; [4]AASK; [5]Spanish Cohort; [6]CRIC.*

Background: In chronic kidney disease (CKD), ambulatory blood pressure (BP) is a better measure of hypertension related risk for cardiovascular disease and ESRD than clinic BP. The International Ambulatory Blood Pressure in Chronic Kidney Disease Collaborative Group is a collaboration among investigators from different countries interested in ambulatory BP in patients with CKD. The main aims of the research facilitated by this collaboration will be to evaluate: 1) the clinical and demographic characteristics associated with elevated ambulatory BP, 2) the prognostic role of ambulatory BP on cardiovascular and renal outcomes, and 3) ethnic and geographic differences in these associations.

Methods: This group will establish a large database derived from individual databases in the various countries to allow for powerful individual participant data meta-analyses of the relationship between clinical and demographic characteristics, CKD severity, ambulatory BP, and clinical outcomes.

Results: Investigators from 5 cohort studies have already agreed to participate. Characteristics of the cohorts are shown below.

	Italy	Spain	AASK	CRIC	CKD-JAC
Subjects	489	4434	617	1492	1075
Age (years)	64.4	69.3	60.3	63.1	60.7
Male/Female	290 / 199	2630 / 1804	382 / 235	833 / 659	682 / 393
eGFR	44.8	45.5	43.5	46.1	28.8
Proteinuria	63%[a]	16%[b]	30%[c]	42%[c]	86%[b]
Diabetics	176 (36%)	1385 (31%)	63 (10%)	626 (42%)	381 (35%)

a. Urine protein >0/15g/day; b. Urine alb/Cr >30mg/g; c. Urine prot/Cr >0.22mg/mg.

Conclusions: This multi-national collaboration will provide greater insights than possible from within-country analyses into the etiology and consequences of high risk ambulatory BP profiles. This information will be instrumental in helping us design prospective international large scale multicenter trials aimed at reducing renal and cardiovascular events in patients with CKD.

PUB498

Clinical Study of Pregnancy Related Kidney Injury Yumei Liu,[1] Ying Fan,[1] Yang Fei,[1] Hongda Bao,[1] Yajuan Huang,[2] Niansong Wang.[1] *[1]Nephrology and Rheumatology, Shanghai Jiao Tong Univ Affiliated Sixth People's Hospital, Shanghai, China; [2]Obstetrics and Gynecology, Shanghai Jiao Tong Univ Affiliated Sixth People's Hospital, Shanghai, China.*

Background: The diagnosis and treatment of pregnancy related kidney injury is a complicated clinical problem for obstetricians and nephrologists. However, information regarding this topic in China is insufficient.

Methods: Totally 18589 women hospitalized between August 2004 and January 2013 from Obstetric and Nephrology Department in Shanghai Jiao Tong University Affiliated Sixth People's Hospital were screened. 569 women were enrolled for the pregnancy related kidney injury, including 494 cases from 2008 to 2013 and 75 cases from 2004 to 2007. The inclusive criteria was women with a history of kidney disease or Scr >= 70mmol/L or proteinuria >= 0.3g/24hour before the termination of pregnancy, or the diagnosis of kidney disease made during or after 6-month delivery.

Results: The prevalence of pregnancy related kidney injury was 3.1%. The incidence of kidney injury caused by obstetric disease was 3.1%, with the most common reason for pre-eclampsia (88.9%). The incidence of chronic kidney disease women with pregnancy is 0.74%, with the most common reason for chronic glomerular nephritis (36.2%). The incidence of kidney disease onset related to pregnancy was 1.5%. The incidence of proceeding to end stage renal disease for pregnancy was 0.21%. Kidney injury in pregnant women with obstetric disease may be more severe than that in pregnant women with kidney disease (with higher maternal blood pressure and proteinuria, lower birth weight and higher proportion of pre-term babies, $P<0.05$). Most women with pregnancy related kidney injury underwent cesarean section (>60%). Their proportion of stillbirth, pre-term and low birth weight babies were higher than healthy parturient, and the proportion of follow-up was low (9.9%). Neonatal death rate was 0.63‰ and pare-natal death rate was 2.1‰ in all.

Conclusions: Prevalence of pregnancy related kidney injury increases due to the foundation of Shanghai First-Aid Center for High-risk Pregnant Women in 2007. Serum creatinine, proteinuria and blood pressure have different indication for maternal condition and pregnancy outcome.

Funding: Government Support - Non-U.S.

PUB499

A New Vasculo-Renal Marker Enhances Accuracy of Hypertensive Nephropathy Recognition Arkadiusz Lubas,[1] Robert Ryczek,[2] Grzegorz Kade,[1] Stanislaw Niemczyk.[1] *[1]Dept of Internal Diseases, Nephrology and Dialysis, Military Inst of Medicine, Warsaw, Poland; [2]Dept of Cardiology, Military Inst of Medicine, Warsaw, Poland.*

Background: Latent and slow beginning of chronic kidney disease (CKD) coexisting with well tolerated, usually not recognized previously hypertension makes difficult to recognize hypertensive nephropathy (HN) from CKD of others origins. The aim of the study was to investigate the best marker helpful in differentiating HN from other causes of CKD.

Methods: Forty patients (4 F; 36 M; age 52,7 ±15,4) with stable CKD (CKD-EPI 53.1 ±27.6 ml/min/1,73m^2) and a history of hypertension (26 with HN) were enrolled in the study. Serum Creatinine (Cre), Cystatin C (Cys), NT-pro brain natriuretic peptide (NTproBNP), Troponin I (TNI) and urinary albumin to creatinine ratio (UACR) were tested. Renal function was estimated according to Cre and Cys based CKD-EPI formula. Echocardiographic examination, carotid Intima-Media Thickness (IMT), ABPM, Renal Resistive Index (RRI) were performed. Vasculo-Renal Index (VRI) was calculated as IMT to UACR ratio.

Results: Groups with HN and CKD of other origins did not differ in renal function (CKD-EPI 46.2 vs 57.1 ml/min/1,73m^2; p=0.22), RRI, NTproBNP, TNI, left venticular (LV) ejection fraction, LV mass index and mean arterial pressure. Patients with HN were older (56,4 ±15,1 vs 45.9 ±14.1; p =0,039), had lower UACR (0.264 ±0.484 vs 0.814 ±0.564 mg/mg; $p<0.001$), but higher IMT (0.858 ±0.217 vs 0.652 ±0.180; p=0.009) and VRI (m. 28.8 [0.36; 1030.00] vs m. 0.78 [0.34; 12.50] $p<0.0001$). In ROC analysis VRI ≥ 1.91, UACR ≤ 0.199, and IMT ≥ 0.87 could recognize HN with sensitivity of 85%, 73% and 62% respectively, specificity of 79%, 93% and 86%, and accuracy of 82.5%, 80% and 70% (AUC 0.874, 0.849 and 0.749; $p>0.05$).

Conclusions: A new Vasculo-Renal Index recognizes HN more accurately, but UACR and IMT are not significantly worse.

Funding: Government Support - Non-U.S.

Association of Percentage of Global Sclerosis with Nocturnal Blood Pressure and Sodium Excretion in Patients with Chronic Kidney Disease

Hiroshi Nagae,[1,2] Akihiro Tsuchimoto,[2] Hisako Yoshida,[2,3] Shigeru Tanaka,[2] Kosuke Masutani,[2] Kazuhiko Tsuruya,[2,3] Ritsuko Katafuchi,[1] Kiyoshi Matsumura,[2] Takanari Kitazono.[2] *[1]Kidney Unit, Fukuoka Higashi Medical Centor, Fukuoka, Japan; [2]Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka; [3]Dept of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.*

Background: In patients with chronic kidney disease (CKD), impaired urinary sodium excretion (UNa) may cause nocturnal hypertension and pressure natriuresis to compensate for daytime sodium retention. The aim of this study was to determine the renal histological lesions which associated with nocturnal blood pressure (BP) and UNa in patients with CKD.

Methods: We analyzed 64 patients biopsied in our institutions from Sep 2010 to Apr 2014 (Forty IgA nephropathy, 6 Purpura nephritis, 4 membranous nephropathy and 14 the others). During the same hospitalization period of renal biopsy, ambulatory BP monitoring and evaluation of UNa were performed simultaneously. The association of histological findings such as global sclerosis (%GS), arteriolar hyalinosis (%hyaline), and interstitial fibrosis (IF), with nocturnal BP and night/day ratio of UNa were assessed using linear regression analysis.

Results: Twenty three patients were male, mean age was 40.5 ± 15.9 years, and mean estimated glomerular filtration rate (eGFR) was 79.0 ± 28.9 mL/min/1.73m^2. Both nocturnal BP and night/day ration of UNa positively associated with %GS, %hyaline, and IF, and negatively associated with eGFR. Multiple regression analysis adjusted for age, sex, eGFR, and usage of antihypertensive drugs showed that %GS was significantly associated with nocturnal systolic BP (β = 0.38, p = 0.012), nocturnal diastolic BP (β = 0.34, p = 0.031), and night/day ratio of UNa (β = 0.52, p = 0.005).

Conclusions: We found that night/day ratio of UNa and nocturnal BP closely related to the percentage of global sclerosis. These findings could be the morphological evidence that decrease in the number of functioning glomeruli causes increase in nocturnal UNa to compensate for daytime sodium retention resulting in elevation of nocturnal BP in patients with CKD.

PUB501

A Brief Intervention to Assign Once Daily Antihypertensive Medications to Morning versus Evening Dosing – A Pilot Study to Assess Feasibility and Efficacy in Chronic Kidney Disease Patients

Julia Chernyakov, Lisa A. Hillman, Paul E. Drawz. *Univ of Minnesota.*

Background: Hypertension is a major risk factor for cardiovascular and renal disease. Evening dosing of antihypertensive medications lowers nighttime blood pressure and, at least in one large randomized trial, reduced risk for cardiovascular outcomes. However, whether evening dosing reduces adverse outcomes in patients with chronic kidney disease (CKD) is unknown. The purpose of this pilot study was to assess the efficacy of a brief pharmacist based intervention on patient adherence to an assigned time of day to take antihypertensive medications and the feasibility of a pragmatic randomized controlled trial.

Methods: Patients with moderate to severe CKD taking ³1 antihypertensive medication once daily were randomized to take one once daily antihypertensive in the morning or the evening. After a nephrology clinic visit, a student pharmacist reviewed participants' antihypertensive medications with a focus on the one once daily study antihypertensive medication assigned to the morning or evening dosing arm. Study participants were contacted by phone three to six weeks after the clinic encounter to assess adherence.

Results: Of 99 potentially eligible patients approached in the nephrology clinic, 18 declined to participate, 2 had medication changes that made them ineligible, and 79 were randomized (39 to morning dosing, 40 to evening dosing). Average (SD) age was 56.5 (14) years, 68% were male, and average (SD) estimated glomerular filtration rate was 36.6 (8.9) ml/min/1.73m^2. Adherence, defined as taking the once daily medication at the time indicated at least 6 times in the last 7 days and not taking it at any other time during the day was 91% in the morning arm and 95% in the evening arm (P=0.57). The average (SD) time spent by the pharmacy student with each participant was 9.9 (6.1) minutes.

Conclusions: This pilot demonstrates the feasibility of a pragmatic randomized trial evaluating the effect of once daily nighttime dosing of antihypertensive medications on adverse outcomes in CKD patients. Patients were willing to participate in the study and adherence to the assigned timing was high in both the morning and evening dosing arms.

PUB502

Bedtime Dosing Regimen Drug Therapy for Chronic Kidney Disease (CKD) Patients with Hypertension: A Meta-Analysis of RCTs

Caixia Wang,[1] Xun Liu,[1] Zhenda Zheng,[2] Linsheng Lv,[3] Shaomin Li,[1] Tan-qi Lou.[1] *[1]Dept of Nephrology, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China; [2]Dept of Cardiology, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong, China; [3]Operation Room, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong.*

Background: Chronotherapeutic formulations are defined as the purposeful timing of medications. Bedtime dosing regimen drug therapy on blood pressure control is used widely, but its clinical benefits and protection for target organs in chronic kidney disease (CKD) patients is not known.

Methods: Randomized controlled trials (RCTs) were searched in PUBMED, EMBASE, ASN-ONLINE, the Cochrane Library and the reference articles of published papers. We identified five RCTs, including 3706 CKD patients with hypertension. Risk ratio (RR), weighted mean difference (WMD) with 95% confidence intervals (CIs) were pooled using fixed or random-effects models.

Results: In our analysis, a significant decrease was observed in bedtime mean SBP by -3.76 mmHg (MD, 95% CI, [-6.81, -0.71]), while there was a significant increase in awake time mean SBP by 1.16 mmHg (MD, 95% CI, [0.10, 2.21]) in the bedtime dosing group. Compared with the routine administration drug therapy, chronotherapy resulted in a larger decrease by 3.55% (MD, 95% CI, [0.22, 6.88]) in the sleep-time relative decline of SBP. Besides, a higher decline of non-dipper BP patterns was found in the chronotherapy group by 0.60 (RR, 95% CI, [0.43, 0.84]). No significant differences were noted for controlled BP, 24h mean SDP and DBP, awake time mean DBP and sleep-time mean decline in DBP and HB. Evidence was insufficient in CVE and proteinuria.

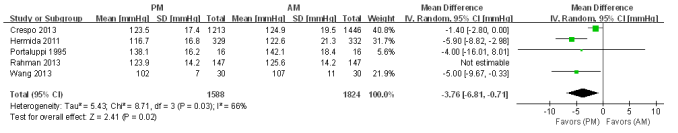

Figure1. Metagraph of bedtime mean SBP

Conclusions: This meta-analysis suggests that the bedtime dosing regimen drug therapy benefits CKD patients in terms of hypertension especially those with non-dipper BP pattern.

The Impact of Glomerular Collapse in Hypertensive Emergency Patients

Takafumi Yamakawa, Toshiyuki Imasawa, Takehiko Kawaguchi, Mao Watanabe, Maiko Nagata, Hiroshi Kitamura. *Dept of Internal Medicine, National Hospital Organization Chiba East Hospital, Chiba City, Japan.*

Background: The prognosis of kidney disease with hypertensive emergency (malignant glomerulosclerosis) is still worse compared with benign nephrosclerosis. Here, further to assess the reasons of worse prognosis and to reconsider more appropriate therapy for malignant nephrosclerosis, we compared pathological parameters between malignant and benign nephrosclerosis.

Methods: 8 patients diagnosed as hypertensive emergency with acute renal failure were performed renal biopsies from October 2005 to May 2015. We selected all patients with pure benign nephrosclerosis (n=20), who were performed renal biopsies during same period, as controls. We compared changes in clinical and pathological data using the paired t-test and the Mann-Whitney U-test.

Results: All 8 patients with hypertensive emergency had characteristic pathological changes of malignant hypertension, such as fibrinoid necrosis, onion-skin thickening and edematous-appearing matrix in arterioles. These changes were never observed in benign nephrosclerosis. The rates of global sclerosis and segmental sclerosis had no statistical differences between these two groups. Interestingly, when glomerular collapsing rate was counted by GCR (GCR=number of glomerular collapse/ total number of glomeruli), GCR scores were much higher in hypertensive emergency cases compared with those in benign nephrosclerosis cases (42.9 ± 23.8 vs. 6.5 ± 7.4 %; p < 0.05). These patient's clinical characteristics showed a high level of plasma renin activity (PRA) (14.9 ± 5.8) and hypokalemia (3.5 ± 2.8). Two of 8 patients reached to end stage kidney disease requiring dialysis.

Conclusions: Glomerular collapse and hyper-renin mean glomerular hypoperfusion. Therefore, if therapy accelerate this glomerular hypoperfusion, it might affect renal prognosis. We should reconsider the way of therapy, such as the selection of anti-hypertensive drugs, and the speed of declining blood pressure and volume control by thinking glomerular hypoperfusion.

PUB504

A Study of Early Treatment with Benazepril in SHR at Different Doses

Qiong-li Yin,[1] Mei Li,[1] Cheng-gang Shi.[2] *[1]VIP Healthcare Center, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, China; [2]Nephrology Dept, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, China.*

Background: To investigate whether early treatment with super high dosage ACEI can reverse glomerulosclerosis in SHR.

Methods: 30 SHRs were randomized and divided into three groups(n=10): model control group(M group), 10 mg·kg^{-1}·d^{-1} Benazepril treatment(HT group),50 mg·kg^{-1}·d^{-1} Benazepril treatment(SHT group),10 Wistar-Kyoto rats were studied as normal control group(N group), placebo , 10 mg·kg^{-1}·d^{-1} Benazepril and 50 mg·kg^{-1}·d^{-1} Benazepril were given through intragastric administration starting from 0 week of the experiment, rats were killed until 12 week of the experiment. Blood pressure(Bp), 24 hours urinary protein(24hUpr) and serum creatinine(Scr) were detected in the 0, 4, 8, 12 week of the experiment. Renal pathology damage was evaluated with paraffin wax section of kidney tissue through HE, MASSON stain; the protein levels for TGF-b1 and PAI-1 were tested through immunohistochemicalstai-ning method.

Results: Compared with model control group, Bp, 24hUpr of HT and SHT groups decreased obviously (P<0.05), the protein levels for TGF-b1 and PAI-1 in kidney tissue of HT group and SHT group were inhibited(P<0.05), glomerular collagen deposition of HT group and SHT group reduced evidently (P<0.05).

Conclusions: This study shows that high dosage ACEI and super high dosage ACEI all can decrease blood pressure, reduce proteinuria, depress the expressions of TGF-β and PAI-1 protein in SHR, and delay glomerulosclerosis. But super high dosage ACEI can not reverse glomerulosclerosis in SHR.

PUB505

Hemolytic Uremic Syndrome Associated with Scleroderma Renal Crisis: The Challenge for Timely and Accurate Diagnosis Amro Elshoury, Syed S. Haqqie, Daniel Sedhom, Arif Asif. *Albany Medical Center, Albany, NY.*

Background: Scleroderma renal crisis (SRC) is a rare cause of atypical hemolytic uremic syndrome (aHUS) and differentiating it from other causes of **thrombotic microangiopathies can be challenging. A 53-year old Caucasian male, with no past medical history was found unresponsive.**BP was elevated to 207/141 mm Hg. Skin examination showed diffuse telangiectasia and edema of his extremities with bilateral sclerodactly (Figure 1). Fundoscopy revealed bilateral retinal hemorrhage and exudates. Labs showed a hemoglobin=5gm/dl, platelet=25x10^3/uL, creatinine=6mg/dl, LDH=1122IU/L, bilirubin=1.6mg/dl, haptoglobin<5%, reticulocytic count=10.4% and schistocytes. ANA and anti-RNA Polymerase III antibody were positive (C3 and C4, coagulation profile, fibrinogen were normal; Coombs negative). CT head showed severe microvascular changes throughout the white matter of the cerebrum and MRI showed evidence of punctuate chronic micro-hemorrhages in the left thalamus and cerebellar tonsils. The presence of MAH, acute renal failure and thrombocytopenia raised suspicion for possible aHUS/TTP. Serum ADAMTS 13 was ordered. Because of the possibility of SRC, the patient was started on capropril. A dramatic improvement in BP, hemoglobin and platelets count along with the normalization of LDH and schistocytes disappearance was observbed. However, there was no improvement in kidney function requiring hemodialysis. ADAMT-13 activity returned at 40% (cut-off for TTP is <5%). Patient did not pursue eculizumab therapy. A significant portion of patients with Scleroderma can develop aHUS. In this case, hypertension might have served as a complement amplifying condition.

Methods: Clinical presentation/course of the patient.

Results: Despite therapy with ACE inhibitors patient ended up on RRT.

Conclusions: Patient presenting with Malignent HTN and MAH was found to be in scleroderma crisis.

PUB506

The Impact of Neck Irradiation on Baroreceptor Reflex and Hypertension Amro Elshoury, Syed S. Haqqie, Daniel Sedhom, Rahim Dhanani, Arif Asif. *Albany Medical College.*

Background: Only a few studies with a very limited sample size have evaluated the impact of neck irradiation on baroreceptor reflex failure and blood pressure (BP) abnormalities. We investigated 60-patients, with head/neck cancer, who received neck irradiation between 2005 to 2010. IRB approval was obtained. Median for age was 61.5 years (range 24-90 years). We used the same cohort of patients, before the received neck irradiation, as a control for BP. Mean systolic BP before neck irradiation was 129.1±2.646 mm Hg, 1-months post-neck irradiation was 121.4±2.178 mm Hg (P=0.02), 3-months post-neck irradiation was 121.9 ± 2.180 mm Hg (P=0.04), 6-months post-neck irradiation was 125.2 ± 2.933 mm Hg (P=0.27), 1-year post-neck irradiation was 123.4 ± 4.087 mm Hg (P=0.32), 2-years post-neck irradiation was 122.7 ± 3.655 mm Hg (P=0.06) and 5-years post-neck irradiation was 124.8±2.833 mm Hg (P=0.35). Mean diastolic BP before neck irradiation was 76.28±1.802 mm Hg, 1-month post-neck irradiation was 69.88±1.585 mm Hg (P=0.009), 3-months post-neck irradiation was (72.84±1.764 mm Hg (P=0.17), 6-months post-neck irradiation (71.00±1.957 mm Hg, P=0.07), 1-year post-neck irradiation was 72.22±2.341 mm Hg (P=0.17), 2-years post-neck irradiation was 74.09mmHg±1.757 mmHg (P=0.47), 5-years post-neck irradiation was 70.17mmhg ± 3.131 mm Hg (P=0.16). Patients with head/neck cancer did not have clinically significant change in their BP after neck irradiation. These data do not support either acute fulminant hypertensive crisis or a chronic labile hypertension after neck irradiation. The study suggests that carotid baroreceptors might not have been damaged by radiation or baroreceptors in other locations might have been able to control BP.

Methods: Retrospective study of blood pressure in patients with neck radiation for cancer.

Results: Blood pressure before and after radiation showed no increase.

Conclusions: The study suggests that carotid baroreceptors might not have been damaged by radiation or baroreceptors .

PUB507

Sympathetic Nervous System Activity Reflected by Renalase and Catecholamines in Different Aged Patients with and without Chronic Kidney Disease Edyta Zbroch,[1] Dominika Maciorkowska,[1] Ewa Koc-Zorawska,[2] Jolanta Malyszko.[1] *[1]2-nd Dept of Nephrology and Hypertension with Dialysis Centre, Medical Univ, Bialystok, Poland; [2]1st Dept of Nephrology and Transplantation, Medical Univ, Bialystok, Poland.*

Background: Sympathetic nervous system activity is elevated in patients with chronic kidney disease (CKD) as well as in older persons. It contributes to hypertension and cardiovascular diseases. It is due to a reduction of catecholamines clearance and in elderly also to an increased sympathetic discharge from different organs. Renalase may play a role in the catecholamines degradation. The aim of the study was to assess the sympathetic nervous system activity, according to serum renalase and catecholamines concentration in a cohort of 211 patients with hypertension and with or without chronic kidney disease.

Methods: The study group was divided according to age below and above 65 years. The older persons (61) was also divided into group with (75%) and without CKD stage 5. The serum renalase, dopamine and norepinephrine concentration as well as pressure control, residual renal function rate and echocardiography were assessed.

Results: The older group had higher renalase (p=0,02) and dopamine (p<0,001) concentration and it was elevated in patients with CKD comparing to those without. They also had advanced abnormalities in echocardiography, like thicker interventricular septum (p=0,03) and lower ejection fraction (p<0,001) as well as CKD patients comparing to those without CKD – pronounced left ventricular hyperthrophy (p=0,007) and lower ejection fraction (p=0,004). They more often suffered from coronary artery disease. The residual renal function was less in older patients with CKD. The main used hypotensive drugs in studied group were beta-blockers. There was the significant correlation between age and renalase, norepinephrine and dopamine concentration.

Conclusions: The advanced aged especially combined with chronic kidney disease is associated with elevated renalase and dopamine level. It may reflect the sympathetic nervous system hyperactivity due to impaired kidney function and reduction of residual diuresis. It may have an impact on the development of cardiovascular complications.

PUB508

Heart Rate Variabilities During Day and Night Can Alter the Circadian Blood Pressure (BP) Rhythm Toshiyuki Miura,[1] Michio Fukuda,[1] Yoshiaki Ogiyama,[1] Ken Kiyono,[2] Yoshiharu Yamamoto,[3] Junichiro Hayano,[1] Nobuyuki Ohte.[1] *[1]Nagoya City Univ, Japan; [2]Osaka Univ, Japan; [3]Tokyo Univ, Japan.*

Background: We previously reported in patients with chronic kidney disease (CKD) that the circadian rhythms of BP and urinary sodium excretion ($U_{Na}V$) were both impaired into non-dipper pattern as renal function deteriorated.Elevated salt-sensitivity of BP and inappropriate activation of the renin-angiotensin-aldosterone system and the sympathetic nerve system play important roles in high BP and the high incidence of cardiovascular diseases in patients with CKD.

Methods: In 39 patients with CKD,we analyzed HRV in 24-h electrocardiography,BP monitoring and urine collection,separately for daytime and nighttime. Patients,who took antihypertensive agents,were excluded.We evaluated the relationship between systolic blood pressure(SBP)and λ,HF,or $U_{Na}V$. The non-Gaussianity index of HRV(l_{2Sa}),which reflects the probability of intermittent large deviations of heart rate(HR)from the trend,and the power of high frequency(HF, 0.15–0.40 Hz),obtained by frequency domain analysis of HRV,was used as a marker of sympathetic cardiac overdrive,and as vagal nerve activity,respectively.

Results: As renal function deteriorated, 24h-λ and daytime λ increased,24h-SBP showed significant relationships with daytime λ(r=0.40, p=0.01) and night-time HF(r=-0.37, p=0.02). Night/day ratios of SBP and $U_{Na}V$ were also elevated as GFR was reduced. Night/day ratios of SBP correlated inversely with night-time HF(r=-0.36, p=0.02). When analyzed by stepwise multiple regression analysis, the main determinants of 24h-SBP were 24h-$U_{Na}V$, daytime λ, and night-time HF. Night/day SBP ratios was determined by night/day ratio of $U_{Na}V$, rather than any HRVs.

Conclusions: Our study clearly demonstrated that as renal function deteriorated, sympathetic nerve activity is activated during the day, and vagal activation was impaired during the night, both of which can contributes to high BP in patients with CKD. However, non-dipper type of circadian BP rhythm was associated with the circadian $U_{Na}V$ rhythm rather than sympathetic or vagal nerve activity, even though the sympathetic activity can stimulate tubular sodium reabsorption.

PUB509

The Effects of the Insight Meditation Practice on Blood Pressure Reduction in Buddhist Exemplary People Jutamas Vareesangthip,[1] Kriengsak Vareesangthip.[2] *[1]Dhamma Communication Div, Graduate School, Mahachulalongkornrajavidyalaya Univ, Bangkok, Thailand; [2]Renal Div, Dept of Medicine, Faculty of Medicine Siriraj Hospital, Bangkok, Thailand.*

Background: Hypertension (HTN) is a leading risk factor for preventable cardiovascular disease, with over one in five adults affected worldwide. Lifestyle modification is a key strategy for the prevention and treatment of HTN. Stress has been associated with greater cardiovascular risk, and stress management is a recommended intervention for hypertensives. For many patients, maximal medical therapy is insufficient

to adequately treat refractory hypertension. Lifestyle modification remains an important approach in management. Buddhist meditation encompasses a variety of meditation techniques that aim to develop mindfulness, concentration and insight.

Methods: We aimed to study whether Buddhist Insight Meditation (IM) Practice, composing of Walking Meditation and Sitting Meditation, could reduce the level of blood pressure in Buddhist Exemplary People. 65 exemplary people were divided into 3 groups according to the schedule they performed IM Practice. Group 1 (n=25) performed 30 minutes of the Walking and 30 minutes of the Sitting Meditation, group 2 (n=20) performed 45 minutes in each Meditation and group 3 (n=20) performed 60 minutes in each Meditation. Their blood pressures (BP), pulse pressures (PP) and pulses (P) were measured before and after Walking and Sitting Meditations.

Results: The results clearly showed that systolic BP, PP and P were significantly decreased after the Walking Meditation at 30-45-60 minutes. After IM Practice schedule, an arterial pulse has been significantly decreased in all 3 groups, PP has been significantly decreased in group 2 and systolic BP has been significantly reduced in group 3.

Conclusions: In conclusion, the Buddhist IM Practice could meaningfully reduce the sympathetic activities including systolic BP, PP and P. Therefore, this Buddhist Practice should be added to be one modality of the standard hypertensive treatments.

PUB510

ENaC as a Novel Mechanism for Hypertension and Volume Expansion in Type 2 Diabetes Mark L. Unruh,[1] V. Shane Pankratz,[1] Evan C. Ray,[2] Rebecca P. Hughey,[2] Thomas R. Kleyman.[2] *[1]Div of Nephrology, Univ of New Mexico; [2]Renal-Electrolyte Div, UPMC.*

Background: Renal Na retention and extracellular fluid volume expansion are hallmarks of nephrotic syndrome. There is evidence that this occurs even in the absence of activation of hormones that are known to stimulate renal Na transporters. Recent studies suggest that plasmin-dependent activation of ENaC may be responsible for renal Na retention in the setting of nephrotic syndrome. We hypothesized that the ENaC inhibitor amiloride would be an effective therapeutic agent in inducing a natriuresis and lowering blood pressure in individuals with macroscopic proteinuria.

Methods: We conducted a pilot double-blind randomized cross-over study comparing the effects of daily administration of either oral amiloride (10 (low dose) followed by 20 (high dose) mg/d) or HCTZ (Na,Cl co-transporter inhibitor) to patients with type 2 diabetes and macroscopic proteinuria. We examined safety and feasibility of amiloride by monitoring kidney function, adherence, blood pressure, weight, urinary Na excretion and serum electrolytes during diuretic administration.

Results: 9 subjects were enrolled in the trial. Systolic blood pressure (SBP) decreased in both treatment groups, but there was not a significant difference between HCTZ and amiloride (p=0.53). Amiloride treatment was associated with a 1.1±0.4 kg greater decline in weight (p=0.02), and a 0.78 ± 0.18 mmol/L greater increase in serum potassium (p=0.002) over the low dose portion of the study. 2 subjects developed acute kidney injury and hyperkalemia when treated with amiloride. 5 subjects had readily detectable levels of urinary plasminogen/plasmin, and 4 did not. Among those receiving amiloride, the low plasmin group experienced a change of 1.1±4.6 mmHg in SBP and the high plasmin group experienced a change of -13.9±8.7 mmHg, although there was insufficient evidence to conclude that there were differential treatment effects by high/low plasminogen status (p=0.113).

Conclusions: Among patients with type 2 diabetes, normal renal function, and proteinuria, there was suggestion of increased naturiesis for those treated with amiloride vs. HCTZ, however, acute kidney injury and severe hyperkalemia was a safety concern.

PUB511

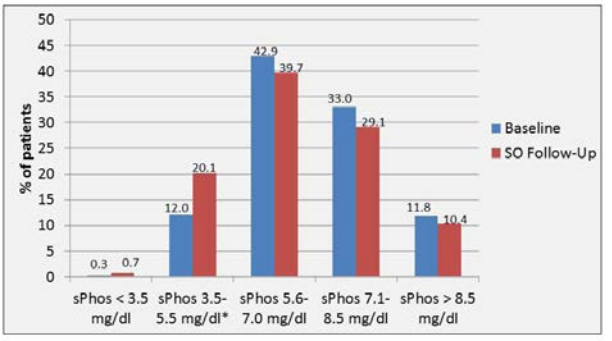
Serum Phosphorus Control and Reduced Phosphate Binder Pill Burden Among Hemodialysis Patients Who Switched from Sevelamer to Sucroferric Oxyhydroxide Vidhya Parameswaran, Lin Ma, Linda H. Ficociello, Claudy Mullon, Franklin W. Maddux, Robert J. Kossmann. *Fresenius Medical Care North America, Waltham, MA.*

Background: Clinical management of hyperphosphatemia among hemodialysis (HD) patients (pts) can present challenges. A retrospective database analysis was conducted to study the effectiveness of sucroferric oxyhydroxide (SO) among in-center HD pts who switched from sevelamer to SO as part of routine clinical care.

Methods: Pts who switched from sevelamer and had ³1 serum phosphorus (sPhos) measured during SO treatment were included. Changes in sPhos, serum calcium (sCa), intact parathyroid hormone (iPTH), transferrin saturation (TSAT), ferritin (FER), and pill burden were assessed at baseline (3-months prior to SO) and at follow-up (3-months during SO treatment).

Results: Pts (n=1487) were, on average, 54 years old, with dialysis vintage of 4.4 years and hyperphosphatemia (baseline sPhos=6.94 mg/dl). Figure shows sPhos distribution at baseline and follow-up. Pts with in-range sPhos (3.5-5.5 mg/dl) increased from 12% to 20.1% (68% increase). Mean sPhos decreased from 6.94 to 6.7 mg/dl (p<0.001) and mean sCa decreased from 9.3 to 9.25 mg/dl (p<0.001). There was a significant decrease (4.7 pills/day, p<0.001) in pill burden (8.5 to 3.7 pills). No significant change in iPTH levels was observed (626.1 to 637.6 pg/ml). TSAT and FER significantly increased (p<0.001) from 33.7% to 35.5% and 983.5 to 1051.4 ng/ml, respectively. In pts not receiving IV iron (n=149), there were no significant changes in TSAT (36.3% to 35.9%) or FER (1221.5 to 1177.4 ng/ml).

Distribution of sPhos during baseline compared to sucroferric oxyhydroxide (SO)-treated follow-up for HD patients who switched from sevelamer (N=1487)



*Change in %in-range and %out of range baseline compared to SO Follow-up, p =<0.001

Conclusions: HD patients who switched from sevelamer to sucroferric oxyhydroxide as part of routine clinical care had decreased serum phosphorus (0.24, p<0.001). There was a 68% increase in the number of patients with in-range serum phosphorus (p<0.001). Patients were prescribed 4.7 fewer pills per day (p<0.001).

PUB512

An Investigation of the Inverse Relationship Between Fractional Excretion of Phosphate and the Tubular Maximum for Phosphate per Volume of Filtrate Kenneth R. Phelps,[1,2] Darius Mason.[1,2,3] *[1]Stratton VAMC, Albany, NY; [2]Albany Medical College, Albany, NY; [3]Albany College of Pharmacy and Health Sciences, Albany, NY.*

Background: The serum P concentration ($[P]_s$) is the sum of urinary excretion and tubular reabsorption rates of P per volume of filtrate (E_P/C_{cr} and TR_P/C_{cr}). The two ratios also determine fractional excretion of P (FE_P) [Clin Nephrol 83:167], and E_P/C_{cr} is approximately proportional to the concentration of P ($[P]_f$) in the cortical distal nephron (CDN) [Clin Nephrol 82:191]. Maximal TR_P/C_{cr} (i.e. Tm_P/GFR) exceeds actual TR_P/C_{cr} when FE_P is < 20%; as FE_P falls, Tm_P/GFR and (Tm_P/GFR - TR_P/C_{cr}) rise [Clin Chim Acta 26:15]. We investigated these phenomena.

Methods: We measured [cr] and [P] in fasting serum (s) and urine (u), and [PTH]1-84 (Scantibodies) and intact [FGF23] (Immutopics) in plasma from 28 subjects without renal or parathyroid disease. We calculated E_P/C_{cr} as $[P]_u[cr]_s/[cr]_u$, TR_P/C_{cr} as $[P]_s - E_P/C_{cr}$, and FE_P as $[P]_u[cr]_s/[cr]_u[P]$. We then determined Tm_P/GFR from the Walton-Bijvoet nomogram. We performed simple linear regressions (y on x) as indicated in the table.

Results: All y-variables correlated inversely with FE_P. Tm_P/GFR correlated directly with TR_P/C_{cr} but was unrelated to E_P/C_{cr}. Other y-variables correlated inversely with E_P/C_{cr} but were unrelated to TR_P/C_{cr}. None of the y-variables correlated with [PTH] or [FGF23].

x	FE_P, %		E_P/C_{cr}, mg/dL		TR_P/C_{cr}, mg/dL	
y	R^2	*P*	R^2	P	R^2	*P*
Tm_P/GFR, mg/dL	0.39	< 0.001	0.04	0.34	0.89	< 0.001
$(Tm_P/GFR)/[P]_s$	0.83	< 0.001	0.76	< 0.001	0.05	0.27
(Tm_P/GFR) - TR_P/C_{cr}, mg/dL	0.69	< 0.001	0.56	< 0.001	0.10	0.10
$(Tm_P/GFR)/(TR_P/C_{cr})$	0.62	< 0.001	0.64	< 0.001	0.01	0.60

Conclusions: Correlations of y-variables with FE_P ultimately reflect correlations with E_P/C_{cr}, TR_P/C_{cr}, or both [Clin Nephrol 83:167]. As expected, Tm_P/GFR was closely associated with TR_P/C_{cr}. The other y-variables, which depicted comparisons of Tm_P/GFR to TR_P/C_{cr}, were inversely related to E_P/C_{cr}, a specific indicator of P influx and a surrogate for $[P]_f$ in the CDN. As $[P]_f$ fell in the CDN, the difference rose between actual and maximal P reabsorption in the proximal nephron. We did not identify an endocrine mediator of this interaction.

PUB513

Observational Study at the Mexican Institute for Social Security and Services for State Worker's National Medical Center 20 de Noviembre Nephrology Department Outpatient Clinic Using Cinacalcet as Renal Replacement Therapy for Secondary Hyperparathyroidism Caused by Chronic Kidney Disease Elvira González, Jesús Alejandro Nava Martínez, Juvenal Torres Pastrana. *Nephrology, CMN 20 Noviembre, Mexico, DF, Mexico; Nephrology, CMN 20 de Noviembre, Mexico, D.F., Mexico; Nephrology, CMN 20 de Noviembre, Mexico, D.F., Mexico.*

Background: Secondary hyperparathyroidism is a highly prevalent clinical condition in persons with advanced chronic kidney disease (CKD). It can be seen in the early stages of the disease and consists of disorders in bone metabolism.

Methods: A descriptive, retrospective observational study was done using patient records from the Institute for Social Security and Services for State Worker's (ISSSTE) National Medical Center 20 de Noviembre Nephrology outpatient clinic, located in Mexico City, Mexico. 50 cases of adult patients with advanced chronic kidney disease were reviewed in renal replacement treatment, dperitoneal dialysis and/or hemodialysis who were managed with Cinacalcet for Secondary Hyperparathyroidism, with PTHi >300 pg/ml.

Results: The baseline level of serum parathyroid hormone of the 42 patients was 1371.6 pg/ml prior to the use of cinacalcet, with a percentage reduction of 33% per month and 6 months of treatment 55% with a mean of 1133 pg/ml and 615.48 pg/ml respectively. A total of 42 patients; 19 (45%) achieved targets at the end of the 6-month study. 36 patients underwent to scintigraphy of parathyroid gland, because they did not obtain parathyroid hormone decreased over 30% at the 3rd month of treatment; 5 patients showed hyperplasia and 11 parathyroid adenoma.

Conclusions: Cinacalcet combined with conventional treatment succeeds in reaching goals compared to standard treatment only. Hypocalcemia is a common side effect however when administered together with calcium salts and / or vitamin D or its analogues decrease side effects According to previous studies cinacalcet it increases the achievement of goals in mild hyperparathyroidism. In our study was more important for the response time in the RRT than the severity of hyperparathyroidism.

"Binder Reminders" for Persistent Hyperphosphatemia in Hemodialysis Patients: A Fellow's Quality Improvement Project Divakar Jammalamadaka, N. Stanley Nahman, John Jason White. *Medicine, Georgia Regents Univ, Augusta, GA.*

Background: Despite regular quality improvement (QA) processes, control of mineral metabolism remains poor. One root cause is patient non-adherence to phosphate (Pho) binders. Evolving data suggest SMS/text reminders improve medication adherence in a wide range of chronic illnesses. Here, we report our initial experience with text reminders on Pho control in HD patients.

Methods: 40 patients with Pho > 5.5 mg/dL for 2 of last 3 months, and possessing cell-phones with texting capabilities were studied. We randomly assigned 20 to receive the phrase "Binder Reminder" at mealtimes x 7 days prior to their monthly lab draw. The remaining 20 received usual care. Group assignment and messaging was performed by a nephrology fellow, not part of the multidisciplinary team. Patients were excluded if they declined participation, missed any dialysis sessions during the 7 day period, or if they were unable to obtain their binders. Pho level after intervention was the primary outcome.

Results: After exclusions, 13 patients received the intervention and were compared to 14 controls. Pre-intervention Pho levels were 6.81 +/- 0.88 and 6.60 +/- 0.93 mg/dL (Mean +/- SD) in the control and intervention groups respectively. After intervention, Pho levels declined in the intervention group to 6.00 +/- 1.2 mg/dL(P = 0.10). Pho also declined in the control group to 6.19 +/- 0.76 mg/dL. Hence there was no difference between the groups (P = 0.76). Each group had 8 patients with improved Pho levels, and 5 patients at goal.

Conclusions: Our initial QA project utilizing SMS/text messaging appears to have no effect on short-term Pho control in a group of HDs patients with chronic hyperphosphatemia. A major drawback is the small number of patients and the number excluded (33%). However, this study does provide useful preliminary data for the planning of a larger pilot project, highlights the importance of contemporary control groups in QA to exclude the Hawthorne effect, and, given its simplicity, may be a model for fellow-driven QA projects and education.

Niacin Improves Cardiac Function in Alport Mice with Progressive Chronic Kidney Disease and Hyperphosphatemia Kelly Ambler,[1] Evgenia Dobrinskikh,[1] Veronica A. Hogg-Cornejo,[1] Xiaoxin Wang,[1] Yuhuan Luo,[1] Jason R. Stubbs,[2] Moshe Levi.[1] *[1]Univ of Colorado Denver; [2]Univ of Kansas Medical Center.*

Background: Increase in serum phosphate (Pi) level (hyperphosphatemia) is a common clinical problem in chronic kidney disease (CKD). Systemic Pi homeostasis is balanced through three major mechanisms: intestinal uptake, retention or release from bone, and renal reabsorption. Sodium-phosphate co-transporter type 2b (NaPi2b) is a major phosphate transporter in the small intestine. Alport syndrome is a genetic disorder characterized by CKD, hearing loss and cardiac dysfunction.

Methods: By 9-10 weeks of age Alport mice, which have a mutation in a COL4A3 gene on the SvEv129 background, develop signs of CKD and hyperphosphatemia.

Results: We have found by western blot that there is an increase in intestinal NaPi-2b protein abundance and Everted Sac studies showed increased NaPi transport in the Alport Ileum compared to the WT littermate controls. Cardiac echo studies revealed that Alport mice have decreased ejection fraction (EF: 67±2% compared to 75±3% in the WT littermate) and diastolic dysfunction (mitral Doppler flow E/A ratio: 1.2±0.1 compared to 1.6±0.1 in the WT littermate, p<0.05), which could be corrected by treatment with Niacin (intestinal phosphate uptake inhibitor). In the treated Alport mice EF increased to 78±2% (p<0.05) and E/A ratio improved to 1.3±0.1 (p<0.05). In addition, there were significant decreases mRNA relative expression in β-MHC (0.08±0.02 in control vs. 2.19±0.34 in Alport, p<0.001, vs. 0.2±0.001 in Alport+Niacin, p<0.05), PAI-1 (0.12±0.01 in control vs. 1.05±0.15 in Alport, p<0.05, vs. 0.15±0.05 in Alport+Niacin, p<0.05), and TGF-β (0.03±0.01 in control vs. 0.77±0.23 in Alport, p<0.01, vs. 0.07±0.23 in Alport+Niacin, p<0.01), markers of heart failure and cardiac fibrosis.

Conclusions: Inhibition of intestinal phosphate transport with Niacin therefore improves systolic and diastolic cardiac dysfunction in CKD.

PUB516

Establishing Regulatory Networks of Phosphorus Metabolism in HD Patients – A New Path of Treating Hyperphosphatemia Mengjing Wang,[1] Panpan Wang,[2] Yulin Zhang,[1] Li Ni,[1] Minmin Zhang,[1] Jing Chen.[1] *[1]Nephrology, Huashan Hospital, Shanghai; [2]MOE Key Laboratory of Contemporary Anthropology, School of Life Sciences, Fudan Univ, Shanghai.*

Background: The clinical efficiency of current treatment of hyperphosphatemia in HD varies widely on different patients. We assume that it is due to phosphorus regulation in vivo. In physiological conditions, phosphorus is regulated by a biological network consisting of interacting hormones and minerals. In HD, the networks change dramatically and affect serum phosphorus. This study aims to establish the regulatory networks of phosphorus in HD and identify the key factors that may have a causal effect on circulating concentrations of phosphorus.

Methods: 30 MHD patients were enrolled and divided into three groups (n=10, PTH£300 ng/l; n=10, 300 ng/l<PTH≤600 ng/l; n=10, PTH>600 ng/l). Predialysis blood samples were obtained on the mid-week dialysis day for detection of PTH, FGF23, 25(OH) D3, Klotho, and Ca every week for 12 weeks every patient. Causal inference, a widely used process of concluding a causal connection, was adopted to establish the regulatory networks of phosphorus metabolism within different PTH levels.

Results: The networks show that when PTH<600 ng/l, FGF23 can stimulate the increase of serum Pi, Ca, and PTH, in turn, serum Ca and Pi can also stimulate the increase of FGF23. When PTH>600 ng/l, FGF23 becomes the stimulator of only serum Ca, and serum Pi has a positive causal effect on PTH, besides, the rise of PTH increases serum Pi level, too. So, serum Pi is affect by FGF23 when PTH<600 ng/l and by PTH when PTH>600 ng/l. Since FGF23 promotes the increase of PTH when PTH<600 ng/l, FGF23 becomes the key factor in disorders of phosphate metabolisms. The figures also shows that Klotho and 25(OH)D3 may be not important in the therapy of hyperphosphatemia.

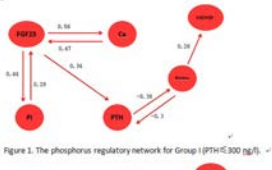

Figure 1. The phosphorus regulatory network for Group I (PTH≤300 ng/l).

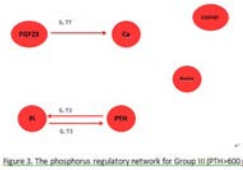

Figure 3. The phosphorus regulatory network for Group III (PTH>600 ng/l).

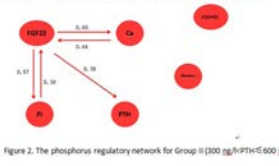

Figure 2. The phosphorus regulatory network for Group II (300 ng/l<PTH≤600 ng/l).

The arrows represent causal relationship, the source node is the predictor, and the target node is the response variable. The edge label is the causal effect from the source node to the target node.

The edges were selected by applying stability selection to algorithm of sparse structure equation.

Conclusions: Reducing FGF23 levels might contribute to the control of phosphorus.

PUB517

Evolution of Renal Calcium Excretion Throughout Chronic Kidney Disease Carmen Gonzalez Corvillo,[1] Paula Batalha-Caetano,[1] Silvia Ros-Ruiz,[2] Fernando Vallejo Carrión,[3] José G. Hervas,[4] Mercedes Salgueira Lazo.[1] *[1]Nephrology, Hospitales Virgen Macarena-Rocio, Sevilla, Spain; [2]Nephrology, Hospital Regional, Malaga, Spain; [3]Nephrology, Hospital Puerto Real, Cadiz, Spain; [4]Nephrology, Universidad, Granada, Spain.*

Background: Chronic kidney disease(CKD)patients have a normal serum calcium(Ca) concentration until the end of renal disease(ESRD).The decrease of VitaminD levels,and that a percentage of patients develops hypocalcemia at ESRD,lead us to think that our patients have a negative Ca balance,this could justify the treatment with Ca supplements. Objetive:analyze renal Ca excretion at different stages of CKD and the effect of the treatments.

Methods: Observational multicenter,retrospective and transversal study,with the participation of 5hospitals.63patients were included,in different stages of the disease(66,7%men,mean age 66years).None on renal replacement therapy. Variables:blood,urine analysis and treatment.The sample was stratified by stage of the disease and urine Ca(>or<100 mg/d).

Results: Sample:6,3%CKD1,4,8%CKD2,28,6%CKD3,38,1%CKD4 and 22,2%CKD5. Mean serum Ca:9,47 mg/dl,mean serum phosphate(P): 3,77mg/dl.PTH level 174pg/dl,VitD 27ng/ml.Mean Ca excretion:126mg/day.Mean P excretion:477mg/d.47%was on Ca based binders,22.2%on calcifediol,12.7%on calcitriol and 28.6%on paricalcitol.70%of the sample had Ca excretion<100mg/d.When classifying by stages of the disease,increases the amount of patients with Ca excretion<100 mg/d(CKD1 25%,CKD2 50%,CKD3 50%,CKD4 80%,CKD5 83%),decreasing the mean Ca excretion.The subgroup of patients with lower Ca excretion had a higher PTH level(155 vs 111pg/dl)p0,05. 94%of patients treated with Ca based binders had a Ca excretion<100mg/d with no difference in serum Ca.Patients on calcifediol,paricalcitol or calcitriol had lower Ca excretion than those without treatment.

Conclusions: According to our results,patients within CKD show a decrease in renal Ca excretion that become exacerbated as the renal disease progresses.Supplementation with hypercalcemic drugs is not balanced out with the expected increase of renal Ca excretion. Therefore,we think that CKD patients are exposed to a chronic Ca overload,sometimes underestimated,with the resulting negative impact in morbidity and mortality.

PUB518

Effect of Parathyroid Hormone on Serum Magnesium Level: The Neglected Relationship in Hemodialysis Patients with Secondary Hyperparathyroidism

Bing Tang, Li Fang, Junwei Yang. *Center for Kidney Disease, Second Affiliated Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: Chronic kidney disease–mineral and bone disorder (CKD–MBD) is an important complication in patients with end-stage kidney disease which is associated with cardiovascular morbidity and mortality. Since recent studies have shown that serum magnesium play an important role in secondary hyperparathyroidism, vascular calcification and cardiovascular mortality, the interest on magnesium (Mg) has grown.

Methods: This cross-sectional study was conducted on 111 patients with end-stage renal disease on maintenance hemodialysis who was hospitalized for secondary hyperparathyroidism. The interventional study was conducted on 23 patients underwent total parathyroidectomy.

Results: In our study, hypermagnesaemia (>2.5mg/dl) occurs in up to 44% of cases and hypomagnesemia did not present. No significant correlations were found between serum magnesium and parathyroid hormone (r =-0.143, p = 0.134). Correlation analysis and logistic regression analysis suggested that the derangement of magnesium homeostasis was correlated with the derangement of calcium/phosphate homeostasis. After parathyroidectomy, serum magnesium levels dropped immediately and reached the lowest level at one day after surgery; however, it gradually restored three days later. The changes of serum magnesium after surgery was positive correlated with the changes of serum phosphate (r=0.558, p=0.003).

Conclusions: The effect of PTH on magnesium metabolism could not be neglected, especially in hemodialysis patients with secondary hyperparathyroidism. The role of magnesium metabolism and therapeutic strategies to achieve optimum serum magnesium levels in CKD-MBD should take into account the varying stages of disease development.

PUB519

Calciphylaxis in Patient with Chronic Renal Disease Not Dialytic and Multiple Myeloma

Patricia Junqueira Freitas, Aline Lourenco Baptista, Clovis Antonio lopes Pinto, Joubert Araujo Alves, Pedro Caruso, Benedito Jorge Pereira, Fernanda Lemos Moura, Marina Harume Imanishe, Luis Andre Andrade, Germana Alves Brito. *Nephrology, AC CAMARGO, Sao Paulo, Brazil.*

Background: Calciphylaxis, also known as calcifying uremic arteriolopathy, is a rare medical condition, which is normally diagnosed in patients with terminal CKD who are already in renal replacement therapy (RRT).Objective:report the presence of calciphylaxis in CKD, in patient with oncologic disease.

Methods: Female patient, 71 years old,caucasian, conducted to AC Camargo Hospital for etiological investigation of injuries in lower limbs associated with renal failure, hypercalcemia, anemia and astenia. Has history of hypertension and obesity. Physical examination: poor general state, dyspneic, respiratory and cardiovascular systems without changes, ulcerated lesions of necrotic center in lower limbs (FIGURE). Laboratory tests: Creatinine 8.8 mg/dL;Urea 169 mg/dL;K 4.1 mEq/U; HCO3:16.3 mmol/U; pH 7.29; Cai: 1:58 mmol/U;PTH: 295 pg/ml; : 3.6mg/dL; otal Ca:12,9mg/dL;albumin 1.8g/dL.Renal US: regular.Parathyroid US: regular.Held biopsy(Bx) of skin:chronic inflammatory process sharpened with necrosis and calcification dystrophic in dermis and hypodermis.Bx of Bone marrow:neoplastic infiltration of plasma cells. The patient was transferred to ICU due septic shock of cutaneous focus, performed antibiotic therapy, hemodialysis (HD) with Calcium (Ca) 2.5, initiated sodium thiosulfate three times a week and cinacalcet, presenting improvement of the injuries.

Conclusions: The calciphylaxis is a complex clinical entity and pathogenesis not fully elucidated, what makes the treatment still not uniform. It is characterized by dermal ischemic necrosis, of acute and progressive installation. It must be paid attention to its presence even in non dialytic stages of CKD as happened in the described case.

PUB520

Calcium Binders Are They All Equal? Comparaison Calcium Acetate (CA) versus Carbonate Calcium (CC) in CKD 5D: Multicentric Study

Philippe Brunet,[1] David Attaf,[2] Laurent Juillard.[3] *[1]Nephrology - Dialyse, Conception Hospital, Marseille, Bouches-du-Rhône, France; [2]Dialyse, Fresenius, Paris, IDF, France; [3]Nephrology - Dialysis, Edouard Herriot Hospital, Lyon, Rhone, France.*

Background: CA's phosphate binder is available since 2010 in France. A monocentric study indicates that CA is equivalent to CC based on phosphatemia reduction **while reducing calcium intake by 60%**. This study compare CA to CC in different dialysis centers i.e different CKD MBD protocols.

Methods: 28 hemodialysis centers are involved. CC is switched to CA at M_0 with 6 months follow up (M_0-M_6). We compared M_O's biologic datas with M_6's datas.

Results: 293 patients (70+/-14 y) in 28 centers. At M_6 CA dosage was 3.8 +/- 2 pills/day. Demographic characteristics are consistent with our National French registery. At M6 mineral values are similar to M0 : Ph mM (1,54 +/- 0,55 vs 1,52 +/- 0,65 , NS), Ca mM (2,23 +/- 0,17 vs 2,21 +/- 0,15 , NS), PTH pg/ml (221 +/- 204 vs 262 +/- 217 , NS), Vit. D nM (75 +/- 32 vs 79 +/- 24 , NS), % pts with non calcium binder (43 vs 49 , NS), % pts w. Ca > 2,6 mM (2 vs 1 , NS), % pts w. Ph > 1,5 mM (39 vs 38 , NS). **The only difference is related to a decrease of Calcium Intake (g/d) from MO (1,51 +/- 1,13) to M6 (0, 63 +/- 0,31 , P<0,05).**

Conclusions: At M_6 Calcium intake is reduced by 57% vs M_O while Ph. is similar vs M_0. Mean serum calcium is not altered. The frequency of Ca > 2.60 mM and Ph > 1.5 mM are not modified at M_6/M_0. A M_6 PTH and 25-OH vit D are stable. **This multicenter study (ie different therapeutic strategies) confirm that CA is equivalent to CC with a reduced Ca Intake.**

PUB521

Hemodynamic Changes in Maintenance Hemodialysis Patients with Hypotension After Parathyroidectomy

Meijuan Meng, Bing Tang, Hong Ye, Junwei Yang. *Center for Kidney Disease, Second Affiliated Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: Parathyroidectomy (PTX) is applied to treat secondary hyperparathyroidism in hemodialysis patients. Some patients suffered from hypotension after PTX althrough hypocalcemia was corrected. The aim of this study was to demonstrate the hemodynamic changes in hemodialysis patients after PTX.

Methods: Twelve patients were included in this study. Among them 4 have hypotension after PTX (Group 1) and the other have their blood pressure remained after PTX (Group 2). Before PTX, systolic blood pressures (SBP) of all the 12 patients were above 90 mmHg. Noninvasive hemodynamic evaluation was performed before, during and after dialysis.

Results: Comparing with group 2, cardiac index (CI) was higher (P=0.252) while systemic vascular resistance index (SVRI) was lower (P=0.05) in group 1. The mean thoracic fluid capacity (TFC) of the two groups were similar (P=0.424) before dialysis. Serum Ca, PTH, ALP, ventricular ejection fraction and vascular calcification score of thoracic aorta, abdominal aorta and heart valve before PTX, as well as the weight of the removed parathyroid glands, serum Ca, ALP, hemoglobin after PTX of the patients were determined. No statistical differences were found. However, the phosphorus level was lower in group 1 both before and after PTX. CI, SVRI and TFC were similar in both groups during hemodialysis.

Conclusions: Patients with hypotension after PTX have a lower systemic vascular resistance index and a higher cardiac index, which might be associated with serum phosphorus level.

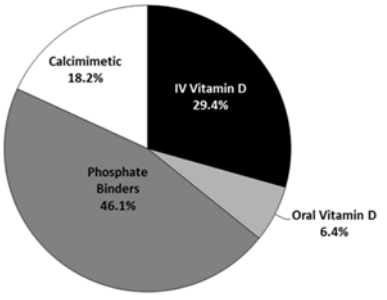
Cost of Medications Used in the Management of Secondary Hyperparathyroidism (SHPT) in Patients with End Stage Renal Disease (ESRD) Mark E. Bensink,[1] Leigh Darryl Quarles,[2] Vasily Belozeroff,[1] Kerry Cooper,[1] Jonathan D. Campbell.[3] *[1]Amgen Inc., Thousand Oaks, CA; [2]Univ of Tennessee, Memphis, TN; [3]Univ of Colorado, Aurora, CO.*

Background: Management of SHPT associated with ESRD is complex, typically requiring combinations of medications. Eighty-two percent of the ESRD population is covered by Medicare with detailed drug expenditures reported annually by the US Renal Data System. For the remaining 18% covered by commercial health plans, drug expenditure information is unknown. The purpose of this study is to estimate the cost of medications used in the management of SHPT in ESRD patients from the US commercial health plan perspective.

Methods: Economic analysis with one-year time horizon to estimate per-member-per-month (PMPM) cost for SHPT related medications: calcium and non-calcium-based phosphate binders, calcitriol or active vitamin D analogs, and calcimimetics. Input parameters include: prevalence of ESRD in commercial health plans (MarketScan®); medication utilization and non-adherence (IMS Health for oral medications and Outcomes Plus for intravenous [IV] medications); and medication wholesale acquisition costs (WAC) (AnalySource.com) with one-way sensitivity analysis.

Results: The total PMPM (2014 US Dollars) cost of SHPT-related medications is $0.34: cinacalcet $0.06, phosphate binders $0.16, oral vitamin D $0.02, and IV vitamin D $0.10.

Figure 1. Total PMPM Cost Breakdown



Results are most sensitive to variation in ESRD prevalence and cinacalcet WAC parameters.

Conclusions: Results indicate that the collective cost of medications for the management of SHPT in commercial health plans is substantial with the cost of cinacalcet being lower compared to phosphate binders and IV vitamin D, but higher compared to oral vitamin D.

PUB523

Medullar Compression by Bone Tumor: Case Report Cinthia Sobral Vieira, Nicole D.T. Carvalho. *Nephrology Unit- Clinefro, Hospital Ernesto Dornelles, Porto Alegre, RS, Brazil.*

Background: The presentation of vertebral tumors may have different kinds of manifestation. They can mimic neoplastic, inflammatory and congenital diseases. The following report is about a patient with a lytic bone lesion in the thoracic spine causing medullar compression symptoms.

Methods: A 66 years old masculine patient, with chronical renal disease in hemodialysis for 5 years, non-adherent to treatment or diet, had his levels of phosphor, calcium/phosphor, alkaline phosphatase and parathyroid hormone (PTH) elevated in the last year. He did not take the medication prescription: Calcitriol and Sevelamer. The patient came to the ER of a general hospital referring constipation and abdominal distention. During the hospitalization he started to refer paresthesia in inferior members with progressive march dysfunction. The neurological exam showed ataxic/calcaneal gait and strength reduction (4+/5+) in the inferior members.

Results: At first, an angiotomography study of the mesenteric vessels were made, thinking of the possibility of mesenteric ischemia, but the exam showed multiple lytic lesions in the corps of lumbar vertebras and in the hipbones, mimicking secondary implants. The spine MRI demonstrated one lytic bone lesion at the level of D6 and D7 causing medullar compression. The bone scintigraphy was suggestive of a metabolic bone disease and the parathyroid scintigraphy showed a hyperfunctioning tissue, in the parathyroid left pole. The patient was submited to a compressive laminectomy, the biopsy revealed a Brown Tumor. Then, it was indicated a parathyreodectomy. The pathological result showed no evidence of malign disease. Nowadays, the patient is still in hemodialysis, receiving calcium and under physiotherapy to recover muscle strength, already walking.

Conclusions: Brown Tumor or osteoclatoma is a rare bone lesion, an incidence of 1,4 to 13% in chronic renal patient due to a secondary hyperparathyroidism and less than 5% in primary hyperparathyroidism. It is more frequent in women. The vertebra involvement is uncommon. This case report has its importance for calling attention to importance to include brown tumor as a differential diagnosis in compressive spines lesions especially in chronic renal patients.

PUB524

Rescue-Therapy with Lanthanum-Carbonate (LC) in Uncontrolled Hyperphosphoremia in Dialysis Nicola Giotta, Angela maria Marino. *Dept of Medicine, Nephrology and Dialysis Unit, Cardinal Massaia Hospital, Asti, AT, Italy.*

Background: Control of hyperphosphatemia in hemodialysis provides an approach based on changes in diet, dialysis efficiency improvement, and use of phosphate binders. The latter, however, in some patients do not prove effective, conditioning the indirect increase of mortality and morbidity of the subject on dialysis. The objective of this study was to evaluate the difference in efficacy of a regimen of lanthanum carbonate plus standard therapy (LTS) compared to standard therapy alone (TS) in the treatment of patients with persistent hyperphosphatemia, as rescue-therapy.

Methods: We conducted an observational study of data on consecutive patients in hemodialysis who have presented more than four phosphorus values greater than 6 mg/dL in three months. Patients treated with TS, have varied therapeutic scheme introducing LC. Patients treated with sevelamer have outstanding this therapy and were treated with LC. The data analysis has been done considering a retrospective phase (FR) of three months and a prospective phase (FP) of six months, for each subject analyzing the effectiveness of therapy before and after enrollment.

Results: In a cohort of 163 patients on hemodialysis, we have selected for the study, 14 patients who had a mean age of about 65 years and length of dialysis than 6 years. The combination of LC plus TS produced a significant increase in the proportion of patients achieving the therapeutic targets as defined by the K/DOQI Guidelines. Reduction of 2.12 mg / dL (-32.7%) than the average of the P phase prospective (4:55 mg/dL) than the retrospective phase (6.77 mg/dL), was statistically significant ($p < 0.001$), is associated with the reduction of 19:21 mg2/dl2 (-32.9%) of the average value of CaxP in the prospective phase (39.07 mg2/dl2) compared to the retrospective phase (58.28 mg2/dl2), also statistically significant ($p < 0.001$). The patients at target at the end of FP accounted for 92.31% for P and 100% for the CaxP, respectively vs. the 7.14% and 50% of FR.

Conclusions: The introduction of the LC-as rescue therapy in the treatment of hemodialysis patients with uncontrolled hyperphosphatemia resulted very effective allowing more easily reach the therapeutic objectives.

PUB525

Glucocorticoid-Induced Osteoporosis in Renal Patients Gabrielle Goldet,[1] George Greenhall,[2] Alan D. Salama.[2] *[1]Basildon and Thurrock Univ Hospital; [2]Royal Free Hospital, London; [3]Royal Free Hospital, London.*

Background: Glucocorticoid-induced osteoporosis (GIO) is associated with severe morbidity due to fragility fractures as well traumatic fractures and 30-50% of patients on long term steroids are affected by GIO. GIO is relevant in the renal context as steroids are widely used to treat renal disease and as part of immunosuppression in transplant. Also, renal patients are already at higher risk of fractures in association with renal bone disease.

Methods: We designed and undertook an audit to assess screening and management of GIO in nephrology outpatients in a university hospital in London, using national guidelines as a benchmark for our performance. We then presented the results at a local meeting, produced posters and leaflets on GIO to be placed in the outpatient waiting area for patients so as to raise awareness of this issue and provided a simple algorithm to be followed by clinicians in all the clinic rooms. We then re-audited after 6 months.

Results: 100 patients were audited in each audit cycle. Measures audited were a) whether all patients over 65 were treated with bone-sparing agents (BSA); b) whether all patients with documented fragility fracture were treated with BSA; c) whether all patients under 65 without fragility fracture underwent DXA scan; d) whether all patients with T-score below -2.5 were treated with BSA; e) whether all patients with T-score 0 to -1.5 underwent repeat DXA within 3 years; f) whether BSA was prescribed for all patients where indicated; g) whether all patients are managed according to national guideline (cycle 1: 29%; cycle 2: 41%). See table for breakdown of results.

Audit measure	Audit 1 percentage (%)	Audit 2 proportion of patients meeting target	Audit 2 percentage (%)	Audit 2 proportion of patients meeting target
a	11	1/9	9	1/11
b	0	0/0	0/1	0
c	56	48/86	61	50/82
d	13	1/8	43	3/7
e	40	8/20	75	15/20
f	19	5/26	26	8/31
g	29	29/100	41	41/100

Conclusions: Our intervention has improved performance as measured against national guidelines, though the rate of GIO screening remains low. Many patients could potentially benefit from bone protection, though larger studies would be needed to demonstrate an effect on fracture incidence.

The Kidney Stone and Increased Water Intake Trial in Steel Workers: Results from a Pilot Study Hakam Gharbi,[1] Yair Lotan,[2] Jodi Antonelli,[2] Inmaculada Buendia Jimenez,[1] Allison Ahrens Beaver,[1] Aphrihl Dennis-Barrie,[1] Dendra K. Von merveldt,[1] Suzie Carter,[1] Adam B. Cohen,[1] John Poindexter,[3] Orson W. Moe,[3] Margaret S. Pearle.[2] *[1]Danone Research, Palaiseau, France; [2]Urology, Univ of Texas Southern Medical Center, Dallas, TX; [3]Mineral Metabolism, Univ of Texas Southern Medical Center, Dallas, TX.*

Background: Preventing dehydration in subjects at risk may provide a means of primary prevention of kidney stones. The purpose of this pilot study was to assess the hydration status of an at-risk group of steel plant workers based on end-of-shift ('post-shift') spot urine osmolality and 24-hour urinary stone risk parameters.

Methods: 100 volunteers were recruited from Gerdau Midlothian steel mill in Texas on 11/14/14 and 12/5/14. Clinical data was recorded and a post-shift spot urine sample was obtained for measurement of urine osmolality. In addition, participants were invited to submit a 24-hr urine sample within 4 weeks of enrollment.

Results: Mean age was 41 and 95% were men. The majority of subjects were white (75%), followed by 10% Hispanic and 9% Black. Mean body mass index was 30.1 kg/m^2 and overall 16% had past history of stone disease. Mean post-shift urine spot osmolality was 704.5 mOsm (169-1165 mOsm) and was >800 mOsm and >700 mOsm in 39% and 57%, respectively. Among 59 24-hour urines samples, mean volume was 1.89 ± 0.92 l/day, with 56% <2 liters and 17% <1 liter. Elevated levels of urinary analytes were found in 29% of subjects for calcium (>250mg/TV), 39% for uric acid (>700 mg/TV), 25% for oxalate (>45mg/TV) and 50% for sodium (>200 meq/TV).

Conclusions: The prevalence of stone disease in this population of steel workers is higher than the published prevalence of stone disease in the general population. A significant number of workers had concentrated post-shift and 24-hour urines and elevated levels of urinary analytes.

PUB527

Chronic Renal Pain in Medullary Sponge Kidney Giovanni Gambaro,[1] Jackie Hirsch,[2] Rocco Baccaro,[1] Nicole Topilow,[2] Matteo Bargagli,[1] David S. Goldfarb,[2] Pietro Manuel Ferraro.[1] *[1]Nephrology, Catholic Univ, Rome, Italy; [2]NY Univ, School of Medicine, New York, NY.*

Background: MSK usually occurs with recurrent stones;less frequently it is asymptomatic;very rarely the main manifestation is severe chronic flank pain. Often these pts are accused of seeking pain medications. Because of the rarity of such a presentation it is not know if pain is due to intense lithogenic activity or is independent of it, something like a form of the "loin pain hematuria syndrome". Three Facebook support groups exist for North American patients with MSK and chronic pain. Their cooperation allowed us to investigate chronic pain in MSK.

Methods: An ad hoc questionnaire and the Brief Pain Inventory were administered through a dedicated web site; 92 patients (89 females) participated after verification of the diagnosis of MSK (imaging and diagnosis certified by a nephrologist or urologist).

Results: Mean age of patients was 39.8y, (range 24-66). Age at onset of manifestations and MSK diagnosis were 23y (4-47) and 31y (7-57), respectively. Manifestations at onset were: flank pain (31%), reno-ureteral colic (RUC) (26%), hematuria (19%), cystitis (14%), pyelonephritis (10%). 71% of pts have daily pain, 76.5% have taken painkillers in the previous week and 69.1% needed them at the time of questionnaire administration; 58% take them ³1 time/day. The strong pain (5.4 in a scale from 0 to 10), jeopardizes general activities, mood and sleep. Only 4.6% of pts have RUC like pain; in 52.9% it is non-radiating flank pain with manifestations of possible UTI or stone passage (painful micturition, urgency, frequent urination, hematuria, fever); in 42.5% it is non-radiating lumbar pain without other manifestations (however only in 3 cases the pain was a unilateral flank pain). Pain is frequently associated with stone (67%) or sand passage (46%), hydronephrosis (42%), hematuria (42.4%).

Conclusions: Although in these MSK pts the chronic pain -that dominates the clinical manifestations - is usually associated with some of the typical symptoms of stone passage, in a fraction of pts this is not the case and pain is not associated with lithogenic activity. The etiology of this pain syndrome remains uncertain and merits investigation.

PUB528

Difference in Vitamin D Level Between Older and Younger Kidney Transplant Recipients Mohamed Amin Elesnawi, Abdullah Hamad, Fadwa S. Al-Ali. *Nephrology, Fahd Bin Jasim Kidney Center, Hamad General Hospital, Doha, Qatar.*

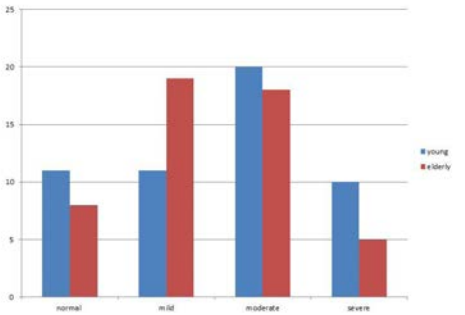
Background: Vitamin D deficiency is more common in older than younger people. In kidney transplant recipients, vitamin D deficiency has a high prevalence of up to 80 % according to recent studies. We compared vitamin D status in older versus younger patients with kidney transplant.

Methods: We reviewed all available record of kidney transplant recipients that came to our clinic at Hamad General Hospital in Qatar between September 1st 2013 and March 1st 2014. We recorded background data and laboratory tests. Patients divided into 2 groups younger and older (below and above 60 years old respectively). All patients were receiving vitamin D supplement.

Results: 102 patients were included. 52 patients in the younger group and 50 patients in the older. Age was 68.8+/-5.9 years in the older versus 41.9+/-10.4 years in the younger group. Table (1) compare laboratory values between the two groups. Vitamin D status was classified(normal above 30, mild 20-29, moderate 10-19 and severe below 10 ng/mL) figure (1).

	Younger (<60 Years) n=52	Older (>60 years) n=50
Male/Female	25/27	42/8
vitamin d	21.2+/-16.8 ng/mL	21+/-9.93 ng/mL
calcium	2.3+/-0.16 mmol/L	2.27+/-0.12 mmol/L
phosphorus	1.14+/-0.29 mmol/L	1.22+/-0.2 mmol/L
alkaline phosphatase	90+/-39.2 u/L	74.1+/-41 u/L
intact parathyroid hormone	126+/-142 pg/mL	140.8+/-223 pg/mL

Vitamin D status in elderly versus young kidney transplant patients



Conclusions: In a comparative study, we found that older trasnplant recipient group had more male patients (pValue<0.05), lower alkaline phosphatase and higher intact parathyroid hormone (not statistically significant) but similar vitamin D, calcium and phosphorus level. There was a trend towards milder vitamin D deficiency in the older group that could be due to better compliance with vitamin D supplement. Despite vitamin D supplement protocol and long sunny days in Qatar we still found high rate of vitamin D defeciency in transplant recipients (81.4%).

PUB529

Efficacy of Low Dose, Alternate Day Cinacalcet for Treatment of Secondary Hyperparathyroidism in Hemodialysis Patients: A Randomized Controlled Trial Pongsathorn Gojaseni, Dolnapa Pattarathitinan, Kolasorn Pakchotanon, Anutra Chittinandana. *Medicine, Bhumibol Adulyadej Hospital, Royal Thai Air Force, Bangkok, Thailand.*

Background: Secondary hyperparathyroidism (SHPT) is common in hemodialysis patients and has been associated with increased mortality. Cinacalcet, a modulator of calcium-sensing receptor, effectively reduced serum parathyroid hormone (PTH) in clinical studies. We tested whether prescription of low dose, alternate day cinacalcet could be an option for treatment of SHPT.

Methods: An open-labeled, randomized controlled trial enrolled hemodialysis patients with severe secondary hyperparathyroidism (intact PTH > 585 pg/ml). Patients were randomized to received low-dose cinacalcet (25 mg alternate day) or standard-dose (25 mg daily) for 16 weeks. At 8 weeks, doses of cinacalcet could be increased to achieve KDIGO PTH target of less than 585 pg/ml. The primary outcome was the difference in percentage of patients achieving KDIGO target at 16 weeks. The changes of serum iPTH, other biochemical data were also tested.

Results: Between July 2014 and January 2015, a total of 30 hemodialysis patients (15 females, 15 males) were randomly assigned to a treatment group: 16 to low-dose and 14 to standard-dose. Baseline iPTH in low-dose and standard-dose group was 1,065.9 ± 477.7 and 1,211 ± 466.5 pg/ml respectively (p = 0.409). During study period, 4 patients (2 from each group) were dropout from study due to adverse events. Intention to treat analysis showing that the percentage of patients who achieving KDIGO PTH target was not different (38.5% in low-dose group compared with 30.8% in standard-dose group, p = 1.0). Serum iPTH reduction during 16 weeks of study period in low-dose and standard-dose group was 253.5 ± 316.1 and 330.6 ± 698.2 respectively (p = 0.731). The adverse events were not different between both groups except hypocalcemia that tend to be higher in standard-dose (38.5% vs 13.3%, p = 0.274).

Conclusions: Among patients with SHPT, cinacalcet 25 mg alternate day may be sufficient effectively decrease serum iPTH levels with low incidence of hypocalcemia. The role of low dose cinacalcet in SHPT should be determined in large-scale, adequately powered randomized controlled trials.

Parathormone Stability in Hemodialyzed Patients: Comparison on Non-Centrifuged EDTA and Serum Samples with 2nd and 3rd Generation Assays

Marie Dohet,[1] Pierre Delanaye,[2] Etienne Cavalier.[1] *[1]Clinical Chemistry, Univ of Liege, CHU Sart-Tilman, Liege, Belgium; [2]Nephrology, Univ of Liege, CHU Sart-Tilman, Liege, Belgium.*

Background: PTH stability is of importance. Many studies have shown divergent results between EDTA and serum, mainly linked to differences in protocols or cut-offs used to decipher whether PTH remained stable or not. No studies have yet compared PTH as measured by 2nd and 3rd generation assays on the same samples in hemodialyzed (HD) patients.

Methods: Five pairs of samples (EDTA and gel tubes) were obtained in 10 HD patients before session. One pair was centrifuged and run immediately to establish the "T0". Two pairs were kept at +4°C and +25°C. They were centrifuged after 4 and 18 hours. Supernatant was kept at -80°C for one week. Then, all samples were measured in a single batch, on Roche Cobas and DiaSorin XL 2nd and 3rd generation PTH assays. Samples were considered as stable if 90% of subjects had a decrease lower than a total change limit (TCL) that takes both analytical and biological variability into consideration. All determinations were run in duplicates.

Results: At T0, no difference was observed between plasma and serum for any of the methods. PTH decreased in all samples and degradation was the same with 2nd or 3rd generation assays, whatever the method used. Percentages of decrease were systematically lower in EDTA plasma compared to serum and none of our subjects presented a decrease higher than the TCL with EDTA plasma. In serum, PTH was not considered as stable, but only when kept at 25°C for 18 hours.

Conclusions: PTH stability is of paramount importance for correct interpretation of the results. Many studies have tried to evaluate this stability but are not free from criticisms, mainly due to a poorly defined T0 and questionable acceptation limits. In this study, we used an unfrozen T0 and decision limits based on analytical and biological variations. Moreover, we tested 2nd and 3rd generation PTH on two automated platforms. Our results show that, if PTH is basically more stable in EDTA plasma than in serum, this advantage is only clinically significant when samples are stored for a long period (18h) at +25°C.

PUB531

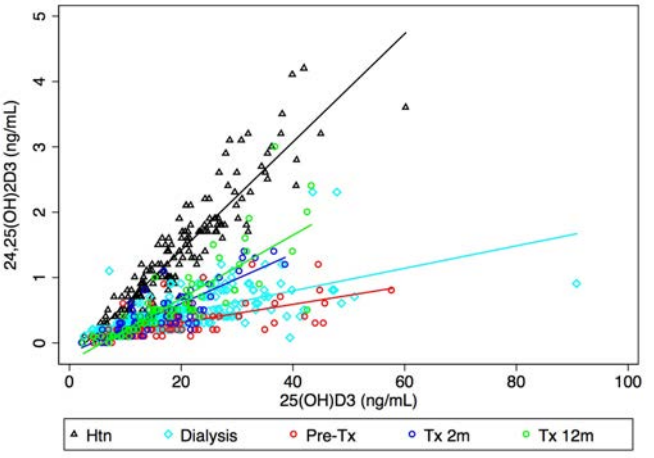
Vitamin D Metabolism Is Incompletely Restored After Kidney Transplantation

Thomas F. Hiemstra,[2] Stephen M.S. Ting,[1] Ragada El-Damanawi,[2] Kenneth Lim,[3] Martin Kaufmann,[4] Glenville Jones,[4] Daniel Zehnder.[1] *[1]Univ of Warwick, United Kingdom; [2]Univ of Cambridge, United Kingdom; [3]Massachusetts General Hospital, Boston; [4]Queen's Univ, Kingston, Canada.*

Background: Vitamin D deficiency is widely reported in patients with renal impairment and is associated with adverse outcomes. The extent and rate of recovery of vitamin D metabolism after kidney transplantation is uncertain.

Methods: We enrolled 175 dialysis patients (HD) listed for kidney transplantation, and 85 hypertensive but otherwise healthy controls (HTN). We determined blood markers of mineral metabolism including intact FGF23 and vitamin D metabolites at entry (or immediately pre-transplantation), 2 and 12 months. As a surrogate for vitamin D deficiency, we assessed the 25(OH)D3: 24,25(OH)2D3 ratio (D-ratio, normal 5-25).

Results: Of 175 dialysis patients, 76 were transplanted (TXR) during the study. TXR were younger with a lower BMI than controls. FGF23 was higher in HD patients than HTN at baseline, but normalised after 12 months (p=0.13). At baseline, vitamin D insufficiency (defined as 25(OHD <30 ng/mL) was present in 82% of subjects and did not differ between groups. However, vitamin D deficiency (defined as 25(OHD <10 ng/mL) was more common in dialysis (15% versus 4%, p=0.49). The baseline D-ratio was higher in HD (48, IQR 27-67) than in HTN (16, IQR 14-18, p<0.0001) patients. Transplantation resulted in significant reduction in D-ratio after 2 and 12 months compared to HD (p=0.0008 and p=0.005 respectively). The slope of D-ratio vs 25(OH)D3 increased after transplantation, but remained lower than for HTN controls, suggesting reduced expression or activity of the catabolic CYP24A1 (25-OH-D3-24-hydroxylase) in kidney failure.



Conclusions: Vitamin D insufficiency is highly prevalent in patients on dialysis and in hypertensive controls, and only partially resolves after kidney transplantation.

PUB532

Low Time-Averaged Serum Intact Parathyroid Hormone Level Is an Independent Risk Factor for Overall Mortality and Major Adverse Cardiac and Cerebrovascular Events in Incident Dialysis Patients

Sul A Lee,[1] Mi Jung Lee,[1] Kyoung Sook Park,[1] Jong Hyun Jhee,[1] Jae Eun Um,[2] Meiyan Wu,[2] Hyung Jung Oh,[1] Jung Tak Park,[1] Seung Hyeok Han,[1] Shin-Wook Kang,[1,2] Tae-Hyun Yoo.[1] *[1]Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea; [2]Severance Biomedical Science Inst, Brain Korea 21 PLUS, Yonsei Univ College of Medicine, Seoul, Korea.*

Background: Chronic kidney disease-mineral bone disorder (CKD-MBD) is known as a major risk factor for cardiovascular disease in end-stage renal disease (ESRD) patients. CKD-MBD is classified into low turnover and high turnover bone disease according to the bone dynamics, both of which are related with vascular calcification in ESRD. To evaluate the prognostic value of abnormal serum parathyroid hormone (PTH) levels on ESRD patients, we investigated the effects of time-averaged serum intact PTH (TA-iPTH) levels on overall mortality and major adverse cardiac and cerebrovascular events (MACCEs) in incident dialysis patients.

Methods: In this prospective observational study, 413 patients who started dialysis between January 2005 and September 2010 at Yonsei University Health System were enrolled. Patients were divided into three groups according to TA-iPTH levels during the 12 months after initiation of dialysis (group 1: <65pg/ml, group 2: 65 to 300 pg/ml, group 3: >300pg/ml). Cox regression analysis was performed to determine the prognostic value of TA-iPTH on overall mortality and MACCEs.

Results: The mean age was 56.5±14.5 years and 222 patients (53.8%) were male. During a median follow-up of 50.8 months, 49 patients (11.9%) were dead and MACCEs were occurred in 55 patients (13.3%). Multivariate Cox regression analysis demonstrated that low TA-iPTH level was an independent risk factor for both overall mortality [group 2 as reference; group 1, hazard ratio (HR)=2.08, 95% confidence interval (CI)=1.12-3.85, P=0.02] and MACCEs (HR=1.88, 95% CI=1.04-3.40, P=0.04) in incident dialysis patients after adjusting confounding factors.

Conclusions: This study demonstrates that low TA-iPTH is an independent risk factor for overall mortality and MACCEs in incident dialysis patients.

PUB533

Combined Analysis of Hypercalcemia and PTH Levels as Clue to Unveil Persistent Transplant Hyperparathyroidism

Melani Custodio,[1,2] Maria Julia C. L. N. Araujo,[1,2] Wagner Dominguez,[1] Rosa M.A. Moyses,[1,3] Elias David-Neto,[1] Vanda Jorgetti.[1] *[1]Nephrology Div, Univ de Sao Paulo; [2]Transplant Unit, Univ de Sao Paulo; [3]UNINOVE, Sao Paulo, Brazil.*

Background: Mineral and bone metabolism disorders in chronic kidney disease (CKD-MBD) are not always corrected after kidney transplantation (TxR). The persistence of hyperparathyroidism may have a negative impact on patient and graft outcome. Our objective was to evaluate the evolution off CKD-MBD and the incidence of hyperparathyroidism after 12 months of TxR.

Methods: In this study, we included all consecutive patients submitted to a TxR during the period between Jan 2010 and Dec 2014 in a University based center. We excluded patients with a PTH <300 pg/ml before TxR, multi-organ transplants, patients with an eGFR<30mL/min and those who underwent parathyroidectomy after TxR. Twelve-month eGFR, plasma levels of total calcium (Ca), phosphorus (P), alkaline phosphatase (AlkP), magnesium (Mg), parathormone (PTH), and 25-hydroxi vitamin D (25-OH vit D) were compared to baseline values. A PTH >100pg/mL and a total calcium >10.2mg/dL were considered abnormal. We defined high PTH, with or without hypercalcemia as the primary endpoints for the analysis.

Results: During the observation period, 408 patients were evaluated. There was a significant increase in eGFR and in calcium levels 12 months after the TxR. Compared to the baseline, PTH, AlkP, and P significantly decreased. 25-OH Vit D did not change during the period. Fifteen percent of patients presented both PTH and Ca above the reference levels, while 37% presented isolated high PTH and 8% hypercalcemia only. Multivariate analysis disclosed that post-TxR hyperparathyroidism was dependent on pre-transplant PTH (OR 1.001; CI 95%: 1.001-1.002) and Ca (OR 1.233; CI 95%: 1.036-1.468).

Conclusions: Monitoring Ca and PTH before and after TxR may be important to detect patients at high risk of persistent hyperparathyroidism, and to identify patients in need of treatment to prevent its complications.

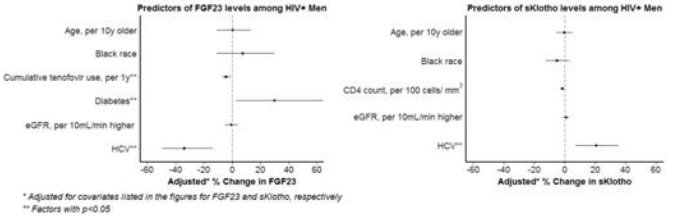
PUB534

Predictors of FGF23 and Soluble Klotho in HIV Infection Ruibin Wang,[1] Michael Shlipak,[2] Joachim H. Ix,[3] Michelle M. Estrella.[1] *[1]Johns Hopkins Univ; [2]UCSF; [3]UCSD.*

Background: In the general population, FGF23 and its co-receptor, soluble klotho (sKlotho), have been implicated in the aging process. HIV+ individuals are at higher risk of age-related comorbidities compared with HIV- persons. We evaluated whether FGF23 and sKlotho levels differed by HIV status and determined clinical factors associated with each hormone in HIV+ men.

Methods: 384 HIV+ and 225 HIV- men in the Multicenter AIDS Cohort Study (MACS) were randomly selected for FGF23 and sKlotho measurements from samples stored in 2008-2010. We compared FGF23 and sKlotho levels by HIV status, adjusted for age and race. Multivariable linear regression models were used to determine predictors of FGF23 and sKlotho levels among HIV+ men.

Results: Mean age was 53y; 34% were black; and median eGFR was 90mL/min. 99% of HIV+ men were antiretroviral-treated. FGF23 and sKlotho were not significantly correlated (r=-0.09). In adjusted analyses, HIV was associated with 11% (p=0.002) higher sKlotho but not FGF23 levels (-1%; p=0.84). Among HIV+ men, diabetes was associated with 30% (95% CI: 3-65%) higher FGF23, whereas HCV (-34%; 95% CI: -14%, -49%) and cumulative tenofovir (TDF) exposure (-4%/year; 95% CI: -1%, -7%) were associated with lower FGF23 levels. In contrast, only HCV was associated with higher sKlotho (21%; 95% CI: 7%, 36%). [**Figure**] Neither CD4 count nor HIV RNA were associated with FGF23 or sKlotho concentrations.



* Adjusted for covariates listed in the figures for FGF23 and sKlotho, respectively
** Factors with p<0.05

Conclusions: HIV+ individuals had similar FGF23 but higher sKlotho levels compared to HIV- counterparts. Among HIV+ men, clinical predictors associated with FGF23 differed from those associated with sKlotho. Mechanisms by which HIV treatment and co-morbid conditions may impact these hormone levels need further study.

PUB535

Response of Fibroblast Growth Factor 23 to Sodium Interventions in Diabetic Nephropathy and Arterial Hypertension Jelmer K. Humalda,[1] Sarah Seiler,[2] Arjan J. Kwakernaak,[1] Marc G. Vervloet,[3] Gerjan Navis,[1] Gunnar H. Heine,[2] Martin H. De Borst.[1] *[1]Nephrology, Univ Medical Center Groningen, Groningen, Netherlands; [2]Nephrology and Hypertension, Saarland Univ Medical Center, Homburg, Germany; [3]Nephrology, VU Medical Center, for NiGrAm, Amsterdam, Netherlands.*

Background: Fibroblast growth factor 23 (FGF23) rises progressively in chronic kidney disease (CKD) and is associated with adverse cardiorenal outcomes. Both CKD patients with diabetic nephropathy (DN) and patients with hypertension are vulnerable to the effect of excess sodium on volume status. FGF23 putatively induces sodium retention by up-regulating the sodium-chloride cotransporter (NCC). We studied whether, conversely, intervention in sodium status affects FGF23 levels.

Methods: We performed a post-hoc analysis of a randomized controlled 2x2 cross-over trial in 45 DN patients on background ACE-inhibition (ACEi) with four 6-week treatment periods with add-on hydrochlorothiazide (HCT) or placebo, combined with regular (RS) or low sodium (LS) diet. Plasma C-terminal FGF23 was measured by ELISA (Immutopics). Additionally, FGF23 was measured in 12 patients with arterial hypertension but without overt CKD before and after 4 hours of intravenous administration of 2 liters sodium-chloride 0.9%. Changes in FGF23 were assessed by Friedman's test and Wilcoxon Signed Rank test as appropriate.

Results: DN patients were 65±9 years old (mean±SD). During ACEi+RS eGFR was 65±25 mL/min/1.73m², HbA1c 7.1±0.8% and albuminuria 649 mg/d median [1st-3rd quartile: 230-2008 mg/d]. FGF23 levels were 94 [73–141] RU/mL . FGF23 did not change significantly after adding either HCT (99 [74–148] RU/mL) or low sodium diet (99[75–135 RU/mL]) or both HCT and low sodium diet (111 [81–160] RU/mL), *P*=0.15. The patients with arterial hypertension were 45±13 years old with an eGFR of 101±18 mL/min/1.73m². Sodium-chloride infusion did not affect FGF23 (before: 68 [58–97] RU/mL, after: 67 [57–77] RU/mL, *P*=0.4).

Conclusions: Chronic and acute changes in sodium status did not materially change FGF23 in DN and hypertensive patients, respectively. Our data thus do not support a direct feedback loop between volume status and FGF23 in diabetic nephropathy or hypertension.

PUB536

Hypocalcaemia Management Post Parathyroidectomy in Renal Patients – Our Experience and Change in Practice Rajkumar Chinnadurai, Maharajan Raman, Constantina Chrysochou, Smeeta Sinha. *Dept of Renal Medicine, Salford Royal NHS Foundation Trust, Salford, United Kingdom.*

Background: Hypocalcaemia is common post parathyroidectomy in renal patients with secondary hyperparathyroidism due to hungry bone syndrome with an incidence as high as 51%. Hypocalcaemia can be prevented by effectively preloading patient with Vitamin D supplements and close monitoring of calcium levels post operatively. Currently there is no clear guidance on the preloading dose of One-alphacalcidol in literature. Our current practice is to preload all patients with 2 mcg one-alphacalcidol for 5 days pre operatively. Our aim was to study the management of hypocalcemia post parathyroidectomy in renal patients and factors influencing length of hospital stay (LOS). To identify if any changes in current practice could improve outcome.

Methods: Retrospective observational study of all renal patients who underwent parathyroidectomy under a single surgeon over 6 years (April 2008 to September 2014). Data was collected from the Electronic Patient Record. Data were analysed using Stats direct and Fisher Exact test was used for testing statistical significance.

Results: 72% of our sample (n = 25) were male with a mean age of 54.Of the 25 there were 13 transplant, 9 haemodialysis and 3 CKD patients. The mean hospital stay was 5 days shorter than quoted in the literature (5.6 Days). 3 of 25 patients were not preloaded.40% of our patients needed intravenous calcium replacements which was the main cause for increased LOS (p=0.0002). Haemodialysis patients had longer LOS than CKD and Transplant patients(p=0.0002), this group were more likely to not have received pre-loading. Those undergoing total parathyroidectomy had increased LOS compared to subtotal parathyroidectomy (p=0.0009). There were no surgical complications contributing to a delay in discharge.

Conclusions: Insufficient preloading was identified as a major risk factor for hypocalcaemia,which significantly increased LOS. Further to consensus between renal and surgical teams we have increased the preloading dose of one-alphacalcidol to 5 mcg for 5 days pre operatively. A follow up study is planned in 12 months to observe the outcome of this change.

PUB537

Links Between Urinary Phosphate Handling, FGF23 and Klotho: An Australian Single-Centre Cross-Sectional Study Sven-Jean Tan,[1,2] Edward Robert Smith,[1] Stephen G. Holt,[1,2] Tim Hewitson,[1,2] Nigel David Toussaint.[1,2] *[1]Nephrology, The Royal Melbourne Hospital, Melbourne, Victoria, Australia; [2]Medicine (RMH), The Univ of Melbourne, Melbourne, Victoria, Australia.*

Background: Aim: To examine the links between measured phosphate parameters and regulators of phosphate homeostasis (fibroblast growth factor-23 [FGF23] and soluble α-klotho [sKl]). Background: FGF23, via the FGF-Receptor/Klotho complex, reduces expression of sodium-phosphate co-transporters thereby inhibiting tubular phosphate reabsorption. Chronic kidney disease (CKD) leads to FGF23 excess and deficiency of sKl. Elevated serum phosphate (sPi) results as remaining functioning nephrons are unable to compensate for reduction in total phosphate excretion. Complex relationships between these parameters in health and disease, and the impact on phosphate handling, are not fully understood.

Methods: Blood samples and spot and 24-hour urine were collected from patients with CKD (Stages 1-5) and healthy volunteers. Serum and urine biochemistry, intact FGF23 and sKl were analysed. FGF-23 and sKl were log-transformed (Ln). Fractional excretion of phosphate (FEPi) and maximal tubular phosphate reabsorption (TmP) were calculated. Pearson correlation coefficients were used to assess correlation between phosphate handling and regulatory hormones.

Results: 116 participants (77 CKD and 39 controls) were recruited. 74 (63.8%) were male. Median (IQR) age of all participants was 61 (49-71) years. FGF23 and FEPi were higher, while sKl and TmP were lower, in CKD compared to controls (all p<0.005). Adjusting for eGFR, LnFGF23 correlated with FEPi (*R*=0.222, p=0.026) and sPi (*R*=0.268, p=0.007) while LnKlotho displayed robust relationships with TmP (*R*=0.336, p=0.001) and sPi (*R*=0.309, p=0.002). There was no association between LnFGF23 and LnKlotho.

Conclusions: Disruption of phosphate regulatory mechanisms is characteristic of CKD. In this small cohort, we established that FGF23 contributes to phosphate excretion. However, sKl may provide insight into a greater physiological role of Klotho in regulating TmP at a cellular level. Causal relationships should be explored further *in vitro*.

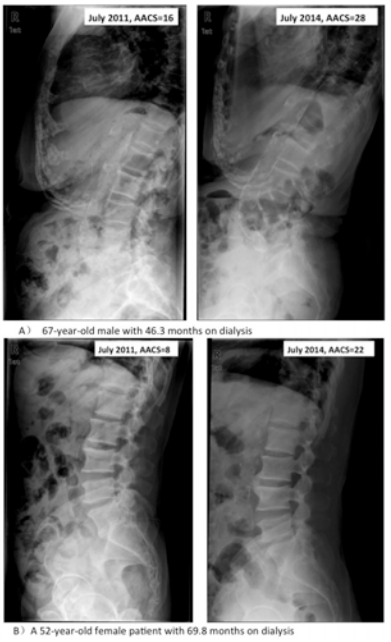
PUB538

Fibroblast Growth Factor 23 Can Predict the Progress of Aortic Artery Calcification in Dialysis Patients Zijin Chen,[1] Xiaonong Chen,[1] Xiaobo Ma,[1] Bei Ding,[2] Huawei Ling,[2] Nan Chen.[1] *[1]Nephrology, Ruijin Hospital, Shanghai Jiaotong Univ School of Medicine, Shanghai, China; [2]Radiology, Ruijin Hospital, Shanghai Jiaotong Univ School of Medicine, Shanghai, China.*

Background: To investigate the factors associated with progress of aortic artery calcification in maintenance haemodialysis (MHD) patients and to determine whether plasma FGF23 level is related to progress of aortic artery calcification.

Methods: MHD patients from Ruijin Hospital from July 1st 2011 to July 31th 2011 were involved in our study. Follow up 36 months. Aortic artery calcification (AAC) was detected by a lateral lumbar X-ray plain and read by two radiologists.

Results: 120 MHD patients were enrolled and followed up for 36 months. To July 2014, a total of 67 MHD patients finished the study. Among 67 patients, 32 were male, mean age 53.9±13.1 years old, mean dialysis vintage 44.1±38.1 months, median FGF23 level 48052 (11372-35750.4)Ru/ml, LgFGF23 3.79±0.83. In July 2011, 53.7% of patients had visible calcification in the abdominal aorta and mean involved segment was 1.42 with mean AAC scores(AACS) 3.96. In July 2014, 73.1% had AAC and mean involved segment was 2.34 with mean AACS 10.7. There are significant differences between two AAC involved segments and AACS (both P<0.001). Age, dialysis vintage and FGF23 level had significant difference between AAC progress group and no AAC progress group (P = 0.007, <0.001 and 0.020, separately). Logistic analysis showed that the independent parameters associated with AAC progress were age (OR=1.114, CI:1.045-1.186) and Lg FGF23 (OR=3.848, CI:1.429-10.346) (P<0.001).



Conclusions: The severity of vascular calcification progress yearly in maintain heamodialysis patients. Age and FGF23 are independently associated with the progress of AAC. FGF23 level could predict the progress of AAC in MHD patients.

PUB539

Could FGF23 Be a Regulator of Hepcidin in Liver Cells? Justine Bacchetta, Nathalie Demoncheaux, David Durantel. *Hospices Civils de Lyon and INSERM, Univ Claude Bernard Lyon 1, Lyon, France.*

Background: Hepcidin is a 25-amino-acid protein synthesized in hepatocytes and macrophages that acts as a post-translational inhibitor of ferroportin, the only receptor known to export iron from intracellular compartments to systemic circulation. Thus, higher hepcidin levels are associated with greater intracellular sequestration of iron, and increased risk of anemia. Vitamin D is an inhibitor of hepcidin expression; the working hypothesis is that FGF23 could be an 'inverse' regulator of iron metabolism in comparison to vitamin D, with a stimulation of hepcidin expression, an increase of intracellular ferritin and an inhibition of ferroportin expression on the cell membrane, leading to a further intracellular sequestration of iron.

Methods: Three different types of liver cells were used: HepG2, HepaRG and primary human hepatocytes (PHH). Cells were exposed to FGF23 (1, 10 et 100ng/mL), at different time points (H6, H24, H48). Cultures were performed in triplicates, and QRT-PCR in duplicates (StepOne Plus Real-Time PCR). Western Blots were also performed (Erk and Akt phosphorylation pathways, FGFR1, FGFR3, ferritin).

Results: In HepG2, even though FGFR-1 expression was found by Western blot analysis, FGF23 did not modify hepcidin expression by QRT-PCR, and Erk/Akt pathways were not activated by FGF23. In HepaRG cells, hepcidin expression was modified with FGF23 by QRT-PCR, i.e. increased at 6 hours and decreased at 24 hours,

Fold change of hepcidin mRNA expression in comparison to PBS	FGF23, 1 ng/mL	FGF23, 10 ng/mL	FGF23, 100 ng/mL
6 hours	1.34±0.22 *	1.53±0.18 *	1.17±0.01*
24 hours	0.68±0.12 *	0.73±0.08*	0.90±0.04

* p<0.05; Western blot analyses demonstrated the presence of FGFR1 and FGFR3, with an activation of the Erk pathway at 30 and 60 minutes with FGF23. However, there was no modification of ferritin by Western blots analysis with FGF23. In the only batch of PHH that was available, hepcidin expression increased at 6 and 24 hours.

Conclusions: FGF23 does not appear to play a crucial role in iron regulation in liver cells, even though its potential role in PHH deserves further studies.

PUB540

Prevalence of Hyperparathyroidism and Its Correlates in a Large Cohort of Hemodialysis Patients Pasquale Esposito,[1] Fabio Malberti,[2] Elena Caramella,[1] Marta Calatroni,[1] Edoardo La Porta,[1] Marina Foramitti,[2] Rosanna Coppo,[3] Antonio Dal Canton.[1] *[1]Nephrology, Fondazione IRCCS, Pavia, Italy; [2]Nephrology, Istituti Ospitalieri di Cremona, Cremona, Italy; [3]Nephrology, Regina Margherita Children's Hospital, Turin, Italy.*

Background: Beyond experimental setting of randomized trials, little is known about the occurrence of mineral bone disorders (MBD) in the real-life clinical practice of hemodialysis (HD). This is the reason why we designed this observational study to define the prevalence of hyperparathyroidism (HPT) and its correlates in a large cohort of HD patients.

Methods: We enrolled HD prevalent patients from 38 Dialysis Units collecting data on: clinical information, dialysis parameters, biochemical and instrumental evaluations and pharmacological therapy. According to the KDIGO guidelines we divided the patients in: patients affected by HPT (i.e. PTH> 9 the upper reference limit of each laboratory) vs patients on target.

Results: Out of 495 patients, 34 (6.8%- 59.9±15.5 years, 53%M) presented HPT with mean PTH of 1064±536 pg/ml, while 461 patients resulted OT (93.2%- 66.9±13.7 years, 66%M), mean PTH 242±151 pg/ml (p<0.0001). HPTs were younger than OT (59.9±15 vs 69.9±13.7 years, p=0.008), with a longer HD history (126.2±125 vs 64.3±69.4 months, p=0.0003). There were not significant differences in both clinical and dialysis parameters. Similarly, there were not differences in laboratory examination except from serum ALP that resulted higher in HPTs (194.8±142 vs 144.1±108 U/l OT, p=0.01). Moreover, there were not differences in the use of phosphate binders, whereas a significantly higher percentage of HPTs was taking paracalcitol and calcimetics and the prescribed vitamin D doses (both as calcitriol and paracalcitol) were significantly higher in HPT patients.

Conclusions: The prevalence of HPT in our population was surprisingly lower, compared to that reported in previous studies. This finding could be due to the general application of KDIGO guidelines, which recommend more permissive PTH levels compared with the previous K-DOQI guidelines, such as to the availability of effective drugs, probably used more appropriately than in the past.

PUB541

Effect of Vitamin D Receptor Activators on Glomerular Filtration Rate: A Meta-Analysis and Systematic Review Qian Zhang, Jing Chen. *Div of Nephrology, Huashan Hospital, Fudan Univ, Shanghai, China.*

Background: Vitamin D receptor activators (VDRAs) can protect against mineral bone disease, but they may also elevate serum creatinine and reduce glomerular filtration rate (GFR).

Methods: We conducted a systematic review and meta-analysis of randomized clinical trials (RCTs) to evaluate the effect of VDRAs on kidney function and adverse events. MEDLINE, EMBASE, the Cochrane Controlled Trials Register were searched for RCTs that evaluate vitamin D receptor activators (alfacalcidol, calcitriol, doxercalciferol, falecalcitriol, maxacalcitol and paricalcitol) up to March 2015.

Results: We included 31 studies, all of which were performed between 1976 and 2015, which enrolled 2621 patients. Patients receiving VDRAs had lower eGFR (weighted mean difference WMD -1.29 mL/min /1.73 m^2, 95% CI -2.42– -0.17) and elevated serum creatinine (WMD 7.03 µmol/L, 95% CI 0.61–13.46) in sensitivity analysis excluding studies with dropout rate more than 30%. The VDRAs and control groups had no significant differences in all-cause mortality (relative risk RR 1.41, 95% CI 0.58–3.80), cardiovascular disease (RR 0.84, 95% CI 0.42–1.71), and severe adverse events (RR 1.15, 95% CI 0.75–1.77). Episodes of hypercalcemia (RR 3.29, 95% CI 2.02–5.38) were more common in the VDRAs group than in the control group.

Conclusions: Although administration of VDRAs slightly reduced the eGFR, all-cause mortality and severe adverse events were comparable between the groups. Future RCTs with larger sample sizes are needed to assess whether the mild reduction of eGFR is of clinical significance.

PUB542

Low Dose Cholecalciferol Supplementation on Serum Inflammatory Markers in Hemodialysis Patients with Hypovitaminosis D Yeon Joo Lee,[1] Insun Kim,[1] Eunyoung Lee,[2] Joo-Hark Yi,[2] Hee Joon Baek,[3] Sang-Woong Han,[2] Sang sun Lee.[1] *[1]Food and Nutrition, Hanyang Univ, Seoul, Korea; [2]Internal Medicine, Hanyang Univ Guri Hospital, Guri, Korea; [3]Nutirtion, Hanyang Univ Seoul Hospital, Seoul, Korea.*

Background: Vitamin D deficiency is common in hemodialysis(HD) patients and has been reported to be associated with mortality due to cardiovascular disease and an inflammatory response. The aim of this study was to investigate the hypothesis that low dose cholecalciferol supplementation improves serum 25(OH)D and $1,25(OH)_2D$ levels, and reduces inflammatory markers. Moreover, it was to analyze the association of FGF-23 and 25(OH)D levels.

Methods: This study was an one-year intervention study for hemodialysis patients with hypovitaminosis D (25(OH)D<30 ng/mL). During the first six months, the patients received 3,000 IU of cholecalciferol after each hemodialysis (9,000 IU/week), thereafter, they stopped taking supplements. Serum levels of 25(OH)D, $1,25(OH)_2D$, and other biological variables were measured every 3 months for one year. We investigated the effects of cholecalciferol supplementation on the biological variables and inflammatory markers. In addition, the effective factors on the levels of 25(OH)D and $1,25(OH)_2D$ after cholecalciferol supplementation were assessed by multivariate regression analysis.

Results: Twenty-nine patients with hypovitaminosis D participated in our study. During cholecalciferol supplementation, the 25(OH)D and $1,25(OH)_2D$ concentration significantly increased from baseline to six months [9.9 to 34.3 ng/mL ($p<0.001$) and 19.7 to 22.9 pg/mL ($p<0.05$), respectively]. At 6 months, 65.5% of the patients had 25(OH)D levels within the target range [³30 ng/mL] with a low dose of cholecalciferol supplementation. Also serum calcium and phosphorus levels did not increase above the normal range. However, the inflammation markers, hsCRP, e-selectin, VEGF-A, were not shown significant improvements after taking cholecalciferol supplements. The effective factors on serum 25(OH)D levels were BMI, baseline $1,25(OH)_2D$ and 6 months FGF-23 concentration by multivariate regression analysis.

Conclusions: The low dose cholecalciferol supplementation was effective in correcting serum vitamin D deficiency or insufficiency and safe for hemodialysis patients. However, 6 months of low dose cholecalciferol supplementation in these patients did not improve the levels of inflammatory markers.

The Effects of sKlotho on Left Ventricular Mass and Echocardiographic Changes in Patients with Chronic Kidney Disease Marc-Sebastian Baier,[1] Lucie Bauer,[1] Franziska Sandermann,[1] Insa E. Emrich,[1] Kathrin Untersteller,[1] Sarah Seiler,[1] Vincent Brandenburg,[2] Danilo Fliser,[1] Gunnar H. Heine.[1] *[1]Internal Medicine IV - Nephrology and Hypertension, Saarland Univ Medical Center and Saarland Univ Faculty of Medicine, Homburg, Saarland, Germany; [2]Dept of Internal Medicine I – Cardiology, Univ Hospital of the RWTH Aachen, Aachen, Nordrhein-Westfalen, Germany.*

Background: Recently experimental data suggest that elevated circulating levels of soluble Klotho (sKlotho), which is the beyond FGF-23, may directly induce myocardial damage. In our prospective CARE FOR HOMe study we analyzed the effect of serum sKlotho levels on patients with left ventricular hypertrophy at baseline and on echocardiographic changes during five years of follow-up.

Methods: The ongoing CARE FOR HOMe study recruits chronic kidney disease G2-G4 patients. At baseline serum FGF-23 (c-terminal; Immuntopics; San Clemente; CA) and serum sKlotho (Immuno-Biologic Laboratories, Fujiokashi, Gunma, Japan) were measured in all patients. Cardiovascular and renal risk factors were evaluated by a questionnaire. The present analysis includes 398 patients with an echocardiography at baseline. 94 patients received an echocardiography after five years of follow-up according the American Society of Echocardiography guidelines. Moreover the echocardiography was done by one physician.

Results: At baseline 155 patients (40%) had a normal ventricular geometry, 134 patients (34%) had an apparently concentric remodelling, 61 patients (16%) had a concentric hypertrophy and 39 patients (10%) had an excentric hypertrophy. At the beginning of our study, left ventricular mass (LVMI) correlated with the following parameters: glomerula filtration rate (eGFR; $r = -0.19$; $p < 0.001$), serum FGF-23 ($r = 0.18$; $p < 0.001$), age ($r = 0.18$; $p < 0.001$) and pulse pressure ($r = 0.15$; $p < 0.001$). LVMI was not correlated with sKlotho ($r = -0.07$; $p = 0.183$) and mean blood pressure ($r = 0.10$; $p = 0.052$).

Conclusions: In contrast to recent animal data our results show neither an association of sKlotho with prevalent left ventricular hypertrophy nor with LVMI changes in patients with chronic kidney disease.

PUB544

Cost-Minimization Analysis of Sucroferric Oxhydroxide and Sevelamer Carbonate in Patients on Dialysis with Secondary Hyperparathyroidism in Germany Joris Van Stiphout,[1] Matthias Schwenkglenks,[1] Peter Braunhofer,[2] Thomas Szucs,[1] Viatcheslav Rakov,[2] Patricia R. Blank.[1] *[1]Univ of Basel, European Center of Pharmaceutical Medicine, Univ of Basel, Basel, Switzerland; [2]Vifor Pharma, Glattbrug, Zurich, Switzerland.*

Background: Many patients with chronic kidney disease (CKD) on dialysis require vitamin D (Vit.D) agents for managing secondary hyperparathyroidism (SHPT). It has been shown that the concomitant administration of oral phosphate binders (sucroferric oxhydroxide, SFOH or sevelamer carbonate, SEV) and Vit.D therapies might impair the therapeutic effect of the Vit.D due to drug-drug interaction. Based on clinical trials (NCT01324128/ NCT01464190), this cost-minimization analysis assessed the economic impact of using SFOH compared to SEV treatment with Vit.D agents from a German third-party payer perspective.

Methods: Costs of patients with serum phosphate concentrations ≥6.0 mg/dL receiving either SFOH (1.5g/day [3 tablets/day]) or SEV (6.4g/day [8 tablets/day]) were assessed. Due to lack of interaction, it was assumed that patients on SFOH were treated exclusively with oral Vit.D (calcitriol, 0.28mg/day), whereas SEV patients received intra-venous Vit.D agents (paricalcitol, 1.84mg/day). Costs for the administration of paricalcitol and for adverse events were not included.Drug acquisition costs were calculated on the basis of the German standard pharmacy prices (Rote Liste 2015). Uncertainties were addressed in one-way sensitivity analyses.

Results: Over an observation period of one year, costs for SFOH or SEV resulted in EUR3'416 or EUR 3'592, respectively. Annual Vit.D therapy costs yielded in EUR 209 for calcitriol and EUR 3'306 for paricalcitol, respectively. SFOH treatment with calcitriol versus SEV with paricalcitol resulted in an annual cost-saving of EUR 3'273 per patient. The variation of drug prices by ±25% did not change the conclusion of the base-case.

Conclusions: This study provide evidence that SFOH treatment with calcitriol has an economic benefit compared to SEV with paricalcitol to treat German CKD patients with SHPT.Economicsavings might be substantial for the German health care system, but real world data will be needed to confirm these findings.

PUB545

Effect of Intravenous Saccharated Ferric Oxide on FGF23 Metabolism in Dialysis Patients Masahiro Koizumi,[1] Hirotaka Komaba,[1] Yoko Takeda,[2] Masafumi Fukagawa.[1] *[1]Div of Nephrology, Endocrinology and Metabolism, Tokai Univ School of Medicine, Isehara, Kanagawa, Japan; [2]Div of Nephrology and Kidney Center, Kobe Univ Graduate School of Medicine.*

Background: Fibroblast growth factor 23 (FGF23) is a phosphaturic hormone, secreted from the bone. It has been well known that the reduction in serum phosphate occurs following intravenous administration of saccharated ferric oxide. A recent clinical study showed that both production and degradation of FGF23 is enhanced in the setting of iron deficiency (M Wolf. *J Bone Miner Res* 2013). These findings suggest that iron may be a key regulator of FGF23. However, its precise mechanism remains to be elucidated.

Methods: We previously reported that intravenous saccharated ferric oxide further increase in elevated serum FGF23 levels in hemodialysis patients with iron deficiency anemia, using the intact FGF23 assay that only detects the full-length protein (*Am J Nephrol* 2011). In this study, we additionally examined the FGF23 levels by the C-terminal FGF 23 assay which detects both the full-length protein and C-terminal fragments, and compared the results of these two assays ($N = 27$).

Results: We previously reported that intravenous saccharated ferric oxide further increase in elevated serum FGF23 levels in hemodialysis patients with iron deficiency anemia, using the intact FGF23 assay that only detects the full-length protein (*Am J Nephrol* 2011). In this study, we additionally examined the FGF23 levels by the C-terminal FGF 23 assay which detects both the full-length protein and C-terminal fragments, and compared the results of these two assays ($N = 27$).

Conclusions: Collectively, in hemodialysis patients with iron deficiency anemia, substantial amounts of C-terminal fragments of FGF23 accumulate by increase in both the production and the degradation. The administration of saccharated ferric oxide suppresses both the production and degradation, leading to increase in values by Intact FGF23 assay and decrease in those by C-terminal assay. Specific preparations of iron for intravenous use may regulate both the production and degradation of FGF23.

PUB546

Serum Levels of Sclerostin (SOST) in Renal Transplantation (Tx) Marzia Pasquali, Lida Tartaglione, Silverio Rotondi, Maria luisa Muci, Sandro Mazzaferro. *Cardiovascular, Respiratory, Nephrologic, Anesthesiologic and Geriatric Sciences, Sapienza Univ, Rome, Italy.*

Background: SOST, by inhibiting the Wnt pathway, suppresses osteoblasts activity and stimulates their apoptosis. Recent evidence has shown a role of SOST in alterations of bone metabolism in CKD. In CKD patients SOST serum levels are higher than in the general population and in HD patients SOST correlate negatively with histomorphometric parameters of bone turnover. Little is known about serum levels of SOST in Tx. Aim of our study was to evaluate serum SOST levels in Tx in whom few data are available.

Methods: We performed a cross sectional study in 80 Tx (55±10 y.o.;49M/31W) with CKD stage 2-4 (eGFR 47±16 ml/min). 30 healthy subjects (34±12y.o.;eGFR95±19 ml/min) were the control group. We evaluated in all patients SOST, Ca, Pi, PTH, FGF23 and Alkaline Phosphatase (AP).

Results: SOST was not different between Tx and controls (27,6±10,3vs31,0±6,0 pmol/l, p: n.s).The table shows the mean values of the parameters evaluated With mild vitamin D insufficiency (25D:26±11ng/ml), TX had normal 1,25D values, mild increment of PTH and Ca, and normal values of P.

Sclerostin, pmol/l	Cas, mg/dl	Ps, mg/dl	A.P, U/l (80-275)	PTH, pg/ml	25D, ng/ml	1,25D, pg/ml	FGF23, pg/ml
27.6± 10.3	10.1± 0.8	3.0± 0.7	178± 65	59± 51	26± 11	42± 15	47.3± 28.8

Serum levels of FGF23 were increased compared to controls (47,3±28,8 vs 30,0±19,0 pg/ml, p<.05). SOST showed a negative correlation with AP (r=-.375; p<.05) and a positive correlation with FGF23 (r=.236; p<.05) and 25D (r=.238; p<.05). No correlation existed with others parameters

Conclusions: eGFR does not seem to affect serum levels of SOST in Tx. The negative correlation whit AP indicates that SOST maintains its modulatory role of osteoblastic activity in this population. The correlation with FGF23, which is in agreement with low FGF23 in SOST null mice, suggests modulatory effects of both proteins on osteoblasts: direct, through Wnt inhibition, for SOST; indirect, through effects on 1,25D levels, for FGF23. Serum SOST may be an additional marker of bone metabolism, useful to understand metabolic pathways in normal subjects and in CRF.

PUB547

Comparison of Cholecalciferol Supplementation Dosing with a Bolus Dose Versus Daily Administration in Chronic Hemodialysis Patients Pablo Molina, Belen Vizcaino, Mercedes Gonzalez Moya, Sandra Beltrán, Marco Montomoli, Cristina Castro, Jose L. Gorriz, Luis M. Pallardo. *Nephrology, Dr Peset Univ Hospital, Valencia, Spain.*

Background: The aims of this study were to assess the safety profile of bolus cholecalciferol supplementation and compare its effectiveness to daily oral administration in hemodialysis (HD) patients.

Methods: This 6-month prospective, intervention study enrolled 60 stable HD patients with 25-hydroxyvitamin D [25(OH)D levels] <30ng/ml, who received cholecalciferol 25,000 IU once or twice monthly (n=30) or 700 IU daily (n=30). Differences in biochemical parameters, including 25(OH)D, calcium, phosphorous, parathyroid hormone(PTH), alkaline phosphatase and C-reactive protein levels, were analyzed monthly. Primary outcome was 25OH(D) level at 6 months. For safety purposes, in the subgroup of patients receiving the bolus regimen, biochemical parameters were also assessed on days 2,4 and 7 after the first bolus dose.

Results: At baseline, patient and biochemical characteristics were similar in both groups. No changes were observed in calcium, phosphorus and 25OH(D) levels in the first week after the first bolus dose. Throughout the 6-month follow-up, similar responses in 25OH(D) levels and other biochemical parameters were observed in both groups.

Parameter	Fortnightly 25,000 IU cholecalciferol (n=30)			Daily 700 IU cholecalciferol (n=30)			p-value between groups at month 6
	Baseline	Month 6	Pre-post p-value	Base-line	Month 6	Pre-post p-value	
25(OH)D (ng/ml)	10.5 ± 6.5	22.0 ± 6.5	<0.001	11.4 ± 5.2	24.8 ± 10.0	<0.001	0.195
25(OH)D status (n,%) Sufficiency (≥20ng/ml) Deficiency (<10ng/ml)	4 (13%) 15 (50%)	18 (60%) 30 (100%)	0.001 <0.001	4 (13%) 13 (43%)	20 (67%) 29 (97%)	<0.001 <0.001	0.395 0.500
iPTH (pg/ml)	257 (128-318)	281 (151-354)	0.107	193 (130-266)	187 (132-315)	0.778	0.176
Ca_{alb} (mg/dl)	9.1 ± 0.6	9.1 ± 0.5	0.571	9.0 ± 0.6	8.9 ± 0.6	0.943	0.199
Phosphorous (mg/dl)	4.0 ± 1.4	3.8 ± 1.2	0.465	4.0 ± 1.3	3.8 ± 0.6	0.031	0.417

Conclusions: Supplementation of 25,000 IU fortnightly or monthly oral cholecalciferol seems to be safe, being equally effective for raising 25(OH)D levels than 700 IU daily cholecalciferol administration.

PUB548

The Prevalence of Vitamin D Deficiency Among IgA Nephropathy: A Cross-Section Study from One Center Minxia Li,[1] Li Yuehong,[1] Guangyan Cai,[2] Xueying Cao,[2] Xiang-Mei Chen.[2] *[1]Dept of Nephrology, Beijing Tsinghua Changgung Hospital Medical Center, Tsinghua Univ, Beijing, China; [2]Dept of Nephrology, Chinese PLA General Hospital, Chinese PLA Inst of Nephrology, State Key Laboratory of Kidney Diseases, National Clinical Research Center for Kidney Diseases, Beijing, China.*

Background: Low serum vitamin D concentrations have been reported in chronic kidney disease (CKD). Very few studies concerns vitamin D deficiency of IgA nephrology (IgAN) in Chinese patients. Our aim is to assess the deficiency of serum 25(OH)D concentrations in patients with IgAN, and to explore the possible correlated factors contributing to Vitamin D deficiency.

Methods: 283 patients who were come from north China and were not receiving vitamin D supplementation were included in this study from February 2013 and April 2014. We collected blood samples to determine levels of Scr, BUN, UA, serum phosphate (P) and calcium (Ca), iPTH, albumin, as well as urinary excretion of creatinine, protein, P and Ca within 24h. Electrochemiluminescence immunoassay measured total 25-hydroxyvitamin D. Vitamin D deficiency should be defined as a 25(OH) D of < 15 ng/ml.

Results: All of the 283 patients, 25(OH)D concentration was 10.25±6.94 ng/ml. Only 18.82% of the patients had a circulating 25(OH) D level greater than 15ng/ml. The prevalence of deficiency(<15ng/ml) were 87.2%, 72.9%, 75.0%, 85.45%, 93.1%(P=0.000) at different CKD stages.All the 120 IgAN patients were divided into 4 groups according to eGFR. The prevalence of vitamin D deficiency were higher in CKD stage 1 and 4-5(P=0.000), but there is no difference of average 25(OH) D concentration according to eGFR(P=0.059). The 25(OH)D concentration was higher in IgAN patients than MN and DN patients. But, 24UPR in IgAN patients was lower than MN and DN patients. In different age, gender, season, BMI or iPTH group, 25(OH)D levels were not affected, but 25(OH)D level was lower in ³3.5g/24h group.

Conclusions: For the IgAN patients in north China, kidney function might be related to vitamin D deficiency, and 24UPR may play a very important role in maintaining 25(OH) D serum concentrations.

PUB549

Utility of Whole Exome Sequencing in the Diagnosis of a Family with Apparent Mineralocorticoid Excess Ranjit Narayanan. *Nephrology, KMCT Medical College, Calicut, Kerala, India.*

Background: Apparent Mineralocorticoid Excess (AME) is a rare familial disorder with hypertension, hypokalemia, metabolic alkalosis and low plasma renin and aldosterone due to mutations in the 11-β-hydroxysteroid dehydrogenase-2 (HSD11B2) gene. Five siblings of a third degree consanguineous family with unaffected parents were evaluated for hypertension of juvenile onset. They had varying degrees of hypokalemia, medullary nephrocalcinosis, concentric left ventricular hypertrophy and renal dysfunction. Plasma renin and aldosterone levels were low. Given the clinical picture and autosomal recessive inheritance pattern, a provisional diagnosis of AME was made. 24 hour urinary cortisol and cortisone estimation was unavailable. We decided to confirm the diagnosis using next generation gene sequencing.

Methods: Whole blood was collected from the parents and the affected members after informed consent. 50 ng of the isolated high quality DNA was used to prepare library and exome capture. Sequencing was performed using v3 reagents to generate over 49.48 million paired end reads of 101bp. The reads were aligned to the Human genome (hg19 build, UCSC) and was further filtered for read duplicates, recalibrated and realignment was performed around well-annotated Indels from the 1000 genome project using GATK and Picard tools. Variations were called using the GATK Unified Genotyper and analysed using ANNOVAR and annotated ClinVar.

Results: Analysis revealed the presence of homozygous variation p.R337C in HSD11B2 gene annotated to be pathogenic in ClinVar and predicted to be deleterious using PROVEAN in the affected siblings. The variant was further validated using Sanger sequencing of the amplicons, confirming the diagnosis. Both parents were heterozygous for the variation. This variation has been reported to be associated with the similar phenotype in two independent studies on native American populations.

Conclusions: A homozygous mutation (p.R337C variation) in the 11HSDB2 gene was demonstrated in the family using whole-exome sequencing. This is the first genetically characterized report of AME from Indian population. Our study underscores the utility of using next generation sequencing in the diagnosis of rare inherited diseases.

Genetics of Thrombotic Microangiopathies – The Viennese TMA Cohort Christof Aigner,[1] Martina M. Gaggl,[1] Zoltan Prohaszka,[2] Raute Sunder-Plassmann,[3] Gere Sunder-Plassmann,[1] Alice Schmidt.[1] *[1]Dept of Medicine III, Div of Nephrology and Dialysis, Medical Univ of Vienna, Vienna, Austria; [2]IIIrd Dept of Internal Medicine, Research Laboratory, Semmelweis Univ, Budapest, Hungary; [3]Dept of Laboratory Medicine, Laboratory for Molecular Diagnostics, Medical Univ of Vienna, Vienna, Austria.*

Background: Thrombotic microangiopathies (TMA) classified as hemolytic uremic syndrome (HUS) are characterized by acute kidney injury (AKI), mechanical hemolysis and thrombocytopenia, caused by an excessively activated alternative pathway of the

complement system. This is a result of either genetic alterations within complement factors and regulatory proteins or secondary causes. The aim of this study was to systematically investigate our cohort of patients with TMA regarding genotype and triggers of disease episodes.

Methods: Data were analyzed by means of patient records: Demographic and laboratory data, results of kidney biopsies, results of genetic sequencing of complement regulatory proteins, CFB, thrombomodulin (THBD) and C3, and medical history for triggering factors were analyzed.

Results: Out of 92 patients with TMA we classified 30 as atypical HUS (aHUS), 1 as typical HUS, and 61 as secondary HUS. At onset of disease patients with aHUS had a mean age of 25 years (range: 1-47), 20 were female (67%), and 13 (43%) were kidney transplant recipients. First presentation of 24 patients was AKI, 3 showed hemolysis, 2 had pre-eclampsia and 1 HELLP-syndrome. Distinct triggering factors in 20 patients were: infection (n=10), pregnancy (n=5), hypertension (n=2), surgery, diarrhea and renal transplantation (each n=1). Thirteen and 3 showed a CFH-H3 and a MCPggaac risk haplotype, respectively; potentially disease-causing mutations were identified in 22 patients (7 CFH, 6 CD46, 5 CFI, 4 C3, 2 CFB, 1 THBD; 4 of them with more than 1 mutation); 7 showed wild-types and no data existed for 1 patient.

Conclusions: In our cohort of TMA patients we identified 30 cases of aHUS. In 22 patients (74%) we identified a mutation within genes of the complement regulatory proteins or C3, whereas 7 subjects showed wild-type sequences despite presenting with a classic phenotype of aHUS.

PUB551

Under-Diagnosis of Alport Syndrome in First-Degree Relatives of Affected Individuals Clifford E. Kashtan,[1,2] Theresa F. Cassidy,[1,2] Michelle N. Rheault.[1,2] *[1]Pediatrics, Univ of Minnesota, Minneapolis, MN; [2]Alport Syndrome Treatments and Outcomes Registry (ASTOR).*

Background: Alport syndrome (AS) is an important inherited cause of progressive renal disease. Hematuria, the cardinal feature of AS, is highly penetrant in affected individuals. Urinalysis is a sensitive method for detecting AS in relatives of AS patients. This report describes a cohort of at-risk individuals (first-degree relatives of known AS patients) who underwent a first urinalysis as part of a clinical trial feasibility study.

Methods: For a study entitled "Multi-center Controlled Clinical Trials in Alport Syndrome - A Feasibility Study" (R21 DK91480, Clinicaltrials.gov #NCT01696253) conducted during 2013-14, first morning urine collection kits were sent to 104 people registered with ASTOR who carried a diagnosis of AS or were first-degree relatives of people known to have AS. 45/104 participants (43%) had been classified as unknown because a urinalysis had not been performed previously.

Results: 17/45 unknowns did not return the urine kit. Of the 28 who returned a urine kit, 11 had hematuria and 17 had normal urinalyses. Of the 11 who were reclassified from unknown to affected, 6 were siblings of a known affected child, 3 were sons of a known affected mother and 2 were mothers of known affected children. 3/11 had microalbuminuria (urine microalbumin:creatinine ratio > 30 mg/g); none had overt proteinuria.

Conclusions: The results are consistent with the following conclusions: 1) it is not unusual for first-degree relatives of known AS patients to have never been screened by urinalysis; 2) screening of first-degree relatives of known AS patients frequently identifies affected individuals (39% [11/28] of those who returned urine kits) who may benefit from early intervention. Early initiation of ACE-inhibitor therapy appears to slow renal disease progression in AS (Gross et al, Kidney Int 2012). It is recommended that treatment be initiated in AS patients as soon as they develop overt proteinuria (Kashtan et al, Pediatr Nephrol 2013; Savige et al, JASN 2013). Screening urinalyses should be performed in all first-degree relatives of AS patients in order to identify those who are or may become candidates for treatment.

PUB552

Urinary Biomarkers (UBio) Predict Renal Damage in Primary Hyperoxaluria (PH) Gauri Bhutani,[1] Lisa E. Vaughan,[2] Felicity T. Enders,[2] Samuel Edeh,[1] Andrea G. Cogal,[1] Nick Voskoboev,[1] Dawn S. Milliner,[1] John C. Lieske.[1] *[1]Nephrology, Mayo Clinic, Rochester, MN; [2]Biostatistics, Mayo Clinic, Rochester, MN.*

Background: PH often results in kidney stones and CKD/ESRD. We investigated diverse UBio for correlations with urinary chemistries (UChem) and as predictors of GFR decline.

Methods: UBio (Table1) were measured in biobanked urine from PH cases and healthy controls. Clinical details and outcomes for PH cases were obtained from the Rare Kidney Stone Consortium Registry, including 24 hour UChems oxalate (Uox), calcium (UCa), citrate (UCit) and calculated CaOx supersaturation (CaOx SS) and proximal tubular Ox (PTOx= (UOx* serum Cr* 4)/ UCr). Univariate and multivariate models were used to compare UBio with UChem and outcomes.

Results: Urine was available from 30 cases (114 samples) and 47 controls (47 samples). Significant correlations were present between UChem and UBio including: U RBP, NGAL, MCP1, L-FABP with U Ca; U MCP1, L-FABP with U CaOx SS; L-FABP, H-FABP with PTOx (all P<0.05). Compared to controls NGAL was increased and OPN decreased in PH cases. Both NGAL and OPN independently predicted subsequent eGFR (P<0.001).

Whole Exome Sequencing Identifies Advillin Mutation as a Novel Single-Gene Cause of Nephrotic Syndrome Jia Rao,[1] Shazia Ashraf,[1] Svjetlana Lovric,[1] Weizhen Tan,[1] Merlin Airik,[1] Eugen Widmeier,[1] Heon Yung Gee,[1] Richard P. Lifton,[3,4] Friedhelm Hildebrandt.[1,4] *[1]Div of Nephrology, Boston Children's Hospital, Harvard Medical School, Boston, MA; [2]Dept of Pediatric Nephrology, Faculty of Medicine Univ of Istanbul, Istanbul, Turkey; [3]Dept of Genetics, Yale Univ School of Medicine, New Haven, CT; [4]Howard Hughes Medical Inst, Chevy Chase, MD.*

Background: Identification of single-gene causes of steroid resistant nephrotic syndrome (SRNS) has furthered the understanding of its pathogenesis. However, many genes and disease mechanisms remain unknown. To identify additional genes that if mutated cause SRNS, we combined homozygosity mapping (HM) and whole human exome sequencing (WES) in a consanguineous families with NS.

Methods: An individual of consanguineous parents from Turkey with SRNS, deafness, cataract, microcephaly, and mental retardation histologically exhibited diffuse mesangial sclerosis. HM yielded >11 segments of homozygosity by descent with cumulative homozygous segments of ~200 Mb. We performed WES in this individual to identify the underlying single-gene disease-causing mutation.

Results: We identified a homozygous missense mutation (p.Leu425Met) in the AVIL (advillin) gene in an amino acid residue conserved since Ciona intestinalis. The mutation segregated with the affected status in this family and was absent from >6,500 European controls in the Exome Variant Server. AVIL (advillin) is a member of the gesolin superfamiy of actin binding protein. AVIL (advillin) is known to be involved in neurite outgrowth and morphogenesis via interaction with the cytoplasmic domain of the Type F scavenger receptor, SREC-I.

Conclusions: We identified mutation of AVIL (advillin) as a novel single-gene cause of SRNS. Further genetic and functional studies will shed light on the gesolin superfamily of actin binding proteins in the pathogenesis of NS and will provide further understanding of the disease mechanism.

Adult-Onset Familial Thrombotic Microangiopathy and Pulmonary Arterial Hypertension Related to Cobalamin C Deficiency Steven Grange,[1] Elise Artaud-Macari,[1] Soumeya Bekri,[3] Arnaud Francois,[4] Christophe Girault,[1] Fabienne Tamion,[1] Dominique Guerrot.[2] *[1]Intensive Care Unit, Rouen Univ Hospital, France; [2]Nephrology Dept, Rouen Univ Hospital, France; [3]Dept of Metabolic Biochemistry, Rouen Univ Hospital, France; [4]Dept of Pathology, Rouen Univ Hospital, France.*

Background: Cobalamin C (cblC) deficiency is the most frequent inherited disease of vitamin B12 metabolism, related to mutations in the MMACHC gene. The presentation in adults is dominated by neuro-psychiatric symptoms, and usually constitutes a diagnostic conundrum. We describe a unique presentation of cblC deficiency in 2 brothers, with the association of renal thrombotic microangiopathy (rTMA), atypical glomerulopathy, and pulmonary arterial hypertension (PAH).

Methods: An 18 year-old patient was referred for dyspnea. The investigations revealed stage 5 CKD, nephrotic syndrome, haemolytic anemia, and PAH. Renal histology showed major stenosing fibroproliferative myxoid lesions in the interlobular arteries. The glomeruli presented an ischemic appearance, with thickened and ribbon-like glomerular basement membranes. Immunofluorescence showed granular glomerular deposits of IgM,

without IgG or C3. Metabolic analyses showed an elevation of plasma homocysteine, methylmalonic acid, and propionylcarnitine concentrations. Genetic analyses found a compound heterozygosity in MMACHC gene, with c.271dupA and c.82-9delTTC mutations. The patient's brother died at the age of 17. Autopsy revealed pulmonary capillary hemangiomatosis, while the kidney histology showed similar lesions to those of his brother.

Conclusions: This is the first report of late-onset rTMA, atypical glomarulopathy, and PAH associated with cblC deficiency. We suggest that the association of rTMA and/or glomerular proteinuria with PAH in children and young adults should prompt metabolic investigations to identify cblC deficiency, and provide early specific management including hydroxycobalamin, folinic acid, and betaine.

PUB555

The DS3 Scores and Quality of Life in Japanese Patients with Fabry Disease Nobuhito Hirawa,[1] Keisuke Yatsu,[2] Sanae Saka,[1] Gen Yasuda,[1] Satoshi Umemura.[2] *[1]Dept of Nephrology and Hypertension, Yokohama City Univ Medical Center, Yokohama, Kanagawa, Japan; [2]Dept of Medical Science and Cardiorenal Medicine, Yokohama City Univ Graduate School of Medicine, Yokohama, Kanagawa, Japan.*

Background: Fabry disease (FD) is the lysosomal storage disorder, caused by the deficiency of lysosomal hydrolase alfa-galactosidase A activity. Various symptoms associated with renal disease, heart lesion and cerebrovascular disease occur in Fabry disease patients. Thus, the quality of life (QoL) would be alterd with the disease progressed. We evaluated the clinical severity and the QoL in a sample of Japanese patients with Fabry (FD) disease using the Disease Severity Scoring System (DS3) and the SF-36 survey in male and in female.

Methods: Observational cross-sectional study. The DS3 and SF-36 survey was administered to the patients of the hospitals, which belong to the research group of Kanagawa enzyme replacement therapy. Participants were treated with agalsidase-alpha or agalsidase-beta. Disease activity was assessed by the Disease Severity Scoring System (DS3). The QoL was measured by Short forum-36 (SF-36) and the Kidney Disease QoL Short Forum version 1.3 (KDQoL).

Results: Fifteen patients were included in the study. Mean age was 45 years (M/F=10/5), and all patients were receiving ERT. The mean serum Cr was 2.9 mg/dl. The DS3 scores were follows; mean assessment score: 26.5 +/- 10.1, average domains: 10.5 +/- 0.9. The renal domain and the cardiac domain showed relatively high score compared to PNS and CNS scores. The QoL scores of the FD patients were lower than those of general population, but the scores were better than the previous reports of FD from U.S. or EU. The mental component summaries of women were similar to those of the general population. The physical component summaries of QoL were negatively associated with the assessment score of DS3 ($r=-0.545$, $p<0.05$).

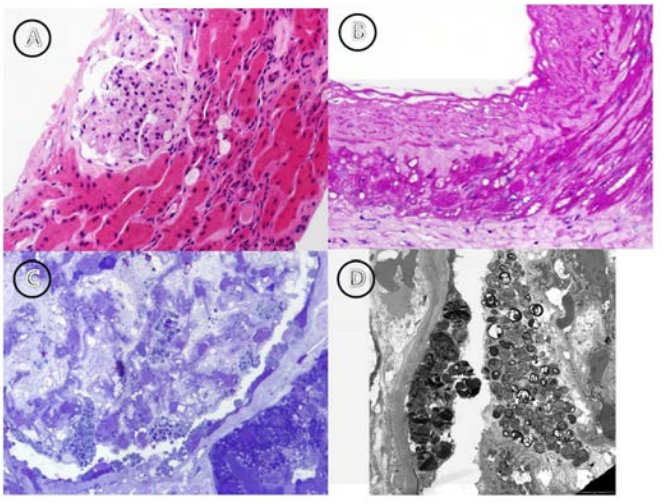
Conclusions: Japanese patients with FD receiving ERT had a relatively good QoL beyond anticipation. DS3 score is useful for assessing disease severity, and may predict some components of QoL.

PUB556

Two Cases of Fabry Disease in Women with Proteinuria Diagnosed by Molecular Analysis of α-Galactosidase A Gene and Kidney Biopsy Jong Oh Yang,[1] Eun-Young Lee.[2] *[1]Internal Medicine, Soonchunhyang Univ, Cheonan, Chungcheongnam-do, Korea; [2]Internal Medicine, Soonchunhyang Univ, Cheonan, Chungcheongnam-do, Korea.*

Background: Fabry disease is a X-linked lysosomal storage disorder caused by deficiency of α-galactosidase A. This abnormality in enzyme results intracellular accumulation of globotriaosylceramide and leads to severe painful neuropathy with progressive renal, cardiovascular, and cerebrovascular dysfunction and early death. We report 52 and 55 year-old women with proteinuria and hematuria, which were proven to be due to Fabry disease.

Methods: A 52 and 55 year-old women was admitted to the hospital due to proteinuria. They denied previous histories of hypertension, diabetes mellitus, pulmonary tuberculosis, and hepatitis. Their sister and cousin diagnosed fabry disease. Physical examination revealed nonspefic findings. On admission, blood pressure 110/60 mmHg, heart rate 64/min, respiratory rate 16/min, body temperature 36.5°. Lungs were clear and heart was normal. The extremities showed no edema, cyanosis or skin rashs. The laboratory data showed the WBC 5650/mm^3, Hb 13.2 g/dL, Platelet 212,000/mm^3, BUN 10.2 mg/dL, serum creatinine 0.7 mg/dL. Urinaylsis showed pH 5.0 SG 1.023 protein 2+ RBC 5-9/HPF WBC 5-9/HPF. 24-hour urine protein was 533 mg. Abdomen & Pelvic CT and echocardiography were normal. The serologic study was normal. The kidney biopsy showed expansion of mesangial matrix and glomerular hypertrophy. The cytoplasm of podocytes was vaculoated, which consisted of multiple, variable-sized, concentric electron-dense lamellated structures, by electron microscopy.



The enzyme activity for a-galactosidase in serum was 0.59 nmol/min/mg protein.

Conclusions: The patients received enzyme replacement therapy every other week. They had reduction in proteinuria and normal renal function.

PUB557

Intradyalisis Partial Parenteral Nutrition (IDPN) in Hemodialysis Patients (HDP) with Protein Caloric Malnutrition (PCM): Preliminary Results Susana Beatriz Asia,[1] Marcela Fabiana Munizaga.[1] *[1]Servicio de Nefrologia, Hospital Nacional de Clínicas, Cordoba, Argentina; [2]Servicio de Nefrologia, Hospital Nacional de Clinicas, Cordoba, Argentina.*

Background: PCD is higly prevalence in HDP and predicts morbi-mortality. NPID is according Espen Guides (march2012) and the SMOFF formule(soja,TG,olive oil and fish oil), improve inflamation and lipid status.Our goal is to define the evolution of nutritional parameters in HDP and caracterize them for future interventions. OBJETIVE: To evaluate if severe PCD in HDP, improve malnutrition and inflamation markers such as albumine,(Alb),cholesterol (Ch), reactive C protein(RCP).

Methods: Prospective and observationa study that included 14 patients up this time,both sexs,age27-80 years old, in maintenance HD from a University Hospital and Army Hospital.Patients signed informed consent. Patients received each HD session and during six months,SMOF lipids 4 grs/kg/d,by IV continuous infussion. We analized weight, Hematocrit,Alb,Ch,TG,creatinine,RCP and Global Subjetive Valoration(GSV) in pre HD blood samples at the beginnig,three and six months.Cuantitative demographic variables(age,sex,biochemic parameters)were expressed as medium ,SD and applied Student Wilcoxon Test and Chi Test (p:<010).

Results: fourteen patients improved weight(63,1+/-3,3vs64,9+/-3,5,p:0,351),alb(gr/dl)(3,7+/-0,4vs3,9+/-0,1,p:0,016),TG(mg/dl)(190,1+/-26,9vs179,4+/-30,8,p:0,03)and RCP(mg)(28,9+/-6,7vs10,1+/-2,5,p:0,009).there were not statical significance inHto(gr/dl)(33,3+/-1.9vs33,7+/-1.9vs33.7+/-1.7,p:0.856)CH(mg/dl)(163.9+/-15.9vs165.6+/-13,p:0.846),creatinine(mg/dl)(7.7+/-0.7vs7.4+/-0.5,p:0.233).

Conclusions: 1- NPID is a successfull tool as partial supplementation in HDP with oral dietary intake.2-In spite of our sample is small,the improvement of Nutritional and inflammatory status, applying Internatinal Guides was observed after three months of treatment.3- Medical awareness about nutritional risks in HDP, is the best tool to prevent alteration of nutritional status 4-We´ll expand the sample.

PUB558

Association of Protein Energy Wasting with Income in Chronic Kidney Disease Stage 3 Patients Anita Saxena, Amit Gupta. *Nephrology, Sanjay Gandhi Post Graduate Inst of Medical Sciences, Lucknow, Uttar Pradesh, India.*

Background: Protein energy wasting (PEW) is a major challenge in CKD. Purpose: Assessment of PEW in predialysis patients at first visit to a nephrologist.

Methods: Three day dietary intake of 484 CKD stage 3 patients. Patients were divided in to groups based on appetite and BMI.

Results: Male and female parameters: Serum albumin 3.7±0.84/ 3.68.8±.81g/dL, total protein 7.02±1.27/6.94 ±1.26 g/dL, creatinine 4.68± 4.19 / 3.74±3.36 mg% creatinine clearance 33.22± 30.48/ 37.55±33.87 ml/minute, BMI 22.60±4.29/23.43±4.77kg/m^2 energy/kg 16.97±0.65/16.8±0.64, protein g/kg 0.65 ±0.28/0.64±0.30, carbohydrate g/kg 2.98 ±1.54/2.98±.1.36, fat g/kg 2.98±0.23/2.79±0.22, respectively. As appetite decreased dietary protein and energy intake decreased significantly.

Varible/Sex	Normal N 1/126	Average N 70/20	Poor N 88/47	Anorexic N 64/36
Protein g/kg /Male	0.79±.23	0.58 ± .17	0.50 ± .20	0.27 ±.17
Protein g/kg / Female	0.79±.23	0.56 ±.16	0.48 ±.15	0.29 ±.20
Energy cal/kg / Male	21.57 ± 7.85	25± 3.70	12.36±4.26	6.92 ±4.36
Energy cal/kg / Female	21.19 ±5.81	14.67 ±3.09	12.79±3.92	7.25± 3.95

Appetite was average 14.46%/4.13% poor 9.7%/18.18%, anorexic 13.2%/ 7.4% in males and females. Income correlated with BMI (p.000), dietary protein (p.000) energy (p.000) and carbohydrate (p.000). Appetite correlated with creatinine (p 0.019), dietary energy, protein, carbohydraate and fat (p.000) intake. BMI correlated (p0.000) with fat, carbohydrate, energy and creatinine clearance. Anova showed significant difference between appetite groups in energy, protein, fat, carbohydrate, creatinine clearance (p0.000) and serum albumin (p 0.025). There was significant difference in protein (p0.026) energy intake (p 0.000) and creatinine clearance (p0.038) between BMI groups. Based on income there was significant difference between groups in BMI (0.000), energy (p0.019), protein (p 0.031), albumin (0.001).

Conclusions: With decline in renal function, appetite worsened and nutritional intake decreased. Energy intake was significantly deficient. 84% patients had reduced appetite and 69.2% had PEW. Low income is a risk factor for PEW in CKD.

PUB559

Study on Correlation Between Serum Creatinine, Cystatin-C, Urinary Albumin Creatinine Ratio and Body Composition Xuemei Li, Jie Ma. *Nephrology, Peking Union Medical College Hospital, Beijing, China.*

Background: Based on an epidemiological survey in Peking, China, to study the correlation between serum creatinine, Cystatin-C and urinary albumin creatinine ratio (ACR)and body composition.

Methods: Rresidents over the age of 35 of the Beijing Pinggu District by random sampling method. Laboratory test: take morning ACR, blood samples were taken for blood routine, kidney function.Test body composition after emptying the bladder by using INBODY-720 machine.Use SPSS 17.0 software for data statistical analysis, count datas were analysised by using multivariate linear regression .

Results: A total of 9283 people participated in the survey, which 4324 males, age 54.7±10.7 years, 4959 females, age 53.4±11.2 years. Male: 1) Human body cell mass (BCM) and ACR, Cystatin-C, no correlation, was positively correlated with height (B=0.43, P<0.01), and serum creatinine was that positive correlation (B=.01, P<0.01) . 2) Lean body mass (FFM) and ACR, serum creatinine, Cystatin-C, no correlation. 3) Skeletal muscle content and ACR, serum creatinine, Cystatin-C, no correlation. 4) Body fat mass and ACR, no correlation, and Cystatin-C was positively correlated with (B=7.09, P < 0.01). Female: 1) Human body cell mass (BCM) with height and cystatin-C, no correlation , but positively correlated with serum creatinine (B=0.035, P<0.01), and ACR was negative correlation (B=-0.005, P<0.05). 2) Lean body mass (FFM) and ACR, Cystatin-C, no correlation, and serum creatinine were positively related (B=0.035, P<0.01). 3) Skeletal muscle content and ACR, Cystatin-C, no correlation, and was positively correlated with height (B=0.031, P<0.01), and serum creatinine were positively related (B=0.035, P<0.01). 4) Body fat mass and ACR was negative correlation (B=-0.01, P<0.05) ,Cystatin-C were positively correlated (B=12.3, P<0.01), and age were negatively correlated (B=-0.13, P<0.01), and serum creatinine was negative correlation (B=-0.092, P<0.01).

Conclusions: There was a positive correlation between serum creatinine and the human body cell mass (BCM), lean body mass (FFM) in men, and skeletal muscle content, body fat weight in women, but the correlation is not strong. The blood cystatin-C and body fat weight was positively correlated.

PUB560

Worsening Nutritional Status Assessed Is an Independent Predictor of All-Cause Mortality in Incident Dialysis Patients Jong Hyun Jhee, Young Eun Kwon, Tae-Hyun Yoo, Shin-Wook Kang. *Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea.*

Background: Malnutrition is closely associated with mortality in end-stage renal disease (ESRD) patients. However, little is known whether improvement or deterioration of nutritional status after dialysis initiation affects clinical outcome. This study was aimed to elucidate the association between the changes of subjective global assessment (SGA) after dialysis initiation and mortality in ESRD patients.

Methods: Data were recruited from the Clinical Research Center for ESRD cohort. SGA score was measured by trained investigators at the time of dialysis initiation and after 12 months. Nutritional status was defined as well-nourished (SGA 6-7, A), mildly to moderately malnourished (SGA 3-5, B), or severely malnourished (SGA 1-2, C). Severely malnourished patients (SGA C) were excluded due to small sample size. The patients were divided into four groups according to the change of SGA; group 1, A to A; group 2, B to A; group 3, A to B; and, group 4, B to B.

Results: A total of 911 patients were enrolled. The mean age was 54.6±14.1 years, 554 patients (60.0%) were male. During a median follow-up duration of 30 months, 109 patients (12.0%) died. Survival rate of group 1 was the highest, and that of group 4 was the lowest (group 1, 91.2%; group 4, 71.4%; P<0.001). Worsening nutritional status was a significant risk factor for mortality (group 3 vs. 1, HR=3.15, CI=1.51-6.54, P=0.002), while baseline nutritional status at dialysis initiation was not (group 1 vs. 2, P=0.063; group 3 vs. 4, P=0.107).

Conclusions: Improvement of nutritional status after dialysis initiation could be beneficial for patient outcomes regardless of baseline status, suggesting that intervention to improve nutritional status after dialysis initiation might be a strategy to reduce mortality in ESRD patients.

PUB561

Prophylactic Effect of Erythropoietin Injection to Prevent Acute Mountain Sickness: An Open-Label Randomized Controlled Trial Hyungjin Cho, Soon Bae Kim. *Div of Nephrology, Dept of Internal Medicine, Univ of Ulsan, College of Medicine, Asan Medical Center, Seoul, Republic of Korea.*

Background: This study was performed to evaluate whether increasing hemoglobin before ascent by prophylactic erythropoietin injections prevents acute mountain sickness (AMS).

Methods: This open label,randomized, controlled trial involved 39 healthy volunteers with hemoglobin £15.5g/dL who were divided randomly into erythropoietin (n = 20) and control (n = 19) groups. Epoetin alpha 10,000 IU injections were given weekly for four consecutive weeks. On day1, and 7 days after the last injection (day 29), oxygen saturation (SaO2), and hemoglobin were measured. The subjects departed Seoul on day 30 and arrived at Annapurna base camp (ABC, 4,130 m) on day 34. AMS was diagnosed when headache and Lake Louise score (LLS) of ≥ 3 were present. Immediate descent criteria followed US Army recommendations.

Results: Two groups differ in hemoglobin levels on day 29 (15.4 ± 1.1 vs 14.2 ± 1.0 g/dL, P = 0.001). At ABC, erythropoietin group had a significantly lower mean LLS, AMS incidence, and number of subjects who met immediate descent criteria. Multiple logistic regression analysis showed that SaO2 < 87% and control group, but not hemoglobin < 15.0 g/dL, independently predicted satisfaction of immediate descent criteria.

Criteria	EPO (n=20)	Control (n=19)
HACE(ataxia) plus HAPE (PR>110)		1
HACE(ataxia)	1	0
HACE(severe lassitude)		1
Severe AMS plus HAPE (PR>110)	1	1
Severe AMS alone		4
HAPE(PR>110)	1	3
Total	3	10
*p=0.019. HACE, high altitude cerebral edema; HAPE, high altitude pulmonary edema; AMS, acute mountaine sickness; PR, pulse rate		

Erythropoietin-related adverse effects were not observed.

Conclusions: Erythropoietin-related adverse effects were not observed. In conclusion, erythropoietin may be an effective prophylaxis for AMS.

PUB562

Nutritional Assessment for the Chronic Dialysis Patients with/without Sarcopenia Miho Suzuki, Yuya Sakai, Ikuto Masakane. *Yabuki Hospital.*

Background: A recent arising problem of chronic dialysis patients is sarcopenia closely related to malnutrition. Muscle loss deteriorates daily activities of dialysis patients and ultimately worsens the QOL and prognosis of the patients. The aim of this study was to clarify the relationship between the nutritional status and sarcopenia and to analyze the status of nutrientintake in these patients.

Methods: 90 chronic hemodialsis patients were enrolled to the current study. (age 62.8yrs. Men were 76%, DM 41%).Skeletal muscle mass (SMM) was estimated by bioelectrical impedance analysis and a low muscle mass was defined by the SMM index (SMI: SMM [kg] / height [m^2] as > men: 7.0kg, women: 5.7kg).Muscle function was estimated by grip strength and walking speed as the Timed up and go test (TUG).A low grip strength was defined as less than 26 kg (men) or 18 kg (women). TUG less than 11 second was diagnosed as a low walking speed.Malunutrition was defined as by the Malnutrition-Inflammation Score(MIS)(≥6point) , GNRI(<92) and the criteria of protein energy wasting (PEW).The dietary assessment was performed by the food frequency questionnaire.

Results: Sarcopenia was identified in 22% of the subjects. The sensitivity to detect sarcopeia was not sufficient as 35% in MIS, 50% in GNRI and 10% in PEW. In the patients with sarcopenia, the average of total energy intake and protein was significantly lower than those in non-sarcopenia, 1618±122kcal vs 2041±65kcal in energy; 52±4g vs 68±2g in protein. The intake of fishes and meats (110±15g vs 153±8g),beans (31±11g vs 61±6g),confectionery, beverages and sugar (126±77g vs 306±41g) were significantly lower in sarcopenia than non-sarcopenia.

Conclusions: Malnutrition-related sarcopenia was only 10-50% among sarcopenia. It is important to measure muscle mass and muscle function regularly for dialysis patients because it is not enough to screen sarcopenia only by nutritional measurements. Sufficient protein and energy intake are essential for the prevention of sarcopenia. If patients don't have appetite,confectionery or a beverage or sugar may beacceptable for the prevention of muscle loss.

PUB563

Stomach Acid Reducers May Predict Nutritional Deficiency in Dialysis Patients Klara Berta, Mihaly B. Tapolyai, Maria Faludi, Melinda Forró, Ákos Géza Peth?. *Dialysis, Fresenius Medical Care Semmelweis Univ, Budapest, Hungary.*

Background: Malnutrition is a major predictor of mortality among dialysis patients. Malnutrition markers are thus regularly monitored in order to intervene when the nutritional status may decline. We investigated whether taking stomach acid reducing medications may indicate nutritional risk.

Methods: This is a cross sectional study of 103 patients undergoing chronic hemodiafiltration in Budapest, Hungary at a university hospital based dialysis unit. The patients' nutritional indicators such as serum albumin, phosphorus, nPCR and whether they were receiving cholecalciferol replacement were examined among those who did and those who did not take an acid reducing agent, such as a Proton Pump Inhibitor (PPI) or H2 blocker.

Results: Six patients were excluded because data were incomplete or the patients had not been on dialysis for more than 2 months. Of the 96 patients 44.9% took an acid reducer on a regular basis. The serum albumin (3.78 ±0.02 mg/dL vs. 3.56 ±0.01 p:0.008), phosphate (1.88 ±0.49 mmol/L vs. 1.64 ±0.54 p:0.04) and nPCR (1.00 ±0.20 vs. 0.91 ±0.25 p: 0.06) were lower among PPI takers. PPI takers were much more likely to be taking cholecalciferol for measured 25-OH-vitamin-D deficiency (1.8% vs. 18.1% p:0.01). While PPI takers were older (59.7 ±16.2 years vs. 65.7 ±13.3 p:0.04), there was no difference in the two populations in the presence of an AV Fistula, delivered Kt/V, calcium or serum bicarbonate.

Conclusions: We conclude that taking PPI's or H2 Blockers in dialysis patients may be an indicator of being at risk for malnutrition.

PUB564

Impact of the Potassium Additives on the Total Content of This Element in Processed Foods Margareth Lage L. de Fornasari,[1,2] Maria raquel Manhani,[2] Yvoty As Sens.[1,2] *[1]Post Graduation, Santa Casa of Sao Paulo School of Medical Sciences, Sao Paulo, SP, Brazil; [2]Nutrition, Sao Judas Tadeu Univ, Sao Paulo, SP, Brazil.*

Background: The additives of potassium salts are allowed in processed foods to preserve, to inhibit mold, to emulsify products. Patients with chronic kidney disease need to control the intake of potassium, and are advised for doctors and dietitians to restrict fresh foods and those rich in potassium. The addition of potassium to processed foods is permitted but frequently not specified on food labels in Brazil.The purpose of this study was to determine the actual potassium content of a number of products often consumed by end-stage renal disease patients and to compare the actual content with that estimated in a reference source.

Methods: Twenty-five frequently processed products consumed in the diet of end-stage renal patients treated at the hemodialysis unit were analyzed. The processed foods were milk beverages, yogurt, a type of cream cheese, margarine, tomato sauce, salad dressing, powdered juices, and had potassium sorbate or others potassium salts. The concentration of potassium (mg K/100g of food) was determined by flame photometry according to the Adolfo Lutz Institute methodology, and in triplicate. The comparison of the potassium obtained with the expected potassium was based on two national reference tables.

Results: All products had potassium-containing additives listed among their ingredients. The medium values of potassium (mg for 100 g or mL) for the different foods were: milk beverages 102.6 to125.3; type of cream cheese 80.3 to 194.4; margarine 21.6 to 37.3; tomato sauce 253.3 to 258.2; salad dressing 78.5 to 128.4; powdered juices 33 to 240.8. Processed food that had higher potassium values than the content expected from the food label were, milk beverages (1.6 to 2 times); type of cream cheese (0.9 to 2.1 times); salad dressing (1.6 to 2.6 times); margarine (1.4 to 2.5 times) and powdered juices (376 to 726 times). Tomato sauce had less potassium values than expected levels (0.6 times).

Conclusions: Processed foods with potassium additives contain higher levels of potassium than those listed in reference tables.

PUB565

Differences in Eating Patterns Between Maintenance Hemodialysis Patients from the U.S. and the UK Annabel Biruete,[1] Brandon Kistler,[1] Patrick Highton,[2] Kristin P. Wiens,[3] Peter J. Fitschen,[1] Alice C. Smith,[2] Ken Wilund.[1] *[1]Univ of Illinois; [2]Leicester Kidney Exercise Team, Univ of Leicester, United Kingdom; [3]Univ of Delaware.*

Background: Maintenance hemodialysis (HD) patients in the United States (US) have poorer nutritional status and higher mortality than European patients. Patient characteristics and clinical practices are hypothesized to contribute to these differences. Therefore, our aim was to compare eating patterns between HD patients from the US and the United Kingdom (UK).

Methods: HD patients (US=60,UK=29) were recruited. Four 24-hour diet recalls were collected, two dialysis days (DD) and two on non-dialysis days (NDD) using the USDA 5-pass method. Dietary information was entered and analyzed using diet analysis software and then grouped into eight food categories according to NHANES. Food security was assessed by the USDA 10-item survey. Statistical analysis was performed using independent samples t-test and Pearson's correlations.

Results: Patients from the UK consumed more energy on DD (24.9±2.1 vs. 18.5±1.1 kcal/kg/d;p=0.004) and NDD (24.5±1.5 vs. 20.5±1.2 kcal/kg/d;p=0.048) than US patients. Additionally, US patients had lower energy intake on DD than NDD (p=0.007), while there were no differences in UK patients (p=0.85). UK patients consumed more baked goods/breads, whereas US patients consumed more energy from beverages, entrees, and deli (p=<0.05 for all). Moreover, some degree of food insecurity was more frequently observed in the US (54.2% vs. 10.3) and was associated with younger age (r^2=-0.29,p=0.033), higher BMI (r^2=0.41,p=0.005), higher dietary sodium (r^2=0.29,p=0.03) and sugar (r^2=0.27,p=0.05).

Conclusions: HD patients from the US had lower energy intake on DD and NDD compared to UK patients. Furthermore, US patients had lower dietary intake on DD. This may be in part due to US clinics' restrictive policy on eating during dialysis. Furthermore, there were differences in food pattern consumption and food insecurity. These differences may help explain global differences in nutritional status and outcomes. Further studies are needed to assess the contribution of eating patterns and socioeconomic status on clinical outcomes in HD patients.

PUB566

Is Reverse Epidemiology in BMI of Maintenance Hemodialysis Patients Adaptable to the Patients without PEW? Yuya Sakai, Miho Suzuki, Ikuto Masakane. *Yabuki Hospital.*

Background: Reverse epidemiology has been addressed in Body mass index (BMI) of chronic hemodialysis patients; the lowest mortality rate in BMI 24-26 as reported by the Japanese Society for Dialysis Therapy. The higher BMI the lower mortality as stated by the Dialysis Outcomes and Practice Patterns Study. However, because these survey subjects included lower BMI patients with malnutrition and chronic inflammation, the high BMI patients' mortality risk might have been relatively low. The optimal BMI derived from these epidemiological analysis may not be well indicated for the patients' who do not have malnutrition and inflammation. So, we aim to study the optimal BMI of maintenance hemodialysis patients without Protein Energy Wasting (PEW).

Methods: 183 patients on maintenance hemodialysis patients were enrolled in the current study. All subjects have over 2 years of dialysis vintage and are not applicable to PEW and don't have inflammation which was defined as CRP less than 0.3 mf/dL as of December 2009. The observation period is from December 2009 to December 2014.The subjects were classified into 4 groups on a BMI scale (n)(<18.5 (13),18.5≤<22 (81),22≤<25 (47),25≤ (42)). The 5-year cumulative survival rate, the death risk factor, and each BMI groups' relative mortality risk for BMI 22≤<25 group were examined.

Results: During the observation period, clinical deaths resulted in 19 patients, changing hospital or accidental death resulted in 22 patients. There was no significant difference in the crude 5-year cumulative survival rate of BMI groups. Age, diabetes mellitus, albumin were dependent risk factors for death. When the mortality risks were adjusted by these 3 parameters, the mortality risk of BMI <18.5 was significantly higher than each of the 3 BMI groups (HR 6.97, P=0.0417).The mortality risk of BMI <25 was relatively higher than BMI 22≤<25 group but not significant.

Conclusions: In the maintenance hemodialysis patient without PEW syndrome and inflammation, the patients of BMI <18.5 have a higher risk of death so they require nutritional management to maintain and/or achieve a BMI ³18.5. Reverse epidemiology in BMI was not adaptable to the Japanese dialysis patients without PEW and inflammation.

PUB567

Body Weight and Proteinuria Determine Plasma Triglycerides via Hepatic Syndecan-1/Heparan Sulfate in Experimental Nephrosis Saritha Adepu,[1] Harry Van Goor,[2] Gerjan Navis,[1] Stephan J.L. Bakker,[1] Jacob van den Born.[1] *[1]Nephrology, Univ Med Center, Groningen, Netherlands; [2]Pathology, Univ Med Center, Groningen, Netherlands.*

Background: Dyslipidemia contributes to a high cardiovascular risk profile of proteinuric patients. Via its heparan sulphate (HS) side chains, hepatic syndecan-1(syn-1) is a major uptake receptor of remnant lipoproteins. We hypothesized that proteinuria induces changes in hepatic synd-1/HS metabolism leading to dyslipidemia, which is reversed by caloric restriction (CR).

Methods: We used the hypertensive rat MWF proteinuria model. Male rats (22 wks) were uni-nephrectomized and fed ad libitum (AL) food (MWF-AL; n=14), or CR (MWF-CR; n=13, 60% of MWF-AL food intake). Wistar rats matched for sex, age, nephrectomy on AL food intake served as controls (W-AL; n=13). Sacrification is at 48 wks. Wistar control rats were sacrificed at 22 wks (Young W-AL; n=6). Body weight, blood pressure, plasma creatinine, cholesterol, triglycerides, and proteinuria were measured at 22 and 48 wks. Livers were used for qRT-PCR and immunostaining. Correlation analysis was done by linear regression analysis.

Results: Renal aging (W-AL vs Young W-AL) was associated by mild proteinuria and dyslipidemia (both p<0.05). Compared to W-AL rats, at 48 wks MWF-AL rats developed hypertension, proteinuria, reduced creatinine clearance (all p<0.05) and comparable dyslipidemia. CR reversed all these parameters in MWF-CR comparable to W-AL rats (p<0.05). Hepatic syn-1/HS profiling revealed striking increase in syn-1 protein and altered HS sulfation pattern in proteinuric W-AL and MWF-AL. CR normalized syn-1 protein levels and increased HS sulfation. Syn-1 appeared positively (r=0.366, p<0.02) and HS sulfation inversely (r=-0.450, p<0.005) associated with plasma triglyceride concentrations. Both associations were lost after adjustment for body weight or proteinuria.

Conclusions: CR normalized hypertension, renal function, proteinuria, dyslipidemia and synd-1/HS in MWF rats. Regression analysis suggests that body weight and proteinuria reduce hepatic HS sulfation, leading to hampered TRL binding and uptake and increased TG values.

PUB568

Obese Donors: The Multidisciplinary Approach in Improving Outcomes Giselle Guerra,[1] Ian Thomas,[1] Panagiotis Tryphonopoulos,[2] Linda J. Chen,[2] Gaetano Ciancio.[2] *[1]Dept of Medicine, Miami Transplant Inst, Miami, FL; [2]Dept of Surgery, Miami Transplant Inst, Miami, FL.*

Background: Living donation appears safe over the years but concerns still exists long-term. Small analyses after unilateral nephrectomies have resulted in proteinuria and slight decrease in renal function (eGFR) if patient tended to be obese; thus raising a concern for accepting living kidney donors (LKD) with body mass index (BMI) greater than 30 but less than 35 Aim: Determine the outcomes of obese LKD with BMI greater than 30 but less than 35.

Methods: A single center retrospective analysis was performed at out transplant center from January 1, 2013 - November 30, 2014. LKD ages 18-65 were assessed: 1. Study Arm (SA): obese LKD with BMI>30 who were enrolled into a nutritional program and 2. Control arm (CA): non-obese living kidney donor candidates at the time of referral. Weight loss prior to surgery and afterwards, surgical complications, loss of kidney function (eGFR), and proteinuria (spot urine protein/spot urine creatinine ratio) after 6 months from donation were reviewed.

Results: Patient demographics - SA:15African Americans (AA), 13 Hispanics (H), 7 White, 1 Other, 3 Unknown versus CA: 55 H; 49 Whites; 20 AA; 5 Other [figure1]. In the SA: 24/40 had BMI >35 at time of referral and placed in nutritional program; 8/24 dropped BMI to less than 35 prior to surgery and 3/24 pending surgery now; 4/24 ruled out due to medical issues & (9/24) were non-compliant. Surgical complications 1/8: Parasthesia. After donation in SA, blood pressure remained stable, 2/8 gained weight ,kidney function at 6 months: 47% of obese donors had a derease in eGFR at 6 months of 40% or greater. The mean decrease in eGFR was 33.9% in the study arm. In the control arm: 55Hispanics; 49 Whites; 20 AA; 5 Other. 15% had a decrease in eGFR at 6 months 40% or greater and the mean decrease in eGFR was 28.9.

Conclusions: Obesity in living donors needs careful analysis especially in minortiy populations since there is a trend to have a greater loss in kidney function after donor nephretomy. Donation is possible but strict nutritional and guidelines and medical evalulation need to persist for the wellness of these patients long-term.

PUB569

The Role of Renal Pharmacist in Prescribing Immunosuppressant Medication for Renal Transplant Patients to Improve Safety Israr Baig, Preetham Boddana. *Pharmacy Dept, Gloucestershire Hospitals NHS Foundation Trust, Gloucester, Gloucestershire, United Kingdom.*

Background: This paper describes the safe and efficient repatriation of renal immunosuppressant prescribing from General Practitioners (GPs) to secondary care using hospital Pharmacist Independent Prescribers (PIPs).

Methods: From March 2015 the UK commissioner NHS England required all renal immunosuppressant medication, which was traditionally prescribed by GPs following nephrologists' advice, to be prescribed by hospital renal prescribers. Gloucestershire hospitals NHS Foundation Trust decided to use Pharmacist Independent Prescribers to implement this change and provide the ongoing service using commercial Homecare Companies. All Patients were initially sent detailed information about the changes and asked to consent. On receipt of the completed consent form the PIP wrote the initial homecare prescription which was then processed by the pharmacy homecare team. Patients continued to be reviewed at regular intervals by their nephrologists. Details of these consultations were documented using a central renal database which included graft function, drug levels and communication with GPs. The Pharmacist Prescribers subsequently reviewed the renal database prior to generating ongoing homecare prescriptions and, when necessary, contacted the nephrologist for clarification and interventions.

Results: This service reconfiguration has resulted in safe and robust pathway. The use of Pharmacist Independent Prescribers has insured the whole pathway is efficient and closely monitored. Patients are satisfied with the new homecare service and clinicians value the pharmacists' input. Pharmacist prescribers have made a number of interventions which have included patient compliance issues, changes to doses in response to serum drug levels and appropriate brand changes to improve cost effectiveness.

Conclusions: The use of Pharmacist Independent Prescribers to prescribe and manage the renal immunosuppressant homecare service at Gloucestershire Hospitals NHS Foundation Trust has been shown to be safe and efficient.

PUB570

Tools for Adverse Events Prevention in a Hemodialysis Facility: A Local Experience Cinthia Sobral Vieira,[1] Cassiana G. Prates.[2] *[1]Nephrology Service, Hospital Ernesto Dornelles, Porto Alegre, RS, Brazil; [2]Hospital Epidemiology and Manager Risks Service, Hospital Ernesto Dornelles, Porto Alegre, RS, Brazil.*

Background: After the publication "To err is human" there has been a new approach to prevent risks in health system. According to the International Patient Safety Goals there are six steps to be followed like patient identification, proper communication, right surgery in the right side, fall prevention, high alert medication and infection prevention. The goal is to show how a hemodialysis unit, for ambulatory and hospitalized patients leads with adverse event prevention.

Methods: This experience happens in a hemodialysis unit with 101 patients, 3 shifts of 4 hours. It is located in a general hospital in Porto Alegre, south Brazil.

Results: Every patient has an id badge with colored marks according to the risk possibilities (falls, allergies, multi resistant germ, no access condition, hypoglycemic risk). There are no medication facilities. There are checklists for dialysis . The staff has continued medical education for patient safety. There is a map risk (adverse events possibilities) and its approach. If it happens, a notification formulary is filled and reported to the Hospital Epidemiology and Manager Risks Service, that analysis the root causes. The chosen tool is Ishikawa diagram resulting in a plan of action. Every month, one case (not only hemodialysis) is discussed together with a multidisciplinary group and the hospital high direction. The quality patient safety indicators are evaluated, as mortality incidence (21,33 % y); sera conversion to hepatitis C and B (0) and catheter infection (5,24% y).

Conclusions: Chronic renal patient is at high risk of advent events because of frequent treatment, comorbidities, many medication and the pathology consequences. Needle dislodgment, hematomas, lack of registration of weight and arterial pressure at the beginning of dialysis, more than 2 vascular access needle insertion attempts, dialysis interruption may occur, so the unit must be prepared to intervention. Health staff rarely reveals mistakes afraid of consequences and blame. It is necessary to promote the Safety Culture, stimulating to talk about bad events or even near miss to prevent other ones.

PUB571

Zinc Deficiency Correction and Phosphaturia in Children with CKD – A Pilot Study Vladimir Belostotsky,[1] Stephanie A. Atkinson,[1] Michelle N. Rasiah,[1] Steven Arora,[1] Ji Cheng,[1] Joanne Grimmer,[2] Guido Filler.[2] *[1]Pediatrics, McMaster Children's Hospital, Hamilton, ON, Canada; [2]Pediatrics, Children's Hospital, London Health Sciences Centre, London, ON, Canada.*

Background: There are no guidelines for correction of Zinc (Zn) deficiency in Chronic Kidney Disease (CKD). Experimental data (Morishita 2001) suggests that Zn modulates the phenotype of Klotho deficient mice and this can potentially increase phosphaturia. Aims: To identify Zn deficiency and determine whether 3 months of oral Zn therapy normalizes Zn status in children with CKD. To assess feasibility of conducting a clinical trial similar to Morishita's in mice and gather information on clinical outcomes and relationship between Zn status and correction of Zn deficiency and phosphate (P) excretion.

Methods: 40 patients (pt) 4-18 yr with primary CKD and CKD due to declining graft function were enrolled from 2 tertiary pediatric nephrology centers. Plasma Zn was measured by High Resolution Magnetic Sector Inductively Coupled Plasma Mass Spectrometry at baseline and 3 months with routine blood and urine parameters. Pt with Zn<11.5 mmol/L were treated for 3 months with Zn citrate tablets (10mg Zn/day for 4-8 yr and 20 mg/day for 9-18 yr). Statistical analysis was done using nonparametric methods and relative risk ratio.

Results: Of 21 pt (M-13, F-8) with completed data, Zn deficiency was found in 10. Stages of CKD were: 2-11 pt, 3-5 pt, 4-5 pt. One pt was hyperphosphatemic. 2 Zn deficient pt had abdominal discomfort whilst taking Zn. Plasma Zn improved in 8 out of the 10 treatment pt (4.4 times more frequently than in control pt) after 3 months of Zn therapy. Zn therapy over 3 months did not change serum P (median 1.23 mmol/L to 1.25 mmol/L) or its fractional excretion (median 24.08% and 21.71%).

Conclusions: Zn deficiency occurred in about 50% of CKD pt. Preliminary analysis indicates that 3 months of oral Zn supplementation is likely beneficial in Zn deficient pt but a larger sample size is required to evaluate the impact of correction of Zn deficiency on other metabolic parameters. Correction of Zn deficiency does not alter P excretion in pt with normal blood P. Similar studies are feasible to perform in hyperphosphatemic pt.

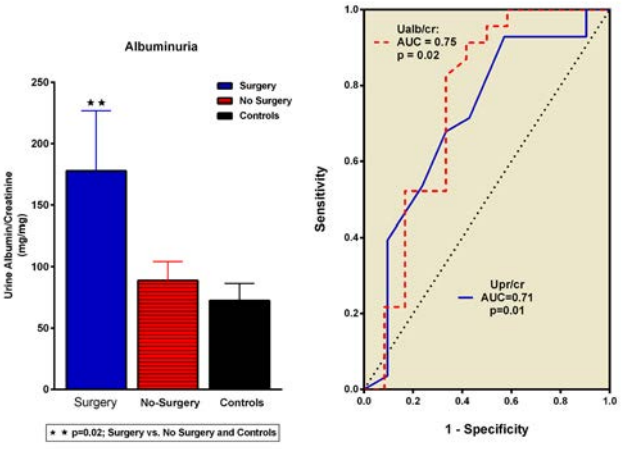
PUB572

Proteinuria as a Marker of Severe Unilateral Ureteral Obstruction in Infants Mariselis Rosa-Sanchez, Jayanthi Chandar, Wacharee Seeherunvong, Chryso P. Katsoufis, George N. Sfakianakis, Rafael Gosalbez, Andrew Labbie, Gaston E. Zilleruelo, Carolyn L. Abitbol. *Pediatric Nephrology, Nuclear Medicine, Pediatric Urology, Holtz Children's Hospital/Univ of Miami, Miami, FL.*

Background: Unilateral ureteral obstruction (UUO) is a common congenital anomaly in infants. Controversies remain regarding clinical indications for timely surgery. The objective was to compare the radiologic and laboratory parameters of a cohort presenting with significant unilateral hydronephrosis that were managed either conservatively or surgically.

Methods: This retrospective analysis included 81 infants during a 10 year period with high grade hydronephrosis designated by renal ultrasound. Further assessment included renal function by nuclear scintigraphy and proteinuria. Proteinuria was determined by random urine total protein to creatinine ratio (Upr/cr) and albuminuria by random urine albumin to creatinine ratio (Ualb/cr). Receiver operator characteristic (ROC) area under the curve (AUC) statistics were applied to Upr/cr and Ualb/cr ratios with determination of likelihood ratios (LR) for requiring surgery.

Results: In this cohort, 22/81 (27%) were operated, including 21 pyeloplasties and 1 nephrectomy for severe UUO. Initial proteinuria was significantly greater in UUO patients who underwent surgery compared to those without surgery (p=0.02). ROC-AUC demonstrated that both Upr/cr and Ualb/cr predicted the presence of severe UUO requiring surgery (Upr/cr: AUC=0.71; p=0.01 and Ualb/cr: AUC=0.75;p=0.02). Upr/cr and Ualb/cr was similar in normal control infants and those with non-surgical UUO.



Conclusions: Proteinuria and albuminuria were significantly elevated in UUO infants who required surgery compared to normal term infants and those with non-surgical UUO. Although both were sensitive markers of renal injury, albuminuria was superior in predicting the need for surgery in patients with UUO.

PUB573

High Prevalence of Glomerular Hyperfiltration in Obese Adolescents

Anitha Ezekiel, Jennifer Therese Potonia, Pedro Anis Rahnemaye rabbani nourani, Samhar I. Al-Akash. *Driscoll Children's Hospital - Kidney Center, Corpus Christi, TX.*

Background: Glomerular hyperfiltration (GHF) has been described in diabetic and obese (O) adults, and usually precedes proteinuria or clinical disease, and may indicate underlying renal damage and chronic kidney disease (CKD). GHF is poorly studied in adolescent children (AC). We hypothesized that GHF is present in AC and that GFR correlates with the BMI.

Methods: We queried the electronic medical records from 6/2010 to 12/2013 to include AC 12-21 years of age with at least one serum creatinine (SCr) and BMI in the same encounter, and excluded pts with CKD, HTN, DM, proteinuria, or renal transplant. Pts were separated into 2 groups; Control (C) - BMI < 30 and O - BMI ≥ 30 kg/m2. We used the original Schwartz formula (OSF) to calculate GFR as our lab uses the Jaffe method to measure SCr. We defined GHF as GFR > 150 ml/min/1.73m^2.

Results: Demographic data and results are shown in table 1.

	C (control) BMI < 30	**O (obese) BMI ≥ 30**	**P-value**
N (encounters)	730	246	
Mean age - years	18.5±0.8	15.5±2.0	<0.0001
Mean BMI - kg/m^2	21.7±4.1	38.4±6.8	<0.0001
Male	48%	49%	NS
Prevalence of GHF (GFR > 150)	3%	16%	0.0001 (OR 6.2)
- Male	0	28%	0.0001
- Female **4%** **5%**			NS
Mean GFR	**A** 89.6 (85-95)	**B** 128.2 (114-141) (BMI ≥ 30)	<0.0001
		C 120 (114-127) (BMI 30-34.9)	<0.0001 (**A** vs. **B, C, D, E**) 0.01 (**C** vs. **E**)
		D 130 (124-136) (BMI 35-39.9)	
		E 134 (128-141) (BMI ≥ 40)	
Prevalence of GFR > 130	20%	43%	<0.0001 (OR 6.9)
- Male	14%	62%	<0.0001 (OR 19.1)
- Female	12%	25%	<0.0291 (OR 2.5)

Conclusions: Using the OSF, we showed a higher prevalence of GHF in obese AC, and a showed that GFR correlated with BMI. Males have a greater risk of GHF. Due to the increased incidence of obesity in AC, special attention needs to be paid to renal function. In the absence of proteinuria or signs of clinical disease, GHF may be the earliest sign of renal disease, and should be assessed in obese AC. The choice of GFR estimation formula specifically in the obese has not been well established. This study provides preliminary data for a prospective trial for comparison of standard GFR measurement with existing GFR estimation formulas to allow the use of the most appropriate formula in obese pts.

PUB574

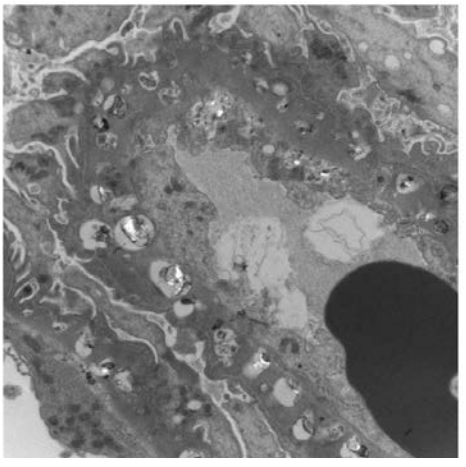
Familial Lecithin-Cholesterol Acetyltransferase Deficiency Masquerading as Membranous Nephropathy in Childhood

Ania B. Koziell, Katrina Soderquest. *Experimental Immunobiology, King's College London, London, United Kingdom.*

Background: Familial Lecithin-cholesterol acetyltransferase (LCAT) deficiency is a rare autosomal recessive disorder of lipid metabolism characterised by severely reduced HDL concentrations and impaired esterification of cholesterol. It is characterised clinically by glomerulopathy and mild haemolytic anaemia presenting in adulthood leading to ESRD by the fourth decade of life through the deposition of abnormal lipoproteins in the renal stroma. Paediatric cases are rarely described.

Methods: 2 siblings aged 8 and 11 years presented with asymptomatic non-nephrotic range proteinuria detected on routine testing. There was no family history of renal disease, although parents were consanguineous. Initial screens revealed normal renal function and normal serum albumin. Other investigations demonstrated raised lipid profiles but in keeping with nephrotic syndrome. A renal biopsy was performed in view of escalating protein and albumin creatinine ratios.

Results: Renal biopsy initially demonstrated light microscopic features of membranous nephropathy. However, electron microscopy demonstrated inclusions that were not typical of the adult form of the disease but clearly lipid filled (Figure 1). Confirmation of the diagnosis was by demonstration of significantly reduced HDL-cholesterol, and detection of a novel LCAT gene missense mutation G54V as well as reduced LCAT enzyme activity on assay.



Conclusions: LCAT deficiency may present with mild symptomatic proteinuria in childhood. Although rare, it should be considered in a differential in paedatric membranous nephropathy. The diagnosis was made on characteristic EM appearances, genetics and reduced enxyme activity. A trial of enzyme replacement is planned. Interestingly, the older sibling has higher lipids yet the younger worse renal disease opening up new hypotheses for how LCAT deficiency might cause renal pathology.

PUB575

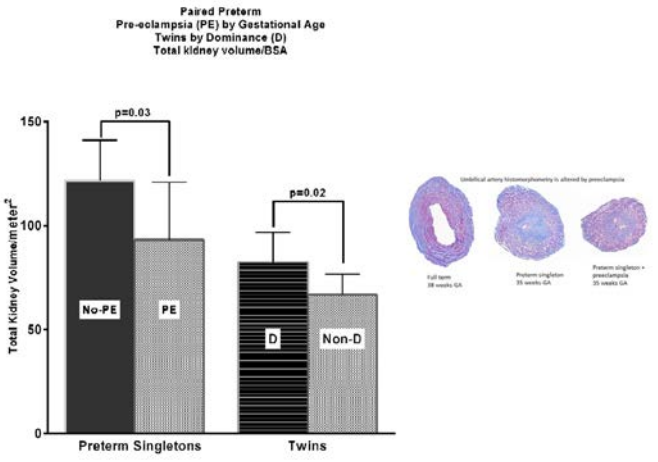
Umbilical Artery Histomorphometry: Linking the Intrauterine Environment and Nephrogenesis

Marissa J. Defreitas, Deepan Mathur, Wacharee Seeherunvong, Shahnaz Duara, Salih Y. Yasin, Maria Matilde Rodriguez, Carolyn L. Abitbol. *Pediatric Nephrology, Pediatric Pathology, Neonatology, Perinatology, Univ of Miami/Holtz Children's Hospital, Miami, FL.*

Background: An adverse intrauterine environment is linked to the developmental origins of aortic stiffness, nephron deficit, and adult onset cardiovascular and renal disease. We hypothesized that umbilical artery histomorphometry(UAH), a direct extension of the central vascular tree, would provide insight into nephrogenesis across gestational age (GA)groups.

Methods: From 156 newborns enrolled in the Gerber Infant Kidney Study, a subcohort of 32 had umbilical cord specimens evaluated (7 term(T-S), 15 preterm singletons(PT-S) and 10 preterm twins(PT-T)).The umbilical cord was sectioned, stained with Trichrome and digitalized.Muscular(MA) and collagenous areas(CA) of the umbilical arteries were measured in pixels using the ImageJ1.48q software and converted to mm^2. The combined total kidney volume(TKV) was measured by ultrasound and factored by the infants' ponderal indices and BSAs.

Results: TKV/PI of T-S (6.9±1.8) and PT-S(7.5±1.9) were similar; while TKV/PI of PT-T was significantly less than either of the singleton groups (4.5±0.8;p<0.001). Among PT-S, 6(40%) were from pre-eclamptic (PE) mothers. When paired by GA to other PT-S not from PE mothers, they demonstrated stunted TKV/BSA (93±28 versus 122±19μm^2/m^2;p=0.02). Among twin pairs, there was also a discordance in TKV/BSA (68±10 versus 81±15 μm^2/m^2;p=0.04). UAH demonstrated a positive correlation with increasing %MA and a negative correlation with increasing %CA.



Conclusions: UAH links an adverse and/or competitive intrauterine environment with nephrogenesis independent of GA. An enhanced umbilical artery muscule area reflects an increased renal mass while increased vascular collagen parallels decreased renal mass in discordant twins and singletons of PE mothers.

PUB576

Insulin-Like Growth Factor/Growth Hormone and Insulin-Like Growth Factor Binding Proteins in Normal Heighted and Short Children with CKD John D. Mahan,[1] Rose M. Ayoob,[1] Larry A. Greenbaum,[2] Amira Al-Uzri,[3] Frederick J. Kaskel,[4] Susan L. Furth,[5] Bradley Warady.[6] *[1]Pediatrics, Nationwide Children's/OSU, Columbus, OH; [2]Pediatrics, Emory Univ, Atlanta, GA; [3]Pediatrics, Oregon Health & Science Univ, Portland, OR; [4]Pediatrics, Albert Einstein COM, New York, NY; [5]Pediatrics, Univ of Pennsylvania, Philadelphia, PA; [6]Pediatrics, Children's Mercy Hospital, Kansas City, MO.*

Background: Earlier reports indicated that children with chronic kidney disease (CKD) have 'normal' Growth Hormone (GH) and Insulin-Like Growth Factor-1 (IGF-1) levels, suggesting that intracellular resistance and increased IGF-1 Binding Proteins (BPs) account for the poor growth seen in 35% of these children. We explored key growth mediators in subjects with CKD enrolled in the Chronic Kidney Disease in Children (CKiD) study with either normal height or short stature to explore potential explanatory differences in these two subsets.

Methods: 232 children in CKiD (206 normal height: 26 short stature; none on GH therapy) were matched by gender, age and GFR. Short stature = Height Standard Deviation Score (SDS) < -1.88. GH, IGF-1, and IGFBP-1 and 3 were determined by chemiluminometer and ELISA.

Results: Normal height CKD children had higher serum IGF-1/GH, higher IGF-1/IGF-1 BP1 and similar IGF-1/IGF-1 BP3 compared to short CKD children.

	IGF-1/GH*	IGF-1/IGF-1 BP1*	IGF-1/IGF-1 BP 3*
Children height SDS < -1.88	356.7 [152.3, 1017.2]	0.0056 [0.0012, 0.0161]	37.91 [22.62, 56.97]
Children height SDS > -1.88	811.8 [168.2, 2360.0]	0.0136 [0.0055, 0.0582]	53.44 [35.34, 77.50]
P-value (Kruskal-Wallis ANOVA)	*0.0002*	*0.02*	*0.07*

* = (median [IQR])

Height SDS correlated with IGF-1 in normal height children (r = 0.323), but not well in short children not on GH RX (r=0.046).

Conclusions: Differences in IGF-1, IGF-1/GH, and IGF-1/IGF-1BP1 may explain some variance in growth in CKD children. Height is more highly correlated to IGF-1 in normal height than short CKD children. Analyses in paired subjects may provide further insights in children naïve to and those on rGH to allow detection of critical thresholds that explain and/or predict growth in children with CKD.

Assessment of Cochlear Sensitivity of the Pediatric Chronic Kidney Disease and Hemodialysis Patients Rahime Renda,[1] Levent Renda,[2] Ömer Tark Selçuk.[2] *[1]Antalya Research and Training Hospital Pediatric Nephrology; [2]Antalya Research and Training Hospital Otorhinolaryngology Dept.*

Background: Abnormalities in auditory system are frequent in patients with chronic renal disease and hemodialysis. The aim of this study was to throw light on the relationship between cochlear sensitivity and chronic kidney disease with or without hemodialysis.

Methods: Children aged 6-18 years were evaulated in three groups; 36 nondialytic patients with chronic kidney disease, 16 end stage renal disease patients undergoing hemodialysis, and 30 age and sex-matched control subjects. Hearing outcomes were obtained by pure-tone audiometry and distortion product otoacoustic emissions measurements.

Results: No significant difference was found except in the both ears at 500 Hz frequencies between the study group and the control group. The signal/noise ratio levels and distortion product levels were significantly lower in the nondialytic and dialytic group at all frequencies. Patients with normal hearing were found to have significanly lower signal/noise ratios and distortion product levels than those observed in the healthy controls.

Conclusions: These results showed lower cochlear functions in the dialytic and non-dialytic group regardless of hearing loss than in the control group. Patients with chronic renal disease with or without hemodialysis should be monitored periodically even if the hearing thresholds seem to be within normal limits.

Percutaneous Renal Biopsy at OPD Level Byoung-Soo Cho,[1] Yumi Choi,[2] Jin-Soon Suh.[3] *[1]TheAll Medical Hub Kidney Center, MIRAE ING Research Inst, Seoul, Republic of Korea; [2]Dept of Pediatrics, Gwangmyeong Sung-Ae Hospital, Gwangmyeong-si, Gyeonggi-do, Republic of Korea; [3]Dept of Pediatrics, College of Medicine, The Catholic Univ of Korea, Bucheon-si, Gyeonggi-do, Republic of Korea.*

Background: Renal biopsy is a prerequisite procedure for the final diagnosis and to evaluate the treatment effect or to determine the prognosis, however due to serious complication of the procedure, should be done by nephrologist and has been perfomed at admission state.

Methods: Our center perfomed percutaeous renal biopsy 3,000 cases without major complications during last 30 years, when patients were admitted for 3days. During last 18 months, we performed percutaneous renal biopsy at OPD level under the ultrasound guide (LOGIQ E9).

Results: The youngest one is 1 year old male and the oldest was 64 years old. Mean age was 26 years old. Male to female ratio was 3:2 Mean glomeruli numbers were 31. We used disposable kidney biopsy needle (TSK ACECUT). We checked ultrasound 3 times after renal biopsy for checking AV fistula, hematoma formation during 6 hours hospital stay. Of the 100 case 8 cases received follow up biopsies. Among 100 samples renal medulla was not detected. Two patients(2%) among 100 biopsies showed small(less than 1cm) hematomas. No AV fistula were detected. All patients went home 6hours after renal biopsy without any problems. Renal biopsy results showed IgAN(23%), Nonspecific GN(21%), Diffuse mesangial proliferative GN (17%),HSPN (6.7%), MGN(5.6%),FSGS (5.6%),Others were Alport,Lupus nephritis,DM nephropathy,MPGN type I,Thin GBM nephropathy.

Conclusions: In conclusion, percutaneous renal biopsy under the ultra-sound guide at OPD level with 6 hour ABR is safe and effective if perfomed at renal cortex level.

PUB579

Acute Lymphocytic Leukemia with Bilateral Renal Masses Masquerading as Nephroblastomatosis Salim Aljabari, Poonam Thakore, Curtis W. Turner, Tetyana L. Vasylyeva. *Pediatrics, Texas Tech Univ Health Sciences Center, Amarillo, TX.*

Background: While leukemia has a wide spectrum of presenting features, renal involvement at presentation of the disease is rarely seen. We are reporting a child with bilateral renal lesions resembling nephroblastic rests as the first and the only finding subsequently developing classic features of acute lymphocytic leukemia (ALL).

Methods: A 4 year old boy was presented with low grade fever and abdominal pain for few days. A complete blood count (CBC) and abdominal CT scan were done to rule out appendicitis. WBC of 8.1 K/UL,hemoglobin of 13.3 g/dL,Platelets of 170 K/UL, neutrophils 22%,Lymphocyte of 68.9% and absolute neutrophil count of 1.8 K/UL.CT scan showed bilateral renal enlargement with multiple hypodense lesions in the cortical and subcortical regions. Blood urea nitrogen of 7 mg/dl and creatinine of 0.38 mg/dl. The patient was diagnosed with viral gastritis and sent home on supportive treatment. CT scan was later interpreted as nephroblastomatosis by pediatric radiologist as an incidental finding advised to follow up with the pediatric nephrologist. After 14 days he again had low grade fever with abdominal pain. CBC showed WBC of 3.5 k/UL,Hemoglobin of 11.1 G/DL,platelets count of 21 K/UL,neutrophils 6 % and lymphocyte 85% ,absolute neutrophilic count was 351 and ESR of 71 mm/hr. The pediatric oncology service was consulted for possible malignancy. Peripheral blood smear showed the presence of abundant immature lymphoid cells representing 90 % of the total white cells. Bone marrow aspirate and biopsy,flow cytometry and cytogenetic studies showed early B cell leukemia. Treatment was initiated following the guidelines of COG AALL0932. After one week of induction therapy,the CT scan showed a complete interval resolution of all renal hypodense lesions.

Conclusions: Renal involvement in leukemia is challenging to diagnose due to its variable presentation on imaging. On CT scan, it may present as enlargement of kidneys (unilateral or bilateral), or a low-attenuation focal parenchymal. These focal lesions can be difficult to distinguish from nephroblastomatosis which has a similar radiological picture on CT scan.

PUB580

Modality of Treatment of Pediatric Patients with Diarrheal HUS in Acute Renal Failure Does Not Affect Long Term Outcome and Survival
Sonia Solomon, Julia W. Tzeng. *Pediatrics, Valley Children's Hospital, Madera, CA; Pediatrics, Univ of California, San Francisco - Fresno, Fresno, CA.*

Background: Diarrheal HUS is a disease process usually resulting from infection by *E. coli* H7:0157 and leading to the development of microangiopathic hemolytic anemia, thrombocytopenia, and acute renal failure. Acute renal failure typically follows in five days from presentation, with about two-third of the patients requiring renal replacement therapy. Studies have demonstrated that these patients are at risk for long term renal insufficiency and end-stage renal disease. Indications to start dialysis and the mode of dialysis vary from institution to institution. There is no current study comparing which mode of dialysis, hemodialysis or peritoneal dialysis, has greater benefit and less complications. The aim of this study is to compare dialysis modalities and determine whether one modality will result in less complications and better outcomes.

Methods: This is single center, retrospective review. We studied a total of 102 patients from 1999 to 2014. We compared patients with dHUS started on PD or HD. We compared the number of complications and the types of complications from each modality. Long term outcomes were measured by each patient's CKD staging at least one year after diagnosis. EGFR was calculated using the Schwartz formula. Fisher's exact statistical test was used to assess statistical significance.

Results: No statistical significance was found between the modality of dialysis and associated complications (p=0.4). There was also no statistical significance between modality of dialysis and long term outcome (p=0.9). Complications of PD were catheter malfunction (n=6), peritonitis (n=5), and the need to switch to HD or CVVHDF (n=3). Complications of HD included central line infections (n=1).

Conclusions: PD and HD are equally effective in treating patients with dHUS in renal failure and have comparable long term outcome and risks for complications. An important complication to consider for patients on PD is the potential need to switch to HD or CVVHDF; this exposes the patient to an additional surgical procedure that may result in further complications.

PUB581

Self-Reported Health Care Transition Readiness Among Mexican Adolescents with Chronic or End-Stage Kidney Disease
Guillermo Cantu,[1] Ana Catalina Alvarez-Elias,[3] Saul Valverde,[2] Maria E. Ferris,[3] Mara Medeiros.[2] *[1]Univ Panamericana, Mexico, DF, Mexico; [2]Univ of North Carolina at Chapel Hill, NC; [3]Hospital Infantil de México Federico Gómez, Mexico, DF, Mexico.*

Background: 90% of pediatric patients with chronic disease live more than 20 years after being diagnosed. When pediatric patients are transferred to adult-focused health services, generally they do not have the skills and abilities to manage their disease. Adolescents tend to have poor adherence to treatment, and there is a period when there may be complications and increased morbi-mortality. Performance on self-reported health care transition readiness (HCTR) needs to be assessed in patients with chronic or end-stage kidney disease. The aim of the study was to measure self-reported HCTR using the STARx (Self-management and Transition to Adulthood with Rx=Treatment) Questionnaire1, among adolescents in the Nephrology Service at Hospital Infantil de Mexico Federico Gomez.

Methods: The Spanish version of the STAR$_x$ Questionnaire was translated and back translated and applied to adolescents with chronic or end-stage kidney disease, in the outpatient nephrology department over a 9-month period. The 18-question tool diagnoses actions, knowledge and skills on chronic disease self-management, medications adherence and ability to find new health providers. Age was divided at 16 years. Student's T-tests were performed and p-values of < 0.05 were considered significant.

Results: We enrolled 68 adolescents (53% males) who had a mean age of 15.75 years (± 1.87). Patients who received hemodialysis in the past were 22 (34%). Females had significantly greater scores than males in the "action" category. Those who received hemodialysis in the past had greater knowledge about the disease (p 0.013).

Conclusions: The self-reported HCTR among Mexican adolescents with chronic or end-stage kidney disease differs by sex and treatment modality.

Italian Survey on Patients on Peritoneal Dialysis Treatment: ATENA
Alessandro Possidoni,[1] Sara Di fino,[1] Flavia Caputo,[2] Carlo Crepaldi,[3] Roberto Dell'Aquila,[4] Emilio Giulio Galli,[5] Anna Maria Costanzo,[1] Umberto Di luzio paparatti,[1] Roberto Russo.[6] *[1]AbbVie Italy; [2]H. Civico of Palermo; [3]H. Civile San Bartolo; [4]Bassano del Grappa; [5]H. of Treviglio; [6]H. of Bari.*

Background: in Italy,there are few epidemiological data concerning the clinical management of patients(pt)on Peritoneal Dialysis(PD)and the impact of PD on clinical outcomes.

Methods: epidemiological,multicenter study with a retrospective phase(12 months) and a prospective phase(6 months)of subjects on PD.Primary objective:evaluate anaemia,hypertension and mineral metabolism compared to K-DIGO and K-DOQI guidelines(GL).Secondary objectives:comorbidities,hospitalizations,therapeutic strategies,mortality and quality of life(QoL).

Results: 377 consecutive pt. were enrolled(at baseline,CAPD 50.4%/APD 49.6%;Male 59%;mean age:67 years;dialysis duration:39.7 months).The most frequent comorbidities were hypertension(88%),cardiovascular diseases(CVD=56%),vascular diseases(25%),dyslipidaemia(25%)and diabetes II(20%).The main cause of hospitalization was peritonitis(27%; no death associated),followed by CVD(20%).At 6 months,anaemia–not corrected or not adequately corrected(Hb£11g/dl)-occurred in 30% of pt. 73% received ESA.Systolic value>130 mmHg and diastolic value>80 mmHg occurred in 50% and 30% of pt,respectively.Left ventricular hypertrophy was observed in about 60% of echocardiograms. 25(OH)D levels were<10 ng/mL in 30% of executed tests.Secondary hyperparathyroidism(SHPT)occurred in 30% of pt.The drugs used to manage SHPT were calcitriol(36.3%),paricalcitol(29.2%),colecalciferol(23.6%) and cinacalcet(21.5%). Considering a group of pt under therapy for a year with similar basal PTH levels,a significant reduction of iPTH occurred with paricalcitol(1.05 mcg/day),but not with cinacalcet(39.4 mg/day)(p<0.001 vs p=0.626).No effect on Ca and P occurred in the paricalcitol group.At the end of the study,PD didn't modify the QoL significantly.

Conclusions: hypertension and CVD are the most common comorbidities of PD.Peritonitis is the main cause of hospitalization.Anaemia and SHPT are frequent and have to be treated and monitored carefully.There are significant differences in efficacy between different treatment options to treat SHPT.

PUB583

Advancements in Automated Peritoneal Dialysis Cycler Technology Driving Improved Quality of Care
Catherine Firanek, James A. Sloand. *Global Medical Affairs, Baxter Healthcare, Deerfield, IL.*

Background: Enhancements to APD technology directed at greater ease of use and health care professionals' (HCPs) oversight of patient status may help overcome barriers to home dialysis. Use of connectivity to enable remote patient monitoring (RPM) and prescription modification may facilitate patient management, increase HCP and patient communication, and improve outcomes. Advancements in design may also help simplify APD for patients. Objective is to understand and qualify importance of enhanced graphical user-interfaces (GUI), voice-guided instruction, and RPM embedded into APD cycler for HCPs and patients.

Methods: Forty-minutetelephoneinterviews and web-based surveys, including cycler videos, were conducted with 214 nephrologists, 138 renal nurses, and 193 CKD patients from UK and US. HCPs included those in practice for >3 yrs, spending > 75% of their time treating patients, and experience with use of conventional cyclers. Patients included those considered candidates for PD or those currently on dialysis, including incenter HD, home HD or PD. In double-blinded study, participants compared 2 conventional cyclers and a cycler with new technology with information screen, enhanced GUI and clinic connectivity.

Results: On a scale of 1-7 (7 the most important), cycler features rated most important to nephrologists, nurses, and patients include size and portability, GUI with voice-guided instructions, and data connectivity/RPM. When rating each cycler on favorability of attributes, the cycler with new technology scored highest. Attributes of 1st conventional cycler scored an average of 0.5 (on a scale of -3 to 3), while attributes of the cycler with new technology from the same manufacturer scored an average of 2.6 (p<0.0005). The attributes of the 2nd conventional cycler compared to the cycler with new technology scored on average 1.15 and 2.3 (p<0.0005), respectively.

Conclusions: HCPs and patients identified enhanced GUI, voice guidance, and data connectivity allowing RPM as favorable attributes to cycler usability and patient management. Technological enhancements that facilitate ease of cycler use and connectivity may increase PD acceptance by patients and HCPs.

PUB584

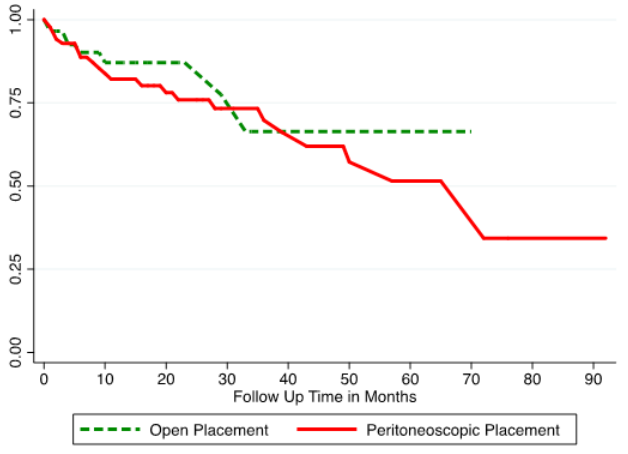
A Single Center Ten-Year Experience in PD Catheter Placement
Yorg Al Azzi, Etti Deborah Zeldis, Girish N. Nadkarni, Harry Schanzer, Jaime Uribarri. *Nephrology, Mount Sinai Hospital - Icahn School of Medicine, New York, NY.*

Background: In our early implantation practice, curly tip catheters had better function and less migration when compared with straight catheters and as such, we for the past 10 years have implanted almost exclusively the curly catheters. This is in disagreement with some current literature that favors straight catheters. Due to this discrepancy, we decided to review our single center experience with PD catheters over the past 10 years.

Methods: PD catheters placed over the period of 2004–2014 at our hospital were reviewed. Demographics, comorbidities, operative note, type of catheter, surgical approach, complications and overall survival were collected.

Results: 170 PD catheters were inserted during 10 years (49.7% men,mean age 54.7 years,167 curly catheters vs 1 straight intra-peritoneal,63% placed by open surgical technique vs 37% by Y-Teck peritoneoscopy). Diabetes mellitus was the most common cause of ESRD. 60 peritonitis cases occurred during the period of observation (24 lost their catheter), 30 had exit site infection, 9 had a leak out of which 4 lost their catheter, 3 had primary non-function of their catheter, 4 had hernias (1 taken off PD). There was no difference in hazard ratios in catheter survival after adjusting for demographics; diabetes status and number of previous catheter placement for overall follow up. But, looking at 2-year catheter survival, open placement of catheters had a higher adjusted hazard ratio for catheter loss compared to peritoneoscopic placement (aHR 2.61; 95% CI 1.02-6.71;p=0.04)

PD catheter cumulative survival stratified by placement technique



Conclusions: Our single-center experience demonstrated similar PD catheter survival rate and a better 2-year survival for catheters placed by peritoneoscopy. Our predominant use of the curly PD catheters suggests no significant difference in outcome compared to the straight catheters.

PUB585

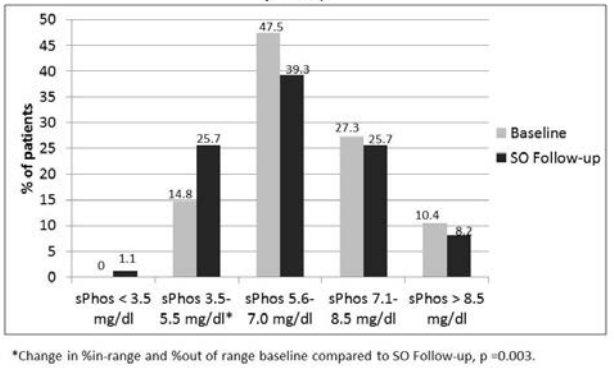
Peritoneal Dialysis Patients Who Switch Phosphate Binders from Sevelamer to Sucroferric Oxyhydroxide as Part of Routine Clinical Practice: A Retrospective Database Study Linda H. Ficociello, Vidhya Parameswaran, Phaneth Keo, Claudy Mullon, Franklin W. Maddux, Robert J. Kossmann. *Fresenius Medical Care North America (FMCNA), Waltham, MA.*

Background: A retrospective database study on the real-world effectiveness of sucroferric oxyhydroxide (SO), an iron-based phosphate binder (PB), in a cohort of adult peritoneal dialysis (PD) patients (pts) was conducted. This analysis examines PD pts from that cohort who switched from sevelamer (SEV) to SO (n=183).

Methods: All pts were prescribed SO as part of routine clinical practice at FMCNA clinics. Pts eligible for analysis had ³1 serum phosphorus (sPhos) during SO and the most recent PB used during the 3 months before SO was SEV. Changes in sPhos, serum calcium (sCa), intact parathyroid hormone (iPTH), transferrin saturation (TSAT), ferritin (FER), and PB pills per day were assessed 3-months before starting SO (baseline) and 3-months during SO treatment (follow-up).

Results: Pts (n=183) were, on average, 53 years old with a dialysis vintage of 3.9 years. Pts with in-range sPhos increased from 14.8% to 25.7% (74% increase). There was a significant reduction in sPhos (6.8 to 6.5 mg/dl,p=0.005), sCa (9.2 to 9.1 mg/dl,p=0.02), and PB pills per day (8.4 to 3.8 pills,p<0.001). iPTH changed minimally (544.6 to 559.8 pg/ml,p=0.5). TSAT increased significantly (35.0 to 37.5%, p=0.02) but not FER (782.1 to 840.3 ng/ml) when pts treated with IV iron were included; there was minimal TSAT change (35.2 to 36.3%) and no increase in FER (823.2 to 732.9) in pts not treated with IV iron (n=77).

Distribution of serum phosphorus during baseline compared to sucroferric oxyhydroxide (SO)-treated follow-up for PD patients who switched from sevelamer (N=183)



*Change in %in-range and %out of range baseline compared to SO Follow-up, p =0.003.

Conclusions: In a cohort of PD patients who switched from sevelamer to sucroferric oxyhydroxide as part of routine clinic practice, an increase in patients with in-range serum phosphorus (74%, p=0.003) and significant decreases in serum phosphorus and calcium were observed. Phosphate pill burden was decreased by 4.6 pills (8.4 to 3.8 pills per day, p<0.001).

PUB586

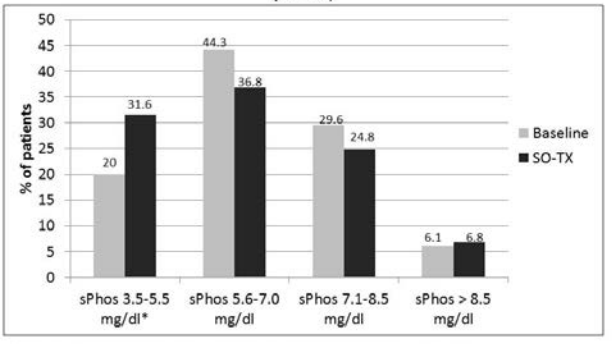
Improved Serum Phosphorus Control and Decreased Phosphate Binder Pill Burden Amongst African American Peritoneal Dialysis Patients Taking Sucroferric Oxyhydroxide Vidhya Parameswaran, Linda H. Ficociello, Claudy Mullon, Franklin W. Maddux, Robert J. Kossmann. *Fresenius Medical Care North America, Waltham, MA.*

Background: This study evaluated the real world effectiveness of sucroferric oxyhydroxide (SO) use among peritoneal dialysis (PD) patients (pts) who self-reported race as Black or African American (AA).

Methods: A retrospective database analysis was conducted on a cohort of AA PD pts who were prescribed SO as part of standard care at FMCNA clinics. Pts had ³1 serum phosphorus (sPhos) measured while using SO and had been on sevelamer, calcium-based phosphate binders or had no phosphate binder specified prior to SO treatment. Differences in sPhos, pill burden(PB), serum calcium(sCa), ferritin, transferrin saturation(TSAT), and intact parathyroid hormone(iPTH) were noted between baseline (BL; 3 months prior to SO) and follow-up (SO-TX; 3 months during SO).

Results: 117 AA PD pts (mean age=50 years, dialysis vintage=4.2 years) were included. At BL, 37% were on sevelamer, 31% on calcium-based phosphate binders, 2% on dual therapy and 31% had no phosphate binder specified. Figure shows increase in pts who have in-range sPhos (20% to 31.6%; 58% increase). Mean sPhos decreased from 6.55-6.38 mg/dl (p=0.06). A significant decrease in PB was observed (4.5 pills/day, p<0.001) between BL(8.8 pills) and SO-TX(4.3 pills). No significant differences were observed between BL and SO-TX for sCa (BL=9.1 mg/dl, SO-TX=9.1 mg/dl), ferritin (BL=861.9 ng/ml, SO-TX=870 ng/ml), TSATs (BL=34.7%, SO-TX=36.8%) and iPTH (BL=729.5 pg/ml, SO-TX=696.4 pg/ml).

Distribution of serum phosphorus during baseline compared to sucroferric oxyhydroxide (SO)-treated follow-up among African American PD patients (N=117)



*Change in %in-range and %out of range baseline compared to SO-TX, p =0.006.

Conclusions: In a cohort of African American peritoneal dialysis patients who were prescribed sucroferric oxyhydroxide as part of routine clinical care, there was a 58% increase in the number of patients with serum phosphorus levels in-range (p=0.006). Furthermore, there was a significant reduction in pill burden (4.5 fewer pills, p<0.001).

Funding: Pharmaceutical Company Support - Fresenius Medical Care North America

PUB587

Peritoneal Dialysis for Management of Refractory Heart Failure Girish Singhania, Abhilash Koratala, Amir Kazory. *Nephrology, Univ of Florida, Gainesville, FL.*

Background: Refractory heart failure (RHF) is associated with significant morbidity and mortality. There is growing interest in the use of peritoneal dialysis (PD) for management of patients with RHF. In this study, we explored the currently available data on the safety and efficacy of PD in this setting.

Methods: A search of PubMed database using key words "peritoneal dialysis" and "heart failure" from 1985 to 2015 was performed by two of the authors independently and found 763 articles, from which those including at least 20 patients who had initiated PD for cardiac indication were selected. Relevant data on efficacy and safety such as changes in the quality of life and cardiac function as well as the rate of hospitalization were extracted and compared.

Results: Seven studies (4 prospective and 3 retrospective) met the inclusion criteria with a total of 398 patients and a mean age of 70.4 years. PD was associated with improvement in functional status (1 to 2 NYHA class reductions) in 5 of the 7 studies (not reported in 2) as well as an increase in the ejection fraction in 6 studies. A variety of PD regimens were used that in general showed efficacy in removal of fluid as suggested by notable reduction in patients' weight in 6 studies by up to 8.3 kg (unavailable in 1). It was also shown to significantly reduce the number of days of hospitalization for acute HF in 6 studies by up to 90%. Five studies reported increase in responsiveness to diuretics as well as perceived improvement in the quality of life. The PD-related complications were found to be minimal in 6 studies while one reported 0.75 episode/patient/year of peritonitis.

Conclusions: Currently available evidence suggests that PD is an efficacious option for management of patients with RHF that can result in significant improvement in their functional status, hospitalization rate, and the quality of life. Based on the findings of these studies PD is safe in this population and its related morbidity does not replace HF-

associated morbidity. Larger controlled trials are warranted to explore the potential impact of PD on the mortality of patients with RHF and to define those subgroups most likely to benefit from this therapy.

PUB588

Procalcitonin, Is It a Useful Biomarker for Peritoneal Dialysis Peritonitis? Shinhan Song, Hyeon-Cheol Park, Jae Seok Kim, Jae Won Yang, Byoung Geun Han, Seung-Ok Choi. *Internal Medicine, Yonsei Wonju College of Medicine, Wonju, Korea.*

Background: Peritonitis is a common complication in peritoneal dialysis (PD). Procalcitonin is a peptide hormone which has been used as a biomarker for the diagnosis of bacterial infection. We aimed to investigate the usefulness of procalcitonin in the patients with PD peritonitis.

Methods: This study included 33 episodes of peritonitis in 27 patients for follow-up period of 450 days. In addition, we collected samples of PD effluents from 7 PD patients without peritonitis to compare with those of peritonitis. We investigated clinical characteristics, serum and PD effluent levels of procalcitonin at the time of initial visit and discharge.

Results: The mean value of dialysis vintage of patients with peritonitis was 1774 days, incidence of total peritonitis for period of PD maintenance; 4.3 times, interval from symptom onset to visit; 13.6 hours, duration of intraperitoneal antibiotic treatment; 8.2 days, and interval from clinical improvement to recurrence; 80.7 days. Initial serum procalcitonin increased to 0.97 ± 3.67 ng/mL (mean ± standard deviation) compared with reference values (healthy <0.05, PD patients <0.30, PD peritonitis >0.50 ng/mL), and PD effluent procalcitonin also increased compared with in the subjects without peritonitis, but not significantly (0.07 ± 0.19 vs. 0.01 ± 0.01 ng/mL, p=0.503). The serum procalcitonin decreased to 0.33 ± 0.54 ng/mL with clinical improvement but not significantly (p=0.308), and the PD effluent procalcitonin also showed the decreased level of 0.03 ± 0.08 ng/mL but not the statistical significance (p=0.360). Pearson's correlation analysis showed that the serum and PD effluent procalcitonin did not have relationships with existing inflammatory markers such as ESR, CRP. Lastly, procalcitonin could not predict recurrence and mortality of peritonitis.

Conclusions: Collectively, procalcitonin showed the tendencies corresponding to the clinical course of PD peritonitis, but not statistical significance. We believe that procalcitonin is not superior biomarker in PD peritonitis compared with other existing markers.

PUB589

Epidemiological Survey of Maintenance Peritoneal Dialysis in China Xiang-Mei Chen, Xueying Cao, Delong Zhao, Guangyan Cai. *Chinese PLA General Hospital, Chinese PLA Inst of Nephrology, State Key Laboratory of Kidney Diseases, National Clinical Research Center for Kidney Diseases.*

Background: To analysis epidemiology and trend of peritoneal dialysis during 2011 - 2014 in China.

Methods: Patient-reported outcome data from the peritoneal dialysis centers were collected online during the study.

Results: (1) By the end of 2014, there were 55373 cases of maintenance peritoneal dialysis patients in China, had increased by 17 % per year over this time period . The annual incidence rate was 5.81/100 million people.The prevalence was 34.3/100 million.**(2)**The average age was 53 years. Male to female ratio was 1.2:1. The average age at initiation of dialysis was about 50 years old. The average residual renal function was 3ml/min. The average dialysis time was 2 years. The primary causes were primary glomerular disease 54%, diabetic nephropathy 16%, hypertensive renal damage 14%. **(3)**In 2014, DOR fell to 6.6%. TOT was 27.2 months. The death patients accounted for about 51.3% of exit patients. The average death age was 64.8 years. The average therapy time was more than 28.6 months. The cause of death was the cardiovascular and cerebrovascular events.**(4)** Peritoneal dialysis access was the two cuffs, no gooseneck, straight. 78% patients were the continuous ambulatory peritoneal dialysis patients. The therapeutic dose was 6L to 8L. High peritoneal transport type was the largest. **(5)**PD patients with hemoglobin 100g/L ratio was raied every year. The albumin level in plasma was greater than or equal to 35g/L with more than 50% patients. Serum calcium, phosphorus, parathyroid hormone level was improved year by year. The average Kt/V was maintained at 2.1/ weeks. Ccr could reach 62 L/1.73m^2/ weeks.

Conclusions: There is a 17% annual increase in peritoneal dialysis patients. The incidence and prevalence was stable. DOR and TOT improved year by year. Anemia, plasma albumin, calcium, phosphorus metabolism and dialysis adequacy control were better than before.

PUB590

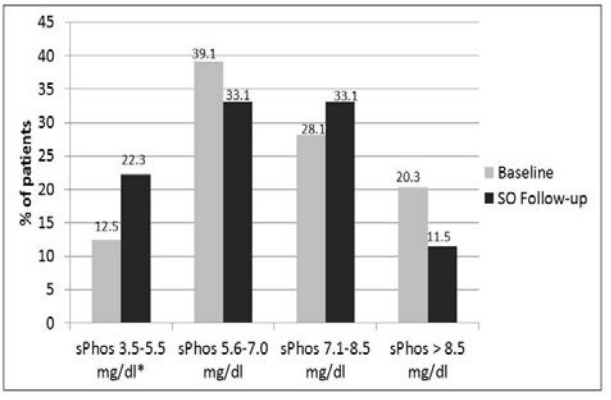
Peritoneal Dialysis Patients Who Switch from Calcium-Based Binders to Sucroferric Oxyhydroxide as Part of Routine Clinical Practice: A Retrospective Database Study Linda H. Ficociello, Vidhya Parameswaran, Phaneth Keo, Claudy Mullon, Franklin W. Maddux, Robert J. Kossmann. *Fresenius Medical Care North America (FMCNA), Waltham, MA.*

Background: A retrospective database study on the real-world effectiveness of sucroferric oxyhydroxide (SO), an iron-based phosphate binder (PB), was conducted in a cohort of adult peritoneal dialysis (PD) patients (pts). This analysis examines pts who switched from a calcium-based phospate binder (CaPB); either calcium acetate (n=95) or calcium carbonate (n=35) to SO.

Methods: All pts were prescribed SO as part of routine clinical practice at FMCNA clinics, had ³1 serum phosphorus (sPhos) measured during SO, and the most recent PB used was a CaPB. Changes in sPhos, serum calcium (sCa), intact parathyroid hormone (iPTH), % transferrin saturation (TSAT), ferritin (FER), and PB pills per day were assessed 3-months before starting SO (baseline) and 3-months during SO treatment (follow-up).

Results: Pts who had in-range sPhos increased from 12.5% to 22.3% (78% increase) between baseline and follow-up (Figure). There were significant reductions in sPhos (7.1 to 6.8 mg/dl, p=0.004) and PB pills per day (7.4 to 3.6 pills, p<0.001). Minimal change in sCa (8.99 to 8.95 mg/dl, p=0.5) and iPTH (519.2 to 544.4 pg/ml, p=0.4) was observed. There was significant change in FER (708.5 to 788.3 ng/ml, p=0.008, but not TSAT (35.8 to 35.5%, p=0.8) when pts treated with IV iron were included. There was minimal increase in FER (733.6 to 735.0 ng/ml, p=0.98) or TSAT (38.0 to 39.1%, p=0.6) in pts not administered IV iron (n=43).

Serum phosphorus during baseline compared to sucroferric oxyhydroxide (SO)-treated follow-up for patients who switched from calcium-based binders to SO (N=130)



*Change in %in-range and %out of range baseline compared to SO Follow-up, p =0.003.

Conclusions: In a cohort of PD patients who switch from calcium-based binders to sucroferric oxyhydroxide as part of regular clinic practice, there was a 78% increase in patients achieving in-range serum phosphorus (p=0.003). Additionally, phosphate binder pill burden was lessened from 7.4 to 3.6 pills per day (3.7 fewer pills, p<0.001).

Effects of Chlorhexidine-Impregnated Patches on Catheter Exit Site and Tunnel Infections in Peritoneal Dialysis Patients Chiaki Kawabata. *General Internal Medicine, Japanese Red Cross Kumamoto Hospital, Kumamoto, Japan.*

Background: Exit-site infections and tunnel infections are major causes of catheter loss in peritoneal dialysis (PD) patients. We studied the effects of chlorhexidine-impregnated patches (Biopatch), which are used as central-line dressings or drain site dressings, on PD catheter exit site infection and tunnel infections.

Methods: A retrospective review was conducted of 45 patients whose PD catheter exit site was made between January 2007 and December 2014. We compared acute exit site infections, chronic exit site infections, and tunnel infections of the two groups, (the Biopatch Group and the Non-Biopatch Group), 6 months after the exit site was created.

Results: The Biopatch was used until the exit site had healed perfectly. The mean time of using the Biopatch was 63±26 days. The two groups had no significant differences in age [49.4±12.0 years vs 52.3±16.3 years], diabetes mellitus co-morbidity or pattern of peritoneal dialysis. There were no statistical differences in acute exit site infections [15.4% vs 6.1% (p=0.27)], chronic exit site infections [0% vs 9.1% (p=0.28)] or tunnel infections [15.4% vs 15.2% (p=0.90)] during the 6 months.

Conclusions: Using the Biopatch until the exit site has healed perfectly does not reduce either exit site infections or tunnel infections.

PUB592

The UK Peritoneal Dialysis Catheter Study (UK Cath): An Ancillary Study to the Peritoneal Dialysis Outcomes and Practice Patterns Study
Martin E. Wilkie,[1] Simon J. Davies,[2] Mark Lambie,[2] Francesca Tentori,[3] Jeffrey Perl.[4] *[1]Sheffield Kidney Inst, Sheffield Teaching Hospitals NHS FT, Sheffield, United Kingdom; [2]Keele Univ, Keele, United Kingdom; [3]Arbor Research Collaborative for Health, Ann Arbor, MI; [4]St. Michael's Hospital, Toronto, ON, Canada.*

Background: Delivering high quality peritoneal dialysis (PD) access placement and outcomes is limited by lack of standardization of PD access definitions and events, variable reporting of outcomes, and a paucity of robust evidence regarding optimal PD catheter insertion pathway(s). The UK Renal Registry PD access audit (2013) demonstrated 82% catheter survival at 1 year, with considerable variation between centres. Moreover, catheter function at 3 months was poorer for a medical (percutaneous) compared to a surgical (open surgical) insertion pathway.

Methods: UK-Cath, a multi-centre prospective cohort study (1350 patients, 45 dialysis centres, 18 month recruitment window) will assess the outcomes associated with different pathways of catheter insertion, dialysis unit-level policy associated with pathway use, and patient-level factors (e.g. case-mix, urgent start). Health economic benefits of these pathways will be determined using the cohort data, enriched by additional information obtained from more long-term follow-up study in a subset of patients using Hospital Episode Summary (HES) data linkage. The study has received funding from the UK NIHR Research for Patient Benefit Programme, NIHR PB-PG-0613-31028. A subset of study 20 centres will contribute to International Peritoneal Dialysis Outcomes & Practice Patterns Study (PDOPPS) with the primary objective of understanding variations in PD technique failure.

Results: We will present information on study design, instrument development, governance mechanisms, and recruitment plan. We will discuss the impact of patient engagement on study design.

Conclusions: The UK Peritoneal Dialysis Catheter Study will inform dialysis units' decision to either focus their efforts on improving a single surgical pathway or to practise a mixture of surgical and medical insertions, with the ultimate goal to improve PD catheter survival, patient experience and optimise health economic efficiency.

Preparedness for Telemedicine in Outpatient Peritoneal Dialysis
Kana N. Miyata, Panida Ditsawanon, Tiane Dai, Sharon G. Adler, Ramanath B. Dukkipati, Anuja P. Shah, Lili Tong, Anne A. Ugalde, Jenny I. Shen. *Nephrology, Harbor UCLA Medical Center, Torrance, CA.*

Background: Peritoneal dialysis (PD) is generally performed daily by patients at home, where questions may arise. Telemedicine has the potential to improve the delivery of healthcare services and outcomes for PD patients. We studied the preparedness for telemedicine of a PD clinic run by a large dialysis organization (LDO) serving an urban under-resourced population.

Methods: Adult PD patients cared for by the clinic were asked about their interest and ability to use VSEE® (HIPPA-compliant tool for video calls) to remotely manage clinical concerns about PD. We compared patient characteristics between interested and non-interested groups. We also assessed the clinic's ability to implement VSEE®.

Results: Initial barriers encountered were with the LDO. These included a firewall that prevented video products from being loaded onto clinic computers, consent issues, concerns regarding unequal care potentially being provided to patients with and without internet access, and lack of video equipment for on-call nurses. All of these barriers were overcome. We then assessed interest in 56 patients. Their age (mean±standard deviation) was 43±13 years, 63% were male, English was the primary language for 66%, and they had been on PD for 3.0±3.2 years. 34 patients (61%) showed some interest in telemedicine, 16 (29%) downloaded the software to their laptop, tablet, or cell phone, and downloading in process for the remaining 18 (32%). The most common reason for not being interested was "no device" or "no internet access at home", which was reported by 15 patients (27%). The only additional difference in characteristics between the interested and non-interested groups was that those interested lived further away from the clinic (12.9 vs 9.3 miles, p=0.03).

Conclusions: Multiple barriers to delivering telemedicine to PD patients exist, both on the clinic and patient side. 61% of patients were telemedicine-ready. Future evaluations will determine the impact on clinically significant outcome, patient satisfaction, and clinic workflow in this population.

PUB594

When to Remove the Peritoneal Dialysis (PD) Catheter After Renal Transplantation? (RT)
Saul Enrique Pampa,[1] Maite Rivera,[1] Victor Burguera,[1] Fernando Caravaca-Fontan,[1] Estefania Yerovi,[1] Nuria Rodriguez mendiola,[1] Sara Jimenez alvaro,[1] Cristina Galeano,[1] Fernando Liano.[1] *[1]Nephrology, Hospital Univ Ramón y Cajal, Madrid, Spain; [2]Urology, Hospital Univ Ramón y Cajal, Madrid, Spain.*

Background: There seems to be consensus that the time of removal of the peritoneal catheter after RT may be delayed until renal function and the patient is stabilized, but there are few publications about it.

Methods: We analyzed retrospectively patients on Peritoneal Dialysis Unit (PD) who have received a RT between May 1995 and March 2015 gathering medical history data relating to the peritoneal catheter removal and complications.

Results: 108 patients transplanted from PD, 32 women/76 men with a mean age at the time of TR 50 +/- 13 years (range 16-80) were analyzed. Two patients received RT of living donor and 106 of cadaver. The catheter used in all was a straight Tenckhoff with two cuffs . If renal therapy substitution was needed postransplantation all patients were treated with hemodialysis. The catheter was removed during surgery in nine patients (8%) due to exit or tunnel infection by Staphylococcus aureus or Pseudomonas aeruginosa. The withdrawal was delayed in 91 patients (84%) and 8 has not yet been removed. The average withdrawal time was 4.1 +/- 2.7 months. The indication of withdrawn was: stable renal function in 85 (93%), stable pancreatic and renal function in 4 and exit site infection in 2 (3%). Mean creatinine at the time of removal was 2.1 mg/dl +/- 1.8 mg / dl. All catheters were removed surgically under local anesthesia. The mean duration of hospitalization was 2.1 +/- 1.8 days (0-12). Four patients (3.7%) had complications during withdrawal (one hematoma, two hemorrhagic shock and one surgical wound infection). 15 (18%) patients suffered complications before withdrawal: 13 exit site infection, one peritonitis associated with urinary fistula and one spontaneous peritonitis.

Conclusions: In our experience the removal of the peritoneal catheter may be delayed until renal graft function were stabilize since the rate of complication is low compared with another studies.

PUB595

Clinical Outcomes by Differences in Therapy Among Peritoneal Dialysis Patients
Hironori Nakamura, Anayama Mariko, Yasushi Makino, Masaki Nagasawa. *Dept of Nephrology, Shinonoi General Hospital, Nagano, Japan.*

Background: Studies evaluating the outcomes of peritoneal dialysis (PD) technique and patient survival, including those among patients who switch from PD to hemodialysis (HD), are scarce.

Methods: This retrospective study screened 120 patients in whom PD was initiated between January 1998 and December 2012 at our hospital. Of these, patients those who were transferred to another hospital, those who received transplantation, or those who did not have follow-up data were excluded. Fifty-two patients (age, mean ± SD: 69.2 ± 12.6 years) were included to investigate the time of survival based on PD technique and overall survival, including those patients who switched to HD, and to evaluate the correlation between survival time and pharmacotherapy at the initiation of PD.

Results: Time (in months) on PD, HD, and overall survival were 34.3 ± 30.0, 18.5 ± 43.4, and 52.6 ± 52.3, respectively. Comparison between the APD (n = 20) and non-APD patients (n = 28) showed that time on PD was 45.3 ± 34.4 vs. 31.3 ± 26.0 months, time on HD was 39.0 ± 40.6 (n = 8) vs. 81.8 ± 72.5 (n = 8) months, and overall survival time was 60.9 ± 49.9 vs. 54.7 ± 55.4 months, respectively. Comparison between groups with (n = 41) and without use of icodextrin (n = 7) showed time on PD was 10.8 ± 6.0 vs. 41.4 ± 30.1 months, time on HD was 49.6 ± 45.0 (n = 3) vs. 62.9 ± 65.3 (n = 13) months, and the survival time was 32.1 ± 41.7 vs. 61.6 ± 53.6 months. When analyzed by age groups of <60, 61–70, 71–80, and >81 years: time on PD (months) was 47.2 ± 38.4 (n = 14), 45.2 ± 23.4 (n = 15), 19.8 ± 27.0 (n = 10), and 21.2 ± 19.2 (n = 13), respectively. Time on HD was 22.8 ± 44.2 (n = 6), 14.6 ± 36.3 (n = 5), 8.7 ± 28.2 (n = 1), 26.3 ± 60.1 (n = 4), respectively; and survival time was 70.1 ± 52.8, 59.2 ± 41.9, 28.5 ± 39.7, and 46.7 ± 67.2 months.

Conclusions: The time on dialysis and survival time may be underestimated because of the exclusion of patients who are currently on dialysis. Compared with non-APD patients, APD patients had longer time on PD and overall survival time. Patients who needed icodextrin when commencing PD had shorter time on PD and overall survival time.

PUB596

Combined Markers of Protein-Energy Wasting and Inflammation Predict Clinical Outcomes in Incident Peritoneal Dialysis Patients
Chan Ho Kim,[1] Jung Tak Park,[2] Seung Hyeok Han,[2] Tae-Hyun Yoo,[2] Shin-Wook Kang.[2] *[1]Internal Medicine, Catholic Kwandong Univ College of Medicine, Incheon, Korea; [2]Internal Medicine, College of Medicine, Yonsei Univ, Seoul, Korea.*

Background: Protein-energy wasting (PEW) and chronic inflammation are not only common but are known as predictors of adverse clinical outcomes in end stage renal disease (ESRD) patients. Whether the combined values of serum albumin, high sensitivity C-reactive protein (hs-CRP), and body mass index (BMI) have an additive impact on clinical outcomes compared to each variable by itself in incident peritoneal dialysis (PD) patients was evaluated.

Methods: A prospective cohort of 565 incident PD patients from the Clinical Research Center for ESRD in Korea was selected. Patients were divided into two groups based on the baseline levels of albumin (≥ and <3.8 g/dL), hs-CRP (≥ and <0.45 mg/dL), and BMI (≥ and <23 kg/m²). Primary outcome was the composite of all-cause mortality and unplanned hospitalization.

Results: The mean age was 51.4 years and 60.0% were male. During a median follow-up duration of 27 months, 50 patients (8.8%) died and unplanned hospitalization events occurred in 123 patients (21.8%). Univariate analysis revealed an increase in primary outcome risk with lower albumin and elevated hs-CRP compared to higher albumin and lower hs-CRP, respectively. A similar tendency was observed with lower BMI and primary outcome, although without statistical significance. Regarding the combination of these variables, Cox proportional hazards analysis revealed that patients with any two risk factors and all three risk factors exhibited significantly higher hazard ratios for primary outcome compared to patients without any single risk factor. The combination of these factors retained a significantly higher HR for predicting primary outcome, even after adjusting for other confounders.

Conclusions: The combination of serum albumin, hs-CRP, and BMI at the time of PD commencement was a significant independent risk factor for the composite outcome of all-cause death and unplanned hospitalization in incident PD patients.

PUB597

Single Center Experience with a Peritoneal Dialysis Cycler with Advanced Patient Interactive Screen: Impact on Patient Training

Lili Chan,[1] Ma shelda Cabus-Fojas,[1] Marcia A. Duffoo,[1] Catherine Firanek,[2] James A. Sloand,[2] Jaime Uribarri.[1] *[1]Mount Sinai; [2]Baxter.*

Background: Learning proper device use and clinical concepts of care must be internalized by patients to successfully perform PD at home. With increasingly diverse patients going on PD and increasing adoption of urgent start PD, there is a need for simpler devices. Enhancing the learning environment with methods including visual, graphical and voice will improve the educational experience leaving the patient with better understanding of the procedure.

Methods: Automated PD training was undertaken at a university based home dialysis program using a novel APD device (AMIA). 5 patients were trained on the device in a 1:1 nurse to patient ratio. The cycler provided on screen instructions using a touch screen interface with voice guidance, text instructions and animation. Each patient was trained according to standardized outlines and sequential training progression from CAPD to APD techniques. Training included RN demonstration followed by patient direct interaction with the device. Instructions were displayed on a touch screen, along with verbal and graphical cues. Patient training completion required consistency of error free setup.

Results:

Patient	Age (years)	Gender	Etiology of renal disease	Incident (I)/ Prevalent (P)	Urgent (U)/ Routine (R)	Training Days
1	30	F	Hypertension/ NSAID	I	U	2
2	47	F	FSGS	I	U	3
3	49	F	Calcineurin Inhib Toxicity	P-HD	R	5
4	68	M	FSGS	P-HD	R	4
5	41	F	Lupus Nephritis	P-APD	R	4

5 patients aged 30-68 yrs (mean 47), 80% female with a minimum of HS education completed training. Device training ranged from 2-3 days for urgent start patients and 4-5 days in routine start patients.

Conclusions: From our experience, training times were similar or reduced using the AMIA cycler and allowed the ability to efficiently train urgent start patients. Observed advantages of the new cycler included: 1) less need for memorization 2) distinction of a beginner vs advanced mode 3) online alarm troubleshooting 4) presence of an air detector in patients' line 5) multiple prescription capability. The step by step instructions and online problem solving of the new device may impact positively the efficiency and understanding of these patients.

PUB598

Peritoneal Dialysis-Related Peritonitis in a Single Center: 10 Years Experience

Patricia O. Costa, Carla M V Melo, Jordanio P. Oliveira, Flavia A. Nobrega, Jandson P. Oliveira, Kleyton Andrade Bastos. *Dept of Medicine, Federal Univ of Sergipe, Aracaju, Sergipe, Brazil.*

Background: Peritonitis remains as the main Peritoneal Dialysis (PD)- related complication. It is estimated that it contributes directly to 20% of dropout and is related to 16% of all deaths. This study proposes to evaluate episodes of PD-related peritonitis and describe its incidence, causative organisms and possible predictors in patients belonging to a DP program from a reference center at Aracaju-Sergipe-Brazil.

Methods: Retrospective cohort study that evaluated 565 patients who stayed for at least 30 days in the technique, between 01/01/2003 and 12/31/2012, with a mean age of 54 ± 19 years, 55% male, 62% less than 8 years of regular study and 88% with monthly income less than 5 national minimum wages. They remained in DP by an average of 713.5 ± 714.2 days. Since 2011, was initiated daily use of gentamicin at the exit site of the peritoneal catheter.

Results: Most patients (59%) showed no peritonitis. The global index was 1 episode every 27.03 months. It was recorded the lowest rate in 2012 (1 episode every 45.6 months), while the highest were in 2003 and 2005 (1 episode every 23.2 and 22.2 months, respectively). S. aureus was the most prevalent germ (23%), followed by E. coli (9%) and Alcaligenes sp (6%). The culture was negative in 31% of cases. There was healing of peritonitis in 71% of cases, with better outcome in gram-positive bacteria (83%). Gram-negative healed in 61% of cases. It identified a higher risk of peritonitis in patients with history of exit site infection (relative risk = 1.24; 95% confidence interval = 1.02 - 1.50; p <0.05). There was no significant difference between the groups, with or without peritonitis, in terms of sociodemographic factors.

Conclusions: Despite the bad social indicators of the study population, the incidence of peritonitis follows the recommendations of the International Society for Peritoneal Dialysis (ISPD), with a reduction of rates along the years, especially after the introduction of gentamicin. Similar as described by other authors, exit site infection was recognized as a peritonitis´ predictor, so it is extremely important to perform preventive strategies.

PUB599

Placement of Peritoneal Dialysis Catheters: Not Limited to Operating Rooms

Sijie Zheng,[3] Todd Drasin,[2] Jeanne A. Darbinian,[4] Paul Dybbro,[2] Neelam M. Bhalla.[1] *[1]Nephrology, Kaiser Permanente Northern California, Hayward, CA; [2]Interventional Radiology, Kaiser Permanente Northern California, Hayward, CA; [3]Nephrology, Kaiser Permanente Northern California, Oakland, CA; [4]Div of Research, Kaiser Permanente, Oakland, CA.*

Background: As of December 2012, only 7% of ESRD patients in the USA utilize Peritoneal Dialysis (PD) for renal replacement therapy, despite many advantages of PD over hemodialysis (HD). One factor leading to low PD utilization is the lack of experienced surgeons available to place PD catheters in a timely manner. Interventional Radiologists (IR) can help with catheter placement. As of December 2014, Kaiser Permanente achieved a 23% PD rate among its ESRD population. One factor that contributed to the high percentage of PD utilization is a skilled IR service in the Greater Southern Alameda Area (GSAA) that facilitates the placement of PD catheters in a timely manner. We report a large number of PD catheters placed by GSAA IR physicians from January, 2011 to December, 2013 and compare to PD catheters placed by laparoscopic surgeons in the nearby East Bay Area (EBA) and Diablo Service Area (DSA) during the same time period.

Methods: We retrospectively analyzed KPNC electronic data base from 1/1/2011 – 12/31/2013. We extracted data from GSAA where IR placed PD catheters using an Advanced Image guided Percutaneous (AIP) technique. We also extracted data from the EBA and DSA where surgeons placed PD catheters using the Advanced Laparoscopic Surgical (ALS) technique.

Results: We identified 203 PD catheters placed by GSAA IR with the AIP technique and 316 PD catheters placed by EBA/DSA surgeons using the ALS technique. Overall, GSAA IR placed 39% of all PD catheters across the 3 areas during the study time period.

Conclusions: : IR placed a significant percentage of overall PD catheters in 3 areas of our integrated health care system. In doing so, they overcame one of the barriers to high PD penetration in ESRD patients. In areas where there is a shortage of skilled surgeons, one can consider utilizing IR to solve this problem. Currently we are studying the outcomes of these two approaches.

Body Composition and Cardiovascular Outcomes Using Continuous Automated Peritoneal Dialysis – A Prospective Cohort Study

Carlos Alberto Garza, Gabriela Leal, Bernardo Moguel. *Dept of Nephrology, National Inst of Cardiology, Mexico City, Federal District, Mexico.*

Background: Fluid overload (FO) due to compliance in **C**ontinuous **A**mbulatory **P**eritoneal **D**ialysis (**CAPD**) is common. Efforts to achieve dry weight and avoid cardiovascular outcomes (CO) are lessen from inaccurate body composition(BC) estimations despite best clinical assessment.

Methods: We'll follow BC, multiple frequency bioelectrical impedance(InBody S10, InBody Co),standard laboratories and CO, in all new patients to continuous **A**utomated **P**eritoneal **D**ialysis(**APD**) previously in a CAPD. Measurements at baseline (CAPD), 1 month and every visit to the dialysis clinic thereafter (APD) for a 5 year period.

Results: These are the first data of **BODY** cohort study. Initial 10 subjects are described, 4 men and 6 women, median age 27 years(17-46), height 159.5cm(146-166), baseline and first follow up variables are in Table 1. Wilcoxon rank test for related samples was performed. We found that PD modality switch to APD, at 1 month, reflected a body composition transition with statistical significance (P <0.05), within the EBW/TBW ratio at expense of trunk compartment. Most likely from improved dialysis adherence

Variable	Unit	Baseline	30 days	P
Weight	Kilogram (K)	60.75(42.7-104.2)	58.65(45.2-108.4)	-
BMI	Kg/m^2	23.6(17.2-39.7)	23.4(18.6-41.3)	-
Systolic pressure	mmHg	152(110-175)	136(117-180)	-
Diastolic pressure	mmHg	97.5(64-108)	91(59-127)	-
Body water (TBW)	Liters(L)	31.95(22.2-45.3)	31.5(24.8-45.2)	-
Extracellular water (EBW)	L	12.5(9.3-17.9)	12.2(9.4-17.5)	-
Intracellular water (IBW)	L	19.4(12.9-27.4)	19.4(14.7-27.7)	-
EBW/TBW	Ratio	**0.39(0.38-0.42)**	**0.38(0.38-0.41)**	**P<0.05**
EBW/TBW Trunk	Ratio	**0.39(0.38-0.42)**	**0.38(0.38-0.41)**	**P<0.05**
Lean Muscle	K	43.5(30.1-60.6)	43(33.4-60.6)	-
Body Fat	K	15.5(3.3-43.6)	16.2(5.7-47.8)	-
Metabolic Rate (BMR)	Kcal/day	1310(1019-1679)	1298(1091-1678)	-
Dialysis	L	**7L(2-10)**	**8L(8-12)**	**P<0.05**

"-"not statistically significant

Conclusions: We consider that APD, on the ground of increased, uninterrupted and rigorously performed therapy, is an appropriate method to optimize FO and aim for dry weight in PD. Further recruitment of patients and follow up of the BODY Cohort study is expected to confirm this hypothesis.

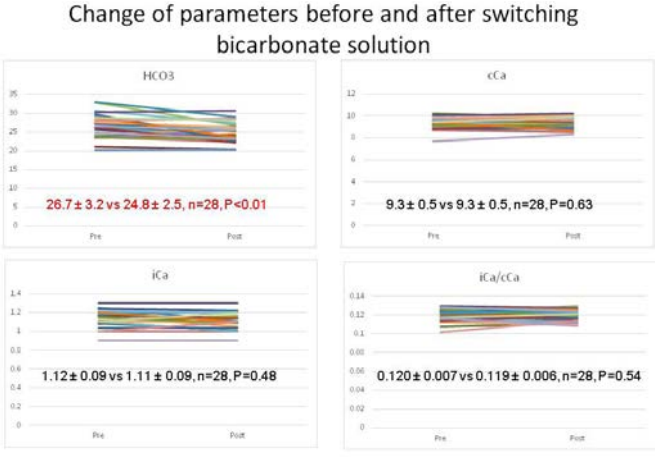
The Changes in Bicarbonate Level and Ionized Ca/ Corrected Ca Ratio of Patients Receiving Peritoneal Dialysis Using Bicarbonate/Lactate-Buffered Solution Emi Kimoto, Nanae Matsuo, Masamitsu Morishita, Mami Nakamura, Yukio Maruyama, Yasuyuki Nakada, Masatsugu Nakao, Yudo Tanno, Ichiro Ohkido, Hiroyasu Yamamoto, Keitaro Yokoyama, Takashi Yokoo. *Div of Nephrology and Hypertension, Dept of Internal Medicine, Jikei Univ School of Medicine, Tokyo, Japan.*

Background: Recently,PD solution which contains 25mEq/L bicarbonate and 10mEq/L lactate (Bicarbonate/Lactate-buffered peritoneal dialysis solution; B/L solution)is developed in Japan. Because of high concentration of lactate (40mEq/L) of conventional peritoneal dialysis (PD) solution, patients have generally higher serum bicarbonate level than those of patients receiving hemodialysis (HD). The new B/L solution is expected not only its biocompatibility but also improving excess correction of acidosis. Under the metabolic alkalosis environment, we reported that PD patients have lower levels of ionized Ca (iCa) at the same corrected Ca (cCa) levels. Thus, we hypothesized that iCa / cCa ratio increased after switching PD solution from Lactate-buffered to B/L solution.

Methods: We recruited 28 patients (55 ± 13 years, male 82%, PD duration 42 ± 21 months) who switched from Lactate-buffered to B/L solution, and investigated changes in serum bicarbonate, iCa, and cCa levels.

Results: After switching solution, serum bicarbonate decreased (26.7 ± 3.2 vs 24.8 ± 2.5, P<0.01), and cCa did not change (9.3 ± 0.5 vs 9.3 ± 0.5, P=0.63). Neither iCa nor iCa/cCa ratio increased significantly (1.12 ± 0.09 vs 1.11 ± 0.09, P=0.48; 0.120 ± 0.007 vs 0.119 ± 0.0006, P=0.54, respectively).



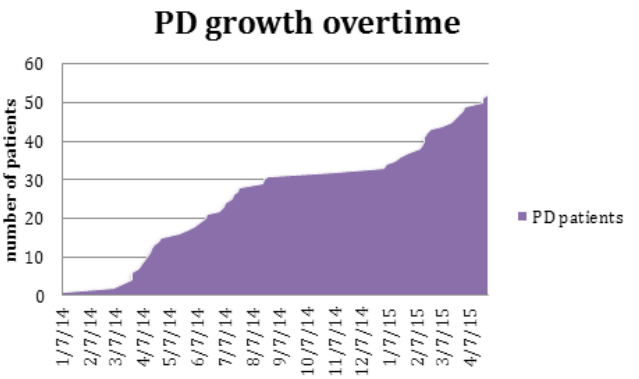
Conclusions: Conversion to B/L solution from lactate solution was associated with lower serum bicarbonate. Unfortunately, iCa did not change. Further investigations are needed to confirm the utility of the monitoring of iCa for the management of chronic kidney disease - mineral and bone disorder (CKD-MBD) in PD patients.

PUB602

Road to Success: One Academic Medical Center's Experience Building a Peritoneal Dialysis Clinic Yazan M. Alia, William A. Schlueter, Erwin E. Morales, Maria A. Gavino, Shubhada N. Ahya, Robin E. Watson. *Nephrology, Northwestern Memorial Hospital, Chicago, IL.*

Background: Peritoneal Dialysis (PD) is an option for renal replacement therapy. The US Renal Data System 2012 Annual Report states that the annual per-patient HD cost is approximately $87,500 whereas for PD it is $66,750. In addition, studies have demonstrated that some aspects of quality of life are improved in PD patients compared with HD patients. Despite this, PD is underutilized in the US. Northwestern Medicine's PD Program was initiated in 01/2014 with 4 nephrologists and 10 patients who transferred from a neighboring PD Unit. From 02/2014 to 04/2015, Northwestern's Peritoneal Dialysis Clinic grew to 50 peritoneal dialysis patients.

Methods: We included all patients who started on PD (or transferred to PD) in PD Clinic between the periods of 2/14 and 4/15. Patients excluded from this analysis stopped PD within this period for the following reasons: switched to HD, expired, recovered kidney function, or underwent transplantation.



Results: From January 2014 to April 2015, PD Clinic grew to 50 patients. The age range is 22-86 years and mean age is 54.4 years. Thirty-one (62%) are men. Twenty-one (42%) are African American, 13 (26%) are Caucasian, 11 (22%) are Hispanic, and 5 are of Asian descent.

Conclusions: We describe a single, academic medical center experience on growth of PD Clinic from 0 to 50 patients within 14 months. Obstacles to PD Clinic growth included lack of availability of dialysate in mid 2014 and lack of experience with Urgent Start PD. However, with time, both nephrologist and surgeons and medical staff grew comfortable with this method of dialysis initiation. Features that facilitated successful and timely growth are: 1-realtime options training, 2-surgeon cooperation, 3-physical proximity to CKD Clinic and to inpatient floors, 4-continuity of care for patient-physician from outpatient CKD Clinic to inpatient setting to outpatient Home Dialysis Clinic.

PUB603

Peritoneal Membrane Transport Evaluation in Peritoneal Dialysis Using Traditional PET, Modified PET and Mini-PET Miguel C. Riella,[4] Jacek Waniewski,[2] Bengt Lindholm,[3] Marcelo Nascimento.[1] *[1]Univ Federal do Parana, Curitiba, Parana, Brazil; [2]Inst Biocybernetics and Biomedical Engineering, Warsaw, Poland; [3]Baxter Novum and Renal Medicine, Karolinska Inst, Stockholm, Sweden; [4]Pro-Renal Foundation, Curitiba, Parana, Brazil.*

Background: Peritoneal equilibration test (PET) is widely used for evaluating peritoneal transport; however, additional methods have been described to facilitate and improve this evaluation. Here we compared traditional PET (PET) with two newer methods, mini-PET and modified PET (mod-PET), which are increasingly used to investigate ultrafiltration capacity and peritoneal membrane characteristics in patients undergoing peritoneal dialysis.

Methods: Twenty-one non-diabetic adult patients on peritoneal dialysis (PD) for >3 months underwent: PET (2.27%; 4 h), mini-PET (3.86%; 1 h) and mod-PET (3.86%; 4 h). Results of dialysate to plasma concentration ratios for creatinine (D/P Cr) and sodium (D/P Na), and dialysate to initial glucose concentration (D/D0 glucose) at the end of each test were compared by analysis of variance (ANOVA), Pearson correlation and Bland-Altman test.

Results: Whereas D/P Cr was not significantly different between PET and mod-PET (p=0.746) there were significant differences between mini-PET and both PET (p<0.001) and mod-PET (p<0.001). D/P Cr for PET correlated with D/P Cr for mod-PET (r=0.387; p=0.009) but not with D/P Cr for mini-Pet (r=0.088; p=0.241). Bland Altman test showed no significant bias of D/P Cr for PET vs mod-PET (-0.029; p=0.201) but a systematic difference (0.206; p<0.001) of D/P Cr for PET vs mini-PET. Whereas measurements of D/D0 glucose and D/P Na were in general not comparable nor significantly correlated, ultrafiltration during PET and mini-PET were weakly correlated (r= 0.260; p=0.009).

Conclusions: These results confirm that characterization of transport status based on D/P Cr may not necessarily differ between conventional PET and mod-PET.

PUB604

Low Level of Albumin Is a Risk Factor for Short-Term Mortality of PD Patients Kenji Harada. *Kokura Memorial Hospital; Kokura Memorial Hospital.*

Background: Mortality of HD(hemodialysis) patients are reported, but few reports about PD(peritoneal dialysis) patients. This study aims to investigate clinical features of PD patients, their prognostic risk factors, and to establish a prognostic model for predicting their short-term mortality(1-2 years).

Methods: We investigated the mortality about PD patients(n=269, age:65 year old±13.7, male/female 173/96, PD vintage within 2 years, DM:121), and the influence of several parameters from 2009 to 2012. The dead and the transferred HD were excluded within 90 days. Finally 241 patients are remained. The survival rates for one year and two years were 91 % and 72 %. Infection was the most causes of death(53%). We investigated between death and several parameters(age, sex, blood pressure, albumin, hemoglobin, Ca, P, whole PTH, TC) by univariate analysis with JMP12, SAS. Those physical and laboratory data are measured at one month after PD started. Age and level of albumin were correlated with death. We hypothesized that low albuminuria and malnutrition influenced the rate of death. We divided three categories, from group A(albumin³3.3, n=82) and group B(2.8£albumin<3.3, n=89), group C(albumin<2.7, n=73).Cox proportional hazards regression model was used to analyse prognostic risk factors and establish prognostic model.

Results: There were significant differences between group B and A(Hazard Ratio:2.611, p=0.0116, 95%CI:1.232-6.009), group B and C(Hazard Ratio:6.031, p<0.001, 95%CI:2.975-13.53), group C and A(Hazard Ratio:2.309, p=0.0029, 95%CI:1.33-4.09). In addition these groups were analysed by adjustment factor such as age, sex, blood pressure, hemoglobin, Ca, P, whole PTH, TC with multivaliable analysis. The results proved that there were tended to be correlation between group B and A(Hazard Ratio:1.963, p=0.09, 95%CI:0.901-4.61). There were significant differences between group B and C (Hazard Ratio:4.00, p=0.003, 95%CI:1.866-9.35), group C and A(Hazard Ratio:2.037, p=0.0029, 95%CI:1.165-3.63).

Conclusions: Low level of albumin increases the mortality of PD patients gradually. Therefore we may decrease the mortality of PD patients by improving nutritional condition and infection control when PD patients are introduced.

PUB605

The Effect of Neutral pH versus Conventional Peritoneal Dialysis Solutions on Peritoneal Permeability Atsushi Ueda, Kei Nagai, Toshiaki Usui, Joichi Usui, Kunihiro Yamagata, Chie Saito. *Univ of Tsukuba, Tsukuba, Japan.*

Background: Biocompatible peritoneal dialysis (PD) solutions have been anticipated to reduce oxidative stress more than conventional PD solutions,however, previous reports suggested peritoneal permeability have not been changed. This study was undertaken to investigate the peritoneal transport status from PD initiation, using biocompatible or conventional PD solutions.

Methods: We employed retrospectively 101 patients who started PD and divided into three groups. Acid group was consisted of 76 patients who used only conventional low pH solutions, and neutral pH group was consisted of 19 patients who used only biocompatible neutral pH solutions during the subsequent two years. The rest of six patients used low pH solutions at the initial phase of PD, then switched to neutral pH solutions. The ratios of dialysate to plasma creatinine concentration at 4 hour (D/Pcre) in peritoneal equilibration test were measured at every year. We evaluated D/Pcre levels at the initiation and two years after between acid and neutral pH groups, and also the D/Pcre movements before and after switching PD solutions of the six patients.

Results: There was no significant difference on the D/Pcre values between at the start and two years after in the acid and neutral pH groups respectively. D/Pcre change between at the start and two years after in the acid group was not significant different compared to that of the neutral pH group. However, D/Pcre declined significantly one year after switching PD solutions from acid to neutral pH.

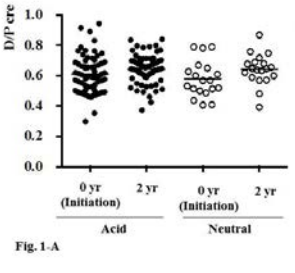

Fig. 1-A

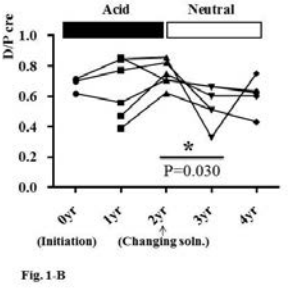

Fig. 1-B

Conclusions: It was not observed obvious beneficial effects of neutral pH solutions on peritoneal permeability within two years PD duration. However, the transient effect in decreasing peritoneal permeability was found, and suggested that biocompatible solutions may preserve peritoneal functions compared to conventional solutions in a long time period.

PUB606

Predictive Power of Serum Cystatin C Assessing Residual Renal Function in Patients on Peritoneal Dialysis Jong Man Park,[1] Sang Heon Song,[1] Eun Young Seong,[1] Harin Rhee,[1] Ihm Soo Kwak,[1] Il Young Kim,[2] Dong Won Lee,[2] Soo Bong Lee,[2] Woo Jin Jung,[1] Su Min Park,[1] Min Jung Kim,[2] Joo Hui Kim.[2] *[1]Internal Medicine, Pusan National Univ Hospital, Busan, Republic of Korea; [2]Internal Medicine, Pusan National Univ Yangsan Hospital, Yangsan, Republic of Korea.*

Background: Residual renal function (RRF) is of considerable importance for patient survival on peritoneal dialysis. In clinical practice, the RRF is usually measured by assessing the urine concentrations of urea and creatinine and total urine output and the process is cumbersome and time consuming. Cystatin C has proposed to be used in place of RRF measurement. This study aims to investigate the predictive power of cystatin C in peritoneal dialysis patients.

Methods: This study included 54 patients on peritoneal dialysis who had evaluated RRF, serum cystatin C and serum creatinine. RRF was measured using the 24-hour urea–creatinine clearance method and cystatin C based glomerular filtration rate (eGFRcysC) was estimated using the Hoek's formula. RRF and cystatin C were followed up for 6 months at least. The rate of RRF decline and slope of serum cystatin C were assessed by regression.

Results: Patients were on peritoneal dialysis for a median of 30 months and average serum concentrations of cystatin C was 5.41 ± 1.06 mg/L. Among the 54 patients, sixteen was anuric and seven became anuric during follow up. The patients with RRF had significantly lower cystatin C levels ($p = 0.001$). RRF was correlated with cystatin C ($\gamma = -0.687$, $p < 0.01$). In simple linear regression, RRF was associated with cystatin C ($\gamma = 0.687$, $p < 0.001$), eGFRcysC ($\gamma = 0.741$, $p < 0.001$) and creatinine ($\gamma = 0.662$, $p < 0.001$). The slope of serum cystatin C was correlated with the rate of RRF decline ($\gamma = 0.616$, $p < 0.001$) during follow up. The overall loss of RRF group had a higher level of serum cystatin C at the point of dialysis initiation ($p = 0.017$).

Conclusions: Serum cystatin C level might be convenient parameter for estimating the RRF and serum cystatin C at the point of dialysis initiation might be a predictive marker of preservation of RRF. Further studies about the cystatin C based equations are required to replace creatinine/urea clearance measured RRF.

PUB607

Peritoneal Dialysis: A Decade Experience at a Reference Centre in Brazil Patricia O. Costa, Carla M.V. Melo, Flavia A. Nobrega, Jordanio P. Oliveira, Jandson P. Oliveira, Kleyton Andrade Bastos. *Dept of Medicine, Federal Univ of Sergipe, Aracaju, Sergipe, Brazil.*

Background: Peritoneal Dialysis (PD) is underutilized in most countries. The Brazilian prevalence is around 9%. This study aims to describe the ten years experience on PD in a dialysis center in Northeast of Brazil (Aracaju-Sergipe). Unlike other national programs, negative selection for DP is not an attribute of this dialysis unit.

Methods: Retrospective cohort study that evaluated the sociodemographic and clinical profiles, comorbidities, peritonitis, hospitalizations and death causes of 565 patients who remained in PD for at least 30 days from 01/01/2003 to 12/31/2012.

Results: Patients were mostly men (55%), living outside Sergipe's capital (56%), had a mean age of 54 ± 19 years old when started on dialysis, were illiterate or had less than 4 school years (62%) and had a family income less than 5 national minimum wages per month (88%). The etiology of nephropathy was identified in 54% of cases, diabetic nephropathy (46%) and hypertensive nephrosclerosis (22%) were the most prevalent. Hypertension was the main comorbidity (76%). DP was the initial dialysis modality for 53% of patients, mainly as an emergency (58%), and only 9% of patients had undergone predialysis care for at least six months. Patients remained in PD by an average of 710.5 (± 714.2) days, and 61% of them also underwent hemodialysis (HD) at some point during their dialysis treatment. 676 peritoneal catheters were implanted (1.19/patient), 75% by trocar, by nephrologist, mostly Tenckhoff (58%). The main cause of dropout were infectious complications related to therapy (17%). The peritonitis index was 1 episode every 27.03 months, and S. aureus was the most prevalent etiological agent (22%). There were 1045 hospitalizations during follow up, most frequently due to infections (48%). The cause of death was identified in 64% of cases, mostly from cardiovascular diseases (50%).

Conclusions: In this study, patients had predominantly low socioeconomic status and did not have access to predialysis treatment, however, peritonitis rates and catheter complications are similar to those reported in other international series. HD and PD are shown as complementary techniques.

PUB608

Implementation of Clinical Practice Guidelines on Antimicrobial Prophylaxis in Peritoneal Dialysis Patients Denise Campbell,[1] Fiona Brown,[2] John F. Collins,[3] Jonathan C. Craig,[1] Martin P. Gallagher,[4] David W. Johnson,[5] Geoffrey S. Kirkland,[6] Subramanian K. Kumar,[7] Wai Hon Lim,[8] Dwarakanathan Ranganathan,[9] Walaa W. Saweirs,[10] Germaine Wong,[1] David Mudge.[5] *[1]School of Public Health, Univ of Sydney, Sydney, New South Wales, Australia; [2]Nephrology, Monash Univ, Clayton, Victoria, Australia; [3]Renal Medicine, Auckland City Hospital, Auckland, New Zealand; [4]Renal and Metabolic Div, George Inst for Global Health, Sydney, New South Wales, Australia; [5]Nephrology, Princess Alexandra Hospital, Woolloongabba, Queensland, Australia; [6]Nephrology, Royal Hobart Hospital, Hobart, Tasmania, Australia; [7]Renal Unit, Gosford Hospital, Gosford, New South Wales, Australia; [8]Renal Medicine, Sir Charles Gairdner Hospital, Perth, Western Australia, Australia; [9]Nephrology, Royal Brisbane & Women's Hospital, Herston, Queensland, Australia; [10]Renal Unit, Whangarei Hospital, Whangarei, New Zealand.*

Background: Despite the existence of international guidelines, peritoneal dialysis (PD)-related infections vary widely across Australian and New Zealand units, with multiple units reporting suboptimal rates and variable practice.

Methods: The current practice and barriers to guideline uptake were evaluated in eight PD units located in Australia and New Zealand in 2011. A multifaceted intervention was developed which included case report forms, a patient diary, a 'Preventing Peritonitis Checklist', an Emergency Department flyer, a letter to the patient's general practitioner, a medical card, and a poster summarizing ISPD and KHA-CARI guidelines.

Results: At baseline (1 Jan-31 Dec 2011), exit-site infection (ESI) rates ranged from 0.06-0.53 episodes/patient-year; peritonitis from 0.31-0.86 episodes/patient-year; and fungal peritonitis from 0.00-0.08 episodes/patient-year. After implementation (9 Dec 2013-8 Dec 2014), the ESI rates were 0.00-0.22 episodes/patient-year; peritonitis was 0.29-0.49 episodes/patient-year; and fungal peritonitis was 0.00-0.14 episodes/patient-year.

Conclusions: Implementing the various tools resulted in improvement in the ESI and peritonitis rates but the difference was not statistically significant (P=0.15 and P=0.08). There was no statistically significant difference in the fungal peritonitis rate (P=0.64).

PUB609

Survival Analysis of 326 Continuous Ambulatory Peritoneal Dialysis (CAPD) Patients Hao Zhang, Liu Li, Bin Yi, Wei Li. *The Third Xiangya Hospital, Central South Univ, Changsha, Hunan, China.*

Background: This study aimed to identify clinical outcomes and risk factors that may affect potential prognosis of ESRD (end-stage renal disease) patients who receiving continuous ambulatory peritoneal dialysis(CAPD) in Southern China.

Methods: ESRD patients who initiated CAPD between period Aug 1st 2002 to Mar 31st 2010 in The Third Xiangya Hospital, affiliated with Central South University were reviewed retrospectively. Demographic data including age at initiation, gender, body mass index(BMI), blood pressure, primary causes of ESRD and dialysis vintage, biochemical data including hemoglobin (HB), serum albumin(Alb), HDL(high-density lipoprotein), LDL(low-density lipoprotein), TL(total cholesterol), TG(triglyceride), immunoreactive parathyroid hormone (iPTH), serum phosphorus , serum calcium and residual renal function(eGFR) were collected from medical records. Outcome of death or technique failure from any causes were selected. All-cause mortality and survival rate were analyzed using variance analysis and COX regression.

Results: A total of 326 CAPD patients(199 male and 127 female)were identified in this study. The mean age was 50.73±14.99 years, median dialysis vintage was 46(2-144) months. Primary glomerulonephritis was the most common cause of ESRD (50.6%). The overall 1- , 3- and 5- patient survival rate were 95.4%, 79.3% and 46.2%, and 1-, 3-and 5- technique survival rate were 90.8%, 67.2% and 43.6%, respectively. Significant differences in age, BMI, hemoglobin, albumin, eGFR between groups were found. No statistical significances were found in gender and primary causes of ESRD. In multivariate cox regression analysis, patient technique survival were associated with BMI (HR=1.230(1.154-1.310), p=0.000), Alb (HR=0.913(0.882-0.945), p=0.000), HB (HR=0.981(0.971-0.992), p=0.000), eGFR (HR=0.818(0.750-0.884), p=0.000).

Conclusions: The results suggested that obesity, anemia, hypoalbuminemia, lower eGFR at the commencement were independent risk factors for technique survival in CAPD patients.

PUB610

Factors Influence the Baseline Peritoneal Transport Status Hao Zhang, Bin Yi, Cuiling Hou. *The Third Xiangya Hospital, Central South Univ, Changsha, Hunan, China.*

Background: Baseline peritoneal solute transport rate(PSTR) is an independent risk factor for total and cardiovascular(CV) mortality in the PD(peritoneal dialysis) population. The determinants of PSTR in incident PD patients are still under debate. Our objective was to explore the influence factors of baseline PSTR.

Methods: (1) 205 incident PD patients who had a standard peritoneal equilibration test(PET) within 1-3 months after commencing PD and without peritonitis history were enrolled. Pre-dialysis clinical parameters and biochemical indexes were assessed. 205 individuals were divided into two groups according to the baseline PET. High transport group: PET³0.65,Low transport group: PET < 0.65. (2) Pre-dialysis serum advanced oxidation protein products (AOPP) and dialysate AOPP, GPx, hsCRP, IL-1beta, TGF-beta1 of 59 patients among the enrolled 205 individuals were detected.

Results: (1) High baseline PET are more likely to be male(male: 77.3% vs 52.5%, p = 0.001), had lower serum albumin(34.0±4.40g/L vs 35.9±4.55g/L, p=0.005) and TG levels(1.11±0.62 mmol/L vs 1.28±0.57mmol/L, p=0.047) compared to the low baseline PET. Gender (r = 0.299, p = 0.299), serum albumin(r = 0.199, p = 0.199) and TG level(r = 0.140, p = 0.140) are correlated with the baseline PET respectively. Multiple stepwise linear regression analysis shows that gender (B = 0.085, p = 0.085), serum albumin (B = 0.005, p = 0.005)) are associated with baseline PET independently. Multivariate Logistic analysis showed that men (OR = 3.314, p = 0.001), hypoalbuminemia (OR = 2.552, p = 2.552) are independent risk factors for high baseline PET.ROC curve display that when serum albumin < 35.8 g/L, it is likely to have a high baseline PET. (2) High baseline PET had a relatively high level of dialysate TGF-beta1(1.58±0.33ng/ml vs 1.75±0.30 ng/ml, p=0.049) than the low transport status. No statistical differences were found in serum AOPP and dialysate AOPP, GPx, hsCRP, IL-1beta between groups. Dialysate TGF-beta1 (r = 0.336 ,p = 0.009) relative to the baseline PET independently.

Conclusions: (1) Male, hypoalbuminemia, high dialysate TGF-beta1 level are independent predictors of fast baseline PSTR. (2) When serum albumin < 35.8 g/L, it is likely to have a high baseline PSTR.

PUB611

Influence of Peritoneal Transport Rate in Diabetic Patients on Peritoneal Dialysis: A Single Center Experience in Saudi Arabia Naveed Aslam. *Nephrology, Prince Sultan Military Medical City, Riyadh, Saudi Arabia.*

Background: Measurement of the peritoneal membrane transport features is crucial for both the characterization of its functional state and for the prescription of the adequate dialysis dose. It has been reported that increased peritoneal transport rate (PTR) is associated with lower patient survival, but the influence of diabetes mellitus (DM) on the PTR is still controversial. The objective of this study is to describe the PTR and its correlation, in terms of technique and patient survival, in diabetic patients on peritoneal dialysis (PD).

Methods: In a retrospective, single-center study, we evaluated a total of 84 diabetic patients, newly started on PD between January 2004 and December 2010. Peritoneal equilibration test (PET) status was recorded and patients were classified as one of the following four peritoneal transport types: high (H), high average (HA), low average (LA) and low (L) transporters. Inflammatory and nutritional markers along with routine renal parameters were assessed. Withdrawal from PD and death were recorded.

Results: The average age of patients starting PD was 76.3 ± 7.2 with a prevalence of male gender (70%). 80% of the patients showed high peritoneal transport rate (High: 28%, High-Average: 52%, Low-Average: 20%, Low: 2%). The 1, 3 and 5 year patient survival rates were 78%, 62% and 42% respectively. Technique survival rates were 64%, 52% and 24% respectively. Only 10% of the patients could perform their PD therapy without the assistance of any family member or nurses. Only 70% of the patients were on APD among high transporters. Albumin level and CRP were negatively associated with patient survival.

Conclusions: Our data suggest that diabetic PD patients tend to be significantly high peritoneal transporters with worse prognosis in terms of patient and technique survival. This result is similar to what several large studies had reported in the literature. For diabetic PD patients, PET should be carefully evaluated and accordingly the prescription of short dwells, which have found their natural application in APD, should be kept in mind as a treatment option. The high transport rate is a contributory factor in low serum albumin levels.

PUB612

Practical Experience with Acute Peritoneal Dialysis (PD) as Initial Dialysis Modality Jiri Vlasak. *FMC, Sokolov, Czech Republic.*

Background: Hemodialysis (HD) is the predominant renal replacement therapy (RRT) in new end-stage renal disease (ESDR) patients in the Czech Republic. One of many reasons for this situation is that roughly 40% patients with ESDR are "late referral". Due to the lack of predialysis education, these pacients have limited knowledge about dialysis options. Usually, hemodialysis is performed after the central catheter placement.

Methods: Between November 2012 and April 2015, 15 patiens with urgent need of dialysis were successfully initiated in our center on PD as the first option treatment.

Results: In two patients, we started PD immediately after the catheter insertion and on the second or third day in 13 patients. Exchanges were conducted in the out-patient dialysis center under the constant supervision of an experienced PD nurse in the modified mode-supine position, small volume solutions with 1,5% of glucose, 6-8 exchanges daily, using automated peritoneal dialysis (APD). Only one patient was treated in the local hospital because of severe uremia related symptoms. Exchanges were well tolerated. We did not observe any early complications (leak, malfunction of the catheter, infection, bleeding etc). All patients were educated 2-3 weeks after the start of acute PD regimen and we observed a strong adherence to PD method in all 15 patients.

Conclusions: Based on our experience, acute peritoneal dialysis can be successfully administered under the conditions of outpatient care in the majority of ESDR patients with the urgent need of dialysis if three preconditions are met. First, the team of well-educated staff in PD, especially in APD. Second, a close cooperation with surgeon experienced in laparoskopically assisted puncture technique of PD catheter. Third, the ability to introduce the PD catheter as urgent surgery.

PUB613

Cause of Failure in Chronic Peritoneal Dialysis Catheters Elizabeth Huerta calixto. *Nephrology, Hospital Angeles Puebla, Puebla, Mexico.*

Background: One of most common treatment of end stage kidney failure is peritoneal dialysis. Encapsulating peritoneal sclerosis is a complication in wich the osmotic capacity of peritoneal barrier is lost, mainly due to infections. This patology has different clinical presentations that obligue to use different diagnostic and therapeutic methods.

Methods: I was a survey conducted retrospective, descriptive and cross that included June 1, 2008 to May 30, 2014 in nephrology deparment of Angeles Hospital.

Results: Clinical and imagine presentation in three different patients, we analyze each separately as well as their solutions. These include delimitation of the affected zone, sterilization of the cavity and it's collapse, even the renal transplatation.

Conclusions: Different clinical presentations of the encapsulating peritoneal sclerosis oblige to design evaluation and treatment for each patient in particular, using all the imagine and laparoscopic methods.

PUB614

Take on Characteristics of Incident PD Patients in a Multicentre Multinational Integrated Care Setting Belen Marron,[1] Marietta Torok,[2] Delia Timofte,[3] Janusz Ostrowski,[4] Jose C. Divino-Filho.[1] *[1]Diaverum Home Therapies. Medical Office, Diaverum, Munich, Germany; [2]Szeged Diaverum Clinic, Diaverum, Szeged, Hungary; [3]Sema Diaverum Clinic, Diaverum, Bucharest, Romania; [4]Wloclawek Diaverum Clinic, Diaverum, Wloclawek, Poland.*

Background: Our institution as a Renal Service provider is committed to integrated care, offering all types of RRT and focusing in patient´s choice. Objectives: To analyze HD and PD take on and its relationship with the type of previous referral and provided care.

Methods: Retrospective analysis of 547 incident patients starting dialysis in 23 HD/PD clinics in 2012. Early referral (ER) considered if patient known ≥ 3months in Nephrology, and scheduled initiation of dialysis with a permanent access was considered planned (P).

Results: Population: 30% diabetes, mean age 64 years, 84% with previous medical care of renal disease, 49 % late referral, 80% modality informed, 58 % unplanned start, 11% PD (3% early switch from urgent HD). PD therapy in non-planned start applied in 5/59 PD patients. No differences in HD/PD take on were observed for gender, diabetes, initial renal and predialysis follow up, at structured units or in elapsed time between early

follow up and dialysis start. PD patients (p=0.02) received more modality information than HD (92% vs. 78%) and were mainly under 50 years (p <0.001). PD incidence varied according with different studied groups

Studied groups: n (% vs.col.)	All patients n=547	HD n=488	PD n=59	p value
ER + P	168 (31)	133 (27)	35 (59)	< 0.001
Late referral + P	63 (12)	58 (12)	5 (9)	
ER + Unplanned start	113 (20)	104 (21)	9 (15)	
Late referral + Unplanned start	203 (37)	193 (40)	10 (17)	
Optimal care: ER + modality informed + P	121 (22)	96 (20)	25 (42)	

Conclusions: Despite commitment to offer PD/HD as complementary treatments, PD incidence is still low. Optimal care provision is important to improve outcomes but also to involve patients in their therapy choice.

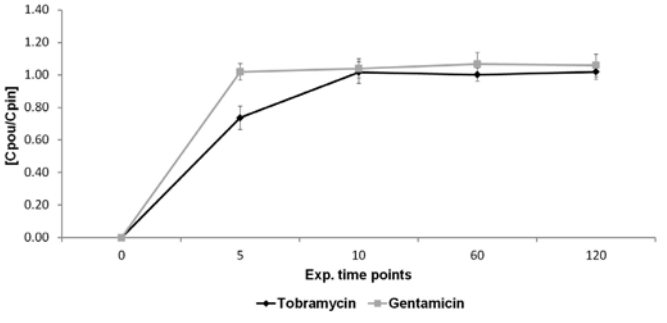
PUB615

The Adsorption Kinetics Profile of Aminoglycoside Antibiotics During Lixellle S-35 Cartridge Hemoperfusion Marco Sartori,[1,2] Angela Casas,[1] Silvia De Rosa,[1] Mirella Zancato,[2] Leopolda Zampieri,[1] Davide Giavarina,[1] Claudio Ronco.[1] [1]*International Renal Research Inst of Vicenza, St. Bortolo Hospital, Vicenza, Italy;* [2]*Dept of Pharmaceutical and Pharmacological Sciences, Univ of Padua, Padua, Italy.*

Background: The bactericidal activity against Gram(-)mo of Tobramycin(TOB)and Gentamicin(GEN)is concentration-dependent.It is therefore fundamental achieving the maximum drug plasma levels.Lixelle S-35 cartridge is a sorbent used in dialysis-related-amyloidosis which can modified the drug plasma levels.The aim of *in vitro* study was to evaluate the TOB and GEN adsorption removal by Lixelle S-35.

Methods: We performed mock direct hemoperfusion (DHP;Q_B=100ml/min;Bellco prototype dialysis machine)for 120 min using Lixelle S-35 cartridge.Human blood was diluted with fresh frozen plasma in order to achieve appropriate rheological characteristics(Hct 30%;650mL each bag;n=6).Blood was separately spiked with TOB(11.00±0.42 mg/L;n=3)and GEN(12.80±1.06mg/L;n=3)then it was circulated into the system.Samples were taken from arterial(Cpin)and venous(Cpout)lines at 5,10,60 and 120 min.Sample levels were mesured by TOBR and GENT Flex methods(Siemens Healthcare,Newark,NJ.USA)for TOB and GEN,rispectively.The adsorption kinetics profiles were calculated.

Results: At the of DHP TOB and GEN levels were 7.13±0.18 and 7.20±0.90mg/L. Ratio Cpout/Cpin rose rapidly during the first 5 min then reach plateau for both antibiotics as shown Fig.On mass balance analysis,the total mass of antibiotics introduced into the system decreased from 5.12±0.25 to 3.22±0.50 and from 6.16±0.51 to 3.32±0.41mg for TOB and GEN,respectively.The TOB mass adsorption was 37.20% whereas GEN was 46.20%.



Conclusions: Our *in vitro* study indicates an high adsorption rate for both aminoglicosides.This should be considered when TOB or GEN are used in pts treated with Lixelle S-35 cartridge.A supplemental dose may be needed to maximixed efficacy.

PUB616

Analysis of Some Aminoglycoside Antimicrobials in Human Plasma by HILIC-MS/MS Shinya Omiya,[1,2] Xiao-Pen Lee,[2] Takeshi Kumazawa,[2] Keizo Sato,[2] Kiyoko Inui,[1] Tomoaki Miyazaki,[1] Yoshihiko Inoue,[1] Ashio Yoshimura.[1] [1]*Dept of Medicine, Div of Nephrology, Showa Univ Fujigaoka Hospital, Kanagawa, Japan;* [2]*Dept of Legal Medicine, Showa Univ School of Medicine, Tokyo, Japan.*

Background: Aminoglycoside(AG) antimicrobials(AMBs) have been used for a treatment of bacterial infections,especially by acid-fast bacteria.However,their acute overdose or chronic abuse can cause serious side effects,such as difficulty in hearing, interstitial nephritis resulting in renal failure and even sudden death from anaphylactic shock.In such cases,there is a great need to identify and quantify AG AMBs in the blood from patients or cadavers.We earlier reported an analytical procedure for nine AG AMBs in human serum by capillary HPLC/mass spectrometry(MS).Although this method works well for identification of the drug,it is semi-quantitative unless a suitable isotopic internal standard is used.

Methods: A simple,rapid,sensitive and quantitative method is presented for the analysis of six AG AMBs (streptmycin, ribostamycin, kanamycin, amikacin, dibekacin, arbekacin) in human plasma samples by hydrophilic interaction liquid chromatography(HILIC)-tandem MS(MS/MS).A small volume(150ul) of plasma spiked with six drugs was diluted with 350ml of acetonitrile containing 0.1% formic acid.After centrifugation,100ul of the clear supernatant extract was directly injected into the HILIC-MS/MS,without any solvent evapolation and reconstitution steps.The chromatographic separation of the AG AMBs was achieved on Unison UK-Amino HILIC column(50mm x 3mm i.d.,particle size 3um)with a linear gradient elution system composed of 0.1% formic acid and acetonitrile.

Results: All drugs showed base peaks due to [M+H]+ ions by HILIC-MS with positive ion electropray ionization,and the product ions were produced from each [M+H]+ ion by HILIC-MS/MS.Quantification was made by selected reaction monitoring.The data obtained from actual determination of the AG antimicrobials in human plasma after their oral or intramuscular administration are also presesnted for validation of the methods.

Conclusions: This method would seem to be useful in clinical and forensic medicine because of its ability in both identification and quantification of the drugs.

PUB617

Prevalence of Chronic Musculoskeletal Pain Among Hemodialysis Patients Magdy M. Elsharkawy, Cherry Reda, Haitham Ezzat, Amr Mohab. *Nephrology Dept, Ain Shams Univ, Egypt.*

Background: Chronic musculoskeletal (MS) pain is common in patients with end stage renal disease (ESRD) undergoing hemodialysis; however information regarding its frequency and prevalence is relatively scarce.

Methods: A cross-sectional study was conducted on 100 ESRD patients on maintenance hemodialysis 3 times per week for at least 3 months. Chronic musculoskeletal pain was evaluated using the VON KROFF questionnaire for grading the severity of musculoskeletal pain. Correlation was done between chronic MS pain and physical findings of motor and sensory systems examination. In addition, correlation was also done between chronic MS pain and serum intact Parathormone (i-PTH), serum corrected calcium, serum phosphorus, serum alkaline phosphatase, serum albumin & hemoglobin level.

Results: Mean age was 57.46 years. Mean dialysis duration was 3.80 years. 42% were females and 58% males. In our study, 37% of the patients had low disability low intensity of pain i.e. little affection on the daily, social & work activity(grade 1),37% of the patients had low disability high intensity of pain (grade 2) while 26% of them had high disability high intensity of pain i.e. moderate limitation of the daily, social, recreational & work activities (grade 3). Chronic musculoskeletal pain showed positive correlation with muscle state, tenderness and power (p<0.001, p<0.001, p=0.001 respectively). Grade 3 disability patients had the highest level of serum Ca and i-PTH which were significantly different from grade 1 and 2 patients (p<0.001, p=0.013 respectively).While serum albumin level was lowest in grade 3 patients (p=0.025).

Conclusions: Chronic MS pain is common in ESRD patients.Disturbed mineral metabolism is strongly associated with chronic MS pain in long-term HD patients. Musculoskeletal system involvement remains a common problem that limits the physical function of patients with ESRD.

PUB618

Practice Patterns of United States Nephrologists in Blood Pressure Medication Use when Transitioning Patients to Dialysis Mary C. Mallappallil,[1] Steven Fishbane,[2] Rimda Wanchoo,[2] Andrea Roche-Recinos,[1] Subodh J. Saggi,[1] Moro O. Salifu.[1] [1]*Internal Medicine- Div of Nephrology, SUNY Downstate School of Medicine, Brooklyn, NY;* [2]*Internal Medicine -Div of Nephrology, Hofstra North Shore LIJ School of Medicine, Great Neck, NY.*

Background: As there is no standard approach to transition a patient in chronic kidney disease (CKD)-5 to CKD5-Dialysis in regards to adjustment of diuretics, BP medication, optimal frequency of medication reconciliation (MR) and determination of dry weight (DW) we conducted a survey to determine how US nephrologists transition a patient from CKD5 to CKD5D in these aspects.

Methods: We designed an anonymous electronic survey with 39 questions and sent it to practicing nephrologists in the US after IRB approval.

Results: 120 US Nephrologists replied to the survey; 60% were in Nephrology for more than 10 years. Most (79%) used furosemide in CKD 5, (66%) used a combination of furosemide and metolazone. The first choice of diuretics in CKD5 was furosemide (79%), bumetinide (12%) and torsemide (9%) (p<0.005). In CKD5D, 45% used diuretics daily, 29% on non-dialysis days and 26% discontinued them(p=0.02). In CKD 5, 63% would continueACEI or ARB. In CKD5D, 84% of responders had at least 30% of patients on ACEI/ARB and most (64%) would not stop these medications despite hyperkalemia. The majority (79%) did not change ACEI to those that were not dialyzed out. The perceived most effective BP medication in CKD5D in decreasing order: Nifedipine/amlodipine (36%), ACEI/ARB(29%), beta blockers(17%), diuretics(13%) and others(4%); (p<0.0005). Most responders (70%) prescribed BP medication on non-dialysis days only and 88% thought that high BP in the first month could be controlled with ultrafiltration. The first MR in new CKD5D was monthly (78%), weekly (12%) and as needed only (8%). DW was determined in the first week(31%) and the first month(52%). Of those surveved, 59% felt HTN in CKD5D hadt multiple causes.

Conclusions: Transitioning patients from CKD5 to CKD5D continues to remain challenging in terms of adjustment of BP medication. Variations in practice regarding the frequency of medication use may benefit from guidelines.

PUB619

First Dialysis Prescription and Access Use: A Survey of United States Nephrologists Mary C. Mallappallil,[1] Steven Fishbane,[2] Rimda Wanchoo,[2] Andrea Roche-Recinos,[1] Subodh J. Saggi,[1] Moro O. Salifu.[1] *[1]Internal Medicine-Renal Div, SUNY Downstate School of Medicine, Brooklyn, NY; [2]Div of Nephrology, Hofstra North Shore LIJ School of Medicine, Great Neck, NY.*

Background: As there is no standard approach to initiate renal replacement therapy in CKD5patients in regard to location of first treatment, access and dialysis prescription we conducted a survey of US nephrologists to better identify current practice patterns.

Methods: We created an anonymous electronic survey with 39 questions that was validated then approved by the IRB.Aggregate data was analyzed using descriptive statistics, avoiding duplicate responses.

Results: 120 US nephrologists replied to the survey, 60% were in nephrology practice for more than 10 years. The first hemodialysis (HD) treatment was as inpatient (22%), outpatient (29%) or either (49.5%). At the first HD, most nephrologists (92%) used a blood flow (BF)<300 mL/minute; 65% would use lower than usual dialysate flow rates (DFR) and 47% would use a smaller dialyzer. Ninety six percent prescribed less time than usual, even with blood urea nitrogen less than 100 mg/dL. About 45% replied that only 10 -50% of patients meeting criteria for peritoneal dialysis were actually started on this modality ($p<0.005$). Of the participants 47% noted that only 10 – 50% of patients who were eligible for transplant were listed, and the majority of responders (83%) noted that less than 10% of their patients got a preemptive transplant ($p<0.0005$). A patient educator was available to 64% of the participants. First dialysis with a permanent access was noted among 30-60% of patients by 43% of responders and in more than 60% of patients by 22% of responders. Of the participants 73% replied that the majority (>60%) of their patients got vein mapping before access creation. The time between vein mapping and access creation was one week to one month (61%) and more than one month (26%), ($p<0.005$) . The number of angioplasties that were acceptable prior to primary access failure was noted as 2, (25%) 3 (25%) or more than 4(24%).

Conclusions: There is variation in practice in several areas in regard to the initial dialysis session in CKD5D which may benefit from guidelines.

PUB620

How to Dialyze a Patient with Left Ventricular Assist Device in a Chronic Dialysis Unit? A Practical Protocol Sadiq Ahmed,[1] Debbie Baker.[2] *[1]Univ of Kentucky; [2]Davita.*

Background: To provide chronic HD treatments to ESRD patients with LVAD in a chronic unit in the community is a challenge and a relatively new experience for nephrologists. As LVADs have revolutionized the treatment of advance heart failure there are rising numbers of these patients developing ESRD with need for HD in the community. Development of a practical , simple and safe protocol is needed to dialyze these patients in the chronic units.

Methods: This protocol and safety check list is developed to provide routine HD treatment for patients with LVAD and successfully implemented in a chronic dialysis unit in the community setting.The special policy and procedure relevant to this protocol , safety check list and standing orders for the dialysis nurses were approved by the governing body before dialysis staffs were trained. The VAD coordinator is present during first training.

Results: This protocol is a step by step guidance for the dialysis staff. The whole process has 3 components. 1.A supplemental informed consent signed by the patient to cover for additional higher risk of HD with LVAD. 2.Guidance and check list for the dialysis staffs for assessments of LVAD patients with additional documentation before starting HD treatment. 3.Standing order to be followed by staff during dialysis of LVAD patient on top of regular dialysis orders. # 2 and 3 covers patient assessment, verification of LVAD equipment ,power supplies and special hemodynamic monitoring of these patients during HD.

LVAD check list
Presence of support person who waits in lobby after power base is connected
Fully charged extra batteries for LVAD & backup system controller
Power base unit connected to electrical outlet & Patient connected to unit
Charge nurse to review LVAD log and trends
Document Pump Flow, Pump Speed & Pulsativity index for treatment and previous day
Obtain doppler, lubricant & sphygmomanometer for every 30 minute BP check
Initiate HD
Document LVAD assesment, doppler pressure, communications with MD and VAD coordinator
Review Post weight with carge Nurse if > 1 KG above TW notify MD

Conclusions: This protocol to provide incenter HD to patients with LVAD in a chronic unit is simple & safe. It can be implemented in a chronic HD unit.

PUB621

Association Among Calcium, Phosphorus, and Parathyroid Hormone with Aortic Ring Calcification in a Cohort of Hemodialysis Patients Arturo Reyes Marin. *Nephrology, Hospital Juarez de Mexico, DF, Mexico.*

Background: The prevalence of vascular calcification in dialytic therapy is 40-92%, values increased in serum levels of calcium (Ca), phosphorus (P) and parathyroid hormone (PTH) have been associated with high calcification progression and cardiovascular mortality. It has been described association among serum levels of Ca, P, Ca-P product and PTH with aortic ring calcification in patients with chronic renal disease (CRD). We did an observational and descriptive study, in the nephrology department of Hospital Juarez de Mexico, with a cohort of 95 hemodialysis patients, the aim of study was to evaluate the association among aortic ring calcification by torax radiography with the serum levels of Ca, P and PTH.

Methods: Adult patients in hemodialysis were included, patients with severe malnutrition, cancer and mental abnormalities were excluded. We used 2 scales (torax radiography), in order to assessment the aortic ring calcification and we did correlation coefficient among Ca, P, PTH and 2 scales. We used Pearson correlation coefficient for analysis and Bland-Altman test for analysis of concordance among Ca, P, PTH and 2 scales.

Results: They were 95 adult patients: 50 (52%) men and 45 (48%) women, average age was 40.7 years old. We found weak negative correlation between Ca and PTH ($r = -0.28$, $p > 0.05$)), weak positive association was found between P and PTH ($r = 0.30$, $p > 0.05$), correlation between PTH and CaxP ($r = 0.36$), $p > 0.05$), PTH and 2 scales ($r = 0.5$, $p>0.05$). In the scales that we used to evaluate vascular calcification (torax radiography) showed high scores, however the intraclass correlation coefficient between scales and PTH, Ca and P (0.33) showed not statistical significance.

Conclusions: Despite that vascular calcification was high by torax radiography, the association among scales (torax radiography) and serum levels of Ca, P and PTH was not statistical significant. There are other important factors that can explain the progression of vascular calcification and the traditional markers for calcification: Ca, P and PTH are not enough for explain it.

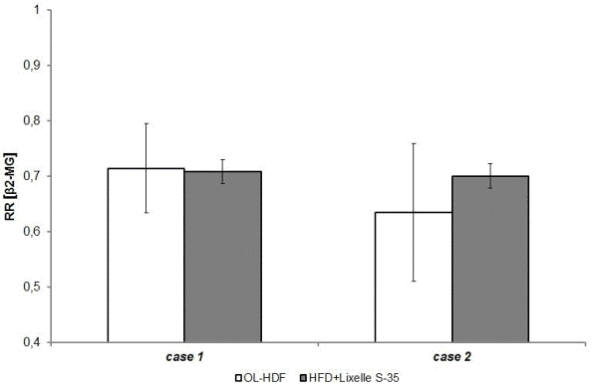
β2-Microglobulin Removal: Comparison Between Lixelle S-35 Cartridge Coupled with High-Flux Dialysis versus Online-Hemodiafiltration Marco Sartori,[1,2] Sara Samoni,[1] Federico Nalesso,[1] Alessandra Brendolan,[1] Mauro Neri,[1] Francesco Garzotto,[1] Silvia De Rosa,[1] Mirella Zancato,[2] Claudio Ronco.[2] *[1]International Renal Research Inst of Vicenza, St. Bortolo Hospital, Vicenza, Italy; [2]Dept of Pharmaceutical and Pharmacological Sciences, Univ of Padua, Padua, Italy.*

Background: Lixelle is a sorbent used to treat dialysis-related amyloidosis due to β2-microglobulin(β2-MG)deposit.The aim of this study was to assess the impact of Lixelle S-35 coupled with High-Flux Dialysis(HFD)vs online Hemodiafiltration(OL-HDF)in 2 pts.

Methods: We enrolled 2 pts with β2-MG levels over15mg/L,treated with OL-HDF.*Case 1*.Male,57yrs old with BMI35.5Kg/m^2.We collected samples previous and after pre/post-reinfusion OL-HDF(n=3).Then the pt was shifted to HFD+Lixelle S-35(n= 3;Q_B=380mL/min;Q_D=500mL/min;ΔBW=2.87±0.42Kg).*Case 2*.Male,72yrs old,BMI26.8Kg/m^2.We collected samples previous and after post-reinfusion OL-HDF(n=3).Then the pt was shifted to HFD+Lixelle S-35(n=3;Q_B=300mL/min;Q_D=500mL/min;ΔBW=3.1±0.53Kg). We compared the data obtained in each treatment.

Results: *Case 1*.Before and after pre/post-reinfusion OL-HDF and HFD+Lixelle S-35, β2-MG levels were 18.26±3.91 and 5.00±0.18, 27.34±1.45 and 7.96±0.77mg/L,respectively. There was no difference between pre/post-reinfusion OL-HDF(71.48%)and HFD+Lixelle S-35(70.90%)β2-MG removal rate[RR].*Case 2*.Before and after post-reinfusion OL-HDF and HFD+Lixelle S-35 β2-MG levels were 13.68±4.10 and 4.66±0.24, 17.23±1.55 and 5.13±0.60mg/L,respectively.There was difference between post-reinfusion OL-HDF(63.44%)and HFD+Lixelle S-35(70.09%)β2-MG removal rate.We did not observe any adverse reactions and/or side effects potentially related to Lixelle S-35.



Conclusions: Our preliminary results indicate that HFD+Lixelle S-35 seems to be more efficient in β2-MG removal than post-reinfusion OL-HDF,whereas no differences have been found with pre/post-reinfusion OL-HDF.More studies are needed.

Does Dialysis Influence Treg Cells? A Meta-Analysis Carlotta Caprara,[1] Gilbert R. Kinsey,[2] Wenjun Xin,[3] Jennie Z. Ma,[3] Valentina Corradi,[1] Elisa Scalzotto,[1] Francesca K. Martino,[1] Mark D. Okusa,[2] Mitchell H. Rosner,[2] Fiorenza Ferrari,[1] Claudio Ronco.[1] *[1]International Renal Research Inst Vicenza (IRRIV), Dept of Nephrology, Dialysis & Transplantation, St. Bortolo Hospital, Vicenza, Italy; [2]Medicine, Univ of Virginia, Charlottesville; [3]Public Health Sciences, Univ of Virginia, Charlottesville.*

Background: The immunological state of patients with ESRD is dysregulated. Regulatory T (Treg) cells comprise a small proportion of the total lymphocyte population yet regulate key immune responses across a variety of disease settings. Contrasting results have been reported about the influence of dialysis on Treg cells. Our aim is to determine whether the available literature support a positive or negative influence of dialysis on Treg cells.

Methods: After screening 84 published studeies (PubMed and Web of Science) we included 10 that evaluated Treg cells in ESRD patients. Of these, 5 studies that included comparable healthy controls (HCs) and hemodialysis (HD) patients and used similar criteria for determining the percentage of Treg cells in total CD4 T cells were subjected to a meta-analysis.

Results: A total of 99 HD patients and 88 age-matched HCs were included in these 5 studies. Using the fixed effect model a significant difference in the percentage of Treg cells in total CD4 T between HD and HCs was observed (P<0.001). The mean difference in Treg percentage was -2.34% in HD patients vs. HCs. Several discrepancies were noted between studies that may be due to the lack of consistent criteria for Treg cell identification and use of different typse of dialysis membranes which was not specified in all articles.

Conclusions: The available literature comparing Tregs in HD patients and HCs suggest HD is associated with a reduction in Tregs. A limitation is that only a few articles consider uremic patients (ESRD not on dialysis) as a control group for HD. Furthermore, no studies have investigated Treg cells in the same patient before and then after initiating dialysis. This type of study will be critical to understanding the influence of dialysis on Treg cells. Furthermore, the clinical significance of these changes in Treg cell numbers will need to be elucidated.

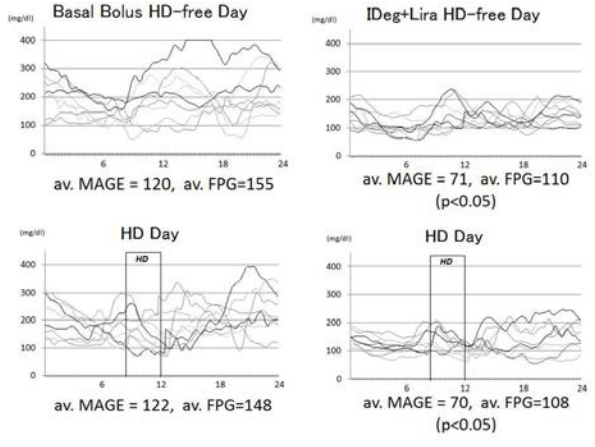
PUB624

Combination of Insulin Degludec (IDeg) and Liraglutide (Lira) (IDeg+Lira) Is Potentially Superior to Basal-Bolus Insulin Therapy (BB) in Hemodialysis (HD) Patients with Type 2 Diabetes (T2DM) – An Assessment by Continuous Glucose Monitoring (CGM) Satoshi Funakoshi,[1] Jyunichiro Hashiguchi,[1] Kenji Sawase,[1] Osamu Sasaki,[1] Hiroshi Ichinose,[1] Miwa Shirahama,[1] Miki Yano,[1] Yutaka Mori,[3] Takuhisa Uchino,[1] Kazunori Utsunomiya,[3] Yoko Obata,[2] Tomoya Nishino,[2] Takashi Harada.[1] *[1]Nagasaki Kidney Center, Japan; [2]Dept of Internal Medicine, Nagasaki Univ Graduate School of Medicine, Japan; [3]Dept of Diabetology, Jikei Univ, Japan.*

Background: During HD, plasma glucose (PG) level drops due to various factors including clearance gap between glucose and insulin, and then rebounds to hyperglycemic state after HD. Therefore, it may be difficult for conventional BB to control these complicated PG changes in HD patients with T2DM. Recently a free combination of any insulin and Lira has been approved in Japan.

Methods: Eight adults with T2DM, glycoalbumin (GA) of >20%, fasting C-peptide of >8 ng/ml and treated with BB including IDeg (5-74 units) + insulin lispro (5-30 units) were converted to daily injections of the free combination of same dose of IDeg and 0.9mg of Lira (IDeg+Lira), then IDeg was titrated to achieve an appropriate fasting plasma glucose level. Glycemic control was assessed by CGM and the mean amplitude of glycemic excursions (MAGE) was calculated before and after the conversion.

Results: As shown in figure 1, after 4-8 weeks of change from BB, mean both MAGE and PG were significantly decreased as shown in figure. Six out of 8 patients reported gastrointestinal adverse events, but these events were transient.



Conclusions: IDeg+Lira can potentially be superior compared with BB in controlling glycemic fluctuations in HD with T2DM.

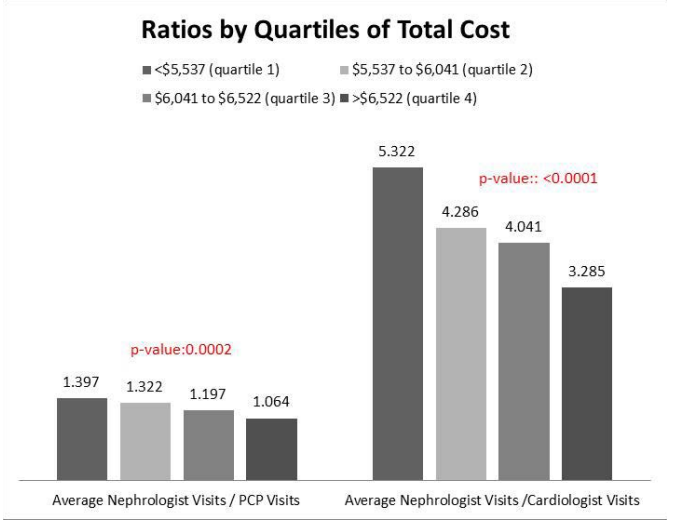
PUB625

More Nephrologist Visits Are Associated with Lower Cost of Care for Dialysis Patients Hao Han, Jane Brzozowski, Sheetal Chaudhuri, John W. Larkin, Mahathi Mothali, Len A. Usvyat, Terry Ketchersid, Franklin W. Maddux. *Fresenius Medical Care North America, Waltham, MA.*

Background: Medicare patients with end stage renal disease (ESRD) are treated by nephrologists, primary care providers (PCPs), cardiologists and other specialties on a regular basis. We investigated the relationship of visits to these providers and total costs of care.

Methods: Medicare 100% ESRD data for patients with evidence of dialysis at any time during January 1, 2010 through December 31, 2011 were analyzed. Nephrologist, PCP and cardiologist visits were determined by specialty codes of Part B claims (including both in- and out-patient visits). All data was aggregated at the Metropolitan Statistical Area level (MSA). We computed a ratio of nephrologist visits to PCP visits per MSA as well as nephrologist visits to cardiologist visits per MSA during the above period (visits were calculated on a per patient per month basis). Total costs of care (per member per month [PMPM]) were determined by aggregating Medicare Part A and B costs. Comparisons of ratios were performed using t-tests for quartiles of PMPM for two specialty visit ratios.

Results: Claims for 368,711 patients were analyzed. Patients in the lower quartiles of total cost had significantly more nephrology visits relative to PCPs and cardiologists.



Conclusions: These results indicate that higher ratios of nephrologist visits to cardiologist/PCP visits are significantly associated with decreased cost on a MSA level. Taken that nephrologist visits tend to be constant (due to the monthly capitated payment), these results may be reveling a "sicker" and therefore more expensive population of patients on a MSA level that require more medical attention from a cardiologist or PCP, likely due to hospitalizations. Adjustments for underlying disease should be considered.

Prediction of Non-Adherence to Hemodialysis Treatment Regimens Yue Jiao,[1] Daniel E. Geary,[1] Theresa J. Hetzel,[1] Sheetal Chaudhuri,[1] Mahathi Mothali,[1] Terry Ketchersid,[1] Dugan Maddux,[1] John W. Larkin,[1] Peter Kotanko,[2,3] Brian Scott Ash,[1] Len A. Usvyat,[1] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]Renal Research Inst, New York, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Non-adherence with hemodialysis (HD) treatment regimens is known to be associated with increased morbidity and mortality. The aim of this project was to develop a predictive model (PM) to identify HD patients who will likely have unexcused no shows to routine dialysis treatments within the next week.

Methods: Using data between 1/1/2014 and 12/31/2014 from the Fresenius Medical Care Knowledge Center and 2014 weather data from the National Oceanic and Atmospheric Administration's National Centers for Environmental Information, PMs were designed and developed for prediction of unexcused no shows in patients not residing in a nursing home. Various PMs were investigated and included the generalized linear model, partitioning and regression trees, artificial neural networks, and generalized additive model (GAM). In all, 1,554,833 records stratified in weekly intervals on 60 variables from 172,854 patients were utilized. Variables included data on the patient's history of unexcused no shows, demographics, comorbidities, laboratories, holidays, sporting events, and weather. A multi-tier prediction process was performed with respect to the availability of data. The area under the curve (AUC), sensitivities and specificities were investigated to determine the model with the highest performance.

Results: Best performing model had AUC of 0.87 for the multi-tier PMs utilizing a 30% test dataset. A small pilot test on 860 patients for three weeks utilizing optimal Youden index as the cutoff value to predict the high probability of the unexcused no show events achieved an average sensitivity of 0.57 and specificity of 0.95.

Conclusions: This pilot test of the developed modeling demonstrates that PM can assist in identifying patients with a high probability for unexcused missed HD treatments. Additional studies are needed to further analyze the potential of predictions for and interventions associated with reducing unexcused no show events.

PUB627

Factors Influencing Residual Renal Function Decrease in Hemodialysis Treated Patients Fernando Caravaca-Fontan, Milagros Fernandez-Lucas, Jose L. Teruel, Saul Enrique Pampa, Estefania Yerovi, Maria Delgado yagüe, Fernando Liano. *Nephrology, Hospital Univ Ramon y Cajal, Madrid, Spain.*

Background: We have shown in previous studies that maintenance of residual renal function in hemodialysis treated patients is conditioned by the number of weekly sessions, and is better in patients who start treatment with a twice weekly schedule. The aim of this study is to analyse the influence of other variables in the preservation of residual renal function.

Methods: Of the 174 consecutive patients who started hemodialysis treatment in the hospital, 98 began with 2-weekly sessions (2HD group), and 76 with 3-weekly sessions (3HD group). Residual renal function was measured every two months (mean urea and creatinine clearance).

Results: Decrease in residual renal function was lower in the 2HD group (median 0.19 vs 0.46 ml/min/month, p=0.005). In both groups the residual renal function decrease was higher in the patients from the transplant program than in those from predialysis: 2HD group: median 0.93 vs 0.17 ml/min/month, p=0.003; 3HD group: median 0.76 vs 0.32 ml/min/month, p=0.005. Neither the initial schedule, sex or etiology of the renal disease influenced the decrease in residual renal function in either of the two groups of patients. Moreover we found no correlation between the decrease in residual renal function with age, the renal function at the start of dialysis or with the Charlson comorbidity index. Of the 98 patients who began with the 2HD schedule, 45 went on to dialysis three times a week when the residual renal function was less than 3 ml/min: these patients had a mean of 10±8 months on the 2HD schedule. The length of time on this model was not influenced either by age, sex, etiology of the nephropathy, comorbidity index, scheduled start or basal renal function.

Conclusions: The decrease in residual renal function in the patient treated with hemodialysis depends basically on the number of weekly sessions with which the dialysis treatment was started. Of all the variables analysed only the return to dialysis due to graft loss conditioned a higher decrease in residual renal function in both groups of patients.

PUB628

Circadian Blood Pressure Behaviour in Hemodialysis Patients Dimitrios Petras,[1] Kyriakos Dimitriadis,[2] Panagiota E. Giannou,[1] Eirini Andrikou,[2] Konstantinos Tsioufis.[2] *[1]Nephrology Dept, Hippokration Hospital, Athens, Greece; [2]First Cardiology Clinic, Hippokration Hospital Univ of Athens, Athens, Greece.*

Background: Blood pressure (BP) evaluation and management in haemodialysis (HD) patients is often a matter of debate. During HD hypotension as well as a paradoxical rise in BP may be documented. Indradialytic BP is also variable depending mostly from the weight gain between the HD sessions. We investigated circadian BP behavior in the setting of HD.

Methods: We studied 38 patients with ESRD (68% men, mean age 62±19 years, 52% hypertensive) that underwent HD three times a week in the HD unit of our hospital and were at their ideal dry weight. Ambulatory BP monitoring was applied one hour before an HD session and was set to measure BP every 30 minutes and until arrival for the next HD session, for a total of two subsequent 24-hour periods. Blood pressure dipping was defined as [(daytime systolic BP – nighttime systolic BP)/ daytime systolic BP]. Patients were defined as dippers if BP dipping was >10% and risers if BP dipping <0%.

Results: Body weight before and after the HD session was 78±28Kgr and 75±27mmHg respectively. Ambulatory systolic/diastolic BP increased not significantly from 127±23/70±13mmHg to 130±19/71±11mmHg (p>0.05) from the first to the second 24-hour period. Mean dipping was 1.5±7.8% in the first day and further decreased to -0.94±6.8% in the second day. Accordingly, in the first 24-hour period, only 6 patients (16%) were dippers and reduced to 2 patient in the following day (5%). Sixteen patients (42%) and 18 patients (47%) were risers at the first and second 24-hour period respectively.

Conclusions: Daytime systolic BP does not substantially change during the 48-hour period extending from HD to HD session. Yet, prevalence of the non-dipper as well as the riser pattern is high and further increases during the interdialytic period. Patients with this BP pattern are at high risk for coronary artery disease, especially if other comorbidities coexist. Ambulatory BP monitoring in ESRD patients is a promising non invasive technique for the recognition of future heart disease.

PUB629

In Vitro Dialysability of SNF472, a Novel Inhibitor of Vascular Calcification, Using Conventional Hemodialysis and Hemodiafiltration Joan Perelló,[1] Miquel Gomez Umbert,[2] Nestor Yesid Rodriguez,[2] Carolina Salcedo,[1] Miquel D. Ferrer,[1] Juan Manuel Buades,[3] Maria del mar Perez,[3] Eva Martín Becerra,[4] Francisco Maduell.[2] *[1]Sanifit, Palma, Spain; [2]Nephrol. and Renal Transpl., Hosp. Clínic, Barcelona, Spain; [3]Nephrol., Hosp. Son Llàtzer, Palma, Spain; [4]Kinrel, Madrid, Spain.*

Background: SNF472 is being developed for the treatment of calciphylaxis and cardiovascular calcification in end stage renal disease patients on hemodialysis. The intended use of SNF472 is intravenous infusion during dialysis; therefore our aim was to assess its possible dialyzation and its effects on calcium (Ca) chelation.

Methods: Dialysability of SNF472 was assessed using online hemodiafiltration (OL-HDF) and conventional hemodialysis (HD) systems. The interaction of SNF472 with the system was assessed under bypass conditions (dialysis in off-mode). One liter of heparinized fresh blood spiked with 8 mg/dl creatinine was introduced in a container maintained at 37 ºC and a one hour dialysis session was simulated. 66.6, 30 and 10 mg/L SNF472 were infused during the first 20 minutes of dialysis. Samples were obtained at different time points and creatinine, total and ionized Ca and SNF472 levels were quantified.

Results: No dialyzation of SNF472 was detected at 30 and 66.6 mg/L neither in OL-HDF nor in HD systems. Dialyzation was measured at 10 mg/L SNF472 both in OL-HDF and in HD, with an estimated clearance (Cl) of 39 and 18 mL/min, respectively. Creatinine showed a Cl of 231 and 220 mL/min, respectively. In bypass conditions, blood Ca was chelated during the 20 minutes of SNF472 infusion when added at 66.6 mg/mL. However, when the system was switched to the dialysis mode, the Ca in the dialysis bath compensated the chelating effect of SNF472 and Ca levels remained unaltered.

Conclusions: SNF472 dialyses with a low Cl. SNF472 levels increase in blood during infusion and dialysis does not prevent from attaining potentially therapeutic levels. As SNF472 will be infused during the whole dialysis session, this low Cl is not expected to affect system exposure. The chelating effects of SNF472 on Ca are compensated by the Ca in the dialysis bath, so no hypocalcemia is expected. Supported by REDINREN RD012/0021 and RETOS COLABORACIÓN RTC-2014-2460-1 grants.

PUB630

A Simple and Cost Effective Approach to Ultra-Pure Dialysate Anthony M. Valeri,[1] Bobby C. Lee,[2] John Duffy,[3] Robin Ferrer,[4] Ronald Villota,[4] Greg C. Riccardi,[3] Edmond P. Wong.[3] *[1]Dept of Medicine, Columbia Univ, New York, NY; [2]Dept of Pharmacy, New York-Presbyterian Hospital (Columbia), New York, NY; [3]Dept of Biomedical Engineering, New York-Presbyterian Hospital (Columbia), New York, NY; [4]Dept of Nursing, New York-Presbyterian Hospital (Columbia), New York, NY.*

Background: Ultrapure dialysate has been shown to reduce inflammation and improve nutritional and anemia parameters in patients on chronic maintenance hemodialysis. The Nephros(R) DSU (Dual Stage Ultrafilter, Nephros(R) Inc, River Edge, NJ) has been shown to reduce bacterial counts and endotoxin levels by at least a 5-log order of magnitude.

Methods: We performed an observational trial of this filter in a hospital-based acute dialysis facility in the USA.

Results: There were 23 chronic stable hemodialysis outpatients treated during the 6 months before and after the installation of the Nephros(R) filters. The mean age was 51 (range 12-91), 61% male, predominantly Hispanic (70% Hispanic, 17% African-American, 9% Caucasian, 4% Asian) and 30% diabetic. Comparing data from the 6 month period after the installation of the filters to the preceding 6 months, there was an increase in the mean hemoglobin level of 0.5 gms/dL (p=0.010) with a reduction in the mean weekly darbopoietin dose of 14.6 mcg or 40% (P<0.001) translating to a reduction in the ESA resistance index (weekly ESA dose/hemoglobin level) of 1.52 (p<0.001). During this time period, indirect inflammatory markers showed a reduction in the mean WBC count from 7,000 to 6,600 x 10^9 /L (p=0.008) and an increase in serum albumin from 3.6 to 3.7 (p=0.024). The mean spKt/V was unchanged during the 2 time periods (from 1.609 to 1.607, p=0.30).

	Hemoglobin (gms/dL)		Darbopoietin dose (mcg/week)		ESA resistance index (ESA/Hgb)	
	Pre	Post	Pre	Post	Pre	Post
Mean	10.3	10.8	36.3	21.7	3.54	2.03
Interquartile Range	10.1-10.8	10.5-11.1	21.5-40.0	15.9-25.6	2.06-4.42	1.46-2.25
p-value (post vs. pre)		**0.010**		**<0.001**		**<0.001**

Conclusions: In conclusion, the use of the Nephros® DSU filter to further reduce endotoxin exposure in chronic hemodialysis patients can result in improved ESA responsiveness and a lower ESA dose.

PUB631

Care Delivery Models for End Stage Renal Disease: A Systematic Review
Maria Lourdes Gonzalez Suarez,[1] Priya Ramar,[2] Sagar Chawla,[3] LaTonya J. Hickson,[1,2] Nilay D. Shah,[2] Bjoerg Thorsteinsdottir.[1,2] *[1]Dept of Medicine, Mayo Clinic; [2]Mayo Clinic Kern Center for the Science of Health Care Delivery, Mayo Clinic; [3]Mayo Medical School, Mayo Clinic, Rochester, MN.*

Background: Reimbursement for dialysis care has led the way for the broader transition to a value-based payment model. As payment policy for dialysis evolves, a better understanding of the evidence around care delivery models that optimize outcomes and increase the value of care for dialysis patients is essential. Limited evidence exists about which care delivery models are most effective.

Methods: Multiple databases were searched for comparative studies of care delivery models for ESRD published between 2000 and 2014. The intervention had to include >5 dialysis patients over age 18 years and receiving treatment, >6 months follow up, and reported patient important outcomes i.e. mortality, important clinical outcomes, hospitalizations and quality of life. Data was abstracted by reviewer pairs; study quality was evaluated using Cochrane and Newcastle-Ottawa tools.

Results: 1841 abstracts were screened, 59 full-text articles were reviewed, and 23 studies with 87,281 patients were included for final analysis. The interventions included nutritional (n=4), multidisciplinary care (n=6), satellite programs (n=3), home dialysis (n=3), access monitoring (n=2), physician contact (n=4), and nocturnal dialysis (n=1). Most were observational studies of decent quality with representativeness and incomplete follow up being the main potential sources of bias. Two randomized studies on home dialysis and pharmacist care, had attrition as the main risk of bias. Most interventions showed positive effect raising concern of publication bias. Overall, hospitalizations were significantly lower in the intervention group despite large heterogeneityIRR: 0.824, 95% CI 0.781, 0.868,p<0.001, I2=95.6%.

Conclusions: Multiple interventions have the potential to improve the outcomes of dialysis patients but have not been compared in terms of safety and effectiveness. Limited evidence is available to inform dialysis practice redesign to adapt to new payment structures. Further studies are needed to define best delivery models for dialysis care.

PUB632

Symetrical Dimethylarginine (SDMA) Is Poorly Cleared by Standard Hemodialysis
Mirela A. Dobre,[1] Peter B. De Oreo,[2] Timothy W. Meyer,[3] Thomas H. Hostetter.[1] *[1]Case Western Reserve Univ; [2]Centers for Dialysis Care, Cleveland; [3]Stanford Univ School of Medicine.*

Background: High SDMA levels have been associated with an increased risk for cardiovascular disease in patients with normal or reduced renal function. The effect of hemodialysis on SDMA has not been thoroughly studied.

Methods: We measured SDMA levels and its handling by hemodialysis and by the normal kidney in subjects with ESRD on chronic hemodialysis (n= 7) and in normal controls (n=6).

Results: The mean (SD) SDMA levels in ESRD were six times higher than in normal controls, 3.35(0.65) vs 0.53(0.25) µM, p<0.001. For comparison pre-dialysis BUN levels was 44.1(23.1)mg/dl in ESRD, and 14.9(3.2) mg/dl in controls. The fractional reduction of SDMA was significantly lower than that of urea, 47.4(11.5)%, vs 76.7(4.7)%, p<0.001; and the volume of distribution was much higher 58.5(14.5)L vs 35.5(10.4)L for urea. Also the urinary clearance of SDMA [78.2 (33.5) ml/min)] in normal individuals was higher than that of urea 55.2(13.7) ml/min. SDMA production rates were similar 46.7(9.4) vs 52.3 (13.9) mmoles/day, ESRD vs normals, p>0.05.

Conclusions: In summary, SDMA circulates at high levels in hemodialysis patients due at least in part to its relatively high clearance by the normal kidney, relative to urea, and its larger volume of distribution. The latter suggests that SDMA is likely to be localized in the intracellular compartment, and therefore less available for clearance by standard hemodialysis.

PUB633

On-Line Hemodiafiltration Is Efficient for Inflammation and Phosphorus Control
Nadia Guimaraes- Souza, Thais Nemoto Matsui, Adriano Luiz Ammirati, Maria C.C. Andreoli, Ana C M S Ramos, Fabiana Dias Carneiro, Bento C. Santos. *Dialysis Center, Hospital Israelita Albert Einstein, Brazil.*

Background: High efficiency on-line hemodiafiltration is efficient to remove uremic toxins and phosphorus. Many studies had demonstrated the impact of this modality in mortality. The main objective of this study was to analyze the high efficiency on-line hemodiafiltration ability to remove phosphorus and reactive C protein.

Methods: This is a prospective study with end stage chronic kidney disease patients undergoing dialysis with high levels of phosphorus. High efficiency on-line hemodiafiltration, as described as a reposition volume higher than 22lts, was used for a period of at least one year of follow-up. Beta-2- microglobulin, pre dialysis urea, post dialysis urea, reactive C protein, hemoglobin and phosphorus were collect from patients before starting on-line hemodiafiltration treatment and every month.

Results: Patients included in this study were 54.45±16.75 years old; they were on hemodialysis for at least for one year. 58% had hypertension or coronarypathy. Hemodialysis dose as single pool Kt/V were significantly higher (1.21±0.20 vs 1.36±0.16; p<0.001) and this difference was kept for all follow-up. In six months of high efficiency hemodiafiltration we also found a decrease on phosphorus levels (7.9±2.4 vs 7.3±2.01 p<0.001) in one year follow up, phosphorus levels were still significantly lower than in the conventional hemodialysis (7.3±2.01 vs 5.6±2.03 p=0.001). We also observed a decline in the need for erythroietin doses in six months (p=0.04) associated with a higher hemoglobin levels (p<0.001). Reactive C protein showed significantly lower levels after six months of online hemodiafiltration (p=0.004).

Conclusions: High efficiency on-line hemodiafiltration is an efficient method of reduction of reactive C protein and may reduce costs due to reduced doses of erythropoietin analogous.

PUB634

On-Line Hemodiafiltration Filters a Comparative Study
Nadia Guimaraes- Souza, Adriano Luiz Ammirati, Thais Nemoto Matsui, Maria C.C. Andreoli, Fabiana Dias Carneiro, Ana C M S Ramos, Bento C. Santos. *Dialysis Center, Hospital Israelita Albert Einstein, Brazil.*

Background: High efficiency on-line hemodiafiltration is the best method for middle molecules and phosphorus remotion. Many studies had demonstrated the efficiency of this method in mortality reduction. The main objective of this study was to compare the three filters available for on-line HDF comparing the ability to remove urea, phosphorus and beta-2-microglobulin.

Methods: Prospective cross-over study including four patients and three available filters for hemodiafiltration. All section of on-line hemodiafiltration was made with high efficiency (23-25lt). Filters HDF 100, FX100 e HDF80COR were compared. Urea, phosphorus and beta-2 microglobulin were collected before and after first use of each filter A reduction ratio was calculated to compare the treatments.

Results: 76% of patients were man, the middle age (61.3±5), 76% of patients were diabetics and had peripheral neuropathy and 34% had coronarypathy. FX100 filter showed significantly higher dialysis dose compared to FX80COR (p=0.03); the same was observed for urea reduction ratio(p=0.04). Beta-2-micrglobulin and phosphorus reduction ratio were similar between all filters.

Conclusions: FX100 and HDF100 filter were similar for urea remotion ratio. There were no differences for other molecules.

PUB635

Satisfaction of Patients on Dialysis Unit
Jorge Nicolas Abdala. *Nephrology, Militar Hospital, Cordoba, Capital, Argentina.*

Background: The assesment of the nsatisfaction of patients in Dialysis, is a useful tool to meet patient needs; axis on which the care serevice is based.In turn it allows to identify the deficient áreas.

Methods: Objetive 1) To know the views of patients aboute the service that is offered in each of the áreas of focus. 2) To analyze the profile of satisfactionof patients they expressed their overall dissatisfaction. Prospective, descriptive study conducted at the Dialysisi Unit of the Military Hospital Córdoba, conducted between 15/11/2014 to 15/12/2014. Inclusión criteria: All patients attending the service, wich received some form of dialysisi (hemodialysis-DP) in the period. Exclusión criteria: a) diagnosos of cognitive dementia, b) Carryng less tan three month of treatment c) not be psychological and physical conditions to answer the survey. A qualitative survey, structured ajar, applied voluntary and anonymous.

Results: 95 surveys of the total population comprised 111 patients were taken; of wich 85 are for patients undergoing henodialysis and 10 patients on CAPD. By studying the "General Satisfaction" in all aspect of the service that is offered to the patients responses they were largely positive, 80 % of the sample expressed feeling satisfied, while 20 % responded negatively. The results denote that carriers are those who receive the worst assessment by patients. The ambient temperatura for both dialysis room to the waiting room appears as an aspect also of disagreement. The most valued aspect is the power receiduring treatment, both the quality and quantity as well as the attention of the professionals: technical, medical and social worked, in that order.

Conclusions: 1. As a managment tool, it should be rated as positive aspects stimulate and work on correcting the negative aspects. 2. The level of dissatisfaction is directly related to dialysis treatment time of the patient, the longer, higher degree of dissatisfaction. 3. It is advisable conduct regular surveys on the degree of patient satisfaction Dialysis, and that will help improve their quality of life.

PUB636

Correlation Between Calcium Phosphorus Product and Hypertension in ESRD Patients on Maintenance Hemodialysis
Shoaib Islam,[1] Hafiz I. Ahmad,[1] Syed Rizwan Bokhari,[1] Arif Asif.[2] *[1]Dept of Nephrology, Allama Iqbal Medical College/ Jinnah Hospital, Lahore, Pakistan; [2]Div of Nephrology and Hypertension, Albany Medical College, Albany, NY.*

Background: Increased levels of serum calcium, phosphorous and product of serum calcium and phosphorus (Ca x P) in end stage renal disease (ESRD) patients has been shown to be associated with increased mean arterial blood pressure (MAP). The available data is limited and no study has been done in Pakistan. We conducted a cross sectional study to determine the correlation between mean arterial blood pressure (MAP) and serum calcium-phosphorous product in our ESRD patients on hemodialysis.

Methods: Blood Pressure of all the prevalent ESRD patients in a single dialysis center was recorded and mean arterial blood pressure (MAP) was calculated pre and post dialysis. All patients were clinically euvolemic. Serum calcium and phosphorous levels were measured and Calcium-phosphorus product (CaxP) was calculated. The product above 50 and the MAP above 93 were taken as high.

Results: Of the 60 ESRD patients, 35(58.3%) were males with mean age was 39.5±5 years. High CaxP product was seen in 18 (30%) patients with high pre-dialysis MAP in 8 (44%) and high post-dialysis MAP in 4 (22%) patients respectively. Of 42 (70%) patients with CaxP product below 50 high pre-dialysis MAP was seen in 31(73%) and high post dialysis MAP was seen in 29 (69%) patients.

Conclusions: This study showed that high CaxP product (>50) is not correlated with high pre and post-dialysis MAP. The results are not consistent with earlier studies done in developed countries. Larger studies are needed to re-evaluate these findings.

PUB637

Behaviour of Ankle-Brachial Index During Hemodialysis: Effect of Calcium Dialysate Concentration Zaida Noemy Cabrera Jimenez,[1] Rosa M.A. Moyses,[1,2] Bruno C. Silva,[1] Luciene dos Reis,[1] Wagner Dominguez,[1] Fabiana Graciolli,[1] Rosilene M. Elias.[1] *[1]Nephrology, Univ of Sao Paulo, Sao Paulo, SP, Brazil; [2]Univ Nove de Julho- UNINOVE, Sao Paulo, SP, Brazil.*

Background: Ankle-brachial index (ABI) is a simple way to access cardiovascular risk. Both low (<0.9) and high (>1.3) ABI are associated with increased mortality risk in patients on hemodialysis (HD). However, little is known regarding the acute variation of ABI (from pre to post hemodialysis), and also whether the calcium dialysate content [Ca] may interfere with this variability. We aimed to investigate the impact of [Ca] 3.5 vs. 2.5 on the variability of ABI during HD.

Methods: Incident patients on HD for up to 90days were included. ABI was evaluated pre- and post-HD in the midweek session of two consecutive weeks with [Ca] 3.5 and 2.5, respectively. Biochemical variables, electrical bioimpedance and non-invasive hemodynamic (Finapress®) were assessed.

Results: 17 patients (10 men) aged 42 ± 17 years were included. ABI pre- and post-HD with [Ca] 3.5 and 2.5 were 1.2 ± 0.1, 1.1 ± 0.1, 1.1 ± 0.2, and 1.2 ± 0.1, respectively. Although the mean ABI values were within normal range, there was a great variability in the ABI, such that in 9 patients it increased using [Ca] 3.5, with 5 patients (29%) changing classification while in 6 patients it increased using [Ca] 2.5 with 3 patients (18%) changing classification. A [Ca] 3.5 was associated with an increase in serum calcium and a decrease in parathyroid hormone, while during a [Ca] 2.5 occurred a more pronounced blood pressure drop and consequent raise of peripheral arterial resistance. As the ultrafiltration rate was similar with [Ca] 3.5 and 2.5, there was no difference in total, extra- and intracellular water removal. ABI correlated with pre HD serum aldosterone (r= -0.515, p=0.002). Multiple regression analysis revealed that pre HD aldosterone and also a [Ca] were independently associated with the delta of ABI during dialysis, even adjusting for cardiac debit and ultrafiltration rate.

Conclusions: ABI presents great variability during a conventional HD. However, whether an acute decrease in ABI by using a [Ca] 2.5 may impact the long-term mortality deserves further investigation.

PUB638

Variation in the Intracranial Pressure During Hemodialysis in a Patient with Subdural Hematoma on Propofol Rhea Bhargava,[1] Omkar U. Vaidya.[1,2] *[1]Dept of Internal Medicine, Univ of Missouri- Kansas City, Kansas City, MO; [2]Dept of Nephrology and Hypertension, Univ of Missouri- Kansas City, Kansas City, MO; [3]Dept of Critical Care, Saint Lukes Hospital, Kansas City, MO.*

Background: Dialysis disequilibrium syndrome (DDS) is a rare but potentially serious complication of hemodialysis. Pathophysiology of this disorder is explained by the 'reverse urea effect'. This can be difficult to detect in patients in the neuro-intensive care unit given their compromised CNS status. However it is imperative to diagnose DDS especially in this population as intracranial pressure (ICP) instability during hemodialysis can lead to micro circulatory defects.

Methods: 60 y/o male with ESRD admitted for left frontal subdural hematoma, underwent evacuation with ventricular drain placement. He was intubated and sedated. BP 142/69 mmHg, Pulse 122 bpm, Temp of 37.3 °C, RR of 34 and SpO2 100%. The remaining physical examination was unremarkable. Hemodialysis (HD) was performed on 3 contiguous days. ICP and the changes in cerebral perfusion pressure (CPP) were monitored every 15 minutes during hemodialysis. Sedation with propofol which was started on Day1, was weaned off completely by the session on day three. The patient seized after the 3rd hemodialysis session. CT scan of the head was unremarkable. He was eventually discharged on day 14 and made full recovery.

Results: ICP and CPP during hemodialysis decreased in the first 30 minutes and maximum variation was between 45-120 minutes. Peak ICP pressure during HD: Day 1: 5 mmHg; Day 2: 15 mmHg and Day 3: 25 mm Hg. Maximum change in CPP from basline during HD: Day1: 20 mm Hg; Day 2: 22mm Hg and Day 3: 47 mmHg.

Conclusions: ICP monitoring during hemodialysis is a useful modality to identify neurological complications in patients who have undergone neurosurgical interventions. Propofol along with being a sedative can lower ICP and hence prevent or mask the effects of hemodialysis on ICP. In the present case, net change in CPP could have led to seizure activity on the 3rd day of hemodialysis.

PUB639

Characterization of T Regulatory Type 1 (Tr1) Cells in Naïve and Transplanted Non-Human Primates Ruichao Yu, Makoto Tonsho, Philip Spencer, Sibylle Bernard-stoecklin, Gilles Benichou, Joren Madsen. *Center for Transplantation Sciences, Harvard Medical School, Massachusetts General Hospital, Boston, MA.*

Background: T regulatory Type 1 (Tr1) cells are peripheral $CD4^+FoxP3^-$ regulatory T cells expressing CD49b and LAG-3 in mice and humans. Mouse Tr1 cells inhibit antigen-presenting cell (APC) activation via secretion of IL-10 and TGF-β and via cell-contact dependent mechanisms mediated through their expression of programmed cell death (PD)-1. However, the phenotype and functions of Tr1 cells non-human primates are still unknown.

Methods: Mononuclear cells were isolated from the peripheral blood of cynomolgus monkeys(PBMCs). First, co-expression of CD49b and LAG-3 was compared among bona fide $CD4^+CD25^{high}FoxP3^+$ Tregs and $CD4^+CD25^-Foxp3^-$using flow cytometry. Second, cytokines(IL-10, TGF-β, IFN-γ, IL-4, IL-17 etc.,) were processed after polyclonal activation via anti-CD3/CD28 Ab-coated beads. Next, we compared PD-L1 and CD45RO expression by Tr1 cells collected from the PBMCs of naïve monkeys, monkeys undergoing rejection of kidney allografts and monkeys which have been rendered tolerant of kidney allografts via donor mixed hematopoietic chimerism induction and leukocyte costimulation blockade.

Results: In cynomolgus monkeys, CD49b and LAG-3 were co-expressed on $CD4^+CD25^-Foxp3^-$ Tr1lymphocytes but not on $CD4^+FoxP3^+$Tregs. After polyclonal activation via anti-CD3/CD28 Ab-coated beads, virtually all Tr1 cells secreted high levels of IL-10 anti-inflammatory cytokine but no pro-inflammatory IFN-γ or IL-17 cytokines. We observed a significant expansion of Tr1 cells expressing a memory phenotype (CD45RO) and the immunomodulatory receptor PD-L1 in tolerant but not other animals.

Conclusions: Our data show that the surface markers CD49b and LAG-3 can be used to distinguish Tr1 from "classical" FoxP3+ Tregs in cynomolgus monkeys. Tr1 cells are likely to inhibit T cell responses mediated by PD-1/PD-L1 interactions. The contribution of these activated Tr1 cells to induction and maintenance of organ allograft tolerance in non-human primates is under investigation.

PUB640

Urinary MicroRNA-25 as a Potential Biomarker for Detection of Renal Damage in Rats and Renal Transplant Patients Kumiko Nishihara,[1] Masayuki Kanki,[1] Moto Kajiwara,[2,3] Kei Kurihara,[4] Takahisa Yano,[2] Hidehisa Kitada,[4] Satohiro Masuda,[2] Akira Unami.[1] *[1]Drug Safety Research Laboratories, Astellas Pharma Inc., Osaka, Japan; [2]Dept of Pharmacy, Kyushu Univ Hospital, Fukuoka, Japan; [3]Dept of Research and Development of Next Generation Medicine, Faculty of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [4]Dept of Surgery and Oncology, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.*

Background: Circulating microRNAs (miRNAs) were proposed as potential biomarkers of various biological functions and diseases in the kidneys. We have found that some urinary miRNAs were useful for detection of cisplatin-induced proximal tubular injury in rats (Kanki M et al., Toxicology. 324, 158, 2014). In this study, we examined the feasibility of miRNAs for renal damage in Japanese patients receiving kidney transplantation as well as rats.

Methods: Gentamicin (100 mg/kg) (model of tubular injury) was daily given for 7 days and puromycin (50 mg/kg) (model of glomerular injury) was given as a single injection to male SD rats. Seven days after the treatment, the urinary levels of 15 miRNAs were determined by real-time PCR. The receiver-operator characteristics (ROC) curve analysis for proximal tubular necrosis was performed including previous cisplatin study. Human urine samples were collected from 30 healthy volunteers and 11 renal transplant patients at 7 days and 2, 10, and 11 weeks after surgery. The levels of 4 miRNAs were determined.

Results: In gentamicin treated rats,the levels of miR-328, let-7a-1, miR-1839, miR-25, miR-140, and miR-378 were increased more than 2-fold with high values of the area under the ROC curve, which were the same or more than those of BUN and serum creatinine, while they were not changed in rats treated with puromycin. Among these miRNAs, miR-25, miR-140-3p, miR-328 and miR-378 were measured in the human urine samples. In human samples, miR-25 at postoperative day 7 in some patients exhibited higher levels than the highest value of those in the volunteers.

Conclusions: Urinary miR-25 but not other miRNAs might be available for detecting renal damage in the postoperative course of renal transplant patients as well as that in the rats with proximal tubular injury.

PUB641

Early Activation of Complement in Renal Ischemia/Reperfusion (I/R) Injury Is Mediated by Pentraxin 3 (PTX3) Synthetized by Peripheral Blood Mononuclear Cells (PBMCs) Giuseppe Castellano,[1] Chiara Divella,[1] Alessandra Stasi,[1] Paola Pontrelli,[1] Matteo Accetturo,[1] Marco Fiorentino,[1] M. Rossini,[1] Vincenzo Montinaro,[1] G. Lucarelli,[1] M. Battaglia,[1] Loreto Gesualdo,[1] Giuseppe Grandaliano.[2] *[1]Dept of Emergency and Organ Transplantation, Univ of Bari, Bari, Italy; [2]Dept of Medical and Surgical Sciences, Univ of Foggia, Foggia, Italy.*

Background: PTX3 has been recently implicated in the promotion of vascular inflammation via the activation of Complement. Aim of this work was to investigate the possible involvement of PTX3 in renal I/R injury.

Methods: PBMCs were isolated from blood of patients with Delay graft function (DGF,n=10) and Early graft function (EGF, n=10) at T0 and T24h from transplant. Gene expression profiles of PBMCs from both groups were assessed by Affymetrix technologies. Results were evaluated by statistical analysis and functional pathway analysis and validated by confocal analysis on a swine model of I/R injury. Renal I was induced in 5 pigs by arterial clamping for 30 min and tissues were analyzed at different time points after R (T15',30',60').

Results: Microarray analysis (FDR<5% and a FC>1,5) revealed that the expression of PTX3 and C3 were downregulated in EGF compared to DGF patients. On the contrary, the gene CR1 was upregulated in DGF. Furthermore, in the pig model, confocal laser microscopy demonstrated PTX3 deposits already at 15' of R, localized at peritubular (7.7±1.1;p=0.005) and glomerular (8.2±2.5;p=0.03) capillary levels. We found a significant increase in infiltrating interstitial leucocytes such as $CD163^{+}/PTX3^{+}$ monocyte-macrophages (6.2±2.1;p=0.05) and $SWC3a^{+}/PTX3^{+}$ dendritic cells (3.7±0.5;p=0.05) compared to T0. Finally, we identified tubulo-interstitial $FSP1^{+}/PTX3+$ myofibroblast(4.1±1.3;p=0.04). Co-localization between C5b-9/PTX3, PTX3/C1q and PTX3/MBL clearly demonstrated the activation of Classical and Lectin Complement pathways in presence of PTX3 deposits.

Conclusions: Our data would suggest a key role of PTX3 synthetized by peripheral blood mononuclear cells (PBMCs) during DGF leading to an early activation of complement in transplant kidney.

PUB642

The Effect of Combined Treatment of Dipeptidyl Peptidase IV Inhibitor and Metformin in Sirolimus-Induced Diabetes Mellitus Long Jin, Jian Jin, Sun Woo Lim, Byung Ha Chung, Chul Woo Yang. *Transplant Research Center & Div of Nephrology, Dept of Internal Medicine, Seoul, St Mary's Hospital, The Catholic Univ of Korea, Seoul, Korea.*

Background: Optimal treatment of post-transplant diabetes mellitus is still controversial. This study was performed to evaluate whether the combined treatment of DPP IV inhibitor with metformin (MET) is effective in sirolimus (SRL)-induced diabetes mellitus.

Methods: SRL-induced diabetes mellitus was made by treating SRL (0.3 mg/kg) for 3 weeks in rats, and then started to treat DPP IV inhibitor (LC15-0444[LC], 5mg/kg), and/or MET (200 mg/kg) for further 3 weeks. The effect of combined treatment of LC and MET on SRL-induced diabetes mellitus was evaluated by IPGTT and islet size. The oxidative stress was evaluated by measuring 8-OHdG, 4-HHE, MnSOD, and catalase in samples. Insulin secretion capacity was evaluated by glucose-stimulated insulin secretion (GSIS) test using normal isolated rat islets treated with SRL, exendin-4 and/or MET.

Results: SRL treatment for 6 weeks decreased body weight and increased water intake and urine volume compared with vehicle group. SRL treatment significantly increased AUCg from the values obtained during the IPGTT, but LC or MET treatment recovered these value compared with the SRL treatment alone. Combined treatment with LC and MET has more significantly decreased blood glucose level than LC or MET treatment alone. Islet size which was significantly decreased in the SRL group was recovered with combined treatment of LC and MET. SRL treatment significantly increased intense nuclear expression and larger positive area for 8-OHdG and 4-HHE, but combined treatment LC and has significantly decreased expression of 8-OHdG and 4-HHE. The decreased expression of MnSOD and catalase in the SRL group was recovered with combined treatment with LC and MET. The result of GSIS also showed that combined treatment of LC and MET showed higher insulin level than exendin-4 or MET treatment alone.

Conclusions: Combined treatment with LC and MET exerts better glucose control by decreasing oxidative stress caused by SRL. This finding provides the rationale for the combined use of DPP IV inhibitor and MET in SRL-induced diabetes mellitus.

Incidence and Outcomes of Hyponatremia Early Post Lung Transplantation Ekamol Tantisattamo,[1] Aneesha A. Shetty,[1] Bing Ho,[1] John J. Friedewald,[1] Opas Traitanon,[1] Sangeeta Bhorade,[2] Alexander Haynes,[2] Amber Nieland,[2] Lorenzo G. Gallon.[1] *[1]Div of Nephrology and Hypertension; [2]Pulmonary and Critical Care, Dept of Medicine, Northwestern Univ Feinberg School of Medicine.*

Background: Outcomes of in-hospital hyponatremia in lung transplant recipients are unclear. The aim of this study is to describe the frequency of hyponatremia and outcomes associated with hyponatremia during the early postoperative period.

Methods: We performed a retrospective chart review of all lung transplant recipients at Northwestern Memorial Hospital since the first case performed in July 2014 until May 2015. The severity of hyponatremia was defined as mild, moderate, and severe with serum Na of <135, <130, and <125 mEq/L, respectively.

Results: A total of 13 lung transplant recipients were included. Age at the time of transplantation was 61.5+/-2.2 (SEM) years and 69% was female. The most common indication for transplantation was severe COPD (54%). Serum creatinine at the time of transplantation and at hospital discharge was 0.8+/-0.1 and 1+/-0.2 mg/dL, respectively. Seven patients with postoperative acute kidney injury (AKI) had >2 times longer length of hospitalization (26.2+/-4.8 vs. 10.0+/-1.1 days; p 0.0046) and were more likely to develop postoperative hyponatremia (100% vs. 71%; p=0.151). Among 11 patients with postoperative hyponatremia, 7 were readmitted (5 with hyponatremia and 4 with AKI). At the time of transplant, 8% of the patients had hyponatremia but the incidence was up to 46% at the time of discharge (Table1). Almost half of the patients had persisent hyponatremia during 1 month follow-up.

Conclusions: Lung transplant recipients commonly develop hyponatremia during the immediate post operative period and are more likely to be readmitted with hyponatremia. The incidence of hyponatremia remains high up to 1 month post transplantation. AKI is also a risk for readmission and predicts longer length of hospital stay.

Degree of serum sodium	At trans-plant	3 days	7 days	At dis-charge	30 days	90 days	180 days

Motivations, Challenges, and Attitudes to Self-Management in Kidney Transplant Recipients: A Systematic Review of Qualitative Studies Nathan Jamieson,[1,2] Camilla Sara Hanson,[1,2] Michelle A. Josephson,[3] Elisa J. Gordon,[4] Jonathan C. Craig,[1,2] Fabian Halleck,[5] Klemens Budde,[5] Allison Tong.[1,2] *[1]Centre for Kidney Research, The Children's Hospital at Westmead, Sydney, New South Wales, Australia; [2]School of Public Health, Univ of Sydney, Sydney, New South Wales, Australia; [3]Dept of Medicine, The Univ of Chicago, Chicago, IL; [4]Center for Healthcare Studies and Comprehensive Transplant Centre, Northwestern Univ Feinberg School of Medicine, Chicago, IL; [5]Dept of Nephrology, Charité, Universitätsmedizin Berlin, Berlin, Germany.*

Background: Kidney transplantation offers superior life expectancy and quality of life outcomes compared to other renal replacement therapy modalities. However, the complex and ongoing medication and self-management regimens impose a treatment burden on patients, and non-adherence remains a leading cause of graft loss.

Methods: MEDLINE, Embase, PsycINFO, and CINAHL were searched from database inception to October 2014. We used thematic synthesis to analyse the findings.

Results: Fifty studies involving 1238 participants aged from 18 to 82 years across 19 countries were included. We identified five themes: *empowerment through autonomy* (achieving mastery, tracking against tangible targets, developing bodily intuition, routinising and problem-solving, adaptive coping), *prevailing fear of consequences* (inescapable rejection anxiety, aversion to dialysis, minimising future morbidity, trivialisation and denial, defining acceptable risks), *burdensome treatment and responsibilities* (frustrating ambiguities, inadvertent forgetfulness, intrusive side-effects, reversing ingrained behaviours, financial hardship), *over-medicalising life* (dominating focus, evading patienthood, succumbing to burnout), and *social accountability and motivation* (demonstrating gratitude towards medical team, indebtedness to donor, peer learning).

Conclusions: Self-efficacy and social accountability are motivators for self-management, but ongoing adherence can be mentally and physically taxing. Multi-component interventions that incorporate education, psychosocial support, decision aids, and self-monitoring tools may foster self-management capacity and improve transplant outcomes.

Characteristics of Patients with Vitamin D Deficiency After Kidney Transplantation in Qatar Mohamed Amin Elesnawi, Abdullah Hamad, Fadwa S. Al-Ali. *Nephrology, Fahd Bin Jasim Kidney Center, Hamad General Hospital, Doha, Qatar.*

Background: Vitamin D deficiency is common among normal people and in patients with chronic kidney disease including dialysis patients. Vitamin D deficiency continues to be prevalent after kidney transplantation (studies showed prevalence of 50-80%) especially with immunosuppression use and sun protection needed for elevated risk of skin cancer . We studied characteristics of kidney transplant patients with vitamin D deficiency in Qatar.

Methods: We reviewed all available records of kidney transplant patients presented to our clinic at Hamad General Hospital in Doha, Qatar between 1/9/2013 and 1/3/2014 and have vitamin D level less than 30 ng/mL. Background data and laboratory tests of patients were obtained. All patients were receiving vitamin D supplements and prednisone within their immunosuppression per institution protocol.

Results: We studied 83 patients. Mean age was 55.5 +/- 16 years. There were 55 males (66%) and 28 females (34 %). Vitamin D deficiency was severe (level than 10 ng/mL) in 15 patients, moderate in 38 (10-19 ng/mL) and mild in 30 patients (20-29 ng/mL). Duration of transplant was 7.9 +/- 2.5 years. Glomerular Filtration Rate was 65.5 +/- 20.6 ml/min. We found no correlation between vitamin D and PTH levels or between vitamin D and GFR levels. Table 1 summarize bone mineral panel in our patients.

	Plasma Level +/- SD
Vitamin D	16.4+/-6.7 ng/ml
Calcium	2.28+/-0.14 mmol/L
Phosphorus	1.2+/-0.26 mmol/L
Alkaline Phosphatase	86.9+/-37.8 u/L
Intact Paathyroid Hormone	146+/-2.1pg/mL

Conclusions: In a study of kidney transplant patients with vitamin D deficiency in Qatar we found that they were predominantly males, have normal calcium, phosphorus and alkaline phosphatase levels, while they have variable degree of elevated PTH with no correlation to vitamin D level. Most patients have mild to moderate vitamin D deficiency (82%) despite receiving vitamin D supplement although the supplement could have decreased the number of patients with severe vitamin D deficiency (18%). Further study could help to evaluate the role of vitamin D supplement in improving vitamin D level in kidney transplant recipients.

PUB647

Comparison of Vitamin D Deficiency Between Young and Elderly Kidney Transplant Recipients Mohamed Amin Elesnawi, Abdullah Hamad, Fadwa S. Al-Ali. *Nephrology, Fahd Bin Jasim Kidney Center, Hamad General Hospital, Doha, Qatar.*

Background: Vitamin D deficiency is common in normal population and in patients with chronic kidney disease including kidney transplant recipients. Elderly patients are vulnerable to vitamin D defeciency with less sun exposure and having multiple medical problems. We compared young versus elderly kidney transplant recipients with vitamin D deficiency in Qatar.

Methods: We reviewed all available records of kidney transplant recipients presented to our clinic at Hamad General Hospital in Qatar between 1/9/2013 and 1/3/2014. Background data and laboratory tests of patients were collected. All patients were receiving vitamin D supplements and prednisone per institution protocol.

Results: 83 patients were included. 41 patients in the young group (< 60 years old) and 42 in the elderly group (> 60 years old). There were 21 females versus 20 males in the young group and 35 males versus 7 females in the elderly group (pValue<0.05). Time on transplant was 9.1 +/- 4.93 years in the young group versus 8.6+/-2.7 in the elderly. Table 1 summarizes laboratory values for kidney transplant patients with vitamin D deficiency.

	Age over 60 years (n=42)	Age less than 60 years (n=41)
Vitamin D	17.7+/-6.4 ng/mL	15.1+/-6.7 ng/mL
Calcium	2.28+/-0.13 mmol/L	2.29+/-0.15 mmol/L
Phosphorus	1.22+/-0.18 mmol/L	1.16+/-0.3 mmol/L
Parathyroid Hormone	148.7+/-238.3 pg/mL	143.9+/-154.8 pg/mL
Alkaline Phosphatase	75.8+/-29 u/L	91.9+/-39.9 u/L
Glomerular Filtration Rate (GFR)	69.9+/-21.4 ml/min	61.2+/-19.2 ml/min

Conclusions: We compared vitamin D deficiency in young versus elderly kidney transplant recipients in Qatar. Although elderly patients have higher vitamin D levels, it was not statistically significant. This could be due to better compliance with vitamin D supplement in the elderly. Although duration on transplant, calcium, phosphorus and intact parathyroid hormone were similar, Glomerular Filtration Rate (GFR) was higher in the elderly. We explain it that almost all kidney tranplants in Qatar are from live donors which lead to a higher GFR in the elderly as they are receiving kidneys from younger donors. There was statistically significant smaller number of females than males in the elderly group.

The Current Status of Plasmapheresis Before Living Donor Kidney Transplantation in Japan Norio Hanafusa,[1] Tomoko Usui,[1] Akihiko Matsumoto,[1] Satoko Sakurai,[1] Eisei Noiri,[1] Hideo Yasunaga,[2] Masaomi Nangaku.[1] [1]*Dept of Hemodialysis and Apheresis, The Univ of Tokyo Hospital, Bunkyo-ku, Tokyo, Japan;* [2]*Dept of Clinical Epidemiology and Health Economics, School of Public Health, The Univ of Tokyo, Bunkyo-ku, Tokyo, Japan.*

Background: Plasmapheresis (PP) is utilized to remove alloantibodies before the living donor kidney transplantation (LDKT). The detailed practice patterns of PP before LDKT remains unknown. There also are concerns about the depletion of coagulation factors [Transfus Apher Sci 49: 254, 2013] by PP. We investigated the current status of PP before LDKT with use of the nationwide database.

Methods: The Japanese Diagnosis Procedure Combination Database includes all the patients discharged from hospitals participating in this program between July 2010 and March 2013. Those who received LDKT and PP before LDKT were included into this study. The modalities of PP, fresh frozen plasma (FFP) use, and albumin use were examined. We also investigated the relationship between modalities selected and outcomes such as the length and total costs of the hospital stay, or the amount of blood transfusion as the proxy of bleeding.

Results: In total 775 patients received PP before LDKT during the period. Among them 209 patients were treated only by simple plasma exchange (PE). Remaining 566 patients received double filtration plasmapheresis (DFPP), or cascade filtration. Interestingly, 274 patients treated by DFPP received also PE before transplantation. FFP was used during PP on 109, 180, and 42 patients treated by PE only, DFPP followed by PE, and DFPP only, respectively. Moreover, FFP was infused before the operation on 161 patients who were not used FFP during PP. As a whole 63.5% of total patients received FFP from the start of PP to the day of operation. DFPP followed by PE groups received less amount of blood transfusion (p=0.047), though the length of stay was longer and total costs were higher, compared to DFPP only group.

Conclusions: Many of the patients received FFP, which suggests concerns about the depletion of coagulation factors during PP. The practice patterns were quite heterogeneous and the standardization of the practice patterns is needed to maximize the benefits of PP.

PUB650

Age as a Risk Factor for Acute Rejection in the Renal Transplant Patient Sarah Lamarche, Jean-Philippe Lafrance, Michel Vallee, Duy Tran. *Nephrology, Univ de Montréal, Montréal, QC, Canada.*

Background: It has previously been shown that younger age is associated with a higher risk of acute rejection post renal transplantation. However, those studies were undertaken in times with differing use of immunosuppressive therapies. We thus sought to examine if this trend was still relevant in a contemporary cohort of patients with a new prescription profile.

Methods: We retrospectively reviewed the charts of 217 patients who underwent renal transplantation between the years 2006-2012 at our institution. Baseline characteristics of donors and recipients were examined. Recipients were stratified according to age <30, 30-40, 40-55, 55-65 and >65 years old. Our primary endpoint was the incidence of acute rejection at one year post renal transplantation. Multivariate Cox regression models predicting acute rejection were also fitted to adjust for several confounders.

Results: Regarding baseline recipient characteristics, there was a significant difference in the leading cause of end-stage kidney disease among the groups (glomerulopathy in young recipients and diabetic nephropathy in old recipients). Also, hypertension, diabetes and coronary heart disease were more prevalent in older recipients. Overall, the incidence rate of acute rejection at 1 year in all groups was 19 per patient-year. Statistically significant differences in Kaplan-Meyer estimates of rejection at one year were recorded (log rank p=0.03) and those differences were confirmed in multivariable Cox regression analyses. Indeed, individuals aged 30-40 years had a higher risk of developing acute rejection (HR 6.5, 95% CI: 1.9, 22.5) compared to the reference group (40-55). Other significant predictors of acute rejection at 1 year included PRA > 20% (HR 6.8), unrelated living donor (HR 10.2), donor after cardiac death (HR 3.7) and length of initial hospitalisation stay (HR 1.03).

Conclusions: In a contemporary cohort, we recorded a significant difference in patterns of acute rejection following renal transplantation according to age. Indeed, individuals aged 30-40 years were more prone to transplant rejection, even after adjusting for several covariates. This research should fuel additional investigations regarding the biology of this disease.

PUB651

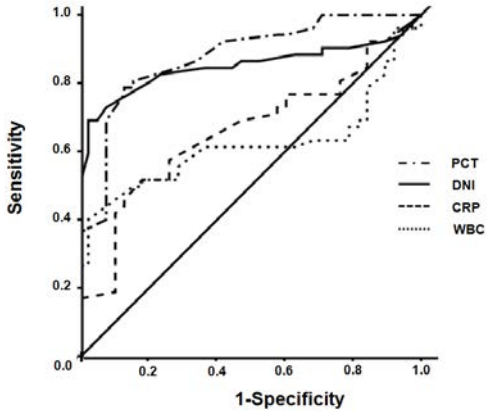
Delta Neutrophil Index as a Marker for Differential Diagnosis Between Acute Graft Pyelonephritis and Acute Graft Rejection Soyon Rhee, Eunjung Kim, Hee Jung Jeon, Ja-Ryong Koo. *Internal Medicine, Nephrology, Hallym Univ of College of Medicine, Seoul, Republic of Korea.*

Background: Acute graft pyelonephritis (AGPN) versus acute graft rejection is a frequently encountered diagnostic and therapeutic dilemma in renal transplant recipients, but little is known about the clinical usefulness of the delta neutrophil index (DNI) value in the differentiation of the two conditions.

Methods: We reveiwed the medical records of 86 renal transplant recipients, 45 patients with 51 acute graft rejection episodes and 41 patients with 54 AGPN episodes, at the Kangdong Sacred Heart Hospital from January 2008 to February 2014. Of theses episodes, 15 were excluded due to neutropenia (n=4), other infections (n=5), and no available data of procalcitonin levels (n=6). As a result, 72 renal transplant recipients with 90 episodes were enrolled in this study.

Results: AGPN group had significantly higher DNI values than acute graft rejection group (2.9% vs. 1.9%, P<0.001). The area under the ROC curve for DNI value was 0.85 (95% confidence interval [CI]; 0.76-0.92, P< 0.001).

Figure 1



A DNI value of 2.7% was selected as cut-off value for AGPN, and renal transplant recipients with a DNI ≥ 2.7% were found to be at a higher risk of infection than those with a DNI < 2.7% (odd ratio [OR] 40.50; 95% CI 8.68-189.08; P <0.001). In a multivariate logistic regression analysis, DNI was a significant independent factor for predicting AGPN after adjusting age, sex, log WBC count, log neutrophil count, log lymphocyte count, DNI value, CRP concentration and procalcitonin concentration (OR 4.32; 95% CI 1.81-10.34, P < 0.001).

Conclusions: The present study demonstrated that a DNI value above 2.7% was an independent predictive marker for AGPN and an effective marker to differentiate between AGPN and acute graft rejection. Thus, these finding suggest that DNI may be a useful marker in the management of theses patients.

PUB652

Effect of Pre-Transplant Dialysis Modality on Outcomes of Living-Donor Kidney Transplantation Recipients Chiaki Kawabata. *General Internal Medicine, Japanese Red Cross Kumamoto Hospital, Kumamoto, Japan.*

Background: There are few studies on living-donor kidney transplantation that compare the outcomes after pre-transplant dialysis modality. We examined the short-term outcomes of living-donor kidney transplantation recipients after peritoneal dialysis (PD) and hemodialysis (HD), respectively.

Methods: 112 patients have undergone living-donor kidney transplantation procedures in our hospital between January 2001 and May 2014. We studied 40 patients, under 40 years of age, with dialysis durations of less than 5 years. We compared 13 PD patients with 27 HD patients and investigated the short-term outcomes.

Results: These two groups showed no significant differences as regards baseline characteristics including dialysis duration, body mass index, type of calcineurin inhibitor or ABO blood type incompatibility. The PD group was younger than the HD group as regards recipient age and donor age (22.5±8.0 years vs 29.1±6.0 years [p=0.005] : and, 50.7±8.2 years vs 56.9±7.1 years [p=0.02], respectively). There were no differences in early post-transplant complications, such as wound infection, bleeding, thrombosis, delayed graft function, or acute rejection. The PD group was better than the HD group in the estimated glomerular filtration rate (eGFR) at discharge (74.3±27.3 ml/min/1.73 m2 vs 48.3±12.3 ml/min/1.73 m2 [p=0.001]) and eGFR 1 year post-transplantation (68.4±21.8 ml/min/1.73 m2 vs 45.6±13.2 ml/min/1.73 m2 [p=0.003]).

Conclusions: In the case of younger and less than 5 years of dialysis duration, PD and HD demonstrated no differences in early post-operative complications. PD is significantly better than HD as regards eGFR up to 1 year post-transplantation.

PUB653

Bright Field Microscopy of the Unstained Urine Sediment: A Basic Tool to Identify Decoy Cells due to Polyomavirus BK on Kidney Allograft Recipients During Routine Urinalysis José A. Poloni,[1,2,3] Gabriel Godinho Pinto,[2] Maria Giordani,[1] Elizete Keitel,[1,2] Alessandro C. Pasqualotto,[1,2] Liane Rotta.[2] *[1]Irmandade da Santa Casa de Misericórdia de Porto Alegre, Porto Alegre, RS, Brazil; [2]Univ Federal de Ciências da Saúde de Porto Alegre, Porto Alegre, RS, Brazil; [3]Control Lab, Rio de Janeiro, RJ, Brazil.*

Background: Polyomavirus BK (BKV) is an important pathogen that can be reactivated in kidney allograft recipients, potentially leading to BKV nephropathy (BKVN), an important cause of graft loss. Decoy cells (DC), urothelial cells or renal tubular epithelial cells modified by the proliferation of BKV, are one of the hallmarks of BKV reactivation and it can be identified in the fresh urine sediment.

Methods: A cohort of 102 kidney transplant patients was followed during months 3 and 6 after the transplant procedure. Urine samples were obtained to detect the presence of DC in the fresh and unstained urine sediment under bright field microscopy (BFM) by two experienced analysts, as well as BKV viruria by qPCR.

Results: DC were found in 15 patients.

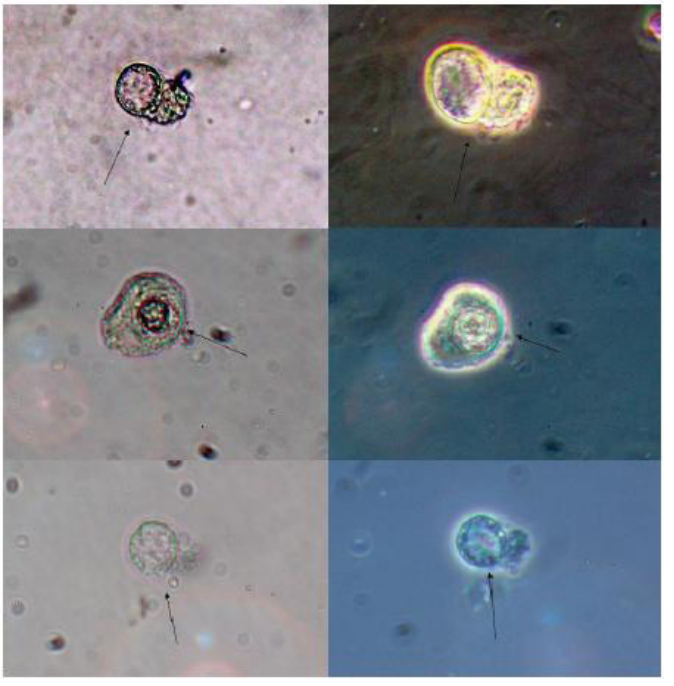


Figure 1 – Three decoy cells presented under bright field microscopy (left panel) and under phase contrast microcopy (right panel). Original magnification 400x.

Urine sediment analysis revealed a strong agreement (P<0,001) between the microscopists to both qualitative and quantitative identification of DC. Also, the qualitative comparison of both microscopists to BKV viruria revealed agreement (P<0,001). The positive predictive value, negative predictive value, specificity and accuracy of BFM were 80%, 75%, 97% and 75%, respectively. The sensitivity was 16%.

Conclusions: Despite its limited sensitivity, fresh and unstained urine sediment analysis under BFM is a method that can be used to identify DC due to BKV reactivation. The analysis procedure is fast, cheap and painless. The information obtained during routine urinalysis can be lead to the early diagnosis of BKV reactivation helping on the clinical management of the patients. The ability of less trained observers to perform such diagnosis requires further validation.

PUB654

Intravenous Immunoglobulin in the Management of Pneumocystis Pneumonia: A Case Series Musab Elgaali, Muhammad Imran, Matthew Edey. *Hull Royal Infirmary, Hull, United Kingdom.*

Background: Pneumocystis pneumonia (PCP) is a well-recognized complication of renal transplantation. We present 2 cases of severe PCP treated successfully with intravenous immunoglobulin (IVIg), trimethoprim-sulfamethoxazole (TMP-SMX) and withdrawal of immunosuppression. Graft function was maintained despite a high baseline immunological risk.

Methods: Case A: A 32 year-old woman presented 2 years post-transplant with acute cellular rejection treated with steroids. 2 months later she was admitted with respiratory failure due to PCP. She required intubation and ultimately oscillatory ventilation. CMV DNA was detected at low levels in bronchoalveolar lavage (BAL) fluid. IVIg 30g on alternate days (10 doses) was added, in addition to withdrawal of immunosuppression and hydrocortisone replacement. She made a full recovery, with preservation of transplant function throughout. Case B: A 47 year-old woman received a second kidney transplant. Early post-transplant she developed acute antibody mediated rejection managed with plasma exchange then maintenance prednisolone, tacrolimus and mycophenolate. 9 months later she was admitted with respiratory failure and Pneumocystis jirovecii in BAL. She required invasive ventilation and inotropic support. She was treated with intravenous TMP-SMX, but her clinical condition deteriorated with acute kidney injury (AKI) requiring hemofiltration and escalating ventilator requirements. She received IVIg 25g/day for 5 days, replacement hydrocortisone and immunosuppression was withdrawn. Her AKI resolved and later she became ventilator-independent. Graft function was at baseline on discharge. Maintenance immunosuppression was recommenced.

Conclusions: It is understood that immunity against Pneumocystis jirovecii is both B- and T-cell mediated. Thus pooled immunoglobulin might be expected to have some anti-Pneumocystis activity. It is also recognized that IVIg has immunomodulatory properties. In both cases the administration of IVIg allowed withdrawal of immunosuppression apart from replacement steroid without graft rejection despite high immunological risk. Both patients survived life-threatening PCP. We suggest adjunctive therapy with IVIg be considered in severe PCP.

PUB655

Ethical Issues Related to Kidney Donation/Transplantation: Perspective of Indian Doctors Richard S. Fernandes Almeida,[1] Nirmala Almeida,[2] Karen Almeida,[3] Alan F. Almeida.[4] *[1]Lifesupporters Inst of Health Sciences; [2]Human Development, Nirmala Niketan College of Home Science; [3]Psychology, Mumbai Univ; [4]Nephrology, PD Hinduja Hospital, Mumbai, India.*

Background: Dearth of kidneys for transplantation has provoked the need to evaluate new policies and practices. This spurred the current study which addressed the perspective of doctors regarding emerging ethical issues pertaining to kidney donation/transplantation.

Methods: The sample consisted of 140 doctors from Mumbai (Age Range=21-80 years, M=38.1, SD=17.95, Males=44.3%, Females=55.7%). A questionnaire, presenting ethical issues related to kidney donation/transplantation, in an agree/disagree format with supporting reasons was employed. The research design was exploratory; data was analyzed quantitatively and qualitatively.

Results:

Question	Agree%	Reasons (%)*	Dis-agree%	Reasons (%)*
Unrelated transplants should be promoted by the government	75.7	Saves lives (16.4) Remedies organ donor shortage(16.4)	24.3	Misuse of organs (7.1) Higher chances of mismatch/organ rejection(7.1)
Kidney selling should be made legal	22.9	Greater donor availability(7.9) Avoidance of malpractice(6.4)	77.1	May lead to illegal/unethical practices(41.4)
Handicapped should not be kidney donors	24.3	Should not burden them as already challenged healthwise(10.7)	75.7	If informed consent given(20) If kidneys effectively functioning(14.3)
Substance abusers should not be transplant recipients	50.7	Chose to bring deterioration in life(10) Might abuse the transplant(15.7)	49.3	All are entitled to be kidney recipients(22.1)
Younger individuals should be given transplantation preference	60	Longer life expectancy (20) Greater transplantation success(12.9) Higher productivity(12.9)	40	Need-based rather than age-based preference(11.4)
Families of cadaver donors should be given incentives	45.7	Motivates donation(22.9)	54.3	Would lead to commercialization and criminal activities(20.7)
Kidney donation should be made compulsory after death	44.3	Saves lives(26.4)	55.7	Donation is individual's choice, coercion is unethical(44.3)

*Representative

Conclusions: This study is relevant in view of the dearth of Indian research. Educating doctors about medico-ethical issues is the need of the hour.

PUB656

Cardiovascular Risk Management of Renal Transplant Patients Joseph C. Newton, Thalakunte M. Muniraju. *Dumfries and Galloway Royal Infirmary, Dumfries, United Kingdom.*

Background: There is a high burden of cardiovascular disease amongst renal transplant recipients, and it is the most common cause of death with a functioning graft. We have assessed the medical management of all transplant patients in our region by comparing regular monitoring of glycaemia, blood pressure and serum lipids, with appropriate prescription of medicines based on their cardiovascular risk.

Methods: Using the electronic health record information was collected on cardiovascular comorbidities, all current medications, frequency of clinic monitoring, BP and most recent biochemical results for glycaemia, proteinuria and lipid results for the local transplant cohort of 69 patients. Prescription of statins, antihypertensives and aspirin were audited against guidelines from the UK Renal Association (RA) and KDIGO. Cardiovascular risk was calculated using the Joint British Societies Guidelines (JBS2).

Results: Amongst hypertensive patients, 2/28 (7.1%) were not on antihypertensive therapy. Significant proteinuria (uPCR >50) was not common (6/68 = 8.8%), but of these only 2/6 (33.3%) were receiving an ACE inhibitor or ARB. Glycaemic control of diabetic patients was generally good, with 9/12 (75%) achieving target HBa1c of <48 mmol/mol. For non-diabetic patients, 11/56 (19.6%) were found to have a random glucose ≥7. Of these 4/11 (36.4%) had HbA1c checks, one of which confirmed new diabetes. The remaining 7 patients (63.6%) have not had a follow up HbA1c. 20/69 (29.0%) of patients were calculated as >20% cardiovascular risk on the basis of comorbidities or using JBS2. Of these only 12/20 (60%) were on statin therapy. Almost all (6/7 = 85.7%) of patients with vascular disease were taking regular aspirin.

Conclusions: We have identified room for improvement in the management of hypertension and proteinuria. Rates of statin prescription suggest that we often underestimate cardiovascular risk clinically, however, further analysis will be required to determine whether valid reasons exist to support decisions to omit statins or renin-angiotensin blockade. These audit results will be discussed with local clinicians, and will be added to the electronic record to highlight areas where individual management differs from national guidelines.

PUB657

Preemptive Transplantation Is Associated with Improved Graft Survival: Results from the French Transplant Database Mathilde Reydit,[1,2] Christian Combe,[2] Jerome Harambat,[2] Christian Jacquelinet,[3] Pierre Merville,[2] Lionel Couzi,[2] Karen Leffondré.[1] *[1]INSERM U897, Bordeaux School of Public Health, Bordeaux, France; [2]Nephrology and Transplantation, Bordeaux Univ Hospital, Bordeaux, France; [3]Agence de la Biomédecine, Paris, France.*

Background: Kidney transplantation (KT) is the treatment of choice for end-stage renal disease. In France, preemptive kidney transplantation (PKT) should be considered when glomerular filtration rate is under 20 ml/min/1.73m² but European reports on the results of PKT are scarce. Our objective was to evaluate the impact of PKT on graft and patient survival.

Methods: We analyzed all first kidney-only transplants performed in adults in France between 2002 and 2012. A Cox multivariable model was used to study the impact of PKT on the hazard of graft failure defined as death, return to dialysis, or retransplant, whichever came first.

Results: Between 2002 and 2012, 22 288 patients received a first KT, including 3112 (14%) who had a PKT. Mean recipient age at KT was 50.5 ± 13.4 years, 61.9% were men. Median time of follow-up was 4.7 years. In multivariable analysis, after adjustment for age and sex of recipients, primary kidney disease, donor type (living or deceased donor, expanded criteria donor or standard), HLA mismatches, cold ischemia time, center and year of transplantation, PKT was associated with a 43% reduction in the hazard of graft failure when compared with patients who were treated by dialysis before KT (Hazard ratio (HR) 0.57;IC95% 0.51-0.64). This reduction in the hazard of graft failure was greater after the first year of transplant (HR during the first year 0.69,IC95% 0.57-0.83;HR after the first year 0.51,IC95% 0.45-0.59) and the impact of PKT was also greater in living than in deceased donor recipients (HR in living donor 0.34,IC95% 0.19-0.55;HR in deceased donor 0.59,IC95% 0.52-0.66). Among the subgroup of patients registered on the waiting list before the initiation of dialysis, PKT was associated with a 29% reduction in the hazard of graft failure (HR 0.71;IC 95% 0.58-0.87).

Conclusions: In France, PKT is associated with better graft survival than KT performed after the initiation of dialysis. Nephrologists should prepare patients to PKT rather than to dialysis.

PUB658

Novel Potential Theranostic Targets in Individuals with Kidney Allograft Dysfunction Roberto Bassi,[1,2] Monika A. Niewczas,[3] Stefania Bussolino,[5] Valentina De Zan,[2] Giuseppe Paolo Segoloni,[6] Antonio Secchi,[2] Anil K. Chandraker,[4] Luigi Biancone,[6] Paolo Fiorina.[1,2] *[1]Nephrology, Boston Children's Hospital, Boston, MA; [2]Medicine, San Raffaele Scientific Inst, Milan, Italy; [3]Section of Genetics and Epidemiology, Joslin Diabetes Center, Boston, MA; [4]Transplantation Research Center, Brigham and Women's Hospital, Boston, MA; [5]Internal Medicine, San Giovanni Battista Hospital, Turin, Italy; [6]Univ of Torino.*

Background: The lack of early diagnostic and therapeutic targets for chronic allograft dysfunction (CAD) is among the major determinants of poor long-term graft survival. Metabolic abnormalities in serum and kidney graft parenchyma may worsen allograft function, while alterations of urinary metabolites may be used as diagnostic biomarkers.

Methods: To explore this hypothesis, we recruited individuals with stable allograft function (n=20), chronic allograft dysfunction (n=20) and healthy controls (n=10), and analyzed their metabolomic profile by *ex vivo* liquid/gas cromatography-mass spectrometry (LC/GS-MS) of serum and urine and *in vivo* two dimensional correlated spectroscopy (2D-COSY) of the kidney graft.

Results: LC/GS-MS revealed serum and urinary abnormalities of amino acids, biogenic amines and acylcarnitines in individuals with worse allograft function (T3) compared to conserved graft function (T1). Particularly, CAD was associated with reduction of serum tryptophan and glutamine (T3 vs. T1, $p<0.01$) and of urinary histidine (T3 vs. T1, $p<0.05$). Derivatives of dimethylarginine (DMA; symmetric (S)DMA: T3 vs. T1, $p<0.001$; $p<0.01$) and short-chain acylcarnitines (C4; C12: T3 vs. T1, $p<0.01$; $p<0.05$) increased in serum, while dopa and dopamine (T3 vs. T1, $p<0.01$; $p<0.001$) together with DMA, SDMA and ADMA (T3 vs. T1, $p<0.001$, $p<0.001$, $p<0.01$) decreased in urine. *In vivo* 2D-COSY performed on the same patients revealed reduction ($p<0.05$) of the parenchymal content of choline, creatine, taurine and threonine in individuals with CAD. Notably, taurine was selectively reduced within the graft parenchyma and increased in serum and urine of individuals with CAD.

Conclusions: Novel potential theranostics targets have been identified with an unbiased *ex vivo* and *in vivo* metabolomic profiling of individuals with CAD.

Funding: Government Support - Non-U.S.

PUB659

Good Patient and Graft Survival in Recipients of Kidney Transplantation due to Diabetic Nephropathy Amgad E. El Agroudy. *Internal Medicine Dept, College of Medicine and Medical Sciences, Arabian Gulf Univ, Manama, Bahrain.*

Background: Compared with non-diabetic subjects, patients with type 2 diabetes and end-stage renal disease (ESRD) have seldom been selected for renal transplantation. The aim of this study is to compare patient and graft outcome in kidney transplant patients with diabetes mellitus.

Methods: We retrospectively studied 358 patients who underwent kidney transplantation between 1979 and 2014, including 88 with diabetic ESRD (DM group) (type 1, $n = 8$; type 2, $n = 80$) and 270 with non-diabetic ESRD (NDM group). Mean follow-up was 92±9 (0.1–389) months.

Results: Mean age was higher in the DM group (52.8 vs 44.6 years; $P < .0001$), and there was no significant difference in recipient gender, donor age or donor source. At the end of follow-up, there was no differences between the groups in terms of blood pressure control (DM 139.3±16.7/81.7±7.6 mmHg *vs* NDM 138.3±19.7/82.1±8.1 mmHg, $P = 0.83/0.80$) and renal function (creatinine, 115.4±47.1 *vs* 133.4±80.2 µmol/l, $P = 0.18$; calculated creatinine clearance, 66±24 *vs* 68.4±24 ml/min/1.73 m^2, respectively, $P = 0.9$). In total, 26 patients had acute transplant rejections [8 patients with diabetes *vs* 18 patients without diabetes, $P = 0.11$].There was no significant difference in post transplant surgical complications as wound dehiscence or infections. There was a significant high incidence of the urinary tract infection rate in DM group (17 vs 32 patients; $P = .012$). Four out of 22 patients died (18.2%) in the DM group and 10 out of 47 patients died (21.3%) in the NDM group died from cardiovascular disease ($P = 0.17$). The 1-, and 10-year patient survival rates in the DM and NDM groups were 97.5% vs 99% (ns), and 56.8% vs 58.8% (ns), respectively. The 1-, and 10-year graft survival rates were 97.5% vs 70.7% (ns) and 58.9% vs 66.1% (ns), respectively.

Conclusions: Renal transplantation in diabetic ESRD patients yields good results in terms of patient survival and complications, suggesting that renal transplantation can be performed in these patients and should become a more established treatment option.

PUB660

Impact of Pre-Transplant Peritoneal Dialysis Compared with Hemodialysis on the Incidence of Delayed Graft Function in Kidney Transplant Recipients with Lupus Gabriel Contreras, Javier Pagan, Antonio A. Armstrong, Jorge M. Diego, Ian Thomas, Patricia Marie Byers, Alberto J. Sabucedo, Jair Munoz Mendoza, David Roth. *Univ of Miami Miller School of Medicine.*

Background: Delayed graft function (DGF) increases the risk of allograft failure in recipients of kidney transplants.

Methods: In this study, we assessed the impact of pre-transplant peritoneal dialysis (PD) compared with hemodialysis (HD) on the risk of DGF in patients with lupus using logistic regression models.

Results: Three hundred-fifty three of 2513 (14 %) recipients transplanted between 3/22/1994 and 9/27/2006 with complete records in the United Network for Organ Sharing files had DGF. The incidence of DGF was lower in recipients who used PD (68/613 = 11.1%) compared with HD (285/1900 = 15%) prior to transplantation (P = 0.013). After adjusting for donor and recipient age, gender and race-ethnicity, type of donor, recipient education and insurance, time of dialysis prior to transplantation, panel reactive antibodies (PRA), human leukocyte antigen (HLA) mismatch, and ABO blood type compatibility, the lower risk for DGF associated with the use of PD compared with HD remained significant (Odds-ratio 0.70 [95% confidence interval 0.53-0.94]; P = 0.015). Donor age (1.01 [1.00-1.02] per 1 year), deceased donor transplantation (3.64 [2.59-5.12] living donor as reference), HLA mismatch (1.08 [1.01-1.15] per 1 antigen mismatch), and PRA (1.01 [1.00-1.01] per 1%) were also independently associated with DGF.

Conclusions: In lupus recipients of kidney transplants, the use of PD compared with HD is associated with lower risk of DGF after adjusting for important predictors.

Association Between Dipstick Proteinuria and Allograft Outcomes in Living Donor Kidney Transplant Recipients Joon-sung Park, Jong Wook Choi, Chang Hwa Lee, Gheun-Ho Kim. *Dept of Internal Medicine, Hanyang Univ College of Medicine, Seoul, Republic of Korea.*

Background: Proteinuria is one of the important factors suggestive of kidney function impairment. Previous epidemiologic studies had demonstrated that greater than trace amounts of protein on a casual urine dipstick may be an important predictor of long-term clinical outcomes in general population. In kidney transplant (KT) recipients, there were few data concerning it.

Methods: Thus, we retrospectively analyzed 238 living donor KT recipients to investigate impact of dipstick proteinuria on allograft outcomes. All KT recipients were divided into 2 groups according to dipstick proteinuria: control group (n=190), negative; case group (n=48), ≥ trace. Cox's proportional hazard model with time-dependent covariates was used to encompass compounding effect of covariates that change over time, including vintage and allograft survival time.

Results: . As compared with controls, the change of estimated glomerular filtration rate was prominent in recipients with dipstick proteinuria after 3-year post-KT (-1.5 ± 7.1 vs. -4.4 ± 7.4 mL·min^{-1}·1.73 m-2·year^{-1}, P<0.0174).In Kaplan-Meier analysis, KT recipients in control group had a better dialysis-free survival as compared with cases (201 ± 6 vs. 164 ± 10 months; log-rank P=0.0118). In Cox proportional hazard models, trace or more dipstick proteinuria was closely associated with long-term allograft loss (HR=1.964, 95% *CI*=1.152-3.348), and further adjustment for age and gender did not attenuated this association (HR=1.764, 95% *CI*=1.050-3.065).

Conclusions: Our results may suggest that presence of small amount protein in urine may be the first sign of deteriorating allograft renal function.

Cytomegalovirus Exposure Is Associated with Immunological Sensitization in End-Stage Renal Disease Robert Lam,[1] Rita Suri,[2] Amitabh Singh,[1] Lakshman Gunaratnam.[1,3] *[1]Schulich Medicine & Dentistry, Western Univ, London, ON, Canada; [2]Univ of Montreal, Montreal, QC, Canada; [3]Matthew Mailing Center, London Health Sciences, London, ON, Canada.*

Background: The presence of antibodies to Human Leukocyte Antigen (HLA) is associated with long transplant wait-times, acute rejection, and poor graft outcomes. While prior transplant, pregnancy, and blood transfusion can trigger HLA antibodies, many sensitized patients have none of these known risk factors. Previous infections have been proposed as a potential cause of "spontaneous" sensitization, but this has not been well studied. Because cytomegalovirus (CMV) is known to modulate the host's immune defenses to avoid identification and clearance, we hypothesized that prior CMV exposure would be associated with HLA sensitization.

Methods: We conducted a cross-sectional study of 150 patients aged ³18 years attending a University Hospital renal pre- transplant assessment clinic over 16 months. Patients with prior transplant were excluded. Demographics, comorbidities, viral serology, peak combined Panel Reactive Antibody (cPRA), blood transfusions, and pregnancies were obtained by chart review; sensitizing events were confirmed by patient questionnaire. Logistic regression was used to identify potential risk factors associated with sensitization, defined as cPRA>20%.

Results: Mean age was 54.2±12.5 yrs, 61% were male, and mean years on dialysis was 2.7±4.2. Fifty percent were CMV IgG positive and 32% had cPRA>20%. A cPRA>20% was significantly associated with CMV positive IgG (adjusted odds ratio 2.8, 95%CI 1.3-6.6; p=0.012), prior pregnancy (adj OR 4.0, 95%CI 1.7-9.4; p=0.002), and blood transfusion (adj OR 3.9, 95%CI 1.7-8.7; p=0.001), whereas age, sex, hypertension, diabetes, and years on dialysis were not. In the subgroup of 83 patients with no previous pregnancy or blood transfusion, the prevalence of cPRA>20% was 24% in CMV positive patients, versus 12% in CMV negative patients (unadj OR 2.3, 95%CI 0.7-7.5; p=0.152).

Conclusions: We identified previous CMV exposure as a novel independent risk factor strongly associated with the presence of HLA antibodies. Whether CMV infection triggers HLA sensitization requires further study in prospective longitudinal studies.

The Role of Plasmapheresis in the Treatment of Recurrent Focal Segmental Glomerulosclerosis Juliana Busato Mansur,[1,3] Gustavo Ferreira da Mata,[1] Tainá Veras de sandes Freitas,[3] Gianna Mastroianni-kirsztajn,[1,3] Helio Tedesco Silva,[1,3] J. Medina-Pestana.[1,3] *[1]Nephrology, Federal Univ of Sao Paulo, Sao Paulo, Brazil; [2]Nephrology, Federal Univ of Sao Paulo, Sao Paulo, Brazil; [3]Nephrology, Hospital do Rim, Sao Paulo, Brazil.*

Background: Focal segmental glomerulosclerosis (FSGS) has a high recurrence rate after kidney transplantation (Tx).There is no established treatment, although plasmapheresis (PP),alone or with rituximab(RTX), is the most frequent therapeutic intervention. The purpose of this study was to evaluate the clinical-laboratorial profile and outcomes of patients diagnosed with rFSGS or with highly probable rFSGS submitted to PP.

Methods: Retrospective cross-sectional study involving patients with rFSGS submitted to PP between 2003-2014 at Hospital do Rim/UNIFESP.

Results: 70 patients (median age:29 years,5-62 years) were included. In 51%, FSGS was identified as the cause of ESRD. Proteinuria >0.5g/g and >3g/g was present, respectively, 15 and 64 days after kidney Tx; 70% of patients received a kidney from a deceased (DC)donor; cold ischemia time was 23 H(mean). Tacrolimus, prednisone, azathioprine/micophenolate were the most frequently used imunossupressive drugs. Incidence of DGF was of 70% and of 19% in cases of DC and living donor's, respectively. The 1st biopsy was on the 24th day (mean) post-Tx and the most prominent diagnosis were acute cellular rejection (21.9%) and acute tubular necrosis (29.7%),with only 17% of rFSGS. Histological diagnosis was confirmed on the 124th day and the beginning of the PP was on the 77th day;48% presented partial remission after 83 sessions;complete remission occurred in 22% of cases (means). Infectious episodes were the main complication during PP(69%).Part of the patients underwent methylprednisolone(80%)and RTX treatment(34%).The allograft survival in the 1st year was 70.8%, followed by 41.4% and 32.7% at 3 and 5 years respectively.

Conclusions: Laboratorial manifestations of rFSGS occurred early after renal Tx and preceded histological diagnosis. Treatment with PP was related to infectious episodes, low complete remission and important graft loss rates, which reinforces the need for further studies to determine a more efficient treatment.

Successful Treatment of BK Nephropathy with Tacrolimus and mTOR Inhibitors Natalia I. Polanco fernandez, Enrique Morales, Manuel Praga, Esther Gonzalez monte, Eduardo Gutierrez-martinez, Amado Andres. *Nephrology, Hospital Univ 12 de Octubre, Madrid, Spain.*

Background: BK nephropathy (BKN) is a relevant cause of graft dysfunction in kidney transplantation. mTOR inhibitors (mTORi) have been suggested as the best immunosuppression in BKN. However Tacrolimus-free therapy could increases risk of rejection. Since 2009 in patients with BKN we conducted a protocol discontinuing Mycophenolate and decreasing Tacrolimus (TAC) dose in association with mTORi, both with target levels of 5 ng/mL.

Methods: From 2007 to 2013 we diagnosed 22 BKN. Patients diagnosed since 2009 (n= 14, group 1) were treated beginning mTORi and decreasing TAC dose. The others 8 patients suffered significant reduction of immunosuppression (group 2). We analyze renal function, plasma quantitative BK PCR, antiHLA antibodies, rejections and dialysis or dead at final follow-up.

Results: 22 patients were identified. The BKN was diagnosed at 7th month after transplantation (range 2-55). The medium duration of follow-up was 53 months (6-85). Baseline characteristics and evolution are listed in table 1.

	Group 1 (n= 14)	Group 2 (n= 8)
Serum Creatinine at baseline (mg/dl)	1.3 ± 0.36	1.68 ± 0.57
AntiHLA antibodies positives at BKN diagnosis	43% (6)	12.5% (1)
Serum Creatinine at BKN diagnosis (mg/dl)	1.93 ± 0.37	2.4 ± 0.63
Serum Creatinine at final follow-up (mg/dl)	1.6 ± 0.7	3.2 ± 2.2
Dialysis at final follow-up	7.1% (1)	12.5% (1)
Plasma BK viral load at diagnosis (copies/ml)	84369 (10035-8234680)	20674 (10715-1543440)
Patients with negative plasma BK viral load at final follow-up	78.6% (11)	75% (6)
Acute rejection after BKN	0%	12.5% (1)

Although group 1 had a greater immunologic risk and a higher plasma BK viral load at diagnosis, the renal function during follow-up was more favorable than patients from group 2. No rejection episodes were diagnosis in group 1. Only one patient in each group started chronic dialysis at the end of the follow-up (52 and 85 months after BKN diagnosis).

Conclusions: An immunosuppression regimen based in TAC and mTORi is an effective and safety treatment in patients with BKN. This treatment reduces viral load and increases graft survival without increases the rejection risk.

PUB665

A Rare Case of Guillian-Barré Syndrome Associated with Cytomegalovirus Disease in a Renal Transplant Patient Jessica Bian, George P. Bayliss. *Medicine, Rhode Island Hospital, Providence, RI.*

Background: While cytomegalovirus (CMV) infection is associated with Guillian-Barré syndrome (GBS) in the general population, there are few reports of GBS associated with CMV disease in the renal transplant patients. We describe the case of one renal transplant patient who developed GBS after treatment for documented CMV disease.

Methods: The patient is a 62 year-old woman with ESRD from polycystic kidney disease status post deceased donor renal transplant (CMV donor positive/recipient seronegative) on tacrolimus and prednisone. She completed 6 months of CMV prophylaxis with valgancyclovir. Fourteen days after stopping valgancyclovir, she presented with fevers, myalgias, and headache. Tacrolimus level was 6.6 ng/mL on admission. She was diagnosed with CMV disease (serum CMV PCR 2200 copies; CSF CMV PCR undetectable) and started on treatment-dose valgancyclovir. Ten days later, she returned with numbness of her hands and feet. CSF studies were notable for albuminocytologic dissociation. MRI brain and spine was normal. Electromyography showed diffuse sensory motor polyneuropathy consistent with GBS. She developed ascending motor weakness, sensory loss, and areflexia without progression to respiratory compromise, improving with IVIG therapy. She was discharged to rehabilitation.

Results: She returned 7 days later with compartment syndrome of her right arm due to deep venous thromboses of her right subclavian, axillary, and brachial veins with associated hematomas requiring emergent fasciotomy and hematoma evacuation. This was attributed to recent IVIG therapy, as thromboses may occur even in the absence of other risk factors (US boxed warning). She was bridged to warfarin prior to discharge. Of note, she maintained excellent allograft function throughout this complicated course.

Conclusions: This vignette details a case of CMV-associated GBS after renal transplantation. The case is notable for the development of CMV disease shortly after cessation of valgancyclovir prophylaxis in a CMV donor positive/recipient negative renal transplant despite only being only being on a two-drug immunosuppressive regimen. This may support a longer course of CMV prophylaxis in donor positive/recipient negative transplants.

A Prolonged Warm Ischemia Time Is Associated with Graft Failure and Mortality After Kidney Transplantation Karthik K. Tennankore,[1] Joseph Kim,[2] Ian P. Alwayn,[3] Bryce A. Kiberd.[1] *[1]Medicine, Div of Nephrology, Dalhousie Univ, Halifax, NS, Canada; [2]Medicine, Div of Nephrology, Univ of Toronto, Toronto, ON, Canada; [3]Dept of Surgery, Multi-Organ Transplant Program, Dalhousie Univ, Halifax, NS, Canada.*

Background: Warm ischemia time is a potentially modifiable insult to transplanted kidneys, but little is known about its effect on long term patient and graft survival. The purpose of this study was to determine if a prolonged warm ischemia time was associated with death and graft failure after kidney transplantation.

Methods: We conducted a cohort study of adult kidney transplant recipients in the Scientific Registry of Transplant Recipients between 1/1/2000 and 12/31/2013. Warm ischemia time was defined as the time of organ removal from cold storage to reperfusion with warm blood, including surgical anastomosis time. Times were categorized as 0-10, 10-20, 20-30, 30-40, 40-50, 50-60 and ≥60 minutes. Acknowledging that times of <10 minutes were potentially attributed to coding error, 10-20 minutes was chosen as the reference group. The primary outcome was all-cause mortality and graft failure adjusted for recipient, donor, immunological and surgical factors.

Results: Overall, 131,677 patients were included and there were 35,901 events. Relative to patients with warm ischemia times of 10-20 minutes, a longer warm ischemia time was associated with an increased relative hazard for death or graft failure (table 1). The association between warm ischemia time and the composite outcome persisted after stratification by donor type (living versus deceased donor) and delayed graft function status.

Conclusions: Warm ischemia time is associated with long term patient and graft survival after kidney transplantation. Strategies to reduce warm ischemia time should be an important consideration for future study.

Table 1. Adjusted Cox survival analysis for death or graft failure

Warm Time (Minutes)	Death or graft failure Relative Hazard [95% CI]	Death censored graft Failure Relative Hazard [95% CI]
	Events: 35,901	Events: 20,032
0-<10	1.17 [1.09-1.26]	1.15 [1.04-1.27]
10-<20	Ref	Ref
20-<30	1.07 [0.99-1.15]	1.04 [0.94-1.14]
30-<40	1.13 [1.06-1.22]	1.13 [1.03-1.24]
40-<50	1.17 [1.09-1.26]	1.17 [1.06-1.29]
50-<60	1.20 [1.12-1.30]	1.23 [1.11-1.36]
≥60	1.23 [1.15-1.33]	1.25 [1.13-1.37]

Adjusted for donor type (living, standard, expanded criteria), donor race, donor sex, donor diabetes status, donor body mass index categories, number of human leukocyte antigen mismatches, panel reactive antibody categories, induction type, cold ischemia time, and recipient characteristics (age, sex, gender, cause of end-stage renal disease, dialysis vintage, diabetes, coronary artery disease, hypertension, cerebrovascular disease, peripheral vascular disease, chronic lung disease, prior malignancy, previous kidney transplant, body mass index categories)

Clinical Significance of Pre-Transplant 25-Hydroxyvitamin D Levels on Post-Transplant Clinical Outcome Tae Hyun Ban,[1,2] In-Ae Jang,[1,2] Bum Soon Choi,[1,2] Cheol Whee Park,[1,2] Chul Woo Yang,[1,2] Yong-Soo Kim,[1,2] Byung Ha Chung.[1,2] *[1]Internal Medicine, Seoul St. Mary's Hospital, Seoul, Korea; [2]Transplant Research Center, Seoul St. Mary's Hospital, Seoul, Korea.*

Background: It is well known that vitamin D shows immune modulating effects in various immunologic disorders and infectious disease. The aim of this study is to investigate the clinical significance of 25(OH)D levels on acute rejection or infection in kidney transplant recipients.

Methods: We included 174 kidney transplant recipients with low immunologic risk between 2011 and 2013. We measured 25(OH)D levels right before transplantation, and investigated whether the level of 25(OH)D predicts the development of acute rejection or infectious complications.

Results: During the first year after the KT, a total 27 cases of biopsy proven acute rejection was detected. 25(OH)D levels showed significant association with the development of acute rejection within the first year from KT. In the high tertile, the rate of acute rejection was 6.9 % (p=0.012). It was significantly lower incidence toward the high tertile. There was significant distinction between each tertile (low and second, p=0.032; second and high, p=0.002). For the prediction of infectious complications, after the 1 year predictive values of 25(OH)D levels were dissipated. During 1 year after KT, a total of 82 (47.1%) cases of infectious complications were detected. Most common causes were 23 (13.2%) cases of CMV and UTI respectively.25(OH)D levels did not show significant association with either the overall or different types of infectious complications.

Conclusions: Pre-transplant serum 25(OH)D levels are independent predictor of acute rejection in the first year from kidney transplantation. However, they were not associated with infectious episode.

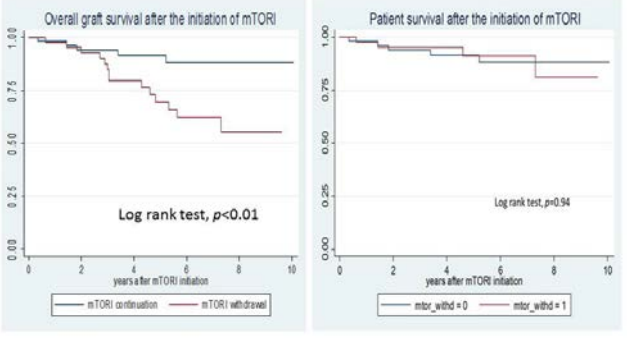
PUB668

Mammalian Target of Rapamycin Inhibitors Withdrawal in Kidney Transplant Recipients: Risk Factors and Related Transplant Outcomes
Lee-Moay Lim,[1] Mei-Chuan Kuo,[1,2] Hung-Tien Kuo.[1,2] *[1]Div of Nephrology, Dept of Internal Medicine, Kaohsiung Medical Univ Hospital, Kaohsiung, Taiwan; [2]Faculty of Renal Care, College of Medicine, Kaohsiung Medical Univ, Kaohsiung, Taiwan.*

Background: With its antiproliferative and antineoplastic properties, Mammalian Target of Rapamycin Inhibitors (MTORi) potentially have important long-term therapeutic consideration in kidney transplantation. Treatment cessation frequently occurs following its unique adverse effects. The objective of this study was to investigate the risk factors for MTORi withdrawal and its impacts on transplant outcomes.

Methods: This retrospective observational study consisted of kidney transplant recipients followed up from January 1999 till May 2015. We examined the risk factor for MTORi withdrawal using multivariate logistic regression analysis. The impacts of MTORi withdrawal on transplant outcomes were analyzed using multivariate Cox regression and logistic regression. $P<0.05$ was considered as statistically significant.

Results: A total of 111 kidney transplant recipients who received MTORi treatments were included, with 46 patients withdrew (41.0%). The risk factors for mTORi withdrawal included initial proteinuria (adjusted OR= 4.61, $P=0.007$), higher initial serum creatinine (per 1 mg/dl increment, adjusted OR=2.73, $P=0.035$), and glomerulonephritis as primary renal disease (adjusted OR=5.00, $P=0.035$). MTORi withdrawal was associated with an increased risk of graft failure (adjusted HR=3.79, $P=0.027$), but not with patient survival (adjusted HR=0.61, $P=0.595$).



Conclusions: MTORi withdrawal is a strong risk factor for renal graft failure. Proteinuria, poor initial graft function and primary renal disease of glomerulonephritis are predictors for MTORi withdrawal. Earlier identification of risk factors may assist physician to decide the best candidate for MTORi conversion in order to optimize transplantation outcomes.

PUB669

Impact of Donor Age on Longterm Outcomes in Living Donor Kidney Transplants: A Propensity Score Matched Analysis Using Multicenter Cohort
Kyung Don Yoo,[1] Jung Nam An,[1] Jang-Hee Cho,[3] Chan-Duck Kim,[2] Su-Kil Park,[3] Dong-Wan Chae,[1] Yun Kyu Oh,[1] Chun Soo Lim,[1] Yon Su Kim,[1] Young hoon Kim,[3] Jung Pyo Lee.[1] *[1]Seoul National Univ College of Medicine; [2]Kyungpook National Univ Hospital; [3]Asan Medical Center and Univ of Ulsan College of Medicine.*

Background: Recently, kidney transplantation from elderly living donor has been increasing. However, the impact of donor age on outcomes in kidney transplantation recipients has not been well established in Asian.

Methods: This multicenter cohort study included 2,595 adult kidney transplant recipients admitted to 5 major tertiary hospitals in Korea between 1997 and 2012. Patient survival, allograft survival, and biopsy-proven acute rejection (BPAR) were compared between the elderly donors (≥ 50 years) and young donors (18~49 years) by the propensity score matched (PSM) analysis.

Results: The proportion of donor with over 50 years was 21.2 % (N=553). The mean age in the elderly donor was 54.9 ± 4.3 years old. Despite of difference of donor age, mean recipient age was similar between the groups. Elderly donors were more likely to donate to unrelated recipients. The proportions of recipients with diabetes mellitus (22.8%), serum creatinine and BMI of donor were significantly higher in the elderly donor group than in the young donor-age group. In elderly donor group, recipients' patient survival was worse than younger age group before PSM (p=0.014). After PSM, donor age did not affect the recipient's survival (p=0.305) and allograft survival (p=0.077), however, BPAR was frequently occurred in the allograft from elderly donor (p=0.019). In the multivariate Cox regression analysis, elderly donor affected the BPAR-free survival (p=0.01, hazard ratio 1.52, 95% confidence interval 1.07-2.17).

Conclusions: Kidney transplantation from elderly donor needs more meticulous management, because donor age could affect acute rejection.

PUB670

Long-Term Outcome of Randomized Trial Comparing Cyclosporine and Tacrolimus Therapy with Steroid Withdrawal in Living-Donor Renal Transplantation: 10-Year Follow-Up
Jin Hae Kim, Jee Eun Park, Do Hee Kim, Hye Ryoun Jang, Jung Eun Lee, Dae Joong Kim, Yoon-Goo Kim, Ha Young Oh, Wooseong Huh. *Dept of Medicine, Samsung Medical Center, Sungkyunkwan Univ School of Medicine, Seoul, Republic of Korea.*

Background: The use of steroid withdrawal protocols after kidney transplantation has been increasing because of well-known adverse effects of steroids and the introduction of new effective immunosuppressants. Long-term efficacy and safety of tacrolimus plus mycophenolate mofetil (TAC group) compared with cyclosporine A plus MMF (CsA group) for 10 years were analyzed in renal transplantation patients with low immunologic risk who underwent steroid withdrawal at 6 months after operation.

Methods: Overall 10-year follow-up data of patients who underwent their first living-donor renal transplantation at Samsung Medical Center between September 2000 and August 2003 were retrospectively analyzed. Patients were randomized to CsA or TAC groups and underwent steroid withdrawal at 6 months after renal transplantation. End points were patient and graft survival, and the incidence of acute rejection and post-transplant de-novo comorbidity such as diabetes mellitus.

Results: A total of 117 patients who successfully discontinued steroid treatment were included (55 in CsA group vs. 62 in TAC group). The 10-year patient survival was 96.2% in the CsA group and 98.4% (61/62) in the TAC group (p=0.495). The 10-year graft survival rate did not differ between groups (81.3% in CsA vs 91.2% in TAC; p=0.412). The cumulative incidence of acute rejection for 10 years after transplantation was 24.5% and 15.6% in the CsA and TAC groups, respectively (p=0.201). The incidence of post-transplantation diabetes mellitus was higher in the TAC group compared to the CsA group (10.0% vs 23.3%, respectively; p=0.046).

Conclusions: Long-term graft and patient survival, and the incidence of acute rejection were similar between CsA- and TAC-based regimens combined with MMF in low immunologic risk patients who underwent steroid withdrawal 6 months after kidney transplantation.

PUB671

Dysregulation of Circulating Immunoglobulins in Renal Transplant Recipients
Mukut Minz,[1] Ravi Dhital,[1] Ranjana Walker Minz,[2] Ashish Sharma,[1] Ritambhara Nada,[4] Deepesh Kenwar,[1] Sarbpreet Singh.[1] *[1]Transplant Surgery, Post Graduate Inst of Medical Education and Research, Chandigarh, India; [2]Immunopathology, Post Graduate Inst of Medical Education and Research, Chandigarh, India; [3]Nephrology, Post Graduate institute of Medical Education and Research, Chandigarh, India; [4]Histopathology, Post Graduate Inst of Medical Education and Research, Chandigarh, India.*

Background: Peripheral levels of serum immunoglobulin reflect humoral immunity. Gross derangements in the immunoglobulin levels might occur in the post- transplant period.

Methods: Peripheral venous blood was periodically collected from patients before (pre-Tx) and after kidney transplantation at 1Month, 3 Months, 6 Months, 12 Months and at the time of Rejection. Serum was isolated from clotted blood after brief centrifugation at 3000g for 10 minutes. Serum level of IgM, IGA, IgG, IgG1, IgG2, IgG3 and IgG4 were quantified by Nephleometry (MiniNeph™, UK).

Results: This study includes 75 first kidney transplant recipients who were divided into two groups: Rejection group (R, n=35) and Non Rejection group (NR, n=35). Rejection group was further segregated as cellular (n=25) and antibody mediated (n=9). Thirty five age and sex matched healthy donors were recruited as control. No differences in the levels of IgG, IgA and IgM were noted in the pre-tx sera and healthy donor sera. Post- transplantation, there is an early decrease in serum IgG and IgA levels in both R and NR groups between 1- 3 months and the rate of decrease is higher in patients with rejecting grafts. IgG3 and IgG4 are significantly reduced during rejection (p= <0.0001 and 0.0006 respectively). IgG3 levels correlated with cellular rejection, while the rate of decrease of IgG2 and IgG4 was higher in antibody mediated rejection.

Conclusions: Post- transplantation: there is a fall in serum levels of IgA, IgG and its subtypes in both non rejecters and rejecters, more so in the later. Low serum levels of IgG3 and IgG4 could be a pointer to rejection. Significant correlation of IgG3 with cellular rejection embarks that IgG subtypes are dysregulated in cell- mediated rejection.

PUB672

Impact of Kidney Transplantation on Arterial Stiffness in Patients with ESRD
Hyunseon Kim, Chul Woo Yang, Byung ha Chung, Cheol Whee Park, Yong-Soo Kim, Bum soon Choi. *Div of Nephrology, Dept of Internal Medicine, Seoul St. Mary's Hospital, The Catholic Univ of Korea, Seoul, Republic of Korea.*

Background: Arterial stiffness is closely associated with cardiovascular mortality in end-stage renal disease (ESRD) patients, We investigated whether kidney transplantation (KT) can improve arterial stiffness in patients with ESRD.

Methods: We enrolled 171 KT recipients and we measured brachial-ankle pulse wave velocity (baPWV) and ankle-brachial blood pressure index(ABI) before KT, and post KT baPWV and ABI was assessed in a subgroup of 84 patients. First, we investigated cardiovascular(CV) events risk and established influence factors. Second, these patients divided into improvement and non-improvement groups based on change of baPWV after KT which was very strong marker of CV disease prediction. We also compared risk factors which affect arterial stiffness between two groups.

Results: 10 CV events occurred in the overall group, and 7 events in the post KT baPWV subgroup. Risk factors affected CV events of these group were diabetes, high body mass index(BMI) and high baPWV. Overall arterial stiffness measured by baPWV after KT showed significant improvement (1417.5 ± 234.5 cm/s) compared to those of before KT (1503.5 ± 255.2 cm/s) ($p<0.05$ vs after KT).55 out of 79 patients (69.6%) showed improvement of baPWV after KT, but 24 patients did not. Between two groups, improvement group showed higher pre-transplant baPWV than no-improvement group (1561.0 ± 263.9 vs. 1371.6 ± 177.1), and multivariate analysis revealed that gender and BMI, degree of decrement of calcium level were an independent risk factor of change of baPWV.

Conclusions: We could expect CV event risk in KT recipients by diabetes, BMI and baPWV, and these were very strong prediction marker of CV event. Arterial stiffness in ESRD patients improves after transplantation, and lower BMI, the amount of calcium decreased, gender affected the improvement of baPWV. PUB673

The Correlation of Donor:Recipient Body-Mass Index (BMI) Ratio and 6-Month Post-Transplant Kidney Function in Known End-Stage Renal Disease (ESRD) Patients Joseph justin Hipolito Regalado. *Internal Medicine, Cardinal Santos Medical Centre (CSMC), San Juan, Metro Manila, Philippines.*

Background: Kidney Transplant (KT) is the preferred treatment for ESRD. The challenge rests in finding appropriate donors. Donor-recipient size mismatch was shown to correspond to donor-recipient nephron supply mismatch, affecting prognosis. Matching nephron supply to recipient needs was proposed to improve outcomes. Patients with a higher BMI relative to their donors were shown to have poorer post-KT graft function. Determining whether measures such as BMI are valid predictors of outcomes is a legitimate area of study. This research sought to determine the association and correlation between Donor-Recipient BMI Ratio and the 6-month post-KT creatinine (crea).

Methods: A review of patients who underwent KT in 2005-2014 at the CSMC was done. Inclusion criteria were Filipinos aged 18 years and above with a graft, coming from a Living Donor, functioning for at least 6 months post-KT (25 Donor-Recipient pairs). Association using Chi-Square and correlation using Multiple Regression Analysis between Donor-Recipient BMI and renal function based on 6 months post-KT crea were determined.

Results: Data showed no statistically significant association ($p=0.64$) and correlation ($p=0.77$) between Donor-Recipient BMI ratio and post-KT crea. Statistically significant correlations ($p<0.10$) were noted between the post-KT crea and the recipient and donor BMI (strong correlation, $r=0.78$), with a 22.51umol/L increase in post-KT crea per 1 point increase in the donor BMI, and a 13.51umol/L decrease in post-KT crea per 1 point increase in recipient BMI.

Conclusions: The data support two schools of thought on donor-recipient selection in improving outcomes. First, recipients are to lose weight to improve BMI before KT due to the increased risk of graft damage from hyperfiltration and lipotoxicity. Second, donors with larger BMI's are better due to a higher nephron reserve. It could be surmised from the study that the donor and recipient BMI's influence the 6-month post-KT crea. The appropriate mathematical instrument defining the relationship between these measures predicting KT outcomes more accurately, however, is yet to be universally established.

PUB674

Incidence of Malignancies in Kidney Transplant Patients – Report from Eastern Province of Saudi Arabia Abdul Razack Amir.[1] *[1]Nephrology, Internal Medicine, Johns Hopkins Aramco Healthcare, Dhahran, Eastern, Saudi Arabia; [2]Internal Medicine, Univ of Dammam, Dammam, Eastern, Saudi Arabia.*

Background: Renal transplant patients have a higher incidence of malignancies due to the use of immunosuppressive medications and concommittent infections.

Methods: Based on the follow up of a single center in Saudi Arabia, the incidence of malignancies patients who underwent kidney transplantation was analyzed.

Results: During the 15 years study period, a total of 221 patients underwent renal transplantation. Eleven patients developed post-transplant malignancies with an average incidence of 4.9%. Two patients had Kaposi sarcoma (0.9%) and two developed Non-Hodgkins lymphoma (0.9%). One case was reported to have transitional cell carcinoma of urinary bladder (0.45%), one had breast cancer (0.45%), one had cervical cancer (0.45%), one developed angiosarcoma (0.45%), and one had hepatocellular carcinoma (0.45%). In addition, two patients developed renal cell carcinoma, one in the native kidney (0.45%), and the other in the transplanted kidney (0.45%). The duration to cancer development ranged from 6-120 months. Mortality rate in renal transplant patients with cancer was higher (55%) than those who did not develop cancer. Risk factors that determined cancer development included patient age, gender, duration of the transplantation and type of immunosuppression. Type of transplant was not found to be a determining factor of cancer development.

Conclusions: The incidence of malignancies in post renal transplant patients in the Kingdom of Saudi Arabia is evidently comparable to that reported in literature. In addition, the data highlights the importance of long term close follow up of renal transplant patients.

PUB675

Left Ventricular Global Longitudinal Strain as Early Detection of Subclinical Myocardial Dysfunction in Renal Transplant Recipients Secundino Cigarran,[1] Jose Lomban,[3] Ana Maria Sanjurjo Amado,[1] Diego Coronel,[1] Sheila Casas,[3] Juan Latorre,[1] Mª Milagros López hernández,[1] Jesus Calvino.[2] *[1]Nephrology, Hospital Da Costa, Burela, Lugo, Spain; [2]Nephrology, Hospital Lucus Augusti, Lugo, Spain; [3]Cardiology, Hospital Da Costa, Burela, Lugo, Spain.*

Background: Echocardiographic global longitudinal strain (GLS) is recognised as a technique to detect subtle changes in left ventricular function. As in CKD pts, kidney transplant recipients (TXKR) has an increased mortality risk by CV events. Early detection of CV risk is the utmost importance in the TXKR outcomes.The aim of this cross sectional study is to assess the grade of myocardial dysfunction in TXKR without previous CV events & normal left ventricular ejection fraction (LVEF).

Methods: 37 TXKR following >1 yr were included. 44.4% F, 24.5% DM, age 55.4±12.12 yo, GFR-EPI 51.93± 23.2 ml/min/m^2, No previous CV events & LVEF >55%.All of them on stable treatment with ACEI/ARB, CCHB, diuretics added to immunosuppressive drugs (TAC, CSA). Echocardiography 2D Vivid 9 (GE Vigmed Ultrasound ,Horten, Norway), was performed:GLS,LAVI (ml /bsa), E/e´, E/A,LVEF following recommendations of American Society of Echocardiography.Body composition analysis were performed by BIVA and serum biomarkers of inflammation,anaemia,mineral bone disease, renal function (GFR-EPI) and CV risk markers.Normal GLS (-20%) LAVI 24 ml/m^2 were considered as published for general population Rev Esp Cardiología 2014;67:651-8.

Results: Mean GLS was -18.6 ± 3.78%, LVEF 70.8 ± 8.7%,LAVI 30.16± 20.4 ml.GFR correlated negatively with GLS (r: -338, $P<0.016$) and LAVI (r: 372, $p = 0.14$). GLS progressed positive as GFR decline (P adjusted 0.025). E/E´ 13.06±6.48; E/A 0.93±0.28. Multivariate analysis was significant the relationship between GLS with ACR ($\beta = -.151$, $p =0.43$) e P excretion index ($\beta= .377$; $p = 0.14$).LAVI correlated with age ($\beta=.467$ $p= 0.004$), net acid load ($\beta= .345$; $p= 0.23$) and AGEs ($\beta=.314$; $p= 0.35$).No other correlations were met.

Conclusions: 66% TXKR show GLS >- 20% and 41.6 % LAVI > 24 ml/m2.GLS & LAVI echocardiography derived are two valuable measures to assess early subclinical myocardial damage in TXKD. GLS appears more sensitive predictor than LVEF.Studies on TXKD pts are required.

Seronegative Invasive Gastro-Intestinal Cytomegalovirus Disease in Renal Allograft Recipients – A Diagnostic Dilemma! Tissue PCR the Saviour? Anupama Kaul, Dharmendra Bhadauria, Narayan Prasad, Amit Gupta, Raj K. Sharma. *Nephrology, Sanjay Gandhi Post Graduate Inst of Medical Sciences, Lucknow, UP, India.*

Background: CMV as oppurtunistic infection affecting the gastrointerstinal tract is the most common cause for tissue invasive CMV disease occuring in 10-30% of organ transplant recepients. Gastrointerstinal CMV disease can be diagnosed in presence of clinical suspecion along with histopathological findings (CMV inclusions) and presence of mucosal lesion(s) on endoscopic examination with collaborative evidences via molecular technique.

Methods: Few cases of CMV infection affecting the gastrointerstinal tract show no evidences of dissemintion despite use of highly sensitive molecular techniques.

Results: We encountered 6 cases where in despite strong clinical suspecion of Gastrointerstinal CMV disease there were seronegative and endoscopic negative evidences for CMV ,blind tissue biopsy yeilded positive results for CMV disease with excellent improvement with antiviral therapy.

Conclusions: Blind biopsy specimen for tissue PCR could serve as saviour in an immunocompromised individiual who has a strong clinical symptomatology for GI-CMV disease in absence of viremia ,normal endoscopy and histopathology ,so that the early therapeutic interventions could help in excellent patient and graft survival.

PUB677

Allograft Outcome After Desensitization with IVIg: A Single Center Experience Nitender Goyal, Phanicharan Sistla, Anshul Bhalla, Wendy Mccallum, Richard Rohrer, Ronald D. Perrone. *Tufts.*

Background: The presence of antibodies to donor human leukocyte antigens (HLA) is a significant barrier to transplantation. High dose intravenous Ig (IVIg) is widely used for desensitization. There is no general consensus on the best approach for desensitization, and long-term data on efficacy of IVIg are unknown.

Methods: We reviewed kidney transplants done from Jan, 2010 to Dec, 2014 at Tufts. Sensitization was defined as PRA >20% and/or presence of donor specific antibody (DSA). Patients who were desensitized with IVIg were identified as cases; those without desensitization served as controls. No attempt was made to desensitize patients awaiting deceased donor kidneys. Baseline characteristics and follow up data were collected at months 3, 6, 12 and 24. A sensitivity analysis was done for patients who received a living donor kidney.

Results: There were 19 patients in the desensitized group and 37 patients in the control group. Mean age at transplant in two groups was 47±12 and 49±12 respectively. In the desensitized group, there were more patients with prior transplant (37% vs 22%), receipt of living donor (95% vs 54%) and positive DSA (89% vs 22%). One patient developed severe side effects from IVIg, requiring discontinuation. Leukopenia and BK viremia were

seen more in non-desensitized patients at 3 months, but significance was not sustained after 3 months (Table). The leukopenia effect was not significant when adjusted for steroid. There was no difference in eGFR in either group, however mean eGFR was higher in those desensitized. Incidence of rejection was very low in both groups (5% vs 8%). When living donor recipients from both groups were compared, the eGFR and leukopenia effect was similar in both groups, and there was no significant difference in BK Viremia.

	No desensitization	Desensitization	p-value
Leukopenia			
3 month	18(49%)	4(21%)	0.04
12 month	5(18%)	5(36%)	0.22
Mean eGFR(sd)			
3 month	61.2(19.5)	68.7(24.8)	0.26
12 month	63.7(20.2)	72.2(25.1)	0.29
BK Viremia			
3 month	7(19%)	0	0.04
12 month	3(12.5%)	1(8%)	0.65

Conclusions: Desensitization with IVIg appears to be safe and effective. The lower incidence of leukopenia in desensitized group can be explained by greater use of steroids.

PUB678

Results of Chinese Renal Transplant Recipients with Post-Transplantation Malignancies Lihui Qu, Hong Jiang, Jianghua Chen. *The Kidney Disease Center, The First Affiliated Hospital, Medical College, Zhejiang Univ, Hangzhou, Zhejiang, China.*

Background: Malignancies are a severe complication of immunosuppressive therapy among renal transplant recipients, representing an important cause of long-term morbidity and mortality.

Methods: A retrospective study of 2700 recipients who underwent renal transplantation between July 1977 and July 2013 was carried out. 51 patients developed the following malignancies at a mean of 55.2 months (range = 1-207) after kidney transplantation. According to the regimen of immunosuppressive agents, all the recipients occurred malignancies were divided into azathioprine group (Aza group, n =21) and mycophenolate mofetil group (MMF group, n=30). The recipient age, gender, interval from renal transplantation to tumor development, long term survival of patient and graft and the ratio of converting to rapamycin of patients were made a comparison in detail between two groups.

Results: 29 patients survived without a recurrence including 28 with graft function (Survival group, n=29), and 22 patients died of malignancies including 21 with graft function (Death group, n=22). In the survival group, only one patient lost the graft after 26 months after immunosuppressant adjustment due to chronic rejection. Renal graft function remained stable in all other patients from diagnosis throughout follow-up. Moreover, 10 patients in the survival group were switched from calcineurin inhibitor-based immunosuppression to rapamycin after the diagnoses of malignancy, otherwise no patient in death group switched to rapamycin. At a mean follow-up of 34.0 months (range = 4-74), all the 10 patients are cancer-free and survived with functional graft. The incidence of death was similar in the Aza group and MMF group.

Conclusions: Our results demonstrate that the incidence of malignancy in renal allograft recipients is much higher than normal population, closely related to the long term use of immunosuppressant. Treating cancer thoroughly and maintaining the function of the transplanted kidney can decrease the risk of death with functional graft. Rapamycin-based immunosuppression blocks the recurrence of nonmetastatic tumors.

PUB679

Basiliximab Induction Therapy, Graft and Patient Survival Sergio Santiago Pedroza-Orozco, Paloma Arleth Zavalza-Camberos, Benjamin Gomez-Navarro. *Nephrology and Transplantation, Inst Mexicano del Seguro Social, CMNO, Guadalajara, Jalisco, Mexico.*

Background: Basiliximab is widely used in clinical practice for induction therapy of renal transplant recipients, expecting to reduce the incidence of acute rejection and improved graft function without increasing adverse events. We evaluate the impact of induction therapy using Basiliximab on relevant clinical outcomes: graft and patient survival,incidence of acute rejection (AR) and incidence of infectious or malignancy complications.

Methods: This retrospective study included all renal allograft recipients who were transplanted between January 2010 and April 2014 and who received Basiliximab as induction therapy. We collected the baseline characteristic of recipients, type of donor, donor´s age, HLA matches and immunosuppression at the time of transplantation. The clinical outcomes were evaluated at the first year of transplantation and include: AR incidence, infectious or malignancy complications, serum creatinine and estimated glomerular filtration rate (eGFR) using the 4-variable MDRD formula, as well as graft and recipient survivals.

Results: The demographic characteristics of recipients and donors are in Table 1. Among 662 renal transplant recipients including in this study, only 10.6% (n=70) experienced AR during the first year follow up. The incidence of infectious complications in the first year after transplantation was 32.3%, mostly urinary tract infection (82%). No episode of malignancy was reported. Graft and patient survival rates were 96.9% and 98.5% respectively.

Recipients mean age (year ± DE): 26 ± 10
HLA matching number: 4 IQR 1
Type of donor: Living related 89% Living unrelated 7% Deceased 4%
Donor´s mean age (year ± DE): 38 ± 11
eGFR year 1 (mL/min/1.73m2): 82 ± 26 sCr year 1 (mg/dl): 1.2 ± 0.4

Conclusions: Our findings support previous studies, with similar incidence of AR episodes during the first year posttransplant, accompanied by a similar incidence of infectious and malignant complications, and similar patient and graft survivals at 1 year follow up. We can conclude that basiliximab is associated with excellent graft and patient survival and low rates of AR episodes.

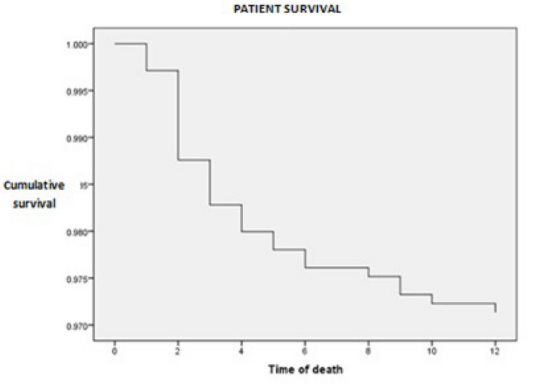
PUB680

Death within the First Year After Kidney Transplantation Paloma Arleth Zavalza-Camberos, Sergio Santiago Pedroza-Orozco, Benjamin Gomez-Navarro. *Nephrology and Transplantation, Inst Mexicano del Seguro Social, CMNO, Guadalajara, Jalisco, Mexico.*

Background: A successful kidney transplant improves the quality of life and reduces the risk of death in most patients when compared with staying on dialysis, however, the survival of transplant patients is lower than general population patients of the same age. This study was performed to evaluate mortality and characteristics of the dead patients.

Methods: It was a retrospective observational study that included all kidney transplant patients between January 1, 2010 to April 30, 2014, at HE-CMNO, IMSS, Guadalajara, Jalisco, Mexico. The follow-up time was one year. Mortality was calculated, the causes of death and characteristics of deceased patients were identified.

Results: During this time 1,047 transplants were performed. 30 deaths (2.86%)were recorded during the first year after transplantation. Regarding the type of donor: 12/102 (11.76%)patients with brain death donor died, and 18/945 (1.9%)patients with living donor died. The causes of death were 20 (66.66%)infections, 6 (20%)cardiovascular events, 2 (6.66%)related to graft rejection event and 2 (6.66%)unknown. The average time of transplantation to death was 2 months 27.4 days with a SD of ± 2 months 29.1 days; 70% of deaths occurred in the first 3 months after transplantation. The average time in dialysis was 5 years, with a SD ± 3 years 4.4 months; 83.3% of patients had more than two years on dialysis. Most patients who died had thymoglobulin induction, but patients were older, had more comorbidities, more time on dialysis, increased immunological risk and they had a brain death donor. Finally, 76.7% of patients who died had functional graft.



Conclusions: In our hospital, 1 year mortality postkidney transplantation is low, but there are many individual patient factors that contribute to the risk of mortality increases significantly in them and there we could intervene.

PUB681

Granzyme B Level and Acute Kidney Allograft Rejection: Impact on One Year Survival in Mexican Population Perla Edith Simancas Ruiz,[1] Caridad Aurea Leal,[2] Benjamin Gomez-Navarro.[1] *[1]Nephrology and Transplant, Inst Mexicano del Seguro Social, Guadalajara, Jalisco, Mexico; [2]Surgical Research, Inst Mexicano del Seguro Social, Guadalajara, Jalisco, Mexico.*

Background: Exposure to insufficient levels or discontinuation of immunosuppressants often increases the risk of rejection. Creatinine is the most useful test to monitor graft function. However, it is a poor predictor of rejection and often raises only after significant damage has occurred to the graft, so the identification of early biomarkers is mandatory. Granzyme B has been tested as a marker of acute rejection, with high specificity and sensitivity in different types of sample and has also enabled the identification of subclinical

rejection. The elevation of both the mRNA and protein has been associated with a worse prognosis of allograft. **OBJECTIVE**: Explore the association between serum levels of Granzyme B and acute rejection after one year post-transplant.

Methods: Kidney recipients transplanted between January 2008 and March 2009. Donors (n=38) and healthy subjects (n=6) were also included. The relation of granzyme B levels determined by ELISA with graft function and rejection was studied.

Results:

Receptor age (n=94)	26 ± 10 yr
Induction therapy: Basiliximab Daclizumab Thymoglobulin	 46% 39% 2%
CMV High Moderate Low	 21% 72% 7%
One year creatinine	1.66 mg/dL
Rejection: Borderline Banff 1A Banff ≥1B	46% : 31% 56% 14%
Chronic nephropathy	46%

Granzyme level in patients (n = 43) was 12.5 pg/ml while the reference group (n = 6) was 1.5 pg/ml (p <0.001). Comparison between patients with rejection (n = 14) and non-rejection (n = 20) was not statistically significant, nor the development of interstitial fibrosis year. The correlation between creatinine, GFT and granzyme level showed a trend to significance (n = 66, r = 0.30, p = 0.06).

Conclusions: The level of granzyme B was not associated with one year post-transplant rejection. However immune system activation is suggested by the higher level of granzyme in patients vs control group. Continuous analysis of patients.

PUB682

Epidemiological Analysis of Post Transplant Glomerulonephritis Pratik Das, Santosh Kumar, Rohit Rungta. *Nephrology and Transplantation, Rabindranath Tagore International Inst of Cardiac Sciences, Kolkata, West Bengal, India.*

Background: Post-transplant glomerulonephritis is an important cause of graft dysfunction and consequent graft loss. Aim of the study is to identify the incidence and outcome of glomerulonephritis in post-transplant patients.

Methods: We retrospectively evaluated all the patients who underwent renal allograft biopsy between January 2010 to January 2014, for graft dysfunction, proteinuria or active urinary sediments. All protocol biopsies were excluded from the study. Graft biopsies were evaluated by light microscopy and indirect immunofluorescence study. Out of 285 graft biopsies 242 biopsies were taken into study. Biopsies showing evidences of glomerulonephritis were further evaluated for incidence of individual types of glomerulonephritisand their outcome at the end of one year post diagnosis.

Results: Based on biopsy findings among 242 renal allograft biopsies taken in study 42(17.35%) had post-transplant glomerulonephritis. Further the incidence of individual glomerulonephritis were 14(33.3%) for focal segmental glomerulosclerosis, 13(31%) for IgA nephropathy, 8(19%) for mebranoproliferative glomerulonephritis, 4(9.6%) for pauci-immune crescentic GN, 2(4.8%) for anti-glomerular basement membrane disease and 1(2.3%) for membranous nephropathy. On follow up for one year 30(71.4%) patients lost their graft and became dialysis dependent irrespective of treatment. When compared to this outcome with other causes of graft dysfunction (rejection or infection) , results are inferior in terms of graft and patient loss.

Conclusions: We conclude that post-transplant glomerulonephritis is strongly associated with poor kidney allograft survival. Therefore, optimal management of recurrent or *de novo* glomerulonephritis should be the critical focus of post-transplant care.

PUB683

Impact of Hemoglobin Concentration on Mortality After Renal Transplantation Vitoria C. Vilela,[1] Marcos A. Meniconi,[1] J. Medina-Pestana,[1] Miguel Cendoroglo Neto,[1,2] Miguel A Goes.[1,2] *[1]Nephrology Div, Federal Univ of Sao Paulo, Sao Paulo, Brazil; [2]Nephrology Div, Hospital Israelita Albert Einstein, Sao Paulo, Brazil.*

Background: Kidney transplant recipients have chronic anemia, irrespective of the time from transplantation. Objective: To assess the impact of hemoglobin concentration on mortality after renal transplantation.

Methods: A total of 233 patients who underwent renal transplantation at one center (Hospital do Rim) were prospectively analyzed. Follow-up time was 6 years, from January 2008 through December 2014. Data on demographics, ESRD etiology, pre-transplantation dialysis, transplant characteristics, and immunosuppression regimen. Two-sample t test were used to compare differences between two groups (mortality versus non-mortality groups) and X^2 to analyze categorical variables. Binary logistic regression was used to determine the impact of factors on outcome-mortality.

Results: The main causes of ESRD were diabetes (35%) and hypertension (20%). Transplants from living donors occurred in 59%. During the entire follow-up period, there were 24 (10%) deaths within 3+1 yr after renal transplantation. 7 (29%) from cardiovascular disease and 17 (71%) died from infection. We observed that mortality group were older (p<0.001) and longer time on dialysis (4+2.5, 2.5+2.0 yr; p=0.006). Hemoglobin (Hb) concentration was lower in mortality (10.7 +2.3) than non-mortality (12.0+2.42; p=0.01) group**.** Patients who used mycophenolate had lower mortality (p = 0.04). There is no correlation between Age and Hb (r=-0,02; p=0,8). Age (p = 0.01) and Hb concentration (p =0.02) were independent predictors of mortality.

Conclusions: This study shows that a lower Hb concentration is an independent predictor of mortality in renal transplant patients.

PUB684

Prediction of Recipients Survival in Deceased Donor Kidney Transplant Using Korean Network for Organ Sharing Database Kyung Don Yoo,[1] Junhyug Noh,[2] Hajeong Lee,[1] Dong Ki Kim,[1] Chun Soo Lim,[1] Young hoon Kim,[3] Yon Su Kim,[1] Gunhee Kim,[2] Jung Pyo Lee.[1] *[1]Seoul National Univ College of Medicine; [2]Seoul National Univ College of Engineering; [3]Univ of Ulsan.*

Background: The Korean Network for Organ Sharing (KONOS) was founded in 2000 for organ allocation in Korea. It has been allows medical doctors and researchers to fully access the national population-based raw data about KT recipients. We propose a novel prediction approach of recipient survival based on machine learning techniques using KONOS data.

Methods: Our dataset is collected from 2000 to 2014 by the KONOS. We design a novel prediction model that uses all of the follow-up recipients' data including censored ones, on which estimated death risks are weighted accordingly. We compare this approach with the baseline model that uses only uncensored data by the CART (Classification And Regression Trees) modeling.

Results: We analyze 5,430 recipients' records with more than 31 attributes, among which we choose 15 independent attributes to learn our models. The proposed weighted algorithm leads a better performance when predicting survival rates of transplant recipients within 6 years, but fails to show any significant difference from the baseline for those more than 7 years after transplantation. Using the decision-tree models, we find that the inotropic agent usage of donor management is the most important predictor, which estimates in 51.3% of 10-year mortality. In the age ≥51.5 group, non-diabetes recipients, waiting period < 4years, and donor age < 23.5 years show significant associations with better 10YRS. The results are consistent with our hypothesis that poor donor status, recipients' longer waiting time and advanced age are associated with poor prognosis.

Year after transplantation	1	3	5	7	9
Baseline model AUC	0.644	0.665	0.759	0.832	0.862
Weighted Model AUC	0.653	0.678	0.777	0.822	0.794

Conclusions: In this study, we show that the proposed machine learning based models with weights of estimated-death risks can present more accurate and flexible than baseline models for predicting in long-term survival rates of kidney transplant recipients.

PUB685

Perforin Expression in Renal Allograft Biopsies Michele T. Rooney,[1] Ping L. Zhang,[2] Dilip Samarapungavan,[3] Randolph Alexander Hennigar.[4] *[1]Incyte Diagnostics, Spokane, WA; [2]Anatomic Pathology, William Beaumont Hospitals, Royal Oak, MI; [3]Nephrology, William Beaumont Hospitals, Royal Oak, MI; [4]Nephropathology Associates, Little Rock, AR.*

Background: Perforin is a cytotoxic protein in effector lymphocytes that facilitates targeted cell killing and it has an established role in allograft rejection. A diagnostic value has not been delineated. We examined perforin expression in renal transplant biopsies by immunohistochemistry (IHC) and found that positive lymphocytes are confined largely to the microvasculature in cases of active cellular rejection (ACR). The goal of this study is to investigate whether perforin IHC is a useful metric in identifying and classifying acute rejection in renal transplant biopsies.

Methods: Renal transplant biopsies accessioned over a one-year period were selected to include cases showing no acute rejection, acute tubular injury, BK nephritis, ACR types 1 and 2, and C4d+ antibody-mediated rejection (AMR), according to the 2013 revised Banff Classification. IHC using a mouse monoclonal anti-perforin antibody was performed on each case. Perforin positive cells/10 high power (400X) fields (hpf) were counted from slides identified by number only.

Results: Most rejection-negative cases had < 10 perforin-positive cells/10 hpf. Biopsies showing type 1A ACR, excluding one outlier, did not exhibit a significant increase in perforin-positive cells relative to rejection-negative cases. In contrast, cases of type 1B and 2 ACR, and C4d+ AMR displayed significantly increased perforin-positive cells (p = 0.0001) with most showing > 40/ 10 hpf. Cases of AMR contained the highest number of perforin-positive cells (p = .0352). Cases of BK nephritis varied widely from < 10 to > 50/ 10 hpf. 2 of 3 cases with > 50 had a recent history of ACR developing BK infection upon increasing immunosuppression, raising the possibility of coexisting BK and rejection.

Conclusions: Further study is needed, but our data suggests that increased numbers of perforin-positive lymphocytes correlate with more aggressive forms of rejection, and that perforin IHC may be a useful ancillary test for acute allograft rejection of type 1B or higher.

PUB686

Is It Safe to Transplant Sensitized Patients? Analysis of 1,002 Consecutive Kidney Transplants Anna Rita Aguirre, Patricia Soares Souza, Fabiana Agena, Daisa R.S. David, Flavio Jota Paula, Elias David-Neto, Maria Cristina R. Castro. *Renal Transplant Service, Hospital das Clinicas - Univ of Sao Paulo School of Medicine, Sao Paulo, Brazil.*

Background: From 2009-13, 24% of kidney recipients in our center had antiHLA antibodies(aHLA abs). Obj: To compare the risks of rejection, patient and graft survival when transplants(Tx) were performed with or without aHLA abs and with or without DSAs. To compare mortality between patients transplanted with aHLA abs to mortality in the waiting list.

Methods: Retrospective study, which included all isolated kidney Tx in patients older than 18yo, performed between jan09 and dec13(N1002). We analysed the incidence of TCMR and ABMR in the 1st year after Tx. Median follow-up time was 32mo. Graft and patient survival were evaluated by Kaplan Meyer estimates.

Results: In 741 Tx(74%), no aHLA abs were detected(ARP=0) and 261(26%) had PRA>0. Among Tx with PRA=0, 658(89%) did not have rejection in the 1st year, 77(10,4%) had TCMR and 6(0,81%) had ABMR. Among Tx with PRA>0 without DSAs(149), 129(86,6%) did not have rejection, 16(11%) had TCMR and 7(4,7%) had ABMR. In Tx with PRA>0% with DSA(91), 58(62,4%) did not have rejection, 7(7,5%) had TCMR and 31(33,4%) had ABMR. ABMR was more frequent when there was a DSA($p<0,0001$). Graft survival did not differ according to ARP or DSA in groups with no rejection, TCMR and ABMR. There were more graft losses in the whole sample when a DSA was detected($p<0,0001$) or when RAMA occurred, in comparison to no rejection($p<0,0001$) and TCMR(p 0,0143) . Regarding patient survival, there was no influence of aHLA abs and DSAs, nor influence of TCMR or ABMR. In recipients with aHLA abs, mortality was 11% in 32mo, or 4,12% per year, smaller than in the waiting list in our state, which was 5,61% in the same period.

Conclusions: There was no difference in patient survival after 32 mo between patients with or without aHLA abs or DSAs, or even between patients with or without ABMR. However, there were more graft losses in recipients with aHLA abs and with ABMR. Mortality after Tx among sensitized patients hasn't been larger than in the waiting list. We conclude that transplanting the sensitized patient does not increase mortality risk.

PUB687

Response of Anti Blood Group Antibodies to Desensitization Procedures and Kidney Transplantation Bharat V. Shah, Zaheer Amin Virani, Prashant J. Rajput. *Inst of Renal Sciences, Global Hospitals, Mumbai, Maharashtra, India.*

Background: ABO-incompatible (ABOi) kidney transplantation (KT) is option for overcoming the shortage of organ donors. Before performing ABOi transplant, it is important to reduce anti-blood group antibody titers (ABGAT) by desensitization. The aim of our study was to determine: 1) Baseline ABGAT in patients undergoing ABOi KT, 2) Response of ABGAT to desensitization and 3) Behavior of ABGAT after KT.

Methods: Nineteen (13 male and 6 female) ABO-I patients (6-O, 8-A and 5-B blood groups) studied. The IgG and IgM ABGAT were determined using column agglutination technique (CAT). Desensitization was attempted if baseline IgG ABGAT > 1:32. For desensitization, besides rituximab, Plamapheresis (PP) and/or Glycosorb was used. Desensitization considered successful if IgG ABGAT dropped to < 1:32. ABGAT monitored daily or alternate days for 1 week after transplant, twice a week in the 2nd week and weekly for next 2 weeks.

Results: The baseline IgG antibody titres ranged from 1:4 to > 1:512 (median 1:64) while IgM antibody titres ranged from 1:2 to > 1:512, (median 1:32). In one case with baseline titre <1:4 no desensitization was done. In 15 cases, PP alone was attempted. In 3 of these cases (with baseline titre > 1:512), the titres could not be reduced to < 1:32 and transplant was not done. Based on this experience, we used Glycosorb with or without PP in next 3 cases with titres > 1:512. All of these 3 cases could be desensitized. Of the 16 patients who were transplanted, the titres remained < 1: 64 (median 1:8) after transplant in 15. None of them required PP or Glycosorb treatment after transplant. In one patient, IgG ABGAT rose to > 1:128 in the first week after KT. Biopsy was suggestive of acute antibody mediated rejection and was treated with PP, Rituximab and Bortezomib.

Conclusions: Majority of our patients have low baseline ABGAT. In cases with low ABGAT, Rituximab (2 doses of 200 mg weekly) and 2 to 3 sessions of PP bring down titres to < 1:32. For baseline titres > 1:512, use of Glycosorb may be required. After KT titres remain < 1:64 in most and this is not associated with any graft dysfunction. One may consider an allograft biopsy if IgG ABGAT is > 1:128 in the first 2 weeks.

PUB688

Temporal Characteristics of End Stage Renal Disease due to Tuberous Sclerosis in United States, 2001- 2010 Donna J. Claes,[1] Sarah J. Kizilbash,[1] Hassan N. Ibrahim,[2] Robert N. Foley,[2] Scott Reule.[2] *[1]Pediatrics, Nephrology, Univ of Minnesota, Minneapolis, MN; [2]Internal Medicine, Nephrology, Univ of Minnesota, Minneapolis, MN.*

Background: Tuberous sclerosis (TS) is an autosomal dominant, multisystem disorder characterized by hamartomas in various organs with renal involvement occurring in approximately 50 to 80% of patients. Although renal involvement may result in end-stage renal disease (ESRD), studies examining the characteristic of ESRD in patients with TS are limited.

Methods: Census data was combined with data from the USRDS for all patients diagnosed with ESRD from 2001-2010 (n=1,072,161). A total of 367 patients with ESRD due to TS were identified. Incidence rates and standardized incidence ratios (SIR) were computed using Poisson distribution and standardized using 2001-2002 as reference. Hazards ratios adjusting for age, sex, race and ethnicity (AHR) were calculated for outcomes.

Results: In 2001-2002, the overall incidence rate of ESRD due to TS was 1 per 10 million person years (PMPY) and the SIR remained largely unchanged over the observation period. Those with ESRD due to TS were more likely to be < 40 years (23.2% vs. 9.2%), white ethnicity (81.5% vs. 65.5%), and lack diabetes (81.2% vs. 48.1%). Compared to those with ESRD due to other causes, odds ratios adjusted for age, sex, race and ethnicity (AOR) were highest for females (1.83) and those with eGFR > 15ml/min (1.31). Factors associated lower AOR included age 40-64 years (0.29), age ≥ 65 years (0.25), and black race (0.33). Over the study period, 53.7% of TS patients died, 27.3% were listed and 10.6% were transplanted. The AHR for outcomes demonstrated those < 40 years of age were more likely to be listed for renal transplant, receive renal transplant and survive.

Conclusions: The incidence of ESRD due to TS remained largely unchanged from 2001 through 2010. Our results indicated gender and racial differences in the odds of ESRD due to TS.

PUB689

The Impact of Hepatitis C Virus Infection on the Clinical Course, Short-Term and Long-Term Outcome in Renal Transplant Recipients – A Retrospective Study Pratik Das, Rohit Rungta, Santosh Kumar. *Nephrology and Transplantation, Rabindranath Tagore International Inst of Cardiac Sciences, Kolkata, West Bengal, India.*

Background: Hepatitis C infection is common in patients of end stage renal disease with increased morbidity and mortality post-transplant. The aim of the study was to find out the impact of HCV infection on graft and patient outcome and compare it with the non HCV infected post-transplant cohort.

Methods: We retrospectively analysed patient and graft survival of HCV infected (after virological remission) post renal transplant patients from 2008 to 2014 with a median follow up of 24 months and compared them with our HCV negative statistically matched cohort.

Results: Outcome analysis was done at 6, 12, 18 and 24 months in terms of liver dysfunction, acute rejections, infections, hospitalization and death. Results were further tabulated as shown.

VARIABLES	HCV positive patients	hcv negative patients	P value
1.Patients(n)	51	1381	
2.Induction with ATG	26(50%)	700(50.68%)	NS
3.Tacrolimus	34(66.67%)	1196(86.9%)	<0.05
4.Cyclosporin	17(33.3%)	185(13.1%)	<0.05
5.Infection	05(9.8%)	117(8.5%)	NS
6.Abnormal LFT	08(15.6%)	NA	-
7.1 year patient survival	96.1%	97%	NS
8.2 year patient survival	92%	93.2%	NS
9.Hospitalization	24 episodes	621 episodes	NS

Results were found not to be statistically different from non HCV infected renal allograft recipients.

Conclusions: HCV infected end stage renal disease patients may undergo renal transplantation safely after virological remission and outcome is not different from other renal transplant recipients.

PUB690

Patient and Graft Survival in Pediatric Kidney Transplantation: A Single-Center Experience According to Transplant Era Marta Monteverde,[1] Juan Carlos Lopez,[1] Gerardo Nyman,[1] Liliana Briones.[1] *[1]Nephrology Unit, Hospital JP Garrahan, Buenos Aires, CABA, Argentina; [2]Urology Unit, Hospital JP Garrahan, Buenos Aires, CABA, Argentina.*

Background: Improvements in the management of kidney transplantation has improved in the last 20 yeras. However the long term results in terms of graft survival and morbidity still require more research.

Methods: We evaluated 744 pediatric renal transplants (RTX), 551 with deceased donor (DD) and 222 with living-related donor (LRD), between 1988- 2015. We divided this time in 2 periods: 1988-2000 and 2001-2015. Patient and graft survival were calculated for each period for LD and DD recipient. We analyzed causes of mortality, causes of graft failure and risk factors for graft loss. Mean age at RTX was 11.6 y (r: 3.7-19.5). Median time of follow-up was 54.5 months (IQR: 22.4-90.1) months.

Results: Patient and graft survival for DD have significantly increased in the recent era ($p=0.0002$; $p=0.0013$ resp).Chronic rejection was the first cause of graft loss in both eras (61.9% vs 61.11%); Vascular thrombosis decreased (14.9% vs 5.5%; p= <0.001), and also Death with a Functioning Graft (15.8% vs 8.3%; p=<0.001). Acute rejection during the first 30 days post RTX + relapse of the original disease increased (0% vs 9.7%). First cause of death in both eras was bacterial infection (77% vs 66%). No death due to PTLD were seen in 2001-2015. Independent Risk factors for graft loss for DD recipients were: FSGS

as cause of ESRD (HR: 3.1; CI 95%: 2-4.8), DGF (HR: 2.8; CI 95%: 2-4) and Receiving no induction therapy (HR: 2.1; CI 95% 1.3-3.5). For LRD recipients: DGF (HR: 5.2; CI: 2.9-9.3) and Age at RTX > 12y (HR: 2.2; CI95%: 1.2-3.9).

Conclusions: Patient and graft survival has significantly improved for DD in the recent era. Chronic rejection remains a major cause of graft failure. No death from malignancy were observed in the recent era.

Graft Survival	1y (% SE)	3y (%SE)	5y (%SE)	7y (%SE)	10y (%SE)
LD(1988-2000)	97 (0.001)	90.5 (0.02)	85 (0.03)	78.2 (0.03)	65.3 (0.04)
LD(2001-2015)	96 (0.02)	90 (0.03)	87 (0.03)	80.6 (0.06)	76.1 (0.07)
DD(1988-2000)	83.2 (0.03)	74.5 (0.03)	67.9 (0.03)	62.6 (0.03)	51 (0.04)
DD(2001- 2015)	94.7 (0.01)	86.8 (0.02)	82.7 (0.02)	74.5 (0.03)	58.6 (0.07)

PUB691

Impact of Rituximab Induction on Short Term Outcome of Kidney Transplant Recipients Bharat V. Shah, Prashant J. Rajput, Zaheer Amin Virani. *Inst of Renal Sciences, Global Hospitals, Mumbai, Maharashtra, India.*

Background: Acute graft rejection remains a major problem in kidney transplant (KT) recipients. Induction with Thymoglobulin or Basiliximab is a KDIGO recommendation to minimize the risk of acute rejection. However, these induction agents do not eliminate the risk of antibody mediated rejection. Recent studies of ABO incompatible (ABOi) transplant using Rituximab, in addition to standard induction and maintenance immunosuppression (IS) have shown better outcome than ABO compatible (Kohei N, Tanabe K Am J Transplantation 2012; 12: 469-476) transplants. Therfore our aim was to study efficacy and safety of Rituximab induction in addition to single dose Thymoglobulin induction in living donor (LD) KT patients.

Methods: The study included 53 adult LD KT recipients transplanted between 3/1/14 and 2/28/15 and followed for at least 3 months after KT. Of these, 39 were (ABOc) transplants and 14 were (ABOi) transplants. Rituximab 200 mg was given within a week before transplant. ABOi recipients received an additional 200 mg Rituximab on the day of transplant. Thymoglobulin 1 mg/kg was used only on the day of transplant. Maintenance immunosuppression included Tacrolimus, MMF and tapering doses of prednisolone in all. All patients received valgancyclovir and cotrimoxazole prophylaxis. The short term outcome of these patients (Ritux group) was compared to that of 53 historic controls (control group) who received only thymoglobulin 1 mg/kg on the day of KT.

Results: There was no difference in characteristics (age, sex, etiology of CKD, donor characteristics, HLA mismatch) of patients in the 2 groups. Six patients in the Ritux group developed acute rejection (5, cellular and 1 antibody mediated). Six patients in the control group developed acute rejection (2 cellular and 4 antibody mediated). The patient and graft survival at 3 months was 100% in Ritux group. The patient survival was 100% in control group. One graft was lost from antibody mediated rejection in control group. Infections within 3 months after KT were similar in both groups.

Conclusions: Rituximab induction is safe in KT. It reduces the risk of antibody mediated rejection without increasing infectious complications in the early period after KT.

PUB692

Epo Use in Pregnant Renopancreas Transplant Patients Amelia R. Heguilen, Alicia M. Lapidus, Liliana Susana Voto, Ricardo M. Heguilen. *Medicine, Hospital Juan A. Fernandez, Buenos Aires, Argentina.*

Background: Pancreas-kidney transplantation (Tx) improvemes life and reproductive function. Anaemia (AN) is common in this population. Prenatal counselling address potential fetal complications; as well as worsening anaemia, hypertension, preeclampsia, gestational diabetes, acute rejection or graft loss. The aim of this study was to evaluate the use of Erythropoietin (rHuEpo) during pregnancy in Tx recipients.

Methods: Four double Tx (cadaveric donor) recipients, underwent successful pregnancies after a complex medical history of diabetes in their childhood with retinopathy & polyneuropathy, two with hypothyroidism, and end stage renal disease. They were all switched into a pregnancy-friendly schedule with azathioprine, tacrolimus and low prednisone dose. Iron supplements (IS) and rHuEpo were prescribed because of anaemia progression. Because of hypo-responsiveness to rHuEpo, doses were incresed to 8000 U/ week in the 4 pt.in the third trimester.

Results: Serum creatinine (mg/dL) remained initially stable (1.28 ± 0.1); increased near delivery (36.2 wks) to 1.45 ± 0.1 and remained (1.32 ± 0.09) mg /dl postpartum. Blood pressure also increased near term without need of medication, serum uric acid rose to 6.2 ± 0.6 mg/dl and mild proteinuria (550 ± 155 mg/d) developed. They were all normoglycemic, with normal pancreatic and hepatic function throughout pregnancy and postpartum. rHuEpo and IS were stable mothers H^{to} (24.7%) and HB (8.2 g/dl) with normal ferric parameters. and reticulocytes. Fetal heart rate was normal. One pt developed preterm premature rupture of membranes; all pt delivered vaginally healthy babies, weight: 2100 ± 320 g. (IUGR) with no evidence of congenital anomalies. There was no postpartum hypertension and they continued with stable renal and HCT parameters. Three months later serum creatinine returned to baseline and no proteinuria was detected. rHuepo need to be decreased in all pt. postpartum, newborns outcome was uneventful.

Conclusions: According to our study the administration of human recombinant erythropoietin has a beneficial effect in pregnancy without side effects. Preterm delivery, IUGR and low birth weight are common in this population probably due to other drug adverse effects.

PUB693

Acute Rejection Incidence in Deceased Kidney Transplant Recipients with Delayed Graft Function After Single Dose Thymoglobulin Igor Gouveia Pietrobom, Laila Almeida Viana, Cinthia Montenegro Teixeira, Andre Caires Alvino Lima, Mayara Ivani de paula, Geovana Basso, Tainá Veras de sandes Freitas, J. Medina-Pestana, Helio Tedesco Silva. *Hospital do Rim, Federal Univ of Sao Paulo, São Paulo, Brazil.*

Background: Thymoglobulin (rATG) induction has proven efficacy. However, it remains unclear what is the best dosing regimen.

Methods: From August 8th, 2014 immunosuppression protocol was changed at our institution to induction with single dose thymoglobulin to all deceased donor kidney transplant recipients. This retrospective study evaluated the incidence of acute rejection (AR) in deceased kidney transplant recipients with delayed donor graft function (DGF) before and after the adoption of a new induction protocol.

Results: Pre-protocol Group 1 - 96 patients transplanted between 12/31/2013 and 08/08/2014; Standard criteria deceased donors (SCD) (without induction, tacrolimus 0.1mg/kg/dose, prednisone and azathioprine) or expanded criteria deceased donors (ECD) (induction with thymoglobulin 6mg / kg, tacrolimus 0.05 mg/Kg/dose, prednisone and mycophenolate sodium) versus Group 2 (new protocol) , 87 patients transplanted between 08/08/2014 and 03/31/2015, subdivided in the same way, receiving the same maintenance therapy and thymoglobulin induction 3mg/kg single dose. In both groups, the population was overwhelmingly male (63% vs. 55%), young (47 vs. 46 years) and low immunological risk. The incidence of AR in G1 vs. G2, SCD subgroup was 13%, vs. 4% (p = 0.09). When compared ECD recipients, the incidence of rejection was similar between G1 vs. G2 (15% vs. 14%, p = 1.0), respectively.

Conclusions: In the SCD kidney transplant recipients, the incidence of AR was numerically lower in the group that received induction with single dose rATG 3mg / kg and induction with a reduced dose of rATG was not inferior in the ECD group.

PUB694

Cardiovascular Changes After Kidney Donation Fernando H. Margulis. *Nefrologia y Trasplante Renal, Hospital General de Agudos Cosme Argerich, CABA, Buenos Aires, Argentina.*

Background: The aim of our study was to investigate the changes in cardiovascular structure and endothelial function after donation in kidney donors.

Methods: Fourteen living kidney donors (both genders) without history of kidney disease, diabetes, cardiovascular events or hypertension, who participated in the donor screening protocol with subsequent donation, were included. Office blood pressure (OBP), ambulatory blood pressure monitoring (ABPM), left ventricular mass index (LVMI), arterial stiffness (AS) and endothelial function (EF) were measured before and one year after the donation. AS was assessed from the left index finger using a digital photoplethysmograph (Pulse Trace; Micro Medical), that uses a simplified analysis of the digital volume pulse wave, to assess endothelium dependent arterial vasodilation, 400 ug of salbutamol was given by inhalation. Data were expressed as mean ± SD or median and IR. Student t test and Wicoxon test were used for data with normal and nonparametric distribution respectively, $p<0.05$ were considered to be statistically significant.

Results: The mean age of the cohort was 47 ± 8 (range, 30 – 56) years. At one year after donation the mean BMI (27.1 ± 2.6, P<0.006), median OBP (89 (86, 92), P<0.023) and median serum creatinine (1.14 (0.99, 1.42), P<0.001) were significantly increased as compared to baseline (26.4 ± 3; 85 (76, 92) and 0.78 (0.74, 0.97), respectively). The estimated glomerular filtration rate levels by MDRD 4 formula at 1 year (57.4 ± 12ml/ min/1.73 m^2, P<0.0001) were significantly decreased as compared to baseline (82.2 ± 10 ml/ min/1.73 m^2). We did not find significantly differences in mean 24hs ABPM (84 ± 8 mmHg, P=0.940), mean LVMI (96.6 ± 17 g/m^2, P=0.727), mean AS (7.78 ± 2.3 m/s, P=0.210) and median EF (5.1% (0.8, 13.3), P=0.374) compared to baseline (85 ± 7 mmHg; 99.8 ± 31.6 g/m^2; 9.03 ± 2.3 m/s and 10% (-1.6, 34.6), respectively).

Conclusions: Our study demonstrated that after an year, reduced nephron mass because of kidney donation was not associated with changes in cardiovascular structure and endothelial function.

PUB695

A Rare Case of Chronic Lymphocytic Inflammation with Pontine Perivascular Enhancement Responsive to Steroids (CLIPPERS) After Kidney Transplantation Maria C. Bermudez, Mayurkumar Gohel, Ali Javed, Michael F. Schultz. *Nephrology, Geisinger Medical Center, Danville, PA.*

Background: Chronic lymphocytic inflammation with pontine perivascular enhancement responsive to steroids (CLIPPERS) is a recently described inflammatory condition of the central nervous system. To date 50 cases have been reported in the literature, however none have been reported following renal transplantation.

Methods: 47 year old Hispanic male, status post diseased donor kidney transplant in 2008, with history of hypertension and diabetes, presented to our clinic with several months of progressive dizziness, unsteady gait and right facial numbness that progressed to diplopia and right facial palsy. An MRI of the brain with gadolinium revealed a 1.3 cm mass with a ring-like target appearance in the right brachium pontis and dorsal pons. MR spectroscopy revealed mild elevation of choline, suggesting demyelinating disease versus lymphoma or other high-grade malignancy. Given his long term immunosuppression, malignancy or an infectious process were considered as the main diagnostic possibilities. An extensive evaluation included serial lumbar punctures for cytology and a variety of

viral, fungal and bacterial cultures. Cytologic and serologic studies were unremarkable. Flow cytometry analysis of the spinal fluid showed no evidence of lymphoma. A brain biopsy was performed revealing non-specific perivascular lymphoplasmocytic infiltrate with no evidence of lymphoma or infection. Additionally, myelin stain was positive ruling out demyelinating disease. Our patient was started on high-dose steroids with remarkable improvement of his symptoms. Diagnosis of CLIPPERS was made.

Conclusions: CLIPPERS is a rare and poorly recognized CNS inflammatory condition. To our knowledge, this is the first case reported after renal transplantation. More studies are needed to determine the pathophysiology of CLIPPERS in immunosuppressed patients and whether it could represent a pre-malignant state. Duration of treatment and follow up is yet to be determined. In this case, treatment with steroids has let to symptomatic improvement over a month and close follow-up continues.

PUB696

The Impact of Post-Transplant Hemoglobin and Creatinine Level on Renal Allograft Survival Luiz Fernando Christiani, Fernanda Paula Feres Rios Da Costa, Ana Flavia Baldoni, Alicia Imada, Kelly Rodrigues, Maria Izabel Neves de Holanda Barbosa, Géssika Marcelo Gomes, Cláudia Fagundes. *Nephrology, Hospital Federal de Bonsucesso, Rio de Janeiro, Brazil.*

Background: Anemia is a common finding after kidney transplantation. The roll and the prevalence of Posttransplantation anemia (PTA) in predicting renal allograft outcomes still vary between different studies. In this study, we aim to assess the prevalence of anemia at one and six months post transplant and its correlation with 1 year renal allograft survival.

Methods: Anemia was defined by an absolute level of hemoglobin less than 11 g/dL. Hemoglobin and creatinine level were assessed at one, six and twelve-month after transplantation.

Results: We included 261 consecutive patients who underwent renal transplant from January/2010 to June/2012. Mean recipient age was 42±10 years and 56% were male. Prevalence of anemia was 42% at 1 month, 16% at 6 months and 9% at 12 months. Hemoglobin and creatinine level at first month of transplantation were 11.2± 2 and 1.8± 1.0 for patients with functional allograft vs. 9.4± 2.1 and 4.8± 3.4 for those who return to dialysis within 12 months ($p<0.001$ for both comparisons). Overall patient and graft survival was 8% and 10%, respectively. On multivariate analysis, creatinine and hemoglobin level were independently associated with poor graft survival at 12 months. The best cut-off selected by receiver operating characteristic curve analysis was 10.8 g/dL for Hemoglobin level, (AUROC 0.74 (0.63-0.86), p□0.001), and 2.25 mg/dL, for serum creatinine (AUROC 0.77 (0.62-0.91, p□0.001). Combining the best points of those two variable could identify patients at risk of graft loss. Patients who met both criteria (Hb □ 10.8 g/dL and Creatinine □ 2.25 mg/dL) had 59% graft survival at 1-year, whereas allograft survival was 98.5% for patients without any criteria (Hb □10.8 g/dL and Creatinine □ 2.25 mg/dL).

Conclusions: Prevalence of anemia was high in the first month after transplant and persisted in a substantial proportion of functioning kidney transplant recipients. Early (1-month) hemoglobin and creatinine level can predict 1 year-graft survival.

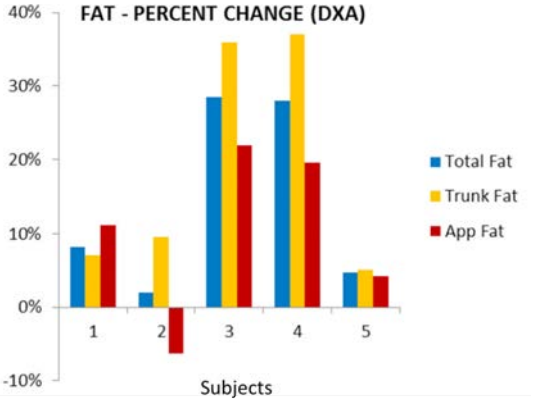
PUB697

Examining Adverse Weight Gain After Kidney Transplantation Biruh Workeneh,[1] Linda W. Moore,[2] William E. Mitch.[1] *[1]Medicine/Nephrology, Baylor College of Medicine, Houston, TX; [2]Transplant Medicine, Houston Methodist Hospital, Houston, TX.*

Background: Between 15,000-17,000 patients with end-stage renal disease (ESRD) receive a kidney transplant in the United States every year. Among the most consequential complications to these patients are adverse weight gain and the development of diabetes, commonly termed New-Onset Diabetes After Transplantation (NODAT) with consequent CV mortality. However, there is no consensus about the exact nature of the weight gain that routinely occurs after kidney transplantation (i.e., relative changes in fat vs. muscle vs. fluid volume) and how this relates to insulin resistance. We wish to test the hypothesis that weight gain is primarily due to an increase in fat mass.

Methods: We are conducting a longitudinal study in ESRD patients anticipating receiving a live donor kidney transplant. We are studying subjects before kidney transplant, at 12 weeks and 1 year after they have received living donor kidney transplant to measure changes body composition and other indices. Body composition was characterized by DEXA as well as total body potassium (a gold standard measure of muscle mass).

Results: Results from 5 subjects who completed baseline assessment and 3 months post-transplant reveals there is significant gain in adipose weight gain in all cases.



Additionally, we discovered there is significant loss in skeletal muscle mass ($p=0.032$) measured by total body potassium.

Conclusions: We have not studied enough to conclude whether changes in energy expenditure and diet contribute to adipose weight gain and whether there is acute nitrogen (muscle) loss perioperatively. Ultimately, methods to identify patients at high risk for adverse weight gain and related metabolic disorders before transplant are greatly needed.

PUB698

Effect of Mycophenolate Mofetil Dose on BK Virus Infection in Kidney Transplant Recipients Vedran Pasara,[1] Danica Galesic Ljubanovic,[2] Mladen Knotek.[1] *[1]Dept of Medicine, Renal Div, Univ of Zagreb Medical School, Merkur Hospital, Zagreb, Croatia; [2]Dept of Pathology, Univ of Zagreb Medical School, Dubrava Univ Hospital, Zagreb, Croatia.*

Background: Intensity of overall immunosuppression is a risk factor for BK virus infection (BKVI). However, the exact impact of exposure to tacrolimus and mycophenolate mofetil (MMF) to BKVI is unclear. The aim of this study was to determine if BKVI in kidney transplant (KT) recipients (KTR) is associated with drug exposure to MMF.

Methods: This prospective randomised controlled clinical trial (NCT01860183) included 36 KTR who underwent KT from May 2013 to February 2015 at Clinical Hospital Merkur. Immunosuppression consisted of basiliximab induction, with tacrolimus, MMF±steroid maintenance. KTR were randomized in two groups, with respect to MMF dose (2g or 3 g daily). Urine cytology for decoy cells was performed at prespecified time-points posttransplant. KTR were followed up to 12 months post KT. Graft biopsy was performed per protocol at 2, 6 and 12 months, or in case of graft dysfunction. Kaplan-Meier analysis with log-rank test was used to assess graft survival. A Cox regression was used to determine variables associated with graft survival.

Results: 13 (37.1%) KTR had decoy cells in urine, 4 (11.4%) KTR had biopsy-proven BK virus-associated nephropathy (BKVAN). The mean time-to-occurrence was 4.8 months for decoy cells and 4.3 months for BKVAN. Cumulative one-year overall graft survival was 93.5%. Incidence of decoy cells, BKVAN, or acute rejection was similar in the two MMF groups. Rejection was not a risk factor for decoy cell positivity or for BKVAN.

Conclusions: MMF dose may not increase risk for BKVI after kidney transplantation.

Malignancy following Renal Transplantation Lourdes de la Vara Iniesta,[1] Francisco Llamas Fuentes,[2] Inmaculada Lorenzo Gonzalez,[2] Carmen Gomez Roldan.[2] *[1]Virgen de la Luz Hospital, Cuenca; [2]Univ Hospital of Albacete, Albacete.*

Background: There is retrospective experience in many reports about the association between the intensity of immunosuppression and the higher frequency of malignancy. Objective: Analyse and describe our centre's experience.

Methods: 275 transplant patients were analyzed. A record was made of the frequency, anatomic-pathological diagnostics, location, the mean interval between transplantation and diagnostics (latency time), follow-up time, use of antilymphocyte-antibodies, affectation by cytomegalovirus, rejection and immunosuppressive therapy.

Results: Of 273 patients, 9.52%(26) were diagnosed of cancer. The majority, 93.43%(24), corresponded to De novo malignancy, 7.7%(2) were recurrences of pre-existing disease. The mean age at diagnosis was 63.19±7.24years. The latency time was 63.65months (11-114), although there is a notable but unexplained reduction over the last five year (33,50vs63,65 months). The average follow-up time was 97.54months. The most frequent malignancies were skin cancers, predominantly Basal-cell and Squamous-cell carcinomas. The incidence of other tumors was similar to the general population. The most common causes of chronic renal failure was the glomerular and interstitial disorders. The risk of neoplasm was 0.36%, 4,36% and 9,52% at one, five and ten years after the kidney transplant. No association was detected with use of antilymphocyte-antibodies, CMV infection, rejection episodes or different immunosuppressive therapy. At the time of analysis, 84.60%(22) of patients had functioning graft, 7.70%(2) had returned to dialysis and 7.70%(2) had died, both due to the cancer.

Conclusions: Our experience is similar to what is reported in the literature. The incidence of cancer is higher than expected in the general population and increases according to the duration of the immunosuppression. Skin cancers were the most frequent malignancies. Unlike other studies, there was a low incidence of lymphoproliferative disorder and Kaposi's sarcoma, and the incidence of other solid malignancies being similar to that of the general population. To reduce the development of malignancies must be one of our objectives.

PUB700

Lipidapheresis in 3 Sisters with Familial Hypercholesterolemia

Christina Taylan,[1] Andrea Schlune,[2] Thomas Meissner,[2] Lutz Thorsten Weber.[1] *[1]Pediatric Nephrology, Univ Hospital of Cologne, Cologne, Germany; [2]Dept of Pediatrics, Neonatology and Cardiology, Univ Hospital of Duesseldorf, Duesseldorf, Germany.*

Background: Familial hypercholesterolemia (FH) is the most common monogenic form of hypercholesterolemia. It carries the risk of premature coronary heart disease. As the atherosclerotic burden is dependent on the degree and duration of exposure to raised LDL-cholesterol levels, early diagnosis and effective treatment are imperative. Statins are the mainstay in the management of these patients. Lipoprotein-apheresis becomes recently more established in patients with severe dyslipidemia. Together these treatments improve the prognosis of FH. Most children fail to attain targeted lipid goals owing to persistent shortcomings in diagnosis and treatment.

Methods: Three siblings with a LDLR mutation (p.Trp577Arg) beeing on statins (20 mg/d Atorvastatin) and Ezetimib (10 mg/d) for 12 months with still LDL-C plasma concentrations of above 300-500 mg/dl started once weekly a double filtration plasmapheresis (DFPP) with with a single plasma volume to be treated.

Results: After each LDL-apheresis LDL-C concentration of 100-150 mg/dl could be reached. (66-70% reduction). After 6 months plasma volume to treat was doubled because of a rebound within 7 days with LDL-C concentration up to 300-350 mg/dl. But though after each session LDL-C concentration decreased to 50-100 mg/dl the rebound was still evident after 7 days of therapy pause. With a treatment regime with twice plasma volume every 3-4 days the children finally attained a stable pre-treatment LDL-C concentration of 120-170 mg/dl. Another 2 months later statin therapy was stopped because of underlying mutation with assumed non receptor function. Neither the effectiveness of each apharesis nor the LDL-C concentration after 4 days showed any change.

Conclusions: In pediatric FH patients with high levels of LDL-cholesterol plasma concentration it might be necessary to treat instead of conservative medication with apheresis in high frequency and with high plasma volumes to reach a durable decrease in LDL-cholesterol plasma concentration. The use of cholesterol uptake-inhibitors should be considered.

PUB701

Thrombomodulin Up-Regulation in Preeclamptic Nephropathy Is Associated with Parietal Cell Activation

Rosanne Jane Turner,[1] Maria Elisabeth Penning,[1] Malu Zandbergen,[1] Eliyahu V. Khankin,[2] S. Ananth Karumanchi,[2] Jan A. Bruijn,[1] Kitty Bloemenkamp,[3] Hans J. Baelde.[1] *[1]Pathology, LUMC, Leiden, Netherlands; [2]Howard Hughes Medical Inst and Dept of Medicine, Obstetrics and Gynecology, Beth Israel Deaconess Medical Center, Boston, MA; [3]Obstetrics, LUMC, Leiden, Netherlands.*

Background: Preeclampsia is a pregnancy-specific syndrome characterized by angiogenic imbalance and endothelial dysfunction. This endothelial dysfunction leads to kidney damage, i.e. glomerular endotheliosis, increased podocyte turnover and proteinuria. Thrombomodulin (TM) facilitates maintenance of glomerular endothelium by inhibiting coagulation, inflammation and apoptosis. In preeclampsia, levels of soluble thrombomodulin in the circulation are increased. We hypothesize that glomerular thrombomodulin expression is increased in preeclampsia and set out to correlate thrombomodulin expression with endothelium and podocyte damage.

Methods: A nationwide, ethics committee-approved search of the Dutch Pathology Registry (PALGA) was conducted; this revealed renal autopsy material from 11 women with preeclampsia according to the ISSHP definition, from 22 normotensive pregnant controls and from 14 hypertensive non-pregnant controls. Kidneys from 13 sFLT-1 transfected mice and controls were collected. Samples were stained for TM and fibrin and markers of endothelium and podocyte damage were investigated.

Results: TM expression was increased in glomeruli from preeclampsia patients (82%) compared to pregnant, (41%, P=0.03) and hypertensive controls (21%, P=0.004). In sFLT-1 transfected mice TM expression was the same as in controls. TM expression correlated with activation of parietal epithelial cells (P=0.023), but not with endotheliosis or endothelial fibrin deposits (P>0.05).

Conclusions: TM expression in the kidney is increased in preeclampsia. This is associated with parietal cell activation and not with endothelial damage or fibrin deposits. TM apparently exerts cytoprotective and not anticoagulant effects in the kidney in preeclampsia. Glomerular damage induced by sFLT-1 did not increase TM expression in a mouse model; this indicates that the increased TM expression in humans is probably not caused by this anti-angiogenic factor alone.

PUB702

Cadmium Induces Matrix Metalloproteinase-9 Expression via NADPH Oxidase/ROS-Dependent EGFR Signals in Human Endothelial Cells

Nam ho Kim. *Internal Medicine, Chonnam Natuinal Univ Hospital, Gwangju, Korea.*

Background: Cadmium, a widespread cumulative pollutant, is a known human carcinogen, associated with inflammation and tumor. Matrix metalloproteinase-9(MMP-9) plays a pivotal role in inflammatory reaction and tumor metastasis, however, the mechanisms underlying MMP-9 expression induced by cadmium remains obscure in human endothelial cells.

Methods: Here, cadmium elevated MMP-9 expression and enzyme activity, as well as MMP-9 promoter-driven luciferase activity, in a dose and time dependent manner in ECV304 human endothelial cells. Moreover, cadmium activated phosphorylation of EGFR, Akt, Erk1/2, JNK1/2, P38MAPK and promoted NF-κB and AP-1 binding.

Results: Specific inhibition and mutagenesis study shows that EGFR, Akt, Erk1/2, JNK1/2 and transcription factor NF-κB and AP-1 were related to cadmium-induced MMP-9 expression in ECV304 cells. Akt and MAPKs (Erk1/2 and JNK1/2) functioned as upstream signaling molecules in the activation of NF-κB and AP-1, respectively. Furthermore, Cadmium increased ROS production and the ROS-producing NADPH oxidase. Cadmium translocates p47phox,akeysubunitofNADPHoxidase,tothecellmembr ane.The exogenous H2O2 increased MMP-9 mRNA expression. And that, inhibition of ROS by ROS scavenger (NAC) or NADPH oxidase inhibitor (DPI) attenuated EGFR, Akt, MAP(Erk1/2,JNK1/2,p38MAPK) activation, and MMP-9 expression. Likewise,inhibition of EGFR phosphorylation prevented the activation of AKT,MAPKs(Erk1/2,P38MAPK). Finally,ECV304cellstreated with cadmium displayed markedly invasiveness, which was partially abrogated by MMP-9 neutralizing antibodies.

Conclusions: These results demonstrated that cadmium induces MMP-9 expression via NADPH oxidase/ROS-dependent EGFR/AktNF-κ Band EGFR/MAPKs(Erk1/2,JNK1/2)/ AP-1 signaling pathways and, inturn, stimulates invasiveness in human endothelial ECV304cells. These findings provide further insight into the molecular mechanisms in the carcinogenesis effect of cadmium.

PUB703

Exosomes from Activated Kidney Fibroblast Have Ambivalent Potential Effect on Atherosclerosis

Fumitoshi Nishio, Noritoshi Kato, Yoshio Funahashi, Takuji Ishimoto, Tomoki Kosugi, Naotake Tsuboi, Shoichi Maruyama, Seiichi Matsuo. *Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Aichi-Pref, Japan.*

Background: Exosomes are small (50-140nm) membrane vesicles of endosomal origin that contain host cell's proteins, mRNAs, and microRNAs (miRNAs). The body of evidence revealed that these contents were biologically active, and had roles in intracellular communication. Especially tumor-derived exosomes has been intensively exploit and proven to be associated with distant metastasis. On the other hand, it is well known that CKD patients are at risk of cardiovascular diseases, but the mechanism of this distant organ crosstalk is not fully understood. Under the hypothesis that exosomes are involved in cardio-renal syndrome (CRS), the aim of this study is to explore the role of exosomes from kidney fibroblasts, which are activated in diseased kidney, on vascular endothelial cells.

Methods: We isolated Exosomes from culture media of TGF-β stimulated rat kidney fibroblasts cell line (NRK-49f) by ultracentrifugation technique. Cultured vascular endothelial cells (RAOEC; Rat Aortic Endothelial Cells) were stimulated by these exosomes or exosomes from unstimulated fibroblast. Then we evaluated the expression of genes, which associated with atherosclerosis by qPCR.

Results: RAOEC stimulated with exosomes form TGF-β activated kidney fibroblast (RAOEC-T) showed higher expression of PlGF and lower expression of Flt-1, ABCA-1 than control (RAOEC-C). This expression pattern is compatible with atherosclerotic change. On the other hand, RAOEC-T showed reduced expression of adhesion molecules such as ICAM-1/VCAM-1 and E-selectin compare with RAOEC-C.

Conclusions: So far, CRS is supposed to caused by uremic factor, RAS system, chronic inflammation, and so on. From this study, we showed that exosomes from activated kidney fibroblasts have ambivalent roles in atherosclerosis by modulating the expression of adhesion molecules, metabolic factor, and VEGF system on endothelial cells. Farther studies are needed to elucidate the contribution level of exosomes on CRS.

PUB704

Prevalence of Metabolic Syndrome in Patients with End Stage Renal Disease: Relevance of Biomarkers

Vinod K. Bansal,[1] Jennifer Saluk,[2] Debra Hoppensteadt,[2] Daneyal Syed,[2] Schuharazad Abro,[2] Jawed Fareed.[2] *[1]Nephrology, Loyola Univ Medical Center, Maywood, IL; [2]Pathology, Loyola Univ Medical Center, Maywood, IL.*

Background: Since the metabolic syndrome (MetS) and chronic kidney disease (CKD) share many of the same risk factors and similar inflammatory pathogenesis, many studies have suggested a correlation between CKD and MetS, and shown that patients with MetS are more likely to develop CKD. The purpose is to investigate metabolic biomarker levels in ESRD patients to evaluate their relevance to ESRD and to provide insight into the pathogenic ESRD processes and the development of associated comorbidities.

Methods: Plasma samples were retrospectively collected from 89 ESRD patients prior to maintenance hemodialysis. Normal human plasma samples (female & male, 18-35 years old) were purchased from George King Biomedical Inc. (Overland Park, KS). Samples

were stored at -80°C. Biochips were purchased from RANDOX (Co. Antrim, Northern Ireland) to test C peptide, ferritin, IL-6, resistin, insulin, TNFα, IL-1a, leptin, PAI-1. These biomarkers were tested on 82 ESRD and 17 normal samples.

Results: All biomarkers, except insulin, were significantly elevated in Patients with ESRD compared to normal (p values are 0.05 - .0001). MetS patients with ESRD, as compared to non-MetS Patients with ESRD, had significantly elevated Leptin (P=0.002), and the correlation between MetS and Leptin levels was significant (P<0.0001, r=0.43). All other biomarkers showed no significant difference between ESRD+MetS and ESRD-MetS patients. Furthermore, when leptin levels for Patients with ESRD were broken down into ESRD+MetS and ESRD-MetS, ESRD+MetS vs. normal was significant (P=0.0003), but ESRD-MetS vs. normal was not (P=0.6).

Conclusions: Elevated biomarkers suggest an ongoing inflammatory process in ESRD patients. Insulin levels were not significantly elevated in ESRD patients, possibly attributed to the high Leptin levels, which can interfere with insulin secretion and signaling. ESRD+MetS and ESRD-MetS populations are not statistically different for all other biomarkers. This suggests that biomarker elevation is due to ESRD pathogenesis, rather than due to MetS as a comorbidity.

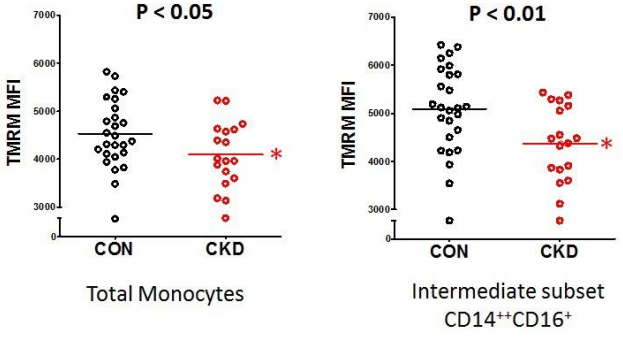
PUB705

Decreased Mitochondrial Membrane Potential in Monocyte Subsets from Patients with Chronic Kidney Disease Ying Wang,[1] Eric Joseph Lai,[1] Annie Febus,[1] Yuan Zhang,[2] Linda Vernocchi,[1] Anjali Ganda.[1] *[1]Div of Nephrology, Dept of Medicine, Columbia Univ Medical Center, New York, NY; [2]Dept of Biostatistics, Mailman School of Public Health, Columbia Univ, New York, NY.*

Background: Particular monocyte subsets are associated with future cardiovascular events in patients with chronic kidney disease (CKD), and the underlying mechanisms require further investigation. Previous studies have suggested impaired mitochondrial function in patients on dialysis, while little is known about mitochondrial functionality in monocyte subsets from non-dialyzed patients with CKD. Given that mitochondrial dysfunction has been linked to atherosclerosis, we hypothesized that non-dialyzed patients with CKD would have mitochondrial dysfunction in monocyte subsets which could accelerate atherosclerosis in patients with CKD.

Methods: Monocyte subsets from 18 adult CKD patients (eGFR<30 ml/min/1.73 m^2) and 26 matched controls (eGFR ≥60 ml/min/1.73 m^2) were freshly analyzed by flow cytometry. Mitochondrial membrane potential (DYm), as a measure of mitochondrial functionality, was determined by the mean fluorescence intensity (MFI) of TMRM (tetramethylrhodamine methyl ester).

Results: DYm was significantly reduced by 10% in patients with CKD vs. controls in total monocytes (P<0.05). Interestingly, the intermediate monocyte subset ($CD14^{++}CD16^{+}$), which has the highest DYm among all the monocyte subsets and has been shown to predict future cardiovascular events in CKD patients, had the most pronounced reduction in DYm (14% lower, P<0.01) in patients with CKD vs. controls.



Conclusions: Patients with CKD demonstrate mitochondrial dysfunction in total monocytes and monocyte subsets. Mechanistic and prospective studies are needed to examine the relationship between monocyte mitochondrial dysfunction, atherosclerosis, and future cardiovascular events in CKD patients.

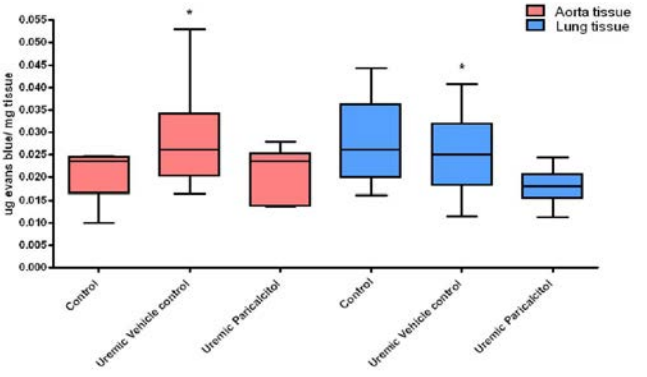
PUB706

Paricalcitol Upregulates Renal Klotho and Restores Uremia-Induced Endothelial Integrity Disruption Marc Vila cuenca,[1] Robert H.j. Beelen,[1] Marc G. Vervloet.[2] *[1]Molecular Cell Biology & Immunology, VU Univ Medical Center, Amsterdam, Netherlands; [2]Nephrology, VU Univ Medical Center, Amsterdam, Netherlands.*

Background: Klotho deficiency in chronic kidney disease (CKD) is associated with the disruption of the endothelial integrity. Active vitamin D induces klotho expression. Hence, active vitamin D may limit endothelial layer disruption.

Methods: Male wistar rats were assigned into one of four groups: Control; Vitamin D deficiency, induced with Vitamin D deficient diet; Uremic, developed after ¾ nephrectomy; Uremic + Vitamin D deficiency. Animals were treated with Paricalcitol or vehicle control during 7 weeks. Serum samples were analyzed for 25D and 1,25D. Evans Blue was injected for estimation of the endothelial thoracic aorta and lung permeability and quantified using spectrophotometry. To determine the levels of Klotho, qPCR and WesternBlot was performed in kidney tissue.

Results: Average 25D levels were 9.83 nmol/L while 1,25D levels were below the detection levels (20pmol/L) after the induction Vitamin D deficiency. mRNA and protein levels of Klotho in the Kidney were decreased in Vitamin D deficient and uremic rats and restored after Paricalcitol treatment. Aortic Evans blue leakage increased in all uremic rats regardless of vitamin D level, compared with the control group and restored after Paricalcitol treatment (p=0.03). Uremia did not induce pulmonary leakage, but paricalcitol lowered it compared to control and uremic condition (p=0.04). Figure shows uremic with/ without D-deficiency together.



Conclusions: CKD induces aortic endothelial leakage, while the deficit of vitamin D on its own did not. Paricalcitol completely rescued endothelial leakage induced by CKD. In parallel, Klotho expression increased upon this treatment and may mediate the beneficial effect on the endothelium. To explain the difference between aortic and pulmonary tissue, additional studies are required.

PUB707

Altered Intra-Aortic Expression of the Renin-Angiotensin System Is Associated with Arterial Aging in Mice Hye Eun Yoon,[1,2] Eun Nim Kim,[1] Min Young Kim,[1] Ji Hee Lim,[1] Cheol Whee Park,[1] Bum Soon Choi.[1] *[1]Internal Medicine, The Catholic Univ of Korea, Seoul, Korea; [2]Internal Medicine, Incheon St. Mary's Hospital, Incheon, Korea.*

Background: Aging is the major risk factor of cardiovascular disease and results in progressive decline in physiological function and structural abnormalities of vasculature. The renin-angiotensin system (RAS) is the key player in cardiovascular diseases. This study evaluated whether the change in the RAS is associated with arterial aging.

Methods: Histologic changes and expressions of angiotensin, angiotensin converting enzyme 1 (ACE1), angiotensin II type 1 receptor (AT_1R), angiotensin II type 2 receptor (AT_2R), and antioxidant enzymes, superoxide dismutase 1 (SOD1) and superoxide dismutase 2 (SOD2), were measured in the thoracic aortas from 2-month-old, 12-month-old, and 24-month-old C57/BL6 mice.

Results: Twenty-four-month-old mice showed significantly increased aortic media thickness compared to 2-month-old mice (1.6-fold). The aortic expression of angiotensin was increased in 12-month-old (1.2-fold) and 24-month-old mice (1.3-fold) compared to 2-month old mice. Similarly, the expression of ACE1 was increased in 12-month-old (1.2-fold) and 24-month-old mice (3-fold) compared to 2-month-old mice. The AT_1R/ AT_2R ratios were increased in 12-month-old (1.3-fold) and 24-month-old mice (1.5-fold) compared with 2-month-old mice. The expressions of SOD1 and SOD2 were decreased in 12-month-old (0.8-fold and 0.6-fold, respectively) and 24-month-old mice (0.6-fold and 0.5-fold, respectively) compared with 2-month-old mice.

Conclusions: Age-related intra-aortic activation of the RAS was associated with reduced antioxidant enzymes and hypertrophy of the aorta. These results suggest that the altered expression of the RAS contributes to the increased susceptibility to vascular injury in the elderly population.

Upregulation of Microparticles, Tissue Factor, Adhesion Molecules, Nitric Oxide and Adiponectin in End Stage Renal Disease Vinod K. Bansal,[1] Daneyal Syed,[2] Debra Hoppensteadt,[2] Jawed Fareed.[2] *[1]Nephrology, Loyola Univ Medical Center, Mayood, IL; [2]Pathology, Loyola Univ Medical Center, Maywood, IL.*

Background: End stage renal disease (ESRD) represents the final stage of chronic kidney disease characterized by kidney failure (GFR <15 mL/min/1.73 m^2). To understand the pathophysiology of ESRD, we measured the circulating levels of microparticles (MP), tissue factor (TF), adhesion molecules, such as p-selectin (P-Sel), soluble ICAM (s-ICAM), nitric oxide (NO) and adiponectin (AD).

Methods: Plasma samples were collected from 119 ESRD patients undergoing maintenance hemodialysis to profile various inflammatory biomarkers. 100 normal plasma samples were collected from healthy individuals. MP levels were measured using an annexin

binding method (Hyphen Biomedical, Paris, France). NO was measured using a kit from R&D systems (Minneapolis, Minnesota) and ELISA methods for TF, P-Sel, s-ICAM and adiponectin were obtained from R&D systems. A chromogenic substrate method was used to measure heparin.

Results: MP levels were elevated in the ESRD group (28.1nm + 6.1nm vs. the control 8.9nm +1.3nm). Tissue factor levels were found to be increased in the ESRD group (20.4±6.1pg/ml) vs the control (11.9±2.8pg/ml). The nitric oxide level was markedly higher in the ESRD group (32±17uM) vs the controls (7±3uM). The p-selectin levels were elevated in the ESRD group (46±20ng/ml) vs the control (31±3ng/ml). The soluble ICAM levels were higher in the ESRD group (250±112ng/ml) vs the control (180±19ng/ml). Interestingly, the adiponectin levels were also increased in the ESRD group (19.2±9.3ug/ml) vs the control (11.2±4.1ug/ml). Detectable levels of heparin (.05 – 0.20 U/ml) were measured in the ESRD group.

Conclusions: These studies suggest that MP, TF, NO, p-selectin and s-ICAM levels are increased in the ESRD patient. It is of interest to note that despite that a significant number of ESRD patients were diabetic; the AD levels were increased. These results also suggest that while ESRD represents a pro-inflammatory/hypercoagulable state, the repeated administration of heparin and other drugs may contribute to the regulation of the hemostatic process and inflammatory balance.

PUB709

Coronary Artery Calcification and All-Cause Mortality in RRT Patients with Diabetes: 5 Year Survival Analysis Ramin Tolouian,[1] Sean M. Connery,[2] Kyari Sumayin Ngamdu.[2] *[1]Internal Medicine, Eastern Virginia Medical School, Norfolk, VA; [2]Internal Medicine, Texas Tech Univ HSC El Paso, El Paso, TX.*

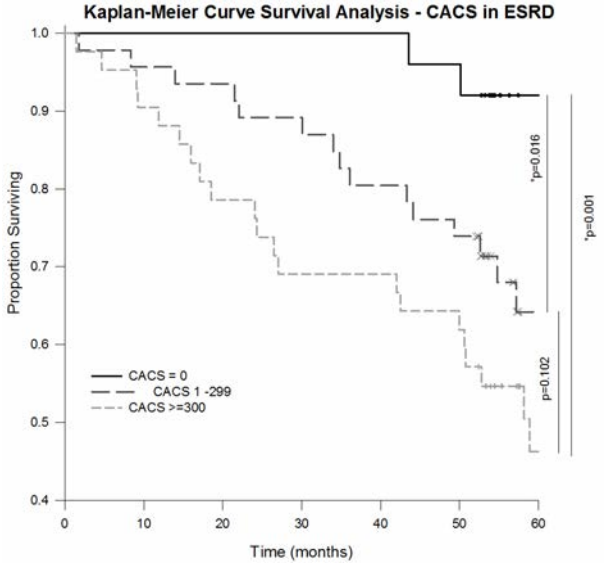
Background: Vascular calcification is a significant sequela of ESRD. A Coronary Artery Calcification (CAC) Agatston score ≥ 300 has been associated with adverse cardiovascular events & increased mortality. The purpose was to evaluate all-cause mortality rates in ESRD with diabetes.

Methods: 113 diabetic pts undergoing RRT had CAC scoring by sub-second gated helical CT standard Agatston scoring system, slice thickness 3mm. Patients were categorized into 3 groups according to CAC score: 0, 1-299, ≥ 300 (Low, Medium, High Risk). Survival of 3 groups was calculated using Kaplan-Meier curves for all-cause mortality for 5 year period after CAC. Unadjusted and risk-factor adjusted for age & length of time on dialysis Cox proportional hazard modeling was used to estimate time to all-cause mortality.

Results: 5 year survival was 92%, 60%, 46% for Low, Medium, High Risk CAC groups.

	Low (n=25)	**Medium** (n=46)	**High** (n=42)
Age, yrs	47 ±11	57 ±11*	61 ±9**
Months on Dialysis	40 ±35	23 ±20	40 ±35□
Mean ±SD, p<0.05 *Low vs Medium, **Medium vs High, □Medium vs High ANOVA			

There was a statistically significant difference between survival curves, Gehan-Breslow p = 0.031, but no difference between Medium & High Risk curves pairwise multiple comparison procedures Holm-Sidak method (p=0.1). Adjusting for covariates of age & length of time on dialysis at time of scan did not make a significant difference in survival curves, Age HR = 1.034 (0.99-1.07 95% CI), time on dialysis HR = 1.004 (0.99-1.01 95%).



Mortality in Medium & High groups was 40% & 50% while only 8% in low group.

Conclusions: Any level of CAC, regardless of severity, in HD pts with diabetes has a significant impact on survival. CAC might be usefull prediciting mortality in this population.

PUB710

Elevated Toll Like Receptor 4 Expression and Macrophage Infiltration Is Found in High Dose Vitamin D-Induced Non-Uremic Vascular Calcification Jianheng Zhou,[1,2] Yuan Min Wang,[1] Helen Williams,[3] Anne M. Durkan,[1] Geoff yu Zhang,[1] Huiling Wu,[4] Andrew Sawyer,[1] Stephen I. Alexander,[1] David C. Harris,[2] Vincent W.S. Lee.[2] *[1]Centre for Kidney Research, Children's Hospital at Westmead, Sydney, NSW, Australia; [2]Centre for Transplantation and Renal Research, Univ of Sydney at Westmead Millennium Inst, Westmead, Sydney, NSW, Australia; [3]Vascular Biology Research Centre, Surgery, Univ of Sydney, Westmead Hospital, Sydney, NSW, Australia; [4]Transplant Research Group, Royal Prince Alfred Hospital, Sydney, New South Wales, Australia.*

Background: Vascular calcification is strongly associated with cardiovascular morbidity and mortality. Several studies have suggested that monocytes/macrophages are involved in arterial vascular calcification, while the involvement of the TLR4 pathway in vascular calcification has also been proposed.

Methods: Male C57BL/6 mice aged 8 weeks were injected with a high dose of vitamin D (500000IU/kg/day) subcutaneously for 3 days at 0, 24 and 48 hours. All mice were sacrificed 3 days after the final administration of vitamin D. Kidneys were assessed histologically. Whole aortas were dissected. Macrophage infiltration and TLR4 expression was assessed by immunohistochemistry and histology and vascular calcification by Von Kossa staining.

Results: High dose vitamin D treatment did not induce kidney fibrosis or injury in C57BL/6 mice within the short time frame, as assessed by GT fibrosis score and PAS tubular damage score. High dose vitamin D treated mice demonstrated significantly higher calcium deposition in the aortic arteries (17.45% of vessel area) compared to controls (1.2% p<0.05). This was accompanied by a greater level of macrophage infiltration and TLR4 expression in these arteries compared to controls.

Conclusions: Accelerated vascular calcification was induced in mice with high dose vitamin D treatment. These data also identify a potential role for macrophages and the TLR4 pathway in vascular calcification.

PUB711

Lack of Correlation of Pyrophosphate Levels with Survival and Coronary Artery Calcification in Hemodialysis Patients Ramin Tolouian,[1] Sean M. Connery.[2] *[1]Internal Medicine, Div of Nephrology, Eastern Virginia Medical School; [2]Internal Medicine, Texas Tech Univ HSC El Paso.*

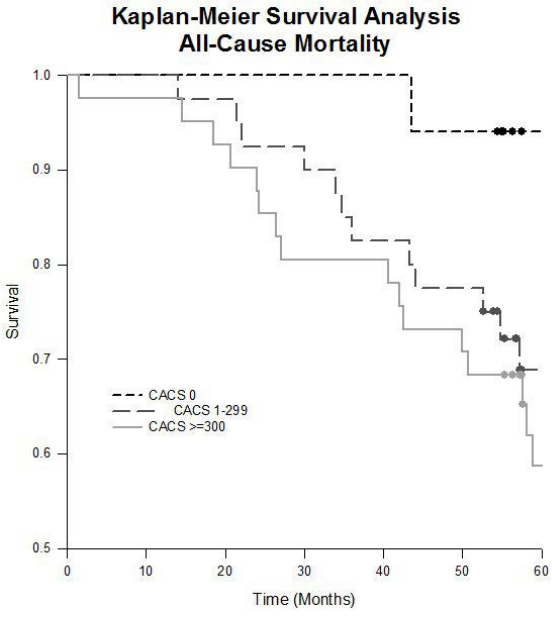
Background: Vascular calcification is an important predictor of cardiovascular mortality in ESRD. Decreased levels of inorganic pyrophosphate (PPi) are thought to increase vascular calcification. The purpose of this study was to evaluate the association of PPi & coronary calcification scores in maintenance HD patients and all-cause mortality over 5 years.

Methods: 98 maintenance HD patients were studied (mean ±SD): Age (yr.) 57 ±10.7, HD vintage (month) 36 ±37.6. Platelet free plasma PPi was measured by radiometric, enzymatic method as described by Tolouian. Coronary arterial calcification score (CACS) was measured by sub-second gated helical computed tomography with an Imatron C-150 XL ultra fast CT scanner using a standard protocol for vascular calcification. Patients were categorized into 3 groups according to their CAC score: 0, 1-300, and > 300.

Results:

	CACS 0 (n=17)	CACS 1-299 (n=40)	CACS ≥300 (n=41)
PPi (μM)	1.49 ±0.37	1.60 ±0.56	1.56 ±0.46
Age (yrs)	51 ±11.0	58 ±11.3	60 ±9.0*
Months on HD	32 ±27.2	25 ±21.5	47 ±49.5 ‡
* p<0.5 Low vs High, ‡Medium vs High ANOVA, Dunnett T3			

The covariate PPi had no significant effect on the hazard rate, log rank p=0.61. After adjusting for covariates of PPi, age, length of time on HD at time of measurement the log rank statistic for the survival curves is not great enough to exclude the possibility that the difference is due to random sampling variability; there is not a statistically significant difference (P = 0.614).



Conclusions: The difference in 5 year survival rate in dialysis patients based on the severity of vascular calcification is not influenced by pyrophosphate levels. This supports the multi-factorial nature of vascular calcification.

PUB712

Aortic Artery Calcification and Cardiac Valve Calcification Is Associated with Mortality in Chinese Heamodialysis Patients: A 3.5 Year Follow-Up

Xiaonong Chen,[1] Zijin Chen,[1] Xiaobo Ma,[1] Bei Ding,[2] Huawei Ling,[2] Zhongwei Shi,[3] Nan Chen.[1] *[1]Nephrology, Ruijin Hospital Affiliated to Shanghai Jiaotong Univ, Shanghai, China; [2]Radiology, Ruijin Hospital Affiliated to Shanghai Jiaotong Univ, Shanghai, China; [3]Cardiology, Ruijin Hospital Affiliated to Shanghai Jiaotong Univ, Shanghai, China.*

Background: Aim to investigate the relationship among aortic artery calcification(AAC), cardiac valve calcification(CVC) and mortality in maintenance haemodialysis(MHD) patients.

Methods: The study included 110 MHD patients. All MHD patients were treated in Shanghai Ruijin Hospital in July 2011. Follow-up these patients for 42 months.

Results: Totally 110 MHD patients were involved in this study. 64(58.2%) patients were male, and the mean age was 55.2±15.0 years old, the mean dialysis duration was 41.7±38.1 months. 25.5% patients had cardiac valve calcification ,while 61.8% had visible calcification. After 42 months follow-up, 26(22.7%) patients died, including 16 cases death from cardiovascular events, 5 cases respiratory failure, 3 cases tumor metastasis, 1 case deep venous thrombosis and 1 case abandon treatment. Kaplan-Meier analysis showed that patients with AAC or CVC had a significant greater number of all-cause and cardiovascular deaths than those without. In multivariate analyses, the presence of AAC was a significant factor associated with all-cause mortality (HR 3.149, P=0.025) in addition to lower albumin level and lower 25(OH)D level. The presence of CVC was a significant factor associated with cardiovascular mortality (HR 3.800, P=0.029) in addition to lower albumin level and lower 25(OH)D level .

Table1. multivariate Cox proportional hazards analysis for all-cause mortality

	Cox proportional hazards model		
	Hazard Ratio	95% Confidence Interval	P
Sex (male vs female)	1.673	0.634-4.417	0.299
Age (/1 y)	1.034	0.992-1.078	0.112
ALB (/1g/L)	0.820	0.725-0.927	0.002
25(OH)D (/1nmol/L)	0.981	0.965-0.998	0.024
CVC (presence vs absence)	1.563	0.637-3.836	0.330
AAC (presence vs absence)	3.149	0.889-11.159	0.025

Table2. multivariate Cox proportional hazards analysis for cardiovascular mortality

	Cox proportional hazards model		
	Hazard Ratio	95% Confidence Interval	P
Age (/1 y)	1.008	0.975-1.062	0.757
ALB (/1g/L)	0.847	0.728-0.984	0.030
25(OH)D (/1nmol/L)	0.962	0.941-0.984	0.001
CVC (presence vs absence)	3.800	1.150-12.558	0.029
AAC (presence vs absence)	2.391	0.631-9.060	0.200

Figure1. The Kaplan-Meier analysis of all-causemortality (P=0.002 and P=0.001)

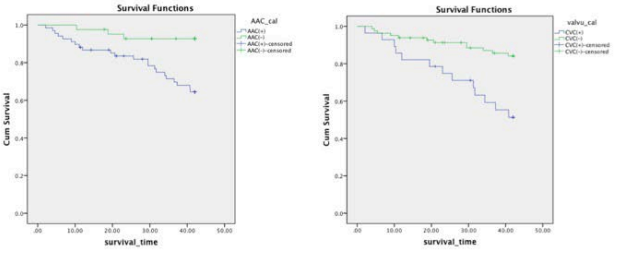


Figure2.The Kaplan-Meier analysis of cardiovascular mortality (P=0.049 and P<0.001)

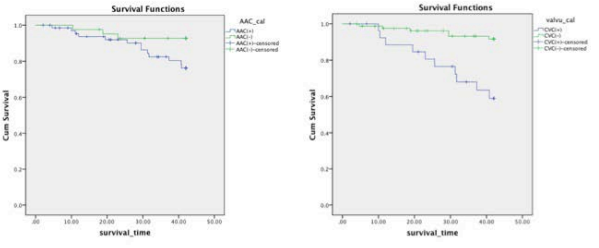

Conclusions: The presence of AAC and CVC were independently associated with mortality in MHD patients. Regular follow-up by X-ray and echocardiography could be useful method to stratify mortality risk in MHD patients.

Beneficial Effect of the Vasopressin AV1a and AV2 Receptor Blocker Conivaptan (C) on the Renal Alterations Resulting from Mild Heat-Induced Dehydration (MHID) and Rehydration with a 10% Fructose (F) Beverage

L. Gabriela Sanchez-Lozada,[1] Fernando E. García-arroyo,[1] Monica Gabriela Blas-Marron,[1] Jose Pedraza-chaverri,[2] Cecilia Zazueta,[3] Magdalena Cristobal,[1] Edilia Tapia.[1] *[1]Renal Physiopathology, INCICh, Mexico City, DF, Mexico; [2]Biology, UNAM, Mexico City, DF, Mexico; [3]Cardiovasc BioMed, INCICh, Mexico City, DF, Mexico.*

Background: The aims of this study were: 1.To define a possible synergistic effect between fructose and vasopressin during MHID, and 2. To evaluate the potential therapeutic benefit of C (3mg/kg BW) on this condition.

Methods: Six groups of male Wistar rats were MHID (37°C/ 1 h/day) and rehydrated with the selected beverage during 30 days: Water (W)+Veh, W+C, F+Veh, F+C, Stevia (S)+Veh and S+C. A group of normal control (NC) rats was studied as reference. After 30 days plasma and urine parameters were evaluated, renal cortex mitochondria were isolated and respiratory control rate (RCR) was evaluated with malate/glutamate (M/G) and succinate/rotenone (S/R) substrates.

Conclusions: These data suggest a crosstalk between F and vasopressin on this particular condition. In addition, C treatment prevented renal and mitochondrial alterations induced by rehydration with F.

Lack of Aquaretic Effects of the Kappa Opioid Agonist Nalbuphine following Multiple Ascending Oral Doses in Healthy Volunteers

Amale Hawi,[1] Thomas Sciascia,[2] Vandana S. Mathur.[3] *[1]Hawi Consulting, Ridgefield, CT; [2]Trevi Therapeutics, New Haven, CT; [3]Mathur Consulting, Woodside, CA.*

Background: Nalbuphine is a mixed μ-antagonist and κ-agonist opioid drug that may suppress itch in hemodalysis patients with pruritus following oral administration of nalbuphine HCl extended release (ER) tablets. However, as a class, kappa opioid agonists have aquaretic effects in both animals and humans, which can be treatment-limiting. In this Phase 1 study, the potential of nalbuphine to induce aquaretic effects was explored in healthy subjects.

Methods: Healthy male and female subjects (n=9) were administered oral doses of nalbuphine escalated every 2-3 days from 30 mg QD on Day1 to 30 mg BID, 60 mg BID, 120 mg BID, and 180 mg BID over a 2-week period. Urine output and vital signs were measured pre-treatment and at multiple time points on Days -1 through 14.

Results: Repeated measurements of urine volume with progressively higher nalbuphine doses over the 6-fold dose range showed no evidence of increased urine output related to dose or duration of time on nalbuphine. Urine specific gravity remained within the normal range (1.001-1.03) and did not decline in any subject during treatment. None of the subjects developed hypernatremia nor was there a trend of rising serum sodium with all values remaining within the normal range. There were no dose-related reductions in blood pressure and none of the subjects developed hypotension. The mean systolic blood pressure remained consistently in the 108–128 mmHg range. Likewise, heart rate remained normal throughout the study with no HR >73 beats per minutes.

Conclusions: There was no evidence of an aquaretic effect at nalbuphine oral doses up to 180 mg BID in healthy subjects, the most sensitive population in which such effects may be observed.

Dose (mg) AM/PM	Study Day	24-hour Urine Volume (L)	Serum Na (mEq/L)
0	-1	-	139.8 (1.56)
30/0	1	2.7 (1.5)	-
30/60	4	3.1 (1.6)	-
60/60	6	3.0 (2.0)	-
60/120	7	-	140.7 (1.41)

Urinary Excretion Pattern of Exosomal Aquaporin-2 in Nephronophthisis Mice

Hiroko Sonoda, Nobuyuki Mikoda, Sayaka Oshikawa, Masahiro Ikeda. *Veterinary Pharmacology, Univ of Miyazaki, Miyazaki, Japan.*

Background: Nephronophthisis (NPHP), an inherited disorder, is the most frequent genetic cause of end-stage renal failure in children. So far, twenty responsible genes have been identified, including the *NPHP3*. The pcy mouse with missense mutation in *Nphp3* gene orthologous to human *NPHP3* is an animal model of NPHP. So far, renal aquaporin-2 water channel (AQP2) expression in pcy mice has been shown to be up-regulated, accompanied by both polyuria and urinary concentrating defect. Urinary exosomes, known to be released into urine from epithelial cells in all nephron segments, have been reported to selectively contain renal functional proteins, including AQP2. In this study, we examined whether the level of urinary exosomal AQP2 excretion was altered in pcy mice.

Methods: Urine samples were collected for 20 hrs from either pcy mice or the control DBA/2 mice, at 7, 16, and 21 weeks of age, respectively. Urinary exosomes were isolated by differential centrifugation. The levels of urinary exosomal and renal protein were analyzed by immunoblotting.

Results: Although urinary volume in pcy mice was not altered at 7 weeks of age, those were significantly increased at 16 and 21 weeks of age in comparison with age-matched control mice. Urine osmolality was significantly decreased in pcy mice at all ages examined in this study. Urinary exosomal AQP2 protein levels in pcy mice were dramatically increased at 16 weeks of age, whereas those at 7 and 21 weeks of age were not significantly increased. Similarly, a transient increase in urinary excretion of exosomal tumor susceptibility gene 101 protein (TSG101), frequently used as an exosome marker protein, was observed in pcy mice at 16 weeks of age. The levels of renal AQP2 protein in pcy mice at 16 weeks of age or older were significantly higher than those in the control mice.

Conclusions: Urinary exosomal AQP2 protein excretion was transiently increased in pcy mice and this increase appeared to be related to both the number of exosomes excreted into the urine and its renal abundance.

PUB716

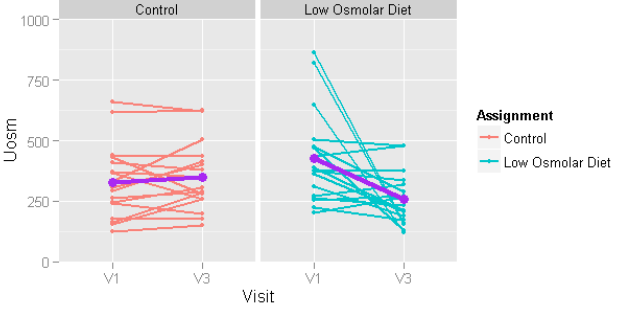
Low Osmolar Diet and Adjusted Water Intake for Vasoprssin Suppression in ADPKD

Osama W. Amro,[1,2] Jessica K. Paulus,[2] Farzad Noubary,[2] Ronald D. Perrone.[1,2] *[1]Nephrology, Tufts Medical Center; [2]Tufts Univ School of Medicine.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) affects 12.5 million persons worldwide and accounts for 10% of patients with end-stage renal disease in the United States. Vasopressin is a known detrimental factor in disease progression and cyst enlargement.

Methods: This randomized controlled trial examined the effect of a novel approach of combining low osmolar diet and adjusted water intake on vasopressin, measured by change in urinary osmolality, and total daily urinary solute in 34 patients with early ADPKD. Participants were randomized to receive a low osmolar diet (low sodium (1500 mg/day), low protein (0.8 gram/kg body weight) diet) followed by adjusted water intake to achieve a urine osmolality of 280 mOsm/kg versus no intervention for two weeks duration, with equal (1:1) allocation. Permuted block randomization was performed within strata of age and sex.

Results: Baseline characteristics of the two groups were similar. Compared with baseline, the mean urine osmolality significantly declined from 426 (±193) to 258 (±110) mOsm/kg (P= 0.007) but not in the control group. At 2 weeks, levels significantly differed between groups (P= 0.04).



Total urinary solute decreased only in the low osmolar diet group and significantly differed between groups at 2 weeks (P=0.03). The two week adherence rate to diet and adjusted water intake was 70% with a mean water prescription of 2.6 liters/daily.

Conclusions: We identified a novel step wise dietary intervention that led to significant reduction in vasopressin as measured by reduction in 24 hour urine osmolality in patients with early ADPKD. Furthermore, this dietary intervention led to significant reduction in water required for vasopressin suppression. Long-term studies are needed to evaluate diet and adjusted water intake adherence, and determine if the reduction in vasopressin slows ADPKD progression.

CRISPR-Cas9-Mediated Deletion of Myosin Light Chain Kinase in Cultured Collecting Duct Cells Kiyoshi Isobe, Viswanathan Raghuram, Pablo Sandoval, Chin-Rang Yang, Chung-Lin Chou, Mark A. Knepper. *Systems Biology Center, NHLBI, NIH.*

Background: Regulation of osmotic water transport in the renal cortical collecting duct by vasopressin is in part dependent on membrane trafficking of aquaporin-2 (AQP2) to the apical plasma membrane of the principal cells. It is known that trafficking of AQP2 is in part dependent on changes in AQP2 phosphorylation. We previously proposed that AQP2 trafficking is dependent on the protein kinase Myosin Light Chain Kinase (MLCK; gene symbol: *Mylk*). Here, we test the role of MLCK in AQP2 phosphoryation and trafficking, utilizing CRISPR-Cas9 generated mutations in MLCK in cultured mouse mpkCCD cells.

Methods: We used CRISPR-Cas9 genome-editing to mutate the catalytic region of the Mylk gene. Clones were generated with 4 different guide RNAs and were characterized by genomic sequencing and immunoblotting. Effects of the deletions were assessed by immunoblotting and immunofluorescence immunocytochemistry of AQP2.

Results: Multiple clones with mutations in the catalytic domain of MLCK were generated. Western blots showed absence of MLCK protein in MLCK-deleted clones. Controls were clones that express MLCK without mutations in the catalytic domain, but may contain off-target modifications. AQP2 protein abundance varied over a broad range, among all MLCK-deleted (n=4) and control (n=4) lines, but, on average, was not affected by the deletion. Immunocytochemistry showed that vasopressin stimulates redistribution of AQP2 to the apical plasma membrane in both control cells and MLCK-deleted cells. Vasopressin-dependent phosphorylation of AQP2 at Ser256 and Ser269 was not significantly reduced in MLCK-deleted cells.

Conclusions: The results demonstrate the feasibility of CRISPR-Cas9-mediated genome editing in mouse mpkCCD cells. Our experiments in mouse cultured collecting duct cells provide evidence that vasopressin-induced phosphorylation of AQP2 and redistribution of AQP2 to the apical plasma membrane can occur independently of myosin light chain kinase.

PUB718

The PDZ Domain-Containing Protein Harmonin Is a Binding Partner of Sodium-Coupled Monocarboxylate Transporter 2 Nobuyuki Onizawa,[1,2] Naoyuki Otani,[1] Promsuk Jutabha,[1] Motoshi Ouchi,[1] Hajime Hasegawa,[2] Naohiko Anzai.[1] *[1]Dept of Pharmacology and Toxicology, Dokkyo Medical Univ School of Medicine, Mibu, Tochigi, Japan; [2]Dept of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical Univ, Kawagoe, Saitama, Japan.*

Background: Lactate is freely filtered and extensively reabsorbed in the proximal tubule to prevent the loss of this valuable metabolite from the body. Sodium-coupled monocarboxylate transporter SMCT2(SLC5A12) mediates the transport of pyruvate, nicotinate and lactate (Gopal et al., BBA. 2007). In contrast to its well characterized transport properties, less information is available on the regulatory mechanism of SMCT2. The C-terminal domain of SMCT2 is exposed to the cytoplasmic compartment and contains thePDZ motif, one of the famous protein-protein interaction modules, suggesting that it may interact with PDZ proteins.

Methods: We used the yeast two-hybrid screening to investigate the putative SMCT2-associated proteins that modulate its transport function. Using the SMCT2 C-terminal tail (SMCT2-CT) as bait, we performed a yeast two-hybrid screen of a cDNA library constructed from the human adult kidney. Next, to further confirm the interaction between SMCT2 and harmonin, we performed a co-immunoprecipitation study using anti-harmonin antibodies.

Results: In the yeast two-hybrid screening, 34 positive clones were obtained from a total of 1.2 × 107 independent colonies screened. Of these, 8 yielded an identical sequence encoding the gene for the PDZ protein PDZK1 (manuscript in preparation), and 1 yielded an identical sequence encoding the gene for the PDZ protein Harmonin. Deletion of C-terminal PDZ motif abolished the interaction with harmonin in the yeast two-hybrid system.Furthermore, co-immunoprecipitation studies revealed that the SMCT2 interacted directly with harmonin.

Conclusions: Harmonin was identified as the binding partner for SMCT2. The elucidation of these interactions may further our understanding of the function and regulation of monocarboxylate (e.g., lactate) transport in the human kidney.

Stimulation of V1a Receptor Increases Renal Uric Acid Clearance via ABCG2 Transporter – Insight into Hypouricemia in SIADH Kei Taniguchi, Yoshifuru Tamura, Shigeru Shibata, Shunya Uchida. *Dept of Internal Medicine, Teikyo Univ School of Medicine, Itabashi, Tokyo, Japan.*

Background: Hypouricemia seen in the subjects with syndrome of inappropriate secretion of antidiuretic hormone (SIADH) is pathognomonic but the mechanism of hypouricemia remains to be clarified. V2 receptor agonist 'desmopressin' induced hyponatremia but not hypouricemia in human unlike SIADH (G Decaux, JASN, 1996). Therefore, we hypothesized that V1 receptor but not V2 receptor may play a role in inducing hypouricemia. In the present study, we examined the changes in serum uric acid, urinary uric acid excretionand expression of uric acid transporters in response to V1a receptor agonist 'terlipressin'.

Methods: Terlipressin was subcutaneously infused by osmotic mini pump to 7-weeks-old male Wistar rats (n = 9). Control rats were infused with normal saline (n = 9). The rats were sacrificed to obtain renal cortical tissues at 3 days.

Results: Serum uric acid significantly decreased and the excretion of urinary uric acid significantly increased in the terlipressin group. Thus, fractional excretion of uric acid increased from 1.20± 0.28 % to 3.10 ± 0.56 % ($P < 0.001$). The expression of ATP-binding cassette transporter, sub-family G, member 2 (ABCG2) significantly increased in the terlipressin group. Other uric acid transportersdid not significantly change.

Conclusions: These results suggest that stimulation of V1a receptor increases renal uric acid clearance probably via upregulation of ABCG2, leading to hypouricemia seen in SIADH patients.

PUB720

Fluorescein Angiography and the Kidney: Friend or Foe? Mohamed E. Elraggal,[1] Ahmed Fathy Elkeraie,[2] Ahmed M. Abdelhadi,[3] Ashraf Nabiel Abdalla.[4] *[1]Nephrology, Kidney and Urology Center, Alexandria, Egypt; [2]Nephrology, Alexandria Univ, Alexandria, Egypt; [3]Ophthalmology, Alexandria Univ, Alexandria, Egypt; [4]Pharmacology, Umm Al-Qura Univ, Saudi Arabia.*

Background: Fluorescein angiography (FA) is an indispensable tool for diagnosis and management of diabetic retinopathy (DR). However, safety of fluorescein sodium on renal functions is not fully understood.

Methods: 100 type 2 diabetic patients presenting to the ophthalmology outpatient clinic at Alexandria main university hospital were included in our study. Serum creatinine and cystatin-C were measured just before and 2 days after FA. Urinary NGAL as a tubular biomarker was measured also before and 4 hours after FA. Renal injury was defined as 25 % increase in serum creatinine or cystatin-C.

Results: The mean of serum creatinine was 0.99 ± 0.36 mg/dl and 1.0 ± 0.36 mg/dl before and after FA respectively with no statistically significant change ($P=0.061$). Only one patient (out of 100) experienced more than 25% rise in serum creatinine from baseline. Serum Cystatin-C and urinary NGAL increased significantly after FA ($P>0.001$). Mean of serum Cystatin-C was 0.89 ± 0.34mg/l and 0.95 ± 0.36 mg/l before and after FA respectively. 11 patients experienced more than 25% rise in serum cystatin-C from baseline. Mean of urinary NGAL was 21.78 ± 23.90 ng/ml and 27.15 ± 28.17 ng/ml before and after FA respectively.

Conclusions: Using ordinary renal biomarkers as serum creatinine, FA was thought to be kidney friendly. Nevertheless, using more sensitive early biomarkers as serum cystatin-C and urinary NGAL, FA is not as innocent as previously thought. A creatinine negative, biomarker positive change may implicate a form of subclinical AKI.

PUB721

Transcultural Adaptation and Validation of the Mexican Version of the Kidney Disease Questionnaire KDQOL-SF36 Version 1.3 Edgar Dehesa Lopez,[1] Ricardo Correa-Rotter,[2] David Olvera,[3] Carlos Gonzalez Parra,[4] Rafael Baizabal.[5] *[1]Dept of Nephrology, Research and Teaching Center in Health Sciences (CIDOCS), Culiacan, Sinaloa, Mexico; [2]Dept of Nephrology, National Inst of Medical Sciences and Nutrition Salvador Zubiran, Mexico, D.F, Mexico; [3]Dept of Nephrology, Hospital ISSSTE, Ciudad Valles, San Luis Potosí, Mexico; [4]Deparment of Nephrology, Christus Murgueza UPAEP, Puebla, Mexico; [5]Dept of Nephrology, Hospital ISSSTE, Xalapa, Veracruz, Mexico.*

Background: The evaluation of health-related quality of life through the application of efficient, reliable and simple instruments is a relatively new concept in the practice of nephrology.The aim of the study was to translate the Kidney Disease Quality of Life Short Form 36 KDQOL-SF36 v1.3 questionnaire into the Spanish language, to adapt it culturally and to validate it in the Mexican population.

Methods: The translation,transcultural adaptation and validation of the Mexican version of KDQOL-SF36 was performed according to the recommendations of RAND Health. The validity was evaluated using Cronbach's α.The test-retest reliability was evaluated using interobserver and intraobserver intraclass correlation coefficients (ICCs).

Results: The questionnaires were applied to 194 Mexican patients with end stage chronic kidney disease in chronic hemodialysis.The average age was 54±16 years,and 54.6.1% were males.The Mexican version proved reliable with intra-and interobserver ICCs ≥ 0.7 in most of the dimensions evaluated, with a range between 0.5 and 0.9.The validity of the questionnaire was acceptable,with an internal items-dimensions consistency between 0.4 and 0.9, dimensions-total of 0.725 and items-total of 0.921.

Table 1.-Reliability and construct validity of the Mexican version of KDQOL-SF36 v1.3.

Scales	ICC (n=18) Interobserver	ICC (n=18) Intraobserver	Cronbach α (n=194)

ICC = Intraclass Correlation Coefficient;

Conclusions: The psychometric properties evaluated in the Mexican version of the KDQOL-SF36 v1.3 demonstrated that it is a valid and reliable instrument,with psychometric results similar to the original version.

PUB722

Urinary Neutrophil Gelatinase Associated Lipocalin Beyond AKI, Relation to Renal and Patient Survival Ahmed Fathy Elkeraie,[1] Mohammed Megahed,[2] Ahmed Elkhodary.[2] *[1]Nephrology, Alexandria Univ, Alexandria, Egypt; [2]Critical Care, Alexandria Univ, Alexandria, Egypt.*

Background: Neutrophil gelatinase-associated lipocalin (NGAL) has been postulated as an early, sensitive, non-invasive biomarker for acute kidney injury (AKI). The aim of this study was to evaluate urinary NGAL levels as a predictor of early AKI (first 5 days) in severely traumatized patients associated with hemorrhagic shock.

Methods: This is a prospective observational study on 57 adult trauma patients presented with severe trauma (ISS ≥ 16) and hemorrhagic shock to the units of Critical Care Medicine Department in Alexandria Main University Hospital and Mostafa Kamel Armed Forces Hospital. Urinary NGAL was measured upon admission and 48 hrs after trauma. Presence of AKI was defined by Acute Kidney Injury Network (AKIN) criteria.

Results: Using AKIN criteria, a total of 13 patients were identified with AKI (incidence of 37.14%). Those who subsequently developed AKI had a striking rise in urinary NGAL early after trauma and a sustained increase over next 48 hrs. The urinary NGAL levels of the AKI group (group A) were significantly higher than non AKI (group B) both on admission and 48 hrs later. For cut-off point >29 ng/mL, urinary NGAL 48 hrs after trauma sensitivity, specificity, positive and negative predictive values were 84.62, 95.45, 91.67and 91.30, respectively. In the analysis of urinary NGAL (on admission) performance for predicting clinical outcomes; Using a cutoff value of 30 ng/mL the area under the receiver-operating characteristic curve for in-hospital mortality and the need for RRT during the first week was 0.768, 0.903 respectively. Odds of in-hospital mortality increased by 12.7% for every 30ng/ml increase in urinary NGAL on admission, confirming the usefulness of NGAL in predicting clinical outcomes.

Conclusions: Urinary NGAL is an early and reliable predictive marker of AKI in severely traumatized patients presented with hemorrhagic shock and also a predictor of adverse clinical outcomes. The important clinical utility of this biomarker in patient care, might facilitate early renal protective interventions with the hope of improvement in the renal and patient outcomes.

PUB723

Epidemiology and Prognosis of Community Acquired Acute Kidney Injury versus Hospital Acquired Acute Kidney Injury Edgar Dehesa Lopez,[1] Melissa Rodriguez,[2] Rodolfo Radames Salas Zazueta,[2] Daniel Antonio Hernandez Quintero,[2] Hector Guillermo Peña Peredia,[2] Berenice Tamayo Garcia.[2] *[1]Dept of Nephrology, Research and Teaching Center in Health Sciences (CIDOCS), Culiacan, Sinaloa, Mexico; [2]Research and Teaching Center in Health Sciences (CIDOCS), Culiacan, Mexico.*

Background: The epidemiological characteristics and prognosis of patients with community acquired acute kidney injury (C-AKI) vs hospital acquired acute kidney injury (H-AKI) have not been thoroughly studied.

Methods: A total of 192 patients admitted to internal medicine service were studied. AKI was diagnosed and classified at time of admission (C-AKI) or posteriorly during hospitalization.AKI was defined according to the Acute Kidney Injury Network (AKIN) and serum sCr. The etiology, severity and evolution of the AKI episodes were compared among patients with C-AKI and H-AKI.

Results: C-AKI incidence was 22.4% (n=43) and H-AKI was 5.7% (n=11),giving an overall incidence of 28.1%.AKIN 1 stage was present in 51.7%,AKIN 2 in 12.9% and AKIN 3 in 35.4%.Renal factors were the most frequent etiology of AKI in 55.6%, prerrenal in 38.9% and obstructive in 5.6%.Oliguric AKI was observed in 25.9%. Hemodialysis was required in 9.3% of cases.The recovered AKI was observed in 75.9% at the time of hospital discharge.The length of hospital stay (9±9 vs 7±6 days;p<0.05) and mortality (18.5 vs 7.2%; p=0.02) were greater in patients with AKI compared with patients without AKI.Patients with H-AKI had a longer hospital stay (15±12 vs. 8±8; p<0.05) and a statistical trend to higher mortality (36.4% vs 14%;p=0.08) in relation to patients with C-AKI.

Table 1.-Clinical and prognostic differences between C-AKI vs H-AKI

	C-AKI		H-AKI		P
	n=42	%	n=11	%	
AKI severity					
Stage 1	17	39.5%	2	18.2%	NS
Stage 2	5	11.6%	5	45.5%	0.03
Stage 3	21	48.8%	4	36.4%	NS
Etiology of AKI					
Prerenal	15	34.9%	3	27.3%	
Renal	25	58.1%	8	72.7%	0.54
Postrenal	3	7.0%	0	0.0%	
Oliguria	8	18.6%	6	54.5%	0.01
Hemodialysis	5	11.6%	0	0.0%	0.23
Discharged with recovered AKI	33	76.7%	8	72.7%	0.78
Etiology of renal AKI:					
Acute tubular necrosis	19	76.0%	6	75.0%	
Glomerulonephritis	6	24.0%	2	25.0%	0.95
Nephrotoxic drugs	0	0.0%	0	0.0%	
AKI days	5±4		5±3		NS

AKI= Acute kidney injury; **C-AKI** = Community acquired acute kidney injury; **H-AKI**= Hospital acquired acute kidney injury

Conclusions: AKI was a frequent diagnosis on hospital admission or during hospitalization.C-AKI and H-AKI added a negative effect on the prognosis.H-AKI episodes were more severe and were associated with a longer hospital stay and an statistical trend in mortality in comparison with C-AKI.

PUB724

Drug Utilization Patterns and Factors Associated with Acute Kidney Injury in an Intensive Care Unit at a Brazilian Public Hospital – A Prospective Cohort Study Danielly Botelho Soares,[1] Gabriela Rebouças Botelho,[1] Flávia Fialho Girundi,[1] Fernando Antonio Botoni,[2] Maria Auxiliadora Parreiras Martins.[1] *[1]School of Pharmacy, Univ Federal de Minas Gerais, Belo Horizonte, Minas Gerais, Brazil; [2]School of Medicine, Univ Federal de Minas Gerais, Belo Horizonte, Minas Gerais, Brazil.*

Background: Acute kidney injury (AKI) is associated with a significant increase in morbidity, mortality and health care costs. In intensive care units (ICU), the cause of AKI is commonly associated with multiple factors, among which the use of potentially nephrotoxic drugs is often neglected as a preventable cause of AKI.

Methods: This is a prospective cohort study that evaluated the AKI as a primary outcome in ICU patients at a teaching hospital in Belo Horizonte, Brazil. Length of stay greater than 24 hours and hospital stay lower or equal to 7 days were evaluated for potential eligibility. To be enrolled, patients should not present kidney dysfunction at the time of ICU admission.

Results: Data collection was performed from October 2014 to February 2015, including 122 patients, mostly originated from the surgical department (46.7%). An average of 22.0 ± 9.4 drugs was prescribed and 2-24 potentially nephrotoxic drugs were used per patient. Mechanical ventilation was required for 67.2% of patients and at least one vasoactive drug was used in 68.0% of cases. An incidence of AKI was observed in23.8% of patients, among them 34.5% required dialysis, 24.1% reached the third stage of AKI and 31.8% were referred to additional treatment after ICU discharge. Eleven (9%) patients died and 63.6% of them developed AKI. The bivariate analysis showed that age (p = 0.006) and APACHE II score (p = 0.003) had higher median among patients who developed AKI compared to those who did not develop AKI. In the logistic regression, the number of medications (OR: 1.15; 95% CI: 1.05 to 1.26) presented a statistically significant correlation with the development of AKI.

Conclusions: These results demonstrate that the identification of factors associated with AKI in ICU patients is very important for the early identification of renal dysfunction induced by drugs, providing conditions for appropriate prevention and treatment of the extent of kidney damage.

PUB725

Clinical, Dialytic and Laboratorial Factors Associated with Poor Health Related Quality of Life in Mexicans Hemodialysis Patients

Edgar Dehesa Lopez,[1] David Olvera,[2] Carlos Gonzalez parra,[3] Rafael Baizabal.[4]
[1]Dept of Nephrology, Research and Teaching Center in Health Sciences (CIDOCS), Culiacan, Sinaloa, Mexico; [2]Dept of Nephrology, Hospital ISSSTE, Ciudad Valles, San Luis Potosi, Mexico; [3]Dept of Nephrology, IMSS, Puebla, Mexico; [4]Deparment of Nephrology, Hospital ISSSTE, Xalapa, Veracruz, Mexico.

Background: The evaluation of health related quality of life (HRQOL) in hemodialysis patients has recently gained great importance because it has proven to be an independent predictor of clinical outcomes.

Methods: Cross-sectional study. The validated Mexican version of the KDQOL-SF36 v1.3 questionnaire were applied to 194 adult patients with ESRD on hemodialysis in different regions of Mexico. According to the global score of questionnaire, patients were grouped in: patients with poor HRQOL (global score below the median) and patients with good HRQOL (global score greater than the median). Logistic regression was used to investigate the effects of clinical, dialytic and laboratorial factors on HRQOL.

Results: The average age was 54+16 with 54.6.1% male. Comorbidities were: hypertension in 86.6%, diabetes mellitus 2 in 57.2% and dyslipidemia in 7.2%. The vascular access was a catheter in 55.2% and fistula in 44.8% of the cases. Diabetes mellitus and the use of catheters as vascular access were more frequent in patients with poor quality of life . On the other hand, phosphorus >5.5 mg/dl and albumin >4g/dl were more frequent in patients with good quality of life .There were no differences in age, KtV, hemoglobin and calcium between groups. Table 1 shown the clinical, dialytic and laboratorial factors studied in the multivariate logistic analysis.

Table 1.-Multivariate logistic regression analysis of clinical, dialytic and laboratorial factors associated with poor HRQOL.

Variables	OR	CI 95%		p

Calcium (>10 mg/dl)	0.55	0.18	1.65	0.28
Phosphorus (<4.5 mg/dl reference)				
Phosphorus (4.5-5.5 mg/dl)	2.45	0.30	19.77	0.40
Phosphorus (>5.5 mg/dl)	1.15	0.14	9.28	0.90
Hemodialysis stay (months)	1.02	1.00	1.04	0.03

OR=odds ratio; CI:Confidence interval; HRQOL: Health related quality of life

Conclusions: The associated factors with poor HRQOL in Mexicans hemodialysis patients were: the time spent in hemodialysis, serum albumin <4 g /dl and use of catheter for vascular access.

Empagliflozin and Cardiovascular Outcomes in Patients with Type 2 Diabetes and Chronic Kidney Disease Christoph Wanner,[1] John M. Lachin,[2] David H. Fitchett,[3] Silvio E. Inzucchi,[4] Maximilian von Eynatten,[5] Michaela Mattheus,[5] Odd Erik Johansen,[6] Hans-Juergen Woerle,[5] Uli Christian Broedl,[5] Bernard Zinman.[7,8] *[1]Dept of Medicine, Würzburg Univ Clinic, Würzburg, Germany; [2]The Biostatistics Center, The George Washington Univ, Rockville, MD; [3]St Michael's Hospital, Div of Cardiology, Univ of Toronto, Toronto, Canada; [4]Section of Endocrinology, Yale Univ School of Medicine, New Haven, CT; [5]Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany; [6]Boehringer Ingelheim Norway KS, Asker, Norway; [7]Lunenfeld-Tanenbaum Research Inst, Mount Sinai Hospital, Toronto, Canada; [8]Div of Endocrinology, Univ of Toronto, Toronto, Canada.*

Background: Patients with type 2 diabetes (T2D) and chronic kidney disease (CKD) are at high risk of cardiovascular (CV) events and premature death. Empagliflozin is a sodium glucose co-transporter (SGLT)-2 inhibitor used in the treatment of T2D.

Methods: In EMPA-REG OUTCOME®, we explored long-term CV outcomes with empagliflozin vs placebo when added to standard of care in 7020 T2D patients with established CV disease. Inclusion criteria included eGFR ³30ml/min/1.73m². Patients (mean age 63 years, male 71%, mean HbA1c 8.1%) were randomized 1:1:1 to empagliflozin 10 mg, 25 mg or placebo.

Results: Most patients had impaired kidney function (52.2% stage 2, 17.8% stage 3a, 7.7% stage 3b CKD) while 28.7% and 11.0%, respectively, had moderately (30-300mg/g) or severely (>300 mg/g) increased urine albumin to creatinine excretion. After a median follow-up of 3.1 years, the primary outcome (first occurrence of non-fatal myocardial infarction, non-fatal stroke, or CV death) occurred in a lower percentage of patients on empagliflozin (10.5%) than placebo (12.1%) (HR 0.86 [0.74-0.99]; p=0.04). This result was driven by a 38% reduction in CV death vs placebo (HR 0.62 [0.49-0.77]; p<0.001), with no difference in the risk of heart attack or stroke. Empagliflozin reduced hospitalization for heart failure by 35% (HR 0.65 [0.50-0.85]; p=0.0017). Pre-defined subgroup analyses on CV outcomes in patients with T2D and CKD will be presented.

Conclusions: Empagliflozin reduces CV morbidity and mortality in patients with T2D and various degrees of CKD.

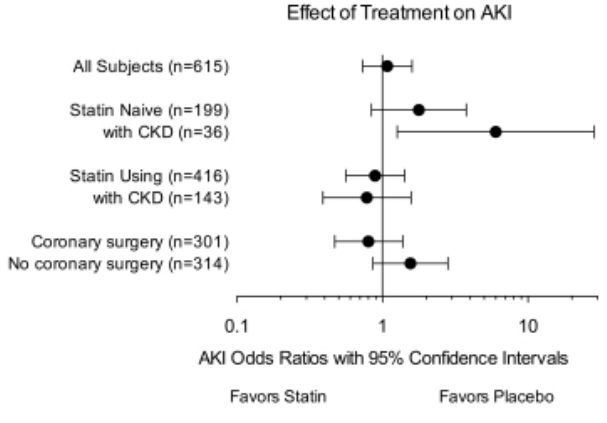
High Dose Perioperative Atorvastatin and Acute Kidney Injury Following Cardiac Surgery Frederic Tremaine Billings, Chad E. Wagner, Patty Hendricks, Yaping Shi, Michael R. Petracek, Nancy J. Brown. *Vanderbilt Univ, Nashville, TN.*

Background: Hydroxy-methylglutaryl-coenzyme A reductase inhibitors (statins) affect several mechanisms underlying acute kidney injury (AKI), a common and dangerous complication after cardiac surgery. We hypothesized that short-term high-dose perioperative atorvastatin would reduce AKI following cardiac surgery.

Methods: We randomized elective cardiac surgery patients, stratified by chronic kidney disease (CKD), to atorvastatin or matching-placebo starting the day prior to surgery until hospital discharge in pre-study statin naïve subjects or until the day after surgery in pre-study statin-using subjects. Our primary endpoint was AKI by AKIN criteria.

Results: The study was stopped on recommendations of the DSMB after 653 of 820 subjects completed the study due to futility and an increased incidence of AKI among statin-naïve subjects with CKD randomized to atorvastatin. AKI occurred in 20.8% of subjects randomized to atorvastatin versus 19.5% randomized to placebo (P=0.75). Among statin-naïve subjects (n=199), however, AKI occurred in 21.6 % randomized to atorvastatin versus 13.4% randomized to placebo (p=0.14), and 52.9% vs. 15.8%, P=0.03, in patients with CKD (n=36). Serum creatinine concentrations increased a median of 0.11 (-0.11 – 0.56) versus 0.05 (-0.12 – 0.33) mg/dl in statin-naïve patients randomized to atorvastatin versus placebo (P=0.007), and this effect was magnified among those with CKD, whereserum creatinine concentrations increased by 0.26 (-0.22 – 0.94) versus -0.06 mg/dl (-0.16 – 0.41), P=0.04.



Conclusions: High-dose perioperative atorvastatin treatment does not reduce AKI following cardiac surgery and may increase risk in patients with CKD who are naïve to statin treatment. Perioperative continuation or short-term withdrawal of statin treatment in statin-using patients does not affect AKI.

HI-OR03

Effect of Methylprednisolone on Acute Kidney Injury in Patients Undergoing Cardiac Surgery with Cardiopulmonary Bypass Amit X. Garg,[1] Richard P. Whitlock.[2] *[1]Western Univ, London, Canada; [2]McMaster Univ, Hamilton, Canada and the Population Health Research Inst; for the SIRS Investigators.*

Background: Acute kidney injury is a common complication of the 20 million cardiac surgeries performed worldwide each year. We conducted a substudy of the Steroids In caRdiac Surgery (SIRS) trial to determine whether methylprednisolone alters the risk of acute kidney injury in patients undergoing cardiac surgery with cardiopulmonary bypass [substudy protocol BMJ Open 2014 Mar 5;4(3): e004842].

Methods: This was a randomized clinical trial of 7,286 high-risk patients undergoing cardiac surgery with cardiopulmonary bypass from 79 centres in 18 countries between June 2007 and December 2013. Patients were assigned to take intravenous methylprednisolone (250 mg at anesthetic induction and 250 mg at initiation of cardiopulmonary bypass) or placebo. Patients, care givers and outcome-assessors were blinded to allocation. Acute kidney injury was defined as ≥50% or ≥ 26.5 mmol/L (≥ 0.3 mg/dL) increase in the postoperative serum creatinine concentration from the preoperative concentration in the 14 days following surgery, or new dialysis in the 30 days following surgery.

Results: Methylprednisolone (n=3,647) versus placebo (n=3,639) did not alter the risk of acute kidney injury (40.9% versus 39.5%, respectively; relative risk 1.03 [95% CI, 0.96 to 1.11]). Results were consistent with multiple alternate continuous and categorical definitions of acute kidney injury, and in the subgroup with baseline chronic kidney disease.

Conclusions: Amongst patients undergoing cardiac surgery with cardiopulmonary bypass, the use of corticosteroids in the perioperative period did not alter the risk of acute kidney injury. Trial Registration: NCT00427388

	Number of Events (%)		Relative Risk (95% CI)
	Methylprednisolone n = 3647	Placebo n = 3639	
AKI	1490 (40.9%)	1439 (39.5%)	1.03 (0.96 to 1.11)
Alternative Definitions			
AKI or death	1513 (41.5%)	1463 (40.2%)	1.03 (0.96 to 1.11)
≥ stage 2 AKI	362 (9.9%)	359 (9.9%)	1.01 (0.87 to 1.16)
≥ stage 3 AKI	145 (4.0%)	162 (4.5%)	0.89 (0.71 to 1.12)
Acute dialysis	95 (2.6%)	88 (2.4%)	1.08 (0.81 to 1.43)

The NEFIGAN Trial: NEFECON, a Novel Targeted Release Formulation of Budesonide, Reduces Proteinuria and Stabilizes eGFR in IgA Nephropathy Patients at Risk of ESRD Bengt C. Fellstrom,[1] Rosanna Coppo,[2] John Feehally,[3] Jürgen Floege,[4] Johan W. De Fijter,[5] Alan G. Jardine,[6] Francesco Locatelli,[7] Bart D. Maes,[8] Alex Mercer,[9] Fernanda Ortiz,[10] Manuel Praga,[11] Søren Schwartz Sørensen,[12] Vladimir Tesar.[13] *[1]Uppsala Univ Hospital; [2]Univ Turin; [3]Univ Leicester; [4]RWTH Univ Aachen; [5]Leiden Univ Medical Center; [6]Univ Glasgow; [7]Ospedale A Manzoni, Lecco; [8]AZ Delta Roeselare; [9]Pharmalink; [10]Helsinki Univ Hospital; [11]Hospital 12 de Octubre, Madrid; [12]Rigshospitalet, Copenhagen; [13]Charles Univ, Prague.*

Background: IgA nephropathy (IgAN) is the most prevalent primary chronic glomerular disease. Despite RAS blockade, >25% of patients progress to ESRD within 20 years. This study evaluated a novel budesonide formulation (NEFECON) targeted for release in the distal ileum, where Peyer's patches reside, in patients at risk of ESRD despite optimized RAS blockade.

Methods: Double-blind, placebo-controlled study in 150 patients (62 sites, 10 EU countries) with primary IgAN, proteinuria (UPCR ³0.5 g/g OR urine protein ³0.75 g/d) and eGFR CKD-EPI ≥45 mL/min/1.73m² randomized to 8 or 16 mg/d NEFECON or placebo (1:1:1), after 6 mo run-in phase to optimize RAS blockade. Primary endpoint: reduction in UPCR at 9 mo of treatment; secondary: mean percentage change in eGFR.

Results: Baseline data were similar across groups; BP was 127-128/78-80 mmHg, UPCR 0.76–0.83 g/g, and eGFR 72-85 mL/min/1.73m². Primary endpoint was met at the pre-specified interim analysis. Mean UPCR decreased by 24% (NEFECON 8+16 mg/d) vs 3% increase (placebo) at 9 mo (p=0.007); reduction in the 16 mg/d group was 27% (p=0.009). At final analysis, mean change in eGFR was -4.7 mL/min/1.73m² for placebo compared with 0.32 and 1.95 mL/min/1.73m² for NEFECON 8 and 16 mg/d, respectively; difference in mean percentage change in eGFR achieved statistical significance for 8 mg/d (p=0.006) and 16 mg/d (p=0.003). Adverse event rates were higher in NEFECON groups (88–94%) than placebo (84%). Two serious adverse events were assessed as possibly related to NEFECON; deteriorated renal function (in follow-up) and deep vein thrombosis.

Conclusions: NEFECON reduced UPCR and maintained eGFR in patients with primary IgAN at risk of progression to ESRD despite optimized RAS blockade. Treatment was generally well-tolerated.

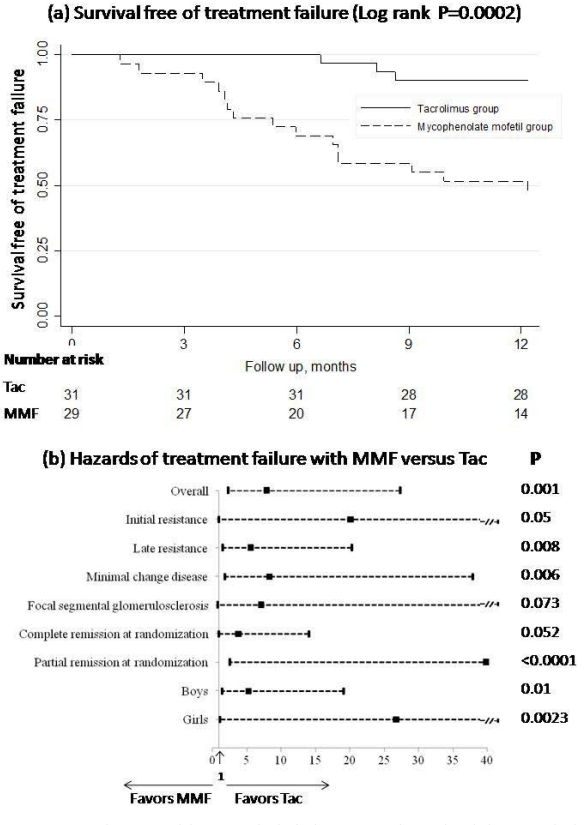
Randomized Trial on Efficacy of Mycophenolate Mofetil versus Tacrolimus in Maintaining Remission in Children with Steroid Resistant Nephrotic Syndrome Aditi Sinha, Arvind Bagga. *All India Inst of Medical Sciences, New Delhi, India.*

Background: Since prolonged therapy with tacrolimus (Tac) causes nephrotoxicity, this RCT examined non-inferiority of mycophenolate mofetil (MMF) to Tac in maintaining remission in patients with steroid resistant nephrotic syndrome (SRNS). CTRI/2012/03/00247

Methods: Following approvals, 84 patients with SRNS (1-18 yr; minimal change 48, FSGS 36) & eGFR >60 ml/min/1.73m^2 received Tac (0.15 mg/kg/d; trough 4-8 ng/ml) for 6-months. Stratifying for histology & type of response, patients with complete (Up/Uc <0.2 mg/mg) or partial remission (Up/Uc 0.2-2, albumin >2.5 g/dl) were randomized to continue Tac or receive MMF (0.75-1 g/m^2/d), prednisone & enalapril. Primary outcome, at 12-mo, was proportion with remission or infrequent relapses. Therapy failure was recurrent SRNS, frequent relapses or >1 SAE. Enrolment was closed after interim intention-to-treat analysis of outcome in 1/3 sample.

Results: Baseline features were similar. Therapy with MMF led to significantly higher treatment failure, prednisone dose & SAE; eGFR change was similar. On multivariate regression, hazards of treatment failure were high with MMF (HR 9.7, adjusted for histology, type of resistance & remission; P<0.0001).

Baseline	**Tac, N=31**	**MMF, N=29**
Minimal change/FSGS	17/16	17/12
Initial resistance	15	13
Age months	76±46	77±46
Complete/partial remission	19/12	18/11
Albumin g/dl	4.2±0.5	4.3±0.5
OUTCOMES		
Satisfactory remission^	28; 90%	13; 48%
Complete/partial remission	17	12
Infrequent relapses	11	1
Treatment failure^	3	16
Frequent relapses	3	8
Steroid resistance	0	8
Relapse/yr	0.8±1.0	1.3±1.3
Prednisone mg/kg/d#	0.3±0.2	0.5±0.4
Change eGFR ml/min/1.73m^2	-6±35	-19±31
P^<0.0005;#0.028		



Conclusions: Therapy with MMF is inferior to Tac in maintaining Tac induced remission in patients with SRNS

HI-OR06

Prevention of Bone Mineral Density Loss in De Novo Kidney Transplant Recipients with Twice-Yearly Denosumab: A Randomized Controlled Trial (ClinicalTrials.gov number NCT01377467) Rudolf P. Wuthrich,[1] Diana P. Frey,[2] Jens Gunther Brockmann,[3] Thomas Fehr,[1] Thomas F. Mueller,[1] Lanja Saleh,[4] Arnold Von Eckardstein,[4] Nicole Graf,[5] Marco Bonani.[1] *[1]Div of Nephrology; [2]Div of Rheumatology; [3]Div of Visceral and Transplantation Surgery; [4]Inst of Clinical Chemistry, Univ Hospital, Zurich, Switzerland; [5]Graf Biostatistics, Winterthur, Switzerland.*

Background: Kidney transplantation is associated with bone loss and an increased risk of fracture. Since current therapeutic options to prevent bone loss are limited we assessed the efficacy and safety of Receptor Activator of Nuclear Factor κB Ligand (RANKL) inhibition with denosumab to improve bone mineralization in the first year after kidney transplantation.

Methods: We enrolled 108 kidney transplant recipients and randomized 90 patients two weeks after surgery in a 1:1 ratio to receive denosumab (subcutaneous injections of 60 mg denosumab at baseline and after 6 months) or no treatment. The primary endpoint was the percentage change in bone mineral density (BMD) measured by DXA at the lumbar spine at 12 months.

Results: After 12 months, the primary outcome of total lumbar spine BMD increased by 4.6% (95% CI 3.3-5.9%) in 46 patients in the denosumab group and decreased by -0.5% (95% CI -1.8-0.9%) in 44 patients in the control group (between-group difference 5.1%, 95% CI 3.1-7.0%, p<0.0001). Denosumab also significantly increased BMD at the total hip by 1.9% (95% CI, 0.1 to 3.7%; p=0.035) over that in the control group at 12 months. HR-pQCT in a subgroup of 24 patients showed that denosumab also significantly increased BMD and cortical thickness at the distal tibia and radius (p<0.05). Biomarkers of bone resorption (β-CTX, urine deoxypyridinoline) and bone formation (P1NP, BSAP) markedly decreased with denosumab (p<0.0001). Episodes of cystitis and asymptomatic hypocalcemia occurred more often with denosumab, whereas graft function, rate of rejections and incidence of opportunistic infections were similar.

Conclusions: Antagonizing RANKL with denosumab effectively increased BMD in *de novo* kidney transplant recipients, but was associated with more frequent episodes of urinary tract infection and decreased calcemia.

Funding: Government Support - Non-U.S.

HI-OR07

Randomized, Double-Blind, Placebo-Controlled, Parallel, 3-Arm Study of Safety and Anti-Pruritic Efficacy of Nalbuphine HCl ER Tablets in Hemodialysis Patients with Uremic Pruritus Vandana S. Mathur,[1] Jayant Kumar,[5] Paul W. Crawford,[3] Howard Hait,[4] Thomas Sciascia.[2] *[1]MathurConsulting; [2]Trevi Therapeutics; [3]Research by Design; [4]Edenridge Consulting; [5]Renal Medical Associates.*

Background: Uremic pruritus (UP) is associated with decrements in quality of life and sleep and higher mortality. UP pathogenesis may involve endogenous κ/μ opioid ligand ratio imbalance. Nalbuphine ER tablets (NAL) are a κ-opioid agonist/μ-opioid antagonist being developed for chronic pruritic conditions.

Methods: 373 hemodialysis patients (HDP) with mean baseline numerical rating scale score (NRS) ≥ 4.5 for worst itching (0 [no itch] -10 [worst possible itching]) were randomized 1:1:1 to NAL 60 mg (n = 128), NAL 120 mg (n=120), or placebo (n = 125) and treated for 8 weeks.

Results: Demographics, dialysis adequacy and vintage, phosphorus, parathyroid hormone, pruritus duration, and antihistamine use were similar in the 3 arms at baseline. The primary efficacy endpoint was the change from Baseline to the Evaluation Period (Weeks 7 and 8) in the NRS for each dose of NAL, with pre-specified hierarchical ordering – the 120 mg vs. placebo comparison was performed first. The mean (SD) NRS in the NAL 120 mg group declined from 6.94 (1.46) to 3.51 (2.11), with an LS mean decline vs. placebo = -0.73 (0.31), p = 0.017. The mean NRS in the NAL 60 mg group declined from 6.87 (1.40) to 4.95 (2.10), with an LS mean decline vs. placebo = -0.24 (0.31), p = 0.432. A statistically significant mean reduction for NAL 120 compared to placebo was observed as early as one week following titration. The most common adverse events were nausea, vomiting, dizziness and somnolence with incidence rates of these events quickly approaching that of placebo after the first week of titration. Among subjects with NRS ≥7 (post-hoc analysis), NAL 120 reduced NRS by 4.48 (SD) vs. 3.16 (SD) vs. placebo (p=0.007) with sleep quality (Itch MOS sleep scale) improved significantly (p=0.006).

Conclusions: Nalbuphine ER tablets at a dose of 120 mg BID were safe and significantly reduced itching intensity.

HI-OR08

The Omega-3 Fatty Acids (Fish Oils) and Aspirin in Vascular Access Outcomes in Renal Disease (FAVOURED) Study: A Randomised Placebo-Controlled Trial Ashley B. Irish.[1,2] *[1]Nephrology, Fiona Stanley Hospital, Perth, Western Australia, Australia; [2]Australasian Kidney Trials Network, Univ of Queensland, Brisbane, Queensland, Australia.*

Background: Increasing the use of arteriovenous fistulae (AVF) to improve haemodialysis access is limited by early thrombosis and maturation failure. Omega-3 polyunsaturated fatty acids (w3FA) may prevent these complications by inhibition of platelet aggregation, vasoconstriction, intimal hyperplasia and inflammation.

Underline represents presenting author/disclosure.

Methods: This international, randomised, double-blind, placebo-controlled trial examined whether 3 months therapy with w3FA (4g/day) reduced primary AVF failure at 12 months after AVF creation. AVF failure was defined as AVF thrombosis and/or abandonment and/or cannulation failure. A subset of patients received aspirin (100mg/day) or matching placebo in addition to w3FA or placebo in a factorial design (n=388).

Results: The 567 randomised participants had a mean age of 55 years, 63% were male and 46% diabetic. AVF failure occurred in 128/270 (47%) participants assigned to w3FA compared with 125/266 (47%) assigned to placebo (relative risk adjusted for aspirin use [RR] 1.03, 95% confidence interval [CI] 0.86-1.23, p= 0.78). Regarding each component of AVF failure, w3FA did not reduce the risk of thrombosis (22% vs 23%, RR 0.98, 95% CI 0.72-1.34, p=0.90), AVF abandonment (19% vs 22%, RR 0.87, CI 0.62-1.22, p=0.43) or cannulation failure (40% vs 39%, RR 1.03, 0.83-1.26, p=0.81). A subgroup difference was observed for diabetes mellitus (interaction p =0.038; RR 1.30 vs 0.78; diabetics vs non-diabetics) but not for age, gender, AVF site, dialysis modality and cardiovascular disease. There was no difference in any serious adverse event (AE), 9.2% vs 13.0%, p=0.14; bleeding, 8.1% vs 10.9% p=0.26, or gastrointestinal AE, 4.9% vs 5.4%, p=0.86. The risk of AVF failure was similar (45% vs 43%, RR 1.05, 95% CI 0.84-1.31) in the subset of participants randomised to aspirin or placebo-aspirin as part of the factorial design.

Conclusions: Three months of w3FA intake was ineffective in reducing primary AVF failure at 12 months. Aspirin may be similarly ineffective. There was no increased risk of bleeding. Neither w3FA nor aspirin increased the proportion of useable de novo AVF.

The Remote Ischemic Preconditioning in Cardiac Surgery Trial (Remote IMPACT) Michael Walsh.[1,2] *[1]McMaster Univ; [2]Population Health Research Inst.*

Background: Cardiac surgery is frequently complicated by ischemia-reperfusion injury which can lead to kidney and myocardial injury. Preoperative Remote Ischemic Preconditioning (RIPC), cycles of brief ischemia to a limb alternating with reperfusion, may reduce the frequency or severity of organ injury after cardiac surgery.

Methods: We randomly allocated 258 patients at high risk for death after cardiac surgery to receive either RIPC or a sham procedure immediately after induction of anesthesia. RIPC consisted of 3 cycles of thigh tourniquet inflation to 300 mmHg for 5 minutes followed by 5 minutes reperfusion. The sham group tourniquets were inflated to 15 mmHg. Patients and care providers were blinded. The main clinical outcomes were change in creatinine over the first 4 postoperative days and the peak CK-MB within 24 hours of surgery. Other outcomes were assessed to 30 days after randomization. Analyses were performed according to the intention-to-treat principle.

Results: We randomized 128 patients to RIPC and 130 to sham. No patients were lost to follow-up. There was no significant between group differences in postoperative change in creatinine (p=0.79) or peak CK-MB (p=0.18) (Figure 1). We found no significant differences in the frequency of acute kidney injury (34% vs 31%), myocardial injury (24% vs 19%), stroke (4% vs 3%) or mortality (6% vs 5%) at 30 days.

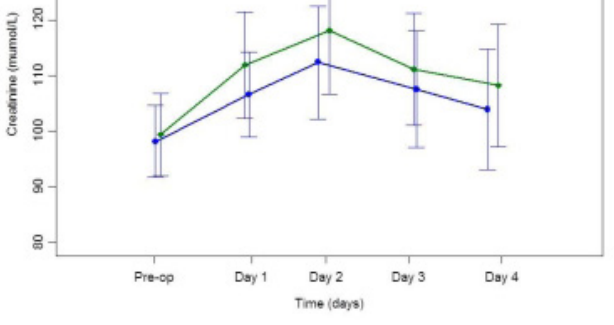

Figure 1. Mean and 95% confidence intervals of creatinine over time for the RIPC (green diamonds) and sham (blue circles) groups.

Conclusions: In this trial RIPC did not affect markers of kidney and myocardial injury. These results fail to provide proof-of-concept that RIPC may impact clinically important outcomes in the cardiac surgery setting.

SA-PO1092

Nephrotoxicity of Invasive and Noninvasive Coronary Angiography: Randomized Controlled Study of Intracoronary and Intravenous Contrast Agent Administration Eva Schönenberger,[1] Patricia D. Bady,[2] Peter Martus,[3] Elke Zimmermann,[2] Michael Laule,[4] Marc Dewey.[2] *[1]Anesthesiology, Charité, Berlin, Germany; [2]Radiology, Charité, Berlin, Germany; [3]Inst for Clinical Epidemiology and Applied Biostatistics, Eberhard Karls Univ, Tübingen, Germany; [4]Cardiology, Charité, Berlin, Germany.*

Background: Iodinated contrast agents can have nephrotoxic effects. It is unknown whether nephrotoxicity is more likely following intracoronary or intravenous contrast agent administration.

Methods: We randomly assigned patients with suspected coronary disease to either intracoronary contrast agent for invasive coronary angiography (ICA) or intravenous administration for coronary computed tomography angiography (CTA). The same low-osmolar nonionic contrast agent with a concentration of 350 mg iodine per milliliter was used for ICA and CTA. Blood samples were taken before and at two time points after ICA and CTA (18 to 24 hours and 46 to 50 hours) to identify contrast-induced acute kidney injury defined according to the most commonly used definition as an increase in creatinine of at least 0.5 mg per deciliter or 25%.

Results: We enrolled 340 patients of whom 10 and 4 dropped out from the ICA and CTA group, respectively, leaving 161 and 165 patients who underwent ICA and CTA until September 8, 2015. Baseline creatinine levels in the ICA (0.85±0.19) and the CTA group (0.87±0.21 mg per deciliter) were similar (P=0.34). Follow-up creatinine was not available in 3 and 5 patients in the ICA and CTA group, respectively. Twenty-one of the 158 patients in the ICA group (13%) had an increase in creatinine of at least 0.5 mg per deciliter or 25%, as compared with 9 of the 160 patients in the CTA group (6%; P<0.05). In patients without coronary disease on ICA or CTA, such a creatinine increase was found in 17 of the 134 patients in the ICA group (13%) and 6 of the 139 patients in the CTA group (4%; P<0.05). No patient without coronary disease in the CTA group had an increase in creatinine according to the KDIGO definition of at least 0.3 mg per deciliter or 50%, but 6 of the 134 patients in the ICA group (4%; P<0.05).

Conclusions: Nephrotoxicity may be more likely after intracoronary than after intravenous contrast agent administration.

Funding: Government Support - Non-U.S.

Efficacy and Safety of Bosutinib in Autosomal Dominant Polycystic Kidney Disease: A Phase 2, Randomized, Double-Blind, Placebo-Controlled Study Kazimierz Ciechanowski,[1] Vladimir Tesar,[2] York P. Pei,[3] Irina Barash,[4] Megan Shannon,[5] Ruifeng Li,[6] Jason Williams,[7] Matteo Levisetti,[8] Steven Arkin,[6] Andreas L. Serra.[9] *[1]Pomeranian Medical Univ, Szczecin, Poland; [2]Charles Univ, Prague, Czech Republic; [3]Univ Health Network, Toronto, Ontario, Canada; [4]Icahn School of Medicine at Mount Sinai, New York, NY; [5]Pfizer Inc, San Diego, CA; [6]Pfizer Inc, Cambridge, MA; [7]Sanofi US, Bridgewater, NJ; [8]Roche Pharma Research and Development, Basel, Switzerland; [9]Inst fur Allgemeine Innere Medizin und Nephrologie, Suisse ADPKD Hirslanden, Zurich, Switzerland.*

Background: Src overactivation has been linked to the pathogenesis of autosomal dominant polycystic kidney disease (ADPKD). We assessed efficacy and safety of bosutinib (BOS), an oral dual Src/Abl tyrosine kinase inhibitor, in ADPKD patients (pts).

Methods: In this phase 2, multicenter study (NCT01233869), ADPKD pts with estimated glomerular filtration rate ≥60 mL/min/1.73 m^2 and magnetic resonance image (MRI)-confirmed total kidney volume (TKV) ≥750 cc were randomized 1:1:1 to placebo (PBO), 200 mg/d, or 400 mg/d of oral BOS for £24 mo. The primary endpoint was annualized TKV % change. Pts treated for ³2 wk who had an MRI after a 30-d washout period were in the modified intent-to-treat (mITT) analysis.

Results: 169 of 172 enrolled pts received ³1 dose of treatment. 24 pts who initially received 400 mg/d BOS were later reduced to 200 mg/d BOS per protocol. 88 pts (52%) were in the mITT population (200 mg/d, n=27; 400 mg/d, n=7; 400 to 200 mg/d, n=21; PBO, n=33) after discontinuations (unrelated to study drug, 27%; study drug-related adverse events, 17%; consent withdrawal, 14%). Annual rate of kidney enlargement was significantly reduced for pooled BOS vs PBO (0.84% vs 4.74%, respectively, 95% CI for difference in annualized rates [2.02-5.74]; p<.0001) and was 65.2% lower for BOS 200 mg/d vs PBO (1.63% vs 4.74%, respectively, 95% CI [0.93 to 5.23]; p=.005). Gastrointestinal (GI) effects were dose-dependent for BOS; the overall safety profile, including GI toxicities, was consistent with the known profile of BOS.

Conclusions: BOS reduced the annual rate of kidney enlargement vs PBO in ADPKD pts, and the safety profile was consistent with the BOS label.

Low Osmolar Diet and Adjusted Water Intake for Vasopressin Suppression in ADPKD: A Randomized Controlled Trial Osama W. Amro,[1,2] Jessica K. Paulus,[1,2] Farzad Noubary,[1,2] Ronald D. Perrone.[1,2] *[1]Nephrology, Tufts Medical Center, Boston, MA; [2]Tufts Univ School of Medicine.*

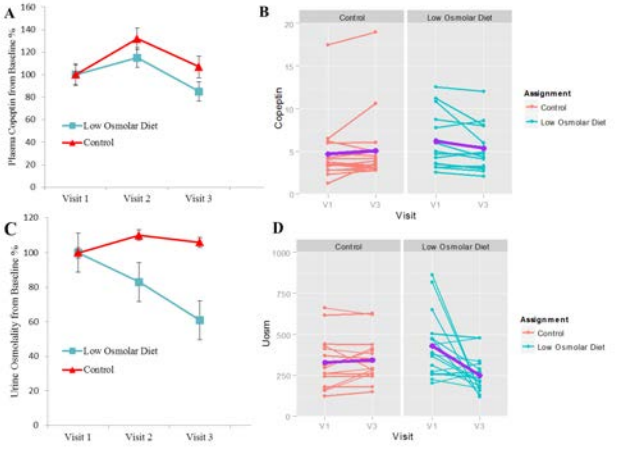
Background: Autosomal dominant polycystic kidney disease (ADPKD) affects 12.5 million persons worldwide. Vasopressin promotes disease progression.

Methods: This randomized trial examined the effect of combining a low osmolar diet and adjusted water intake on vasopressin as measured by change in plasma copeptin, and

Underline represents presenting author/disclosure.

urinary osmolality in 34 ADPKD patients. Participants were randomized to receive a low osmolar diet (low sodium (1500 mg/day), low protein (0.8 gram/kg body weight) diet) followed by adjusted water intake to achieve a urine osmolality of £280 mOsm/L versus no intervention for two weeks.

Results: Change from baseline to two weeks between intervention and control groups was statistically significant for the primary outcome of copeptin and urine osmolality (-0.86 ±1.3 pmole/L versus +0.39 ±1.2 pmole/L (p=0.009) and -167±264 mOsm/L versus +20±80 mOsm/L (0.007) respectively). Mean plasma copeptin and urine osmolality declined from 6.2 ±3.05 to 5.3± 2.5 pmole/L (p=0.3) and from 426 ±193 to 258 ±117 mOsm/L (p=0.003) respectively in the intervention group compared to a non-significant increase from 4.7 ±3.6 to 5.07 ±4 pmole/L (p=0.7) and from 329 ±159 to 349 ±139 mOsm/L (p=0.6) in the control group.



Total urinary solute decreased only in the intervention group and significantly differed between groups at week one (p=0.03) reducing mean water prescription from 3.2 to 2.6 liter/day.

Conclusions: we developed a step wise dietary intervention that led to significant reduction in vasopressin in ADPKD patients. Furthermore, this intervention led to reduction in water required for vasopressin suppression. Long-term studies are needed to determine if vasopressin suppression slows ADPKD progression.

Funding: Other NIH Support - Dr. Amro is supported by NIH 5T32DK007777 institutional training grant. This project was performed and Dr. Perrone were supported in part by the National Center for Advancing Translational Sciences (NCATS), National Institutes of Health (NIH), Grant Number UL1 TR001064.

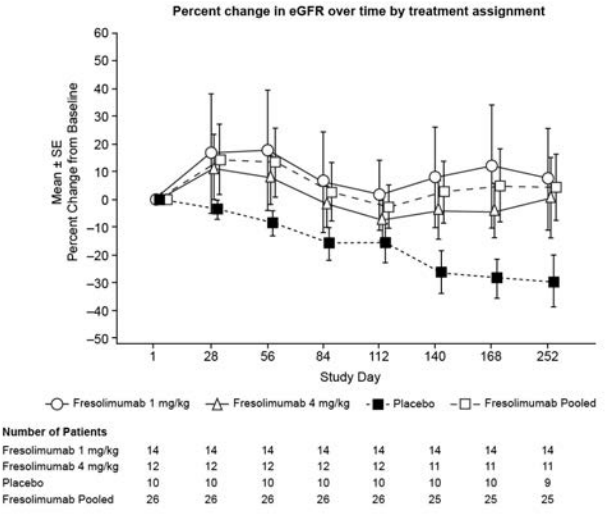
A Phase 2, Double-Blind, Randomized Study of Fresolimumab or Placebo in Patients with Steroid-Resistant Primary Focal Segmental Glomerulosclerosis

James A. Tumlin,[1] Flavio Vincenti,[2] Fernando C. Fervenza,[3] Kirk N. Campbell,[4] Montserrat M. Diaz Encarnacion,[5] Manuel Praga,[6] Denyse Thornley-Brown,[7] Francisco Veríssimo Veronese,[8] Beverly Accomando,[9] Sara Engstrand,[10] Steven R. Ledbetter,[10] Julie Lin,[10] John F. Neylan.[10] *[1]UT Coll. of Med., Chattanooga, TN; [2]UCSF, San Francisco, CA; [3]Mayo Clinic, Rochester, MN; [4]Icahn Sch. of Med. at Mt. Sinai, New York, NY; [5]Fundacion Puigvert, Barcelona, Spain; [6]Hosp. Univ 12 de Oct., Madrid, Spain; [7]Univ of Alabama at Birmingham, AL; [8]Hosp. de Clínicas de Porto Alegre, Brazil; [9]Sanofi, Cambridge, MA; [10]Formerly Genzyme, Sanofi.*

Background: Steroid-resistant primary FSGS confers substantial risk of morbidity & progressive kidney failure. Fresolimumab (freso), a neutralizing mAb to all 3 isoforms of TGF-β, is a potential new treatment.

Methods: 36 pts with biopsy-proven nephrotic-range FSGS randomized to freso 1mg/kg (n=14) v 4mg/kg (n=12) v placebo (PL) (n=10) for D112, allowed immunosuppressives after D112 & followed up double-blind for D252. 1° outcome: proteinuria remission; 2° outcomes included changes in Up/c & eGFR.

Results: Pts: 53% male; median 41 y; 17% Black, 31% Hisp. Baseline (BL) median Up/c: 6.19mg/mg; eGFR, 63 ml/min/1.73 m². 72% pts received prior CNI. Durable partial remission (>50% Up/c decrease from BL to <3mg/mg): 3 pts, 1mg/kg; 2 pts, 4mg/kg; 1 pt, PL; 1 additional pt on 1mg/kg had steep & consistent Up/c decline from 17–4mg/mg. All 7 freso responders were Black/Hisp. Mean Up/c changes at D112: -18.5% (1mg/kg,*P*=0.008), +10.5% (4mg/kg,*P*=0.52), +9.0% (PL,*P*=0.91). eGFR showed nonsignificant trend for stability in freso v decline in PL. Freso was generally well tolerated with no significant difference in AEs in low v high doses.



Number of Patients								
Fresolimumab 1 mg/kg	14	14	14	14	14	14	14	14
Fresolimumab 4 mg/kg	12	12	12	12	12	11	11	11
Placebo	10	10	10	10	10	10	10	9
Fresolimumab Pooled	26	26	26	26	26	25	25	25

Conclusions: In steroid-resistant FSGS, freso may be associated with proteinuria remission. Black & Hisp pts may have higher response rates. Freso merits continued evaluation in FSGS.

Effects of Sustained-Release Beraprost Sodium in Patients with Primary Glomerular Disease or Nephrosclerosis: The CASSIOPEIR Study

Toshiro Fujita,[1] Xueqing Yu,[2] Suhnggwon Kim,[3] Hidetomo Nakamoto,[4] Hideki Origasa,[5] Hajimu Kurumatani,[6] Takashi Kiriyama.[7] *[1]The Univ of Tokyo, Tokyo, Japan; [2]The First Affiliated Hospital, Sun Yat-sen Univ, Guangzhou, Guangdong, China; [3]Seoul National Univ Hospital, Seoul, Korea; [4]Saitama Medical Univ, Saitama, Japan; [5]The Univ of Toyama, Toyama, Japan; [6]Toray Industries, Inc, Tokyo, Japan; [7]Astellas Pharma Inc., Tokyo, Japan.*

Background: No single treatment, except RAS inhibitors, can delay progression of CKD. TRK-100STP, a sustained-release tablet of an orally-active prostacyclin analogue, beraprost sodium, is suggested to suppress worsening of renal filtration function. We aimed to demonstrate superiority of TRK-100STP over placebo in patients with CKD, either as primary glomerular disease or nephrosclerosis; determine the recommended dose of TRK-100STP; and evaluate its safety profile.

Methods: We performed a randomized, double-blind, placebo-controlled, parallel-group comparative study at 160 sites in seven Asian-Pacific countries and regions (CASSIOPEIR: CRF Asian Study with Oral PGI_2 Derivative for Evaluating Improvement of Renal Function). Patients entered a run-in period with oral administration of placebo twice daily for two to eight weeks. Patients meeting the inclusion/exclusion criteria at the end of the run-in period (n=892) were randomized to TRK-100STP 120 mg, TRK-100STP 240 mg, or placebo for a treatment period of two to four years. The primary efficacy endpoint was the time to first occurrence of a renal composite endpoint: doubling of SCr or occurrence of end-stage renal disease. ClinicalTrials.gov identifier : NCT01090037.

Results: No significant differences were evident observed in renal composite endpoints between TRK-100STP and placebo (2-sided 5% significance level, P=0.5674). The overall incidence of adverse events and adverse drug reactions was comparable between the treatment arms.

Conclusions: TRK-100STP did not demonstrate superiority over placebo, and the recommended therapeutic dose for patients with CKD either primary glomerular disease or nephrosclerosis was not determined. However, no findings raised safety concerns in the comparison between TRK-100STP and placebo.

Corticosteroid Monotherapy versus Combined Immunosuppression in IgA Nephropathy: Insights from the STOP-IgAN Trial

Jürgen Floege,[1] Thomas Rauen,[1] Frank Eitner,[3] Christina Fitzner,[2] Ralf-Dieter Hilgers.[2] *[1]Nephrology, RWTH Aachen Univ, Aachen, Germany; [2]Biostatistics, RWTH Aachen Univ, Aachen, Germany; [3]Bayer AG, Wuppertal, Germany; [4]For the STOP-IgAN Investigators.*

Background: In high-risk IgA nephropathy (IgAN) the value of immunosuppression is controversial.

Methods: We recently reported a randomized, controlled trial in IgAN patients (STOP-IgAN trial). Following 6 months of optimized supportive treatment 162 trial participants, who still displayed a proteinuria >0.75 g/d, entered a 3 year study phase and were randomized to continue on supportive therapy (SUP) or to receive additional immunosuppression (IMM). IMM-patients with an eGFR >60 ml/min/1.73m² received a 6-month corticosteroid monotherapy ("Pozzi-protocol"). Patients with an eGFR of 30 to

Underline represents presenting author/disclosure.

59 ml/min/1.73m² received cyclophosphamide for 3 months, followed by azathioprine, plus oral prednisolone ("Ballardie protocol"). Primary endpoints were (i) full clinical remission (proteinuria < 0.2 g/g and eGFR loss of < 5 ml/min) and (ii) eGFR loss >15 ml/min from baseline to trial end.

Results: Here we report a secondary analysis of the two IMM subgroups versus corresponding SUP patients matched for eGFR. The intention-to-treat (ITT) analysis assuming a worst-case scenario at 3 years is shown in the table.

Endpoint	GFR >60 ml/min/1.73m² IMM vs. SUP (n = 55 vs. 54)	GFR 30-59 ml/min/1.73m² IMM vs. SUP (n = 27 vs. 26)
Full clinical remission	OR 5.23 (95%-CI 1.29-21.15), p=0.020	OR 2.77 (95%-CI 0.38-32.29), p=0.319
eGFR loss >15 ml/min	OR 0.65 (95%-CI 0.27-1.56), p=0.333	OR 1.62 (95%-CI 0.49-5.61), p=0.428

Patients treated with the Pozzi protocol had a transient decrease in proteinuria after 12 months and significantly less microhematuria at trial end compared to matched SUP patients. In the group with the low eGFR range, there were no significant differences between both arms. Compared to supportive care, more patients receiving immunosuppression developed severe infections, impaired glucose tolerance and weight gain in year one.

Conclusions: Our secondary analyses provide little evidence for a stabilization of renal function with immunosuppression in the group with an eGFR >60 ml/min and no evidence for a benefit in patients with a lower eGFR.

SA-PO1098

A Randomized Trial of Rituximab in Advanced IgA Nephropathy

Richard A. Lafayette,[1] Pietro A. Canetta,[2] Brad H. Rovin,[3] Gerald B. Appel,[2] Marie C. Hogan,[4] Stephen B. Erickson,[4] Fernando C. Fervenza.[4] *[1]Stanford Univ, Stanford, CA; [2]Columbia Univ, New York, NY; [3]Ohio State Univ, Columbus, OH; [4]Mayo Clinic, Rochester, NY.*

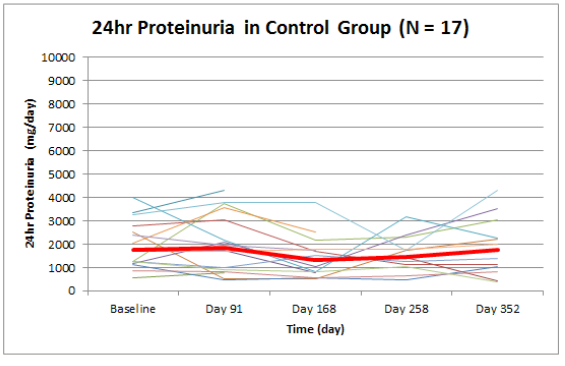
Background: IgA nephropathy (IgAN) frequently leads to progressive renal dysfunction. Present immunosuppressive treatment remains uncertain in terms of benefit and risks side effects. B cells are an attractive target in IgAN so we performed a pilot trial of rituximab in subjects at high risk of progression.

Methods: Patients with biopsy proven IgAN, more than 1 g/d of proteinuria despite RAASi (or ³0.5 g/d if on dual RAASi), well controlled blood pressure (BP) and eGFR <90ml/min were randomized to 1 year of rituximab therapy (4g total) vs ongoing BP control, fish oil and use of RAASi. They were followed for B cell depletion, effects on proteinuria and changes in eGFR. Safety signals were also followed.

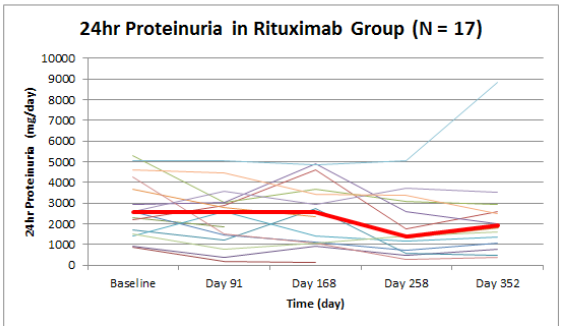
Results: 34 patients were randomized. Baseline serum creatinine was 1.5±0.5 mg/dl and proteinuria was 2.1, 0.6-5.5 g/d. There was no change in BP during the study. Treatment with rituximab resulted in significant B cell depletion and was generally well tolerated. There was no change in renal function during the study in either group. Rituximab treatment had no significant effect on proteinuria compared to baseline or control patients, and 3/17 patients in each group experienced a ≥ 50% reduction in proteinuria during the study.

Figure 1: Proteinuria in (A) Control vs. (B) Rituximab Groups. The heavy weight red line represents median data.

A)



B)



Conclusions: In this small study, rituximab therapy had no influence on renal function or proteinuria in subjects with advanced disease due to IgA nephropathy. There were numerically greater reductions in proteinuria, but this did not reach significance. Few patients had substantial responses in either group. These results do not support the use of rituximab as treatment for patients with IgA nephropathy.

Establishing Endpoints for Lupus Nephritis Clinical Trials: Progress by the Kidney Health Initiative/Lupus Nephritis Trials Network Collaboration

Brad H. Rovin,[1] Meggan Mackay,[2] Joanna Stein,[2] Maria Dall'Era,[4] Kenneth Kalunian,[3] Martin L. Lesser,[2] Melissa West.[5] *[1]Ohio State Univ; [2]Feinstein Inst; [3]Univ Calif San Diego; [4]Univ Calif San Francisco; [5]American Society of Nephrology.*

Background: There are no universally accepted endpoints for lupus nephritis (LN) clinical drug trials. To obtain approval of new therapies a uniform endpoint that can be applied to future LN trials is needed. The optimal endpoint is a short-term measurement that accurately reflects long-term kidney survival. The present work was undertaken to define LN trial endpoints.

Methods: Clinical data at LN flare (baseline) and during serial follow-up (minimum 22 months) from 751 patients were analyzed. Clinical variables at baseline and after 6 and 12 months were tested as predictors of adverse long-term renal outcomes, in this case time to new chronic kidney disease (CKD), defined as a sustained increase in serum creatinine (SCr) ³30%. Multivariable Cox regression analysis was used to model time to CKD.

Results: After accounting for missing data 507 patients were included in the final analysis. This cohort was 89% female, 56% White, 20% Asian and 14% Black. The average baseline SCr was 1.2±0.7 mg/dl, proteinuria was 4.1±3.4 g/d, and eGFR by CKD^{epi} was 81±35 ml/min. Median follow-up was 42 months (range: 22-147 months). By univariate analysis urine RBCs, race, complement C3, SCr, eGFR and proteinuria were potential significant predictors of time to CKD. By multivariate modeling the significant predictors of future CKD were: SCr at 12 months (p=0.0005, Hazard Ratio (HR) 1.8 (95%CI:1.3-2.5)); proteinuria at 12 months (p<0.0001; HR 1.6 (1.3-1.8)); and an increase in eGFR>10% from baseline to 12 months compared to no change in eGFR (p<0.0001; HR 0.4 (0.3-0.6)).

Conclusions: We have identified 3 highly significant predictors of time to CKD in LN patients that can be measured during the first 12 months of treatment for flare. These can be developed into a composite endpoint for future LN therapeutic trials. Unexpectedly, small improvements in eGFR appear to predict renal survivial. Also, because urine RBCs do not appear to predict time to CKD, it may be possible to exclude urinalysis as an endpoint component in future clinical trials.

SA-PO1100

Grazoprevir (GZR)/Elbasvir (EBR) Treatment of Hepatitis C Virus (HCV) Infection in Patients with Chronic Kidney Disease Stage 4/5: Final Results of the C-SURFER Phase 3 Study

David Roth,[1] Annette Bruchfeld,[2] Paul Martin,[1] David R. Nelson,[3] Marcelo Silva,[4] Howard Monsour,[5] Laurent Alric,[6] Shuyan Wan,[7] Beth Jackson,[7] Bach-Yen Nguyen,[7] Janice Wahl,[7] Eliav Barr,[7] Wayne L. Greaves.[7] *[1]Univ of Miami, Miami, FL; [2]Karolinska Inst, Stockholm, Sweden; [3]Univ of Florida, Gainesville, FL; [4]Hospital Univ Austral, Pilar, Buenos Aires, Argentina; [5]Houston Methodist Hospital, Houston, TX; [6]Hôpital de Purpan, Toulouse, France; [7]Merck & Co., Inc., Kenilworth, NJ.*

Background: Limited options are available for treating HCV infection in patients with advanced kidney disease. C-SURFER is the first randomized, placebo-controlled phase 3 study to evaluate an all-oral, ribavirin-free regimen in CKD 4/5 patients.

Methods: 224 patients with HCV genotype (G)1 and CKD 4/5 ± hemodialysis (HD) were randomized to GZR/EBR 100/50mg (Immediate Treatment Group, ITG; n=111) or placebo for 12 weeks. Placebo subjects (deferred treatment group, DTG; n=113) received GZR/EBR after placebo therapy. 11 additional subjects received GZR/EBR with intensive pharmacokinetic (PK) sampling. The primary safety comparison was GZR/EBR vs. placebo. The primary efficacy endpoint, sustained virologic response (SVR) 12 weeks post-therapy in the ITG+PK group, was reported previously. Here we report the final results, including data from subjects who received GZR/EBR after placebo.

Results: In the placebo-controlled phase, serious adverse events (AEs) occurred in 16 (14%) GZR/EBR and 17 (15%) placebo subjects; discontinuation due to an AE in GZR/EBR and placebo subjects was 0% and 4%. SVR12 in all subjects who received GZR/EBR was 94.6% (ITG+PK, 94.3% [115/122]; DTG after placebo, 95.0% [96/101]). 12 subjects failed to attain SVR12: virologic relapse, n=3; discontinuation for AE, n=1; admin reason, n=8. Excluding subjects who discontinued for reasons unrelated to study drug, overall SVR12 was 98.6% (211/214). PK data indicate no need for dose adjustment in HD patients (geometric mean ratio [HD/non-HD] ranged from 0.67-0.85 for GZR and 1.43-1.67 for EBR).

Conclusions: Once-daily GZR/EBR for 12 weeks was highly effective with a low rate of adverse events in patients with advanced kidney disease and HCV G1 infection.

Underline represents presenting author/disclosure.

SA-PO1101

Long-Term (52-Week) Efficacy and Safety of ZS-9 in the Treatment of Hyperkalemia: Interim Results From a Phase 3 Open-Label, Multi-Center, Multi-Dose Maintenance Study

James A. Tumlin,[1] Mikhail Kosiborod,[2] Pablo E. Pergola,[3] Wajeh Y. Qunibi,[4] David K. Packham,[5] Simon D. Roger,[6] Edgar V. Lerma,[7] Steven Fishbane,[8] Henrik S. Rasmussen,[9] Bruce S. Spinowitz.[10] *[1]U of Tennessee College of Medicine, TN; [2]Saint Luke's Mid America Heart Inst., MO; [3]Renal Associates PA, TX; [4]U of Texas Health Science Center, TX; [5]Melbourne Renal Research Group, Australia; [6]Renal Research, Gosford, Australia; [7]U of Illinois, IL; [8]North Shore U. Hospital, NY; [9]ZS Pharma, Inc., TX; [10]Weill Medical College, NY.*

Background: Hyperkalemia (HK) is a common and potentially lethal electrolyte disorder, often induced with the use of renin-angiotensin-aldosterone inhibitors (RAASi). Currently, the use of RAASi is prevented by HK and thus the potential for cardiac and renal protective effects of these agents is limited. In previous studies, ZS-9 (sodium zirconium cyclosilicate), a selective K^+ion trap, significantly lowered serum $K^+$and maintained normokalemia (NK) for up to 28 days. We present the results to date of the largest ever phase 3 trial examining the efficacy of ZS-9 in treating HK patients for up to 52wks.

Methods: ZS-005 (target N=750) is a multicenter, ongoing, open-label study evaluating ZS-9 treatment for 52wks in ambulatory pts with HK ($K^+ \geq$ 5.1 mEq/L) with or without concurrent RAASi therapy. In the acute phase (AP), pts with HK received 10g ZS-9 TID over a 24-72hr period until NK (K^+ 3.5-5.0 mEq/L) was achieved. Pts achieving NK were enrolled in a 52wk maintenance phase (MP) starting with 5g ZS-9 QD. There were no restrictions on diet and ZS-9 could be titrated to maintain NK. Primary outcomes were proportion of pts with mean $K^+ \leq$5.1 mEq/L during MP and safety of ZS-9.

Results: To date, 583 pts with a mean baseline K^+ of 5.6 mEq/L (15% ≥6.0 mEq/L) entered the study. Overall, 575 (99%) normalized K^+in AP and transitioned to the MP. To date, K^+ was maintained at ≤5.1 and <5.5 mEq/L in 87% and 99% of patients, respectively. The incidence and severity of adverse events were similar to that of previous studies.

Conclusions: ZS-9 acutely reduced K^+ levels in pts with HK and maintained NK for up to 52wks irrespective of RAASi use. ZS-9 may control HK, both emergent and long-term, while allowing continued use of cardio- and reno-protective RAASi.

SA-PO1102

Interleukin-1 Inhibition and Vascular Function in Patients with Chronic Kidney Disease (CKD): A Randomized Controlled Trial

Kristen L. Nowak,[1] Michel Chonchol,[1] Talat Alp Ikizler,[2] Heather Farmer,[1] Natjalie Salas,[2] Rafia I. Chaudhry,[2] Wei Wang,[1] Gerard John Smits,[1] Adriana Hung.[2,3] *[1]Univ of Colorado Denver; [2]Vanderbilt Univ; [3]VA Tennessee Valley Healthcare System.*

Background: Vascular endothelial dysfunction and increased arterial stiffness contribute to increased cardiovascular risk in CKD patients who exhibit chronic systemic inflammation. As chronic inflammation is a key mechanism contributing to vascular dysfunction, blocking inflammation may reduce cardiovascular risk in CKD.

Methods: In a two-site, double-blind trial, n=42 patients with stage 3-4 CKD were randomized to receive either the interleukin-1 (IL-1) trap rilonacept (subcutaneous injection; loading dose of 320 mg followed by 160 mg/wk) or placebo for 12 weeks. All patients were receiving optimal treatment of hypertension, diabetes, and/or hypercholesterolemia, with 64% and 62% receiving a statin and an ACE inhibitor or ARB, respectively. The co-primary endpoints were change in brachial artery flow-mediated dilation [FMD_{BA}]) and aortic pulse-wave velocity [aPWV]) after 4, 8 and 12 weeks using mixed effects models. Secondary endpoints were change in high-sensitivity C-reactive protein (hsCRP), ΔFMD_{BA} following an acute infusion of ascorbic acid known to inhibit superoxide production (n=23), and vascular endothelial cell protein expression of NADPH oxidase (n=13).

Results: Participants were 63±11 (mean±s.d.) years of age, 24% female and 24% Black, with eGFR 38±13 ml/min/1.73m^2. Rilonacept improved FMD_{BA} (baseline: 3.8±3.1%, 12 wks: 4.9±3.2%) compared to placebo (baseline: 3.4±2.1%, 12 wks: 2.5±2.3%; p<0.01), without changing aPWV (p=0.52). Rilonacept also reduced hsCRP levels (baseline: 4.6 (1.9, 8.22) [median (interquartile range)], 12 wks: 2.16 (0.96, 7.38) mg/L; p<0.01), and endothelial cell NADPH oxidase expression (p<0.05). Acute infusion of ascorbic acid tended to improve FMD_{BA} in the placebo (p=0.07) but not the rilonacept group (p=0.56), indicating reduced vascular oxidative stress. Overall, rilonacept was well tolerated.

Conclusions: 12 weeks of treatment with an IL-1 trap improved FMD_{BA} without changing aPWV in patients with stage 3-4 CKD. This was associated with a reduction in systemic inflammation and vascular oxidative stress.

SA-PO1104

Impact of Vitamin D Supplementation on Endothelial and Vascular Function in Patients with Chronic Kidney Disease: A Randomized, Double Blind, Placebo-Controlled Trial

Vivek Kumar,[1] Ashok Kumar Yadav,[1] Vinod Sharma,[1] Manphool Singhal,[2] Anupam Lal,[2] Debasish Banerjee,[3] Vivekanand Jha.[1] *[1]Nephrology, Postgraduate Inst of Medical Education and Research, Chandigarh, Chandigarh, India; [2]Radiodiagnosis, Postgraduate Inst of Medical Education and Research, Chandigarh, Chandigarh, India; [3]Nephrology, St. George's Univ Hospitals NHS Foundation Trust, London, London, United Kingdom.*

Background: Vitamin D deficiency is associated with mortality in CKD patients. We investigated the effect of Vitamin D supplementation on endothelial and vascular function in patients with non-diabetic CKD stage 3-4.

Methods: In a prospective, randomized, double blind, placebo-controlled trial, 120 patients with non-diabetic CKD stage 3-4 and vitamin D deficiency [serum 25(OH)D <20ng/ml] aged 18-70 years were randomized (1:1) to receive either two directly observed oral doses of 300,000 IU of cholecalciferol at 0 and 8 weeks or matching placebo. The pre-specified primary outcome was 40% change in endothelium dependent brachial artery flow mediated dilatation (FMD) at 16 weeks. Secondary outcome measures included changes in pulse wave velocity (PWV), augmentation index (AI), and serum biomarkers.

Results: Baseline FMD was identical in both arms (7.65±2.24% vs 7.85±2.34%). Intervention arm showed a significant increase in serum 25(OH)D (+ 24.9 ng/ml, 95% CI: 21.8 to 28.06, p<0.0001), and the number of subjects meeting the primary end point (70% vs 5%, p<0.0001). FMD change was 5.42% (95% CI: 4.44 to 6.40%) in the intervention arm and -0.07%, (95% CI, -0.70 to 0.58%) in placebo arm. Intervention led to favorable changes in PWV (-0.94 m/s, 95% CI: -1.30 to -0.58, p<0.0001), E-selectin (-3.68 ng/ml, 95% CI: -8.1 to 0.7 p=0.028), IL-6 (-2.0 pg/ml, 95% CI: -2.96 to -0.8 p=0.001), FGF-23 (-14.7 pg/ml, 95% CI -28.5 to -1.0 p=0.036) and 1,25$(OH)_2$D (+15.5 pg/ml, 95% CI: 5.4 to 25.5, p=0.003). These did not change significantly in the control group. No changes were observed in AI, vWF and hs-CRP in either group.

Conclusions: In non-diabetic patients with stage 3-4 CKD and vitamin D deficiency, vitamin D supplementation leads to improvement in endothelial function, markers of inflammation and arterial stiffness.

Funding: Government Support - Non-U.S.

SA-PO1105

Effect of Cholecalciferol versus Calcitriol on Vascular Endothelial Function in CKD: A Randomized Active-Controlled Trial

Jessica B. Kendrick,[1,2] Gerard John Smits,[1] Emily Decker,[1] Heather Farmer,[1] Michel Chonchol.[1] *[1]Univ of Colorado School of Medicine, Aurora, CO; [2]Denver Health Medical Center, Denver, CO.*

Background: Epidemiological studies have shown that vitamin D is associated with decreased cardiovascular morbidity and mortality, but the effects of vitamin D administration on patient outcomes in chronic kidney disease (CKD) are lacking. We conducted a prospective, double-blinded, randomized trial to determine the effects of oral cholecalciferol vs. calcitriol on vascular endothelial function over 24 weeks in patients with CKD stage 3-4.

Methods: 128 patients with CKD stage 3-4 (estimated GFR 15-44 ml/min/1.73m^2) with vitamin D deficiency, defined as serum 25-hydroxyvitamin D level (25(OH)D) < 30 ng/mL, were randomly assigned to receive either cholecalciferol (4000 IU daily x 4 weeks then 2000 IU daily x 20 weeks) or calcitriol (0.25 mcg daily x 4 weeks then 0.5 mcg daily x 20 weeks). The primary endpoint was change in brachial artery flow mediated dilation (FMD_{BA}) over 24 weeks. Secondary endpoints included changes in parameters of mineral bone disease and plasma concentrations of inflammatory cytokines (C-reactive protein and interleukin-6).

Results: 115 patients completed the study. The mean (SD) age and eGFR was 58.1 ± 12.4 years and 33.1 ± 10.2 ml/min/1.73m^2, respectively. In the cholecalciferol group, mean 25(OH)D levels increased from 22.7 ± 7.5 ng/mL to 33.5 ± 7.9 ng/mL. There was no change in 25(OH)D levels in the calcitriol group. Parathyroid hormone levels decreased significantly in the calcitriol group compared to the cholecalciferol group (p=0.001). At 24 weeks, the change in FMD_{BA} did not differ significantly between treatment groups (cholecalciferol group -0.72%, 95% CI -1.97 to 0.54 vs. calcitriol group 0.29%, 95% CI -0.72 to 1.29, p=0.44). There was no significant change in C-reactive protein or interleukin-6 concentrations between the two groups. Episodes of hypercalcemia were more frequent in the calcitriol group (n=4) compared with the cholecalciferol group (n=1).

Conclusions: Twenty-four week therapy with cholecalciferol or calcitriol did not improve vascular endothelial function or reduce inflammation in patients with CKD.

Vitamin D Receptor Activation and Dietary Sodium Restriction to Reduce Residual Albuminuria in Chronic Kidney Disease Martin H. De Borst,[1] Charlotte A. Keyzer,[1] Fenna van Breda,[2] Marc G. Vervloet,[2] Gozewijn Dirk Laverman,[3] Marc H. Hemmelder,[4] Wilbert M. Janssen,[5] Hiddo Jan Lambers Heerspink,[1] Stephan J.L. Bakker,[1] Gerjan Navis.[1] *[1]UMC Groningen; [2]VUmc Amsterdam; [3]ZGT Almelo; [4]MC Leeuwarden; [5]Martini Hospital Groningen, Netherlands.*

Background: Reduction of residual albuminuria during single-agent RAAS-blockade is associated with improved cardiorenal outcomes in CKD. Both vitamin D receptor activators (VDRA) and dietary sodium restriction reduce residual albuminuria. Previous data suggested that sodium restriction is not required for optimal albuminuria reduction by VDRA. We studied the individual and combined effects of paricalcitol and sodium restriction on residual albuminuria during optimally dosed ACEi in CKD.

Methods: In a multi-center, randomized, placebo-controlled cross-over trial, 45 patients with non-diabetic CKD stage 1-3 and residual albuminuria >300 mg/24h despite ramipril 10 mg/d and BP <140/90 mmHg were treated during four 8-week periods with paricalcitol (PARI, 2 µg/day) or placebo (PLAC), each combined with a low (LS, 2.5 gr Na^+/d) or regular sodium (RS, 4 gr Na^+/d) diet, in random order. Linear mixed-effect models for repeated measurements were used to determine treatment effect.

Results: In the *intention-to-treat* analysis, albuminuria was 1,060 [778 to 1,443] (geometric mean [95% CI]) mg/24h during RS+PLAC. During RS+PARI, albuminuria was 990 [755 to 1,299] mg/24h (-12.5% [-26.0% to 26.3%] vs. RS+PLAC, *P*=0.2). LS+PLAC reduced albuminuria to 717 [512 to 1,005] mg/24h (-25.4% [-52.6% to -2.3%] vs. RS+PLAC, *P*<0.001). LS+PARI provided the strongest albuminuria reduction to 683 [502 to 929] mg/24h (-31.7% [-55.0% to -0.9%], *P*<0.001 vs. RS+PLAC), although the additional reduction by PARI beyond the effect of LS was non-significant (*P*=0.6). However, in a *per protocol* analysis (≥95% compliance, N=34) PARI did reduce residual albuminuria beyond the effect of LS (*P*=0.04).

Conclusions: The combination of paricalcitol and moderate dietary sodium restriction provided the strongest reduction of residual albuminuria during optimal ACEi; the effect was mainly driven by sodium restriction. Our findings underline the relevance of sodium restriction, possibly combined with paricalcitol, to optimize albuminuria reduction.

SA-PO1107

Vascular Function and Uric Acid Lowering via Allopurinol in Stage III CKD: Results of a Double-Blinded Randomized Placebo-Controlled Study Diana I. Jalal,[1] Emily Decker,[1] Loni J. Perrenoud,[1] Nina Bispham,[2] Tapan Mehta,[1] Gerard John Smits,[1] Richard J. Johnson.[1] *[1]Medicine/ Renal Div, UC AMC, Aurora, CO; [2]Integrative Physiology, UC Boulder, Boulder, CO.*

Background: Observational studies suggest that asymptomatic hyperuricemia associates with vascular disease in chronic kidney disease (CKD). A recent study suggested that lowering serum urate with allopurinol improves endothelial function in elderly adults with stage III CKD. It remains unknown if lowering serum urate improves endothelial function in adult subjects with stage III CKD.

Methods: 80 adult subjects (18-70) years of age with stage III CKD and asymptomatic hyperuricemia (≥7 mg/dL in men and ≥6 mg/dL in women) were randomized to receive placebo or allopurinol (100 mg tablets) for 12 weeks. The study was double-blinded and subjects were instructed to take 1 tablet for 1 week, 2 tablets for another week, and 3 tablets thereafter. Changes (from baseline) between both groups were compared by Wilcoxon rank-sum test.

Results: No significant differences existed between both groups at baseline. After 12 weeks, allopurinol lowered serum urate significantly. FMD increased in the allopurinol group compared to placebo; but this was not statistically significant. NMD increased with allopurinol but decreased with placebo; p value = 0.14. These data are shown in Table 1. There were no significant differences between allopurinol and placebo for systolic or diastolic blood pressure, markers of inflammation, or markers of oxidative stress. 10 subjects withdrew from the study. A few adverse events were noted in both groups including 1 gout attack in each group. 1 subject died during the study due to a cardiac event.

Variable	Placebo	Allopurinol	P value
Serum Urate(mg/dL)	0.05(1.54)	-3.24(1.35)	<0.0001
FMD(%change)	0.16(4.05)	0.91(3.9)	0.47
NMD(%change)	-1.29(5.33)	0.93(6.05)	0.14

Conclusions: Allopurinol effectively and safely lowered serum urate in adults with stage III CKD and asymptomatic hyperuricemia but this did not improve endothelial function significantly. There was tendency towards improved NMD suggesting that hyperuricemia may negatively impact vascular smooth muscle function in stage III CKD.

SA-PO1108

Podocyturia Is an Earlier and Superior Predictor of Cardiovascular Outcomes Than Is Albuminuria Assaad Antoine Eid,[1] Robert Habib,[2] Kamal F Badr.[2] *[1]Anatomy, Cell Biology and Physiological Sciences, American Univ of Beirut - Faculty of Medicine, Beirut, Beirut, Lebanon; [2]Internal Medicine, American Univ of Beirut - Faculty of Medicine, Beirut, Beirut, Lebanon.*

Background: Increased urinary albumin excretion rate (AER), a predictor of cardiovascular events, results from abnormally increased albumin filtration accompanying injury to glomerular endothelial and epithelial cells ("podocytes"). Since AER is modified by renal proximal tubule albumin retrieval, we hypothesized that urinary podocyte shedding, podocyturia, would be a more relevant and earlier biomarker of endothelial injury (and CVD) than moderate albuminuria.

Methods: 106 Type II diabetic subjects (mean age: 46/60 men/women) with normal AER [<2.26 mg/mmole (20 µg/mg) creatinine] and free of overt cardiovascular disease (CVD) were enrolled. AER and podocyte-specific proteins (podocin and nephrin) mRNA were measured at baseline (visit 1), 3-4 years later (visit 2) and at 7 years (visit 3). Development of cardio vascular diseases VD - defined as coronary disease, cerebrovascular disease and/or peripheral vascular disease (can be removed to fit words counting)– was collected as outcome. 7-year Kaplan-Meier time-to-event (log rank) data were compared in baseline biomarker tercile groups (low, intermediate, high).

Results: All three biomarkers increased significantly between visits (P<0.001). AER terciles exhibited similar time to CVD (p=0.127), which was in contrast with the step-wise and substantial increase in CVD events with increasing podocin and nephrin levels (P<0.001). Considering all three biomarkers as continuous factors, the covariate-adjusted hazard ratios (95% confidence intervals) [HR] were highest for podocin mRNA [HR=15.9 (6.1-41.8); p<0.001], intermediate for nephrin mRNA [HR=7.61 (3.75-15.5); p<0·001] and lowest for AER [HR=1.17 (1.01-1.36); p=0·041].

Conclusions: Compared to traditional AER, podocyturia predicts more accurately and at an earlier time point the presence of silent systemic vascular injury, that manifests as overt cardiovascular events.

SA-PO1109

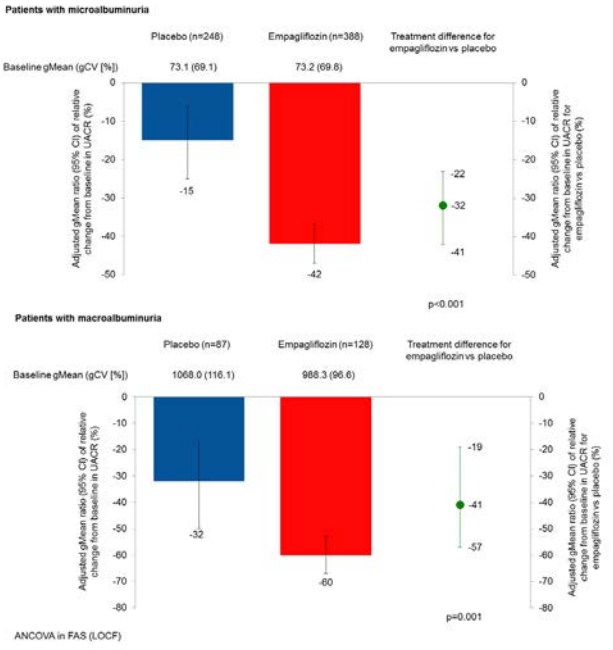
Empagliflozin Reduces Microalbuminuria and Macroalbuminuria in Patients with Type 2 Diabetes David Cherney,[1] Søren Søgaard Lund,[2] Bruce A. Perkins,[3] Per-Henrik Groop,[4,5] Mark E. Cooper,[5] Stefan Kaspers,[2] Susanne Crowe,[2] Hans-Juergen Woerle,[2] Maximilian von Eynatten.[2] *[1]Toronto General Hospital, Univ of Toronto, Canada; [2]Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany; [3]Mount Sinai Hospital, Univ of Toronto, Canada; [4]Univ of Helsinki and Helsinki Univ Hospital, Folkhälsan Research Center, Helsinki, Finland; [5]Baker IDI Heart and Diabetes Inst, Melbourne, Australia.*

Background: Reductions in HbA1c, systolic blood pressure (SBP), and weight with the highly selective SGLT2 inhibitor empagliflozin in patients with type 2 diabetes (T2D) may favorably impact albuminuria.

Methods: Using data pooled from 5 Phase III, randomized clinical trials, we assessed the effect of empagliflozin 10 or 25 mg for 24 weeks on urine albumin to creatinine ratio (UACR) in patients with T2D and prevalent microalbuminuria (UACR 30–300 mg/g; n=636) or macroalbuminuria (UACR >300 mg/g; n=215) at baseline.

Results: Empagliflozin reduced UACR vs placebo in patients with T2D and microalbuminuria (-32%; p<0.001) or macroalbuminuria (-41%; p=0.001) after controlling for baseline log (UACR), HbA1c, SBP, estimated glomerular filtration rate (MDRD), region, study and treatment (Figure). Adjusted mean (SE) changes in HbA1c, weight, SBP and diastolic BP with empagliflozin vs placebo were -0.50 (0.07) %, -1.6 (0.2) kg, -4.4 (1.1) mmHg and -2.3 (0.6) mmHg, respectively, in patients with microalbuminuria (all p<0.001), and -0.53 (0.13) %, -1.8 (0.4) kg, -6.3 (2.0) mmHg and -2.2 (1.1) mmHg, respectively, in patients with macroalbuminuria (all p<0.05). Linear regression analyses showed that changes in HbA1c, weight and SBP accounted for a maximum of half the UACR-lowering effect.

Underline represents presenting author/disclosure.



Conclusions: SGLT2 inhibition with empagliflozin reduced UACR by >30% in patients with T2D and prevalent microalbuminuria or macroalbuminuria, independent of its known metabolic and hemodynamic effects.

Vadadustat, a Novel Oral Treatment for Anemia of Chronic Kidney Disease, Maintains Stable Hemoglobin Levels in Dialysis Patients Converting from Erythropoiesis-Stimulating Agents

Volker H. Haase,[1] Charlotte S. Hartman,[2] Bradley J. Maroni,[2] Ramin Farzaneh-Far,[2] Peter A. McCullough.[3] *[1]Div of Nephrology and Hypertension, Vanderbilt Univ Medical Center, Nashville, TN; [2]Akebia Therapeutics, Inc., Cambridge, MA; [3]Baylor Univ Medical Center, Dallas, TX.*

Background: Vadadustat is a novel, oral agent that stimulates erythropoiesis by stabilizing hypoxia-inducible factor (HIF). Prior studies in patients with Non-Dialysis Dependent Chronic Kidney Disease (NDD-CKD) have shown that vadadustat results in controlled, dose-dependent increases in hemoglobin (Hb) and enhances iron mobilization and utilization. Here we present data from a Phase 2 trial of vadadustat in hemodialysis patients.

Methods: A multi-center, open-label, 16-week trial was designed to assess Hb response, safety, and tolerability of vadadustat. The trial enrolled 94 hemodialysis patients (Hb 9 - 12 g/dL), who were maintained on erythropoiesis-stimulating agents (ESAs) prior to study entry. Patients were converted from ESA to vadadustat, and assigned to 1 of 3 dose cohorts: 300 mg once daily (QD); 450 mg QD; or 450 mg three times weekly (TIW). The primary efficacy analysis was to evaluate mean Hb changes from baseline at weeks 7/8, and weeks 15/16. From week 8, dose could be adjusted as needed to maintain Hb. All patients were iron replete at baseline and throughout the study; IV iron use was allowed.

Results: Vadadustat maintained stable Hb levels in all 3 dose cohorts during the 16 week treatment period following conversion from ESA.

Mean Hb levels (g/dL) in Modified Intent-To-Treat (MITT) population			
Dose Cohort	**Baseline**	**Week 7/8**	**Week 15/16**
300mg QD	10.4	10.4	10.3
450mg QD	10.6	10.3	10.5
450mg TIW	10.5	10.2	10.4

One subject in the 300mg QD cohort had a single Hb excursion to 13.1 g/dL. Adverse events were balanced across the 3 cohorts. Serious adverse events (SAEs) were reported in 13 subjects (13.8%), which was within the expected range (13 – 17 subjects). No drug-related SAEs, nor deaths, were reported.

Conclusions: Vadadustat safely and effectively maintained Hb levels in dialysis patients who were converted from injectable ESAs.

Autologous Erythropoietin Production by the TARGT Gene Therapy Platform Maintains Stable Hb for 6-12 Month in ESRD Patients without the Need for ESA Administration

Shany Blum,[1] Nir Shapir,[1] Reem Miari,[1] Shai Efrati,[3] Pablo E. Pergola,[4] Garry A Neil.[2] *[1]Medgenics Medical Israel Ltd., Misgav, Israel; [2]Medgenics Inc, Wayne, PA; [3]Research & Development and Nephrology Units, Assaf-Harofeh Medical Center, Zerifin, Israel; [4]Renal Associates PA, San Antonio, TX.*

Background: Recombinant human erythropoietin (rHuEPO) administration to iron replete patients corrects anemia in most patients with ESRD, but doses result in supra-physiological peak serum concentration (C_{max}) of EPO that may cause thromboembolic complications. The **T**ransduced **A**utologous **R**estorative **G**ene **T**herapy system (TARGT™) is an ex-vivo gene therapy, providing autologous, continuous protein therapies at physiological ranges that was used encoding for the human erythropoietin gene ($TARGT_{EPO}$) for these studies. Patient dermal tissue biopsies (MOs) are transduced with a Helper-Dependent Adenoviral Vector containing the EPO gene and then re-implanted subcutaneously to deliver the required EPO dose.

Methods: We present initial results from 3 ongoing open label ascending dose studies of $TARGT_{EPO}$ in patients with anemia due to CKD undergoing either Hemo or Peritoneal Dialysis.

Results: Thus far 14 patients were enrolled in all protocols. Follow up is ongoing with the first implanted patient being followed with stable EPO secretion and stable Hb for over 14 months from a single implantation without the need for rHuEPO or blood transfusion. Results obtained suggest that treatment with $TARGT_{EPO}$ stabilize serum EPO levels at the physiological range of £20 mIU/ml resulting in Hb levels between 9-12 g/dL. Comparative analysis of serum EPO levels revealed significantly lower C_{max} with $TARGT_{EPO}$ compared to rHuEPO and an order of magnitude less overall EPO exposure as calculated by Area Under the Curve which may confer significant clinical benefit. No treatment related serious adverse events have been reported.

Conclusions: $TARGT_{EPO}$ is a promising novel therapy for the treatment of anemia of CKD and potentially for other protein deficient diseases.

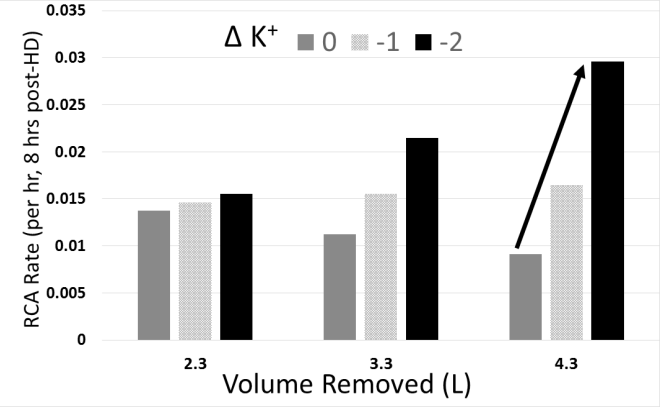
Monitoring in Dialysis (MiD) Study: Exploring the Timeline and Etiology of Increased Arrhythmias in Hemodialysis (HD) Patients

Prabir Roy-Chaudhury,[1] Don E. Williamson,[2] James A. Tumlin,[3] Vijay K. Kher,[4] Vikranth Reddy,[5] Kowdle Chandrasekhar Prakash,[6] David M. Charytan,[7] Suresh Chandra Tiwari,[8] Saurabh Pokhariyal,[9] Amber S. Podoll.[10] *[1]Univ of Arizona, Tucson; [2]Nephrology Associates, Augusta; [3]Univ of Tennessee, Chattanooga; [4]Medanta Medicity; [5]CARE Hospital, Hyderabad; [6]Apollo Hospitals-Chenna; [7]Brigham and Women's Hospital; [8]Fortis-Vasant Kunj, Delhi; [9]Fortis, Gurgaon; [10]Univ of Texas, Houston.*

Background: Sudden cardiac death (SCD), likely due to cardiac arrhythmias (CA) is the most important cause of mortality in the HD population. We herein present data on the timeline and potential etiology of CA in HD patients (pts).

Methods: The MiD study (n=66) characterized the type and frequency of CA in 3x/wk HD pts over 6 mths, using an implanted loop recorder (Medtronic Reveal). Reviewer confirmed arrhythmias (RCA;all documented CA) and clinically significant arrhythmias (CSA;brady/asystole/VT/ symptomatic), were linked to the dialysis cycle, pt wt and pre/post-session electrolytes, using negative binomial mixed effects regression analyses.

Results: Mean age was 56.3±12.2; 64% diabetic; 70% male; HD vintage 4.3±5.1 yrs. 97% and 67% of pts had a RCA/CSA. Most CSA occurred during the intradialytic period of the first weekly HD and then decreased in subsequent sessions. Univariate analyses identified increased pre and post wt, high pre HD potassium (K) and drop in K as risk factors for RCA. Multivariate analyses (adjusted for DM, yrs on HD, pre-wt), identified higher pre HD K levels as a predictor for increased RCA. The highest risk of arrhythmia occurred in pts with high K drops AND substantial volume removal (p=0.03).



Underline represents presenting author/disclosure.

Conclusions: These data establish linkages between intra-dialytic CSA and the long interdialytic period, and also identify a unique interaction between fluid removal and K in the generation of RCA. This suggests for the first time, that future data driven targeting of these parameters might reduce CA and potentially SCD in HD pts.

Funding: Pharmaceutical Company Support - Medtronic

SA-PO1113

The Occurrence of Cardiac Arrhythmias in Hemodialysis Patients is Linked to the Hemodialysis Procedure and to Electrolyte Abnormalities as Recorded by Implantable Loop Recorders

Christian Combe,[1,2] Antoine Benard,[1,2] Hélène Savel,[1,2] F. Sacher.[1,2] *[1]CHU & Univ. Bordeaux, Bordeaux, France; [2]Rythmodial Study Group.*

Background: Sudden cardiac death (SCD) is the most common mode of death among hemodialysis (HD) patients (pts). Little is known about the terminal arrhythmic events in these pts. Our objective was to identify the mechanisms which may lead to SCD in HD pts using an implantable loop recorder (ILR, Reveal XT®, Medtronic).

Methods: Pts from 9 HD centers have been included in the study. Continuous monitoring of the cardiac rhythm has been performed using the remote monitoring capability of the ILR device (Carelink®). Clinical, biological, and technical HD parameters and medications have been recorded for at least 1 year. General joint frailty model for recurrent event data were used to analyze associations between these parameters and the occurrence of cardiac rythm events.

Results: 72 pts (65.1±8.6 yrs, 52M) have been included. Causes of ESRD were diabetes (n=32) and hypertension (n=19). 22 pts had an ischemic cardiomyopathy. In multivariate analyses, the occurrence of conduction abnormalities (n=64) was associated to high potassium (K+) concentrations (K+>5mM, RR=5.22, $p<10^{-4}$) and to body weight (bw) variation during HD (RR per %bw/h 3.22, $p<10^{-2}$). There was no association with serum calcium, hemoglobin, HD bath ions, blood pressure. Ventricular arrythmias >150/min (n=11) were associated only to high K+ levels (K+>5mM, RR=13.35, p<0.05), to low K+ levels (K+<4 mM, RR=24.48, p<0.01), and to high phosphate levels (Pi>45mg/L, RR=5.64, p<0.04). Atrial fibrillation was the most frequent event (n=255), with less clear associations with patient-dependent and HD-dependent variables. In 6 SCD patients, ILR tracings demonstrated progressive bradycardia followed by asystole.

Conclusions: Our data show that the various types of arrythmias and conduction abnormalities occurring in HD pts are linked to different pathophysiological mechanisms, with a central role of serum K+ levels, levels lower than 4 mM or higher than 5 mM being deleterious. Rapid body weight variations were linked to ventricular arrythmias. Therapeutic strategies aimed at controlling these factors can be drawn from our study.

Abstract Withdrawn

SA-PO1115

Comparison of the Efficacy and Safety of Intravenous (IV) Etelcalcetide (AMG 416) and Oral Cinacalcet (CIN) in Patients on Hemodialysis (HD) with Secondary Hyperparathyroidism (sHPT)

Kevin J. Martin,[1] Geoffrey A. Block,[2] Sunfa Cheng,[3] Bastian Dehmel,[3] Reshma Kewalramani,[3] David M. Spiegel,[4] Hao Wang,[3] Glenn Matthew Chertow.[5] *[1]St Louis Univ SOM, St. Louis, MO; [2]Denver Neph, Denver, CO; [3]Amgen; [4]Relypsa; [5]Stanford Univ SOM, Palo Alto, CA.*

Background: This is a randomized, active controlled, double-blind, double dummy study comparing the efficacy and safety of a novel IV calcimimetic, AMG 416, with CIN.

Methods: Patients receiving HD with PTH >500 pg/ml, albumin-corrected calcium (cCa) ≥8.3 mg/dL, and no CIN use for 3 months were randomized 1:1 to AMG 416 IV/oral placebo or oral CIN/IV placebo for 26 weeks (wks). Doses were titrated at wks 5, 9, 13, 17 based on the prior wk's PTH and cCa. AMG 416 was started at 5mg and titrated by 2.5 or 5mg up to 15mg 3 times weekly with HD. CIN was started at 30mg and titrated up to 180mg daily per label. Target PTH was ³100 and £300 pg/ml. Primary endpoint was noninferiority on >30% reduction in PTH during wks 20-26. Secondary endpoints were >30% reduction in PTH (superiority analysis), >50% reduction in PTH, mean days of nausea or vomiting (n/v) (patient reported outcome) per wk in the first 8 wks.

Results: 683 subjects were randomized (340 AMG 416, 343 CIN), 553 completed the trial (84% AMG 416, 86% CIN). AMG 416 was noninferior to CIN on the primary endpoint. AMG 416 was superior on >30% reduction in PTH (68% AMG 416, 58% CIN, p=0.004) and >50% reduction in PTH (52% AMG 416, 40% CIN, p=0.001). Mean days of n/v in the first 8 wks did not differ (0.4 AMG 416, 0.3 CIN, NS). The most common adverse event (AE) in either group was blood calcium decreased (69% AMG 416, 60% CIN), mostly mild to moderate severity. Heart failure related AEs were reported in 10 (3.0%) AMG 416 subjects and 2 (0.6%) CIN subjects, of which 5 and 1, respectively, were serious. 9 (3%) subjects receiving AMG 416 and 6 (2%) receiving CIN had fatal treatment-emergent AEs – all unrelated to study drug.

Conclusions: AMG 416 achieved a >50% and a >30% reduction in PTH in more subjects compared to CIN. Hypocalcemia was seen more often with AMG 416. Nausea and vomiting did not differ. IV AMG 416 is more efficacious than oral CIN for the treatment of sHPT in patients on HD.

A Trial Assessing Use of a Wearable Artificial Kidney (WAK) in Patients Undergoing Maintenance Hemodialysis

Victor Gura,[1] Matthew B. Rivara,[2] Raj P. Munshi,[2] Scott D. Bieber,[2] Masoud Beizai,[3] Carlos J. Ezon,[3] Larry Kessler,[2] Jonathan Himmelfarb.[2] *[1]Cedars Sinai- UCLA, Los Angeles, CA; [2]Univ of Washington, Seattle, WA; [3]Blood Purification Technologies Inc, Beverly Hills, CA.*

Background: Current stationary dialysis machines hinder mobility and limit activities of daily life during dialysis treatments. There is a critical need for new technologies to increase patient autonomy, enhance quality of life, and allow for increased patient rehabilitation.

Methods: This is the first FDA-approved human trial of the WAK, a miniaturized, wearable hemodialysis machine based on dialysate-regenerating sorbent technology (NCT02280005). We aimed to determine the safety and efficacy of the WAK in maintaining euvolemia and achieving solute clearance and electrolyte homeostasis over 24 hours.

Results: All patients remained hemodynamically stable, and there were no serious adverse events. Serum electrolytes and hemoglobin remained stable over the treatment period for all subjects. Six out of seven patients ambulated while receiving WAK treatment. Fluid removal was consistent with prescribed ultrafiltration rates. Mean blood flow was 42 ± 24 and dialysate flow was 43±20 ml/min with no laboratory evidence of hemolysis. Mean BUN, creatinine, and phosphorus clearances were 21 ± 13, 20 ± 11, and 22 ± 12 ml/min respectively during the first hour of treatment. In one subject, treatment was discontinued due to clotting after 4 hours. In a second subject, treatment was discontinued due to discoloration of dialysate observed after 10 hours. The trial was stopped after the 7th subject due to device-related malfunctions. These included excessive CO2 bubbles in the dialysate, variable blood and dialysate flows, and tubing leaks during the priming phase. Redesign and re-manufacturing of the WAK prototype will be required prior to additional human studies.

Conclusions: Treatment with the WAK was well tolerated, resulted in effective uremic solute clearance and maintenance of electrolyte and fluid homeostasis. These results serve as proof-of-concept of the WAK as a viable novel dialysis technology.

CR845, a Novel Kappa Opioid Receptor Agonist Reduces Moderate-to-Severe Pruritus and Improves Quality of Life in Chronic Kidney Disease Patients Undergoing Hemodialysis

Robert Spencer,[1] Vandana S. Mathur,[2] James A. Tumlin,[3] Joseph W. Stauffer,[1] Frederique Menzaghi.[1] *[1]Cara Therapeutics, Inc., Shelton, CT; [2]Mathur Consulting, San Francisco, CA; [3]Univ of Tennessee, Chattanooga, TN.*

Background: Approximately 40% of US hemodialysis (HD) patients experience moderate-to-severe itching, which negatively affect their mental and physical health (e.g., sleep loss, depression, higher antibiotic and erythropoietin use and increased mortality). The etiology of this condition is likely multi-factorial, including immune system dysfunction and imbalance of mu/kappa endogenous opioids. CR845 is a novel and well-tolerated kappa opioid receptor (KOR) agonist with limited central nervous system entry, thereby preferentially activating KOR on peripheral neurons and immune cells.

Methods: In this Phase 2 double-blind, randomized (1:1), placebo-controlled clinical study, 65 prevalent US HD patients with persistent (~ 5 years) moderate-to-severe pruritus (baseline VAS ~68 mm, 0=no itch; 100 mm =worst itch) were treated with 1 mcg/kg intravenous CR845 or placebo following each HD session for 2 weeks. Antihistamines were discontinued 1 week prior to the study.

Results: The primary endpoint was met (VAS change in worst itch intensity from baseline to Days 12-15), with a significant difference in itch intensity between placebo and CR845-treated patients (p=0.016). CR845-treated patients had a 50% mean reduction in itch intensity from baseline. The 1st secondary endpoint was also met with a significant improvement in Skindex-10, a validated patient-reported outcome measure of pruritus-related quality of life (p =0.031). Furthermore, a trend for a sleep improvement was observed (SLP9).

Conclusions: Short-term treatment with CR845 significantly reduced itch intensity and improved quality of life in HD patients with moderate-to-severe pruritus. Thus, CR845 appears to have substantial potential to alleviate the symptoms and consequences of this frequently incapacitating condition for which existing treatments have often provided little or no relief. These data also support the opioid/immune etiology of this condition.

The ASSertID Study: Feasibility Randomised Controlled Trial of Drug Treatment for Depression in Patients on Haemodialysis Ayman Guirguis,[1,2,3] Michael K. Almond,[4] Joseph Chilcot,[5] Andrew Davenport,[6] Clara Day,[7] Naomi Fineberg,[2,3] Karin Friedli,[2] Benjamin Spencer,[5] David Wellsted,[2] Ken Farrington.[1,2] *[1]East & North Hertfordshire NHS Trust, United Kingdom; [2]Univ of Hertfordshire, United Kingdom; [3]Hertfordshire Partnership Univ NHS Trust, United Kingdom; [4]Southend Univ Hospitals NHS Trust, United Kingdom; [5]King's College London, United Kingdom; [6]Royal free London NHS Trust, United Kingdom; [7]Univ Hospitals Birmingham NHS Trust, United Kingdom.*

Background: Major Depressive Disorder (MDD) is common in patients on Haemodialysis (HD) but there is little evidence of benefit from antidepressants. Hence we undertook a multicentre feasibility Randomised Controlled Trial **(**RCT) of sertraline versus placebo.

Methods: A screening phase identified patients with Beck Depression Inventory (BDI-II) score ³16.Those meeting eligibility criteria, underwent psychiatric assessment (Mini International Neuropsychiatric Interview). Consenting patients with mild to moderate MDD and Montgomery-Åsberg Depression Rating Scale (MADRS) score ³18 were randomised to sertraline or placebo. Follow-up by study psychiatrist;week 2, month 2, 4 and 6 and monthly by study nurses. Initial dose was 50 mg with titration to 100 mg if required.

Results: Of 1355 patients approached, 715 consented for screening. BDI-II ³16 was present in 231(32.3%), 58 (25.1%) were ineligible due to current treatment for MDD. Sixty-three underwent psychiatric assessment. MDD was diagnosed in 37; 30 consented to the RCT (mean age 61 ±15; 71% male; 60% white). Twenty-one (70%) completed the trial, 8(of 15) on sertraline and 13(of 15) on placebo. Over 6 months, BDI-II and MADRS scores decreased ($t(17)=6.3$, $p<0.001$ and $t(20)=11.3$, $p<0.001$ respectively). There was no reliable difference between the sertraline and placebo groups. Fewer on sertraline completed (6 withdrawals and one death versus 2 withdrawals on placebo [$C2=3.97$, $p=0.046$]). There was a trend towards a greater fall in MADRS scores by month 2 on sertraline (effect size 0.37: lower bound >0).

Conclusions: This feasibility study is the largest RCT investigating the use of anti-depressants in HD patients with MDD. Similar significant improvement in MDD occurred over 6 months in both groups. Recovery may have been quicker on sertraline.

Randomised Controlled Trial to Determine the Appropriate Time to Initiate Pertioneal Dialysis after Insertion of Catheter to Minimise Complications Helen G. Healy,[1] George T. John,[1] Edward Yeoh,[1] Nicola Williams,[1] Thin M. Han,[2] Lakshmanan Jeyaseelan,[3] Kavitha Ramanathan,[3] Dwarakanathan Ranganathan.[1] *[1]Renal Dept, Royal Brisbane & Women's Hospital, Brisbane, Queensland, Australia; [2]Renal Dept, Rockhampton Hospital, Rockhampton, Queensland, Australia; [3]Dept of Statistics, Christian Medical College, Vellore, India.*

Background: The optimal time for the commencement of peritoneal dialysis (PD) after PD catheter insertion is not well known. If dialysis is started too soon after insertion, dialysate leaks and infection may occur. However by starting PD earlier, morbidity and costs can be reduced through less need for haemodialysis. This is the first randomised controlled trial to determine the safest and shortest interval to commence PD after catheter insertion.

Methods: All consecutive patients undergoing PD catheter insertion at the Royal Brisbane and Women's Hospital and Rockhampton Hospital from 1st March 2008 to 31st May 2013, and who met the inclusion and exclusion criteria were invited to participate in the study. Participants were randomised to one of three groups. Group 1 (G_1) commenced PD at one week, group 2 (G_2) at two weeks and group 3 (G_3) at four weeks after Tenckhoff catheter insertion. The groups were stratified by hospital and the presence of diabetes. Primary outcomes were the incidence of peritoneal fluid leaks or PD related infection during the 4 weeks after commencement of PD.

Results: 122 participants were recruited, with 39, 42 and 41 randomised to groups G_1, G_2 and G_3 respectively. The primary outcome of either catheter leaks or infection was significantly different in both intention to treat (ITT) and per protocol (PP) analyses ($p=0.016$ and 0.006 respectively). Multiple pairwise comparison showed a significant difference between G1 and G3 in PP analysis (p-value=0.010) but not in the ITT analysis.

Conclusions: Overall complications were higher in patients commencing PD one week after catheter insertion compared with the other two groups.

The Effects of Normal Saline and an Acetate-Buffered Crystalloid Solution on Hyperkalemia in Deceased Donor Renal Transplantation: A Randomized Blinded Trial Laura Elisabeth Harris, Peter F. Mount, Francesco L. Ierino, David A. Story, Glenn M. Eastwood, Larry Mcnicol, Rinaldo Bellomo, Laurence Weinberg. *Austin Health, Melbourne, Victoria, Australia.*

Background: Perioperative administration of 0.9% normal saline (NS) in deceased donor renal transplantation is associated with hyperchloremic metabolic acidosis, but the effect of NS on the risk of hyperkalemia or delayed graft function is unknown. We compared the effect of NS to an acetate buffered crystalloid solution (Plasmalyte-148) (PL), on the incidence of hyperkalemia, acid base status, and delayed graft function in deceased donor renal transplant patients.

Methods: Blinded randomized single-centre trial conducted in a renal transplant unit of a tertiary hospital. Patients were randomized to NS or PL for perioperative fluid management. The primary outcome was hyperkalemia (≥ 5.5 mM) within the first 48 h postoperatively. Secondary outcomes were acid base disturbances; delayed graft function and hospital length of stay.

Results: Forty-nine patients were randomized: 25 to NS and 24 to PL. Baseline characteristics were similar in both groups. The median [IQR] total volume of fluid administered was 6446mL [4807,8075] for NS and 7776mL [5140,9080] for PL ($p=0.3$). The incidence of hyperkalemia in the first 48 hours postoperatively was higher in the NS group: 20 patients (80%) vs. 12 patients (50%) in the PL group ($p=0.04$). Sixteen patients (64%) in the NS group required treatment for hyperkalemia compared to 5 patients (21%) in the PL group ($p=0.003$). The peak serum potassium in the 48 h postoperative period was higher in the NS group (6.1±0.8 vs. 5.4±0.9 mM, $p=0.009$). Patients receiving NS were more academic (pH: 7.32 ±0.06, vs. 7.39 ±0.05, $p=0.001$) and had higher serum chloride (107 mM vs. 101 mM, $p<0.001$) at the end of surgery. There were no significant differences in delayed graft function or hospital length of stay.

Conclusions: Deceased donor renal transplant patients that received NS developed hyperchloremic metabolic acidosis with an increased incidence of hyperkalemia when compared to PL. This study supports the use of acetate buffered crystalloid solutions for perioperative fluid management in patients undergoing deceased donor renal transplantation.

Eculizumab in Prevention of Acute Antibody-Mediated Rejection in Sensitized Deceased-Donor Kidney Transplant Recipients: Updated 12-Month Outcomes D. Glotz,[1] G. Russ,[3] Lionel Rostaing,[3] Christophe M. Legendre,[3] Steven J. Chadban,[3] J. Grinyo,[3] Nizam Mamode,[3] Gunnar Tufveson,[3] Lionel Couzi,[3] P. Riggoti,[3] Y. Lebranchu,[3] S. Sandrini,[3] W. Marks.[2] *[1]Hôpital Saint-Louis, Paris, France, Metropolitan; [2]Alexion Pharmaceuticals, Inc., Cheshire, CT; [3]The International Eculizumab Transplant Study Group.*

Background: Complement activation by preformed DSA is the major mechanism of acute antibody-mediated rejection (aAMR) in sensitized, kidney transplant recipients (SKTR). In a previous interim study report, the C5 inhibitor eculizumab (Ec) appeared effective in preventing aAMR in deceased donor (DD) SKTR compared to historical controls. We now report 12-mo efficacy and safety data from a Sept 2015 update of this ongoing, open-label, single-arm trial.

Methods: SKTR defined as current DSA >3000MFI detected by SAB; or B- or T-cell flow cytometric crossmatch ³300 and ≤500 mean channel shift; or historical positive complement-dependent cytotoxicity crossmatch to donor HLA. All recipients received Ec 1200mg postoperative day (POD) 0 prior to reperfusion, 900mg on POD 1, 7, 14, and 28, and 1200mg at wks 5, 7, and 9. Recipients received Rabbit ATG for induction and corticosteroids, tacrolimus, and mycophenolate for maintenance immunosuppression. Plasmapheresis was not allowed through Post-transplant week 9. The primary composite endpoint was clinically significant, biopsy (bx)-proven aAMR grade II/III (Banff 2007, based on centrally read bx), graft loss, death, or loss to follow-up at 9wks. Graft and patient (pt) survival were estimated by K-M.

Results: 80 pts were transplanted (48 F, 32 M); median age 52y (range, 24–70). 7 of 80 SKTR had aAMR (8.8%) compared to 30% expected for historical controls. 11/80 SKTR met the 9wk composite primary endpoint based on local bx (13.8% [95% CI 7.1–23.3]). Graft survival at 6 and 12mo was 93.7% and 88.7%, respectively; pt survival at 6 and 12mo was 97.4%. SCr levels (mg/dL) at baseline, 1 and 12mo were 7.43 (±2.51), n=79; 1.86 (±1.07), n=74; and 1.63 (±0.76), n=69. No new safety concerns were identified.

Conclusions: Ec appeared to be effective in reducing aAMR in SKTR. Pt and graft survival and kidney function at 12mo were similar to those expected for non-sensitized KTR. Ec was well tolerated.

Impact of De Novo Donor Specific Antibodies on Graft Outcomes in Kidney Transplant Recipients following Early Switch from Calcineurin Inhibitor to Everolimus: Analysis of the ELEVATE Trial Johan W. De Fijter, Hallvard Holdaas, Patricia M. Lopez, Peter Bernhardt, Zailong Wang, Frans Claas, Wolfgang Arns, Josep M. Cruzado, Markus van der Giet. *For the ELEVATE Study Group.*

Background: Development of *de novo* donor specific HLA-antibodies (dnDSA) after kidney transplantation (KTx) is associated with an increased risk of antibody-mediated rejection (AMR) and graft failure. The ELEVATE study evaluated the impact of early conversion from CNIs to everolimus (EVR) after KTx and prospectively explored the status and development of DSAs.

Methods: In this 24 month (M), multicentre study KTx recipients were randomized at 10–14 weeks post-Tx to convert from CNI to EVR (n=360: C0 6–10 ng/mL) or continue CNI (n=357: C0, tacrolimus 5–10 ng/mL, cyclosporine 100–250 ng/mL); all received enteric-coated mycophenolate sodium (MPS) + corticosteroids. Blood samples were collected at

Underline represents presenting author/disclosure.

baseline, randomization (RND), M12 and M24 or at time of rejection episodes and analysed by Luminex/SAB assay in one central lab. dnDSA was defined by a MFI value ≥500 any time post-RND in patients with MFI <500 at RND.

Results: Baseline characteristics were comparable between groups. Incidence of preformed DSA (MFI ≥500 at baseline) against HLA class-I or -II was low (table A). Overall, incidence of dnDSA HLA class-I was higher with EVR/MPS treatment vs CNI/MPS at M12 and M24. The incidence of dnHLA Class-II antibodies was dominated by anti-DQ in the CsA/MPS [lrm]group (table B). No association between *de novo* (either HLA class-I or -II) antibodies and a diagnosis of AMR or tBPAR was evident in this population up to M24 (table C, D).

Conclusions: Early conversion to EVR at 3M post-Tx did not increase the risk of dnDSA formation vs CNI continuation. Moreover, no association was observed between development of dnDSA and AMR or tBPAR, even with the lowest detection thresholds.

TABLE 3: DSA outcomes

A) Incidence of pre-formed DSA

HLA Class I		Baseline EVR	Baseline CNI Total	Baseline CNI TAC	Baseline CNI CsA	HLA Class II	Baseline EVR	Baseline CNI Total	Baseline CNI TAC	Baseline CNI CsA
MFI ≥ 500	HLA A	3.4	3.9	4.6	2.6	MFI ≥ 500	HLA DR	6.8	4.1	4.5	3.1

Donor-Derived Cell-Free DNA in Plasma Increases with Rejection and Decreases after Treatment in Kidney Transplant Recipients

Marica Grskovic,[1] Brian Christie,[1] David Hiller,[1] Robert Woodward,[1] Jim Yee,[1] Flavio Vincenti.[2] *[1]CareDx, Inc., Brisbane, CA; [2]UCSF, San Francisco, CA.*

Background: Donor-derived cell-free DNA (dd-cfDNA) is an emerging biomarker of acute cellular rejection in organ transplant recipients. The utility of determining plasma levels of dd-cfDNA aimed at diagnosing rejection and evaluating treatment response was assessed in kidney transplant recipients in a longitudinal observational trial.

Methods: Clinical status, biopsy grade (performed in response to elevated serum creatinine) and plasma were collected at 326 routine surveillance visits from 101 patients. Samples from nine patients assigned a biopsy grade I, II or III (NIH criteria) were classified as rejection (R). Samples from seventeen patients assigned a biopsy grade 0 were classified as quiescent (Q). cfDNA extracted from plasma was amplified at targeted SNPs and analyzed using a sensitive and accurate Next Generation Sequencing assay to quantify dd-cfDNA levels without the need to separately genotype the donor. Standard statistical measures of significance were used.

Results: dd-cfDNA levels were significantly higher (p=0.029) in patients with biopsy-confirmed rejection (R, mean 4.23%) compared to quiescente patients (Q, mean 0.96%). Creatinine levels were not significantly different between R and Q patients (p=0.69; mean 4 and 3.1 mg/dL, respectively). Longitudinal sample analysis from 15 patients showed increased dd-cfDNA levels following transplant (mean 2.8%) with reduction to levels below 1% by two weeks post transplantation. In 3 cases with clinically treated biopsy-confirmed rejection and 2 serial samples following the rejection, levels of dd-cfDNA decreased following rejection treatment.

Conclusions: dd-cfDNA shows promise as a biomarker of rejection that may be used for non-invasive surveillance of kidney allograft status and treatment response. The ongoing measurement of cfDNA may allow clinicians to better personalize care and improve patient outcomes.
