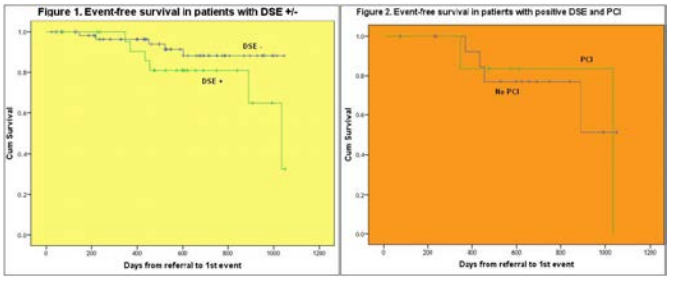
Results: 92 high risk patients underwent DSE. 28 of 92 patients had a positive DSE (i.e. suggestive of myocardial ischaemia) and 6 of these 28 had an event (event rate 13% per year) whereas there were only 5 events amongst the 64 patients in the DSE negative group (event rate 5% per year) (figure 1; log rank p=0.13). There were no perioperative events. 23 of 28 patients with a positive DSE had a CA, 14 had significant (> 50% stenosis) coronary artery disease (CAD) and another 3 had non-significant CAD (<50% stenosis). 7 of 14 patients with significant CAD had coronary stents; and 6 of 14 had events (event rate 26% per year). There was no difference in survival between the patients stented and those who were not (figure 2; log rank p=0.9).



Conclusions: DSE is a suitable method to stratify cardiovascular risk and predict significant CAD on CA, however subsequent PCI does not conclusively show decreased event rates. Larger studies are required to establish the role of revascularisation.

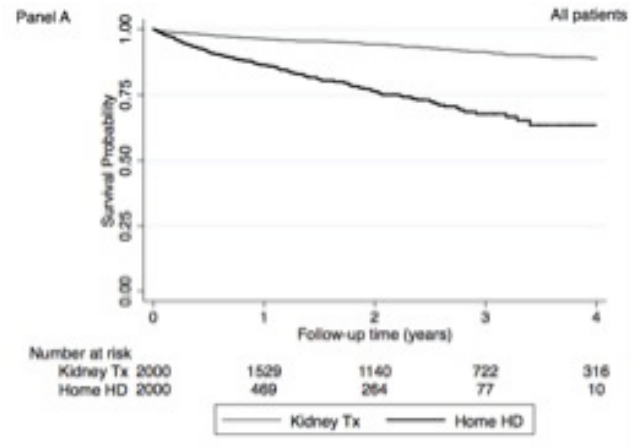
FR-PO1007

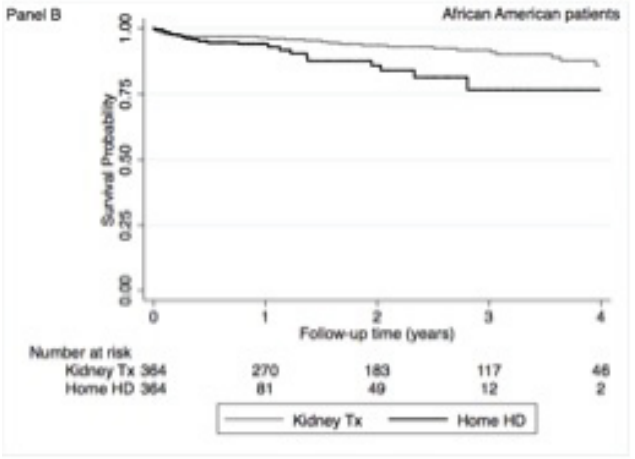
Racial Differences in Survival of Incident Home Hemodialysis and Kidney Transplant Patients Miklos Zsolt Molnar,[1] Vanessa A. Ravel,[2] Elani Streja,[2] Csaba P. Kovesdy,[1] Rajnish Mehrotra,[3] Kamyar Kalantar-Zadeh.[2] *[1]Univ of Tennessee Health Science Center, Memphis, TN; [2]Univ of California, Irvine, CA; [3]Univ of Washington, WA.*

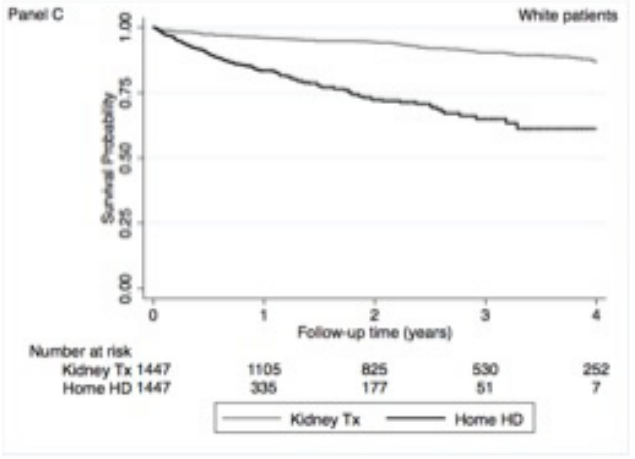
Background: Previous studies have indicated that patients on maintenance dialysis have worse survival compared to kidney transplant (KTx) recipients. However, none of these studies have compared mortality in United States(US) patients using alternative dialysis modalities such as home hemodialysis(HD) with KTx recipients.

Methods: Comparing patients who started home HD with those who received KTx in the US between 2007-2011, we created a 1:1 propensity-matched cohort of 4,000 patients and examined the association between treatment modality and mortality using Cox proportional hazard models.

Results: The mean±SD age of the matched home HD and KTx patients at baseline were 54±15 and 54±14 years, 65% were male (both groups), 70% and 72% of patients were white and 19% were African American (both groups), respectively. Over 5 years of follow-up, home HD patients had 4-times higher mortality risk compared to KTx recipients in the entire patient population (HR:4.06, 95%CI:3.27-5.04)), and similar differences were found across each race stratum (Figure).







However, during the first year of therapy, while white home HD patients had higher mortality risk (HR:4.21, 95%CI:3.10-5.73) compared to their KTx counterparts, there was no significant difference in mortality risk between African American home HD and KTx patients (HR: 1.62, 95%CI:0.77-3.39). These results were consistent across different types of kidney donors.

Conclusions: Among all patients, home HD is associated with 4 times higher mortality compared to KTx regardless of the type of kidney donor, whereas among African Americans home HD and KTx have similar survival during the first year of therapy. Further studies on racial disparities of home HD and KTx are warranted.

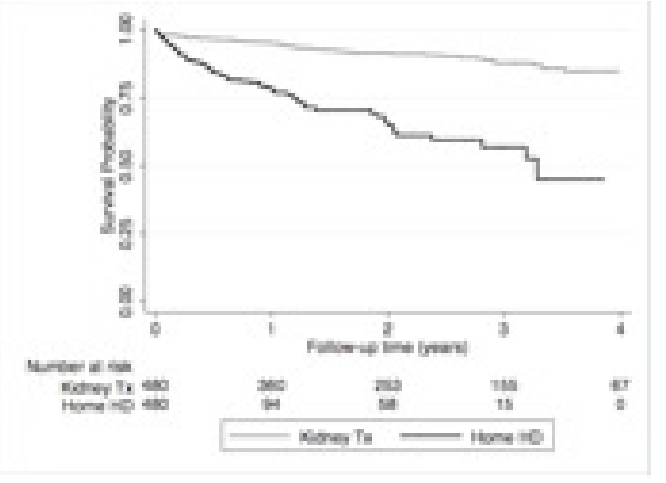
FR-PO1008

Survival of Elderly Incident Home Hemodialysis and Kidney Transplant Patients Miklos Zsolt Molnar,[1] Vanessa A. Ravel,[2] Elani Streja,[2] Csaba P. Kovesdy,[1] Danh V. Nguyen,[2] Rajnish Mehrotra,[3] Kamyar Kalantar-Zadeh.[2] *[1]Univ of Tennessee Health Science Center, Memphis, TN; [2]Univ of California, Irvine, CA; [3]Univ of Washington, WA.*

Background: The proportion of elderly (≥65 years) patients with kidney failure is increasing. Previous data suggest that the projected increases in the life spans of kidney transplant (KTx) patients compared to conventional dialysis were 2.8 and 1.1 years for patients aged 65-69 and 70-74 years, respectively. However, no studies have compared mortality of elderly patients using alternative dialysis modalities such as home hemodialysis (HD) with KTx recipients.

Methods: Comparing elderly patients, who started home HD with those who received KTx in the US between 2007-2011, we created a 1:1 propensity score (PS) matched cohort of 960 elderly patients (480 KTx and 480 HD) and examined the association between treatment modality and all-cause mortality using Cox proportional hazard models.

Results: The mean±SD age of the PS matched home HD and KTx patients at baseline were 71±6 years and 71±5 years, 69% were male (both groups), and 81% and 79% of patients were whites in home HD and KTx group, respectively. Median follow-up time was 205 days (IQR: 78-364 days) for home HD patients and 795 days (IQR: 366-1,221 days) for KTx recipients. There were 97 deaths (20%, mortality rate 253 [297-309]/1000 PY) in the home HD group, and 48 deaths (10%, 45 [34-60]/1000 PY) in the KTx group. Over 5 years of follow-up, home HD patients had almost 5-times higher mortality risk compared to KTx recipients in the entire patient population (HR: 4.74, 95%CI:3.25-6.91).



These results were consistent across different types of kidney donors and recipients characteristics.

Conclusions: Elderly home HD patients appear to have almost 5 times higher mortality compared to KTx recipients regardless of the type of kidney donor.

FR-PO1009

Beyond the Bones – The Association Between Vitamin D, Graft Outcomes and Vascular Disease Aravind Cherukuri,[1] Santhanakrishnan Balasubramanian,[2] Rebekah Molyneux,[2] Richard J. Baker.[2] *[1]Univ of Pittsburgh; [2]Univ of Leeds.*

Background: Vitamin D deficiency in KTRs is an emerging theme. The purported associations between Vitamin D deficiency and various metabolic, cardiovascular and non-metabolic adverse events have not been thoroughly studied in kidney transplant recipients (KTRs).

Methods: Here, we examined the association between Vitamin D deficiency and graft loss, mortality, NODAT, cardiovascular events and development of cancers.

Results: 504 KTRs had their vitamin D checked in 2008 and were followed up for 6 years. Vitamin D deficiency was defined as a level<50nmol/L. In this population, the prevalence of vitamin D deficiency was high at 66.5% with a significantly higher prevalence in older (71.9% vs. 60.9%, P=0.006) and female recipients (male 62.1% vs. female 73.2%, P=0.006) and in relatively new transplants (recent transplants 72.3% vs. old transplants 60.6%, P=0.003). KTRs who were vitamin D deficient had significantly worse overall (77% vs. 92%, P<0.0001), death censored graft survival (89% vs. 96%, P=0.009), development of NODAT (19.8% vs. 10% p=0.005) and cardiovascular events (9.9% VS. 2.9%, p=0.002) when compared to those with normal levels. In a stratified analysis, this was noted to be worse in KTRs on maintenance steroids, with relatively worse baseline renal function and proteinuria, with secondary hyperparathyroidism, deceased donor transplants and earlier vs. late transplants. Although vitamin D deficiency is not associated with a higher incidence of malignancy, it is associated with higher mortality in those with cancer (33.3% VS. 12.9%, p=0.005). In a multivariate Cox model, vitamin D deficiency was associated with significantly worse overall graft (HR 2.7, P=0.001) and death censored graft survival (HR 2.4, P=0.04), NODAT (HR 2.3, p=0.03) and cardiovascular events (HR 4.0, P=0.004) independent of age, PTH levels, gender, graft number, type of transplant, time since transplantation, graft type and renal function measured by both proteinuria and eGFR.

Conclusions: In conclusion, vitamin D deficiency which is highly prevalent in KTRs is associated with adverse clinical outcomes. Our study stresses the need for a prospective trial of vitamin D replacement in KTRs.

Acute Tubular Necrosis Changes in Living Kidney Donor Implant Biopsy Associates with Higher Rejection Rates Post-Transplant Chunping Yu, Nissreen Elfadawy, Andres G. Chiesa-vottero, Leal C. Herlitz, Emilio D. Poggio. *Dept of Nephrology and Hypertension, Glickman Urological and Kidney Inst, Cleveland Clinic, Cleveland, OH.*

Background: Ischemic injury may occur during organ retrieval. In deceased kidney donor transplants, delayed graft function, a form of acute tubular necrosis (ATN), associates with acute graft rejection. Histological changes consistent with ATN can also be seen in implant biopsies of living donors(LD), however, the influence of ATN-like changes at time on donation from LD on recipient graft outcomes is unclear, especially its impact on graft rejection.

Methods: We retrospectively studied all LD kidney transplants at our center from Jan 2005 to Dec 2014 who had an implant biopsy. We perform protocol biopsies at 3-6,12 and 24 months post-transplant and for cause biopsies in all of our patients. Post-transplant biopsy results were reviewed, and patients with subclinical and clinical borderline and/or BANFF scored graft rejection were captured.

Results: The study included 350 LD kidney transplant recipients, the mean age was 47.8±13.7 years (range 10-75) and224(64%) were male. The incidence of ATN in implant biopsies was 16% (n= 56). Patients with ATN had a trend toward higher risk of graft rejection in post-transplant biopsy compared with those without ATN (32.1% vs. 21.7%, p=0.09). When the study population was stratified by time interval from transplant to post-transplant biopsy, there was a statistically significant higher incidence of graft rejection in those biopsies performed between 1 and 24 months post-transplant (31.0% in the ATN group vs.17.8% in the non-ATN group, respectively, p=0.02). No statistical correlation was found between ATN and graft rejection after 24 months post-transplant. Importantly, implant ATN has no impact on GFR at 3, 6, 12, 24 months post-transplant.

Conclusions: Histological changes consistent with ATN in LD kidney implant biopsy are associated with higher rates of graft rejection between 1 and 24 months post-transplant. However, ATN does not affect graft function at 3, 6, 12, or 24 months.

FR-PO1011

Impact of Pre-Transplant Cardiovascular Risks on Renal Allograft Survival: A Multi-Center Prospective Study Jung Nam An,[1,2] Song Vogue Ahn,[3] Chun Soo Lim,[1,2] Yon Su Kim,[2] Young hoon Kim,[4] Jung Pyo Lee.[1,2] *[1]Seoul National Univ Boramae Medical Center; [2]Seoul National Univ College of Medicine; [3]Yonsei Univ Wonju College of Medicine; [4]Asan Medical Center and Univ of Ulsan College of Medicine, Republic of Korea.*

Background: Cardiovascular (CV) disease is a leading cause of mortality in patients with end-stage renal disease. Even after successful renal transplantation, CV risks can induce CV morbidity and mortality in renal transplant recipients. However, the impact of pre-transplant CV risks on renal allograft outcomes has not been reported.

Methods: We analyzed the graft outcomes of 2902 renal transplant recipients who were enrolled in a multi-center cohort from 1997 to 2012. We calculated pre-transplant CV risk scores by the Framingham risk model using age, sex, total cholesterol levels, smoking and a history of hypertension. Cox proportional hazard models were used to assess hazard ratios (HRs) with and without competing risks of post-transplant CV deaths, adjusting for risk factors of allograft failure including recurrence of glomerulonephritis and acute rejection.

Results: Hypertension and vascular disease (a composite of ischemic heart disease, peripheral vascular disease, and cerebrovascular disease) were noted in 84.1% and 6.5% of the patients, respectively. During a median 6.4 years of follow-up, 122 (4.2%) patients died and 286 (9.9%) patients developed allograft failure. In multivariable-adjusted models, pre-transplant vascular disease was associated with increased risk of renal allograft failure (HR 2.43; 95% confidence interval [CI] 1.58-3.71). The HR for renal allograft failure comparing the highest with the lowest tertiles of pre-transplant CV risk scores was 1.49 (95% CI 1.11-2.00). In competing risk models, the HR of pre-transplant vascular disease was 2.01 (95% CI 1.20-3.36) and the HR for renal allograft failure comparing the highest with the lowest tertiles of pre-transplant CV risk scores was 1.44 (95% CI 1.05-1.98).

Conclusions: Both pre-transplant CV risk and vascular disease are independently associated with renal allograft failure in this multi-center prospective study. Pre-transplant CV risk assessment could be useful to predict renal allograft failure.

FR-PO1012

Blood Pressure (BP) Control in Kidney Transplant Recipients: A Single Centre Experience Kristin Vibeke Veighey, Jacqueline C. Nevols, Panagiotis Chondrogiannis, Amanda Jane Laird, Irene Synodinou, Doreen Zhu, Katherine A. Alington, Nichola Dawn Pugh, Chuin ying Ung, Gopalakrishnan Venkat-Raman. *Wessex Kidney Unit, Portsmouth Hospitals NHS Trust, Portsmouth, United Kingdom.*

Background: Cardiovascular disease is the leading cause of death among kidney transplant recipients (KTRs), however there remains uncertainty regarding optimal BP targets. Current UKRA, KDIGO and KDOQI guidelines advocate BP control to 130/80 in KTRs; UKRA/KDIGO advocate tighter control (125/70) in proteinuric KTRs. We examined BP control and proteinuria in all KTRs under longterm follow up at one centre, and adherence to these recommendations.

Methods: As of 1 March 2015, 839 KTRs were attending for regular clinic review (excluding recent KTRs<1yr). We performed a retrospective database review of BP, proteinuria, renal function and antihypertensive use.

Results: The cohort was 60% male with mean allograft age 10±0.28 years. Mean decline in eGFR was 0.83ml/min/m^2 per year (p=0.0004). Mean SBP was 134±0.56, DBP 79±0.37. 48% had SBP <130, 62% DBP <80, 39% both. 78% received ³1 antihypertensive, 42% 2-3, 4% ≥4 agents. Only 9% had PCR measured. In those with PCR≥50, 19% had BP treated to 125/75. Dipstix proteinuria was recorded in 58% and showed a significant association with SBP (p=0.01). There were significant correlations between reducing eGFR and increasing PCR (R^2=0.11, p<0.0001), and between PCR and ACE/ARB use (p= 0.0002). There was no correlation between CNI level and BP (CyA p=0.88, FK506 p=0.49). There was a significant stepwise decrease in renal function (sCr p=0.005, eGFR p=0.01) and increase in dipstix proteinuria (p=0.03) when data were analysed in SBP groups <120, 120-140 and >140. In terms of DBP, the stepwise decrease in renal function remained (sCr p=0.01, eGFR p<0.0001) when data were analysed in groups <70, 70-90 and >90. DBP≥90 had the most significant impact on eGFR. DBP was not associated with proteinuria.

Conclusions: The optimal BP target remains uncertain. Adherence to current guidelines is reasonable in our unit but could be improved. This study again demonstrates that SBP is the key risk factor for proteinuria, however increases in DBP >90 were most strongly associated with graft dysfunction.

FR-PO1013

Dobutamine Stress Echocardiography (DSE) Significantly Reduces the Need for Coronary Angiography in Renal Transplant Recipients Robin Ramphul, Maria Ventura, Sami Firoozi, Juan Carlos Kaski, Rajan Sharma, Debasish Banerjee. *Renal and Cardiology Unit, St. Georges Univ Hospitals NHS Foundation Trust, United Kingdom.*

Background: There is significant controversy regarding optimal cardiac workup strategy for kidney transplantaion. Some centres perform coronary angiograms (CA) in all patients whereas others have adopted a tailored approach using non-invasive techniques such as Exercise Tolerance Testing (ETT) and ischaemia assessment with cardiac imaging. This study examines the role risk stratification and DSE for cardiac workup in this patient group.

Methods: We analysed data on patients referred between 1/2/2012 and 31/12/2014 who were risk stratified and investigated according to the protocol (figure 1).

Results: Of 233 patients referred 92 were high risk and went on to have DSE. All other patients underwent echocardiography with/without ETT (35 ETT, 122 echocardiography and 33 CA). 16 patients had CV events, but none were perioperative. Overall event rate was 4% per year. 11 of 92 patients who had DSE had events. 11 of 33 patients who had CA had event. 28 of 92 patients had a positive DSE (i.e. suggestive of myocardial ischaemia) and of these 23 went on to CA. 6 of 28 patients with a positive DSE and 5 of 64 with a negative DSE had an event (figure 2, log rank p=0.1). 25 of 33 patients had evidence of coronary artery disease (CAD) at CA of which 13 received coronary artery stents. There was no significant difference between those with significant (>50% stenosis) CAD on CA who had events (8 of 21 patients) compared to those without significant (<50% stenosis) CAD who had events (3 of 12) (log rank p = 0.7). 6 patients with significant CAD who had PCI had events. 35 patients underwent ETT, 4 had CA following positive ETT. One patient with negative ETT had an event.

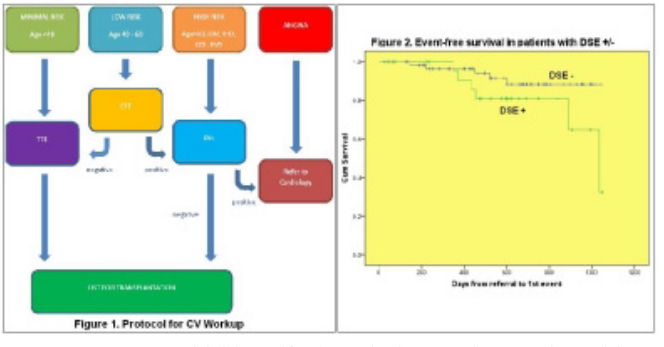

Figure 1. Protocol for CV Workup

Conclusions: A careful risk stratification and using DSE decreases the need for CA and achieves very low event rates.

FR-PO1014

Levels of Indoxyl Sulfate in Kidney Transplant Patients, and the Relationship with Hard Outcomes Sophie Liabeuf,[1] Lucie Desjardins,[1] Ziad Massy,[2] François Brazier,[1] Dimitri Titeca Beauport,[1] Momar Diouf,[1] Griet Lrl Glorieux,[3] Raymond C. Vanholder,[3] Maite Jaureguy,[1] Gabriel Choukroun.[1] *[1]Nephrology, Amiens; [2]Nephrology, Ambroise Paré; [3]Nephrology, Gent.*

Background: Kidney transplant recipients are at greater risk of cardiovascular disease (CVD). Indoxyl sulfate (IS) is a protein-bound uremic toxin that is known to be associated with the risk of CVD and mortality in both pre-dialysis and dialysis patients. Data on levels of protein-bound uremic toxins in kidney transplant patients are scarce. The objective

of the present study was to evaluate the levels of IS in kidney transplant patients and their relationships with biochemical parameters and hard outcomes (including mortality, cardiovascular (CV) events and graft loss).

Methods: In 311 consecutive kidney transplant patients, total and free IS levels were measured immediately before transplantation (T0) and then 1 month (M1) and 12 months (M12) afterwards. In a case controlled substudy (n=90), IS levels in transplant patients were compared with those in non-transplant patients with chronic kidney disease matched for age, gender and estimated glomerular filtration rate (eGFR). Over a mean ± standard deviation follow-up period of 113 ± 29 months, 55 deaths, 70 CV events and 71 graft losses were recorded.

Results: We observed a rapid, consistent, significant decrease in IS levels after kidney transplantation. Majority of IS levels were below or near the normal value at M1 and M12. We did not observe a correlation between IS levels and eGFR at M1 and M12. Total and free IS levels at M12 were significantly higher in non-transplant patients (0.34±0.23 mg/dl and 0.04±0.007 mg/dl, respectively) than in transplant patients (0.21±0.17 mg/dl and 0.01±0.1 mg/dl; (p=0.003 and <0.0001 respectively), despite having similar eGFRs. Lastly, IS levels were not associated with overall mortality, CV events or graft loss at T0, M1 or M12.

Conclusions: Free and total IS levels were significantly lower in transplant recipients than in non-recipients matched for, age, gender and renal function - suggesting that kidney transplantation protects against an increase in IS levels. Importantly, serum IS levels were not associated with hard outcomes at any of the three time points.

FR-PO1015

Identification of Metabolic and Cardiovascular Risk in Pediatric Kidney Transplant Recipients: Body Mass Index, Waist Circumference, or Waist-to-Height ratio?

Kristen Sgambat, Asha Moudgil. *Children's National, Washington DC.*

Background: In the general population, abdominal obesity is more closely associated with metabolic and cardiovascular (CV) risk than high BMI. The ideal measure of obesity to identify risk in pediatric kidney transplant (Tx) recipients, who have impaired growth and altered body composition, has not been established. In this prospective study we compared ability of BMI, Waist Circumference (WC), and Waist-to-Height ratio (WHr) to identify metabolic and CV risk in pediatric kidney Tx recipients.

Methods: Kidney Tx recipients 3-20 years old and 0-30 months post-Tx had WC, BMI, WHr, blood pressure (BP), fasting lipids, leptin, HbA1c%, standard and speckle echocardiogram and carotid intima-media thickness (CIMT) measured. Patients were classified as obese or lean by 3 methods: WC (ATP cut-point males>94th%ile,females>84 th%ile), WHr(CDC cut-point>0.539), and BMI(≥95th%). Logistic regression determined association of groups with metabolic and CV risk factors.

Results: The study group comprised of 33 Tx recipients, age 13.6±0.3 years. Prevalence of obesity by BMI, WC, and WHr was 21.2%, 33.3%, and 48.5%. Prevalence of hypertriglyceridemia(TG) was 24.2%, high LDL 15.2%, low HDL 57.5%,high leptin 39.3%, high HbA1c% 12.1%,left ventricular hypertrophy(LVH) 30.3%, hypertension(HTN) 69.6%, and high CIMT48.4%. In all groups (WHr, WC, and BMI), obese children were more likely than lean to have HTN(OR4.5,2.2,3.6,p<0.01),LVH(OR5.4,7.4,8.8,p<0.001), low HDL(OR5.0,7.4,3.8, p<0.001), and high leptin(OR19,13.1,7.3,p<0.001). Obese children in WHr and WC groups, but not BMI group, had greater chance of high TG(OR5.4,3.2,p<0.01), high CIMT(OR2.0,4.5,p<0.05),and impaired myocardial strain(OR1.2,1.1,p<0.01). Five patients with short stature (height z -2.56) and CV risk factors (3.0±0.5 factors/patient) were not identified as obese by WC criteria(height z-0.08,p=0.003).

Conclusions: WC and WHr are more effective than BMI for detecting metabolic and CV risk amongst pediatric Tx recipients. WC may underestimate prevalence of obesity in children of short stature, and therefore WHr may be a more sensitive method for identification of children with increased metabolic and CV risk in the kidney Tx population.

FR-PO1016

Knowledge About Benefits of Kidney Transplant: A Survey of Dialysis Patients

Naman Trivedi, Fareeha Khalil, Ming Wang, Eric Chang, Nasrollah Ghahramani. *Pennsalvania State Univ College of Medicine.*

Background: Kidney transplant (KT) is the treatment of choice for end stage renal disease (ESRD). Knowledge of dialysis patients about the benefits of KT is an important determinant of their active engagement in the decision making process. We studied factors associated with patients' knowledge about benefits of KT.

Methods: We sent flyers to 1,283 dialysis units. Of 2536 interested participants fulfilling inclusion criteria, we randomly selected and invited 1400 to complete the questionnaire. Independent variables were demographic factors, distance to dialysis unit, and modes of education about options. In multivariate analysis, we calculated odds ratios (OR) and 95% confidence intervals (CI) for the probability of responding correctly to each of 4 questions about benefits of KT.

Results: 673 participants responded to questions about overall survival benefit of KT (correct: 32%), benefits of KT for diabetic patients (correct: 46%), for patients > 60 (correct: 29%) and for patients transplanted pre-emptively (correct: 17%). Receiving 3 or more modes of education about KT was associated with higher likelihood of correct response to questions about overall survival benefit of KT (OR:2.19;CI:1.50 to 3.20), survival benefits of KT for diabetics (OR:2.04;CI:1.39 to 3.01) and patients transplanted pre-emptively (OR:1.67;CI:1.06 to 2.64). White race was associated with higher likelihood of correct response to questions about overall survival benefit of KT (OR:1.59;CI:1.11 to 2.28) and the benefit of KT for patients > 60 (OR:1.54;CI:1.07 to 2.21). Age > 60 was associated with lower likelihood of correct response to the question about overall survival benefit of KT (OR:0.65;CI:0.45 to 0.94), benefits of KT for diabetics (OR:0.54;CI:0.38 to 0.77), and for patients > 60 (OR:0.64;CI:0.44 to 0.93). Patients on dialysis > 5 years were less likely to be aware of the benefit of KT for diabetics (OR:0.68;CI:0.48 to 0.98).

Conclusions: Dialysis patients' knowledge about survival benefits of KT is rather limited. The most significant modifiable contributor to improvement in knowledge is diversity of modes of education about KT. Other factors include race, age and number of years on dialysis.

FR-PO1017

Pretransplant HbA1c Predicts New-Onset Diabetes After Transplantation Among Renal Transplant Recipients

Jung-Im Shin, Mari Palta, Arjang Djamali, Brad C. Astor. *Univ of Wisconsin School of Medicine and Public Health, Madison, WI.*

Background: New-onset diabetes after transplantation (NODAT) is a common complication among renal transplant recipients and is associated with a higher risk of cardiovascular events and poorer graft and patient survival. The association of pretransplant HbA1c with NODAT remains unclear. Identifying recipients at greatest risk of NODAT may help guide monitoring and treatment strategies to prevent or delay the onset of NODAT.

Methods: We assessed the association between pretransplant HbA1c and NODAT in 1522 non-diabetic recipients using data from the United States Renal Data System (USRDS) from 2004-2011. Cox proportional hazards models adjusted for demographics, cause of ESRD, year of transplantation, number of prior transplants, duration of pretransplant dialysis, comorbidities, lipid levels, hemoglobin level, body mass index, HCV and CMV serostatus, donor type and age, HLA mismatch, and posttransplant steroid and tacrolimus use.

Results: Median HbA1c was 5.4% and 531 (34.9%) patients had HbA1c ≥ 5.7% (i.e., prediabetes) A total of 404 (26.5%) patients developed NODAT during a median follow-up of 1.7 years. Pretransplant HbA1c was associated with the risk of NODAT in a non-linear fashion. The adjusted hazard ratio (HR) associated with 1% higher pretransplant HbA1c was 0.94 (95% confidence interval (CI): 0.62, 1.42) for HbA1c lower than 5.4% and 1.87 (95% CI: 1.30, 2.68) for HbA1c higher than 5.4%.

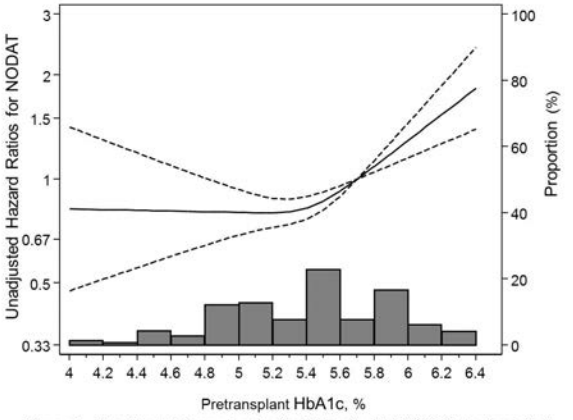

Figure 1. Unadjusted hazard ratio (solid line) with 95% CI (dashed line) for development of NODAT, by pretransplant HbA1c.

Conclusions: Pretransplant HbA1c is independently associated with the risk of NODAT among renal transplant recipients. A continuous relationship between pretransplant HbA1c and the risk of NODAT suggests that greater risk starts at levels below the standard threshold for prediabetes.

FR-PO1018

Choice of Equation to Estimate Kidney Function Has Large Impact on Timing of Kidney Transplant Waitlist Qualification

Benjamin J. Lee,[1] Charles E. McCulloch,[2] Isabel Elaine Allen,[2] Sindhu Chandran,[1] Chi-yuan Hsu.[1] *[1]Medicine, UCSF, San Francisco, CA; [2]Epidemiology and Biostatistics, UCSF, San Francisco, CA.*

Background: Because mortality on the kidney transplant waitlist is high (4-6% per year), being placed on the waitlist earlier versus later has important clinical consequences. Per U.S. Organ Procurement and Transplantation Network (OPTN) rules, patients begin accruing time on the waitlist when renal function declines beyond a threshold defined as "measured (actual urinary collection) creatinine clearance level or calculated glomerular filtration rate (Cockcroft-Gault or other reliable formula) less than or equal to 20 mL/min".

Methods: We assessed the relative performance of three commonly used kidney-function equations (Cockroft-Gault, MDRD, and CKD-EPI). We first compared the equations mathematically to determine under what age and serum creatinine combinations each pair of equations yields discordant waitlist qualification statuses (i.e., a patient would qualify for the waitlist if one equation were used but not the other). We then applied the equations to serial creatinine measurements from three patient cohorts: one of waitlisted patients at a major U.S. academic center and two national, multicenter cohorts of CKD patients (the NIH-sponsored AASK and MDRD studies).

Results: Mathematically (assuming average weights), the Cockroft-Gault equation almost always yields higher numeric values compared with the MDRD and CKD-EPI equations. When applied to the three actual patient cohorts, Cockroft-Gault consistently disadvantaged patients, delaying average time to waitlist qualification by 1 to 2 years.

Conclusions: This study identified a potential source of significant inequity (on the order of 1-2 years) in wait-time accrual for kidney transplantation that stems from imprecise rules for waitlist qualification. The OPTN may need to revise the language in their kidney transplantation policies so that consistent methods to assess renal function are adopted and patients are not inadvertently disadvantaged.

Funding: NIDDK Support

New Onset Diabetes Has Unfavorable Effect on Patient but Not on Allograft Survival

Thomas Dienemann,[1,2,3] Naohiko Fujii,[1,2] Roy D. Bloom,[1,2] Harold I. Feldman,[1,2] Yimei Li.[2] *[1]Dept of Medicine, Perelman School of Medicine- Univ of Pennsylvania, Philadelphia, PA; [2]Dept of Epidemiology and Biostatistics, Perelman School of Medicine, Philadelphia, PA; [3]Dept of Renal Medicine and Hypertension, Univ of Erlangen, Erlangen, Germany.*

Background: New onset diabetes after transplantation (NODAT) has been linked to higher rates of graft loss and shorter patient survival. More recent awareness, improvements in care, and changes in immunosuppression may have modified this association.

Methods: Retrospective single center analysis of 1427 (age>18) first time renal transplant recipients (KTR) without pre-transplat(Txp) diabetes. Patients with <1 year of follow up and those with allograft failure in the first year post-Txp were excluded. NODAT was defined as prescription of a glucose lowering medication 1 year after Txp. Cox models adjusted for mult. potential confounders were used to examine the relationship of NODAT with allograft and patient survival.

Results: The incidence of NODAT was 16.1%. Median follow up was 5.9 years(IQR3.5-9.2) for allograft and 6.3(IQR3.8-9.8) for patient survival. Age, BMI, non-white race and HCV were independently associated with NODAT (all p<0.01). Compared with KTRs without DM NODAT was not associated with an increased risk of overall graft failure (aHR1.15, CI0.86-1.52) or death censored graft survival (DCGS) (aHR1.12, CI0.73–1.71) in multivar. analysis. NODAT remained borderline significant after adj. for multiple other factors for patient survival (aHR1.39, CI1.00–1.91 p=0.49), but not for death with functioning graft (aHR1.34, CI0.89–2.02). The associations between NODAT and outcomes were not detectably different over time (p=0.095 for patient survival and p=0.25 for DCGS).

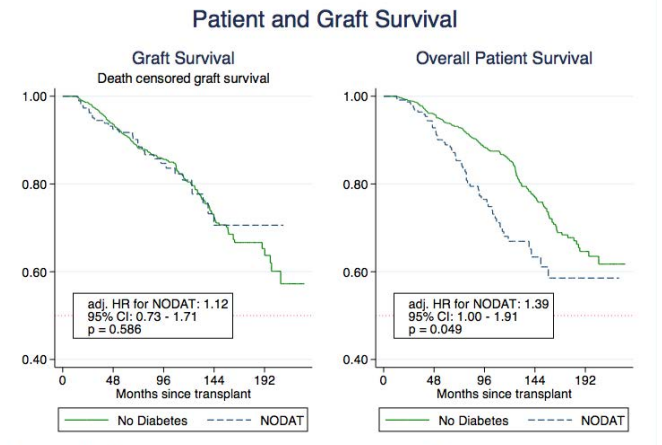

Figure 1. Kaplan-Meier curves for death censored graft survival and overall patient survival

Conclusions: In this cohort of KTRs NODAT had no impact on graft survival but was indep. associated with reduced overall survival.

FR-PO1020

Frequency of Hospital Readmission Post Kidney Transplantation

Essy Mozaffari,[1] Jay Lin,[2] Melissa Lingohr-Smith.[2] *[1]Chimerix Inc., Mendham, NJ; [2]Novosys Health, Green Brook, NJ.*

Background: Early hospital readmission following kidney transplantation has been identified to be a strong predictor of adverse sequelae that can have significant clinical and economic implications. Our goal was to quantify the frequency of hospital readmissions post kidney transplantation, as well as the reasons for the rehospitalizations.

Methods: Patients who received a kidney transplant between Jan 2009 and Sept 2013 were identified from the Premier Hospital database by ICD-9-CM code. The first transplant procedure was defined as the index event. The frequency and causes for hospital readmissions were evaluated during the first 12-month after index transplant hospitalization using hospital discharge records.

Results: Of patients who received kidney transplant (n=5,402; mean age: 50.8 years) 61% were male. Most patients received transplant in urban (98%), large (≥600 beds: 61%), teaching hospitals (84%). During index transplant hospitalizations 35 deaths occurred, resulting in 5,367 evaluable patients. Among this study population, 43% had a hospital readmission for any cause during the 12 months following kidney transplant, with 41% occurring within 1 month and 67% occurring within the first 3 months. Readmissions were most frequently related to opportunistic infections (25%) including viral infections (6%), followed by renal impairment (25%), and neutropenia (4%). Among the readmissions related to viral infections, the majority were related to CMV (79%). Readmission of patients with high severity APR-DRG levels of 3 (major) and 4 (extreme) at 30% and 9%, respectively (severity of illness level rated 1-4: minor, moderate, major, and extreme).

Conclusions: Over 4 in 10 of the kidney transplant recipients in this study were rehospitalized post transplantation. A significant number of the readmissions occurred in the first month post-transplant and the majority were within the first three months; almost 4 in 10 readmissions were classified as major or extreme severity level. Among hospital readmissions, more than half of them were related to an opportunistic or viral infection, underscoring unmet needs for the prevention of these infections.

Role of Non-Invasive Cardiac Stress Studies During Assessment for Kidney Transplantation in Pre-Dialysis Recipients

Talvinder S. Bhogal, Simon James Gray, Patrick Hamilton, Durga A.K. Kanigicherla. *Manchester Inst of Nephrology & Transplantation, United Kingdom.*

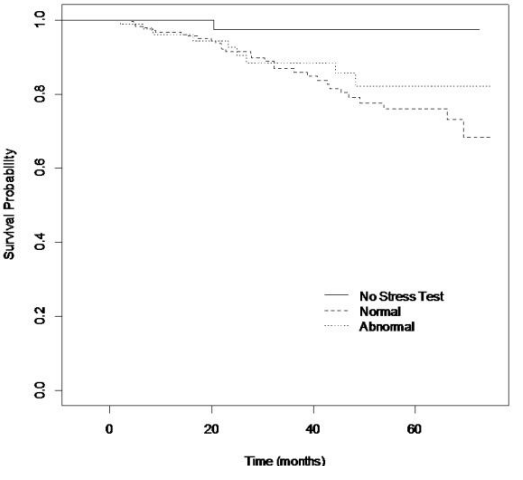
Background: Non-invasive cardiac stress studies (NISS) are routinely undertaken during listing of patients for kidney transplantation. Although guidelines recommend NISS in high risk patients based on studies reported on patients on RRT. However role of NISS in pre-dialysis population is unknown. We analysed the role of NISS in listing process and impact on longer term outcomes.

Methods: Retrospective study of all patients undergoing assessment for kidney transplantation at our centre between 2009 and 2014. 695 patients were assessed, including 397 who were pre-dialysis (naïve to RRT).

Results: 306 (77.1%) patients underwent NISS (98% were myocardial perfusion studies). Baseline and outcomes during follow-up are below.

	No NISS	Normal NISS	Abnormal NISS
Number of patients	91	225	81
Baseline % or Median			
Age	36	57	60
Males	59	51	69
BMI	27	28	30
Diabetes	5	31	53
Any vascular disease	3	24	31
Follow up			
Follow-up (in months)	34	25	29
Coronary intervention before listing	0	0	4
Number listed for kidney Tx	77	71	53
Transplants completed	57	28	17
Cardiovascular events	0	7	19
Death	1	14	11

Only 3 patients with abnormal NISS (1% of all who had NISS) had flow limiting lesions, needing interventions (2CABG and 1PCI). At last follow up, compared to those with normal NISS, patients with abnormal studies a) were less likely to be listed for kidney transplantation, b) had increased cardiovascular events (p=0.01). But there was no significant difference in patient survival.



Conclusions: Our study illustrates lack of benefit of non-invasive myocardial perfusion studies in identifying treatable coronary artery disease during pre-transplant assessment in pre-dialysis patients. Better risk stratification strategies are needed to inform assessment of kidney transplantation.

FR-PO1022

Longitudinal Association of Recipient Nonmuscle Myosin IIA Gene rs5756168 with Transplanted Kidney Doppler Ultrasound Blood Flow Indexes Joanna Pazik,[1] Ewa Nowacka-Cieciura,[1] Zbigniew Lewandowski,[2] Monika Oldak,[3] Dominika Ozi?b?o,[4] Magdalena Durlik.[1] *[1]Transplantation Medicine and Nephrology, Medical Univ of Warsaw, Warsaw, Poland; [2]Epidemiology, Medical Univ of Warsaw, Warsaw, Poland; [3]Histology and Embryology, Medical Univ of Warsaw, Warsaw, Poland; [4]Inst of Physiology and Pathology of Hearing, Warsaw, Poland.*

Background: MYH9 gene polymorphisms associate with nephron injury in hypertensive nephrosclerosis and FSGS. We have shown the association of rs5756168 with transplanted kidney eGFR(ATC 2015). MYH9gene polymorphisms correlate with cerebrovascular blood flows. In transplanted kidneys resistance and pulsatility indexes predict graft function.

Methods: The study aims at evaluating the association of donor/recipient *MYH9* SNPs (rs3752462, rs11089788, rs5756168, rs136211 rs2239784) and transplanted kidney pulsatility (PI) and resistive (RI) indexes. Recipients engrafted 2007-2012 with availabile: donor/recipient DNA, kidney spectral Doppler ultrasound (US) were included. For genotyping custom TaqMan genotyping assays were used. Mixed models were used to assess relations of SNPs and PI, RI values.

Results: Genotyping was performed in 295 kidney recipients and their donors, in 202 at least one US was done. In the longitudinal observation between first day and 2 years after engraftment, recipients carrying two T alleles in rs5756168 showed significantly different PI indexes in opposition to allele C carriers, p=0.04, for RI the differences did not reach statistical significance (p=0.14). In two-factor analyses the effects of rs5756168 was maintained in first transplants for RI (p=0.02) and PI (p=0.02), in recipients with TIT >24h (p 0.03 and 0.07, respectively), with grafts from donors>55 years old (p=0.05 for PI only), with panel reactive antibodies <20% (p=0.01 and 0.04 for PI and RI), patients on immunosuppression without induction (p=0.07 for PI only) and on tacrolimus treatment (p=0.05 for PI p=0.05).

Conclusions: Identified association of transplanted kidney blood flow parameters and *MYH9* polymorphism additionally confirms *MYH9* effect on graft functioning shown in our previous study cited above. The study supported by grant from National Science Center NN402566840.

FR-PO1023

Determinants of Hepcidin, the Key Regulator of Iron Homeostasis, in Renal Transplant Recipients Michele F. Eisenga,[1] Stefan P. Berger,[1] Robin P.F. Dullaart,[1] Aiko P.J. De Vries,[2] Stephan J.L. Bakker,[1] Carlo A. Gaillard.[1] *[1]Internal Medicine, UMCG; [2]Internal Medicine, LUMC.*

Background: Hepcidin is synthesized in the liver and secreted into the circulation. Circulating concentrations may be influenced by body iron availability, inflammation, insulin resistance and tissue hypoxia. Moreover, hepcidin is a small 2.8 kD molecule. Therefore, renal clearance may be an important additional determinant of circulating hepcidin. We aimed to investigate whether markers of iron availability (ferritin), inflammation (C-reactive protein (CRP)), insulin sensitivity (fasting insulin), tissue hypoxia (erythropoietin) and estimated glomerular filtration rate (eGFR) are determinants of serum hepcidin in a population of renal transplant recipients (RTR) with a large variation in renal function.

Methods: The study was performed in an extensively phenotyped RTR cohort recruited in the University Medical Center Groningen. Serum hepcidin was assessed by ELISA ECL immunoassay. Statistical analyses were performed using univariable linear regression followed by stepwise backward linear regression. P-values for inclusion and exclusion were set at 0.2 and 0.1, resp.

Results: We included 561 RTR (age 51±12 years; 55% males at 7.8±6.4 years after Tx). Mean hemoglobin (Hb) was 8.6 ±1.0 mmol/l. Median [IQR] serum hepcidin was 7.2 [3.2-13.4] ng/mL. Mean eGFR was 47±16 ml/min/1.73m2. In univariable analysis, ferritin (ß=0.69, p<0.001), CRP (ß=0.24, p<0.001), eGFR (ß=-0.14, p=0.001), Hb (ß=-0.12, p=0.006), EPO (ß=0.12, p=0.006), fasting insulin (ß=-0.09, p=0.03) and age (ß=0.09, p=0.03) were associated with serum hepcidin. In multivariable analysis, concentrations of ferritin (ß=0.66, p<0.001), CRP (ß=0.19, p<0.001), erythropoietin (ß=-0.13, p<0.001), fasting insulin (ß=-0.08, p=0.01) and Hb (ß=-0.06, p=0.06) (total model R^2=0.53) were identified as independent determinants of serum hepcidin, while the univariable association of eGFR was lost.

Conclusions: Despite large variation in eGFR, fifty-three percent of the variation in serum hepcidin concentrations in RTR can be attributed to variation in iron status, inflammation, insulin sensitivity and tissue hypoxia reflected by erythropoietin, rather than to variation in renal clearance.

FR-PO1024

Associations of Serum Soluble α-Klotho, Fibroblast Growth Factor 23, and 25 (OH) Vitamin D with Kidney Function and Left Ventricular Hypertrophy in Japanese Kidney Transplant Recipients Makoto Tsujita,[1] Shoichi Maruyama.[2] *[1]Transplant Surgery, Nagoya Daini Red Cross Hospital, Japan; [2]Nephrology, Nagoya Univ School of Medicine, Japan.*

Background: Deterioration of kidney function and left ventricular hypertrophy (LVH) is crucial for kidney transplant recipients. Any marker for predicting kidney function and LVH is needed to prevent complications.

Methods: This was a retrospective cohort study. Forty-seven consecutive patients were enrolled in this study at Nagoya Daini Red Cross Hospital in 2011.

Table1. Study population characteristics (n=47)

	Value
Age, years	51.8±11.6
Gender (male), n	32
DMN, n	9
Systoric BP, mmHg	127.0±11.5
Diastoric BP, mmHg	77.5±7.7
Corrected Calcium, mg/dl	9.6±0.7
Phosphate, mg/dl	3.4±0.4
Intact parathyroid hormone, pg/ml	110.0±133.3
Triglyceride, mg/dl	122.5±65.6
Low Density Lipoproteon Cholesterol, mg/dl	96.0±17.3
Hb, g/dl	12.3±1.6
Urinary protein, g/day	0.12±0.25
Soluble α-Klotho, pg/ml	516.3 (412.8, 612.0)
Fibroblast growth factor 23, pg/ml	58.7 (47.6, 68.5)
25(OH)vitamin D, ng/ml	5.7 (4.2, 11.3)
eGFR(1y), ml/min/1.73m^2	43.0±12.8
eGFR(3y), ml/min/1.73m^2	43.2±14.3
LVMI at 1 year, g/m^2	105.2±27.1
LVMI at 3 year, g/m^2	100.2±24.2
Use of Cycrosporine / tacrolimus, n	27 / 20
Use of mycophenolate mofetil , n	45
Use of ARB, n	33
Use of statin, n	25

Serum intact fibroblast growth factor (FGF) 23, soluble α-Klotho(sαKlotho), 25(OH) Vitamin D[25(OH)D], estimated glomerular filtration (eGFR), left ventricular mass index (LVMI) and other clinical parameters after 1 year and eGFR after 3 years since kidney transplantation were measured to investigate the usefulness of these markers for predicting kidney function and LVH.

Results: The median serum sαKlotho, intact FGF23, 25(OH)D were 516.3 pg/ml, 58.7 pg/ml, and 5.7 ng/ml, respectively. Serum sαKlotho levels were associated with difference between eGFR after 1 year and after 3 years (DeGFR) (r = 0.37, p= 0.01), but not with difference between LVMI after 1 year and after 3 years (ΔLVMI). Patients were divided into two groups based on median serum FGF23 level. Higher serum intact FGF23 levels were associated with ΔLVMI. Serum 25(OH)D levels were associated with eGFR after 1 year (r = 0.34, p < 0.05), but not with DeGFR and ΔLVMI. Multivariate regression analysis revealed that serum sαKlotho was the strongest predictor of kidney function and serum intact FGF23 was that of LVMI.

Conclusions: Serum sαKlotho may be a good marker for kidney function and intact FGF23 for LVH in Japanese kidney transplant recipients.

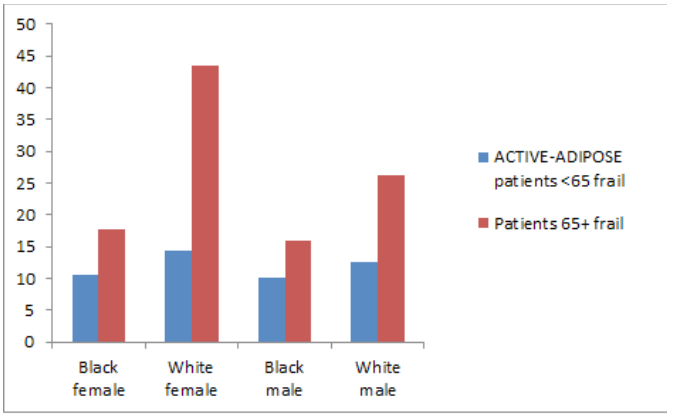
FR-PO1025

Lower Frailty Risk but Fewer Kidney Transplants in Blacks: USRDS Special Study Data Nancy G. Kutner, Rebecca H. Zhang, Janice P. Lea, Stephen O. Pastan, Rachel E. Patzer. *Emory Univ, Atlanta, GA.*

Background: Frailty, a measure of physiologic reserve, may indicate risk for adverse outcomes among kidney transplant (KT) recipients according to recent research. Non-frailty may therefore be a preferred characteristic of candidates for KT. Frailty status, age, race, and KT receipt were investigated during the 2009-13 USRDS study of a maintenance hemodialysis (MHD) cohort (ACTIVE-ADIPOSE study).

Methods: Frailty was assessed at study enrollment in 745 prevalent MHD patients (Atlanta and San Francisco areas; mean [SD] age = 57.1 [14.1]) using the Fried index (includes recent unintentional weight loss, reported exhaustion, low measured grip strength, slow measured walk speed, low reported physical activity; these indicators are both performance-based and patient-reported, and presence of 3+ criteria indicates frailty). Additional (1-2) frailty assessments were obtained annually for participants who remained on MHD post baseline. KT following most recent frailty assessment was monitored in the USRDS through February, 2013.

Results: % frail varied by age, gender, and race (Figure). 95% of the 40 KT recipients during the study period were non-frail; 82.5% were < 65 years old; 52% were men. Among all non-frail patients <65 (n=115 whites and 358 blacks) in the study cohort, 10.7% of whites and 3.1% of blacks received a KT. However, a multivariable regression analysis, with adjustment for a large number of demographic, treatment and clinical variables, showed that blacks had lower odds for frailty compared with whites (OR 0.58; 95% CI 0.34-0.99; p = 0.04).



Conclusions: Most study participants who received a KT were non-frail, but the proportion of black KT recipients was small despite blacks' lower observed risk for frailty compared with whites. Closer alignment of frailty status with support for KT access may have implications for reducing racial disparity in KT rates.

FR-PO1026

Circulating Inflammatory Cell Subsets Are Associated with Cardiac Function in Renal Transplant Recipients

Jill Neale,[1] Danielle Richler-Potts,[1] Maurice Dungey,[1] Patrick Highton,[1] N. Martin,[2] Nicolette C. Bishop,[2] Alice C. Smith.[1] *[1]Leicester Kidney Exercise Team, Univ of Leicester, United Kingdom; [2]School of Sport, Health and Exercise Sciences, Loughborough Univ, United Kingdom.*

Background: Cardiovascular (CV) disease is a major cause of mortality and morbidity in renal transplant recipients (RTRs). Systemic and vascular inflammation is paradoxically common despite immunosuppression and is an important non-traditional CV risk factor. Monocytes are heterogenous: the intermediate phenotype (CD14++CD16+) is particularly pro-atherogenic and pro-inflammatory compared to the classical phenotype (CD14++CD16-). Regulatory T-cells (TRegs) maintain peripheral tolerance and minimise tissue damage. This study aimed to explore the association of circulating inflammatory cell subsets with cardiac function in RTRs.

Methods: 18 stable RTRs (Mean age 55 years, 61% male) and 5 healthy controls participated. Blood monocytes and T cells were analysed by flow cytometry, and cardiac hemodynamic function measured by bioreactance (NICOM).

Results: Circulating pro/anti-inflammatory cell subsets differed significantly in RTRs and controls. Mean %[SEM] intermediate monocytes was higher in RTRs (7.2[0.8]) vs controls (3.2[0.5], p=0.01), while classical monocytes and TRegs were lower in RTRs (83.2[1.3] vs 89.1[1.6], p=0.03 and 2.8[0.2] vs 5.0[1.0], p=0.001 respectively). In RTRs, % intermediate monocytes was inversely correlated with stroke volume (SV: r=-0.48, p=0.05) and cardiac output (CO: r=-0.52, p=0.03) and positively correlated with total peripheral resistance (TPR: r=0.50. p=0.04), while the opposite was seen with % classical monocytes (SV r=0.56, p=0.02; CO r=0.62,p=0.006; TPR r=-0.54, p=0.02).

Conclusions: Our results reveal a significant bias towards pro-inflammatory circulating leucocyte subsets in RTRs (increased intermediate monocytes, reduced classical monocytes and TRegs), which likely promotes an atherogenic environment. Furthermore, the observed significant correlations between pro- and anti-inflammatory monocyte subsets and indices of cardiac function strongly support an important pathogenic role for these cell subsets, which represent a potential therapeutic target in this vulnerable population.

FR-PO1027

Iron Deficiency Is Associated with Mortality Independent of Anemia in Renal Transplant Recipients

Michele F. Eisenga,[1] Stefan P. Berger,[1] Jenny E. Kootstra-Ros,[2] Else van den Berg,[1] Gerjan Navis,[1] Peter Van der meer,[3] Stephan J.L. Bakker,[1] Carlo A. Gaillard.[1] *[1]Nephrology; [2]Clinical Chemistry; [3]Cardiology, UMCG.*

Background: Anemia and iron deficiency (ID) are highly prevalent in renal transplant patients (RTR). Anemia is associated with poor outcome, but the role of ID is unknown. Therefore, we aimed to investigate the association of ID, irrespective of anemia, with all-cause mortality in RTR.

Methods: In a previously defined cohort of RTR, with hemoglobin data available, we additionally assessed serum iron, transferrin and ferritin. ID was defined as transferrin saturation(TSAT)<20% and ferritin <300 ng/ml. Anemia was defined as Hb<13 g/dL (M) or <12 g/dL (F). Cox regression analyses were used to investigate prospective associations with all-cause mortality.

Results: We included 701 RTR (age 53±13 years; 57% males at 8.1±7.5 years after renal transplantation). Mean Hb was 8.2±1.1 mmol/L, serum iron 15.3±6.0 µmol/L, and ferritin 118 (55-222) µg/L. Prevalences of anemia, ID, and iron deficiency anemia (IDA) were 34%, 30%, and 13%, resp. During follow-up for 3.2±0.8 yr, 81 (12%) of RTR died. In univariable analysis, ID was associated with mortality (HR 2.04 [95%CI 1.31-3.16], p=0.001; fig. 1). Furthermore, both anemia (1.72 [1.11-2.66], p=0.02) and IDA (2.43 [1.48-4.00, p<0.001) were associated with mortality. After adjustment for age, gender, BMI, eGFR and anemia, the association of ID with mortality remained (1.82 [1.16-2.85], p=0.009). In contrast, the association of anemia with mortality disappeared after adjustment for eGFR and ID (1.15 [0.71-1.86, p=0.57), while the association of IDA remained after adjustment for eGFR (1.83 [1.10-3.05], p=0.02).

Conclusions: ID is highly prevalent among RTR and is associated with an increased risk of mortality, independent of anemia. Since iron deficiency is a modifiable factor, correction of iron deficiency could be a target to improve survival.

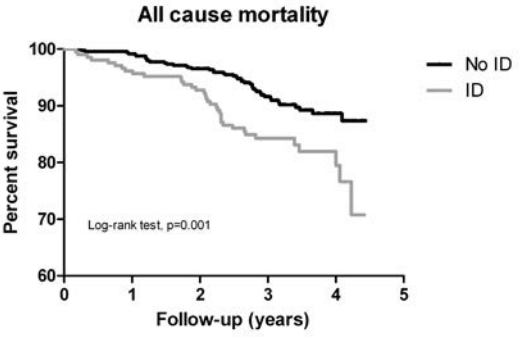

Figure 1: Survival curve for all-cause mortality based on the presence of ID

FR-PO1028

Indoleamine 2,3-Dioxygenase Activity and Late Graft Failure After Kidney Transplantation

Laura V. de Vries,[1] Claude P. Van der Ley,[2] Casper F.M. Franssen,[1] Gerjan Navis,[1] Stephan J.L. Bakker,[1] Ido Peter Kema.[2] *[1]Dept of Nephrology, UMCG, Netherlands; [2]Dept of Laboratory Medicine, UMCG, Netherlands.*

Background: Long-term graft survival after kidney transplantation remains a major clinical problem. Therefore, markers that allow for early identification of patients at risk for late graft failure (LGF) are urgently needed. Indoleamine 2,3-dioxygenase (IDO) catabolizes tryptophan along the kynurenine pathway. Recent studies found IDO activity associated with occurrence of acute rejection and renal function decline shortly post-transplant. We hypothesized that IDO activity could also be a marker for LGF after kidney transplantation.

Methods: We prospectively included outpatient renal transplant recipients (RTR) with a functioning graft >1 yr, between 2001-2003. Follow-up was recorded until May 2009. Death-censored GF was defined as return to dialysis or re-transplantation. Serum kynurenine (KYN) and tryptophan (TRP) were measured with LC-MS/MS; KYN/TRP is a widely accepted measure of IDO activity.

Results: We studied 562 RTR (age 51±12 yrs, 56% men, 6.0 [2.6-11.6] yrs post-transplant). Baseline concentration of serum KYN was 1.8 [1.4-2.2] µmol/l, that of TRP was 40.0 [34.5-46.0] µmol/l, and KYN/TRP was 44.3 [35.0-57.9] µmol/mmol. In multivariable linear regression analyses, KYN/TRP was positively associated with proteinuria (β=0.17, P<0.001) and waist circumference (β=0.12, P<0.001), and inversely with eGFR (β=-0.54, P<0.001) and HDL-c (β=-0.14, P<0.001). During follow-up for 6.9 [6.1-7.4] years, 51 (9.2%) RTR developed GF. In multivariable Cox-regression analyses, KYN/TRP was positively associated with GF (age, sex, eGFR, and proteinuria adjusted HR 3.6 [95% CI 1.3-9.9], P=0.01). Further adjustment for waist circumference and HDL-c did not materially change this association (HR 3.1 [95% CI 1.3-8.9], P=0.02).

Conclusions: IDO activity, as measured by KYN/TRP, is cross-sectionally associated with eGFR, proteinuria, waist circumference, and HDL-c. Prospectively, it is associated with increased risk for LGF after kidney transplantation. Increased IDO activity may not only be a marker for LGF, but also an interesting target for intervention to prevent decline of renal transplant function leading to LGF.

FR-PO1029

The Significance of Preoperative Left Ventricular Diastolic Dysfunction and Left Atrial Enlargement on Clinical Outcomes in Kidney Transplantation

Jin Ho Hwang,[1] Jung Nam An,[2] Jaeseok Yang,[3] Curie Ahn,[3] Chun Soo Lim,[2] Yon Su Kim,[4] Young hoon Kim,[5] Jung Pyo Lee.[2] *[1]Internal Medicine, Chung-Ang Univ Hospital, Seoul, Republic of Korea; [2]Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul, Republic of Korea; [3]Transplantation Center, Seoul National Univ Hospital, Seoul, Republic of Korea; [4]Internal Medicine, Seoul National Univ College of Medicine, Seoul, Republic of Korea; [5]Surgery, Asan Medical Center and Univ of Ulsan College of Medicine, Seoul, Republic of Korea.*

Background: In spite of improved survival of kidney transplant (KT) recipients, cardiovascular mortality is the leading cause of death following KT. Echocardiography is commonly performed as a screening test to evaluate cardiac function before KT. However, there are only limited data on echocardiographic parameters to evaluate the effect of left ventricular diastolic dysfunction (LVDD) and left atrial enlargement (LAE) on the long term outcome in KT recipients.

Methods: A total of 2,779 adult recipients who underwent pretransplant echocardiography from 1997 to 2012 were evaluated. We divided the patients into two groups by two different categories: LVDD grade 0-1 vs. 2-3, and LA size£38 mm vs. >38 mm. Post-KT fatal/non-fatal acute coronary syndrome (ACS), graft failure (GF), and all-cause mortality was evaluated.

Results: During a mean follow-up of 4.5 years, fatal/non-fatal ACS was occurred in 49 (1.8%) patients. A total of 231 (12.4%) patients experienced GF and 116 (6.2%) died. The recipients with LVDD grade 2-3 (P=0.005) and LAE (P=0.001) showed higher occurrence of fatal/non-fatal ACS after KT. Graft failure and all-cause mortality was not different between the groups depending on both the LVDD grades and LAE. In a multivariate analysis, increased age (P<0.001), previous history of CV event (P<0.001) and LVDD of grade 2-3 (hazard ratio[HR]:2.98, 95% confidence interval[CI]:1.535-5.787;P=0.001), and LAE (HR:1.052, 95% CI:1.006-1.101;P=0.025) were associated with ACS. However, none of LVDD and LAE was significantly associated with mortality and GF in a multivariate analysis.

Conclusions: In patients of KT candidate, pretransplant LVDD and LAE were independently associated with high occurrence of ACS after KT.

FR-PO1030

Effect of Dietary Sodium Restriction on Blood Pressure and Urinary Protein Excretion in Renal Transplant Recipients on RAAS-Blockade

Laura V. de Vries,[1] Linn Charlotte Dobrowolski,[2] C.T.P. (Paul) Krediet,[2] Frederike J. Bemelman,[2] Stephan J.L. Bakker,[1] Gerjan Navis.[1] *[1]Dept of Nephrology, UMCG, Netherlands; [2]Renal Transplant Unit, AMC, Netherlands.*

Background: In CKD patients on RAAS-blockade, it is well established that dietary sodium restriction exerts renoprotection by reduction of blood pressure (BP) and by reduction of urinary protein excretion (UPE), which is partly independent of BP. In renal transplant recipients (RTR), the effect of sodium restriction is not well-documented. We therefore studied the effects of dietary sodium restriction on BP and UPE in RTR.

Methods: We performed a randomized, cross-over trial in stable outpatient RTR with creatinine clearance >30 ml/min, BP >120/80 mmHg, UPE <1.5g/day, and use of RAAS-blockade. Exposures consisted of a 6-week regular sodium (RS) diet (target: 150 mmol/24h) and 6-week low sodium (LS) diet (target: 50 mmol/24h). End points were BP, UPE, urinary albumin excretion (UAE), and eGFR at the end of each diet period. Dietary compliance was assessed by 24h urinary sodium excretion.

Results: We randomized 23 RTR, of which 22 RTR (age 58±8 yrs, 50% men, eGFR 51±21 ml/min) completed the study. One patient dropped out, due to orthostatic complaints on the LS diet. Sodium intake was 156 [130-193] vs. 68 [55-86] mmol/24h on RS vs. LS diet resp. (P<0.0001). Sodium restriction significantly reduced systolic and diastolic BP. There was, however, no material change in UPE, UAE and eGFR.

	RS	LS	P-value
SBP (mmHg)	140±14	129±12	<0.0001
DBP (mmHg)	86±8	79±8	<0.0001
Serum creatinine (µmol/l)	123 [108-146]	125 [107-157]	0.3
eGFR (ml/min*1.73)	50±18	49±20	0.8
UPE (g/24h)	0.2 [0.0-0.3]	0.2 [0.0-0.3]	0.9
UAE (mg/24h)	29 [11-99]	22 [13-94]	0.3

Conclusions: Dietary sodium restriction effectively reduces BP in stable RTR on RAAS-blockade, but, at variance with findings in CKD, has no material effect on UPE or UAE, even with strict dietary compliance. This discrepancy might be due to relatively low UPE in the study population, or differences in pathogenesis of UPE/UAE or co-medication in RTR. Sodium restriction, therefore, is relevant to BP management in RTR on RAAS-blockade, but our data do not support independent renoprotective effects.

FR-PO1031

Individual Blood Calcification Propensity in a Cohort of Renal Transplanted Patients

Carlo M. Alfieri,[1] Andreas Pasch,[2] Anna Regalia,[1] Maria Meneghini,[1] Maria Teresa Gandolfo,[1] Valentina Binda,[1] Deborah Mattinzoli,[1] Masami Ikehata,[1] Piergiorgio Messa.[1] *[1]Nephrology, Dialysis and Renal Transplantation, Fondazione IRCCS Ca'Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Nephrology, Hypertension and Clinical Pharmacology, Univ Hospital and Univ of Bern, Bern, Switzerland.*

Background: Vascular calcifications and related cardiovascular disease have a strong impact in kidney transplantation(KTx).Calciprotein particle maturation time(T50) is a new measure of individual blood calcification propensity.Our aim is to explore in a cohort of KTx patients:1)the levels of T50 and their modifications during the 1st year of KTx;2)the relationship between T50 and routine clinical and biochemical parameters;3)the relationship between T50,bone mineral density(BMD)and aortic calcifications(ACI).

Methods: 70 KTx pts(M=38,Age:48±12 yrs),transplanted between 2005 and 2009 were recruited.Along with T50 evaluation,routine clinical and biochemical parameters and FGF-23,OPG, fetuin A and 25-(OH)-Vitamin D were tested at 1st,6th and 12thmth after KTx. At 1st and 12th mth, femoral Dual X-ray absorptiometry and vertebral column X-ray for BMD(g/cm^2) and ACI(Kauppila) evaluation were performed.T50(min.) was determined using a Nephelostar nephelometer(BMG Labtech, Offenburg, Germany) in the laboratory of one of the authors.

Results: T50 at 1st,6th and 12th mth were of 243[72–283],218[79-275] and 227[79-279] resp.,with a reduction of T50 at the 12thmth of KTx(p=0.04).In multivariate analysis,T50 was influenced by acid uric and fetuin-A(1st mth:p=0.02 and 0.001), by alkaline phosphatase,fetuin-A and 25-(OH)-Vitamin D (6th mth:p=0.01, p=0.001 and p=0.03 resp.), and by estimated glomerular filtration rate,body mass index and 25-(OH)-Vitamin D(12th mth:p=0.01, p=0.03 and 0.01 resp).Both at baseline and at 12thmth of Ktx a direct correlation between BMD and T50 was demonstrated (p=0.002-p=0.04 respectively).No correlation between T50 and ACI score was demonstrated.

Conclusions: The main results of our study are that 1)during the 1st year of KTx,T50 decreases significantly, and 2)has a strong and direct relation with Fetuin-A and 25OH vitamin-D,both implicated in bone-vascular axis;3)T50 is associated with BMD but not of ACI status.

FR-PO1032

Prediction of Acute Rejection in Kidney Transplant Recipients Using a Multicenter Cohort

Kyung Don Yoo,[1] Junhyug Noh,[2] Hajeong Lee,[1] Dong Ki Kim,[1] Chun Soo Lim,[1] Young hoon Kim,[3] Yon Su Kim,[1] Gunhee Kim,[2] Jung Pyo Lee.[1] *[1]Seoul National Univ College of Medicine; [2]Seoul National Univ College of Engineering; [3]Ulsan Univ College of Medicine.*

Background: More than 20% of kidney transplant recipients (KTR) are likely to have rejection episode, which is associated with graft loss. However, the impact of risk factors on acute rejection had not been well clarified. Here, we aimed to build new prediction models through considering variables related to immunologic and non-immunologic factors using machine learning methods.

Methods: This multicenter cohort study included adult KTR admitted to 2 major experienced tertiary hospitals in Korea between 1997 and 2014. A total of 3,117 KTRs were enrolled. Biopsy-proven acute rejection (BPAR) of these recipients were investigated by the individual learners such as decision tree, logistic regression, and ensemble learners such as random forest.

Results: We analyzed 2,045 recipients' records, with more than 50 attributes. Among them, we chose 21 independent attributes which could affect BPAR incidence for building our models. In the decision tree model for the prediction of BPAR after three years of KT, HLA DR mismatch was found to be the most important predictor. In the case of HLA DR mismatch, donor specific antibody (+) predicted in 66.6% of BPAR incidence at three year after transplantation, and also posttransplant infection episode showed significant association with BPAR. In the case of HLA full matched, old age with heavy weighted recipient showed high probability of BPAR (71.4%). The final modeling represent AUC performance 0.670 (logistic regression) and 0.665 (random forest) in the BPAR prediction.

Conclusions: In this study, machine learning modeling could present an accurate and versatile tool for forecasting probability of having BPAR episode during the early years following the transplant.

FR-PO1033

Prediction of Long-Term Prognosis of the Kidney Transplantation Using Comorbidity Score

Jae Yoon Park, Eunjin Bae, Sejoong Kim, Dong Ki Kim, Chun Soo Lim, Kwon Wook Joo, Yon Su Kim, Jung Pyo Lee. *Seoul National Univ College of Medicine, Seoul, Korea.*

Background: Comorbidity assessment is important to the informed interpretation of kidney allograft outcomes. Weights assigned to comorbidities to predict survival may vary based on the type of index disease and advances in the management of the comorbidities. We aimed to develop a modified Charlson comorbidity index (CCI) in renal allograft recipients (mCCI-KT), thereby improving risk stratification for mortality.

Methods: A total of 3,765 recipients in multicenter cohort were included to develop comorbidity score. The weights of comorbidities per the CCI were recalibrated using a Cox proportional hazards model. The modified score was validated in an independent nationwide cohort (n=1,538).

Results: The Cox proportional hazards model revealed that peripheral vascular disease, mild liver disease, and diabetes with end-organ damage in the CCI significantly predicted mortality. Thus, the mCCI-KT included 3 comorbidities with recalibrated severity weights. In the validation cohort, both the CCI and the mCCI-KT were correlated with mortality. The mCCI-KT showed modest increases in ***c*** statistics compared with the CCI (0.565 versus 0.534, P=0.002).

Conclusions: The mCCI-KT stratifies the risk better for mortality in renal allograft recipients compared with the CCI, suggesting that it could be a preferred index for use in clinical practice.

FR-PO1034

Patient Uncertainty Regarding Kidney Transplantation Associated with Length of Dialysis prior to Transplant Evaluation

Laura J. McPherson,[1] Mohua Basu,[1] Stephen O. Pastan,[1] Sumit Mohan,[2] Rachel E. Patzer.[1] *[1]Emory Univ, Atlanta, GA; [2]Columbia Univ, New York, NY.*

Background: End stage renal disease (ESRD) patients' uncertainty about undergoing kidney transplantation (KTx) ---i.e., decisional conflict---may be affected by cumulative time spent on dialysis prior to KTx evaluation. We aimed to investigate the association between time from dialysis start to KTx evaluation and decisional conflict.

Methods: In an ongoing clinical trial of study patients measuring the effectiveness of a shared decision tool at a single KTx center, ESRD patients were asked 10 questions assessing decisional conflict related to KTx, with possible scores ranging from 0 (none)

to 100 (high). Patients were dichotomized as having (score > 0) or not having (score of 0) decisional conflict. Time from dialysis start to KTx evaluation was abstracted from electronic medical records, and time on dialysis prior to evaluation was categorized as never on dialysis, <1 year, and >1 year. Logistic regression was used to assess odds ratios (ORs) for decisional conflict by time on dialysis prior to KTx evaluation.

Results: Of 70 surveyed patients, 64% were male, 62% were African American, and 66% had hypertension; the average age was 51 years. Patients with any decisional conflict (65%) were more likely to be male and African American in addition to having lower literacy and numeracy scores. Crude logistic regression showed that, compared to patients who had never been on dialysis prior to KTx evaluation, patients on dialysis for <1 year and >1 year evaluation were 1.4 (95% CI: 0.4, 4.9) and 2.5 (95% CI: 0.7, 9.2) times more likely to have decisional conflict, respectively.

Conclusions: Results suggest that longer time on dialysis prior to KTx evaluation may be associated with decisional conflict regarding KTx. Identifying characteristics of patients with longer time on dialysis prior to KTx evaluation could help inform intervention efforts to improve patients' abilities to make decisions about treatment of their kidney disease.

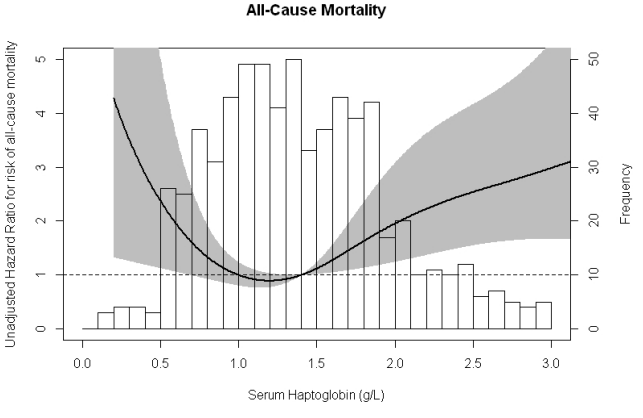
FR-PO1035

Haptoglobin and Long-Term Outcomes in Renal Transplant Recipients Isidor Minovic,[1] Ineke J. Riphagen,[1] Else van den Berg,[1] Jenny E. Kootstra-Ros,[2] Ido Peter Kema,[2] Andy P. Levy,[3] Johanna M. Geleijnse,[4] Gerjan Navis,[1] Stephan J.L. Bakker.[1] *[1]Nephrology, UMCG, Netherlands; [2]Laboratory Medicine, UMCG, Netherlands; [3]Medicine, Technion, Israel; [4]Human Nutrition, Wageningen Univ, Netherlands.*

Background: Haptoglobin (Hp) is a hepatocyte-derived protein that protects against oxidative damage by binding free hemoglobin (Hb). Being an acute-phase protein, Hp is upregulated by inflammation. We hypothesized that both low and high Hp are risk factors for all-cause mortality and graft failure in renal transplant recipients (RTR).

Methods: Hp was measured using a turbidimetric immunoassay in a well-characterized prospective RTR cohort. Cox regression analysis was used to assess the association of Hp with endpoints.

Results: We included 707 RTR (57% male, age 53±13 y, eGFR 49±18 ml/min/1.73m^2 and 58% used a calcineurin inhibitor). Median Hp was 1.4 [IQR 1.0-1.8] g/L. Hp phenotype 1-1, 1-2, and 2-2 distribution was 18%, 50%, and 33% resp., with Hp levels of 1.7 [1.3-2.1], 1.4 [1.1-1.8] and 1.1 [0.9-1.7] g/L resp. (P<0.001). After median 38 [32-46] mnths follow-up, 81 (12%) RTR died and 45 (6%) developed graft failure. Hp showed a U-shaped association with mortality (P=0.01, fig. 1), but not with graft failure (P=0.7). Accordingly, the lowest (<0.9 g/L) and highest (>1.6 g/L) quintile of Hp levels were associated with mortality (HR 2.65 [95% CI 1.11-6.35] and 3.30 [1.41-7.72], resp.). Adjustment for sex, age, hsCRP, serum albumin, eGFR, BMI, HbA1c, LDH and Hp polymorphism did not materially influence the association of low Hp with mortality (HR 3.55 [1.42-8.84]). However, adjustment for hsCRP and serum albumin markedly weakened the association of high Hp with mortality (HR 2.06 [0.84-5.08]).



Conclusions: Low Hp is independently associated with mortality, but not graft failure, in RTR. High Hp was also associated with mortality, but this association largely depended on hsCRP and serum albumin.

FR-PO1036

Pre-Transplantation Flow-Citometry Crossmatch Can Be a Predictor of Outcome when Donor-Specific Antibodies Are Present Anna Rita Aguirre, Patricia Soares Souza, Gislene Oliveira Bezerra, Flavio Jota Paula, Elias David-Neto, Maria cristina R. Castro. *Renal Transplant Service, Hospital das Clinicas - Univ of Sao Paulo School of Medicine, Sao Paulo, Brazil.*

Background: Clinical relevance of pre-transplant (Tx) donor-specific-antibodies (DSA) detected by single antigen beads (SAB) when pre-Tx CDC-AHG crossmatch (XM) is negative is still unclear. The aim of this study was to evaluate the importance of a positive flow-citometry-XM (FCXM) in patients with DSA over patient and graft survival.

Methods: Retrospective study, performed between Jan09 and Dec13 evaluating FCXM influence over antibody-mediated rejection (AMBR) incidence, and over graft and patient survival. Biopsies were classified according to Banff'09 criteria and DSA by Luminex SAB.

Results: From 2009-2013, 1002 kidney transplants (Tx) were performed in our center. 261(26%) were sensitized (PRA>0%) and 87 (8.7%) presented pre-Tx DSA. 60 (69%) of them had FCXM performed with serum collected before transplantation: 22 (36%) positive and 38 (64%) negative. There was no difference between the highest DSA-MFI between Tx with positive or negative FCXM [FCXM+ 5080 (1046-13560) vs FCXM– 3120 (597-14600)], or between the sums of all DSA-MFI of each patient between these groups [FCXM+ 6589 (1046-13560) vs FCXM– 3247 (597-15669); P 0,05]. DSA+/FCXM+ Tx had a significantly higher incidence of ABMR than DSA+/FCXM- Tx [FCXM+ 12 (54.5%); FCXM– 9 (23.7%); p 0.024]. After a median follow-up time of 34 mo, graft survival (GS) between Tx with positive and negative FCXM differed significantly (41% vs 92%; p < 0.0001). Among FCXM+ patients, GS was not influenced by ABMR (p=0,256). However, among patients with ABMR, FCXM+ had worse graft survival then FCXM- (FCXM+ 25% vs FCXM– 90%; p 0.011). Patient survival did not differ between FCXM+ (82%) and FCXM- (95%) neither was affected by ABMR.

Conclusions: A positive pre-Tx FCXM is related to a higher incidence of ABMR in the first year after Tx and to worse graft survival, and did not influence patient survival.

FR-PO1037

Pre-Transplant Mental Health Disorders and Non-Adherence and Post-Transplant Outcomes in Kidney Transplant Recipients Istvan Mucsi, Franz-Marie Gumabay, Marta Novak, Joseph Kim, Olusegun Famure. *Multi-Organ Transplant Program, Univ Health Network and Univ of Toronto, Toronto, ON, Canada.*

Background: Mental health disorders (MH) and non-adherence (NA) have been associated with lower access to kidney transplantation (KT) and poorer clinical outcomes. We examined the relationship between history of MH problems, NA, and post-transplant outcomes (i.e., biopsy proven acute rejection: BPAR; death censored graft failure: DCGF; or total graft failure: TGF).

Methods: This was a single-centre retrospective cohort study of adult patients transplanted at our KT program from July 1, 2004 and Dec 31, 2012, and followed up until June 30, 2014. Patients with complete information about pre-transplant MH problems or pre-transplant history of NA in their medical record (n=955) were included. Univariable and multivariable associations between MH, NA and time to event (for BPAR, TGF and DCGF) were explored using log rank analysis and Cox proportional hazards models.

Results: The mean (±SD) age was 50.5 (±13.4) years, 61% of patients were male and 27% had a history of diabetes. Twenty-two percent had a positive history of MH disorders and 11% had a history of NA. Fifteen percent of the patients had BPAR, 5.6% had DCGF and 13% had TGF (death or DCGF). Participants with a history of pre-transplant NA but not with history of MH had higher risk for BPAR (log rank test p = 0.049 and p=0.46 for NA and MH, respectively). This difference, however, was not significant after adjusting for socio-demographic characteristics, donor type and HLA mismatch: adjusted HR (95% CI) 1.36 (0.84-2.23) and 1.16 (0.77-1.75) for Na and MH, respectively. Neither the history of pre-transplant MH nor pre-transplant NA was associated with DCGF or TGF. These results remained qualitatively unchanged after multivariable adjustment : adjusted HR (95% CI) 1.81 (0.96-3.42) and 0.99 (0.58-1.70) for Na and MH, respectively.

Conclusions: A history of pre-transplant mental health disorders or non-adherence are not associated with poor post-transplant outcome in a select group of patients who are cleared for transplantation. Patients with such problems should have equal access to kidney transplantation compared to patients with no MH problems.

FR-PO1038

HLA Profile and Short and Long Term Outcomes in African American Donors and Recipients Rabi Yacoub, Girish N. Nadkarni, John C. He, Paolo Cravedi, Rebecca L. Kent, Ioannis Konstantinidis, Karen Lok yee Keung, Sander Florman, Peter S. Heeger, Barbara T. Murphy, Madhav C. Menon. *Mount Sinai, NY.*

Background: We have previously reported the apparent greater impact of HLA-matching over HLA-mismatching on both early allograft events as well as graft survival in the United Network for Organ Sharing database (UNOS). Here, we specifically studied the influence of HLA-matching and mismatching on allograft outcomes among African-American (AA) recipients and AA-donor organs in deceased donor kidney transplantation (DDKT).

Methods: We utilized data from the UNOS database (1995 – 2012), and analyzed 10 year death censored graft survival (DCGS), 1 year clinical acute rejection (1y-AR), and delayed graft function (DGF) using Cox-regression and logistic regression in a combined multivariable model including HLA-matching and mismatching adjusted for key covariates. We performed sensitivity analysis using a subgroup of DDKT patients after 2003 with less heterogeneous HLA nomenclature, and resampling analysis using bootstrapping.

Results: We had complete data (outcomes and predictors) for 96236 recipients (Age 49.23±15.13, 60.4% male). AA-recipients constituted 30.2% while AA-donor organs were utilized 13.1% of DDKT (n=29071&12575, respectively). Similar to the whole UNOS cohort, among AA-recipients both HLA-matching and –mismatching individually had significant stepwise association with all outcomes (10-yr DCGS, 1y-AR & DGF). However, distinct from the whole cohort, we identified that when added in a combined model along with other covariates and adjusted for each other, HLA-matching and -mismatching had equal effects on each of the three examined outcomes. Among AA-donors, neither HLA-

matching, nor –mismatching had any effect on the three examined outcomes in either individual or combined multivariable models. Sensitivity analysis in the 2003-2012 cohort showed similar results.

Conclusions: Our analysis in this large cohort reports for the first time the absence of any effect from HLA-matching or –mismatching on allograft outcomes among AA-donor kidneys. These findings suggest that the allocation algorithm for AA-donor organs may need to be re-evaluated without including HLA-match status.

FR-PO1039

Femoral Bone Mineral Density Is Related with Aortic but Not with Coronary Calcifications in KTx Patients Carlo M. Alfieri, Anna Regalia, Maria Meneghini, Maria Teresa Gandolfo, Valentina Binda, Masami Ikehata, Deborah Mattinzoli, Piergiorgio Messa. *Nephrology, Dialysis and Renal Transplantation, Ospedale Maggiore Policlinico, Milan, Italy.*

Background: Our study wants to evaluate in a cohort of kidney transplanted(KTx) patients,undergone to femoral DEXA:1)the prevalence of bone mineral anomalies;2)the factors related to femoral bone mineral density(f-BMD) 3)the relationship of f-BMD with aortic calcifications(ACI) and coronary calcifications(CAC).Lumbar DEXA was not considered to avoid confounders between abdominal vascular calcifications(VC)and BMD.

Methods: 293pts(M=170) transplanted in our Unit(2004-2013) were evaluated.Clinical and routine biochemical exams(plus PTH,FGF-23,Fetuin and VitD) were tested at 1(T0) and 12(T1)mths of KTx.At the same time,DEXA,lumbar X-Ray(193pts) and coronary tomography(86pts) for f-BMD(g/cm^2),ACI(Kauppila) and CAC(Agatson) evaluations were performed.ACI increase(ACI-Prog):any increase in ACI.Presence of CAC(CAC+):Agatson score >400,CAC increase(CAC-Prog):assessed using Sevrukov formula.

Results: At T0 and T1,OPN in 53%and 52%,OPR in 15% and 12% of pts resp.F-BMD was associated with:age,alkaline phosphatase(ALP) (at T0 and T1), fetuin and P (at T0).A logistic regression with BAbn(OPN+OPR as a whole)as dependent variable confirmed age and ALP as the only independent associated variables(T0 and T1).ACI were found in 55% and 61% of pts(T0-T1).ACI were higher in BAbn(T0 and T1).ACI-Prog(26%) had lower f-BMD(T0 and T1);F-BMD showed a discriminatory role in ACI-Prog(ROC-Curve, T0:AUC 0.66,p=0.02;T1:AUC=0.70,p=0.005).CAC+was found in 13%,20% and 28%pts at T0,T1 and T2.CAC-Prog was found in 13% at T1 and in 49% of pts at T2.F-BMD did't correlated with CAC at T0,T1,T2, and both at T1 and at T2 its levels weren't different between CAC-Prog and CACnot-Prog.

Conclusions: High prevalence of BAbn and VC from the beginning of KTx is present. Age and ALP are strongly associated with f-BMD;2)ACI and CAC progress in a high %of patients, in the early post-KTx period;3)However,though f-BMD was significantly related with ACI-Prog,no association was observed with CAC worsening,possibly suggesting that different mechanism(s) might underlie VC processes at different sites.

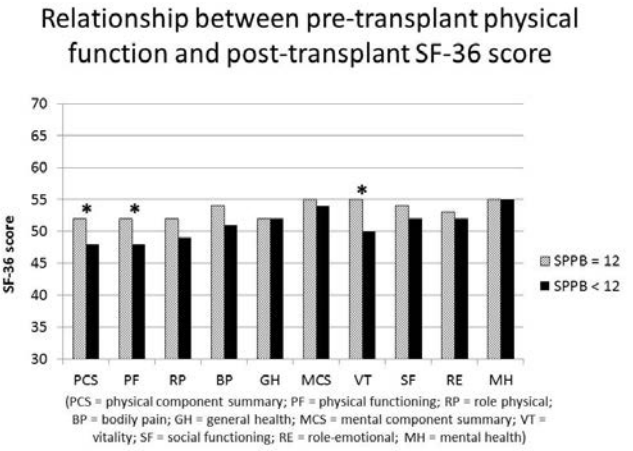
FR-PO1040

Relationship Between Pre-Transplant Physical Function and Quality of Life following Kidney Transplant Elizabeth C. Lorenz, Andrea L. Cheville, Walter K. Kremers, Fernando G. Cosio, Nathan Lebrasseur. *Mayo Clinic, Rochester, MN.*

Background: Decreased physical function predicts adverse outcomes following non-transplant surgery. The goal of this study was to assess whether pre-transplant physical function predicts impaired quality of life (QOL) following kidney transplant.

Methods: We conducted a prospective cohort study involving all recipients of living donor kidney transplants at our center from 2012 until 2014. Physical function was measured using the Short Physical Performance Battery (SPPB), a composite measure of gait speed, balance and chair rise time (score range 0-12, with higher score indicating better physical function). QOL was measured 12-months post-transplant using the Short Form 36 Health Survey (SF36) with standardized scores adjusted for age and gender. Below-average physical and mental QOL was defined as physical (PCS) and mental component summary scores (MCS) < 45, respectively.

Results: Among the cohort of 140 patients, mean age was 51 ± 15 years, 61% were male, 91% were Caucasian, 21% had diabetes and 26% had a pre-transplant SPPB score < 12. A pre-transplant SPPB score < 12 was associated with a significantly lower 12-month PCS score (48.1 ± 9.0 vs 51.6 ± 8.5, p=0.04) but not a lower MCS score (54.2 ± 9.4 vs 55.2 ± 8.4, p=0.90) .



Below-average physical QOL at 12-months was observed in 23% of patients and was associated with pre-transplant BMI (OR 1.12 per 1 kg/m^2 increase, CI 1.02-1.23, p=0.02) and a pre-transplant SPPB score < 12 (OR 3.05, CI 1.17-7.97, p=0.02). In contrast, pre-transplant dialysis, diabetes, maintenance steroids and 12-month eGFR were not associated with physical QOL.

Conclusions: Decreased pre-transplant physical function predicts impaired physical QOL one year after kidney transplant. Further studies are needed to determine whether physical rehabilitation interventions can improve post-transplant QOL.

FR-PO1041

1st Report of Korean Organ Transplantation Registry (KOTRY) Tai Yeon Koo,[1] Hye Jin Lim,[1] Kyungok Min,[1] Hyunjin Ryu,[1] Jong Cheol Jeong,[2] Jaeseok Yang,[1] Myoung Soo Kim,[3] Jae-Joong Kim,[4] Curie Ahn,[1] Kotry Study Group.[5] *[1]Transplantation Center, Seoul National Univ Hospital; [2]Dept of Nephrology, Ajou Univ School of Medicine; [3]Dept of Surgery, Yonsei Univ College of Medicine; [4]Devision of Cardiology, Asan Medical Center; [5]Korean Organ Transplantation Registry, Republic of Korea.*

Background: The Korean Organ Transplantation Registry (KOTRY) were launched in 2014 to construct the nationwide transplant database system which encompasses outcomes of various transplanted organs by support of the Korea Centers for Disease Control and Prevention.

Methods: In 2014, kidney, liver and heart transplant cohorts were established with participation of 29/58 centers for kidney, 13/35 centers for liver, and 4/8 centers for heart, covering more than 80% of total cases. Lung and pancreas transplant cohorts are also in progress since 2015. A web-based database system and attached biobank system have been developed. Annual data report and related information of database development process are available at http://www.kotry.org. From July 2014 to December 2014, 419 transplants in kidney transplantation (KT), 430 in liver transplantation, and 77 in heart transplantation were registered.

Results: Among 419 KT, deceased donor (DD) was performed in 156 patients (37.2%). Mean age was 47.7±11.2 and 56.8% of transplants were males. Diabetic recipients were 23.2%, and 5.5% of transplants were older than 65 years. Their original kidney disease was most often chronic glomerulonephritis (39.6%), followed by diabetic nephropathy (18.6%). Preemptive KT was 29.3% among living donor KT. The high panel-reactive antibody (>50%) accounted for 9.8% of transplants. Positive results of T or B flow cytometric crossmath were found in 1.9% and 4.5% of transplants, respectively. ABO incompatible KT was performed in 21.7% of living donor KT. Mean age of donors was 45.3±13.2 and 59.9% were males. Among DD, expanded-criteria donor was 23.7%. Mean serum creatinine of living donor before and after KT were 0.81±0.18mg/dl, and 1.16±0.27mg/dl, respectively.

Conclusions: The KOTRY is expected to provide infrastructures for research in the field of KT and invaluable data for the Asian organ transplantation field.

FR-PO1042

Pre-Transplant Midodrine Use: A Newly Identified Risk Marker for Complications After Kidney Transplantation Tarek Alhamad,[1] Daniel C. Brennan,[1] Zaid Brifkani,[1] Mark Schnitzler,[2] Vikas R. Dharnidharka,[1] Krista L. Lentine.[2] *[1]Washington Univ; [2]St. Louis Univ.*

Background: Midodrine is increasingly prescribed to decrease the severity and complications of hypotension in dialysis patients. The impacts of midodrine use before kidney transplantation on graft and patient outcomes early after transplantation are not well described.

Methods: We analyzed linked national U.S. transplant registry, pharmacy records and Medicare claims data to follow 16,322 kidney transplant recipients (2005-2008), of whom 308 (1.9%) had filled midodrine prescriptions in the year prior to transplantation. We examined associations of midodrine use with DGF, graft survival and death as reported to the registry, and with clinical complications captured in Medicare claims.

Results: At 3mo, patients who used midodrine before transplant had higher rates of DGF, 32% vs. 19%; hypotension, 14% vs. 4%; acute myocardial infarction (AMI), 4% vs. 2%; cardiac arrest, 2% vs. 0.9%, graft failure, 5% vs. 2%; and death, 4% vs. 1% than the non-users (P<0.05). After multivariate adjustment including recipient, and donor factors, as well as for the propensity of midodrine exposure, pretransplant midodrine use was independently associated with risks of DGF (aOR 1.95; CI 1.49-2.56), death-censored graft failure (aHR 1.94; CI 1.14-3.27), death (aHR 3.55; CI 1.99-6.33), as well as many potentially mediating complications. Patterns were similar at 12mo.

FIGURE 1A: INCIDENCE OF COMPLICATIONS AT 3-MO & 12-MO POST-TRANSPLANT, ACCORDING TO PRE-TRANSPLANT MIDODRINE USE

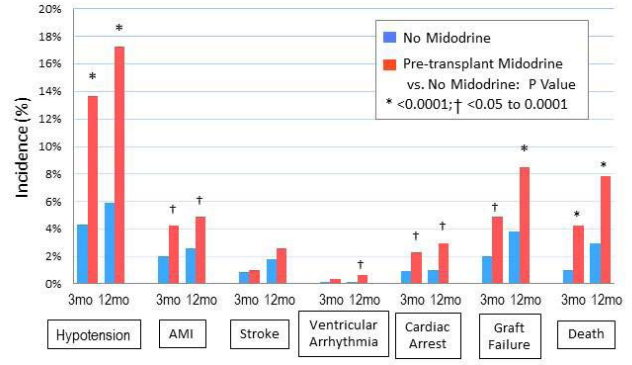

FIGURE 1B: ADJUSTED ASSOCATIONS OF PRE-TRANSPLANT MIDODRINE USE WITH POST-TRANSPLANT COMPLICATIONS

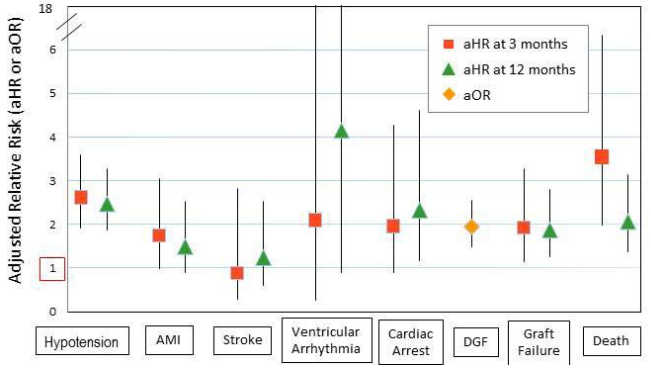

Conclusions: Although associations may in part reflect underlying conditions, the need for midodrine before kidney transplantation is a bio-marker for increased risks of complications including graft failure and death. As the new KAS is expected to increase ESRD duration at the time of allocation for many patients, monitoring recipient comorbidity burden through novel methods including pharmacy claims, and associated impacts on transplant outcomes, are important priorities.

Funding: NIDDK Support

FR-PO1043

Impact of Proton Pomp Inhibitors on Hypomagnesemia and Arterial Stiffness in Renal Transplant Recipients

Siren Sezer,[1] Bahar Gurlekdemirci,[1] Saliha Uyanik,[2] Mehtap Erkmen Uyar,[1] Mehmet Haberal.[3] *[1]Dept of Nephrology, Baskent Univ Faculty of Medicine, Ankara, Turkey; [2]Dept of Internal Medicine, Baskent Univ Faculty of Medicine, Turkey; [3]Dept of General Surgery, Baskent Univ Faculty of Medicine, Turkey.*

Background: Hypomagnesemia predicts cardiovascular morbidity and mortality in the general population and accelerated loss of kidney function in renal transplant recipients (RTRs). Proton pomp inhibitors (PPIs) or H_2 receptor blockers (H_2RBs) are frequently used agents after RT. The aim of this study was to evaluate the effects of PPIs on serum magnesium levels and arterial stiffness in RTRs.

Methods: We performed a retrospective study of 354 maintenance RTRs (mean age: 38.6 ± 10.7 years) with stable allograft function who had received their transplant at least 36 months previously. All acute cellular and humoral rejections were excluded. According to using stomach-protecting agents (SPAs), patients were divided in to three groups: PPIs (Group 1, n: 164), H2RBs (Group 2, n: 96) and control group who don't receive SPAs (Group 3, n: 94). Estimated glomerular filtration rate (eGFR) was calculated by using the MDRD4 equation. Pulse wave velocity (PWv) was determined from pressure tracing over carotid and femoral arteries using the SphygmoCor system.

Results: Groups were similar in means of demographic characteristics and eGFR levels. Mean serum magnesium levels were significantly lower in group 1, however similar in group 2 and 3 (1.5 ± 0.04 mg/dl, 1.7 ± 0.02 mg/dl and 1.7 ± 0.01 mgdl, respectively). PWv values were significantly higher in group 1, whereas similar in group 2 and 3 (7.3 ± 0.2 cm/sec, 6.3 ± 0.1cm/sec and 6.2 ± 0.1 cm/sec, retrospectively). In linear regression analysis; type of SPAs (p: 0.001), serum calcium (p: 0.031), magnesium (p: 0.07) and folic acid levels (p: 0.013) were detected as the predictors of PWv.

Conclusions: We concluded that PPIs inhibit magnesium absorbtion independent from calcium metabolism in RTRs. Moreover, PPIs leads to increased arterial stiffness and cardiovascular risk in RTRs. Thus physicians should be aware of the side effects of PPIs to scale down the cardiovascular morbidity and mortality.

FR-PO1044

Comorbidity Burden of Kidney Transplant Recipients Predicts Emergency Usage Despite increased Family Physician Visits

Hatem A. Alnasser,[1] Sita Gourishankar,[1] Kevin C. Wen.[1] *[1]Univ of Alberta, Canada; [2]King Fahad Specialist Hospital, Saudi Arabia.*

Background: Kidney transplant(KTX) recipients utilize many aspects of the healthcare system, especially emergency(ER) visits. Unterman et al showed that within a four year period, 378 KTX recipients generated 828 ER visits1. This study aims to understand factors leading to ER usage by KTX recipients.

Methods: This is a single center retrospective study in conjunction with patient questionnaire, collected from March 2012 - 2013. The questionnaire inquired the frequency of the family physician(GP) visits and ER usage within the past year. Patient demographics and comorbidities were collected from chart reviews. Univariate logistic regression was used to define factors that are predictive of ER usage. Significant covariates were then used in multivariate backward stepwise logistic regression model to predict ER visits.

Results: Number of GP visits(OR = 1.6, p=0.003), diabetes(OR = 1.7, p=0.016), coronary artery disease(OR = 2.5, p=0.001), below knee amputation(OR = 4.3, p=0.037), and number of comorbidities(OR = 1.35, p=0.001) significantly predict ER visits. Number of transplant clinic visits does not significantly decreased ER visits(p=0.32). By multivariate backward stepwise logistic regression, number of GP visits(OR = 1.5, p=0.007) and coronary artery disease(OR = 2.1, p=0.011) remain significantly predictive of ER usage.

Conclusions: This single center study showed that KTX recipients with more comorbidities have increased ER usage, particularly coronary artery disease, despite higher frequency of GP visits. However, kidney transplant recipients with more ER usage are not seen more frequently by our transplant clinic. The results suggest that KTX recipients with higher comorbidity burden may need to be followed more closely by transplant clinics, rather than relying on GP's, to improve effective usage of ER visits.

Stroke Predictors and Outcome in Renal Transplant Recipients

Mark Duncan Findlay,[1,2] Peter C. Thomson,[2] Patrick B. Mark.[1,2] *[1]Univ of Glasgow, Glasgow, United Kingdom; [2]Glasgow Renal and Transplant Unit, Glasgow, United Kingdom.*

Background: End-Stage renal disease is associated with a high incidence of cerebrovascular disease. Conventional risk factors do not always apply & established preventive strategies may be ineffective. The incidence, predictors & outcomes following stroke in those with a functioning renal transplant is not well described.

Methods: All adult patients with a renal transplant attending Glasgow Renal and Transplant Unit between 1st Jan 2007 and 31st Dec 2012 were identified using the electronic patient record. Clinical, demographic & laboratory data were collected including presence of diabetes, cardio- or cerebrovascular disease (CeVD), atrial fibrillation, deprivation, serum renal and bone chemistry and use of immune suppressants. Stroke was identified via discharge codes, cerebral imaging or death certification. Independent predictors of stroke were identified via multivariable regression analysis. Fatality & causes of death are presented.

Results: 636 patients were identified, mean age 38 years (SD 12.9). 60.5% were male and 9.1% had AF. During follow-up 7.1% received a transplant as first RRT modality. 24 patients experienced a stroke during 3455 patient years of follow-up. 83.3% were ischemic. Stroke incidence was 6.9/1000 patient years for all stroke and 3.76/1000 patient years for first stroke. A stepwise backward regression revealed predictors of stroke as older age (HR 1.05, p=0.025) and previous CeVD (HR 18.16, p<0.001). Significant independent predictors for first stroke were age, diabetes and AF (p<0.05). There were no cases of SAH in PCKD. AF associated with time to stroke (p=0.003), but there was no detectable benefit from use of warfarin. 134 died during follow-up. 62.5% deaths followed stroke with 7, 28 and 365 day fatality of 20.8, 25 and 45.8%. Cardiovascular (75%) or malignancy (13%) were the cause of death in most cases.

Conclusions: Renal transplant recipients have a high incidence of stroke and poor outcome following stroke. Risk factors include prior CeVD, age, diabetes and AF. Although AF associated with time to stroke, the role of warfarin in prevention is poorly defined, requiring further study.

Factors Influencing Racial Disparities in Renal Transplantation Outcomes
Sumit Mohan,[1] Barry I. Freedman,[2] William Mark Brown,[2] Stephen O. Pastan,[3] Ajay K. Israni,[4] David P. Schladt,[5] Robert S. Gaston,[6] R. Bray,[3] Amber M. Reeves-Daniel,[2] Bruce A. Julian,[6] Jasmin Divers.[2] *[1]Columbia Univ; [2]Wake Forest School of Medicine; [3]Emory Univ; [4]Univ of Minnesota; [5]Minneapolis Medical Research Foundation; [6]Univ of Alabama at Birmingham.*

Background: Kidney transplants from African American (AA) deceased donors have worse outcomes than kidneys procured from donors of other ethnic groups; deceased-donor kidney transplants (DDKTs) engrafted into AAs fare worse than kidneys placed into recipients of other ethnic groups. The role of biological and environmental factors in these disparities remains unclear. We sought to identify factors contributing to these ethnic differences in AA and European American (EA) recipients of kidneys from AA and EA donors in a study using donor-matched design to eliminate donor-specific confounding effects.

Methods: We compared allograft survival of DDKTs in 4 types of donor/recipient pairs (TDRP) (AA/AA, AA/EA, EA/AA and EA/EA). Models were fitted using a mixed effect Cox model with particular focus on effect modifiers of the TDRP association with allograft survival.

Results: We identified 669 AA and 3,383 EA donors resulting in 669 AA/AA, 669 AA/EA 3,383 EA/AA and 3,383 EA/EA DDKTs. In agreement with previously reported trends, AA donors were more likely to be younger, male, hypertensive, and with higher serum creatinine, while EA recipients were more likely to be employed (46 and 45% vs. 37 and 33%) and less likely to experience delayed allograft function (DGF) (19 and 18% vs. 28 and 23%). Adjusted analyses controlling for donor and recipient characteristics identified strong interaction effects between the TDRP and incidence of DGF (P=0.009) and between the TDRP and employment status (P=0.04). Observed hazard ratios varied from 0.9 for an employed (EA/EA) pair without DGF to 4.3 for an unemployed (AA/AA) pair with DGF.

Conclusions: Ethnic differences in employment status and incidence of DGF were the strongest effect modifiers of the association between the TDRP and allograft survival for DDKTs. These differences partially explain the observed racial disparity in outcomes for DDKTs.

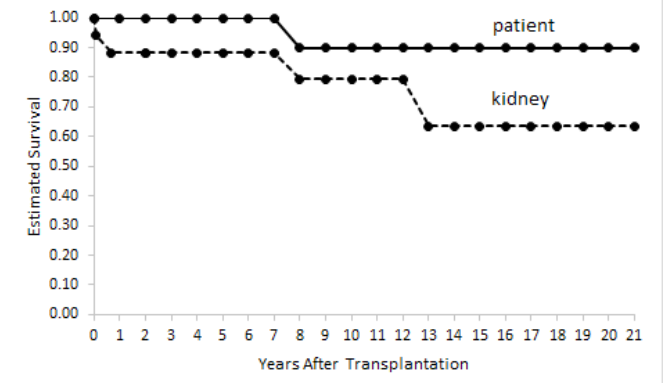
Renal Transplantation in Bardet-Biedl Syndrome
Robert M. Haws,[1] Aditya Joshi,[1] Siddharth A. Shah,[3] Omar M.A.A. Alkandari,[4] Martin A. Turman.[2] *[1]Dept of Pediatrics, Marshfield Clinic, Marshfield, WI; [2]Dept of Pediatrics, Univ of Oklahoma Health Sciences Center, Oklahoma City, OK; [3]Dept of Pediatric Nephrology, Univ of Louisville, Louisville, KY; [4]Dept of Pediatrics, Mubarak Al-Kabeer Hospital & Hamid Al-Essa Transplant Center, Safat, Kuwait.*

Background: Bardet-Biedl syndrome (BBS) is a rare, multisystemic genetic disorder frequently associated with chronic kidney disease (CKD). Data regarding renal transplantation (RT) in BBS is lacking and reports tend to highlight complications. We report RT outcomes in the largest BBS cohort examined to date.

Methods: An international BBS registry was interrogated to identify individuals that had undergone RT and capture age, gender, body mass index (BMI), transplant and patient survival, donor source, and comorbidities.

Results: RT was performed in 19/171 (11%) registry subjects (mean age 9 y; range 2-25 y). RT patients were younger (9 vs. 17.9 y, p <0.05) and more likely to be female (82% vs. 50%). Deceased donors provided 12/21 kidneys; one patient received a combined liver/renal transplant. Two patients that underwent RT in the 1980s and died at <10 y of age were excluded from further analysis. Patient and kidney survival is shown.



Thrombosis and infection resulted in graft loss in the first year in 1 patient with 2 kidneys. One patient died awaiting a second RT. Acute reversible rejection in the first year occurred in 1/17 kidneys. Diabetes, hypertension, and obesity were present in 18%, 71%, and 88% of subjects, respectively. Malignancy was not observed (mean follow-up 9.8 y; range 1-21 y). BMI was increased compared to age-matched BBS patients without RT (42.2 vs. 35.2, p < 0.05).

Conclusions: Outcomes following RT in patients with BBS is favorable. Female predominance raises questions regarding gender as a potential modifying factor impacting CKD prevalence.

FR-PO1048

Kidney Transplant Recipient Hospital Readmission: Examination of Discharge-Level Factors
Michelle L. Lubetzky, Maria Ajaimy, Layla Kamal, Graciela De Boccardo, Enver Akalin. *Transplantation, Montefiore, Bronx, NY.*

Background: Early rehospitalization after kidney transplantation (KTx) is common and is considered a quality metric. Few studies have examined preventability or discharge factors associated with early rehospitalization.

Methods: We performed a single-center, retrospective cohort study between 2011-2015 of adult KTx recipients. The primary outcome was at least one readmission within 30 days after discharge. Secondary outcomes were reason for readmission, potential for process improvement to reduce readmission, and all-cause graft failure.

Results: Of 462 KTx, 31.4% were readmitted within 30 days of discharge. The reason for readmission was surgical in 20.1%. Of those with non-surgical reasons, 21.7% were from infection, 20.9% graft dysfunction, 21.7% gastrointestinal, 21.7% metabolic, and 13.9% other. Readmission was significantly associated with all-cause graft failure (p=0.006). The assessment of preventability showed that the reason for readmission was present at the time of discharge in 11.7%, additional hospital resources may have abrogated the readmission in 15.8%, and 12.4 % could have been managed as outpatient. On univariate analysis, risk factors for rehospitalization were: presence of comorbidities (p=0.03), complication during hospitalization (p<0.001), discharge electrolyte abnormalities (p<0.001) and kidney function at discharge (p=0.003), Table 1. On multivariate analysis, the presence of 3 comorbidities pre-KTx (aOR 2.01 95% CI 1.84-3.86), electrolyte abnormalities at discharge (aOR 1.77 CI 1.17-2.69), delayed graft function (aOR 1.65 95% CI 1-2.7), and post KTx complication (aOR 1.7 95%CI 1.1-2.61) were associated with increased risk of readmission

Table 1: Comparison of Patients Requiring Readmission versus No Readmission

Characteristic N(%) or mean +/- SD	Readmission No N=317	Readmission Yes N=145	p-value
Recipient Age, years	53.8 ±. 13.2	53.4 ±. 13.5	0.7933

Discharge WBC < 4 or > 12	51 (16.1)	33(22.8)	0.0845
Kidney Function at discharge DGF but recovery by time of discharge DGF and not recovered by time of discharge No DGF	76 (24.0) 69 (21.8) 172 (54.3)	37 (25.5) 51 (35.2) 57 (39.3)	0.0032
Follow-up duration, days	286.0±203.8	285.8±245.8	0.3346*

*Wilcoxon log rank

Conclusions: Early readmission is associated with worse graft survival. Many readmissions may be preventable and review of process improvement may reduce early readmission after KTx.

FR-PO1049

Kidney Transplant Outcomes for Patients with Amyloidosis – A United Network for Organ Sharing Database Analysis Ali Khalil, Tim E. Taber, Muhammad Ahmad Mujtaba, Muhammad S. Yaqub, Asif A. Sharfuddin. *Medicine/Neph, Indiana Univ, Indianapolis, IN.*

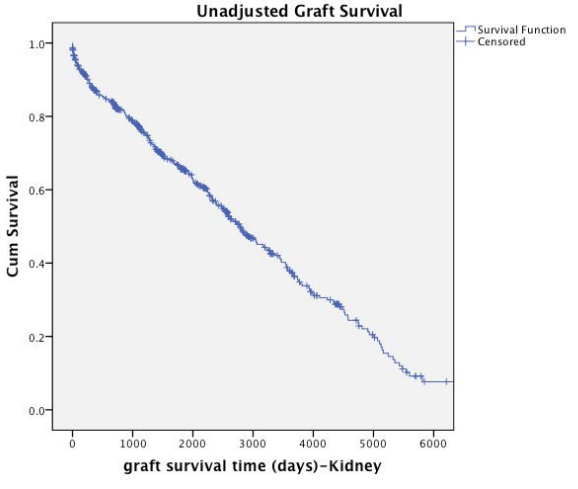
Background: Outcomes of patients with Amyloidosis who receive a kidney transplant have not been extensively studied. We examined UNOS database for outcomes of such recipients.

Methods: UNOS database was queried for recipients with code "3016" which corresponds to " Amyloidosis". Duration of study period was Nov 1987 to Dec 2014.

Results: A total of 625 recipients were identified as in the table.

Variable	Result
Mean Age at time of transplant (yrs) SD	54.8±11.1
Mean Donor Age	40±15.1
Median Time On Wait List (days)(range)	261(0-2706)
Caucasian/African American/Hispanic/Other (%)	80.5/7.2/9.1/3.2
Deceased/Living (%)	56.5/43.5
M/F (%)	62.4/37.6
On Dialysis at time of transplant (%)	80.2
Mean BMI (SD)	25.7±4.8
Diabetes (%)	6.3
Repeat Kidney Transplant (%)	3.8
PRA >80 (%)	3.6
Zero Mismatch (%)	8.6
Blood Type A/AB/B/O (%)	40.7/5.3/12.5/41.6
ECD Donor/DCD (%)	9.6/2.9
Multi-Organ Transplant (%) - Heart(n) - Liver(n) - Panc(n)	6.6 - 21 - 23 - 2
Delayed Graft Function (%)	14.6
Serum Creatinine (mg/dL) at discharge (SD)	2.3±2.1
Treated for Rejection within 6mo (%)	11.2
Treated for Rejection within 1 yr (%)	12.8
Death With Functioning Graft (%)	28.3
Unadjusted 1 yr/3yr/5yr/10 yr Graft Survival (%)	87.5/79.3/71.2/58.2
Actual Patient Survival 1yr/3 yr/5yr/10 yr	91.0/83.0/75.8/61.2

After excluding multi-organ transplants, the 1 year unadjusted graft survival was 88.6% and the 1 year patient survival was. 92.1 %. Kaplan Meier Survival Curves are in the Figure.



Conclusions: Although 1 year graft and patient survival of kidney transplants in recipients with Amyloidosis is inferior to standard outcomes, long-term outcomes are not remarkably different. Careful selection of this population can lead to satisfactory outcomes. To our knowledge this is the first and largest report on the outcomes of these patients from the US national database.

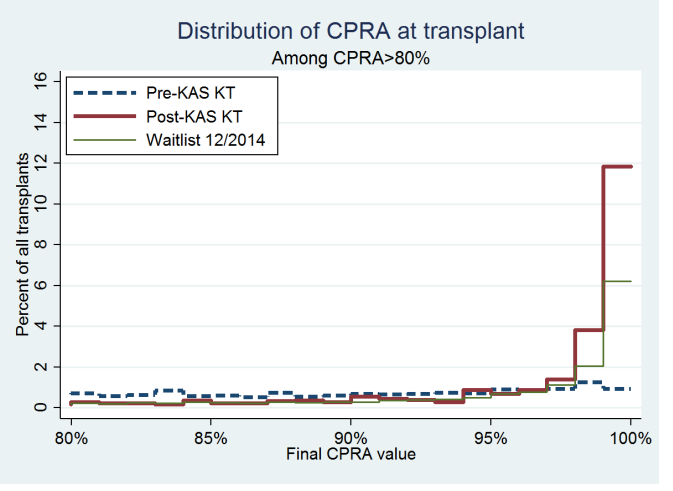
FR-PO1050

Early Experience with the New Kidney Allocation System Allan Massie, Dorry L. Segev. *Johns Hopkins.*

Background: On December 3, 2014, major changes to deceased donor kidney allocation were implemented under the new Kidney Allocation System (KAS).

Methods: Using national registry data, we compared changes in rate of DDKT among adult kidney-only waitlist registrants 1/2011-3/2015 pre vs post-KAS via Poisson regression, adjusting for age, sex, race, ABO blood type, calendar year, calculated panel reactive antibody (CPRA), and wait time. We compared donor service area-level geographic disparity pre vs post-KAS using multilevel Poisson regression and median incidence ratio ratio (MIRR). We also compared CPRA of DDKT recipients pre vs post-KAS, and incidence of delayed graft function (DGF).

Results: Pre-KAS, access to DDKT was poorer for women (IRR=$_{0.91}$ 0.92 $_{0.94}$), African-Americans (AAs) (IRR=$_{0.86}$ 0.88 $_{0.90}$), and Hispanics (IRR=$_{0.77}$ 0.79 $_{0.81}$, all p<0.01). Access was best for patients of ABO type AB (IRR vs O=$_{2.19}$ 2.29 $_{2.39}$, p<0.01) and worst for ABO type B (IRR vs O=$_{2.19}$ 2.29 $_{2.39}$, p<0.01). KAS was associated with no change in overall DDKT access (p=0.7), but with improved access for AAs (IRR=$_{1.09}$ 1.16 $_{1.24}$, interaction p<0.001) and patients of ABO type AB (IRR=$_{1.11}$ 1.29 $_{1.50}$, interaction p=0.001). Geographic disparity declined post-KAS (MIRR=1.76 pre-KAS, 1.64 post-KAS). Median CPRA at transplant was 0 both pre and post-KAS; the proportion of recipients with CPRA 80-99 decreased from 13.6% to 10.1% (p<0.001), but the proportion with CPRA>99 rose from 1.6% to 14.0% (p<0.001, Figure 1).



DGF incidence increased from 26.5% pre-KAS to 31.6% post-KAS (chi^2 p<0.001); in a multilevel (center-level) model, DGF increased 37% (OR=$_{1.21}$ 1.37 $_{1.55}$, p<0.001).

Conclusions: After recent changes to kidney allocation, DDKT access improved for AA patients and geographic disparity declined. Women and Hispanic patients are still disadvantaged, and disparity by ABO type worsened. The proportion of recipients with CPRA>99 rose dramatically. Increase in DGF may suggest risk of poorer long-term outcomes.

Kidney Transplantation Tourism: High Risk and Bad Outcome for the Recipients Amgad E. El Agroudy. *Internal Medicine Dept, College of Medicine and Medical Sciences, Arabian Gulf Univ, Manama, Bahrain.*

Background: While the ethical aspects of transplant tourism have received much attention recently, less has been written about the medical safety of this practice. We retrospectively evaluated the outcomes of patients who purchased organs internationally and presented to our center for follow-up care.

Methods: We report the outcome parameters of 270 local recipients of unrelated kidney (URT) vendor transplants presenting to our institute between 1986 and 2014. Their outcome was compared with 123 recipients of living-related donor transplants matched for age, gender and transplant duration done in our center as controls (RT).

Results: Age of unrelated recipients was 42.6 ± 13.4 years with Male % of 68. The country of transplant was mainly in Philippines (n = 85), Pakistan (n = 56), India (n = 57), Iran (n = 40) and Egypt (n= 25). Comparison of commercial recipients with controls showed high co morbidities (P = 0.01) with hepatitis-C (n=2 vs. 0) and hepatitis-B (n=2 vs. 0) and cytomegalovirus (n=4 vs. 1). Donor age was 25.9 ± 3.8 vs. 34.6 ± 8.6 years (P = 0.0001) and 90.4% were male. Biologic agents induction in 74 (27.4%) vs. 123 (100%) (P = 0.00001), acute rejections in 65 (24.1%) vs. 26 (21.1%) (P = 0.7), while recurrent rejection in 13 (4.8%) vs. 1 (0.8%) (P = 0.04), surgical complications including lymphocele 16 (5.9%) vs. 0 (0%) (P = 0.0001), ureteral obstruction 7 (2.6%) vs. 0 (0%) (P = 0.007), hematoma 4 (1.5%) vs. 1 (1.1%) (P = 0.06) and recurrent urinary tract infection 18 (9.9%) vs. 6 (6.8%) (P = 0.3). Overall 1- and 10-year for graft survival was 91% and 22% vs. 98% and 44% and for patient survival 96% and 70% vs. 98% and 78% in URT and RT, respectively (P = 0.001).

Conclusions: Although recent developments increased success in renal transplantation, receiving a kidney from a paid living donor at a commercial transplant center still carries great risks for the recipient.

FR-PO1052

The Negative Effect of First Transplant Nephrectomy for Second Transplant Outcome Masaki Muramatsu,[1,2] Michael Sheaff,[3] Arun Gupta,[4] Atsushi Aikawa,[2] Carmelo Puliatti,[1] Muhammad M. Yaqoob.[1] *[1]Nephrology and Transplantation, The Royal London Hospital, London, United Kingdom; [2]Nephrology, Toho Univ Faculty of Medicine, Tokyo, Japan; [3]Cellular Pathology, The Royal London Hospital, London, United Kingdom; [4]Clinical Transplant Laboratory, The Royal London Hospital, London, United Kingdom.*

Background: The impact of failed renal allograft nephrectomy on the outcome of retransplant is unclear. This single center study was conducted to address this question.

Methods: We analyzed 93 patients who received a 2nd transplant at The Royal London Hospital between November 1994 and January 2015. 59 patients did not receive primary transplant nephrectomy (TNx) and had failed allograft in-situ at the time of second graft (group A) whilst 34 patients underwent TNx prior to second graft (group B). 2nd transplant survival was the primary end point. Sensitization, waiting time for 2nd graft, graft function and rejections were secondary end points.

Results: Group A patients had significant longer graft survival than group B (100.6 months vs 40.2 months, $p<0.001$). Waiting time from primary graft loss to second transplant in group A was shorter than group B (36.7 months vs 59.1 months, $p=0.013$). In total, 35 patients had pre-formed anti-HLA antibodies (low titer). Group B had significantly higher rate of pre-formed ant-HLA antibodies than group A (50.0% vs 29.3%, $p=0.047$). The rate of HLA class I in group B was also significantly higher than that in group A (47.1% vs 25.7%, $p=0.038$). Group B had numerically higher rate of acute rejection than group A (32.4% vs 15.3%, $p=0.053$). eGFR between both groups did not differ until 3 years post-transplant. In group A, 2nd graft survival rates at 6month, 1, 3 and 5 years were 94.9%, 93.0%, 87.0% and 82.3%, and were significantly better group B (73.3%, 70.0%, 60.6% and 46.8%, $p<0.001$). On multivariate analysis, waiting time for second transplant, TNx, second transplant donor age and delayed graft function were independently associated with second graft survival. TNx had highest hazard ratio (2.83, 95% CI 1.22-6.67, $p=0.015$).

Conclusions: Prior TNx is associated with inferior 2nd renal graft survival in this observational study and calls for an urgent randomized control trial.

FR-PO1053

Induction Agent Use, Mortality and Acute Rejection in Older KT Recipients Mara McAdams-DeMarco, Xun Luo, Babak Orandi, Dorry L. Segev. *Johns Hopkins.*

Background: Induction agents are commonly used as an initial intensive immunosuppression after kidney transplantation (KT) to prevent acute organ rejection; this practice is mostly off label. Little is known about induction agent use in older KT recipients.

Methods: Data on 19,546 older KT recipients (2005-2013) was ascertained from the Scientific Registry of Transplant Recipients. Induction agents were classified as thymoglobulin/ATG, IL-2, or other induction agents. The risk of mortality was estimated using a Cox Proportional Hazards model (hazard ratio (HR)) adjusting for all recipient and KT factors (age, sex, race, BMI, peak PRA, history of diabetes, years on dialysis) and KT factors (HCV, HLA mismatches, cold ischemia time, donor type, donor age, and donor sex). The relative risk (RR) of 1 year acute rejection was estimated using modified Poisson regression adjusting for all recipient and KT factors.

Results: The mean age was 69 (SD=3.8 years), 36% female, 19% black and 27% live donor recipients. There is an increasing utilization by year of induction agents, with 84% use in older recipients. Compared to those who did not receive induction, the risk of mortality for older recipients was decreased for those who received thymoglobulin/ATG (HR=0.86, 95%CI:0.79-0.94), IL-2 induction agents (HR=0.89, 95%CI:0.81-0.97), and other induction agents (HR=0.85, 95%CI:0.75-0.97). Additionally, compared to those who did not receive induction, the risk of 1 year rejection for older recipients was increased for those who received IL-2 induction agents (HR=1.36, 95%CI:1.15-1.61), as well as other induction agents (HR=1.27, 95%CI:1.03-1.57) but not thymoglobulin/ATG (HR=1.06, 95%CI:0.90-1.25).

Conclusions: For older KT recipients, there is an increasing trend in the use of induction agents and a decreased risk of mortality regardless of the type of induction agent used. However, there is little evidence for a protective effect of induction agent use for 1 year acute rejection.

FR-PO1054

Immunosuppression and the Elderly – Can They Take It? Mariana C. Chiles, Shefali Patel, Sumit Mohan, Russell J. Crew. *Columbia Univ, New York, NY.*

Background: The aging immune system has fewer naïve T cells, more memory T cells, and less T cell receptor variability. Older transplant patients tend to have more comborbidities and less functional reserve. This combination makes them more difficult to immunosuppress with higher risk of infection, and potentially increased mortality from rejection treatment.

Methods: In order to determine the impact of rejection treatment on outcomes in our transplant recipients >70 years of age, we reviewed the outcomes of patients transplanted at our center from 1/2009-12/2013. Induction regimens varied; maintenance immunosuppression consisted of tacrolimus, mycophenolate, and rapid steroid withdrawal.

Results: During this time period, we transplanted 110 over 70 years of age. Of these, 27 patients had rejection—24 ACR, 1 combined AMR/ACR, 1 AMR, 1AMR followed by ACR (see table). 11 of these patients received Tcell depleting agents, the rest received IV steroids +/- IVIg. There was no difference in age, race, donor type, prior transplant, or induction therapy between the two groups. Mean creatinine was higher in the rejection group. However, treatment appeared to stabilize function- the rate of decline in estimated GFR after rejection treatment was no different between groups. Within 6 months of rejection treatment, there were 12 infectious complications, only 3 of which required hospitalization (urosepsis-2, CMV-1). There were no differences in rates of BK viremia, CMV viremia, graft survival, or mortality. 7 of the 27 patients died at some point after rejection. only one was related to infection >1 year later and not related to treatment.

Conclusions: Among our >70 patients, rejection treatment appeared well tolerated with few complications requiring hospitalizations and no treatment related mortalities. In addition, it appeared that treatment stabilized function in the majority of patients.

Mortality After Kidney Allograft Failure and Return to Dialysis Amarpali Brar,[1] Edem Nguamon Timpo,[1] Rahul M. Jindal,[3] Nabil Sumrani,[2] Fasika M. Tedla,[1] Moro O. Salifu.[1] *[1]Medicine, SUNY Downstate Medical Center, Brooklyn, NY; [2]Surgery, SUNY Downstate Medical Center, Brooklyn, NY; [3]Surgery, Uniformed Services Univ of Health Sciences, Bethesda, MD.*

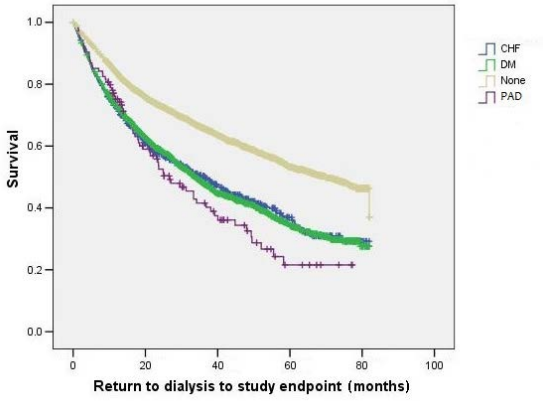
Background: Our hypothesis was that kidney allograft failure (KAF) and return to dialysis (RTD) results in greater mortality versus patients with end-stage renal disease (ESRD). We also sought to identify variables associated with mortality after KAF.

Methods: We used an incident cohort of patients from the United States Renal Data System who initiated any form of dialysis between Jan 2003 and Dec 2008 after KAF. We followed patients until retransplantation, death or Sept 2009. Multivariable Cox analysis was used for statistical associations.

Results: 7,156 patients were followed for a mean of 30.8 ± 22.6 months. 3,622 (50.6%) patients died; main causes of death cardiac (47.0 %), infectious (17.5%), other (16.4%) and metabolic/endocrine (7.9%) causes. Predictors of all-cause mortality included age at KAF [hazard ratio (HR)= 1.03, 95% confidence interval (CI) 1.03-1.04], diabetes (DM) as cause of kidney failure (HR= 1.52, CI 1.3-1.8), congestive heart failure [CHF] (HR= 1.19, CI 1.04-1.36), peripheral arterial disease [PAD] (HR= 1.23, CI 1.04-1.55), stroke (HR= 1.27,

CI 1.05-1.55), employment (HR= 0.80, CI 0.67-0.96), BMI (HR = 0.98, CI 0.97-0.99) and serum albumin (HR= 0.82, CI 0.75-0.90). Mortality was higher in those with either DM or CHF, and increased further in those with PAD (P=<0.0001).

Figure 1. Adjusted all-cause mortality (Kaplan-Meier curve)



Gender, number of transplants, donor type (deceased, living), ESRD duration prior to transplant, tobacco use, drug or alcohol abuse and erythropoietin use did not predict all-cause mortality.

Conclusions: DM, CHF and PAD are associated with increased mortality after KAF and RTD. Prevention and early management of these conditions may increase survival. Prospective studies are needed to confirm our findings.

FR-PO1056

Current Trends in Waiting List of Kidney Transplantation and Mortality in Asian: A National Population-Based Cohort Study Using the Korean Network for Organ Sharing (KONOS) Database

Kyung Don Yoo, Sunhwa Lee, Jung Nam An, Yun Kyu Oh, Chun Soo Lim, Yon Su Kim, Jung Pyo Lee. *Seoul National Univ College of Medicine.*

Background: Kidney transplantation has been increasing, globally. However, the clinical outcome of wait-listed patients for deceased donor kidney transplantation has not been well described in Asian patients with end-stage renal disease (ESRD).

Methods: We reviewed the detailed trends of wait-listed patients and conducted survival analysis in kidney transplant recipients using KONOS (The Korean Network for Organ Sharing) database which is a complete enumeration survey. We compared the outcomes according to the transplant era as followings: 2000~2004, 2005~2009, 2010~2014.

Results: From 2000 to 2014, a total of 34,843 patients registered in the waiting list, and 5,164 patients received transplantation from deceased donor. The proportion of deceased donor kidney transplantation has increased up to 45.9% in 2013 from 4.6% in 2000. The number of waiting list for kidney transplantation has increased continually more than 3,000 ESRD patients per year. The mean waiting time of deceased donor kidney transplantation was 54.9 months and has been getting longer. A total of 18,687 patients were remained on the waiting list until Jan 2015. Recently, diabetic nephropathy was the leading cause of primary disease on the waiting list, and the mean age of new registrants was getting older. The crude annual mortality rate during waiting time was 8.4%. The survival analysis revealed that there was no difference of patient survival according to the transplant era in kidney transplant recipients. However, the cumulative survival rate of the recently registered wait-listed patients was significantly improved even though they were older and had more proportion of diabetes (P<0.001, HR 0.51 95% CI 0.46-0.57).

Conclusions: In Korea, deceased donor kidney transplantation has increased. Donor organ is still seriously insufficient, therefore, it is necessary to encourage organ donation. In addition, more meticulous management needs to be provided to wait-listed patients.

FR-PO1057

Factors Affecting Mortality During Waiting Time for Kidney Transplantation: A Nationwide Population-Based Cohort Study Using the Korean Network for Organ Sharing (KONOS) Database

Sunhwa Lee,[1] Kyung Don Yoo,[1] Jung Nam An,[1] Yun Kyu Oh,[2] Chun Soo Lim,[2] Yon Su Kim,[1] Jung Pyo Lee.[2] *[1]Div of Nephrology, Dept of Internal Medicine, Seoul National Univ Hospital; [2]Dept of Internal Medicine, Seoul National Univ Boramae Medical Center.*

Background: Longer waiting times for kidney transplant have been suggested to be more deleterious than shorter waiting times. We analyzed the impact of waiting time on the post-transplant outcome and investigated risk factors for mortality during waiting time based on complete enumeration survey in Korea.

Methods: We analyzed all persons over 18-years-old deceased donor kidney transplant cases enrolled in Korean Network for Organ Sharing (KONOS) data between Jan 2000 to Jan 2015. The primary end point was all cause of death after enrollment.

Results: Of the 24,296 waiting-listed dialysis subjects, 5,255 patients including 588 re-transplant cases received kidney transplantation from deceased donor with median waiting time of 4.5 years. Ten year overall survival was 81.3% in kidney transplant recipients, whereas 68.1% in dialysis patients. Unlike previously known data, the effect of waiting time on mortality after transplantation was insignificant. During waiting time, however, various demographic and clinical factors are associated with increased mortality. Diabetic patients are more likely to die before transplantation (HR 2.25, 95%CI 1.37-3.70, P=0.001). Aging is another significant risk factor for mortality. Only 56% of people aged 65 survive after 10 year of waiting, whereas 86% of people aged 35. Men are more likely to die than women during waiting time (HR 1.22, 1.13-1.31, P<0.001). Moreover, Patients with Rh negative blood type shows higher mortality rate than those with Rh positive (HR 1.60, 1.06-2.42, P=0.024). Pre-transplant experienced patients, however, showed better survival during waiting time (HR 0.63, 0.46-0.86, P=0.003).

Conclusions: Longer waiting times on dialysis do not affect survival after transplantation although transplant itself shows better overall survival. It should be emphasized to have more attention to the patients who are diabetic, old, men, or Rh negative with higher risk for mortality during waiting time.

FR-PO1058

Normal Saline versus Lower-Chloride Solutions for Kidney Transplantation

Susan Wan,[1,2] Matthew A. Roberts,[3] Peter F. Mount.[1] *[1]Dept of Nephrology, Austin Health, Melbourne, Victoria, Australia; [2]Central Clinical School, Univ of Sydney, Sydney, New South Wales, Australia; [3]Eastern Health Clinical School, Monash Univ, Box Hill, Victoria, Australia.*

Background: The ideal intravenous (IV) fluid for kidney transplantation (KTx) has not been defined, despite the common use of normal saline (NS) in the perioperative period. The high chloride content of NS is associated with an increased risk of hyperchloraemic metabolic acidosis, which may increase the risk of hyperkalaemia and delayed graft function (DGF). Balanced electrolyte solutions (BES) have a lower chloride content, which may decrease this risk and avoid the need for dialysis due to hyperkalaemia. Randomised controlled trials (RCTs) have used biochemical outcomes to compare fluids and have been underpowered to address patient-centred outcomes such as DGF. We systematically reviewed the effect of BES versus NS on DGF, hyperkalaemia and acid-base status in KTx recipients.

Methods: We searched the Cochrane Renal Group's Specialised Register to 24th March 2015. We included RCTs of KTx recipients that compared perioperative IV lower-chloride solutions to NS. Two independent investigators assessed studies for eligibility and risk of bias. Data were extracted using standardised forms and pooled according to a published protocol.

Results: Six studies (477 participants) were included in the review. All participants were adult KTx recipients and 70% received live-donor KTx. The overall risk of bias was low for selection bias and unclear for remaining domains. There was no difference in the risk of DGF (RR 1.03, 95%CI 0.62–1.70, P=0.91) or hyperkalaemia (RR 0.48, 95%CI 0.04–6.10, P=0.57) for participants who received BES compared to NS. Compared to NS, BES were associated with higher blood pH (mean difference pH 0.07, 95%CI 0.05–0.09, P<0.00001), higher serum bicarbonate (mean difference HCO_3 3.04mEq/L, 95%CI 2.13–3.94mEq/L, P<0.00001) and lower serum chloride (mean difference chloride -9.93mmol/L, 95%CI -19.96–0.11mmol/L, P=0.05).

Conclusions: Intraoperative balanced electrolyte solutions are associated with less hyperchloraemic metabolic acidosis compared to normal saline. However, these data do not support their use to reduce clinical events.

FR-PO1059

Risk Factors for Delayed Graft Function in Kidney Transplantation

Marcos A. Meniconi,[1] Vitoria C. Vilela,[1] J. Medina-Pestana,[1] Miguel Cendoroglo Neto,[1,2] Miguel A Goes.[1,2] *[1]Nephrology Div, Federal Univ of Sao Paulo, Sao Paulo, SP, Brazil; [2]Nephrology Div, Hospital Israelita Albert Einstein, Sao Paulo, SP, Brazil.*

Background: Renal failure persisting after transplantation necessitating dialysis within the first week is called delayed graft function (DGF). **Objective**:To assess the impact of erythropoietin usage on DGF after renal transplantation.

Methods: A total of 196 maintenance hemodialysis patients who underwent renal transplantation at one center (Hospital do Rim) were prospectively analyzed pre and post-renal transplantation. Data on demographics, ESRD etiology, pre-transplantation hemodialysis, recombinant human erythropoietin (rHuEPO) use, type of donor kidney and immunosuppression regimen were reported. Two-sample t test were used to compare differences between two groups (DGF versus non-DGF groups) and X^2 to analyze categorical variables. Binary logistic regression was used to determine the impact of factors on outcome-DGF.

Results: The mean time duration on maintenance hemodialysis was 18+6 months. The main causes of ESRD were diabetes (37%) and hypertension (15%) followed by chronic glomerulonephritis (9%). There were transplants from deceased-donor kidneys (47%), living unrelated kidney donation (43%) and living related donors (10%). 41patients necessitated dialysis within the first week after renal transplantation (DGF group). We observed that 131 patients (67%) used recombinant human erythropoietin until one week before renal transplantation. We observed that DGF group was older (39+15; p=0.007), higher cold ischemia time (23+10h, 12+10h; p<0.001), longer time on dialysis (4+4, 2+1 yr; p=0.001) and higher rHEPO dose (4930+447, 1658+844 IU; p<0.001). DGF group had higher use of rHuEPO (p<0.001). Cold ischemia time (p =<0.001) was an independent predictor of DGF.

Conclusions: This study shows that rHuEPO was not associated with DGF-protection in renal transplant patients. Cold ischemia time is an independent predictor of DGF.

FR-PO1060

Outcomes of Kidney Transplant Recipients from Donation After Circulatory Death Donors without Pre-Agonal Heparin Administration Layla Kamal, Joel Lindower, Maria Ajaimy, Michelle L. Lubetzky, Graciela De Boccardo, Enver Akalin, Liise K. Kayler. *Montefiore-Einstein Center for Transplantation.*

Background: Protocols of organ donation after circulatory death (DCD) are considerably varied. Heparin administration during the pre-agonal phase has been recommended to improve organ perfusion and prevent blood clots; however some protocols avoid heparin before verification of death based on legal or professional concerns. We assessed outcomes of kidney transplant recipients who received DCD kidneys recovered with and without heparin.

Methods: We retrospectively evaluated recipients of kidney transplants between 2011 and 2014 from controlled DCD donors who received (n=23) or did not receive (n=29) pre-agonal heparin.

Results: All kidneys underwent machine perfusion. No Heparin donors had a similar kidney donor profile index but were more likely to have mild histologic changes, elevated terminal machine perfusion resistive index, and to be imported from non-local donor service areas compared to the Heparin donors. Recipients of no Heparin kidneys were more likely to be female, sensitized, prior solid organ recipients, and to receive thymoglobulin induction but were less likely to have diabetes. None of these differences reached statistical significance. Post-transplantation, 1 patient died early due to a cardiac event (no Heparin group). Graft failure occurred in 2 patients in the no Heparin group (one each of sepsis/intraparenchymal venous thrombosis and chronic histologic changes suggestive of donor disease) and 1 patient in the Heparin group (renal artery thrombosis). Between group differences were small in terms of delayed graft function, 6-month acute rejection, and estimated GFR at 3, 6, and 12 months.

Table: Transplant Characteristics and Outcomes by Group

Characteristic % or mean +/- SD	Heparin No N=29	Heparin Yes N=23	P- Value
Kidney Donor Profile Index	61.7±21.9	59.4±30.0	0.63
Warm ischemia time	28.2±5.98	35.3±16.4	0.21
11-25% Arteriosclerosis or 11-25% Interstitial Fibrosis or ≥ 5% Glomerulosclerosis	38.5	27.8	0.54
Kidney from non-local Donor Service Area	86.2	69.6	0.78
Machine Perfusion Terminal Resistive Index <0.2 mm Hg/mL/min 0.21-0.35 mm Hg/mL/min >0.35 mm Hg/mL/min	 41.7 41.7 16.7	 52.2 43.5 4.4	0.46
Recipient, Black race	51.7	56.5	0.21
Recipient, Female	51.7	30.4	0.16
Recipient Age, years	54.3±16.3	55.4 ±. 10.1	0.78
Recipient, Diabetes Mellitus	44.8	56.5	0.58
Prior Solid Organ Transplant	10.3	0	0.25
Thymoglobulin Induction	55.2	30.4	0.10
Panel Reactive Antibody > 0%	27.6	4.4%	0.03
Human Leukocyte Antigen mismatch > 4	58.6	34.8	0.10
Cold Ischemia Time-hours <30 30-40 40-54	 37.9 27.6 34.5	 47.8 39.1 23.1	0.21
Delayed Graft Function	65.5	60.9	0.78
Cumulative incidence of acute Rejection at 6 months	12.0	5.0	0.62
Overall death Censored Graft Failure	6.9	4.3	0.10
Estimated Creatinine Clearance (Cockgroft-Gault) 3-months 6-months 12-months	 50.4±16.4 54.7±18.6 61.9±15.7	 58.1±15.2 61.2±16.7 58.6±11.1	 0.12 0.24 0.58
Follow-up duration, days	292.4±395.6	233.5±305.1	0.45

Conclusions: Our findings suggest that DCD kidneys recovered without pre-agonal heparin are not at increased risk for primary non-function or thrombosis.

FR-PO1061

Effects of Dopamine Donor Pretreatment on Graft Function After Kidney Transplantation: Five-Year Follow-Up of a Randomized Controlled Trial Urs Benck,[1] Bernhard K. Krämer,[1] Peter Schnuelle.[2] *[1]V. Medical Clinic, Univ Medical Center Mannheim, Mannheim, Germany; [2]Nephrology, Center for Renal Diseases, Weinheim, Germany.*

Background: [For the study Group]: A previous multicenter randomized controlled trial reported reduced dialysis requirements after kidney transplantation with dopamine donor pretreatment. Data on long-term outcomes are needed.

Methods: We calculated five-year graft survival from follow-ups at 60 European centers. We analyzed intention-to-treat and on-study-medication and produced survival estimates as tertiles of dopamine exposure because infusion times varied by treatment arm (range 0-1,929 min). Recipients with functioning grafts at three months were analyzed separately to differentiate early events from long-term consequences of the trial intervention.

Results: Follow-up was complete in 99.2%. Overall graft survival was 72.6 vs. 68.7%, (hazard ratio [HR] 0.85, 95% confidence interval [CI] 0.61-1.19; p=0.35), and death-censored graft survival was 83.3 vs. 80.4%, (HR 0.84, 95%CI 0.54-1.29; p=0.42) in the treatment and control arms, respectively. The HR decreased to 0.46 (95%CI 0.23-0.94; p=0.03) in recipients with functioning grafts at three months, whose donor had received dopamine >270 min. It remained significant after adjusting for donor age (HR 1.05, 95%CI 1.02-1.08; p=0.001), delayed graft function (HR 2.05, 95%CI 1.12-3.73; p=0.02), biopsy-proven rejection (HR 2.13, 95%CI 1.16-3.93; p=0.02), and repeat transplants (HR 2.49, 95%CI 1.19-5.20; p=0.02). There were no differences of graft survival on intention-to-treat.

Conclusions: Dopamine administered for >270 min provided a long-term graft survival advantage independent of early events after Transplantation.

FR-PO1062

Does Calcineurin Inhibitor Timing Matter? Single Center Experience with En-Bloc Kidney Transplantation Maya Campara,[1] Oksana A. Kucher,[1] Sanjeev Akkina,[2] Ignatius Yun-Sang Tang.[2] *[1]Pharmacy Practice, Univ of Illinois at Chicago; [2]Medicine, Nephrology, Univ of Illinois at Chicago.*

Background: En-bloc kidney transplantation (KTx) has excellent outcomes. To minimize vascular complications and nephrotoxicity, calcineurin inhibitor (CNI) therapy is often delayed. The purpose of our study is to investigate the impact of CNI initiation timing on 1-year graft outcomes.

Methods: This is a single-center, retrospective review of adult en-bloc KTx between 2001 and 2013. Timing of CNI initiation was decided by the operating surgeon. Patients were divided into two groups, those that received CNI therapy early (≤48 hours) or delayed (>48 hours) posttransplant. The primary objective was to compare one year estimated glomerular filtration rate (eGFR) between the groups. Secondary outcomes included graft and patient survival, CNI levels, incidence of delayed graft function (DGF), rejection and graft failure rates.

Results: Twenty-one en-bloc KTx recipients were included in the analysis. Ten patients received CNI therapy within 48 postoperative hours (Early CNI Group). There was no difference in age, race, gender, PRA, cause of ESRD or BMI between the groups. Only 50% of Early CNI patients received lymphocyte depleting therapy vs. 100% in the Delayed CNI group (p = ns). In the Early CNI Group, 3 patients were on cyclosporine; all other patients received tacrolimus and mycophenolate maintenance. There was no difference in eGFR between groups at one year or at any other time points. Comparable therapeutic tacrolimus trough was observed at 5, 10 and 30 days posttransplant. There was no difference in DGF or rejection incidence. In the delayed CNI group, one patient died of sepsis at 6 months.

Conclusions: Timing of CNI initiation had no impact on one year graft function and patient survival.

	Early CNI (n = 10)	Delayed CNI (n = 11)
FK506 trough POD-5, ng/ml	5.75+/-2.65	7.34+/-4.9
FK506 trough POD-10, ng/ml	11.5+/- 4.9	12.1+/-7.5

FR-PO1063

Reduction of Pediatric Renal Transplantation Vascular Thrombosis Rates Utilizing Low Dose Heparin Infusion Philip D. Acott,[1,2] James B. Tee,[1,2] Philip Wornell,[1,2] John F.S. Crocker.[1,2] *[1]Pediatrics, Dalhousie Univ, Halifax, NS, Canada; [2]Pediatrics, IWK Health Center, Halifax, NS, Canada.*

Background: Pediatric renal allograft thrombosis rates are 4-10% and often result in allograft loss. Thrombotic risk factors are smaller native vessel size, deceased donor source (DD), delayed renal allograft function, acute rejection, and small centre size (<50 transplants/decade). In our pediatric program from 1971 – 1992, 5 of 69 consecutive renal transplants (7.2%) were lost to vascular thrombosis.This study assesses if low dose continuous heparin reduces the risk and outcome of thrombosis in pediatric renal transplants.

Methods: Over 22 years (1993-2015), 44 of 100 consecutive children post renal transplant received low dose continuous heparin (10 units/kg/hour) for 1 week for thrombotic risk: 1) age < 6yr (n=24); 2) laboratory profile of hypercoagulability (n=10); 3) oliguric delayed function (n=5); 4) surgical complications with venous or arterial anastomosis or double artery (n=4); or 5) patient history of access thrombosis or vasculitis (n=1). Renal scans were obtained on days 1, 3, 5 and when clinical deterioration occurred.

Results: Only 2 thrombotic events were noted which did not cause graft loss: 1) 2yr LRD transplant- venous thrombosis immediately post-op on heparin with successful thrombectomy at 2hr and allograft recovery; 2) 17yr DD double renal artery allograft arterial thrombosis of smaller inferior renal artery on day 10 (heparin stopped day 7). One patient on heparin infusion required laparotomy 3hrs after surgery for thrombosis external to the anastomosis. One patient not on heparin also required laparotomy in the first 24hrs post-op for hematoma evacuation.One patient in each group had primary non-function/surgical loss with removal of the kidney within the first 3 days post transplant. Graft survival at 1yr was 96% andno allograft was lost due to thrombotic complications.

Conclusions: Identification of pediatric patients with who are at high risk of thrombosis post renal transplant appears warranted. We achieved a low thrombosis rate and no thrombotic organ loss, despite a high proportion of high-risk patients < 6yr, utilizing low dose continuous heparin for 1 week post transplant.

FR-PO1064

The Influence of Induction Immunosuppressive Therapies and Diabetes on Graft Loss After Kidney Transplant Hosam A. Farag,[1] Nasrollah Ghahramani,[1] Tarek Alhamad.[1] *[1]Public Health Dept, Penn State College of Medicine, Hershey, PA; [2]Nephrology Dept, Penn State College of Medicine, Hershey, PA; [3]Public Health Dept, Penn State College of Medicine, Hershey, PA; [4]Nephrology Dept, Washington Univ, St. Louis, MO.*

Background: Induction therapy plays a significant role to reduce the rate of acute rejection in kidney transplant (KT). Understanding differences in outcomes associated with induction agents may lead to improvement in long-term care. Our objectives were to examine the influence of various induction therapies and diabetes on graft and patient survival after KT.

Methods: We used the 2000-2013 United Network for Organ Sharing (UNOS) data to evaluate the effectiveness of induction therapies and diabetes on graft and patient survival after KT. The patients were divided into four groups based on induction therapy: Basiliximab (n=24,484), alemtuzumab (n=3,321), rabbit anti-thymocyte globulin (r-ATG) (n=54,974) and daclizumab (n=13,358). Also the patients were divided into four groups based on diabetic status: non-diabetic (n=192,333), type1 diabetes (n=11,863), type 2 diabetes (n=43,543)and new onset of diabetes (n=10,509). The main outcome were the risk of graft loss and death at 1,3,5,10 years. Cox proportional hazards model was used to estimate the hazard ratios.

Results: Graft loss was significantly higher in alemtuzumab group (HR=1.171 ; P= 0.002) and rabbit anti-thymocyte globulin group (HR=1.109 ; P< 0.0001) versus basiliximab group. Daclizumab group showed significantly lower risk for graft loss (HR=0.902%; P< 0.0001) than basiliximab. Death was significantly higher in rabbit anti-thymocyte globulin group (HR=1.075 ; P< 0.0094) versus basiliximab group. Daclizumab group showed significantly lower risk for death (HR=0.850 ; P< 0.0001) than basiliximab group. Graft loss was significantly higher in type 2 diabetes (HR=1.451 ; P< 0.0001).

Conclusions: Induction immunosuppressive therapies and diabetic status play significant role in long-term graft and patient survival. Basiliximab and daclizumab as IL-2 RA receptor antagonists have better long-term graft and patient survival outcomes.

FR-PO1065

Does Induction Type Influence Outcomes in Kidney Transplant Recipients at Different Phases of Hepatitis B Infection? Kalathil K. Sureshkumar, Richard J. Marcus, Bhavna Chopra. *Nephrology and Hypertension, Allegheny General Hospital, Pittsburgh, PA.*

Background: Host response to hepatitis B virus (HBV) infection is variable with some patients progressing to chronic liver disease. Immunosuppression associated with kidney transplantation in such patients may increase the risk of disease progression. We aimed to analyze the impact of potent depleting vs. non-depleting antibody induction on the outcomes in kidney transplant recipients (KTRs) at different serological stages of HBV infection.

Methods: Using UNOS database, we identified adult KTRs from 2001 to 2011 who at the time of transplantation were in one of the 3 serological stages of HBV infection:HBsAg+/HBcAb-; HBsAg+/HBcAb+ and HBsAg-/HBcAb+. All patients received peri-operative induction followed by calcineurine inhibitor/mycophenolate mofetil-based maintenance with/without steroids. Using multivariate Cox model, graft and patient survivals were compared for depleting (antithymocyte globulin or alemtuzumab) vs. non-depleting (basiliximab or daclizumab) antibody induction among the 3 HBV serological groups. Donor, recipient and transplant related confounders including lamivudine therapy were adjusted in the model.

Results: Adjusted graft and patient survivals for depleting vs. non-depleting induction among the 3 groups are shown in the table.

	HBsAg+/HBcAb- group (depleting=652; non-depleting =446)		HBsAg+/HBcAb+ (depleting = 250; non-depleting = 216)		HBsAg-/HBcAb+ (depleting = 3562; non-depleting = 2555)	
Outcome	**HR**	**95% CI**	**HR**	**95% CI**	**HR**	**95% CI**
Overall graft survival	0.97	0.78-1.26	0.81	0.55-1.18	0.96	0.86-1.05
Death-censored graft survival	1.20	0.83-1.60	0.59	0.32-1.12	1.00	0.88-1.14
Patient survival	0.92	0.66-1.30	0.95	0.60-1.49	0.92	0.80-1.05

All p-values non-significant

Conclusions: Our study did not show adverse graft and patient survivals associated with depleting as compared to non-depleting antibody induction in KTRs with either HBsAg+/HBcAb- (early infection), HBsAg+/HBcAb+ (inactive carrier or immune tolerant) or HBsAg-/HBcAb+ (clearing infection) sero-status. These findings support a practice of choosing induction type based on the immunological risk in such recipients rather than the serological status following HBV infection.

FR-PO1066

Health Economic Analysis of Rabbit Antithymocyte Globulin (Thymoglobulin) versus Basiliximab (Simulect) in Renal Transplantation – A German perspective Friedrich Thaiss,[1] Thomas Benzing,[2] John Reitan,[3] Thomas Paivanas,[4] Meghan E. Gallagher,[5] Michael Sean Wiesener,[6] Nikolai Zink.[6] *[1]Univ. Hospital, Nephrology, Hamburg, Germany; [2]Univ. Hospital, Nephrology, Cologne, Germany; [3]RJM Group, Crown Point; [4]TAP & A, Annandale; [5]Sanofi, Cambridge; [6]Univ. Hospital, Nephrology, Erlangen-Nuernberg, Germany.*

Background: Kidney transplantation is now accepted as a proven therapeutic modality prompting a greater need to understand the cost-effectiveness of different treatment approaches.

Methods: The primary objective of this study was to quantify the economic consequences of acute rejection and adverse events in patients undergoing cadaveric kidney transplantation and receiving ATG (Thymoglobulin - Thymo) compared with those receiving basiliximab (Simulect - Sim). Health economic data were collected according to reimbursement calculations from 3 German sites in an existing database (Brennan et al NEJM, 2006).

Results: Based on the clinical data from the Brennan trial, the study quantified current data and changes in treatment patterns. Results demonstrate that at 12 months the cost of the Thymo-regimen is €5,753 more than that of the Sim-regimen. However, costs of delayed graft function, nonfatal graft failure events and post-graft failure dialysis are lower among Thymo treated patients. Thymo treated patients incurred higher graft maintenance costs, consistent with their longer graft survival. In total the associated cost-offset from lower rejection events with Thymo offset the added cost from drug treatment and therefore Thymo is a more cost-efficient resource vs Sim due to cost-avoidance. To further evaluate differences between the two groups we considered quality-adjusted life year differences. The Thymo cohort is projected to enjoy 405,714/ QALY after 1 year. After a decade, the Thymo cohort is projected to cost 332,232 Euros less than the Simulect cohort while enjoying 10.8 more QALYs.

Conclusions: This analysis was intended to provide information that should be considered when weighing the costs and benefits of two immunosuppressive regimens and to investigate if treatment changes might result in more cost-effective care.

FR-PO1067

Design and Rationale of Athena Study: A 12-Month Study Evaluating Everolimus versus Standard Regimen in De Novo Renal Transplant Recipients-Baseline Data Friedrich Thaiss,[1] Claudia Sommerer,[1] Barbara M. Suwelack,[1] Duska Dragun,[1] Ingeborg A. Hauser,[1] Peter Schenker,[1] Daniel Baeumer,[2] Björn Nashan.[1] *[1]Athena Study Group; [2]Novartis Pharma Germany.*

Background: Long-term use of standard calcineurin inhibitor (CNI) post-kidney transplant (KTx) is associated with an increased risk for malignancies, cardiovascular disease, and renal failure. Previous studies have shown everolimus (EVR) to allow CNI reduction and thereby preserve renal function without affecting efficacy. ATHENA study evaluates the renal function comparing EVR with reduced CNI exposure (tacrolimus [TAC] or cyclosporine A [CsA]) vs a standard treatment protocol with mycophenolic acid (MPA) and TAC in de novo (day 0) KTx recipients (KTxR).

Methods: This is a 12-month (M), multi-centre, open-label, prospective study in KTxR (³18 years) receiving renal allografts from deceased or living donors. Patients were randomised prior to Tx to one of three treatment arms (1:1:1): TAC+MPA+steroids (n=204) or EVR+TAC+steroids (n=204) or EVR+CsA+steroids (n=204) (all with basiliximab). The primary objective is to demonstrate non-inferiority in renal function (eGFR, Nankivell) in one of the EVR arms vs TAC+MPA+steroids arm at M12 post-KTx. Secondary objectives are treatment failure (BPAR, graft loss or death) at M12 post-KTx.

Results: Study recruitment is completed in Germany and France. A total of 658 patients were enrolled, of which 614 patients were randomised. To-date, baseline data was available for 367 treated patients (TAC+MPA, 125; EVR+TAC, 116; EVR+CsA, 126); of which 66% were male (65%, 67%, and 66%, respectively). The mean age was 54 years (TAC+MPA, 55 years; EVR+TAC, 54 years; EVR+CsA, 53 years). At baseline mean BMI was 26.8 kg/m^2 (TAC+MPA, 26.7 kg/m^2; EVR+TAC, 26.7 kg/m^2; EVR+CsA, 26.8 kg/m^2). Overall, 18% patients received allograft from living donor (TAC+MPA, 18%; EVR+TAC, 17%; EVR+CsA, 20%). The mean HLA mismatch was 2.8 (TAC+MPA, 2.6; EVR+TAC, 2.8; EVR+CsA, 3.0) The preliminary results of this ongoing trial are expected in 2016.

Conclusions: ATHENA is the largest European renal transplant study and the first study evaluating the non-inferiority of renal function as a primary objective in a de novo EVR-based immunosuppressive protocol.

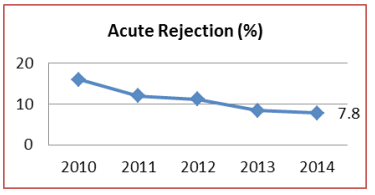
FR-PO1068

Thymoglobulin Induction Therapy; Results for 5 Years – Improving the Survival of Renal Allograft and Patient Virginia Ibarra Pedroza, Benjamin Gomez-Navarro. *Nephrology and Transplantation, Centro Medico Nacional de Occidente, Guadalajara, Jalisco, Mexico.*

Background: The factor that impacts the survival of renal allograft is the presence of acute rejection. In our city, using Thymoglobuline has offered to patients at high immunological risk, and through the years has sought to reduce adverse events use. The objective is to evaluate the frequency of acute rejection during the last 5 years in patients receiving Thymoglobuline induction.

Methods: An ambispective cohort, patients transplanted in UMAE HE-CMNO, Jalisco, Mexico is included in the period June 2010 to June 2014 who received received induction therapy with Thymoglobulin. Was recorded the frequency ofacute rejection, the frequency of infections, use of Filgrastim(rG-CSF), graft loss and death at 12 months of transplantation.

Results: A 370 patients were included,which received initial doses of Thymoglobulin 0.6mg/kg-1.5mg/kg. In 2013, by multivariate analysis Thymoglobuline dose that was associated with a lower incidence of acute rejection was analyzed and found that 1mg/kg for 4 days (cumulative dose 4mg/kg) is a protective factor for the occurrence of acute rejection (IC 95%; 0.11- 0.60, OR 3.7, *p= <0.001*), for this reason almost patients received this dose. In 2010, the rate of rejection was 16%, and actually is 7.8% (p<0.05);



Infections disease was reduced about 30%. Currently few patients use of rG-CSF because leukopenia- neutropenia, lost the renal graft or die during the first year.

	2010	2011	2012	2013	2014
Infetions (%)	62	42	48	34	32
Use of rG-CSF (%)	16	15	13	9.4	4.5
Graft loss (%)	8	8	5.6	3.7	2.2
Death (%)	8	3.7	4.5	2.8	0

Conclusions: Interestingly, in ourhospital, we observed a lower rate of acute rejection and improved patient survival and allograft. Apparently finding the right dose in our patients has allowed thymoglobulin induction is safe and minor complications.

FR-PO1069

Randomized Trial of Tacrolimus/Everolimus versus Tacrolimus/Enteric-Coated Mycophenolate Sodium to Prevent Biopsy-Proven Acute Rejection and Chronic Allograft Injury in Adult, Primary Kidney Transplantation Giselle Guerra,[1] Jeffrey J. Gaynor,[2] David Roth,[1] Warren L. Kupin,[1] Adela D. Mattiazzi,[1] Michael J. Goldstein,[2] Linda J. Chen,[2] George William Burke,[2] Gaetano Ciancio.[2] *[1]Dept of Medicine, Miami Transplant Inst, Miami, FL; [2]Dept of Surgery, Miami Transplant Inst, Miami, FL.*

Background: It was of interest to determine whether everolimus(EVL) might reduce the incidence of biopsy-proven acute rejection(BPAR) during the first 12mo post-kidney transplant.

Methods: We performed a single-center, open-label randomized trial comparing two maintenance immunosuppression regimens: TAC(tacrolimus)/EVL(Group A) vs. TAC/EC-MPS(enteric coated mycophenolate mofetil)(Group B). In both treatment arms, dual induction therapy (anti-thymocyte globulin plus basiliximab) was given along with planned early corticosteroid withdrawal.

Results: Among 30 eligible adult participants(15 per treatment arm), median follow-up was 11mo(range: 3-20mo). Mean TAC levels were 5-8ng/ml in both arms; mean EVL level in Group A was 4-6ng/ml. One patient in Group A vs. 3 patients in Group B experienced BPAR - actuarial estimates at 12mo were 10%+9% vs. 20%+10%, respectively(P=.31). All 3 BPAR's in Group A occurred prior to 6mo vs. the single BPAR in Group B occurring after 6mo (logrank P=.09 during the first 6mo post-transplant). A slight trend for more favorable renal function(eGFR) was also observed in Group A at 1-3mo post-transplant (P=.06, .10, and .18, respectively). No graft failures or deaths have been observed. Regarding the incidence of NODAT, a slight trend against Group A was observed (2/15 vs. 0/15 in Group B, P=.13), and higher mean cholesterol and triglyceride levels also occurred in Group A during 2-12mo(P<.10 at various times).

Conclusions: Although a relatively favorable performance for the experimental maintenance regimen of TAC/EVL in terms of a low BPAR rate during the first 12mo post-transplant was observed, it may occur at the expense of possibly higher rates of NODAT and lipidemia.

FR-PO1070

Early Conversion to Everolimus in *De Novo* Renal Transplant Recipients: 24-Month Results from the ELEVATE Study Johan W. De Fijter, Hallvard Holdaas, Patricia M. Lopez, Cesar Escrig, Zailong Wang, Josep M. Cruzado, Markus van der Giet. *For the ELEVATE Study.*

Background: Long-term therapy with calcineurin inhibitors (CNIs) is associated with nephrotoxicity i.e., glomerulosclerosis and interstitial fibrosis (IF).We present the 24 month results from the ELEVATE study (NCT01114529), which compared an early conversion to everolimus (EVR) vs standard CNI in renal transplant recipients (RTxR).

Methods: ELEVATE, a 24M, multicenter, open-label trial, randomized *de novo* RTxRs 10–14 weeks post-Tx to convert from CNI to EVR (n=360; C_0 6–10 ng/mL) or standard CNI (n=357; C_0: TAC 5–10 ng/mL, CsA 100–250 ng/mL); all received enteric-coated mycophenolate sodium and steroids. Primary endpoint was change in eGFR (MDRD4) from RND to M12. Main secondary endpoint a composite efficacy of treated biopsy-proven acute rejection (tBPAR; Banff ≥IB), graft loss, or death and safety.

Results: At M12, the clinical benefit observed in eGFR did not achieve statistical significance (1.70, 95% CI: -0.53, 3.93, p=0.134) whilst eGFR at M24 for EVR was significantly better (p<0.006). The composite efficacy endpoint was comparable at M12 & M24. Overall acute rejection rates were very low with more tBPAR in EVR, but mild in severity (Banff IA & IB). In both the groups, number of patients with *de novo* DSAs at M12 or M24 was low and unrelated to outcomes. At M24, rate of CAN (IF/TA) was significantly higher in the CNI versus EVR (35.1 vs 26.7%, p=0.029).

Conclusions: Early conversion to EVR at 3 months vs continued CNIs better preserved renal function with comparable overall efficacy and safety up to 2-years.

Table: Outcomes at M12 and M24

	M12			M24		
	EVR	CNI	p-value	EVR	CNI	p-value
Mean eGFR (mL/min/1.73m²)	64.0	60.4	0.054	62.5	57.4	0.006
Composite efficacy[a] (%)	6.2	3.8	0.172[b]	8.1	4.5	0.057
tBPAR ≥1B (%)	4.9	2.0	0.034	5.2	2.3	0.041
Graft loss (%)	0.6	1.2	0.407	1.2	1.1	0.935
Death (%)	2.0	1.5	0.725	2.6	2.6	0.964
Any AE/infection (%)	89.0	83.6	-	91.3	88.9	-
SAEs (%)	42.5	40.7	-	54.3	49.0	-
Proportion of patients with *de novo* DSA[c] (MFI ≥500)						
HLA A (%)	2.9	0.5	-	2.8	0	-
HLA B (%)	2.6	0	-	0.8	0	-
HLA DR (%)	0	0	-	1	1.4	-
HLA DQ (%)	0	4.3	-	0	1.7	-

[a]Defined as tBPAR ≥1B, graft loss or death. [b]p-value of z-test for non-inferiority is <0.001
[c]Patients with MFI=0 at randomization and MFI ≥500 at post-RND measurement

FR-PO1071

Early Conversion from Cyclosporine to Everolimus following Living-Donor Kidney Transplantation: Outcomes at Five Years Post-Transplant in the Randomized ZEUS Trial: A Post-Hoc Analysis Ingeborg A. Hauser,[1] Frank Lehner,[1] Wolfgang Arns,[1] Klemens Budde,[1] Ute Eisenberger,[2] Rudolf P. Wuthrich,[2] Petra Reinke,[1] Rolf A. Stahl,[1] Anja Susanne Mühlfeld,[1] Heiner H. Wolters,[1] Barbara M. Suwelack,[1] Katharina M. Heller,[1] Martina Porstner,[3] Oliver Witzke,[1] Claudia Sommerer.[1] *[1]ZEUS Study Group, Germany; [2]ZEUS Study Group, Switzerland; [3]Novartis Pharma, Germany.*

Background: To study renal function and patient outcome after 5 years in living-donation subgroup of kidney de novo transplant recipients after conversion to an everolimus (EVR) based regimen and withdrawal of calcineurin inhibitor therapy.

Methods: Post hoc subgroup analysis from the prospective, open-label, controlled, multi-center study ZEUS. 300 renal transplant (Tx) patients were randomized at month (mo) 4.5 post Tx to either receive EVR plus enteric coated-mycophenolate sodium (EC-MPS) or cyclosporine (CsA) plus EC-MPS regimen. Of these were 80 living donation recipients (EVR group n=42; CsA group n=38). Patients could enter an observational follow-up (FU) period where outcome on patients' safety and efficacy was recorded until mo 60 post Tx.

Results: Adjusted eGFR (Nankivell) in living-donation subpopulation at mo 60 was 67.2 (95% CI [62.5, 71.9]) mL/min/1.73m2 in EVR vs 60.8 (95% CI [56.0, 65.6]) mL/min/1.73m2 in CsA patients, resulting in a difference of +6.4mL/min/1.73m2 in favor of EVR patients (p=0.031, ANCOVA). Unadjusted mean eGFR after 5 years was 69.5 ml/min for EVR vs 60.6 ml/min for CsA (p=0.006, Wilcoxon). BPARs during FU since mo12 occurred in 4 patients of the EVR and 3 of the CsA group, all BANFF grade IA except one BANFF grade IIA among EVR patients. From randomization to mo 60 one death occurred in CsA living-donor recipients, two in the EVR living-donation subgroup; one graft loss occurred in the EVR, none in the CsA group. Overall safety profile was similar between both treatment groups.

Conclusions: The presented analysis shows that EVR-based regimen with early elimination of CNI-therapy in living-donor kidney transplant recipients is associated with a significant benefit on renal function maintained over 5 years post Tx without compromising safety and efficacy.

Funding: Pharmaceutical Company Support - Novartis Pharma GmbH

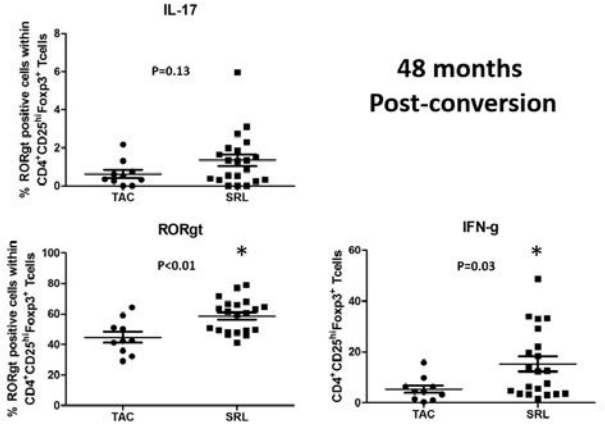
FR-PO1072

Co-Expression of RORgt and IFN-Gamma in Regulatory T Cells of Long-Term Sirolimus-Converted Kidney Transplant Recipients Opas Traitanon, Ekamol Tantisattamo, Mohammed Javeed Ansari, Lorenzo G. Gallon. *Medicine-Nephrology, Northwestern Univ, Chicago, IL.*

Background: Tacrolimus(TAC) and Sirolimus(SRL) are commonly used immunosuppressive drugs in kidney transplantation. SRL has been shown to induce the expansion of regulatory T cells in post-transplant recipients converted from TAC to SRL.

Methods: This study included 84 renal transplant recipients from a randomized trial of SRL conversion(n=55) or TAC maintenance(n=29). The conversion started at 12 months post-transplant. PBMC were collected at 0(baseline), 6, 12, 24, 36 and 48 months post-randomization. T cell subpopulations were analyzed by flow cytometry.

Results: At baseline, frequencies of $CD4^+25^{hi}Foxp3^+$ T cells were similar in both groups (0.63±0.06(SRL) VS 0.66±0.12(TAC) % of Lymphocytes, p=0.79). SRL conversion led to a significant increase in $CD4^+25^{hi}Foxp3^+$ T cells at 6, 12 and 24 months post conversion with highest frequencies observed at 12 months post-conversion (2.23±0.23 (SRL) VS 0.68±0.12 (TAC) %, p<0.01). However, we observed a decline of $CD4^+25^{hi}Foxp3^+$ T cells started at 24 months and the differences were no longer significant compared to the TAC group at 36 and 48 months post-conversion (1.41±0.60 (SRL) VS 1.07±0.44 (TAC) %, p=0.24). Intracellular staining for Interferon Gamma (IFN-γ), Interleukin 17 (IL-17) and RAR-related orphan receptor gamma 2 (RORgt) showed no difference at 24 months. However, at 48 months, we found that PMA-stimulated $CD4^+CD5^{hi}Foxp3^+$ T cells in SRL-converted group had more percentage of cells that co-expressed IFN-γ and RORgt which are Th1 and Th17 markers respectively.



Conclusions: Switching from TAC to SRL results in an expansion of $CD4^+25^{hi}Foxp3^+$ T cells which peaked at 12 months post-conversion but no significant frequency differences were observed at 48 months follow-up and we observed more percentage of regulatory T cells that co-expressed IFN-γ and RORgt in the SRL group.

FR-PO1073

Pulmonary Complications in Kidney Transplant Recipients: Role of Everolimus Gianni Cappelli, Andrea Solazzo, Fabio Nava, Decenzio M. Bonucchi. *Nephrology Dialysis & Renal Transplant Unit, Univ Hospital of Modena, Modena, Italy.*

Background: Kidney transplant recipients are at higher risk to develop pulmonary complications as drug related side-effects.

Methods: 500 kidney transplanted patients were retrospectively analyzed for pulmonary complications based on chest RX and HRCT, BAL, oximetry and clinical data. Results were classified as parenchymal, interstitial and neoplastic complications.

Results: We found 168 pulmonary complications in 161 pts (32%): 137 parenchimal pneumonia, 29 interstitial lung diseases (IP) and 2 cancers. Most pneumonia were bacterial, 96 cases (70%) required hospitalization. IP were from infections in 13 cases (45%) and Pneumocystis jirovecii was present in 42,85 %; 16 cases of IP (55%) resulted as drug-induced IP (DI-IP); all IP and cancer cases required hospitalization. According to antirejection protocols DI-IP occurred in 7 pts (43,7%) while on triple regimen [steroids, Everolimus (EVL) and Cyclosporine (CyA)] and in 7 pts on double regimen (steroid and mTORi: Sirolimus or EVL) (43,7%). In IP cases EVL (through concentration: EVL^{TLC}) and CyA (2-hour concentration: CyA^{C2}) levels were higher than in patients in the same regimen but with no-IP: EVL (ng/mL) 9.84 vs 6.85 and CyA (ng/mL) 303.97 vs 298.56; using the combined blood levels of both drugs ($Everolimus^{TLC}$ + (CyA^{C2}/100) there is a significant difference between pts groups: 12.88±1,61 vs 9.83±1,91. Applying ROC analysis for optimal model to detect risk of developing IP using EVL or the sum of both drugs we obtained a ROC-AUC respectively of 0.9082 (p=0.0028) and 0.8622 (p=0.0081) and a threshold value of 9,03 ng/ml or 11,41ng/ml.

Conclusions: Pulmonary side-effects are frequently drug related and a relationship of IP to EVL concentration is obtained. Based on ROC analysis pts on EVL/CyA combined protocol show a risk of IP when EVL concentration is >9.03 ng/ml or the summatory of both drugs is >11.41 ng/ml and support the use of this formula for better prevention of IP in clinical practice.

FR-PO1074

High Doses of M-TOR Inhibitors May Induce Pulmonary Pro-Fibrotic Effects in Renal Transplant Recipients: Result of a Translational Comparative Research Approach Between Everolimus versus Tacrolimus Gianluigi Zaza,[1] Valentina Masola,[1] Simona Granata,[1] Gloria Bellin,[1] Maurizio Onisto,[2] Giovanni Gambaro,[3] Antonio Lupo.[1] *[1]Renal Unit, Dept of Medicine, Univ of Verona, Italy; [2]Dept of Biomedical Sciences, Univ of Padova, Italy; [3]Div of Nephrology and Dialysis, Columbus-Gemelli Hospital Catholic Univ, School of Medicine Rome, Italy.*

Background: Pulmonary fibrosis is a quite frequent adverse effect occurring in mTOR-I-treated renal transplant (RT) recipients. It has been suggested that epithelial to mesenchymal transition (EMT) in airway cells may determine this condition. However, the exact biological machinery involved is not completely clarified.

Methods: We performed a translational study. First we analyzed the in vivo pulmonary pro-fibrotic potential of Everolimus (EVE) by computing a pulmonary fibrosis index score (PFIS), obtained by using several computerized tomography, hemogasanalytic and spirometric parameters, in 13 RT patients in EVE treatment and 13 patients treated with Advagraf (ADV). Subsequently, we carried out an in vitro study in which we assessed whether EVE at low- (5, 10 nM) or high-dosage (100 nM) or Tacrolimus (5 nM, 500 nM e 5 μM) was able to induce EMT in bronchial epithelial cells (Nuli-1) and human type II pneumocyte-derived A549 cells. Additionally, microarray analysis was performed to identify new elements involved in this complex machinery.

Results: In the in vivo part of the study, we found that the PFIS was higher in EVE-treated patients compared to those treated with ADV (mean±SD 2.58±1.83 versus 1.21±1.25). This effect was positively correlated to the trough levels (TL) in EVE-treated patients (R2=0.35). The higher PFIS score was measured in patients treated with EVE that reached a TL≥6. Interestingly, in vitro, only very high doses of EVE were able to induce up-regulation of alpha-SMA, Fibronectin and Vimentin at gene and protein level in A549. No effects were seen in Nuli-1. Interestingly, microarray analysis confirmed the above-mentioned results.

Conclusions: All togheter, our data suggested that only very high doses of EVE may induce pulmonary fibrosis and that this effect could be mediated by EMT in pnemocyte cells.

FR-PO1075

Efficacy and Safety of Three Different Treatment Regimen in De Novo Renal Transplant Patients: 48 Months Follow-Up Results of the HERAKLES Trial Wolfgang Arns,[1] Volker Kliem,[1] Claudia Sommerer,[1] Johannes Jacobi,[1] Bruno Vogt,[2] Ingeborg A. Hauser,[1] Petra Reinke,[1] Rolf A. Stahl,[1] Thomas Rath,[1] Martina Porstner,[3] Martin G. Zeier,[1] Frank Lehner,[1] Klemens Budde,[1] Oliver Witzke.[1] *[1]HERAKLES Study Group, Germany; [2]HERAKLES Study Group, Switzerland; [3]Novartis Pharma, Germany.*

Background: To compare safety and efficacy of 3 different immunosuppressive regimen at month (mo) 48 after kidney transplantation (KTx).

Methods: 802 patients (pts) were included in this 1 year, prospective, open-label, randomized, controlled multi-center study with observational follow-up (FU) to mo 60 post Tx. After induction therapy all pts received cyclosporine A (CsA), enteric-coated mycophenolate sodium(EC-MPS) and steroids. 3 mo post Tx, 499 pts were randomized 1:1:1 to either a) continue standard CsA(100-180ng/ml)+EC-MPS(n=166) (STD) or convert b) to a calcineurin inhibitor (CNI)-free regimen with everolimus (EVR) (5-10ng/ml) + EC-MPS (n=171) or c) to a CNI-reduced regimen with EVR (3-8ng/ml) + reduced CsA (50-75ng/ml; n=162). All pts continued on steroids. At time of mo 48 FU interims-analysis data were available from 110(73%) STD, 117(79%) CNI-free and 111(76%) CNI-low treated pts of the FU ITT population.

Results: From randomization to mo 48 BPAR was reported in 19/151(13%) STD, 24/149(16%) CNI-free and in 23/147 (16%) CNI-reduced pts (ITT; p=ns). 5 deaths (3%) occurred in STD, 3(2%) in CNI-free and 6(4%) in the CNI-reduced group. 9(6%) graft losses were observed in the STD, 6(4%) in the CNI-free and 2(1%) in the CNI-reduced group. Composite failure (BPAR, death, graft loss, loss to FU) occurred in 32(21 %) STD, 36(24%) CNI-free and in 39(27%) CNI-reduced treated pts. Premature discontinuation due to AEs was reported for 5(3%) of STD, 5(3%) of CNI-free and 1(1%) of CNI-reduced patients (safety-population) since mo 12 to 48. eGFR (Nankivell, LOCF) was significantly improved by +6.8mL/min in favor of the CNI-free regimen at mo 48 (ITT;p=0.02).

Conclusions: Mo48 results from HERAKLES show that immunosuppressive regimen using EVR with reduced-dose or without CNI-exposure reflect an efficacious and safe therapeutic approach offering the opportunity for an individualized immunosuppression to minimize CNI-exposure.

SparTacus: Multicentre, Prospective Randomised Study Comparing Tacrolimus Hexal® versus Prograf® Based Regimen in De Novo Renal Transplant Recipients Wolfgang Arns,[1] Thomas Rath,[1] Lars C. Rump,[1] Klemens Budde,[1] Daniel Baeumer,[2] Peter Schenker.[1] *[1]Spartacus Study Group; [2]Novartis Pharma Germany.*

Background: In a transplant (Tx) setting, studies evaluating pharmacokinetic (PK) parameters and therapeutic equivalence of generic tacrolimus vs the reference drug are lacking. SparTacus (NCT01649427) study was designed to compare PK profile of tacrolimus hexal® with prograf® in renal Tx recipients (RTxR).

Methods: In this prospective, two-phase open-label study, 76 de novo RTxR were randomised to receive tacrolimus hexal® (n = 35) or prograf® (n = 41), both in combination with enteric-coated mycophenolate sodium + corticosteroids + basiliximab induction therapy. Starting dose of tacrolimus was 0.15 mg/kg/day, adjusted to target trough levels (C0) of 8–12 ng/mL from Tx to month (M) 1; 5–10 ng/mL up to M3; and 5–8 ng/mL up to M6. Primary objective of the study in phase I was to demonstrate comparable PK (ratio of $AUC_{0\text{-}12h}$ one month period) of tac. hexal® vs prograf®.Here we present the PK results of the first month.

Results: At M1, the dose-normalised tacrolimus 12-h-AUC (h/10^3XL) was comparable between tac. hexal® vs prograf® (adjusted log-transformed LS mean, 2.9 vs 3.0; difference, 0.076; 90% CI: –0.169, 0.321, p = 0.605; adjusted back-transformed LS mean, 19.0 vs 20.5; ratio, 1.079; 90% CI: 0.844, 1.378, p = 0.605). LS mean value for Cmax (1/10^3XL) and mean 12 h tacrolimus C0 (mg/L) at M1 were comparable between tac. hexal® vs prograf® (Cmax, 1.1 vs 1.2; difference, 0.150; 90% CI: –0.134, 0.435; p = 0.377; C0, 12.2 vs 11.1, respectively). Of 76 patients, 40 (PK-Set 40 pts.) to date completed 6-M treatment; tac. hexal®, n = 19; prograf®, n = 21. At M6, tacrolimus hexal® vs prograf® had a comparable incidence of composite events (ITT, n=76) (5.7% vs 9.8%, p = 0.681) and its individual components (BPAR [5.7% vs 7.3%], graft loss [0.0% vs 2.4%], death [0.0% vs 2.4%]). Incidence adverse events (AEs, SAE) were comparable (AEs: 97.1 % vs 100%; serious AEs: 37.1% and 42.1%).

Conclusions: Tacrolimus hexal® has a PK profile similar to that of prograf®, with comparable efficacy and safety in de novo RTxR.

FR-PO1077

Monitoring of Ciclosporin by NFAT-Regulated Gene Expression Reduces the Cardiovascular Risk – The CIS Trial Claudia Sommerer,[1] Janina Brocke,[1] Stefan Meuer,[2] Martin G. Zeier,[1] Thomas Giese.[2] *[1]Nephrology, Univ Hospital, Heidelberg, Germany; [2]Immunology, Univ Hospital, Heidelberg, Germany.*

Background: Adequate monitoring tools are required to optimize the immunosuppressive therapy of an individual patient. A new pharmacodynamic monitoring tool has been established to measure directly the functional effect of ciclosporin A (CsA) in an individual patient. This is the first randomized controlled study comparing standard pharmacokinetic monitoring by CsA trough (C0) levels to pharmacodynamic monitoring by NFAT-regulated gene expression.

Methods: Stable renal allograft recipients were included in this 6-month, prospective, open-label, randomized, controlled study. All patients received triple immunosuppression (CsA, MPA, steroids). Patients were randomized 1:1 to either continue a) CsA therapy monitored by CsA C0 (80-150ng/ml) or b) CsA therapy monitored by NFAT-regulated gene expression (15-30%). The expression of the NFAT-regulated genes (IL2, IFNγ, GM-CSF) were determined by qRT-PCR at CsA C0 and C2. The cardiovascular risk was assessed by change of pulse wave velocity (PWV) from baseline to month 6.

Results: 55 patients were enrolled (35 male; Age 51.5±12.9y; time after transplantation 69.8±73.7m). CsA dose was 96±25ng/mL in the NFAT-group and 93±22ng/mL in the standard-group. Residual NFAT-regulated gene expression was 13±9%. Patients monitored by the pharmacodynamic assay with NFAT-regulated gene expression showed a significant decline in PWV from baseline to month 6 compared to the standard group (-1.68±2.02 vs. 0.38±1.42 m/s, p<0.0001). Renal function was stable in both study cohorts. An acute rejection episode occurred in one patient of the NFAT-group who refused to increase CsA dose according to results of NFAT regulated gene expression.

Conclusions: Renal allograft recipients on CsA therapy monitored by the residual NFAT-regulated gene expression showed a significantly better cardiovascular risk assessed by PWV compared to patients on standard CsA C0 monitoring. NFAT-regulated gene expression proved in this first randomized controlled trial as an efficacious and safe approach to individualize CsA therapy with the opportunity to improve the cardiovascular risk profile.

FR-PO1078

Follow-Up Results of HERAKLES Trial on Three Different Treatment Regimen and Switching Off Behaviour in De Novo Renal Transplant Patients After 4 Years Claudia Sommerer,[1] Oliver Witzke,[1] Johannes Jacobi,[1] Wolfgang Arns,[1] Bruno Vogt,[2] Petra Reinke,[1] Ingeborg A. Hauser,[1] Rolf A. Stahl,[1] Thomas Rath,[1] Martina Porstner,[3] Frank Lehner,[1] Volker Kliem,[1] Klemens Budde,[1] Martin G. Zeier.[1] *[1]HERAKLES Study Group, Germany; [2]HERAKLES Study Group, Switzerland; [3]Novartis Pharma, Germany.*

Background: To compare switching off 3 different immunosuppressive (IS) regimen 4 years after renal transplantation (Tx).

Methods: 802 patients (pts) were included in this prospective, open-label, randomized, controlled multi-center study with observational follow-up (FU) to month (mo) 60 post Tx. All pts received cyclosporine A (CsA), enteric-coated mycophenolate sodium (EC-MPS) and steroids; at 3 mo post Tx 499 pts were randomized 1:1:1 to either a) continue standard CsA (100-180ng/ml) +EC-MPS(n=166) (STD) or convert b) to a calcineurin inhibitor (CNI)-free regimen with everolimus (EVR) (5-10ng/ml) + EC-MPS(n=171) or c) to a CNI-reduced regimen with EVR (3-8ng/ml) + reduced CsA (50-75ng/ml;n=162). All pts continued on steroids.

Results: At 48 mo post Tx, 40% CNI-free, 30% CNI-reduced and 55% of STD treated pts were still on their initial assigned treatment and available for mo 48 analysis. Drop-out frequency among FU ITT population from randomization to mo 48 was 17%,15% and 14% for STD, CNI-free and CNI-reduced groups, respectively. Premature discontinuation due to AEs occurred in 5(3%) of STD, 5(3%) of CNI-free and 1(1%) of CNI-reduced pts (safety-population) from mo 12 to 48. The CsA trough levels in CNI-reduced group were in the higher end of target levels (50–75 ng/mL) in non-switcher population; whereas in switcher population they were beyond the target levels. In non-switcher population, eGFR (Nankivell) was significantly improved by +13.7 mL/min in favor of CNI-free regimen at mo 48 (p<0.001).

Conclusions: Mo 48 HERAKLES results show that IS regimen using EVR with reduced-dose or without CNI-exposure reflect an efficacious and safe therapeutic approach offering the opportunity for an individualized IS to minimize CNI-exposure. Drop-out rates over 4 years post Tx showed relative similar adherence rates between groups. Pts that never switched off the assigned CNI-free regimen reached a markedly improved GRF.

FR-PO1079

Intensified Dosing of Mycophenolate Mofetil Is Associated with Slower Progression of Chronic Renal Allograft Injury – Results from a Randomized Controlled Trial Mladen Knotek,[1] Miha Arnol,[2] Jadranka Buturovic-Ponikvar,[2] Danica Galessic Ljubanovic,[5] Nika Kojc.[3] *[1]Dept of Medicine, Renal Div, Univ of Zagreb Medical School, Merkur Univ Hospital, Zagreb, Croatia; [2]Dept of Nephrology, Univ Medical Centre Ljubljana, Ljubljana, Slovenia; [3]Inst of Pathology, Univ of Ljubljana Medical Faculty, Ljubljana, Slovenia; [4]Dept of Pathology, Dubrava Univ Hospital, Univ of Zagreb Medical School, Zagreb, Croatia; [5]Univ of Zagreb School of Medicine, Dubrava Univ Hospital.*

Background: Interstitial fibrosis (ci) is a major histological predictor of long-term graft outcome. This randomized controlled trial (NCT01860183) was designed to evaluate the effect of intensified mycophenolate mofetil (MMF) dosing on progression of ci during the first year post kidney transplant (KT).

Methods: Immunologically low-risk KT recipients were randomized on MMF 3g/d, or 2g/d during the first year post KT. Immunosuppression consisted of basiliximab induction, with tacrolimus, MMF ± steroids. Protocol biopsies were performed at implantation, and at 12 months post KT and were scored according to the Banff. Progression of ci (Dci) was calculated as ci12-ci0. MMF dose was calculated as an average dose at 1, 3, 6 and 12 months. Difference in Dci with respect to MMF dose was analyzed in an ITT population using one-way ANOVA.

Results: Here we report interim results from patients who completed 12 month follow-up by June 1st 2015. Patient and KT data are were similar in MMF 3g and MMF 2g group, except for average MMF dose, which was higher in the 3g group (2697.1±321.6 vs. 1745.5±359.0 g, p<0.001). In an overall study population ci progressed during first 12 months post KT from 0.45±0.51 (ci0) to 1.41±0.87 (ci12) (p<0.001). Dci was lower in the MMF 3 g group (0.60±0.74) as compared with MMF 2g group (1.36±0.93; p=0.021). Serum creatinine at 1 year was similar in both MMF groups (116.5±25.0 vs. 115.1±33.7; p=0.899). Incidence of acute rejection was similar and no significant differences were seen in common adverse events between both groups.

Conclusions: Intensified dosing of MMF (3g daily) during the first posttransplant year in a tacrolimus-based regimen may be associated with slower progression of chronic allograft injury.

Safe Conversion from Tacrolimus to Belatacept in Kidney Transplant Recipients with Allograft Dysfunction Anil Regmi, Dhiren Kumar, Hasan Fattah, Anne L. King, Pamela Kimball, Ankur Atal Gupta, Gaurav Gupta. *Virginia Commonwealth Univ, Richmond, VA.*

Background: Belatacept might be an alternative to Calcineurin Inhibitors (CNI) to avoid short and long-term nephrotoxicity. Prior data on low immunologic risk de-novo kidney transplant recipients (KTxp) with stable graft function switched from a CNI to belatacept demonstrated improved renal function. There is minimal data on the use of belatacept for sensitized patients and those with impaired graft function [estimated glomerular filtration rate (GFR) <35].

Methods: EBV seropositive patients were converted to belatacept from tacrolimus for biopsy proven presumed acute CNI toxicity and/or interstitial fibrosis/tubular atrophy. Belatacept was initiated based upon prior published protocol (Grinyo et al., Transpl Int. 2012 Oct). Mycophenolate dose was increased from baseline dose of 1-2g/d to a dose of 2-3g/d to minimize risk of rejection.

Results: Seventeen (mean age=46±10 years) patients were switched from tac to belatacept at a median of 4 months post-KTxp. A majority were African-American (13/17; 76%) and received deceased donor KTxp (76%). Seven patients (41%) were sensitized (median PRA=31%; range=0-99%). Renal function improved significantly from a peak mean GFR of 28±12 ml/min/1.73m^2 to an GFR of 42±16ml/min/1.73m^2 (p=0.001) at a median follow-up of 15 (range=7-30) months post-conversion. Surveillance biopsies performed in 7/17 patients did not show rejection or worsening of chronicity. No evidence of de-novo donor specific antibody (DSA) was noted in 16/17 (94%) patients. One patient with pre-existing DSA and stable creatinine had rising DSA after a viral infection. A biopsy showed subclinical antibody-mediated rejection. There were no cases of BK viremia, CMV disease or malignancies.

Conclusions: In this first study on KTxp patients with significantly reduced GFR we report remarkable improvement in renal function in patients converted from tacrolimus to belatacept with acute CNI toxicity and chronic allograft fibrosis without a significant concurrent increase in risk of rejection, worsening chronicity and DSA. Further studies with protocol biopsies are needed to ensure safety and wider applicability of this approach.

FR-PO1081

Home Infusion of Belatacept in Kidney Transplant Recipients
Flavio Vincenti,[1] M. Abouljoud,[2] JH Helderman,[3] R. Zhang,[4] K. Calderon,[5] S. Chen,[5] SG Rizk,[5] D. Gerber.[6] *[1]Univ of California, San Francisco; [2]Henry Ford Hospital, Detroit; [3]Vanderbilt Univ, Nashville; [4]Tulane Univ Hospital and Clinic, New Orleans; [5]BMS, Lawrenceville; [6]Univ of North Carolina, Chapel Hill.*

Background: Belatacept (bela) is an IV administered selective T-cell co-stimulation blocker approved for preventing organ rejection in EBV-positive adult kidney transplant recipients. The logistics of IV maintenance therapy are challenging for some pts/clinicians; the safety of home infusion has not been well described. Phase 2/3 study participants could have received home infusion of bela under certain circumstances. Here, we compare the safety of bela infused in the home vs a facility.

Methods: Pts in the 008 (BENEFIT/NCT00256750), 027 (BENEFIT-EXT/NCT00114777), 010 (NCT00402168), and 034 (NCT00455013) studies were eligible to receive bela home infusion if the site sought IRB approval and if the pt lived ³2 hrs from the site and had been exposed to bela for >28 wks in 008 or 027, >16 wks in 010, or >6 wks in 034. 008 and 027 compared bela with CsA regimens with basiliximab induction. In 010, pts receiving a stable CNI regimen were switched to a bela regimen. 034 compared bela with tacrolimus steroid-sparing regimens under thymoglobulin induction. Rate and time to pre-specified peri-infusional AEs and peri-infusional serious AEs were recorded in pts who received bela in the home (N=66) or in a facility (N=672).

Results: Pts administered bela in the home received a median of 32.5 (range, 1–61) infusions. No pre-specified or serious peri-infusional AE was reported, including in the 034 study.

Conclusions: No pt (irrespective of steroid use) receiving home infusion of bela had a pre-specified or serious peri-infusional AE. These data suggest that bela was safely administered in the home.

	Facility-Based (N=672)		Home Infusion (N=66)	
	n (%)	Median time to event, days	n (%)	Median time to event, days
Specified Peri-Infusional AEs				
Total patients with an event	1 (0.1)	557	0	0
Device malfunction	0	0	0	0
Device-related infection	0	0	0	0
Infusion site reaction	1 (0.1)	557	0	0
Peri-Infusional Serious AEs				
Total patients with an event	5 (0.7)	783	0	0
General disorders and administration site conditions	2 (0.3)	937	0	0
Pyrexia	2 (0.3)	937	0	0
Nervous system disorders	1 (0.1)	1650	0	0
Dizziness	1 (0.1)	1650	0	0
Vascular disorders	2 (0.3)	159	0	0
Hypertension	1 (0.1)	117	0	0
Hypotension	1 (0.1)	201	0	0

*Pts administered bela in a facility were included in this analysis if they had been exposed to bela for >28 wks in 008 or 027, >16 wks in 010, or >6 wks in 034.

FR-PO1082

Optimizing the Immunosuppression Regimen with Belatacept
David Wojciechowski,[1] Sindhu Chandran,[2] Flavio Vincenti.[2] *[1]MGH; [2]UCSF.*

Background: Belatacept with basiliximab induction plus maintenance MMF/corticosteroids is associated with a higher 3-year eGFR compared to cyclosporine but a higher 1-year incidence of acute rejection. In an attempt to optimize the belatacept immunosuppression regimen we investigated the safety and efficacy of a novel combination utilizing belatacept with rATG induction (3 mg/kg) and maintenance everolimus ± corticosteroids.

Methods: Retrospective single center analysis of the first 33 patients to receive our belatacept regimen compared to a historical control group of 66 patients matched for donor type, KDPI, ESRD cause, CIT, and corticosteroid protocol who met our belatacept criteria (EBV seropositive and low immunologic risk [first transplant, no DSA ≥500 MFI, cPRA £30%]) but received basiliximab induction with maintenance tacrolimus/MMF ± corticosteroids. We compared the 6-month eGFR and the rates of rejection and infection between the groups.

Results: Demographic and transplant characteristics were similar. Mean tacrolimus trough (SD) at months 3 and 6 were 8.7 (2.5) and 8.4 (2.8), respectively. Mean everolimus trough (SD) at months 3 and 6 were 5.5 (2.6) and 5.3 (2.6), respectively. Eleven patients didn't tolerate everolimus and were placed on MMF. Rejection occurred in 3 belatacept (1 of each: type 1a, type 1b and type 2b) and 1 tacrolimus patient (type 2a) (P=0.07). The belatacept rejections occurred in patients who didn't tolerate everolimus and occurred after everolimus was discontinued. By month 6 two grafts were lost in the tacrolimus group with a 100% patient survival for both groups. eGFR at month 6 for belatacept and tacrolimus treated patients was 61.9 (15.3) and 60.1 (21.2), respectively (P=0.51). The incidence of CMV infection, BK viremia, and UTI was similar between the groups.

Conclusions: The findings suggest that a belatacept regimen with limited T cell depletion and an mTORi can maximize efficacy and maintain safety. These results of a synergistic effect of costimulation blockade and mTOR inhibition are consistent with experimental studies and phase 2 data. A larger prospective trial is warranted to fully evaluate this approach.

A Change in Insulin Sensitivity and Lipid Profile in Renal Transplant Recipients Converted from Cyclosporine or Standard Release Tacrolimus to Once-Daily Prolonged Release Tacrolimus
Soo young Kim,[1] Joung wook Yang,[1] Ye na Kim,[1] Ho Sik Shin,[1] Ji-hwan Kim,[2] Yeon soon Jung,[1] Hark Rim,[1] Bong geon Chun,[3] Hyun yul Rhew.[4] *[1]Internal Medicine, Kosin Univ College of Medicine, Busan, Republic of Korea; [2]Internal Medicine, Good GangAn Hospital, Busan, Republic of Korea; [3]Pathology, Kosin Univ College of Medicine, Busan, Republic of Korea; [4]Urology, Kosin Univ College of Medicine.*

Background: New-onset diabetes after transplantation may be associated with the use of tacrolimus (Tac) causing impaired insulin release or reduced insulin sensitivity. And, dyslipidemia commonly occurred after transplantation. Such effects in insulin sensitivity and lipid profile have not been studied in renal transplant recipients receiving traditional twice-daily tacrolimus (TacBID) or cyclosporine and then compared to the new once-daily prolonged release formulation of tacrolimus (TacOD).

Methods: We performed an observational prospective study of 15 stable non-diabetic renal transplant recipients on change in insulin sensitivity and lipid profile in renal transplant recipients converted from cyclosporine or standard release tacrolimus to once-daily prolonged release tacrolimus. We evaluated the level of HbA1c,total cholesterol, HDL, LDL, TG, apolipoprotein A1, apolipoprotein B, serum creatinine, fasting plasma glucose, fasting insulin and HOMA-β at base line, two and four months. To analyze differences in parameter, we performed a t-test in both groups (cyclosporine to TacOD conversion group/TacBID to TacOD conversion group), and GLM-repeated measures ANOVA. HOMA- β = (360 X Fasting insulin)/(Fasting glucoe-63) HOMA-IR(insulin resistance) = (Fasting glucose X Fasting insulin)/405.

Results: At baseline, parametes were not different in both groups (cyclosporine to TacOD conversion group/TacBID to TacOD conversion group). In GLM-repeated measures ANOVA, the result did not showed and any change in insulin sensitivity and lipid profile after conversion at baseline, two and four months.

Conclusions: Conversion from standard TacBID or cyclosporine to TacOD is safe. In spite of a reduced Tac exposure, there was no change in insulin sensitivity and lipid profile in renal transplant recipients.

FR-PO1084

Tacrolimus Dose Requirement Based on the CYP3A5 Genotype in Renal Transplant Patients
Zhoutao Xie, Hong Jiang, Jianghua Chen. *The First Affiliated Hospital, College of Medicine, Zhejiang Univ, China.*

Background: Tacrolimus and ciclosporin A (CsA)are widely used to protect graft function after renal transplantation. The aim of the present study is to determine that whether CYP3A5*A and CYP3A5*G genotype is a predictive index of tacrolimus dose requirement, and even the selection accordance of tacrolimus or CsA treatment.

Methods: We tested archival peripheral blood of 218 kidney recipients for CYP3A5 genotyping with PCR-SSP. The doses and blood concentrations of tacrolimus and CsA for recipients were measured at day7, 1st month , 3rd month,6th month and 12th month after renal transplantation, as well as hepatic and renal function. In addition, we also observed the incident of acute rejection happening on these participants.

Results: 123 patients took tacrolimus treatment and 95 patients took CsA treatment after renal transplantation.In tacrolimus treatment group, genotype CYP3A5*GG was associated with low tacrolimus dose-adjusted concentration after transplantation, showing lower acute rejection rate compared to CYP3A5*AA/AG group but with no significant difference (P=0.154).In CsA treatment group, there was no significant difference in acute rejection rates between CYP3A5*AA/AG and CYP3A5*GG(P=0.494) with no difference in dose-adjusted concentration as well. For CYP3A5*GG patients, tacrolimus treatment cause lower acute rejection rate than CsA treatment (P=0.030), taking shorter time to get a stable immune situation than CsA treatment. For CYP3A5*AA/AG patients, tacrolimus treatment cause similar acute rejection rate with CsA treatment (P=0.982), but took longer time to get a stable immune situation than CsA treatment. What's more, tacrolimus treatment costs much than CsA treatment.

Conclusions: These results indicate that CYP3A5*AA/AG carriers need higher tacrolimus dose than CYP3A5*GG homozygote to achieve the target blood concentration. CYP3A5*GG carriers preferred to tacrolimus treatment and CYP3A5*AA/AG carriers preferred to CsA treatment depended on the incomes. CYP3A5 genotyping is a new approach for detecting tacrolimus dose requirement and a predictive index for the tacrolimus or CsA treatment selection in the kidney recipients.

FR-PO1085

Intrapatient Tacrolimus Level Variability in Pediatric Kidney Recipients Predicts Allograft Loss After Transfer to Adult Care Hilda E. Fernandez,[1] Sandra Amaral,[2] Pamela A. Shaw,[3] Roy D. Bloom,[3] Alden Michael Doyle,[4] Sumit Mohan,[1] Susan L. Furth.[2] *[1]Columbia Univ; [2]CHOP; [3]PENN; [4]Hahnemann Univ.*

Background: Allograft loss is especially common in 17-24 year olds and is associated with non-adherence around the time that transplant care is transferred from the pediatric to adult setting. We explored whether coefficient of variation of tacrolimus (CV TAC) levels prior to transfer, as a marker of non-adherence, predicted allograft loss in a cohort of pediatric kidney recipients transferring to adult transplant centers.

Methods: Retrospective cohort of transplant recipients at Children's Hospital of Philadelphia transplanted 1999 to 2011 who transferred care to University of Pennsylvania or Hahnemann University Hospital, identified by chart review. CV TAC was calculated as SD divided by mean TAC over 12 mos. Date of transfer was defined as the last pediatric visit. We compared pre-transfer TAC CV in those that subsequently lost their graft to those that did not (t-test).

Results: 24 of 65 subjects had sufficient data for analysis. Median age at transplant was 15.9y (8.5-18.9). The cohort was primarily male (66%), White (77%), had CAKUT (8%), and 46% had LRKT. Median age at transfer was 20y (17.4-22.1). Four patients had allograft loss within 365 days post-transfer. Pre-transfer CV TAC for subjects with allograft loss post-transfer (n=4) was significantly higher as compared to subjects without allograft loss (n=20) (49.4% vs 26.2%, p = 0.0275).

Conclusions: CV TAC may aid in identifying patients at risk for allograft loss post-transfer. Future analysis will investigate the effect of race, age at transfer, rejection, *de novo* DSA pre-transfer that may also help predict adolescent kidney transplant recipients at risk for allograft loss following transfer to adult transplant centers.

FR-PO1086

High Tacrolimus Level Variability in the Early Post-Transplant Period Is Associated with Reduced Patients and Graft Survival After Kidney Transplantation Benaya Rozen-zvi,[1] Avry Chagnac,[1] Ruth Rahamimov.[1,2] *[1]Nephrology and Hypertension, Rabin Medical Center, Petach-Tikva, Israel; [2]Organ Transplantation, Rabin Mrdical Center, Petach-Tikva, Israel.*

Background: The effect of Tacrolimus levels variability in the early period after kidney transplantation was not properly studied. We sought to evaluate whether increased drug level variability is associated with reduced graft survival and evaluated the relative effect of exposure to high and low drug levels.

Methods: We screened the Rabin Medical Center registry database for adult patients from 2001 to 2013 that were treated with tacrolimus, micophenolate mofetil and corticosteroids and had at least 6 values of drug level during the first six months after the transplantation. Variability was defined as the time average of the absolute value of the difference from the mean and this value was divided by the mean to get the variability index. Univariate and mulivariate Cox proportional hazard model was used with the combination of death and graft failure as composite outcome.

Results: We identified 803 patients who met the inclusion criteria, ninety eight (12.2%) of them reached the end point during median follow up time of 3.7 years (range 0.5 to 12.9 years). Increased variability index was associated with increased hazard of death or graft failure by univariate (Hazard Ratio (HR) 1.029 per 1%, 95% Confidence Interval (CI) 1.006-1.052, p=0.013) and multivariate models (HR 1.036 per 1%, 95% CI 1.01-1.062, p=0.006). Variability was still significantly associated with reduced graft survival after introducing acute rejection into the model (HR 1.038 per 1%, 95% CI 1.008-1.056, p=0.008). Introducing exposure to levels above 15 ng/ml into the model didn't change the association between variability index and the composite outcome while introducing exposure to levels below 5 ng/ml eliminated the association and made it non-significant (p=0.18).

Conclusions: High variability index in the first six month after kidney transplantation is associated with increased mortality and graft loss. This association is, probably, mediated by exposure to low drug levels.

FR-PO1087

Decision Tree Analysis of Renal Transplantation Recipients Outcomes: A Single Center Data Mining Jingyi Zhou, Jianghua Chen. *Kidney Disease Center, The First Affiliated Hospital, College of Medicine, Zhejiang Univ, Hangzhou, China.*

Background: Results from former literature on factors influencing renal transplant outcomes are quite confusion and few include factors influencing outcomes of rejection cases. This study was intended to get the factors in order and to provide reliable predictive models for clinical practice with decision tree analysis, and attempted to discuss about decision tree integrated with renal transplant database to fulfill the dynamic model growth and to serve personal medical care in big data era.

Methods: Renal transplant recipients registering between May 1988 and April 2014 in Kidney Center of the First Affiliated Hospital of Zhejiang University were included. Living state, rejection state, state post rejection and overall outcomes were analyzed by decision tree.

Results: Totally 3921 cases were included. The loss-to-follow rate is 9.7%. With survival rate as the object, we got the most important factor, steroids ($P < 0.01$). Patients in the following factor combination showed the highest survival rate: steroids, mycophenolate mofetil (MMF), stenting, warm ischemic time (WIT) ≤6.5min, cold ischemic time (CIT) £300min, and aspartate aminotransferase (AST) 6 months post operation£34U/L (survival rate 100%, 305 cases). Patients had the lowest acute rejection rate when in the factor combination: steroids, antihuman thymocyte globulin or basiliximab induction, no blood transfusion history and female (0%, 83). Patients with acute rejection were regarded as a new database. The patients who took steroids and received stents shows similar outcomes with patients who had no rejection. Important factors that could be intervened for long-term outcomes included stenting, statins, steroids, etc.

Conclusions: Decision tree analysis is an outstanding choice for risk stratification, prognosis prediction and dynamic follow-up. Immunosuppression therapy was regarded as the most important factor for renal transplant recipients' survival, rejection and other outcomes. Factors should be considered in combination for each specific patient.

FR-PO1088

Comparison of Clinical Outcome Between ABO Incompatible and Compatible Spousal Donor Kidney Transplantations Ji Hyun Yu,[1] Byung ha Chung,[1] Bum soon Choi,[1] Curie Ahn,[2] Sung-joo Kim,[5] Chul Woo Yang.[1] *[1]Transplantation Research Center, Internal Medicine, Nephrology, Seoul St. Mary's Hospital, Seoul, Republic of Korea; [2]Transplantation Center, Seoul National Univ Hospital, Seoul, Republic of Korea; [3]Surgery, Severance Hospital, Yonsei Univ College of Medicine, Seoul, Republic of Korea; [4]Organ Transplantation Center, Busan Paik Hospital, Inje Univ School of Medicine, Busan, Republic of Korea; [5]Surgery, Samsung Medical Center, Sungkyunkwan Univ School of Medicine, Seoul, Republic of Korea.*

Background: Spousal donor is an important source to overcome shortage of living donor in kidney transplantations (KTs). We aimed to compare the clinical outcomes in ABO incompatible KT (ABOi-KT) to those of ABO compatible KT (ABOc-KT) from spousal donors.

Methods: We analyzed 580 KTs from spousal donors among 3043 living donors KTs registered in the Korean Organ Transplantation Registry. Clinical outcome between ABOi-KT and ABOc-KT were compared by episodes of acute rejection (AR), graft function, grafts and patients survival rates.

Results: The proportion of spousal donors in ABOi-KT was higher than that of ABOc-KT (40.9% vs. 21.4 %, $P < 0.001$). The biopsy proven AR -free survival rate in ABOi-KT was comparable to ABOc-KT (79.7% vs. 82.3%, P=0.188). The renal allograft function showed no difference until 36 months after KT. The 3-year graft survival (92.5% vs. 95.7%), and patient survival (96.4% vs. 98.5%) were not significantly different between ABOi-KT and ABOc-KT groups ($P > 0.05$, respectively). Multivariate analysis revealed that ABOi-KT from spousal donors did not affect the graft, patient survival and BPAR-free survival rate.

Conclusions: The results of our study show that the ABOi spousal donor is an important source of living donor, and can be a good alternative of overcoming donor organ shortage.

FR-PO1089

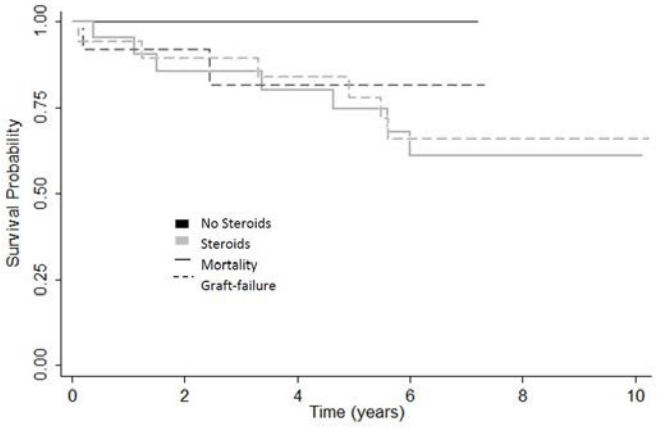
3-Year Outcomes After ABO Incompatible Kidney Transplantation without Steroids Shefali Patel, Mariana C. Chiles, Sumit Mohan, Russell J. Crew. *Columbia Univ, New York, NY.*

Background: Early steroid withdrawal paired antibody induction therapy provides comparable outcomes to steroid maintenance patients. However, ABOi transplantation is considered higher immunologic risk, and it unclear if a steroid free regimen is appropriate for this population.

Methods: We performed 40 ABOi transplants with pre-transplant plasmapheresis(PP) with IVIG to an isohemagglutinin titer £1:16 and 2 post-txp PP/IVIG treatments, immunosuppression with tacrolimus, mycophenolate, and intraoperative rituximab (375mg/m^2). Prior to 2008, patients received an IL-2 receptor blocker, and prednisone tapered to 5 mg by 6 months. After 2008, induction included Thymoglobulin® (6 mg/kg in 4 divided doses) and steroid withdrawal by postop day #3. Patients underwent protocol biopsies at predefined intervals. We compared outcomes at 3 years between those who had and had not received maintenance steroids.

Results: 24 patients received maintenance steroids and 16 underwent rapid steroid withdrawal. There were no differences in sex, starting isohemagglutinin titer, or blood group mismatch between the groups. Antibody mediated rejection was more common in the steroid maintenance group (41% vs 31%) as was cellular rejection (50% vs 47%), though not significantly different. At 3 years, renal function was similar between those with and without steroids- eGFR 46±25 cc/min vs 52±15 cc/min, respectively. Approximately 50% of patients underwent protocol biopsy at 3 years. There were no differences in the degrees of interstitial fibrosis, glomerulosclerosis, or transplant glomerulopathy between groups. Graft survival, patient survival, and infectious complications were also similar.

Conclusions: Even in higher immunologic risk ABOi transplant recipients, rapid steroid withdrawal appears to provide similar medium term results as steroid maintenance therapy without the longterm side effects.



FR-PO1090

Three Year Outcome of a Pioneer ABOi Renal Transplant Programme in Malaysia Si-Yen Tan,[1] Mohan Rao,[2] Eng-Thye Koh.[2] *[1]Medicine, Prince Court Medical Centre, Kuala Lumpur, WP, Malaysia; [2]Surgery, Prince Court Medical Centre, Kuala Lumpur, WP, Malaysia.*

Background: ABO incompatible (ABOi) renal transplantation increases organ donor pool and is an option for patients with no blood group compatible donors. We report here results of a pioneer ABOi renal transplant programme in Malaysia which was first established in Prince Court Medical Centre in 2011.

Methods: Ten patients entered into our ABOi programme between July 2011 and December 2013. Data were analyzed to determine the number of therapeutic plasma exchange (TPE) and/or immunoadsorption (IA) with Glycosorb columns to achieve target pre transplant ABO antibody titres of < 1:16 and ABO titres post transplant. Graft function and rejection rates together with graft and patient survival at 3 years were also determined.

Results: Median baseline ABO titres was 1:128 and all patients achieved target pre transplant ABO titres of < 1:16 after a median of 4 TPE and/or IA. Median follow up was 32 months with all patients maintaining ABO titres of < 1:16 at follow up with no protocol post transplant TPE/IA. There was 1 case (10%) of acute cellular rejection at one year which was reversed with steroids but none had antibody mediated rejection. Patient and graft survival was 100% at 3 years with current median serum creatinine 108umol/L.

Conclusions: The results of our pioneer ABOi renal transplant programme with graft and patient survival of 100% at 3 years is extremely encouraging and suggest that graft and patient outcome is similar to ABO compatible renal transplants. The use of ABO incompatible donors may effectively increase organ donor pools especially in countries where both cadaver and living related kidney transplant rates remain poor. Our results also suggest that national ABOi renal transplant programmes may be effectively introduced and led by a private medical centre to complement and support more established renal transplant programmes in government institutions which are now beginning to perform their own ABOi renal transplants in light of our success.

FR-PO1091

Improved Graft Outcome After Blood Transfusion: Still in Effect? Gowrie Balasubramaniam,[1] Arun Gupta,[2] Neil Ashman,[2] Raj Thuraisingham.[2] *[1]Dept of Medicine, Southend Univ Hospital, Southend, Essex, United Kingdom; [2]Dept of Nephrology and Transplantation, Barts and The Royal London Hospital, London, United Kingdom.*

Background: Blood transfusions can lead to sensitisation in potential transplant patients. We previously quantified the risk of sensitisation from transfusion per se by looking at a cohort of male patients on the transplant waiting list and ascertaining the transfusion history from electronic records and questionaires. Prior to standard triple immunosuppression, transfusions were associated with overall better graft outcome possibly by a tolerogenic effect or by selecting non-sensitisers. The majority of patients who were transfused do not become sensitised, we wanted to characterise graft outcome in this group.

Methods: We obtained graft outcome information on the original cohort of patients. Data was collected prospectively as part of routine surveillance.

Results: 100 out of the initial 126 male patients were transplanted. 10 were excluded from further analysis due to death or graft loss in the immediate post-transplant period. 11 of remaining 90 patients were DSA prior to transplantation, 8 also had a history of previous blood transfusion. 4 of the 8 patients with a previous blood transfusion and DSA had a rejection episode (2 AMR and 2 ACR). Of the remaining 79 patients who were DSA negative prior to transplantation, 26 had a previous transfusion (TR+ DSA-) and 53 did not have a history of transfusion (TR- DSA-). Comparison between the two groups is shown in (table 1).

	TR+ DSA-	TR- DSA-
Rejection rate ACR AMR	2/26 2 0	15/53 12 3
Recipient age	50.1 ± 11.5	48.2 ± 9.9
Donor age	49.0 ± 13.2	45.1 ± 14.4
Donor type LT HB NHB	 2 13 11	 10 28 15
CIT	768.1 ± 284.5	730 ± 368.6
Immunosuppression Induction ATG IL-2 agent Campath Maintenance Cya, MMF, Pred FK, MMF, Pred FK, Aza, Pred FK, Pred	 11 15 0 23 3 0 0	 17 35 1 50 0 2 1

Conclusions: Lack of sensitisation with a history of leuco-depleted transfusion is associated with a lower risk of rejection post-transplantation. This suggest that previous mechanisms of transfusion tolerance or "non-sensitisers" are still relevant in the modern immunosuppression era.

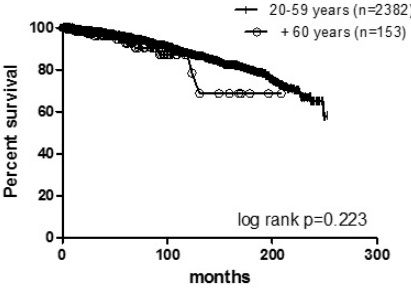
FR-PO1092

Geriatric Renal Transplantation in Deceased Donor Showed Compatibile Clinical Outomes to Younger Recipients Hyungjin Cho, Eunhye Shin, Hyosang Kim, Su-Kil Park. *Dept of Internal Medicine, Div of Nephrology, Asan Medical Center, Seoul, Republic of Korea.*

Background: According to USRDS annaul report, while 50.3% of patients who start hemodialysis were aged over 65 years, only 19.3% of patients who underwent renaltransplantation was aged over 65 years. Elderly ESRD patients still are not underwent renal transplantation as much as younger recipients. There were many previous studies about geriatric renal transplantation outcome in white, however data in Asain were limited. The aim of this study is analysis of geriatric kidney transplanation outcome in Korea.

Methods: From May 1993 to December 2013, kidney transplantations performed in Asan medical center were retrospectively reviewed. Recipients younger than 20 years and who underwent other organ transplantation were excluded. Binary logistic regression was used for evaluating risk factors of graft failure before half-life. Half life of kidney allograft was defined as 10 years according to previous study.

Results: Regardless of donor type, there is no statistically significant difference in death censored graft survival between geriatric population and younger recipients.



Multivariate analysis of deceased donor recipients revealed that recipients aged over 60 years was not a significant risk factor for graft failure before half-life.

	univariate analysis			Multivaiate analysis		
	p	Hazard ratio	95% CI	*p*	Hazard ratio	95% CI
+ 60 years	0.604	1.263	0.522-3.056			
Female	0.219	0.767	0.503-1.171			
Cold ischemic time	0.655	1.000	0.999-1.001			
Donor age	0.031	1.018	1.002-1.035	0.036	1.017	1.001-1.033
Re-transplantation	0.531	1.272	0.599-2.705			
Diabetes mellitus	0.002	2.841	1.475-5.473			
Hypertension	0.931	0.959	0.376-2.447			
HLA DR mismatch	0.932	1.035	0.473-2.266			
Dialysis before transplantation	0.382	2.085	0.402-10.826			

Conclusions: Renal transplantation in geriatric population can be encouraged in Asain ESRD patients.

FR-PO1093

Long-Term Survival and the Associated Risk Factors for Death in Patients (pts) with Kidney Transplantation (Tx) Tanja Abeling,[1] Irina Scheffner,[1] Verena Broecker,[2] Michael Mengel,[3] Hermann G. Haller,[1] Anke Schwarz,[1] Wilfried Gwinner.[1] *[1]Hannover Medical School, Germany; [2]Cambridge Univ, United Kingdom; [3]Univ of Alberta, Canada.*

Background: Deaths over a period of up to 10 years (yrs) and the related risk factors were studied in Tx pts with protocol biopsies (Bx) (total observation: 4805 patient-yrs).

Methods: 892 pts with kidney Tx in 2000-2007 were included. Protocol Bx were taken at 6 weeks, 3 and 6 months post-Tx (n=2251). 862 Bx for cause were taken in the 1st year and 262 thereafter. Lost-to follow-up was negligible (n=15). All acute rejections and clinical borderline cases in protocol Bx were treated.

Results: Patient and graft survival was 80% at 5 yrs and 68% at 10 yrs. Patient survival was 92% at 5 yrs and 82% at 10 yrs. 99 deaths occurred, relating to infection (24%), cardiovascular disease (15%), malignancy (16%), other specified causes (8%). Deaths were less in living-donor or kidney/pancreas Tx and more frequent for extended donor criteria-Tx. A three-level multivariate Cox regression model was created in a stepwise fashion, using significantly different variables from the pre-Tx, peri-operative, and long-term post-Tx period between survivors and deceased pts. Pre-Tx variables in the final model included recipient age, HLA-DR mismatches, diabetes, coronary heart disease, heart failure, and peripheral arterial disease. A significant peri-operative variable was cold ischemia time. In the long-term course, variables for death included increased loss of graft function, urinary tract infection, and higher PTH levels. Compared to the survivors, deceased pts received more therapies for rejection seen in protocol Bx (0.30 vs. 0.43 per patient) and in Bx for cause (0.29 vs. 0.34 per patient), however, this was not a significant factor in the final model. Also, the proportion of anti-rejection treatments was not higher in pts who died from infections, compared to pts dying from other causes. Concordance of the final model was 0.79; 200-fold bootstrapping confirmed its applicability.

Conclusions: Based on these results a tool is presented that readily allows risk calculation and stratification of individual pts, as a pre-requisite for individualized and optimal pre- and post-Tx care.

Funding: Government Support - Non-U.S.

FR-PO1094

Causes of Death-Censored Kidney Allograft Failure: A Matched Case-Control Study of 340 Kidney Allograft Recipients Mohamad M. Alkadi,[1] Jim Kim,[2] Choli Hartono,[1] Thangamani Muthukumar,[1] Meredith J. Aull.[1] *[1]Medicine, Weill Cornell Medical College, New York, NY; [2]Surgery, Weill Cornell Medical College, New York, NY.*

Background: Causes of kidney allograft failure in the current era of immunosuppression have not been clearly defined.

Methods: We did a matched case-control study of death-censored allograft failures among the 1672 adult kidney transplants at our center between 11/2001 and 12/2011. The cases and controls were matched 1:1 for age, donor type and year of transplant. We reviewed the charts and used the last available biopsy diagnosis for each case to determine the cause of graft failure. We divided the causes of graft failure into 8 categories; (i) acute rejection, (ii) transplant glomerulopathy, (iii) IF/TA, (iv) glomerular diseases, (v) BK nephropathy, (vi) others/unclassified, (vii) surgical and (viii) medical causes. We used conditional logistic regression analysis to determine the odds ratio.

Results: We identified 175 graft losses during the study period and matched 170 of them (cases) 1:1, with 170 controls. There was no statistically significant differences between cases and controls in terms of donor sex, recipient sex, donor race, recipient race, number of transplants, induction therapy or maintenance therapy. 86% of patients received antithymocyte globulin induction. The median follow up in the cases and controls was 22 months and 56.5 months, respectively. 72% of cases had a biopsy done within 12 months of graft failure. The proportion of cases and controls in the 8 diagnostic categories and their respective conditional odds ratio is shown in the table below.

	Cases	Controls	OR (95% CI)	P value
Acute Rejection	36	11	4.5 (2-10.3)	< 0.001
Transplant Glomerulopathy	15	4	3.7 (1.2-11.2)	0.01
Glomerular Disease	29	4	7.2 (2.5-20.6)	< 0.001
BKV Nephropathy	10	1	9.9 (1.2-78.1)	0.02
Primary IFTA	7	1	6.9 (0.8-56.8)	0.07
Surgical Causes	18	0	----------	---------
Medical Causes	24	0	----------	---------
Other Histology	31	22	1.5 (0.8-2.7)	0.1

Conclusions: In the modern era of immunosuppression, allo-immune rejection and auto-immune glomerular disease continue to be significant factors associated with graft failure.

FR-PO1095

Effect of Simultaneous Native Nephrectomy on the Outcome of Kidney Transplant Recipients with Autosomal Dominant Polycystic Kidney Disease Jeong Ho Kim, Bum soon Choi, Cheol Whee Park, Chul Woo Yang, Yong-Soo Kim, Byung ha Chung. *Internal Medicine, Seoul St. Mary's Hospital, Seoul, Korea.*

Background: End stage renal disease (ESRD) patients with autosomal dominant polycystic kidney disease (ADPKD) required native nephrectomy because of limited space for renal allograft. However, the appropriate timing for nephrectomy and also its effect on allograftand patient survival has not been fully investigated.

Methods: We retrospectively analyzed 41 kidney transplant recipients with ADPKD in whom transplantation was done either simultaneously, after or without native nephrectomy at Seoul St. Mary's hospital between January 1987 and February 2014. We divided patients into 2 groups; simultaneous nephrectomy group (group A, n=13), after or without nephrectomy group (group B, n=28) and compared the perioperative outcome, post-transplant complications, allograft survival rate.

Results: The mean operative time was significantly longer in group A than group B (6.48 ± 1.84 vs. 5.27±0.84 hours; P = .048). The mean intraoperative blood transfusions was also significantly more needed in group A than B (3.66±3.43 vs. 0.75 ±0.26 units; P = .018). However, there were no differences in the incidence of acute rejection andother complications such as post-operative bleeding, infectious complication between the two groups (P > .05, for all).The graft survival rate also did not differ between the two groups (P > .05).

Conclusions: Our study suggests that the complication rates were acceptable and there was no significant negative impact on graft survival rate when native nephrectomy was done during kidney transplantation in ADPKD patients with ESRD. Therefore, if native nephrectomy is needed in ADPKD for kidney transplantation it can be done safely during transplantation.

FR-PO1096

Predictors of Renal Function Change After Kidney Transplantation Yoshifumi Hamasaki,[1] Kent Doi,[2] Akihiko Matsumoto,[3] Daigoro Hirohama,[1] Nobuhiko Sato,[1] Daisuke Katagiri,[1] Rei Isshiki,[1] Wakako Kawarazaki,[1] Eisei Noiri,[1] Masaomi Nangaku.[1] *[1]Nephrology and Endocrinology, The Univ of Tokyo, Tokyo, Japan; [2]Emergency and Critical Care Medicine, The Univ of Tokyo, Tokyo, Japan; [3]Urology, The Univ of Tokyo, Tokyo, Japan.*

Background: Several perioperative factors including histological findings of allograft biopsy are known to be associated with graft function and graft survival after kidney transplantation (KT). Urinary L-type fatty acid binding protein (uL-FABP) was reported to be correlated with serum creatinine, serum cystatin C, and estimated glomerular filtration rate (eGFR) in a cross sectional study evaluating post-KT patients. It is unclear what factors in post-KT period predict the longitudinal change of renal function.

Methods: The data from post-KT patients followed at The University of Tokyo Hospital were collected retrospectively. Patients followed-up less than 6 months after KT were excluded. To identify predictors of the longitudinal change of renal function, we analyzed data including clinical parameters measured at each outpatient visit. The primary outcome was determined as the change of eGFR during 6 months period.

Results: 32 post-KT recipients were analyzed in this study. Age and eGFR at baseline of these patients were 51.3 ± 12.7 years old and 41.2 ± 16.1 ml/min/1.73m^2 (mean ± SD), respectively. The duration from KT to collection of clinical parameters was 6.8 ± 7.3 years (mean ± SD). Changes of eGFR were evaluated 6 months after. When patients were divided into two groups with (N = 15) and without (N = 17) eGFR decline after 6 months, uL-FABP and urinary protein were significantly higher in the eGFR decline group (uL-FABP; 11.6 vs 5.1 mg/ml, and urinary protein; 272.7 vs 97.2 mg/gCr, respectively). On ROC analysis, uL-FABP and urinary protein predicted eGFR decline after 6 months (AUC [95%CI] = 0.78 [0.60-0.96] and 0.70 [0.51-0.89], respectively). On multiple regression analysis, uL-FABP and urinary protein were significantly correlated with the absolute and relative eGFR changes during 6 months observation period.

Conclusions: uL-FABP and urinary protein measured at outpatient clinic can predict the change of renal function of post-KT patients.

FR-PO1097

Plasma Proenkephalin and Poor Long-Term Outcome in Renal Transplant Recipients Lyanne M. Kieneker,[1] Joachim Struck,[2] Ron T. Gansevoort,[1] Michel M. Joosten,[1] Rudolf A. de Boer,[3] Oliver Hartmann,[2] Stephan J.L. Bakker.[1] *[1]Nephrology, UMC Groningen, Netherlands; [2]Sphingotec GmbH, Germany; [3]Cardiology, UMC Groningen, Netherlands.*

Background: Enkephalins are well-known endogenous opioid peptides. Recent evidence indicates that they are not only involved in regulation of pain, but also in homeostasis of the immune system and the circulation. Proenkephalin (pro-ENK) is stable in plasma and has been established as reliable surrogate marker for unstable enkephalins. Recent studies found associations of pro-ENK with acute kidney injury and prognosis after myocardial infarction. We aimed to investigate whether pro-ENK could be linked to chronic kidney injury and poor long-term outcome in renal transplant recipients (RTR).

Methods: We included 664 RTR who were 8.1±7.6 years after transplantation. Plasma levels of pro-ENK were measured with a double monoclonal sandwich immunoassay.

Results: Mean age was 53±13 years, 56% was male, estimated glomerular filtration rate (eGFR) 49 ml/min/1.73m^2 (interquartile range [IQR]: 37-64 ml/min/1.73m^2) and

urinary albumin excretion (UAE) 40 mg/24h (IQR: 10-196 mg/24h). Median pro-ENK was 110 pmol/L (IQR: 85-148 pmol/L). Pro-ENK was correlated with both eGFR (r=-0.73, P<0.001) and UAE (r=0.35, P<0.001). During a median follow-up of 3.1 years (IQR: 2.7-3.9 years), 45 RTR developed graft failure and 76 died. Pro-ENK was both associated with increased risk of graft failure (hazard ratio per standard deviation increment of the logarithm of pro-ENK, 2.76; 95% confidence interval, 1.69-4.53) and all-cause mortality (1.83; 1.24-2.69), independent of age, sex, eGFR, and UAE. These associations remained materially unchanged after additional adjustment for body mass index, alcohol consumption, smoking, systolic blood pressure, antihypertensive drug use, use of calcinurin inhibitors, and high-density lipoprotein.

Conclusions: High concentrations of pro-ENK are linked to chronic kidney injury as reflected by correlations with eGFR and UAE. In addition, pro-ENK was independently associated with increased risk of graft failure and mortality in RTR. Pro-ENK is an interesting new biomarker which may aid in early identification of RTR at risk for late graft failure and premature mortality.

Funding: Private Foundation Support

FR-PO1098

Serum Albumin Level Has Association with Both Graft Failure and Mortality in Kidney Transplant Recipients Hee Jung Jeon,[1] Soyon Rhee,[1] Eunjung Kim,[1] Jung Pyo Lee,[2] Ja-Ryong Koo.[1] *[1]Dept of Internal Medicine, Hallym Univ of College of Medicine, Seoul, Republic of Korea; [2]Dept of Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul, Republic of Korea.*

Background: The studies concerned the association between post-transplant serum albumin concentration and post-transplant outcomes in kidney transplant recipients (KTRs) are scarce.

Methods: To evaluate the impact of serum albumin level on graft and patient survival, we performed a retrospective multi-center cohort study in Seoul National University Hospital, Asan Medical Center, and Kangdong Sacred Heart Hospital. A total of 2815 KTRs who underwent renal transplantation from Jan 1997 to Jan 2012 were classified into two groups according to the level of serum albumin at 1 year after transplantation (higher albumin group, ≥4.0 g/dL, n=1978 vs. lower albumin group, <4.0 g/dL, n=837). The Cox proportional hazard model was adjusted with age and gender of recipient, donor type, age of donor, diabetes mellitus, and estimated glomerular filtration rate (eGFR) at 1 year after transplantation.

Results: The mean age of the recipients was 41.7±11.3 (range, 18-73) years, and 59.1% were male. The rate of graft failure was higher in lower albumin group compared to higher albumin group (Hazard ratio [HR] 1.840, 95% confidence interval [CI] 1.367-2.477, *P*<0.001), even though eGFR at 1 year after transplantation was not different between the two groups (61.7±19.8 vs. 62.1±15.8 mL/min, *P*=0.615). Both all-cause mortality and non-cardiovascular mortality rates were higher in lower albumin group (HR 2.227, 95% CI 1.258-3.943, *P*=0.006, and HR 2.784, 95% CI 1.254-6.179, *P*=0.012, respectively). Every 1.0 g/dL higher serum albumin concentration was associated with 69.2% lower all-cause mortality (HR 0.308, 95% CI 0.196-0.483, *P*<0.001).

Conclusions: Serum albumin level at 1 year after transplantation is a prognostic factor for graft failure and patients' mortality in KTRs. Therefore, evaluation and management for hypoalbuminemia should be considered to improve outcomes in KTRs.

FR-PO1099

Brain Effects of Renal Transplantation: Association Between Cognition and White Matter Integrity Aditi Gupta,[1] Rebecca J. Lepping,[2] David K. Johnson,[3] Alan S.L. Yu,[1] William M. Brooks,[2] Jeffrey M. Burns.[3] *[1]Kidney Inst; [2]Hoglund Brain Imaging Center; [3]KU Alzheimer's Disease Center; [4]Univ of Kansas Medical Center.*

Background: Cognitive impairment is present in up to 87% patients with end stage renal disease (ESRD). Magnetic resonance imaging (MRI) using diffusion tensor imaging (DTI) shows lower fractional anisotropy (FA) values in these patients. FA values measure structural integrity of white matter and are associated with cognitive impairment. In this study we examine the effect of renal transplantation on cognitive function and determine whether changes in white matter integrity underlie the observed cognitive changes.

Methods: Adults with ESRD were recruited from the renal transplant waiting list. Subjects were evaluated before transplantation and 3 months after transplantation with neuropsychological (NP) tests and a brain MRI. Two-tailed paired t-test was used to analyze changes in NP tests and FA values before and after transplantation.Pearson correlation coefficients were calculated.

Results: Two hundred patients were screened and eighteen enrolled. Ten subjects, 57±11 years of age have been transplanted and have completed the study. After transplantation, there was a significant improvement in NP tests for memory and executive function.

Test	Pre-Transplant	Post-Transplant	P value
Logical Memory I	10.5±4.6	13.9±4.5	0.011
Logical Memory II	8.5±5.2	13±4.8	0.007
Stroop color	68.9±16	74.9±14.5	0.028
Digit Symbol	43.3±11	48±11.5	0.002

There was a significant increase in the FA values in the body of corpus callosum (P=0.017), forceps minor (P=0.058) and left cingulate gyrus (P=0.002). Furthermore, the improvement in NP tests positively correlated with the increase in FA values in these tracts.

Conclusions: Memory and executive function improve after renal transplantation. FA, a DTI metric representing white matter integrity also increases in brain regions important for these functions. This study provides insight into the neural mechanisms underlying cognitive impairment in ESRD and its improvement after transplantation.

FR-PO1100

Pre-Kidney Transplant Left Ventricular Ejection Fraction, Long-Term Allograft Function, and Survival Asjad Sardar, Maha A. Mohamed, Arjang Djamali, Sandesh Parajuli, Didier A. Mandelbrot, Brad C. Astor. *Div of Nephrology, Univ of Wisconsin Hospitals and Clinics, Madison, WI.*

Background: End stage kidney disease patients with low left ventricular ejection fraction (LVEF) are considered high risk for poor outcomes following kidney transplantation (KT). No consensus exists on the level of systolic dysfunction below which patients are at increased risk of unfavorable allograft outcomes.

Methods: We studied 387 KT patients transplanted from 1/02 to 12/09 who underwent pre-transplant invasive and non-invasive cardiac assessment of LVEF. Outcomes included Delayed graft function (DGF), allograft survival, patient survival and allograft function.

LVEF	N	DGF	Patient Survival	Graft Survival	Mean Difference and (95% CI) in Cr		
		OR (95% CI)	HR (95% CI)	HR (95% CI)	1 Year	3 Years	5 Years
<45%	36	1.66 (0.44, 6.26)	1.03 (0.43, 2.49)	0.99 (0.47, 2.02)	-0.10 (-0.66, -0.64)	-0.41 (-1.0, 0.21)	-0.1 (0.66, 0.64)
45-60%	215	1.29 (0.56, 2.94)	0.78 (0.43, 1.42)	0.89 (0.57, 1.40)	0.01 (0.13, 0.15)	-0.22 (-0.56, 0.11)	0.07 (-0.30, 0.44)
>60%	136	Ref	Ref	Ref	Ref	Ref	Ref
P-trend		0.42	0.81	0.80	0.70	0.12	0.86

CI: Confidence Interval, Ref: Reference
Data adjusted for age, sex,race,PRA,Duration of RRT,DM,CAD,LVH and Induction Therapy.

Associations between different LVEF values.

Results: A total of 136 (35.1%) patients had LVEF > 60%, 215 (55.5%) had LVEF between 45-60% and 36 (9.3%) had LVEF <45% before KT. Patients with low EF were more likely to have DM,CAD,LVH and longer duration of dialysis. During median follow up of 4.4 years there were 122 graft losses including 71 deaths. 73 patients (18.9%) had DGF. There was no significant difference in rate of DGF, serum creatinine, allograft survival and patient survival.

Conclusions: Low LVEF does not appear to significantly effect patient and allograft survival and function, suggesting that patients with low LVEF should not be excluded from transplantation.

FR-PO1101

Progression of Coronary Artery Calcification in Renal Transplant Recipients – A Follow-Up of 7 Years Sibel Gulcicek, Nurhan Seyahi. *Dept of Internal Medicine, Div of Nephrology, Istanbul Univ, Cerrahpasa Medical Faculty, Istanbul, Turkey.*

Background: In the general population coronary artery calcification (CAC) and its progression is associated with cardiovascular and all cause mortality.We conducted a study to determine the progression of CAC in renal transplant recipients; we also examined the factors associated with progression and the impact of the analytic methods used to determine CAC progression.

Methods: We used multi-detector computed tomography to examine CAC in 113 prevalent renal transplant recipients, who did not have a documented cardiovascular disease. A baseline and a follow-up scan were performed and changes in CAC scores were evaluated in each patient individually, to calculate the incidence of CAC progression. Univariate and Multivariate logistic regression analysis was used to evaluate the determinants of CAC progression.

Results: Baseline CAC prevalence was 34.5 % and the mean CAC score was 47.08 ± 135.25. At follow-up scan that was performed after an average of 6.9 ± 0.5 years, CAC prevalence increased to 47.6% and the mean CAC score to 140.18 ± 332.11. Progression of individual CAC score was found between 32.7 and 34.5 %, depending on the method used to define progression (Hokanson and Sevrukov). In patients with baseline CAC, median annualized rate of CAC progression was 13.8. Based on univariate analysis, age, presence of baseline CAC, high baseline CAC score, high body mass index were significantly associated with CAC progression defined according to both the Hokanson and Sevrukov methods. Moreover, HDL cholesterol level were significantly associated with CAC progression when progression was defined according to Hokanson's method and donor type, high triglyceride levels and systolic blood pressure were significantly associated with CAC progression according to Sevrukov's method.Based on multivariate analysis baseline CAC and high triglyceride were the independent determinants of CAC progression.

Conclusions: Progression of CAC is the usual evolution pattern of CAC in renal transplant recipients. Beside baseline CAC, high triglyceride level were also associated with progression of CAC.

FR-PO1102

Adiponectin Fractions Influence the Development of Cardiovascular Disease in Japanese Renal Transplant Recipients Hiroki Adachi, Yuki Matsui, Norifumi Hayashi, Keiji Fujimoto, Junko Imura, Hideki Yamaya, Hitoshi Yokoyama. *Div of Nephrology, Kanazawa Medical Univ, Uchinada, Ishikawa, Japan.*

Background: Although the risk for morbidity and mortality has been studied in subjects with renal transplantation (RTx), a few study has investigated the role of adiponectin (ADPN) for cardiovascular disease (CVD) in RTx recipients.

Methods: We studied 57 adult RTx subjects (39 males, 18 females; 10 cadaveric donors) with at least three years of allograft survival (median 251 months). We examined clinical backgrounds such as treated drugs, blood pressure (BP, mmHg), body mass index (BMI), and blood chemistry including cholesterol (total, LDL-C, HDL-C), glucose, glycated hemoglobin (HbA1c), and serum high- and low-molecular-weight(HMW-/LMW-) ADPN fractions with regard to the associations of the visceral and subcutaneous fat areas on CT scan. We also analyzed the associations of CVD and post-transplant diabetes mellitus (PTDM) with ADPN fractions and the fat areas.

Results: The visceral fat area was inversely correlated with serum HMW- and LMW-ADPN levels (r=-0.400, p=0.002 and r=-0.296, p=0.025, respectively). Furthermore, the visceral fat area was inversely correlated with the HMW ratio and positively with the LMW-ADPN ratio (r=-0.444, p<0.001 and r=0.467, p<0.001, respectively), but no significant correlation was noted between the subcutaneous fat area and the ADPN ratio. On multiple regression analysis, eGFR and the visceral fat area were significant reducing factors of HMW-ADPN levels, and the alteration of eGFR was identified as an increasing factor of HMW-ADPN levels. Patients with CVD had larger visceral fat area (p=0.004), lower HMW-ADPN ratio (p=0.022) and higher LMW-ADPN ratio (p=0.049), but not in the subcutaneous fat area. On multiple logistic analysis, the higher HMW-ADPN ratio and statin treatment were identified as reducing factors of the development of CVD, but the LDL-C level was an aggravating factor. Moreover, the higher LMW-ADPN ratio and the visceral fat area were aggravating factors of PTDM.

Conclusions: Even in Japanese renal transplant recipients, visceral fat area and ADPN fractions were significant factors for the development of both CVD and PTDM.

Obesity Before Renal Transplantation: Is Bariatric Surgery the Solution? Ian Thomas, Jeffrey J. Gaynor, David Roth, Warren L. Kupin, Linda J. Chen, George William Burke, Michael J. Goldstein, Gaetano Ciancio, Giselle Guerra, Tameka Joseph. *Univ of Miami, Miami, FL.*

Background: Post transplant outcomes, in obese chronic kidney disease (CKD) patients having bariatric surgery (BS) as a bridge to renal transplantation, have not been widely reported.

Methods: The database at our center of renal transplant recipients having BS prior to transplant from was reviewed. Control group: all obese renal transplant recipients not having BS with body mass index (BMI) greater than 37 at time of transplant. BMI, patient and graft survival, time on wait-list, acute rejections and infections requiring hospitalization were compared between both groups. Immunosuppressant drug levels were assessed in both groups.

Results: 11 patients had BS prior to transplant. There were 25 obese controls. Median follow up post transplant was 12 months (range 2 to 39 months) in BS group versus 63 months (range 48 to 75 months) in the controls. There were no deaths in the BS group but 5 deaths among controls, of which 4 had functioning grafts at time of death. No significant difference in patient survival was found (P = 0.18). There were 2 graft losses in the BS group versus 6 in the controls (P = 0.77), 4 of which were due to death with functioning grafts. Death-censored graft survival was borderline worse in the BS group (P = 0.05). Rejections were more frequent in the BS group. 4/11 patients had acute rejections in the BS group versus 3/25 in the control group (P = 0.01). Tacrolimus levels were at target in cases seen in BS group except in 1 patient who was non-adherent. Tacrolimus levels were lower in cases of rejection seen in the controls. There were no significant differences in time on waitlist, BMI prior to BS or mean eGFR at 6 months (60.6 in BS and 64.8 mL/min/1.73 m2 in controls). However, the rate of infections was significantly higher in the BS group, 9/11 versus 10/25 in the control group (P = 0.02).

Conclusions: Despite possible increased transplant candidacy in obese CKD patients having BS, higher rejection rates and inferior death-censored graft survival compared to matched controls seen in this study suggest that vigilance is mandatory. Further investigation is required.

FR-PO1104

Association Between Serum Magnesium Level and the Risk of New-Onset Diabetes After Renal Transplantation in Korea Hoon Yu, Hyungjin Cho, Eunhye Shin, Su-Kil Park. *Div of Nephrology, Asan Medical Center, Univ of Ulsan College of Medicine.*

Background: New onset diabetes mellitus after transplantation (NODAT) is a serious complication following renal transplantation. Association between serum magnesium level and new-onset diabetes after renal transplantation is controversial. The aim of this study was to identify the association between serum magnesium level and the development of NODAT in Korea.

Methods: The recipients who underwent living donor kidney transplantation between January 2009 and April 2012 were reviewed. Diagnosis of NODAT is defined by American diabetes association criteria. Serum magnesium level were measured at pretransplant, 3 days, 7days and 3 months posttransplant. Univariated and logistic regression analysis were performed to examine the association between serum magnesium level and NODAT at 1 year posttransplant.

Results: Total 419 patients were enrolled. NODAT was diagnosed in 85(20%) patients. Mean magnesium level at 3 and 7 days after transplantation was significantly lower in patients who diagnosed with NODAT. On logistic regression analysis, Age >40, Obesity, pretransplant glucose were associated with NODAT. However, there is a no association between serum magnesium and NODAT.

Table 1. Risk factors of new-onset diabetes - univariate analysis

	Non-NODAT	NODAT	P-value
Number of patients (%)	334 (80)	85 (20)	
Age, years	40.83± 10.52	47.82±10.75	<0.001
Sex, male (%)	117 (53)	53 (62)	0.143
Family history of Diabetes (%)	50 (15)	21 (24.7)	0.036
Tacrolimus (%)	230 (68.9)	59 (69.4)	1.000
Cyclosporine (%)	104 (31.1)	26 (30.6)	1.000
Mycophenolate mofetil (%)	273 (81.7)	64 (75.3)	0.181
Azathioprine (%)	30 (9.0)	11 (12.9)	0.306
Corticosteroids (%)	315 (94.3)	83 (97.6)	0.273
Imparied fasting glucose, pretransplant	12 (3.6)	11 (12.9)	0.002
Glucose, pretransplant	88.7±10.4	96.7±13.5	<0.001
Obesity, pretransplant	51 (15.3)	35 (41.2)	<0.001
Mg, pretransplant	2.17±0.35	2.22±0.34	0.201
Mg, 3 days	1.77±0.20	1.83±0.23	0.026
Mg, 7 days	1.77±0.20	1.82±0.23	0.037

Conclusions: A lower magnesium level at posttransplant may be associated with NODAT after renal transplantation in Korea.

FR-PO1105

Is NODAT Really Associated with Acute Rejection in Kidney Only Transplantation? Rosa M. Montero,[1] Florence R. Delaney,[2] Manohursingh Runglall,[2] Paula Mobillo,[3] Syed K. Hasan,[2] Paramit Chowdhury,[1] Maria P. Hernandez-Fuentes.[2,3] *[1]Nephrology & Transplantation, Guy's & St Thomas' NHS Foundation Trust, London, United Kingdom; [2]NIHR Comprehensive Biomedical Research Centre at Guy's and St Thomas' NHS Foundation Trust in partnership with King's College London and King's College Hospital, London, United Kingdom; [3]MRC Centre for Transplantation, DTIMB, King's College, London, United Kingdom; [4]King's Clinical Trials Unit, Biostatistics Dept, King's College, London, United Kingdom; [5]Nephrology & Transplantation, King's College Hospital NHS Foundation Trust, London, United Kingdom; [6]Nephrology & Transplantation, East Kent Hospitals Univ NHS Foundation Trust, London, United Kingdom.*

Background: Previous reports suggest an association with New Onset Diabetes After Transplantation (NODAT) and rejection however it is unclear whether this effect is secondary to hyperglycaemia or a result of previous episodes of treated rejection. This observational study aims to determine the association between acute rejection(AR) and NODAT.

Methods: 381 renal transplant recipients(RTR) from the KALIBRE study were analysed. Clinical details and laboratory results were collected in this cohort from 2010-2014. Episodes of AR were identified by renal transplant biopsies;Banff 2009 Categories 2&4 and 3 that were treatment responsive. NODAT was defined as HbA1C>6.5% 3months post renal transplant. Cox's regression proportional hazards was used for survival analysis.

Results: 381 RTRs (39%female, 64%white, 39%non-white, Age at transplant range:17-75). 47 patients were diagnosed with NODAT (13.1%) and 93 (24.4%) with AR. 17/47 (36.2%) patients with NODAT had AR. Rejection free survival in NODAT group was significantly lower than patients without NODAT (p=0.036 HR 1.75). Mean tacrolimus

levels between rejectors and non-rejectors were not significantly different (10.1 and 10.3 ng/mL means, respectively). T1DM and T2DM combined did not increase the rates of rejection in the cohort.

Conclusions: An association between NODAT and AR has been observed that was independent of tacrolimus levels. RTRs with diabetes mellitus did not have the same effect on AR rates suggesting a different underlying mechanism specific to NODAT rather than just hyperglycaemia.

Insulin Resistance: Is It a Risk Factor for Left Ventricular Hypertrophy in Pediatric Renal Transplant Recipients? Lale Sever, Nur Canpolat, Gulseren Pehlivan, Salim Caliskan. *Pediatric Nephrology, Istanbul Univ Cerrahpasa Faculty of Medicine, Istanbul, Turkey.*

Background: Renal transplantation reverses uremia-related risk factors for cardiovascular disease; however, immunosuppressive therapy causes metabolic abnormalities such as insulin resistance, hyperglycemia and dyslipidemia.The aim of the present study was to evaluate the effects of these metabolic abnormalities as a risk factor for left ventricular hypertrophy in pediatric renal transplant recipients.

Methods: This is a retrospective study involving 31 renal transplanted children and adolescents (19 male; age 4-20 years) and 19 healthy controls. Anthropometric indices, office blood pressure (BP) and laboratory measurements and also left ventricular mass index (LVMI) at the same time were recorded from the patients' file.The homeostasis model assessment of insulin resistance (HOMA-IR) was calculated. Insulin resistance was defined as a HOMA-IR $\geq$ 2.5. Dyslipidemia was defined as HDL-C<40 mg/dL, and/or LDL-C >130 mg/dL, and/or TG >150 mg/dL.

Results: Age at transplantation was 12.4±4.4 years with a median follow-up of 27 months. One patient received pre-emptive transplantation, 25 were on PD and 5 on HD before transplantation; 25 patients received a kidney from living donor. Triple immunosuppressive therapy was used in all patients, except two who were not using steroids at time of the enrolment. Patients had significantly higher BMI-SDS, fasting glucose, fasting insulin, HOMA-IR and TG as well as lower HDL-C levels than controls ($p<0.05$ for all). Nine patients (29%) had insulin resistance; 11 (42%) were dyslipidemic; and 15 (56%) were hypertensive. LVMI was significantly higher in the patients than the controls (40.0±9.1 vs. 25.8±5.71; $p<0.001$); left ventricular hypertrophy was noted in 11 patients (48%). LVMI was correlated only with indexed diastolic BP ($r=0.433$, $p=0.039$), however, not with any of the lipid parameters or HOMA-IR.HOMA-IR was correlated with only BMI ($r=0.381$, $p=0.035$). There was no association between HOMA-IR and steroid doses.

Conclusions: Although insulin resistance and dyslipidemia are prevalent in pediatric renal transplant recipients, hypertension appears to be the main risk factor for left ventricular hypertrophy.

FR-PO1107

Mediterranean Type Diet Is Associated with Low Risk of New-Onset Diabetes and Mortality After Renal Transplantation Maryse Osté,[1] Eva Corpeleijn,[1] Gerjan Navis,[1] Charlotte A. Keyzer,[1] Sabita Soedamah-muthu,[2] Else van den Berg,[1] Daan Kromhout,[1,2] Stephan J.L. Bakker.[1] *[1]Univ of Groningen; [2]Univ of Wageningen, Netherlands.*

Background: The incidence of new-onset diabetes after transplantation (NODAT) and cardiovascular events leading to premature mortality is high in renal transplant recipients (RTR). We hypothesized that a Mediterranean type diet protects against development of NODAT and premature mortality in RTR.

Methods: In a prospective cohort study consisting of 707 adult stable RTR with a functioning graft for > 1 year, dietary intake at baseline was assessed with a 177 item validated food frequency questionnaire. Patients were divided into two categories, low resemblance (0-4 points) and high resemblance (5-9 points), based on a 9-point score according to the degree that their dietary pattern resembles that of a Mediterranean type diet. RTR with missing dietary data, diabetes mellitus at baseline or who underwent combined pancreas-kidney transplantation were excluded from analyses, leaving 474 RTR. Cox multivariable regression analyses were used to study the association of the Mediterranean diet with the development of NODAT and mortality.

Results: In total 474 RTR (56,8% men) were included with a mean ± SD age of 51.5 ± 13.2 years. At baseline, 256 (54%) had a high resemblance to that of a Mediterranean type diet. During median follow-up of 3.8 (interquartile range [IQR], 3.0-4.6) years from baseline, 28 (6%) developed NODAT and 52 (11%) patients died. RTR with $\geq$ 5 points were both significantly associated with a lower risk of developing NODAT (hazard ratio [HR], 0.43; 95% confidence interval [CI], 0.20-0.94; P=0.04) and mortality (HR, 0.54; 95% CI, 0.31-0.95, P=0.03), both adjusted for age and sex. The results of multivariable analyses, in which we adjusted for potential confounders including total energy intake, physical activity and smoking status, did not materially change the results of the analyses adjusted for age and sex.

Conclusions: Dietary habits that resemble the Mediterranean type diet may protect against NODAT and mortality after kidney transplantation. More attention should be directed to the nutritional habits of renal transplant recipients.

FR-PO1108

Parathyroidectomy for Tertiary Hyperparathyroidism in Kidney Transplant Recipients Brian M. Zwecker,[1] Zahra Deen,[1] Sreedhar A. Mandayam,[1] Luan D. Truong,[2] A. Osama Gaber,[2] Emad H. Asham,[2] Dana M. Hong,[2] Venkat Ramanathan.[1] *[1]Nephrology, Baylor College of Medicine; [2]Transplant, Houston Methodist Hospital.*

Background: Secondary hyperparathyroidism associated with ESRD improves after kidney transplantation (KT) in most patients. However, in some patients, high PTH persists post-KT to cause a tertiary hyperparathyroidism (ThPT) state, leading to hypercalcemia and worsening post-transplant bone disease. New calcimimetic drugs are often denied by insurance post-KT leaving few options for physicians.

Methods: In this retrospective study, we identified kidney transplant recipients between 2008 and 2013 who underwent parathyroidectomy (PTx) for ThPT.

Results: We identified 26 (2.5%) patients who underwent PTx, out of 1001 patients who underwent KT at our center. Pre-surgery mean calcium and iPTH levels were 10.4±1.3 mg/dl and 508±404 pg/ml respectively. Post-KT, median time to PTx was 482 days (Q1,Q3: 225,909); 65% underwent PTx greater than one-year post-KT. PTx indications included persistent hypercalcemia despite medical therapy (62%) and worsening osteoporosis (42%). Sestamibi scan showed hyperplasia and adenoma in 50% and 34% respectively. However, surgical pathology showed hypercellular parathyroid tissue in 25/26 (96%) patients. Predictive value of the Sestamibi scan was poor (Cohen's kappa index 0.1). PTx complications included hypocalcemia (19%), transient renal failure (12%), and temporary nerve paresis (4%). There was no deleterious effect on long-term allograft function after PTx: compared with baseline values, serum creatinine was identical at 1 month (1.3±0.5 vs. 1.3±0.6, NS) and 1 year (1.3±0.8 vs. 1.3±0.6 p=NS). Seven patients had follow up post-surgical DEXA scans revealing an improvement in femur bone mass by 7.5%.

Conclusions: In one of the largest case series, we have shown that (a) Parathyroidectomy is required for tertiary hyperparathyroidism to treat hypercalcemia refractory to medical therapy and worsening osteoporosis (b) Sestamibi scan is inaccurate in differentiating between hyperplasia and adenoma and (c) Parathyroidectomy is well tolerated with no long-term deleterious effect on allograft function.

SA-PO001

Intra-Abdominal Hypertension and Renal Dysfunction in Pregnancy Wonngarm Kittanamongkolchai,[1] Elliott G. Richards,[2] Mari Charisse B. Trinidad,[2] Wendy White,[2] Vesna D. Garovic.[1] *[1]Nephrology, Mayo Clinic, Rochester, MN; [2]Maternal Fetal Medicine, Mayo Clinic, Rochester, MN.*

Introduction: The effects of high intra-abdominal pressure(IAP) on renal function have been known for over a century. However, the diagnosis of peripartum intra-abdominal hypertension(IAH)/abdominal compartment syndrome(ACS) is challenging due to the lack of well-established normative values of IAP in pregnancy.

Case Description: A 32 year old obese primigravida with a twin pregnancy at 33 weeks gestation was admitted for intractable nausea and vomiting. She was oliguric and unresponsive to IV fluid. Her blood pressure was normal. Cr increased from a baseline of 0.5 to 0.9 mg/dL. Urinalysis was bland. A FeNa obtained after fluid resuscitation was 0.02%. Renal ultrasound showed patent renal vessels and no hydronephrosis. A diuretic was given with slight improvement in urine output. IAP measured by an intravesical catheter was 35 mmHg, and abdominal perfusion pressure(APP) (difference between mean arterial pressure and IAP) was 46 mmHg(normal > 50-60mmHg). She was suspected to have IAH/ACS and was closely monitored. 2 days later, she developed hypertension, an increase in liver transaminases, and proteinuria. The decision was made to proceed with delivery due to severe preeclampsia. IAP measured immediately after C-section decreased to 18 mmHg, and it was 7 mmHg prior to dismissal. Urine output increased to 2.5 L per day and Cr declined to 0.7 mg/dL after delivery.

Discussion: Animal and human studies indicate that oliguria and acute kidney injury are frequent consequences of IAH/ACS, and can be present at relatively low levels of IAP. In our case, the IAP of 35 mmHg was quite extreme compared to IAP of 4-28 mmHg observed in cohort studies of peripartum patients. We suspected that obesity and twin pregnancy contributed to the extreme IAH. Her APP was significantly low and restoration of renal function was readily observed after reduction of IAP. Our case may support the theory that IAH plays a role in preeclampsia, as it developed after IAH was detected. Renal dysfunction from IAH is probably underrecognized as IAP is not routinely measured. Further study is needed to elucidate the impact of IAH in pregnancy.

SA-PO002

Diabetes, Deafness and Renal Disease – A Case Report Iolanda Godinho, Joana Gameiro, Noélia Lopez Santos, Sofia C.A. Jorge, Fernando Abreu, Estela Nogueira, Maria Alice Fortes, Jose António Lopes, Patricio Aguiar, Dolores López Presa, António Gomes da costa. *Hospital Santa Maria, Lisboa, Portugal.*

Introduction: Deafness and kidney disease as well as diabetes and kidney disease are associations of which the Nephrologist is well aware. However, the concomitance of the three is not as usual, neither is a family history of these diseases.

Case Description: We present the case of a 47-year-old woman with non-nephrotic proteinuria, no haematuria, normal renal function, slowly progressive bilateral sensorineural hearing loss and recently diagnosed diabetes and maculopathy and a maternal family history of deafness, diabetes and renal disease. The patient progressed with increasing proteinuria despite antiproteinuric measures and a renal biopsy was performed, revealing Focal and Segmental Glomerulosclerosis (FSGS). Alport syndrome and Fabry disease investigation was negative. Facing the personal and maternal family history, the mitochondrial mutation m3243A>G was pursued and identified in heteroplasmy and maternally inherited diabetes and deafness (MIDD) with renal involvement as FSGS diagnosed. Renal biopsy ultrastructural study is ongoing. While waiting the etiologic investigation because of symptomatic nephrosis the patient was started on prednisolone 1mg/kg/d with no antiproteinuric response and with side effects causing her to interrupt this medication.

Discussion: Mitochondrial diseases constitute a group of rare diseases in which renal involvement is uncommon, although possible. This is the case with MIDD, in which patients present with non-insulin dependent diabetes and sensorineural hearing loss, which may be accompanied by other manifestations as cardiomyopathies or maculopathy. Renal involvement is possible, mostly as tubulointerstitial nephritis or less frequently presenting as glomerulopathy, namely FSGS. In this type of FSGS, the proteinuria is usually non-nephrotic, with scarce response to antiproteinuric measures, and slow progression to chronic kidney disease. The association of FSGS with mitochondrial diseases is not well known to the nephrologic community. Its timely diagnosis is particularly important to avoid exposure to ineffective and toxic immunossupression.

SA-PO003

Chronic Inflammatory Demyelinating Polyneuropathy Associated with Advanced Focal Segmental Glomerular Sclerosis Albert Ndzengu,[1] Rada Petrinjac-Nneadic,[2] Lekha K. George,[1] Elvira Gosmanova.[1] *[1]Nephrology, UTHSC, Memphis, TN; [2]Neurology, Tri-State Neurology, PLLC, Memphis, TN.*

Introduction: Chronic demyelinating polyneuropathy (CIDP) is rarely reported in patients with nephrotic syndrome (NS). CIDP tends to manifest concomitantly with NS. We report a case of CIDP developing at a time of focal segmental glomerular sclerosis (FSGS) progression to ESRD and mimicking uremic neuropathy.

Case Description: A 23-yo male with NS due to biopsy proven 1ry collapsing FSGS and serum creatinine (SCr) 1mg/dL was initiated on oral prednisone and lisinopril. He was lost to follow up and returned 1.5 years later complaining on burning pain and numbness in both feet for 4 weeks. Physical exam was normal except for unsteady gait, inability to perform tandem gait, decreased sensation from feet to upper legs, depressed Achilles and ankle flexor reflexes. Laboratory tests showed SCr 44mg/dL, hyperkalemia, metabolic acidosis, normocytic anemia, and normal creatinine phosphokinase. A diagnosis of ESRD due to progression of untreated FSGS was made and dialysis was started. CT head and MRI spine were normal. Cerebrospinal fluid had protein of 74 mg/dL and 1WBC/µL. Electromyography (EMG) showed absent compound muscle action potential (CMAP) and F-waves in both peroneal and tibial nerves, active denervation in tibialis anterior, gastrocnemius and extensor digitorum brevis muscles, and prolonged distal latencies and motor conduction velocity with normal amplitude of CMAP on both arms. Sensory nerves action potentials on sural and peroneal nerves were absent with prolongation of peak latencies on other nerves. The constellation of clinical, EMG and normal inflammatory, infectious and autoimmune laboratory markers was consistent with diagnosis of CIDP. Plasmapheresis was performed with partial improvement of neurological symptoms and was followed by intravenous immunoglobulin infusion as a maintenance therapy.

Discussion: CIDP should be considered in patients presenting with peripheral neuropathy and history of FSGS. Correct diagnosis of CIDP is critical as untreated CIDP leads to inability to walk. Autoimmune mechanisms may be responsible for CIDP and glomerular damage in FSGS but remain to be proven.

SA-PO004

Alloimmune Membranous Nephropathy in Fabry Disease Zubin T. Lathara,[1] Josephine M. Ambruzs,[2] Eric P. Cohen.[1] *[1]Medicine, Medical College of Wisconsin, Milwaukee, WI; [2]Pathology, Nephropath, Little Rock, AR.*

Introduction: Use of enzyme replacement therapies may cause allo-reactivity that causes illness superimposed on the primary disease.

Case Description: A 20 year old male with Fabry disease developed proteinuria. He has the 3.1 kb alu-alu deletion including exon 2. His most recent agalactosidase serum enzyme activity was low at 0.8 nmol/hour/ml (normal 6.2 to 18.6). He has chronic arthralgia and abdominal pain. He has been on treatment with agalsidase beta enzyme since age 10. His medications also include cholecalciferol, dicyclomine, and carbamazepine. He has had infusion reactions with back pain and painful diarrhea. He was premature at 32 weeks gestation. His dizygotic twin sister has no manifestations of Fabry disease. His maternal grandfather has Fabry disease and is on dialysis. On exam, his blood pressure was 127/67 mmHg. There was minimal peripheral edema. Urinalysis showed small blood, 100 mg/dl protein, 0-2 wbc, 0-2 rbc, and free fat. His serum creatinine was 0.78 mg/dl. He had 1 gram of urine protein per gram of urine creatinine. His proteinuria had ranged from 1.3 to 2.9 gram/gram over the preceding four months. Serological testing showed a negative RPR, negative tests for hepatitis B and C, and an antinuclear antibody of 1:640 titer. A kidney biopsy showed Fabry disease and superimposed membranous nephropathy. Lisinopril 2.5 mg/day was started. Rheumatological evaluation showed no evidence of lupus erythematosus. The most recent urine protein to creatinine ratio was 0.71 gram/gram, with a serum creatinine was 0.8 mg/dl.

His kidney biopsy stained positive for anti-agalsidase, but normal control kidney did not. He had anti-agalsidase antibodies in his serum that did not block agalsidase activity. Immunofluorescence for the phospholipase A2 receptor (PLA2r) was negative within the glomeruli and his serum did not have antibodies to PLA2r.

Discussion: Enzyme replacement therapies may lead to allo-reactivity. Membranous nephropathy has been described in three such patients but not in Fabry disease. Its occurrence may change the therapy of the primary disease and force specific treatment of the membranous nephropathy.

Silicone Implant Associated Acute Kidney Injury in a Male Transgender Patient Frank J. O Brien, Brian Y. Young. *Div of Nephrology, Santa Clara Valley Medical Center, San Jose, CA.*

Introduction: Obstructive kidney disease secondary to nephrolithiasis is a well-described cause of acute kidney injury. Stone formation is often due to dietary or metabolic factors, often no predisposing factors are found. We describe a rare case of obstructive acute kidney injury associated with hypercalciuria and hypercalcemia in a 32-year-old transgender patient. Patient was found to have granulomatous disease associated with silicone implants.

Case Description: 32-year-old male to female transgender patient presented to our institution with fatigue. Routine labs showed creatinine 11 mg/dl, BUN 140 mg/dl, K 7 mmol/L. She was emergently dialyzed, and imaging showed obstructing ureteric calculi, requiring bilateral stent insertion. Patient had a history of silicone implants to hip, buttocks and thigh 5 years previous. These were inserted by a non health care professional. There was no history of calcium product ingestion or hormonal therapy use. Diagnostic work up for nephrolithiasis revealed; 24 hour urinary calcium 866 mg/24 hours, serum calcium 12.5mg/dl, ionized calcium 1.7 mmol/L. Other 24-hour urine values were normal. ACE level was 216 units/L. CXR was normal. PTH and malignancy work up was negative. CT abdomen revealed subcutaneous edema in lower back/gluteal area, around the sites of previous silicone implants, and inguinal lymphadenopathy. Subsequent gallium scan showed tracer uptake around inguinal area, buttock and hips, consistent with granulomatous activity around silicone implants. Excisional lymph node biopsy revealed foreign body type giant cells consistent with granulomatous disease. Empty vacuoles were noted within the giant cell cytoplasm consistent with silicone induced granulomas. Hypercalcemia was managed with calcitonin and intravenous fluids and definitive therapy with prednisone was commenced when diagnosis was made.

Discussion: Hypercalcemia due to silicone implant associated granulomatous disease is a rare, but important presentation. Our patient developed symptoms years after initial implant insertion. With the growing prevalence of cosmetic surgery, particularly in the transgender community, physicians need to be increasingly aware of the associated long term complications.

SA-PO006

Isolated Diplopia Caused by Calcineurin Inhibitor Therapy in a Patient with Idiopathic Membranous Nephropathy Nader S. Bahri, Ashwani K. Gupta. *Nephrology and Hypertension, Univ of Florida, Jacksonville, FL.*

Introduction: Neurotoxicity is a common side effect of treatment with calcineurin inhibitors. Tremors are frequently reported as the most common manifestation. Variable presentations can include headaches, seizures, visual hallucinations or blindness. Sixth nerve palsy has been reported in previous cases of bone marrow and cardiac transplant patients receiving calcineurin inhibitors. In many of these previously reported cases, the drug was administered intravenously and very high drug levels were found.

Case Description: 42 year-old Caucasian female with biopsy proven idiopathic membranous nephropathy (iMGN) who was being treated with tacrolimus and prednisone for nephrotic syndrome. Her tacrolimus levels were maintained between 6-8 ng/mL. Her urine protein/creatinine ratio of 8 gm/gm was successfully reduced to less than 1 gm/gm with therapy. She continued to be in complete remission but after 3 months of therapy she presented with diplopia. The diplopia was binocular and vertical. The patient was seen for an ophthalmologic evaluation. Her visual acuity was 20/20. Pupils were equal and reactive to light and accommodation. No nystagmus was observed. Visual fields and color vision was also normal in both eyes. Assay for Acetyl-choline receptor antibody was negative. The patient remained compliant with her medications despite the side effects. At this time she was switched to low dose Cyclosporin (CyA) in anticipation that similar side effects may not be observed. Trough CyA levels were 44 ng/mL and 59 ng/mL on two occasions but her symptoms did not resolve. A consultation with neuro-ophthalmology was sought and the patient was instructed to discontinue CyA. The symptoms completely resolved 4 days after stopping CyA.

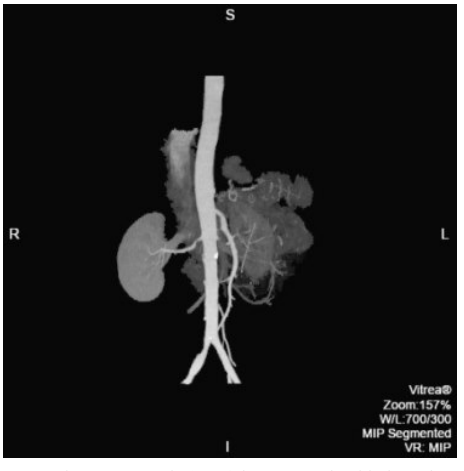
Discussion: This is the first reported case of isolated diplopia secondary to calcineurin inhibitors in low doses for treatment of iMGN. Monitoring of serum concentrations of these drugs has not been correlated with toxicity. The mean duration to onset of symptoms can be as much as 70 days suggesting accumulation of the drug in the central nervous system plays a role. Recognition of this condition is important for prompt diagnosis and appropriate management.

SA-PO007

Bilateral Renal Artery Stenosis in a Patient Treated with Nilotinib for Chronic Myeloid Leukemia Omar M. Shahateet, Milos N. Budisavljevic. *Medical Univ of South Carolina.*

Introduction: The use of tyrosine kinase inhibitors (TKIs) targeting the BCR-ABL1 oncoprotein has been successful in chronic myeloid leukemia (CML). Nilotinib is a second generation TKI designed and used to overcome deficiencies of imatinib such as resistance or intolerance. Nilotinib also received approval in chronic phase (CP)-CML for superior response rate and less progression to blast crisis compared to imatinib. Reports suggest peripheral artery disease (PAD) as an adverse drug reaction associated with the use of nilotinib. We describe a case of bilateral renal artery stenosis in a patient treated with nilotinib.

Case Description: A 45 year old Caucasian male diagnosed with BCR-ABL positive CML at age 31. He was treated with Hydrea followed by Gleevec and was in complete remission (CR) for 4 years when he developed ALL transformation necessitating chemotherapy and peripheral blood stem cell transplantation. He was in CR for 5 years being maintained on dasatinib which was switched to nolitinib due to intolerance from GI upset. He developed worsening creatinine and high blood pressure after being on nilotinib for 2 years. His blood pressure was 170/90, heart rate of 64/min. The remainder of his physical exam was unremarkable for cardiovascular, pulmonary or abdominal findings, including bruits. Creatinine 2.7mg/dl. CT angiogram revealed 70% stenosis of the right and occulsion of the left renal artery with atrophic left kidney.



Discussion: Renal artery stenosis (RAS) is common in elderly patients. RAS due to fibromuscular dysplasia in the renal artery is most commonly observed in younger women. Recent data suggest that nilotinib bind to discoidin domain receptor 1 (DDR1) which has been implicated in plaque formation in atherosclerosis. Nilotinib blocks the receptor kinase KIT which regulates histamine and heparine release. This depresses vascular repair system and predisposes to arterostenotic events.

SA-PO008

A Case of Minimal Change Disease After the Administration of Anti RANKL Monoclonal Antibody Keisuke Horikoshi, Norihiko Sakai, Yasuyuki Shinozaki, Shinji Kitajima, Akinori Hara, Yasunori Iwata, Miho Shimizu, Kengo Furuichi, Takashi Wada. *Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Ishikawa, Japan.*

Introduction: Receptor activator of nuclear factor kappa B (RANK)-RANK ligand (RANKL) has emerged as an important regulator of bone mineral density and microarchitecture. In addition to that, recent study has revealed that RANK-RANKL may contribute to the podocyte survival signal after its injury. Here we report a case that RANKL inhibition might contribute to the onset of nephrotic syndrome.

Case Description: A 59-year-old male without any episodes of proteinuria was given denosumab, a fully human monoclonal antibody to RANKL to treat osteoporosis. Two weeks after its administration, he showed bilateral pretibial edema. Laboratory tests revealed that he had microscopic hematuria, severe proteinuria (15g/gCr), hypoproteinemia (4.0g/dL) and hypoalbuminemia (1.5g/dL). The proteinuria selectivity index was below 0.1, indicating that he had selective proteinuria. Based on the results, he was diagnosed to have nephrotic syndrome. Renal biopsy showed minor glomerular abnormality with less tubulointerstitial damage, indicating minimal change disease (MCD). Taken altogether, glucocorticoid therapy of prednisolone 50 mg/day had started. After four weeks of treatment, the level of urinary protein was still high (4.1g/gCr), but it decreased gradually to the range of partial remission (1.2g/gCr) with another 8 weeks treatment of prednisolone.

Discussion: This may be a rare case to report the association of RANKL inhibition with MCD. The responsiveness to glucocorticoid therapy was not good enough to promptly induce complete remission, suggesting that podocyte injury due to RANKL inhibition could be responsible at least in part for MCD in this case.

SA-PO009

Eculizumab in Management of Thrombotic Lesions in Kidney Allograft of Patient with Anti-Phospholipid Syndrome Anju Yadav, Ravi Sunderkrishnan, Andres Rodrigo Caero. *Nephrology, Thomas Jefferson Univ Hospital, Philadelphia, PA.*

Introduction: Thrombotic microangiopathy (TMA) is one of the hallmark vascular lesions of anti-phospholipid syndrome (APLS). These lesions are at high risk of recurrence after kidney transplantation. The complement pathway is thought to be active in this process by deposition and by presence of apoptotic and vascular cell markers on sequential transplant biopsies. Eculizumab is a humanized anti-C5 monoclonal antibody which has been used in atypical hemolytic uremic syndrome. Recently, there have been reports of use of Eculizumab in transplant patients with APLS/ TMA.

Case Description: We present a case of a 58 year old Caucasian man with history of systemic lupus erythematosus, APLS on warfarin, hypertension, rheumatoid arthritis, transient ischemic attack, coronary artery disease with triple vessel bypass, chronic kidney disease stage 5 for which he received pre-emptive living unrelated kidney transplant. After an uneventful post-transplant course, he was discharged on warfarin. He presented to the hospital 4 days later, with acute renal failure, pain over the graft and sub-therapeutic INR. A perinephric collection was drained. Cytomegalovirus and BK polyoma viremia were ruled out. Transplant kidney biopsy, revealed TMA with segmental necrosis and small vessel fibrin thrombi and no acute rejection. High dose steroids along with aggressive anticoagulation were started. He received two sessions of plasmapharesis. After meningococcal meningitis immunization, Eculizumab 900mg/week was started. After 4 doses, Eculizumab was changed to 1200mg/two weeks. Creatinine trended down from 7.3 to 3.0 mg/dl and dialysis was stopped after 7 sessions. He was positive for IgG anticardiolipin, beta-2 glycoprotein, and lupus anticoagulant and was started on daily aspirin and warfarin with INR goal of 2.5-3.5.

Discussion: Treatment with Eculizumab and plasmapheresis resulted in a relatively rapid and dramatic improvement of graft function in our patient and should be considered in difficult to manage TMA/APLS in transplant patients. Its use permits a safer approach of controlling the complement final common pathway.

SA-PO010

Transient Gestational Diabetes Insipidus in a Patient with Pre-Eclampsia Anju Yadav, Ravi Sunderkrishnan, Andres Rodrigo Caero. *Dept of Nephrology, Thomas Jefferson Univ Hospital, Philadelphia, PA.*

Introduction: Diabetes insipidus (DI) is manifestation of post pituitary insufficiency characterized by polyuria and hypotonic urine. DI can be neurophyseal, nephrogenic, polydispsia related or gestational (GDI). L-deamino-8-d-arginine- vasopressin (DDAVP) is a vasopressin analogue which had higher and prolonged anti-diuretic activity with no effects on smooth muscle. An increase in urine osmolality by at least 50% following administration of DDAVP is diagnostic of disorder.

Case Description: We present a case of 22-year-old African American primigravida woman with no past medical history, in 32nd week of pregnancy, admitted with pre-eclampsia with no liver injury. On admission, blood pressures were between 140-165/60-79mmHg. After an uneventful delivery she had urine output ranging 6-9 liters along with polydipsia. Both of these were present all through out her third trimester. On exam there was no evidence of volume overload or dehydration. Labs were sodium 137mEq/L, Potassium 2.8mEq/L, Alb 3.0mg/dl, TSH 4.16, urea nitrogen <0.3, creatinine 0.4, serum osmolality 284, urine osmolality 141, spot urine protein creatinine ratio of 0.8. With one dose of sub-cutaneous DDAVP increased urine osmolality to 385 within 24hrs. Oral DDAVP

doses were titrated based on clinical response and labs. Hypokalemia was managed with oral repletion and resolved later. On discharge urine osmolality increased up to 523 with 2 liters urine output and no excessive thirst.

Discussion: GDI is attributed to decreased thirst threshold, secretion of vasopressinase from placental cells (cystine amino-peptidase) along with reduced vasopressin secretory capacity, increased degradation of vasopressin by placenta derived vasopressinase, decreased responsiveness to vasopressin by physiologically increased prostaglandin E2 activity in kidney and polyuria with hypokalemia renders collecting ducts resistant to vasopressin. Subclinical DI can manifests itself under the influence of physiological pregnancy changes. DDAVP is the only treatment, as it is not degraded by vasopressinase. Timely diagnosis with high index of suspicion can help with appropriate management and shorter length of stay.

SA-PO011

A Case Report of Baclofen Toxicity in a Hemodialysis Patient Sweta Carpenter, Sandeep Aggarwal. *Nephrology and Hypertension, Drexel Univ.*

Introduction: The dangers of baclofen toxicity in patients with advanced kidney disease and in particular patients on dialysis remain underappreciated by many physicians.

Case Description: We present a case of a 64 year old male who developed an uncommon case of altered mental status during his hospitalization. His medical history included ESRD for which he was receiving in-center hemodialysis, diabetes and hypertension. He initially presented to the hospital with complaints of shortness of breath and hiccups. His shortness of breath was attributed to volume overload and resolved with two consecutive days of dialysis with fluid removal. For his intractable hiccups, he was started on baclofen. During his hospitalization, he became lethargic and was unable to move his lower extremities. Laboratory data including serum sodium, potassium, glucose, calcium, BUN, phosphorus, liver transaminases, thyroid function tests, troponins, infectious work up and ammonia levels were unremarkable. Neuroimaging, including CT head and brain MRI, were unchanged from previous studies and revealed moderate diffuse cerebral atrophy. An EEG was also performed and did not suggest signs of epileptic activity. Further investigation revealed that he had received a total of 20 mg of baclofen over 2 days. After other etiologies were ruled out, we determined that he may have suffered from baclofen induced encephalopathy. His baclofen was stopped and he was prescribed daily sessions of hemodialysis for three days with the intent of clearing baclofen. He was dialyzed for 4 hours during each dialysis session with a high flux dialyzer. After his first session of dialysis, the patient was more alert and would follow simple commands. At 3 days, the patient's mental status returned to baseline and he was able to move his extremities.

Discussion: Although the kinetics of baclofen elimination during hemodialysis are not well understood, this case demonstrates the resolution of baclofen induced encephalopathy with frequent and consecutive dialysis. Furthermore, we hope this case raises awareness among physicians of the toxic effects that baclofen can cause in dialysis patients.

SA-PO012

Utility of Hemodialysis in Urea Cycle Disorders Chintan Shah, Zeinab M. Tamam, Inder Patel, Yahya M. Osman Malik, Nashat Burhan Imran. *Wayne State Univ.*

Introduction: Urea cycle disorders (UCDs) are rare pediatric diseases but partial enzyme deficiency can persist throughout adulthood. Little has been published about the role of hemodialysis in addressing the acute complications of UCDs in adulthood. Catabolic states are well known trigger factors for the life-threatening acute hyperammonemia.

Case Description: We are reporting a 32-year old male patient with history of partial ornithine transcarbamylase deficiency diagnosed at age of 6 months. He presented with altered mental status due to acute hyperammonemia (108mcg/dl). He was treated with a pre-specified protocol (infusion of Na Phenylacetate/benzoate and Arginine HCl, fasting for 36 hours along with intravenous administration of lipids and glucose followed by protein restricted diet of 35 grams per day and Na phenyl butyrate & L-citrulline). This decreased Ammonia level to 34mcg/dl. Later, patient underwent a procedure and was kept NPO without intravenous calorie supplements and developed fever. Due to both of these catabolic states, he developed a second acute hyperammonemia (270mcg/dl). He was treated with the same protocol which was successful initially but due to worsening infection his ammonia continued to worsen regardless of the treatment (258mcg/dl) and developed tonic clonic seizure requiring intubation and mechanical ventilation. He was promptly started on a 7.5-hour hemodialysis session followed by a 5-hour session in following day. He was kept on CVVHD during the second night. Ammonia level decreased to 0 mcg/dl and patient regained consciousness.

Discussion: Partial Ornithine transcarbamylase deficiency is a very rare disorder among adults and its complications can be life-threatening like cerebral edema and herniation. Prompt dialysis is indicated as an emergency treatment or after failure of medical management to prevent such complications. Given the molecular characteristics of ammonia, prolonged (>5hours) hemodialysis sessions are more effective. Subsequent continuous modalities might be required as a maintenance to prevent the potenital rebound elevation. Discontinuation of dialysis is a clinical judgment after considering resolution of both the life-threatening condition and the catabolic event.

SA-PO013

Treatment of Atypical Hemolytic Uremic Syndrome Early in Pregnancy with Eculizumab Rahul N. Pawar,[1] Savneek S. Chugh,[1] Amy R. Patel,[1] Prachi Kale.[2] *[1]Nephrology, Westchester Medical Center, New York; [2]Internal Medicine, Westchester Medical Center.*

Introduction: Atypical Hemolytic Uremic syndrome (aHUS) is known to cause acute thrombotic microangiopathy (TMA) in pregnancy with adverse maternal and fetal outcomes. A French study showed that aHUS usually occurs postpartum when activity of placental related complement regulatory proteins decreases. We present a case of a young lady early in pregnancy with severe thrombocytopenia and acute renal failure suspicious for TTP, but later diagnosed with aHUS, which improved with eculizumab.

A 30 year old G11P5A5L5 10 weeks pregnant with a past medical history of 5 first trimester miscarriages presents with nausea, vomiting and watery diarrhea whose labs show a hemoglobin (Hgb) 7.8 g/dL, platelet (PLT) count 15K/uL, BUN 65 mg/dL, and serum creatinine 2.44 mg/dL along with a LDH of 1,847 U/L, haptoglobin <8 mg/dL, and albumin 3.2 g/dL. Liver function tests (LFTs) and coagulation studies were normal. She was suspected to have TTP and transferred to our tertiary medical center. Urinalysis revealed 3+ protein and 3+ blood. Blood smear showed schistocytes. A diagnosis of TMA was made and plasmapheresis was started. Serologies for lupus and anti-phospholipid antibody syndrome were negative and LFTs remained normal, ruling out HELLP. The ADAMTS-13 activity level was noted to be 129%. Renal function declined requiring the initiation of hemodialysis(HD). On the basis of ongoing hemolytic anemia with thrombocytopenia, renal failure and a negative ADAMTS-13, she was started on Eculizumab. After 2 doses, her renal function and urine output improved and HD was stopped. At discharge, her Hgb was 8.5 g/dL, PLT 150 K/uL, and BUN/creatinine 23/1.84 with the plan to receive monthly eculizumab infusions.

Discussion: aHUS is caused by activation of the complement system due a genetic deficiency of its regulatory proteins, specifically complement factor H, factor I, and/or membrane cofactor protein. It can lead to TMA causing multi-organ failure and the potential for death if not managed in time. Pregnancy can cause aHUS in any trimester. One should maintain a low suspicion for aHUS in a pregnant patient with prompt initiation of eculizimab to prevent negative outcomes.

SA-PO014

I've Got a Fever and the Only Prescription Is More Colchicine: Familial Mediterranean Fever Related Pauci-Immune Glomerulonephritis Ashvin Baru, Anam Khan, Celia A. Peña, Rajeev Raghavan. *Nephrology, Baylor College of Medicine, Houston, TX.*

Introduction: Relatively few renal manifestations have been detected in Familial Mediterranean Fever (FMF). We present a case of biopsy proven pauci-immune glomerulonephritis (GN) in a patient with clinically diagnosed FMF and review past treatments of pauci-immune GN in FMF patients.

Case Description: We present an interesting case of a 22 year old man who had suffered for nearly seven years a constellation of symptoms including fever, nausea, vomiting, abdominal pain, arthralgias, chest pain, and an erythematous rash consistent with a clinical diagnosis of Familial Mediterranean Fever. He had a normal serum creatinine of 1.0 mg/dL which peaked at 2.0 mg/dL. Repeated urinalysis indicated 6-10 RBCs per high powered field (phf) and 6-21 WBCs phf. Laboratory testing revealed only an elevated C-reactive protein. A kidney biopsy was performed which revealed 41% of the total glomeruli globally sclerosed and 54 % of the viable glomeruli with active crescents and 25% interstitial fibrosis with tubular atrophy. Immunofluorescence revealed minimal C3 staining. This was consistent with Pauci-Immune Glomerulonephritis or ANCA negative GN. He was treated with Colchicine, pulse steroids, and maintained with mycophenolate mofetil as detection for mutations in the MEFV gene in the diagnosis of FMF is ongoing. He has had no relapse of his FMF with initiation of colchicine and now has had resolution of his hematuria, proteinuria, and acute kidney injury.

Discussion: In the literature, there is minimal knowledge about the renal manifestations of Familial Mediterranean Fever and fewer documented reports on the treatment protocols for ANCA negative vasculitis in FMF. We were able to treat ANCA negative vasculitis in a patient with FMF with only pulse steroids and maintenance immunosuppression with mycophenolate mofetil with great response.

SA-PO015

Stress of Surgery – Is It Just Mental or Can It Be Renal as Well? Mitul Natu Patel, Maria M. Picken, Kavitha Vellanki. *Nephrology, Loyola Univ Medical Center, Maywood, IL.*

Introduction: Waldenstrom's macroglobulinemia (WM) is a rare clinicopathological disorder with a reported annual incidence of 3 per million people. It is characterized by Ig M monoclonal gammopathy in the blood and lymphoplasmacytic lymphoma in the bone marrow. Clinical manifestations are non-specific and generally related to Ig M infiltration of hematopoietic tissues. While deposits of Ig M in the glomerular basement membrane may be seen, renal failure per se is unusual. Here, we present a unique case of recurrent episodes of acute kidney injury (AKI) post-operatively in a patient with underlying WM with spontaneous recovery each time.

Case Description: 75 year old woman with WM, hypertension, obstructive sleep apnea and paroxysmal atrial fibrillation presented for an elective surgery for lumbar stenosis to our center. Her post-operative course was fairly uncomplicated and she was transferred to rehabilitation floor on day 3. She had gradual worsening of lower extremity swelling and shortness of breath and repeat labs showed a serum creatinine of 3.32 mg/dl (0.94

mg/dl, 5 days prior) and renal service was consulted for AKI. She had a prior episode of AKI with knee replacement in 2008, dialysis dependent for 33 days with subsequent spontaneous recovery. Further work up revealed fairly active urine sediment with new onset 24 hour urine protein of 3.3 grams. C3 was normal, C4 < 5 mg/dl, cryoglobulin was positive, rheumatoid factor of < 20 ug/dl, serum Ig M were elevated at 646 mg/dl (normal 46-304 mg/dl) and serum immunofixation showed an abnormal restricted band between the beta and gamma regions. Kidney biopsy showed strongly PAS positive hyaline-like precipitates in the glomerular capillaries with immunofluorescence strongly positive (3+) for IgM and lambda light chains. There were abundant, confluent electron dense deposits in the mesangium and subendothelial space. Her symptoms improved with diuresis and she refused any other major intervention. Renal function eventually improved with serum creatinine of 1.2 mg/dl at the time of discharge.

Discussion: In conclusion, we believe the stress of surgery precipitated intraglomeruli deposition of Ig M leading to AKI with spontaneous resolution thereafter.

SA-PO016

New Causes of Secondary Hyperparathyroidism: Unforeseen Effects of New Drugs on the PTH-Calcium Axis Muthanna M. Saraireh, Harold M. Szerlip. *Nephrology, Baylor Univ Medical Center, Dallas, TX.*

Introduction: Calcium homeostasis is a function of the interplay between GI absorption, renal excretion and bone resorption. Although numerous effectors control these processes, PTH is primarily responsible. PTH affects the kidney and bone through PTH receptor 1. In the kidney PTH decreases phosphorus reabsorption, increases calcium reabsorption and stimulates 1-hydroxylation of vitamin D. In the bone PTH up-regulates expression of RANKL and decreases expression of osteoprotegrin. This process increases RANKL binding to RANK on osteoclast precursors stimulating them to become osteoclasts that increase bone resorption. New drugs that inhibit RANK are used to treat osteoporosis and bone metastases. We describe two patients treated with recently developed chemotherapeutic agents who developed severe hypocalcemia, and secondary hyperparathyroidism with hypophosphatemia due to renal PO4 wasting . We hypothesize that these drugs inhibit RANK.

Case Description: Case 1: A 72 y/o woman with metatstatic leiomyosarcoma received Trabactedin, an experimental agent which interacts with DNA. She subsequently complained of weakness. Labs are shown. **Case 2:** A 73 y/o man with ALL positive for BCR-ABL was tarted on the tyrosine kinase inhibitor Dasatanib. He subsequently developed the laboratory abnormalities shown.

	Ionized calcium	Pi	Urine Ca	FePi	25-Vit D	1,25-Vit D	PTH
patient 1	0.84 mmol/L	0.9 mg/dl	< 5 mg/dl	44%	33 ng/ml	110 pg/ml	832 pg/ml
patient 2	0.95 mmol/L	1.3 mg/dl	< 5 mg/dl	46%	32 ng/ml	101 pg/ml	509 pg/ml

Creatinine was 0.7 mg/dl in patient 1 and 0.8 mg/dl in patient 2

Discussion: Both patients developed secondary hyperparathyroidism. The renal effects of PTH appeared to be intact with increased calcium resorption, phosphorous excretion and hydroxylation of 25-Vitamin D. The effects of PTH on bone resorption, however, appeared blunted. Because PTH acts on both kidney and bone through the same receptor, we believe that this represents a post receptor phenomena involving the RANKL/osteoprotegrin system. The tyrosine kinase inhibitor, Imatinib, has been shown to decrease bone resorption through a similar mechanism. As new drugs are developed it is important to recognize potential untoward effects.

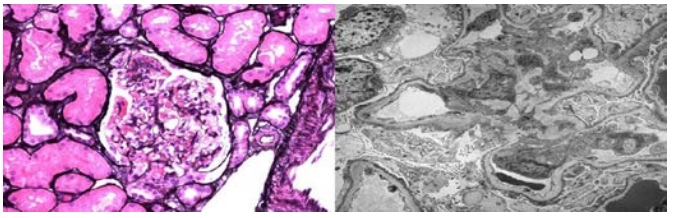
Connection or Coincidence: Behçet's Disease and Focal Segmental Glomerulosclerosis with Nephrotic Syndrome Deanne Leonard, Cherise M. Cortese, Xochiquetzal J. Geiger, Nabeel Aslam. *Mayo Clinic, Jacksonville, FL.*

Introduction: Behçet's Disease (BD) often presents with aphthous and genital ulcers, uveitis, and erythema nodosum. Rarely, renal amyloidosis, IgA nephropathy and crescentic glomerulonephritis result. Here we present a case of nephrotic syndrome from focal segmental glomerulosclerosis (FSGS) in a patient with BD with evidence to suggest a direct connection.

Case Description: 49 y/o female with history of hypertension and BD on etanercept, colchicine and carvedilol. Following a recent prednisone taper, she developed oral ulcers, uveitis, pathergy reaction and proteinuria. Physical exam: Blood pressure: 170/90, aphthous ulcer, uveitis, and 3+ bilateral leg edema. Laboratory data: serum albumin 3.3 g/dL, total cholesterol 282mg/dL, serum creatinine 1.1 mg/dL. Urinalysis: 3+ proteinuria, 10 RBC/hpf and a random protein:creatinine ratio of 8.5. Normal complement levels, DS-DNA, SS-A, SS-B, Sm Ab, RNP Ab, Scl 70 ab, and Jo Ab. Renal biopsy: Light microscopy: focal segmental lesions. Immunofluorescence: IgM trace mesangial granular staining, consistent with immunoglobulin trapping. IgG, IgA, C3, C1q, kappa, and lambda: negative. Electron microscopy: near total visceral epithelial cell foot process effacement with villous formation.



Treatment included losartan and prednisone 1 mg/kg/day which resulted in resolution of edema and reduction of protein to creatinine ratio to 0.14 along with resolution of oral ulcers and uveitis.

Discussion: At present, there is no proven correlation between BD and FSGS with nephrotic syndrome. Our patient presented with BD flare coinciding with the development of nephrotic syndrome both of which improved simultaneously with steroids suggesting a direct connection. Therefore, the clinician should be aware of this possible link and screen accordingly for proteinuria both qualitatively and quantitatively to detect early renal involvement in patients with BD.

SA-PO018

Reversal of Dialysis-Dependent Renal Failure and Nephrotic Syndrome after Conservative Therapy in an Adult with Proliferative Glomerulonephritis with C3-Dominant Deposition Eriko Takehara,[1] Shintaro Mandai,[2] Shinichi Uchida.[2] *[1]Dept of Nephrology, Shuuwa General Hospital, Saitama, Japan; [2]Dept of Nephrology, Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental Univ, Tokyo, Japan.*

Introduction: C3 glomerulonephritis (C3GN) is a recently described entity in a reclassification of membranoproliferative glomerulonephritis, characterized by isolated or predominant glomerular C3 deposits. Although abnormalities in the alternative pathway are known to be involved in the pathogenesis, efficient therapeutic approaches have yet to be established.

Case Description: In December 2012, a 55 year-old man was admitted with rapidly progressive glomerulonephritis and nephrotic syndrome. In May 2011, his serum creatinine(SCr) was 0.63mg/dl. Seven weeks previously, he was admitted to another hospital with hemorrhagic gastric ulcer accompanied by renal failure (SCr 4.61 mg/dL, urinary protein 15 g/gCr, and moderate hematuria), in the absence of preceding infection. At admission to our hospital, SCr increased to 7.60 mg/dL. ANCA, anti-nuclear antibody, and decrease in complement factors were absent. A renal biopsy specimen showed crescentic and endocapillary proliferative GN with dominant C3 and trace IgG. Conservative therapy was started, given the repeated hemorrhagic ulcer, and decreased rate of renal function decline. Hemodialysis was initiated on hospital day 20 because of oliguria, but was ceased on day 60 with recovery of kidney function. SCr decreased to 1.2 mg/dL, and urinary protein decreased to <1 g/gCr. One year after discharge, he developed nephrotic-range proteinuria, and the second renal biopsy revealed the increased sclerotic glomeruli and fibrous crescents with isolated C3 deposits.

Discussion: To our knowledge, this report is the first to describe reversal of dialysis-dependent renal failure after conservative therapy in a C3GN patient. Similarly to the present case, the histological morphology and clinical presentation infrequently mimic the picture of postinfectious GN, although the transient recovery is usually partial. A novel classification of such cases among C3GN may be needed to avoid an unbeneficial immunosuppression.

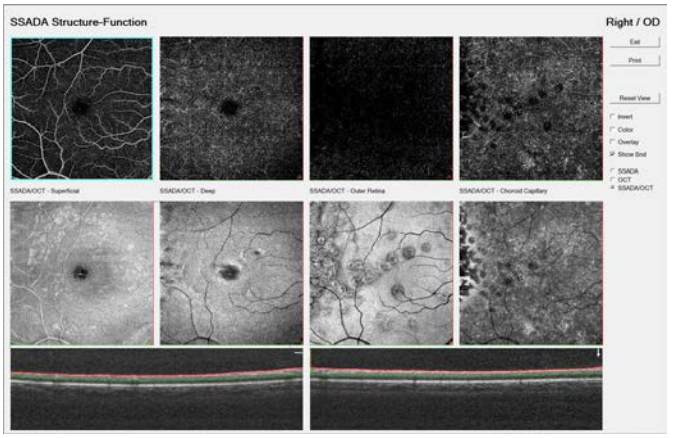
SA-PO019

Optical Coherence Tomography and En Face Retinal Findings in Membranoproliferative Glomerulonephritis Type 2 Paula Delegrego Borba, João Rafael De oliveira dias, Eduardo Amorim Novais, Andre Romano, Gianna Mastroianni-kirsztajn, Rubens Belfort De mattos. *Ophtalmology and Visual Sciences Dept, Univ Federal de Sao Paulo - UNIFESP, Sao Paulo, Brazil; Nephrology Dept, Univ Federal de Sao Paulo - UNIFESP, Sao Paulo, Brazil.*

Introduction: Membranoproliferative glomerulonephritis type 2 (MPGN II) is a condition with electron dense deposits in the glomerule basal membrane that usually affects youngsters of 5-15 years old. Patients may have assymptomatic retinal drusen-like deposits but 10% of cases may have choroidal neovascularization that leads to visual loss. We evaluated patients with a high-speed spectral-domain optical coherence tomography (SD-OCT) device and en face OCT imaging of the retina.

Case Description: Four eyes of 2 patients with MPGN II were scanned using a high-speed 840-nm-wavelength SD-OCT (RTVue XR Avanti; Optovue, Inc, Fremont, USA). The split-spectrum amplitude-decorrelation angiography algorithm was used to detect blood flow. Fluorescein angiography (FA) (HRA System, Heidelberg Engineering) images were obtained in search for drusen-like deposits in the Bruch membrane or choroidal neovascularization.

Both patients (female, 34 years old and male, 25 years old) had best corrected visual acuity of 20/20 in both eyes, unremarkable anterior biomicroscopy, RPE mobilization and macular drusen-like deposits.There was no choroidal neovascularization at the FA. En face OCT showed hyporeflective dots with a hyperreflective ring at the RPE that corresponds to drusen-like deposits underneath the RPE and dilated choroidal image.



Discussion: MPGN II may cause drusen and choroidal neovascularization. Eye examination is useful to diagnose visually threatening complications. The newer high-speed spectral-domain optical coherence tomography instrument may define the precise location of the drusen-like deposits when using En face OCT.

SA-PO020

Severe Hyponatremia following the Treatment of Pulmonary Strongyloides Stercoralis Infection Renu Regunathan-Shenk, Wooin Ahn, Sumit Mohan. *Nephrology, New York Presbyterian-Columbia Univ Medical Center, New York, NY.*

Introduction: Strongyloides sterocoralis is a soil transmitted nematode which can cause serious infection in immunocompromised patients through skin penetration. The helminth can cause abdominal and pulmonary symptoms and can continue to autoinfect patients if untreated. It has been infrequently reported to cause hyponatremia which resolves with treatment of the infection.

Case Description: A 59-year-old Dominican man with a history of single lung transplant and chronic abdominal pain was admitted for treatment of pulmonary strongyloides infection found on routine outpatient bronchoscopy. On admission he was found to have an E. Coli bacteremia which was attributed to gastrointestinal translocation. The patient was started on ivermectin (15 mg/day orally) and piperacillin tazobactam (4.5 grams every 8 hours intravenously in 5% dextrose solution). He developed a rapid decline in his serum sodium concentration from 135 mmol/L prior to admission to 109 mmol/L on hospital day 5. Physical exam at this time was notable for euvolemic appearance, lethargy, and inattention. Laboratory evaluation confirmed a hypo-osmolar hyponatremia with elevated urine osmolality (576mOsm/kg) consistent with Syndrome of Inappropriate ADH Secretion (SIADH). Thyroid studies and cerebral fluid studies were unremarkable. He was treated with hypertonic saline and desmopressin until he achieved normonatremia. He has been continued on weekly ivermectin treatment, daily salt tablets, and furosemide tablets.

Discussion: Strongyloides stercoralis induced SIADH in an under-recognized cause of euvolemic hyponatremia, especially in patients who have traveled to endemic areas or who are immunocompromised. Prior case reports have shown resolution of hyponatremia with strongyloides treatment, however we present a patient who worsened after bronchoscopy and initiation of ivermectin. We propose that this may have occurred due to increased systemic parasite exposure after the bronchoscopy procedure.

SA-PO021

A Case of Disseminated HSV Infection in PD Patient with Bullous Pemphigoid Yujiro Machida,[1] Kentaro Fujii,[1] Ayumi Yoshifuji,[1] Naoki Washida,[1] Hirobumi Tokuyama,[1] Matsuhiko Hayashi,[2] Shu Wakino,[1] Hiroshi Itoh.[1] *[1]Dept of Internal Medicine, Keio Univ School of Medicine, Tokyo, Japan; [2]Apheresis and Dialysis Center, Keio Univ School of Medicine, Tokyo, Japan.*

Introduction: Patients with end stage renal disease (ESRD) are affected by various infections with high mortality because of the immunodeficiency. We report a rare case of disseminated Herpes simplex virus (HSV) infection in peritoneal dialysis (PD) patient, who was treated with high-dose steroid for bullous pemphigoid (BP).

Case Description: A 72-year-old man under the treatment with PD for 2 months for ESRD caused by nephrosclerosis was admitted to our hospital because of blisters and ulceration on his whole body for two weeks. He had had BP and been treated with 60 mg of prednisolone. Twenty-nine days after the admission, peritoneal fluid became yellowish-brown and peritonitis was suspected from the elevation of inflammatory markers. Though the cell count of peritoneal fluid was within the normal range, multinuclear, frosted glass-formed cells were detected in PD fluid, which indicated HSV pritonitis. Serum HSV-DNA elevated to $6x10^5$ copies and he was diagnosed as disseminated HSV infection. After 200 mg of Acyclovir daily was administered, he had a severe disturbance of consciousness. Although differential diagnosis between acyclovir encephalopathy and HSV encephalitis was difficult, the results of spinal fluid tap and head MRI concluded acyclovir encephalopathy. Introduction of hemodialysis recovered his consciousness. HSV-DNA was decreased, although he developed multiple complications of hemophagocytic syndrome, bacterial infection and invasive pulmonary aspergillus, and died 56 days after hospitalization.

Discussion: We experienced a rare case of disseminated HSV infection and PD-related HSV peritonitis. The combination of immunodeficient factors of ESRD, high-dose steroid and BP contributed to the severe immune-compromised state and disseminated HSV infection. Since an early diagnosis determines the prognosis of disseminated HSV infection, cell pathology in peritoneal fluid would assist preemptive therapy.

SA-PO022

Use of Rituximab in Goodpasture's Disease with Pulmonary Hemorrhage Scherly Leon, Vadim Abramov, Farouk Talakshi, Mary C. Mallappallil, Moro O. Salifu. *Medicine, Renal Div, Downstate Medical Center, Brooklyn, NY.*

Introduction: Goodpasture's syndrome (GPS)or anti-GBM disease is a rare autoimmune disease, where pathogenic autoantibodies deposit in the basement membrane. It presents with rapidly progressive glomerulonephritis, with or without pulmonary hemorrhage. The current standard treatment of Anti-GBM disease is immunosuppression to reduce antibody production and plasmapheresis to remove existing antibodies in circulation. Rituximab, a monoclonal antibody directed against CD-20 antigen present on B-lymphocytes, approved for various B-cell lymphoproliferative diseases has been used in ANCA associated vasculitis with success; however it's use in anti-GBM disease is scarce and data regarding safety and efficacy is lacking. We report use of Rituximab in the treatment of GPS with pulmonary hemorrhage.

Case Description: A 35 year-old man presented in 2012 with two week history of nausea, vomiting, intermittent fevers and dark urine. Laboratory findings were creatinine 18 mg/dl, potassium 6.1 mmol/L, Hgb 11.6 g/dL, and platelet count 288 x 10^3 per µL. Urinalysis showed nephritic urine sediment. Serology test including ANCA was negative. Anti-GBM antibodies levels were greater than 8 with peak 27. CT chest with pulmonary hemorrhage. He was given pulse dose steroids and initiated on dialysis. Renal biopsy was consistent with GPS (crescentic GN linear anti-GBM on IF). Plasmapheresis was initiated and patient received four doses of Rituximab. Anti-GBM level on discharge from hospital was 2.9. Since initial presentation, patient had two admissions to the hospital in 2014 and 2015 with undetectable Anti-GBM levels.

Discussion: Patients with anti-GBM renal disease have high mortality, especially when pulmonary involvement is present. The use of steroid, immunosuppressives and plasmapheresis alone or in combination has led to a significant improvement of both patient survival and clinical symptoms. Anti-GBM disease is a rare fulminant disease, data regarding the safety and efficacy of alternative therapies are lacking. There are few reported cases of anti-GBM disease treated with rituximab. We present a case of anti-GBM disease with pulmonary hemorrhage successfully treated with Rituximab.

SA-PO023

A Rare Case of Aluminum Toxicity Khurram Saleem, Khaled Boobes, Yazan M. Alia, Muhammad H. Hasan, Jennifer A. Tuazon. *Nephrology, Northwestern Memorial Hospital, Chicago, IL.*

Introduction: Aluminum toxicity was initially described in encephalopathic patients with renal failure, overdosing of aluminum-based phosphate binders and attributed to contamination of water used for dialysis treatments. Use of alum irrigation for the treatment of refractory hemorrhagic cystitis was first reported in 1982. It was described as a safer alternative to formalin bladder irrigation. We report a case of bladder perforation after alum irrigation, leading to intra-peritoneal aluminum exposure. Our patient expired despite chelation and renal replacement therapy. Her serum aluminum concentration is the highest reported level to date.

Case Description: 67 year old female with cervical cancer, admitted for urosepsis, was noted to have hematuria and urinary retention. Her catheter was changed due to clot obstruction and bladder irrigated with saline. Following day continuous bladder irrigation was instituted for persistent hematuria. She underwent cystoscopy with fulguration for persistent hematuria secondary to radiation cystitis. Her CBI resumed with alum irrigant. Overnight, alum irrigant was placed on a pump for infusion. Hours later, patient transferred to ICU for hypotension. CT abdomen revealed free intraperitoneal air, large volume of new fluid, air around bladder suspicious for bladder perforation, and absence of contrast outside of the bowel. Bilateral percutaneous nephrostomy performed for urinary diversion and to evacuate free fluid. Aluminum levels were drawn. Patient was intubated, placed on vasopressors. Had non-gap metabolic acidosis and worsening renal function, concerning for aluminum toxicity due to intra-abdominal bladder perforation in the setting of alum irrigation. Deferoxamine was started and CVVH for acidosis. However patient developed refractory shock, and expired. Shortly before her death, aluminum level resulted 163.7mcg/L (normal 0 to 20mcg/L). Subsequent levels peaked at 1455.2mcg/L.

Discussion: We report systemic absorption of alum-containing irrigant following bladder perforation. Large aluminum load to the peritoneum resulted in systemic toxicity,multi-organ failure and death. Chelation therapy and CVVH were inadequate. We report the highest serum aluminum level to date.

SA-PO024

Primary Glioblastoma Multiforme in a Renal Transplant Patient Hermes Garcia-Sanchez, Arshad Ali, Stephen O. Pastan. *Nephrology, Emory Univ, Atlanta, GA.*

Introduction: Glioblastoma multiforme is the most common and most aggressive malignant primary Brain tumor in humans, involving glial cells and accounting for 52% of all functional tissue brain tumor cases and 20% of all intracranial tumors. Incidence of 2–3 cases per 100,000. The principal neoplasm involving the CNS of transplant recipients is non-Hodgkin lymphoma while glial tumours are rarely described.

Case Description: We describe 54 year old Male with a history of Deceased Donor Renal transplant in 1999 whose kidney disease was secondary to Hypertensive nephrosclerosis. Donor information is not available. The patient had been in his usual state of health until one week prior to presentation, when he started feeling weak and became confused, reason for hospitalization.

An MRI brain confirmed a large mass measuring 5.4 x 2.9 cms ,in the corpus callosal splenium and second lesion 8 x9 mm, in the left parietal region. He had a biopsy done which revealed a GBM. Neurosurgery was consulted and mass was found to be unresectable. Neuro-Oncology was consulted and he was advised radiation therapy and possible chemotherapy, however he decided to seek second opinion. His Post transplant period has been remarkable for a borderline rejection with donor specific antibodies, treated with plasmapheresis and IVIG. His immunosuppressant medications were Cyclosporine , Mycophenolate mofetil and prednisone.

Discussion: Review of the literature indicates that gliomas do not seem appear in an early post-transplant period. These tumors have been reported mostly after 4–20 years from renal transplantation. Increased risk of tumour occurrence may be related immunological disorders such as HIV, and also to the administration of immunosuppressive drugs. Few studies have shown that cyclosporine may induce phenotypic changes in different tumoural and normal line cells and may play a role in modulating the neoplastic course. There seems to be the existence of a relationship between glioblastoma development and kidney transplant, but this association needs to be studied further. With increasing life expectancy of transplant recipients, evaluation of the risk of serious complications such as glial tumors is necessary.

SA-PO025

Eculizumab in Gemcitabine-Induced Thrombotic Microangiopathy Venkata Buddharaju, Rajat Lamba, Savneek S. Chugh, Rahul N. Pawar, Rudrick V. Ledesma, Praveen N. Chander. *Nephrology, Westchester Medical Center, Valhalla, NY.*

Introduction: Thrombotic microangiopathy (TMA) is a pathological process involving thrombocytopenia, microangiopathic hemolytic anemia and microvascular occlusion particularly the kidney and brain. Eculizumab, a complement C5 inhibitor, has been used to successfully treat cases of atypical HUS but its use has not been widely reported in drug induced TMA. We report a case of Gemcitabine induced TMA treated with Eculizumab.

Case Description: A 68 y/o male with h/o hypertension, Diabetes mellitus, CKD with a baseline Cr 1.9, Prostrate Ca. s/p Whipple procedure, receiving gemcitabine as neo adjuvant chemotherapy was sent to the hospital for worsening creatinine, 20 lbs. weight gain and worsening pedal edema over the duration of one month. On admission, he was in hypertensive urgency with BP 235/110. Labs showed Hb 9, platelet 201, Na 136, K 5.4, Cl 114, HCO3 18, BUN 53 and Cr of 3.0. Urinalysis showed 3+ blood and 4+ protein. Further workup revealed normal complements, negative ANA, ANCA, hepatitis panel and HIV serology, elevated LDH and low haptoglobin. Occasional schistocytes were noted on the peripheral smear. Renal ultrasound showedmildly echogenic kidneys. Urine protein/creatinine ratio was 7.5.A renal biopsy was performed, which showed TMA, clinically suspected to be secondary to gemcitabine. The patient was started on Eculizumab regimen but renal function deteriorated requiring RRT. After 3 months of therapy, his LDH and haptoglobin have improved but he is still on Dialysis.

Discussion: The mechanism of chemotherapy induced TMA is presumed to be a dose dependent direct endothelial injury rather than deficient ADAMTS 13 activity or complement dysfunction. So, Therapeutic plasma exchange is usually not recommended. There are rare case reports of Gemcitabine induced TMA that improved with TPE. This indicates that patients who do get TMA while on Gemcitabine likely have some complement dysfunction or a serum factor induced by Gemcitabine that is responsible for endothelial injury. There might be a role for Eculizumab in underlying complement dysregulation in chemotherapy induced TMA, which needs further studies.

SA-PO026

Improvement of Renal Function with Treatment of Hypothyroidism Ibrahim M. El-Ali, Ana Claudia Onuchic, Ruchir D. Trivedi. *Dept of Medicine, Div of Nephrology, Univ of Connecticut School of Medicine, Farmington, CT.*

Introduction: Association of subclinical hypothyroidism and chronic kidney disease is increasingly being recognized. Early data suggests improvement in renal function with thyroid hormone replacement in patients with clinical and subclinical hypothyroidism. We present a case of dramatic improvement of renal function upon successful treatment of hypothyroidism.

Case Description: 33 y/o AA male with past medical history of nasopharyngeal carcinoma and cisplatin nephropathy (baseline creatinine 2.4 mg/dL)presents with sustained elevation of creatinine kinase (CK). No improvement was noted after stopping statin and reported intense exercise regimen. No detectable urine myoglobin. CK remained about 40,000 IU/L, with gradual worsening of creatinine up to a peak of 3.2 mg/dL. Work up revealed primary hypothyroidism with TSH 117 uU/ml (N=.34 - 5.6) and Free T4 < 0.4 ng/dL. Muscle biopsy showed type ll muscle fiber atrophy and loss which can be correlated with biochemical lack of L-thyroxine. The patient was started on levothyroxine replacement and within days demonstrated improvement in CK and Scr. Seven weeks after initiation of therapy there is ongoing improvement in CK, TSH and Scr to levels of 3271 IU/L, 15.4 uU/ml, and 1.9 mg/dL.

Discussion: Experimental evidence suggests that hypothyroidism is associated with changes in renal function and decrease nephron mass. Similarly, hyperthyroidism can result in glomerular hypertrophy by enhanced expression of renin mRNA. Hypothyroidism blunts compensatory hypertrophy after unilateral nephrectomy in remnant kidney models. Developmentally, thyroid hormone also has important role in tubular function including maturation and density of many tubular transporters. We demonstrate continued improvement in renal function upon thyroid hormone replacement. Subclinical and overt hypothyroidism may be under recognized in CKD and ESRD. Further studies are needed to understand these complex interactions.

SA-PO027

A Case of Rapidly Progressive C3 Glomerulonephritis Aala Jaberi, Jean M. Francis, Craig E. Gordon. *Nephrology, Boston Medical Center, Boston, MA.*

Introduction: C3 glomerulonephritis (C3GN) is a rare glomerular disease,characterized by predominant C3 deposition within the glomerulus. It is thought to be caused by uncontrolled activation of the alternative complement pathway . Eculizumab, a humanized monoclonal C5 antibody, has advanced the treatment of complement mediated diseases such as complement-mediated hemolytic uremic syndrome ,and has emerged recently as a treatment option for C3GN.

Case Description: A 74 year old retired software engineer with history of atrial flutter,and nephrolithiasis was transferred to our center with 2 weeks history of sore throat, fatigue, fever and rigors. Laboratory studies were significant for WBC 19U/L with left shift, platelets 40,000/UL, and serum creatinine 2.2 mg/dl, which rapidly increased to 11 mg/dl over 4 days. Blood cultures grew Streptococcus pyogenes. Further tests revealed a high ASO titre at 800, ANA 1:160, and low C3 and C4. Hemodialysis was started for uremic symptoms and a kidney biopsy was performed. The biopsy revealed an acute glomerulonephritis with C3 predominance, with tubulointerstitial nephritis, there were also features of post infectious GN evident by subepthelial humps. Intravenous Methylprednisolone was started but he remained dialysis dependent. With the consideration that the infection likely induced unregulated activation of the alternative complement pathway. We started eculizumab 900 mg . Patient received a total of six hemodialysis treatments . After 1 dose of eculizumab, the serum creatinine plateaued without dialysis treatment at 3.9 mg/dl, dialysis treatment was discontinued and plan was made to continue weekly infusions of eculizumab.

Discussion: Disorders of alternative complement pathway regulation are becoming increasingly recognized. There are no proven therapies for C3GN, but targeting terminal complement is an attractive approach given the known causes of C3GN. There are few reported cases of the benefit of eculizumab in C3GN and often describe the agent's efficacy earlier in the course. This case represents a unique instance of effective treatment of dialysis-dependent C3GN with early restoration of renal function.

SA-PO028

Nephrotic Syndrome After Scorpion Sting Boju Sangeetha Lakshmi, Chaitanya Vemuri, Anil Kumar Cheni Venkata, Ram R, Siva Kumar Vishnubhotla. *Dept of Nephrology, Sri Venkateswara Inst of Medical Sciences, Tirupati, Andhra Pradesh, India.*

Introduction: Scorpion venom is a water soluble, anti-genic and heterogeneous mixture.The reported incidence of scorpion sting in India is 0.6%. Scorpion sting resulting in acute renal failure has been reported in the past, but not the nephrotic syndrome.

Case Description: A 49-year-old gentleman, non-diabetic and not a hypertensive, presented with history of scorpion sting over the fourth digit of the left hand. Patient had immediate intense local pain, swelling and redness. Within one hour he had hypersalivation, sweating, vomiting and diarrhoea. After three days, the patient complained insidious onset of abdominal distension, followed by paedal oedema and facial puffiness over next one week. There was no history of oliguria, dysuria and haematuria. Investigations revelead serum creatinine: 2.9 mg/dL, 24 hour urine protein was: 9.90 g. He was subjected to renal biopsy at that institute.The diagnosis was minimal change with acute tubular necrosis.He presented to our institute with breathlessness and ansarca. On examination BP 140/90mmHg and bilateral crackles on auscutation. Serum creatinine:7.0 mg/dL, blood urea:148 mg/dL, total serum proteins: 5.5 g/dL, serum albumin: 2.5 g/dL, total cholesterol: 237 mg/dL, triglycerides: 182 mg/dL, haemoglobin: 12.0 g/dL and 24 hour protein: 2872 mg. He was dialyzed for three sessions and subjected to renal biopsy and diagnosed to have minimal change disease and acute tubular necrosis, thepatient was continued on dialysis. Urine output improved after three more weeks. Serum creatininestabilizedto2.0 mg/dL after eight weeks of scorpion sting.

Discussion: The scorpion venom is composed of varying concentration of neurotoxin, cardiotoxin, nephrotoxin, haemolytic toxin, phosphodiesterase, phospholipases, hyaluronidases, glycosaminoglycons, histamine, serotonins, and tryptophan and cytokine releasers. Acute renal failure after scorpion sting is reported but nephrotic syndrome is not reported.We report a patient of nephrotic syndrome after scorpion sting.The lacunae in the present knowledge linking scorpion sting venom with nephrotic syndrome would only be repleted with publications of similar reports.

SA-PO029

Diffuse Crystals Accumulation in the Proximal Tubules, Podocytes, and Interstitial Histiocytes of a Patient with a Multiple Myeloma Satoshi Hara,[1] Kiyoaki Ito,[1] Kazunori Yamada,[1] Ryoichi Miyazaki,[2] Mitsuhiro Kawano.[1] *[1]Rheumatology, Kanazawa Univ Graduate School of Medicine, Kanazawa, Ishikawa, Japan; [2]Internal Medicine, Fujita Memorial Hospital, Fukui, Japan.*

Introduction: Light chain proximal tubulopathy with crystals formation is a rare condition, accompanied by paraproteinemia. In particular, observation of crystal inclusions in the podocytes has seldom been reported. We present a distinct case that revealed diffuse crystal inclusions in a variety of kidney cells of a multiple myeloma (MM) patient, including the proximal tubular cells, podocytes, and interstitial histiocytes.

Case Description: A 66-year-old Japanese woman was admitted to our hospital and diagnosed with gradual deteriorated kidney function (serum creatinine, 2.0 mg/dL), proteinuria (urinary protein, 1.3 g/d), and mild hematuria (urinary red blood cells, 10-19/hpf). Urinary b2-microglobulin was notably elevated (117,700 mg/L); however, Fanconi's syndrome was not detected. Elevated serum IgG levels (IgG 2,559 mg/dL) with IgA and IgM suppression were confirmed, and serum immunoelectrophoresis revealed monoclonal IgG-κ. Examination of kidney biopsies revealed crystal inclusions in the proximal tubules, podocytes, and interstitial histiocytes. The crystals tested negative for eosin, periodic-acid Schiff, and trichrome staining. No segmental glomerulosclerosis was observed. Immunofluorescence staining of both κ and λ was negative. Similarly, immunohistochemistry, using an antigen retrieval method, failed to detect either κ or λ. Transmission electron microscopy revealed highly electron dense crystals that diffusely accumulated in the proximal tubules, podocytes, and interstitial histiocytes. By bone marrow biopsy, the patient diagnosed as MM. Bortezomib treatment attenuated kidney dysfunction and proteinuria. Sequential DNA analysis confirmed that the patient had Vκ subgroup I restriction.

Discussion: Monoclonal light chains are internalized into the lysosomes of proximal tubular cells by receptor-mediated endocytosis, where they form protease resistant crystals. Our case suggests that podocytes can engulf crystals in a similar manner, despite lacking the receptors found on proximal tubular cells.

SA-PO030

Erythematous Skin Rash and Gastrointestinal Bleeding as Presenting Features of ANCA Negative Pauci-Immune Glomerulonephritis

Anusha Lakshmi Badveli, Chanchal Kumar Jana. *Internal Medicine, R.G. Kar Medical College and Hospital, Kolkata, West Bengal, India.*

Introduction: Pauci-immune glomerulonephritis (PGN) is one of the common causes of RPGN. In most patients with PGN, circulating antineutrophil cytoplasmic autoantibody(ANCA) is present, however 10% of the patients are ANCA-negative. Usually extra renal manifestations in ANCA negative PGN are rare, but the case reported here is a rare presentation having skin rash and gastrointestinal (GI) manifestations.

Case Description: A 50-year-old female was admitted with low-grade intermittent fever, erythematous maculopapular rash all over the body and asymmetrical arthralgia involving large and small joints for about 3 months. She had one-week history of pain abdomen and melena followed by decreased urine output and generalized edema. On examination BP 156/94 mmHg, Birmingham Vasculitis Activity Score of 23/63. Investigations: Hb 9.9 g/dL, serum creatinine 4.0 mg/dL, urinalysis - protein ++, RBC 2-3/hpf, 24 hour urinary protein 4.75gm/day. Serum uric acid & C3 were normal. Serum ANA, pANCA, cANCA, and RA factor were negative. Skin biopsy for IgG, IgM, IgA, C3, C1q was negative. USG showed normal sized kidneys. Renal biopsy: Light microscopy showed segmental fibrinoid necrosis and early cellular crescents with mild increase in cellularity of mesangial matrix. Immunofluorescence: IgG, IgM, IgA, C3, C1q, kappa and lambda chains were negative. Diagnosis of ANCA negative pauci-immune GN with crescents was made and patient was started on systemic steroids and cyclophosphamide pulse therapy. Patient improved symptomatically and creatinine levels gradually declined.

Discussion: Patients with ANCA negative PGN rarely present with skin and GI manifestations. In a study done in China comparing clinical features of ANCA negative patients only 7% were found to have GI manifestations and 17.9% had skin rash. These patients were treated similarly to ANCA-positive patients, although no study has focused specifically on the treatment of ANCA-negative patients. Such patients could be easily confused as other forms of systemic vasculitis and therefore early identification and prompt treatment could prevent many life threatening complications and improve prognosis.

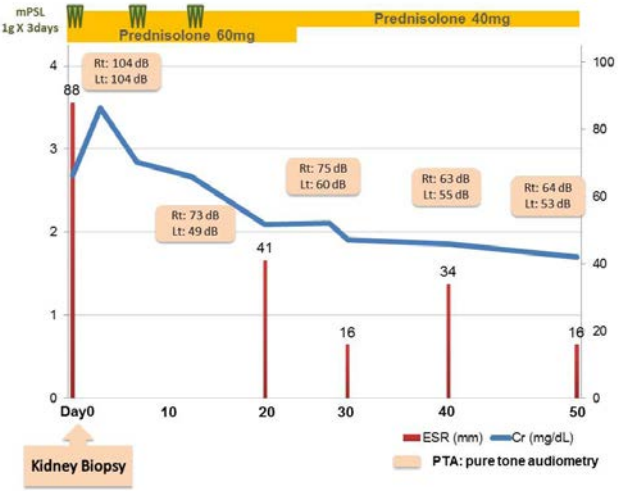
SA-PO031

A Case of ANCA-Associated Nephritis Mainly Localized to the Tubulointerstitial Area, Successfully Treated by Steroid Therapy

Tomo Nakajima, Yosuke Nakagawa, Takuya Isegawa, Masahiro Koizumi, Masafumi Fukagawa. *Div of Nephrology, Endocrinology and Metabolism, Tokai Univ School of Medicine, Isehara, Kanagawa, Japan.*

Introduction: The typical pathological findings of antineutrophil cytoplasmic antibody (ANCA)-associated nephritis consist of extracapillary proliferation and necrotizing crescent formation. Nevertheless, a few cases of ANCA-associated nephritis, in which the tubulointerstitial area was mainly affected, are reported. Here, we present such a case of ANCA-associated tubulointerstitial nephritis, and review its characteristics compared to ANCA-associated glomerulonephritis.

Case Description: A 74 year-old generally healthy female developed bilateral hearing loss, and thereafter suffered from persistent fever. With a diagnosis of bacterial pneumonia, she was admitted to another hospital and treated with several broad-spectrum antibiotics without improvement. Four weeks later, she was referred to our hospital. On admission, weight loss and peripheral numbness and weakness was noted in addition to advanced hearing loss and fever. Serum creatinine level was elevated to 3.5 mg/dl, while urinalysis revealed mild proteinuria with few red blood cells and no cast in the sediment. Sinusitis and alveolar hemorrhage were observed by CT scan. Immunological tests demonstrated positive myeloperoxidase (MPO)-ANCA (104 U/ml). In view of multiple organ involvements, ANCA-associated vasculitis was suspected. Renal biopsy showed diffuse interstitial infiltrates and remarkable vasculitis in small arteries and capillaries with only a small number of crescentic glomeruli, which was consistent with ANCA-associated tubulointerstitial nephritis. Steroid therapy ameliorated not only kidney dysfunction, but also hearing loss.



Discussion: In an atypical case of ANCA-associated nephritis with near normal urinalysis, we need to consider the possibility of tubulointerstitial nephritis.

SA-PO032

Treatment of Severe Resistant Idiopathic Membranous Glomerulopathy with Adrenocorticotropic Hormone Gel: A Case Report

Blaithin A. McMahon,[1] Adam R. Berliner.[2] [1]*Div of Nephrology, Johns Hopkins School of Medicine, Baltimore, MD;* [2]*Nephrology Center of Maryland, Baltimore, MD.*

Introduction: Idiopathic membranous glomerulonephritis is a frequent cause of nephrotic syndrome. Therapy is based on Ponticelli protocol or other immunosuppressive therapies. Adrenocorticotropic hormone has been used with some success for the treatment of resistant idiopathic membranous nephropathy. We present here a case of a 39 year old Caucasian man presenting with severe resistant idiopathic membranous glomerulonephritis who encountered only a partial response with cyclosporine but had a complete remission with single therapy corticotropin.

Case Description: Medical history included chronic kidney disease stage IIIA and hypertension. He attended a work-associated physical examination that revealed proteinuria and subsequent 24hr urine collection revealed 18g of proteinuria. His physical examination was notable for stage 3 hypertension, no chest, cardiac or abdominal abnormalities. He had bilateral +2 pitting edema to the knees. Renal biopsy showed thickened capillary walls with spikes and holes in the glomerular basement and subepithelial deposits. All inflammatory and infectious serological studies were negative. Treatment included corticosteroids and cyclosporine 100mg twice daily. His glomerular filtration rate was 58 ml/min per 1.73/m2. His proteinuria improved from 18g to 5g over an eight week period after initiation of cyclosporine, however, five months later he relapsed to 10g and later to 15.9g. After stopping his cyclosporine, his proteinuria worsened to 20g/24hr urine collection. Magnetic resonance imaging of his renal veins were negative for thrombus. PLA2 receptor antibody testing was negative. At our institution, he was treated with corticotropin (ATHACAR H.P.) 80 unit/mL injectable gel subcutaneously twice weekly. A complete remission was achieved within 12 months. Patient characteristics and clinical course is reviewed.

Discussion: Randomized controlled trials are needed to evaluate the therapeutic efficacy of corticotropin for resistant idiopathic membranous glomerulonephritis.

SA-PO033

HCV-Related Cryoglobulinemic Glomerulonephritis and B Cell Lymphoma: Early Antiviral Therapy Crucial

Sixto G. Giusti, Ivo Lukitsch. *Nephrology, Ochsner Clinic Foundation, New Orleans.*

Introduction: Untreated chronic Hepatitis C Virus (HCV) infection often leads to a spectrum of severe extra hepatic manifestations related to B cell dysregulation, which include cryoglobulinemia, renal diseases, and lymphoproliferative disorders. Type I membranoproliferative glomerulonephritis (GN) associated with type II mixed cryoglobulinemia is the most common HCV related kidney disease, with membranous nephropathy and MPGN without cryoglobulinemia being less frequent.

Case Description: A 58 year-old Caucasian man with history of hypertension, recent biopsy proven membranous nephropathy, and treatment naïve chronic HCV infection Genotype 3a diagnosed 5 yrs ago, presented with complaints of intermittent vasculitis rash in his legs for a year as well as worsening paresthesias of his palms and soles. Initial evaluation showed microscopic hematuria, red blood cell casts, 1.2 grams of proteinuria, and serum creatinine (SCR) of 1.0 mg/dL. Serum C4 was low, and serum positive for type II cryoglobulins. Repeat kidney biopsy was showed a diffuse proliferative GN with characteristics of cryoglobulinemic GN. The patient was referred to hepatology for antiviral treatment, which was delayed due to myocardial infarction requiring bypass surgery. During this time he developed worsening renal function (SCR of 3 mg/dL) with increase in proteinuria to 2-3 gm prompting the decision for immunosuppressive therapy. Rituximab (1 gm) was administered and he was started on ledipasvir 90 mg/sofosbuvir 400 mg with prompt viral response and an improvement of renal function (SCR 1.6). Weeks after, he presented with AKI and diffuse alveolar hemorrhage and was treated with high

dose steroids, plasma exchanges, and a second dose of Rituximab, with clinical and renal improvement. One month after discharge, he was re admitted with ARDS and diagnosed with B-cell lymphoma.

Discussion: There is a paucity of data on anti-HCV therapy in patients with renal failure often resulting in a delay of antiviral therapy. Immunomodulatory therapies may provide transient improvement of symptoms but bear the risk of significant adverse reactions. Early initiation of antiviral therapy is vital in order to prevent spectrum of HCV related complications.

SA-PO034

A Case of Membranous Nephropathy with an Adjacent Smooth Muscle Cell Tumor Laith Al-Rabadi,[1] Cathryn J. Byrne-Dugan,[2] Stanley D. Crittenden,[1] Helmut G. Rennke,[2] Laurence H. Beck.[1] *[1]Boston Medical Center; [2]Brigham and Women's Hospital.*

Introduction: Different stromal tumors can occur in the kidney and potentially skew the true extent of parenchymal injury induced by different glomerular diseases. Most of these stromal tumors are benign. The value of renal biopsy in assessing interstitial sequalae may be compromised by the mass effect of the infiltrating tumor cells.

Case Description: We describe a case of a 65 year old male patient, with a history of primary membranous nephropathy 20 years ago. He had initially been treated with the Pontocelli protocol with favorable response. He continued to be in remission until a few months prior to presentation when he developed anasarca. His 24 hour urine collection revealed 8 grams of protein, and creatinine was 1.8 mg/dl. The decision was made for the patient to undergo a kidney biopsy which confirmed recurrence of primary membranous nephropathy with positive staining for PLA2R. It also revealed advanced chronic changes that included focal global glomerulosclerosis (87%) in addition to interstitial fibrosis 80%. However, adjacent to this atrophic area, there was a tumor of spindle-shaped cells with smooth muscle characteristics. There was no atypia or mitosis and no clear capsule but the tumor cells appeared to infiltrate and surround the tubules and vasculature. This was labeled by the pathologist as a fragment of a smooth muscle cell tumor of undetermined malignant potential. The possibility of leiomyosarcoma could not be ruled out. MRI abdomen and pelvis did not show any evidence of extra renal involvement. The possibility of the parenchymal tissue being significantly influenced by its close proximity to the tumor prompted us to pursue another renal biopsy from the other kidney. Surprisingly, repeat biopsy showed only 15% of tubular atrophy and interstitial fibrosis. The patient was initiated on Rituximab and tolerated two courses of treatment. He achieved partial remission with UPCR less than 3 gram with stable Cr at 1.8 mg/dl.

Discussion: Coexistence of smooth muscle tumors and membranous nephropathy is rare. The extent of parenchymal involvement should be confirmed, with repeat biopsy, when there are concerns about tissue distortion by neighboring tumor.

SA-PO035

Freezing Point: Sjögren's Disease Leads to Cryoglobulin Induced Membranoproliferative Glomerulonephritis Manuel A. Fernandez Palmer, Roberto L. Collazo-Maldonado. *Nephrology, Methodist Dallas Medical Center, Dallas, TX.*

Introduction: Sjögren's disease is chronic autoimmune inflammatory disorder mainly affecting salivary and lacrimal glands but rarely it can present with systemic manifestations including kidney involvement.The kidney manifestations may incluye hypokalemic RTA, interstitial disease and rarely MPGN.

Case Description: This is a 30 year old woman with no medical history who arrived to ER complaining of a three day history of SOB and increasing edema on lower extremities.She denied toxic habits. Review of systems positive for lower extremity rash in the preceding weeks.P/E was pertinent for elevated BP at 159/90 mmHg, 94% O2Sat on NC at 2LPM, bibasilar crackles with decreased breath sounds at bases and lower extremity pitting edema.Labs showed HGB of 10 g/dL, creatinine of 1.32 mg/dL with normal electrolyte,albumin levels 3.4 mg/dL,UA with proteinuria and hematuria, and a BNP that was markedly elevated.CXR showed pulmonary edema and bilateral moderate pleural effusions.Patient was admitted and workup performed, including CTwhich was negative,lower extremity Doppler that was negative for DVT.Creatinine increased to 2.6 and proteinuria was quantified at 4 g/24hrs.Serologic work up was negative except for low Complement levels,along with a positive rheumatoid factor, positive anti-SSa. Clinical presentation and labs consistent with a diagnosis of Primary Sjögren's disease. Cryoglobulin levels where negative but kidney biopsy was performed and results consistent with Membranoproliferative Glomerulonephritis with intra capillary thrombi highly suggestive of cryoglobulins.Patient was started on high dose steroids and received five plasma exchanges. Afterwards, Rituximab 375 mg/m^2 was administered at weekly intervals times four. At the time of discharge creatinine had stabilized at 0.95 mg/dl.

Discussion: Despite being rare, Sjögren's Disease can lead to cryoglobulin formation and subsequent deposition in different tissues of the body. Nephrologists must consider this rare complication when evaluating patients with proteinuria, especially when there is worsening renal function and other systemic symptoms.

SA-PO036

Postinfectious Glomerulonephritis Associated with *Escherichia coli* Infection Caused by Transuretheral Prostatectomy Eleni Chelioti, Alexia Papalexandrou, Evdokia Efthimiou, Maria Sotiraki, Ioannis Xatzis, Maria Tsilivigou. *Dept of Nephrology, General Hospital of Piraeus, Athens, Greece.*

Introduction: Postinfectious glomerulonephritis (PIGN) is an immune-mediated glomerulonephritis(GN) caused by non-renal bacterial infection. In adults, PIGN is more common in immunocompromised patients, particularly diabetics. The major site of infection is the skin, followed by the lungs and the urinary tract. In terms of causative agents, Staphylococcusis the most common cause in elderly people, followed by Streptococcus. Gram-negative bacteria, including Escherichia coli (E. coli), are responsible for up to 10% of cases of adult PIGN and 5% of cases in the elderly. We report a patient with PIGN associated with E. coli infection caused by transuretheral prostatectomy.

Case Description: A 76-year-old Caucasian man with a history of coronary artery disease and recent transuretheral prostatectomy was admitted with complaint of fever, and uremic symptomatology that necessitated dialysis therapy. Blood and urinary cultures were positive forE. coli and resumed antibiotic therapy. After one week, he was afebrile, without amelioration of renal function and with signs of glomerular involvement:urine red blood cells= 20-40/HPF, 24-hour urine proteins=1.7g. Immunological analyses were neg-ative, except for decreased C4.The diagnostic approach led to a renal biopsy that findings were consistent with PIGN: endocapillary proliferative and exudative GN on LM; C3-dominant glomerular staining on IF and hump-shaped subepithelial deposits on EM. After urinary tract infection was controlled by antibiotic therapy, oral methylprednisolone was initiated, and the patient's renal function and nefritic syndrome subsequently gradually improved.

Discussion: For a diagnosis of PIGN, at least three of the following five criteria must be satisfied: 1)clinical or laboratory evidence of an infection preceding the onset of GN 2) decreased serum complement levels 3)endocapillary proliferative and exudative GN on LM 4)C3-dominant or co-dominant glomerular staining on IF and 5) hump-shaped subepithelial deposits on EM. In the present case, all criteria were met. Moreover, recently reported that rarely, *E. coli* , also cause this type of GN.

SA-PO037

A Patient Presenting with Thrombotic Thrombocytopenic Purpura-Hemolytic Uremic Syndrome and Leptospirosis Ali Veysel Kara,[2] Yasar Yildirim,[2] Zülfükar Yilmaz,[2] Melike Elif Celik,[2] Erdal Bodakci,[2] Ali Kemal Kadiroglu,[2] Mehmet Emin Yilmaz.[2] *[1]Nephrology, Dicle Univ, Diyarbakir, Turkey; [2]Internal Medicine, Dicle Univ, Diyarbakir, Turkey.*

Introduction: There are very rare case reports in the literature about leptospirosis in association with TTP-HUS. We present a case report of TTP-HUS syndrome in a patient with leptospirosis.

Case Description: A 27 years old female patient was was transferred to our clinic due to progressive deterioration in the general status and kidney functions. On admission, she was oriented and cooperated. She had blood pressure of 130/65 mmHg, heart rate of 90/min, temperature of 38.3 C and respiratory rate of 25/min. Patient had no urine output. There is minimal swelling on the dorsum of right hand of the patient. When we detailed history about this finding, she remembered that she saw mice in her working place in the night shift. Peripheral blood smear showed large numbers of fragmented red blood cells. Disseminated intravascular coagulation panel was normal. Viral hepatitis markers and serological tests for anti-nuclear anticore , anti-double stranded DNA and also Toxoplasma, Rubella, Cytomegalovirus, Herpes panel were all negative. C3 and C4 levels were normal. There was no reproduction in the blood cultures. ADAMS 13 level was reported as normal. Plasmapheresis was initiated immediately with the preliminary diagnosis of TTP/HUS. Also patient was empirically treated with antibiotics and on the 3rd day of treatment ; doxycycline 200 mg orally per day was added to therapy because of the positive result of Leptospira IgM ELISA test. After 14 days of antibiotherapy and a total of 10 sessions of plasmapheresis, patient general status improved and laboratory findings come to near normal levels. Patient was discharged with the normal laboratory findings.

Discussion: In conclusion; leptospirosis and TTP-HUS can present with the same clinical findings and differential diagnosis is crucial to initiate the right treatment. Also, it is important to consider co-occurrence or association of these two disease in the light of patient's history and laboratory findings although there are very rare reports in the literature.

SA-PO038

For the Eye Altering, Alters the All Marie-Angélique De Scheerder, Anne Marie Bogaert. *Internal Medicine, UZ Gent, Gent, Belgium; Nephrology, Sint-Elisabethziekenhuis, Zottegem, Belgium.*

Introduction: We describe the case of a 26-year-old African female that was treated successfully with belimumab in a case of severe membranous lupus nephritis, resistant to first line therapy.

Case Description: She presented initially with chronic dacryoadenitis and screening showed nephrotic range proteinuria. Biopsy of the kidney confirmed the diagnosis of membranous lupus nephritis. Clinical features (joint pain, dacryoadenitis and lupus nephritis) in combination with serology (positive anti-DNA antibodies, hypocomplementemia) confirmed diagnosis of systemic lupus erythematosus(SLE). Treatment was initiated with glucocorticosteroids (GCS), mycophenolate mofetil (MMF) and Hydroxychloroquine sulphate (Plaquenil®). Tacrolimus was associated but no effect was observed with the proteinuria remaining in nephrotic range and secondary effects of the GCS becoming a real concern. Patient was started on add-on belimumab with quasi-immediate effect on the

proteinuria, making it possible to decrease dosage of the other immunosuppressants and gradually stop them, even the GCS. Patient is now in complete remission after 2 years of treatment with no signs of relapse after stopping additional medication.

Discussion: Belimumab is indicated in treatment of seropositive active SLE in addition to standard therapy, when lack of clinical improvement despite optimal standard therapy. Two large, phase 3, multicenter, prospective, randomized, controlled trials (BLISS-52 and BLISS-76) compared belimumab with placebo in patients with SLE who were receiving standard therapies. Both studies showed significant improvement in SRI (Systemic Lupus Erythematosus Responder Index) with 10mg/kg of belimumab as compared with placebo. A phase 3 study (BLISS-LN) is recruiting patients with lupus nephritis since these post-hoc analysis of the BLISS trials suggest that belimumab may offer renal benefit in patients with SLE. The treatment is so far not recommended in these cases. We can conclude that our case shows excellent results of belimumab in lupus nephritis with persistent nephrotic range proteinuria under conventional treatment. Alternatives are scarce and mostly limited due to toxic effects and by failure to control disease.

SA-PO039

Overlap Syndrome or Drug Reaction? Varun Gaur, Michael T. Eadon, Jesus H. Dominguez. *Medicine, Indiana Univ, Indianapolis, IN.*

Introduction: The overlap of ANCA-Associated Vasculitis (AAV) with other autoimmune diseases is well known. However, the association of AAV with the use of TNF-α antagonists in Rheumatoid Arthritis (RA) patients is less understood.

Case Description: A 44 y/o white female with RA had prior treatment with methotrexate (3 yr), adalimumab (2 yr) and etanercept (2 yr). She concluded all DMARD therapy 3 yr prior to presentation (PTP), and then her RA flared 5 months PTP. After initiation of leflunomide and steroids, she had partial resolution. Two weeks PTP, she received golimumab for onset of severe neurological manifestations including right foot drop, distal extremity numbness, and a right 4th digit ischemic lesion. Upon presentation, she was admitted with persistence of these symptoms. Her serum creatinine increased from 0.9 (mg/dl) to 1.4 with 2 gm proteinuria. Her urinalysis had hematuria and serology was positive for PR3-positive cANCA. Her renal function deteriorated with a peak creatinine of 6.7, necessitating intermittent dialysis. A biopsy revealed pauci-immune diffuse necrotizing and crescentic glomerulonephritis consistent with AAV. She received pulse solumedrol, cytoxan, and plasma exchange. Her neurological symptoms improved after a month of therapy. After 6 weeks, she did not require dialysis and her serum creatinine was 2.4.

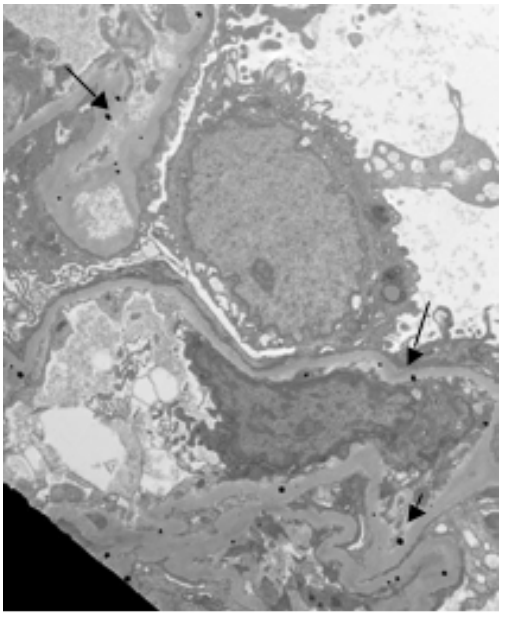
Discussion: We present a case of a patient previously treated with TNF-α inhibitors who then developed PR3-positive AAV years later. An association between AAV and RA has been described and RA may precede AAV by up to 8 years. Different theories explain this association. One reason may be the common genetic predispositions to autoimmunity, involving HLA or PTPN22 genes, reported in a series of both RA and AAV.A second theory suggests TNF antagonists may predispose one to develop secondary autoimmunity. In our case, the patient discontinued DMARDs 3 yr PTP, although had recently received Leflunomide and Golimumab. There are no reports that associate leflunamide use with AAV and only one case report suggests an association of golimumab with AAV. Our case highlights the need to further understand the importance of AAV in RA patients, and the potential role of TNF inhibitors on the development of AAV.

SA-PO040

Pauci Immune Crescentic Glomerulonephritis in a Patient with T-Cell Lymphoma and Argyria Tamer Rezk, James J. Penton, Mark Alan Little, John Cunningham, Alan D. Salama. *Centre for Nephrology, Royal Free Hospital, London, United Kingdom.*

Introduction: Silver is a transition metal element with a range of industrial and ornamental uses and is known to be toxic when ingested in significant amounts. Silver exposure causing argyria (skin deposition) and argyrosis (eye deposition) is well-recognised but the renal consequences of silver toxicity are poorly understood.

Case Description: A 47 year old woman with a T-cell lymphoma who refused conventional chemotherapy for 18 months but self-medicated with a remedy containing colloidal silver was admitted with acute dialysis-dependent kidney injury. The serum silver concentration was strikingly elevated at 127.1 nmol/l (reference value <2.8 nmol/l). Kidney biopsy demonstrated a pauci-immune crescentic glomerulonephritis and glomerular tufts with fine, dark, granular material scattered within the mesangium and along the glomerular basement membrane (GBM). Electron microscopy confirmed the presence of electrondense granules in the mesangium and along and within the GBM.



Electron probe microanalysis demonstrated that these granules contained predominantly silver. The patient recovered independent renal function following immunosuppression with cyclophosphamide and steroids.

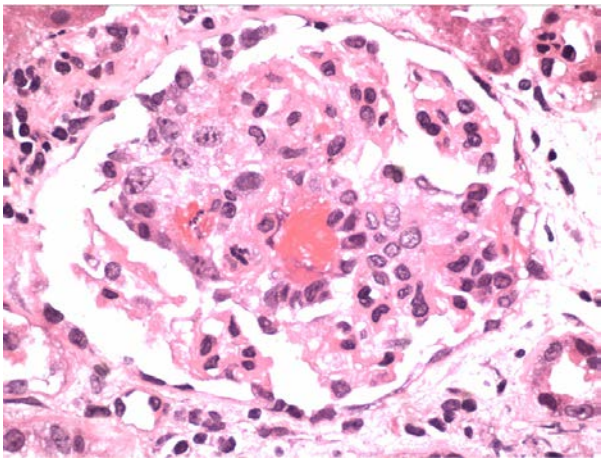
Discussion: Crescentic glomerulonephritis results from disruption of the GBM which may be induced by immune complexes or by cellular mediators. However our patient had no autoantibodies, and no deposited immunoproteins. Our case therefore represents a pauci-immune crescentic glomerulonephritis with intense silver deposition along the GBM. Between 5-10% cases of pauci-immune glomerulonephritis are ANCA negative. The pathogenesis in these cases may be related to other autoantibodies (such as anti-endothelial antibodies) or to direct leukocyte-induced GBM damage via soluble mediators, which in this case we believe was due to a combination of T cell lymphoma and argyria.

SA-PO041

PR3-ANCA Vasculitis following Influenza Vaccination Karim El Hachem, Eduardo J. Zouain, Isha Gupta, Steven D. Smith. *Nephrology, Mount Sinai- St Luke's Hospital, New York, NY.*

Introduction: Influenza vaccination has been associated with the development of autoantibodies and autoimmune rheumatic disease. We report a case of PR3-ANCA associated vasculitis following influenza vaccination.

Case Description: The patient is a 45 year old Hispanic male with no known medical history who presented with subacute onset pleuritic chest pain and shortness of breath. Four weeks prior to presentation, he had received his annual injectable influenza vaccine and reports feeling weak since. On presentation, he was hemodynamically stable. His exam was notable for bibasilar crackles. He had positive Rheumatoid Factor. His CT chest was notable for multiple ground glass nodules at the right upper lobe. His creatinine was 1.64 mg/dL. His urine albumin to creatinine ratio was 225 mg/gm creatinine and his urine protein to creatinine ratio was 500 mg/gm creatinine. He had 25-30 RBC/hpf with no dysmorphic RBCs. He had strongly positive PR3-ANCA antibody (>8 AI). His kidney biopsy revealed acute focal segmental necrotizing crescentic GN, pauci-immune type.



The patient was treated with pulse IV methylprednisolone and Rituximab 375mg/m2 weekly for four doses. Three months following induction therapy his creatinine improved from a peak of 3.6mg/dL to 1.4 mg/dL. His CT findings and hematuria resolved. His PR3-ANCA slowly decreased and became negative 6 months after induction.

Discussion: This patient's presentation with lung nodules on chest CT, necrotizing crescentic GN on kidney biopsy and high serum level of PR3-ANCA support a diagnosis of Granulomatosis with Polyangiitis with a strong temporal relationship to vaccination against influenza. This is the 9th case of ANCA associated vasculitis following influenza vaccination reported in the literature. Clinicians should be aware of the possible association between systemic vasculitis and influenza vaccination.

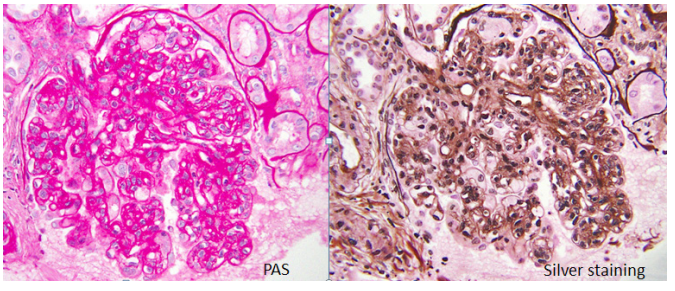
SA-PO042

C3 Glomerulonephritis Associated with Monoclonal Gammopathy

Aumyot Prongdong,[1] Weeraporn Srisung,[1] Mustafa G. Aly,[1] Irfan Warraich,[2] Faisal Jamal.[1] *[1]Nephrology, Texas Tech Univ Health Sciences Center, Lubbock, TX; [2]Pathology, Texas Tech Univ Health Sciences Center, Lubbock, TX.*

Introduction: A case of C3 glomerulonephritis associated with monoclonal gammopathy responding effectually with immunosuppressive therapy.

Case Description: The patient is a 65 year-old Hispanic female who presented with lower extremity edema and dyspnea. She had acute kidney injury with nephritic urinary sediments. C3 and C4 were low. Hepatitis B & C profile, ANA, ANCA, anti-GBM and SPEP were within normal limits. There was a faint monoclonal band in the gamma region on UPEP. Kidney biopsy was consistent with membranoproliferative glomerulonephritis (MPGN), of an undetermined etiology. Patient was readmitted with similar complaints and a rapidly declining renal function. Repeated UPEP showed a significant IGG kappa monoclonal protein and an elevated serum free light chain with kappa/lambda ratio of 2.52. Bone marrow biopsy revealed atypical plasmacytosis without overt myeloma. Repeated kidney biopsy showed global proliferative changes along with splitting of glomerular basement membrane. C3 deposits were seen on immunofluorescence. No reactivity was seen for IgA, IgG, IgM, C1q, C4, fibrinogen and albumin. Electron microscopy showed subendothelial and mesangial immune complex deposits.



Diagnosis was determined as C3 glomerulonephritis associated with monoclonal gammopathy. Patient was successfully treated with pulse glucocorticoids followed by oral glucocorticoids and mycophenolate mofetil. C5b-9 was elevated whereas factor H, C3 nephritic factor, and factor B were within normal limits.

Discussion: C3 glomerulonephritis is related to dysregulation of alternative pathway of complement (AP) that can be associated with monoclonal gammopathy. Treatment of underlying monoclonal gammopathy may be of benefit in such a situation. Genetic studies for dysregulation of AP might be helpful.

SA-PO043

Late-Onset Fabry Disease with a R112H *GLA* Mutation and Mild Increase in Plasma Globotriaosylsphingosine

Akifumi Onishi,[1] Reika Takemoto,[2] Tsutomu Hiromasa,[2] Hidetoshi Kagawa,[2] Hiroki Maruyama,[3] Ichiei Narita,[3] Hitoshi Sugiyama,[1] Jun Wada.[1] *[1]Okayama Univ Graduate School, Okayama, Japan; [2]Himeji Red Cross Hospital, Himeji, Japan; [3]Niigata Univ Graduate School, Niigata, Japan.*

Introduction: Fabry disease (FD), a lysosomal storage disorder caused by α-galactosidase A (GLA) gene variants, has a heterogeneous phenotype. *GLA* variants can lead to a late-onset and non-classical phenotype. We herein describe a 42-year-old patient with FD diagnosed by a renal biopsy exhibiting a R112H *GLA* mutation and a mild increase in plasma globotriaosylsphingosine (Lyso-Gb3).

Case Description: A 42-year-old Japanese male was referred to our hospital due to proteinuria. He had never experienced neuropathic pain, cutaneous angiokeratomas, or hypohidrosis. He had no family history of FD. At 32 years of age, positivity for urinary protein was noted on a health checkup. Thereafter, his urinary protein was annually positive, however, it was untreated because he had no other symptoms. The urinary protein was 0.62 g/gCr, serum creatinine 1.27 mg/dL, and the eGFR 51 mL/min/1.73m^2. Microscopic findings of a renal biopsy showed foamy change and numerous lamellar inclusions in the cytoplasm of podocytes. A significantly low level of leukocyte *GLA* activity (1.0 nmol/mgP/hr), normal level of plasma globotriaosylceramide (Gb3) (2.7 mg/ml), mildly high level of plasma Lyso-Gb3 (4.1 ng/ml), and the c335G>A, p.R112H mutation of *GLA* were found. He was diagnosed with late-onset FD without signs of the classical symptoms, cardiac hypertrophy or cerebrovascular disorder. He began taking enzyme replacement therapy of agalsidase beta every 2 weeks, and his renal function has remained stable for 8 months.

Discussion: FD patients with the R112H *GLA* mutation do not exhibit classical symptoms and are considered to have a late-onset phenotype (*Clin Genet* 2014) with higher plasma Lyso-Gb3 levels than healthy subjects (*PLoS One* 2015). Undiagnosed FD patients may exist because their symptoms are restricted to proteinuria alone, as shown in this case. Further familial examination will help us elucidate this case as sporadic or familial FD to make an earlier diagnosis and treatment.

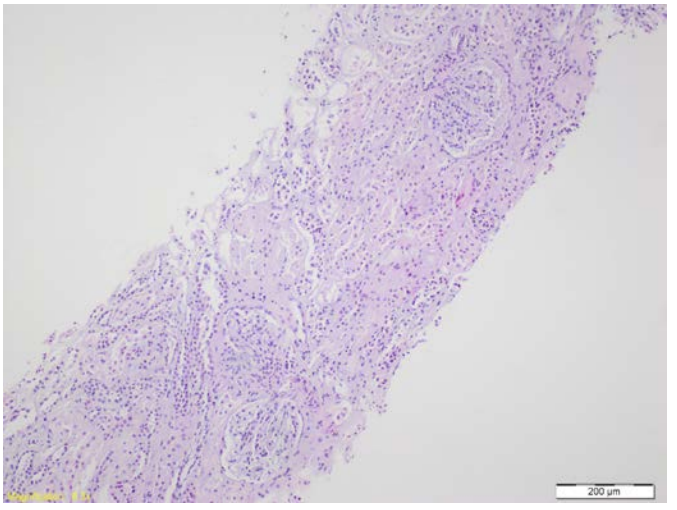
SA-PO044

Another Enemy for Kidneys: Synthetic Cannabinoids

Alper Alp,[1] Hakan Akdam,[2] Aysegul Ormeci,[3] Ibrahim Meteoglu,[3] Alparslan Unsal,[4] Yavuz Yenicerioglu.[2] *[1]Nephrology, Van Region Education and Research Hospital, Van, Turkey; [2]Nephrology, Adnan Menderes Univ, School of Medicine, Aydin, Turkey; [3]Pathology, Adnan Menderes Univ, School of Medicine, Aydin, Turkey; [4]Radiology, Adnan Menderes Univ, School of Medicine, Aydin, Turkey.*

Introduction: Synthetic cannabinoids(SC) are widely used especially among young population.These substances have various physiological,metabolic and psyhciatric(addictive) effects.In last few decades SC related acute kidney injury(SC-RAKI) is pronounced more often.

Case Description: A 20-yo man without a medical history presented to ED with abdominal discomfort,nausea and vomiting for 3-4 days.On physical examination;arterial tension was 150/60 mm/Hg,HR 86/min,without orthostatic signs.He denied any nephrotoxic drug use,OTC medication or contrast media exposure.He has been a synthetic cannabinoid(Bonzai)smoker for last 2 weeks.On admission he was oliguric and creatinine was 7.71mg/dl with normal creatinine kinase levels.Urinary analyse revealed pH 5,5,protein +,leu 3,ery 1.Renal ultrasound showed normal size kidneys with increased echogenities,without hydronephrosis.Intermittent hemodialysis therapy was started.Autoimmune antibodies were negative.Renal biopsy revealed acute interstitial nephritis with increased mesangial matrix.Vascular structures were normal,no specific immunohistochemistry staining was detected.



After 6 sessions of HD his urinary output increased and creatinine levels regressed without a specific therapy.24-h urinary proteinuria was 529,2mg/d.On the 11th day of hospitalisation his creatinine level was 0.6mg/dl.

Discussion: SC-RAKI is usually reported as a consequence of prerenal conditions or rhabdomyolysis.In general renal histopathology reveals acute tubular necrosis. However,rarely these patients may present with interstitial nephritis.In our case complete cure of the patient without specific therapy was quite interesting.

SA-PO045

A Unique Case of Granulomatous Acute Interstitial Nephritis from Ipilimumab

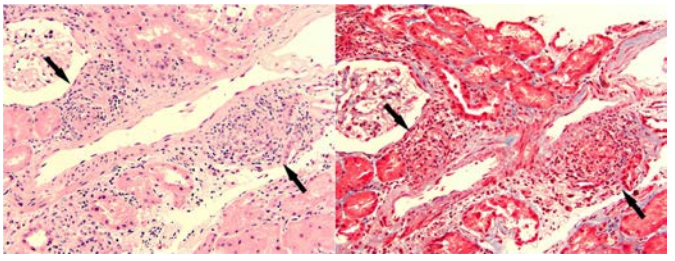
Kenneth Ralto,[1] Seymour Rosen,[2] Melanie P. Hoenig.[1] *[1]Nephrology, Beth Israel Deaconess Medical Center, Boston, MA; [2]Pathology, Beth Israel Deaconess Medical Center, Boston, MA.*

Introduction: Ipilimumab is a CTLA-4 inhibitor which is used for the treatment of melanoma. We report a case of granulomatous interstitial nephritis due to ipilimumab, which developed after the first dose and featured a prominent component of granulomatous vasculitis.

Case Description: A 70 year old man with stage IV melanoma presented with low grade fevers and malaise. He was found to have acute kidney injury with a creatinine of 6.0 mg/dL. Two months earlier, he had received a single dose of ipilimumab at which time his creatinine was 0.9 mg/dL. Laboratory data was notable for the absence of eosinophilia. Urinalysis showed 5-10 WBCs/hpf and many hyaline casts. A renal biopsy showed granulomatous interstitial nephritis with a component of granulomatous vasculitis (figure: H&E, Masson trichrome). He was treated with high-dose prednisone, which resulted in improvement of his renal function without the need for hemodialysis. After ten weeks of steroid therapy, his creatinine had decreased to 1.6 mg/dL.

Discussion: Ipilimumab is a potent activator of T cells and can interfere with the immune system's tolerance of self-antigens. This drug is known to cause a variety of immune-related adverse events including hypophysitis, hepatitis, colitis and dermatitis. Interstitial nephritis is a rare diagnosis, but has been reported to occur after exposure to

ipilimumab. Additionally, there have been reports of a sarcoidal-type response involving the lung and skin. This injury pattern is typified by angiocentric non-necrotizing well formed granulomas. Steroid therapy is effective at treating these immune-related adverse events and does not appear to impair the antineoplastic effects of ipilimumab. With the increasing use of immune-modulating antibodies for treatment of malignancies, it is important to be aware of this potential complication.



SA-PO046

Severe Rhabdomyolysis Secondary to Adenovirus Infection Daniel Tseytlin,[1] Sharon E. Maynard.[2] *[1]Dept of Medicine, Lehigh Valley Health Network, Allentown, PA; [2]Div of Nephrology, Lehigh Valley Health Network, Allentown, PA.*

Introduction: A 38-year-old male presented with renal failure in the setting of a flu-like illness. Urinalysis showed myoglobinuria and granular casts. His CPK was markedly elevated. He is diagnosed with rhabdomyolysis from adenovirus and requires hemodialysis.

Case Description: A 38-year-old AA male presented to the ER with a 4-day history of weakness, subjective fever, and diffuse myalgias as well as recent left eye viral conjunctivitis. He noted dark urine and poor urine output. On arrival to the ER his vitals were stable. He had full muscle strength and no neuro deficits. He was oliguric. His SCr 5.04, CPK 1,149,533 despite volume resuscitation including bicarb-containing fluid. He required HD. Workup was positive for adenovirus. Muscle biopsy was deferred in setting of known cause. He required 4 weeks of HD and was able to come off with impaired GFR of 67.

Discussion: Two cases of rhabdomyolysis from adenovirus have been reported. Most commonly manifests as a febrile illness with pharyngitis. Management strategies have been adopted from studies on crush injury victims. Early volume resuscitation is recommended to mitigate renal failure. Despite the theoretical benefits of bicarbonate-containing resuscitation fluids, no consensus exists. Adenoviral infection can lead to rhabdomyolysis with severe acute kidney injury. Respiratory viral panel should be included in workup of rhabdomyolysis when no other cause is evident. Treatment relies on supportive care, intravenous fluid resuscitation, and hemodialysis in cases of severe renal failure.

Acute Respiratory Distress Syndrome and Posterior Reversible Encephalopathy Syndrome following Rituximab Therapy Eoin D. O Sullivan,[1] Katrina E. Wardrope,[1] Lynn Manson,[2] Wendy Metcalfe.[1] *[1]Dept of Renal Medicine, Royal Infirmary of Edinburgh, Edinburgh, United Kingdom; [2]Scottish Blood Transfusion Service, Royal Infirmary of Edinburgh, Edinburgh, United Kingdom.*

Introduction: The anti CD20 monoclonal antibody Rituximab is an increasingly used therapy in modern medicine. It is associated with rare but potentially serious adverse events, notably Posterior Reversible Encephalopathy Syndrome (PRES), and Acute Respiratory Distress Syndrome (ARDS).

Case Description: A 60 year-old female was admitted with symptoms of peripheral oedema, arthralgia and mucosal bleeding. She was noted to have a widespread vasculitic rash, nephrotic range proteinuria and new acute kidney injury. Renal biopsy demonstrated mesangiocapillary glomerulonephritis with multifocal extraglomerular necrotising vasculitis, in keeping with cryoglobulinemia. She was commenced on plasma exchange, prednisolone and Rituximab. 2 days after the initial dose of Rituximab she developed acute respiratory distress and was found to be in florid pulmonary oedema. This was managed with ultrafiltration, furosemide and oxygen therapy. She received a second dose of Rituximab 1 week later, and rapidly developed tonic-clonic seizures,a further episode of flash pulmonary oedema, encephalopathy and hyperreflexia. MRI brain revealed subcortical white matter high T2 and FLAIR signal in the occipital and posterior parietal lobes consistent with PRES. She received no further Rituximab. Her cryoglobulin levels remained detectable despite alternate day plasma exchange for 2 weeks, prompting the initiation of cyclophosphamide. Following 1 dose of cyclophosphamide the cryoglobulin titre fell to undetectable levels. All reported cases of PRES and ARDS were identified and are presented as a review.

Discussion: There are 7 reported cases of PRES complicating rituximab use. The onset of PRES occurred from immediately to 21 days after administration. All patients recovered completely, and rituximab was reintroduced in half of the cases. Mean recovery time was 4 days, and an additional risk factor was present in 5 cases. The occurrence of ARDS in association with rituximab is rare, only 3 confirmed cases exist . ARDS may occur as a delayed reaction.

SA-PO048

Atypical Hemolytic Uremic Syndrome Associated with Rituximab Kristina Angela Rathmell, Shilpa Gadde. *Nephrology, Tulane, New Orleans, LA.*

Introduction: Hemolytic uremic syndrome (HUS) is classified as a thrombotic microangiopathies (TMA). Atypical HUS (aHUS) occurs in 0.5 to 2 per million population per year, 50% progress to end-stage renal disease (ESRD), and 25% may die in the acute phase. Atypical HUS is linked to uncontrolled activation of the complement system. A variety of genetic abnormalities of the alternative pathway of complement have been described in aHUS, occurring in 60% of cases. aHUS is diagnosis when *toxin producing bacterial infections,* ADAMTS13 deficiency, and systemic-associated diseases are all excluded.

Case Description: A 57 year-old woman with a history of dermatomyositis and associated interstitial lung disease (ILD) was being treated for her ILD with Rituximab. She presented with altered mental status, shortness of breath, and fatigue after receiving an infusion of Rituximab. She was noted on physical exam to have peripheral edema and crackles on lung exam. On laboratory evaluation, her creatinine was 4.5 (baseline 1), hemoglobin 7, and platelets 20 with schistocytes on peripheral smear and a low C3 and C4. ADAMTS13 showed normal activity. She was initially treated with high dose steroids and plasmapharesis. She was started on Eculizumab. She required hemodialysis. Renal biopsy showed thrombi consistent with thrombotic microangiopathy as well as mild acute tubular necrosis. She is still hemodialysis dependent.

Discussion: Overall outcomes of this rare diagnosis vary widely. Initial treatment is usually plasmapheresis and corticosteroids. Confirmed aHUS is usually treated with Eculizumab. Our unique case entertains Rituximab, a monoclonal antibody, as a possible trigger for aHUS. Knowing the mechanism of action of Rituximab, it is possible it mediated a complement imbalance. More investigation is needed to determine Rituximab's causality in inducing aHUS. Given the increasing use of Rituximab for various autoimmune conditions and malignancies it will be notable to see if more cases like this arise. 1. Noris M, Remuzzi G. Acute Renal Failure Associated with Parenchymal Involvement of Lambda-Restricted Neoplastic Plasma Cells Mark C. Sievert, Amanda K. Hall, Mazdak A. Khalighi, Josephine Abraham. *Div of Nephrology, Univ of Utah, Salt Lake City, UT.*

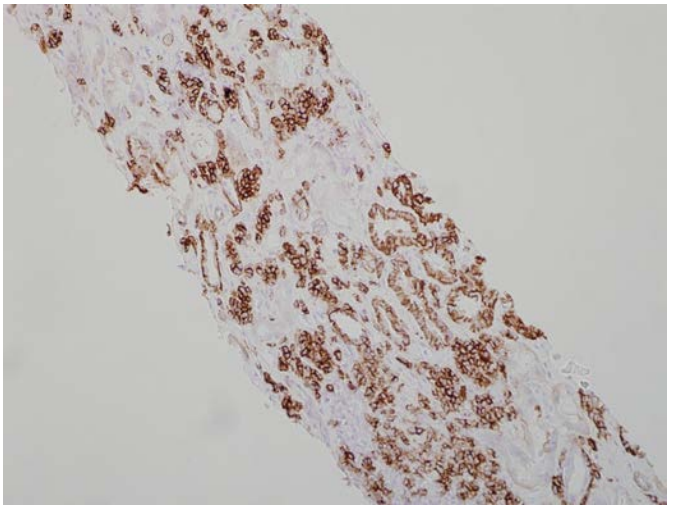
Introduction: The pathogenesis of renal disease in multiple myeloma (MM) is diverse, but biopsies show that cast nephropathy, light chain amyloidosis and monoclonal Ig deposition are most often responsible. Renal function often correlates to the degree of cellular injury, not the degree of cast burden, amyloidosis or light chain deposition and direct involvement by plasma cells is rare. We present a case of diffuse interstitial involvement by neoplastic plasma cells, contributing to renal failure.

Case Description: A 70-year-old male with MM presented with acute renal failure. He was diagnosed with IgG lambda myeloma 8 years prior but refused therapy until 7 months ago. He failed CyBorD (M-protein remained at 9g/dl) prior to staring Carfilzomib-Revlimid.

On day 8 of therapy he was admitted with a Cr of 3.4, acutely elevated from 1.7. He denied hematuria, oliguria, fevers, edema or NSAID use. Renal ultrasound was without obstruction. He underwent renal biopsy. Pathology revealed diffuse interstitial involvement by lambda-restricted neoplastic plasma cells and minimal cast nephropathy, but no significant interstitial fibrosis, tubular atrophy or monoclonal deposition disease. Congo red studies were negative for amyloid. There were no features of TMA. Chemotherapy was resumed.



CD138 IHC stain showing plasma cells.

Discussion: Kidney disease with MM is common but it is rare to see involvement of plasma cells in the renal parenchyma. Several review articles list renal parenchymal involvement of plasma cells as a cause of renal failure and, to our knowledge, one case report suggests the same. It is unknown the extent to which parenchymal involvement by plasma cells contributes to the pathogenesis of renal failure. To our knowledge, this is one of only several cases of renal failure that can be attributed to neoplastic plasma cell involvement.

SA-PO050

AL Amyloidosis with Rapidly Progressive Renal Failure and Massive Liver Involvement: A Case Report Matteo Floris,[1] Maura Conti,[1] Riccardo Cao,[1] Anna Maria Asunis,[2] Elisabetta Tamponi,[2] Alice Atzeni,[1] Patrizia Melis,[1] Gianfranco Pili,[1] Valeria Matta,[1] Nicola Lepori,[1] Doloretta Piras,[1] Andrea Angioi,[1] Antonello Pani.[1] *[1]Nephrology, G. Brotzu Hosp, Italy; [2]Pathology, G. Brotzu Hosp, Italy.*

Introduction: AL amyloidosis is a plasma cell disorder clinically dominated by organized deposits of light chains, mainly in renal and cardiac tissues. Although hepatic disease is described, clinical manifestations are usually mild and frequently undetected. We report a severe case of AL amyloidosis with a massive hepatic involvement and rapidly progressive renal failure (RPRF).

Case Description: One month before coming to our attention, a 67 year old male was admitted to another institution for ascites and scrotal edema. Past medical history included hypertension, previous hepatitis B virus infection and estimated daily alcohol intake of 60g. Renal function was normal(serum creatinine[SCr]0.7 mg/dl),while hepatic lysis indexes were moderately positive. A serum monoclonal component IgA kappa (0.21 g/dl) was detected and the bone marrow aspirate showed 10% plasma cell infiltration. Hepatic ultrasound showed hepatomogaly and portal hypertension. Final diagnosis was compensated alcoholic liver disease. After discharged, nephrotic syndrome(NS) (albumin 2.4 g/dl, proteinuria 12 g/24h), RPRF (SCr 1.6 mg/dl) and cholestasis appeared (ALP 1359 IU/L, GGT 462 IU/L, AST-ALT normal). The patient was admitted to our institution and renal biopsy was performed revealing AL amyloidosis, with prominent IgA(+) and Kappa(++) mesangial deposits, coherently with the serology. The hepatic disease was rediscussed, and the liver biopsy revealed coarse deposits of amyloid as for the kidney. Other organs, heart included, appear to be spared at the time. In accordance with hematologists, a CyBorD based regimen was started. Due to worsening kidney dysfunction, hemodialysis was initiated.

Discussion: This case highlights a rare presentation of AL amyloidosis with severe renal and hepatic involvement. Liver amyloidosis should be suspected in any patient with NS and unexplained cholestasis. Therefore, renal and hepatic biopsies should be considered when the clinical diagnosis is obscure, especially if rapid evolution to multiorgan failure is documented.

SA-PO051

Pulmonary-Renal Syndrome: A Rare Case Joana Gameiro,[1] Sofia C.A. Jorge,[1] Miguel Bigotte Vieira,[1] Estela Nogueira,[1] Maria Alice Fortes,[1] Helena Sousa Viana,[2] Fernanda Carvalho,[2] Jose António Lopes,[1] Antonio Gomes Da Costa.[1] *[1]Service of Nephrology and Kidney Transplantation, Hospital Santa Maria, Portugal; [2]Service of Nephrology, Hospital Curry Cabral, Portugal.*

Introduction: Pulmonary-renal sindrome (PRS) is characterized by acute renal and pulmonary involvement of immunological or non-immunological causes.

Case Description: A 35-year-old African woman with 6-month history of edema, bilateral arthralgias in her knees, shoulders and hands, creatinemia 2,6mg/dL and nephrotic proteinuria referred to Portugal for medical care presenting with bilateral erythematous non pruriginous macular lesions in both thighs. Investigation confirmed renal failure (creatinemia 7mg/dL), nephrotic proteinuria (4.7g/24h), haematuria, hypoalbuminemia, hyperlipidemia, normal sized kidneys with increased parenchymal echogenicity. She began hemodialysis and was transferred to ICU due to pulmonary hemorrhage requiring mechanical ventilation. Plasmapheresis and intravenous high-dose steroids were started. Pneumococal pneumonia was also diagnosed and began antibiotic. Imunologic and serologic tests were negative or normal range. Serum protein electrophoresis showed hypogamaglobulinemia. Echocardiogram revealed type II diastolic dysfunction. Renal biopsy showed nodular glomerulosclerosis. Investigation of haematological disease revealed serum kappa light chain band and urine Bence Jones kappa. Free kappa light chains, serum kappa/lambda ratio and serum Beta-2-microglobulin were elevated. Bone marrow biopsy and aspirate showed 10% monoclonal plasmocytosis. No lytic lesions or masses were detected. Immunofluorescence of the renal biopsy revealed linear staining for kappa light chains along the tubular basement membrane and scarcer in the glomeruly. Electron microscopy is underway. Multiple myeloma was diagnosed and started chemotherapy with Bortezomib. Although there was mantained remission of pulmonary hemorrhage she remained on dialysis.

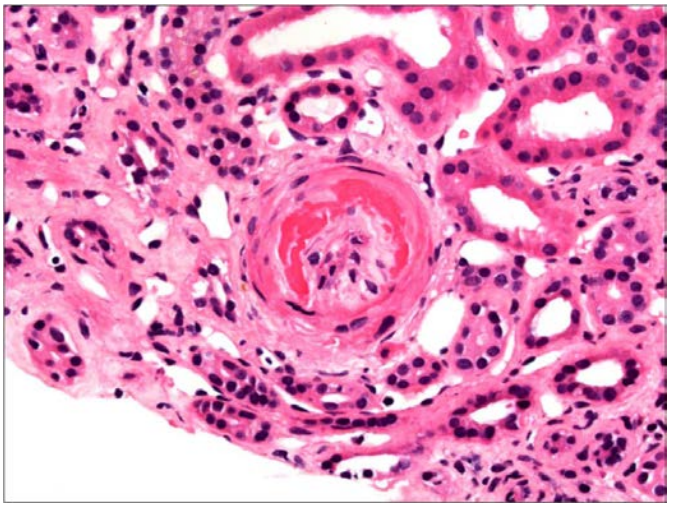
Discussion: Light chain deposits disease (LCDD) should be considered in the differential diagnosis of PRS. Renal involvement is typical in LCDD with nodular glomerulosclerosis as the common pathologic finding. Pulmonary haemorrage is unsual and might suggest coexistence of fibrillary glomerulonephritis.

SA-PO052

Acute Cadriorenal Syndome as a Presenting Symptoms for Scleroderma Renal Crisis Muhammad H. Hasan, Khurram Saleem, Khaled Boobes, Yazan M. Alia, Sadaf S. Khan. *Nephrology and Hypertension, Northwestern Univ, Chicago, IL.*

Introduction: Systemic scleroderma is known to have renal manifistations including scleroderma renal crisis. Acute decompensated heart failure was not descrined in the literature as the presenting symptom.

Case Description: 50 year-old female with benign past history was diagnosed with new acute decompensated diastolic heart failure and hypertension 160/89 and acute kidney injury with elevated serum creatinin (SCr) 2.6 mg/dL from normal kidney function 2 months prior. Right heart catheterization showed elevated right heart pressures. Endomyocardial biopsy showed small vessel vasculitis. Urinalysis was bland. Renal ultrasound was unremarkable. Renal artery Duplex showed high resistant signals with low velocity. Sunsequent immunology screen showed elevated antinuclear antibodies >1:1280, elevated RNA Polymerase III >80 and normal C3 and C4. Renal biopsy showed changes consistent with systemic sclerosis; the glumeruli were ischemic in general and one was sclerosed, the arteriols were with marked walls thickening and swelling of the intima, some undergone occlusive changes with onion skinning of their walls, while others undergone focal fibrinoid necrosis, the tubules were with mild to moderate atrophy, the interstitium was diffusely scarred, with mild to moderate focal and scattered cellular of lymphocytes. (biopsy). Retrospectively, the patient reported skin tightening noticed 6 months prior to admission. Blood pressure was controlled with nicardipine drip, captopril, diuretics and bosentan. SCr peaked up to 6.72 mg/dL but renal replacement therapy was avoided. She was discharged on bosentan, amlodpine and lisinopril. SCr improved to 1.78 mg/dL after 8 months.



Discussion: Scleroderma renal crisis can present as acute cardiorenal syndrome.

SA-PO053

Dent's Disease: An X-Linked Tubulopathy Sambhavi Krishnamoorthy, Tingting Li. *Renal Div, Washington Univ in St. Louis, Saint Louis, MO.*

Introduction: Dent's disease is an X-linked recessive disorder of the proximal tubule characterized by low-molecular weight proteinuria, hypercalciuria, nephrocalcinosis/nephrolithiasis, and progressive renal failure. This disorder is caused by mutations in either the CLCN5 gene, or less commonly the OCRL1 gene, leading to disruption of tubular endocytosis and the characteristic clinical findings.

Case Description: We describe an interesting case of a 24 year old Caucasian male with a longstanding history of excessive thirst and polyuria. He had no known history of renal disease. He denied history of urinary tract infections, nephrolithiasis, or NSAID use. Physical examination was unremarkable. Laboratory data showed a serum creatinine of 1.6. Hemoglobin A1c was normal. Urinalysis showed 2+ blood and 2+ protein. Urine osmolality was 277 msosm/kg. A 24 hour urine collection showed proteinuria of 1.7 g/day. ANA, ANCA, and hepatitis panel were all negative. Renal ultrasound showed multiple bilateral renal calculi and nephrocalcinosis. Further testing showed a daily urinary calcium excretion of 735 mg, phosphate 2150 mg and sodium 257 mg. His urine beta microglobulin level was significantly elevated at 29817 mcg/L. The presence of significant low molecular weight proteinuria, hypercalciuria, hyperphosphaturia, nephrolithiasis/nephrocalcinosis, hematuria/subnephrotic proteinuria, and chronic kidney disease fulfilled criteria for the diagnosis of Dent's disease. No obvious X-linked pattern had been noted in his family history. Further genetic testing is pending at this time. On initiating hydrochlorothiazide, urinary calcium excretion reduced by 50%. Polyuria, which we attributed to nephrogenic diabetes insipidus in the setting of nephrocalcinosis, also improved significantly with the thiazide.

Discussion: This case report highlights the importance of recognizing this rare X-linked tubulopathy when presenting in adulthood. Commercially available genetic testing can be utilized for supporting the diagnosis and for appropriate genetic counseling for family members. The treatment focuses on reducing urinary calcium excretion and formation of nephrocalcinosis/nephrolithiasis with the ultimate goal of slowing progression to end stage renal disease.

SA-PO054

Phlegmasia Cerulean Dolens: Complication of Femoral Vein Catheterization Chaitanya Vemuri, Boju Sangeetha lakshmi, Hari Krishna Reddy Mogili, Ram R, Siva Kumar Vishnubhotla. *Dept of Nephrology, Sri Venkateswara Inst of Medical Sciences, Tirupati, Andhra Pradesh, India.*

Introduction: There are three manifestations of acute massive venous thrombosis and obstruction of the venous drainage of an extremity. They are phlegmasia alba dolens, phlegmasia cerulean dolens (PCD) and venous gangrene.

Case Description: We present a 55-year-old hypertensive,presented with paedal oedema and breathlessness. About a month ago, she fell down and had dislocation of left patella. She was treated with a plaster cast and immobilization for 3 weeks. Her serum creatinine was 8.8 mg/dL. She was initiated on haemodialysis via two single lumen catheters placed in left femoral vein. The femoral vein catheters were removed after third session of haemodialysis. On fourth day, the patient complained pain and blue discolouration of left toes. Examination revealed that the left lower limb was swollen, discoloured and cold up to ankle joint. The left dorsalispedis and posterior tibial arteries were not palpable. Within next 12 hours, the signs extended to upper one-third of left leg and there were blebs.

Doppler revealed thrombosis of left common, external iliac,femoral,popliteal,anterior,posterior tibial vein and superficial veins.The left lower limb was elevated and anticoagulation was started but blebs increased and limb became blue. Below knee amputation of left lower limb was performed.

Discussion: The causative factor in phlegmasia is massive thrombosis and occlusion of major venous channels.Perkins et al reported that in 10 percent of patients no cause is found.It is common in women between fifth and sixth decades of age.Swelling, pain and cyanosis are the triad of PCD.Amputation rates are 12-50%.In our patient the effect of immobilization is compounded by femoral vein catheterization. PCD after femoral vein catheterization for haemodialysis has not been reported yet.

SA-PO055

Successful Treatment of Ischemic Hand Ulcer by Paclitaxel Coated Balloon Jie Cui,[1] Fengyong Liu,[2] Zubin Irani.[3] *[1]Nephrology, Massachusetts General Hospital, Boston, MA; [2]Interventional Radiology, Chinese People's Liberation Army General Hospital, Beijing, China; [3]Div of Vascular Imaging and Intervention, Massachusetts General Hospital, Boston, MA, China.*

Introduction: Hand ischemia is a common complication in end stage renal disease (ESRD) patients. Steal syndrome from dialysis access is the most common cause of ischemic hand and is usually treated with banding procedure. However, exclusion of peripheral arterial disease (PAD) prior to banding is crucial.

Case Description: A 74 year-old women with history of ESRD due to diabetes mellitus on hemodialysis presented to access clinic for right hand ulcer. She had a right side brachiobasilic graft placement 3 years ago and has been dialyzed through this graft without any issues. However, 3 months prior to the presentation, she started to notice severe right hand pain, especially during dialysis treatment. Four weeks ago, she developed an ulcer in the 2nd finger of her right hand.

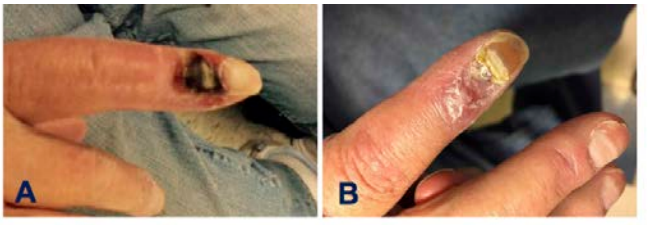


Figure The patient presented with a black ulcer on the second finger of her right hand. The ulcer completely healed 4 weeks later after paclitaxel-coated angioplasty balloon.

Given the concerns for steal syndrome, she was referred for a banding procedure. On physical exam, the graft had good thrill and bruits. Right radial artery pulse was very weak. A black ulcer was noticed on the 2nd finger of the right hand. Decreased sensation in the 1st , 2nd and 3rd fingers of the right hand. Fistulogram was performed which demonstrated occluded lesion in the proximal right radial artery, which was recanalized and angioplastied with 2mm, 3mm and 4mm balloon. However, at one-month clinic follow up, her ulcer only had minimal improvement. Repeat arteriogram showed moderate radial artery stenosis, which was angioplastied with 4mm paclitaxel coated-angioplasty balloon. The ulcer healed completely 1 month later.

Discussion: Paclitaxel coated balloon was recently approved by FDA to treat PAD in the lower extremities. This case report showed upper extremity PAD can also be treated successfully with paclitaxel coated angioplasty balloon.

SA-PO056

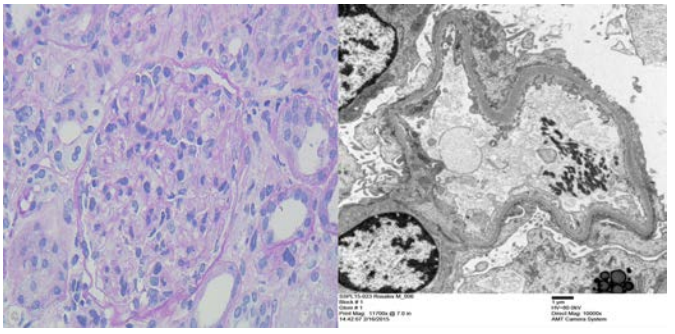
Minimal Change Disease Associated with Invasive Ductal Carcinoma of the Breast: A Case Report and Literature Review Siddhesh R. Lotlikar,[2] Julian D. Rose,[1] Soumya Patnaik,[2] Supakanya Wongrakpanich,[2] Mary Carolina Rodriguez Ziccardi,[2] Mark S. Morginstin,[2] Rasib Raja,[2] Eric J. Bloom.[2] *[1]Sidney Kimmel Medical College; [2]Albert Einstein Medical Center, Philadelphia.*

Introduction: A tenth of malignancies have been associated with nephrotic syndrome, the diagnosis of which may precede the detection of cancer. In an adult with Minimal Change Disease (MCD), paraneoplastic etiology should be explored. Here, we describe a rare case of MCD associated with breast cancer.

Case Description: Our patient is a 72-year-old Caucasian female who presented with bilateral lower extremity edema for 1 week. Home medications were notable for occasional Diclofenac use. Urinalysis on admission showed nephrotic-range proteinuria. MCD was suspected and confirmed on renal biopsy. CT ruled out lymphoma and thymoma. MCD was presumed secondary to Diclofenac use and she was discharged on daily prednisone with instructions to avoid NSAIDs. Two months later, she presented with a pulmonary embolus and CT showed concerning breast changes. Biopsy confirmed a stage IIIc invasive ductal adenocarcinoma. She was tapered off steroids, continued on furosemide and started on Paclitaxel.

Discussion: Breast cancer mainly causes antibody-mediated paraneoplastic syndromes. Yet, studies have shown intratumoral IFN-α expression correlates with induction of autoreactive T-cells, presenting a route for breast cancer to cause a T-cell mediated process such as MCD. Our patient had no lymphoma or thymoma and the lack of evidence of AIN and failure of improvement on discontinuation of NSAIDs argue against NSAID-induced MCD. The relationship of MCD with breast carcinoma is reinforced by her improved proteinuria with chemotherapy.

Time	MCD dx	1 month after dx	1.5 months after dx	1 week after first chemo (week 1)	2nd cycle of chemo (week 2)	3rd cycle of chemo (week 3)	1 week after 3rd cycle of chemo
Urine Protein (mg/dl)	1270.1	1773.4	1407.3	55	35.8	10.6	0



SA-PO057

A Case of Donor-Derived Enterococcal Pyelonephritis in an HIV-Positive Kidney Transplant Recipient Akshatha Rao,[1] Shilpa A. Chaudhari,[2] Dong Heun Lee,[2] Karthik M. Ranganna,[1] Alden Michael Doyle.[1] *[1]Div of Nephrology, Drexel Univ, Philadelphia; [2]Divison of Infectious Disease, Drexel Univ, Philadelphia.*

Introduction: Donor-derived infections are an unusual but recognized complication of solid organ transplantation. Between 2005-2011, there were 118 reported donor bacterial infections, of which 34 recipients had confirmed transmission of infection and 9 deaths due to donor derived bacterial infections. Herein, we describe a unique case of donor-derived enterococcal pyelonephritis in a kidney transplant recipient with HIV infection.

Case Description: 47 year old male with history of HIV infection (CD4 -534 cells/mm3, VL<20 copies), ESRD on peritoneal dialysis, hypertension had deceased donor kidney transplantation. Post-op patient was given 1 dose of cefazolin as surgical prophylaxis. Basiliximab and intravenous immunoglobulin was used for induction therapy. Patient was started on tacrolimus, mycophenolate mofetil and prednisone for maintenance therapy. POD#3 we were notified by organ procurement organization (OPO) that donor urine culture grew >100,000 colonies /ml of Enterococcus faecalis. Our patient was started on intravenous ampicillin to complete a total of 6 days antibiotic course. POD #17 patient was readmitted to the hospital with urinary retention and elevated serum creatinine 2.2.

Renal ultrasound showed no hydronephrosis. Urinalysis showed 2+ leukocyte esterase, WBC 11-20, with occasional bacteria. Blood and urine culture grew Enterococcus faecalis that had same susceptibility pattern of that from donor kidney. Patient was started on intravenous ampicillin to complete a total of 14 days. Serum creatinine improved with treatment.

Discussion: There is no clear consensus on treatment regimens for donor-derived infections. This case demonstrates transmission of donor-derived enterococcal infection despite timely initiation of appropriate antimicrobial therapy. Because of increased morbidity and mortality associated with post-transplant infection extended duration of antimicrobial therapy should be considered in these patients.

SA-PO058

Peritoneal Dialysis: A Better Modality of Renal Replacement Therapy for Liver Cirrhotics with End Stage Renal Disease? Akshatha Rao, Sweta Carpenter, Alden Michael Doyle. *Divison of Nephrology, Drexel Univ, Philalphia.*

Introduction: Managing patients with end stage liver disease associated with portal hypertension, ascites and end- stage kidney disease requiring renal replacement therapy is challenging for a number of reasons including chronic hypotension, poor nutrition, coagulopathy, high infection rates, and encephalopathy. It is difficult to assess accurate dry weights because of the large variation patient weights depending on how much ascites they have at the time of dialysis, with weight fluctuations in excess of 10 kg. There is also a reluctance on the part of the transplant community to utilize PD because of the perception that these patients may not be able to go on to receive a successful liver transplant.

Case Description: Herein, we report our experience with 5 consecutive patients with decompensated cirrhosis who progressed to ESKD and required dialysis support. One patient did not tolerate HD and was switched to PD, the other 3 started with de novo PD. In each case, the patients were admitted to hospital for PD catheter placement with a surgeon experienced with patients who had advanced liver disease and stayed in the hospital for initial recovery period with IV albumin to support blood pressure. By our protocol, ascites fluid was drained in the OR and then drained each morning for the next 2 weeks before dialysis was initiated. Blood pressures ranged from 80/50-110/65 mmHg, patients remained asymptomatic. All patients received oral midodrine for BP support.

Adequate ultrafiltration achieved and edema improved. Serum albumin was monitored at regular intervals, ranged from 2.5-3. One patient had peritonitis from time of surgery, which was treated successfully; no other cases of peritonitis were noted.

Discussion: We suggest that PD should be considered in selected patients who have ascites and end-stage kidney disease. Further research is warranted regarding long term outcomes and potential effects of PD on the ability for these patients to get transplanted.

SA-PO059

Focal Segmental Glomerulosclerosis Presenting Concurrently with Chromophobe Renal Cell Carcinoma Itunu O. Owoyemi, Denise J. Thomson, Hiren J. Joshi, M.J. Barchman. *Nephrology, East Carolina Univ/Vidant Medical Center, Greenville, NC.*

Introduction: Chromophobe renal cell carcinoma (CHRCC) is a rare variant of RCC with distinct histochemical, ultrastructural and genetic characteristics. CHRCC accounts for approximately 4% of all kidney neoplasms. Glomerulopathies are often diagnosed in patient with malignances, particularly hematological cancers with membranous nephropathy being the most common variety. We present a case of resistant hypertension in a young adult male found to have focal glomerulosclerosis (FSGS) with concurrent CHRCC. This case highlights the association and emphasis of screening for secondary hypertension in resistant patients, early referral and the pitfalls of percutaneous biopsy for solid renal masses.

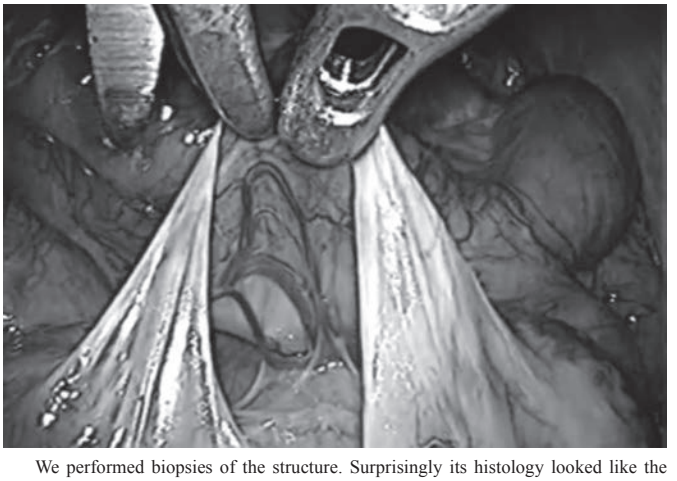
Case Description: A 34 year old Nigerian male initially presented to the Internal Medicine clinic to establish care in 2011. His past medical history was significant for hypertension and gross hematuria. He was subsequently referred to Nephrology due to persistent microalbuminuria, hematuria and passage of blood clots in his urine. On presentation to Nephrology, he was found to have nephrotic range proteinuria. Renal ultrasound was significant for several lesions in the right kidney with the largest measuring 3 cm. Percutaneous renal biopsy performed for proteinuria revealed focal segmental glomerulosclerosis with moderate tubulointersitial scarring. He initiated on steroids however he was lost to follow up for approximately 9 months. Upon return, his renal lesions were readdressed with an MRI of the abdomen which could not exclude multiple solid masses in the right kidney. A subsequent ultrasound-guided fine needle aspiration and core biopsy of the right kidney lesion diagnosed chromophobe renal cell carcinoma. He underwent a right nephrectomy with biopsy result negative for metastasis.

Discussion: We were able to unravel this unique finding of FSGS co-presenting with chromophobe renal cell carcinoma. The prevalence of FSGS in RCC has not been established with precision. This case highlights the importance of timely evaluation of secondary hypertension and biopsy of suspicious renal masses.

SA-PO060

A Case of Peritoneal Dialysis Patient with Unknown Membrane-Like Structure Covering Intestinal Tract Yu Honda, Nanae Matsuo, Yudo Tanno, Yasuyuki Nakada, Taketo Uchiyama, Izumi Yamamoto, Ichiro Ohkido, Keitaro Yokoyama, Takashi Yokoo. *Div of Nephrology and Hypertension, Dept of Internal Medicine, Jikei Univ School of Medicine, Minato-ku, Tokyo, Japan.*

Introduction: A 24-year-old male developed end-stage renal disease (ESRD) and was initially started on hemodialysis (HD). Since he had found difficulty to continue HD because of disdialysis syndrome, he switched to the combination therapy with peritoneal dialysis (PD) and weekly HD on 17years of dialysis duration. Seven years later, he was converted to HD alone.He had no episode of peritonitis. He had no episode of ileus and was not diagnosed with encapsulating peritoneal sclerosis (EPS). Generally the macroscopic appearance of EPS is the whole bowel trapped in a thick, tough peritoneal cocoon. Since his PD duration was long, laparoscopy was performed when his PD catheter was removed. We found his agglomerated small intestine was coated with thin membrane-like structure. It was soft, elastic and easy to separate from intestine.



We performed biopsies of the structure. Surprisingly its histology looked like the normal peritoneum. On the surface of the biopsy, a single layer of mesothelial cells was present. There are no apparent fibrosis (thickening) and sclerosis. This case suggests that his peritoneum-like membrane might be the very early stage of sclerosing capsule of EPS. Since little has been known about transition from a normal state to EPS through pre-EPS state, this case is valuable to identify one part of the mechanisms of EPS. We report this rare case with some literature review.

SA-PO061

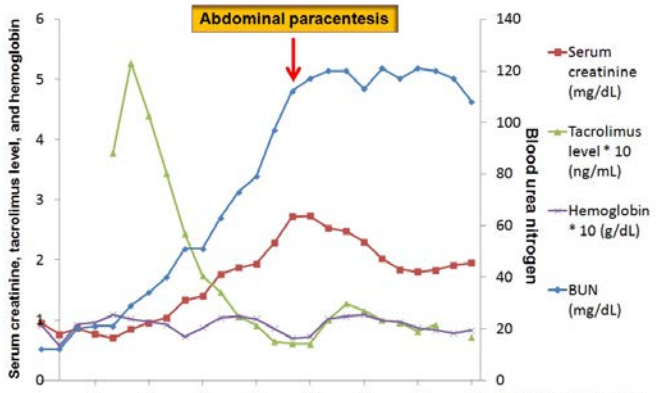
Abdominal Compartment Syndrome: An Overlooked Culprit of Acute Kidney Injury in Immediate Post-Liver Transplantation

Ekamol Tantisattamo,[1] Praveen Ratanasrimetha,[2] Siwadon Pitukweerakul.[3] *[1]Nephrology, Northwestern Univ; [2]Faculty of Medicine Siriraj Hospital, Mahidol Univ, Bangkok, Thailand; [3]Presence St. Francis Hospital, Evaston.*

Introduction: Acute kidney injury (AKI) is a common complication after liver transplantation and often times, dialysis is required. Abdominal compartment syndrome (ACS) is a treatable cause of prerenal AKI without dialysis needed.

Case Description: A 60-year-old man with HCV and alcoholic cirrhosis underwent an OLT. He had massive blood loss during the uncomplicated operation and required massive transfusion and fluid resuscitation. Postoperatively, renal function initially was stable at the baseline serum creatinine(SCr) of 0.8 mg/dL. However, hemoglobin dropped from 9.1 to 5.7 g/dL and tacrolimus level elevated up to 53 ng/mL on postoperative day(POD)4. SCr rose up to 1.3 mg/dL and urine output(UOP) decreased on POD7. Renal function continued to decline with a peak BUN and SCr of 120 and 2.73 mg/dL on POD14, respectively(Figure 1). Dialysis was initially planned. However, he had progressively increased ascites with markedly tense abdomen. Bladder pressure revealed intraabdominal hypertension (IAH) with the pressure of 20 mmHg. FE_{Na} and FE_{urea} were 0.7% and 21%, respectively. Therefore, abdominal paracentesis was performed with an 8 L of yellowish clear ascitis fluid removed. UOP significantly increased shortly after paracentesis. SCr had trended down and dialysis was not required.

Discussion: Our patient presented with prerenal AKI secondary to perioperative hypovolemia concomitant with supratherapeutic tacrolimus level. Massive blood transfusion and fluid resuscitation in the setting of major abdominal surgery caused IAH and subsequently ACS contributing to worsening prerenal AKI. Bladder pressure is a bedside diagnostic tool to detect IAH. AKI could be reversed and dialysis could be avoided by abdominal paracentesis.



Intake (L)	5.7	2.5	2.5	3.5	3.5	2.1	2.1	4
Urine output (L)	2.7	1.2	1	1.2	1.6	1	0.7	0.5

SA-PO062

Rasburicase: A Salvage Strategy to Prevent Renal Allograft Loss in Acute on Chronic Urate Nephropathy

Ekamol Tantisattamo,[1] Praveen Ratanasrimetha,[2] Siwadon Pitukweerakul.[3] *[1]Nephrology, Northwestern Univ; [2]Faculty of Medicine Siriraj Hospital, Mahidol Univ, Bangkok, Thailand; [3]Presence St. Francis Hospital, Evaston.*

Introduction: Chronic hyperuricemia can lead to chronic kidney disease (CKD) and acute on chronic hyperuricemia potentially causes renal failure. Rasburicase is an effective uric lowering agent indicated for the treatment of acute hyperuricemia especially in tumor lysis syndrome. We report a case of kidney transplant recipient with acute hyperuricemia-related acute kidney injury (AKI) which was resolved with rasburicase.

Case Description: A 51-year-old man with ESRD secondary to type 2 diabetes status post renal transplant was admitted with diffuse muscle cramping. Maintenance immunosuppression included cyclosporine (CsA) and mycophenolate mofetil. The baseline serum creatinine (SCr) was 2.5 mg/dL after 2 episodes of borderline changes detected from transplant renal biopsy at 1 and 2 years posttransplant, respectively. However, over the past 9 months, SCr had gradually trended up to 4.4 mg/dL. He had asymptomatic hyperuricemia with a serum uric acid of 9.1–12.5 mg/dL. Two days after admission, he developed severe pain on the right first metatarsal joint presumed from acute gouty arthritis which responded to oral prednisone. However, SCr continued rising up to 4.8 mg/dL. Urinalysis showed a pH of 6 and Sp.Gr. of 1.011. Serum and urine BK virus were undetectable. Transplant renal ultrasound was unremarkable. Serum uric acid was markedly elevated up to 17.7 mg/dL. Given worsening renal function in the setting of acute hyperuricemia, rasburicase was initiated. Serum uric acid had been decreased to 8.1 and 4.5 mg/dL within 20 and 30 hours, respectively and SCr returned to the baseline of 2.5 mg/dL.

Discussion: Our patient presented with AKI on CKD in the setting of symptomatic acute on chronic hyperuricemia. Acute hyperuricemia leads to AKI which was resolved by rapidly lowering uric acid level with rasburicase. AKI in the patient with underlying chronic hyperuricemia should raise a suspicion for acute hyperuricemia-related AKI. Rasburicase should be considered as a salvage therapy to avoid renal allograft loss.

SA-PO063

The Effect of Taurine on Haemodialysis Filtration in Patients with Chronic Heart Failure: A Case Study

Shunji Shiohira,[1,2] Kosaku Nitta,[1] Ken Tsuchiya.[1] *[1]Dept of Medicine IV, Tokyo Women's Medical Univ, Shinjuku, Tokyo, Japan; [2]Dept of Blood Purification, Joban Hospital, Iwaki, Fukushima, Japan.*

Introduction: Taurine, an important factor in the living body, is essential for cardiovascular function and development and function of skeletal muscle, retina and central nervous system. In the present study, its effect on cardiovascular function was specifically taken into consideration. In haemodialysis filtration (HDF) patients, the effect of taurine on patients with chronic heart failure (CHF), in whom dry weight was difficult to control, was evaluated.

Case Description: All patients who were subjected to regular HDF for 4 h three times per week at Joban hospital in this study. Patients with chronic heart failure, in whom dry weight was difficult to control (n = 4), were included in the evaluation of clinical status. X-ray and echocardiography were determined before and after taurine treatment.

Almost all cases were taking nitric acid, warfarin, anti-platelet and vasopressor. Because vital signs were unstable in chronic heart failure, all cases withheld antihypertensive drugs during HDF. For unstable vital signs during HDF, pulmonary congestion was chronically recognized.After taurine was started, vital signs stabilized and lowering of dry weight was possible. In addition, X-ray and cardiac diastolic failure on echocardiography improved.

Discussion: Taurine was effective for CHF patients on HDF in whom dry weight was difficult to control in spite of various medications.

Immune Complex MPGN Associated with Hashimoto's Thyroiditis in a Young Female

Samuel Chakola, Iris J. Lee, Jean Lee, Xu Zeng, Duncan B. Johnstone, Lleras A. Samuels. *Nephrology, Temple Univ, Philadelphia, PA.*

Introduction: Glomerular disease associated with Hashimoto's Thyroiditis (HT) is a rare occurrence infrequently reported in the literature. We present a case of membranoproliferative glomerulonephritis (MPGN) that was thought initially to be due to systemic lupus erythematous (SLE) in a young woman.

Case Description: A 38 year old female presented in 2013 with leg edema and two grams of proteinuria. Creatinine (Cr) was 1.3 mg/dl. Of note, her thyroid function tests were consistent with severe hypothyroidism, with a TSH of 129 IU/ml and thyroid peroxidase and thyroglobulin antibodies >900 IU/ml. Serologic workup for hepatitis B, C and HIV and complements were negative. She had a history of Raynaud's but did not fulfill clinical and immunological criteria for SLE. Kidney biopsy was consistent with immune complex MPGN with immunofluorescence positive for IgG and C3 only. Patient was non- compliant with thyroid replacement therapy and was lost to follow-up. She reappeared in 2015 with arthralgias, dyspnea, and leg edema. Her Cr had worsened to 1.7 mg/dl with 16 gram proteinuria. She was found to have a pericardial effusion. TSH was 174 IU/ml. Repeated testing for SLE was negative and a repeat renal biopsy demonstrated an immune complex mediated MPGN with minimal staining for full house immunoglobulins. She was placed on thyroxine hormone and also initiated on mycophenolate mofetil, given that both her thyroid and renal disease appeared to be driven by an autoimmune antibody mediated process.

Discussion: HT, immune complex MPGN and clinical findings in our patient were initially thought to be due to SLE however patient failed to fulfill any immunologic criteria for SLE. HT is rarely associated with MPGN and specific mechanisms remain unclear. Proteinuria in glomerular disease associated with HT is not correlated with levels of thyroid hormone. However, deposition of thyroglobulin and thyroid-peroxidase antibodies has been found in the kidney in HT. This supports the theory of an autoimmune basis for MPGN in HT, and reinforces that immunosuppression may be required to adequately treat both diseases.

SA-PO065

Hypervitaminosis D – A Rare Complication of PJP in a Transplant Patient

Khaled Boobes, Khurram Saleem, Yazan M. Alia, Muhammad H. Hasan, Aneesha A. Shetty, Mohammed Javeed Ansari. *Nephrology, Northwestern Univ/Norhwestern Memorial Hospital, Chicago, IL.*

Introduction: Pneumocystis Jiroveci Pneumonia (PJP) is a known complication in immunocompromised hosts including transplant recipients, usually in the first six months of transplant. Hypercalcemia (HCa) is not a classic symptom of the disease. We present a case of a patient with simultaneous kidney and pancreas transplantation nineteen years ago who presented with PJP and developed HCa (highest value 14.8mg/dl [8.3-10.5] mg/dl). Parathyroid Hormone (PTH) was appropriately suppressed with a level of (6; [12-88] pg/ml). 1,25-(OH) vitamin D concentration was elevated (123; [18-72] pg/ml). After treatment with trimethoprim-sulfamethoxazole her Calcium concentration returned to normal along with PTH and 1,25-(OH) vitamin D. It is thought that, like other granulomatous disease-induced HCa, it is likely that endogenous extrarenal production of 1-alpha-hydroxylase by activated macrophages and by interferon-gamma involved in granuloma formation results in increased conversion from 25-(OH) vitamin D to 1,25-(OH) vitamin D and, consequently, in HCa and suppression of PTH secretion. Although only few cases of PJP-associated HCa have been reported to date, it is possible that this association is more frequent than previously thought. Hypercalcemia in transplant recipients with pulmonary symptoms must raise suspicion of PJP.

SA-PO066

A Rare Case of Tubulointerstitial Nephritis Associated with Primary Biliary Cirrhosis Jatinder K. Hothi,[1] Jingyin Yan,[1] William F. Glass.[2] *[1]Dept of Nephrology, Baylor College of Medicine, Houston, TX; [2]Dept of Nephrology, Baylor College of Medicine, Houston, TX; [3]Dept of Pathology, Univ of Texas Health Science Center, Houston, TX.*

Introduction: Primary biliary cirrhosis (PBC) is a chronic autoimmune liver disease characterized by positive antimitochondrial antibodies (AMA), immune-mediated epithelial damage of small bile ducts, which leads to liver cirrhosis as the disease advances. In addition to liver injury, other autoimmune diseases, such as Sjögren's syndrome and Raynaud's syndrome, are reported in approximately 2-20% patients with PBC. However, the association of PBC and renal injury is rarely documented.

Case Description: Here we present a case of tubulointerstitial nephritis (TIN) in a patient with PBC. A 35-year-old female with past medical history of PBC developed sub-nephrotic range proteinuria and chronic kidney disease stage 3. A renal biopsy showed moderate to severe renal cortical and focal medullary tubulointerstitial inflammation with infiltration of lymphocytes, plasma cells and occasional eosinophils, as well as significant tubulitis.

The patient was treated with a short course of oral prednisone and her renal function improved.

Discussion: This case highlights a very rare cause of TIN and suggests that steroid therapy is effective in this setting.

SA-PO067

Plasma Exchange as AdjunctiveTherapy for Crescentic IgA Nephropathy Jicheng Lv, Xinfang Xie, Fude Zhou, Minghui Zhao, Hong Zhang. *Renal Div, Peking Univ Inst of Nephrology.*

Introduction: Recent KDIGO guidelines recommend an aggressive immunosuppressive therapy in patients with crescentic IgA nephropathy (CreIgAN). While large cohort study from our center suggest that even with such a therapy, the 1- and 5-year renal survival rates remained low at 65% and 28%, respectively. Especially patients who present with serum creatinine (SCr)>580umol/L hardly recovered from dialysis. In this study we aim to evaluate the efficacy of plasma exchange(PE) in severe CreIgAN.

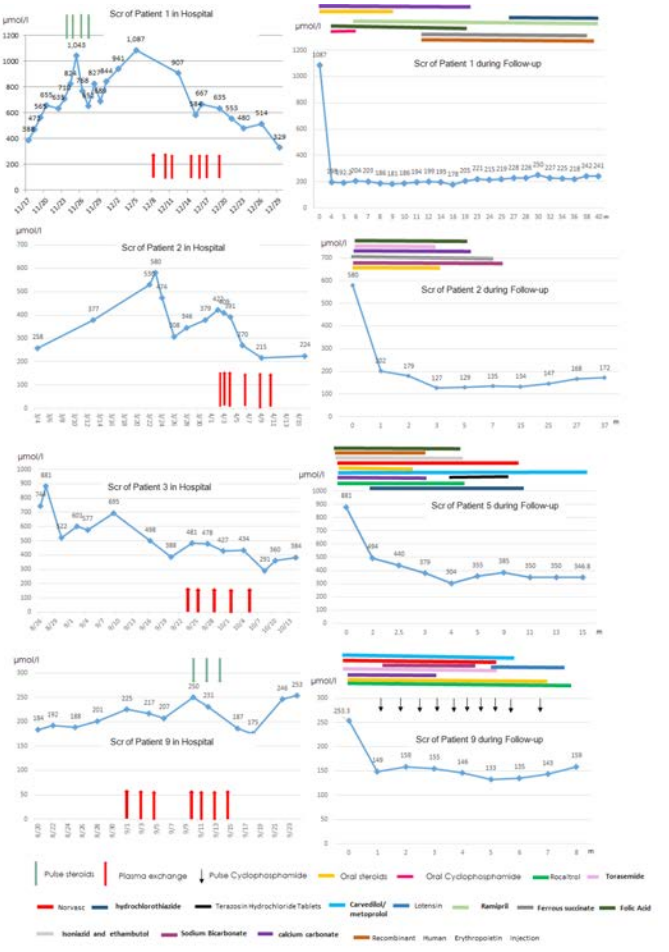
Case Description: In this pilot study we give PE as adjunctive therapy to patients with severe CreIgAN on the back of high dose steroids and cyclophosphamide. Severe CreIgAN is defined as diffuse crescent forming with kidney failure that needs dialysis or presents kidney function declining even with high dose steroids and cyclophosphamide therapy.

Overall ten patients with severe cresentic IgA nephropathy received PE from 2011 to 2015.

Patients	Age	Gender	Dialysis	Scr (μmmol/ L)	Crescents (%)	Course of PE	Pulse of steroids	Follow-up months
1	57	M	Y	1087	61	7	Y	40
2	64	M	Y	580	55	6	N	37
3	26	M	Y	756	67	6	Y	6
4	24	M	Y	710	81	10	Y	6
5	58	M	Y	881	90	5	N	15
6	23	M	N	449	85	7	Y	6
7	39	M	N	394	85	6	Y	6
8	66	F	Y	775	89	7	N	6
9	40	F	N	253	54	7	Y	8
10	44	M	Y	589	43	10	Y	1

Y: yes, N: No

Among them 7 patients reached dialysis at presentation with serum creatinine (768±176mmol/L). Another 3 cases showed progressively kidney decline even after an aggressive immunosuppressive therapy. Patients received 5-10 PEs. After a mean 13 month follow-up, 4 of the 7 patients who had dialysis successfully recovered from dialysis, One of the 3 patients with persistent kidney progression showed serum creatinine decline.



No severe adverse event was observed during the follow-up.

Discussion: Plasma exchange as adjunctive therapy may achieve benefit for patients with severe crescentic IgAN.

SA-PO068

Fibrillary Glomerulonephritis Associated with Demyelinating Polyneuropathy Sixto G. Giusti, Pradeep Vaitla, Jorge C. Garces. *Nephrology, Ochsner Clinic Foundation, New Orleans.*

Introduction: Fibrillary glomerulonephritis (FGN) is characterized by nonbranching randomly arranged fibrils along the mesangium and glomerular capillary walls that do not stain for Congo red, have a diameter of 16-24 nm, and usually show polyclonal IgG, C3, and light chain deposition by immunofluorescence. Found in ≤ 1% of native renal biopsies, FGN is usually idiopathic, although some cases are associated with malignancy, monoclonal gammopathy, and autoimmune diseases. Association of FGN with demyelinating neuropathy has been rarely described.

Case Description: A 38-year-old Indian man with 3-year history of hypertension and 10-month history of end stage renal disease attributed to hypertension, presented to our institution with a 3-week history of progressive, bilateral lower extremity weakness. During his hospital stay, he was diagnosed with non-infectious pleural and pericardial effusions. Lab work revealed normal Anti nuclear antibody, anti double stranded DNA antibody, serum complements, anti nuclear cytoplasmic antibodies. Serologies for hepatitis and human immune deficiency virus were negative. Electromyography revealed demyelinating sensorimotor polyneuropathy. Chest, abdomen and pelvis imaging was unrevealing for malignancy. No monoclonal peaks on serum and urine electrophoresis or immunofixation. Fat pad biopsy negative for amyloid. Bone marrow biopsy showed 60% cellularity with tri lineage hematopoietic activity, no B cell clonality or T cell aberrancy. He was started on high dose steroids with gradual improvements of weakness. Renal biopsy showed findings of chronic FGN with IgG4 dominant deposition. 44 of 48 glomeruli were globally sclerosed with 80% fibrosis and no activity. Sural nerve biopsy results are still pending.

Discussion: FGN is a rare and leads to ESRD in the majority of cases. There are very few cases describing FGN in association with demyelinating polyneuropathy without associated plasma cell dyscrasias. Although FGN renal prognosis remains poor, early identification is important as it may help identify an underlying malignancy or systemic autoimmune disorder with potential for treatment. FGN may be a precursor for future lymphoproliferative disorder.

SA-PO069

Acute Inflammatory Polyarthritis following Kidney Transplantation
Paul P. Maraj. *Nephrology, Baylor College of Medicine, Houston, TX.*

Introduction: An acute inflammatory polyarthritis develops one month after deceased donor kidney transplantation in a 54 year old male. He had no prior diagnosis of any form of arthritis, crystalline, inflammatory or otherwise. Following workup he was diagnosed with Rheumatoid arthritis and improved with an increased dose of steroids. To date there are no case reports which describes rheumatoid arthritis precipitated by kidney transplantation. This case report describes this unique clinical scenario and the dilemmas with diagnosis.

Case Description: 54 year old man with a medical history of end stage renal disease secondary to hypertensive nephrosclerosis who underwent deceased donor kidney transplant one month prior is admitted for joint pains. During kidney transplantation he had induction with thymoglobulin, plasmapheresis and rituximab as per institutional protocol for positive DSA. Maintenance immunotherapy consisted of tacrolimus, mycophenolate mofetil and prednisone taper dose. Following transplantation he was asymptomatic until one month after transplantation when he developed bilateral shoulder pains which then migrated to elbows and wrist; this was associated with significant morning stiffness and malaise. Xrays which were negative for bony abnormalities, MRI wrist revealed small to moderate joint effusion. Fluid analysis was negative for septic arthritis and crystals. Serum uric acid was within normal limits. Autoimmune workup negative including ANA, C3, C4. Rheumatoid factor was positive to titer 1:4, anti CCP was significantly positive at>250. He was treated with oral steroids which resulted in resolution of his symptoms.

Discussion: To date there have been no reports of rheumatoid arthritis in the immediate post-transplant period. There have been reports of an acute inflammatory syndrome related to mycophenolate use which improved on discontinuation, anti-CCP titers were unknown in these cases. Mycophenolate was continued in this patient and his symptoms did not recur after steroid taper making a reaction to mycophenolate less likely. Anti CCP is very specific for diagnosis of rheumatoid arthritis but its validity post transplant is unknown. The temporal relation with transplantation also raises the possibility of a drug induced reaction.

SA-PO070

IgM Nephropathy: A Neglected Pathology of Nephrotic Syndrome
Krystahl Z. Andujar, Carlos Antonio Cortes Sanchez, Hector R. Cordova. *Medical Service, VA Caribbean Healthcare System, San Juan, PR.*

Introduction: IgM nephropathy is defined by the presence of immunoglobulin M (IgM) as the dominant immunoglobulin in the mesangium of the glomeruli in a diffuse and global distribution. Clinically, a poor response to steroids distinguishes this disease from Minimal Change Disease.

Case Description: An 80-year-old man with past history of Hypertension, Alzheimer's dementia, and benign prostatic hypertrophy complained of progressive shortness of breath associated with severe bilateral lower extremity edema and decreased urine output. Vital signs revealed blood pressure of 171/77mmHg. Lung auscultation was remarkable for bibasilar rales. The patient had anasarca. Laboratory tests showed serum creatinine at 2.2mg/dL (baseline of 1.2mg/dL), BUN of 36mg/dL and albumin of 2.2g/dL. Urinalysis showed microscopic hematuria and proteinuria (> 500 mg/dl). Renal sonogram revealed normal kidney size without hydronephrosis or nephrolithiasis. The 24-hour urinary protein excretion was 6.7gms/day. Serum creatinine rose to 7.7mg/dL a week later. Kidney biopsy was performed and steroid pulse therapy was started. Hemodialysis was initiated. Renal biopsy results showed mild increase in mesangial matrix and interstitial fibrosis. Sections stained for IgG, IgA, albumin C1q and kappa and lambda light chains were negative. Staining for IgM showed granular deposits in the mesangial areas compatible with a diagnosis of IgM Nephropathy. Hemodialysis was discontinued after two sessions since the patient had rapid recovery of kidney function after the 3 day steroid pulse therapy. Steroid therapy was tapered and eventually discontinued. Three months later, 24 hour urinary protein excretion was normal and the serum creatinine was 1.6mg/dl.

Discussion: Patients with IgM Nephropathy are less likely to respond to immunosuppressive agents. The presence of mesangial IgM deposits and interstitial fibrosis entails a worse prognosis. However, in our case, the patient had a prompt response to steroid therapy with resolution of the nephrotic syndrome and recovery of renal function.

SA-PO071

Renal Infarct from Traumatic Renal Artery Dissection
Eduardo J. Zouain, Isha Gupta, Karim El Hachem, Germaine Z. Chan, Steven D. Smith. *Nephrology Dept, Mt. Sinai St. Luke's Hospital and Icahn School of Medicine at Mt. Sinai, New York, NY.*

Introduction: Renal infarction is an uncommon condition associated with a thromboembolic event (i.e.: related to atrial fibrillation), hypercoagulable state, renal artery dissection or fibromuscular dysplasia.

Case Description: A 26 y/o male with no significant PMHx presented with left flank pain for 3 days. The pain was described as 10/10 and associated with intermittent nausea. He fell from his motorcycle onto his left side 2 weeks prior. On exam there was a healing laceration over the left knee and tenderness to palpation over the left lower quadrant and L flank. The remainder of his exam including blood pressure was unremarkable. Blood work was pertinent for a WBC of 13.3K/uL and an elevated CRP of 2.5mg/dl. Urinalysis was positive for 30mg/dl protein, and trace blood with 5 RBC/HPF. A basic metabolic panel was normal with a creatinine of 1.1mg/dl. After a non-contrast CT a CT angiogram of the L renal artery was performed.

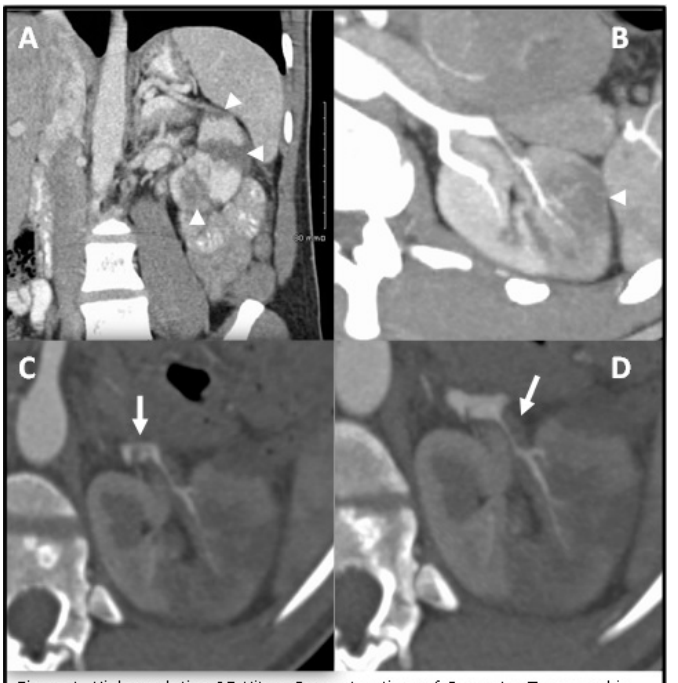

Figure 1. High resolution 3D Vitrea Reconstructions of Computer Tomographic Angiogram. Image A: Multiple areas of hypoattenuation (Arrow head). Image B: Renal Infarct (Arrowhead). Image C: Intimal tear (Arrow). Image D: Thrombosis distally of the false lumen (Arrow).

Discussion: Renal infarcts are characterized by acute onset of flank or generalized abdominal pain, nausea, vomiting, and occasionally fever and hypertension. Elevated WBC, CRP and LDH have also been associated. Renal artery dissection secondary to trauma is rare and has been associated with anatomical variations and acceleration/deceleration injury leading to intimal tearing. The two goals of treatment are organ preservation and improvement of renovascular hypertension. The treatment options include surgical reconstruction, endovascular repair, or conservative treatment. Our patient was initially placed on empiric anticoagulation with heparin. After hypercoagulable disorder, vasculitis, and embolic source was ruled out, anticoagulation was stopped. The patient was discharged on conservative treatment.

SA-PO072

Persistent Fever in a Patient with Wünderlich Syndrome
Marijeta Pekez,[1] Kshitij Thakur.[1] [1]*Dept of Medicine, Crozer Chester Medical Center, Upland, PA;* [2]*Clinical Renal Associates, Crozer Chester Medical Center, Upland, PA.*

Introduction: Wünderlich syndrome is spontaneous, nontraumatic renal hemorrhage confined to the subcapsular and perirenal space. We present a case of a patient with a Wünderlich syndrome complicated by renal abscess.

Case Description: Patient was a 43 year old male who presented with nausea and generalized weakness, found to have sepsis secondary to urinary source. Ultrasound obtained during work up showed a old right perinephric hematoma. Patient continued to be febrile despite IV antibiotics. Repeat imaging with CT scan showed large abscess in place of the previously described subcapsular hematoma. Successful CT-guided drainage of the abscess led to marked improvement and resolution of fever.

Discussion: Wünderlich syndrome is secondary to neoplastic and non-neoplastic causes. It usually presents as mild flank pain, flank tenderness, or hematuria. Depending on blood loss, symptoms, of hypovolemic shock may develop. Treatment varies according to severity, ranging from monitoring of the hematoma to nephrectomy. Our case is interesting since Wünderlich syndrome provided a nidus for infection and eventual abscess formation causing persistent fevers and flank pain with preserved hemodynamic stability. It demonstrated the need for CT imaging in order to fully appreciate the extent of the hemorrhage which in this case converted into an abscess. In the right clinical scenario, Wünderlich syndrome should be evaluated as a possible factor in infectious presentations.

SA-PO073

Gaucher's Disease and Lupus, Two Diseases in the Same Scope?
Ana Pocinho Pimentel, Ana Cabrita, Teresa M. Jeronimo, Joana Vidinha, Viriato J.V. Santos, Pedro L. Neves. *Nephrology, Centro Hospitalar do Algarve, Faro, Portugal.*

Introduction: Gaucher's disease is a rare inherited lysosome storage disease caused by genetic mutations that encodes for glucocerebrosidase enzyme. It's deficiency leads to glucocerebroside (GC) accumulation in mononuclear macrophage system, including liver, spleen and bone marrow. Kidney involvement is usually rare. Systemic lupus erythematosus

(SLE) is an autoimmune disorder where similarly, sphingolipid accumulation occurs when there is glomerular disease.The authors describe a case of a woman with both Gaucher's disease type 1 and SLE.

Case Description: A 32-year-old woman with Gaucher's disease diagnosed at 17 years old, having velaglucerase, presented several clinical clues suggesting SLE. Months later started presenting face and limbs edema and hypertension. She was admitted with microcytic and hypochromic anemia, 77000 platelets, creatinine serum levels of 1.38mg/dL and hypocalcemia. The urinalysis showed hematoproteinuria and proteinuria of 7628mg in the 24h urine collection. The patient had positive anti-nuclear antibodies, Anti-Sjögren's syndrome-related antigen and negative anti-double stranded DNA antibodies, anti-neutrophil cytoplasmic antibodies, viral serologies. Both complement levels were low. A kidney biopsy was performed.

It has been suggested that progressive accumulation of GC may trigger macrophage activation resulting in enhanced cytokine secretion and subsequent clonal B-cell expansion leading to chronic stimulation of the immune system. GC changes natural killer T cell function, a regulatory lymphocyte that have a role in infectious, neoplastic and inflammatory processes, therefore having a potential role in inducing other autoimmune disease. NKT lymphocytes are considered to be a link between innate and adaptive immune responses and were shown to have a role in a number of immune-mediated disorders. In an animal model of SLE, a selective reduction in NKT cells precedes the development of autoimmune phenomena.

Discussion: This case highlights a possible immunologic proximity between Gaucher's disease and SLE, bringing up the already existing doubt that the defects in lipid metabolism, could contribute to the development of autoimmunity.

SA-PO074

Chronic Periaortitis, a Known Cause of Obstructive Uropathy Margaret Duffy,[1] Smita Mahendrakar,[1] Mandeep Samra,[1] Michael Yudd.[2] *[1]Nephrology, Rutgers-New Jersey Medical School, Newark, NJ; [2]Nephrology, East Orange Veterans Administration Hospital, East Orange, NJ.*

Case Description: A 59 year-old man with hypertension presented with one week of gradually decreasing urine output, nausea, generalized weakness, and vague dull left lower quadrant pain with radiation to the left flank. He was afebrile with blood pressure of 170/90 mmHg, pulse of 79 beats per minute, respiratory rate of 16 breaths per minute, and oxygen saturation of 98% on room air. His abdominal exam was unremarkable except for non-tender scrotal swelling bilaterally. Laboratory studies were notable for the following values: WBC 12.1 x 10^9 /L, BUN 62mg/dL, SCr 13.8mg/dL (baseline SCr 1.1mg/dL), ESR 57mm/hr, CRP 67mg/dL, U/A clear, yellow, specific gravity 1.01, pH 6, moderate blood, negative protein, leukocyte esterase, or nitrites. A renal ultrasound showed moderate hydronephrosis with patent renal arteries and veins bilaterally. CT of the abdomen and pelvis revealedmoderate bilateral hydronephrosis, an abdominal aortic aneurysm (3.6cm), and a periaortic soft tissue mass measuring 2 cm in diameter with associated ureteral obstruction. There was no inguinal iliac lymphadenopathy or suggestion of discrete malignancy. Based on combined clinical and radiographic evidence the patient was diagnosed with chronic periaortitis and retroperitoneal fibrosis. He was started on mycophenalate mofetil and prednisone taper with complete resolution of symptoms within 6 months.

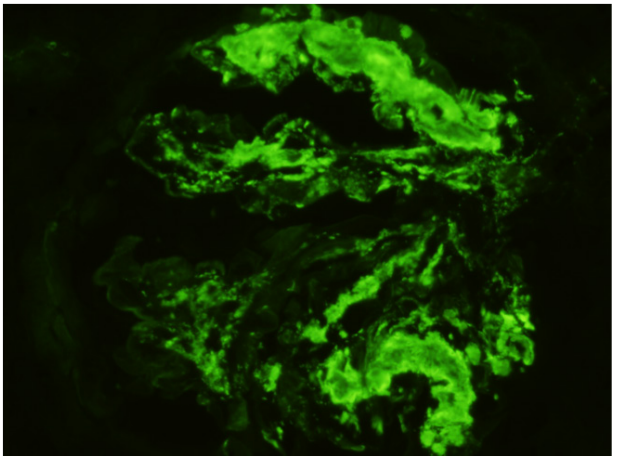
Discussion: Retroperitoneal fibrosis (RPF) is a relatively rare condition characterized by the presence of fibrosis and inflammation of the retroperitoneal tissues that often surrounds the ureters and other abdominal organs and can lead to renal failure in advanced cases. Our case demonstrates the importance of considering RPF as an etiology of flank pain and renal failure as medical treatment is effective in reversing obstructive uropathy.

SA-PO075

IgA Nephropathy in HIV Positive Patient with Acute Kidney Injury Giovanna Y. Arteaga Muller,[1] Lilia Maria Rizo Topete,[1] Elisa Maria Guerrero Gonzalez,[1] Concepcion Sanchez Martinez,[1] Jesus Cruz Valdez,[1] Gabriela Alarcón-Galván.[2] *[1]Nephrology, Univ Hospital José E. González UANL, Monterrey, Mexico; [2]Anatomic Pathology, Univ Hospital José E. González UANL, Monterrey, Mexico.*

Introduction: Acute kidney injury is common in patients with HIV, being prerenal variety the predominant etiology. Among the intrinsic causes are thrombotic microangiopathy, the antiretroviral drugs associated and the immune complexes associated (3.5%-10%) being the collapsing focal segmental glomerulosclerosis the most frequently found.

Case Description: Male 41 year old, with use of cocaine, marijuana, benzodiazepines tattoos and high-risk sexual behavior, diagnosed with HIV nine years ago, treated with antiretrovirals which suspended two years ago. Begins 3 months before with malaise, a week prior to his admission presented progressive dyspnea on moderate to high stresses accompanied by productive cough and fever. Chest radiography showed fine interstitial infiltrate, compatible with pneumocystis jiroveci, laboratories: Hb9.4g/dl, creat.3.0 mg/dl, BUN30 mg/dl, urine protein 4.79g/24 hrs, the urinalysis reported reddish urine, with granular casts, hematuria and pyuria. Hepatitis B, Hepatitis C, CMV and tuberculosis tests were all negative and the renal ultrasonography was normal. Renal biopsy revealed IgA nephropathy.



Direct immunoflourescence technique (400X).Mesangial granular staining (4+) for IgA. Early treatment with anti-proteinuric general measures and prednisone improved renal function with a decreased in creatinine to 1.3mg/dl.

Discussion: The immune complexes associated nephropathy in patients with HIV is more common due to the start of antiretroviral therapy, however IgA nephropathy remains uncommon in this patients. In our patient the indication for renal biopsy was the erythrocyturia and the proteinuria in nephrotic range. Early detection and treatment can prevent progression to ESRD.

SA-PO076

Ketorolac Induced Mesangiolysis: A Clinical Example of Anti-Thy 1.1 Model of Mesangio-Proliferative Glomerulonephritis Fatima Khalid. *Dept of Medicine, Univ of Rochester School of Medicine, Rochester, NY.*

Introduction: NSAIDS are known cause of acute kidney injury, but do not usually cause glomerulonephritis. We share an unusual presentation of glomerulonephritis after only one dose of ketorolac. No renal biopsy findings in acute ketorolac-related acute kidney injury appear to have been published based on an Ovid literature search.

Case Description: This is a 42 year old male with past medical history of nephrolithiasis and urethral stricture, who presented to the hospital for a cystoscopy procedure. The patient had urinary obstruction after the procedure and developed oliguric acute kidney injury with serum creatinine of 3.1 mg/dl (baseline 0.8 mg/dl). Of note, the patient also received one dose of ketorolac during the procedure. Urinalysis showed 2+ blood with many red blood cells, and 9 grams of proteinuria as TP/creatinine ratio. Lab work demonstrated high LDH, low haptoglobin but stable hematocrit and platelet count. Peripheral smear did not reveal schistocytes. Urine microscopy showed RBC casts. Renal ultrasound showed normal sized kidneys with no hydronephrosis. Kidney biopsy showed acute tubule-interstitial nephritis with tubular necrosis and mesangiolysis. Electron microscopy showed patent capillary loops with focal epithelial foot process effacement, visceral epithelial cells with cytoplasmic vacuolization, dilated capillaries with endothelial apoptosis and mesangial lysis. Glomerular basement membrane thickness was increased. There was evidence of acute tubular injury. No electron dense deposits, thrombi or crescents were identified. Immunofluorescence of glomeruli was negative. The patient remained oliguric and required renal replacement for short term followed by full recovery of renal function.

Discussion: Renal toxicity of ketorolac has been described, and appears generally to be reversible, but could lead to glomerulonephritis in a rare setting. The pathological findings in the glomeruli resemble those described in experimental animals with Thy-1 induced glomerulonephritis treated with rofecoxib(COX-2 inhibitors). In this model, glomerular disease is initiated by immune-mediated mesangial cell damage, resulting in mesangiolysis.

SA-PO077

Disseminated Cytomegalovirus Disease in Induction Treatment with Mycophenolate Mofetil in a Lupus Nephritis Patient Ana Pocinho Pimentel, Joana Vidinha, Teresa M. Jeronimo, Ana Cabrita, Ana Paula Silva, Pedro L. Neves. *Nephrology, Centro Hospitalar do Algarve, Faro, Portugal.*

Introduction: Mycophenolate mofetil (MMF) is an immunosuppressive agent that exerts relatively selective antiproliferative effects on T and B lymphocytes and is increasingly being associated with higher incidence of tissue-invasive cytomegalovirus (CMV) disease in transplant receivers and other immune-mediated diseases. The case presented is a patient who developed CMV enteritis while receiving MMF and corticosteroids for lupus nephritis (LN).

Case Description: 59 year-old man with LN class IV G(a) + V under MMF (2,5g/day) and prednisolone (60mg/day) when started having weight loss, diarrhea, nauseas, dysphagia and haematochezia. The blood count showed severe anemia and leucopenia. Comprehensive chemistry profile revealed PCr 2.7mg/dL improving proteinuria from 11.7 to 2g/day and normal urinary sediment. CMV serology IgM came positive (PCR CMV: 834 copies/mL). Immunology tests were negative. Upper endoscopy and colonoscopy were performed. Biopsies showed CMV infection signs and esophageal candidiasis. MMF was tapered to 1g/day and prednisolone to 20mg/day. The patient was started on intravenous ganciclovir

and fluconazole, with favorable clinical response. Proteinuria then worsened to 7,9g/day. Renal biopsy was repeated showing relapse of LN class V. Renal function improved PCr 1.6mg/dL having 2g MMF and prophylactic oral valganciclovir.

CMV virus directly infects the bowel causing mucosal erosions or ulcerations. We can only find little evidence that CMV disease explains the gastrointestinal adverse event profile associated with MMF but we bring up again the hypothesis that high local concentrations of MMF have a direct toxic effect on cells of the small intestine, causing gastrointestinal upset. Data on the incidence of CMV disease with the MMF induction protocol for LN are scarce.

Discussion: Similarly to transplant recipients receiving MMF, LN patients presenting gastrointestinal upset demand exclusion of CMV infection. This report highlights the importance of clinical follow-up of lupus patients with GI symptoms undergoing intense immunosuppression and accurate serological and histological diagnosis.

SA-PO078

Cryoglobulinemic Nephropathy with Successful Childbirth After Recurrent Episodes of Nephrotic Syndrome During Pregnancy Miho Karube, Shinya Kaname, Kazuhito Fukuoka, Hideki Shimizu, Yoshinori Komagata, Yoshihiro Arimura. *The First Dept of Internal Medicine, Kyorin Univ School of Medicine, 6-20-2 Shinkawa Mitaka-city, Tokyo, Japan.*

Introduction: It is unknown whether pregnancy affects clinical course of cryoglobulinemic nephropathy and how to treat pregnant patients complicated with it.

Case Description: A 35-year-old woman was admitted to our hospital because of massive proteinuria that developed during the third pregnancy. The previous two pregnancies had been terminated for similar episodes of nephrotic syndrome. No history of hypertension was observed, but during the course she presented cryoglobulinemia, a high titer of RF and low serum complements. The renal biopsy performed 10 days after the third termination revealed MPGN-like lesions with lobulation in glomeruli, double contour of GBM, endotheliosis, and moderate mesangial cell proliferation. Immunofluorescence study showed IgG, IgA, IgM, C3, C4, and C1q all positive mainly along the glomerular capillaries, and subendothelial deposits were confirmed by EM, thus she was diagnosed as cryoglobulinemic nephropathy. Because the histological findings of repeated renal biopsy were not improved two months after the disappearance of proteinuria, treatment with 30 mg/day of PSL was started, followed bv intravenous cyclophosphamide 6 times and plasma exchange, since she had a desire for baby. Finally at the fourth pregnancy, she bore a healthy baby weighing 2,342g on vaginal delivery at 36 weeks despite of recurrent appearance of nephrotic syndrome. After delivery, she was given 30 mg/day of PSL and proteinuria subsided.

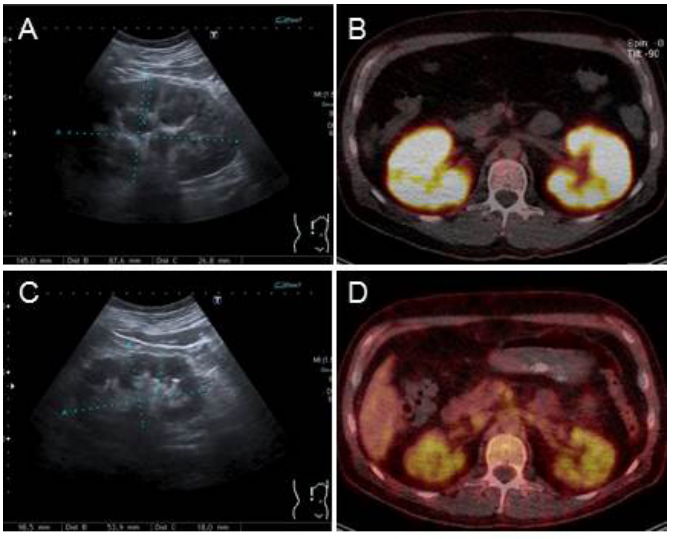
Discussion: We experienced a rare case of type III cryoglobulinemic nephropathy that repeatedly developed nephrotic syndrome during pregnancy, but finally bore a baby after immunosuppressive therapy. Although the pathogenesis of pregnancy-induced exacerbation of cryoglobulinemic nephropathy was not clear in this patient, aggressive treatment may have been helpful for ameliorating it, leading to successful delivery.

SA-PO079

Renal Recurrence of Acute Lymphatic Leukemia Anna Bertram,[1] Jan H. Braesen,[2] Ansgar Reising.[1] *[1]Nephrology and Hypertensiology, Hannover Medical School, Hannover, Germany; [2]Pathology, Hannover Medical School, Hannover, Germany.*

Introduction: Renal complications of hematologic neoplasia can be therapy- or neoplasia-associated. We report a case of acute kidney injury (AKI) in the long term follow-up of a patient with acute lymphatic leukemia (ALL).

Case Description: The 42y old patient was diagnosed with ALL in 2009 and treated according to recommendations with chemotherapy and peripheral blood stem cell transplantation. In 2012, extramedullary ALL recurrence in his right knee was treated with irradiation. Starting from September 2014, molecular markers of minimal recurrence without evidence of lymphoblasts were found in bone marrow biopsies, and the patient received donor lymphocytes to induce graft vs. host reaction. In December 2014, ramipril was started for newly diagnosed hypertension, after which creatinine increased within several days to 290μmol/L. Because of this association, we suspected renal artery stenosis, toxic AKI, or acute interstitial nephritis. Ultrasound revealed diffusely swollen and dense kidneys (Fig.1A). Renal artery stenosis could be excluded, but - untypical for interstitial nephritis - segmental arteries seemed compressed. Kidney biopsy revealed ALL recurrence with extensive lymphoblast infiltration. DOTA-CXCR4-PET-CT confirmed diffuse infiltration of both kidneys (Fig.1B) without bone marrow affection. After starting chemotherapy, creatinine rapidly ameliorated. Ultrasound and PET-CT-controls 10 weeks after starting therapy confirmed good treatment response (Fig.1C-D).



Discussion: This exceptional case of isolated renal ALL recurrence highlights the importance of early evaluation with ultrasound and biopsy in patients with hematologic neoplasia and AKI. An empiric treatment for suspected interstitial nephritis would have delayed chemotherapy and thereby endangered the patient.

SA-PO080

A Rare Cause of Acute Kidney Injury in Non-Renal Solid Organ Transplantation Sameer Gupta, Wasay Humayun, Ramapriya Sinnakirouchenan, Liliana Osadchuk. *Nephrology, Medical College of Wisconsin, Milwaukee, WI.*

Introduction: Acute kidney injury (AKI) is a frequent complication of non-renal solid organ transplantation (SOT). Here we report a case of rapidly progressive renal failure leading to end stage renal disease (ESRD) due to acute oxalate nephropathy (AON) in a patient with non-renal SOT.

Case Description: A 63 year old female with past history of pulmonary fibrosis status post bilateral lung transplant, obesity status post Roux en Y gastric bypass (RYGB) surgery, and hypertension presented with worsening kidney function with BUN and creatinine of 55 mg/dl and 6.18 mg/dl respectively. She had normal kidney function with serum creatinine of 0.5mg/dl prior to transplant 8 months ago. Induction regimen included Basiliximab followed by tacrolimus, prednisone and mycophenolate (MMF) as maintenance therapy. Ensuing transplantation, she had multiple episodes of AKI attributed to calcineurin inhibitor (CNI) toxicity and hypovolemia from MMF and clostridium difficile associated diarrhea. Her average tacrolimus trough level was 12 ng/ml. Several urinalyses showed acute tubular necrosis casts. Renal ultrasound revealed bilateral echogenic small kidneys compared to normal kidney size prior to transplant. Her kidney biopsy unexpectedly revealed oxalate nephropathy. She is currently on hemodialysis.

Discussion: AON has been poorly described in patients with RYGB surgery and SOT. In our patient with prior RYGB, chronic diarrhea, and numerous antibiotics unveiled AON. This superimposed with CNI toxicity resulted in rapid progression to ESRD. Antibiotic use depletes colonization of oxalate consuming bacteria (Oxalobacter formigenes). This combined with fatty acid malabsorption from prior RYGB increases colonic oxalate absorption resulting in hyperoxaluria. Diarrhea causes hypovolemia and metabolic acidosis leading to low urinary pH and hypocitraturia promoting calcium oxalate crystallization. Additional steps should be taken for SOT patients with RYGB, like diet modification, probiotic use, citrate supplementation, administration of fatty acid binding agents, and monitoring for hyperoxaluria. High suspicion for AON in patients with risk factors may lead to early diagnosis and treatment.

SA-PO081

Paraneoplastic Membranous Nephropathy and Myelodysplastic Syndrome – A Rare Combination Krishna K.R. Manda, Madhuri Manne, Dagmar Klinger. *Renal Medicine, Univ of Massachusetts Medical School, Worcester, MA.*

Introduction: We report a case of Membranous Nephropathy(MN) seen in association with Myelodysplastic Syndrome(MDS). This occurrence is rare and only 3 cases have been reported in literature previously. Up to 5-20% of adults with MN have been reported to have most commonly a solid tumor and less frequently, a hematologic malignancy.

Case Description: Our patient is a 58 y/o man who has chronic kidney disease of unclear etiology with serum creatinine(SCr) of 1.3 and MDS. He was admitted with acute kidney injury in the setting of pneumonia and had nephrotic range proteinuria along with dysmorphic red blood cells on the urinary sediment. Renal biopsy showed MN with relatively recent immune complex deposition. There was no colocalization of IgG4 membranous deposits with phospholipase A2 receptor. He was hospitalized again with pancytopenia, marked inflammatory markers and infectious complications. Although bone marrow biopsy was not diagnostic, this syndrome was diagnosed as hemophagocytic

lymphohistiocytosis by clinical criteria and therapy was initiated with high-dose steroids and etoposide. During the hospitalization SCr peaked to 4 but did not require renal replacement therapy. Following this treatment SCr improved to 0.7.

Discussion: MN is the most common cause of the nephrotic syndrome in nondiabetic adults. Histologic change on light microscopy is glomerular basement membrane thickening with little or no cellular proliferation. Patients without known cancer who are diagnosed with MN should undergo age-appropriate cancer screening and this could be life saving. MDS, a group of heterogeneous hematopoietic stem cell disorders, are characterized by abnormal bone marrow differentiation & maturation, morphologically and functionally changed progenitors and a variable risk of evolution to acute leukemia. Paraneoplastic Glomerulonephritis(PGN), a rare secondary cause of glomerulonephritis and a complication of cancer remains a challenge to both nephrologists and oncologists. Studies to identify diagnostic biomarkers of PGN in blood, urine, or kidney biopsy samples by use of proteomic or other approaches are critically needed to facilitate the early diagnosis of this disease.

SA-PO082

Eculizumab in Gemcitabine Induced Atypical Hemolytic Uremic Syndrome aHUS

Mohit Gupta, Rupesh Raina, Natthavat Tanphaichitr. *Dept of Nephrology, Akron General Medical Center, Cleveland, OH.*

Introduction: HUS (aHUS) is caused by endothelial damage due uncontrolled activation of complement system. Gemcitabine a nucleoside analog induced HUS (GiHUS) is rare. We report a patient with unresectable, locally advanced pancreatic cancer who developed a HUS after 1 months of gemcitabine.

Case Description: A 64 year-old female was diagnosed with 4 cm mass adenocarcinoma of the pancreatic head, after extensive evaluation of recurrent abdominal associated with clay colored stool. She underwent three cycles of gemcitabine at 1,000 mg/square meter. Her condition deteriorated over the following 1 weeks and developed microangiopathic hemolysis, rapidly declining renal function with proteinuria and hematuria, and renal biopsy of the last dose. Other markers of hemolysis namely LDH and bilirubin had dramatic improvement after 2 treatment of Eculizumab.

Pt was consequently treated with Eculizumab for management of atypical HUS. She received 1 dose of Eculizumab IV every week after which she was transitioned to once monthly for a total of nine doses. Pt's Creatinine Clearance was closely monitored and had significantly improved from 14 mL/min at the time of onset to 60 mL/min by the time of the last dose. Other markers of hemolysis namely LDH and bilirubin had dramatic improvement after 2 treatment of Eculizumab.

Discussion: HUS associated with gemcitabine is quite rare and no consistent risk factors have been Identified. Conventional treatment with hemodialysis, or corticosteroids or plasmaphresis as minimal response.The rapid clinical response to eculizumab supports the concept that GiHUS might involve aberrant and autonomous complement activation. The dramatic resolution of symptoms after eculizumab administration suggests that chemothearpy induce aHUS is an area deserving further careful investigation of therapeutic complement blockade.

SA-PO083

A Case of Rapidly Progressive Idiopathic Mempranoproliferative Glomerulonephritis Effectively Treated with High-Dose Steroid Therapy

Bernice Kim, Kyung Soo Kim. *Div of Nephrology, Dept of Internal Medicine, Dongguk Univ Ilsan Hospital, Goyang, Republic of Korea.*

Introduction: Membranoproliferative glomerulonephritis (MPGN) is an uncommon kidney disorder which can be idiopathic or secondary in etiology. As diagnostic methods improved over time, secondary cause of MPGN is increasingly defined and the truly idiopathic form is now a very rare condition. Because of the rarity of idiopathic MPGN, treatment guidance is based mainly on case series and the natural history of the disease is unclear. We present a case of rapidly progressive idiopathic MPGN effectively treated with high-dose steroid.

Case Description: A 73-year-old male was admitted because of subtrochanteric fracture. On admission, he had normal kidney function with serum creatinine (sCr) level of 1.02 mg/dL. 5 days after the operation of fracture, he was referred to the nephrology department due to abruptly increased level of sCr. On postoperative day 10, despite adequate intravenous hydration, he became anuric and sCr rose to 4.40 mg/dL requiring hemodialysis. Serum C3 level was low (38mg/dL). Kidney biopsy revealed mesangiocapillary proliferation, duplication of the glomerular basement membranes, subendothelial deposits and predominant C3 immunofluorescent staining suggestive of MPGN type I. Secondary causes such as infection, autoimmune disease, monoclonal gammopathy, neoplasia, complement dysregulation were excluded. He was diagnosed as idiopathic MPGN type I and high dose steroid therapy (40mg/day of prednisolone) was initiated. After 17 days of therapy, urine output was increased and dialysis was discontinued accordingly. Prednisolone was gradually tapered to 5mg over 1 month and he was discharged with sCr of 1.39 mg/dL.

Discussion: The early trials of the treatment of idiopathic MPGN have given inconsistent results, and should be interpreted with great caution since many of the reports likely included cases of secondary MPGN. The clinical presentation of MPGN is variable, from benign and slowly progressive to rapidly progressive, and different therapeutic approach should be applied in regard of the disease course. Studies are needed to identify the natural course and effective treatment of MPGN.

SA-PO084

A Case of Advanced IgG4 Related Tubulointerstitial Nephritis Complicating Multiple Lymphadenopathy and Intrathoracic Nodule, Mimicking Malignant Lymphoma

Shigeto Horita, Hiroshi Fujii, Yuhei Fujisawa, Satoshi Hara, Yasunori Suzuki, Kazunori Yamada, Mitsuhiro Kawano. *Div of Rheumatology, Kanazawa Univ Graduate School of Medicine, Kanazawa, Ishikawa, Japan.*

Introduction: Immunoglobulin G4-related disease (IgG4-RD) is a systemic inflammatory disorder characterized by mass-forming lesions with IgG4-producing plasma cells. We describe a patient with IgG4-RD associated with advanced tubulointerstitial nephritis, membranous nephropathy, and multiple lymphadenopathy, mimicking malignant lymphoma.

Case Description: Four months prior to this admission, an 81-year-old male experienced anorexia and weight loss. Enhanced CT revealed gastric cancer, intrathoracic nodule, multiple defects of contrast medium in the kidneys and abdominal periaortitis. The patient's serum Cr level was 1.1 mg/dl and IgG4 level was 390 mg/dl. One month prior to this admission, the patient had received gastrectomy. After gastrectomy, decreased renal function (Cr 2.09 mg/dl), elevation of IgG4, and hypocomplementemia were detected. A renal biopsy showed marked infiltration by IgG4-positive plasma cells, spiking and bubbling on PAM staining, and granular deposits of IgG on immunofluorescent staining. The patient was diagnosed with IgG4 related tubulointerstitial nephritis and membranous nephropathy. PET showed accumulation of fluorodeoxyglucose in the submandibular glands, lymph nodes, kidneys, abdominal aorta and prostate, which were hard to distinguish from malignant lymphoma. Biopsy of the largest lymph nodes in the axilla and intrathoracic nodule showed reactive lymphadenopathy with IgG4 positive plasma cell infiltration. One month after starting prednisolone (25 mg/day), Cr level was partially decreased to 1.1mg/dl and, the size of the lymph nodes and intrathoracic nodule reduced.

Discussion: Findings of IgG4-RD often mimic those of malignancies, so the differentiation of malignancies from IgG4-RD is important. In this regard, pathological findings of the affected organs are important to make the correct diagnosis. As severe renal dysfunction might develop during a several month period, IgG4-related kidney disease should be considered as a cause of renal dysfunction of unknown origin, especially in elderly men.

SA-PO085

Presence of PLA-2R Autoantibodies in a Patient with Clinical and Histopathological Evidence Suggestive of Secondary Membranous Nephropathy

Kristen P. Tamura, Niti Madan. *Nephrology, UC Davis Medical Center, Sacramento, CA.*

Introduction: Differentiating between secondary membranous and idiopathic membranous nephropathy (IMN) is based on histopathology showing proliferative features in mesangium, full-house staining pattern, electron dense deposits in the mesangium and tubular basement membrane . Phospholipase A2 receptor (PLA2R) has been identified is a major target antigen involved in IMN pathogenesis. We describe here a patient with clinical history and histopathology suggestive of secondary membranous and positive anti-PLA2R antibody suggestive of IMN.

Case Description: A 56 year old Caucasian man with history of colon tubular adenoma, NHL- status post chemotherapy and radiation 30 years back, hypothyroidism presented with new- onset nephrotic-range proteinuria. He was not taking any medications and physical exam noted generalized edema. Laboratory exam as noted in table 1.

	Proteinuria in 24 hrs	Creatinine	Albumin	Anti-PLA2R IFA titres
At Diagnosis	9 gms	0.85 mg/dL	1.8 g/dL	1:1000
6 months of conservative therapy	11 gms	1.3 mg/dL	1.6 g/dL	
3 months of Ponticelli regimen	7.3 gms	1.5 mg/dL	2.2 g/dL	1:20

A renal biopsy showed variable-sized electron dense deposits in subepithelial,intra membranous,mesangial and paramesangial locations. This finding strongly suggested a secondary etiology for the membranous nephropathy. Workup for infectious,autoimmune and neoplastic causes of membranous nephropathy was negative. Proteinuria worsened to 11 g/24h despite six months of conservative therapy with lisinopril and low protein diet. Additional labs obtained came back positive for PLA2R autoantibodies (IFA 1:1000,ELISA 976.6 RU/ml). Kidney stained positive for PLA2R glomerular deposits suggesting IMN. The patient was then treated with a modified Ponticelli protocol using alternating monthly prednisone and oral cyclophosphamide (2 mg/kg/d) for six months. After three months, proteinuria , albumin and edema improved.

Discussion: Relying on histopathologic differences to distinguish between idiopathic and secondary membranous nephropathy may lead to incorrect diagnosis and delay in treatment.The presence of circulating and tissue PLA2R autoantibodies may be more reliable in diagnosing IMN than histopathology.

SA-PO086

Silent Malakoplakia in a Recipient of Kidney-Pancreas Transplant Diagnosed on Surveillance Biopsy of Kidney Allograft: A Patient-Centered Approach to Treatment of Malakoplakia Jun Shoji,[1] Ravinder K. Wali.[2] *[1]Dept of Kidney Disease and Hypertension, George Washington Univ, Washington, DC; [2]Inova Transplant Center, Inova Fairfax Hospital, Falls Church, VA.*

Introduction: Malakoplakia is an inflammatory disease leading to chronic morbidity and organ dysfunction. It was originally described in association with genitourinary tract infections with coliform bacteria and can manifest as acute pyelonephritis, acute or chronic renal failure, or renal mass. We present a case of a 40-year-old female recipient of simultaneous pancreas-kidney transplant who developed an acute rise in serum creatinine without apparent cause and found to have malakoplakia on kidney allograft biopsy. Patient-centered treatment resulted in reversal of allograft dysfunction and resolution of histological features of malakoplakia.

Case Description: 40-year-old Caucasian female with type 1 diabetes mellitus and end-stage renal disease on peritoneal dialysis underwent SPK transplant. After induction with thymoglobulin, she was maintained on tacrolimus and mycophenolate mofetil. Two months later, she was treated for acute T-cell mediated rejection (Banff Grade IA) with thymoglobulin. Serum creatinine returned to baseline and maintenance prednisone was added to her regimen. Her posttransplant course was complicated by multiple infections including parvovirus B19 infection, primary CMV infection, two episodes of urinary tract infections, and influenza A pneumonia. Due to an increase in serum creatinine without apparent cause, a kidney allograft biopsy was performed which revealed lesions consistent with malakoplakia.

Discussion: Treatment of malakoplakia in kidney transplant recipients is not well established but include surgical resection and use of antimicrobial agents. In the era of cyclosporine and azathioprine, it was speculated that the use of azathioprine may be associated with the development of malakoplakia. Discontinuation of azathioprine was shown to restore bactericidal activity of mononuclear cells. This case report illustrates that in the era of immunosuppression with tacrolimus and mycophenolate mofetil, the maintenance therapy with tacrolimus may be continued while treating for malakoplakia.

SA-PO087

Common Weight Loss Medication Pill "Qsymia" Causing Hypokalemia and Renal Tubular Acidosis Jyotsana Thakkar, Mala Sachdeva. *Div of Nephrology, North Shore -LIJ School of Medicine, Great Neck, NY.*

Introduction: The obesity epidemic is growing. Aside from the traditional diet and exercise, weight loss pills are more commonly prescribed. Qsymia is one such weight loss pill consisting of topiramate and phentermine. We report potentially life threatening side effects of Qsymia causing severe hypokalemia, proximal renal tubular acidosis (pRTA), and cardiac dysrhythmia.

Case Description: A 68 year old female with history of hypertension presented with complaints of tingling of her left arm and jaw of one day duration. Her home medications included Aspirin and Hyzaar (Losartan and Hydrochlorothiazide). She had self discontinued the Hyzaar five days prior to presentation. Patient was recently started on the weight loss medication "Qsymia" three months prior. She denied any alcohol use. On initial presentation, she was noted to be in atrial fibrillation (HR 150s) and hypotensive (BP 84/43 mmHg) requiring cardioversion. Subsequent cardiac catherization and echocardiogram were unremarkable. Initial lab data showed severe hypokalemia-2.4 mmol/L, creatinine 1.08 mg/dL, bicarbonate 22 mmol/L, phosphorus 2.1 mg/dL, magnesium 2.2 mg/dL, and calcium 8.9 mg/dL. Urinalysis showed pH 8 with glucosuria. Urine Lytes showed potassium 38 mmol/L, chloride 43 mmol/dL, and sodium 141 mmol/L.

It was suggested that patient's clinical presentation and electrolyte disorders were due to the weight loss medication, and Qsymia was discontinued. Qsymia was approved by FDA in 2012 for weight loss. Most common side effects reported include paresthesia, dizziness, insomnia, constipation and dry mouth. In the U.S., drug label contains warnings for increased heart rate. Topiramate is known to cause pRTA. Our patient had mild acidosis, hypophosphatemia and glucosuria which we believe was a result of an early pRTA, induced by topiramate. Although hydrochlorothiazide is known to cause hypokalemia, our patient was not taking the medication for five days.

Discussion: Weight loss medications are now being more commonly used to treat obesity. Prescribers should be aware of the potential nephrotoxic side effects of Qsymia. Monitoring serum potassium and bicarbonate levels regularly should be taken into consideration.

SA-PO088

Multiple Myeloma as the Underlying Cause of Thrombotic Microangiopathy Venkata Buddharaju, Liga Yusvirazi, Anastasios Papanagnou, Savneek S. Chugh, Rahul N. Pawar. *Nephrology, Westchester Medical Center, Valhalla, NY.*

Introduction: Thrombotic microangiopathy (TMA) describes a pathological process of microvascular thrombosis, consumptive thrombocytopenia and microangiopathic hemolytic anemia, leading to end-organ ischemia and infarction affecting particularly the kidney and brain. TMA is a pathological feature of a number of clinical disorders including Hemolytic uremic syndrome (HUS) and atypical HUS. Rare but important, TMA may also occur in malignancy, connective tissue disease, malignant hypertension, and renal transplantation (rejection or drug toxicity). We present a rare case where patient developed AKI from TMA but found to have plasma cell dyscrasia as possible underlying etiology.

Case Description: A 42 y/o man with h/o myopathy, questionable mixed connective tissue disorder on prednisone and cellcept, Pulmonary Hypertension on home oxygen, CHF with preserved EF and Anemia requiring multiple transfusions went to an outside hospital with SOB and pedal edema found to have AKI with serum creatinine of 4 and 2+ proteinuria. Serologies were negative except for anti-RNP and ESR; with no improvement in renal function the patient had a renal biopsy which showed TMA, mild fibrosis and atherosclerosis. The patient was Started on RRT and then transferred to Westchester medical center for treatment with Eculizimab for atypical HUS. After reviewing the labs we ordered Serum and urine protein electrophoresis which showed monoclonal Ig M spike, the patient underwent bone marrow biopsy which showed Plasmacytoma with 18% Plasma cells. The patient's renal function improved in the hospital stay and stabilized with creatinine of around 2.0 mg/dl, but unfortunately the patient had a severe sepsis and passed away before initiation of management for Multiple myeloma.

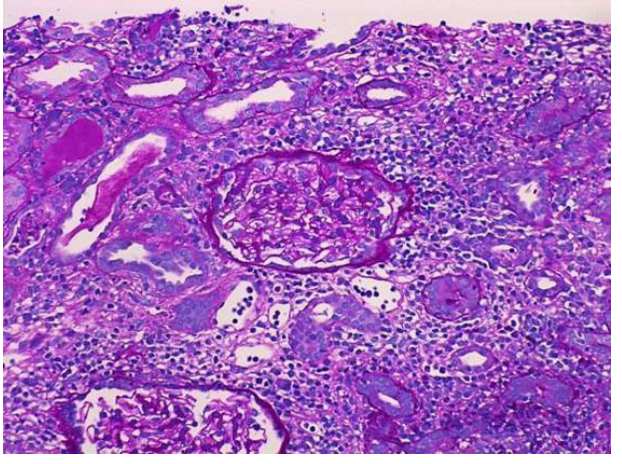
Discussion: Multiple Myeloma accounts for 10% of hematological malignancies. Atleast 50% of patients with MM have evidence renal insufficiency and more than 80% have proteinuria. Multiple myeloma can present as has wide range of renal manifestations including myeloma cast nephropathy, Immune deposition disease, CKD Fanconi syndrome. Though rare Multiple myeloma can cause TMA and the Pathogenesis still remains unclear.

SA-PO089

Drug-Induced Acute Interstitial Nephritis Managed with Early and Aggressive Steroid Therapy Radhika Vemuri, Abhilash Koratala, Keerti K. Bhanushali, William L. Clapp, Saraswathi Gopal. *Nephrology, Univ of Florida, Gainesville.*

Introduction: Pantoprazole (PPZ), a Proton Pump Inhibitor, is known to cause acute interstitial nephritis (AIN). We report a case of PPZ induced AIN in a young adult with just 3 doses of drug exposure.

Case Description: A 21 year old Asian American male with no past medical history was sent to the hospital by his Internist for elevated serum creatinine (Scr). He had nausea and abdominal pain 3 weeks earlier and was prescribed PPZ, which he took for 3 days. He denied use of any other medications including herbal supplements and NSAIDs. Laboratory data showed BUN of 82 mg/dL , Scr 15 mg/dL (baseline 0.6) , bicarbonate of 15 mmol/L and no serum osmolar gap.Urinalysis showed sterile pyuria with no eosinophils , glycosuria with normal blood glucose , mild proteinuria (900mg/24 hrs). Serum and urine toxicology, protein electrophoresis, auto-immune work up were unremarkable. A Renal biopsy revealed diffuse expansion of the interstitium due to accumulation of cellular infiltrates consisting of lymphocytes, plasma cells and eosinophils with accompanying tubulitis consistent with AIN.



He received pulse steroids for 3 days and was continued on prednisone 1mg/kg/day with a plan to taper over 8-12 weeks .He required a few sessions of renal replacement therapy before his renal function started to recover, 6 weeks later his Scr was 1.4 mg/dl.

Discussion: Any drug can cause AIN, although the categories of antibiotics, diuretics and NSAIDs are most commonly implicated. Drug-induced AIN is not dose dependent, and recurrence can occur with a second exposure to the same or a related drug. The data on time of initiation, dosage and duration of steroids in drug induced AIN is limited due to lack of randomized control trials. On review of literature and our experience, we conclude that stopping the culprit agent and early steroid use confers better prognosis in drug induced AIN.

SA-PO090

Metastatic Sarcomatoid Carcinoma of Urothelial Origin in Failed Renal Allograft Venkata Buddharaju, Rajat Lamba, Daniel G. Glicklich. *Nephrology, Westchester Medical Center, Valhalla, NY.*

Introduction: Renal cell carcinomas are more common in ESRD than the general population and renal transplant patients with enhanced longevity may be at particular risk. Sarcomatoid renal cell carcinoma represents 1-15% of all renal cell carcinomas but has been very rarely described in renal allograft. The median age at diagnosis is 60years with 45-77% of patients with locally advanced or metastatic disease at the time of diagnosis. We describe a case sarcomatoid tumor of urothelial origin in a transplanted renal allograft.

Case Description: A 54 y/o man with ESRD from polycystic kidney disease, HTN, aortic dissection repair, mechanical AVR, paroxysmal Afib, who had 2 failed renal transplants in the past and was on dialysis for past 12 years, was admitted for left lower quadrant pain, fever and leukocytosis for which he was started on vancomycin and

aztreonam. On imagine, he was found to have a mass around the left transplant kidney, ascites, omental caking, retroperitoneal lymphadenopathy and heterogeneous liver lesions. Retroperitoenal lymph node biopsy and ascitic fluid cytology was negative for malignant cells. Left kidney mass could not be biopsied because of technical difficulties and he had biopsy of the liver lesions which showed sarcomatoid tumor. He developed respiratory failure and septic shock requiring pressor support and expired. An autopsy was performed which showed Metastatic Sarcomatoiid carcinioma of urothelial origin.

Discussion: Malignancy in post transplant is related to direct effects of immune-suppressants as well as their effects to suppress immune surveillance and to stimulate the activation of oncogenic viruses. It is generally recommended that patients on the active transplant list and renal transplant recipients be screened every several years for renal tumors. However after allograft failure, it is unclear how often to do cancer screening tests. Although in this particular case it is unclear whether screening would have made a difference in outcome, we recommend routine screening for renal cell carcinoma even if the renal allograft has failed.

SA-PO091

Parathyroidectomy on a Patient with Sickle Cell Disease and End Stage Renal Disease Farouk Talakshi, Mary C. Mallappallil, David Kau, Moro O. Salifu. *Suny Downstate Medical Center, Brooklyn, NY.*

Introduction: Patients with End Stage Renal Disease (ESRD) can develop elevated parathyroid hormone (PTH) levels with hypercalcemia. Some fail or cannot tolerate medical therapy. They eventually require parathyroidectomy. Tertiary hyperparathyroidism (3HPTH) is the autonomous function of the parathyroid gland due to increased mass. Our case is unique as there are no reported cases of tertiary hyperparathyroidism in sickle cell patient, where symptoms of renal osteodystrophy mask vaso-occlusive crisis which improved with parathyroidectomy. 25 year old man with sickle cell disease, ESRD on hemodialysis since 2012, (3HPT), presents after many admissions for sickle cell pain crisis. Cause of ESRD was unknown but attributed to sickle cell nephropathy. Current admission for knee pain, imaging of which showed "sclerotic appearance of the bones, likely due to renal osteodystrophy". Intact PTH (iPTH) consistently > 4000 pg/mL, and patient non adherent to cinacalcet, agreed to parathyroidectomy after many admissions for presumed vasoocclusive crisis. CT neck:"moderately enhancing foci inferior to the left and right thyroid lobes, and superior to the left thyroid lobe, could be compatible with parathyroid adenomas. "Sestamibi scan:"equivocal slow washout focus in region of right lower pole of thyroid gland extending posteriorly. Suspicious for but not definitive for parathyroid adenoma".On the day prior to surgery, iPTH =4078 pg/mL with serum calcium (Ca)=10.3 mg/dl. Immediately after surgery, iPTH=265 pg/mL with Ca=8.9 mg/dl. The first day after surgery, iPTH=36 pg/mL with Ca=7.6 mg/dl. Patient admitted for 3 weeks due to his requirement of intravenous calcium and daily hemodialysis. Since discharge, patient has had fewer admissions for pain. He has however, remained hypocalcemic and is on 5 grams of calcium carbonate, 4 mcg of doxercalciferol, and is dialyzed with a 3 mEq/L calcium bath.

Discussion: 3PTH is common in ESRD patients that can leave them debilitated. Those who fail medical therapy may benefit from resection. In sickle cell disease symptoms of 3PTH was masked by vaso-occlusive crises and could be distinguished by marked reduction in symptoms after resection.

SA-PO092

Synthetic Cannabinoid (SC) in End Stage Renal Disease Chyi Chyi Chong,[1] Pallavi D. Shirsat,[1] Ramesh Marahatta,[1] Neville R. Dossabhoy.[1,2] *[1]LSU Health Science Center, Shreveport; [2]VA Medical Center, Shreveport.*

Introduction: Synthetic cannabinoid (SC) are drugs of abuse especially among young adults. They are affordable, widely available and mostly importantly undetectable by standard urine toxicology screen. The avoidance of detection in the urine contributes to their allure and abuse. Acute kidney injury (AKI) related to synthetic cannabinoids has been reported. However, effect of synthetic marijuana in end stage renal disease (ESRD) patients remains unknown.

Case Description: We present a case of severe high anion gap metabolic acidosis (HAGMA) with acute respiratory failure in an ESRD patient. A 37-year-old African American female with ESRD, hepatitis C and hypertension was found smoking synthetic marijuana under a tree, and in a confused state. Upon arrival to the emergency room, patient was severely hypertensive with blood pressure of 230/140 mmHg, and subsequently developed acute respiratory failure requiring intubation. Chest x-ray showed bilateral pulmonary edema. Laboratory data revealed: WBC 18K/uL, Na 138 mEq/L, K 3.6 mEq/L, Cl 104 mEq/L, CO2 10 mEq/L, Anion Gap 24. On Blood Gas: pH 6.95, pCO2 42 mmHg, pO2 73 mmHg, HCO3 8.3 mmHg. Urine drug screen was positive for benzodiazepine and cannabinoid. Patient required emergent hemodialysis for severe high anion gap metabolic acidosis. Patient required dialysis consecutively for 2 days and anion gap metabolic acidosis resolved. She was also successfully extubated on third day of admission.

Discussion: Synthetic Cannabinoids are sold under different trade names and the exact compounds contained in these products change frequently and are frequently unknown. Therefore, risks and adverse consequences of consuming synthetic cannabinoids are unpredictable and can be deadly. Acute tubular necrosis and interstitial nephritis are most common findings for patients who developed synthetic cannabinoid related AKI. Treatment is supportive management. However, effects on ESRD patients remain unknown. Our patient developed (HAGMA), which could very well be related to synthetic marijuana use. Physicians should be aware of designer drugs use in ESRD patients.

SA-PO093

Focal Segmental Glomerulosclerosis Associated with Cocaine Abuse: A Case Report Teg Marcos Veiga, Nathalia K.N. Alecrim, André Luiz De Andrade Araújo, Gisele Vajgel Fernandes, Luis H.B.C. Sette, Lucila Maria Valente, Maria Alina G.M. Cavalcante. *Nephrology, Univ Federal de Pernambuco, Recife, Pernambuco, Brazil.*

Introduction: Cocaine exists in two major forms: cocaine hydrochloride and alkaloidal freebase (crack). Cocaine abuse causes many well recognized systemic adverse effects and acute kidney injury is usually due to rhabdomiolysis, malignant hypertension with thrombotic microangiopathy and renal infarction. In addition, it has been described ANCA-positive vasculitis induced by levamisole-adulterated cocaine causing nephrotic syndrome. We report a case of focal segmental glomerulosclerosis in a patient with history of cocaine use.

Case Description: A 49 year-old man of admixture race presented with progressive edema and dyspnea for the past five months. Lab tests showed Scr 7.0 mg/dL (baseline: 0.9 mg/dL), hypoalbuminemia, hypercholesterolemia and nephrotic range proteinuria (13g/24h). The patient had started using illicit drugs (marihuana and crack) three months before the symptoms begun. There was no sign of infection or hypovolemia. All serologic tests were normal or negative, including complement, antinuclear antibodies, anti-DNA antibody, c-ANCA, p-ANCA, hepatitis B and C, HIV, syphilis and there was no evidence of monoclonal serum spike. Renal ultrasound was normal. The patient underwent hemodialysis and received metylprednisolone. Renal biopsy showed 13 glomeruli, 6 globally sclerotic and 5 with segmental sclerosis and synechiae of the glomerular tuff, tubular atrophy and moderate intersticial fibrosis. Imunofluorescence was negative. There was no recovery of renal function.

Discussion: Although it has been described nephrotic syndrome due to ANCA-positive vasculitis induced by levamisole-adulterated cocaine, we have reported a case that showed association between the use of cocaine and focal segmental glomerulosclerosis.

SA-PO094

A Rare Case of Tumor Lysis Syndrome in a Patient with Angiosarcoma Bilal J. Alturkmani,[1] Michael A. Mao,[2] Edward T. Casey.[2] *[1]Alfaisal Univ, Riyadh, Saudi Arabia; [2]The Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Introduction: To report a rare case of tumor lysis syndrome (TLS) developing in a patient with angiosarcoma and metastasis to the liver.

Case Description: A 63-year-old male presented to his primary care physician complaining of fatigue, night sweats, fever, and newly developed RUQ pain. An ultrasound of the abdomen revealed hepatic lesions and a subsequent CT scan showed two large masses in the liver and a mass in the pancreas. A liver biopsy was obtained and findings were consistent with metastatic angiosarcoma and he was therefore initiated on palliative chemotherapy. The patient then presented to his local hospital with abdominal pain and abdominal bruises. His hemoglobin was 4.9 g/dL and he was found to be bleeding from the liver biopsy site. He was transferred to our institution for embolization in setting of intra-abdominal bleeding and multiorgan dysfunction. His clinical presentation, along with laboratory findings, was consistent with anuric renal failure secondary to TLS.

Table 1			
Laboratory Values	Three days prior to hospitalization	On admission to Mayo	Reference Ranges, Units
Creatinine	1.4	2.7	[0.8-1.3], mg/dL
Potassium	4.3	6.6	[3.6-5.2], mmol/L
Uric Acid	-	16.3	[3.7-8.0], mg/dL
Calcium	8.2	-	[8.9-10.1], mg/dL
Ionized Calcium	-	4.29	[4.65-5.30], mg/dL
Phosphorus	-	8.4	[2.5-4.5], mg/dL

The patient was initiated on allopurinol, rasburicase, and continuous veno-venous hemofiltration (CVVH). He progressively deteriorated during his 11-day hospital course with recurrent episodes of arrhythmia, persistent encephalopathy, continued mechanical ventilator and hemodialysis dependence, and refractory septic shock with candidemia. The family elected for comfort care and the patient expired the next day.

Discussion: TLS is a constellation of laboratory and/or clinical manifestations that can arise either spontaneously or secondary to cancer treatments. Patients with hematological malignancies have a higher tendency to develop this syndrome due to the rapid turnover of cell growth and death. However, patients with solid tumors occasionally present with TLS. To our knowledge, this is the first case report of TLS associated with angiosarcoma.

SA-PO095

Leukocyte Chemotactic Factor 2 (LECT2)-Associated Renal Amyloidosis: A Case Report Alejandro Pepen Romero,[1] James Drakakis,[1] Joseph Mattana.[1] *[1]Nephrology Dept, Winthrop Univ Hospital, Mineola, NY; [2]Pathology Dept, Columbia Univ, New York, NY.*

Introduction: ALECT2 amyloidosis is a frequent form of systemic amyloidosis, represents 2.7-10% of all cases of renal amyloidosis. Most patients are elderly who presents with chronic renal insufficiency and bland urinary sediment.

Case Description: We report a 76-year-old Egyptian male who presented after a recent hospitalization for self limited gastroenteritis and severe acute renal failure presumed secondary to acute tubular necrosis. Due to non-improving renal function and uremic symptoms, renal biopsy was done and showed patchy Interstitial amyloidosis deposits that did not stain for IgG, IgM, IgA, Kappa, Lambda chains or Amyloid A; sample was sent to Mayo Clinic where Liquid chromatography tandem mass spectrometry detected a peptide profile consistent with ALECT2 Amyloidosis.

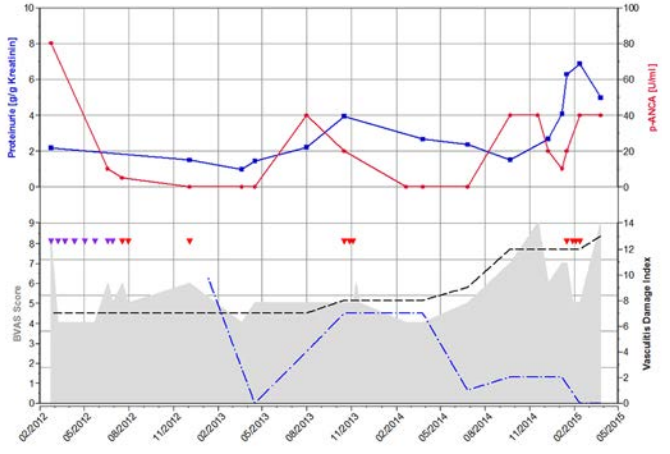
Discussion: This case suggests that ALECT2 Amyloid can present with bland urianalysis and non-nephrotic range proteinuria in elderly patients.

SA-PO096

Monitoring Disease Activity in ANCA Associated Vasculitis (AAV): A Case for Activated Circulating Monocytes? Florian Gunnar Scurt,[1] Leon Brian Schubert,[1] Noemi Rose Emma Doll,[1] Marius Früh,[1] Tobias Hölscher,[2] Andreas Jeron,[2] Dunja Bruder,[2] Peter R. Mertens,[1] Christos D. Chatzikyrkou.[1] *[1]Nephrology, Hypertension, Diabetes and Endocrinology, Otto-von-Guericke Univ Magdeburg; [2]Inst of Microbiology, Otto von Guericke Univ Magdeburg.*

Introduction: We are still in need for more reliable markers to monitor disease activity in AAV.

Case Description: The clinical course of a patient with therapy refractory AAV is presented .



Disease activity was assessed by means of the BVAS and VDI score and by serial measurements of the CD19/CD20 cell count and the MPO titer. The last renal flare was on 11/2014 and was corroborated by renal biopsy. Monocyte subsets were also identified by flow cytometry with the use of the surface markers CD 14, CD 16 CCR2 and CxCR3. The expression of different proteins reflecting antigen presentation or activation status as well as scavenger receptor and toll like receptor functions was quantified in the monocyte subpopulations. Blood samples of a healthy individual were used as controls. Results of the antigen presentation marker HLA-DR and the monocyte activation marker CD 11b are presented here.

Renal and pulmonary disease progressed despite the use of an impressive immunosuppressive therapy. The CD19/CD20 cell count and the MPO titer did not predict relapse. The intermediate CD14++CD16+CCR2lowCXCR1+ monocyte subpopulation was increased but expressed less of the HLA-DR protein. The CD11b antigen expression was reduced in the classical monocyte subpopulation CD14++CD16-CCR2highCXCR1-, whereas no differences in the HLA-DR and CD 11b expression were observed in the non-classical monocyte subpopulation CD14+CD16+CCR2lowCXCR1high.

Discussion: There appear to be functional alterations in the different monocyte subpopulations during relapse of AAV. Their pathophysiological significance remains to be elucidated.

SA-PO097

A Case of Rhabdomyolysis Induced AKI with Two Questions: Serum Myoglobin versus CPK and the Potential Role for Rasburicase Mehdi Nouri kolouri. *Nephrology, Baylor College of Medicine, Houston, TX.*

Introduction: Rhabdomyolysis induced AKI is a common scenario. The mechanisms include myoglobin and uric acid crystal induced tubular injury. The role of uric acid lowering agents in such condition remains to be defined. Here we describe such a case, in which uric acid lowering agent successfully lowered uric acid level and possibly contributed to renal function recovery. In this case CPK level was not high enough to justify AKI and a very high serum myoglobin level established the diagnosis.

Case Description: a 37 years old man without known history was brought to ER with agitation and delusional/combative behavior. Vital signs included temp=100.4, BP=165/85, RR=32/min and PR=120/min. On examination, he was mildly volume depleted. He was found to have AKI with BUN=76, Cr=4, K=6.7 and metabolic acidosis. Urine toxicology was positive for amphetamines. CPK level was 4200 U/L and uric acid level was 21 mg/dL. Supportive management including aggressive IV fluids was initiated for amphetamine toxicity with resultant rhabdomyolysis. Urine exam showed several coarse granular casts. Serial CPK levels were not high enough to justify AKI. However serum myoglobin level was very high at >20000 ng/mL and confirmed severe rhabdomyolysis. one session of dialysis was done due to persistent metabolic acidosis and hyperkalemia. However uric acid level remained high at same range. We used a dose of Rasburicase at 3 mg which reduced uric acid level to 5.5 six hours later. After few days, renal function and clinical status started to improve and he was discharged in stable condition.

Discussion: There may be a therapeutic/prophylactic role for uric acid lowering agents in rhabdomyolysis induced AKI. In our case, Rasburicase successfully lowered uric acid level after it had remained high post-dialysis. Similar results have been reported in the past, however further research is needed in the future. Besides, Although AKI in rhabdomyolysis is usually seen with CPK levels>20000, our patient had much lower levels and a very high serum myoglobin established the diagnosis of severe rhabdomyolysis. Serum myoglobin is more accurate to determine the severity of rhabdomyolysis and predict the risk of AKI.

SA-PO098

Exploring the Utility of Albuminuria Saman Sarani,[1] Ruchika Bhasin,[1] Afsaneh Haftbaradaran,[1] Golriz Jafari,[1] P.T. T. Pham,[2] P.C. Pham.[1] *[1]Div of Nephrology and Hypertension, Olive View-UCLA Medical Center, Sylmar, CA; [2]Kidney Transplant, UCLA Medical Center, Los Angeles, CA.*

Introduction: Patients with underlying glomerular diseases often present with acute kidney injury from either acute tubular necrosis (ATN) due to hemodynamic compromise such as diuretic overuse versus exacerbation of underlying disease. The clinician is often faced with the difficult decision to either provide fluids and supportive care vs. intensification of immunosuppressive therapy. Whereas proteinuria associated with ATN is presumably predominantly non-albumin protein, proteinuria associated with glomerular disease exacerbation is predominantly albuminuria. We follow a case with biopsy proven minimal change disease and concurrent ATN and evaluate sequential urine albumin to creatinine (MAC) ratio to protein to creatinine (PCR) ratio MAC/PCR over the course of treatment for changes.

Case Description: A 63 year old Hispanic male presented with anasarca and blood pressure 214/104 mm Hg. Routine evaluation was significant for a serum creatinine (SCr) of 1.4 mg/dl, peaked at 1.77 mg/dl, PCR of 12.8 g/g Cr, and MAC of 7.9 g/gCr. Physical examination was significant for anasarca. There was no lymphadenopathy noted. Routine proteinuria evaluation for hepatitis B and C, RPR, HIV, C3, C4, CH50, ANCA, serum free light chains, serum and urine protein electrophoresis and immunofixation were negative. A kidney biopsy performed revealed minimal change disease with evidence of marked ATN. Patient was treated with a course of prednisone at 1m/kg/day tapered over a 6 month period. Patient went into full remission without any complications. Over the course of disease, sequential MAC/PCR was noted to increase as PCR and SCr decreased. Presentation: Scr 1.44-1.77, MAC=7.9 g/g Cr, PCR=12.8 g/gCr, MAC/PCR=0.62; 2-month follow-up: Scr 1.3, MAC=1.6, PCR=1.7, MAC/PCR=0.95; 3-month follow-up: Scr 1.3, MAC=1.4, PCR=0.8, MAC/PCR=1.6.

Discussion: The current case indicates that a higher degree of albuminuria relative to proteinuria is noted with eventual resolution of ATN. We suggest that MAC/PCR may be used as a marker of associated ATN complicating underlying GN. Further studies are needed.

SA-PO099

Idiopathic Eosinophilic Peritonitis After Peritonial Dialysis Catheter Placement Nader S. Bahri, Charles W. Heilig. *Nephrology and Hypertension, Univ of Florida, Jacksonville, FL.*

Introduction: Idiopathic Eosinophilic peritonitis (IEP) typically occurs soon after initiation Peritoneal Dialysis (PD) with variable presentation mimicking bacterial or fungal peritonitis. The main etiology of IEP is unclear and many have speculated that it represents an allergic reaction to possible plasticizers in the PD bags or catheter or an eosinophilic reaction to the solutions, methods of catheter placement or air exchanges during the exchanges.

Case Description: 42 year-old AAF with ESRD from T2DM and hypertension in 9/2009 was started on hemodialysis (HD) via fistula. She underwent PD training and started CAPD on 9/18/2010 with Baxter Ultra bag dextrose solution after laparoscopic placement of Quinton Curl PD catheter on 9/2/2010. During follow on 9/30/2010 cloudy PD fluid recognized. The patient didn't have any symptoms of abdominal pain, nausea, vomiting, constipation, diarrhea or fatigue. Vital signs were stable .Physical exam didn't show any evidence of site infection or abdominal tenderness and no skin allergic reaction. There were no new medications or no current antibiotic therapy since placement of PD catheter. PD fluid cell count showed total WBC count of 480/mm³ with 49% eosinophil and 1% neutrophil. Gram stain and all bacterial, fungal and AFB cultures were negative. CBC showed normal WBC count of 9900/ mm³ with 8.9% eosinophilia. The patient kept on PD with close follow ups. empiric antibiotics were discontinued. Repeat PD fluid cell count showed total of WBC 327/ mm³ with 20% eosinophil and 6% neutrophil with all repeated- cultures negative. AT this point the patient has switched to HD on 11/04/2010 via available fistula and PD catheter was kept in place. By 12/28/2010 a sample of peritoneal fluid obtained which showed declining of WBC count to 123/mm³ with 7% eosinophil with

complete resolution of eosinophilia while the patient was on HD. In 3/28/2011, the patient resumed PD via same catheter and same solution, follow up PD fluid sample on 4/07/2011 showed normal WBC count and 4% eosinophil.

Discussion: Our case suggests IEP was a transient reaction to the catheter placement rather than a reaction to the PD set or solution.

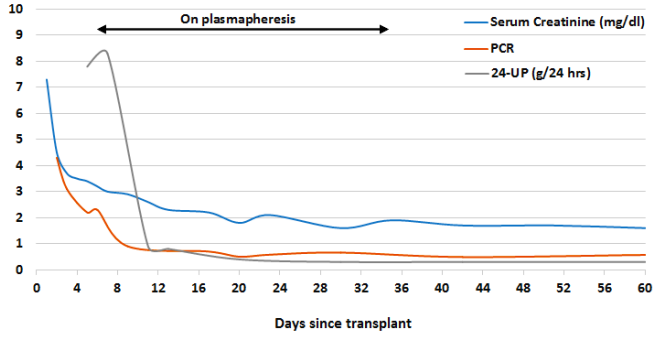
SA-PO100

Post Renal Transplant Follow Up in Focal Segmental Glomerulosclerosis with 24 Hour Urine Protein Collection – Traditional and True

Ravinder Pal S. Bhatti, Manisha Singh, Lakshmi P. Nadimpalli, Sameh R. Abul-Ezz. *Nephrology, Univ of Arkansas for Medical Sciences, Little Rock, AR.*

Introduction: Random Urine Protein Creatinine Ratio (PCR) is commonly used to estimate proteinuria compared to 24 hour urine protein measurement (24-UP). However, there are concerns over the diagnostic accuracy and reliability of such an approach in post-transplant setting. We present a case of post-transplant focal segmental glomerulosclerosis (FSGS) illustrating this.

Case Description: A 39 year old male with primary FSGS, on peritoneal dialysis for 4 years received a cadaveric kidney transplant. His panel reactive antibody was 0% and HLA cross-match was negative. Peri-operative course was uneventful. Given the history of FSGS, PCR was monitored. By post-op day 5, serum creatinine had decreased from 7.3 mg/dl to 3.2 mg/dl and PCR from 4.3 to 2.8. However, his 24-UP came back 8 g, which was markedly different.



Early recurrence of FSGS was diagnosed. A biopsy was withheld to avoid delay in timely management and risk of bleeding with plasmapheresis which was immediately initiated. He was switched from tacrolimus to cyclosporine. He required plasmapheresis for 5 weeks and had satisfactory recovery in the ensuing months.

Discussion: Logistics have led to the widespread use of PCR in follow-up of kidney transplant recipients. However changing creatinine excretion with recovering renal function, lower precision with heavier proteinuria, and limited data on accuracy compared to 24-UP, potentially limit its utility at detecting early post-transplant recurrence of FSGS. Our case highlights marked discordance between the PCR and 24-UP, detection of which allowed a timely change in management. We conclude that it is prudent to monitor proteinuria by timed urine collection in preference to random PCR in the immediate post-transplant setting for recipients with primary FSGS.

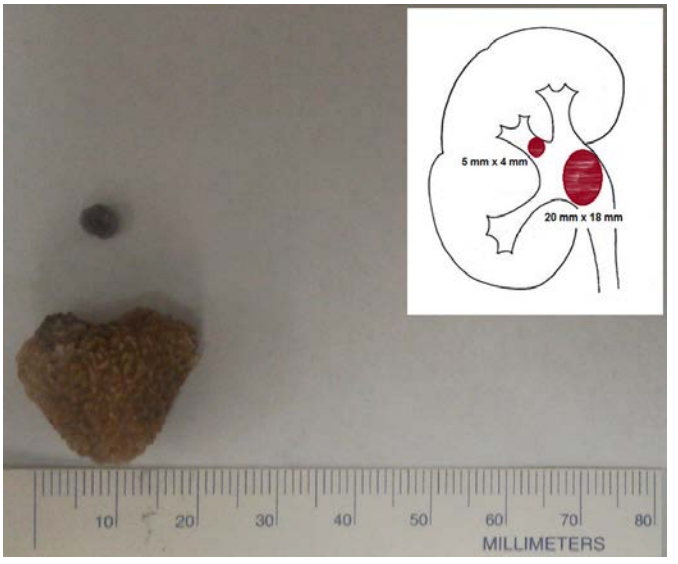
SA-PO101

Donor Kidney Lithiasis: A Case of Throwing Out the Baby with the Bathwater?

Ravinder Pal S. Bhatti,[1] Sameh R. Abul-Ezz,[1] Lakshmi P. Nadimpalli,[1] Gary Wickens Barone.[2] *[1]Nephrology; [2]Transplant Surgery, Univ of Arkansas for Medical Sciences, Little Rock, AR.*

Introduction: Cadaveric kidneys account for a majority of transplants in the United States. However, only 10% of waitlisted patients receive one annually, making optimal utilization critical. Donor nephrolithiasis represent a small yet significant proportion of kidneys discarded. We present a patient who received such a kidney which otherwise could have been discarded.

Case Description: The donor was a healthy 31 year old female who suffered anoxic brain injury in a motor vehicle accident. Her CT abdomen showed 2 stones in the right kidney as represented in the figure's inset. The kidney became available to us on a regional list after it was declined locally due to concerns over kidney quality. Our recipient was a 50 year old female with hypertensive nephropathy, on hemodialysis for the past 2 years. Her panel reactive antibody was 90% and HLA cross match was negative. Intra-operatively, a large stone measuring 2 cm was identified in the hilum of the donor kidney and was extracted via pyelotomy. A smaller middle calyceal stone was localized by fluoroscopy and successfully removed by irrigation.



There were no perioperative complications and the recipient had excellent immediate graft function. Her creatinine progressively improved by time of discharge, remaining normal in subsequent months.

Discussion: The new kidney allocation policy aims to address organ shortage by reducing donor and graft survival mismatch. Traditionally, donor hemodynamics, age, serum creatinine and histopathology have influenced decisions on accepting a kidney. The perceived quality and utilization techniques widely vary for deceased donor kidneys with lithiasis. Our case illustrates how this can lead to non-acceptance of an otherwise healthy kidney, which can be transplanted with a favorable outcome.

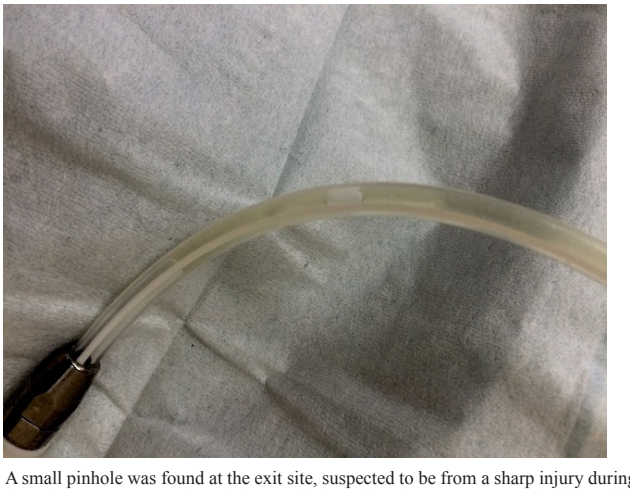
SA-PO102

A Peritoneal Dialysis Catheter Leak Complicated by *Burkholderia Gladioli* Peritonitis

Ravinder Pal S. Bhatti, Dumitru Rotaru. *Nephrology, Univ of Arkansas for Medical Sciences, Little Rock, AR.*

Introduction: Dialysate leaks can occur any time after peritoneal dialysis (PD) catheter placement. Early leaks usually manifest as an exit site leak, though may also present with air in the PD catheter. Leaks increase the risk for exit site infections (ESI) and peritonitis. We present such a patient developing peritonitis with an unusual pathogen.

Case Description: A 74 year old male who had been on Continuous Cycling Peritoneal Dialysis for 3 years, presented with exit site erythema a week after trying to push in an extruded cuff. Prophylactic antibiotics were started but he declined surgery. The ESI recurred soon after completing 3 weeks of antibiotics. He agreed to catheter replacement with an exit site change. He was started on low volume exchanges. Two weeks later, he noted air bubbles in the PD catheter upon draining.



A small pinhole was found at the exit site, suspected to be from a sharp injury during dressing change. He was planned for surgical revision but soon started having turbid drainage. Instilled dialysate was cultured, broad spectrum intravenous antibiotics were started and he was switched to hemodialysis. During surgery, the damaged catheter was spliced to new tubing proximal to the exit site. The cultures grew *Burkholderia Gladioli* by now. PD was resumed the next day. The peritonitis resolved during the 3 weeks of antibiotics. He continued PD uneventfully over ensuing months.

Discussion: A rare observation, air in a PD catheter is almost pathognomic of a dialysate leak. Our case highlights several key points in such a scenario. Firstly, use of sharps is a major risk factor and should be discouraged. Secondly, an increased risk of peritonitis

including by rare pathogens warrants appropriate antibiotic prophylaxis and lastly a more limited approach than catheter exchange may be used even for leaks close to exit sites based on the location and local experience.

SA-PO103

Enteric Hyperoxaluria Related to Celiac Disease Causing Acute Kidney Injury After Kidney Transplantation Ashvin Baru, Venkat Ramanathan. *Nephrology, Baylor College of Medicine, Houston, TX.*

Introduction: Acute kidney injury (AKI) after kidney transplantation can occur from myriad of causes. We present an interesting case of a young woman with history of Celiac disease who developed AKI and biopsy-proven oxalate nephropathy within 3 months post-transplantation, as a result of enteric hyperoxaluria associated with gluten noncompliance.

Case Description: A 35 year-old woman with type 1 diabetes mellitus, and celiac disease underwent living unrelated kidney transplantation for ESRD related to biopsy-proven diabetic nephropathy. Her original renal ultrasound did not show nephrocalcinosis. After transplantation, nadir serum creatinine was 1.0 mg/dL. Three months later, she presented with six-day history of diarrhea and AKI. Serum creatinine peaked at 2.6 mg/dL. Since volume replacement did not improve her allograft function and she had high panel reactive antibody levels pre-transplant, a kidney biopsy was performed that showed acute tubular injury with significant oxalate crystalline deposits. Initial serum oxalate level was undetectable, but 24-hour urine oxalate excretion was elevated at 98 mg/dL. Pending gene testing, she was treated with intravenous fluids, low oxalate diet, gluten free diet, vitamin B6, oral alkali and calcium carbonate. Subsequent gene testing did not reveal gene mutation in the oxalate pathway. Her urine output was maintained between 3 to 4L per day. With strict gluten avoidance and low oxalate diet, urine alkalinization and oral calcium, her allograft function has improved to baseline.

Discussion: Celiac disease exacerbation and subsequent malabsorption can lead to significant gut oxalate absorption and hyperoxaluria. Resulting oxalate nephropathy is a rare cause of AKI after kidney transplantation.

SA-PO104

Unusual Presentation of Tumor Related Membranous Nephropathy Tahir Zaman,[1] Frederic Clayton,[2] Josephine Abraham.[1] *[1]Nephrology, Univ of Utah, Salt Lake City, UT; [2]Pathology, Univ of Utah, Salt Lake City, UT.*

Introduction: The literature is laden with evidence of several solid tumors causing secondary membranous nephropathy. It is also described in the literature that solid tumors could also ANA positivity.[1]

Case Description: A 62-year-old male with a history of hypertension presented with oliguric renal failure following an episode of gastroenteritis. History was unremarkable with patient denying smoking or other vices. Urine analysis revealed rare dysmorphic RBC's and minimal proteinuria (spot protein/creatinine ratio 0.5 gms). Serologic workup revealed +PR3 (ANCA negative) and abnormal Kappa/Lamda Ratio thus renal biopsy was performed, which revealed membranous nephropathy and acute tubular necrosis (ATN). Immunofluorescence was positive for C3, IgG, though negative for PLA-2R, IgA and C1q. ANA was strongly positive (1:10240 speckled pattern), HIV serology was negative. Sublingular mass was found which revealed squamous cell carcinoma. Bone marrow biopsy revealed smoldering multiple myeloma. The patient's ATN resolved and he subsequently underwent left partial glossectomy. His cancer was staged at T2N0 and he is undergoing chemotherapy and radiation therapy.

Sublingular mass.

Discussion: Secondary membranous nephropathy has a known association with solid tumors. The positive ANA raised the concern of concomitant connective tissue disease but C1q negativity on the biopsy made this diagnosis unlikely. Ultimately treatment of the underlying condition is paramount. 1. Imai, H. *et al.* Nucleolar antigens and autoantibodies in hepatocellular carcinoma and other malignancies. *Am. J. Pathol.* **140,** 859–70 (1992).

SA-PO105

A Case of Severe Adrenal Insufficiency due to Long-Term Glucocorticoid Administration for Pediatric Nephrotic Syndrome Yuko Fujii,[1] Akira Ashida,[1] Hideki Matsumura,[1] Akihiko Shirasu,[1] Hyogo Nkakura,[1] Motoshi Hattori,[2] Hiroshi Tamai.[1] *[1]Pediatrics, Osaka Medical College, Takatsuki, Osaka, Japan; [2]Pediatric Nephrology, Tokyo Women's Medical Univ, Shinjyuku, Tokyo, Japan.*

Introduction: One of the adverse effects of long-term glucocorticoid therapy in supra-physiologic doses is suppression of the hypothalamic-pituitary-adrenal axis, although symptomatic adrenal insufficiency is considered to be an unusual complication of glucocorticoid therapy for nephrotic syndrome in pediatric patients. Here we describe a case of secondary adrenal insufficiency due to long-term glucocorticoid therapy for steroid-dependent nephrotic syndrome.

Case Description: A 12-year-old boy who had developed steroid-dependent nephrotic syndrome at the age of 2 years had been treated repeatedly with corticosteroid, cyclosporine and mizoribine. On relapse of the disease at 4 years of age, the nephrotic syndrome had been resistant to steroid therapy including 2 mg/kg prednisolone and 4 courses of methylprednisolone pulse therapy, but had responded to additional cyclophosphamide therapy at 7 months after relapse onset. During tapering of the glucocorticoid therapy, the patient had shown various symptoms, including general fatigue, facial edema, decreased urine volume, appetite loss, and dizziness from the age of 5 years. At that time, the basal value of cortisol was not detectable and a rapid ACTH loading test elicited a low response. In the CRH and insulin loading test, the basal value of ACTH was not detectable and an over-response of ACTH was demonstrated. Therefore the patient was diagnosed as having glucocorticoid-induced hypothalamic adrenal insufficiency and treated with cyclosporine, a decreased dose of prednisolone, and hydrocortisone supplementation. The serum ACTH and cortisol values increased gradually. An insulin loading test at the age of 12 years demonstrated normal responses of the ACTH and cortisol levels.

Discussion: The very long-term nature of the therapy for this patient with idiopathic nephrotic syndrome resulted in glucocorticoid-induced adrenal insufficiency. Periodic evaluation of adrenal function and re-evaluation of the treatment is important for patients with nephrotic syndrome receiving steroid therapy.

SA-PO106

Henoch-Schönlein Purpura in Adult, from a Clinical Case Miguel Goncalves, Pedro Vieira, Jose Duraes, Luis Resende, Nuno Rosa, Jose Alves Teixeira, Gil Silva. *Nephrology, Hospital Dr. Nélio Mendonça, Funchal, Portugal.*

Introduction: Henoch-Schönlein purpura is a small vessel vasculitis mediated by IgA-immune complex deposition with multisystemic involvement. Rare in adults, is characterized by purpura, arthralgias, abdominal pain, and renal involvement. Viral infections have been reported as triggers.

Case Description: The authors present the case of a 25 years old male, without relevant medical history, admitted to the Nephrology Department in May 2014 by severe hypertension, renal failure (creatinine 6.7mg/dL), erythrocyturia and proteinuria. Renal ultrasound was normal. Renal biopsy revealed IgAnephropathy (M1E1S1T2). Our investigation revealed chronic hepatitis B virus (HBV) of vertical transmission origin (viral load 150 IU/mL). Corticosteroid therapy was started, with slight improvement in renal function. He was readmitted 2 months later by asthenia, epistaxis, weight loss, pallor, generalized edema, ascites, and oral and nasal ulcers. Laboratory tests revealed hemoglobin 9.2g/dL, creatinine 4,3mg/dL, normal transaminases, albumin 20g/L, urinary spot protein:creatinine ratio 1300mg/g, hypocomplementemia, negative p-ANCAs, c-ANCAs and cryoglobulins, HBV load 379.980IU/mL. During hospitalization the patient initiated progressive pancytopenia, diffuse abdominal pain, generalized skin purpura and fever (with no identifiable infectious origin and interpreted as immunologic). We made clinical diagnosis of Henoch-Schönlein purpura and started with cyclophosphamide and entecavir. A few days later appeared hypoxemia and oliguria, requiring urgent dialysis. Cranial CT scan showed microangiopathic leukoencephalopathy of unspecified etiology and alveolar hemorrhage in chest CT scan. Due to life threatning multisystemic involvement we started methylprednisolone pulses, intravenous immunoglobulin and plasmapheresis. Patient completely recovered, but remained dependent on dialysis. 6 monthly cycles of cyclophosphamide were maintained, with no signs of recurrence.

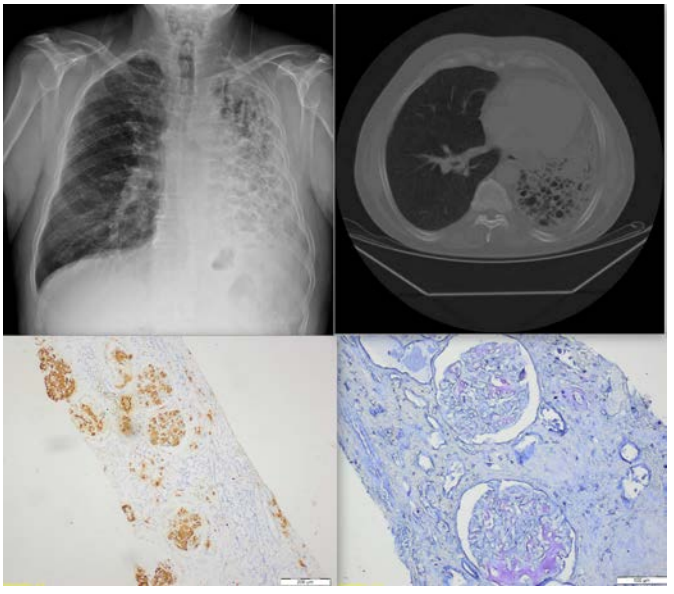
Discussion: We emphasize the rare severe multisystemic involvement of a Henoch-Schönlein purpura in an adult, the onset of the disease with exacerbation of viral infection, and the therapeutic challenge of an HBV patient with an vasculitis.

SA-PO107

Rare Etiology for Chronic Kidney Disease: Bronchiectasis Related Secondary Amyloidosis Alper Alp,[1] Hakan Akdam,[2] Aysegul Ormeci,[3] Ibrahim Meteoglu,[3] Alparslan Unsal,[4] Yavuz Yenicerioglu.[2] *[1]Nephrology, Van Education and Research Hospital, Van, Turkey; [2]Nephrology, Adnan Menderes Univ, School of Medicine, Aydin, Turkey; [3]Pathology, Adnan Menderes Univ, School of Medicine, Aydin, Turkey; [4]Radiology, Adnan Menderes Univ, School of Medicine, Aydin, Turkey.*

Introduction: Here we present an elderly patient with a known posttuberculosis-bronchiectasis.Nephrotic-range proteinuria and renal failure was detected.Renal biopsy revealed AA amyloidosis.Tuberculosis and tuberculosis related systemic disorders still have clinical impact in nephrology practice especially in developing countries.

Case Description: A 67 yo man was referred to our hospital with renal failure and proteinuria.PMH was remarkable for tuberculosis(41 years ago) and posttuberculosis-bronchiectasis for long years.On physical examination pretibial edema was evident.Chest X-ray,thorax CT revealed left sided total bronchiectasis and pulmonary nodules.Malignancy was excluded with PET/CT and bronchoscopy.On admission biochemical tests;urea: 220mg/dl,creatinine: 5.86mg/dl,potassium: 4.8mmol/L,GFR 10.3ml/min/1.73m2,ANA 1/100 positivity(cytoplasmic).Renal ultrasonography revealed bilateral echogenic kidneys with normal size and shape.24 hour urinary proteinuria,albuminuria was 7924 was mg/dl,4789mg/dl,respectively.Renal biopsy was compatible with AA amyloidosis(segmental homogeneous deposits of amyloid in the glomeruli and interstitium.Immunohistochemistry was positive for staining of AA amyloid.There was no immunofluorescen staining with IgG-A-M,C3,fibrinogen.



Tunnelled catheter was placed and hemodialysis was started.

Discussion: FMF and rheumatological disorders are the leading causes of amyloid AA in Turkey.However other rarely seen etiologies should not be missed in clinical practice.Secondary amyloidosis as a multisystemic disease has a high mortality risk.Renal manifestations include nephrotic syndrome and renal failure.

SA-PO108

Sunitinib Induced Acute Renal Failure and Nephrotic Syndrome in a Patient with Metastatic Neuroendocrine Tumor: A Case Report and Review of the Literature Srijita Mukherjee,[1] Carla L. Ellis.[2] *[1]Nephrology, Emory Univ Hospital and School of Medicine, Atlanta, GA; [2]Pathology, Emory Univ Hospital and School of Medicine, Atlanta, GA.*

Introduction: Sunitinib is a chemotherapeutic agent used to treat advanced malignancies via inhibition of tyrosine kinase phosphorylation. We present a case of sunitinib induced acute renal failure with nephrotic syndrome, occurring within one week of initiation for persistent carcinoid syndrome secondary to hepatic metastasis of a primary small intestinal neuroendocrine tumor.

Case Description: A 63 year old man with metastatic neuroendocrine tumor was initiated on sunitinib to treat persistent carcinoid syndrome despite initial therapy. Within one week of initiation, he developed new onset peripheral edema, 20 pound weight gain and acute renal failure with nephrotic range proteinuria. Baseline creatinine was 1.0, and on presentation, had increased to 3.0. There were over 10 grams of proteinuria on urine protein to creatinine ratio. Sunitinib was discontinued, but renal failure progressed, with peak creatinine of 7.1 prior to starting hemodialysis. A kidney biopsy was performed, which showed diffuse podocyte foot process effacement, focal global glomerulosclerosis and acute tubular injury. The patient remains dialysis dependent as of this report.

Discussion: Literature review reveals reports that vary both in time to onset and degree of resolution of renal disease after initiation and discontinuation of sunitinib therapy, respectively. Renal pathology also varies, including acute tubular necrosis, acute interstitial nephritis, diffuse podocyte foot process effacement and thrombotic microangiopathy. Our patient developed a greater severity of renal failure than most reported, including a higher peak serum creatinine, longer duration of renal replacement therapy and current lack of renal recovery. To our knowledge, this is also the first report of the onset of renal failure in the specific clinical scenario described. Given the near immediate adverse effect of sunitinib in our patient, we recommend monitoring of creatinine and urine protein at baseline and within the first three to five days of medication initiation.

SA-PO109

Cryoglobulinemic Glomerulonephritis After Successful Treatment of Hepatitis C Nupur Gupta, Chad A. Zarse, Allon N. Friedman. *Nephrology, IU School of Medicine, IN.*

Introduction: The optimal treatment of cryoglobulinemic glomerulonephritis (GN) in the setting of Hepatitis C (Hep C) with sustained viral response (SVR) is unknown. Only expert opinion obtained from case reports provide guidance to the clinician. Some reports suggest treatment with Rituximab may be beneficial.

Case Description: 58yo male with h/o treated Hep C currently with an undetectable viral load, gastric ulcer, anemia, and HTN presented to clinic for evaluation of CKD. Hep C was initially diagnosed when he was found to have leukocytoclastic vasculitis on a skin biopsy of skin rash. Labs were positive for serum cryoglobulins, rheumatoid factor, low C4, and Hep C viral load. Renal function was normal and he was successfully treated for cryoglobulinemic vasculitis due to Hep C with interferon alpha, telaprevir and ribavirin and achieved a SVR. He presented 1 year later with renal insufficiency (creatinine -2.2 mg/dL) and 500mg proteinuria. He had intermittent flares of vasculitis. SPEP revealed IgM kappa monoclonal with negative UPEP. C4 was low and cryoglobulins remained positive. Kidney biopsy showed immune complex GN with organized deposits. Bone marrow biopsy was negative for lymphoproliferative disease. He was diagnosed with cryoglobulinemic GN with SVR. Initially, he was treated with prednisone followed by Rituximab and plasmapheresis. He failed the treatment and was started on hemodialysis.

Discussion: Cryoglobulinemic GN is frequently due to Hep C but is rare in patients achieving a SVR. In our case an underlying B cell lymphoma was ruled out and it was felt that B cell immune dysregulation due to Hep C was the culprit, in part due to prior published cases. However, in our case treatment with rituximab and plasmapheresis was unsuccessful. It remains possible, as others have demonstrated, that the virus may persist within the liver, macrophages, lymphocytes, and even kidney. The pathological basis for persistent vasculitis in setting of a SVR requires further study so that targeted and more effective treatment strategies can be designed.

SA-PO110

Diagnostic Intrapartum Dilemma: Distinguishing Glomerulonephritis from Preeclampsia in Pregnancy Suzanne L. Katsanos, Fernanda Payan Schober, William Franklin Pendergraft, Volker Nickeleit, JulieAnne G. McGregor, Harsharan Kaur Singh. *UNC Kidney Center, Chapel Hill, NC.*

Introduction: Distinguishing glomerular disease from preeclampsia intrapartum can be challenging due to overlap of clinical findings. Unfortunately, this diagnostic dilemma can result in unwarranted early delivery. Here we present 5 cases of glomerulonephritis (GN) complicating pregnancy.

Case Description: 3 patients (ages 22, 31 and 33) presented during pregnancy with proteinuria, dysmorphic hematuria and, in 2 cases, acute kidney injury. In all 3 cases, the concern for preeclampsia prompted induction of labor (IOL), and postpartum kidney biopsy showed IgA nephropathy. 2 patients were treated with steroids and ACE inhibitors (ACEI) with improvement in proteinuria. The one with the most severe kidney dysfunction was treated with cyclophosphamide (CYC). Unfortunately, she became dialysis-dependent 1 month postpartum. The fourth patient (age 20) presented with HELLP syndrome at 25 weeks and underwent IOL. 5 months post-partum, she developed clinical symptoms of lupus in the setting of proteinuria, dysmorphic hematuria and persistent kidney dysfunction. Kidney biopsy showed diffuse proliferative lupus nephritis, which was treated with IV CYC. Unfortunately, she continued to have renal dysfunction despite treatment. The fifth patient (age 37) had minimal change disease (MCD) and was in remission at the time of pregnancy. She did well on cyclosporine until 25 weeks gestation when she developed hypertension, edema, and nephrotic-range proteinuria. It was unclear whether this represented preeclampsia or a MCD flare so she underwent IOL. Subsequent placental pathology failed to show signs of preeclampsia. She was treated postpartum with steroids and ACEI and re-entered remission.

Discussion: Here we show that pregnancy can aggravate (as in the case of our patient with MCD) or unmask (as in the other 4 cases) underlying glomerular disease. Diagnosis can be delayed due to risks related to kidney biopsy during pregnancy, and treatment is complicated by safety concerns for the developing fetus. Further work is needed to identify meaningful mechanisms to accurately differentiate preeclampsia from GN during pregnancy.

SA-PO111

A Case of Rapidly Progressive Glomerulonephritis Associated with Metastatic Lung Cancer Eduardo J. D. de Sa Carneiro Filho, Victor Longo Silva, Lilian Cordeiro, Veronica T. Costa e Silva, Elerson Costalonga. *Univ of São Paulo, Nephrology Division, São Paulo, Brazil.*

Introduction: Several solid malignancies have been associated with glomerular diseases. Rapidly progressive glomerulonephritis (rPGn) has been reported in association in particular with renal cell carcinoma and lung cancers. We report a case of rPGn associated with metastatic lung cancer treated with chemotherapeutic agents.

Case Description: A 57-year-old male with metastatic epidermoid lung cancer, treated previously with paclitaxel plus carboplatin, cisplatin plus gemcitabine and four cycles of docetaxel, was admitted with dysuria and hematuria for last 1 week. Upon physical examination: edema of the lower limbs. Laboratory results demonstrated normal liver function, positive anti-Hbc, negative HbsAg and anti-Hbs, hemoglobin 6,5 g/dL, serum creatinine of 3,78 mg/dL (baseline 1,5), C3 154 mg/dL, C4 24,8 mg/dL, negative cANCA. Urinalysis showed proteinuria (>1 g/L), more than 100 leukocytes per field and more than 100 red cells even after antibiotic treatment for presumed urinary infection. Due to persistent

proteinuria (3,7g/24h), evidence of dysmorphic hematuria and worsening of renal function (Cr 4,1 mg/dL), he received methylprednisolone 1g for three days and renal biopsy was proposed. It revealed pauci-immune crescentic glomerulonephritis. Immunofluorescence showed mesangial deposition of C3 (3+) and lambda chains (1+). Treatment was followed by monthly i.v. cyclophosphamide and proteinuria decreased to 0.87 g/24h. cANCA became positive (1/160) 4 months after diagnosis.

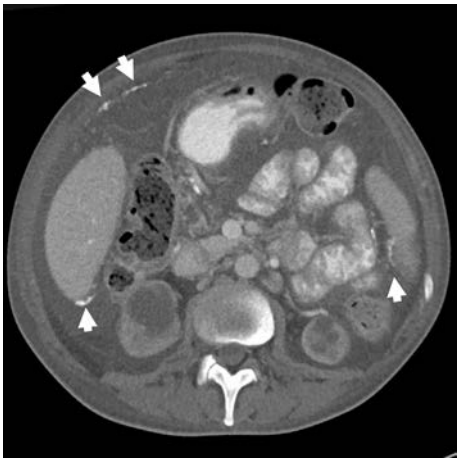
Discussion: Membranous nephropathy is the most commonly reported glomerulopathy especially with pulmonary cancer, but several reports suggest an association between rPGn and malignancies. The increased risk for malignancy has been confirmed in a retrospective review of 200 patients with ANCA-associated vasculitis, demonstrating a significantly increased relative risk (6.02) compared with age-matched controls. Biava et al reported seven cases of rPGn associated with a coexisting nonrenal malignancy (6 carcinomas and 1 lymphoma). The pathogenetic mechanisms by which neoplasms lead to the development of ANCA-associated vasculitis and rPGn are largely unknown.

SA-PO112

A Case of Encapsulating Sclerosing Peritonitis in a Type I Diabetic on Peritoneal Dialysis Zachary Freestone, Josephine Abraham, Akram M. Shaaban. *Nephrology, Univ of Utah, Salt Lake City, UT.*

Introduction: Encapsulating sclerosing peritonitis (ESP) is a rare disorder associated with PD. It is characterized by peritoneal fibrosis and encasement of the bowel. Symptoms associated with ESP are non-specific and may be attributed to other etiologies. Abdominal imaging is required to evaluate ESP and diagnostic confirmation is achieved by laparoscopy. ESP should be considered in patients on peritoneal dialysis with symptoms involving the gastrointestinal tract, weight loss, or inadequate solute clearance.

Case Description: A 34 year old Caucasian male on PD presented to the clinic with complaints of nausea and abdominal pain. He had a history of type I DM, ESRD, neuropathy, and gastroparesis. He was started on PD 8 years ago and has had 3 prior episodes of peritonitis. The patient appeared ill and malnourished. His abdomen was soft on examination and non-tender to palpation. An abdominal x-ray indicated that he had calcification in the abdomen and pelvis. CT imaging showed calcification of the parietal peritoneum, abdominal cavity, omentum, and bowel. The patient underwent exploratory laparotomy with simultaneous PD catheter removal. The visual examination revealed a brown, inflamed rind encompassing the peritoneum, omentum, bowel, and colon. Peritoneal dialysis was discontinued and the patient was transitioned to hemodialysis.



Discussion: Encapsulating sclerosing peritonitis (ESP) is a condition associated with peritoneal dialysis. Its presenting symptoms are often non-specific and may be attributed to other causes. Abdominal imaging is necessary to evaluate for suspected ESP, CT being the preferred method. ESP is characterized by peritoneal thickening and fibrosis that encases the bowel. Treatment includes cessation of PD with transfer to hemodialysis and bowel rest. Other attempted treatments of this disease have included steroids and total enterolysis.

SA-PO113

Acute Kidney Injury from Enterovescical Fistula Secondary to Squamous Cell Carcinoma of Bladder Eleni Chelioti, Evdokia Efthimiou, Alexia Papalexandrou, Maria Sotiraki, Ioannis Xatzis, Maria Tsilivigou. *Dept of Nephrology, General Hospital of Piraeus, Athens, Greece.*

Introduction: Squamous cell carcinoma (SCC) of the bladder is a relatively rare tumor. Predisposing factor is chronic irritation of the bladder by urinary infection, calculi and long-term indwelling catheterization. Enterovescical fistula (EVF) usually has flow from intestine to the bladder and commonly manifests with recurrent urinary tract infections(UTI), fecaluria and pneumaturia. We report a case with SCC of bladder who developed EVF, leading to acute kidney injury(AKI).

Case Description: A 56 year old Caucasian female with hypertension, diabetes mellitus and recurrent UTI was admitted in a uremic state that necessitated the immediate start of hemodialysis. Further clinical and laboratory findingsrevealed hematuria, pyuria,bacteriuria and fecaluria after placing a Foley catheter. Ultrasound scan of the abdomen showedtwo kidneys of normal size and parenchymal thickness. CT scan of the abdomen and pelvis showed a markedly contracted and nodular bladder with a large bladder wall defect and the Foley catheter extending through the bladder wall into a small bowel loop. A diagnosis of EVF with reverse flow from the bladder to intestine was made. She subsequently underwent to a long surgery with total cystectomy, a ileo-hemicolectomy and creation of an ileal conduct. Histopathology examination of specimens revealed SCC of bladder and metastasis in the colon.After surgical intervention,she became hemodialysis dependent, refused further therapy and she is well 6 months later.

Discussion: In the western world SCC represent less than 5% of all bladder tumors. There are no specific diagnostic tests and it is usually diagnosed in advanced stage. Although distant metastasis is infrequentbut the prognosis is poor and most patients die. In our case the only proved predisposing factor is chronic irritation of the bladder by UTI. EVF rarely can have reverse flow leading to urine excretion via GI tract in patients with diminished bladder capacity. The diverted urine stimulates metabolic disorders causing AKI.

SA-PO114

Postoperative Bilateral Ureteroenteric and Enterovesicular Fistulas Complicated by Hydronephrosis and Ursosepis Ayaa M. Zarm, Muner Mohamed, Rohini Chawla, Sunithi Krishnan, Richard E. Seguritan, Vinay N. Kikkeri. *Medicine/Nephrology Div, Richmond Univ Medical Center, Staten Island, NY.*

Introduction: Lower urinary tract fistulas are serious complications of abdominopelvic surgeries, often resulting in poor outcomes.

Case Description: This is a case of a 65-year-old man with a history of colorectal cancer who underwent colon resection with colostomy placement, chemotherapy and radiotherapy. The patient was admitted with signs and symptoms of Urosepsis with MDR Klebsiella and oliguric acute kidney injury. CT abdomen/pelvis demonstrated moderate bilateral hydronephrosis and hydroureter with cystitis and inflammatory changes within the pelvis. Patient was noted to have minimal urinary output after a Foley catheter placement and worsening renal failure due to which a bilateral percutaneous nephrostomy catheter was placed by Interventional Radiology. During this procedure, the patient was found to have bilateral Ureteroenteric and Enterovesicular fistulas (Figure 1, 2) with associated cystitis.

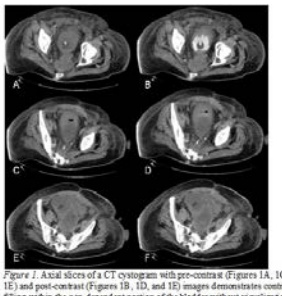


Figure 1. Axial slices of a CT cystogram with pre-contrast (Figures 1A, 1C, and 1E) and post-contrast (Figures 1B, 1D, and 1E) images demonstrates contrast filling within the non-dependent portion of the bladder without visualization of extra-vesicular extravasation, even on delayed imaging (not shown). Figure 1A and 1B shows contrast filling within the non-dependent portion of the bladder suggesting higher density debris within the bladder. Figure 1C and 1D shows a focus of air within the dome of the bladder and diluted contrast material on Figure 1D without any extra-vesicular contrast extravasation. Figure 1E and 1F demonstrate the superior portion of the dome of the bladder and an additional hypodense complex fluid collection just anterior to the bladder. Additionally, 1E and 1F demonstrate an irregularly thick and nodular bladder wall. Furthermore, there is a focus of air seen on the post-contrast image (1F) that was not visualized on pre-contrast imaging (1E) suggesting a possible communication with the collection.

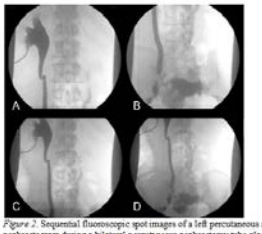

Figure 2. Sequential fluoroscopic spot images of a left percutaneous anterograde nephrostogram during a bilateral percutaneous nephrostomy tube placement procedure. Figure 2A shows normal contrast filling of the left kidney and proximal ureter. Figure 2B shows contrast filling within the mid to distal left ureter and an abnormal collection of contrast projecting over the pelvis. The abnormal collection does not assume the shape of the bladder even with consideration of the contour and irregularity of the bladder dome as demonstrated on prior imaging. Further investigation with real-time fluoroscopic imaging demonstrated active contrast reflux into the mid and distal right ureter. Fluoroscopic spot images were obtained (Figure 2C) demonstrating reflux up to the mid right ureter along with contrast movement within the abnormal collection assuming a tubular shape (Figure 2D) suggesting bilateral ureteral fistulization with bowel lumen.

In order to confirm the diagnosis of these bilateral ureteroenteric fistulas, a sample of colostomy fluid was checked for Creatinine levels. The Creatinine level from the colostomy fluid was equivalent to the urine creatinine level hence confirming the diagnosis. Patient was further treated with intravesical Polymyxin for cystitis.

Discussion: Lower urinary tract infections are a serious complications in patients undergoing abdominopelvic surgeries. However, they are mainly associated with patients undergoing chemotherapy and radiation therapy for colorectal malignancies. These complications can be lethal and have a very poor prognosis.

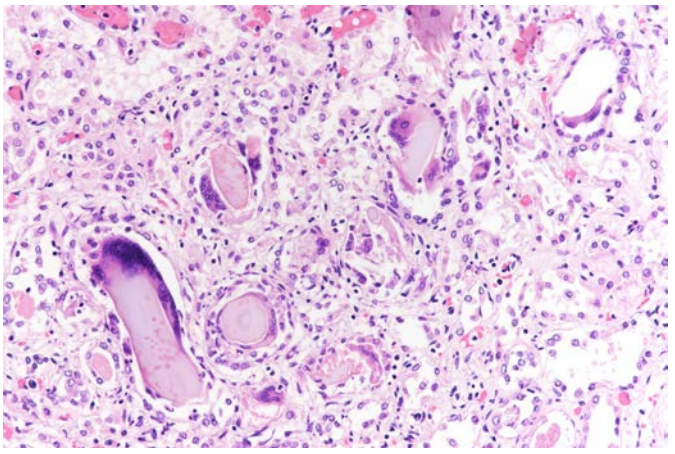
SA-PO115

Clinicopathological Feature of a Patient with IgD-Lambda Type Multiple Myeloma Showing Kidney Involvement Kaori Yamaguchi,[1] Toshiya Okumura,[1] Kengo Furuichi,[2] Takashi Wada,[2] Yasunori Iwata,[2] Taichiro Minami.[1] *[1]Nephrology, Tonami City Hospital, Tonami, Toyama, Japan; [2]Nephrology, Kanazawa Univ, Kanazawa, Ishikawa, Japan.*

Introduction: Kidney involvement sometimes occurs in patients with multiple myeloma (MM). MM associated kidney diseases encompass diverse manifestations, such as cast nephropathy, amyloidosis and immunoglobulin deposition disease. Since the frequency of IgD type MM is relatively low, renal manifestation, especially, renal pathology has not been fully understood. Here, we repots the autopsy case of IgD type MM with kidney involvement.

Case Description: A 81 years old women admitted the hospital because of systemic pain and appetite loss. Laboratory data showed serum Cr 5.14 mg/dl, urea nitrogen 57.2 mg/dl and corrected Ca 16mg/dl. Urine protein was 1+ with dipstic analysis and 9.7 g/gCr. Serological test revealed a monoclonal IgD-lambda chain. Proliferated plasma cells with the positivity of IgD-lambda chain was increased (16%) in bone marrow. After the Ca lowering therapy, dexamethasone (20mg/day X 4days) was administrated to the patient. While serum levels of IgD was decreased by the therapy, renal function deteriorated, requiring dialysis. She died of infection at 64 day after admission. Autopsy specimen of kidney showed cast

formation in tubular lumens with severe tubular atrophy. Cell accumulation and fibrotic lesion were also detected in interstitium. Mesangial matrix was mildly expanded in glomeruli. Amyloid deposition was not observed.



Discussion: Herein, we showed clinical course and renal pathology of the patient with IgD-lambda type MM. Although steroid pulse therapy decreased serum levels of IgD, renal function did not improve. Renal pathology showed cast nephropathy, interstitial fibrosis and cell infiltration. The renal manifestation of IgD type MM requires further investigation.

SA-PO116

Sunitinib-Induced Nephrotic Syndrome and Acute Kidney Injury in a Malignant Insulinoma Patient: A Case Report Wakana Shoda, Naofumi Yui, Shotaro Naito, Soichiro Iimori, Koichiro Susa, Takayasu Mori, Naohiro Nomura, Eisei Sohara, Tomokazu Okado, Tatemitsu Rai, Shinichi Uchida. *Dept of Nephrology, Tokyo Medical and Dental Univ, Bunkyo, Tokyo, Japan.*

Introduction: Sunitinib, a tyrosine kinase inhibitor targeting vascular endothelial growth factor receptors (VEGFR), has been proven to be effective in the treatment of several types of cancer, including pancreatic neuroendocrine tumors. However, its risk of renal complications, such as proteinuria, renal dysfunction, and hypertension, are underestimated.

Case Description: A 71 year-old man with malignant insulinoma treated on sunitinib for six months, developed proteinuria, acute kidney injury and hypertension. Kidney biopsy showed thrombotic microangiopathy (TMA) like lesions such as double contoure, edematous endothelial cells and microaneurysms, suggesting injuries induced by sunitinib. Decreased VEGF expression in podocytes was demonstrated by immunohistochemistry, supporting the diagnosis. Sunitinib was discontinued and partial remission of the renal complication was achieved in two weeks. However, the patient mandatorily needed to restart sunitinib because of poor control of blood glucose level due to pancreatic cancer exacerbation. By reducing the dose of sunitinib and administering losartan concurrently, the patient was able to maintain stable renal function with serum creatinine level of 1.4 mg/dl and urinary protein level under 1.0g/day.

Discussion: VEGF blockade by sunitinib is featured by adverse effects including hypertension and renal injury. In the present case, renal injury partially improved after discontinuing sunitinib. Reducing the dosage of sunitinib and administering losartan made it possible to restart sunitinib treatment while controlling its renal side effects. VEGF, which is expressed and secreted by podocytes, is an important factor for development and maintenance of glomerular endothelium. Renal biopsy in this case showed down regulation of VEGF in podocytes. Although the mechanism of renal dysfunction and proteinuria caused by anti-VEGF therapy is not well elucidated, the findings of this case might provide insights into the mechanism of renal toxicity by sunitinib.

SA-PO117

Liver-Kidney versus Liver Transplant Alone: Decision Making in the Operating Room Ekamol Tantisattamo,[1] Siwadon Pitukweerakul,[2] Praveen Ratanasrimetha.[3] *[1]Nephrology, Northwestern Univ; [2]Presence St. Francis Hospital, Evaston; [3]Faculty of Medicine Siriraj Hospital, Mahidol Univ, Bangkok, Thailand.*

Introduction: Acute kidney injury (AKI) is a common complication of decompensated chronic liver disease and hepatorenal syndrome (HRS) is one of the leading causes. Liver transplantation (LT) is a definitive treatment for HRS; however, simultaneous liver-kidney transplantation (SLK) is pursued due to the severity of preoperative AKI with uncertainty of postoperative renal recovery.

Case Description: A 60-year-old Caucasian woman with ESLD due to alcoholic cirrhosis had been readmitted twice over 2.5 months with AKI from HRS. Even though, she was treated with albumin, midodrine, and octreotide, serum creatinine (SCr) had been elevated from the initial baseline of 1 mg/dL and had never returned to the baseline. Instead, it was worse every times she had AKI (Figure 1). After the last episodes of AKI, SCr had been stable at 2.5 mg/dL and she was listed for SLK. One week later, she was offered for SLK. After the LT, she started making a significant amount of urine immediately; therefore, the kidney was not transplanted and transferred to other potential kidney transplant recipient in another transplant center. Postoperatively, SCr had trended down to 1.1 mg/dL.

Discussion: Even though, our patient had recurrent episodes of AKI from HRS and persistently elevated SCr even <3 months period, it was thought that the chance of meaningful renal recovery was small and SLK was initially planned. Fortunately, her renal function was recovery immediately after the LT alone. Preoperative evaluation for SLK versus LT alone sometimes becomes uncertainly. Intraoperative finding of signs of renal recovery after LT is crucial as it can avoid unnecessarily kidney transplantation and provide an opportunity to utilize kidney organ to other potential kidney transplant recipients.

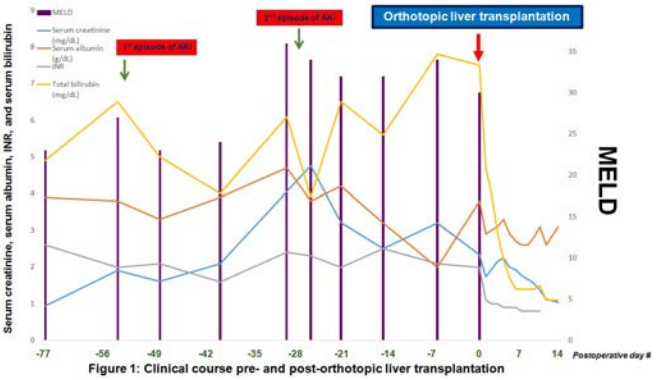


Figure 1: Clinical course pre- and post-orthotopic liver transplantation

SA-PO118

Is Portopulmonary Hypertension Patient a Good Candidate for Liver Transplantation? Ekamol Tantisattamo,[1] Praveen Ratanasrimetha,[2] Siwadon Pitukweerakul.[3] *[1]Nephrology, Northwestern Univ; [2]Faculty of Medicine Siriraj Hospital, Mahidol Univ, Bangkok, Thailand; [3]Presence St. Francis Hospital, Evaston.*

Introduction: Portopulmonary hypertension (PPH) is one of the most feared complications of end-stage liver disease (ESLD). Liver transplantation (LT) may reverse this complication with uncertain outcomes. We report a case of ESLD women complicated by severe pulmonary arterial hypertension (PAH) secondary to PPH and acute kidney injury (AKI) who had prolonged pre- and post-operative simultaneous liver-kidney transplantation (SLK) with partial liver improvement, un-meaningful renal recovery, and bed bound with reconditioning.

Case Description: A 48-year-old woman with ESLD from cryptogenic cirrhosis complicated by portal hypertension, PAH-related to PPH and sarcoidosis presented with AKI requiring CRRT. She was treated with treprostinil, sildenafil, and ambrisentan until suitable for SLK. Postoperatively, liver and renal allografts worked well and PA pressure was decreased. However, she still required treprostinil and dieresis to control PAH and volume status. After 5 months of ICU stay, she developed severe deconditioning and malnutrition. She had AKI with SCr of 0.5 mg/dL up to 1 mg/dL over 3 weeks. Calculated average clearance from 24-hour urine collection was 15 ml/min. Transplant renal allograft biopsy revealed moderate ATN and borderline changes. Diuretic dose was decreased and SCr was improved to 0.7 mg/dL. She still required treprostinil as well as intensive rehabilitation and nutritional supplementation. She remains in ICU for the majority of the time posttransplantation.

Discussion: PPH is one of the challenging scenarios for ESLD requiring LT. Reversibility from PPH after LT is uncertainty. It is still a dilemma in managing this difficult situation between LT to prolong life with poor quality and conservative management. LT is a life-saving surgery but may not always reverse a severe complication of ESLD such PPH and thus prolongs no postoperative quality of life. Therefore, LT in such a complex underlying condition needs to be individualized.

SA-PO119

Flash Pulmonary Oedema in Renal Artery Stenosis: An Indication for Stenting? Elise Chua, Martine David, Neil Chapman. *Medicine, Imperial College, United Kingdom.*

Introduction: Renal artery stenosis (RAS) is an unusual but potentially treatable cause of flash pulmonary oedema. Although national guidelines recommend percutaneous revascularization (level of evidence B), we present a case of recurrent flash pulmonary oedema which suggests a need for further evidence to support use of revascularization therapy in elderly patients with multiple comorbidities.

Case Description: A 78 year old woman presented with a fourth episode of sudden onset dyspnoea in 4 months. Her medical history included CAD, AF, hypertension (HTN) and severe pulmonary HTN due to heart failure with preserved ejection fraction (HFPEF). On admission, there were bilateral respiratory crackles and pulmonary congestion on chest XR. BP was 164/95, creatinine 110umol/L, eGFR 42. Echocardiogram showed concentric LVH, preserved EF and raised PAP. Because of recurrent symptoms despite apparently adequate medical management of HFPEF, she underwent CT angiography which revealed bilateral ostial RAS (70% right, 40% left). Following multidisciplinary team discussion, bilateral balloon angioplasty with stent insertion was performed with radiologically successful results and she was discharged on rivaroxaban for stroke prevention. Since then, she has had no further episodes of pulmonary oedema. However, renal function has deteriorated post-procedure (max creatinine 226umol/L, eGFR 18 at 6 weeks; no evidence of in-stent thrombosis) and she has diuretic-resistant pedal oedema severely impacting quality of life.

Discussion: This case highlights the importance of recognizing RAS as a cause of flash pulmonary oedema, especially in bilateral disease due to lack of compensatory mechanisms. Observational studies and case series have demonstrated that angioplasty +/- stenting reduces the incidence of flash pulmonary oedema. However, there is limited literature to guide management (eg. on risks and benefits of unilateral vs. bilateral intervention, degree of stenosis) and limited experience in the elderly in whom comorbidities may increase the risks of procedural complications such as deterioration of renal function due to contrast nephropathy and/or cholesterol emboli.

SA-PO120

Complement Mediated Hemolytic Uremic Syndrome Secondary to SLE Aala Jaberi, Jean M. Francis, Craig E. Gordon. *Nephrology, Boston Medical Center, Boston, MA.*

Introduction: Complement-mediated hemolytic uremic syndrome (CM-HUS) is a life-threatening disease. Rapid diagnosis and early treatment impact patient outcomes. CM-HUS is often caused by defects in the complement regulatory system leading to uncontrolled activation of the alternative complement pathway, resulting in systemic thrombotic microangiopathy (TMA).

Case Description: 64-year-old female with well-controlled HIV on HAART, presented with new pancytopenia, thrombocytopenia and acute kidney injury. On examination she had no neurological symptoms and no diarrhea. Preliminary blood tests revealed WBC 2.9K/UL, hemoglobin 6.6g/dl, platelets 64 K/UL, and serum creatinine at 4.0 mg/dl. LDH was elevated at 600U/L, haptoglobin was undetectable, with Coombs test negative. Peripheral blood smear revealed numerous schistocytes. Further work up revealed an elevated ANA (>1:2560), and hypocomplementemia. Anti-Smith antibody elevated at >8. These laboratory studies and the presence of lymphadenopathy and pancytopenia established a diagnosis of SLE. Patient received pulse methylprednisolone, but creatinine increased to 6 mg/dl . A kidney biopsy revealed TMA. The patient was treated with plasma exchange but developed uremia and was started on hemodialysis. Neither renal function nor hemolysis improved. In the absence of anti phospholipid antibody, normal ADAMTS13 level and activity, well-controlled HIV, and in the presence of positive serologies for SLE with complement consumption, the diagnosis of CM-HUS secondary to SLE was the most explanation of the patients' presentation, a decision was made to treat with eculizumab. Patient received one treatment,with no immediate improvement in her renal disease or hematologic parameters. Unfortunately her clinical status deteriorated and patient opted to be made comfort measures only and ultimately expired.

Discussion: This case emphasizes the importance of early consideration of CM-HUS as well as prompt initiation of treatment to block terminal complement upon recognition of the syndrome. As clinicians, this class of diseases is challenging and complicated, requiring our rapid attention to aid timely identification and rapid management.

SA-PO121

Idiopathic Nodular Glomerulosclerosis Presenting with Nephrotic Range Proteinuria and Normal Renal Function Hassan E. Osman, Dany H. Issa. *Dept of Internal Medicine - Div of Nephrology, Saint Louis Univ, Saint Louis, MO.*

Introduction: Idiopathic Nodular Glomerulosclerosis (ING) is a well-established but uncommon entity that has been described in 1985 by Chan JY et Al. It is common in older white men with history of long-standing hypertension, obesity, and smoking and typically presents with renal Insufficiency & Nephrotic Range Proteinuria. Multiple reports and meta-analyses of patients with ING demonstrate an average creatinine > 2.0 mg/dl and progressive kidney dysfunction leading to ESRD.

Case Description: We report a case of a 57 year old Caucasian obese female who presented with edema and heavy proteinuria (9 grams/day). She is a 40-pack year smoker with long-standing hypertension with variable control. Serum Creatinine on presentation was 0.7 mg/dl. Hba1c was 6.0% and fasting/random sugars never met criteria for overt Diabetes Mellitus. Urine showed 3-10 rbcs/hpf and none where dysmorphic with an otherwise bland urine sediment. She had a negative work up for paraproteinemias and all other causes of proteinuria. Kidney biopsy showed Class III nodular sclerosis (KW lesions) and moderate atherosclerosis by light microscopy. Immunofluorescence and Congo red staining were negative while EM showed ultra-structural features of Diabetic Nephropathy.

Treatment with diuretics and ACE-Inhibitor lead to improvement in volume status and proteinuria. Nine-months into follow up renal function remain stable.

Discussion: Our case illustrates that Idiopathic Nodular Sclerosis is not limited to male gender and can occur in the setting of preserved renal function, contrary to the common observation revealed in previous case reports.

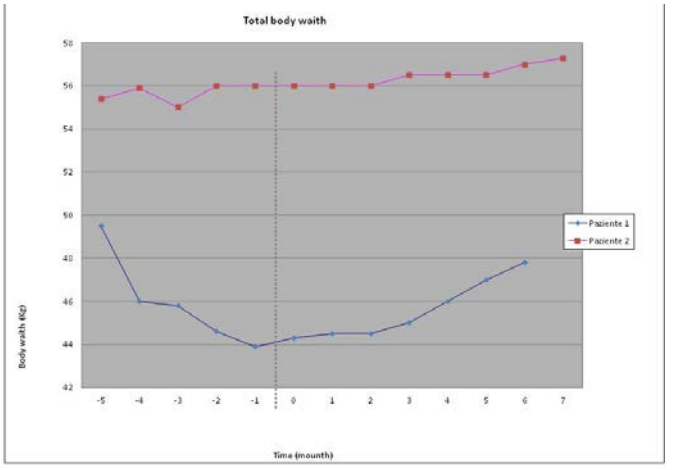
SA-PO122

Hemofiltration Reinfusion Aequilibrium Can Be an Answer to Malnutrition and Hypotension in Dialysis Nicoletta Pertica. *Dept of Nephrology, Verona Hospital (AOUI VR), Verona, Italy.*

Introduction: We analyze the impact of A-HFR on intradialytic tolerance, nutritional status and on the clinical condition of two malnourished patients of our dialysis center.

Case Description: We performed an observational study for 12 months on 2 patients shifted toA-HFR caused to dialysis intolerance towards other methods.We monitored Blood Gas (pre and post treatment),clinical,biochemical, and dialitic data. **Patient 1** 62 years old man: on dialysis since 2008, suffering from malnutrition and anorexia due to cerebellar stroke (BMI 15.8) with intra and interdialytic hypotension. On February 2014 he started IDPN (IntraDialytic Parental Nutrition) + HDF online without any clinical improvement. On June 2014 he shifted to A-HFR+IDPN with improved hemodynamics control, weight (10% compared to its initial), nutritional and inflammatory indexes. In addition, he improved his quality of life with disappearance of hypotensive episodes and reduced consumption of EPO. **Patient 2** 44 years old Woman: kidney-panceas transplanted, on dialysis since 2011. In 2012 she started an antibiotic therapy for curing a pulmonary TBC, burdened by malnutrition and severe peripheral neuropathy with persistent hypotension, also during dialysis. In 2013 she shifted to A-HFR and improvements regarding bodyweight, blood pressure, inflammatory markers and peripheral neuropathy were observed.



Discussion: A-HFR has dynamic profiles of ultrafiltration and conductivity of the dialysate: this aspect creates an iso-osmolar dialysate, ensuring a better periferical refilling and improving compliance during the dialysis treatment. This is due to the use of biosensors. A-HFR also reduces the Amino acids loss.This report has numerical limitations but provides encouraging data on the use of AHFR in malnutrition and disequilibrium syndromes. This experience underlines the importance of further efforts towards customized dialysis procedures.

SA-PO123

Monoclonal Gammopathy of Renal Significance: The Significance Is Not Always Unknown Umair S. Ahmed. *Nephrology, West Virginia Univ, Morgantown, WV; Nephrology, West Virginia Univ, Morgantown, WV.*

Introduction: Membranoproliferative glomerulonephritis (MPGN) is a pattern of glomerular injury noted on microscopy. It is less commonly associated with monoclonal gammopathies, including monoclonal gammopathy of unknown significance (MGUS).

Case Description: Patient is a 67 years old female, with a history of rheumatoid arthritis, on Methotrexate, who presented to an outside facility with progressively worsening fatigue for four months. Investigations showed pancytopenia, following which she was transferred to our hospital for further management. On arrival at our hospital, patient was noted to have an acute kidney injury. A random urine protein/creatinine ratio showed 5.5 gm proteinuria. Serum protein electrophoresis showed a monoclonal spike, with an Ig M kappa clone. Immunoglobulin (Ig) G was low at 161 mg/dl, while Ig M was increased at 378 mg/dl. Bone marrow biopsy done showed 5 % plasma cells, with no morphological features of a plasma cell neoplasm, leukemia or lymphoma. Kidney biopsy done showed MPGN, with positive immunofluorescence for IgM, C3, kappa, along with large subendothelial and mesangial deposits. Both C3 and C4 were low. Work up was negative for hepatitis B and C. Serum cryoglobulin levels were normal. No evidence of lupus was noted. Infectious work up was also unremarkable. Patient was diagnosed as having MGUS by the hematology service. MPGN was assessed to be secondary to MGUS in the absence of other possible etiologies. Patient was started on high dose steroids for 3 days followed by a taper, along with intravenous Rituximab 375 mg/m^2 weekly for 4 weeks. Due to worsening renal functions patient was started on hemodialysis. Unfortunately due to lack of renal recovery, patient was declared as having end stage renal disease.

Discussion: MGUS is the most common plasma cell disorder and may be a precursor for myeloma. It is characterized by a lack of end organ damage. A small subset of patients, however, may rarely have renal involvement, with MPGN being noted on renal biopsy. MGUS can therefore be associated with morbidity and mortality, and therefore its significance may not always be unknown.

SA-PO124

A Case of Chronic Unilateral Hematuria Treated by Segmental Renal Artery Embolization Hansae Kim,[1] Joon Seok Oh,[2] Yong Ki Park,[2] Dongyeol Lee.[1] *[1]Nephrology, Bongseng Memorial Hospital, Busan, Korea; [2]Nephrology, Dongrae Bongseng Memorial Hospital, Korea.*

Introduction: Chronic unilateral hematuria is characterized by intermittent or continuous hematuria that cannot be diagnosed using standard radiologic and hematologic methods. Unilateral hematuria is probably a benign condition that seldom requires surgical treatment, but some cases were managed with partial or total nephrectomy. Recently, a variety of treatments, including the ureteroscopic interventions have been attempted if the bleeding focus is identified. However, if not identified on ureteroscopy, surgical treatment has been considered a priority. We report the case of treatment of chronic unilateral hematuria with segmental renal artery embolization.

Case Description: We experienced a case of chronic unilateral hematuria in a 42-year-old woman who was admitted to our hospital due to intermittent gross hematuria and anemia for 31 months. About 29 and 19 months ago she already underwent CT scan, renal angiography, and renal biopsy at other tertiary hospitals, but didn't found any other specific abnormalities repeatedly except some blood clots in left renal pelvis on ureteroscopy. She underwent CT urography, renal arteriography, cystoscopy and ureteroscopy again. Ureteroscopic findings only showed bleeding in the upper third of left renal calyces but definite bleeding focus could not be identified. Thus we decided to manage with segmental renal artery embolization than partial nephrectomy to minimize the reduction in renal function and to reduce operational risk. The superior and superoanterior segmental renal arteries were successfully embolized with 3mm coils and gelatin sponge. Gross hematuria disappeared on the 4th day after the procedure, microscopic hematuria disappeared on the 5th day. In 11th day, infarction in the upper third portion of left kidney was confirmed on CT scan. In 13th day, the patient was discharged. Thereafter serial urinalysis showed no hematuria.

Discussion: Patients with chronic unilateral hematuria often require surgical or upper urinary tract endoscopic procedures. Segmental renal artery embolization will be a better treatment for patients unable to identify the bleeding focus on the upper urinary tract endoscopy.

SA-PO125

An Unusual Cause of Acute Kidney Injury in a Patient Several Months Post Renal Transplant Sweta Carpenter, Karthik M. Ranganna. *Nephrology, Drexel Univ.*

Introduction: Urinary anastomosis leaks after kidney transplants are no longer a common phenomenon. Due to advancements in reconstruction techniques, urologic complications after renal transplant are now reported to occur in only 2-2.5% of patients. If a urinary anastomotic leak were to develop, it frequently occurs within one month of the transplant and is usually due to technical error or ischemia to the ureter.

Case Description: We present a case of a 60 year male with a history of a living unrelated kidney transplant who developed acute kidney injury 5 months after transplant. He had a baseline creatinine of 1.5-1.7 mg/dL and initially presented to the hospital with fevers and a creatinine of 2.96 mg/dL. A fungal urinary tract infection with Candida Albicans was deemed the culprit of his symptoms and so he was promptly started on fluconazole with only a slight improvement in his creatinine. A renal ultrasound of the allograft revealed that the patient had a 7x5 cm perinephric fluid collection. A perinephric drain was placed in the collection and culture of the fluid grew Candida Albicans. The large amount of perinephric drainage led to concerns of an anatomic urinary leak. Further testing on the perinephric fluid showed similar levels of creatinine in the perinephric fluid and the patient's urine. Cystoscopy later revealed that the patient had a large ureteral anastomotic leak. He underwent a percutaneous nephrostomy tube and nephroureteral stent placement. The patient's perinephric fluid collection subsequently resolved and he was discharged home with a creatinine of 1.47 mg/dL.

Discussion: Improvements in surgical techniques have decreased but not eliminated the incidence of anatomic surgical complications. Urinary anastomotic leaks are a rare but serious complication of kidney transplantation. This case highlights the need for diligence in diagnosing such a leak and favorable outcomes with prompt treatment. Since urinary leaks are uncommon months after kidney transplant, a question could be raised about the possible causative association between the fungal urinary tract infection and the anastomotic leak.

SA-PO126

Early Onset Kidney Stone Formation in Severe Ulcerative Colitis: Prevention Better Than Cure Akshatha Rao, Rozina B. Ali, Ziauddin Ahmed. *Div of Nephrology, Drexel Univ, Philadelphia.*

Introduction: Incidence of kidney stones is higher in patients with inflammatory bowel disease (IBD) than in general population. Studies using screening ultrasound showed 38% of Crohn's disease and 37% of Ulcerative Colitis(UC) patients had asymptomatic renal calculi mostly calcium oxalate and or uric acid stones. Active inflammation was the important risk factor for renal calculi.

Case Description: In our case report we describe a 40 year old male with no significant past medical history except newly diagnosed ulcerative colitis with severe pancolitis on colonoscopy 3 months ago. His pancolitis was treated with steroids and Infliximab therapy with significant improvement of his symptoms. Subsequently patient was readmitted to the hospital with severe abdominal pain, radiating from loin to groin. CT abdomen and pelvis showed multiple bilateral kidney stones, largest measuring 7mm, and a 5mm stone at the ureterovesical junction on the left with hydronephrosis. His serum creatinine (SCr) increased from 1.2 to 4 mg/dl.

Patient underwent cystoscopy, left retrograde pyelogram for renal stone extraction and stent placement with improvement of creatinine. A 24-hour urine collection 4 weeks after the acute episode showed high normal urinary calcium and oxalate excretion and low citrate excretion. A repeat 24 hour collection 8 weeks after the remission of UC showed normal both calcium and oxalate excretion but citrate excretion remained low and urine of pH 6.5. Patient was told to increase fluid intake to 3L /day and potassium citrate was added to his regimen.

Discussion: This case suggests that stone formation may be an early phenomenon in UC. We think there might be a benefit in obtaining 24-hour urine collection for stone analysis following diagnsois of IBD, as this may help us identify patients at increased risk of stone formation. Early simple intervention like increasing fluid intake may prevent stone formation. Benefits from empiric treatment with potassium citrate are not well known. Further studies need to be done for the better understanding and preventing renal stones formation in patients with active and severe IBD.

SA-PO127

Bilateral Renal Artery Stenosis due to Takayasu Arteritis Complicated by Complete Renal Artery Occlusion with Complete Spontaneous Renal Recovery Saifullah Kazi, Ghulam Akbar, Paul Robbins. *Nephrology, Lankenau Medical Center, Wynnewood, PA.*

Introduction: 53 year old female who had established diagnosis of severe bilateral renal artery stenosis from unknown cause, admitted for elective repair of the aortic root aneurysm and aortic valve replacement for severe aortic regurgitation developing acute renal failure from complete renal artery occlusion post operatively due to ischemic insult followed by spontaneous recovery.

Case Description: 53 year old female with past medical history of multiple CVA and negative embolic workup, presented with syncope at an outside hospital. Workup with echocardiogram revealed severe aortic regurgitation. CT angiogram revealed multiple small ulcerations within the aorta starting from ascending aorta until iliac artery bifurcation with severe stenosis of superior mesenteric artery, celiac artery and bilateral renal arteries. Her serum creatinine was at 0.9 and an ultrasound revealed right and left kidnies size to be at 11.4cm and 9.4cm respectively. Her serologies for vasculitis were negative. She underwent elective repair of the aortic root and aortic valve. Immediately in post operative period, patient became anuric due to complete occlusion of the right renal artery based on CT angiogram. She was taken to catheterization laboratory with unsuccessful attempt to open right renal artery. She was started on hemodialysis next day. A week later, reattempt to open right renal artery was again unsuccessful. She was placed on prednisone as her biopsy revealed Takayasu Arteritis. After 2 weeks into her course, patient started to have spontaneous recovery with renal function and she was taken off the hemodialysis.

Discussion: Renal artery stenosis as a manifestation of systemic vasculitis is rare. With an aggressive surgical approach, combined with glucocorticoid therapy, mortality due to Takayasu arteritis is less than 10%. In our patient, it is most likely that slow progression of renal artery stenosis occurred over time with an acute embolic occlusion postoperatively. However, her best functioning kidney on right side likely had spontaneous recovery after ischemia based on renal angiograms and potential benefit of steroids by reducing inflammation.

SA-PO128

A Case of Kidney Dysfunction and Visual Loss Patrick Kosciuk,[1] Muhammad Sohaib Karim,[1] Micah R. Chan,[1] Anthony Krentz.[2] *[1]Div of Nephrology, Univ of Wisconsin School of Medicine and Public Health; [2]PreventionGenetics.*

Introduction: Senior-Loken syndrome is a rare hereditary nephronophthisis (ophthorenal syndrome) often presenting with autosomal recessive inheritance, a reduction in urinary concentrating ability with bland urinary sediment, and chronic tubulointerstitial nephritis with typical progression to end-stage renal disease (ESRD) in individuals younger than 20 years old. It was first described in 1961 by Senior et al., and Loken et al.

Case Description: A 29 year old male and his seeing eye dog presented to the kidney clinic with uncontrolled hypertension, creatinine of 2.6mg/dl and a history of Leber congenital amaurosis since the age of four. Physical exam was unremarkable other than nystagmus and severe visual impairment with 5-degree visual field and 20/300 acuity. Patient was currently pursuing his PhD via braille and did not appear to have any mental impairment. . Family history was remarkable for a healthy sister in her 20s, a paternal uncle who passed away from renal failure in his 20s, and his paternal cousin (son of his deceased uncle) who had been born with hearing loss. Further evaluation was undertaken, which revealed normal electrolytes, unremarkable UA (notably with specific gravity <1.005 and absence of proteinuria, hematuria, leukocyte esterase, nitrates, and pyuria), but findings of minimal proteinuria (urine protein to creatinine ratio of 0.55). A renal ultrasound revealed a 12.4 cm R and 12.6cm L kidney with multiple cysts. Taking into account the history of renal dysfunction, visual impairment and renal cysts, patient was referred to a geneticist. Genetic studies revealed two autosomal recessive heterozygous mutations in the IQCB1 gene. A frameshift mutation was seen in c.424_425 del ITT resulting in premature protein mutation. Another chromosomal mutation was found as a nonsense mutation in IQCB1 as c.1090C>T. This was consistent with a diagnosis of Senior-Loken syndrome.

Discussion: There is no specific treatment for Senior-Loken Syndrome. Uniform progression to ESRD is inevitable, and patients are often good renal transplant candidates as there is no recurrence of the disease.

SA-PO129

Clostridium Difficile Associated Peritonitis in a Patient on Peritoneal Dialysis Dimpu M. Patel, Gaurav Jain. *Nephrology, Univ of Alabama at Birmingham, Birmingham, AL.*

Introduction: Culture negative infectious peritonitis (CNP) is a common and serious complication in peritoneal dialysis (PD) patients. It is usually a result of samples failing to reach the threshold of microbiological detection, recent antibiotic exposure, or simply unusual organisms not routinely tested for. Clostridium difficile (C. diff) infections have become more frequent, and more refractory to treatment, and dialysis patients are often affected by C diff secondary to repeated exposure to antibiotics, as well as hospitalizations. C diff infection should be considered in the differential for CNP in dialysis patients.

Case Description: A 41 AA male on PD since 2012 presented to PD unit with complaints of abdominal pain and cloudy fluid. He was started on intraperitoneal antibiotics (Vancomycin and Ceftazidime) as an outpatient, though his symptoms of abdominal pain worsened requiring a hospital admission within 48 hrs of onset of symptoms. He complained of non-bloody diarrhea for 12 hrs on the day of admission. On exam, he was diffusely tender in his abdomen, with no guarding/rigidity. Lab data was significant for peritoneal fluid WBC count of 7,130 with 85% polys and he was continued on broad-spectrum IV antibiotics. Stool C diff toxin resulted positive on day 2 of hospitalization and he was started on IV metronidazole. His abdominal pain persisted, and a recheck of PD fluid cell counts on Day 3 revealed a WBC count of 17,671 with 79% polys. The PD fluid cultures from the PD unit as well as the hospital were negative for any growth. Microbiology lab was asked to check his PD fluid for C diff, and the C diff PCR from the PD fluid was positive. The vancomycin and ceftazidime were stopped, and oral vancomycin added to the metronidazole. His abdominal pain and diarrhea both improved and he was discharged to complete a 14 day course of PO metronidazole and vancomycin.

Discussion: Our case study describes culture negative peritonitis in a patient with C diff diarrhea that did not respond to broad spectrum IV antibiotics. This prompted further investigation of C. difficile peritonitis that was confirmed on lab testing. This case highlights the importance of suspecting C diff peritonitis in PD patients with CNP.

SA-PO130

Adequacy of Australian Nephrology Training Nicholas A. Gray,[1] Thomas Joseph Beaton,[1] Rathika Krishnasamy,[1] Nigel David Toussaint,[3] Richard K.S Phoon.[2] *[1]Renal Unit, Sunshine Coast Hospital and Health Service, Nambour, Queensland, Australia; [2]Renal Unit, Westmead Hospital, Westmead, New South Wales, Australia; [3]Renal Unit, Royal Melbourne Hospital, Parkville, Victoria, Australia.*

Background: There has been an increase in the number of doctors training in nephrology in Australia. This study aimed to assess the adequacy of nephrology training by measuring self-determined competency and skill relevance among recently graduated nephrologists.

Methods: A survey was developed by the Nephrology Advanced Training Committee of the Royal Australasian College of Physicians. The survey was administered on-line in 2015 via the annual subscription to the Australian and New Zealand Society of Nephrology. Nephrologists who were awarded Fellowship after 2002 were invited to participate.

Results: 113 of a 306 eligible Fellows (37%) completed the survey. 8 respondents had trained overseas and were excluded. Median age was 41 years (interquartile range 37-44) and 63% were male. Medical school was completed in Australia (59%), India (15%), and New Zealand (7%). 35% received at least some training in a rural area and 25% were qualified in another specialty (mainly internal medicine). 56% had completed and 21% commenced a higher degree. Higher degrees were undertaken for career development (43%) and desire for a research career (30%). Respondents indicated good training and competency in most clinical skills that were relevant to their practice. Training in home hemodialysis (37%) and living kidney donor assessment (51%) were considered less adequate, despite these areas being considered very relevant to practice. There was a greater mismatch identified between training and importance of skills for management and research. This included inadequate training in managing complaints (82%), managing a private practice (98%), health system knowledge (86%) and regulations (93%), medical directorship (94%), ethics approval (76%), research funding (88%), and quality assurance (73%).

Conclusions: Nephrology training in Australia meets the clinical needs of new specialists. Similar to findings in USA, training in management and research was considered insufficient for the practices of new specialists and should be addressed in updates of the curriculum.

SA-PO131

Pediatric Nephrology Workforce and Training: An International Perspective Dorey A. Glenn,[1] Adam R. Weinstein,[2] Maria E. Ferris.[3] *[1]Univ of North Carolina at Chapel Hill; [2]Dartmouth Hitchcock Medical Center; [3]Univ of North Carolina at Chapel Hill.*

Background: There is a shortage of pediatric nephrology providers in a number of areas around the world. We sought to determine pediatric nephrologists' perspectives on this issue.

Methods: A voluntary web-based survey was deployed via the Qualtrics™ survey engine. Members of the International Pediatric Nephrology Association responded anonymously to questions about their geographic location, time spent on training, practice setting, and impressions on local workforce challenges and opportunities.

Results: The number of responses to date was 38, representing 21 countries from all continents. Six percent of the respondents treat both children and adults. The number of years required to train in pediatric nephrology was reported as: 2 years (35%), 3 years (58%) and 4 years (8%). Nearly 80% of practices were associated with academic settings. Sub-specialty training programs are reported in 63% of the respondents' institutions and 50% of those with training programs stated that it was difficult or very difficult to recruit trainees. Forty two percent of the respondents stated that it was difficult or very difficult to find a job after training. The themes most frequently cited on qualitative analysis include low availability and interest in the field by trainees, poor compensation, demanding schedule and competing family demands.

Conclusions: In this preliminary study of an international cohort of pediatric nephrologists, our data suggests a perception of a decreased pediatric nephrology workforce. There is also a perceived shortage of available positions in the field. Further data collection on workforce issues as it pertains to country-related factors is needed.

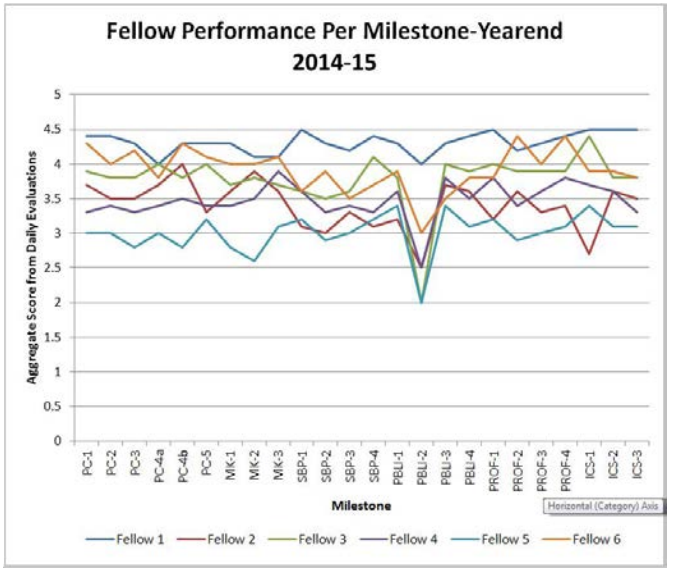
SA-PO132

Take Guessing Out of Milestone Ratings – Simplify the Evaluation System to Easily Achieve the Next Accreditation System (NAS) Report Samantha J. Thompson, Laura J. Maursetter. *Div of Nephrology, Univ of Wisconsin School of Medicine and Public Health, Madison, WI.*

Background: In an effort to translate into competency-based training, the ACGME has developed 24 milestones specific to fellowship. While the milestones are comprehensive, it is challenging to determine an individual's rating through faculty evaluations; many of whom are untrained in this system. We aimed to create a simple scoring system that translates the milestones into observable nephrology activities that can be completed daily on a handheld device.

Methods: For each nephrology rotation, a list of 5-10 frequent activities was developed. For every activity, a description for the five levels of competency was written to standardize the score. The activities were mapped to 1-4 NAS milestones. The evaluations were built in Google Forms and delivered daily to supervising faculty members. Using a four-click system, the observer can submit a fellow evaluation with most done on mobile devices. If faculty members wish to express a narrative, a free-text response box is provided for comments.

Results: Of the 914 possible evaluations over a nine-month period of time 727 evaluations were returned. This provided data points to distinguish scores among all fellows in all of the NAS milestones.



In Clinical Competency Committee meetings thus far, 1 of 276 scores have been adjusted from the scores provided by the evaluation system.

Conclusions: This is an easy to use scoring system that has resulted in immediate feedback that is activity-specific and feed into NAS milestones easily and effectively. By translating the evaluation system into specific activities that any nephrologist can observe, a robust amount of valuable data has been obtained. The 4-click system has yielded an excellent response rate with more narrative comments than were previously obtained with monthly evaluations.

SA-PO133

American Society of Nephrology In-Training Exam for Fellows 2010-2014: Scoring and Item Statistics Suzanne M. Norby,[1] Troy J. Plumb,[2] Nancy Day Adams,[3] Ryan Russell,[4] Mitchell H. Rosner,[5] Mark G. Parker.[6] *[1]Mayo Clinic; [2]Univ of Nebraska Medical Center; [3]Univ of Connecticut Health Center; [4]American Society of Nephrology; [5]Univ of Virginia School of Medicine; [6]Maine Medical Center.*

Background: Since 2009, the American Society of Nephrology (ASN) In-Training Exam (ITE) has been administered annually to fellows. This study reports 2010-2014 overall scale scores, item difficulty, item discrimination, and reliability.

Methods: ITE annual reports provided by the National Board of Medical Examiners were reviewed and summarized.

Results: Scale score for all was 480±104 (mean ± SD); 1st-year fellows (Y1, n=2,020) 445±96, 2nd-year (Y2, n=2,005) 515±100, and 3rd-year and higher (n=112) 509±113. Standard error of the mean ranged 41-45. The 2010 ITE had 150 core items only. 2011 and 2012 ITE had separate 20-item urinalysis and renal pathology modules administered to Y1 and Y2 respectively (not included in total test statistics). In 2013 and 2014, all completed two 10-item modules on these topics (included in statistics). A mean of 6.6 core items (4.4%) were deleted per year after adjudicating items with high difficulty or negative discrimination. Content areas aligned with American Board of Internal Medicine Certification Exam: General Aspects of Chronic Kidney Disease (CKD), Glomerular/Vascular (G/V), Tubulointerstitial/Cystic (TI/C), Acute Renal Failure/ICU Nephrology (ARF/ICU), Kidney Transplant, Hypertension, Sodium/Water (Na/H_20), Acid-Base/Potassium (A-B/K), Mineral Metabolism (MM), and Clinical Pharmacology (CP), plus Ethics. Though examinee abilities typically vary yearly, overall total test average p value was 0.67. ARF/ICU, Na/H_20, MM, and CP tended to be less difficult (average p value 0.7) and TI/C more difficult (average p value 0.58). Total test mean item discrimination biserial correlation averaged 0.21, highest for A-B/K (0.28) and lowest for CKD (0.18). Total test reliability (α) averaged 0.81; highest for G/V (0.46) and lowest for TI/C (0.25).

Conclusions: As expected, scale scores were higher for Y2 than Y1 fellows. Over 95% of administered items were scored; among those, mean item difficulty, item discrimination, and reliability varied among content areas.

Funding: Private Foundation Support

What Are We Doing? A Survey of U.S. Nephrology Fellowship Program Directors Scott E. Liebman, Mahrukh Rizvi, Catherine A. Moore, Rebeca D. Monk. *Medicine- Nephrology Div, Univ of Rochester, Rochester, NY.*

Background: Recent years have seen a decrease in Nephrology fellowship applicants. Long work hours may be partially responsible, and may affect the educational mission of the fellowship. Our survey addresses fellow work load and educational experiences to further explore these issues.

Methods: We distributed a survey for nephrology program directors via the Training Program Directors' website. The survey addressed fellows' service load and the scope of educational activities offered by the fellowship.

Results: 57 out of 147 programs responded (39%). Most are 2 years long, with a mean of 7 fellows, and are "front loaded"- 64% require ≥ 7 months of inpatient service during year one. Inpatient services are usually (93%) covered by one fellow with significant resident involvement. NP's and PA's help cover about 15% of services. The busiest services have about 21-25 patients, although 13% of programs averaged ≥ 26 patients. At their busiest, these services have more than 30 patients, occasionally surpassing 50 patients. About one quarter of programs cap the number of patients and/or notes for which a fellow is responsible. Night call is most often divided equally among all years. Weeknight call is typically one night at time (74%) covering a single hospital (66%). Fellows in the call rotation typically cover ≥ 10 nights over a three month period and ≥ 1 week-end a month. Most fellows do one weekly half day clinic, averaging 4-6 patients per session with a faculty: fellow ratio typically £2:1. Clinic structure is not usually modified during fellows' inpatient service. Longitudinal coverage of HD and PD patients is provided by 82% and 61% of program respectively. Educational conferences ranged from 2-6 hours per week. Faculty didactic teaching varies from < 1 hour a week to 5 hours per week; one hour is typical. Fellows usually give 2-6 formal presentations yearly, although in some programs this is significantly more.

Conclusions: Our survey underscores the large variety in work load, practice patterns and frequency of educational conferences at different institutions and provides a framework to help address the service/education balance during nephrology fellowship.

SA-PO135

Perceptions of Nephrology Among Internal Medicine Residents Michael N. Daniels,[1] Ivan E. Porter,[2] Nabeel Aslam,[2] Deepika Jain,[1] Charity Curtis,[3] Hope Kincaid,[3] Sharon E. Maynard.[1] *[1]Div of Nephrology, Lehigh Valley Health Network/ Univ of South Florida, Allentown, PA; [2]Div of Nephrology and Hypertension, Mayo Clinic College of Medicine, Jacksonville, FL; [3]Network Office of Research and Innovation, Lehigh Valley Health Network/ Univ of South Florida, Allentown, PA.*

Background: As interest in nephrology declines, we sought to identify factors influencing career interest among internal medicine (IM) residents.

Methods: This is a repeated cross-sectional survey of IM residents to assess perceptions of nephrology and the impact of these perceptions on career decisions. All categorical internal medicine residents at two institutions were invited to participate in 2012, prior to the initiation of a nephrology fellowship program (Group 1); and in 2015, three years following initiation of a nephrology fellowship program (Group 2).

Results: 131 of 156 residents (84.0%) completed the survey. A total of 14.8% (19/131) of residents indicated an interest in a nephrology career, with 6.25% (8/131) indicating Nephrology as their first choice. Cardiology (21.1%) and Hospitalist (12.5%) were the most popular career choices. The presence of a Nephrology Fellowship program did not increase resident career interest in nephrology (14.5% in Group 1 vs. 15.1% in Group 2). Residents' perceptions of nephrology were not significantly different in Group 1 vs. Group 2. Negative perceptions of nephrology most commonly endorsed by residents were: renal pathophysiology is too complex (22.9%), poor preparation in medical school (22.14%), few opportunities for procedures (26.7%), long work hours (24.4%), and long hours/burdensome call for nephrology fellows (27.5%). The majority of residents (83.2%) reported exposure to positive role models in nephrology. Experiences cited as having a high impact on career choice included: mentors/role models in the field (71.65% of residents) and rotations during residency (57.14%).

Conclusions: The presence of a nephrology fellowship program had no effect on IM residents' interest in nephrology careers. Residents endorsed several negative perceptions of nephrology which may affect career choice.

SA-PO136

Insight into the Declining Interest in Nephrology Sherry Mansour, Yeunjung Kim, Mark A. Perazella. *Nephrology, Yale School of Medicine, New Haven, CT.*

Background: The decline of interest in nephrology is very concerning with an increasing number of unfilled fellowship spots every year. Identifying the reasons behind such decline is crucial to reverse this trend and preserve the future nephrology workforce. Several surveys have attempted to isolate this problem but none targeted US IM residents. We present the results of a survey targeting IM residents.

Methods: A web-based survey was conducted using survey monkey. 10 questions designed to help understand the reasons behind the decline of interest in nephrology were utilized. The survey link along with recruitment letter and consent form were sent to all US IM residency programs. Email addresses were obtained from the Alliance for Academic Internal Medicine website.

Results: 531 residents responded to the survey. 81% of those who completed the survey answered "**No**" to the question asking if they had interest in nephrology. The most common reason cited was a disheartening patient population, followed by salary, work hours & lack of understanding. 50.9% found nephrology "**difficult"** with the most challenging topics being glomerulonephritis (GN), acid/base & transplant. The respondents noted that exposure to interventional nephrology; transplant & GN might increase their nephrology interest. Of those interested, more exposure to GNs during residency was felt to likely reinforce their interest.

Conclusions: These survey results demonstrate that most IM residents aren't interested in nephrology and that restructuring of nephrology electives in residency programs to include enhanced exposure to GNs, transplant, and nephrology procedures might increase interest. Nephrology rotations are primarily an inpatient experience with exposure to critically ill AKI patients or complicated ESRD patients with significant recidivism. This experience leads to the perception that the nephrology population is disheartening. Since this is the most common reason why residents lack interest, changing the structure of nephrology electives in IM residencies to allow for more outpatient exposure with emphasis on GNs and transplant might be crucial for enhancing interest in nephrology fellowship training and a career in this subspecialty.

SA-PO137

Challenges and Opportunities in the Training and Retaining of Nephrology Workforce in Developing Countries: A Review of the Current Trends and Implications for Optimal Kidney Disease Care Julius Oluoch Okel,[1] Bilal Qarni,[1] Timothy Olusegun Olanrewaju,[2] Aminu K. Bello.[1] *[1]Univ of Alberta, Canada; [2]Univ of Ilorin, Nigeria.*

Background: Nephrology education has undergone rapid advancement leading to the development of comprehensive curricula and standards towards a high quality patient-centered care. These standards are often lacking on issues critical to the practice of nephrology in developing countries.

Methods: We evaluated nephrology training programs within the context of the healthcare systems across 25 upper-middle and high income countries to identify best practices and opportunities for adoption in developing nations. We further reviewed training guidelines from the major professional societies (ISN, major national societies) on content and process of training. Data were obtained from multiple sources (government reports, published literature, and websites of professional/licensing authorities, World Federation for Medical Education (WFME) and its Regional branches. The WFME 3-set of Global Standards on medical education at all levels were applied in evaluating training programs on the domains of training process, assessment, and evaluation.

Results: We found 5 key thematic problems with the current training model in developing countries that included 1)an emphasis on factual information, memory and recall (core knowledge content), 2) absence of needs assessment and evaluation, 3)structure and organization of training is a product of established tradition than of evidence and not in congruent with health system changes and dynamics, 4) a didactic and opportunistic instructional model with other core areas of competencies (professionalism, collaboration, advocacy, managerial skills and of scholarship are not formally taught, and 5) application of summative rather than formative assessment methods.

Conclusions: There are similarities and differences in structure, content and process of training programs across both developed and developing countries. The results have implications for re-design of training programs in the developing world for quality education and better clinical care delivery in patients with kidney diseases addressing local needs and priorities.

SA-PO138

Creating and Enhancing Interest in Nephrology Careers: A Novel Nephrology Elective Experience for Medical Students Hitesh H. Shah, Kenar D. Jhaveri. *Nephrology, Hofstra North Shore-LIJ School of Medicine, Great Neck, NY.*

Background: Interest in nephrology careers continues to decline in the United States (US). The type of nephrology elective that US medical students experience may play an important role in creating and enhancing interest in nephrology careers.

Methods: At our institution, we created a novel 4-week nephrology elective experience for medical students. Our redesigned elective included both 2-week inpatient (IP) and 2-week outpatient (OP) nephrology experiences. The OP rotation included 10 half-days of various nephrology clinic experiences, 2 half-days of immediate post-transplant clinic, 1 half-day of kidney donor evaluation clinic, 2 half-days of peritoneal dialysis clinic and 3 half-days of outpatient hemodialysis unit rounding. The redesigned elective also included education conferences. From 7/2012 to 2/2015, nine 4th year medical students (all from different US medical schools) completed our redesigned nephrology elective. To evaluate the novel elective experience, all medical students were asked to complete an anonymous on-line survey upon completion of their rotation.

Results: All students responded to our survey. All reported adequate OP nephrology exposure during their elective. 89% had worked with 1 or 2 faculty members during the IP setting. In comparison, 78% were exposed to at least 4 different faculty members during the OP experiences. All students had interacted with at least 3 fellows. All reported that the elective experience enhanced their exposure and knowledge in nephrology and that they would recommend this elective to other medical students. They also thought that this elective structure provided them with a better insight into what nephrologists do in practice. 78% reported that this elective experience created an interest in nephrology career. 56% responded that they would consider nephrology as one of their 3 top career choices as a result of this elective experience.

Conclusions: We believe that the restructured nephrology elective provides the medical student with a much needed and realistic exposure to nephrology careers. Based on our experience, we recommend all training programs to consider this elective structure for medical students.

SA-PO139

Journal Publication of Nephrology Fellows Case Report Presentations at ASN Kidney Week 2012-2013 Hitesh H. Shah,[1] Nairuti H. Shah,[2] Rushang Parikh,[3] Kenar D. Jhaveri.[1] *[1]Nephrology, Hofstra North Shore-LIJ School of Medicine, Great Neck, NY; [2]Colgate Univ, NY; [3]SUNY Upstate Medical Univ, NY.*

Background: The inception of the fellows case report (CR) category at the ASN Kidney Week (KW) occurred in the year 2012. However, the number and types of CR abstracts accepted for presentation at ASN KW 2012-2013 is not known. Peer-reviewed journal publication (PR-JP) of these previously presented CR abstracts at ASN KW is also not known.

Methods: All previously accepted fellows CR abstracts from ASN KW 2012-2013 were reviewed and further categorized as follows: glomerular diseases (GN), tubulointerstitial diseases (TIN), acute kidney injury (AKI), fluid-electrolyte and acid-base disorders (FE-AB), dialysis (D), kidney transplant (KT), genetic disorders (GD), mineral diseases (MD), and other (O) cases. To determine the PR-JP rate of these CR abstracts, a literature (PubMed) search was performed in May 2015.

Results: A total of 415 abstracts were presented in the fellows CR category at the ASN KW 2012-2013. Compared to KW 2012, there was a 7.5% increase in CR abstract presentations at KW 2013. Over these previous two KW meetings, nearly one-third (31.6%) were GN related case presentations. The remaining abstracts were FE-AB (15.2%), AKI (14.4%), KT (11.8%), D (11.8%), TIN (5%), MD (4%), O (4%), and GD (2.2%) related presentations. Compared to KW 2012, there was increase in GN related presentations (from 55 to 76) at KW 2013. So far, only 72 (17.3%) out of the 415 abstracts have been published as papers in peer-reviewed journals. One abstract was published as a letter to the editor format. Of those that were published, 31.5% were GN related case reports. Interestingly, 22% of these journal publications did not list the lead author of the KW CR abstract as the primary author of the paper.

Conclusions: Based on our study, it seems that there is an increased interest among fellows to present CR abstracts at ASN KW. Nearly one-third were GN related case presentations. However, so far, less than one-fifth of the fellows CR abstracts presented at KW 2012-13 have been published in peer-reviewed journals. Reasons for this low publication rate is not known. Measures to enhance CR publications need to be considered.

SA-PO140

Analysis of Published Medical Student Related Nephrology Medical Education Research Sarah D. Bayefsky,[1] Hitesh H. Shah,[1,2] Kenar D. Jhaveri.[1,2] *[1]Hofstra NSLIJ School of Medicine; [2]Nephrology, Hofstra NSLIJ School of Medicine.*

Background: Undergraduate (medical student) related medical education research in nephrology is not well studied. This analysis aims to assess the rigor of the studies describing teaching methods used in medical student education in nephrology.

Methods: A review of the English literature on nephrology education of medical students was conducted on two major online academic search engines (PubMed and ERIC). References of the papers discovered in this search were also reviewed. Conference abstracts were not investigated. The empirical studies were categorized by subject within nephrology. The research design of each study was then recorded.

Results: 26 original studies were found in which a method of teaching nephrology to medical students was described. The studies dated from 1977 to 2015. The focus of these teaching experiences was as follows: anatomy (3.3%), physiology (23.3%), pathophysiology (26.7%), pathology(10%), treatment (20%), and general nephrology (16.7%). 4 of the pathophysiology studies were also classified under other categories, so there were 30 total topics. The papers were also categorized into types of assessments, with two papers containing two different types of studies for a total of 28 types of assessment. 14.2% had either no assessment of the educational experience or had a description too vague to categorize it; 3.6% involved a questionnaire about the existing educational approach before a novel method was implemented; 57.1% involved surveys or questionnaires after a practice was carried out; 7.1% assessed the method both before and after; 10.7% were case studies or ethnography; and 7.1% included a randomized controlled trial. The randomized controlled trials involved teaching techniques focused on the pathophysiology of renal disease. Overall, students responded positively to teaching that is interactive.

Conclusions: Rigor is lacking in most studies done in medical student education research in nephrology. Over 50% of the studies done had a survey-based design. More randomized controlled trials are needed to assess reliably the effectiveness of the educational techniques in nephrology medical education research.

SA-PO141

Participation in the Open, Online, Twitter-Based, Nephrology Journal Club, NephJC Joel Topf,[1] Matthew A. Sparks,[3] Edgar V. Lerma,[2] Thomas Oates,[6] Paul J. Phelan,[5] Francesco Iannuzzella,[7] Swapnil Hiremath.[4] *[1]St. John Providence Hospital, Detroit, MI; [2]UIC-Advocate Christ Medical Center, OakLawn, IL; [3]Duke, Durham, NC; [4]Univ of Ottawa, ON, Canada; [5]Royal Infirmary of Edinburgh, United Kingdom; [6]Imperial NHS Trust, London, United Kingdom; [7]Arcispedale Maria Nuova, IRCCS, Reggio Emilia, Italy.*

Background: We established an online nephrology journal club, NephJC, in April 2014 that meets twice monthly to discuss emerging research and clinical practice guidelines. We invite content experts and manuscript authors to the discussion. The meeting occurs on the public forum Twitter, allowing any interested individual to join. The purpose of NephJC is to provide a recurring, academically-minded event on Twitter to help establish this communication channel as one for serious nephrology discourse. In addition, online journal clubs are becoming a critical route for post publication peer review. In order to assess the impact of NephJC we reviewed participation in the discussions over the first year.

Methods: We searched the Symplur analytics database for all tweets with the hashtag #NephJC from March 16, 2014 to June 2, 2015. We measured the numbers of participants, number of tweets and assessed participation over the first 27 NephJC sessions.

Results: From April 29th to June 2nd, 2015, 27 topics were discussed. 27 Chats were at 9PM Eastern for the Americas and starting Dec 18, 2014 a Europe and Africa chat was added at 8PM GMT. 10 GMT chats have been held, generally one day after the American chat. 1,022 Twitter accounts have used the hashtag #NephJC a total of 14,891 times. The median journal club chat has 41.5 (IQR 30.5-56.5) participants and 353.5 (IQR 268.5-633.5) tweets. The number of participants and tweets increased over time ($P<0.01$). The addition of the GMT chat was responsible for some of that growth (median number of tweets increased from 273 to 662.5, $P<0.001$, participants from 35 to 60.5, $P<0.001$).

Conclusions: NephJC has established itself as an integral part of the online digital mentorship curricula. The sustained usage and growth in participation of NephJC demonstrates the positive value of Twitter in medical education.

SA-PO142

Three Years' Experience with the Online Educational Game, NephMadness Joel Topf,[1] Kenar D. Jhaveri,[3] Edgar V. Lerma,[5] Warren L. Kupin,[4] Paul J. Phelan,[6] Matthew A. Sparks.[2] *[1]St. John Providence Hospital, Detroit, MI; [2]Duke, Durham, NC; [3]Hofstra NSLIJ School of Medicine, New York, NY; [4]Univ of Miami Miller School of Medicine, Miami, FL; [5]UIC/ Advocate Christ Medical Center, OakLawn, IL; [6]Royal Infirmary of Edinburgh, United Kingdom.*

Background: NephMadness is an educational project that leverages social media and Free Open Access Medical Education (FOAMed) to highlight advances and important issues in nephrology. NephMadness 2015 was the third year of this project.

Methods: The curriculum takes the form of an online game that mimics the NCAA basketball tournament, March Madness. Participants attempt to predict the winners of hypothetical contests between nephrology concepts. The NephMadness field consists of 64 concepts from 8 different domains of nephrology: cardiorenal, onconephrology, nutrition, obstetrics, infectious disease, vascular surgery, genetics, and critical care. The theme for 2015 was nephrology's interaction with other specialties of medicine. The editorial content was created by a team of nephrologists with experience in social media. Additionally, content experts assisted in building the field (selection committee) and fact-checked the editorial content. A blue ribbon panel of nephrologists determined the winners of each match-up. Engagement in the contest was assessed by participation, website traffic and use of the hashtag #NephMadness on Twitter.

Results: There were 342 entries in NephMadness (25% increase over 2014) representing 26 countries with three quarters from the US. Gender breakdown was 31% female, 69% male. 46% of the contestants were attendings, 24% fellows, 10% residents and 9% medical students. The hashtag #NephMadness was tweeted 4,297 times (190% increase) by 401 people (144% increase) between Jan 16 and June 16. Web traffic to the hosting site was triple its monthly average and included the single highest traffic day ever.

Conclusions: NephMadness is increasing engagement on three unique metrics. We believe this indicates that pairing social media with freely available, expert-generated content can stimulate interest in nephrology.

SA-PO143

Awareness of AKI in Low Resource Settings: A Global Survey Joseph Lunyera,[1] Kajiru Kilonzo,[2] Andrew J.P. Lewington,[3] Karen E. Yeates,[4] Fredric O. Finkelstein.[5] *[1]Duke Univ; [2]KCMC; [3]Leeds Teaching Hospitals; [4]Queen's Univ; [5]Yale Univ.*

Background: The ISN has set a goal of eliminating preventable deaths from AKI by 2025—the "0X25" initiative. However, there is limited awareness of the challenges presented by AKI in terms of diagnosis, treatment and management in low resource settings (LRS).

Methods: We reached out to nephrologists working in LRS using a web-based instrument of 18 questions. Responders were asked what strategies should be considered to increase the awareness of AKI in LRS and recommend approaches to heighten this awareness. 26 respondents were from 5 WHO world regions, including 54% from Africa.

Results: The major barriers to raising awareness cited by all were inadequate training, shortage of adequately trained health workers and lack of awareness of the significance of AKI by healthcare workers, government officials and the general public. Additional factors cited were limited patient access to health facilities, limited diagnostic and treatment facilities, lack of support for AKI programs, lack of clinical practice guidelines for AKI, poor communication systems, limited research funding and lack of linkages of AKI programs to other health projects. Health centers (HCs) were broken down into rural, district and regional HCs. Supplies available for diagnosis (serum creatinine and BUN) and management (IV fluids, antibiotics, anti-venom) of AKI are limited in rural HCs. All noted that hemodialysis services were available but only in selected, large urban centers. Peritoneal dialysis was limited to regional HCs.

Conclusions: Increasing the awareness of AKI in local, district, and regional HCs requires a multi-faceted approach, reaching out to government officials, hospital administrators, physicians, nurses, local health care workers, community leaders, international organizations and the general public. The success of this initiative involves the development of meaningful and targeted educational programs, training materials, and treatment guidelines tailored to the local situations. Alliances will need to be formed with governmental agencies, non-profit organizations and global health programs. Support needs to be provided for additional research programs.

SA-PO144

Acute Kidney Injury Education to Nursing and Assistant Health Care Staff Mansoor N. Ali. *Renal Medicine, Calderdale and Huddersfield Hospitals NHS Foundation Trust, United Kingdom.*

Background: Acute Kidney injury (AKI) is a global healthcare problem. It carries significant mortality and incurs heavy costs to the National Health Service. Extensive work has been done recently both at undergraduate and postgraduate level to ensure front line medical staff have better understanding in managing AKI. One such important area of focus involves the need for training nursing and assistant healthcare staffs who care for patients presenting with AKI.

Purpose of the study: To gauge the understanding of AKI amongst nursing and healthcare assistants working on busy acute medical admissions unit.

Methods: The anonymous questionnaire was aimed at the nursing and assistant health care staff working on the admissions unit at two large district hospitals. The length of time since qualification ranged from few weeks to 16 years. The questionnaire was followed by planned teaching, simulation training and workshop sessions. The process was carried out within a period of 2 months.

Results: The Questionnaire was completed by 50 staff members. It included series of questions aimed at defining and managing AKI from a nursing perspective. 24 out of 50 were able to define AKI. Only 5 out of 50, have never cared for patients with AKI. Not all were aware of the symptoms of AKI; common answers given by 40 respondents were "reduction in urine output" and "dehydration." All participants answered "yes" to monitoring urine output and understood the significance of fluid monitoring but all admitted more needed to be done to ensure accurate documentation in the patient's notes. Other questions asked were if nurses check patient's blood results on the system server to which most replied "no" and if medications were regularly reviewed during drug rounds. Surprisingly, not all were aware of nephrotoxic medications and only 20 respondents would regularly review drug charts in the context of renal failure.

Conclusions: The questionnaire and the training sessions identified lack of better understanding of AKI and its management. There needs to be a stronger emphasis on the introduction of AKI and its management during their training years and development of mandatory online e-learning modules.

SA-PO145

Evaluation and Management of Acute Kidney Injury – A Trainee Survey Savio M. Kumar, Prabhat Singh, Priya S. Srivastava, Adedeji Sodeinde, Charuhas V. Thakar. *Nephrology, Univ of Cincinnati.*

Background: Aki occurs in 1-in-3 hospitalized patients, and majority of those are managed by non-nephrology specialties, including trainees.

Methods: The renal fellowship program designed an online anonymous survey, distributed to trainees (students, residents, fellows), to understand their level of knowledge in recognition and management of AKI. 37 questions were classified into following categories: knowledge of guidelines; prognostic factors; and drug safety. Results are represented as aggregate proportions.

Results: 104 trainees responded to the online survey; 50% were male, 84% US medical graduates and 70% were residents/fellows. 50% were affiliated to medical specialties; and 53% had spent at least one elective in nephrology. In terms of AKI definition: 51% use serum creatinine (SCr) as the most important factor to diagnose AKI, whereas 20% use urine output. Majority (76.1%) agreed that rise of 0.3 mg/dl or 1.5 times of baseline SCr was clinically relevant, in concordance with current guidelines. RIFLE criteria were most commonly used (42%), followed by KDIGO (13%); and 90% agreed that guidelines help in standardization, and management of patients. 85% concurred that AKI impacts short and long-term outcomes, however, majority (60%) felt dialysis requirement was the most important clinical predictor of outcome. Majority (67%) felt that early involvement of nephrology services is helpful in AKI management; 66% sought nephrology input to determine the cause of AKI/co-management, and 7% viewed nephrology role purely for procedural delivery of dialysis. As for drug safety, 89% reported to pay attention to renal function while drug dosing, but 70% felt that this was the responsibility of either pharmacy or ordering team. In terms of follow-up 61% of subjects felt that follow-up was only needed in moderate to severe AKI cases or in non-recovery; 86% preferred that in < 30 days, and 64% preferred that to be with primary care.

Conclusions: Most of the trainees displayed good knowledge of AKI guidelines (RIFLE), seek timely nephrology involvement and view it to be beneficial. More work needs to be done in terms of improving knowledge/practice about drug safety and follow-up care in AKI.

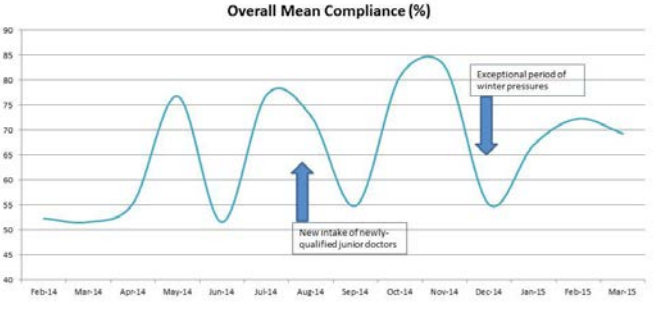
SA-PO146

Adherence to Care Bundles for AKI – Challenges in Supporting Education and Measuring Compliance Melanie Louise Sully, Christopher J. Mulgrew. *Renal Medicine, Royal Devon & Exeter Hospital, Exeter, Devon, United Kingdom.*

Background: AKI typically occurs as a consequence of intercurrent illness in patients with multiple comorbidities and risk factors. The use of clinical guidelines to assist medical and nursing staff in AKI management has been adopted by most secondary care institutions in the UK. We have previously presented our use of e-alerts for AKI as a prompt to improve AKI care (Mulgrew *et al*, ASN, 2013). Clinical guidelines were prompted by the e-alert and widely publicised to staff.

Methods: In a model similar to the NHS Safety Thermometer, snapshots of compliance with 6 key elements of the AKI guidelines on 4 medical wards was measured by identifying patients from AKI e-alerts. These included documentation of AKI, medication review, clinical assessment and ongoing investigation/monitoring. Awareness was supported by an AKI Education nursing team, working with medical and nursing staff. Monthly compliance was assessed over a period of one year.

Results: Mean compliance for all elements of the guidelines improved from 52% to 69% over the year. Significant variability was seen, often associated with notable workforce challenges such as new medical staff or periods of increased activity.



Variability in compliance with individual elements of the care bundle also existed in different clinical areas. Analysis allowed for targeted support and education to clinical teams.

Conclusions: Supporting medical and nursing teams to manage AKI in secondary care in order to prevent progression and treat promptly remains challenging. A number of external factors frequently impact upon adherence to guidelines and support needs to be planned in order to continue to maintain high standards and optimise patient care. The use of a Safety Thermometer, allowing performance to be analysed and comparisons made between clinial areas, may continue to be useful in improving performance and patient outcomes in AKI.

SA-PO147

Internal Medicine Residents Knowledge of Vein Preservation in Chronic Kidney Disease Patients Sandesh Joshi, Jamie Alton Green, Maria C. Bermudez. *Nephrology, Geisinger Medical Center, Danville, PA.*

Background: Vein preservation is important among CKD patients for future arteriovenous fistula potential. House staff plays critical role in managing these patient population and preserving their vein for future arteriovenous fistula. Their knowledge and current practices directly affects the outcome for vein preservation among these patients.

Methods: We conducted a survey among 44 internal medicine residents to understand their baseline knowledge and current practices regarding vein preservation. The survey was conducted at Geisinger Medical center, Danville,PA.

Results: 44 residents were included in the survey. Only 6.8% (3) were able to correctly identify patient population, on whom we should avoid particular arm for IV draws, BP measurements, peripherally access or peripherally inserted central catheters. Two-third (27) answered non-dominant arm to avoid for these procedure and 13.5% (6) responded side does not matter. 81.8 %(36) answered that nephrology should be consulted prior to peripherally inserted central catheters placement for CKD 4 patient. 93.1 %(41) answered

correctly that peripherally inserted central catheters can damage peripheral veins .52 %(23) knew alternative of PICC line was tunneled internal jugular catheter, however 34 %(15) answered tunneled subclavian catheter as an alternative. 55 %(24) did not know preferred site for peripheral access, blood draws. 63 %(28) has never written orders for nurse to request to avoid particular arm for IV draws, BP measurements in advanced CKD patients or patients on HD, 90%(31) have never requested a bedside sign to avoid particular arm for these patients.

Conclusions: Baseline knowledge was poor regarding vein preservation in CKD patients and very few residents have engaged in practices to preserve veins. More resident education is needed to engage them in vein preservation for CKD patients.

SA-PO148

Vascular Access and Transplant Referral Rates in CKD: An Ongoing Performance Improvement Project for Nephrology Fellows Nardos Belayneh, Anuj Regmi, Jusmin Patel, Divakar Jammalamadaka, Elias Ugwu, Noble Iwuagwu, John Jason White, N. Stanley Nahman, Lu Y. Huber. *Medicine, Georgia Regents Univ.*

Background: Referral for vascular access (Ac) and kidney transplantation (Tx) are important management facets of CKD. We previously conducted a performance improvement project assessing Ac and Tx referral rates (RR) in CKD patients from the Nephrology fellows' clinics. Following an educational intervention, there was an improvement in transplant RR (JASN 25:786A, 2014). To evaluate the sustainability of this initiative, we conducted a follow-up analysis.

Methods: This performance improvement project was conducted in 3 phases at the Charlie Norwood VAMC; Phase 1 (baseline, 1/1-4/30, 2013), Phase 2 (post-intervention, 8/1-11/30, 2013) and Phase 3 (follow-up, 1/1- 4/30, 2015). Data extraction was conducted by three, 2-fellow teams, each reviewing the other's RR for all patients seen in the previous 4-month period. The analysis was sorted by eGFR (ml/min/1.73m2): for eGFR<15, both Ac and Tx RR were recorded. In addition, Tx RR for eGFR 15-20 was documented.

Results: 1114 total records were reviewed (349, 361, and 404 for Phases 1, 2 and 3, respectively). Table 1 indicates the number of patients and RR in those with GFR<20. RR for Ac through all 3 phases were steady at 72-73%. Tx RR were improved after intervention and were sustained in Phase 3.

Table 1. Referral in patients with GFR <20 in different study phases. Results presented as number of patients (%)

	Phase 1		Phase 2		Phase 3	
	GFR 15-20	GFR<15	GFR 15-20	GFR<15	GFR 15-20	GFR<15
N	79	36	30	22	18	29
Transplant referral	9 (11%)	18 (50%)	11 (37%)	15 (67%)	8 (44%)	19 (66%)
Vascular Access referral	-	26 (72%)	-	16 (73%)	-	21 (72%)

Conclusions: Referral rates for kidney transplantation by Nephrology fellows improved after a chart review and educational intervention were performed. Vascular access referrals from this study remained stable. This work suggests that outpatient performance improvement projects conducted by Nephrology fellows confer peer review accountability for outpatient practice habits, heightens trainee awareness of key referral issues, and appears to help sustain or improve referral rates for vascular access and kidney transplantation.

SA-PO149

Impact of Standardized Electronic Documentation in an Academic Nephrology Setting Leslie P. Wong,[1] Emilio D. Poggio.[1,2] *[1]Nephrology and Hypertension, Cleveland Clinic, Cleveland, OH; [2]Transplant Center, Cleveland Clinic, Cleveland, OH.*

Background: Reimbursement depends on documentation and billing based on complexity of care. Academic nephrologists are under pressure to improve productivity measured by revenue and relative-value based units (RVUs). Incorrect documentation or billing may result in loss of revenue and RVUs despite services having been provided. Standardized electronic templates were introduced in an academic nephrology setting to help address this issue.

Methods: Standardized templates based on Medicare 1997 Guidelines were introduced in July 2014 for all inpatient nephrology encounters. A training presentation was provided to teach nephrologists proper use of the templates. 73,314 inpatient charges submitted by 22 academic nephrologists between January 2012 and March 2015 were reviewed. Data included the current procedural terminology (CPT) code specifying the type of service, the identity of the nephrologist and any adjustments made by the coding department. Adjusted charges were accompanied by the reason for adjustment, the corrected CPT code and a revenue change based upon Medicare reimbursement. RVUs were calculated using the Medicare National Physician Fee Schedule.

Results: Before July 2014, 6.2% of charges were adjusted compared to only 2.8% after July 2014. The mean work RVU loss per adjustment decreased from 1.15 to 1.00 ($p<0.01$). The mean revenue loss per adjustment improved from $270.88 to $229.56 ($p<0.01$). Multivariate regression identified factors associated with worse productivity adjustments: encounters before July 2014, more than 10 years of academic experience and transplant nephrology (all p-values <0.01). Factors associated with improvement in adjustments were encounters after July 2014, ICU encounters and less than 10 years of academic experience (all p-values <0.01).

Conclusions: Standardized templates led to significant reductions in revenue/work RVU losses per encounter at a large academic nephrology center. Nephrologists with more than 10 years of academic experience and transplant nephrologists performed worse than their peers. Efforts to improve documentation and billing may have important implications for academic nephrologists.

SA-PO150

Nephrology Documentation and Billing Educational Needs at an Academic Medical Center Leslie P. Wong,[1] Emilio D. Poggio.[1,2] *[1]Nephrology and Hypertension, Cleveland Clinic, Cleveland, OH; [2]Transplant Center, Cleveland Clinic, Cleveland, OH.*

Background: Reimbursement in nephrology depends on accurate documentation and billing. Academic nephrologists are under increasing pressure to meet financial productivity targets. An analysis of nephrology reimbursement was performed at an academic medical center to find deficiencies and identify targets for education.

Methods: 75,097 inpatient nephrology encounters by 22 nephrologists from January 2012 and March 2015 were reviewed. Data included the current procedural terminology (CPT) code specifying the type of service and any charge adjustments made by the coding department. Adjusted charges were accompanied by the reason for adjustment, the corrected CPT code and a gross revenue adjustment based upon Medicare reimbursement. Relative value units (RVUs) were calculated using the Medicare National Physician Fee Schedule. Multivariate regression analysis was performed to identify factors associated with RVU adjustments.

Results: 5615 (7.5%) of encounters were adjusted by coders. 3832 (68%) were due to incorrect documentation or billing and 1683 (32%) were due to services performed but not billed by nephrologists. For submitted charges, revenue was reduced by $995,976 and 4227 work RVUs as a result of incorrect documentation or billing. The potential loss of revenue from unbilled services was $693,014 and 2823 work RVUs. Inadequate documentation of physical exam ($p=0.01$) and inadequate documentation of supervision of medical students/residents/fellows ($p<0.01$) were independently associated with RVU adjustments. Incorrect charge selection, duplicate charges, competing charges from another nephrologist and conflicting discharge/observation/post-operative care CPTs were also independently associated with RVU adjustments ($p<0.01$).

Conclusions: There was a substantial loss in gross revenue and work RVUs due to incorrect documentation and billing in an academic nephrology setting. These reductions in reimbursement and productivity might be avoided through better physician education and training. Specific targets include documentation of physical exam and supervision of trainees, correct CPT charge selection and ensuring all services performed are billed.

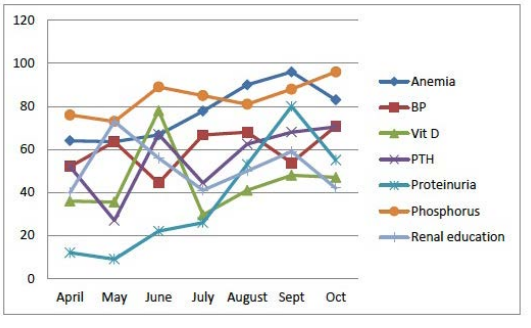
SA-PO151

Reaching Renal Goals – A Quality Improvement Project Mihran V. Naljayan, Oksana I. Nimkevych, Vecheslav Fedorchenco, Sara Jacob Coulon, Kimberly Cox Fremin, Zohayr M. Al Shaial. *Medicine, LSUHSC School of Medicine, New Orleans, LA.*

Background: The purpose of this study was to improve our patient care in a renal clinic at a large university hospital by using three of the core competencies- patient care, systems based practice, and practice based learning and improvement.

Methods: A check-out sheet was developed and given to all trainees in the nephrology clinic. Data was collected for 174 visits over 6 months. Data include age, gender, eGFR, and CKD stage. Each patient's blood pressure, hemoglobin, phosphorus, Vitamin D, PTH, bicarbonate, and the extent of renal replacement therapy planning were acquired and further analyzed to determine whether nephrology goals were met based on KDOQI/ KDIGO guidelines.

Results: Achievements in goals for CKD 3-5 as per KDIGO/KDOQI guidelines based on a percentage value of the patients seen each month. Data are from April to October. Hemoglobin of >10 g/dL were met in 64%, 64%, 67%, 78&, 90%, 96% and 83%, respectively. Blood pressure of <140/90 mmHg (or <130/80) were met in 52%, 64%, 45%, 67%, 68%, 54% and 71%, respectively. Vitamin D of ³30 ng/mL were met in 36%, 36%, 78%, 30%, 41%, 48% and 47%, respectively. PTH of ≤ 150 were met in 52%, 27%, 67%, 44%, 63%, 68% and 71%, respectively. Proteinuria (<300 mg/day) were met in 12%, 9%, 22%, 26%, 53%, 80%, and 55%. Phosphorus of ≤ 5.5 mg/dL were met in 76%, 73%, 89%, 85%, 81%, 88% and 96%, respectively. Attending renal education classes were met in 40%, 73%, 56%, 41%, 50%, 59% and 42% respectively.



Conclusions: Our project was helpful in educating trainees in the treatment goals and guidelines for patients in the renal clinic and standardized an approach to patient care. Overall, the results show a trend towards improvement in all goal areas except for renal education. This study did not account for patients who were new to our clinic and therefore had never received renal education previously.

SA-PO152

A Simulation Exercise to Assess Renal Replacement Therapy and Kidney Biopsy Communication Skills Lisa K. Prince,[1] Maura A. Watson,[1] Anna M. Howle,[2] Christina M. Yuan.[1] *[1]Nephrology, Walter Reed National Military Medical Center, Bethesda, MD; [2]Medical Simulation, Walter Reed National Military Medical Center, Bethesda, MD.*

Background: We piloted a nephrology-specific "Breaking Bad News" simulation to assess Interpersonal Communication Skills and Professionalism during renal replacement therapy (RRT) and kidney biopsy (Bx) counseling. Assessment tools were a 9-point Likert Mini-Clinical Examination Exercise (Mini-CEX) adapted for RRT and Bx counseling, and the Essential Elements of Communication-Global Rating Scale 2005 (EEC-GRS).

Methods: There were three cases: 1) a middle-aged woman with polycystic kidney disease and CKD5, 2) a critically-ill elderly man with AKI whose wife was his surrogate decision maker, and 3) a previously healthy soldier with nephrotic syndrome. There were 5 nephrology fellow examinees. One patient actor performed for each case, assessing each examinee with the EEC-GRS. One faculty assessed all examinees for one case using the EEC-GRS and mini-CEX. Encounters lasted 15 minutes, followed by 5 minutes for examinee counseling by the actor and faculty.

Results: Post-simulation, 3/3 faculty surveyed felt that the exercise met objectives, and was an excellent assessment tool. 4/5 examinees felt the exercise was "good" and met objectives. 5/5 felt that simulation time was too short to assess communication skills. 2/5 felt that a mini-CEX assessing a real patient encounter was superior. Median examinee EEC-GRS performance assessed by actors and faculty was 4 (range 3-5). Median mini-CEX performance was 6 (range 5-9).

Conclusions: Based on feedback, the original mini-CEX was too detailed for a 15-minute encounter, and was simplified. Instructions now stress that, because of encounter brevity, counseling is unlikely to be completed, and completion is not required for satisfactory grading. A second set of scenarios was developed to permit a yearly simulation in a two-year cycle. We plan to test the revised simulation in a larger group of nephrology fellows within the next year. *The views expressed are those of the authors and do not reflect the official policy of the Department of the Army, the Department of the Navy, the Department of Defense or the United States Government.*

Funding: Other U.S. Government Support

SA-PO153

Implementation of KDIGO CKD Guidelines Leads to Decreased Diagnosis of CKD Heather M. Mascio, Deepti S. Moon, Ryan J. Altenburg, Lisa K. Prince, Dustin J. Little. *Nephrology Service, Walter Reed National Military Medical Center, Bethesda, MD.*

Background: Estimated glomerular filtration rate (eGFR) is used to diagnose and classify CKD.The accuracy of creatinine-based eGFR(eGFR-Creat)is inferior to eGFR calculated using multiple renal filtration markers. CKD guidelines suggest using serum creatinine and serum cystatin C to evaluate for CKD in select patients, but methods for, and results of guideline implementation have not been reported.

Methods: We reviewed new patient nephrology clinic encounters for a three month period to establish baseline guideline adherence. Combined creatinine/cystatin CeGFR(eGFR-CreatCysC)was considered indicated in patients with eGFR-Creat 45-59ml/min/1.73m2 and no albuminuria,urine sediment abnormalities, or other markers of kidney damage. Consultation review was modified such that a nephrologist reviewed every referral request,with the option of ordering labs to be obtained prior to a clinic visit. During a six-month implementation period, guideline awareness was targeted via didactics, signs posted in exam rooms, and "cystatin C–just check it" t-shirts. Seven months of charts were reviewed following the intervention period, and pre and post-intervention adherence was compared using Fisher's exact test. Patients with eGFR-CreatCysC≥ 60mL/min/1.73m2 were considered to have no evidence of CKD. Inpatients for whom eGFR-CreatCysC was obtained,mean eGFR-Creat and eGFR-CreatCysC were compared using paired t test.

Results: Guideline adherence was significantly higher in the post-intervention compared to the pre-intervention period (testing obtained in 30 of 40 (75%) vs.12 of 32 (37.5%)indicated cases; p =0.002).Mean eGFR-CreatCysC was significantly higher than eGFR-Creat (77.3± 15.3vs.58.3 ±9.1mL/min/1.73m2; p<0.001). eGFR-CreatCysC was ≥60mL/min/1.73m2 in85.3% of cases.

Conclusions: By modifying our consult review process and raising awareness among nephrology providers, we significantly increased implementation of eGFR-CreatCysC guidelines and determined that the vast majority of tested patients had no evidence of CKD. Our results suggest testing as suggested in the guidelines has the potential to markedly decrease the number of inaccurate CKD diagnoses.

SA-PO154

Improving Pathology Curriculum for Nephrology Fellows Enrica Fung,[1] Orlando Camacho,[1] Michelle M. O'Shaughnessy,[1] Adetokunbo A. Taiwo,[1] Gabriela Velez,[1] Neeraja Kambham,[2] Timothy W. Meyer.[1,3] *[1]Nephrology, Stanford; [2]Pathology, Stanford; [3]Nephrology, VA Palo Alto.*

Background: Stanford fellows were previously exposed to renal pathology through attendance at monthly hour-long "biopsy conferences" where faculty and fellows discussed difficult cases; and informal quarterly "fellows-only conferences" where fellows asked pathologists questions on core topics. Our project sought to improve fellows' education in renal pathology.

Methods: Twelve first to third year fellows participated in this project. Two renal pathologists led five orderly review sessions, dedicated to fellows only: 1. Common renal pathology; 2. Primary glomerulonephritis; 3. Secondary glomerulonephritis; 4. Plasma cell dyscracia-related renal disease; 5. Renal transplant pathology. Second year fellows helped in preparation of teaching material. Fellows were encouraged to ask questions. Participants completed a survey to measure their satisfaction with renal pathology teaching and their confidence in interpreting renal biopsies before and after this project. Five 10-question pre-session quizzes and a comprehensive 40-question post-project final measured knowledge acquisition.

Results: Prior to our project, 55% of fellows felt "somewhat satisfied" to "satisfied" with the current pathology conferences, and 10% of fellows felt "somewhat confident" in their abilities to interpret biopsy findings. Most fellows (83%) viewed renal pathology to be an "important" or "very important" part of their overall nephrology training. After the project, 100% of fellows felt "somewhat satisfied" to "very satisfied" with the project, and 60% of fellows felt "somewhat confident" in their abilities to interpret biopsy findings. To date, fellows answered 63% of quiz questions correctly prior to the project and 60% of final questions correctly after the project.

Conclusions: Survey of nephrology fellows revealed poor confidence in interpreting renal pathology prior to our project despite perceived importance of the topic. To date, post project evaluation suggested improved confidence in renal pathology but lack of significant change in knowledge base. This may be due to issues with knowledge acquisition, inter-test comparability or instruction method.

SA-PO155

Improving the Communication Skills of Nephrology Fellows by Utilizing MBTI Training Anna Marie Burgner, Julia Lewis. *Vanderbilt Univ School of Medicine, Nashville, TN.*

Background: Communication skills can both positively and negatively affect the patient-physician relationship. Although many things impact successful communications, individuals' personality types affect the way they communicate and the way they interpret the communications of others. It has been suggested that a lack of understanding of the basic difference between personality types contributes to poor communication and unsuccessful interactions. Nephrologists work in a unique environment in the dialysis unit with a complex interdisciplinary team and a "captured" audience of anywhere from 10-40 patients in a single room. In the dialysis unit, communication between the multi-disciplinary team and the patients and between the multidisciplinary team's individual members impacts the successful achievement of dialysis outcomes.

Methods: Eleven nephrology fellows underwent a curriculum designed to increase their awareness of their own Myers Briggs Type Indicator (MBTI) personality preferences, their knowledge of the different basic personality preferences, and how those differences impact communication. Knowledge of the MBTI preferences was tested pre-intervention, immediately post intervention, and 8 weeks post intervention. Communication skills were measured prior to the intervention and 8 weeks post intervention by dialysis nurses observing fellow-real patient interactions. Fellows were also asked to describe how they used their knowledge at 8 weeks post intervention.

Results: The intervention led to a sustained increase in the nephrology fellows' MBTI personality preference knowledge. At 8 weeks post intervention, fellows reported utilizing their personality preference knowledge to improve their communication with their patients as well as with members of their team. However, nephrology fellows' communication skills, as measured by the Kalamazoo Essential Elements Communication Checklist Adapted (KEECC-A), did not change.

Conclusions: Although training in MBTI personality preferences led to a significant, sustained increase in MBTI knowledge and fellows continued to report utilizing their knowledge at 8 weeks post intervention, there was no change in their measurable communication skills utilizing nurse observations.

SA-PO156

Lung Ultrasound: A New Skill for Nephrologists for Volume Overload Quantification in End Stage Renal Disease Patients on Hemodialysis Marc M. Saad, Wissam Mansour, Elias Moussaly, Jeanne Kamal, Boutros Karam, Cara Brown, Monica Kapoor, Elie El-Charabaty, Suzanne E. El Sayegh. *Internal Medicine/Nephrology, Staten Island Univ Hospital, Staten Island, NY.*

Background: Many methods have been tried to assess the volume status in patients on hemodialysis (HD). While the estimated dry weight is still the only method widely used, it is often inaccurate and poses a clinical challenge. Pulmonary congestion detected as B lines on ultrasound (BLUS) is rising as a novel parameter for assessing volume status; we evaluate the accuracy and reliability of measuring BLUS performed by residents following a short training course.

Methods: Residents underwent a 3 hour course under the supervision of ultrasound-fellowship trained Emergency Physicians (EP). The course included a didactic section, a simulation hands-on training, and an Objective Structured Clinical Examination prior to enrolling the trainees as investigators; Residents performed lung ultrasound (LU) on ESRD patients post HD sessions in a supine position over 28 intercostal windows. They obtained at each window a 6s clip that were reviewed by 2 blinded EP. BLUS were summed up categorizing patients into different classes of pulmonary congestion:mild (0-14), moderate (15-30) and severe (>30).

Results: A total of 81 ESRD patients on HD were scanned. 71.6% were males; mean age 59.74 years, mean BMI 28.59±5.62 kg/m^2 ; mean test duration was 15 min. The B-lines score found by the study investigators and EPs was 15.8±21.3 and 12.06±21 respectively. The difference was 3.77±16.8 (0.0475). When categorized into the 3 classes, there was no significant difference between both classification (0.085), and were in moderate agreement-kappa 0.56 [0.42-0.71].

Conclusions: B-lines visualized on bedside LU can provide a reliable and quantifiable assessment for lung congestion. Our study shows that a short training course can render novice users of ultrasound capable of performing this quick evaluation. This can aid in objectively assessing volume overload in a timely manner in HD patients who present a unique clinical challenge. LU has emerged as a new technic, readily available at bedside, providing immediate results, yet is an easily learned skill.

SA-PO157

Renal Pathology: What We Think and What Is Ambarish Athavale, Kalyani Perumal, Peter D. Hart, Amit J. Joshi, Albert M. Osei. *Nephrology, John H. Stroger Jr. Hospital of Cook County, Chicago, IL.*

Background: Percutaneous kidney biopsy is the gold standard for diagnosis of kidney disease but is underutilized due to wariness of complications. Based on clinical and laboratory data, Nephrologists try to predict the renal pathology (clinical gestalt). However, no study has compared the diagnostic accuracy of the clinical gestalt with the kidney biopsy result. **Aim:** To compare pre-biopsy diagnosis (PBD) by Nephrologist with final histologic diagnosis. To assess if accuracy of PBD improves with increasing years in clinical practice.

Methods: Division of Nephrology at Stroger Hospital of Cook County conducts a monthly biopsy conference. Three case summaries are presented followed by discussion and presentation of the biopsy findings. Between September 2014 and April 2015, using a structured form Fellows and Nephrologists were asked to provide their top diagnosis for each case and this was compared with the actual histologic diagnosis. All physicians apart from the primary Nephrologist were blinded to the diagnosis. The study was deemed exempt by IRB.

Results: 23 cases were discussed in the biopsy conference involving 13 unique diagnoses and 286 unique responses were obtained. Overall diagnostic accuracy was 53.49% (153/286); Fellows (52.5%) and Nephrologists (54.36%). Diagnostic accuracy for nephrologists was 100% for ANCA vasculitis and Minimal Change Disease (MCD) and 86% for Diabetes but < 50% for stages of Lupus and other seronegative GNs.

Biopsy Diagnosis	Pre-biopsy diagnostic accuracy (%)
ANCA vasculitis	100
MCD	100
DM	86
Lupus class II	80
Amyloid	57.14
Lupus class III +V	50
Idiopathic Membranous	45.45
HIVAN	42.85
IgA	38.46
Lupus class V	33.33
HTN	33.33
Fibrillary GN	25
Normal	0

Nephrologists with > 10 years' experience tended to more accurately predict the diagnosis than those with < 10 years' experience (64.4 vs. 48.3%, p=0.07).

Conclusions: Nephrologists more accurately diagnosed ANCA vasculitis, MCD & Diabetes by clinical gestalt, but were less accurate for stages of lupus and other seronegative GNs. Regardless of training and experience kidney biopsy is still the diagnostic tool of choice in patients with kidney disease.

SA-PO158

Out-Patient Clinic Based Multidisciplinary Patients' Education for Advanced DM Nephropathy Is Effective and Efficient for Reducing ESRD Fumika Taki, Takuya Fujimaru, Masataka Hasegawa, Miyuki Futatsuyama, Yuki Heath, Masahiko Nagahama, Yasuhiro Komatsu. *Nephrology, St. Lukes' International Hospital, Tokyo, Japan.*

Background: Diabetes Mellitus (DM) is the most common etiology of CKD. Patients educations for these patients are known to be important, however, effectiveness and efficiency of them are still unclear. We established multidisciplinary out-patient clinic based education system, specialized for advanced diabetes nephropathy, and assessed their clinical outcomes.

Methods: Education system were started from May 2012, in St. Lukes' International Hospital. Tokyo, Japan. All CKD patients with DM were asked to meet nurse and dietitian, before seeing physicians, on every visit of the CKD clinic. Nurse and dietitian give the specific advices for each patients, within 15 minutes, by using our original short text or materials. Initiation of renal replacement therapy (RRT) were assessed for the primary end point, comorbidity, HbA1c, eGFR, type of RRT were also analyzed, retrospectively.

Results: From May 2012 to March 2015, total 372 individual patients were participated. Their baseline eGFR were 36.5±12.5ml/min, mean age 65.5±13.2 y.o. and 68% of them were male. Two hundred and ninety seven, 82% of patients were educated and their average of frequency of education was 4.3±2.1 times/year. Comparison of educated and non-educated groups, baseline eGFR, HbA1c or other comorbid did not differ. However, preservation of renal function were better in educated group ; delta eGFR: Educated vs. Non-educated: -3.26±1.21 vs. -8.2±3.25 ml/min/1.73m^2 /year, P=0.04, T-Test. More, incidence of ESRD is lower in educated group ; Initiation of Dialysis: Educated vs. Non-educated: 9.4% vs. 33.3%, P=0.033, Chi-Square test. Furthermore, in non-educated group, none of the patient selected peritoneal dialysis or transplants for the RRT.

Conclusions: Our out-patient clinic based education system is simple and useful for diabetic CKD patients for reducing ESRD.

SA-PO159

Our Stories Our Way: Creation of a Digital Story CKD Educational Intervention Stacey Jolly,[1] Marcia Oleary,[2] Ashwini R. Sehgal.[3] *[1]General Internal Medicine, Cleveland Clinic, Cleveland, OH; [2]Missouri Breaks Industries Research Inc, Eagle Butte, SD; [3]Center for Reducing Health Disparities, MetroHealth Medical Center, Cleveland, OH.*

Background: Chronic Kidney Disease and End Stage Renal Disease disproportionately affects American Indian communities, yet there are few culturally appropriate educational interventions for this population.

Methods: Digital storytelling combines first person narrative with digital images and music and can be done with a community-based, learner-centered approach. With these digital tools, people create personal narratives that are powerfully compelling, emotionally engaging, and provide another view or perspective on a topic. We recruited 10 men and women with diverse life experiences related to health and kidney disease from an American Indian community to create digital stories. Each participant was mailed a pre-workshop information sheet about digital storytelling and were encouraged to bring pictures.

Results: We held a 3 ½ day digital story workshop with our partner nDigiDreams, LLC in Nov 2013 at a tribal college. Participants, their family members, and research staff worked together with the facilitators to create their personal digital story related to health and kidney disease in their words. A total of 10 digital stories were created. The process encompassed four areas: develop story idea, gather media such as pictures and music, record the voice parts/edit the digital story, and share or screen the digital stories among the group. Five stories about life on dialysis, having a kidney transplant, and making changes to control diabetes were selected to be in the final DVD.

Conclusions: We created a unique educational tool in the form of digital stories. The DVD has been used in an ongoing pilot observational educational trial looking at the impact on chronic kidney disease knowledge and health behaviors among American Indians.

Funding: NIDDK Support

The Effect of Nephrology Specialty Clinics on Patient Care and Trainee Experiences Frederick H. Kuo, Rajeev Raghavan, Wolfgang C. Winkelmayer, Jose Jesus Perez. *Dept of Medicine-Nephrology, Baylor College of Medicine, Houston, TX.*

Background: As medicine evolves, there has been a trend towards the creation of special clinics which streamline care in hopes of improving patient survival through clinical trials and increased time with "super-specialists". From a trainee perspective, a Nephrology clinic focused on a particular disease affords fellows a unique perspective on disease pathophysiology and treatment and can be a wonderful tool to recruit residents or students into Nephrology. We hypothesized that a majority of Nephrology training programs across the US utilize such subspecialty clinics, and we aimed to characterize the patient and trainee experience by conducting a nationwide survey.

Methods: An e-mail detailing the study's aims and an anonymous 7-question online survey were sent to the 139 program directors of ACGME-accredited nephrology fellowship programs in July 2014.

Results: 54 of 139 program directors (39%) replied. We found Transplant clinics to be the most common subspecialty clinic (83%), followed by Stone clinic (63%), Advanced CKD clinic (50%), and Glomerulonephritis clinic (38%). Transplant clinics were oldest on average, with 67% in existence for over 10 years. Less common clinics included those

for lupus, polycystic kidney disease, and genetics. Regarding patient compliance within specialty clinics, 40% indicated no change, 40% improved, and 20% much improved. On patient satisfaction, 32% indicated no change, 49% improved, and 19% much improved. No respondents perceived decreased patient compliance or satisfaction. Trainees participated in 98% of specialty clinics with a 91% satisfaction rate; 29% were very satisfied. 45% of specialty clinics had ongoing research projects, with an average of 5.5 research projects in those clinics.

Conclusions: Subspecialty clinics can be an invaluable tool for both trainees and patients; both groups reported high satisfaction levels. These clinics also enable research by providing an established database of patients with specific disease processes. Access to such information is essential to quality research and may streamline the development of key clinical trials.

SA-PO161

The Impact of a Patient Education Program on Chronic Kidney Disease Patients' Plans to Initiate Dialysis – Prospective Study (2012-2014) Abdallah Guerraoui, Hallonet Patrick, Agnes Caillette-Beaudoin. *Néphrologie-Dialyse, Calydial, Vienne, France.*

Background: The distribution of renal replacement therapy (RRT) modalities among patients varies from country to country, and is often influenced by non-medical factors. In our department, patients progressing towards end-stage renal disease (ESRD) go through a structured Pre-Dialysis Education Program (PDEP). This PDEP is conceived with patients association and nursing educator.

Methods: Forty nine patients with CKD who were receiving care in a multidisciplinary predialysis clinic (mean age 73.5, 63% men). The participants are accompanied by family membres.They have an initial educational evaluation, followed by two workshops in groups and a final educational evaluation. The workshops are carried out in groups of 6 to 10 patients. The PDEP consisted of: (1) psychosocial assessment, (2) education about dialysis and choice of modalities, (3) counseling sessions with patient, family membres, (4) education about dietetic and dialysis.

Results: - Choice of the substitution method at the end of the workshops: 61% peritoneal dialysis, 18% haemodialysis and 21% absence of choice. - 94% of the patients began the substitution treatment with a chosen modality. - 100% Satisfaction of the patients, 26% decrease of the anxiety. ($p<0,0005$), 25% ($p< 0,0001$) increase in the consent for the treatment, 61% increase in the engagement in the treatment (patient ready to receive treatment) ($p<0,00001$), 47% increase knowledge of RRT($p< 0,00001$).

Conclusions: Most studies dealing with the pre-dialysis information show a balanced choice of the RRT, but only 50% of the patients actually begin DP. Our workshops of help and assistance to the choice enable to significantly reduce the anxiety linked to the dialysis and thus increase the adherence and engagement for the chosen method RRT. A two-phase educational intervention can increase the proportion of patients who intend to initiate dialysis with self-care dialysis. In our centre offering all treatment RRT modalities, a high percentage of patients exposed to a structured PDEP start with a self-care RRT modality.

SA-PO162

Frequency of Use of Social Media in CKD Patients on Hemodialysis: Pilot Study in Ecuador Fabian A. Ortiz-Herbener,[1] Juan Carlos Calderon,[2] Walter Morquecho,[3] Julio Israel Merino,[3] Byron Josué Haz,[2] Ivan Manuel Cherrez.[2,3] *[1]Inst Ecuatoriano de Diálisis y Transplantes, Guayaquil, Guayas, Ecuador; [2]Respiralab, Guayaquil, Guayas, Ecuador; [3]School of Medicine, Univ de Especialidades Espíritu Santo, Samborondón, Guayas, Ecuador.*

Background: CKD on dialysis is defined as <15% of kidney function. In Latin America, 461 per million are on dialysis. Region is the third largest Internet user. Social Media includes communications spread electronically, shared by individuals and discussed by a committed population. Hispanic Americans with CKD used it, to inform and be informed, and for supporting each others.

Methods: Observational, cross sectional, pilot study. Patients were recruited in dialysis center in Guayaquil. Survey included demographical and clinical items, Charlson score and 4 questions about frequency of use of social media were included. Also, questions about obtaining information; and interest in receiving or asking physician questions related to illness in social media. Frequencies and mean (SD) were employed. Chi-square, ANOVA and M-W U was used for comparisons. Also, Cronbach were calculated.

Results: 34 patients participated, with mean age of 56.5 (SD 16.3), mean years on dialysis of 3.9 (SD 4). 52.9% were women. Comorbidity's rate was very high (82.4%). 70.6% of patients believed that dialysis control symptoms of disease. 11.8% hadn´t got cellular-phone neither Internet. 61.8% hadn´t got SMS. Almost half of patients had smartphones. Women had a high comorbidity (41.2%), $p>0.05$. Around 30.0% reported using SMS, Facebook, YouTube, email an Internet at least once a week. 46.7% use Internet as principal source of information, YouTube (20.0%) and email (16.7%). 40.0% of patients reported high interest in receiving information by SMS, Facebook (33.3%) and email (26.6%). 33.3% reported high interest in asking by SMS, email (26.7%) and Facebook (20.0%). Finally, 43.5% reported interest in receiving information and asking by whatsapp. Conbrach was 0.884.

Conclusions: Internet use is very common for searching information related to disease. Whatsapp, SMS, Facebook and email were reported as new tools for providing illness related information to the patient. The survey had a good reliability and consistency.

SA-PO163

The Impact of Predialysis Education on Patient Understanding, Preparedness, and Decisional Conflict Regarding Renal Replacement Therapy Options Syed Amir Hamid Ali Shah,[1] Ion D. Bucaloiu,[1] Amanda Young,[2] Jamie Alton Green.[1] *[1]Nephrology, Geisinger Medical Center, Danville, PA; [2]Center for Health Research, Geisinger Medical Center, Danville, PA.*

Background: Predialysis education is recommended to prepare patients with advanced chronic kidney disease (CKD) for initiation of renal replacement therapy; however, the impact of various approaches on medical decision-making is unknown.

Methods: We surveyed 91 advanced CKD patients before and after a 2-hour nurse led group education class to assess patient understanding of renal replacement therapy options (1=poor to 5=excellent), preparedness to make a decision (1=not at all to 5= very prepared), and decisional conflict using a validated scale (0=no decisional conflict to 100=extremely high). The class included a combination of direct verbal instruction and video presentation, tailored to patients with a variety of health literacy and sociodemographic backgrounds. Content included the advantages/disadvantages of hemodialysis (HD), peritoneal dialysis (PD), transplant, and conservative management.

Results: Mean age was 66, 58% male, 94% white, 44% had a high school or lower level of education, and 46% had low health literacy. Mean level of understanding increased significantly for all modalities pre-post (2.02 vs. 4.10 for HD, 1.95 vs. 4.14 for PD, 2.35 vs. 4.15 for transplant, and 2.10 vs. 4.12 for conservative management; all $p<0.001$). Decision preparedness also increased significantly from 2.44 to 3.50 ($p<0.001$). Improvements were similar regardless of age, gender, educational level, or health literacy. At the end of the class, overall decisional conflict was low (median score 10; IQR 0, 20). Equal proportions of patients preferred HD (24%) or PD (22%), compared with transplant (12%) and conservative management (4%), yet nearly (30%) of patients remained unsure of their decision.

Conclusions: Despite significant improvements in patient understanding and preparedness about renal replacement therapy options, a substantial number of patients remain unsure of their decision after routine predialysis education. Additional decision supporting interventions may be needed to improve decision-making in advanced CKD patients.

SA-PO164

Chronic Kidney Disease Knowledge Among English and Non-English Speakers Anushya Jeyabalan, Pranav S. Garimella, Lesley Inker. *Nephrology, Tufts Medical Center, Boston, MA.*

Background: Patient education regarding CKD is an important part of pre-dialysis care. While educational interventions have also shown to improve clinical outcomes among dialysis patients, there is little information however, on health literacy in CKD populations.

Methods: We performed a cross-sectional survey of patients identifying themselves as primarily English or Chinese (Cantonese or Mandarin) speakers visiting an outpatient nephrology clinic at a single tertiary hospital. A validated Kidney Knowledge Survey (KiKS) that has been used to assess CKD knowledge in previous studies was translated into Chinese and then self-administered in English or Chinese. All patients had at least 1 prior visit with a nephrologist.

Results: 102 participants completed the survey of which 70 were English speakers and 32 were Chinese speakers. Chinese speakers were older, more likely to have less than high school education and had a greater prevalence of diabetes (Table). Estimated glomerular filtration (eGFR) and urine albumin creatinine ratio were not different between groups. Mean KiKS score was lower in Chinese speakers compared to English speakers (11.9 vs. 17.2, $p=0.001$). Chinese speakers scored lower in all domains of the KiKS; general kidney knowledge (6.2 vs. 4.5), knowledge of kidney function (5.5 vs. 4.0) and knowledge of symptoms (5.4 vs. 3.7).

Conclusions: While our results for CKD knowledge among English speakers are comparable to previously published data (mean score 18.6), scores among non-English speaking CKD patients is lower than English speakers. Whether this finding is associated with differences in care management and clinical outcome needs to be evaluated. Furthermore, educational material and programs may need to be tailored to specific populations to improve health literacy.

SA-PO165

Follow-Up with Doppler Ultrasound of Asymptomatic Arteriovenous Fistula (AVF) After Renal Biopsy (RB) Maite Rivera,[1] Saul Enrique Pampa,[1] Virginia López de la Manzanara Pérez,[2] Victor Burguera,[1] Nuria Rodriguez Mendiola,[1] Cristina Galeano,[1] Ingrid Viviana Raoch Michaels,[1] Rodrigo Hernandez Loyola,[1] Fernando Liano.[1] *[1]Nephrology, Hospital Univ Ramon y Cajal.UAH, Madrid, Spain; [2]Nephrology, Hospital Univ San Carlos, Madrid.*

Background: RB is an essential percutaneous technique in Nephrology that entails major and minor complications, one being the AVF which is usually asymptomatic and underdiagnosed because of the absence of routine Doppler examination post RB. We analyzed the natural history of asymptomatic AVF post RB of native kidney (NK) and transplanted (RT) detected by Doppler examination following RB.

Methods: We analyzed the presence of AVF on 327 RB between January 2011 and December 2014 included in our database. 47 (14%) RB developed AVF detected by Doppler ultrasound performed at 24h post RB. We studied the following data: AVF size and its relation to the needle caliber and time to spontaneous closure and its relationship to the AVF size. All RB were real-time ultrasound-guided RB performed with a biopsy gun (Acecut Tsk, Japan), the RT caliber 16G and 14G in the NK.

Results: 45 AVF were asymptomatic (96%), whereas 2 (4.2%) had to be embolized by their large size. Of the 45 asymptomatic AVF, 28 were of RT (62.2%). 69% were male. AVF 28 (62%) were followed until its closure with Doppler. 75% sized <1cm and corresponded to RT (16 G-needle). We noticed that the 50% of AVF had closed at 3 months post RB at an average of 49 days. AVF with a size between 1.1 and 1.9 cm (17.7% of the total) took longer time to close (mean 67 days). Among the 17 patients without follow-up five had died, 3 lost the renal graft and 9 were lost in the evolution. Seven of the 9 patients without follow-up were studied by Doppler after contacting them by phone, 28 months post-biopsy. In the seven AVF had spontaneously closed.

Conclusions: Contrary to published, AVF after RB is a frequent complication but asymptomatic and rarely requires surgery. All asymptomatic AVF closed spontaneously. The size of AVF were related with the caliber of the needle and with the time to close. No AVF grew in evolution. The routine use of Doppler following RB is essential to identify and standardizing management of AVF.

SA-PO166

The Role of Post Biopsy Ultrasound in Predicting Complications After Percutaneous Renal Biopsy of Native Kidneys Umar Hayat, Hafiz I. Ahmad, Syed Rizwan Bokhari, Syed A. Khalid. *Dept of Nephrology, Allama Iqbal Medical College/ Jinnah Hospital Lahore, Lahore, Pakistan.*

Background: The percutaneous renal biopsy (PRB) of native kidneys has been an essential tool in the diagnosis and management of renal diseases. Despite all advances, clinically evident bleeding complications do occur in up to 30% of patients after PRB of native kidneys. Traditionally patients are kept under observation for 24 hours after the procedure. An earlier investigation to anticipate the likelihood of complications will help to reduce the length of stay for these patients and thus the resource burden. Post PRB ultrasound has been studied for this purpose. We conducted a study to evaluate the role of early post PRB ultrasound to predict procedure related complications in our patient population.

Methods: 46 patients undergoing renal biopsy at department of Nephrology, Jinnah Hospital were considered for this study. Renal biopsy was performed using a 16-gauge automated core biopsy needle. After the biopsy, patients were closely monitored in recovery room and after 1 hour, the biopsied kidney was examined by ultrasound. These patients were admitted and were kept under observation to assess any complications for next 23 hours.

Results: Of these 46 patients, 24 (52%) were males with mean age 39 (16 to 60 years). More than 3 cm hematoma was seen in 2 (4.3%) patients at 1 hour post biopsy ultrasound scan. Of these 2 patients, only 1(2%) patient had major complications including hypotension, decrease in hemoglobin etc. Thus 45 (97.8%) patients had uneventful recovery. Sensitivity of more than 3 cm hematoma formation at 1 hour post biopsy in predicting major complications was 100% with specificity of 97.7%.

Conclusions: Our study showed that the frequency of major complications was minimal in patients without >3 cm hematoma formation at one hour post-PRB. Post-PRB ultrasound is a non-invasive, accurate diagnostic tool in predicting procedure related major complications.

SA-PO167

A Multidisciplinary Clinic for Children with Lupus Nephritis (LN) – A Step Towards Personalized Medicine? Nicole A. Hayde,[1] Tamar Rubinstein,[2] Janice Berthe Desir,[1] Dawn Wahezi,[2] Katherine Steigerwald,[2] Beatrice Goilav.[1] *[1]Pediatric Nephrology, Children's Hospital at Montefiore, Albert Einstein College of Medicine, Bronx, NY; [2]Pediatric Rheumatology, Children's Hospital at Montefiore, Albert Einstein College of Medicine, Bronx, NY.*

Background: Most children with SLE develop LN, which significantly worsens morbidity and mortality. Progression to ESRD occurs in 5-10%. Early diagnosis and treatment improve long-term outcomes, thus prompt evaluation is essential. Therefore, a combined pediatric nephrology/rheumatology clinic (LN Clinic) was started in 2013. The primary aim was to evaluate the number of days between onset of proteinuria (first-am urine p/c >0.2) and performance of a renal biopsy (bx) for SLE patients (pts), pre- and post-establishment of the LN Clinic. We aimed for a 20% reduction in time to renal bx within 2yr of establishment of this clinic. The secondary aim was a reduction of steps in the referral process.

Methods: SLE pts with an outpt renal bx were identified by an EMR query. Pts were selected if a bx was performed within 5yr pre or 16mo post establishment of the LN clinic. Our sample selection was cross-referenced with an established lupus registry. A chart review provided the date of proteinuria onset, disease activity markers, and LN class. Pts diagnosed in the inpt setting were excluded. A process map determined the number of steps occurring between new-onset proteinuria and first evaluation by a nephrologist.

Results: We show that pre LN clinic, the median number of days between onset of proteinuria and renal bx was 51 (IQR=25–83.5d), compared to 34 (IQR=14–48d) post (p=0.057). This is a 33% decrease in time. There was a negative association between amount of proteinuria and days to bx (r=-0.5826, p<0.001). There was no association between hematuria or markers of disease activity and days to bx. There was also no association between LN class and days to bx. Pre LN clinic, a referral required 10 steps, which was reduced to 6.

Conclusions: The LN clinic has resulted in earlier renal bx and fewer steps in the referral process. For pts with proliferative LN, this translates to earlier initiation of treatment and a chance at improved outcome.

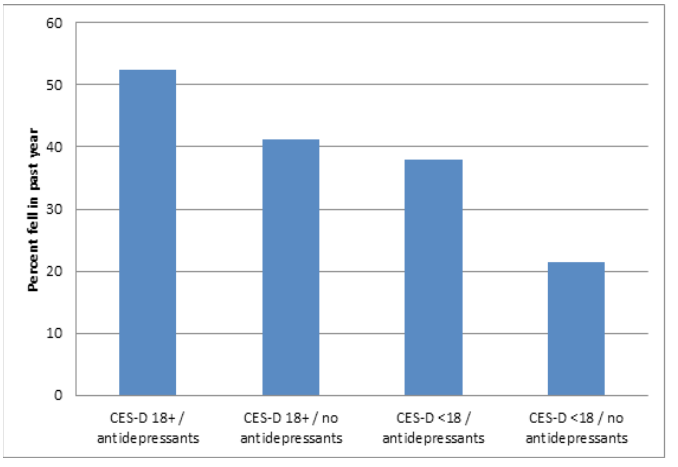
SA-PO168

Antidepressant Efficacy and Safety Observations: USRDS ACTIVE-ADIPOSE Study Nancy G. Kutner,[1] Rebecca H. Zhang,[1] Yijian Huang,[1] C. Barrett Bowling.[1,2] *[1]Emory Univ, Atlanta, GA; [2]Atlanta VA Medical Ctr.*

Background: Although depression is a prominent issue, depression management in advanced CKD and ESRD patients is not well understood. Antidepressant medications are the most frequent therapy, but efficacy and safety data are limited (Hedayati et al. 2012).

Methods: The primary exposure of interest was use of antidepressant medications among 771 maintenance hemodialysis (MHD) patients ages 20-92 in 14 outpatient clinics who were enrolled 2009-2011 in the ACTIVE-ADIPOSE special study (median ESRD treatment 3.2 years). Gender distribution and ESRD etiology were similar to the overall MHD population, but the proportion non-white and younger than age 65 was higher in the study cohort. Medication efficacy was defined by participants' scores (<18 vs. 18+) on the Center for Epidemiologic Studies-Depression (CES-D) scale (Hedayati et al. 2006). Adjusted odds for recent falls observed in association with antidepressant use and CES-D score provided an indicator of safety.

Results: Antidepressants were prescribed for 15% of study participants. 40% of those with prescribed antidepressants had an elevated CES-D score, suggesting lack of drug efficacy. Efficacy did not appear to vary by patients' age or vintage, but more whites had elevated CES-D scores. Recent falls were more frequent among patients on antidepressants with elevated CES-D score (adjusted odds ratio 2.27 [1.05, 4.90], p = 0.04, compared with patients not on antidepressants and CES-D score <18). Fall risk was similar across type of prescribed antidepressant (SSRI, atypical, and tricyclic drugs).



Conclusions: Efficacy of antidepressant medications was unclear for 40% of those with these drugs prescribed, and safety hazard was suggested by increased fall risk. Continued evaluation of nonpharmacologic as well as pharmacologic options for depression management in MHD patients, the focus of a current PCORI trial, is important.

Sofosbuvir Use in Patients with Hepatitis C Virus Infection and Severe Chronic Kidney Disease Alberto J. Sabucedo, Marie Essie Antoine, Delvis Jorge, Aileen Andreu, Fernando E. Pedraza, Maria Del Pilar Hernandez, Lennox Jeffers, Marco A. LadinoAvellaneda. *Dept of Medicine. Divs of Nephrology and Hepatology, Miami VA Medical Center/Univ of Miami, Miami, FL.*

Background: Chronic hepatitis C virus (HCV) infection is a major health problem. The use of new direct acting antiviral (DAA) based regimens has been shown to provide a high sustained virologic response with less adverse reactions compared to interferon-ribavarin regimens. The American Association for Study of Liver Diseases recommends expert consultation on patients with eGFR less than 30 mL/min because safety and efficacy data are not available on these patient populations. We propose that these DAAs are safe to use in patients with advanced kidney disease.

Methods: A total of 23 patients with HCV and estimated glomerular filtration rate (eGFR) less than 45 ml/min were treated with sofosbuvir and simeprevir, dose of sofosbuvir was adjusted to 200 mg PO daily or 400 mg PO every other day for patients with eGFR less than 30 ml/min by Hepatology and Nephrology services. These patients were monitored closely by both services.

Results: A cohort of 23 HCV positive patients had the following descriptive statistics, 20 males (87%) and 3 females (13%). 15 patients had Genotype 1a (65%), 7 patients had Genotype 1b (31%) and 1 patient had Genotype 2b (4%). 3 patients (13%) had End Stage Kidney Disease (ESKD) and were on hemodialysis, 9 patients (39%) had Chronic Kidney Disease grade IV (CKD IV - eGFR <30 ml/min) and 11 patients (48%) had Chronic Kidney Disease grade IIIB (CKD IIIB - eGFR <45 ml/min) The HCV viral load of the 23 patients (100%) had a statistically significant decrease as the therapy progressed through completion with a statistically significant T-test with a $p < 0.05$. No side effects were present on the patients during DAA therapy. Patients with CKD grades IIIB and IV on DAA treatment had a preserved kidney function by the end of therapy.

Conclusions: Sofosbuvir is safe and effective in patients with Hepatitis C Virus infection and severe Chronic Kidney Disease, co-management and close monitoring by Hepatology and Nephrology is imperative due to the lack of data in safety and efficacy.

SA-PO170

Enoxaparin as Bridging Therapy in Veterans with Advanced Kidney Disease
Chai L. Low, Renae A. Minnema. *Pharmacy, VA San Diego Healthcare system, San Diego, CA.*

Background: Patients with CrCl < 30ml/min on anticoagulation require temporary bridging perioperatively. Low-molecular weight heparins (LMWH) have longer half-lives and predictable anticoagulant effect but require anti- Xa monitoring in CKD. This study aims to evaluate the safety and efficacy of lovenox as a bridge therapy in patients with CrCl< 30ml/min.

Methods: A retrospective study was conducted from Jan 1, 2012 to Dec 1, 2014. Patients with CrCl < 30 mL/min, received enoxaparin 1 mg/kg/day as a bridge therapy to warfarin, and had at least one anti-Xa level checked were included in the study. Patients were excluded if they had major bleeding or thromboembolism in previous 3 months before enoxaparin, history of bleeding disorders, or used enoxaparin for other indications. A dosing nomogram was used to guide dosage adjustment to keep anti-Xa levels within the target range (0.5 -1.0 mcg/ml). The primary outcomes are # of minor/major bleeds and thromboembolic events. The proportion of anti-Xa levels within goal range was assessed. Descriptive statistics were used to compare outcomes to the literature.

Results: 12 patients met inclusion and exclusion criteria. The mean age was 62.4 ± 11.9 years, 91.7% were male, 58% were diabetic and 46% had congestive heart failure. 50% were on both warfarin and aspirin. The mean treatment duration of enoxaparin was 11.4 ± 4.6 days, the average CrCl was 17.6 ± 4.5 mL/min. A total of 19 anti-Xa levels were included for analysiss. There were 2 (16.7%) bleeding events, 1 (8.3%) major and 1 (8.3%) minor bleed. None of the patients developed thromboembolic complications. The most common adverse event was bruising at the injection site that did not lead to any early discontinuations of therapy. Seventeen of the anti-Xa levels (89.4 %) were in the target range.

Conclusions: Majority (83.3 %) of patients had minimal or no adverse events and none with thromboembolic outcomes. In patients with bleeds, no correlation was seen with the anti-Xa levels. The dosing protocol is effective, with 89.4 % of anti-Xa levels within goal range. The results of this study support the safety and efficacy of the enoxaparin dosing protocol as a bridge therapy perioperatively in patients with CKD.

Thiopurine Methyltransferase (TPMT) Genotyping to Predict Myelosuppression Risk in Chinese Patients with Nephropathy
Xuemei Li, Jie Ma. *Nephrology, Peking Union Medical College Hospital, Beijing, China.*

Background: Pharmacogenetic study in nephritis is mainly focused ongenes involved in the metabolism of Azathioprine (AZA).Use of AZA is limited by its toxicity. Variants in theThiopurine S-methyltransferase(TPMT)have been associated with AZA toxicity. The aimofthis study was to determine the contribution of TPMT variantsin the development of AZA-relatedmyelosuppression in Chinese patients with nephropathy.

Methods: Variants associated with the decrease of enzymeactivity in TPMT genes were genotypedin 4nephritis patients treated with AZA, andcorrelated with the clinical response and development ofadverse drug reactions in a retrospective case-control study. Three commom mutation alleles of TPMT [TPMT* 3A (G460A/A719G) , TPMT* 3B(G460A) , TPMT* 3C (A719G)]were detected by polymerase chain reaction-high resolution melting and sequencing in 12 patients , included 4 patients with myelotoxicity and 8 patients without myelotoxicity.

Results: Genotypic analysis showed only one of the 4 patients with myelotoxicity was detected *TPMT* *3C polymorphisms, no *TPMT*2, *3A, *3B or *3C polymorphisms were detected in any of the 11 patients.

Conclusions: Single-nucleotide polymorphisms of *TPMT* could not explain the azathioprine-related adverse events.

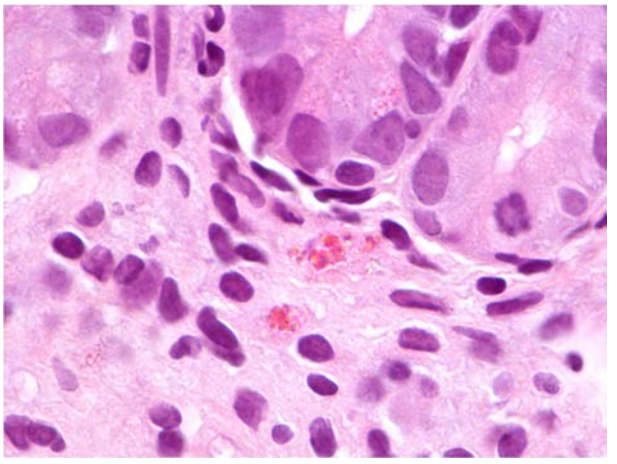
SA-PO172

Lanthanum Carbonate-Induced Granulomatous Gastritis
Francesco Iannuzzella,[1] Loredana De Marco,[2] Sonia Pasquali.[1] *[1]Dept of Internal Medicine, Nephrology and Dialysis Unit, Arcispedale Santa Maria Nuova, IRCCS, Reggio Emilia, Italy; [2]Dept of Human Pathology, Arcispedale Santa Maria Nuova, IRCCS, Reggio Emilia.*

Background: Long-standing non-calcium based phosphate binders administration has been recently associated with a number of different gastroduodenal lesions. We describe a rare case of lanthanum carbonate-induced granulomatous gastritis.

Methods: A 58-year-old woman was admitted to our hospital because of nausea, vomiting, and progressive weight loss. Because of a well-known stage 5 chronic kidney disease, she was started on peritoneal dialysis. About one month later, CAPD was well-tolerated with an adequate dialysis dose. Nevertheless, she continued to complain of nausea, vomiting and dyspepsia. A gastroscopy revealed chronic gastritis with superficial erosions and an histopathology consisting of non-necrotizing, sarcoid-like granulomas with aggregates of multinucleated giant cells. Orange cristalloid material was seen within granulomas. Special stains for fungus and mycobacteria were negative. Her previous medical history was only significant for hypertension and type 2 diabetes mellitus. Physical examination was unremarkable. A chest X-ray was normal. A tubercolin skin test was negative. ANCA titres was negative and serum angiotensin converting enzyme (ACE) level was in the laboratory reference range. At the time of our evaluation, she had been receiving lanthanum carbonate 1 g bid for about 6 months.

Conclusions: At the best of our knowledge, so far, only 7 cases have been described in the literature.



The histopathologic picture in our patient was compatible with a lanthanum carbonate-induced gastritis with some peculiar characteristics: a granulomatous reaction and the appearance of lanthanum carbonate crystals not only within histiocytes/multinuceated giant cells but also inside the cytoplasm of the epithelial glandular cells.

SA-PO173

Relative Incidence of Adverse Events with Ferumoxytol versus Other Intravenous Iron Products in Non-Dialysis-Dependent Chronic Kidney Disease
Eric D. Weinhandl, David T. Gilbertson, Allan J. Collins. *Chronic Disease Research Group, Minneapolis Medical Research Foundation, Minneapolis, MN.*

Background: All intravenous (IV) iron products confer risk of hypersensitivity reaction (HSR). The relative safety of ferumoxytol versus other IV iron products is not established. We used Medicare claims to assess relative safety of ferumoxytol versus other IV iron products in non-dialysis-dependent chronic kidney disease (NDD-CKD) patients.

Methods: We analyzed a 20% sample of Medicare Parts A and B claims in 2009-2012. Patients received a first dose of IV iron between Jan 1, 2010, and Nov 30, 2012, and had diagnosed NDD-CKD without IV iron treatment during the 1 year before first dose. For each ferumoxytol user, we identified 1 propensity score-matched control who used another IV iron product; the score included demographics, comorbidity, and concomitant IV medication. Patients were followed until change in IV iron product, end stage renal disease, death, or Dec 15, 2012. With Cox regression stratified by matched pair and cumulative number of prior IV iron doses, we assessed relative incidence of anaphylaxis, HSR symptoms, hypotension, emergency room (ER) visit, hospitalization, and death within 1 day of first dose and within 1 day of each subsequent dose.

Results: We identified 7358 ferumoxytol users and 7358 matched controls. Baseline characteristics were balanced across groups. There were too few cases of anaphylaxis and death to permit comparisons. However, after first dose, hazard ratios (ferumoxytol users vs. matched controls) were 0.90 (95% confidence interval, 0.80-1.01) for HSR symptoms, 1.06 (0.66-1.72) for hypotension, 0.72 (0.55-0.94) for ER visit, and 0.78 (0.60-1.02) for hospitalization. After subsequent doses, corresponding hazard ratios were 1.07 (0.90-1.27) for HSR symptoms, 0.91 (0.50-1.67) for hypotension, and 0.86 (0.64-1.15) for ER visit, and 0.97 (0.70-1.35) for hospitalization.

Conclusions: Relative to other IV iron products, ferumoxytol was not associated with excess risk of adverse events in NDD-CKD patients, following both first dose and subsequent doses. The incidence of anaphylaxis and death was very low in ferumoxytol users and matched controls.

SA-PO174

Efficacy, Safety and Pill Burden of Sucroferric Oxyhydroxide, an Iron-Based Phosphate Binder, Over 52 Weeks in African American Dialysis Patients
Stuart M. Sprague,[1] Anjay Rastogi,[2] Markus Ketteler,[3] Adrian C. Covic,[4] Jürgen Floege,[5] Viatcheslav Rakov,[6] Llera Armando Samuels.[7] *[1]NorthShore Univ Health System, Chicago; [2]Univ of California; [3]Coburg Clinic and KfH-Dialysis Center, Germany; [4]'Gr.T. Popa' Univ of Medicine and Pharmacy, Romania; [5]RWTH Univ Hospital Aachen, Germany; [6]Vifor Pharma; [7]Temple Univ, Philadelphia.*

Background: A *post hoc* analysis of data from a randomized, open-label, Phase 3 study and its extension investigated the efficacy and safety of the iron-based phosphate binder sucroferric oxyhydroxide (SFOH; VELPHORO®) vs sevelamer carbonate (SEV; Renvela®) in African American dialysis patients.

Methods: Overall, 1059 patients were randomized to SFOH (1.0–3.0 g/day; n=710) or SEV (2.4–14.4 g/day; n=349) for 12 weeks' dose titration then 12 weeks' maintenance. Eligible patients enrolled in a 28-week extension study.

Results: Of the 549 patients who completed the extension study, 100 were African American patients, equally distributed between the treatment groups despite the 2:1 randomization (n=48, SFOH; n=52, SEV). Serum phosphorus decreased rapidly and to a similar extent with SFOH and SEV, and remained relatively constant thereafter (Table). Mean ± standard deviation number of tablets/day was lower for SFOH (3.4 ± 1.35) vs SEV (7.6 ± 2.92) over 52 weeks. The incidence of serious or severe treatment emergent adverse events and deaths were similar in both treatment groups. Gastrointestinal-related disorders were the most frequently observed adverse events for SFOH and SEV.

Conclusions: SFOH efficacy was maintained long-term, with a lower pill burden than SEV and similar safety profile, in African American dialysis patients. *Post hoc* results reflect those from the overall study population.

Table: Treatment efficacy and safety in African American patients.

Efficacy (completer set; N=100)	SFOH (n=48)	SEV (n=52)
Phosphorus, mg/dL*		
Baseline	7.4 (1.97)	7.3 (1.36)
Δ at Week 12	–2.0 (1.88)	–2.3 (1.76)
Δ at Week 24	–2.1 (2.26)	–2.0 (1.79)
Δ at Week 52	–2.1 (2.58)	–2.1 (1.58)
Safety parameters (safety set; N=205), %	**SFOH (n=130)**	**SEV (n=75)**
Withdrawal due to AEs	18.5	8.0
Severe AEs	14.6	20.0
Serious AEs	27.7	30.7
Deaths	3.1	2.7
Anemia	1.5	9.3
Hyperparathyroidism	9.2	14.7
Gastrointestinal-related adverse events	43.1	44.0
Diarrhea	15.4	10.7
Discolored feces	13.8	1.3
Nausea	9.2	14.7
Vomiting	6.9	9.3
Constipation	3.8	8.0

*Mean (standard deviation) serum levels. AEs, adverse events; SEV, sevelamer carbonate; SFOH, sucroferric oxyhydroxide.

Intergrated Dialysis Unit Module and Module Compartment Structure
Stanley Shao-Ying Lee,[1] Ming-cheng Wang.[2] *[1]Chi-Hsien Hemodialysis Center, Taiwan; [2]College of Medicine, National Cheng Kung Univ, Tainan, Taiwan.*

Background: Conventional set-up of hemodialysis (HD) center requires intensive manpower and tedious workload due to the intricate fluid and electricity layouts, and the fixed partitions structure. It is vital to design an integrated module considering rapid assembly, patient privacy and easy access to the fluid pipes and electricity lines for routine maintenance.

Methods: The Integrated Dialysis Partition System was designed for HD center. To ensure patient privacy, an easy-assembled partitions with a herringbone seating arrangement was used to position the HD seats partially and equally askew in one direction. The mobile modules of fluid pipes and electricity lines allow easy access for routine maintenance. Eighty uremic patients were enrolled to examine the differences between conventional and new HD unit in terms of psychological adjustment including depression, anxiety, mood, and illness intrusiveness.

Results: The state-of-the-art HD center with 40 seats could be established within one day.

For the entire patients, BDI scores were significantly higher when dialyzed in the conventional HD unit (M = 13.3 :t 0.9) than in the new HD unit with integrated dialysis partition system (M = 10.3 :t 1.2; t = 1.95, p = 0.014). In the conventional HD unit, patients recorded higher anxiety and lesser positive mood. There were no significant differences regarding negative mood or illness intrusiveness.

Conclusions: The intergrated dialysis unit module allows for rapid assembly, easy pipeline maintenance, and improved patients' quality of life.

SA-PO176

Safety and Adherence in End Stage Renal Disease Patients on Chronic Hemodialysis
Kamran Karimi, Yezina T. Nigatu, Catherine Miranda, Keri Fico, Leonard A. Arbeit, Nand K. Wadhwa. *Nephrology, Stony Brook Univ Medical Center, Stony Brook, NY.*

Background: Missed hemodialysis and abbreviated hemodialysis sessions are common in end stage renal disease patients on maintenance hemodialysis. Dialysis non-adherence has been associated with increased mortality and morbidity in chronic hemodialysis patients. Our quality assessment performance improvement data revealed that on an average 15% of patients missed and abbreviated hemodialysis (HD) sessions over a period of 6 months.

Methods: We evaluated patients' perception about missed and abbreviated sessions, and safety during HD sessions at our dialysis center. A questionnaire regarding patients' views about missed, abbreviated and safe hemodialysis sessions using a visual analog scale (0-100 mm, where 0 means 'No' and 100 means 'Yes') was conducted in-person by a nephrology fellow or a social worker on all HD patients. Data are presented as (mean ± SD).

Results: Ninety patients participated in the survey. Sixty eight (75.6%) patients with a mean score of 78+ 29.6 felt like coming for their HD sessions during the last one month. Fifteen of 89 (16.9%) did not know why they came for HD sessions. Twenty seven percent came because they wanted to live while 18% came because they did not want to die. Eighty nine (98.9%) patients with a mean score of 94.5 + 17.3 felt safe during the HD sessions. Seventeen (18.9%) patients indicated missing the HD sessions. Thirty six of 83 (43.4%) patients with a mean score of 71 + 37.6 wanted to miss HD sessions during the last one month.Fifteen of 89 (16.9%) signed against medical advice for the abbreviated HD sessions during the last one month.

Conclusions: Data suggest that safety of HD sessions does not appear to be a factor for missing HD sessions. Lack of patients' understanding of importance of HD treatments as well as lack of their active participation likely leads to non-adherence and abbreviation to HD sessions. The safety of HD treatment was not the core issue behind increasing patients' absenteeism. Active patients' participation and individualization of HD sessions may improve adherence to HD sessions.

SA-PO177

Validation of a Tool to Assess Nursing Workload in Hemodialysis
Clara Bohm,[1] Brett M. Hiebert,[1] Joe A. Bueti,[1] Jan Schneider.[2] *[1]Univ of Manitoba; [2]Winnipeg Regional Health Authority.*

Background: Patient classification scales (PCS) to assess nursing workload predict staffing needs and facilitate transparency in assignments resulting in improved work environment, patient safety and quality of care. Few validated PCS tools exist for hemodialysis (HD). This study validates a point-of-care PCS developed for in-centre HD at a Canadian tertiary care centre.

Methods: Using LEAN framework, from Sept 1, 2013 to Mar 1, 2014 at the Health Sciences Centre in Winnipeg, Canada, iterative consultations with stakeholders resulted in creation of a PCS consisting of 9 domains and 67 subdomains. At each HD session between April 7-21, 2014, bedside HD nurses completed both a visual analogue scale (VAS), which assessed general level of nursing care required, and the PCS tool. Karnofsky scale and time-series studies were completed in 50 and 28 randomly selected HD patients, respectively. *Analysis*: Internal consistency and reliability were assessed using Cronbach's alpha and Intraclass Correlation Coefficient (ICC), respectively. Multi-trait multi-method analysis (MTMM) determined item homogeneity. Spearman's correlation of PCS with VAS, Karnofsky Score and time-series studies assessed criterion and predictive validity. Linear regression was performed to determine the association of each subdomain with PCS score.

Results: PCS and VAS data for 1640 HD sessions (380 patients) was obtained.

	PCS Score	VAS Score	Karnofsky Score	Time Series
Mean (SD)	10.7 (5)	3.7 (1.9)	66 (14.4)	89 min (48)
N	380	380	50	27

PCS correlated well with VAS (0.769). Correlation of PCS with Karnofsky scale and time-series studies was -0.56 and 0.39, respectively. ICC was 65%. MTMM identified 4 subdomains never used and 2 which were redundant. Linear regression identified 16 subdomains with minimal contribution to overall PCS score. Reconsultation with stakeholders resulted in a revised 41-item PCS tool. Correlation between the revised tool and VAS, Karnofsky score and time-series was similar to the original model (0.77, -0.51 and 0.316, respectively).

Conclusions: Preliminary results suggest excellent reliability and validity of this PCS tool. Validation studies at other HD centres with expanded time-series and reliability studies continue.

SA-PO178

Feasibility of a Hemodialysis Safety Checklist for Nurses and Patients Samuel A. Silver,[1] Alison Thomas,[1] Andrea Rathe,[1] Pamela L. Robinson,[1] Ron Wald,[1] Chaim Bell,[2] Ziv Harel.[1] *[1]Nephrology, St. Michael's Hosp, Toronto, ON, Canada; [2]Medicine, Mt.Sinai Hosp, Toronto, ON, Canada.*

Background: In 4% of ESRD patient deaths, the cause of death is a result of a preventable hemodialysis complication. These include errors related to communication, organization and human factors. We recently developed a hemodialysis safety checklist (Hemo Pause) to be completed by nurses and patients at specified intervals throughout a hemodialysis session, with the goal to improve dialysis unit safety culture. Our objective was to determine the feasibility of using Hemo Pause during every hemodialysis session for 3 months.

Methods: We conducted a single center, prospective time series study. A convenience sample of 14 nurses and 22 prevalent in-center hemodialysis patients participated. All participants were trained in the administration of Hemo Pause, completed the checklist at every hemodialysis session for 3 months and were free to suggest checklist modifications consistent with quality improvement methodology. The primary outcome was Hemo Pause completion, which was determined weekly using the percentage of checklists in the patient chart with all 17 items assessed. We also measured Hemo Pause acceptability using local patient safety surveys.

Results: There were 799 hemodialysis treatments pre-intervention and 757 post-intervention. The checklist was completed for 556 of 757 (73%) treatments. The most common reasons for non-completion were the availability of nursing staff trained in Hemo Pause and patient admission to hospital. Among hemodialysis nurses, 93% (13/14) agreed that Hemo Pause was easy to use and 79% (11/14) agreed it should be expanded to other patients. Among hemodialysis patients, 73% (16/22) agreed that Hemo Pause made them feel safer and should be expanded to other patients. Negative comments by nurses or patients occurred on 4% (7/200) of survey responses.

Conclusions: A hemodialysis safety checklist (Hemo Pause) was acceptable to both nurses and patients over a 3 month period. Our next step is to spread Hemo Pause locally, and conduct a mixed methods study to determine mechanisms by which Hemo Pause may improve safety culture, patient engagement, and reduce adverse events.

Community-Based Parenteral Anti-Infective Therapy (COPAT) for ESRD Patients Evamaria Anvari, Reza Anvari, Laura Ferreira Provenzano, Juan C. Calle. *Nephrology, Cleveland Clinic Foundation, Cleveland, OH.*

Background: Infections are the leading cause of hospital admissions for patients with ESRD. The majority will need to continue antimicrobial therapy when discharged. Community-based parenteral anti-infective therapy (COPAT) refers to the practice of administrating antimicrobial therapy in the outpatient setting. It requires a multidisciplinary and the goals are to improve outcomes, reduce toxicity, drug resistance, and decrease hospital stay. ESRD patients have the advantage that IV antibiotics can be given at their dialysis units. The downfall is that every outpatient dialysis provider has their own policies for the approval of IV/IP therapy. Patients are frequently discharged with an order to continue therapy but it is not continued, leading to adverse outcomes.

Methods: We investigated the policies from the main dialysis providers in our community.

Results:

	Fresenius Medical Care	Davita	Centers for Dialysis Care
IV/IP drugs in unit	Vancomycin, Ceftazidime Cefazolin, Gentamycin	Vancomycin, Ceftazidime, Cefazolin, Gentamycin	Vancomycin, Cefalzolin, Gentamicin, Tobramycin (IP), Ceftazidime (IP)
IV/IP drugs in formulary	Amikacin, Tobracycin, Ceftriazone, Cefepime, Meropenem, Daptomycin, Aztreonam, Ampicillin, Levofloxacin, Amphoteracin B, Fluconazol, Ganciclovir, Pentamidine	-Any other medication needs pre-approval -Daptomycin will not be approved	Any other antimicrobial drug will beapproved
Time for drug arrival	24-48 hrs.	-Pre-approval 24-48 hrs. -Day after approval	48 hrs.
Requirement	Hospital order	-ID consult -Organism with sensitivity -Rational for using other antimicrobial	Hospital order
IP drugs	Receive in unit	-Loading dose in unit and continue self-administer -Drugs orderd Monday - Thursday will arrive at their home the following day -If ordered after 3PM Friday it will arrive Monday	Loading dose in the unit and are given a 5-7 day supply to self-administer
Home Hemo	Dialyze in center for therapy	Dialyze in center for therapy or trained to self-administer	Dialyze in center for therapy

Conclusions: Readmissions and complicated infections in ESRD patients can be prevented if the multidisciplinary team coordinates care with the outpatient dialysis unit before discharge.

SA-PO180

Rapid Response and Cardiac Arrests in In-Patient Hemodialysis - A Retrospective Review Justin Chen,[1] Ladan Golestaneh,[1,2] Lewis Ari Eisen.[1,3] *[1]Albert Einstein College of Medicine, Bronx, NY; [2]Nephrology, Montefiore Medical Center, Bronx, NY; [3]Critical Care, Montefiore Medical Center, Bronx, NY.*

Background: Patients with renal dysfunction requiring hemodialysis are known to be at increased mortality and morbidity risk. Few studies have examined rapid response (RR) and cardiac arrest (CA) events in inpatient hemodialysis. The purpose of this study is to evaluate patient characteristics and predictive factors of RR and CA in inpatient hemodialysis units.

Methods: A retrospective review of all available RR/CA events in two separate hospitals over a 3-year period was performed. Charts were reviewed for abnormalities in vital signs or laboratory values during hemodialysis sessions and for a 24-hour period prior to RR/CA events.

Results: In total, 16 RR and 13 CAC events were recorded for 26 unique patients (average age 64±16 years). Of the 29 total RR/CA events, 9 events resulted in survival <24 hours (31%). Common medical comorbidities included hypertension (92%), diabetes (73%), chronic heart failure (50%), and coronary artery disease (50%). The most common inciting factors for RR/CA activation were altered mental status (72%), systolic blood pressure < 90 (45%), and respiratory distress (31%). Vital sign abnormalities identified prior to hemodialysis included need for supplemental oxygen (72%), respiratory rate > 20 (34%), and systolic blood pressure < 90 (3%). Vital sign abnormalities identified during hemodialysis included systolic blood pressure < 90 (34%) and heart rate < 40 (3%). Of those with labs available, the most common lab abnormalities included low hemoglobin and hematocrit (100%), elevated direct bilirubin (71%), elevated troponin-T (62.5%), and elevated PT (60%).

Conclusions: Our data suggest there are characteristics amongst patients undergoing inpatient hemodialysis that predispose them to RR/CA events. Simple, objective measures such as requirement for supplemental oxygen and abnormal vital signs may be important indicators that patients are at risk for serious adverse events. Knowledge of these factors can aid in decision-making regarding pursuit of dialysis and lead to the study of strategies to prevent patient harm.

SA-PO181

Monitoring of Protective Levels of Hepatitis B Antibody Titre in Pre-Dialysis and Dialysis Patients Ravindra Mukkunda, Zahra Jabir. *Renal Medicine, Doncaster and Bassetlaw NHS Foundation Trust, Doncaster, Yorkshire, United Kingdom.*

Background: Patients on dialysis are at risk of hepatitis B virus infection. Hence it is widely recommended to vaccinate chronic kidney disease (CKD) patients who might need renal replacement therapy. Antibody titre of >10iu/L is generally regarded as protective against Hepatitis B infection. The frequency of antibody level monitoring remains unclear. Once adequate antibody response achieved levels would wane with time. We monitored antibody levels in pre-dialysis and dialysis patients who achieved antibody response of >100iu/L, yearly for 2 years in order to explore the sustainability of the levels.

Methods: We selected 112 predialysis and dialysis patients who had Hepatitis B antibody response of >100 iu/L and has had antibody titres checked subsequently for 2 consecutive years. Results analysed retrospectively to see how long the protective antibody levels lasted.

Results: Total number of patients who had antibody response of >100 iu/L from 2007 to 2015 was 112 from our dataset at Doncaster Royal Infirmary Renal Unit. Of these 34% (38) of patients had hepatitis B antibody titres checked for 2 consecutive years. Patients maintaining antibody level of atleast >10iu/L for 2 years or more were 95%(36 out of the 38).

Conclusions: The outcome of this study confirms that protective antibody levels (>10iu/L) are maintained in 95% of those monitored for 2 years. This result reiterates the need for more robust evidence to inform nephrologists about the appropriate frequency of antibody monitoring in CKD patients.

SA-PO182

Improving Emergency Room (ER) to Dialysis Flow in a Busy Inner City ER Anjali Acharya,[1] Cherryll Moore,[2] Raymond Mcclinton,[1] Naheed Ansari,[1] Bonnie Carnes.[2] *[1]Nephrology, Jacobi Medical Center/Albert Einstein College of Medicine, Bronx, NY; [2]Nephrology, Atlantic Dialysis, Queens, NY.*

Background: Delays in access to hemodialysis during hospitalization are not uncommon and negatively impact on quality of patient care and lead to avoidable complications and unnecessary hospitalizations. Triple Aim is a sought after goal for health organizations to optimize health system performance. We hoped to target one of the three components which is to improve the experience of care.

Methods: The objective was to ensure initiation of dialysis for all non- emergent patients within four hours of ER triage. We analyzed retrospectively in a 8 week observation period, Electronic Medical Record (EMR) data on all hemodialysis patients >18 years of age presenting to the ER, with emphasis on time from triage to initiation of dialysis (TID). We also analyzed factors contributing to delays in dialysis initiation. Data were collected daily on each patient and tabulated weekly. We instituted two measures to address the obstacles.

These were-i) educating the ER staff about timeliness of informing the renal team and ii) the second was to institute a tracking system to systematically gather detailed data on patient transport metrics such a time to patient pick up from initial contact with the transport office.

Results: Baseline data revealed average TID from triage was 8 hours. Two major contributory factors identified were late notification by ER to renal team and delays in transport. By instituting measures targeting these, we were able to achieve being able to provide dialysis within 4 hours of triage in over 80% of our non-urgent hemodialysis patients.

Conclusions: We were able to improve the patient experience and care with simple measures. This has a positive impact on patient safety by minimizing late treatments and staff fatigue. Though Triple Aim is a goal at the population and health care delivery level, we believe processes can be implemented at a local level that align with the CMS goals of triple aim. In today's environment it is incumbent upon us to make efforts to innovate for better patient care and to minimize health care costs.

SA-PO183

Quality Improvement Project in Dialysis: Improving Access to Dialysis for Patients Presenting to the Emergency Room (ER) Nikulkumar Chaudhari,[1] Bonnie Carnes,[2] Cherryll Moore,[2] Roshni Upputalla,[1] Parikshit Thakur,[1] Naheed Ansari,[1] Anjali Acharya.[1] *[1]Nephrology, Jacobi Medical Center/Albert Einstein College of Medicine, Bronx, NY; [2]Nephrology, Atlantic Dialysis, Queens, NY.*

Background: Hemodialysis patients presenting to the emergency room are a vulnerable patient population. Majority of them have significant comorbid conditions. Delays in evaluation and institution of dialysis are common in busy emergency rooms. We undertook a project to improve quality of patient care as well as the patient experience with a goal to provide timely dialysis.

Methods: We analyzed baseline data from electronic medical record (EMR) pertaining to all hemodialysis patients presenting to the ER in a specified 8 week period. After brain storming within the team we identified a few factors that were seen as obstacles in providing timely dialysis. One of them was the time from patient triage to notification of the renal team. We instituted an educational program with the ER staff with focus on the timeliness of informing the renal team, establishing "triage to renal team notification time" of less than 30 minutes as a meaningful metric. Data was collected at pre and post intervention. The objective was to meet this goal >80% of the time over the 2 month intervention period.

Results: There was a positive impact on the triage to renal notification time. The percentage of timely notifications as defined, rose to >85% from a baseline of <25% and this effect was sustained over the 8 weeks. Most patient notifications happened within 10 minutes of triage.

Conclusions: A simple intervention on educating the ER staff made a significant impact on timely evaluation of dialysis patients presenting to the ER. There was an observable positive impact on patient experience. We view this as a simple first step in optimizing patient care and experience towards a seamless journey through the hospitalization. Simple innovative steps such as this could contribute to cost control by avoiding /minimizing dialysis treatments during off hours. In addition it could help mitigate staff fatigue and treatment errors thus improving patient safety.

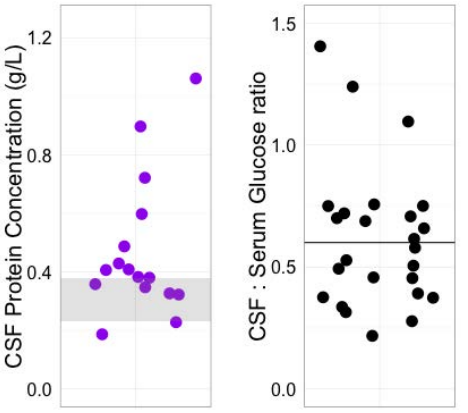
SA-PO184

Diagnostic Reference Values for Cerebrospinal Fluid May Not Be Useful in Haemodialysis Patients Suspected of Having Central Nervous System Infection Thomas Oates, Damien Ashby. *Imperial NHS Trust, London, United Kingdom.*

Background: Invasive investigations in haemodialysis (HD) patients can be associated with complications due to bleeding, and standard diagnostic tests, such as pleural fluid biochemistry, have been shown to be of limited value in this patient group. As a result, we examined the utility of cerebrospinal fluid (CSF) analysis in HD patients suspected of central nervous system (CNS) infection.

Methods: We used electronic records to retrospectively examine laboratory data from HD patients who had CSF analysis in a 5 year period. All patients were initially suspected of having a CNS infection but relevant culture and polymerase chain reaction tests ultimately proved negative for bacterial, mycobacterial, fungal or viral infections in all cases.

Results: 30 CSF samples from 29 patients were identified in the study period. CSF protein concentration was available for 16 samples (median 0.40g/L, range 0.19-1.06g/L, corrected for number of red cells in sample) and paired CSF and plasma glucose concentrations, allowing calculation of CSF:serum glucose ratio, for 25 samples (median ratio 0.58, range 0.21-1.40). Using the accepted normal CSF protein concentration of 0.23 to 0.38 g/L (see Figure shaded region), 8 out of 16 samples showed an elevated protein concentration suggesting CNS infection. Additionally, 13 out of 25 samples had a CSF:serum glucose ratio of less than the normal value of 0.6 (see Figure horizontal line) which is also suggestive of CNS infection.



Conclusions: CSF biochemistry is frequently used in the diagnosis of CNS infection. Our preliminary results suggest CSF protein and glucose concentrations should be interpreted with caution in HD patients and may not add diagnostic information in suspected CNS infection. We are currently investigating the hypothesis that CSF biochemistry may be influenced by duration of chronic kidney disease and HD vintage.

Continuous Renal Replacement Therapy (CRRT) and Hypoglycemia: A Retrospective Study on Patients Undergoing CRRT and Development of Hypoglycemia in Diabetic and Non-Diabetic Individuals Mamtha Balla,[1] Adam Lyons,[1] Mary C. Naglak,[1] Doron Schneider,[1] Robert A. Sirota.[2] *[1]Internal Medicine, Abington Jefferson Health, WillowGrove, PA; [2]HTN Nephrology Associates, Abington Jefferson Health, WillowGrove, PA.*

Background: Hypoglycemia is a little known complication of CRRT. There are no studies available to evaluate the prevalence or intensity of hypoglycemia during CRRT. This study attempts to determine the frequency, timing, and severity of hypoglycemia as a complication of CRRT in diabetic and non-diabetic patients in the intensive care unit.

Methods: This was a retrospective observational study to assess the effect of CRRT on plasma glucose in diabetic and non-diabetic individuals who were admitted to Abington Jefferson Health. A chart review was used to complete a detailed data collection form for patients who underwent CRRT for several diagnosis (sepsis, medication overdose, acute renal failure) in 2013 and 2014 who met the selection criteria. Hypoglycemia is defined as Blood sugar less than 70mg/dl. Dialysate contained 100mg/dl glucose.

Results: After reviewing the charts for 218 CRRT events in 119 patients admitted to Abington Jefferson Health, 100 patients were studied based on selection criteria. The mean age of the study population was 66.3 + 15.3 years. Thirty-six of the 100 patients studied had hypoglycemia during CRRT. The number of episodes was as follows: 14/36 (38.9%) had one episode, 7/36 (19.4%) had two, 7/36 (19.4%) had three and 5/36 (13.9%) had five episodes (mean number of episodes was 2.7±1.9). Hypoglycemia occurred on average 9.9±6.1 hours from start of CRRT. Patients who had hypoglycemia during CRRT were more likely to have it again after CRRT (53%; 19/36) ($p<0.0005$). Of the 36 patients with hypoglycemia, 78% (28/36) had sepsis vs. 22% (8/36) who did not have sepsis but had hypoglycemia ($p>0.05$). No association was found between development of hypoglycemia and history of diabetes and CKD.

Conclusions: Our study showed that hypoglycemia is a frequent complication during CRRT. In order to prevent hypoglycemia from being under-recognized protocols including frequent blood glucose monitoring during CRRT should be in place.

SA-PO186

The Safety of Intravenous Hydration for the Prevention of Contrast Induced Nephropathy Yvonne R.P. de Waal,[1] Corinne E.A. Balemans,[1] Marc A.G.J. Ten Dam,[2] Louis J.M. Reichert,[3] Jack F. Wetzels.[1] *[1]Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands; [2]Nephrology, Canisius Wilhelmina Hospital, Nijmegen, Netherlands; [3]Nephrology, Rijnstate Hospital, Arnhem, Netherlands.*

Background: Contrast-induced nephropathy (CIN) is associated with marked morbidity and mortality. To prevent CIN, current guidelines advise intravenous hydration in high risk patients. Thus far, the possible side effects of hydration have received little attention. We evaluated the incidence of (serious) adverse events ((S)AEs) after intravenous hydration.

Methods: In a retrospective study we analyzed the incidence of (S)AEs after intravenous hydration in two Dutch hospitals. In one hospital (Rijnstate Hospital Arnhem) we evaluated all AEs related to hydration. In the other hospital (CWZ Nijmegen) the analysis was limited to SAEs, i.e. those necessitating prolonged hospital stay. Patient and outcome characteristics were retrieved from the hospital records.

Results: In the Rijnstate Hospital Arnhem we evaluated 233 records of patients hydrated in the period from February till July 2013. AEs occurred in 18 patients (8%). The most common AE was overhydration, which occurred in 11 patients (5%) and necessitated

prolonged hospitalisation in 4 (2%). Admission to the coronary care unit was needed in one patient. Almost all patients with overhydration (91%) had pre-existent cardiac disease and used diuretics. Infusion related AEs also occurred, like extravasation and phlebitis, in one case leading to S. Aureus bacteremia. In the CWZ Nijmegen we evaluated 257 medical records of patients hydrated from May 2013 till January 2014. Prolonged hospitalisation due to overhydration was necessary in 10 patients (4%).

Conclusions: Our study demonstrates that overhydration is a common adverse event after intravenous hydration and necessitates prolonged hospital stay in 2-4% of patients. These data provide arguments against routine hydration in patients with moderate increased risk of CIN. Patients with pre-existent cardiac disease are most prone to overhydration. However, these patients are also at highest risk for the development of CIN. Risk and benefits must be weighed when choosing strategies to prevent CIN.

SA-PO187

Cystatin C in Predicting Cardiorenal Syndrome Type 1 and Mortality in Patients with Acutely Decompensated Heart Failure with Preserved Renal Function

Carlos Federico Varela,[1] Ivan Constantin,[2] Gustavo Cristian Greloni,[1] Griselda Bratti,[1] German Barrera Hugalde,[1] Cesar Belziti,[2] Rodolfo Pizarro,[2] Guillermo Javier Rosa diez.[1] *[1]Nephrology, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina; [2]Cardiology, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina.*

Background: Cardiorenal Syndrome type 1 (CRS 1) is defined as a worsening renal function that complicates acutely decompensated heart failure (ADHF). These patients experience higher mortality and morbidity. Serum creatinine (SC) is slow to reflect changes in kidney function. Cystatin C (Cys C) has emerged as a novel biomarker with a stronger correlation with cardiovascular disease than SC. The aim of our study was to evaluate Cys C in predicting CRS 1 and outcomes in patients admitted with ADHF and preserved renal function.

Methods: We conducted an observational and prospective study. We included patients above 18-years old with ADHF with preserved renal function defined as a SC below 1.3 mg/dL. We excluded patients with heart valvular disease and acute coronary syndrome. Cys C blood samples were collected on admission. We defined CRS 1 as a rise in creatinine by 0.3 mg/dL or more during five days.

Results: 166 patients aging 85 median (IQR 77-89) years old were enrolled. The incidence of CRS 1 was 29.7 %, with an in-hospital mortality of 3.1 %, and a total mortality (TM) of 24.4 %. The median follow-up was 193 days. Cys C was significantly higher in patients with CRS 1 compared to those without (1.72±0.58 vs1.51±0.41, p=0.03) and predict TM but did not predict in-hospital mortality (1.69± vs 1.57±0.48, p=0.58) or readmission (1.47±0.4 vs 1.6±0.5, p=0.58). In the multivariable analysis Cys C was an independent predictor of mortality (OR 3.31, IC1.38-7.93) while SC at admission was not (OR 0.48, IC 0.05-3.48). The area under the receiver-operating characteristic curve of Cys C for CRS 1 was 0.60 and for TM was 0.65. The best cutoff value was 1.6 mg/dL for both end points. It had a sensitivity and specificity of 61.2 % and 60.3 % for CRS 1, and 61.5 % and 62 % for TM, respectively.

Conclusions: Above a cut-off value of 1.6 mg/dL, Cys C predicts CRS 1 and mortality in patients admitted with ADHF with preserved renal function.

SA-PO188

Is Cystatin C a Better Biomarker of AKI in ICU to Compare NGAL?

Itir Yegenaga, Fatih Kamis. *Internal Medicine, Kocaeli Univ Medical School, Kocaeli, Izmit, Turkey.*

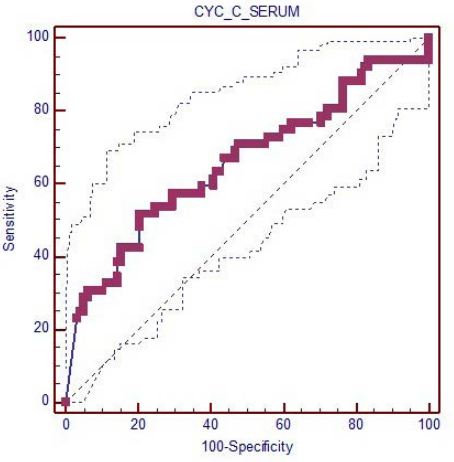
Background: Serum creatinine levels can be affected with many variable factors. We concluded that better bio-marker is needed to recognize AKI as early as possible. We studied Cystatin C (CysC) and Neutrophyl Gelatinase Associated Lipocalin (NGAL) in ICU patients to determine which is more predictable.

Methods: Hundred and eighty three (85 male; mean age: 65) critically ill patient with no previous chronic renal failure history were included to this study. Clinical, laboratory evaluations were noted and blood was taken in 48 hours for CysC and NGAL and followed for 7 days, if they meet the RIFLE criteria.

Results: CysC and NGAL values for every stages RIFLE and serum CysC value were significant only for RIFLE-L stages (p=0.25) but not urinary CysC. NGAL in serum and also in urine were significantly different in RIFLE-I,F. Biomarkers were compared when fulfilled the RIFLE criteria in first 48 hour and following 3-7days to non-AKI values .

	S-CysC mean+/- SD	U-CycC	S-NGAL Median(25-75)	U-NGAL Median(25-75)
(1) No-AKI N:122	30.42+/- 10.17*	7.38+/-2.58	75.69(53.76-91.58)*	17.98(8.72-39.25)*
(2)AKI in 48 h N:14	32.23 +/- 9.70	6.78+/-1.65	95.28(67.98-110.90)	21.74(19.99-50.52)*
(3) AKI in 3-7 days N:15	31.40+/- 13.45	7.74+/-2.42	123.68(90.89-166.31)	12.32(24.59-96.63)*
(4)AKI in 7days N:32	40.75 +/-13.38*	7.74+/-1.82	136.38(117.96-220.54)*	66.06(59.39-75.17)*
	(1-4) P<0.001	p=0.714	(1-3) p=0.028 (1-4) p<0.001	(1-3)p=0.23 (1-4) p<0.001 (2-4) p=0.040

While sNGAL and u NGAL were significantly different between these two groups. Serum CysC level was related to mortality (figure 1)(AUC-ROC 0.68 CI; 0.575-0.733).



Conclusions: In our cohort NGAL obtained in 48 hours is more predictable biomarker than CysC for early AKI diagnosis following 7 days. But CysC levels were fairly predictive for mortality.

SA-PO189

The Effect of Point of Care (POC) Creatinine/eGFR Measurement on the Incidence of Contrast-Induced Acute Kidney Injury (CI-AKI) following Primary Percutaneous Coronary Intervention (PPCI) for the Treatment of ST Elevation Myocardial Infarction (STEMI)

Firas Al-Janabi, Shah MohdNazri, John R. Davies, Thomas Roger Keeble, Ellie Gudde. *Interventional Cardiology, Essex Cardiothoracic Centre, Basildon, Essex, United Kingdom.*

Background: Contrast-induced acute kidney injury (CI-AKI) is a predictor of mortality, morbidity and length of hospital stay. During STEMI treatment with primary percutaneous coronary intervention (PPCI) there are a number of predictors of AKI including existing renal dysfunction (eGFR < 60) and contrast volume used.

Methods: A retrospective audit over 6 months at the Essex Cardiothoracic Centre identified 348 patients who had presented with STEMI and had PPCI. These patients formed the standard care control group. Prospectively 131 consecutive patients presenting with STEMI and under-going PPCI had a point of care creatinine measurement (STATSENSOR, Nova Biomedical). A comparison in rates of AKI was made between the two groups.

Results: In the standard care group, 9.7% of patients with normal renal function and 26.6% of patients with impaired renal function developed AKI. When creatinine was measured pre-PPCI, 8% of patients with normal renal function and 16.1% of patients with renal impairment developed AKI, a 39.5% reduction in AKI in those with renal dysfunction in the POC creatinine group. The average contrast volume in the standard care group was 159 ml, compared to 117.5ml when renal function was found to be impaired (eGFR < 60) pre-PPCI. 186ml was used on average in the POC group when creatinine was found to be normal.

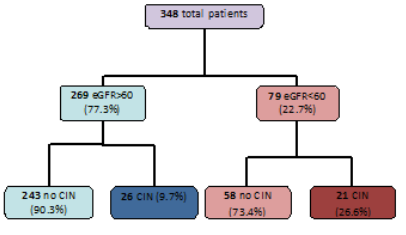


Fig. 1: Breakdown of patients included in the study according to admission and 48 hour creatinine and subsequent development of CIN

Pre-angiogram Creatinine not known

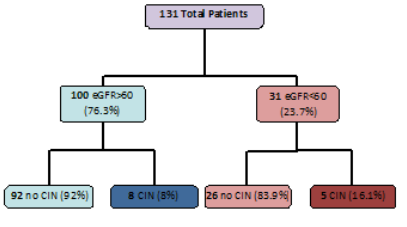

Fig. 2: Breakdown of patients included in the study according to admission and 48 hour creatinine and subsequent development of CIN -

Pre-angiogram Creatinine known

Conclusions: Measuring the POC creatinine of 131 patients presenting with STEMI and undergoing PPCI reduces the rates of AKI by 39.5% in those with renal dysfunction. This appears to be mediated in part by a reduction in contrast volume in those patients identified with renal dysfunction (117.5ml) compared to normal renal function (186 ml).

Serum Creatinine Variability Predicts Progression to CKD4

Carlos E. Palant,[1,2] Lakhmir S. Chawla,[1,2] Ping Li,[1,2] Paul L. Kimmel,[2,3] Charles Faselis,[1,2] Richard Amdur.[1,2] *[1]Medicine, Washington DC VA Medical Center, Washington, DC; [2]Medicine, George Washington Univ Medical School, Washington, DC; [3]NIDDK, National Insts of Health, Bethesda, MD.*

Background: Pre-dialysis patients have high serum creatinine (SC) variability. SC variability is associated with high death rates. We examined the association between SC variability and CKD progression in a large cohort of US veterans with a wide range of baseline eGFR.

Methods: VA patients admitted 10/1999 - 12/2005 with at least 4 months with SC and initial eGFR>30 ml/min/1.73 m^2 (using CKD-EPI) were selected. Autoregression-based slope was computed for each patient using monthly peak SC. SC variability was root mean-square residual of peak SC readings from the regression line. CKD4-date was the first date when eGFR permanently fell below 30 ml/min/1.73 m^2. Logistic regression was used to predict CKD4 using: initial eGFR, SC variability, SC slope, age, race, sex, months with SC readings, and comorbidities (DM, CAD, PNE, MI, angina, AKI, COPD, CHF). Kaplan-Meier (KM) analysis was used to examine time from first admission to entry into CKD4, stratified by SC variability quartile and baseline eGFR, and Cox regression was used to adjust survival estimates for the covariates above.

Results: Of 342,086 patients, 36,108 (10.6%) reached CKD4. The logistic model had strong prediction accuracy (c=.94) with sensitivity and specificity both .86. SC variability was strongly associated with entry into CKD4 (adjusted OR 3.79 [3.67-3.91], p<.001). Time to CKD4 differed by level of SC variability in KM (p<.0001; Figure) and Cox (HR 1.34 [1.31-1.36], p<.0001).

Conclusions: SC variability is strongly independently associated with rate of decline in renal function, at all baseline eGFR levels, after accounting for covariates, and is an important risk factor for entry into CKD4.

KM Estimated freedom from CKD4 by level of SC variability

SA-PO191

Assessment of Methods Used to Substitute for Missing Preadmission Creatinine Values in the Diagnosis and Staging of Acute Kidney Injury

Amelie Bernier-Jean, Anatolie Duca, Francois Madore, Remi Goupil, Stephan Troyanov, Josee Bouchard. *Nephrology, Hopital du Sacre-Coeur de Montreal, Canada.*

Background: Missing preadmission serum creatinine values (SCr) are a common obstacle to the diagnosis and staging of acute kidney injury (AKI). As a workaround, the KDIGO guidelines suggest using a baseline SCr computed from the MDRD formula assuming a baseline estimated glomerular filtration rate (eGFR) of 75 ml/min per 1.73m^2. We hypothesized that surrogates for preadmission SCr will misclassify AKI incidence and severity when compared to a known preadmission SCr.

Methods: Over a 12-month period, we performed a retrospective single-center study of critically ill patients with known preadmission SCr to identify the most accurate method to estimate baseline SCr for AKI diagnosis and staging (KDIGO criteria). We assessed three surrogate methods: 1) the first hospital admission SCr, 2) the minimal SCr after ICU admission and 3) SCr computed for a eGFR of 75 ml/min per 1.73 m^2 using MDRD.

Results: Of 1001 randomly selected patients, a preadmission SCr was available for 498 and 14 were excluded for requiring acute renal replacement therapy. Median age was 67 (IQR 58-76), 60% were male and 98% were Caucasian or Asian. The median time between SCr measurement and admission was 116 (IQR 78-179) days. AKI incidence according to preadmission SCr was 24.8%. We reported in table 1 the AKI incidence, sensitivity, specificity and kappa values for each surrogate method.

N=484	AKI incidence (%)	SEN	SPE	Kappa
Known baseline creatinine	120 (24.8)	-	-	-
Hospital admission creatinine	93 (19.2)	75.0	99.2	0.80
Minimal creatinine	227 (46.9)	99.2	70.3	0.54
MDRD GFR 75ml/min/m2	131 (27.1)	91.7	94.2	0.83

For AKI staging, we found the following kappa values: 0.75 using the first SCr upon admission, 0.43 using the minimal SCr, and 0.66 using the computed MDRD eGFR of 75ml/min per 1.73m^2.

Conclusions: In our cohort, the MDRD computed SCr for a eGFR of 75 ml/min per 1.73m^2 was the best surrogate method for diagnosing AKI. Using the minimal SCr significantly overestimated the incidence of AKI. Concerning AKI staging, the first hospital admission SCr was the most accurate method.

SA-PO192

Fluid Balance and Oliguria in Early AKI Diagnosis After Liver Transplant

Camila Lima,[1] Luciana Haddad,[2] Luiz M. Malbouisson,[3] Luiz Augusto Carneiro D'Albuquerque,[2] Etienne Macedo.[1] *[1]Nephrology, Univ of Sao Paulo, Brazil; [2]Gastrointestinal Surgery, Univ of Sao Paulo, Brazil; [3]Anesthesiology, Univ of Sao Paulo, Brazil.*

Background: AKI is a frequent complication of liver transplant (LT), associated with increased morbidity and mortality. Early diagnosis can translate into secondary preventive measures and improve outcomes. We hypothesized that adjusting Scr for positive fluid balance (FB) and applying urine output(UO) criterion would improve timing of AKI diagnosis. In addition, we investigate whereas sequential assessment of urinary biochemistry after LT can improve prediction of early post-operative AKI development.

Methods: In a prospective cohort study, we recorded UO, FB and labs of patients undergoing LT. We assessed urine and blood biochemistry perioperative (before induction of anesthesia, after portal reperfusion, 6, 18, 24 hours after surgery). AKI diagnosis was based on UO and the sCr KDIGO criterion before and after correcting scr for FB (Scr adjusted), using the formula: ((weight*0,6)+(FB)/(weight*0,6).

Results: Fifty-five patients >18 years undergoing LT from Jun13 to Oct14 were included in the analysis. twenty-seven percent (15) of patients developed AKI based on Scr criterion within 48h of surgery (early AKI). By adjusting Scr for fluid balance 38%(21) patients were classified as early AKI. Applying the UO criterion, 43patients were classified exclusively by this criterion as early AKI. All patient showed a decline in FeNa and the FeU after portal reperfusion. Patients developing early AKI had a higher decline and maintained lower levels for 24h. FeUreia values were significantly different 6 hours after surgery in early AKI patients. Patients with early AKI based on both criteria or exclusively by UO had a higher mortality and longer ICU and hospital stay than non-AKI patients.

Conclusions: Applying UO criteria and adjusting Scr for FB can help in the early identification of patients developing AKI after liver transplant. Tubular function assessment could be utilized along with biomarkers of kidney injury to identify patients with increased risk of developing AKI. Standardized approach for early AKI diagnosis in high-risk patients could improve outcomes.

SA-PO193

Renal Angina Index a Practical Tool to Identify Patients at Increased Risk of Acute Kidney Injury

Rolando Claure-Del Granado,[1] Andrea Pero,[1] Josee Bouchard,[2] Ravindra L. Mehta.[3] *[1]IIBISMED, Univ Mayor de San Simon, School of Medicine, Bolivia; [2]Hospital du Sacre-Coer de Montreal, Canada; [3]Univ of California San Diego Medical Center.*

Background: Reliable prediction of acute kidney injury (AKI) has the potential to optimize treatment. Recently Goldstein SL et al. proposed an empiric clinical model of renal angina using patient demographic factors and early signs of injury to identify critically-ill children who would be at higher risk of AKI. We test the hypotheses that in a cohort of adult critically-ill patients, a modified renal angina index (RAI) will identify patients at high risk of developing AKI, and could be related to in-hospital mortality.

Methods: We included 124 consecutive patients admitted to our medical ICU. We measured serum creatinine (sCr) every 24 h for 7 consecutive days after ICU admission. RAI was calculated at ICU admission (day 1) and 24 h after (day 2) using the following formula: **Risk level** (vasopressors and invasive mechanical ventilation = 5; diabetes mellitus = 3; and sepsis = 1) **X Injury level** (decreases in eGFR: no change=1, 0-24.9%=2, 25-49.9%=4, and ≥50%=8). The composite range of the RAI is therefore: 1, 2, 3, 4, 5, 6, 8, 10, 12, 20, 24, and 40. We analyzed the value of a RAI score ≥8 to predict subsequent AKI (after 48 h, day 3) and survival.

Results: We identified 50(40.3%) patients with AKI *(KDIGO guidelines sCr criteria)*, and 74(59.7%) patients who did not develop AKI. Patients with a RAI ≥8 were at higher risk of developing AKI within 7 days of follow-up (RR 1.64 95% CI 1.31–2.05; p<0.0001). A **RAI** ≥8 at ICU admission (day 1) and 24 h after admission (day 2) was able to identify individuals who developed AKI (day 3-7) with an AUC of 0.861 (95% CI 0.777-0.945); p < 0.0001 and an AUC of 0.891 (95% CI 0.815-0.966); p < 0.0001, respectively. No difference was found in terms of 28 day in-hospital mortality in patients with a **RAI** ≥8 vs a **RAI** ≤8.

Conclusions: The RAI provides a clinically feasible methodology to identify critically-ill patients at high risk of developing AKI before a rise in sCr occurs. This tool would permit the early identification of AKI to initiate preventive and treatment strategies minimizing extension of kidney injury.

SA-PO194

The Renal Angina Index Identifies Patients at High-Risk of Acute Kidney Injury – Analysis from AWARE: A Prospective Multinational Study of AKI in Critically Ill Children Rajit K. Basu,[1,2] Ahmad Kaddourah,[1,2] Stuart Goldstein.[1,2] *[1]Pediatrics, Center for Acute Care Nephrology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]On Behalf of the AWARE Study Investigators, Multinational Pediatric ICU.*

Background: We conducted a global, prospective observational study of critically ill children to study the epidemiology of pediatric acute kidney injury (AKI). We analyzed the discrimination of the renal angina index for prediction of AKI and patient outcomes.

Methods: Data from 32 centers (5 continents, data collection for 3 consecutive months in 2014) from children (aged 3 months to 25 years) admitted to a pediatric intensive care unit were analyzed. The renal angina index (RAI) was calculated on the day of admission (Day 0) as previously described. A cut-off of > 8 on Day 0 was used to determine fulfillment or absence of renal angina (RA+ vs. RA-). The primary outcome was the presence of severe AKI on Day 3, defined by change in serum creatinine from baseline using KDIGO stage 2-3 criteria (Day 3 AKI). Other patient outcomes were assessed at 28 days.

Results: 9.6% (501/5231) of children were RA+ on Day 0. The area-under-curve receiver operating characteristic of the Day 0 RAI for Day 3-AKI was 0.797 (95% confidence interval 0.759-0.836). RA+ was associated with a higher net fluid balance on Day 3 than RA- ($p<0.001$). Compared to RA-, Day 0 RA+ was associated with prolonged duration of mechanical ventilation, longer length of stay, increased use of extracorporeal therapies, and higher incidence of mortality.

Table 1. Outcome of Patients in AWARE Stratified by Day 0 Renal Angina

Outcome	RA (-)	RA (+)	p value
Day 3 AKI (%)	4.8	33.5	< 0.001, χ^2 = 156.4
MV duration (days)	7.4 ± 7.0	8.5 ± 7.3	0.04
Length of Stay (days)*	7.2 + 7.1	8.9 + 6.9	<0.001
RRT use (%)	1.4	11.6	< 0.001, χ^2 = 100.2
ECMO use (%)	0.8	2.8	0.002, χ^2 = 9.3
Mortality (%)	3.6	11.0	< 0.001, χ^2 = 33.3

*= patients who died within 48 hours were excluded
RRT = Renal Replacement Therapy
ECMO = Extracorporeal Renal Replacement Therapy

Conclusions: In AWARE, the largest prospective multi-center epidemiologic assessment of AKI in critically ill children, we demonstrate the ability of the renal angina index to identify patients at high risk of AKI, three days in advance. Fulfillment of renal angina early in the ICU course is associated with poor patient outcome.

SA-PO195

Phase Angle and Extracellular Hypervolemia, as a Prognostic Markers in Acute Kidney Injury Francisco Javier Lavilla, Maria Jose Molina Higueras, Diana Lopez Espinosa, Pelayo Moiron Fdez-Felechosa, Nuria Garcia-Fernandez, Paloma L. Martin Moreno, Pedro Errasti. *Nephrology, Clínica Univ de Navarra, Pamplona, Navarra, Spain.*

Background: The bioelectrical impedance analysis (BIA) is a noninvasive and painless technique and easy to perform , which is used for determining body composition . Can offer information about membrane cell integrity, volemia and clinical status. We evaluate use of BIA and two bioelectrical parameters (Phase angle –PA-, and extracelular/intracelular watter ratio –ECW/ICW-) as a prognostic markers in acute kidney injury (AKI).

Methods: We include a cohort of 83 patients (mean age 64 years SD 1.8, and male 72.3 %) with AKI and BIA. We evaluate clinical prognostic index (individual severity index –ISI-), inflammatory and protein metabolism analitical parameters (C-reactive protein, albumin, prealbumin) and chronic health index (Karnofsky –K-).

Results: Exitus 14.5%. PA and ECW/ICW was associated with prognosis in AKI.

	ISI	CRP	Alb	PreAlb	K
PA	r=-0.228, p=0.038	r=0.250, p=0.027	r=0.369, p=0.006	NS	r=0.516, p<0.001
ECW/ICW	r=-0.271, p=0.001	r=0.248, p=0.004	NS	r=-0.410, p=0.008	r=-0.253, p=0.003

PA: PHASE ANGLE ECW/ICW: EXTRACELLULAR/INTRACELLULAR WATTER RATIO. ISI: INDIVIDUAL SEVERITY INDEX. CRP: C-REACTIVE PROTEIN. Alb: ALBUMIN. PreAlb: PREALBUMIN. K: KARNOFSKY.

PA was associated with protective risk mortality OR 0.425, p=0.007, CI 95% 0.229-0.780 and ECW/ICW with risk mortality OR 2.247 CI 95% 1.266-3.98. The AUC with PA was 0.770 (p=0.003, CI 95% 0.652-0.888) and with ECW/ICW was 0.778 (p=0.001, CI 95% 0.678- 0.879).

Conclusions: BIA is a useful technique to evaluate AKI. Lower PA and higher ECW/ICW are associated with worse prognosis in AKI. There are relation with inflammatory and protein metabolism status, and with health clinical status prior to the event.

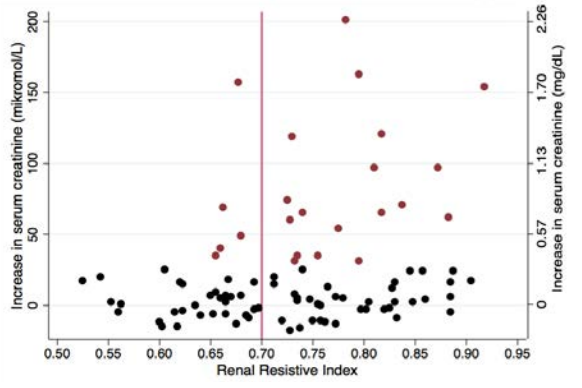
Preoperative Renal Resistive Index Predicts the Risk of Acute Kidney Injury in Patients Undergoing Cardiac Surgery Daniel P. Olsson Hertzberg,[1] Ulrik Sartipy,[2] Martin Holzmann.[1] *[1]Dept of Medicine, Karolinska Inst, Stockholm, Sweden; [2]Dept of Anesthesiology, Surgical Services and Intensive Care Medicine, Karolinska Univ Hospital, Stockholm, Sweden; [3]Dept of Molecular Medicine and Surgery, Karolinska Inst, Stockholm, Sweden.*

Background: Previous studies have indicated that Renal Resistive Index (RRI), an ultrasound-based measurement, can predict AKI in a variety of settings. To our knowledge, there are no studies investigating the predictive value of preoperative RRI and the risk of AKI in cardiac surgery patients. The aim of this study was to investigate whether an elevated preoperative RRI predicts AKI in a general cardiac surgery population.

Methods: Patients undergoing elective cardiac surgery were included prospectively between September 21, 2014 and April 22, 2015 at the Karolinska University Hospital. RRI was measured the day before surgery. An elevated RRI was defined as >0.7. The outcome AKI was defined as an absolute increase in post- compared to preoperative serum creatinine by 0.3 mg/dL (>26µmol/L) or a relative increase by >50%. The odds ratio for AKI was calculated by logistic regression in patients with a RRI >0.7 versus those with a RRI ≤ 0.7.

Results: 98 patients were included. In patients with a RRI £0.7, 6 (15%) patients developed AKI, compared to 19 (33%) in patients with a RRI >0.7. The mean increase in postoperative serum increase in patients with RRI £0.7 was 0.12 mg/dL (11 µmol/L) compared to 0.34 mg/dL (30 µmol/L) in those with RRI >0.7 (P=0.03). The odds ratio for developing AKI in patients with a RRI >0.7 compared to those with a RRI £0.7 was 2.76 (0.99-7.71).



Conclusions: We found that patients with an elevated RRI before cardiac surgery had an increased risk of developing AKI postoperatively. RRI might be a valuable tool for identifying patients with an increased risk of developing AKI connected to cardiac surgery.

Development of a Postoperative Risk Stratification Tool via Bayesian Model Averaging for Acute Kidney Injury After Cardiac Surgery Allison Meisner,[1] Kathleen F. Kerr,[1] Heather Thiessen Philbrook,[2] Francis Perry Wilson,[3] Amit X. Garg,[2] Michael Shlipak,[4] Peter Kavsak,[5] Richard P. Whitlock,[5] Steven G. Coca,[6] Chirag R. Parikh.[3] *[1]Univ of Washington, Seattle, WA; [2]Western Univ, ON, Canada; [3]Yale School of Medicine, New Haven, CT; [4]UCSF; [5]McMaster Univ, ON, Canada; [6]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Acute kidney injury (AKI) is a frequent complication of cardiac surgery. We sought predictive combinations of biomarkers measured 0-6 hours after surgery, potentially in combination with cardiopulmonary bypass (CPB) time (to account for the degree of insult).

Methods: The primary endpoint was sustained mild AKI, defined as an increase of 50% or more in serum creatinine over preoperative levels lasting at least two days during the hospital stay. Severe AKI (secondary endpoint) was defined as a serum creatinine increase of 100% or more or dialysis during hospitalization. Data were from a cohort of 1219 adults undergoing cardiac surgery at 6 medical centers; among these, 117 developed sustained mild AKI and 60 developed severe AKI. We considered CPB time and 22 biomarkers as candidate predictors. We used Bayesian Model Averaging (BMA) methods to develop center-adjusted combinations for sustained mild AKI by (1) maximizing the posterior model probability and (2) retaining predictors with posterior variable probabilities above 0.5.

Results: The maximum posterior model probability combination included plasma NT-proBNP, plasma h-FABP and change in serum creatinine; the median probability combination additionally included plasma IL-6. The center-adjusted, optimism-corrected AUCs for these combinations were 0.80 (95% CI: 0.78, 0.88) and 0.81 (0.77, 0.88), respectively, for predicting sustained mild AKI, and were 0.81 (0.77, 0.90) and 0.83 (0.76, 0.90), respectively, for predicting severe AKI. For these data, the BMA methods yielded combinations with predictive capacity comparable to that achieved by standard frequentist methods but with smaller models.

Conclusions: Pending external validation, the identified combinations could be used to identify individuals at high risk of AKI immediately after cardiac surgery and could facilitate clinical trials of renoprotective agents.

SA-PO198

Low Pre-Operative Serum Bicarbonate Levels Predict Acute Kidney Injury After Cardiac Surgery Jong Hyun Jhee, Kyoung Sook Park, Hyung Jung Oh, Seung Hyeok Han, Tae-Hyun Yoo, Jung Tak Park. *Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea.*

Background: Low serum bicarbonate levels are known to be risk factors for renal function deterioration in chronic kidney injury patients. However, it is not well known whether preoperative low serum bicarbonate levels are associated with the development of acute kidney injury (AKI) in patients who undergo cardiac surgery. Therefore, clinical implications of preoperative serum bicarbonate levels on AKI occurrence after cardiac surgery were evaluated.

Methods: The patients who underwent coronary artery bypass or valve surgery at Yonsei University Health System from January 2013 to December 2014 were enrolled. The patients were categorized into three groups according to pre-operative serum bicarbonate levels (group 1 <23 mEq/L, group 2 23-24 mEq/L, group 3 >24 mEq/L). Multivariate logistic regression analysis was performed to determine the effect of pre-operative serum bicarbonate levels on development of AKI at 48 hours after cardiac surgery.

Results: Among 452 patients, 228 patients (26.1%) developed AKI at 48 hours after cardiac surgery. Incidence of AKI was higher in group 1 (34.6%) than group 2 (26.3%) and group 3 (39.0%) (P <0.001). The duration of post-operative intensive care unit (ICU) stay was longer in AKI patients (AKI vs. non-AKI, 6.2 vs. 2.7 days, P<0.001). In addition, post-operative ICU stay was longer in the low pre-operative serum bicarbonate level groups [group 1 (4.4 days), group 2 (3.6 days), group 3 (3.3 days), P<0.001]. In multivariate logistic regression analysis, low pre-operative serum bicarbonate levels were significantly associated with post-operative AKI development even after adjusting for age, sex, hypertension, diabetes mellitus, operation type, hemoglobin, and glomerular filtration rate (group 3 as reference, odds ratio=2.36, 95% confidence interval=1.57-3.54, P<0.001).

Conclusions: Low serum bicarbonate levels were associated with higher incidence of AKI and prolonged ICU stay. Correction of low serum bicarbonate levels before cardiac surgery may reduce the risk of AKI development.

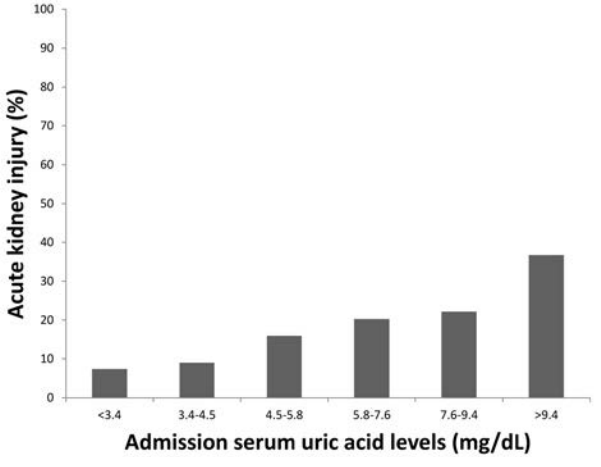
SA-PO199

Admission Hyperuricemia Increases the Risk of Acute Kidney Injury in Hospitalized Patients Wisit Cheungpasitporn,[1] Charat Thongprayoon,[2] Stephen B. Erickson.[1] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Internal Medicine, Bassett Medical Center, Cooperstown, NY.*

Background: The association between elevated admission serum uric acid and risk of in-hospital acute kidney injury (AKI) is limited. The aim of this study was to assess the risk of developing AKI in all hospitalized patients with various admission serum uric acid (SUA) levels.

Methods: This is a single-center retrospective study conducted at a tertiary referral hospital. All hospitalized adult patients who had admission SUA available from January 2011 through December 2013 were analyzed in this study. Admission SUA was categorized based on its distribution into six groups (less than 3.4, 3.4 to 4.5, 4.5 to 5.8, 5.8 to 7.6, 7.6 to 9.4, and greater than 9.4 mg/dL). The primary outcome was in-hospital AKI occurring after hospital admission. Logistic regression analysis was performed to obtain the odds ratio of AKI of various admission SUA levels using the most common SUA level reference range (5.8 to 7.6 mg/dL) as the reference group.

Results: Of 1,435 patients enrolled, AKI occurred in 263 patients (18%). The incidence of AKI and need for dialysis was increased in patients with higher admission SUA levels. After adjusting for potential confounders, SUA greater than 9.4 mg/dL was associated with an increased risk of developing AKI with odds ratios of 1.79 (95% CI 1.13-2.82). Conversely, admission SUA of less than 3.4 mg/dL and 3.4 to 4.5 mg/dL were associated with decreased risk of developing AKI with odds ratios of 0.38 (95% CI 0.17-0.75) and of 0.50 (95% CI 0.28-0.87) respectively.



Conclusions: Elevated admission SUA was associated with an increased risk for in-hospital AKI.

SA-PO200

Hypoalbuminemia Is a Strong Risk Factor for Acute Kidney Injury Progression in Elderly Patients in Intensive Care Unit Yu Kurata,[1] Keita Hirano,[2] Fumio Omata,[3] Yasuhiro Komatsu.[2] *[1]Div of Nephrology, Mitsui Memorial Hospital, Chiyoda-ku, Tokyo, Japan; [2]Div of Nephrology, St. Luke's International Hospital, Chuo-ku, Tokyo, Japan; [3]Center for Clinical Epidemiology, St. Luke's International Hospital, Chuo-ku, Tokyo, Japan.*

Background: Population aging is a global issue; especially, Japan is experiencing rapid aging, at a faster speed than any other developed country, and those aged 65 or older comprised 25.9% of Japan's population as of September 2014. Previous studies showed elderly patients are at high risk for developing acute kidney injury (AKI). AKI is also a common clinical syndrome in the ICU setting, but its clinical presentation varies from mild to severe. Predicting whether AKI progress or not is difficult but can guide clinical decision making. The aim of the present study is to elucidate risk factors of AKI progression among elderly patients in ICU.

Methods: A retrospective study of patients age 65 and older developed AKI during ICU stay between January 2004 and September 2013. AKI was defined as increase in serum creatinine (sCr) of ³1.5 times baseline. The primary outcome was the progression to AKIN stage 3 (increase in sCr of 3 times over baseline or need for renal replacement therapy (RRT)) within 14 days after AKI development. Prerenal AKI, postrenal AKI, and AKIN Stage 3 at diagnosis of AKI are excluded; prerenal AKI is diagnosed when serum BUN-to-creatinine ratio is ≥ 20 and postrenal AKI is diagnosed based on clinical situation.

Results: 418 patients were included. The mean of age was 80.6 ± 8.2 years, baseline sCr 0.89 ± 0.40 mg/dl, and baseline eGFR 66.1 ± 32.3 ml/min/1.73m2. Among 418 patients, 77 (18.4%) experienced AKI progression and 83 (19.9%) died. Of the 77 patients with AKI progression, 25 (6.0%) patients received RRT. AKIN stage 2 at diagnosis (OR=2.33, 95%CI=1.23-4.36), RAS inhibitor use (OR=2.84, 95%CI=1.33-5.93), bacteremia (OR=1.69, 95%CI=0.89-3.14), hypoalbuminemia (OR=5.10, 95%CI=2.94-9.06) were risk factors for AKI progression.

Conclusions: Hypoalbuminemia is a strong risk factor for AKI progression in older patients in ICU. Further study is needed to evaluate whether correction of hypoalbuminemia could prevent AKI progression or not.

SA-PO201

Impact of Preexisting Serum Prealbumin on All-Cause Mortality in Community-Acquired and Post-Operative Acute Kidney Injury Patients Yanfang Zou,[1] Dan Wen,[1] Jingyuan Xie,[1] Xiaonong Chen,[1] Wen Zhang,[1] Nan Chen.[1] *[1]Nephrology, Ruijin Hospital, Shanghai, China; [2]Nephrology, Ruijin Hospital; [3]Nephrology, Ruijin Hospital.*

Background: To explore the impact of pre-existing prealbumin concentration on all-cause mortality in AKI (acute kidney disease, AKI) patients.

Methods: From 2000 to 2010, 477 patients diagnosed with community-acquired AKI (CA-AKI) and treated in the Department of Nephrology, Ruijin Hospital, Shanghai Jiaotong University were enrolled in the CA-AKI group. 138 patients diagnosed with AKI after cardiac operations were enrolled in the post-operative AKI (PO-AKI) group. Data were collected at the time point of AKI onset and one year after the discharge.

Results: Patients with CA-AKI were younger than PO-AKI patients. Compared with PO-AKI patients, more patients in CA-AKI group suffered from chronic kidney disease, obesity and hyperlipidemia and less patients with cerebrovascular disease (CVD), anemia, shock, arrhythmia and so on. Risks for CA-AKI were atherosclerosis, CVD, arrhythmia, multiple organ dysfunction syndrome (MODS) and usage of vasoactive agents, and for PO-AKI were elderly age, arrhythmia and RRT(renal replacement therapy, RRT)-requiring. A higher level of preexisting serum prealbumin (PA) lead to better outcome in CA-AKI(HR 0.92, 95%CI 0.85-1.00)and PO-AKI group(0.91, 95%CI 0.84-0.99). In CA-AKI group, cumulative survival rate of patients in normal PA group(PA>20mg/dL) was higher than that in lower PA(PA£20mg/dL) group (95.4% vs 88.3%, P=0.031). Similarly, in PO-AKI group, normal PA level was associated with a higher survival rate (74.1% vs 47.6%, P=0.019).

Conclusions: A significant difference was detected between CA-AKI group and PO-AKI in general characteristics, comorbidities, laboratory examinations, outcome, and risks. Patients with PA>20mg/dL showed better survival rate.

SA-PO202

Usefulness of Serum Ischemia-Modified Albumin Levels to Predict Dialysis Reqirement in Patients with Acute Renal Injury Mehmet Uzun, Harun Akar. *Internal Medicine, Izmir Tepecik Education and Research Hospital, Turkey.*

Background: Ischemia-modified albumin is a promising biomarker for early diagnosis of diseases related with ischemia. Ischemia leads to modification in albumin molecule by reducing its binding to cobalt. The aim of this study was to evaluate the levels of ischemia-modified albumin in patients with acute kidney injury (AKI).

Methods: Serum levels of ischemia-modified albumin were estimated in 51 patients with AKI.

Results: The mean age of 28 female and 23 male patients were 65.39±15.28 and 70.11±15.25, respectively. Levels of IMA were found to be high in 75.5 % of the patients (>400) and were found to be normal in 25.5 % of the patients (<400). Kaplan-Meier survival analysis showed that the survival was not different between IMA groups. Urine amounts were significantly different between IMA groups. The urine volume was lower in patients with higher IMA levels (>400).

Conclusions: In the present study, the levels of IMA were found to be significantly higher who needed hemodialysis treatment. IMA levels do not predict mortality.Taking these results together, serum IMA levels might give an idea about dialysis requirement in patients with AKI. More studies with larger sample groups may help to establish the role of IMA on decisions regarding dialysis initiation.

SA-PO203

Urinary TIMP-2 and IGFBP7 Elevate Early After Vancomycin Administration in Critically Ill Patients Who Develop AKI

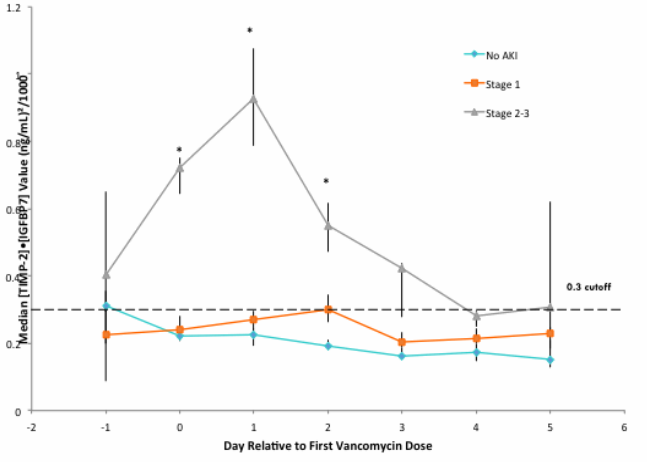
Maria Ostermann,[1] Lui G. Forni,[2] Lakhmir S. Chawla,[3] Jing Shi,[4] Kianoush Banaei-Kashani,[5] John A. Kellum.[6] *[1]King's College London, London; [2]Royal Surrey County Hospital, Guilford; [3]George Washington Univ, Washington; [4]Walker Bioscience, Carlsbad; [5]Mayo Clinic, Rochester; [6]Univ of Pittsburgh, Pittsburgh.*

Background: We previously validated a biomarker combination of tissue inhibitor of metalloproteinase-2 (TIMP-2) and insulin-like growth factor binding protein 7 (IGFBP7) for risk stratification of acute kidney injury (AKI).[1] A cutoff of 0.3 (ng/ml)^2/1000 for [TIMP-2]•[IGFBP7] indicated AKI stage 2-3 at least 24h prior to serum creatinine.[2] We also showed that nephrotoxic drug use was common in patients developing AKI and that the [TIMP-2]•[IGFBP7] test could have identified patients earlier.[3] In this sub-analysis of the Sapphire study[1], we examined the temporal changes in [TIMP-2]•[IGFBP7] following vancomycin.

Methods: We identified patients who received vancomycin and grouped them according to their maximum KDIGO AKI stage within 3 days of 1st dose of vancomycin. We calculated the median daily [TIMP-2]•[IGFBP7] value from day prior to 1st dose of vancomycin until 5 days after. A bootstrap analysis was used to calculate 1-sided p-values for comparison to the 0.3 (ng/mL)^2/1000 cutoff.

Results: 249 patients received at least 1 dose of vancomycin. 137 (55%) developed AKI within 3 days [AKI 1 (n=81), AKI 2 (n=44), AKI 3 (n=12)]. In patients without AKI or with AKI 1, median [TIMP-2]•[IGFBP7] values were £0.3 (ng/mL)^2/1000 for all time points.

Figure 1 Kinetics of urinary [TIMP-2]•[IGFBP7] in critically ill patients who received vancomycin.



In patients with AKI 2-3, median [TIMP-2]•[IGFBP7] values were significantly elevated on the day of the 1st vancomycin dose and remained elevated for the following 2 days.

Conclusions: In patients with AKI 2-3 after vancomycin administration, urinary [TIMP-2]•[IGFBP7] was significantly elevated on the first 2 days after the 1st dose. These biomarkers have the potential to improve management in patients receiving vancomycin.

Peri-Operative Serum IL-33 Concentrations in Matched AKI and Non-AKI Patients Undergoing Cardiac Surgery

Charles L. Edelstein,[1] Heather Thiessen Philbrook,[2] Jay L. Koyner,[3] Michael Shlipak,[4] Steven G. Coca,[2] Chirag R. Parikh.[2] *[1]Univ Colorado Denver; [2]Yale Univ; [3]Univ Chicago; [4]UCSF.*

Background: Endothelial cell damage and death in the nephron is an early feature of AKI. Damage–associated molecular patterns (DAMPS) are endogenous molecules released by damaged cells including endothelial cells. IL-33, a DAMP, has been shown to be present in blood vessels in the kidney and released into the blood, but not the urine, in cisplatin-induced AKI in mice before the increase in serum creatinine. We sought to determine whether serum IL-33 levels are a biomarker of AKI in humans in a nested case-control study.

Methods: Perioperative plasma samples were obtained from patients enrolled in the TRIBE-AKI cohort. 35 cases of AKIN Stage 2 AKI or higher within the first 4 post-op days were matched to 70 controls with no AKI by pre-op GFR, age, sex, site and cohort. Blood samples were available pre-op, day 1 (0-6 hours), days 2 and 3. Serum IL-33 was measured by ELISA.

Results: The pre and post-operative levels of IL-33 are shown in Table 1. Using a mixed model accounting for the matching in the data, the first post-operative value of IL-33 was significantly different (p=0.005) between cases and controls after adjusting for pre-op values. There was a non-significant trend towards higher IL-33 levels on day 2.

Time point		Cases Mean (SD)	Cases Median (P25,P75)	Controls Mean (SD)	Controls Median (P25, P75)	P
Pre-op	Actual	1082 (2174)	155 (0,516)	1160 (2214)	58 (0, 641)	0.87
Day 1	Actual	1452(2131)	331 (71, 1922)	1172(2094)	72 (0,759)	0.048
Day 1	Delta from pre	355(926)	0 (-63, 202)	12(759)	-5 (-166, 0)	
Day 2	Actual	1591(2082)	315 (34, 2731)	1272(2236)	158 (0, 905)	0.08
Day 2	Delta from pre	456(1252)	0 (-97, 592)	111(1069)	0 (-163, 5)	
Day 3	Actual	1367(2098)	413 (12, 1391)	1383(2294)	135 (0, 1170)	0.38
Day 3	Delta from pre	282(1402)	0 (-152, 382)	222(1190)	0 (-82,30)	

Conclusions: Immediate post-operative serum IL-33 concentrations were higher in matched AKI cases compared to non-AKI controls. Further studies are needed to clarify the role of serum IL-33 in human AKI.

First Post-Operative Urinary Kidney Injury Biomarkers and Association with the Duration of AKI in the TRIBE-AKI Cohort

Steven G. Coca, Girish N. Nadkarni, Amit X. Garg, Jay L. Koyner, Heather Thiessen Philbrook, Eric Mcarthur, Michael Shlipak, Chirag R. Parikh. *TRIBE-AKI Consortium.*

Background: We previously demonstrated AKI duration improves risk-stratification for AKI prognosis in addition to the magnitude of serum creatinine rise. We evaluated whether kidney injury biomarkers within 6 hours after cardiac surgery associate with post-operative AKI duration.

Methods: We included 1199 adults undergoing cardiac surgery in TRIBE-AKI cohort that survived to discharge and examined association between five urinary biomarkers: neutrophil gelatinase-associated lipocalin (NGAL), interleukin-18 (IL-18), kidney injury molecule-1 (KIM-1), liver fatty acid binding protein (L-FABP) and albumin with duration of serum creatinine-based AKIN criteria for AKI (0 (no AKI), 1-2, 3-6, ≥7 days).

Results: Overall, 406 (34%) patients had AKI, of which 48 had stage 2/3 AKI. Of 358 with stage 1 AKI, 115 (32.1%) had AKI duration >3 days. An additional 41 (85%) with stage 2/3 AKI had duration of >3 days. Concentrations of all biomarkers increased with AKI duration and each log increase in biomarker was independently associated with greater odds of longer duration category (IL-18 OR 1.25, 95% CI 1.16-1.35; KIM-1: 1.36, 95%CI 1.21-1.52; albumin 1.21, 95% CI 1.10-1.33; L-FABP 1.14, 95% CI 1.07-1.21; NGAL 1.10, 95% CI 1.03-1.17).

Biomarkers at 0-6 hours	**AKI Duration in days**			
	0 (No AKI) (n=788)	**1-2 (n=250)**	**3-6 (n=118)**	**≥7 (n=38)**
Urine IL-18 (pg/mL)	9.3 (3.6-27.9)	15.8 (5.9-82.4)	23.1 (6.0-88.9)	45.9 (16.6-188.6)
Urine NGAL (ng/mL)	8.4 (3.3-32.8)	14.1 (5.2-79.9)	15.0 (5.6-86.3)	26.5 (10.3-418.3)
Urine KIM-1 (ng/mL)	0.4 (0.1-0.8)	0.5 (0.2-1.0)	0.7 (0.3-1.5)	1.0 (0.7-2.2)
Urine LFABP (ng/mL)	16.0 (3.3-79.0)	21.2 (6.4-178.7)	34.0 (6.6-183.3)	61.1 (13.9-371.9)
Urine Albumin (mg/L)	12.5 (6.4-30.8)	18.0 (7.9-53.7)	20.0 (9.0-61.3)	43.3 (19.0-70.4)

Conclusions: While most patients in the TRIBE-AKI Cohort experienced stage 1 AKI when classified by peak serum creatinine increase, one-third of those have duration of AKI of >3 days. Elevated urinary kidney injury biomarker within 6 hours of surgery may help in identifying of patients at risk for longer AKI duration, which may serve as a reliable metric for drug development trials.

Urinary Biomarker Evaluation in Cancer Patients Receiving Cisplatin
Blessy George,[1] Amandla Roque- Atilano,[2] Cara A. Chang,[2] Nickie L. Johnston,[2] Madeleine Gomez,[2] Lucas Ellison,[2] Xia Wen,[1] Lauren Aleksunes,[1] Daniel Bowles,[2] Cindy L. O'Bryant,[2] Melanie S. Joy.[2] *[1]School of Pharmacy, Rutgers Univ, NJ; [2]Schools of Pharmacy and Medicine, Univ of Colorado, CO.*

Background: The study explored the time dependency of urinary biomarker changes and correlations between the biomarkers and traditional markers of kidney injury in a cohort of patients receiving cisplatin.

Methods: Urine was obtained at 1)baseline, 2)Day 3 and 3)Day 10 from patients (n=42) receiving cisplatin (³25 mg/m²). Urinary kidney injury molecule-1 (Kim-1), calbindin, beta-2 microglobulin (B2M), clusterin, monocyte chemoattractant protein-1 (MCP-1), cystatin C, trefoil factor 3 (TFF3), tissue inhibitor of metalloproteinase 2 (TIMP2), and insulin growth factor binding protein 7 (IGFBP7) were measured with multiplex or ELISA.

Results:

Mean±SEM	Baseline	Day 3	Day 10
Kim-1 (ng/mL)	0.42±0.1[A,B]	0.77±0.1	0.97±0.2
Calbindin (ng/mL)	59.0±13.8[B]	70.1±12.2[C]	544±163
B2M (ng/mL)	144±39.1[A]	502±71.8[C]	185±41.5
Clusterin (ng/mL)	42.0±23.5[B]	27.7±8.5	52.9±16.1
MCP-1 (ng/mL)	0.62±0.2[B]	0.45±0.1	1.0±0.23
Cystatin C (ng/mL)	39.5±7.7	77.3±22.8	64.9±19.0
TFF3 (ng/mL)	865±154[B]	1441±202	1616±264
TIMP2 (ng/mL)	2.2±0.5	2.3±0.6	3.2±0.7

A: baseline vs. Day 3 p<0.05, B: baseline vs. Day 10 p<0.05, C: Day 3 vs Day 10 p<0.05

The biomarker-GFR correlations were: TFF3 (r: -0.2590), B2M (r: -0.2017), Kim-1 (r: -0.1758), MCP-1 (r: -1390), cystatin C (r: -0.0936), IGFBP7 (r: -0.0764), clusterin (r: -0.0767), calbindin (r: -0.0647), and TIMP2 (r: -0.0619). The biomarker-albumin correlations were: calbindin (r: 0.7813), TFF3 (r: 0.5949), clusterin (r: 0.5869), Kim-1 (r: 0.3186), TIMP2 (r: 0.3016), MCP-1 (r: 0.2340), IGFBP7 (r: 0.2217), cystatin C (r: 0.1375), and B2M (r: 0.1149).

Conclusions: Urinary biomarkers display time dependent increases post cisplatin and exhibit variable degrees of correlation with GFR and urinary albumin. TFF3 had high concordance with both GFR and urinary albumin, which may be a favorable characteristic.

Prediction of Long-Term Renal Outcomes in AKI Survivors by Urinary Biomarkers
Rei Isshiki,[1] Kent Doi,[2] Maki Sumida,[1] Yoshifumi Hamasaki,[1] Naoki Yahagi,[2] Masaomi Nangaku,[1] Eisei Noiri.[1] *[1]Nephrology and Endocrinology, Univ Hospital, Univ of Tokyo, Tokyo, Japan; [2]Emergency and Critical Care Medicine, Univ Hospital, Univ of Tokyo, Tokyo, Japan.*

Background: Although several epidemiological studies suggested that acute kidney injury (AKI) increases the risk of chronic kidney disease (CKD) development and progression, it is still unclear whether any AKI biomarker can predict long-term renal outcomes in AKI survivors. This study was aimed to evaluate the performance of urinary biomarkers for long-term renal outcome prediction.

Methods: We conducted an observational study examining the association of three urinary biomarkers measured at ICU admission [L-type fatty acid-binding protein (L-FABP), neutrophil gelatinase-associated lipocalin (NGAL), and N-acetyl-β-D-glucosaminidase (NAG)] with CKD progression after discharge without major adverse kidney events (MAKE). MAKE were determined with death, incident dialysis dependency, or 50% reduction of eGFR at hospital discharge. Two different long-term renal outcomes were defined as follows; 30% reduction of eGFR or incident end-stage renal disease within two years after hospital discharge (*Outcome 1*) and halving of eGFR or incident end-stage renal disease in three years (*Outcome 2*).

Results: Among all the enrolled 495 patients, 393 patients discharged from the hospital without MAKE. Of them, 173 patients were followed up for two years after ICU discharge and 63 patients (36.4%) were positive for long-term renal outcomes (*Outcome 1*). A step-wise logistic regression analysis demonstrated that only urinary NGAL showed a significant association. For *Outcome 2*, 26 of 159 followed-up patients (16.4%) were positive and urinary L-FABP and NGAL were significantly associated with CKD progression in a univariate logistic regression analysis.

Conclusions: Urinary biomarkers measured at ICU admission were significantly associated with long-term renal outcomes after hospital discharge in MAKE-free AKI survivors.

SA-PO208

Significance of Serial Measurement of Acute Kidney Biomarker in Intensive Care Unit
Rei Isshiki,[1] Kent Doi,[2] Maki Sumida,[1] Naoki Yahagi,[2] Masaomi Nangaku,[1] Eisei Noiri.[1] *[1]Nephrology and Endocrinology, Univ Hospital, Univ of Tokyo, Tokyo, Japan; [2]Emergency and Critical Care Medicine, Univ Hospital, Univ of Tokyo, Tokyo, Japan.*

Background: AKI biomarkers have been developed with the concept of earlier detection of kidney damage than serum creatinine. However, single time point measurement appears not to provide sufficient information for detecting and predicting AKI in ICU patients who frequently suffer from multiple and transient/persistent renal insults. This study was aimed to evaluate whether serial measurement enables to predict AKI progression and recovery in these patients.

Methods: Serial measurements of AKI biomarkers including plasma and urinary NGAL, urinary L-FABP, and urinary NAG at ICU admission (day 1) and 24 hr after (day 2) were conducted in adult critically ill patients who were treated in a mixed ICU.

Results: Among the enrolled 272 patients, 33 were determined as newly developed AKI after ICU admission, 64 showed worsening of kidney function and 63 recovered from AKI. ROC analysis showed that biomarkers at day 2 showed no significantly additional benefit in predicting these three AKI outcomes compared with those measured at day 1. However, net reclassification improvement (NRI) analysis demonstrated adding AKI biomarkers at day 2 to the clinical model consisted of clinical variables and biomarker at day 1 significantly improved prediction of these AKI outcomes.

	Newly AKI		Worsening AKI		Recoveryof AKI	
	AUC-ROC	Continuous NRI	AUC-ROC	Continuous NRI	AUC-ROC	Continu-ous NRI
Clinical model +D1uNGAL	0.89		0.86		0.78	
+D2uNGAL	0.92	0.92 (0.59 to 1.26)*	0.91	0.60 (0.33 to 0.88)*	0.80	0.39 (0.042 to 0.73)*
Clinical model +D1plNGAL	0.85		0.85		0.79	
+D2plNGAL	0.87	0.74 (0.39 to 1.092)*	0.87	0.61 (0.33 to 0.88)*	0.79	0.13 (-0.22 to 0.48)
Clinical model +D1uL-FABP	0.89		0.87		0.79	
+D2uL-FABP	0.89	0.63 (0.26 to 0.99)*	0.88	0.51 (0.23 to 0.79)*	0.82	0.42 (0.0077 to 0.076)*
Clinical model +D1uNAG	0.87		0.86		0.79	
+D2uNAG	0.89	0.85 (0.52 to 1.19)*	0.87	0.32 (0.0030 to 0.60)*	0.79	-0.031 (-0.38 to 0.32)

Conclusions: Serial measurement of AKI biomarkers involved in clinical models could contribute to prediction of AKI outcomes in a heterogeneous cohort of adult mixed ICU.

SA-PO209

Role of Carbonyl Stress Revisited in Pathogenesis of Tropical Acute Kidney Injury
Pinaki Mukhopadhyay. *Nephrology, NRS Medical College, Kolkata, West Bengal, India.*

Background: Malaria and snake bite are two common causes of Acute Kidney Injury (AKI) in tropics with lot of morbidity and mortality. The aim of this study was to (I) evaluate the carbonyl and oxidative stress in these group and their pathogenesis link and (II)prognostic predictability of carbonyl and oxidative stress marker in this AKI.

Methods: All cases of falciparum malaria mediated AKI (FMAKI) (n=50),confirmed by antigen and/or in peripheral blood smear and snake bite mediated AKI(SAKI) (n=58) were included. AKI was calculated as per RIFLE criteria. Demographical, clinical and biochemical data were analysed and were followed from hospitalization to discharge/ death. Oxidative and carbonyl stress markers [advanced oxidation protein product (AOPP), advanced glycation end product (AGE), pentosidine, dityrosine, thiobarbituric acid reactive substance (TBARS) and methyl glyoxal (MG)] were measured consecutively according to standard protocol. Predictive importance was assessed from trend analysis, receiver operated characteristic(ROC) curve analyses and multiple logistic regression with AKI as positive response.

Results: The Oxidative stress index(OSI) of FMAKI patients were 1.89 higher than controls.The TBARS, MG level were 6.49 and 5.56 times higher indicating a significant carbonyl stress in these patients. AOPP level was 2.33 times higher indicating proteins being highly insulted in FMAKI.Similarly in SAKI,significantly elevated total oxidant stress with decreased total antioxidant stress leads to net oxidative stress in SAKI patients depicted by increased OSI values (p<0.001). MG was increased by 3.48 times (p<0.001).Only AOPP (p=0.001) and MG (p=0.004) were found to be significantly elevated in expired patients than the survived indicating their predictive power for adverse outcome. At univariate level,

all parameters can differentiate between AKI and the non-AKI group. At multivariate level, methylglyoxal, AOPP and dityrosine appeared to be independent predictor of AKI in snake bite and malaria infected patients ($p<0.05$).

Conclusions: 1.MG,the carbonyl stress marker along with oxidative stress are significantly raised and possibly linked to the pathogenesis of AKI. 2.MG and AOPP can be used as a surrogate marker in these tropical AKI.

SA-PO210

Prediction of Short-Term and Long-Term Outcomes of AKI-Based on Plasma NGAL

Karina Soto,[1,3] Fernando Pereira,[1] Liliana Maria goncalves Cunha,[1] Iola Pinto,[2] Ana Luisa Papoila,[3] Prasad Devarajan.[4] *[1]Nephrology, Hospital Fernando Fonseca; [2]Inst Superior de Engenharia de Lisboa; [3]Nova Medical School/FCM, Univ Nova de Lisboa, Portugal; [4]Nephrology, Cincinnati Children's Hospital Medical Center, OH.*

Background: We have previously shown a good performance of Plasma NGAL (pNGAL) as an AKI biomarker in emergency settings. Now we investigated a new AKI classification based on pNGAL for prediction of kidney dysfunction at discharge and at the end of follow-up.

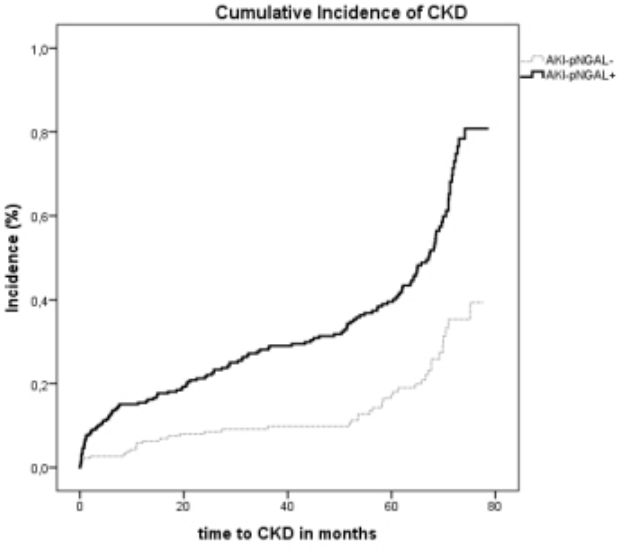
Methods: Patients from a previous study at ED were followed for >5y. During the index hospitalization, 21% were AKI (based on SCr), 26% transient azotemia, 51% normal function and 2.4% stable CKD. All patients had SCr and pNGAL meassured at 0, 6,12, 24 and 48H of admission. A new AKI classification based on pNGAL levels (AKIpNGAL+) defined AKI as pNGAL=>110 ng/mL (cut-off by GAMS). A multivariable logistic and cox regression models were applied.

Results: Of 599 patients admitted, 97.8% were available at discharge and 54.4% at last follow-up. At admission 42.6% were reclassified as AKIpNGAL+ whereas only 21.7% were based on SCr. . All significant clinical variables were included in multivariable analysis at discharge.

Variables	OR	95% CI
AKIpNGAL+	4.2	2.3-7.6
Age	1.1	1.0-1.1
CVD	1.2	1.2-3.2
DM	1.5	1.5-4.0

p<0.001 all unless CVD=0.007

Having pNGAL>110 at ED corresponded to 4-fold increased odds for eGFR<60 mL/min (p<0.001 ROC-AUC 0.82). The cumulative incidence of CKD showed that most of AKIpNGAL+ developed CKD at 60 mo (the highest proportion 77%) (figure 1) HR for CKD: 2.4 for patients AKIpNGAL+ in long-term (p<0.001 ROC AUC 0.74) NRI 56.3 and IDI 0.03.



Conclusions: Patients who were AKIpNGAL+ had significant lost kidney function at discharge and more than 2-fold risk of developing CKD in long-term evolution. Plasma NGAL is a useful tool for CKD prediction, independent of serum creatinine.

SA-PO211

The Use of Novel Serum and Urinary Biomarkers to Predict the Development of Hepatorenal Syndrome in Patients with Advanced Cirrhosis

Desmond Y.H. Yap,[1] Wai Kay Seto,[1] James Yy Fung,[1] See-Ching Chan,[2] Siu-Ho Chok,[2] Man-Fung Yuen,[1] Daniel Tak Mao Chan.[1] *[1]Medicine, The Univ of Hong Kong, Hong Kong, Hong Kong; [2]Surgery, The Univ of Hong Kong, Hong Kong, Hong Kong.*

Background: Hepatorenal syndrome (HRS) is associated with high mortality rates in advanced cirrhotic patients without liver transplantation. Prediction of the development of HRS remains difficult.

Methods: We prospectively recruited patients with Child's B or C cirrhosis and followed them at 2-week intervals 12 weeks or until HRS developed. Serum cystatin C (CysC), serum Neutrophil Gelatinase-Associated Lipocalin (NGAL), serum IL-18, urine kidney injury molecule-1 (KIM-1) and urine liver-type fatty acid binding protein (LFABP) were measured at recruitment (Baseline).

Results: 43 patients were included. 12 developed HRS at 7.3±5.1 weeks from Baseline. Patients who developed HRS had higher Baseline levels of serum CysC (1.42±0.51 mg/L vs. 1.07±0.50 mg/L, p=0.021), serum NGAL (129.10±68.66 ng/mL vs. 72.84±48.91 ng/mL, p=0.025), serum IL-18 (759.91±477.05 mIU/mL vs. 358.13±153.00 mIU/mL, p=0.001), urine KIM-1 and LFABP (3.64±3.34 ng/mL vs. 1.18±1.68 ng/mL and 10.17±8.37 ng/mL vs. 3.28±4.20 ng/mL, p=0.023 and 0.035 respectively) when compared to patients who did not develop HRS. The cut-off and positive and negative predictive values for HRS were shown in Table 1.

	Cut-off Value	AUC	95%CI	PPV (%)	NPV (%)	P-value
Baseline serum Cystatin C (mg/L)	0.899	0.748	0.572-0.924	52.4	90.9	0.021
Baseline serum NGAL (ng/mL)	90.47	0.756	0.592-0.939	72.7	75.0	0.025
Baseline serum IL-18 (mIU/mL)	442.84	0.858	0.708-1.000	73.3	92.9	0.001
Baseline urine KIM-1 (ng/mL)	1.499	0.785	0.607-0.963	75.0	84.2	0.008
Baseline urine LFABP (ng/mL)	3.398	0.765	0.578-0.949	54.5	86.7	0.035

Serum NGAL and IL-18 and urinary KIM-1 at Baseline were significantly associated with the development of HRS (OR 1.017, 95%CI 1.001-1.033, p=0.035; OR 1.007, 95%CI 1.002-1.013, p=0.012; OR 1.003, 95%CI 1.009-2.237, p=0.045, respectively).

Conclusions: Serum IL-18 and NGAL and urinary KIM-1 could serve as biomarkers to predict HRS in patients with advanced cirrhosis.

Robust Risk Assessment of Acute Kidney Injury After Acute Myocardial Infarction Using the Novel Biomarker C-Terminal Fragment of Agrin (CAF)

Spyridon Arampatzis,[1] George Chalikias,[2] Vasileios Devetzis,[1] Stefan Hettwer,[3] Dimitros Tziakas,[2] Uyen Huynh-do.[1] *[1]Nephrology, Hypertension and Clinical Pharmacology, Uni. Hospital Bern, Inselspital, Switzerland; [2]Cardiology, Democritus Univ of Thrace, Greece; [3]Neurotune AG, Switzerland.*

Background: Acute kidney injury (AKI) complicating acute myocardial infarction (AMI) increases subsequent morbidity and mortality. The objective of this study was to validate c-terminal fragment of agrin (CAF) as a novel AKI biomarker in patients with AMI.

Methods: 403 consecutive patients with AMI were enrolled, samples were collected at presentation for serum (sCAF), urine (uCAF) CAF, neutrophil gelatinase-associated lipocalin (NGAL), interleukin-18 (IL-18) and cystatin-C analysis. The presence of AKI was evaluated at 48 hours post admission and at discharge.

Results: The incidence of AKI was 6.7%-14.6% depending on time-point and criteria used and increased across quartiles of uCAF (x^2:10.99, $p<0.001$). Both uCAF and sCAF significantly correlated with serum creatinine on admission ($r=0.233$, $p<0.001$ & $r=0.175$, $p<0.001$), at 48 hours ($r=0.263$, $p<0.001$ & $r=0.226$, $p<0.001$) and with peak creatinine as well ($r=0.317$, $p<0.001$ & $r=0.225$, $p<0.001$). The predictive accuracy for AKI of uCAF was good (AUC:0.630, 95%CI:0.552-0.708) and slightly better as that of urine NGAL (AUC:0.616, 95%CI:0.540-0.692, uCAF vs. uNGAL p=0.733), whereas that of sCAF was moderate (AUC:0.587, 95%CI:0.509-0.666). A uCAF value of 1033pM is suggested to have the best discriminating ability. The sensitivity of uCAF was 37% and the specificity 85% (NPV: 89%, PPV: 30%). Univariate analysis showed a strong association of uCAF with AKI incidence (OR:1.45, 95%CI:1.15-1.82, p=0.002) which remained significant even after adjustment for several confounders (OR:1.35, 95%CI:1.05-1.74).

Conclusions: Urine CAF analysis allows a robust risk stratification of AKI after AMI and thus optimized management in such patients.

SA-PO213

At Myeloma Diagnosis, Age and Free Light Chain Level Predict Renal Function and These Factors with Free Light Chain Response Predict Renal Outcome Punit Yadav,[1,2] Mark Trehane Drayson,[1,2] Mark Cook,[1,2] Jennifer H. Pinney,[1] Hannah V. Giles,[2] Yu sandar Aung,[1,2] Paul Cockwell.[1,2] *[1]Univ Hospital Birmingham, UK; [2]Univ of Birmingham, UK.*

Background: Elevated involved immunoglobulin free light chain (FLC) is a major cause of renal impairment (RI) in myeloma. Relationships between presentation and post-induction (PI) renal function and serum FLC levels are not established.

Methods: We used central laboratory data from the MRC Myeloma IX trial which compared bisphosphonate and thalidomide-based therapies. Patients were divided into 3 eGFR categories: eGFR ≥60 ml/min, normal renal function; eGFR 30-59 ml/min, mild-moderate RI; eGFR <30 ml/min, severe RI. Linear regression and Logistic regression modelling were used to explore independent determinants of renal function.

Results: 52.8% had an eGFR ≥60 ml/min; 37.3% had an eGFR 30-59 ml/min and 9.8% had an eGFR <30 ml/min. Median eGFR in patients with involved λFLC was significantly lower than those with κFLC (58 [IQR 42-77] vs 63 [IQR 46-80]; P=0.01). Median eGFR for light chain only myeloma (LCO) was also significantly lower than those with IgG and IgA myeloma (49 [IQR 28-78] vs 62 [IQR 47-79] vs 63.5 [IQR 42.2-82.0] respectively; P<0.0001). Patients with a difference between involved and uninvolved FLC (dFLC) ≥500 mg/L had a lower eGFR compared to those with dFLC 100-499 mg/L and dFLC <100 mg/L (52 [IQR 35-72] vs 66 [IQR 52.0- 82.2] vs 67 [IQR 54.2-82.0] respectively; P<0.0001). A dFLC level of 700 mg/L was the optimal cut-off value for prediction of severe RI, with an AUC of 0.80. Factors associated with eGFR at presentation were: age, $\log_{10}$ dFLC, male gender and LCO myeloma. On censoring those with dFLC <700mg/L; age and $\log_{10}$ dFLC were still associated with eGFR at presentation but not male gender and LCO myeloma. Factors that were independently associated with RI at PI were: age (odds ratio [OR] 1.033, P=0.041); presentation eGFR (OR 0.93, P<0.0001) and attainment of ³VGPR (very good partial response) compared to <PR (partial response) serum FLC response (OR 0.52, P=0.005).

Conclusions: Age and serum FLC level predict eGFR at presentation and age, presentation eGFR, and serum FLC response predict PI renal outcome.

SA-PO214

Urinary Biomarkers Improve the Prediction and Prognostic Assessment of Acute Kidney Injury in Critically Ill Patients Patrick T. Murray, Teresa Martin, Eoin J. Cotter. *UCD Clinical Research Centre, School of Medicine, Univ College Dublin, Dublin, Ireland.*

Background: Acute kidney injury (AKI) is common in intensive care unit (ICU) patients, and is diagnosed late by serum creatinine. New biomarkers may permit earlier detection and better management.

Methods: All patients admitted to the ICUs of two university hospitals were screened for this prospective cohort study. Clinical information and urine were collected on admission and daily for 7 days. Urine biomarkers analysed were neutrophil gelatinase-associated lipocalin (NGAL), α- and π- glutathione-S-transferases (GSTs), kidney injury molecule-1 (KIM-1), liver fatty acid binding protein (L-FABP), creatinine, and albumin. AKI was defined by modified KDIGO criteria, using ICU admission creatinine as reference. Values were compared between those who did or did not develop AKI or 30d adverse clinical outcomes (RRT or death). ROC curves were generated for prediction of AKI and outcomes by a clinical score (including age, gender, serum creatinine & urea, urine output) and urine biomarker values on admission. In patients developing AKI, ROC curves were similarly generated for the prediction of clinical outcomes with values obtained at time of AKI diagnosis.

Results: 659 patients were enrolled;181 patients (27%) developed AKI within 7d of ICU admission. AKI stages at diagnosis were:Stg1(n=81,45%),Stg2(n=17,9%),Stg3(n=83,46%). On admission, addition of a panel of AKI biomarkers significantly but modestly improved prediction of AKI developing within the first 48h in ICU (AUC±SD: 0.79±0.12), compared to clinical score alone (0.77±0.11;p=0.0001). AKI biomarkers similarly improved the prediction of AKI developing within the first 7d (0.73±0.15), compared to clinical score alone (0.69±0.07;p=0.0003); and marginally improved the prediction of 30d RRT or death (0.7±0.1 vs 0.69±0.1;p=0.05). In patients developing AKI, AKI biomarkers at the time of diagnosis significantly improved prediction of 30d adverse clinical outcomes (RRT or death): 0.77±0.19, compared to clinical score alone (0.68±0.13;p=0.01).

Conclusions: Urinary biomarkers combined with standard clinical tests improved prediction of AKI and outcomes in ICU patients, on admission and at AKI diagnosis.

Association of Growth Factor Biomarkers with Acute Kidney Injury and Long-Term Mortality in Adults following Cardiac Surgery William R. Zhang, Richard P. Whitlock, Heather Thiessen Philbrook, Eric Mcarthur, Amit X. Garg, Steven G. Coca, Peter Kavsak, Chirag R. Parikh. *TRIBE-AKI Consortium.*

Background: Following the structural damage and functional impairment from acute kidney injury (AKI), the kidney undergoes a coordinated process of repair involving regenerative growth factors. We conducted an ancillary analysis of a large, prospective study of adults undergoing cardiac surgery to investigate the utility of epidermal growth factor (EGF) and vascular endothelial growth factor (VEGF) in predicting kidney injury and mortality.

Methods: Patients undergoing cardiac surgery at high risk for AKI were enrolled at six academic centers. AKI was defined as a doubling in serum creatinine from baseline or receiving acute dialysis during the hospital stay. Postoperative plasma levels of EGF, VEGF, and a combination model of the two growth factors were evaluated for association with outcomes of AKI or long-term, all-cause mortality at a mean follow-up of 3 years.

Results: First postoperative and peak plasma EGF were not associated with AKI. Elevated peak plasma VEGF was independently associated with increased risk of AKI (adjusted odds ratio [OR] 7.4, 95% confidence interval [CI]: 1.1-47.9). Elevated first postoperative EGF was inversely associated with a lower risk of mortality (adjusted HR=0.67; 95% CI: 0.47-0.97). Elevated first postoperative VEGF was likewise associated with a lower risk of mortality (unadjusted HR=0.36; 95% CI: 0.16-0.82), though the association was attenuated following adjustment (adjusted HR=0.36; 95% CI: 0.15-1.04). When assessed conjointly, elevated levels of first postoperative EGF and VEGF together were independently associated with a lower risk of mortality (adjusted HR=0.28; 95% CI: 0.11-0.72).

Conclusions: Postoperatively, EGF and VEGF are released in response to AKI, and their concentrations were inversely associated with long-term mortality. These growth factors may serve as biomarkers of long-term outcomes in adults undergoing cardiac surgery.

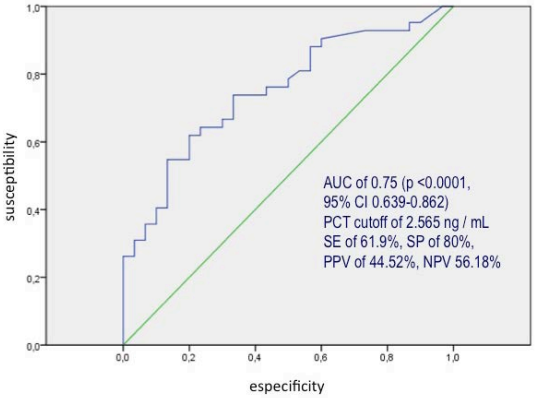
SA-PO216

Procalcitonin as a Predictor of AKI in Patients with Sepsis Jonathan Chavez,[1] Maria de la luz Alcantar Vallin,[1] Guillermo Garcia-Garcia,[1] Luis Arnoldo Muñoz.[2] *[1]Nephrology Service, Hospital Civil de Guadalajara, Guadalajara, Mexico; [2]Internal Medicine, Hospital Civil de Guadalajara, Guadalajara, Mexico.*

Background: Sepsis is a common cause of AKI. Identifying patients at risk for AKI could improve clinical outcomes. Procalcitonin (PCT) reflects accurately the presence of sepsis and its severity. We evaluated the role of PCT as predictor of AKI in septic patients.

Methods: Cross-sectional study of 72 septic patients between January to December 2014. Patients with SCr ³1.5 mg/dl before admission, ESRD patients and those with autoimmune comorbidity were excluded. PCT, Scr, urea, and WBC were measured on admission, and at 24 h and 48 h of hospitalization. X2 and t-test were used when appropriate. A ROC curve for PCT value on admission as well as the area under the curve (AUC), the standard AUC error, and sensitivity and specificity of PCT values were determined.

Results: Patients' mean age was 50.8 y (18-79); 37 (51.4%) were women. 18 (25%) patients had PCT value at <0.5 ng / mL (negative) and 54 (75%) ³0.5 ng / mL (positive) on admission. Forty-two (58.3%) patients developed AKI, 19 (45.2%) KDIGO 1, 12 (28.6%) KDIGO 2, and 11 (26.2%) KDIGO 3. Of the 42 patients who developed AKI , 37 (88.1%) had a positive value of PCT at admission (p <0.01, OR 5.659, 95% CI 1.738 to 18.425). The ROC PCT presented an AUC of 0.75 (p <0.0001, 95% CI 0.639 to 0.862). The cutoff of 2.565 ng / mL of PCT had the highest validity for predicting AKI with an SE of 61.9%, one SP of 80%, a PPV of 44.52%, 56.18% NPV, LR + LR of 0.80 and 0.77, respectively. Fig. 1



Conclusions: We found a significant association between levels of PCT and development of AKI in patients with sepsis. A cutoff PCT value of 2,565 ng /mL on admission had the highest validity for predicting AKI. Early recognition of septic patients at risk for AKI with PCT could improve clinical outcomes in this population.

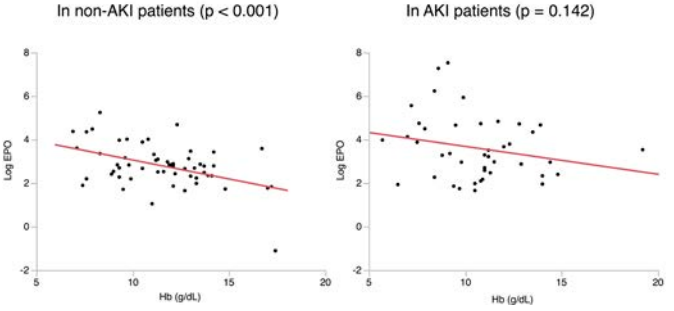
SA-PO217

Elevated Erythropoietin Concentration in AKI Is Associated with IGFBP-1 Rather Than Hemoglobin Tetsushi Yamashita, Eisei Noiri, Yoshifumi Hamasaki, Naoki Yahagi, Masaomi Nangaku, Kent Doi. *The Univ of Tokyo, Tokyo, Japan.*

Background: EPO expression will be increased by hypoxia in the kidney and hypoxic injury plays a crucial role in pathogenesis of AKI. However, little is known about blood EPO levels in critically ill patients complicated with AKI.

Methods: This study prospectively enrolled 98 adult critically ill patients who admitted to the adult mixed ICU. We measured plasma EPO and also measured plasma IGFBP-1 as a hypoxic marker, which is produced mainly by liver, and plasma NGAL and urinary NAG as renal damage biomarkers on ICU admission. This study was conducted to evaluate whether plasma EPO levels in AKI patients. was regulated by other factors than anemia.

Results: AKI occurred in 42 (42.9%) patients. Significantly higher plasma EPO in the AKI group was detected compared with the non-AKI group (16.13 [9.87–28.47] mIU/mL versus 27.81 [10.16–106.02] mIU/mL, p<0.05). Plasma EPO concentration was strongly and negatively correlated with hemoglobin in the non-AKI group but not in the AKI group.



In AKI group, plasma IGFBP-1 was strongly and positively correlated with plasma EPO. Multiple logistic regression analysis revealed plasma EPO in the AKI group was significantly associated only with plasma IGFBP-1 and complication of diabetes mellitus.

Conclusions: EPO production in AKI was enhanced by not anemia but systemic hypoxic stimuli evaluated by IGFBP-1, indicating unknown independent pathway of renal EPO production in AKI.

Predictive Value of Plasma Neutrophil Gelatinase-Associated Lipocalin (NGAL) to Distinguish Prerenal AKI to Other Causes of AKI Chae Ho Lim, Young-Il Jo. *Div of Nephrology, Dept of Internal Medicine, Konkuk Univ Medical Center, Gwangjin-gu, Seoul, Republic of Korea; Div of Nephrology, Dept of Internal Medicine, Konkuk Univ Medical Center, Gwangjin-gu, Seoul, Republic of Korea.*

Background: Plasma Neutrophil gelatinase-associated lipocalin (NGAL) is a promising biomarker for acute kidney injury, but it's role for distinguishing prerenal AKI from other causes are not well known. The aim of this study was to evaluate the predictive value of plasma NGAL to distinguish prerenal AKI to other causes of AKI.

Methods: We reviewed all NGAL test from December 26, 2011to February 28,2015 in Konkuk University Medical cencer (Seoul, Republic of Korea) and subtract patients who taken factional excretion of sodium(FENa) test at the same time. Patients were first grouped with Acute Kidney Injury Network (AKIN) stages and evaluated it's diagnostic role for AKI and second divided with prerenal AKI and other causes of AKI.

Results: Total 5814 NGAL test were done from December 26, 2011to February 28,2015 in Konkuk University Medical center, and 495 patients taken FENa test at the same time.

		No AKI(N =215)	AKIN stage 1(N=162)	AKI stage 2(N=60)	AKI stage 3(N=58)	p-value
Age (years)	Age	65.7 (SD 15.44)	67.8(SD 14.1)	60.5 (SD 15.9)	60.9 (SD 11.4)	No AKI vs Stage3 (*P=0.01) S1 vs S2 (**P=0.007), S1 vs S3 (**P=0.001)

DM (%)	21(16%)	27(18%)	0.5131
NGAL (ng/ml)	535.8 (SD 453.6)	616.7 (SD 425.6)	0.1142

Table 2. Comparison according to prerenal AKI and other causes of AKI

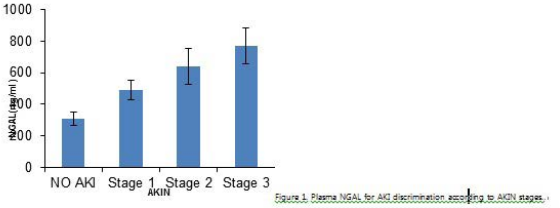

Figure 1. Plasma NGAL for AKI discrimination according to AKIN stages.

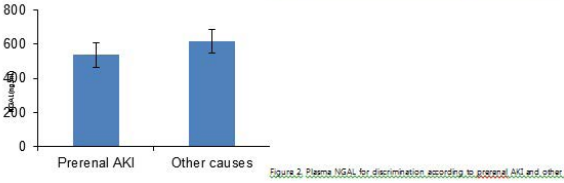

Figure 2. Plasma NGAL for discrimination according to prerenal AKI and other causes of AKI.

Conclusions: Plasma NGAL had a predictive value for diagnosing AKI but it itself had a limited value for distinguishing prerenal AKI from other causes of AKI.

SA-PO219

Neutrophil/Lymphocyte Ratio for Early Detection of Acute Kidney Injury (AKI) in Patients Admitted to the Emergency Room Mohsen Abu Alfeilat, Itzchak N. Slotki, Linda Shavit. *Adult Nephrology, Shaare Zedek Medical Center, Jerusalem, Israel.*

Background: Neutrophil to lymphocyte ratio (NLR) is a readily available biomarker of systemic inflammation. Several studies have provided evidence of an association between elevated NLR and adverse outcomes in a variety of medical and surgical conditions, including CKD. In this study, we evaluated the predictive capacity of single Emergency Room (ER) measurement of NLR for early diagnosis of acute kidney injury (AKI).

Methods: We prospectively studied 294 patients aged 71.6 ± 17. NLR was measured at presentation to the ER.AKI was defined as a new-onset 1.5-fold or more increase in serum creatinine or a 25% decrease in estimated GFR sustained for at least 3 days despite volume resuscitation. The primary outcome was AKI. Secondary outcome was in-hospital mortality.

Results: 36 patients (12.2%) developed AKI and 26 (9%) died. Mean NLR was significantly higher in AKI compare to non-AKI patients (11.7 ± 15.2 vs 6.45± 7.19, p=0.048). A multivariate model adjusted for age, gender, blood pressure, and plasma albumin levels confirmed that NLR is higher in AKI patients (p=0.048). Receiver operating characteristics curve revealed AUC 0.715 (95% CI 0.63-0.8) sensitivity 0.78, specificity 0.65, OR 6.423 (CI, 2.659 to 16.026) for a cutoff value of NLR 5.5. The association between NLR and in hospital mortality was not statistically significant (p = 0.92).

Conclusions: Single ER measurement of NLR can be a useful tool for early diagnosis of AKI. This finding is particularly important in light of the widespread availability and low cost of NLR, especially compared with other biomarkers currently under study in the context of AKI.

SA-PO220

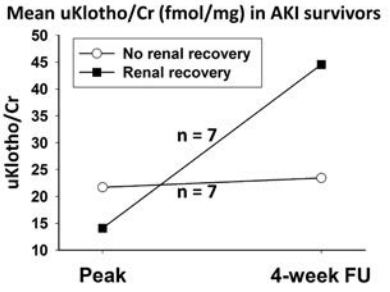
Urine Klotho in Human AKI Javier A. Neyra,[1] Xilong Li,[2] Beverley Adams-Huet,[2,3] Carolina De La Flor,[3] Ming Chang Hu,[3] Robert D. Toto,[1,2] Orson W. Moe.[1,3] *[1]Nephrology, UT Southwestern; [2]Clinical Sciences, UT Southwestern; [3]Mineral Metabolism, UT Southwestern, Dallas, TX.*

Background: AKI is associated with increased morbidity and carries increased risk for subsequent CKD. Klotho deficiency has been observed in experimental AKI and low Klotho post-AKI is associated with progression to CKD in rodents. We report the first study of Klotho in human AKI.

Methods: We conducted a prospective study of 29 AKI patients and 29 controls without AKI in the ICU setting. We excluded patients with baseline eGFR<60 or kidney transplant. Urine samples were obtained within 24h of peak serum creatinine (SCr) or at RRT initiation

in AKI cases, and within 24h of ICU admission in frequency-matched controls. AKI was defined by KDIGO criteria. Longitudinal data from AKI cases were obtained throughout hospital stay. Renal recovery was defined as the ratio of follow-up SCr/baseline SCr ≥1.5. Urine Klotho was measured by immunoprecipitation-immunoblot. Mixed-effects linear models were constructed to assess longitudinal trends of Klotho in AKI survivors.

Results: Mean (SD) age was 58 (17) years, 62% were men and 75% white. Patients with AKI had higher critical illness scores than controls without AKI. Five (17.2%) patients died and 8 (27.6%) required RRT in the AKI group. Only 3.5% patients died in the control group. Urine Klotho adjusted by urine creatinine (uKlotho/Cr) was significantly lower in AKI cases than in controls, median 10 [IQR 4–20] vs 28 [14–52] fmol/mg, p=0.003. Furthermore, uKlotho/Cr significantly increased with time in patients that exhibited renal recovery (n=7, Δ+216%, p=0.05) but not in those that did not (n=7,Δ+8%, p=0.91), median follow-up 24 days.



Conclusions: uKlotho/Cr is significantly lower in patients with AKI when compared to ICU controls without AKI. uKlotho/Cr recovered only in patients that recovered kidney function. Klotho may serve as a prognostic marker for AKI recovery.

Funding: Other NIH Support - University of Texas Southwestern Medical Center O'Brien Kidney Research Core Center (NIH, P30 DK079328-06) and the National Center for Advancing Translational Sciences of the National Institutes of Health (NIH, UL1TR001105).

SA-PO221

Biomarkers of Acute Kidney Injury in Children Treated with Cisplatin

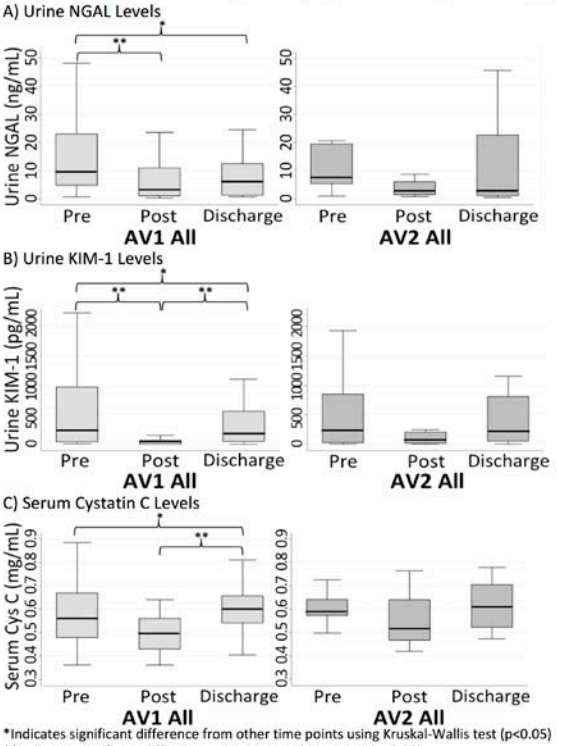
Kelly Mcmahon,[1] Shahrad Rod Rassekh,[2] Kirk Raymond Schultz,[2] Maury N. Pinsk,[3] Tom D. Blydt-Hansen,[2] Cherry Mammen,[2] Ross T. Tsuyuki,[3] Prasad Devarajan,[4] Michael Zappitelli.[1] *[1]McGill U, Montreal; [2]U British Columbia, Vancouver; [3]U Alberta, Edmonton, Canada; [4]Cincinnati Children's Hosp, Cincinnati.*

Background: Cisplatin(CisP) causes acute kidney injury(AKI) and may cause chronic kidney disease(CKD). Biomarkers(BioM) may allow early AKI diagnosis and treatment. Applying BioM to Long-Term Effects in Child/Adolescent Cancer Treatment(ABLE) is a Canadian study of cancer treatment toxicities, including nephrotoxicity. We study BioM of child CisP treatment for early and late renal outcome prediction. This analysis evaluates neutrophil gelatinase-associated lipocalin(NGAL), kidney injury molecule-1(KIM-1) and serum Cystatin C(CysC) with CisP therapy in the first 1/3 of subjects.

Methods: Ongoing, 8-site, prospective cohort of 150 children receiving CisP. Excluded: severe CKD. Protocol includes 2 "acute" visits[AV] around CisP infusion(pre, post, discharge urine/blood) for serum creatinine(SCr), CysC, urine NGAL, KIM-1. Outcomes: AKI (Kidney Disease Improving Global Outcomes[KDIGO] SCr criteria; AKI by National Cancer Institute(NCI) criteria(based on serum electrolytes).

Results: Data available in 44/60 (mean±SD age 7±6yrs; AV1/AV2 hospital stay 16±27/12±26 days; 55% male). AV1: 11% KDIGO AKI, 46% NCI AKI, 50% with either. AV2: 14% KDIGO AKI, 72% NCI AKI, 75% with either. BioM drop immediately post-CisP (n=25), followed by a rise at discharge.

Figure 1: BioM Levels During AV1 and 2 CisP Infusions. AV1 refers to first or second CisP cycle of treatment plan and AV2 refers to third or later CisP cycle of treatment plan. BioM collected at 3 time points: Pre-Infusion (just before infusion start), post-infusion (morning after infusion), discharge (just before hospital discharge).



A similar pattern is seen in AKI and non-AKI groups and when expressing BioM/urine creatinine(not shown).

Conclusions: This is a novel study of AKI BioM excretion in CisP-AKI. NCI-AKI is more common than SCr-AKI. The immediate BioM drop post-CisP may be related to injury protection from high fluid rate and/or urinary alkalinization peri-CisP. Our larger sample size will allow to further characterize BioM excretion and evaluate BioM associations with AKI definition and outcomes.

SA-PO222

Elevated Renal Injury Biomarkers Fall Transiently After Stenting in Human Atherosclerotic Renal Artery Stenosis (ARAS)

Wei Wang,[1,2] Ahmed Saad,[1] Sandra Herrmann,[1] Alfonso Eirin,[1] Hui Tang,[1] Lilach O. Lerman,[1] Stephen C. Textor.[1] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Nephrology, Dalian Municipal Central Hospital, Dalian, Liaoning, China.*

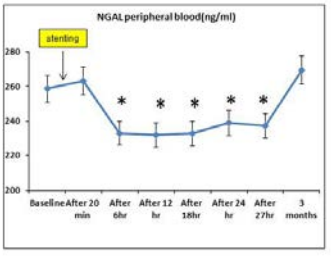
Background: ARAS reduces blood flow and perfusion pressures to the post-stenotic kidney (STK), ultimately producing inflammatory injury. The aim of our study was to identify and track renal injury biomarkers for 24 hours and 3 months after combined CT imaging and stent revascularization.

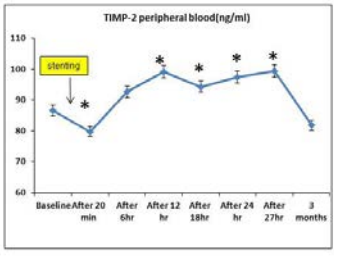
Methods: 12 patients with severe ARAS scheduled for revascularization for clinical indications were enrolled in a 3 day inpatient and restudied 3 months later. All subjects maintained ACE/ARB Rx and fixed Na^+ intake, and were compared with Essential Hypertensives(EH) (n=12) undergoing the same biomarkers and imaging studies. Glomerular filtration rate (GFR) was measured by iothalamate clearance, blood flow and perfusion by Multidetector Computerized Tomography (MDCT) and NGAL, MCP-1, IL-10, TNF-α, KIM-1, IGFBP7 and TIMP-2 in renal vein and peripheral blood/IVC samples every 6 hours for 24 hours and after 3 months.

Results: Kidney perfusion, whole kidney blood flow, single kidney iothalamate GFR were reduced in the STKs compared to kidneys from EH and increased after stent revascularization.

	EH (N=12)	ARAS (N=12)		
		Baseline	20 minutes after stenting	3 months
Creatinine (mg/dl)	1.0±0.3	1.7±0.5		1.5±0.4
Cortical perfusion, mL/min per mL of tissue	3.61±1.26	2.36 ± 0.87*		2.65 ± 0.87
Cortical flow, mL/min	316±183	162 ± 84*		195 ± 86*
Single kidney GFR, mL/min per kidney	39±14	26± 14*		31 ± 19#
NGAL(renal vein)ng/ml	72±32	228± 63*	247 ±73	268 ± 74#
MCP-1(renal vein)ng/ml	153±78	663± 431*	403±292#	744±461

* P value < 0.05 vs EH. # P value ≤ 0.05 Vs baseline





Basal renal biomarkers were higher in ARAS than in EH. MCP-1 and IGFBP7 fell immediately then rose by 6 hours, while NGAL remained below baseline for 24 hours. All biomarkers rose to or above baseline by 3 months, despite increased STK GFR.

Conclusions: Renal biomarkers were universally elevated as compared to EH. Despite intense contrast exposure and renal artery stenting, our results demonstrate transient reductions during the 24 hours after revascularization in ARVD, before returning to sustained elevations by 3 months. These data reinforce ongoing inflammatory injury in ARVD despite restoration of blood flow to stenotic kidneys.

SA-PO223

Comparison of Urinary Angiotensinogen Level Between Septic and Dehydrated AKI Hiroyuki Suzuki, Eri Muso. *Dept of Nephrology, Kitano Hospital, Osaka, Japan.*

Background: Increasing evidences have suggested that urinary (U) angiotensinogen (ATG) is one of potential biomarkers related with severity of chronic kidney diseases (CKD). Recently, in addition to CKD, U-AGT has been reported to be a useful prognostic biomarker in acute kidney injury (AKI) especially after cardiac surgery, however, little is known about U-AGT in AKI due to other etiologies. In this study, we measured U- AGT in patients with pre-renal (dehydration) and renal (sepsis) AKI.

Methods: Fifteen patients who were hospitalized due to sepsis, and 6 patients who had AKI due to dehydration were included in the study. The patients included 13 women and 8 men with a mean age of 71.4 yr (range 41 to 94 yr). U-ATG levels were measured when sepsis or AKI was diagnosed and compared with clinical parameters and other known urinary renal injury biomarkers such as urinary liver-type fatty acid-binding protein (L-FABP), b2-microglobuline (MG), and NAG.

Results: Among 15 patients with sepsis, 7 were diagnosed as AKI. The number of cases in each AKIN stage from I, to III were 4, 1, and 2 in sepsis, and 3, 1, and 2 in dehydration, respectively. No patients have died from AKI. During AKI, peak Cre levels were 1.79mg/dl (238% increase) in sepsis group, and 2.88mg/dl (213%) in dehydration group. U-ATG in sepsis with AKI (84297±70397 ng AngI Eq/gCr) were significantly higher than in sepsis without AKI (12598 ±8916 ng AngI Eq/gCr) and dehydration group (14960±6771 ng AngI Eq/gCr). Among urinary markers, in sepsis group, U-ATG were strongly correlated with U-ß2MG (r=0.914, p<0.01). U-NAG (r=0.552, p=0.033) and L-FABP (r=0.594, p=0.020) were also correlated with U-ATG. In contrast, in dehydration group, U-ATG were not correlated with U-ß2MG, NAG, nor with L-FABP. In comparison with the severity of AKI and the levels of U-ATG , in sepsis group, ΔCre (peak – basal Cre) were positively correlated with U-ATG significantly (r=0.716, p=0.003). On the contrary, in dehydration group, U-ATG tended to decrease as maximum Cre increased.

Conclusions: Apparent difference of dynamism between in AKI due to septis and dehydration indicates that U-ATG could be a potent biomarker to distinguish renal from pre-renal AKI, before developing to CKD.

SA-PO224

AKI Development Upon SIRS Is Associated with Platelet Activation, Possibly Triggered by Mitochondrial DNA Derived from Damaged Cells Marcel Jansen,[1] Wilco P. Pulskens,[2] Diba Emal,[1] Sandrine Florquin,[1] Joris J. Roelofs,[1] Jaklien Leemans.[1] *[1]Nephrology, Academic Medical Center, Amsterdam, Netherlands; [2]Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands.*

Background: Multiple inflammatory pathways are activated by non-infectious agents during Systemic inflammatory response syndrome (SIRS) leading to collateral damage, including the development of acute kidney injury (AKI). Pattern recognition receptors (PRRs) of the innate immune system sense Damage-Associated Molecular Patterns (DAMPs) leading to an immune response. Components of mitochondria e.g. unmethylated CpG-enriched mitochondrial DNA (mtDNA) that leak upon cell injury, are a source of DAMP. Platelets express several PRRs and play an important role in innate immunity. To date, it is unclear which intrinsic factors trigger the onset of SIRS and associated AKI. We investigated the role of mtDNA during systemic inflammation and AKI and the role of platelets herein.

Methods: Human platelets were stimulated with mitochondrial DNA, genomic DNA or unmethylated CpG-enriched oligonucleotides (CpG ODN). Platelet activation was measured with FACS. In a single centre prospective observational study we included 37 patients diagnosed and classified for the onset of SIRS with or without the development of AKI that were admitted to the ICU. As a control we included (n=25) patients after elective major surgery without a diagnosis of either SIRS or AKI. Blood and urine samples were isolated and processed. Free circulating plasma and urinary mtDNA was determined by RT-PCR. Inflammatory mediators and PF4 in urine were measured using specific ELISA.

Results: Mitochondrial DNA, but not genomic DNA triggered platelet activation. Unmethylated CpG ODN, dose dependently stimulated platelet activation. Compared to ICU-controls, critically ill patients with SIRS demonstrated elevated levels of plasma and urinary mtDNA and proinflammatory cytokines. Compared to SIRS patients without AKI, the patients with AKI displayed elevated levels of urinary PF4 –indicative of platelet activation.

Conclusions: The development of AKI in critically ill patients is associated with platelet activation, possibly triggered by mitochondrial DNA.

SA-PO225

Invaders in the Night: Sleep Apnea and Sub-Clinical Renal Injury Aaron A. Rampersad,[1] Shahab Bozorgmehri,[1] Areef Ishani,[2,3] I. David Weiner,[1,4] Satish P. Ramachandrarao,[5] Rebecca Beyth,[1,4] Muna T. Canales.[1,4] *[1]Univ of Florida, Gainesville, FL; [2]Minneapolis VAMC; [3]Univ of Minnesota, Minneapolis, MN; [4]Malcom-Randall VAMC, Gainesville, FL; [5]Univ of California, San Diego, CA.*

Background: Sleep apnea is common in patients with CKD. We postulated that sleep apnea may cause renal injury through repeated ischemia-reperfusion. The current study correlated overnight changes in urinary excretion of renal injury biomarkers with severity of sleep apnea.

Methods: 39 consecutive participants in the SNORE Study, a longitudinal study of sleep apnea and kidney function decline, underwent overnight sleep study and provided spot urine samples before and after sleep. We measured urinary NGAL, L-FABP, KIM-1, and urinary cystatin-c levels, and correlated differences between AM and PM levels (AM-PM) with severity of sleep apnea or hypoxia. Sleep apnea was defined by the apnea-hypopnea index (AHI, events/hour); hypoxia was % total sleep time <90% SaO2 (%TST90). Data were log-transformed to normalize distribution.

Results: Patient characteristics: Mean age, 73.6±8.4 years; 90% male; 87% Caucasian, 13% black; BMI, 29.4± 4.2 kg/m^2; MDRD eGFR, 34.3±8.1 ml/min/1.73m^2; Median urinary albumin/creatinine ratio, 46 mg/g Cr [IQR 9-357 mg/g Cr]. 69% had sleep apnea (AHI≥5); median AHI, 10 [IQR 2-23]; median %TST90, 15 [IQR3-22] with 34% %TST90³10%. Higher %TST90 was correlated with higher AM KIM-1 values (r=0.40, p=0.01) and greater increase in urinary KIM-1 (AM-PM) (r=0.32, p=0.04). None of the remaining biomarkers correlated with %TST90. Also, none of the overnight urinary biomarker changes correlated with AHI.

Conclusions: The correlation of KIM-1 with hypoxia suggests that SA may contribute to CKD through ischemic renal injury. Future studies with larger sample size and in non-CKD populations are needed to further test this hypothesis.

SA-PO226

Body Mass Index and Acute Kidney Injury in Hospitalized Patients Yan Lun Allen Liu, Milind Nikam, Lee Ying Yeoh. *Dept of Medicine, Khoo Teck Puat Hospital, Singapore.*

Background: Acute kidney injury (AKI) is common in hospital settings. The association between AKI and Body Mass Index (BMI) in general hospitalized patients is not known. This study is to explore the incidence of AKI and the impact of BMI on AKI in hospitalized patients.

Methods: This was a single centre, retrospective, case-control study. All patients aged 21 or above under in-hospital care from January to December 2013 were recruited for analysis. We calculated the incidence of AKI according to the Kidney Disease: Improving Global Outcomes (KDIGO) criteria among different BMI groups (underweight [BMI < 18], normal [BMI 18-23], overweight [BMI 23-25] and obese [BMI > 25]), and then analyzed the risks of developing AKI within and between groups. Baseline creatinine was defined by the most recent value obtained in hospital up to 12 months before admission. If no previous serum creatinine was available, the lowest serum creatinine during hospitalization was used instead. If only one serum creatinine result was known during hospital stay, the baseline creatinine was estimated by the use of simplified Modification of Diet in Renal Disease (MDRD) formula (assuming a glomerular filtration rate [GFR] of 75 ml/min per 1.73 m^2).

Results: A total of 12567 patients were recruited for analysis. Mean age was 62.5 ± 18.5 years. Male patients constituted 53.8% of the study population. 61.9% were Chinese ethnicity. There were 2656 patients suffered from AKI (21.1% of the whole study population), among which 10.7%, 6.1% and 4.4% had stage 1, 2 and 3 AKI respectively. Underweight patients (BMI < 18) had statistical significantly more stage 1 AKI than the rest of the population, while patients with BMI ≤ 25 had more stage 2 AKI (stage 1 AKI for underweight, normal, overweight and obese patients was 15%, 10.2%, 9.4% and 10.3% respectively; stage 2 AKI, 7.6%, 6.3%, 6.4% and 5.2% respectively). There was no difference in frequency of stage 3 AKI among different BMI groups.

Conclusions: Preliminary results revealed underweight hospitalized patients had increased risks of developing stage 1 AKI. Stage 2 AKI was more commonly seen in patients with BMI ≤ 25. BMI status was not associated with the development of severe AKI (stage 3).

SA-PO227

Hypermagnesemia as a Risk Factor for the Mortality in Intensive Care Unit Patients with Acute Kidney Injury Shunichi Shibazaki,[1] Makoto Araki,[1] Kohei Miura,[1] Daijo Inaguma.[2] *[1]Dept of Nephrology, Suwa Central Hospital, Chino, Nagano, Japan; [2]Dept of Nephrology, Nagoya Daini Red Cross Hospital, Nagoya, Aichi, Japan.*

Background: We need an easily measured biomarkers predicting for the mortality in acute kidney injury (AKI) because of high mortality rate. Therefore, we paid attention for serum magnesium (sMg) levels which reflects the renal tubular damage, and study the relationship sMg and prognosis in intensive care unit (ICU) patients with AKI.

Methods: A cohort study was conducted by collecting data from January to December 2014 in Nagoya Daini Red Cross Hospital. According to sMg at ICU 1st day, three groups were divided; low Mg group(sMg <1.8mg/dL), normal Mg group (1.8mg/dL £sMg <2.6mg/dL), and high Mg group (sMg ³2.6mg/dL). AKI was defined as serum creatinine (sCr) abrupt (within 7 days) increase to ³1.5 times baseline or sCr increase by ≥ 0.3mg/dL The primary endpoint was 28 days morality after ICU admission. The secondary endpoint was the renal recovery rate, the renal replacement therapy (RRT) induction rate, and the transition rate to maintenance dialysis. Renal recovery was defined as an absence of AKI.

Results: Out of 1614 ICU patients, 200 patients were included. The number of each groups are following; low Mg group was 55, normal Mg group was 115, and high Mg group was 30. The mortality was higher in high Mg group than in other Mg group (p =0.011). A multivariate analysis identified high Mg group as an independent risk factor for the mortality (p =0.041). High Mg group had 2.39-fold increased odds of mortality against normal Mg group (95% CI 1.04 -5.50). Kaplan-Meier curves showed the high Mg group was associated with higher mortality.

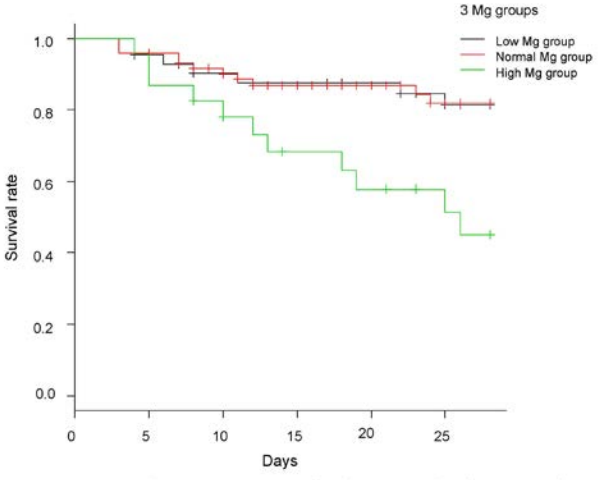

Figure 1: Kaplan-Meier curves for the mortality (p =0.003)

There was no significant association between each groups and the secondary endpoints.

Conclusions: Hypermagnesemia is an independent risk factor for the mortality in ICU patients with AKI.

SA-PO228

Gemcitabine-Induced Thrombotic Microangiopathy (TMA): A Report from the French Pharmacovigilance Network Noemie Jourde-chiche,[1] Florence Daviet,[1] Frank Rouby,[2] Bertrand Gondouin,[1] Marion Sallée,[1] Julie Moussi-Frances,[1] Stephane Burtey,[1] Pascale Poullin,[3] Bertrand Dussol,[1] Joelle Micallef.[2] *[1]Nephrology, Aix-Marseille Univ, Marseille, France; [2]Pharmacology and Pharmacovigilance, Aix-Marseille Univ, Marseille, France; [3]Hemapheresis, Aix-Marseille Univ, Marseille, France.*

Background: Gemcitabine is a chemotherapy which use can be limited by renal adverse events, in particular thrombotic microangiopathy (TMA). This study evaluated the occurrence of gemcitabine-induced TMA, and described therapeutic strategies and outcomes.

Methods: All spontaneous reports of TMA attributed to gemcitabine in the French Pharmacovigilance Network database, between January 2000 and May 2015, were reviewed using a standardized questionnaire.

Results: 81 cases of TMA were reported in 48 male (59%) and 33 female (41%), with a median age of 63.5 yrs (range 39-87). Gemcitabine was prescribed for pancreatic (58%), pulmonary (15%), breast (8%), biliary tract (6%), urinary tract (5%), uterine (3%), testicular (1%) or liver (1%) cancers, or T lymphoma (3%). TMA occurred after a median of 7 months (range 0.2-60), and a median cumulative dose of 21.8g (range 1.1-48.6). Main symptoms were hypertension (51%), diffuse edema and/or congestive heart failure (42%), acute renal failure (86%), thrombocytopenia (67%), hemolytic anemia (86%). Median creatinine level was 1.8 mg/dL (range 0.8-17). In 6 patients, renal TMA was biopsy-proven. Renal replacement therapy was required in 10 (12%) patients, plasma exchanges (PEx) were performed in 17 (21%), 8 (10%) received fresh frozen plasma infusions, 9 (11%) corticosteroids, and 3 (4%) eculizumab (after PEx failure). Evolution data were available for 59 (73%) patients, among which the 17 treated with PEx. Hematological and renal remission was achieved in 35% with PEx versus 50% without, hematological remission without renal improvement in 18% with versus 26%, and no improvement was observed in 47% with versus 24% without PEx. Only one patient improved with eculizumab.

Conclusions: Gemcitabine treatment can be associated with TMA and severe renal adverse effects. The benefit of plasma exchange or eculizumab in this setting remains uncertain.

SA-PO229

Contribution of Drugs versus Risk Factors in Drug-Induced Renal Injury Celina D. Cepeda,[1] Linda Awdishu,[1] Etienne Macedo,[1] Dinna Cruz,[1] Stuart Goldstein,[2] Jorge Cerda,[3] David T. Selewski,[4] Michael Zappitelli,[5] Andrew J.P. Lewington,[7] Ravindra L. Mehta.[1] *[1]Nephrology, Univ of California San Diego, San Diego, CA; [2]Nephrology, Univ of Cincinnati, Cincinnati, OH; [3]Nephrology, Albany Medical College, Albany, NY; [4]Nephrology, Univ of Michigan, Ann Arbor, MI; [5]Nephrology, Univ of Montreal, Montreal, QC, Canada; [6]Nephrology, Cares Hospital India, Hyderbad, India; [7]Nephrology, St. James's Univ Hospital, Leeds, London, United Kingdom.*

Background: Drug-induced renal injury (DIRI) is an increasing cause of acute kidney injury (AKI). Attribution of DIRI requires consideration of the drug exposure, the number of drugs involved and underlying or concomitant risk factors (RF). We hypothesized that underlying RF would influence attribution of DIRI.

Methods: The drug induced renal injury (DIRECT) study is an ongoing prospective multicenter study evaluating genetic determinants of DIRI. Each enrolled case was adjudicated for causality by two independent nephrologists. We analyzed the first consecutive 86 adult and pediatric AKI cases. We evaluated the percent agreement, kappa statistic, and contribution of each drug (in setting of multidrug injury) and AKI RF.

Results: Adjudicators agreed 87.2% (n=75) had DIRI. For non-DIRI cases, causality could not be established because of competing AKI RF. RF contributed to AKI in 86% of adults and 70% of children. Adjudicators disagreed on the percent attribution for each drug in 52%. For DIRI cases, inter-rater agreement on percentage attributed to drug 1 was 48% with kappa=0.239 (p=0.001). For non-DIRI cases, inter-rater agreement for drug 1 was 81.8% and RF attribution was 80%.

Percent Attribution of Drugs versus Risk Factors		
	DIRI n=75	
Percentage attributed to drug	Number of cases agreed upon	Percentage distribution for risk factors
No agreement	39	30 (10-50)
0-25%	1	65 (60-65)
26-50%	20	40 (12.5-50)
51-75%	2	40
76-100%	13	0 (0-20)

Conclusions: Underlying RF are common in DIRI associated AKI. Causality assessment in DIRI is complex due to difficulty in determining the attribution of drug and RF. CAT for DIRI should incorporate AKI RF and their interaction with drugs.

SA-PO230

Reduced Incidence of Post-Operative Acute Kidney Injury After Cardiovascular Surgery Dadi Helgason,[1] Þórir E. Long,[1] Sólveig Helgadóttir,[2] Tomas Gudbjartsson,[3,6] Gisli H. Sigurdsson,[2,6] Martin I. Sigurdsson,[2,4] Olafur S. Indridason.[5] *[1]Dept of Medicine; [2]Dept of Anesthesia and Intensive Care; [3]Dept of Cardiothoracic Surgery, Landspitali, Reykjavik; [4]Dept of Anesthesia, Brigam and Women´s Hospital, Boston; [5]Div of Nephrology, Landspitali; [6]Faculty of Medicine, Univ of Iceland, Reykjavik, Iceland.*

Background: Acute kidney injury (AKI) is a serious complication of cardiac surgery. The aim of this study was to examine time trends in incidence and survival of patients diagnosed with AKI following cardiac and thoracic aorta surgery.

Methods: This was a retrospective study of all heart and thoracic aorta operations performed on adults in Iceland from 2007 to 2014. AKI was diagnosed according to the KDIGO criteria based on serum creatinine values in the electronic database of the clinical laboratory at our institution. Survival status was verified at Statistics Iceland. The incidence of AKI and its outcome was compared between the first and second half of the 8 year study period using Chi squared and the Kaplan Meier method. Outcome between AKI and non-AKI patients was compared by propensity score matching (1:2, non-replacement matching).

Results: A total of 2224 patients underwent 2502 operations during the study period, of which 28.4% were acute operations. Median (range) age at operation was 67 (18-97) years and 70.7% of patients were men. AKI occurred after 417 operations (16.7%). Of these 302 (12.1%), 69 (2.8%) and 46 (1.8%) were of stage 1, 2 and 3, respectively. Incidence of AKI

decreased from 19.2% in the first period to 14.5% in the second period (p=0.002). Survival of AKI patients at 30 days and 1 year did not differ between time periods, being 82.6% vs 83.8% and 79.5% vs 76.8%, respectively (p>0.10). Survival was worse for patients with AKI compared with the propensity score matched control cohort, both at 30 days (86.1% vs, 96.5%, p=0.0001) and at 1 year postoperatively (81.2% vs. 91.5%, p=0.0001).

Conclusions: The incidence of AKI following cardiac and thoracic aorta surgery is decreasing. Nevertheless it still affects one in seven patients and even though most patients have mild AKI, it is associated with increased mortality which remains unchanged over the past decade. *Funding:* Private Foundation Support

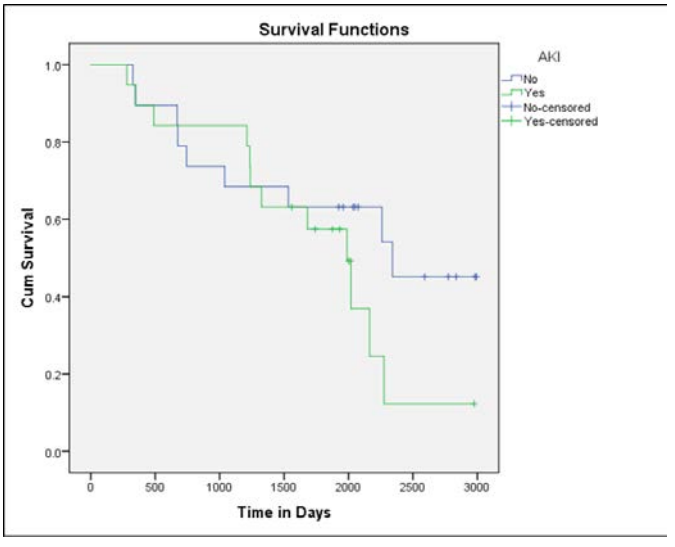
SA-PO231

Acute Kidney Injury in Patients with Chronic Kidney Disease: Aetiology and Survival Comparisons to Non-Acute Kidney Injury Chronic Kidney Disease Population Akib Khan,[1] James Ritchie,[2] Smeeta Sinha.[3] *[1]Senior House Officer, Imperial NHS Foundation Trust, London, United Kingdom; [2]Renal Medicine, Univ of Manchester, Manchester, United Kingdom; [3]Nephrology, Salford Royal Foundation Trust, Salford, United Kingdom.*

Background: AKI, described by an acute (hours to days) fall in kidney function, is associated with significant morbidity and mortality. Poor outcomes exist when AKI is superimposed on CKD, a disease involving structural or functional renal abnormalities in a chronic setting (>3 months). We present a single-centre prospective observational study; retrospectively analysed. We determine the factors surrounding AKI on CKD. Aetiology, length of stay, specialist review and medication data were examined. We compare AKI on CKD patients' survival to matched non-AKI CKD patients.

Methods: CRISIS database CKD patients matching inclusion criteria treated at Salford Royal Foundation Trust were studied (n=542). A 2.0-3.0 and >3.0 times serum creatinine increase from last measurement was used to define Acute Kidney Injury Network stages 2 (n=17) and 3 (n=10) events respectively. Controls were matched by age, eGFR and blood pressure. Logistic Regression, Cox-Hazard Ratio and Kaplan-Meier Survival Plots were used.

Results: Aetiological factors associated with AKI included sepsis (48.1%), drug-induced (29.6%) and dehydration (25.9%). Septic-AKI had a 1.405 odds ratio (95%CI:0.099-19.936,p=0.801) of death compared to non-septic events. Hazard ratio for death due to AKI on CKD compared to non-AKI CKD was 1.77 (95%CI:0.72-4.33,p=0.207). Kaplan-Meier survival function clearly demonstrates this.



Conclusions: Aetiology of AKI in our patient group was similar to that seen in non-CKD studies. There was a clear trend towards increased all-cause mortality in patients with AKI on CKD in comparison to non-AKI CKD patients. Renal function decline rate following AKI on CKD should be explored in the future.

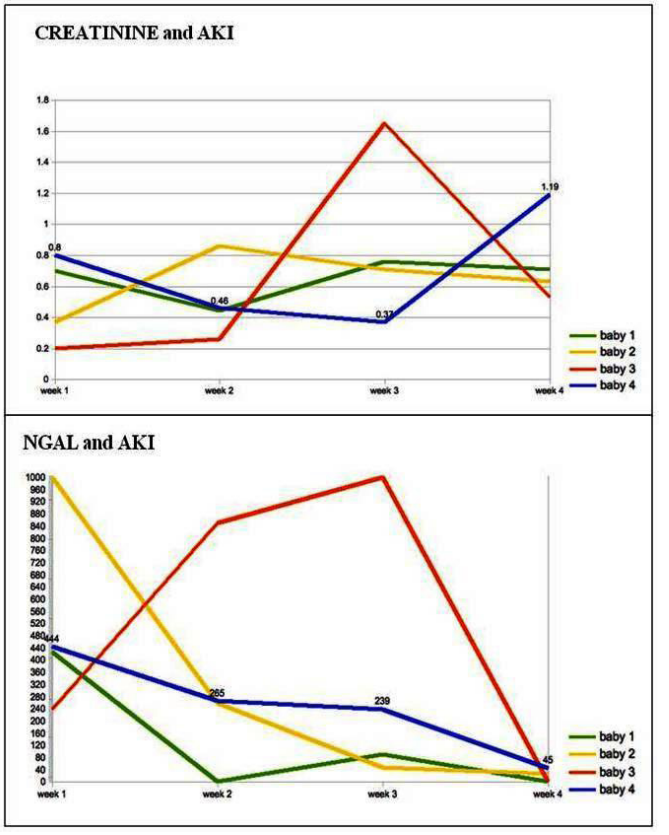
SA-PO232

Prospective Study of Incidence and Early Detection of Acute Renal Failure in Preterm Babies in a Tertiary Center in South India Indira Agarwal, Nithya Ponmudi, Anil K. Kuruvilla, Vijayakumar Theophilus-Sunder. *Pediatric Nephrology, Christian Medical College, Vellore, Tamil Nadu, India; Neonatology, Christian Medical College, Vellore, Tamil Nadu, India; Nephrology, Christian Medical College, Vellore, Tamil Nadu, India.*

Background: Preterm babies are at risk for ischemia, hypovolemia and hypotension and thus vulnerable to Acute kidney injury (AKI). We aimed to study the incidence and predisposing factors for AKI in preterm babies and to assess the usefulness of urinary NGAL as a predictor of kidney injury.

Methods: Babies born < 32 weeks+6 weeks were recruited; those with abnormal antenatal renal scans and major congenital anomalies were excluded. Weekly monitoring of urine output, clinical progress, interventions, ventilation, unexpected events and use of nephrotoxic drugs was done. Serum creatinine and urine NGAL was collected at 72 hours of age and weekly thereafter. Descriptive statistics using mean+/- SD for continuous variables, ANOVA and chi square test / Fishers exact test for categorical variables and Risk factor analysis using log binomial was performed.

Results: Of the 4823 live births, 80 fulfilled inclusion criteria (10.14%).The incidence of AKI was 12.6%.The risk factors included oligoanuria, PDA, nephrotoxic drugs, low Apgar, mechanical ventilation, CPAP and abnormal antenatal scans. Urine NGAL was estimated in 31 babies. It rose earlier and was significantly elevated in those on mechanical ventilation by week 2 while Creatinine rose only by week 3.



NGAL was inversely proportionate to gestational age and birth-weight. Both NGAL rise and creatinine were higher in babies with AKI associated with NSAIDS, umbilical lines and asphyxia.

Conclusions: NGAL holds promise as an early marker of AKI and a non invasive test for serial monitoring of renal function in preterm babies. A study with a larger sample size is required to establish reference values for NGAL in preterm babies.

SA-PO233

Acute Kidney Injury Electronic Alerts in Primary Care Conor Patrick Moran,[1] Ying C. Kuan,[1] Patrick Lm Lynch,[2] Francis Mccarroll.[1] *[1]Dept of Nephrology, Altnagelvin Hospital, Londonderry, United Kingdom; [2]Dept of Clinical Chemistry, Altnagelvin Hospital, Londonderry, United Kingdom.*

Background: Acute Kidney Injury, (AKI), is common with a variably reported mortality, (15-60%). A UK national audit reported that up to 30% of cases were avoidable and that as much as 43-61% of post-admission AKI experienced an unacceptable delay in recognition. AKI is regarded as the remit of Secondary Care and there have been few studies examining Community Acquired AKI, (CA-AKI). Guidelines have recommended the use of electronic alerts (e-alerts) for AKI detection in both Primary and Secondary care. We examined the incidence and mortality of CA-AKI.

Methods: We introduced AKI e-alerts with accompanying e-guidance in late October 2014 and prospectively collected data on the patients identified with severe AKI in Primary, (n=121), and Secondary care, (n=110), environments. Data collection was carried out for 3 months. The demographics of both cohorts were compared.

Results: Median age, (74.5 years vs. 75 years), gender distribution, (M:F: 48% / 52% vs. 44.5% / 55.5%), and median time to death, (8 days vs. 11 days), were comparable. 44 Alerts were from Primary Care and 77 from Emergency Department. Of the Primary Care Alerts, 20 patients were subsequently admitted. Of those who were not, 3 died within 30 days, (1. Died at 5 days, 2. Died at 8 days, 3. Died at 21 days). Despite this, Community-acquired AKI was associated with a 30-day mortality of 10.7%. Hospital-acquired AKI, (HA-AKI), was associated with a 28.2% 30-day mortality, (p=<0.001). Sub-group analysis showed Primary care alert associated with 13.64% mortality and Primary Care alerts with 9.76%, (p=<0.001). Median Age at Death; CA-AKI 80 years. Median time to death; CA-AKI 5 days, HA-AKI 11 days.

Conclusions: AKI is common and associated with a significant morbidity and mortality. CA-AKI is common opportunities at diagnosis and intervention are often missed with grave

consequences. Appropriate management of CA-AKI could help reduce the economic and physical burden associated with AKI and reduce the long-term burden of CKD. Further work is required to expand the role of AKI e-Alerts in Primary Care.

SA-PO234

Acute Kidney Injury Causes and Outcome: A Single Center Experience from Sudan Dalia Elrashid M Yousif,[1,2] Maha Farah,[2] Len A. Usvyat,[3,4] Roberto Pecoits-Filho,[1] Peter Kotanko.[3] *[1]PUCPR, Curitiba, PR, Brazil; [2]Nephrology, SOBA Univ Hospital, Khartoum, Sudan; [3]Renal Research Inst, New York, NY; [4]Fresenius Medical Care, Bad Homburg, Germany.*

Background: Acute kidney injury (AKI) is a challenging problem in Africa—a diverse continent with regards to population and financial and medical resources. There are no reliable statistics about the incidence of AKI in Africa. Based on sporadic regional publications the incidence has been estimated at 150 per million population. In addition to infectious diseases; toxins play a major etiologic role in AKI.

Methods: In this study we analyzed data from Omer Belail Renal Center in Soba University Hospital, Sudan, a tertiary referral center with a catchment area of 3 million citizens. All hemodialysis (HD) patients treated for AKI in the period between 1/1/2013 and 12/31/ 2014 were included in the study.

Results: Out of 520 hemodialysis patients we identified 69 patients with AKI; 39 (56.5%) were males. The mean±SD age was 40.5±17.4 years. Serum creatinine and blood urea levels on admission were 14.7±6.7 and 245±125 mg/dl, respectively. Serum creatinine and blood urea levels at discharge were 2.5±2.1 and 53±32 mg/dl, respectively. 29 patients (42%) experienced recovery of normal renal function; the recorded mortality was 13 %. AKI causes.

Acute tubular necrosis	15 (21.7%)
Obstructive uropathy	10 (14.5%)
Glomerulonehritis	7 (10.1%)
Acute interstitial nephritis	6 (8.7%)
Sepsis	6 (8.7%)
Snake bite	5 (7.2%)
Hair dye poisoning	4 (5.8%)
Hemolytic uremic syndrome	3 (4.3%)
Fluid depletion	1 (1.4%)
Others	12 (17.4%)

Conclusions: AKI has become increasingly prevalent in developing countries, and is associated with severe morbidity and mortality. Many causes of AKI can be prevented by interventions at the individual, community, and regional levels. Efforts should be directed to eradicate causes of AKI, expedite diagnosis, and aggressively manage pre-renal conditions and specific infections.

SA-PO235

Usefullness of Presepsin, Procalcitonin and IL6 as a Biomarkers of Adverse Renal Outcome and Mortality After Cardiac Surgery Alessandra Brocca, Grazia Maria Virzì, Maria Jimena Mucino-Bermejo, Davide Giavarina, Massimo de Cal, Claudio Ronco. *S Bortolo Hospital, Vicenza.*

Background: Cardiac surgery (CS) is now possible in increasingly high-risk patients (pts): accurate evaluation of surgical risk is crucial. Mortality and negative impact on distant organs must be evaluated. In a large number of clinical scenarios, biomarkers have been proven to be reliable tools in clinical settings either for single a single biomarker or a biomarker panels. Presepsin has been reported to be useful for stratifying mortality risk among septic pts in the ICU and thus it may also be helpful in many different clinical situations. Procalcitonin is related to the development of postoperative complications. IL6 is considered to be a major mediator of the acute phase response to cardiopulmonary bypass. The main aim of this study is to assess the usefulness of Presepsin, Procalcitonin and IL6 as a biomarkers in predicting mortality and negative renal outcome among CS pts.

Methods: Observational single center study that includes 122 adult CS pts. Blood samples were collected at the second day after surgery. Presepsin was tested by the PATHFAST Immunoanalyzer system, Procalcitonin by BRAHMS PCT sensitive KRYPTOR and IL6 by ELISA assay. A p-value of <0.05 was considered statistically significant.

Results: We observed that Presespin and IL6 are better predictors of inhospital (AUC=0.831 and 0.819), 30-day (AUC=0.723 and 0.785) and global mortality (AUC=0.759 and 0.793) than Procalcitonin ($p<0.05$). Pts with worse renal outcome (defined as AKI, change on CKD stage or need for CRRT) have significantly higher Presepsin and Procalcitonin levels ($p<0.05$). IL6 is not significantly different in pts with adverse renal outcome compare whit those without.

Conclusions: Presepsin and IL6 levels correlate with the risk of death better than Procalcitonin. Higher Presepsin and Procalcitonin levels are associated with adverse renal outcomes in this population. It is possible that a combination of these three biomarker in an inflammatory multi-biomarker panel as opposed to a single biomarker should betaken as "add-value" rather than a "unique-predicting" data.

SA-PO236

Allopurinol Attenuates Rhabdomyolysis-Induced Acute Kidney Injury: Renal and Muscular Protection Pedro H.F. Gois, Daniele Canale, Rildo A. Volpini, Daniela Ferreira, Mariana Veras, Maria H.M. Shimizu, Antonio C. Seguro. *Univ of São Paulo.*

Background: Myoglobinuric acute kidney injury(AKI) is the most severe complication of rhabdomyolysis.**Aim:**To evaluate the efficacy of allopurinol(Allo) on rhabdomyolysis-induced AKI.

Methods: Male Wistar rats were injected intramuscularly with 5ml/Kg body weight(BW) of either 50% glycerol(Gly) or 0.9% saline(S).Five groups were studied: S(n=5),S+Allo(n=6),Gly(n=7),Gly+Allo(n=7),Gly+ivAllo(n=7).S+Allo and Gly+Allo rats received Allo(300mg/L) in drinking water 7 days prior to and for 24h after Gly/S injection.Gly+ivAllo: intravenous Allo(50mg/Kg BW) 30' after Gly injection and 300mg/L in drinking water thereafter.

Results: Gly rats showed markedly reduced glomerular filtration rate(GFR,inulin clearance) associated with renal vasoconstriction,renal tubular damage,increased oxidative stress,apoptosis and inflammation.Allo treatment ameliorated all these alterations.Allo reduced muscular oxidative stress and accelerated its recovery.

	S	S+Allo	Gly	Gly+Allo
GFR(mL/min/100gBW)	1.12±0.03	1.02±0.05	0.49±0.04[ace]	0.78±0.08[af]
RBF(3h)mL/min	6.6±0.3	6.7±0.2	3.8±0.3[ace]	5.3±0.5
Plasma TBARS(nmol/mL)	1.4±0.2	1.1±0.2	6.8±1.0[ace]	3.7±0.8
Muscular TBARS	0.9±0.1	0.8±0.1	1.6±0.2[ace]	0.8±0.1
Renal MnSOD(%)	100±2	113±27	311±55[ace]	126±25
Renal Caspase-3(%)	100±8	103±6	158±18[bce]	67±5
CPK(3h)mg/dL	467±75	298±31	13.101±2.388[ae]	11.265±2.100[ae]
CPK(24h)	374±37	398±50	917±358[ace]	358±45
TIS	0.06±0.01	0.22±0.05	1.48±0.13[ad]	0.81±0.17[ae]
Intrarenal Lymphocytes	7±1	6±1	27±2[ace]	13±2[bf]
Muscular Injury Score	0	0	2.2±0.2[ade]	1.5±0.2[ae]

[a]$p<0.001$,[b]$p<0.01$**vs.SF**;[c]$p<0.001$,[d]$p<0.01$**vs.Gly+Allo**;[e]$p<0.001$,[f]$p<0.01$**vs.SF+Allo**.

Therapeutic Allo also improved GFR(0.78±0.06),renal blood flow(RBF) (6.5±0.3),plasma TBARS(1.2±0.3) and tubular injury score(TIS)(0.89±0.17).

Conclusions: Prophylactic and therapeutic Allo attenuates Gly-induced AKI by reducing oxidative stress (systemic, muscular and renal),inflammation and apoptosis.It may represent a new therapeutic approach for rhabdomyolysis and myoglobinuric AKI.(FAPESP)

SA-PO237

Cell Cycle Progression in the Early Phase of Septic Kidney Daisuke Nakano, Akira Nishiyama. *Dept of Pharmacology, Kagawa Univ, Kagawa, Japan.*

Background: The recovery of renal function after acute kidney injury (AKI) is likely controlled by proliferation of survived tubular cells in damaged nephrons containing cell death or sloughing. However, recent studies revealed that AKI concomitant with sepsis had significantly less tubular cell death than other forms of AKI, such as ischemic- and drug-induced AKI. It has not been examined whether septic AKI accelerates tubular cell proliferation in the condition with less cell death. In the present study, we examined the time-course changes in tubular cell proliferation after sepsis.

Methods: Lipopolysaccharide (LPS) and cecum ligation and puncture (CLP) model were used to induce sepsis in mice. Cell cycle progression was assessed by intravital imaging of Tg(FucciG1)#596Bsi (Fucci) mice, which express monomeric Kusabira-Orange2 in G1/0 phase cells, and immunohistochemistry for Ki67 or bromodeoxyuridine in young (8-12 weeks of age) and old (18-20 months of age) C57Bl/6 mice.

Results: Fucci mice (8 weeks of age) showed an increase in G1/0 to S transition of tubular cell cycle in the early phase of sepsis (within 2 hours in LPS and 4 hours in CLP). Ki67 and bromodeoxyuridine staining were increased only in young mice ($Ki67^+$ cell number: 1.5±0.1 fold increase in both LPS and CLP mice compared to normal control), not in old mice ($Ki67^+$ cell number: 0.8±0.1 fold in LPS mice and 1.0±0.1 fold in CLP mice compared to the control) at a similar time course observed in Fucci mice. Etoposide, an anti-cancer drug, abolished the cell proliferation after LPS injection in young mice. Importantly, old mice or etoposide-treated young mice showed much worse AKI as compared to young mice at 24h after sepsis. Moreover, mice lacking p21, a cyclin-dependent kinase inhibitor, showed a marked increase in $Ki67^+$ cells after LPS (2.2±0.1 fold increase vs. WT mice).

Conclusions: These results indicate that sepsis induces tubular cell proliferation in the early-phase of septic kidney. This situation may be a compensatory mechanism against the development of AKI since the frequency of cell proliferation is inversely correlated with the severity of sepsis. Moreover, cell senescence may worsen this compensation leading to an increased risk of AKI.

SA-PO238

Hepcidin Mitigates Endotoxin-Induced AKI Yogesh M. Scindia, Paromita Dey, Sundararaman Swaminathan. *Medicine, Univ of Virginia, Charlottesville, VA.*

Background: Sepsis is a common cause of acute kidney injury (AKI). Sepsis-associated inflammation induces hypoferremia and thereby limits iron availability to pathogens. It has been shown that hepcidin-induced degradation of ferroportin and consequent iron restriction are key for this hypoferremic state. Since, iron has been implicated in the pathogenesis of both sepsis and AKI, we hypothesized that hepcidin pretreatment would mitigate bacterial endotoxin-induced AKI.

Methods: C57BL/6 were treated with saline or 50 mg of hepcidin, 24 hours prior to LPS (*Escherichia coli O111:B4*) injection (6.5 mg/kg). Renal function, injury and inflammatory markers were examined up to 24 hours post LPS injection. Mouse glomerular endothelial cells (MGEC) were cultured with 100 ng/mL LPS for 6 hours after treating them with and without 1 mg/mL hepcidin for 12 hours.

Results: Kidney function (as measured by serum BUN) significantly declined 2 hours post LPS injection and progressively deteriorated for 24 hours. This was prevented by hepcidin treatment (BUN: LPS; 83.55 Vs Hepcidin + LPS; 32.33, $p < 0.001$). Renal NGAL expression paralleled the changes in BUN (NGAL: LPS; 6.74 Vs Hepcidin + LPS; 0.78, $p < 0.001$. Hepcidin treatment also reduced early systemic TNF alpha production following LPS injection (TNF alpha: LPS; 2266 Vs Hepcidin + LPS; 1248, $p < 0.01$). The ultra-structural morphology of the glomeruli revealed extensive loss of endothelial fenestrae and epithelial mitochondria in LPS treated mice, which was prevented by hepcidin treatment. However, MGEC cultures treated with or without hepcidin up-regulated endothelin gene to similar levels after stimulation with LPS.

Conclusions: Our results demonstrate a novel protective role of hepcidin in endotoxin-mediated AKI, which is largely exerted through down regulation of systemic cytokine production.

SA-PO239

ELK-B Peptide Prevents Renal Histological Damage and Mortality in Septic Mice Ana C. Souza,[1] Irina Baranova,[2] Jonathan Street,[1] Xuzhen Hu,[1] Peter S.T. Yuen,[1] Robert A. Star.[1] *[1]Kidney Diseases Branch, NIDDK, NIH, Bethesda, MD; [2]Clinical Center, NIH, Bethesda, MD.*

Background: Targeting SR-BI/II and CD36 receptors with L-37pA, an antagonist peptide, reduced multi-organ failure, peritoneal bacterial counts, and increased survival from 6 to 27% in antibiotic-treated mice subjected to cecal ligation and puncture (CLP)-induced sepsis (J Immunol. 2012). We tested ELK-B, a peptide more specific to the CD36 receptor.

Methods: Because the free peptide was toxic, ELK-B was formulated with micellar 1-palmitoyl-2-oleoyl-sn-glycero-3-phosphocholine. For survival study, animals were randomized into two groups: CLP (N=16) and CLP+ELK-B (15 mg/kg, N=15). A blinded observer administered treatments every 12h until death or until euthanized per protocol. For acute studies, 10 mice/group were subjected to CLP+saline (CLP) or CLP+ELK-B; saline or ELK-B was administered IV 0 and 6h after CLP. 18h post-CLP mice were euthanized for peritoneal lavage, and blood/organs collection. Serum creatinine (Cr) was measured by HPLC, BUN by colorimetry, and AST, ALT by an autoanalyzer. PAS-stained kidney sections were scored for renal tubular damage. Peritoneal bacterial cell counts were expressed per mouse. Caspase-3 IHC was performed on spleens. Data were analyzed by ANOVA and log-rank test.

Results: ELK-B significantly increased survival: all CLP+vehicle mice died by 78h, whereas 31% of ELK-B treated mice were still alive at 7 days. The survival curves did not diverge until 36h. At 18h (before survival curves diverged), ELK-B did not alter Cr (sham, CLP, CLP+ELK-B= 0.07±0.01, 0.30±0.06, and 0.21±0.06 mg/dl); BUN, AST, or ALT. ELK-B significantly reduced tubular damage ($p<0.001$ vs sham; $p<0.01$ vs CLP+ELK-B). Spleen caspase-3 $^{+}$cells were increased 18X in CLP and 6.8X in CLP+ELK-B but not statistically different. Log peritoneal bacterial counts were decreased 2X in CLP+ELK-B ($p<0.05$).

Conclusions: ELK-B reduced 7 day mortality and 18h renal histological damage after sepsis. However, it did not alter other biochemical outcomes at 18h. This suggests that it may act late in sepsis, perhaps by increasing bacterial killing.

SA-PO240

Renal Ischemic Preconditioning Protects against Septic Acute Kidney Injury via miR-21 Ping Jia,[1] Yi Fang,[1] Mingyu Liang,[2] Xiaoqiang Ding.[1] *[1]Dept of Nephrology, Zhongshan Hospital, Fudan Univ, Shanghai, China; [2]Dept of Physiology, Medical College of Wisconsin, Milwaukee, WI.*

Background: Septic acute kidney injury(AKI) is one of the most common and life-threatening complications in critically ill patients, and there is no approved effective treatment. We have showen ischemic preconditioning upregulates miR-21, provides renoprotection against subsequent ischemia reperfusion injury. Here we studied the effects of ischemic preconditioning on septic AKI and its mechanism.

Methods: Bilateral renal pedicles were clamped for 15 min in mice 24 h before the induction of septic AKI, and septic AKI was induced by intraperitoneal injection of lipopolysaccharide. The effects of renal ischemic preconditioning on LPS-induced AKI were investigated, including changes of renal function, histology, inflammation and apoptosis in kidneys. The role of microRNA, miR-21, in renal protection conferred by the ischemic preconditioning was examined using in vivo knockdown of miR-21 and miR-21 signaling pathways were analyzed.

Results: We observed that renal ischemic preconditioning provided morphological and functional renoprotection, characterized by attenuation of renal tubular damage, cell apoptosis, and a reduction in inflammation in circulation. Furthermore, we found that renal ischemic preconditioning significantly upregulated the expression of miR-21 in kidneys, suppressed proinflammatory factor PDCD4 expression and NF-κB activity, increased IL-10 production. Meanwhile, renal ischemic preconditioning also suppressed the expression of PTEN which is a proapoptotic protein, activating Akt signaling pathway, subsequently increasing the expression of Bcl-2 and inhibiting Caspase-3. A locked nucleic acid-modified anti-miR-21, given before renal ischemic preconditioning, knocked down miR-21 effectively, and upregulated its target effector PTEN expression, resulting in increase of apoptosis, exacerbated LPS-induced AKI.

Conclusions: Our findings domenstrate that renal ischemic preconditioning protects against LPS-induced AKI, and miR-21 coordinates its downstream signaling to reducing cell apoptosis and circulatory inflammation, contributing to renal protection.

SA-PO241

Remote Ischemic Preconditioning Protects against Contrast-Induced Nephropathy via Renalase Induced by TNFα/NFκB Pathway Feng Wang, Zeyuan Lu, Jianyong Yin, Guangyuan Zhang, Niansong Wang. *Nephrology, Shanghai Jiao Tong Univ Affiliated Sixth People's Hospital, Shanghai, China.*

Background: Renalase is a flavin adenine dinucleotide-dependent amine oxidase which has recently been suggested to be a reno-protective molecule. Herein we suggested that renalase expression induced by circulatory TNF-α which was evoked by remote ischemic preconditioning (rIPC) play a key role in contrast-induced nephropathy(CIN) protection.

Methods: CIN model was setup by Ioversol intravenous injection to SD rats. Limbs ischemic preconditioning was carried out 24 hours before CIN inducing. TNF-α blocking, NF-κB blocking, HIF blocking and renalase blocking were performed respectively. TNF-α administration was also performed as rIPC mimic. Renal injury, kidney oxidative stress, renal function, renalase expression, and circulating TNF-α after IPC were assessed. HK2 exposure to TNF-α and its blocker were studied and renalase expression was assessed.

Results: Reduced tubular injury, decreased oxidative stress and improved renal function were observed in CIN rats following rIPC. The therapeutic effects could be neutralized by renalase blocking. Renalase expression was significantly up-regulated after rIPC. rIPC induced renalase expression could be abolished by TNF-α blocking or NFκB blocking but not HIF blocking. Up-regulated renalase triggered by TNF-α could also be blocked by NFκB both in vivo and in vitro.

Conclusions: Renalase expression which mediated by TNFα/NFκB pathway played an essential role in reno-protection of rIPC for CIN.

Funding: Government Support - Non-U.S.

DNA Methylation in Cisplatin-Induced Acute Kidney Injury Chunyuan Guo,[1,2] Xiao Xiao,[1,2] Qingqing Wei,[1,2] Zheng Dong.[1,2] *[1]Cellular Biology and Anatomy, Georgia Regents Univ, Augusta, GA; [2]Charlie Norwood VA Medical Center, Augusta, GA.*

Background: DNA methylation is a major epigenetic modification, which plays an important role in regulating gene transcription without changing primary nucleotide sequence. DNA methylation has been implicated in major diseases, such as cancer. However, the changes of DNA methylation in kidney diseases, such as cisplatin-induced nephrotoxicity, remain unclear.

Methods: We determined the global DNA methylation changes in cisplatin-induced AKI by reduced representation bisulfite sequencing (RRBS) using kidney cortex from mice treated with cisplatin. We also established proximal tubule-specific DNMT1 (PT-DNMT1) knockout mice to determine the role of DNA methylation in cisplatin-induced AKI.

Results: Totally 1.5 and 1.9 millions of CpG sites were analyzed in the control and cisplatin treated kidney samples, respectively. Compared with control, cisplatin-treated samples showed aberrant DNA methylation changes, resulting in the identification of 236 differentially methylated regions (DMRs). Further analysis identified 15 genes that contained DMRs at 5' end regulatory promoter region or 5' UTR. To determine the pathological role of DNA methylation, we established the PT-DNMT1 model, in which the DNA methyltransferase 1 gene was specifically deleted from kidney proximal tubules. Compared with wide type mice, PT-DNMT1 knockout mice showed higher necrotic tubular damage at 4 day after cisplatin injection. Although BUN did not show difference between wide type and knockout mice, serum creatinine was increased in knockout mice treated with cisplatin.

Conclusions: Cisplatin induced significant changes in DNA methylation in kidney tissues, which may contribute to gene regulation and related kidney injury.

Blockade of KCa3.1 Potassium Channels Protects against Cisplatin-Induced Acute Kidney Injury Cheng-Lung Chen,[1] Li-Heng Pao.[1,2,3,4] *[1]Graduate Inst of Life Sciences; [2]School of Pharmacy, National Defense Medical Center, Taipei, Taiwan; [3]Graduate Inst of Health-Industry Technology; [4]Research Center for Industry of Human Ecology, Chang Gung Univ of Science and Technology, Taoyuan, Taiwan.*

Background: Anti-tumor efficacy of cisplatin chemotherapy is mainly limited by its toxicity to normal tissues, particularly the kidney toxicity. Tubular apoptotic cell death significantly contributes to the pathogenesis of cisplatin-induced acute kidney injury (AKI). KCa3.1, a calcium-activated potassium channel, has been reported to participate in cell apoptosis. However, the involvement of KCa3.1 in cisplatin-induced AKI is unknown.

Methods: We examined KCa3.1 mediates cispaltin-induced tubular apoptotic cell death *in vitro*, as well as the development of cisplatin-induced AKI in KCa3.1$^{-/-}$ and pharmacological blockade mouse models *in vivo*.

Results: Cisplatin treatment triggered an early induction in KCa3.1 expression, which is associated with apoptotic cell death in HK-2 cells, as well as with the development of renal tubular damage and cell apoptosis in mice. By treating with highly selective blocker TRAM-34, we found KCa3.1 inhibition suppressed cisplatin-induced apoptotic cell death in HK-2 cells. In the *in vivo* study, KCa3.1 deficiency reduced renal function loss, renal tubular damage and apoptotic marker caspase-3 inducution in kidneys after cisplatin administration in KCa3.1$^{-/-}$ mice. Pharmacological blockade of KCa3.1 by TRAM-34 similarly attenuated cisplatin-induced AKI in mice. Furthermore, we dissected the underlying mechanisms in which KCa3.1 blocking reduces cisplatin-induced apoptosis. We found KCa3.1 inhibition attenuated the cytochrome c release and the increase of intrinsic apoptotic mediator Bax, Bak and caspase-9 after cisplatin treatment. We also found KCa3.1 blocking inhibited cisplatin-induced the increase of ER stress mediator caspase-12, which is independent of calcium-dependent protease m-calpain activation.

Conclusions: Blockade of KCa3.1 protects against cisplatin-induced AKI through the attenuation of tubular apoptotic cell death by interference with intrinsic apoptotic and ER stress-related mediators, and that provides a potential target for the prevention of cisplatin-induced AKI.

Bax Mimotope Therapy: Effective Treatment for Ischemic Acute Kidney Injury (AKI) Zhiyong Wang, Ryan M. Mulhern, Andrea Havasi, Ramon G. Bonegio, Steven C. Borkan. *Renal Section, Boston Univ Medical Center, Boston, MA.*

Background: Ischemic AKI causes renal cell death partly by Bax-mediated apoptosis. Recent studies show that Bax requires the chaperone nucleosphosmin (NPM) for mitochondrial targeting and apoptosis. We propose that a mimotope that interferes with Bax-NPM interaction is an effective treatment for ischemic AKI.

Methods: To assess mimotope efficacy, 2 mg control or therapeutic Bax mimotope was administered by a single tail vein injection in 6-week old B6 mice either before or after renal ischemia caused by 22 min of bilateral renal pedicle clamping, an insult that produces severe AKI. BUN/Cr, histologic injury score, caspase 3 activity, Bax activation and Bax-NPM interaction were compared in each experimental group at the above time points (n = 8 each group).

Results: Compared to control, Bax mimotope administration 15 min before or 15 min, 1, 2 or 3 hr after ischemia significantly improved renal function. No protection was observed if Bax mimotope exposure was delayed for 4 or more hours after ischemia. Although 12% of controls died of AKI, only 2% of animals died in the Bax mimotope groups. Despite equivalent Bax activation in both groups, the Bax mimotope improved histologic injury score, reduced caspase 3 activation and decreased Bax-NPM interaction as assessed by co-immunoprecipitation.

Conclusions: Selective interference of Bax-NPM interaction with a Bax mimotope within several hours of acute ischemia improves survival, significantly reduces the severity of AKI (lower BUN and Cr), decreases histologic injury score and inhibits Bax-mediated apoptosis downstream of Bax activation.

Role of AMPK in Aristolochic Acid-Induced Acute Kidney Injury Anne-Emilie Decleves,[1] Inès Jadot,[2] Vanessa Colombaro,[2] Eric De prez,[1] Isabelle Habsch,[2] Kumar Sharma,[3] Nathalie Caron,[2] Joelle L. Nortier.[1] *[1]Free Univ of Brussels; [2]Univ of Namur; [3]Univ of California, San Diego.*

Background: Experimental aristolochic Acid nephropathy (AAN) is a pertinent model of tubulo-interstitial nephritis characterized by an early phase of acute kidney injury (AKI) leading to progressive fibrosis and chronic kidney disease (CKD). Here, the present model was used to determine the role of AMPK in renal outcome and its involvement in the AKI-to-CKD transition.

Methods: C57BL/6J male mice were randomly subjected to i.p. injection of either sterile saline solution, AA, AA+AICAR (the specific AMPK activator) for 4 days. Mice were then euthanized either at day 5 or day 20.

Results: AA-treated mice displayed loss of renal function, as reflected by significant increases in plasma creatinine level and proteinuria at days 5 and 20. In addition, impairment of tubular cells was also observed by the significant increase in urinary excretion of lysosomal enzyme N-acetyl-ß-D-glucosaminidase in AA-treated mice. These changes were prevented by AICAR treatment. To further determine the role of AMPK in AA-induced oxidative stress, Nox1, 2 and 4 were investigated at the mRNA levels. No changes were observed for Nox1 and 4. However, Nox2 was significantly increased in AA-treated mice while this rise was prevented by AICAR treatment at day 5 but not at day 20. Moreover, the urinary hydrogen peroxide level, a stable product of ROS production, was significantly higher after AA intoxication and reduced with AICAR. Regarding inflammation, AA mice exhibited a significant increase in MCP-1 mRNA level. This rise was only prevented by AICAR at day 5. Finally, at day 5, there was no significant macrophage infiltration with AICAR while at day 20, this significant increase was not prevented by AICAR.

Conclusions: These findings show a beneficial effect of AMPK in AA-induced AKI. In view of these data, we suggest that chronic AICAR treatment is necessary for complete nephroprotection and recovery. The activation of AMPK represents a potential strategy to prevent the transition from AKI-to-CKD.

Nrf2 Activation in Tubular Cells Prevents Progression of AKI to CKD Masahiro Nezu,[1,2,3] Tomokazu Souma,[1,2,3] Sadayoshi Ito,[2] Norio Suzuki,[3] Masayuki Yamamoto.[1] *[1]Dept of Medical Biochemistry, Tohoku Univ Graduate School of Medicine, Sendai, Miyagi, Japan; [2]Div of Nephrology, Endocrinology, and Vascular Medicine, Tohoku Univ Graduate School of Medicine, Sendai, Miyagi, Japan; [3]Div of Interdisciplinary Medical Science, Tohoku Univ Graduate School of Medicine, Sendai, Miyagi, Japan.*

Background: Acute kidney injury (AKI) is one of the major risk factors for chronic kidney disease (CKD). Reactive oxygen species are generated by ischemia-reperfusion injury (IRI) during transition of AKI to CKD, and oxidative stress contributes to defects of renal tubular cells. Nrf2 is a master transcription factor for cellular defense against oxidative stress, and an E3 ubiquitin ligase subunit Keap1 negatively regulates Nrf2 activity. Here, we evaluated protective roles of the Keap1-Nrf2 system in AKI-to-CKD transition.

Methods: Unilateral ischemia reperfusion injury (UIRI) was performed to induce rodent model of AKI-to-CKD. Hypomorphic Keap1 knockdown mutant (KKD) and tubular-specific Keap1-null mutant (TKO) mice were used for genetic activation of Nrf2. A Keap1 inhibitor CDDO-Im was used for pharmacological activation of Nrf2.

Results: Remaining tubular areas at 14 days after UIRI were 64%, 51% and 34% in KKD, TKO and wild-type mice, respectively compared with their contralateral kidneys. CDDO-Im treatmetne after UIRI to wild type mice also protected againtst tubular defects (CDDO-Im, 63%). Nrf2-induceible antioxidant genes (*Nqo1, Hmox1, Gclc, Gclm, and Srxn1*) were transiently up-regulated in 3-6 hours after UIRI in wild-type kidneys, while both genetic and pharmacological activation of Nrf2 maintained expression of these genes at high levels throughout the observation period.

Conclusions: Activation of Nrf2 alleviates IRI-induced tubular loss through enhancing the antioxidant response system. Nrf2 inducers are one of prospective therapeutic candidates for preventing AKI-to-CKD transition.

Acute Kidney Injury in the Rat Is Prevented by Pirfenidone Ixchel Quetzaliztli Lima Posada,[1] Francesco Fontana,[1,3] Nathan Berman,[1,2] Gianni Cappelli,[3] Norma Bobadilla.[1] *[1]Inst de Investigaciones Biomédicas, UNAM e Inst Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico, Mexico; [2]Univ Panamericana, Mexico, Mexico; [3]Univ degli studi di Modena e Reggio Emilia, Modena, Italy.*

Background: Pirfenidone (PFN) is an orally active small molecule which acts mainly through an anti-fibrotic effect, but also possesses antioxidant and anti-inflammatory properties.This study was designed to evaluate the effect of the prophylactic treatment with PFN on acute kidney injury (AKI) due to bilateral renal ischemia (I/R) in the rat.

Methods: We studied three groups of rats: 1) sham operated (S) 2) rats undergone 20 min of ischemia and 24-h of reperfusion and, 3) rats treated with PFN (700 mg/kg), 24-h before ischemia (I/R+PFN). Serum creatinine, creatinine clearance (CrC) protein excretion, urinary levels of Hsp72 (UHsp72V) and nitrates and nitrites (UNO2/NO3V) were assessed. Mean arterial pressure (MAP) and renal blood flow (RBF) were recorded 24-h after surgery. Tubular injury (TI) was evaluated in fixed kidneys by counting the cast number and the number of injured tubules per field.

Results: As expected, the I/R group showed a reduction in CrCl (I/R 0.22 ± 0.04 vs. S 0.36 ± 0.06 ml/min/100 g BW; $p<0.05$), urinary output (I/R 20±9.5 vs. S 32.7±19.3 ml/day; $p<0.05$), RBF (I/R 1.08 ± 0.37 vs. S 1.53±0.17 ml/min/100 g BW; $p<0.05$), and a significant increase in UHsp72V assessed by Western blot. Extensive TI was evidenced by histological analysis. These alterations were associated with a decrease in UNO2/NO3V (I/R 3.1±1.3 vs. S 5.4±2.5 mmol/24-h). In contrast, I/R+PFN group showed restoration of CrCl (I 0.33± .04 ml/min/100g BW; $p<0.05$), urinary output (47.5 ± 5.7 ml/day; $p<0.05$), RBF (1.51±0.15 ml/min/100g weight; $p<0.05$). The levels of urinary Hsp72 were undetectable or very low and the histological signs of TI were significantly reduced. Interestingly, UNO_2/NO_3V was completely recovered (7.05±0.78 mmol/24-h; $p<0.05$).

Conclusions: Our results revealed that pre-treatment with PFN prevents AKI in the rat. Part of its renoprotective effects seems to be related with the restoration of NO production. These findings suggest that PFN could be a promising tool in the prevention of AKI.

HDAC8 Plays a Critical Role in the Epigenetic Activation of Fibroblasts and the Pathogenesis of Renal Fibrosis Scott R. Manson, Qiusha Guo, Katelynn H. Moore, Paul F. Austin. *Dept of Surgery, Div of Urology, Washington Univ, St. Louis, MO.*

Background: The development of renal fibrosis is associated with changes in the expression of approximately 10% of the genome, suggesting widespread transcriptional dysregulation. Nonetheless, the roles of critical epigenetic pathways in disease progression remain poorly understood. Here, we examine the biological and therapeutic importance of histone deacetylases (HDACs) in the function of fibroblasts and the pathogenesis of renal fibrosis.

Methods: Renal fibrosis was modeled *in vitro* by treatment of NRK-49F fibroblasts with the pro-fibrotic cytokine TGF-β and *in vivo* in mice by unilateral ureteral obstruction (UUO). The role of HDAC proteins was assessed by treatment with the broad spectrum HDAC inhibitor Trichostatin A (TSA) and the HDAC8-specific inhibitor PCI-34051. The translational relevance of these findings was assessed in patients who underwent a nephrectomy following UPJ obstruction.

Results: UUO leads to a 6.1-fold increase in HDAC8 expression that localizes specifically to myofibroblasts. In NRK-49F cells, treatment with PCI-34051 promotes myofibroblast differentiation and apoptosis, but suppresses proliferation and matrix synthesis. These findings extend to the injured kidney *in vivo*, where HDAC inhibition results in a 41.6% decrease in *COLIA1* and a 61.6% decrease in α-*SMA*. Furthermore, there is a 77.9% decrease in the interstitial proliferative response, a 43.0% decrease in myofibroblast number, and a 31.1% decrease in renal fibrosis. Finally, the development of renal fibrosis in patients with obstructive kidney disease is associated with a 32.1% increase in the number of HDAC8-positive cells.

Conclusions: Together, these findings demonstrate that HDAC8 plays a critical role in regulating fibroblast activation. Treatment with HDAC inhibitors is also an effective therapeutic approach to reverse the epigenetic changes associated with the pathogenesis of renal fibrosis. Finally, since an increase in HDAC8 expression occurs in patients during disease progression, HDAC8-targeted therapies have therapeutic potential for the treatment of chronic kidney disease.

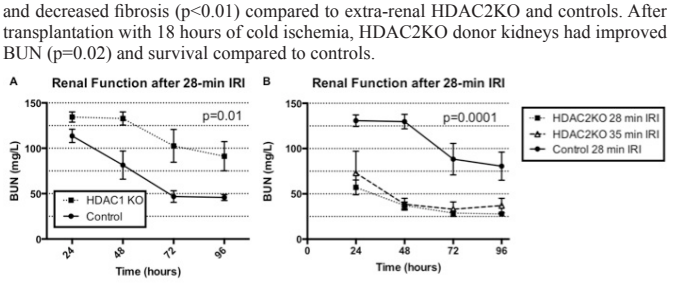
Reciprocal Effects of HDAC1 and HDAC2 Deletion on Renal Ischemia-Reperfusion Injury David Dean Aufhauser,[1] Zhonglin Wang,[1] Guanghui Ge,[1] Tricia Bhatti,[2] Wayne W. Hancock,[2,3] Matthew H. Levine.[1] *[1]Surgery, Hospital of the Univ of Pennsylvania and the Children's Hospital of Philadelphia, Philadelphia, PA; [2]Pathology and Laboratory Medicine, The Children's Hospital of Philadelphia, Philadelphia, PA; [3]Pathology and Laboratory Medicine, Hospital of the Univ of Pennsylvania, Philadelphia, PA.*

Background: Histone/protein deacetylases proteins (HDACs) have been implicated in renal ischemia-reperfusion injury (IRI). HDACs 1 and 2 are highly homologous Class I HDACs thought to have similar function.

Methods: This study included wild type C57BL/6 (B6) and inducible HDAC1- or 2- gene deleted mice (HDAC1KO and HDAC2KO). Renal-specific or extra-renal gene deletion was achieved with transplantation, native nephrectomy, and subsequent gene deletion. Warm IRI consisted of unilateral clamping of the renal pedicle and contralateral nephrectomy. Cold IRI was achieved through procurement, controlled interval of cold storage, and transplantation.

Results: HDAC1KO mice had impaired renal IRI tolerance compared to controls with higher BUN levels ($p<0.01$; Figure 1A) and increased fibrosis post-injury. HDAC2KO mice had improved early renal function ($p<0.01$; Figure 1B) and decreased fibrosis ($p<0.01$) compared to controls and tolerated extended periods of ischemia. In transplant models, renal-specific HDAC2KO mice had superior IRI tolerance with less renal impairment ($p<0.01$) and decreased fibrosis ($p<0.01$) compared to extra-renal HDAC2KO and controls. After transplantation with 18 hours of cold ischemia, HDAC2KO donor kidneys had improved BUN ($p=0.02$) and survival compared to controls.



Conclusions: HDAC1 and 2 have reciprocal effects on murine renal IRI tolerance, with HDAC1 deletion increasing vulnerability and HDAC2 deletion providing protection. The effect of HDAC2 deletion is profound, is intrinsic to the kidney, and extends to cold ischemia and renal transplantation.

Renoprotective Effect of Long Acting Thioredoxin by Modulating Oxidative Stress and Macrophage Migration Inhibitory Factor against Rhabdomyolysis-Associated Acute Kidney Injury Hiroshi Watanabe,[1] Kento Nishida,[1] Masafumi Fukagawa,[2] Toru Maruyama.[1] *[1]Dept of Biopharmaceutics, Graduate School of Pharmaceutical Sciences, Kumamoto Univ, Kumamoto, Japan; [2]Div of Nephrology, Endocrinology and Metabolism, Tokai Univ School of Medicine, Kanagawa, Japan.*

Background: Rhabdomyolysis-associated acute kidney injury (AKI) is a serious life-threatening condition. As such, more effective strategies are needed for its prevention and treatment. Although thioredoxin-1 (Trx) possesses superior biological activities, such as anti-oxidative and anti-inflammatory effect via the modulating macrophage migration inhibitory factor (MIF), its short blood retention limits the therapeutic application. To overcome this, we engineered long acting Trx by genetically fused with human serum albumin (HSA-Trx), and examined its renoprotective effect against glycerol-induced AKI.

Methods: HSA-Trx was prepared by using Pichia expression system. The mouse model of rhabdomyolysis-associated AKI was induced by the administration of a 50% glycerol solution.

Results: An intravenous HSA-Trx pre-treatment attenuated the glycerol-induced decline in renal function, compared to a PBS, HSA or Trx alone. HSA-Trx caused a reduction in the tubular injuries and in the number of apoptosis-positive tubular cells. Renal superoxide, 8-hydroxy deoxyguanosine, nitrotyrosine and the plasma Cys34-cysteinylated albumin were clearly suppressed by the HSA-Trx treatment. Prior to decreasing TNF-α and IL-6, HSA-Trx suppressed an increase of plasma MIF level. In LLC-PK1 cells, HSA-Trx decreased the level of reactive oxygen species and lactate dehydrogenase release induced by myoglobin. HSA-Trx treatment resulted in a threefold increase in the survival of lethal glycerol-treated mice. The post-administration of HSA-Trx at 1 and 3 hr after glycerol injection exerted a significant renoprotective effect.

Conclusions: HSA-Trx, a long acting Trx, has potential for use in the prevention and treatment of rhabdomyolysis-associated AKI *via* its extended effects of modulating oxidative stress and MIF.

SA-PO251

Selective Endothelin-A Receptor Antagonism Prevents the Progression of Acute Kidney Injury to Chronic Kidney Disease Neeraj Dhaun. *Queen's Medical Research Inst, Univ of Edinburgh, Edinburgh, United Kingdom.*

Background: AKI is common and associated with significant morbidity and mortality. AKI often progresses to CKDand endothelin-1 (ET-1) contributes to this. We hypothesized that therapeutic administration of selective ET_A receptor antagonism would protect from the transition of AKI to CKD.

Methods: 28 FVB mice underwent prolonged (50min) unilateral ischemia-reperfusion injury (IRI) with 28d recovery. 14 mice received daily selective ET_A antagonism (sitaxentan) starting 24h after IRI. We assessed blood pressure (BP) *via* telemetry, vascular function, renal injury and measures of the ET system.

Results: Systolic BP increased by ~5mmHg after IRI and was associated with vascular dysfunction in both resistance and conduit vessels. Sitaxentan partly prevented both of these. At 28d after IRI kidney weight was reduced (-55%) and associated with significant macrophage infiltration and fibrosis compared to the contralateral control kidney. Mice treated with sitaxentan had normal kidney weight, reduced macrophage infiltration and less fibrosis: IRI kidney *vs.* control kidney *vs.* IRI kidney with sitaxentan: F4/80 stain/high power field: 2.5*vs.*0.2*vs.*0.8%; picosirius red stain/high power field: 8.6*vs.*0.48*vs.*3.1%. For both macrophage infiltration and fibrosis, $p<0.05$ for IRI*vs.*control and for IRI*vs.*IRI with sitaxentan, p=ns for control *vs.* IRI with sitaxentan. Furthermore, an up-regulation of both the ET_A (28-fold) and ET_B (2-fold) receptors as well as pre-pro-ET-1 (10-fold) mRNA was seen in both the cortex and medulla of the IRI kidney relative to control. With sitaxentan treatment ET_A/ET_B receptor and pre-pro-ET-1 mRNA remained similar to baseline levels. Finally, renal ET-1 production increased following IRI and this was prevented by ET_A receptor antagonism (fractional excretion of ET-1: IRI*vs.*IRI with sitaxentan: 47*vs.*16%, $p<0.05$).

Conclusions: In an *in vivo* model of AKI progressing to CKD, ET_A receptor antagonism reduced BP and vascular dysfunction and prevented progression of renal injury and ET system activation after AKI. Therefore, selective ET_A receptor antagonism offers a potentially novel therapy for AKI. Translational studies are now warranted.

SA-PO252

Inhibition of Vascular Adhesion Protein-1 Suppresses Neutrophil Infiltration and Preserves Renal Function in the Rat Model of Renal Ischemia–Reperfusion Injury Shinji Tanaka, Tetsuhiro Tanaka, Reiko Inagi, Masaomi Nangaku. *Div of Nephrology and Endocrinology, The Univ of Tokyo Graduate School of Medicine, Tokyo, Japan.*

Background: Vascular adhesion protein-1 (VAP-1) is an adhesin expressed in endothelial cells. With its unique properties as an ectoenzyme which catalyzes oxidative deamination of primary amines, VAP-1 plays a critical role in leukocyte trafficking. In light of a growing body of evidence that VAP-1 controls inflammation in various organs, such as the liver and the lung, we examined the effect of VAP-1 inhibition in the rat model of renal ischemia–reperfusion injury.

Methods: Rats were subjected to left renal ischemia for 45 min after right nephrectomy, followed by reperfusion for 48 h. A specific VAP-1 inhibitor, RTU-1096 (R-Tech Ueno, Tokyo, Japan), or vehicle was administered to rats since 7 days before the surgery (mixed with feed, 40 mg/kg/day).

Results: Immunofluorescence studies suggested that VAP-1 is expressed not only in endothelial cells of peritubular capillaries but also in interstitial cells of non-endothelial lineage. In vitro, higher mRNA expression of VAP-1 was confirmed in cultured pericytes. In vivo, VAP-1 enzyme activity in the whole kidney was unaffected by the surgery, but following VAP-1 inhibition by RTU-1096 (0.9±0.1 vs. 7.0±1.3 pmol/mg protein/min), renal function was significantly better preserved as compared to the vehicle group (BUN: 69±6 vs. 139±15 mg/dL, Cr: 1.4±0.1 vs. 2.5±0.2 mg/dL; p<0.01), which was accompanied by amelioration in histological tubular injury and decreased KIM-1 mRNA levels. Immunohistochemical analysis revealed a significantly decreased number of neutrophils in the corticomedullary junction in the drug group, whereas the number of macrophages was similar. VAP-1 inhibition resulted in significantly lower mRNA levels of CXCL1 and CXCL2 in the kidney without affecting chemokines involved in macrophage recruitment, such as MCP-1, or major adhesion molecules, VCAM-1 and ICAM-1.

Conclusions: These data suggest that VAP-1 plays an important role in renal ischemia–reperfusion injuries by controlling neutrophil infiltration, and offer a promising view that its inhibition can be a novel therapeutic target in ischemic acute kidney injury.

Funding: Government Support - Non-U.S.

Kim-1 Overexpressing Transgenic Zebrafish Identify mTOR as an Effector of Kim-1-Mediated Kidney Injury in Fish and Mice Wenqing Yin, Said Movahedi naini, Dirk M. Hentschel, Benjamin D. Humphreys, Joseph V. Bonventre. *Renal Div, Brigham and Women's Hospital, Boston, MA.*

Background: Mammalian kidney injury molecule 1 (KIM-1), an epithelial phagocytic receptor, is markedly upregulated in the proximal tubule in various forms of acute and chronic kidney injury in humans and many other species. Here, we characterized the zebrafish Kim family to consist of Kim-1, Kim-3 and Kim-4. By genetically expressing constitutive or tamoxifen-induced Kim-1 in zebrafish kidney tubules, we identified mTOR as an effector in Kim-1-mediated kidney injury. We then validated mTOR as a therapeutic target for kidney injury and fibrosis in KIM-1 overexpressing transgenic mice.

Methods: We created two transgenic zebrafish models of Kim-1 overexpression in nephrons employing the cdh17 promoter. One model utilized a constitutively active promoter while the other utilized a tamoxifen-induced Cre-ERT2 recombinase to express Kim-1 in nephrons in a temporally-controlled manner. The role of mTOR signaling was evaluated using the inhibitor rapamycin. Zebrafish GFR was determined using the elimination rate of fluorescein-labeled dextran.

Results: Kim-1 was markedly upregulated after gentamicin-induced kidney injury and had conserved phagocytic activity in zebrafish. Both constitutive and tamoxifen-induced expression of Kim-1 in zebrafish kidney tubules resulted in shedding of the tubule brush border, reduced GFR, pericardial edema and increased mortality rate. Kim-1-induced kidney injury was associated with inhibition of growth of adult fish. Kim-1 expression led to mTOR pathway activation, and inhibition of this pathway with rapamycin increased survival. mTOR pathway inhibition in KIM-1 overexpressing transgenic mice also significantly reduced serum creatinine, proteinuria, tubular injury and kidney inflammation.

Conclusions: Persistent Kim-1 expression resulted in chronic kidney damage and growth impairment in zebrafish. Kim-1-mediated kidney tubular injury was mediated by the mTOR signaling pathway. This observation in zebrafish predicted the role of the mTOR pathway and therapeutic efficacy of rapamycin to protect the mouse kidney against KIM-1-mediated kidney injury and fibrosis.

SA-PO254

Treg and ILC2 Contribute to IL233 (a Novel Fusion Cytokine)-Mediated Protection in AKI Marta Stremska,[1] Liping Huang,[1] Sheethal Jose,[1] Amandeep Bajwa,[1] Diane L. Rosin,[1,2] Mark D. Okusa,[1] Rahul Sharma.[1] *[1]CIIR, Univ of Virginia, Charlottesville, VA; [2]Dept of Pharmacology, Univ of Virginia.*

Background: Inflammation is an early event in AKI and studies have shown regulatory T cell (Treg)-mediated protection in inflammation driven injuries. Since we found that interleukin (IL)-2 upregulates IL-33 receptor-ST2 on CD4 T-cells, we hypothesized that IL-2 and IL-33 cooperate to expand endogenous Tregs. Indeed, a proportion of Tregs constitutively expressed ST2 and IL-33 contributed to promote Tregs. IL-2 and IL-33 in combination or as IL233 fusion cytokine, but not alone protected mice from IRI, with IL233 being more efficient than the combination.

Methods: We designed a fusion cytokine (IL233) containing the activities of IL-2 and IL-33 for better targeting of Tregs. The cytokines were expressed in *E.coli,* purified to homogeneity and tested in a mouse model of ischemia reperfusion injury (IRI). C57BL/6 male mice were pretreated (ip) with different doses of cytokines prior to 26 min of bilateral ischemia and 24 hours of reperfusion. Kidneys were characterized for function, acute tubular necrosis and the profile of infiltrating cells.

Results: IL-2 and IL-33 in combination or as IL233 fusion cytokine, but not alone protected mice from IRI, with IL233 being more efficient. Our data suggests that the IL233 treatment first increases splenic levels of Tregs followed by their mobilization. Since both IL-2 and IL-33 also promote Th2 response, an increase in IL-4 and IL-5, and a decrease in Th1 cytokines IFNγ and TNFα was seen, indicating a shift towards a protective Th2 response. Protected mice had a higher proportion of innate lymphoid cells 2 (ILC2) in the blood and the kidneys. Neutrophil infiltration in the kidneys was significantly lowered in IL233 treated mice. Treg adoptive transfer studies revealed higher degree of protection in mice injected with Tregs obtained from mice pretreated with IL233. Adoptive transfer of ILC2, pretreated with IL233 also protected against IRI. In vitro experiments with IL233 pre-treated Tregs revealed their higher suppressive function.

Conclusions: Thus, IL233 cytokine attenuates kidney inflammation to protect from IRI and bears strong potential to be a therapeutic agent for AKI.

Vagus Nerve Stimulation (VNS) Protects Kidneys from Ischemia-Reperfusion Injury Through Alpha 7 Nicotinic Acetylcholine Receptor (α7nAChR) Expressing Splenocytes Tsuyoshi Inoue,[1] Chikara Abe,[2] Stefan Moscalu,[1] Liping Huang,[1] Hong Ye,[1] Diane L. Rosin,[1,2] Patrice G. Guyenet,[2] Mark D. Okusa.[1] *[1]Depts of Medicine, Univ of Virginia Health System; [2]Depts of Pharmacology, Univ of Virginia Health System, Charlottesville, VA.*

Background: The nervous and immune systems interact in complex ways to maintain homeostasis and respond to stress or injury. The inflammatory reflex referred to as the *cholinergic anti-inflammatory pathway (CAP)* modulates innate and adaptive immunity, and modulation of the reflex by VNS is effective in inflammatory disease models. The effect of VNS on AKI has never been examined. Experimental activation of vagal efferent fibers suppresses inflammation in a manner that depends on α7nAChR in the CAP. However, the site of the essential α7nAChR was not established.

Methods: We applied electrical VNS (5 Hz, 50 μA for 10 min) 24 hr prior to kidney IRI and assessed kidney injury by evaluating plasma creatinine (PCr, mg/dl), kidney Kim-1 mRNA expression and histology (H&E). The effect of VNS on IRI was assessed by: a) prior splenectomy and b) adoptive transfer of splenocytes from VNS-stimulated mice to recipient mice subjected to IRI.

Results: VNS applied 24 hr prior to IRI markedly attenuated IRI. VNS reduced the IRI-induced increase in PCr by 65% (P<0.01) and Kim-1 mRNA expression in whole kidney by >70% (P<0.01). H&E–stained kidney sections confirmed the functional data. When splenectomy was performed 7 d before VNS and IRI, the protection by VNS was abolished. Adoptive transfer of splenocytes from VNS-treated mice to recipient mice subjected to IRI provided greater protection than splenocytes from mice who received sham VNS stimulation (PCr: 0.41 and 1.54 (P<0.001) for VNS- and sham VNS-treated splenocytes, respectively). To evaluate the role of α7nAChR, VNS was initiated 24 hr prior to IRI in α7nAChR knock out (α7KO) and WT mice. Compared to the protective effect of VNS on IRI in WT mice, no protection was observed in α7KO mice. In addition, recipient mice were protected (PCr) from IRI if they received splenocytes from VNS-treated WT mice (0.41) but not from VNS-treated α7KO mice (1.57, P<0.001).

Conclusions: VNS-induced protection from IRI is consistent with activation of the CAP.

Elevations of Intraglomerular Pressure Exacerbate Ischemia Reperfusion Injury-Induced Acute Kidney Injury Jie Zhang, Lei Wang, Shaohui Wang, Gensheng Zhang, Jin Wei, Ruisheng Liu, Kay-Pong D. Yip. *Molecular Pharmacology & Physiology, Univ of South Florida, Tampa, FL.*

Background: The physiological and pathophysiological mechanisms of renal ischemia reperfusion (IR)-induced acute renal injury (AKI) are complex and have not been elucidated. We sought to determine whether intraglomerular hydrostatic pressure (Pg) during the ischemic phase plays a critical role in IR-induced AKI.

Methods: AKI was induced in three groups of C57BL/6J mice at 37° C with IR by 18 min of bilateral clamping of renal arteries (RA), pedicles (RP), and pedicles plus pre-clamping of ureters 20 min before ischemia (PU). Free flow proximal tubular pressure (Pf) was measured with servo-nulling method during ischemia. Pf was used as an index of Pg.

Results: We found that mean Pf was higher in PU mice (48.9±7.5 mmHg) than in RP mice (34.6±3.6 mmHg). The RA mice had lower Pf (1.6±1.2 mmHg) when compared to Sham operated mice (9.54±2.2 mmHg). In separate experiments, the renal injury was determined 24 hours after IR in these mice. Plasma creatinine was significantly increased in all three groups compared with sham-operated group. The mean plasma creatinine were 2.1±0.07 mg/dl, 1.85±0.08 mg/dl, and 0.45±0.7 mg/dl for PU, PR and RA, respectively. The mean plasma Kidney Injury Molecule-1(KIM-1) levels were 2761±493 pg/ml in PU, 1548±220 pg/ml in RP and 734±234 pg/ml in RA group, respectively. Histology by PAS staining showed that all AKI mice had a significant increase in renal tubular necrosis compared with sham-operated mice. However, there were more tubular necrosis in the cortex, medulla or cortex-medulla junction area in PU mice (3.1±1.3%, 34.1±8.5% and 54.4±6.9%) than in RP mice (1.2±0.5%, 23.0±9.2% and 50.1±12.7%). RA mice had the least tubular necrosis (0.23±0.1%, 8.9±4.5% and 31.7±10.2%).

Conclusions: We found that RA mice had lowest intraglomerular pressure and renal injury and that PU mice had highest intraglomerular pressure and most severe renal injury. These data indicate that elevations of intraglomerular and tubular pressure exacerbate IR-induced AKI. Intraglomerular and tubular pressure may be a novel therapeutic target for AKI.

GFR in Conscious Mice After Sepsis: Role of Tubuloglomerular Feedback Jonathan Street, Yuning George Huang, Peter S.T. Yuen, Robert A. Star. *NIDDK, Bethesda, MD.*

Background: Reabsorption of glomerular filtrate by the tubules is an energy intensive process. During sepsis the ability of the tubules to meet this energy demand may be impaired. To prevent renal salt wasting during sepsis it is hypothesized that activation of tubuloglomerular feedback reduces GFR and subsequently the metabolic demand on the tubules – "acute renal success". Mice without tubuloglomerular feedback should maintain higher levels of GFR. In conscious mice we detected early changes in GFR using a novel transcutaneous measurement of a fluorescent filtration marker. Because adenosine 1a receptor (A1aR) signaling is required for tubuloglomerular feedback we directly measured GFR following sepsis in A1aR knockout mice.

Methods: Sepsis was induced in male A1aR knockout mice and littermate controls by cecal ligation and puncture. GFR was monitored in awake mice for 5 hours by plasma disappearance of FITC-Sinistrin, injected at 0 and 90 minutes after surgery, and its transcutaneous fluorescence measured by a miniaturized fluorimeter attached to the mouse back.

Results: The baseline GFR was similar in A1aR WT and KO mice. In WT mice, GFR was stable during the first hour following induction of sepsis. GFR slowly declined over hour two, and then fell rapidly to <10 % of normal and remained low for 5 hours. In contrast, the GFR was lower in KO mice than in WT mice in the first hour following sepsis ($p=0.0226$), then fell gradually to 27% of normal, with a smaller decrease observed after 2 hours compared to WT mice ($p=0.0286$).

Conclusions: In mice lacking tubuloglomerular feedback, unexpectedly, GFR begins to decrease earlier after sepsis suggesting impaired autoregulation. The sudden decrease in GFR in WT mice at 2 hours after induction of sepsis does not occur in A1aR KO mice. Tubuloglomerular feedback modestly supports, not suppresses, GFR in the first hour following sepsis, and only later acts to suppress GFR.

Renal Functional Reserve May Be Inferred from Variation of Renal Resistive Index: Preliminary Evidence Sara Samoni,[1,2] Federico Nalesso,[2] Gianluca Villa,[2] Silvia De Rosa,[2] Ilaria Petrucci,[1] Massimo de Cal,[2] Fiorenza Ferrari,[2] Alessandra Brendolan,[2] Mario Meola,[1] Claudio Ronco.[2] *[1]Sant'Anna School of Advanced Studies, Pisa; [2]IRRIV, Vicenza.*

Background: The increase of glomerular filtration rate(GFR)after a protein load represents the renal functional reserve(RFR).Mechanical abdominal stress(MAS),through the compression of renal arteries and the consequent reduction of renal blood flow,can activate the autoregulation mechanism to maintain glomerular perfusion.Both phenomena are related to the afferent vasodilation,which can be displayed by the drop of renal resistive index(RI)measured by colorDoppler.We hypothesized that the variation of RI during MAS may predict the RFR.

Methods: In 15 healthy volunteers,MAS was performed through the application of a saline bag on abdominal wall.According to the performed dose-response curve,we used bags which weigh 10% of subject's BW.We recorded RI in mesorenal interlobar arteries each min for the 10 min of MAS.The RI reduction was defined by the difference between baseline RI and the lowest RI reached during MAS and expressed as percentage reduction(pDRI). RFR was measured through a standardized protein loading test.Spearman's correlation was applied to evaluate if pDRI correlates with RFR.

Results: We enrolled 9M and 6F with a median age of 30(24-57)yrs old.The median baseline CrCl was 99.2(70.3-132.8)ml/min/1.73m^2.The RFR ranged between 11.55%and 134.66%with a median value of 38.55%.The median baseline RI was 0.60(0.50-0.67)while pDRI ranged between 13.33%and 29.23%with a median value of 20%.The correlation between pDRI and RFR was 80.71%($p<0.001$).According to physiology,RFR and pDRI may not be directly proportional;indeed,while ranges of RFR may widely broaden,pDRI should reach a plateau value.For this reason,we analyzed the linear regression model between pDRI and logarithm(ln)of RFR.According to this model,we found that an increase in pDRI was associated to an increase in the ln of RFR(coef0.10,$p<0.001$,95%CI:0.06;0.15,$R^2$0.66).

Conclusions: Our results suggest that the variation of RI during MAS is an indirect measure of RFR,putting the bases for the development of a stress test that could be used for a rapid screen of RFR before potentially nephrotoxic procedures.

SA-PO259

5-Aminolevulinic Acid Attenuates Rhabdomyolysis-Induced Acute Kidney Injury in Mice Atsushi Uchida, Minoru Satoh, Tamaki Sasaki, Naoki Kashihara. *Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Okayama, Japan.*

Background: Rhabdomyolysis often occurs after severe skeletal muscle injury, and high mortality have been reported with the acute kidney injury (AKI) that develops subsequently. Thus, the establishment of effective prevention and treatment is a pressing problem. 5-Aminolevulinic acid (ALA) is the naturally occurring metabolic precursor of heme, and serves as protein material related to energy production. Previous study demonstrated that ALA has the potential to prevent cisplatin-induced AKI via the induction of heme oxygenase (HO)-1, and prevention of tubular apoptosis. We hypothesize that ALA plays a renoprotective role via the induction of HO-1 and anti-apoptotic pathway in rhabdomyolysis-induced AKI.

Methods: Male C57BL/6 mice were used.Rhabdomyolysis-induced AKI was induced by intramuscular injection of glycerol (50%) 5 ml/kg bw. ALA (30 mg/kg) was administrated at 24 hr before or 24 hr after glycerol administration. These mice were sacrificed at 72 h after glycerol injection, and the blood and renal tissues were harvested. In vitro experiment, human proximal tubule cells were stimulated by 100 uM hemin to induce apoptosis. Cells were incubated for 24 hr with or without 1 mM ALA. Apoptotic cells were examined by TUNEL staining and caspase-3 expression.

Results: In vivo experiments, serum creatinine, blood urea nitrogen and urine NGAL excretion were increased in glycerol-injected group compared with saline-injected control group. ALA significantly reduced these changes in both pre and post treatment. ALA also ameliorated glycerol-induced morphological tubular damages. HO-1 level was increased in glycerol-injected group and further up-regulated by ALA treatment. ALA significantly attenuated macrophage infiltration and pro-inflammatory cytokine (IL-1beta and TNFα) expression. In vitro experiments, TUNEL-positive cells and caspase-3 expression were increased by hemin and were significantly reduced by ALA co-treatment.

Conclusions: ALA has renoprotective effects in glycerol-injected AKI. ALA is already used for tumor diagnosis in human. So the safety of the drug is proved in clinical use. ALA treatment may be a new therapeutic target in rhabdomyolysis-induced AKI.

SA-PO260

Ferroptosis as a Cause of Proximal Tubule Injury Joel M. Weinberg,[1,2] Andreas Linkermann.[3] *[1]Nephrology, VA Healthcare System Ann Arbor, Ann Arbor, MI; [2]Nephrology, Univ of Michigan, Ann Arbor, MI; [3]Nephrology, Christian Albrechts Univ, Kiel, Germany.*

Background: 'Ferroptosis' has recently been described as a form of iron-dependent, lipid peroxidation-mediated cell death with a distinct injury pattern relative to other forms of necrosis and there is evidence that it contributes to AKI in vivo (PNAS 111:16835,2014, Nat. Cell Biol. 16:1180,2014). Here, we have refined approaches to study ferroptosis in freshly isolated proximal tubules (PT) and assessed new agents being developed to ameliorate it.

Methods: Freshly isolated rabbit (R) and mouse (M) PT were treated with either tert-butylhydroperoxide (tBHP, 5 mM) or hydroxyquinoline + ferrous ammonium sulfate (HQ+Fe,10 uM each) followed by incubation for 120 min, then measurement of LDH release, malondialdehyde (MDA) production, mitochondrial membrane potential, and GSH.

Results: tBHP and HQ+Fe induced progressive LDH release that was more severe in M PTs (for HQ+Fe: R60'-35.5±6.8%, R120'-51.4±9.0%; M60'-72.1±2.6%, M120'-87.4±3.25%). These changes were accompanied by 5 fold increases of MDA levels and GSH depletion. LDH release and MDA production were iron and NAPH oxidase (Nox)-dependent since they were blocked by deferoxamine or the Nox1/4 inhibitor GKT 137831. Fer-1, the prototypical ferroptosis inhibitor that emerged from chemical library screening, strongly alleviated both forms of injury and associated MDA production at concentrations of 0.1 to 2 uM as did a panel of 23 other ferrostatin analogs with potencies similar to those seen in isolated non-renal cell systems. Interestingly, the lipophilic antioxidant, diphenyl-p-phenylenediamine (DPPD), was even more potent than the highly active ferrostatins. Ferrostatins were not effective against acute cell killing and energetic deficits induced by hypoxia/reoxygenation, indicating that the benefit seen during in vivo ischemia/reperfusion does not target that phase of injury.

Conclusions: Ferroptosis is strongly expressed in fully differentiated PTs, is suppressed by both newly developed ferrostatins and the classical lipophilic antioxidant, DPPD, and is an injury process that can be targeted to alleviate AKI.

Identification and Characterization of IGFBP7 and TIMP2 Expression in Human Proximal and Distal Tubule Cells David R. Emlet,[1] Nuria M. Pastor-Soler,[2] Allison L. Marciszyn,[2] Xiaoyan Wen,[1] Jacob K. Volpe,[1] John A. Kellum.[1,2] *[1]1Center for Critical Care Nephrology, Dept of Critical Care Medicine, Univ of Pittsburgh, Pittsburgh, PA; [2]Renal Electrolyte Div, Dept of Medicine, Univ of Pittsburgh, Pittsburgh, PA.*

Background: IGFBP7 and TIMP2 have been identified as biomarkers for Acute Kidney Injury (AKI), but little is known regarding any role in the pathogenesis of the disease. To study this question we established primary cell culture models of human proximal and distal tubule epithelial cells.

Methods: The cortex of human kidneys were dissociated and viable cells cultured. Proximal and distal tubule epithelial cells (PTECs and DTECs) were isolated with antibodies against CD13 and CD227 using the Dynabead pan-mouse IgG system. Isolated cells were cultured on transwell supports and characterized by immunoblot and immunofluorescence.

Results: CD13 isolated cells were positive for the PTEC markers Gamma Glutamyl Transpeptidase and Aquaporin-1. CD227 isolated cells were negative for GGT and AQP1 but positive for the distal tubule markers CD227 and E-cadherin. Microscopy demonstrated that both PTECs and DTECs formed tight junction monolayers with a low percentage of cells in cycle as identified by Ki-67. Analysis of conditioned media demonstrated that these cells can indeed express and secrete IGFBP7 and TIMP2. Importantly, we identified a preferential expression of IGFBP7 in PTECs and of TIMP2 in DTECs. Furthermore, we discovered evidence suggesting that TIMP2 is primarily secreted across the apical surface, while the majority of IGFBP7 is secreted across the basolateral surface. Despite this, we also found evidence to suggest that some IGFBP7 can be secreted apically, primarily in PTECs.

Conclusions: We have developed human cell culture model systems of PTECs and DTECs for the cellular/molecular analysis of AKI. We confirmed that IGFBP7 and TIMP2 can be expressed and secreted by these cells, and we have identified differential expression and secretion of these proteins across cell types and spatially within cells. These systems and knowledge will now allow for investigation of the potential role of these biomarkers in the molecular etiology of AKI.

Klotho and S100A8/A9 as Discriminative Markers Between Pre-Renal and Intrinsic AKI Ji Yong Jung,[1] Ae Jin Kim,[1] Eul Sik Jung,[1] Byoungho Choi,[1] Yun Jung Oh,[2] Chungsik Lee,[2] Han Ro,[1] Jae Hyun Chang,[1] Hyun Hee Lee,[1] Wookyung Chung.[1] *[1]Div of Nephrology, Dept of Internal Medicine, Gachon Univ Gil Medical Center, Incheon, Republic of Korea; [2]Div of Nephrology, Dept of Internal Medicine, Cheju Halla General Hospital, Jeju, Republic of Korea.*

Background: Early detection and accurate differentiation of the cause of acute kidney injury (AKI) may improve the prognosis of the patient. However, to date, there are few reliable biomarkers for the discrimination of pre-renal and intrinsic AKI. The purpose of this study was to determine whether AKI is associated with an altered level of klotho and S100A8/A9 (an endogenous toll-like receptor 4 ligand), and NGAL (neutrophil gelatinase-associated lipocalin) protein that may contribute to differentiate between pre-renal and intrinsic AKI.

Methods: Volume depleted pre-renal AKI model was induced by Male Sprague-Dawley rat were fed a low-salt diet (0.03%) without water 96hr before two times at intraperitoneal (IP) injection of furosemide (20 mg/kg) at 24hr intervals. In contrast, cisplatin-induced intrinsic AKI model were given by a single IP injection of cisplatin (5 mg/kg). All animals were euthanized 72hr after first IP injection. We also performed a proof of concept cross-sectional study to measure serum and urinary biomarkers in 77 hospitalized patients with established AKI.

Results: Compared with intrinsic AKI group, pre-renal AKI group caused a marked depression of urinary klotho level (13.21 ± 17.32 vs. 72.97 ± 17.96 pg/ml; P = 0.002). In addition, intrinsic AKI group caused a marked elevation of S100A8/A9 level than those of pre-renal AKI group (2629.97 ± 598.05 ng/ml vs. 685.09 ± 111.65 ng/ml; P = 0.002 in serum; 3361.11 ± 250.86 ng/ml vs. 741.72 ± 101.96 ng/ml; P = 0.003 in urine). Serum and urinary NGAL showed no difference between pre-renal and intrinsic AKI group. The proof of concept study with hospitalized AKI patients also demonstrated decreased urinary klotho in pre-renal AKI patients and increased urinary S100A8/A9 concentrations in intrinsic AKI patients.

Conclusions: The attenuation of urinary klotho and increment of urinary S100A8/A9 may contribute to discriminate the pre-renal AKI and intrinsic AKI.

Release of Extra Cellular DNA Contributes to Renal Ischemia Reperfusion Injury Through Platelet Activation and Formation of Neutrophil Extracellular Traps Marcel Jansen, Diba Emal, Sandrine Florquin, Joris J. Roelofs. *Pathology, Academic Medical Center Amsterdam, Amsterdam, Noord-Holland, Netherlands.*

Background: Renal ischemia reperfusion injury (I/R) results from a complex interplay between coagulation and inflammation, resulting in tissue damage. It has been shown that platelet inhibition protects from I/R. How platelets are activated upon renal I/R is not entirely known. In this study we investigate renal cell death, extracellular DNA release and neutrophil extracellular traps (NETs) as potential triggers for platelet activation and renal I/R injury.

Methods: We stimulated platelets with necrotic renal cells in presence or absence of deoxyribonuclease 1 (DNase1). Platelet activation and platelet-leukocyte formation were measured by FACS. We stimulated granulocytes with activated platelets and measured DNA release –indicative of NET formation. Vice versa we stimulated platelets with NETs and measured PF4 release. Mice were subjected to renal I/R and treated with DNAse1 or vehicle, and sacrificed after 1 day. As marker for NET formation in tissue we stained renal tissue for citrullinated histone H3 and granulocyte marker Ly6G. In blood we measured Platelet Factor 4 (PF4), DNA, creatinine and urea.

Results: Supernatant from necrotic renal cells stimulated platelet activation and platelet-leukocyte complex formation and incubation with DNase1 reduced platelet activation. Activated platelets generated NETs in vitro and, vice versa, NETs stimulated platelet activation ex vivo. Mice subjected to renal I/R showed a significant increase of extracellular DNA and PF4 levels in the circulation. Treatment with DNase1 improved renal function upon I/R. Immunostainings revealed presence of NETs in renal tissue after I/R. DNase1 treatment resulted in a trend towards fewer NETs and granulocytes in tissue.

Conclusions: Both DNA from necrotic kidney cells and NETs activate platelets, which in their turn cause further NET formation, leading to a vicious triad in the pathogenesis of I/R injury. Treatment with DNase1 may have therapeutic benefits in the context of renal I/R injury.

SA-PO264

The Role of Senescence of Bone Marrow Cells in Acute Kidney Injury Myung-Gyu Kim,[1] Sung Yoon Lim,[1] Jihyun Yang,[1] Young Ju Na,[1] So-Young Lee,[2] Sang-Kyung Jo,[1] Won-Yong Cho.[1] *[1]Dept of Internal Medicine, Korea Univ Anam Hospital, Seoul, Republic of Korea; [2]Dept of Internal Medicine, Eulji Univ Hospital, Seoul, Republic of Korea.*

Background: There have been considerable growth in older population and age-related kidney disease in the world. It was demonstrated that the impairment in the potentiality to repair and regenerate of renal resident cells is a hallmark of biological processes associated with aging. However, the impact of senescence of bone marrow derived cells (BMDC) on kidney injury is not known. Here, we investigated the role of senescence of BMDC in the development and progression of ischemic acute kidney injury (AKI).

Methods: Seven wk-old female mice were sublethally irradiated and reconstituted with bone marrow from 12-mo-old (old-to-young, old BMT) or 7-wk-old (young to young, young BMT) mice. Then we performed renal ischemia reperfusion injury (IRI) in old or young BMT mice, and functional, histological kidney damage and inflammation were compared.

Results: The Y chromosome was detected in peripheral blood of BMT mice indicating successful reconstitution of female mice with male bone marrow. Although the population of immune cells in spleen between young and old BMT mice was not significantly different, old BMT mice showed less renal functional deterioration and histological damage after IRI. This was associated with less infiltration of F4/80 macrophages and lower level of tissue cytokine (IL-12). In vitro study with BMDCs also revealed that LPS-induced cytokine productions (IFN-r, MCP-1 and IL-10) were significantly suppressed in old BM cells than young BM cells.

Conclusions: Our data shows that senescence of BMDC could affect susceptibility and response to renal ischemic injury possibly via immune modulatory effect. A better understanding of these processes may help us to develop new strategies that are specifically tailored for treatment of the elderly population.

SA-PO265

Optimal Transplantation Timing of Mesenchymal Stem Cell in Rat Model of Renal Ischemia Reperfusion Injury Xiaoyan Liu,[1] Xiaofang Yu,[1,2] Jieru Cai,[1] Xiaoqiang Ding.[1,2] *[1]Kidney and Dialysis Inst of Shanghai, Shanghai, China; [2]Div of Nephrology, Fudan Univ Zhongshan Hospital, Shanghai, China.*

Background: To investigate whether timing of mesenchymal stem cells (MSCs) transplantation can determine the survival and therapeutic potential of MSCs in ischemic kidney.

Methods: The model of renal IRI was induced by the release of bilateral renal pedicle clamps following 60 min of occlusion. Six rats per group were sacrificed per time point, at 0h, 1h, 12h, 24h, 48h, 72h and 1 week post-I/R respectively. Passage 3 rat MSCs were cultured with different time points kidney homogenate supernatants. After reperfusion, CM-Dil-labeled MSCs or vehicles only were administered through the carotid artery of the animals 1h before reperfusion(-1h) and immediately(0h), 12h, 24h after reperfusion. The animals were sacrificed 48h after reperfusion and 24h after MSCs transplantation.

Results: The serum creatinine level peaked at 24h of reflow(470.6±41.65mmol/l, P<0.05) and NGAL peaked at 12h(7607±1066 pg/ml, P<0.05).The highest expression of inflammatory factor was in 12h and 24h groups, and the lower was in -1h, 0h and 1w groups. In vitro, there was lower cell apoptosis and higher proliferation in -1h and 0h groups compared with other groups. Significant kidney function and histological damage improvement was observed after the treatment of MSCs in -1h and 0h groups. Meanwhile, the expression of proinflammatory factor significantly decreased and anti-inflammatory factor significantly decreased in -1h and 0h groups compared with other point time groups and control group. In addition, we also observed more obvious inhibition of renal tubular cell apoptosis and promotion of proliferation in -1h and 0h groups compared with other groups. Consistent with the improvement above, the viability of implanted MSCs also increased in -1h and 0h groups.

Conclusions: MSCs transplantation 1h before reperfusion or immediately after reperfusion produces the most dramatic improvement in renal function and morphology in rat model of renal I/R injury. It is the optimal timing to transplant MSCs in IRI before the inflammatory response is established.

Reno-Protective Role of Par1b in Acute Kidney Injury Abhijeet Pal,1 Natalie S. Uy,1 James M. Pullman,2 Zhongfang Du,1 Kimberly J. Reidy.1 1Pediatric Nephrology, Children's Hospital at Montefiore, Montefiore Medical Center/ Albert Einstein Medical College, Bronx, NY; 2Pathology, Montefiore Medical Center/ Albert Einstein Medical College, Bronx, NY. **Background:** Partitoning defective Par1 (aka MARK) is a member of the Par polarity protein family and that localizes to the basolateral aspect of renal tubular cells. Defects in apico-basal polarity and cell-cell adhesion occur in acute kidney Injury (AKI). Mammalian homologues Par1a and 1b are serine threonine kinases that

are functionally redundant on kinase assays. We have identified a role for Par1a/1b in glomerular and proximal tubular development in mice associated with downregulation of Notch signaling. We hypothesized that Par1a/1b would contribute to renal epithelial repair in the setting of acute kidney injury.

Methods: Expression of Par1a/1b and Notch signaling was examined using western blotting and immunostaining in mouse models of tubular injury and human kidney tissue (leftover from clinically indicated renal biopsy). Proximal tubular injury was induced by in wild-type(WT) and Par1b knockout mice by injecting cisplatin (30mg/Kg, ip) or folic acid (250 mg/kg, ip). The degree of histological damage was assessed by light microscopy.

Results: Par1a/1b proteins are highly expressed in developing mouse kidneys and down regulated in the adult. Increased basolateral Par1a/b expression was observed after cisplatin/folic acid injury in the wild type mice compared to untreated controls. More severe dilated tubular injury was observed in the cisplatin and folic acid injured Par1b knockout vs WT mice. Preliminary data indicate that Notch ligand Jag1 expression was increased in cisplatin treated wild-type mice but not Par1b-/- mice. In human biopsy samples, we identified tubular expression of Par1a and 1b.

Conclusions: Our data demonstrates that Par1 proteins has a reno-protective role in tubular injury. Further studies of the mechanisms of this effect and interaction with Notch signaling are ongoing.

Small Heat Shock Protein Beta-1 (HSPB1) Is Upregulated and Regulates Mitophagy and Apoptosis of Renal Tubular Cells in Acute Kidney Injury Tatsuki Matsumoto, Kazu Hamada-Ode, Yoshiko Shimamura, Koji Ogata, Kosuke Inoue, Taro Horino, Yoshinori Taniguchi, Shimpei Fujimoto, Yoshio Terada. *Dept of Endocrinology, Metabolism and Nephrology, Kochi Medical School, Kochi Univ, Nankoku, Kochi, Japan.*

Background: Heat shock protein beta-1 (HSPB1, also known as HSP27) is a small heat shock protein involved in many cellular processes and reportedly protects cells against oxidative stress. Autophagy protects cells from many types of stress and is thought to play a key role in preventing stress in acute kidney injury (AKI). However, little is known about the role of HSPB1 in autophagy and apoptosis in the pathogenesis of AKI.

Methods: We used a rat ischemia/reperfusion AKI model and cultured renal tubular cells as an *in vitro* model. To elucidate the regulation of HSPB1, we evaluated the promoter activity and expression of HSPB1 in normal rat kidney (NRK)-52E cells in the presence of H_2O_2. To examine the regulation of autophagy by HSPB1, we established NRK-light chain 3 (NRK-LC3) cells that were stably transfected with a fusion protein of green fluorescent protein and LC3.

Results: The results of immunohistological examination showed that HSPB1 was expressed in proximal tubule cells after AKI. Real-time quantitative reverse transcription-polymerase chain reaction and western blot analysis showed that HSPB1 mRNA and protein expression were upregulated 6–72 h and 12–72 h, respectively, after ischemia/reperfusion injury. HSPB1 promoter activity as well as mRNA and protein expression indicated dose-dependent induction by H_2O_2. HSPB1 overexpression-induced autophagy in NRK-LC3 cells under normoxic conditions was confirmed with confocal microscopy, which revealed the presence of LC3-positive granules. Furthermore, H_2O_2-induced autophagy was inhibited by the transfection of small interfering RNAs for HSPB1. Overexpression of HSPB1 reduced BAX activation and H_2O_2-induced apoptosis, as measured by caspase 3 activity and terminal deoxynucleotidyl transferase deoxyuridine triphosphate nick end labeling assay.

Conclusions: These results indicate that HSPB1 upregulation plays a role in the pathophysiology of AKI.

Developing a More Clinically Relevant Mouse Model of Cisplatin-Induced Acute Kidney Injury Cierra Sharp, Mark A. Doll, Tess Dupre, Deanna L. Siow, Parag P. Shah, Levi J. Beverly, Leah J. Siskind. *Univ of Louisville, Louisville, KY.*

Background: Cisplatin, a commonly used chemotherapeutic for the treatment of many solid cancers is known to induce acute kidney injury (AKI) in 30% of patients. Patients that develop cisplatin-induced kidney toxicity must either have the dose severely reduced or be switched to an alternative therapy to prevent long-term renal damage. In many cases the alternative therapy may be less effective at treating the tumor. Due to cisplatin's complex nephrotoxic mechanism of action, the development of renoprotective agents remains a challenge. Currently there are no FDA approved drugs for the protection of cisplatin-induced AKI. The standard mouse model of cisplatin-induced AKI is a single high dose of cisplatin (10-30 mg/kg), and animals are sacrificed 72h after injection. This model does not accurately represent the clinical dosing regimen, which involves repeated dosing of cisplatin.

Methods: In this study we compared the standard single dose model to a new multiple dose model where mice received lower doses of cisplatin once a week for 4 weeks. We measured and compared indicators of kidney function (KIM-1, NGAL, BUN, and Serum Creatinine) as well as inflammatory cytokines and chemokines (i.e. TNFα, IL6, CXCL1, MCP-1). Indicators of apoptosis and cell death were measured as well as indicators of fibrosis (i.e. TGF-β, CTGF, BMP-7, and Sirius Red staining).

Results: In comparing the results of the single and multiple dose models, BUN values were similar, suggesting a comparable loss of kidney function. However, KIM-1 and NGAL were reduced by roughly 10-fold and 100-fold, respectively. Inflammation was also decreased in this model with TNFα, IL6 and IL1-β reduced by 4, 10 and 5-fold, respectively. Fibrosis was nearly non-existent in the single dose model; however, the multiple dosing model showed a significant increase in fibrosis. Also, expression of PAI-1, a mediator of fibrosis was significantly increased in the multiple dosing model compared to the single dose model.

Conclusions: Taken together, we propose that the multiple dosing model is a more relevant model for the discovery of renoprotective agents in the prevention/treatment of cisplatin-induced AKI.

SA-PO269

Genetic Knock Out of CHOP Protects against Ischemia-Mediated Acute Kidney Injury Rachel Carlisle, Elise Brimble, Jeffrey G. Dickhout. *Nephrology, St. Josephs's Healthcare Hamilton and McMaster Univ, Hamilton, ON, Canada.*

Background: Acute kidney injury (AKI), a major cause of morbidity and mortality in North America, is characterized by a sudden increase in serum creatinine. Renal ischemia, a common cause of AKI, induces endoplasmic reticulum (ER) stress and activates the unfolded protein response. This leads to a subsequent upregulation in the expression of the pro-apoptotic gene, CHOP. Transgenic knock out of CHOP inhibits ER stress-mediated acute tubular necrosis, implicating CHOP in the pathogenesis of AKI.

Methods: Bilateral renal ischemia/reperfusion (I/R) was performed in mice, using atraumatic vessel clamps, and confirmed via colour change (red to dark purple) of the kidney. Surgeries were performed on C57BL/6 mice to determine the appropriate time point to cause significant renal damage. Various time points for renal ischemia were examined, between 25-55 mins, with 48-72 h of recovery. I/R surgeries were subsequently performed on C57BL/6 and CHOP knock out mice. Ischemia was induced for 55 mins, and mice recovered for 48 h. Plasma creatinine was measured using an enzymatic assay, and kidneys were stained to analyze renal damage. Imaging of the kidneys was focused on the juxtamedullary region, as this area is the most vulnerable to ischemic damage.

Results: Creatinine levels increased in response to I/R surgery in both wild type and CHOP knock out mice; however, creatinine levels from CHOP knock out mice were significantly lower than from wild type mice. Stained kidney sections confirm renal protection in CHOP knock out mice, demonstrating reduced cellular damage and vacuolization in kidneys from these animals.

Conclusions: These results suggest that CHOP plays a significant role in ischemia-mediated renal injury, and attenuating its expression may provide new therapeutic strategies to protect against AKI.

SA-PO270

The Protective Role of Doxycycline for Cisplatin-Induced AKI by Its Anti-Inflammatory and Anti-Oxidative Effects Terumasa Nakagawa,[1] Yutaka Kakizoe,[1] Yoshikazu Miyasato,[1] Teruhiko Mizumoto,[1] Manabu Hayata,[1] Yuichiro Izumi,[1] Takashige Kuwabara,[1] Taku Miyoshi,[1] Masataka Adachi,[1] Kenichiro Kitamura,[2] Masashi Mukoyama.[1] *[1]Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan; [2]Internal Medicine III, Univ of Yamanashi Faculty of Medicine, Yamanashi, Japan.*

Background: Cisplatin (CDDP) is a chemotherapeutic drug widely used for the treatment of solid tumors. However, its nephrotoxicity is the major dose-limiting factor. Doxycycline (Dox) is a tetracycline antibiotic commonly used in a variety of infections, but several other properties have been suggested such as an anticancer effect or the inhibition of matrix metalloproteinase (MMP). In this study, we investigated whether Dox exerts the protective effects on CDDP-induced acute kidney injury(AKI).

Methods: Ten-week-old male C57BL/6J mice were divided into following four groups: 1) Control, 2) Dox (2mg/ml in drinking water), 3) CDDP (25 mg/kg, intraperitoneally) and 4) CDDP+DOX. After 7 days pretreatment with Dox, CDDP was administrated, and animals were sacrificed 3 days later. BUN and serum creatinine (Cr) were measured and renal histological changes as well as, inflammation, and oxidative stress markers were evaluated. MMP and serine protease activities in the kidney tissue were accessed with zymography.

Results: No apparent adverse effects were observed in Dox group. Dox did not affect mRNA expression of transporters for CDDP (OCT-1, OCT-2 and MATE1) in the renal tubules. CDDP caused severe tubular damages along with elevated BUN and Cr levels. It also increased mRNA expression of inflammatory and profibrotic molecules, together with enhanced oxidative stress in the kidney. Dox alleviated significantly those detrimental changes (Cr: Control, 0.13±0.01; Dox, 0.13±0.03; CDDP, 1.04±0.20;and CDDP+Dox, 0.30±0.12 mg/dL). Moreover, Dox suppressed the activities of MMP-2 and 9 as well as serine proteases, which were enhanced by CDDP in the kidney tissue.

Conclusions: Dox mitigated CDDP-induced AKI through its pleiotropic effects, i.e., anti-inflammatory, anti-oxidative and enzyme-inhibiting effects. Our results suggest that Dox could become a new strategy for the prevention of CDDP-induced nephrotoxicity in humans.

Involvement of Indoxyl Sulfate in Exacerbated Susceptibility of Streptozotocin (STZ)-Induced Diabetic Rat Kidney to Ischemia/Reperfusion-Induced Acute Kidney Injury (AKI) Yuna Shimokawa,[1] Naoko Oyama,[1] Takashige Kuwabara,[2] Masashi Mukoyama,[2] Hirofumi Jono,[1,3] Hideyuki Saito.[1,3] *[1]Clinical Pharmaceutical Sciences, Kumamoto Univ School of Pharmacy, Kumamoto, Japan; [2]Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Kumamoto, Japan; [3]Pharmacy, Kumamoto Univ Hospital, Kumamoto, Japan.*

Background: Diabetes mellitus (DM) is one of the potential risk factors in progression of acute and chronic kidney failures. In patients with DM, AKI tends to be severer and the restoration delays compared to that in non-DM patients. However, the precise mechanism is unclear. Indoxyl sulfate (IS) is a representative oxidative stress-inducible uremic toxin and involved in the progression of renal failures. In this study, we examined the toxicological involvement of IS in ischemic AKI in DM rats.

Methods: STZ-induced DM rats and nondiabetic rats without STZ treatment (non-DM) were subjected to 20 min of renal ischemia/reperfusion (I/R), and the development of renal injury in DM and non-DM rats were compared. An oral indole adsorbent AST-120 was orally administered to rats (2.5 g/kg) at 24 h, 1 h before and 24 h after I/R. Serum and kidney tissues were collected at 48 h following I/R.

Results: In DM ischemic AKI group, serum creatinine (SCr) (4.3-fold vs non-DM ischemic rats) and BUN (7.0-fold) were increased. The kidney of DM rats with I/R exhibited severetubular injury compared to that of non-DM rats with I/R in association with a marked increase in serum Kim-1 level (25-fold). Hydroperoxide (1.7-fold) and IS levels in serum (14.7-fold) and kidney (5.8-fold) were also elevated. Immunoblot analysis revealed that renal expression of organic anion transporters rOAT1/rOAT3 mediating renal excretion of IS were significantly downregulated. AST-120 treatment prevented the increases in SCr and BUN, and renal tubular injury in DM rats with I/R, in association with the reduction of serum and renal IS levels.The downregulation of rOAT1/rOAT3 was restored by AST-120 treatment.

Conclusions: In conclusions, DM could be a pivotal factor in progression of ischemic AKI, and AST-120-removable uremic toxin(s) including IS could play a toxico-physiological role as a mediator in the DM-exacerbated ischemic AKI.

Discoidin Domain Receptor 1 Is a Key Mediator of the Ischemia-Reperfusion Induced Renal Injury Aude Dorison, Yi-chun Xu-dubois, Christos E. Chadjichristos, Eric Rondeau, Christos Chatziantoniou, Jean-claude Dussaule. *UMRS 1155, INSERM, Paris, France.*

Background: Discoidin Domain Receptor 1 (DDR1) is a non-integrin collagen receptor, expressed by different cell types in the kidney, which displays tyrosine-kinase activity.

We have previously demonstrated that a *de novo* expression of DDR1 in target cells was driving renal inflammation and fibrosis in different models of chronic kidney disease. The aim of our study was to investigate whether DDR1 participates in the pathophysiological mechanisms of ischemia/reperfusion (I/R), a model of acute renal injury.

Methods: To this end, male mice subjected to I/R were injected either with oligodeoxynucleotide (ODN) antisense sequences directed against DDR1 (AS, n=8) or with scrambled sequences (SCR, n=7). Mice were sacrificed after 24h and parameters of renal function, structure and inflammation were measured.

Results: DDR1 protein expression was strongly induced in proximal tubular cells after I/R and this expression was inhibited by the AS administration. Increased uremia (BUN) showed impaired renal function in SCR+I/R animals, whereas AS treatment lowered BUN levels. In addition, histological damage such as brush border alterations and tubular necrosis were significantly decreased and E-cadherin protein expression was preserved in AS+I/R mice. Kim-1, NGAL, vimentin and VCAM-1 mRNA expressions were increased in SCR+I/R compared to controls and significantly decreased in mice treated with AS. Moreover, the AS-induced inhibition of DDR1 was accompanied by decreased T-lymphocyte infiltration and mRNA expressions of TNFα, MCP1, IL-1β, IL-6 and TGFβ.

Interestingly, DDR1 staining performed on transplant patient biopsies with a delayed graft function showed a strong expression of DDR1 which was associated with the severity of tubular necrosis and vimentin expression.

Conclusions: DDR1 inhibition protects mice from the I/R-induced histological damage, inflammation and loss of renal function. DDR1 overexpression plays a deleterious role in this model of kidney injury, thus reinforcing the interest to develop agents capable of specifically blocking the function of this receptor.

Heat Shock Factor 1 and Crystallin-αB in Cisplatin-induced Renal Tubular Cell Apoptosis and Nephrotoxicity Qiang Lou,[1,2] Zheng Dong.[2] *[1]Medical College of Henan Univ, Kaifeng, Henan, China; [2]Dept of Cellular Biology and Anatomy, Georgia Regents Univ, Augusta, GA.*

Background: Cisplatin, a wildly used chemotherapy drug, induces nephrotoxicity that is characterized by renal tubular cell death. In response to toxic stress, renal tubular cells may activate cytoprotective mechanisms, such as the expression of heat shock proteins. However, the heat shock response during cisplatin nephrotoxicity is largely unclear. The present study analyzed the heat shock response during cisplatin treatment of renal tubular cells in vitro and mice in vivo, and examined the relevant regulatory mechanisms.

Methods: For *in vivo* study, male C57BL/6 mice were given a single intraperitoneal injection of cisplatin. In vitro, cultured renal proximal tubular cells (RPTC) were incubated with cisplatin. To determine the role of heat shock factor 1 (HSF1), HSF1 was knocked down by stable transfection of specific shRNAs.

Results: In RPTC, cisplatin induced a rapid expression of HSF1 and specific heat shock proteins, including Hsp70, Hsp27, and Crystallin-αB. The induction of these proteins was transient and decreased at late time points of cisplatin treatment. Similar changes were verified in kidney tissues following cisplatin injection, whereas Hsp90 did not change significantly. Knockdown of HSF1 decreased Crystallin-αB expression and increased RPTC apoptosis. Interestingly, p38 activation was enhanced in these cells. Moreover, inhibition of p38 with SB203580 markedly inhibited cisplatin-induced apoptosis in HSF1-knockdown cells.

Conclusions: Induction of HSF1 is a cytoprotective response during cisplatin nephrotoxicity. Crystallin-αB appears to be a key heat shock protein induced by HSF1 for its protective effect. Heat shock response may regulate or co-operate with other signaling pathways, such as p38, to regulate tubular cell apoptosis.

The Effect of the Cytoplasmic Domain of Tissue Factor in Contributing to Renal Ischemic Reperfusion Injury Is Both Protease Activated Recptor-1 (PAR-1) and Strain Dependent Jonathan H. Erlich,[1,3] Sean E. Kennedy,[1,2] Joseph J. Murphy,[1] Calum Wai Kit Chong.[1] *[1]Dept of Medicine, Univ of New South Wales, Randwick, Australia; [2]Dept of Nephrology, Sydney Childrens Hospital, Randwick, NSW, Australia; [3]Dept of Nephrology, Prince of Wales Hospital, Randwick, NSW, Australia.*

Background: The cytoplasmic domain of tissue factor plays a role in cell signaling and regulation of angiogenesis and inflammation. It may do this both by regulating intracellular signaling and via modulating protease activated receptor signaling. Previously we have shown that mice on a mixed genetic background deficient (MGB) in the cytoplasmic domain of tissue factor ($TF^{deltact/deltact}$) mice developed serve renal injury. $TF^{deltact/deltact}$ have increasedcytokine and PAR-1 expression. We further investigated the importance of increased PAR-1 signaling and the strain background of the mice.

Methods: Mice WT or $TF^{deltact/deltact}$ on MGB or mice backcrossed onto CB7BL6 mice background underwent 25 min bilateral warm ischemia and 24 reperfusion. Renal function was assessed by serum cretainine and renal injury was further assessed by histology and expression of inflammatory mediators form renal tissue. The role of PAR-1 was assessed using the inhibitor SCH79797.

Results: $TF^{deltact/deltact}$ mice on the MGB developed more severe injury at 24 than WTon a similar genetic background. These mice developed greater PAR-1 mRNA expression and treatment of these mice with the PAR-1 inhibitor reduced injury similar to PAR-1 deficient mice. In contrast the effect of TF cytoplasmic depletion was not seen in mice on C57BL6 background. These mice had similar PAR-1 induction to that observed in WT C57BL6. WT mice with a MGB had lesser renal injury and lower basal PAR-1 expression than WT C57BL6 mice. $TF^{deltact/deltact}$ mice on MGB having simialr basal PAR-1 expression and much greater inducible PAR-1 expression(5 fold compared to 2.8 fold for WT). $TF^{deltact/deltact}$ on a C57bL6background had similar renal injury and PAR-1 induction to WT mice.

Conclusions: The cytoplasmic domain of TF may contribute to renal IR injury be regulating PAR-1 expression. The role of the TF cytoplasmic domain in regulating renal injury is genetic background dependent.

SA-PO275

Protective Effects of Endonuclease Inhibitors on Cisplatin-Induced Acute Kidney Injury Dae Song Jang,[1] Tariq Fahmi,[1] Todd Fite,[1] Narsimha Reddy Penthala,[3] Dolapo Taiwo Odeniyi,[1] Alena Savenka,[1] Peter A. Crooks,[3] Sudhir V. Shah,[1,2] Alexei G. Basnakian.[1,2] *[1]Univ of Arkansas for Medical Sciences, Dept of Pharmacology and Toxicology, Little Rock, AR; [2]Central Arkansas Veterans Healthcare System, Div of Nephrology, Little Rock, AR; [3]Univ of Arkansas for Medical Sciences, COP Pharmaceutical Science, Little Rock, AR.*

Background: Cisplatin is one of the most commonly used and the most nephrotoxic anticancer drugs. Acute kidney injury induced by cisplatin cannot be overcome and may lead to chronic kidney failure. Our previous studies showed that genetic inactivation of two kidney apoptotic endonucleases, DNase I and EndoG, was partially protective against tubular epithelial cell death induced by cisplatin. Until very recently, pharmaceutically meaningful inhibitors of the endonucleases, which would be non-toxic and effective in vivo, were not available.

Methods: This study was aimed to determine if the two new endonuclease inhibitors recently identified by us, IG-17 (1,3-phenylene-bis-aminoguanidine hydrochloride) for DNase I and PNR-3-82 (5-((1-(2-naphthoyl)-5-methoxy-1H-indol-3-yl)methylene)-2-thioxodihy dropyrimidine-4,6(1H,5H)-dione) for EndoG, could ameliorate cisplatin toxicity to kidney tubular epithelial cells in vitro and in vivo.

Results: In vitro experiments using NRK-52E cells showed that the compounds are able to suppress endonuclease activity inside the cells provide partial protection against cisplatin toxicity measured using LDH release assay and TUNEL, and are non-toxic at the used concentrations. The inhibitors were found to markedly suppress the total-body endonuclease activity in mice at the dose of 5 mg/kg administered subcutaneously, and were non-toxic up to 25 mg/kg as measured using 14 blood plasma markers of organ toxicities.

Conclusions: Importantly, cisplatin-induced kidney injury was functionally (creatinine) and structurally (acute tubular necrosis, TUNEL) reduced by the administration of the inhibitors (5 mg/kg) in mice suggesting their potential therapeutic value.

Involvement of CYLD as a Regulatory Factor in Fibrotic Response of Ischemic AKI Kidney and Hypoxic HK-2 Cells

Go Yoneda,[1] Naoki Suenaga,[1] Nozomi Yabuuchi,[1] Kazuhiko Nishi,[2] Hirofumi Jono,[1,3] Hideyuki Saito.[1,3] *[1]Clinical Pharmaceutical Sciences, Kumamoto Univ Graduate School of Pharmaceutical Sciences, Kumamoto, Japan; [2]Hemodialysis and Apheresis, Kumamoto Univ Hospital, Kumamoto, Japan; [3]Pharmacy, Kumamoto Univ Hospital, Kumamoto, Japan.*

Background: Cylindromatosis (CYLD), a tumor suppressor, regulates various signaling pathways by acting as a deubiquitinating enzyme. Recent studies have revealed that CYLD is associated with not only tumors, but also chronic inflammatory diseases, such as tissue fibrosis. It is well-documented that tissue fibrosis is common hallmark of chronic kidney disease (CKD), and CKD progresses toward end-stage renal disease through renal fibrosis. However, the molecular pathogenesis of renal fibrosis is not fully uncovered yet. In this study, we elucidated the roles of CYLD in renal fibrosis by using in vivo and in vitro models.

Methods: We generated model mice of ischemia/reperfusion (I/R)-induced acute kidney injury (AKI) and hypoxic human kidney (HK)-2 cells. CYLD expression in kidney tissue and HK-2 cells was determined by immunoblot analysis. Fibrosis gene expression of PAI-1, CTGF and COL1A1 were examined by RT-PCR.

Results: In I/R-induced AKI mice, serum creatinine (SCr) and BUN were elevated 2 days after I/R treatment, and renal fibrosis was induced 28 days after I/R treatment. In those kidney tissues of I/R-AKI mice, CYLD protein expression was markedly decreased (0.4-fold) in a time-dependent manner. Interestingly, fibrosis gene expression (PAI-1: 12-fold, CTGF: 2.5-fold, COL1A1: 4-fold) was significantly increased in response to the CYLD down-regulation. In HK-2 cells, siRNA knockdown of CYLD gene expression significantly increased the PAI-1 gene expression (12-fold). Moreover, CYLD mRNA expression was significantly suppressed (0.5-fold) under hypoxic condition, an important factor of CKD progression, whereas the PAI-1 gene expression (2-fold) was elevated in HK-2 cells. These results suggested that CYLD could play a pathological role in regulating renal fibrotic response.

Conclusions: In conclusion, CYLD may be a novel regulatory factor involved in renal fibrosis and its down-regulation may trigger fibrosis under ischemic and/or hypoxic conditions.

Attenuation of Renal Fibrosis After Unilateral Ischemia Reperfusion May Require a Multi-Target Approach

Nathalie Le Clef,[1] Bruce L. Riser,[2] Patrick C. D'Haese,[1] Benjamin Arthur Vervaet.[1] *[1]Laboratory of Pathophysiology, Univ of Antwerp, Wilrijk, Antwerpen, Belgium; [2]BLR Bio LLC, WI.*

Background: Acute kidney injury (AKI) is an important risk factor of chronic kidney disease (CKD). We optimized a mouse model of AKI to CKD by unilateral ischemia-reperfusion (UIRI) with development of renal fibrosis. To validate this model for use in therapeutic intervention studies, 3 experimental treatments were tested: administration of 1) recombinant human CCN3 (CCN2/CTGF antagonist), 2) TGFb1 neutralizing antibody (1D11) or 3) dexamethasone (corticosteroid).

Methods: Male C57Bl/6 mice underwent 21 min of unilateral ischemia-reperfusion (UIRI) at 36°C body temperature. 8 treatment groups (n>4/group, ip) were included: dexamethasone (10 mg/kg, daily), vehicle (PBS, daily), rhCCN3 (5 µg/kg, daily), vehicle (PBS, daily), antibody to TGFβ (0.5 mg/kg, every other day), vehicle (PBS, every other day), an untreated UIRI group and a sham group. Three weeks after UIRI renal fibrotic outcome was determined by gene expression analysis (qPCR) of collagen I, TGFβ, CTGF, CCN3, PAI-1 and TNFα.

Results: UIRI induced a ~40% reduction in renal mass. Treatment with rhCCN3, anti-TGFβ or dexamethasone did not attenuate this reduction. UIRI induces significant upregulation of the fibrosis-related genes. rhCCN3 treatment had no effect on gene expression. Anti-TGFβ antibody treatment induced significantly less upregulation of TGFβ and CCN3 gene expression, however, vehicle also reduced TGFβ expression. Dexamethasone treatment induced significantly less upregulation of collagen I and CCN2/CTGF gene expression and a trend towards higher CCN3 upregulation.

Conclusions: Despite the earlier proven benefits of TGFβ antagonism and CCN3 treatment on the development of fibrosis, neither treatment (at doses demonstrated to be effective in more mild injury models) showed effect in the UIRI model. Broad anti-inflammatory suppression by dexamethasone attenuated fibrotic gene expression. We speculate that the natural course of renal demise after UIRI is very robust and highly likely to require a multi-target approach. Whether some combination of the therapies tested here could have efficacy in this model remains to be determined.

The Effect of Oxygen and Hypothermic Therapy on the Prevention of Acute Kidney Injury

Sang H. Woo,[1] Cholawat Pacharinsak.[2] *[1]Medicine, Thomas Jefferson Univ, Philadelphia, PA; [2]Dept of Comparative Medicine, Stanford Univ.*

Background: There is no effective therapy for acute kidney injury. The effect of oxygen, hypothermic therapy delivered through urinary tract on the treatment of acute kidney injury has not be known. This pilot study was performed as a proof of concept of a catheter-based oxygen and hypothermic oxygen therapy in preventing and treating acute kidney injury.

Methods: Rats (n=6) were used for the experiment. Three rats were used to compare oxygen therapy and control. The other three rats were used to compare hypothermic oxygen therapy and control. Oxygen was cooled for hypothermic oxygen therapy before it was delivered to the kidney. Right kidneys received treatment (oxygen or hypothermic oxygen) and left kidneys were used for control. After a catheter was placed in a bladder, oxygen (or cooled oxygen) was delivered to the right kidney from the bladder through the catheter for five minutes for pretreatment before clamping. Both right and left renal arteries were clamped for 30-45 mins to induce acute kidney injury. Only right kidneys continued to receive oxygen or hypothermic oxygen during the clamping of renal arteries. The kidneys were extracted after the induction of acute kidney injury with the clamping. Gross examination of both kidneys during the clamping and after the extraction was performed.

Results: Gross examination of kidneys demonstrated less ischemic changes of kidneys treated with oxygen or hypothermic oxygen during and after the induction of acute kidney injury. As shown in Figure 1, right kidneys that received oxygen therapy or hypothermic oxygen therapy showed less ischemic changes on gross examination during the clamping and after extraction.

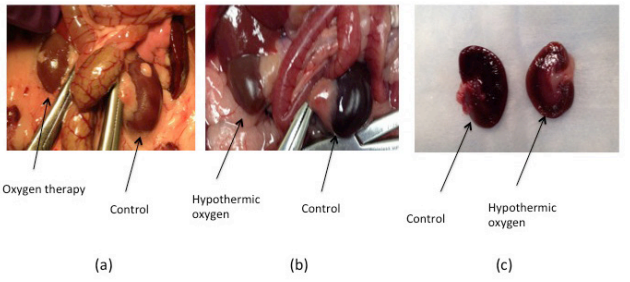

Figure 1

Conclusions: This pilot study shows novel methods for the prevention and treatment of acute kidney injury. Further study is necessary to investigate the benefits of catheter based oxygen and hypothermic therapy in the prevention and treatment of acute kidney injury.

MicroRNA-17 Is Induced via P53 to Protect against Renal Ischemia-Reperfusion Injury by Targeting Death Receptor 6

Jielu Hao,[1,2] Qingqing Wei,[2] Changlin Mei,[1] Zheng Dong.[2] *[1]Nephrology, Shanghai Changzheng Hospital, Shanghai, China; [2]Cellular Biology and Anatomy, Georgia Regents Univ, Augusta, GA.*

Background: Ischemia-reperfusion injury is the critical cause of acute kidney injury (AKI) in clinical settings, which unavoidably develops into chronic kidney disease (CKD) due to lack of understanding of mechanism and effective therapies. In the present study, we investigated the role of microRNA-17 (miR-17) regulation in kidney against damage in ischemia-reperfusion injury.

Methods: Renal ischemia-reperfusion was induced in C57 mice by bilateral clamping of renal arteries, followed by releasing of the clamps. BUN and serum creatinine were measured to indicate the loss of renal function. In vitro, rat kidney proximal tubular cells (RPTC) were treated with hypoxia (1% oxygen). To test the effect of miR-17, anti-miR-17-LNA and miR-17 mimic were transfected before hypoxia. The change of p53 and DR6 were detected by Western blot. Pifithrin-α and dominant-negative p53 were used to determine the role of P53 in miR-17 expression.

Results: By real time PCR, we identified that miR-17 was significantly increased in kidney tissues after 30 minutes of bilateral renal ischemia and 12h-48h reperfusion. In the moderate injury model of 25 minutes of ischemia, miR-17 was induced at day 1 and the induction lasted for a week. In vitro, hypoxia also induced miR-17 in RPTC cells. Functionally, miR-17 mimic reduced apoptosis and caspase activation, whereas anti- miR-17-LNA increased apoptosis during hypoxia, suggesting a cytoprotective role of miR-17. Blockade of p53 with pifithrin-α or a dominant-negative mutant led to the suppression of miR-17 induction in hypoxia, supporting a role of p53 in this inductive response. Bioinformatics analysis predicted Death receptor 6 (DR6) as a target of miR-17. In line with this, we showed that the expression of DR6 was inhibited by miR-17 mimic, in contrast, increased by anti-miR-17-LNA.

Conclusions: MiR-17 is one of the microRNAs that are induced significantly during renal ischemia-reperfusion. MiR-17 induction is mediated by p53 and, upon induction, it may suppress downstream target genes, such as DR-6, to protect kidney cells and tissues from injury.

Proximal Tubule-Derived CSF-1 Mediates Expansion and Polarization of Renal Macrophages/Dendritic Cells and Recovery in Acute Kidney Injury
Yinqiu Wang, Bing Yao, Raymond C. Harris, Ming-Zhi Zhang. *Medicine, Vanderbilt Univ, Nashville, TN.*

Background: Colony-stimulating factor-1 (CSF-1)-mediated renal macrophage expansion and polarization play an essential role in recovery from acute kidney injury in ischemia/reperfusion (I/R)-injury and selective apoptotic proximal tubule injury in transgenic mice expressing the human diphtheria toxin receptor (DTR) and exposed to DT (DTR-AKI). In the kidney, a major site of CSF-1 production is in proximal tubular epithelial cells.

Methods: Male DTR mice with CSF-1$^{f/f}$(wild type) or with γ-GT-Cre:CSF-1$^{f/f}$(CSF-1 KO in renal proximal tubule) were used for DTR-AKI and for I/R injury (30 min of ischemia and contralateral nephrectomy).

Results: CSF-1 expression in the proximal tubule and its deletion in CSF-1 KO mice were confirmed with immunostaining. Six days after DTR-AKI, activation of the CSF-1 receptor (p-c-fms) was markedly attenuated in both renal tubules and interstitial cells, including macrophages (F4/80 and p-c-fms dual positive cells). Flow cytometry and qPCR indicated fewer renal macrophages/dendritic cells and reduced mRNA levels of M2 phenotype markers (CD206, IL-4Rα, TGF-β and 15-LOX) in CSF-1 KO mice 6 days after DT injection. Although selective proximal tubule CSF-1 deletion did not affect the severity of kidney injury, it delayed renal functional recovery, in association with increased oxidative stress, increased secondary necrosis (HMGB1 expression) and severe tubulointerstitial fibrosis, with increased Picro-sirius red staining of fibrillary collagen and increased profibrotic and fibrotic components (α-SMA, CTGF, fibronectin, collagen I and IV). Selective proximal tubule CSF-1 deletion also led to delayed functional recovery after I/R injury, with decreased mRNA levels of M2 phenotype markers in isolated renal macrophages/dendritic cells and more severe renal fibrosis. In both I/R injury and DTR-AKI, selective proximal CSF-1 deletion had minimal effects on the expression of M1 phenotype markers.

Conclusions: These studies demonstrate that proximal tubule is a major source of CSF-1 that mediates the expansion and polarization of renal macrophages/dendritic cells that play an essential role in recovery following AKI.

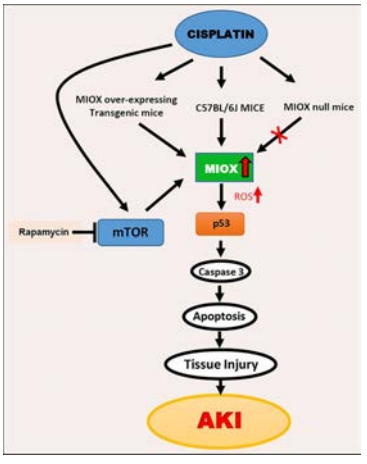
SA-PO281

Ablation of Myo-Inositol Oxygenase Protects against Cisplatin-Induced Acute Kidney Injury by Inhibiting p53 Activation
Rajesh K. Dutta, Yashpal S. Kanwar. *Dept of Pathology, Northwestern Univ, Chicago, IL.*

Background: MIOX is a renal tubular enzyme. Its role in the pathogenesis of diabetic nephropathy is currently being investigated. Conceivably, it modulates redox imbalance and apoptosis in tubular cells in diabetes via modulation of glucuronate-xylulose (G-X) pathway. However, its role in acute kidney injury (AKI) is unknown.

Methods: In this study we used both MIOX-over-expressing transgenic and MIOX null mice to elucidate its role in a model of cisplatin induced AKI.

Results: We observed severe cisplatin-induced proximal tubular injury in MIOX transgenic and protection in null mice compared to wild type mice. In transgenic mice an increased serum creatinine and urea levels, caspases-3 activity and tubular apoptosis along with marked deterioration of tubular morphology was observed. Renal injury was remarkably less in null mice compared to wild type mice. Cisplatin treatment led to p53 activation in wild type and MIOX transgenic mice, whereas minimal p53 activation was observed in MIOX null mice. Likewise, we noted that cisplatin induces mTOR pathway in both wild type and MIOX transgenic mice while such an effect was not observed in MIOX null mice. Treatment with mTOR inhibitor, rapamycin, prevented cisplatin-induced MIOX expression, p53 activation and deterioration of tubular morphology in control mice. In vitro studies revealed significantly high levels of ROS generation, caspases-3 activity and apoptosis in MIOX over-expressing cells compared to control cells transfected with empty vector following cisplatin treatment.



Conceivably, this was attributed to the accentuated induction of GX-pathway and its associated myriad enzyme system.

Conclusions: Overall this study suggest that MIOX is a mediator of cisplatin induced AKI via activation of G-X-ROS-p53 pathway, and genetic deletion of MIOX protects the kidney tubules from cisplatin induced renal injury.

Precision Medicine for AKI: Novel RNA Labeling Technique Demonstrates Unique Transcriptional and Cellular Responses in Different Injury Models
Katherine Xu,[1] Tian Shen,[1] Alexandra Jacunski,[1] Paul Rosenstiel,[1] Neal A. Paragas,[2] Jonathan M. Barasch.[1] *[1]Columbia; [2]Univ of Washington.*

Background: The clarity brought to CKD patients by Precision Medicine has not been applied to AKI, which is currently defined by the rise of a single analyte, the Pcreatinine (Pcr).

Methods: To identify specific molecular responses we investigated 3 models: (i) ischemia (10min bilateral pedicle clamping), (ii) volume depletion (72 hr water deprivation which matched the Pcr of the ischemic model) and (iii) a model of cystitis (small volume UPEC inoculation). We generated a novel technique of cell and time-specific Cre mediated in-vivo RNA labeling to purify specific RNA species directly from the kidney.

Results: We analyzed RNA pools from the entire Collecting Duct (CD) and its subset Intercalated Cells (IC). We found a robust genetic response of CD to volume depletion (94.5% of the induced genes) but a limited genetic response to ischemia (3.2% of induced genes) with very little overlap (2.3%). In contrast, the IC subset demonstrated a greater response to ischemia (62% of the induced genes) compared to volume depletion (32% of induced genes) and only 6% of the genes were shared. Remarkably, the IC cell population demonstrated an overwhelming specific response to cystitis (95% of induced genes). Region specific laser capture microdissection validated the cellular distinctions: ischemia and volume depletion induced different transcriptional changes in different cells with limited overlap. Moreover, functional analyses demonstrated activation of different molecular pathways, and different secreted proteins. Testing the urine of 100 Emergency Department patients revealed five new candidate biomarkers that distinguished ischemia and volume depletion.

Conclusions: We found that despite identical Pcr, ischemia and volume depletion targeted different regions, cell types and genes with limited overlapping genetic responses: the CD responded robustly to volume depletion while the IC were unique sensors of ischemia and infection. These data demonstrate that while Pcr can not distinguish between models of injury, the specific responses of the nephron provide Precision AKI diagnoses.

Calcium Oxalate Crystal-Induced Acute Kidney Injury Involves Ripk3-Mlkl Mediated Tubular Cell Necroptosis
Hans J. Anders,[1] Jyaysi Desai,[1] Santhosh Kumar Vr,[1] Jonathan Nicodemos Eberhard,[1] Dana Thomasova,[1] Simone Romoli,[1] Andreas Linkermann,[2] Shrikant R. Mulay.[1] *[1]Ludwig Maximillians Univ, Munich, Germany; [2]Christian-Albrechts-Univ, Kiel, Germany.*

Background: Crystalline nephropathy (CN) & nephro-/urolithiasis involves crystal-induced renal inflammation via NLRP3 inflammasome (Mulay et al, JCI 2013), but the mode of direct crystal cytotoxicity remains elusive. The aim of the study was to investigate mechanisms of crystal cytotoxicity in kidney.

Methods: All *in vivo* experiments were approved by the local government authorities. Acute oxalate nephropathy (AON) was induced by i.p. injection of sodium oxalate (NaOx) (100mg/kg) and 3% NaOx in drinking water for 24hr. IHC, EM, RT-PCR, MTT assay, PI stain and multicolour FACS were used for data analysis.

Results: We found that crystals of calcium oxalate (CaOx), monosodium urate, calcium pyrophosphate dehydrate & cystine trigger caspase-independent necrosis of mouse tubular cells, human kidney cells & human renal progenitor cells. Pretreatment with RIPK1 inhibitor necrostatin-1 (Nec-1), MLKL inhibitor & RNA interference of RIPK3 or MLKL blocked crystal cytotoxicity. Consistently, deficiency of RIPK3 or MLKL protected mice from AON (e.g. plasma creatinine, BUN, tubular injury score, renal KIM-1 & π-GST mRNA expression, neutrophil count and TUNEL+ve cells) despite similar crystal deposition. I.p. injection of crystals induced neutrophil recruitment into peritoneal cavity, which was unaffected by Nec-1 as was crystal injection into air pouches at the back of mice. However, Nec-1 significantly reduced microvascular permeability & leukocyte extravasation from post-ischemic cremaster muscles. Thus RIPK1 signaling per se does not affect neutrophil recruitment. Next, we found that AON was significantly reduced in *Tnfr1*-deficient mice, with no additive effects with concomitant *Tnfr-2* deficiency. Thus, TNFR1 signaling activates RIPK3-dependent necroptosis in this model. Finally, etanercept, TNFR inhibitor R-7050 & Nec-1 protected mice from AON.

Conclusions: Crystal-cytotoxicity involves TNFR1-RIPK1-RIPK3-MLKL pathway. All components of this pathway represent novel molecular targets for therapeutic interventions to limit CN.

SA-PO284

Allopurinol Protects against Rhabdomyolysis and Acute Kidney Injury Induced by a Membrane Protein (Lp25) from Pathogenic *Leptospires*
Antonio C. Seguro,[1] Daniele Canale,[1] Patricia A. Abreu,[2] Denize Monaris,[2] Tatiana B. Gotti,[2] Larissa R. Matos,[2] Thales de Brito,[1] Pedro H F Gois,[1] Antonio J. Magaldi.[1] *[1]Nephrology, Hospital das Clínicas FMUSP, São Paulo, Brazil; [2]Lab. de Bacteriologia, Inst Butantan, São Paulo, Brazil.*

Background: Acute kidney injury (AKI) in leptospirosis is frequently nonoliguric, hypo or normokalemic. Higher serum potassium levels, elevated creatine phosphokinase (CPK) associated with maximum serum creatinine level were observed in nonsurvivor patients suggesting that rhabdomyolysis contributes to more severe AKI in leptospirosis. Previous study from our group demonstrated that Lp25, a protein membrane from pathogenic Leptospires, was responsible for hyperkalemic AKI induced by rhabdomyolysis in guinea pig. Recent studies suggest that Allopurinol (Allo) protects individuals from exercise-induced rhabdomyolysis. The aim of this study was to evaluate the effect of Allo on guinea pigs injected with Lp25.

Methods: Three groups of guinea pigs were studied:1- Sham (phosphate-buffered solution);2- Lp25;3- Lp25+Allo. One mL of PBS and Lp25 (400µg of Lp25/mL) were intraperitoneally injected for 4 days. Lp25+Allo received Allo (300mg/L) in drinking water during this time. On the 5th day, animals were placed in metabolic cages for 12 hour urine collection. We measured urinary volume (Ur V/12h), creatinine clearance (ml/min/100gBW), serum potassium (mEq/L), CPK (U/L), uric acid (mg/dL), phosphate (mg/dL).Data are mean±SEM.

Results: Lp25 induced hyperkalemia, rhabdomyolysis (elevated CPK, uric acid, phosphate) and oliguric AKI. Allo ameliorated CrCl, serum potassium, CPK and uric acid.

	Cr Cl	Ur V	K	CPK	Uric acid	P
Sham (n=7)	1.10± 0.18	25.1± 4.9	4.8± 0.3	897± 277	1.08± 0.19	6,9± 0.3
Lp25 (n=8)	0.48± 0.05 [b]	11.1± 1.8 [a]	6.8± 0.5 [a]	2852± 495 [a]	4.15± 0.48 [b]	9.3± 0.6 [a]
Lp25+ Allo (n=6)	0.91± 0.14 [d]	17.0± 3.7	5.1± 0.6 [c]	1331± 374 [c]	0.47± 0.07 [d]	8.4± 0.5

[a] p<0.05, [b] p<0.01 vs. Sham; [c] p<0.05, [d] p<0.001 vs. Lp25

Conclusions: These data demonstrate that Allo attenuates rhabdomyolysis and AKI induced by Lp25 in guinea pigs. This may represent a new therapeutic approach for AKI in patients with leptospirosis. (CNPq, FAPESP).

SA-PO285

Conventional Autophagy Regulates the Degradation of AQP2 in Hypokalemia
Wan-Young Kim,[1] Sun-ah Nam,[1] Yumi Kim,[1] Arum Choi,[1] Yong kyun Kim,[2] Jin Kim.[1] *[1]Anatomy and Cell Death Disease Research Center, The Catholic Univ of Korea, Seoul, Korea; [2]Internal Medicine and Cell Death Disease Research Center, The Catholic Univ of Korea, Buchoen, Korea.*

Background: Autophagy is a catabolic pathway utilized to maintain a balance among the synthesis, degradation, and recycling of cellular component, thereby playing a role in homeostasis. Abundance of AQP2 is regulated through balance between production by tralation and removal by degradation. Although AQP2 degradation is supposed to be occurred via lysosomal or proteasomal degradation, the precise mechanisms still remain unknown. It has been known that prolonged hypokalemia causes vasopressin-resistant polyuria and induces autophagy especially in principal cells (PC) of collecting duct.

Methods: To investigate the role of autophagy in the degradation of AQP2, we generated *AQP2-cre;Atg7$^{f/f}$* mice, in which Atg7, an essential gene for mammalian autophagy, was selectively inactivated in PCs. Hypokalemia was induced by K^+-depleted diet for 2 weeks.

Results: In control *AQP2-cre;Atg7$^{f/f}$* mice, the distribution pattern of AQP2 was not different from *Atg7$^{f/f}$* mice. Immunolabeling of pS261-AQP2 was localized mostly subapical and punctate in appearance in the PCs. In contrast to pS261-AQP2, immunolabeling of pS256-AQP2 was localized mainly at the apical plasma membrane and subapical domains. In hypokalemic *Atg7$^{f/f}$* mice, the abundance of pS261-AQP2 was significantly reduced and redistributed to intracellular vesicles, and co-localized with LC3-positive vacuoles. In hypokalemic *AQP2-cre;Atg7$^{f/f}$* mice, there was a decrease of convertion of LC3-I to LC3-II and a marked accumulation of p62 selectively in PCs. Rab9 protein, an essential molecule for alternative autophagy pathway, and Rab9-positive vacuoles were markedly increased. Interestingly, pS261-AQP2 was distributed throughout the cytoplasm and not co-localized with Rab9- or LC3-positive vacuoles in the PCs of *AQP2-cre;Atg7$^{f/f}$* mice. There was no difference in localization of pS256-AQP2 at the plasma membrane from each genotype.

Conclusions: These results suggest that down regulation of AQP2 in hypokalemia could in part be caused by degradation of pS261-AQP2 in PCs through a LC3/Atg7-dependent conventional autophagy pathway.

Early Autophagy Precedes Angiotensin II-Induced Podocyte Apoptosis
Tae-Sun Ha. *Pediatrics, Chungbuk National Univ, Cheongju, Chungbuk, Korea.*

Background: Autophagy is a highly regulated catabolic process that is involved in the turnover of unwanted cellular materials, on the other hand, apoptosis removes damaged or unwanted cells. Therefore, autophagy and apoptosis constitute the two processes through which injured/aged cells or organelles are eliminated. Angiotensin II (Ang II) induces podocyte injury resulting in apoptosis in vitro and in vivo. However, the relationship between autophagy and apoptosis in Ang II-induced podocytes is not elucidated and the role of Ang II-induced autophagy in podocyte survival remains unclear. We investigated the sequential relationship between autophagy and apoptosis in Ang II-induced podocytes.

Methods: Mouse podocytes were incubated in media containing various concentrations of Ang II and at different incubation times. The changes of podocyte autophagy and apoptosis were observed by electron microscopy, confocal imaging, Western blotting, and FACS assay according to the presence of Ang II. **Results:** Ang II-treated podocytes showed an increase in autophagosomes compared with control cells at early phase in a dose-dependent manner. This pro-autophagic effect of Ang IIwas inhibited by pretreatment with 3-methyladenine, an inhibitor of PI3-kinase class III. Ang IIalso enhanced podocyte expression of autophagic proteins such as LC3-II and beclin-1. Atg5 siRNA further reduced the expression of LC3-II and cleaved caspase-3 suppressed by Ang II at 12 hrs. However, Atg5 siRNA did not affect the expression of Atg5, LC3-II, and cleaved caspase-3 in the presence of Ang II at 24 hrs. Thereafter, Ang II induced podocyte apoptosis significantly in concentration- and time-dependent manners in FACS assays. LY294002 and Atg5 siRNA further increased podocyte apoptosis induced by Ang II. Therefore, high concentrations of Ang II induced apoptosis, while autophagy response decreased, which implicated that autophagy preceded apoptosis for cytoprotection in angiotensin II-induced podocyte injury.

Conclusions: We suggest that Ang II induced autophagy in mouse podocytes prior to apoptosis as an early adaptive cytoprotective mechanism for podocyte survival after Ang II treatment and the imbalance between autophagy and apoptosis causes podocyte injury.

Emodin Ameliorates Cisplatin-Induced Renal Tubular Cell Apoptosis Through Activation of Autophagy
Hong Liu,[1] Wei Sun,[1] Yigang Wan,[2] Liubao Gu.[3] *[1]Dept of Nephrology, Affiliated Hospital of Nanjing Univ of Chinese Medicine, Nanjing, China; [2]Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing Univ Medical School, Nanjing, China; [3]Center for Diabetes Care, Education and Research, Jiangsu Province Inst of Geriatrics, Nanjing, China.*

Background: Autophagy plays a key role in regulating cell survival. Emodin can ameliorate cisplatin-related nephrotoxicity. Thus, we explored the effects and mechanisms of emodin on cisplatin-induced apoptosis in NRK-52E cells by activation of autophagy.

Methods: NRK-52E cells were treated with cisplatin with or without emodin, cell morphology and expressions of cleaved Caspase-3 and autophagy makers LC3 I/II, were detected. Red fluorescent protein-LC3 (RFP-LC3) plasmid was transiently transfected into NRK-52E cells, and changes of RFP-LC3 fluorescent particles were observed by fluorescence microscopy. The level of LC3 was tested after treated with Bafilomycin A1 and mTOR inhibitor rapamycin. Besides, morphological changes of apoptotic cells were observed and cell death was evaluated by FACS analysis. Finally, AMPK/mTOR signaling pathway related proteins were detected. Further, changes of cell morphology and the level of cleaved Caspase-3 were detected after the addition of compound C, which is an AMPK inhibitor.

Results: Emodin improved cisplatin-induced cell shape change, cell viability and caspase 3 cleavage. This protective effect of emdoin was associated with increased LC3 conversion and occurrence of RFP-LC3 punctate structures. Further studies revealed that the suppressive effect of emodin on cisplatin-induced apoptosis could be abolished by suppression of autophage with bafilomycin A1 and mimicked by activation of autophagy with rapamycin. Additionally, AMPK/mTOR signaling pathway was important for the induction of autophagy and inhibition of apoptosis.

Conclusions: Induction of autophagy could be an important mechanism by which emodin protected renal tubular cells against cisplatin-induced cell injury, and the potentially mechanism of emodin-induced autophagy may be attributed to the activation of AMPK and inhibiting mTOR signaling pathway. Emodin may have a therapeutic potential in the prevention of cisplatin-induced nephrotoxicity.

Autophagy in Renal Tubular Epithelial Cells Plays a Protective Role in Renal Fibrosis
Yong Kyun Kim,[1] Sun-Ah Nam,[2] Wan-Young Kim,[2] Arum Choi,[2] Yumi Kim,[2] Ho Cheol Song,[1] Jin Kim.[2] *[1]Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Seoul, Korea; [2]Dept of Anatomy and Cell Death Disease Research Center, College of Medicine, The Catholic Univ of Korea, Seoul, Korea.*

Background: Renal tubulointerstitial fibrosis (TIF) is the final common pathway of various renal injuries. Autophagy is a cellular process of degradation of damaged cytoplasmic components and regulates cell death or proliferation. Recent studies reported that autophagy has protective role in renal TIF. However, the mechanism of autophagy

regulating fibrosis is not fully understood. In this study, we investigated the proposed mechanisms of autophagy in renal TIF induced by UUO by using conditional knockout mice in which Atg7 is genetically ablated specifically in tubular epithelial cell (TEC).

Methods: Atg7-floxed mice were crossed with Ksp-Cre mice to generate TEC-specific Atg7 knockout mice ($Atg7^{f/f}$;$Ksp\text{-}Cre^{+}$). Unilateral ureteral obstruction (UUO) was performed. We examine the expression of epithelial-mesenchymal transition (EMT) markers. The expression of TGF-β, plasminogen activator inhibitor 1 (PAI-1) and p62 as the regulators of EMT were examined. We determined apoptosis and proliferation of TECs and the expression of c-Myc as a regulator of cell apoptosis and proliferation.

Results: In vitro, TGF-β treatment induced autophagy. In vivo, TEC-specific Atg7 deletion enhanced renal TIF after UUO. TEC-specific Atg7 deletion increase expression of TGF- β and enhance tubular EMT (decrease E-cadherin and increase α-smooth muscle antibody and vimentin) after UUO.In electron microscopy,TEC-specific Atg7 deletion results in ultrastructural alterations of TEC after UUO. TEC-specific Atg7 deletion increase expression of PAI-1, P62 after UUO. TEC-specific Atg7 deletion enhanced apoptosis and proliferation of TECs after UUO. The expression of c-Myc was significantly increased mice with TEC-specific Atg7 deletion after UUO.

Conclusions: Our data suggest that autophagy regulate EMT through TGF-β, PAI-1 and P62 during renal TIF. Autophagy also regulates apoptosis and proliferation of TECs through the expression of c-Myc during renal TIF. Autophagy could represent a therapeutic target for renal TIF.

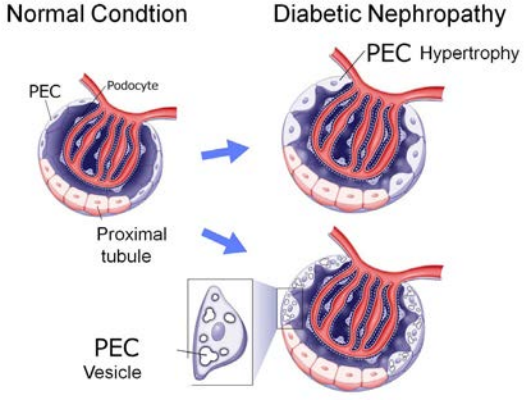
SA-PO289

Partial De-Differentiation of Parietal Epithelial Cells Caused by Reduced Expression of Sirt1 and Concomitant Increased Expression of p21 and CD133 in Diabetic Nephropathy Kazuhiro Hasegawa, Shu Wakino, Hiroshi Itoh. *Keio Univ.*

Background: We have previously reported the role of proximal tubular **Sirt1** in diabetic nephropathy (DN). **Parietal epithelial cells (PECs)** and their cellular metabolism reportedly play a pivotal role in kidney. Sirt1 is a key energy sensor, whereas DN disrupts energy metabolism.

Methods: Thus, we examined the effect of Sirt1 expression in PECs on DN.

Results: In two DN murine models including streptozotocin-treated and db/db mice, expression of **Sirt1** in proximal tubules and **PECs** was decreased at 8 weeks after the onset of DN, corresponding to the early stage of DN. Sirt1 expression was also downregulated in podocytes at 24 weeks. We further investigated the changes in PECs at 8 weeks. No change was found in **the number of PECs**. **The morphology of** all PECs showed hypertrophy, and some PECs contained autophagic vesicles, especially in the periphery or the border of the plasma membrane at basolateral sides.



HG treatment of cultured PECs resulted in significant reductions in cell proliferation and migration, while increasing the production of extracellular and basement membrane components such as type IV collagen. We performed DNA microarray, confirmatory real-time PCR, and immunofluoresence, revealing that an increase in **Glut1** (glucose transporter) expression promoted influx of high amounts of glucose into PECs, which led to a **reduction in Sirt1 expression** and lysine acetylation-mediated **activation of p21**. Among the main molecular markers of precursor cells, including CD24, CD44, and CD133, only **CD133** showed remarkable elevation, indicating that the decrease in Sirt1 expression caused the **partial de-differentiation** of PECs.

Conclusions: Sirt1 may be a promising target for protection against DN-induced de-differentiation of PECs, which would prevent not only hypertrophy of PECs but also the concomitant thickening of the basement membrane of Bowman's capsule.

APOL1 Variants are Critical to Induce Vitamin D Receptor (VDR) Down Regulation in Dedifferentiated Podocytes Shabirul Haque,[1] Ashwani Malhotra,[1] Karl Leon Skorecki,[2] Pravin C. Singhal.[1] *[1]Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY; [2]Medicine, Rambam Health Care Campus, Haifa, Israel.*

Background: African Americans carrying APOL1 variants (Vs) are prone to develop HIV-associated nephropathy (HIVAN). Recently, vitamin D receptor (VDR) has been reported to play a critical role in the development of HIVAN. We hypothesized that HIV-induced dedifferentiation of podocytes is the first hit but to accelerate the injury a sustained second hit is needed and may be the sustained down regulation of VDR. Down regulation of VDR has been reported to activate renin angiotensin system in kidney cells. HIV-induced low VDR status in kidney cells has been shown to contribute to the progression of HIVAN. We asked whether APOL1 variants would be contributing to accelerate podocyte injury in HIV milieu through down regulation of VDR. In the present study, we evaluated the effect of APOL1 variants on podocyte VDR expression both in differentiated (DPs) and dedifferentiated podocytes (DDPs).

Methods: RNAs were extracted from human podocytes (both DPs and DDPs) stably expressing vector, G0, G1 and G2. cDNAs were amplified with a specific VDR primer specific. Vector, G0, G1 and G2 expressing DPs and DDPs were infected with HIV followed by Western blotting and probing for SNAIL (a transcriptor of VDR). Additionally, the effects of APOL1 variants were evaluated on glycosylation and methylation status of SNAIL.

Results: DDPs expressing G1 and G2 displayed moderate decrease in VDR mRNA expression, whereas, G0 expressing DDPs displayed only mild decrease in VDR expression. There was no alteration in VDR mRNA expression in DPs expressing either G0 or G1/G2. Vector-expressing DPs and DDPs did not reveal any expression of SNAIL. On the other hand, G0 and G1/G2 expressing DPs and DDPs displayed moderate expression of SNAIL. HIV further enhanced SNAIL expression by DPs and DDPs expressing G1/G2.

Conclusions: We conclude that APOL1 modulates VDR expression in DDPs only. Since HIVAN occurs in APOL1 variants only, presence of APOL1 variants seems to be critical to sustain HIV-induced podocyte injury.

SA-PO291

Post-Transcriptional and Post-Translation Status of APOL1 (G0) and Its Variants (G1and G2) in Podocytes and 293T Cells Post-Transcriptional and Post-Translation Status of APOL1 (G0) and Its Variants (G1and G2) in Podocytes and 293T Cells Shabirul Haque,[1] Xiqian Lan,[1] Gauri P. Patil,[1] Amrita Kaur Chawla,[1] Ashwani Malhotra,[1] Karl Leon Skorecki,[2] Pravin C. Singhal.[1] *[1]Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY; [2]Mediciine, Rambam Health Care Campus, Haifa, Israel.*

Background: *APOL1 gene* variants have been reported to contribute to higher prevalence of kidney diseases in African Americans. *APOL1* gene is known to contribute to kidney cell injury but the mechanisms involved are not clear. Interestingly, renal biopsy specimens in kidney disease patients with of APOL1 variants displayed lower podocyte expression of APOL1. However, the involved mechanism for lower APOL1 expression in these patients is not clear. Gene sequence alterations/mutations hamper either mRNA transcription stability or defects in protein translation. We hypothesized that mutation in APOL1 would lead to modulation of protein expression in podocytes.

Methods: Protein blots of human podocytes (HPs) stably expressing vector, APOL1G0, APOL1G1 and APOL1G2 were probed for APOL1 and reprobed for acitn. RNAs were extracted with HPs expressing Vec, G0, G1 and G2 and cDNA were amplified with APOL1 specific primer. 293 T cells were transfected with equal amount of plasmids (vector, G0, G1, and G2) for 48 hours. Protein blots were probed for APOL1 and reprobed for actin. To evaluate stability/decay rate of APOL1 mRNA, APOL1/APOL1variants expressing HPs were pulsed with actinomycinD and RNAs were harvested at different time points (0.0, 0.5, 1.0, 3.0, 8.0, and 24 hours) by Trizol method.

Results: APOL1 variants (G1/G2) expressing HPs displayed lower expression of APOL1 when compared APOL1G0. 293 T cells also displayed lower expression of G1 and G2. However, there was no difference in mRNA expression in APOL1G0 and APL1G1/G2 expressing cells. Stability/decay kinetic assay revealed that variants (G1 and G2) of APOL1 mRNA decayed in an accelerated mode (more than 35%) during ½ to 24 hours after actinomycin D exposure.

Conclusions: These findings suggest that APOL1 variants protein instability may be related to loss/decay of variants APOL1 mRNA or to some extent defects in protein translation/stability.

HIV Promotes NLRP3 Inflammasome Complex Activation in HIVAN Shabirul Haque, Xiqian Lan, Amrita Kaur Chawla, Rivka Lederman, Rabani Bharara, Ramachandra prasanna Bongu, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY.*

Background: Dysregulated growth and loss of podocytes are important features of HIV-associated nephropathy (HIVAN). In a recent report, HIV induced programmed cell death in T cells has been implicated to pyroptosis as a consequence to inflammasome formation. We hypothesized HIV would also be promoting podocyte loss through the induction of pyroptosis. We evaluated the role of HIV in podocyte NOD-like receptor family, pyrin domain containing (NLRP) 3 protein complexes (inflammasomes) formation both *in vitro* and *in vivo*.

Methods: Renal cortical sections of control and Tg26 (HIVAN) mice (n=4) were labeled for inflammasome molecular markers (IMMs; NLRP3, ASC, cleaved caspase-1 and IL-1β). Protein blots of renal tissues of control and Tg26 mice were also probed for IMMS and actin (n=11). Protein blots of empty vector (EV) - and NL4-3 (HIV)-transduced human podocytes (HPs) were probed for IMMs and actin (n=4). EV/HPs and HIV/HPs were evaluated for pyroptosis by PI staining under a fluorescence microscope as well as by FACS analysis. Effect of Tempol (SOD mimetic), caspase-1 inhibitors, and glyburide (an inhibitor of K-efflux inhibitor was evaluated on HIV induced podocyte pyroptosis by morphologic assay and FACS analysis.

Results: Renal cortical sections of HIV-transgenic mice (Tg26) displayed increased podocyte expression IMMs. Renal tissues of Tg26 mice also displayed enhanced mRNA

expressions as well as protein expressions of IMMs. Serum from Tg26 mice showed higher levels of IL-1β. HIV promoted pyroptosis in podocytes in a dose as well as time dependent manner. Since caspase-1 inhibitor not only attenuated podocyte expressions of caspase-1 and IL1β in addition to protection against pyroptosis; this would confirm that HIV induced podocyte injury was mediated by caspase-1 activated complexes. Interestingly, HIV-induced podocyte pyroptosis could be partially inhibited by tempol as well as by glyburide.

Conclusions: These findings indicate that generation of reactive oxygen species and potassium efflux contributed to HIV-induced pyroptosis in podocytes.

SA-PO293

Urinary Cytochrome C (Cyto C) Detects Subliminal Injury and Correlates with Apoptosis in Acute (AKI) and Acute on Chronic Kidney Disease (A-CKD) Lena Succar,[1] Philip Peake,[1] Zoltan H. Endre.[1] *[1]Prince of Wales Hospital and Clinical School, Univ of New South Wales, Sydney, NSW, Australia; [2]Prince of Wales Hospital and Clinical School, Univ of New South Wales, Sydney, NSW, Australia; [3]Prince of Wales Hospital and Clinical School, Univ of New South Wales, Sydney, NSW, Australia.*

Background: Mitochondrial Cyto C is a potentially specific biomarker of apoptotic kidney injury in AKI. We investigated urinary Cyto C in detecting subliminal kidney injury (histological injury without an increase serum creatinine, sCr) in two models of A-CKD.

Methods: In male Sprague Dawley rats (i) adenine-CKD was induced by diet supplementation with 0.025% adenine, days (d) 0 to 28 and monitored until d56 (n=8). On d56, AKI was induced in rats by a subnephrotoxic (2mg/kg; n=8) or nephrotoxic (4mg/kg; n=8) cisplatin (Cis) dose ip and monitored to d63 (n=8 in matched controls). (ii) Aristolochic-acid nephropathy (AAN) induced by AA-1 (10m/kg) ip for five days and monitored to d21 (n=6) or d42 (n=6) then given 2mg/kg (n=6) or 4mg/kg (n=6) Cis and monitored to d28 and d49 respectively. Cyto C was measured by ELISA. Tubulointerstitial damage (TID) and TUNEL were quantified on d63.

Results: Cyto C levels increased in subliminal AAN (d1 to d7) and adenine-CKD (d3 to 21) without change in sCr, but increased in both CKD groups after 2mg/kg and 4mg/kg Cis dose in controls. In AAN, Cyto C levels increased progressively (d22 to d28) after Cis exceeding controls given 4mg/kg whereasCyto C was lower after Cis on d42 to d49. Regardless of Ci dose, Cyto C increased in controls and adenine-CKD. A-CKD rats displayed diffuse medullary and cortical TID with positive TUNEL staining while injury in CKD alone was largely in outer medulla. In ANN peak Cyto C,72 hours post Cis, correlated significantly with outer medullary (Spearman R=0.86*)and cortical apoptosis (R=0.81*). In adenine fed rats, Cyto Ccorrelated only with medullary apoptosis (R=0.79*). sCr correlated only with severe diffuse cortical TID (R=0.94*) (*P<0.05).

Conclusions: Cyto C detected subliminal injury and correlated strongly with outer medullary apoptosis in A-CKD, which alone did not increase sCr. Cyto C is a useful biomarker for early detection of apoptotic kidney injury.

Assessment of Graphene Toxicity to Kidney Tubular Epithelial Cells and Cell Spheroids Using DNase Activity Probe Tariq Fahmi,[1] Zeid A. Nima,[2] Julietta Sargsyan,[1] Alexandru S. Biris,[2] Alexei G. Basnakian.[1] *[1]Pharmacology and Toxicology, Univ of Arkansas for Medical Sciences, Little Rock, AR; [2]Univ of Arkansas at Little Rock, Center for Integrative Nanotechnology Sciences, Little Rock, AR.*

Background: Recently invented nanomaterial, graphene, consists of monomolecular carbon sheets, which are extremely strong, light and flexible. It will be used widely because of its versatility. However, little is known about its potential for being a toxicant and environmental hazard, and methods to study graphene toxicity are not established. Kidney is one of the primary organs for the assessment of nanomaterial toxicity. We hypothesized that graphene induces nephrotoxicity mainly through DNA destruction, and measuring of DNase activity by using near infrared fluorescence (NIRF) DNase activity probe would be a reliable tool for assessing graphene cytotoxicity.

Methods: Non-modified graphene (50 μg/ml) exposed with cultured rat kidney tubular epithelial NRK-52E cells induced TUNEL-type DNA fragmentation usually associated with cytotoxicity. Raman spectroscopy showed the TUNEL-positive cells have significantly higher graphene content than TUNEL-negative cells. DNase activity was quantified in live cells using the oligonucleotide-based NIRF probe. Quantitative immunocytochemistry (qICC) was then used to measure apoptotic DNases such as caspase-activated DNase (CAD), endonuclease G (EndoG), and DNase I, and the marker of oxidative stress, heme oxygenase-1 (HO-1).

Results: The NIRF fluorescence and all of the above qICC markers were induced in NRK-52E cells by graphene exposure. In addition, a 50% colocalization of HO-1 with DNase activity was observed suggesting a possible link between oxidative stress and the DNases. Furthermore, we developed kidney spheroids (mini-kidneys) model by culturing NRK-52E cells using 3D hanging drop method, and tested the graphene toxicity in this model by measuring the DNase activity using the NIRF probe. The result showed a strong dose-dependent increase of DNase activity induced by graphene.

Conclusions: Measuring of DNase activity by using NIRF probe in combination with TUNEL assay and qICC are appropriate tools for assessment of graphene toxicity.

SA-PO295

Identification of a Novel Bidirectional Regulatory Mechanism Involving AKT/β-Catenin and Anillin That Drives Podocyte Proliferation Gentzon Hall,[1,3,4] Jose A. Gomez,[1] Brandon M. Lane,[2,4] Guanghong Wu,[4] Himani Vaidya,[4] Robert F. Spurney,[1,3] Rasheed A. Gbadegesin.[2,3,4] *[1]Internal Medicine, Duke Univ; [2]Pediatrics, Duke Univ; [3]Nephrology, Duke Univ; [4]Duke Molecular Physiology Inst, Duke Univ.*

Background: Mutations of the F-actin binding protein Anillin (ANLN) have been shown to cause familial FSGS. Although ANLN is a suspected modulator of phosphoinositol-3 kinase (PI-3K) signaling, specific interactions with PI-3K pathway intermediates and the role of these interactions in the pathogenesis of FSGS remains unknown.

Methods: siRNA-mediated gene knockdown studies, immunoblot and proliferation assays were performed by standard methods in conditionally immortalized human podocytes (CIHP) to examine the effects of *ANLN* depletion on PI-3K pathway signaling in podocytes. CIHP lines stably expressing tGFP-vector control or tGFP-$ANLN_{WT}$ were established via lentiviral transduction to characterize the effects of ANLN overexpression on PI-3K signaling in podocytes.

Results: We evaluated the effect of ANLN overexpression and targeted *ANLN* knockdown (KD) on AKT activation in podocytes. Additionally, we explored the effects of pharmacologic inhibition of AKT on ANLN expression in podocytes. Finally, we examined the role of AKT-mediated activation of β-Catenin via the direct phosphorylation of serine 552 in podocyte *ANLN* expression. We determined that ANLN overexpression significantly attenuated AKT activation. Conversely, *ANLN* KD significantly enhanced AKT activation and upregulated AKT-mediated phosphorylation/activation of β-Catenin at serine 552. Pharmacologic inhibition of AKT also inhibited basal podocyte proliferation. Finally, we demonstrated that pharmacologic inhibition and targeted gene knock down of β-Catenin significantly attenuated podocyte ANLN expression.

Conclusions: These findings elucidate a novel mechanism of reciprocal regulation involving AKT/β-Catenin signaling and ANLN which may provide valuable insights into the role of ANLN in the pathogenesis of FSGS and other proliferative podocytopathies.

SA-PO296

Akt Mediates Cell Survival in Proteinuric States Elif Erkan, Jian Gao, Sam Z. Coffey. *Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: The degree of proteinuria correlates with progression in association with tubulointerstitial injury in glomerulonephritis. High concentrations of albumin in the glomerular filtrate results in apoptosis. Protein kinase B (Akt) is a serine/threonine kinase involved in multiple signaling events including cell survival. We hypothesize that down regulation of survival protein, protein kinase B (Akt) triggers tubular apoptosis in proteinuric states.

Methods: We utilized *in-vitro* and *in-vivo* model of albumin overload. Human kidney proximal tubule epithelial cells (HKC-8) are exposed to 10mg/ml albumin for 24-hours to induce apoptosis. C57BL/6C mice are exposed to 10mg/g of intraperitoneal(ip) albumin injections for 6 weeks to induce albuminuria. Fluorometric caspase-3 assay and TUNEL staining were utilized to asses apoptosis. Protein expression was assessed by Western blotting and immunofluorescence. Kidney sections from bigenic (Fyn-/-Cd2ap+/-) mice model of FSGS and patients with FSGS were evaluated for apoptosis and Akt expression.

Results: Albumin overload *in-vivo* and *in-vitro* resulted in proximal tubule epithelial cell apoptosis in association with down regulation of pser473 Akt and Thr-308 Akt expression. Furthermore mice model of FSGS and patient kidney biopsies confirmed down regulation of tubular pser473 Akt expression in association with apoptosis. Overexpression of Akt by a constitutively active mutant ameliorated the albumin induced apoptosis where as chemical inhibition of Akt by of MK2206 enhanced albumin induced apoptosis in HKC-8 cells. Phosphorylation of downstream targets of Akt, transcriptional factors forkhead family Foxo1 and 3 is inhibited in association with apoptosis in response to albumin overload.

Conclusions: Down regulation of Akt expression in proteinuric states results in tubular apoptosis which is a precursor to tubular atrophy. We postulate that decreased Akt phosphorylation of Foxo proteins allow them to translocate to nucleus and induce apoptotic gene expression. Therapeutic interventions directed to increase Akt expression in tubular epithelial cells can serve to prevent tubulointerstitial injury by inducing cell survival in proteinuric states.

Altered Protein Kinase Signalling Causes Major Phenotypical Changes in Renal Cells from Patients with Nephropathic Cystinosis Ekaterina A. Ivanova,[1] Fanny Oliveira Arcolino,[1] Maria Pia Rastaldi,[2] Lambertus P.W.J. Van den Heuvel,[1] Elena N. Levtchenko.[1] *[1]Pediatric Nephrology, UZ Leuven, KU Leuven, Leuven, Belgium; [2]IRCCS Policlinico, Milano, Italy.*

Background: Cystinosis is caused by mutations affecting the lysosomal cystine transporter cystinosin and results in lysosomal cystine accumulation. Cystinosis causes proximal tubular dysfunction, but also glomerular damage, which is present starting from early age. Current therapy of cystinosis is based on cystine-lowering cysteamine treatment, which greatly improves the prognosis, but does not cure the Fanconi syndrome and fails to prevent kidney damage in the majority of patients. It is therefore likely that, apart from the transporter function, cystinosin is implicated in other important cellular processes. We have investigated the mTORC-Akt signalling cascade in cystinosin-deficient renal cells. Akt kinase lies at the crossroads of cellular signalling regulating cytoskeleton, motility,

response to stress and survival, and is a target of mTORC2 and an upstream activator of mTORC1. mTORC1 is the master regulator of autophagy and metabolism. mTORC1 and 2 are also implicated in the regulation of cytoskeleton and cell motility.

Methods: Using conditionally immortalized proximal tubular epithelial cells (PTECs) and podocytes originating from cystinosis patients and healthy donors, we performed biochemical and microscopic analysis of phosphorylation and activation of protein kinases in response to various stimuli.

Results: Phosphorylation of Akt1 and 2 was increased in cystinosis podocytes and PTEC in response to nutrient/growth factor replenishment and wounding of cellular monolayer. In podocytes, such increased phosphorylation, was associated with altered cytoskeleton, disturbed focal adhesion sites and increased motility. Treatment with specific Akt inhibitor demonstrated a prominent decrease of motility and Akt phosphorylation. mTORC1 activation in response to nutrient replenishment was delayed in cystinosis PTECs accompanied with abnormal subcellular distribution of the kinase complex, as revealed by antibody staining of mTOR.

Conclusions: We demonstrate that cystinosin dysfunction is associated with disturbed signalling of protein kinases mTORC1 and Akt1 and 2.

Interstitial Pericytes Decrease in Aged Mouse Kidneys Anna Maria Stefanska,[1] Diana G. Eng,[1] Natalya V. Kaverina,[1] Jeremy Stuart Duffield,[2] Jeffrey W. Pippin,[1] Stuart J. Shankland.[1] *[1]Div of Nephrology, Dept of Medicine, Univ of Washington, Seattle, WA; [2]Biogen Idec, Cambridge, MA.*

Background: With increasing age, the kidney undergoes characteristic changes in the glomerular and tubule-interstitial compartments, which are ultimately accompanied by reduced kidney function. Studies have shown age-related loss of peritubular vessels. Normal peritubular vessel tone, function and survival depend on neighboring pericytes. Pericyte detachment leads to vascular damage, which can be accompanied by their differentiation to fibroblasts and myofibroblasts, a state that favors matrix production.

Methods: To better understand the fate of pericytes in the aged kidney, 27-month-old mice were studied. Picrosirius red staining was performed to evaluate kidney fibrosis. Histological sections were stained against endothelial antigen CD31 together with pericyte markers PDGFRß and NG2. Additionally, immunoreactivity of myofibroblast marker aSMA was assessed together with pericytes.

Results: Compared to 3 month-old young adult mice, aged kidneys showed a substantial decrease in capillaries, identified by CD31 staining, in both cortex and medulla. This was accompanied by a marked decrease in surrounding $NG2^+$/ $PDGFR\beta^+$ pericytes. This decrease was more pronounced in the medulla. Capillaries devoid of pericytes were typically dilated in aged mice. Aged kidneys were also characterized by interstitial fibrosis due to increased collagen-I and -III staining. This was accompanied by an increase in the number of pericytes that acquired a pro-fibrotic phenotype, identified by increased $PDGFR\beta^+$/ $aSMA^+$ staining.

Conclusions: These findings are consistent with the decline in kidney interstitial pericytes as a critical step in the development of changes to the peritubular vasculature with aging, and accompanying fibrosis.

Interactions of Urotensin II and Mitophagy in Diabetic Nephropathy and Its Implications on Drug Design Guan-Jong Chen, Fei Wu, Ai-hua Zhang. *Dept of Nephrology, Peking Univ Third Hospital, Beijing, China.*

Background: Urotensin II (UII), an important vasoactive neuropeptide, and the processes of mitophagy have been considered as possible therapeutic targets for treating diabetic nephropathy (DN). The present study is to define the interaction between UII and the process of mitophagy under the setting of DN.

Methods: Immunohistochemistry and western blot analysis were conducted on the protein extracts harvested from the kidney tissues of DN mice that were induced eighteen weeks after the injection of streptozotocin. For in-vitro cell experiment, HK-2 cells were cultured and treated with different concentrations of UII (10^{-7}-10^{-9} mol/L) for 12 h and 3-MA treatment was used as a negative control. The cell protein extracts were then analyzed by western blot. For immunohistochemistry and western blot analysis, BNIP3 was used as a marker for mitophagy.

Results: Immunohistochemistry and western blot analysis results of the animal renal extracts show that the expressions of UII and BNIP3, marker of mitophagy, are upregulated for DN kidney compared to that of controls. In-vitro cell experiment results also demonstrate UII can upregualte BNIP3. Our data indicates that UII expression is positively associated with the expression of BNIP3.

Conclusions: Our results indicate that UII expression can upregulate mitophagy in DN. Past studies already demonstrate that mitophagy can have a therapeutic role in DN. Our study carries the implication that UII and its effect on the process of mitophagy presents potential opportunities for developing novel treatments for DN.

Reduction in CTGF Leads to Increased Proliferation Through Influences on Claudin-1 and Extracellular Matrix Protein Spondin 2 Leighton R. James, Yongxin Gao. *Medicine, Univ of Florida, Jacksonville, FL.*

Background: Accumulation of extracellular matrix is a characteristic feature of diabetic kidney disease. We have recently demonstrated that connective tissue growth factor (CTGF) mediate increases in extracellular matrix production, proteinuria and scarring in mice. In addition, CTGF may have anti-proliferative properties. In specific human neoplasm (breast, colon), increased CTGF have been linked to reduced proliferation, improved response to therapy and prognosis but data is not consistent. On the other hand, metastatic melanoma progression correlates with CTGF levels and inhibition of CTGF reduces invasion and migration.

Methods: To define a possible role for CTGF in proliferation, embryonic fibroblasts (MEF) generated from wild-type and a previously reported CTGF knock mice line were studied. Expression array (Illumina) was used to identify changes in gene expression in MEF. Protein expression was assessed by Immuno-blotting. Inhibitors of MAPK (SP600126, SB203580 and U0126) were used to assess role of MAPK in glucose-mediated CTGF expression by cultured MEF.

Results: CTGF gene disruption lead to enhanced proliferation (3-fold) in CTGF knockout cells compared with wildtype cells. Reduced CTGF led to 50% decreased expression of the gene for the extracellular protein, procollagen 4, alpha 2 (Col4a2; confirmed at protein level)) in association with 2.8-fold increased expression of cluadin-1, a member of the tight junction proteins. In addition, there was a 3.2-fold increased expression of spondin-2 and a 1.6-fold increased expression of Secreted protein, acidic and rich in cysteine-like 1 (SPARCL1). Immunoblotting confirmed the observation for claudin 1. Glucose induced CTGF expression (2-3 fold) was attenuated by inhibitors of p38MAPK and JNK, but unaffected by inhibition of ERK (p42/44 MAPK).

Conclusions: In MEF, CTGF gene disruption leads to increased proliferation and altered matrix protein linked to increased expression of claudin 1 and other extracellular protein. Secondly, glucose-induced CTGF level is mediated by MAPK (p38 and JNK). Targeted alteration in CTGF along with one or more of these extracellular protein may offer new approahes to manage glomerulosclerosis.

miR21 Upregulates YY1 to Increase Renal Cell Apoptosis in Diabetes Adam Kosti,[1,2] Sitai Liang,[1,2] Samy L. Habib.[1,2] *[1]Geriatric Research, Education and Clinical CTR, South Texas Veterans Health System, San Antonio, TX; [2]Cellular and Structural Biology, The Univ of Texas Health Science Center, San Antonio, TX.*

Background: The regulation of miRNAs in response to hyperglycemia that contributes to the pathogenesis of kidney disease has been underscored.

Methods: In the current study, we investigated the role of miR21 in regulation of cells apoptosis in human renal proximal tubular cells (Hk2) cells exposed to high glucose and in type II diabetes mouse model.

Results: Cells pretreated with either miR21 inhibitor or antisense before exposed to HG resulted in decrease YY1 expression and decrease cleavage of caspase 3. Nuclear extracts from Hk2 cells exposed to high glucose for 48hrs showed increase in binding of YY1 to the miR21 promoter element in nuclear extracts of cells by EMSA. On the other hand, pretreatment with miR21 inhibitor or antisense significantly decrease the binding of miR21 to YY1 in nuclear extracts of cells grown in NG or treated with HG. The DNA-protein complexes were significantly decreased in the presence of the YY1 antibody, indicating that YY1 is indeed a component of these complexes. Transfected the cells with promoter/ reporter construct of miR21 showed significant increase in miR21 promoter activity in cells exposed to HG while cells pretreated with miR21 inhibitor reverse the effect of HG. In addition, significant increase in the percentage of TUNEL-positive tubular cells stained in the kidney sections of dbdb mice compared to kidney sections of the wild type mice. Quantitation of miR21 by real-time PCR showed significant increase miR21 levels in kidney of diabetic mice (db/db) compared to kidneys from wild type mice. Immunostaining analysis of miR21 showed that majority of miR21 staining within the tubular cells and glomerular compartments.

Conclusions: In summary, expose renal cells to HG and increase hyperglycemia in kidney of diabetic mice resulted in significant increase in miR21. Increase binding of YY1 to miR21 under HG condition suggesting the important role of miR21 in regulating YY1 to increase cell apoptosis. The data provide a novel role of miR21 as a target for controlling renal cell death that induced by hyperglycemia during diabetic nephropathy.

SA-PO302

The Role of miR-302 and Let7 in Macrophage Polarization Thomas K. Dodd, John Crean, Letizia De Chiara, Orina Belton. *Diabetic Complications and Reneal Disease, Univ College Dublin, Dublin, Ireland.*

Background: Recent advances in the pathogenicity of renal injury highlighted the critical role of the immune system in the onset and resolution of disease. Monocytes canto differentiate along two pathways: pro-inflammatory (MI) due to the secretion of cytokines such as IL-6 and a pro-resolution attributable to the secretion of cytokines such as IL-10. Banerjee et al. have suggested that the ratio of M1 and M2 macrophages is controlled by

interplay between two micro RNAs, miR302 and Let7. We have recently shown that the silenced targets of miR302 and Let 7 are the TGFβ type II and type I receptors respectively and hypothesize that this circuitry plays a critical role in macrophage differentiation.

Methods: The pro-resolving lipid mediator, conjugated linoleic acid (CLA), inhibits the acquisition of a pro-inflammatory macrophage phenotype by priming monocytes towards an anti-inflammatory M2 phenotype. To identify pathways associated with this phenotype we performed proteomic analysis of THP-1s treated with CLA. Exosomes were isolated from urine samples taken from patients with renal injury and analyzed for miRNA expression. Renal cells were transduced with miR-302 and let7 virus. TGFβ receptor expression and signaling was analyzed by Western blot. Additionally, Thp-1 cells were transduced with miR302 and let7 and their effect on macrophage differentiation assessed for expression of CD68 and CD206.

Results: Bioinformatic and Western blot analysis revealed enrichment of the TGFβ signaling pathway in THP-1 cells treated with CLA. miR302 expression was increased in the urine of patients compared to controls. Cells transduced with miR302 and Let7 displayed low levels of expression of the TGFβ type 2 and type 1 receptors respectively and dampened Smad3 phosphorylation. miR302 and let7 prevented renal epithelial cell dedifferentiation. THP-1 cells transduced with both miRs demonstrated similarly enhanced plasticity.

Conclusions: miR302 and let7 have potential injury resolving roles in renal disease. Manipulation of this circuitry results in enhanced cell plasticity. In vitro studies suggest that this results in the generation of pro-resolution cellular phenotypes in both resident cells and macrophages.

SA-PO303

Dopamine D2 Receptor Regulates Wnt3/β-Catenin Signaling and Apoptosis in Human Renal Proximal Tubule Cells Fei Han,[1] Prasad Konkalmatt,[2] Jianghua Chen,[1] Pedro A. Jose,[2] Ines Armando.[2] *[1]Kidney Disease Center, First Affiliated Hospital, College of Medicine, Zhejiang Univ, Hangzhou, Zhejiang, China; [2]Dept of Medicine, School of Medicine, Univ of Maryland, Baltimore, MD.*

Background: Dopamine D2 receptor (D2R) in the kidney has a direct role in regulating renal inflammation and injury, and blood pressure. Some common single nucleotide polymorphisms (D2R SNPs; rs 6276, 6277, and 1800497) in the human *DRD2* gene are associated with decreased D2R expression and function.

Methods: We measured apoptosis and activation of Wnt3/β-catenin signaling pathway in human renal proximal tubule cells (RPTC) carrying these D2R SNPs (RPTC-D2R SNPs), and in RPTC carrying D2R wild type (RPTC-D2R WT).

Results: RPTC-D2R SNPs showed increased apoptosis compared with RPTC-D2R WT(11± 0.8% vs 2.3±0.4% TUNEL positive cells, P<0.01). We found that Wnt3 expression was increased in RPTC-D2R SNPs in comparison with RPTC-D2R WT (mRNA: 2.6±0.35 vs 1±0.11 fold; P<0.05; protein: 133±4% vs 100±5%; p<0.05). RPTC-D2R SNPs showed activated Wnt3/β-catenin signaling pathway demonstrated by decreased β-catenin phosphorylation (64±4% vs 100±8%; P<0.05) and increased expression of downstream pro-apoptotic factors Bax (136±4.6% vs 100±5%, P<0.05) and FasL (128±5.6% vs 100±6.5%, P<0.05). Silencing D2R in RPTC-D2R WT increased Wnt3 expression, decreased β-catenin phosphorylation and increased expression of Bax and FasL. In contrast treatment of RPTC-D2R WT with a D2R agonist (quinpirole,1μM, 24h) or transfection of RPTC-D2R SNPs with a *DRD2* which restored D2R expression decreased Wnt3 expression, increased β-catenin phosphorylation and decreased Bax and FasL expression. Moreover Wnt3 silencing in RPTC-D2R SNPs increased β-catenin phosphorylation (132±5% vs100±9%, P<0.05), decreased Bax (68±2.5% vs100±9%, P<0.05) and FasL (70±3% vs100±9%, P<0.05) expression and reduced the number of apoptotic cells (6±1.0% vs12± 0.9% TUNEL positive cells, P<0.01).

Conclusions: D2R protect cells from apoptosis by regulating the Wnt3/β-catenin pathway. These results may have clinical relevance for subjects bearing D2R SNPs.

SA-PO304

Effect of Omega-3 Fatty Acids on Nrf-2 Expression and Its Regulation in Cyclosporine Induced Rat Model Won Suk An,[1] Eu Gene Jeong,[1] Hansae Kim,[2] Dongyeol Lee,[2] Yun Jung Oh,[3] Su Mi Lee,[1] Sung Hyun Son,[4] Young Ki Son,[1] Seong Eun Kim.[1] *[1]Dept of Internal Medicine, Dong-A Univ Hospital, Busan, Republic of Korea; [2]Dept of Internal Medicine, Bong Seng Memorial Hospital, Busan, Republic of Korea; [3]Dept of Internal Medicine, Cheju Halla General Hospital, Cheju, Republic of Korea; [4]Dept of Internal Medicine, BHS Han Seo Hospital, Busan, Republic of Korea.*

Background: Cyclosporine (CsA)-induced kidney injury is characterized by kidney dysfunction with inflammatory cell infiltrations, apoptosis, and fibrosis. Although Nrf-2 regulates antioxidant and anti-inflammatory process in kidney injury model, it is not clear omega-3 fatty acid (FA) role on Nrf-2 expression. The aim of this study is to investigate whether omega-3 FA affects the Nrf-2 expression and has anti-inflammatroy, anti-apoptotic, and anti-fibrotic processes in CsA-induced nephropathy.

Methods: Male Sprague-Dawley rats fed a low-sodium diet were divided into three treatment groups: control (0.9% saline injection; n=5), CsA (15 mg/kg/day by subcutaneous injection; n=6), CsA with Omega-3 FA (300 mg/kg/day by gastric gavage; n=6). Kidney function was measured at the end of 4 weeks. The expression of Ik-b, ED-1, transforming growth factor-b1 (TGF-b1), α-smooth muscle actin (α-SMA), E-cadherin, Smads for inflammation and fibrosis, caspase-3, caspase-7, and BAX/Bcl-2 ratio for apoptosis, and Nrf-2 were examined by western blot analysis.

Results: Kidney function was decreased in CsA-treated rats compared with control. Compared with control, CsA group significantly upregulated ED-1 protein expression and Ik-b. Omega-3 FA supplementation attenuated increased ED-1 expression and Ik-B. We found that caspase-3, caspase-7, Bax/Bcl2 ratio, TGF-b1, Smad-2/3 and Smad-4 were activated in CsA group and that omega-3 FA prevented these activation related with apoptosis and fibrosis. The expression of Nrf-2 was decreased in CsA-treated rats but Nrf-2 was increased by omega-3 FA.

Conclusions: We suggest that Nrf-2 is one of potential mediator induced by omega-3 FA supplementation attenuating inflammatory pathway, fibrotic process and apoptosis. Further studies are necessary to elucidate cross-talks between Nrf2 expression and related signals of omega-3 FA.

SA-PO305

The Role of High Mobility Group Box 1 in Renal Epithelial Cell Survival During Hypertonic Stress Michael M. Yeboah,[1] Marla A. Chesnik,[1] Hayley Lund,[2] Kevin R. Regner,[1] David L. Mattson.[2] *[1]Div of Nephrology, Medical College of Wisconsin, Milwaukee, WI; [2]Dept of Physiology, Medical College of Wisconsin, Milwaukee, WI.*

Background: High mobility group box 1 (HMGB1) is a ubiquitous and evolutionarily conserved, DNA-binding protein and is characterized as an alarmin or damage associated molecular pattern because of the ability of extracellular HMGB1 to trigger an inflammatory response when it binds to its putative receptors, including RAGE, TLR2 and TLR4. New and emerging evidence suggest that intracellular HMGB1 is involved with numerous cell survival functions. The aim of this study was to examine the functional role of HMGB1 in tubular epithelial cells during hypertonic stress.

Methods: In vivo, 2 groups of Dahl Salt sensitive rats were placed on high salt diet (4% NaCl, n=5/group) and were treated with either daily intraperitoneal injection of a HMGB1 inhibitor (glycyrrhizic acid) or a vehicle for 3 weeks while their blood pressure was monitored by telemetry. In vitro, NRK52E cells were incubated in control medium (332 mOsmol/kg) or hypertonic medium that contained NaCl (500 or 600 mOsmol/kg) for 6 hours in the presence or absence of the HMGB1 inhibitor. In other experiments, cells were transfected with scrambled siRNA or siRNA against HMGB1 and were exposed to control medium or hypertonic medium.

Results: Following exposure to a high salt diet, pharmacologic inhibition of HMGB1 resulted in more severe kidney damage as assessed by the percentage outer medullary area with tubular dilatation and protein casts, when compared with vehicle-treated rats. Inhibition of HMGB1 was associated with a significant increase in tubular cell apoptosis in comparison to vehicle treatment on TUNEL staining. Also, inhibition of HMGB1 led to significantly higher urinary albumin excretion and blood pressure at day 21 compared with vehicle treatment. Exposure of NRK52E cells to hypertonic medium resulted in increased expression and release of HMGB1 from the cells. Both pharmacologic inhibition and siRNA-mediated knock-down of HMGB1 led to reduced cell viability as determined by MTT assay.

Conclusions: HMGB1 plays an important role in renal tubular epithelial cell survival during hypertonic stress.

SA-PO306

KIM-1-Mediated Phagocytosis Defines a New Mechanistic Paradigm for Kidney Epithelial Cells, which Involves Autophagy and Anti-Inflammatory Antigen Presentation Craig R. Brooks, Melissa Y. Yeung, Takaharu Ichimura, Joseph V. Bonventre. *Renal Div, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Background: The expression of kidney injury molecule-1 (KIM-1), the protein most upregulated with proximal tubule cell (PTC) injury, transforms PTCs into semi-professional phagocytes. The processing of phagocytosed cells to the lysosome can determine the immunogenicity of antigens derived from the phagosomal cargo. Here we compare the phagocytic processing of KIM-1-expressing PTCs to that of professional phagocytes and establish distinct mechanisms.

Methods: LLC-PK1 cells expressing KIM-1 were exposed to apoptotic cells. LC3 localization to the phagosome, phagosomal acidification and degradation were measured by live cell imaging, phagosome isolation and western blotting. NADPH oxidase (NOX) activity was blocked with diphenyleneiodonium and reactive oxygen species (ROS) were measured with fluorescent probes. MHC presentation was measured in primary PTCs directly using specific antibodies by flow cytometry. Functional implications were determined by activation of CD4+ and CD8+ T cells.

Results: KIM-1 binds to and induces phagocytosis of apoptotic cells within ~5-30 min, similar to professional phagocytes. Following uptake, however, PTCs process phagosomes more slowly than professional phagocytes, with delayed phagosomal acidification and phagosome degradation (4-12 hrs vs 1-2 hrs). Mechanistically, PTCs do not upregulate NOX-induced production of ROS, a process necessary for efficient acidification and degradation of the phagosome. LC3 associated phagocytosis (LAP), an important NOX-dependent feature of professional phagocytic function, is not observed in PTCs. PTCs instead induce canonical autophagy to clear phagocytosed debris. Delayed phagosomal processing and increased autophagy result in increased PTC antigen presentation and decreased T cell activation.

Conclusions: Autophagy plays a critical role in KIM-1-mediated phagocytosis in PTCs, distinguishing the epithelial cell process from the mechanism used by professional phagocytes. The PTC has evolved a distinct process which leads to anti-inflammatory antigen presentation which is beneficial in acute kidney injury.

Apoptotic Cells Activate AMPK and Inhibit Proximal Tubular Cell (PTC) Growth without Change in Intracellular Energy Stores Philip Speigel,[1] Snezana Vujicic,[1] Lanfei Feng,[1] Natalia O. Litbarg,[1] Vimal Patel,[1] Wilfred Lieberthal,[2] Jerrold S. Levine.[1] *[1]Nephrology, Univ of Illinois at Chicago, Chicago, IL; [2]Nephrology, Stony Brook Univ Medical Center, Stony Brook, NY.*

Background: Apoptosis plays an indispensable role in the maintenance and development of tissues. We have shown that receptor-mediated recognition of apoptotic target cells by viable kidney PTCs inhibits the proliferation and survival of these viable PTCs. Here, we examined the effect of apoptotic target cells on PTC cell growth (cell size during G1 phase of cell cycle).

Methods: We used BU.MPT cells, a conditionally immortalized PTC line, as responder cells. BU.MPT cells, induced to undergo apoptosis in several ways, were used as apoptotic targets.

Results: Apoptotic cells potently activated AMP-activated protein kinase (AMPK), a highly sensitive sensor of intracellular energy stores. AMPK activation led to decreased activity of its downstream target, ribosomal protein p70 S6 kinase (p70S6K) and concomitant inhibition of cell growth. Importantly, these events occurred without detectable change in intracellular levels of AMP, ADP, or ATP. Inhibition of AMPK, either pharmacologically by compound C or molecularly by shRNA, diminished the effects of apoptotic targets, and largely restored p70S6K activity and cell size to normal levels. Apoptotic targets also inhibited Akt, a second signaling pathway regulating cell growth. Expression of a constitutively active Akt construct partially relieved cell growth inhibition, but was less effective than inhibition of AMPK. Inhibition of cell growth by apoptotic targets was dependent on physical interaction between apoptotic targets and PTCs, but independent of phagocytosis.

Conclusions: We conclude that receptor-mediated recognition of apoptotic targets mimics the effects of intracellular energy depletion, activating AMPK and inhibiting PTC cell growth. By acting as sentinels of environmental change, apoptotic death may enable nearby viable cells, especially non-migratory epithelial cells, to monitor and adapt to local stresses.

SA-PO308

The Effect of Uremia on Cardiac Autophagy William White, Steven Michael Harwood, Petros Andrikopoulos, Muhammad M. Yaqoob. *William Harvey Research Inst, Barts & The London School of Medicine & Dentistry, Queen Mary Univ of London, London, United Kingdom.*

Background: Autophagy is the process by which cells remove and recycle unwanted structures, contributing to intracellular homeostasis and energy production. Cardiac autophagy has a role in ischemia protection and ventricular remodelling, and decreasing autophagy is central to aging. Evidence suggests these processes are disordered in CKD. We have previously demonstrated that autophagy may be down-regulated at a transcriptional level in uremic hearts, and now present data concerning cardiac autophagic-protein expression (LC3, p62) and senescence marker p53 in models of uremia.

Methods: ***In Vitro*** Rat cardiac myoblast cells (H9C2) were cultured in the presence of indoxyl sulphate (IS) to simulate a uremic milieu, for 24 or 48 h, with or without 25 mM chloroquine (CQ, a late-stage autophagy inhibitor) for the last 6h. Cells were lysed and underwent immunoblotting for LC3B and p62. ***In Vivo*** Rats were rendered uremic using an adenine diet (controls given normal feed), fasted for 24 h (to control for calorie intake) and given 10 mg/kg *IP* CQ prior to sacrifice. Cardiac tissues were homogenised and immunoblotted for LC3B, p62 and p53.

Results: ***In Vitro*** At 24 and 48 h the amount of LC3BII (a marker of autophagic flux) expressed increased with IS in a dose-dependent manner with and without CQ. At 48 h p62 expression decreased with IS in the absence of CQ, but increased in its presence. ***In Vivo setting*** LC3BII and p62 expression increased in the uremic hearts in line with the *in vitro* data. Interestingly p53 expression was increased in the uremic group.

Conclusions: Uremia appears to stimulate autophagy in cardiac tissues at the protein level, in contrast to our autophagy transcriptome data. Previous authors have found that changes in autophagic activity are not always mirrored at a transcriptional level. Interestingly p53 expression was greater in uremia, suggesting an increase in senescence, which we are currently investigating. Changes in autophagy activity and senescence in uremic hearts may contribute to the pathogenesis of uremic cardiomyopathy, and provide targets for therapy.

SA-PO309

Decorin Potentially Alleviates TGF-β1 Induced Podocyte Injury by Inactivating mTORC1 and Increasing Autophagy Xing Mao, Zhigang Zhang, Huijuan Wu. *Dept of Pathology, Shanghai Medical College, Fudan Univ, Shanghai, China.*

Background: TGF-β1 is the major factor mediating podocytes injury during mesangialoproliferative glomerulonephritis (MsPGN), manifested by decreased autophagy, cytoskeleton relocation and increased apoptosis. Decorin (DCN), mainly secreted by mesangial cells (MCs) in glomuruli, is a natural antagonist of TGF-β1 and has been shown to induce autophagy via Peg3 and Vps34. However, the mechanism underlying the aberrant autophagy in injured podocytes of MsPGN and the possible effect of DCN/TGF-β1 axis on the crosstalk of MCs and podocytes are still not clear.

Methods: We used immunohistochemistry(IHC) to detect p-smad2 and LC3 in rat anti-Thy1.1 nephritis, and TGF-β1 in human nephritis. Then we treated podocytes with TGF-β1 or DCN and detected the expression of Vps34, p-S6K1(Thr389), TGF-β1, p62 and LC3 by western blot.

Results: In this study, we firstly found increased p-smad2 and decreased LC3 by IHC in podocytes of rat anti-Thy1.1 nephritis with obvious proteinuria, and consistently, increased TGF-β1 staining in human nephritis featured by MCs proliferation and proteinuria. Then we treated podocytes by TGF-β1 (20ng/ml) for 1, 3, 6 and 12h, and found decreased protein expression of Vps34 and increased p-S6K1(Thr389) representing mTORC1 signaling, accompanied by increased P62 and decreased LC3II/Iratio. However, treatment of mouse soluble DCN (6.25nM or 100nM) for 1, 3, 6 and 12h on podocytes led to an increased protein expression of Peg3, decreased p-S6K1(Thr389) , decreased P62 and increased LC3II/I ratio. Moreover, it also decreased TGF-β1 in podocytes.

Conclusions: These results showed that TGF-β1 evoked an activation of mTORC1 signaling and the abortion of macroautophagy in podocytes, whereas DCN downregulated TGF-β1 protein expression, and thus inactivate mTORC1 signaling and induce autophagy on podocytes, indicating DCN may have a potential in alleviating TGF-β1 induced podocyte injury in MsPGN.

Albumin Endocytosis in the Proximal Tubule Causes Accumulation of Dysfunctional Mitochondria Angela Nolin, Ryan M. Mulhern, Ramon G. Bonegio, Zhiyong Wang, Steven C. Borkan, John H. Schwartz, Andrea Havasi. *Renal, Boston Univ Medical Center, Boston, MA.*

Background: Proteinuria is a major risk factor for chronic kidney disease progression. Furthermore, exposure of proximal tubular epithelial cells (PTEC) to excess albumin promotes tubular atrophy and fibrosis, key predictors of progressive organ dysfunction. The mechanism by which protein exposure causes tubular cell injury is uncertain. We hypothesize that albumin endocytosis causes tubular cell injury by inhibiting autophagy, including mitophagy, resulting in an accumulation of dysfunctional mitochondria leading to enhanced ROS production, mitochondrial and cellular injury.

Methods: The effect of proteinuria was examined both in *in vivo* and *in vitro* experiments. Proteinuria was induced in mice by injection of a sheep nephrotoxic serum that causes acute immune-complex glomerulonephritis with massive proteinuria by 24-48 hrs. *In Vitro*, to mimic nephrotic glomerular filtrate, PTECs were exposed to albumin. Autophagy was assessed in tissue samples from mice and primary PTECs. Steady state LC3-II, an autophagy marker was quantified by immunoblot. Autophagosomes (APs) were visualized in cell culture using fluorescent markers and in renal cortical tissue using immunohistochemistry. Mitochondrial respiration was measured in primary cells. Mitochondrial morphology and colocalization with autophagosomes were imaged using confocal microscopy. Reactive oxygen species production was measured using a 2',7'-dichlorofluorescin diacetate assay.

Results: Exposure to excess albumin induced defective autophagy and mitophagy *in vitro*. In renal cortices, proteinuria decreased both the number of LC3-II positive APs and the amount of LC3-II detected in cell lysates. Albumin-exposed cells accumulated damaged mitochondria with altered mitochondrial function and morphology. Albumin exposure caused mitochondrial dysfunction as evidenced by decreased oxygen consumption rate from coupled ATP production. Increasing albumin exposure time caused an increase in ROS production.

Conclusions: Dysfunctional autophagy caused by proteinuria likely contributes to tubular cell toxicity leading to renal progression.

Association Between a Marker of Aging and Cardiovascular Pathology in End-Stage Renal Disease Patients Karin Luttropp,[1] Dagmara Mcguinness,[2] Abdul Rashid Tony Qureshi,[3] Hannes Olauson,[3] Annika Wernerson,[3] Louise Nordfors,[3] Jonaz Ripsweden,[4] Peter F. Barany,[3] Peter Stenvinkel.[3] *[1]Dept of Molecular Medicine and Surgery, Karolinska Inst, Stockholm, Sweden; [2]Inst of Cancer Sciences, Univ of Glasgow, Glasgow, United Kingdom; [3]Dept of Clinical Science, Intervention and Technology, Div of Renal Medicine, Karolinska Inst, Stockholm, Sweden; [4]Dept of Clinical Science, Intervention and Technology, Div of Radiology, Karolinska Inst, Stockholm, Sweden.*

Background: Patients with chronic kidney disease (CKD) display a progeric phenotype, with a high incidence of cardiovascular disease (CVD) and vascular calcification (VC). The process of VC is complex, and has been linked to apoptosis. A potential contributor to the calcification process is the pro-apoptotic factor cyclin-dependent kinase inhibitor 2A (CDKN2A). This study aims to investigate possible associations between *CDKN2A* expression, VC and CVD in a CKD population.

Methods: *CDKN2A* expression was determined in epigastric arteries (n=43) from patients with end-stage renal disease (ESRD) undergoing living donor renal transplantation (RTx). All arteries were scored for degree of calcification in percent. Coronary artery calcification (CAC) score was also obtained.

Results: The arterial expression of *CDKN2A* was significantly associated with VC ($p=0.01$, $\rho=0.4$), CVD ($p=0.0002$), CAC score ($p=0.008$, $\rho=0.5$) and diabetes mellitus ($p<0.05$). In addition, arterial *CDKN2A* expression was associated with *MGP* ($p=0.007$, $\rho=0.4$) and *RUNX2* ($p=0.046$, $\rho=0.3$) expression in artery, both of which are involved in osteogenic transformation of vascular smooth muscle cells.

Conclusions: These findings provide evidence that cell senescence and apoptosis are important in the development of VC and CVD in the uremic milieu, and further strengthen the hypothesis that comorbidities present in CKD could be caused by a premature ageing process. Attempts to ameliorate any progeric process in this patient group is therefore of great interest.

Role of RTN1-A in Mediating Tubular Cell Injury Induced by Albumin Overload

Ying Fan,[1] Wenzhen Xiao,[2] Peter Y. Chuang,[2] Kim Lee,[2] Niansong Wang,[1] John C. He.[2] *[1]Dept of Nephrology, Shanghai Jiao Tong Univ Affiliated Sixth People's Hospital, Shanghai, China; [2]Dept of Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: We performed mRNA sequencing in the kidneys from the murine model of HIV-associated nephropathy and identified an association between the expression of an endoplasmic reticulum (ER)-associated protein reticulon-1, *RTN1*, and the severity of kidney disease. Of the three known RTN1 isoforms, only RTN1A protein expression was increased in kidneys of multiple murine models and patients with kidney disease. Interestingly, both mRNA and protein expression of RTN1-A in the kidneys correlated inversely with estimated glomerular filtration rate (eGFR) in patients with diabetic kidney disease.

Methods: To determine how RTN1-A mediates the progression of kidney disease, we studied the role of RTN1-A in HK2 cells treated with or without human serum albumin (HSA) at different concentrations. Then, we studied the role of RTN1-A in vivo by generating a protein overload mouse model in both wild-type and RTN1-A knockdown mice.

Results: HSA induced both ER stress markers (GRP78 and CHOP) and apoptosis in HK2 cells. However, treatment with 4-PBA (inhibitor of ER stress) or knockdown of RTN1-A expression attenuated HSA-induced ER stress/apoptosis in HK2 cells. These data suggest that RTN1-A mediate HSA-induced ER stress and apoptosis of kidney tubular cells. To determine the effect of albumin overload on tubular injury in vivo, we generated tubular cell-specific RTN1-A shRNA knockdown mice, in which RTN1-A expression was reduced by 80%. Then, we inject BSA intraperitoneally in these RTN1-A knockdown mice and their control littermates to generate albumin overload mouse model. Mice with BSA injection developed significant proteinuria in both knockdown and wild-type mice. However, RTN1-A knockdown mice developed less tubulointerstitial injury than wild-type mice. Also, there was less apoptosis and lower expression of ER-stress markers in tubular cells of RTN1-A knockdown mice than wild-type mice.

Conclusions: These data suggest that RTN1-A likely mediates proteinuria-induced tubular cell injury and progression of kidney disease through ER stress and apoptosis.

Inhibition of Caspase-1, but Not of Caspase-3, Ameliorates Diabetic Nephropathy: Does Apoptosis Play a Role in Diabetic Kidney Disease?

Fabian Bock,[1,2] Khurrum Shahzad,[1,3] Moh'd Mohanad Ahmad Al-Dabet,[1] Shrey Kohli,[1] Hongjie Wang,[1,4] Ihsan Khan Gadi,[1] Satish Ranjan,[1] Peter Nawroth,[1,2] Madhusudhan Thati,[1] Berend Heinrich Isermann.[1] *[1]Inst of Clinical Pathology and Pathobiochemistry, Otto-von-Guericke-Univ Magdeburg, Magdeburg, Sachsen-Anhalt, Germany; [2]Dept of Internal Medicine I and Clinical Chemistry, Univ of Heidelberg, Heidelberg, Baden-Württemberg, Germany; [3]Khayaban-e-Jamia Punjab, Univ of Health Sciences, Lahore, Pakistan; [4]Dept of Cardiology, Huazhong Univ of Science and Technology, Wuhan, China.*

Background: Glomerular apoptosis is thought to contribute to diabetic nephropathy (dNP), but insights into its pathogenetic relevance in dNP are incomplete.

Methods: Here we employed two partially distinct caspase inhibitors in db/db mice: M-920 (inhibiting caspases-1,-3,-4,-5,-6,-7) and CIX (inhibiting caspases-3,-6,-7,-8,-10). The nephromine database was interrogated for glomerular expression of apoptosis and inflammasome markers in human dNP. *In vitro* glucose stimulated podocytes were used. Findings were validated in caspase-1 and caspase-3 deficient mice.

Results: Both M-920 and CIX reduced glomerular cell death and caspase-3 and -7 activity, but only M-920 ameliorated dNP. Nephroprotection by M-920 was associated with reduced renal caspase-1 and inflammasome activity. Glomerular expression of inflammasome markers (NLRP3, CASP1, IL18, ASC), but not of apoptosis markers (CASP3, CASP7, PARP1), was significantly elevated in patients with dNP compared to non-diabetic controls. Markers of inflammasome activation (Nlrp3, caspase-1 cleavage) precede those of apoptosis activation (caspase-3,-7, and PARP cleavage) in glucose stressed podocytes *in vitro*. Finally, caspase-3 deficiency in mice does not protect from dNP, while both homozygous and hemizygous caspase-1 deficiency is protective.

Conclusions: Manifestation of diabetic nephropathy is independent of caspase-3 dependent cell death (apoptosis), but requires caspase-1 activation in mice. These data support a critical role of caspase-1 dependent inflammasome activation in dNP. Targeting the inflammasome may be superior to targeting apoptotsis.

Endothelial Autophagy Is Essential for Vascular Lipid Homeostasis

Kumiko Torisu,[1,3] Subodh Verma,[2] Takehiro Torisu,[1,3] Krishna K. Singh,[2] Toren Finkel.[1] *[1]Center for Molecular Medicine, National Heart, Lung, and Blood Inst, NIH, Bethesda, MD; [2]Div of Cardiac Surgery, St. Michael's Hospital, Univ of Toronto, Toronto, ON, Canada; [3]Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.*

Background: Caridiovascular disease is one of the common complications in chronic kidney diseases. It is known that autophagy plays a critical role in the course of kidney diseases. The resulting cardiovascular diseases are presumably regulated by autophagy. However the physiological role of autophagy in the vascular endothelial cells remains poorly understood.

Methods: Using human umblical vein endothelial cells (HUVECs), induction of autophagy by ox-LDL, and uptaking or transcytosis of LDL are analyzed. To inhibit autophagy pharmacologically, chroloquine is used. The essential autophagy gene, Atg7 shRNA-mediated knockdown are performed to inhibit autophagy genetically. To assess an acute and chronic *in vivo* model of lipid exposure, we generated endothelial specific Atg7 knockout in ApoE deficient mice (Atg7endo/ApoE KO).

Results: Ox-LDL induced autophagosome formation in HUVECs. Moreover, native or ox-LDL appeared to be engulfed within autophagosomes by live cell imaging and electron microscopy. Atg7 knockdown or pharmacological inhibition of autophagy resulted in higher accumulation of intracellular LDL, suggesting that in vascular endothelial cells, autophagy is one of the degradation machinery of excess lipids. As an acute model of lipid exposure *in vivo*, Atg7endo/apoE mice showed longer retention of ox-LDL within the retina after infusion of DiI ox-LDL. In a chronic model of lipid excess, we analyzed atherosclerois in ApoE KO or Atg7endo/ApoE KO mice. Atg7endo/ApoE KO mice demonstrated markedly increased atherosclerosis.

Conclusions: In endothelial cells, autophagy appears to play a critical role in regulating excess intracellular lipids. Moreover, in both acute and chronic *in vivo* model, endothelial autophagy is essential to attenuate LDL accumulation within endothelial layer. Prevention of the decline in autophagy flux accompanied by kidney diseases pharmacologically might be beneficial to treat atherosclerotic diseases.

Targeted Mutations at the p66 Locus Antagonize Stem Cell Aging and Delay Expression of Senescent Phenotypes in Diabetic Kidneys

Himanshu Vashistha,[1] Antonio G. Jimenez,[1] Sixto G. Giusti,[1] Allyson E. Bradley,[1] Ashwani Malhotra,[2] Pravin C. Singhal,[2] Leonard G. Meggs.[1] *[1]Nephrology, ITR, Ochsner Health System, New Orleans, LA; [2]Nephrology, Feinstein Inst for Medical Research,North Shore Long Island Jewish Health System, New York, NY.*

Background: Senescence has important implications for the biologic function of tissue stem cells, which maintain tissue homeostasis by replacement of old or dying cells and via the repair of tissue injury. The p66 longevity gene plays a key role in the activation of gene programs that induce senescent and apoptotic phenotypes. We hypothesize gene base strategies targeting p66 will delay or prevent stem cell senescence and premature aging phenotypes in diabetic kidneys.

Methods: Mesenchymal stem cells (MSCs) were isolated from kidneys of p66 KO mouse (p66 KO-MSCs) using established methods and plated in high glucose (HG) containing media. Microarray was used to profile secreted factors expressed by MSCs. p66 KO diabetic mice were generated to evaluate survival of MSCs in diabetic kidneys, glomerulosclerosis, interstitial fibrosis and tubular atrophy. Confocal imaging and immunofluorescent staining was used to identify MSCs, podocytes, renal tubular cells and to detect senescent protein $p16^{INK4a}$ and proliferation marker Ki-67.

Results: Cultured p66 KO-MSCs at HG escape entry to senescent and apoptotic programs and display enhanced secretion of IGF-1, VEGF and HGF. Microarray detected unexpected cross talk between p66 and Wnt regulatory genes that antagonize senescence. Kidney sections from p66 KO diabetic mice show increased numbers of MSCs in glomeruli and tubules, with barely detectable histologic markers of aging and near normal urine albumin excretion. Kidney nuclei staining (+) for Ki-67 was upregulated, whereas $p16^{INK4a}$ was downregulated.

Conclusions: These findings suggest a genetic link between p66 longevity gene, stem cell aging and senescent phenotype(s) in diabetic kidneys.

SA-PO316

The Full Time Course and Localization of mTOR Activation in Compensatory Renal Hypertrophy

Jinxian Xu,[1] Meichu Cheng,[1] Jianchun Chen,[2] Jian-Kang Chen.[1] *[1]Cellular Biology & Anatomy and Medicine, Georgia Regents Univ, Augusta, GA; [2]Medicine, Vanderbilt Univ, Nashville, TN.*

Background: Previous studies documented an essential role for mTOR activation in mediating compensatory renal hypertrophy induced by unilateral nephrectomy (UNX) but the time course and localization of the mTOR activation are unclear.

Methods: 8-week-old male FVB/NJ mice were subjected to right UNX or sham surgery, followed by sacrifice at different time points to collect left kidney and determine the time course and localization of mTOR activation by immunoblotting and immunofluorescence staining for phospho-S6K1 and phospho-rpS6, along with nephron segment-specific markers.

Results: In this inbred mouse strain, UNX induced 8.27 ± 0.93% renal hypertrophy within 24 h. The hypertrophy continued to rise up to 12.74 ± 3.32%, 39.78 ± 7.06%, 45.56 ± 7.72%, 45.92 ± 2.80%, 49.13 ± 2.09%, and 50.26 ± 9.87% by 48 hours, 1 week, 2 weeks, 1 month, 3 months, and 4-7 months, respectively. Thus, the hypertrophy is complete within 3-4 months, with ~50% hypertrophy on average. Immunoblotting indicated that UNX increased T389-phosphorylated S6K1 within 3 min, indicating mTOR activation, but had no effect on Akt, TSC2, AMPK, or ERK1 and ERK2 phosphorylation in the remaining kidney at any time points examined. The mTOR activity peaked at 24 h, remained at the plateau level even after 48 h, declined but still activated by 1 month, and returned to the basal level by 3 months after UNX. Immunofluorescence staining visualized the most prominent mTOR activation in the cytoplasm of LTL-positive tubules in response to UNX, although the basal mTOR activity in the kidney of sham-operated control mice was largely confined in THP-, calbindin-, and DBA-positive tubules, with very little in LTL-positive tubules. n=5-6 mice for each group and time point.

Conclusions: This is the first report on the full time course of dynamic mTOR activation and the first demonstration that UNX-induced mTOR activation is primarily localized in the proximal tubules of the remaining kidney. The present study also indicates that compensatory renal hypertrophy largely occurs within 1 week but is not complete until 3-4 months after UNX.

EGF Dependent Regulation of VEGF-A Secretion by Proximal Tubule Cells Diana Zepeda-Orozco,[1] Hsiang M. Wen,[1] Nandita S. Raikwar,[2] Christie P. Thomas.[2] *[1]Pediatrics, Univ of Iowa, Iowa City, IA; [2]Internal Medicine, Univ of Iowa, Iowa City, IA.*

Background: Vascular endothelial growth factor A (VEGF-A) plays a critical role in peritubular capillary development by promoting vasculogenesis and angiogenesis. It is now recognized that there is increased expression of VEGF-A by proximal tubular epithelial cells in ischemia reperfusion injury and in chronic tubulointerstitial injury. Although hypoxia is known to increase the expression of VEGF-A in proximal tubular epithelial cells *in vitro and in vivo*, the mechanisms regulating VEGF-A secretion by proximal tubule epithelial cells in normoxia has not been established.

Methods: We utilized HK2 cells, an immortalized human proximal tubule cell line, to characterize the epidermal growth factor (EGF)-dependent regulation of VEGF-A secretion by proximal tubular epithelial cells.

Results: EGF increases HIF1-a expression, stimulates VEGF-A secretion and promotes proliferation of HK2 cells under normoxic conditions. HIF1-a knockdown decreases EGF-dependent VEGF-A secretion indicating that the EGF effect is at least partly HIF1-a dependent even in normoxia. EGF stimulates HIF1-a and VEGF-A via activation of the EGF receptor and upregulation of mTOR and p42/44 MAPK pathways. P42/44 MAPK inhibition significantly downregulates HIF1-a dependent VEGF-A secretion and cell proliferation. Although mTOR inhibition reduces HIF1-a, it upregulates MAPK with a very modest reduction of VEGF-A secretion indicating that mTOR and p42/44 MAPK may act via parallel pathways in VEGF-A regulation. Finally, we demonstrate that the EGF-stimulated proliferation of HK2 cells is reduced by VEGF Receptor 2 (VEGFR2) blocker indicating that EGF stimulates proximal tubular cell proliferation via the secretion of VEGF and the activation of the VEGFR2 receptor.

Conclusions: EGF stimulates VEGF-A secretion via activation of the EGF receptor, and stimulation of HIF1-a. EGF stimulates proliferation of HK2 cells via the secretion of VEGF-A indicating that VEGF is an autocrine proximal tubular epithelial cell growth factor. The effects of EGF on HIF1-a, and VEGF-A in HK2 cells are modulated by complex crosstalk between p42/44 MAPK and mTOR pathways.

SA-PO318

Selective Regulation of a Novel Truncated CCN3 Protein by TGFb1 in Human Tubule Epithelial Cells Matthew Pottle,[1] Bruce L. Riser,[2] Mark E. Dockrell.[1] *[1]SWT Inst for Renal Research, London, United Kingdom; [2]BLR Bio, WI.*

Background: CCN3 is a member of the matricellular CCN family of proteins along with the structurally similar CCN2/CTGF, a powerful fibrotic agent, but recent work supports our hypothesis that CCN2 and 3 act in opposition to each other regulating fibrosis. In renal cell carcinoma tubular expression of CCN3 is reduced in patients with cancer. TGFb1 has been shown to counter regulate the expression of CCN2 and CCN3 in the vertebral nucleus pulposus and in mesangial cells. We have previously characterised TGFb1 induction of CCN2 in proximal tubule epithelial cells (PTEC); here we investigate the expression of CCN3 in primary human PTEC and its potential regulation by TGFβ.

Methods: Primary human PTEC were cultured on collagen IV in supplemented medium. At 80% confluence cells were treated with TGFβ-1 (0.25 -2.5 ng/ml) for 24 & 48h, medium was collected and cells lysed. Equal amounts of lysate were subjected to PAGE and Western blotting then probed with antibodies (Ab) to the C-terminal, N-terminal and hinge region of CCN3, as well as the hinge region of CCN2/CTGF.

Results: Under control conditions the anti-CCN3 hinge Ab revealed the expression in PTEC of the 51KDa full-length protein as well as a 39KDa isoform. The antibodies to the respective termini detected bands of approximately 23-28KDa. The C-terminal ab did not detect the 39KDa band. The antibody to the N-terminal detected proteins of approximately 45KDa as well as the 39KDa form. Treatment with TGFβ for 24h had no effect on the 51KDa protein but significantly inhibited the expression of the 39KDa.

Conclusions: At a concentration that induces CCN2/CTGF expression in PTEC, TGFβ does not regulate the expression of full length CCN3. However, it does reduce the expression of a truncated form apparently lacking the CT domain. The characteristics of this smaller protein are not consistent with any known splice variants and may represent an intracellularly cleaved form regulated by TGFb1. The lack of the CT domain would change the 3 dimensional conformation of the protein, inhibit its binding to various integrins and potentially remove the ability of the molecule to inhibit cell proliferation.

SA-PO319

Deletion of TGF-Beta Receptor in Renal Proximal Tubule Cells Impairs HGF Signaling Stellor Nlandu Khodo,[2] Leslie S. Gewin.[1,2] *[1]Research, Tennessee Valley Veterans Affairs, Nashville, TN; [2]Medicine, Div of Nephrology, Vanderbilt Univ, Nashville, TN.*

Background: The growth factors TGF-beta and HGF have antagonistic and synergistic interactions that govern renal development and response to injury. We previously showed that TGF-beta worsens the epithelial response to acute renal injury, so we postulated that epithelial TGF-beta signaling may inhibit responsiveness to HGF, a growth factor that mediates beneficial effects following epithelial injury.

Methods: To address how TGF-beta signaling alters epithelial responsiveness to HGF, we generated proximal tubule (PT) cells with the TGF-beta type 2 receptor, necessary for all signaling, either intact ($TbRII^{fl/fl}$) or deleted in vitro with adeno-Cre ($TbRII^{-/-}$). Responsiveness to HGF was assessed by receptor (cMet) phosphorylation, and the biological relevance of altered HGF signaling was determined by branching morphogenesis studies in 3D gels and migration assays.

Results: $TbRII^{-/-}$ PT cells had increased tubular branching and impaired migration compared to cells with the receptor intact. Unexpectedly, PT cells lacking TbRII had impaired response to HGF in both branching morphogenesis and migration assays compared to $TbRII^{fl/fl}$ cells. Consistent with this, $TbRII^{-/-}$ PT cells had impaired cMet phosphorylation associated with reduced membrane expression of cMet and transcriptional downregulation of the HGF receptor. Notch signaling, a known inducer of cMet transcription, was increased in cells with TbRII intact, and Notch inhibition by gamma-secretase equalized the responses to HGF by PT cells with and without the receptor.

Conclusions: PT cells lacking TbRII have impaired responsiveness to HGF signaling, and this effect is due to reduced Notch-mediated cMet transcription. Thus, efforts to block TGF-beta signaling may inadvertently inhibit signaling pathways of other growth factors such as HGF.

SA-PO320

Enhancement of HGF-Induced Tubulogenesis by Endothelial Cell-Derived GDNF Masao Nakasatomi, Akito Maeshima, Shunsuke Takahashi, Hidekazu Ikeuchi, Toru Sakairi, Yoriaki Kaneko, Keiju Hiromura, Yoshihisa Nojima. *Dept of Medicine and Clinical Science, Gunma Univ Graduate School of Medicine, Maebashi, Gunma, Japan.*

Background: Renal proximal tubular epithelium can regenerate itself after a variety of insults. However, the microenvironment that regulates regeneration process of renal tubules after injury remains unclear. We previously established an in vitro 3D tubulogenesis assay which at least partly mimics in vivo regeneration processes of renal tubules after injury (Am J Physiol Renal Physiol: 301: F387-95, 2011). Utilizing this system, the endothelial cell-derived factors that regulate tubular formation was examined.

Methods: Human renal proximal tubular epithelial cells (RPTEC) were cultured in gels (type I collagen/matrigel mixture) in the presece of HGF with or without human umbilical vein endothelial cells (HUVEC) using Transwell filter system. The signaling pathways activated by co-culture with HUVEC in tubular structures were examined using phospho-receprtor tyrosine kinase (RTK) array.

Results: HGF, a potent renotropic factor, induced aquaporin-1-positive tubular structures with microvilli, suggesting that these structures are morphologically equivalent to renal tubules in vivo. When co-cultured with HUVEC, HGF-induced tubular formation was significantly enhanced. Tubulogenic effect of HGF was also enhanced in the presence of HUVEC-conditioned media (HUVEC-CM), but not in the presence of VEGF, basic FGF or PDGF. Co-culture with HUVEC did not induce tubular structures in the absence of HGF. RTK array revealed that phosphorylation of RET (GDNF receptor) was markedly enhanced in tubular structures cultured with HUVEC-CM compared to those without HUVEC-CM. HUVEC produces GDNF and RPTEC expresses both RET and GFR alpha1 (co-receptor). HGF-induced tubular formation was significantly enhanced by addition of GDNF.

Conclusions: These data indicate that endothelial cell-derived GDNF potentiates tubulogenic action of HGF in a paracrine manner. GDNF-RET signaling may play a role in the crosstalk between renal tubules and surrounding endothelium during tubular regeneration after injury.

SA-PO321

Massive Formation of Ang(1-7) from AngII(1-8) Is Largely ACE2 Independent Peter Daniel Serfozo, Jan A. Wysocki, Minghao Ye, Daniel Batlle. *Div of Nephrology, Northwestern Univ - Feinberg School of Medicine, Chicago, IL.*

Background: AngII(1-8) degrading mechanisms are complex including cleavage by aminopeptidases that form AngIII and carboxypeptidases like ACE2 and Prolylcarboxypeptidase (PRCP) that cleave Phenylalanine to form Ang(1-7). The relative importance of these peptidases to the formation of Ang(1-7) is unknown but ACE2 has been assumed to be the main Ang(1-7) forming enzyme resulting from cleavage of AngII(1-8). We tested the hypothesis that Ang(1-7) formation largely occurs independently of ACE2.

Methods: After acute AngII(1-8) infusion to WT mice plasma concentrations of AngII(1-8), Ang(1-7) and Ang(1-5) were measured by LC-MS/MS. Additional measurements of Ang(1-7) by RIA and ELISA were performed for confirmatory purposes. Plasma ACE2 and PRCP activity in WT mice was measured using a fluorogenic substrate.

Results: Following AngII(1-8) infusion to WT mice plasma Ang(1-7) levels measured by MS were extremely high. Similarly high levels were also found when this peptide was measured by RIA and ELISA (Table).

	AngII(1-8)	Ang(1-7)
MS	244 ± 21 pg/ml	766 ± 199 pg/ml
RIA	n.a.	1527 ± 240 pg/ml
ELISA	1012 ± 223 pg/ml	1137 ± 394 pg/ml

In an ACE2 KO line there was no significant difference in Ang(1-7) levels as compared to WT mice and the levels of ACE2 activity in plasma of WT mice were low. Moreover, activity of PRCP, another Ang(1-7) forming enzyme is very low at the normal plasma pH. We therefore hypothesize that Ang(1-7) formation after AngII(1-8) infusion must be largely ACE2 and PRCP independent. To give further support for this hypothesis, we infused a different set of mice with AngII(1-8) in the presence of recombinant murine ACE2 or ACE2 + MLN, a specific inhibitor. Under all these conditions the levels of Ang(1-7) were massively increased and therefore unaccountable only by the conversion of AngII(1-8) to Ang(1-7) by ACE2 cleavage.

Conclusions: Formation of Ang(1-7) during AngII(1-8) infusion is massive and largely ACE2 independent. The increase in Ang(1-7) after AngII(1-8) infusion suggests the presence of unknown Ang(1-7) forming enzymes that are very active in plasma.

HIF1a and HIF2-Induced Erythropoietin Production Along the Nephron

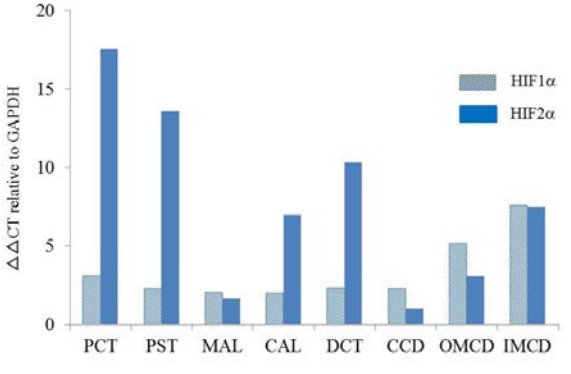
Yuichiro Izumi,[1] Yukiko Yasuoka,[2] Yushi Nakayama,[1] Hideki Inoue,[1] Masashi Mukoyama,[1] Katsumasa Kawahara,[2] Hiroshi Nonoguchi.[3] *[1]Nephrology, Kumamoto Univ Graduate School of Medical Science, Kumamoto, Japan; [2]Physiology, Kitasato Univ School of Medicine, Sagamihara, Kanagawa, Japan; [3]Internal Medicine, Kitasatro Univ Medical Center, Kitamoto, Saitama, Japan.*

Background: Kidney peritubular interstitial cells produce erythropoietin (Epo) in response to hypoxia and/or anemia. By using in situ hybridization method, we have shown that Epo is also produced by the cortical nephron segments (mainly in PCT, DCT and CCD) in control and/or hypoxic conditions (Nagai, et al, 2014). The use of renin-angiotensin-aldosterone inhibitor has been suggested to exacerbate anemia in chronic kidney disease, suggesting aldosterone-regulated erythropoietin production.

Methods: To characterize the molecular machineries for Epo production in renal tubules, we examined the mRNA expressions of HIF1α, HIF2α, PHD2, mineralocorticoid receptor (MR) and EGF-receptor (EGFR) along the nephron in basal condition. Each nephron segment from SD rats was microdissected in the presence of ribonucleoside vanadyl complexes. After the extraction of RNA, mRNA expression was measured using RT-PCR and real-time PCR.

Results: Epo mRNA expression was confirmed in whole nephron segments by RT-PCR in basal condition. The expressions of HIF1α, HIF 2α and PHD2 mRNAs were detected in whole nephron segments both in RT-PCR and real time PCR. The largest expression of HIF2α mRNA was observed in PCT. HIF2α mRNA expression was larger than HIF1α mRNA expression in most segments (ΔΔCT relative to GAPDH). MR and EGFR mRNAs expression was observed not only in distal but also in proximal tubules.

HIF1α and HIF2α mRNAs expression along the nephron in control rat



Conclusions: The results suggest the presence of HIF2a induced-Epo roduction in renal tubules. The presence of MR in whole nephron segments suggest that aldosterone may have physiological effects for Epo production not only in distal but also in proximal tubules.

Cytokine Response of Primary Human Mesangial Cells Is LPS Strain Dependent

Margaret M. O'Neill, Carine Boustany, Steven S. Pullen. *CardioMetabolic Diseases Research, Boehringer Ingelheim Pharma. Inc, Ridgefield, CT.*

Background: LPS stimulation of Toll-like receptor 4 (TLR4) induces the release of proinflammatory cytokines which activate potent immune responses. LPS is an important structural component of the outer membrane of Gram-negative bacteria and consists of three parts: lipid A, a core oligosaccharide, and an O side chain. It has been studied extensively in models of inflammation with E.coli 0111:B4 most often referenced in the literature. The antigenicity of LPS varies from strain to strain depending on the composition its O side chain. A comparative study was designed to identify the optimal strain to be used for LPS-stimulated release of proinflammatory mediators from primary human mesangial cells (HMC).

Methods: HMC were stimulated with 7 strains of LPS and 24 hour supernatants were analyzed for production of inflammatory mediators (IL-1β, IL-6, IL-8, TNF-α and MCP-1). Culture supernatants were assessed with MSD kits ProInflammatory 4-Plex II and MCP-1. TLR4 antagonists EX00076824 a small molecule and FHAN_2014062 an antibody were tested to evaluate inhibition of LPS activity in HMC using 3 LPS strains with most pronounced inflammatory effects.

Results: LPS induced strain-dependent increases in IL-6, IL-8, and MCP1 in HMC, while there was no effect on IL-1β and TNF-α. When compared to controls, IL-6 production was significantly ($p<0.05$) increased: E.coli 0111:B4 (25X), LPS-EB (10X), E.coli K12 (44X), E.coli 055.B5 (8X), S.Minnesota (99X), S.typhosa (18X) and P.gingivitis (6X). All strains induced IL-8 and MCP-1 except for E.coli 055.B5 (no IL-8) and P.gingivitis (no IL-8 or MCP-1). Both TLR4 antagonists blocked LPS induced production of IL-6, IL-8, and MCP-1 in a dose dependent manner. IC_{50} values for both inhibitors (EX00076824: 30-60nM; FHAN_2014062: 800-2700ng/ml) were consistent across LPS strains and analyte detected.

Conclusions: In this study we demonstrate that LPS-stimulated release of inflammatory mediators in HMC is strain dependent, and can be blocked using TLR4 antagonists. These data highlight the importance of identifying the most effective LPS strain in a cell type of interest, prior to initiating pharmacology studies.

Effect of Angiotensin II Type 1 Receptor Blocker on 12-Lipoxygenase Activity and Slit Diaphragm Protein Nephrin and P-Cadherin Expression in Type 2 Diabetic Rat Glomeruli

Wan-ning Wang, Yuanyuan Zhang, Hongzhao Xu, Fu-zhe Ma, Tao Sun, Hang Yuan, Mindan Sun, Zhong-gao Xu. *Nephrology, The First Hospital of Jilin Univ, Changchun, Jilin, China.*

Background: 12-lipoxygenase (12-LO) and angiotensin II(Ang II) interaction plays an important role in the development of diabetic nephropathy (DN), in which proteinuria was thought to be associated with decreased expression of glomerular slit diaphragm protein nephrin and P-cadherin. However, it is unclear whether Ang II type 1 receptor blocker (ARB) regulates 12-LO activity and slit diaphragm protein expression in type 2 diabetic rat glomeruli and hence was investigated in this study.

Methods: Podocytes and glomeruli isolated from rats were used in this study. The 12-LO product 12(S)-HETE and Ang II wereinfused to rats by osmotic mini-pump. Rats fed high fat diet received low dose streptozotocin to make type 2 diabetes. Glomeruli were isolated with sieving method and classified into small glomeruli (SG, on the 75mm sieve) and large glomeruli (LG, on the 125mm sieve). ELISA, RT-PCR and Western blot for related targets were performed respectively.

Results: Ang II increased 12(S)-HETE levels in podocytes and glomeruli. Direct infusion of rats with 12(S)-HETE and Ang II significantly decreased LG nephrin, but increased SG nephrin expression compared to control. The glomerular P-cadherin expression was reduced after Ang II and 12(S)-HETE treatment and there was no difference between LG and SG. ARB did not affect blood glucose levels but completely attenuated increases in 12(S)-HETE content, AT1 expression and proteinuria induced by diabetes. Nephrin protein expression was significantly reduced in diabetic LG but increased in diabetic SG compared to control. P-cadherin expression was decreased in both diabetic LG and SG. These abnormalities were partially but significantly prevented by ARB treatment.

Conclusions: ARB could amelioratethe progression of DN via upregulation of glomerular nephrin and P-cadherin expression through inhibition of 12-LO activation in type 2 DN rat.

APOL1 Risk Variants and HIV Stimulate Induction of PDGF-β Receptor in Podocytes

Xiqian Lan,[1] Hongxiu Wen,[1] Ashwani Malhotra,[1] Karl Leon Skorecki,[1] Pravin C. Singhal.[1] *[1]Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY; [2]Medicine, Rambam Health Care Campus, Haifa, Israel.*

Background: Clinical reports demonstrated that two coding sequence variants (G1 and G2) in the APOL1 gene are responsible for the higher percentage of kidney disease in African Americans. This disparity between patients with APOL1 variants versus wild type APOL1 increases by 10 fold for the development of HIVAN in patients of HIV infection who are not on antiviral therapy. Podocytes do not express platelet-derived growth factor (PDGF) receptors constitutively. Nonetheless, in experimental animal models, podocyte

upregulated expression of PDGFs manifested as progressive glomerulonephritis. We hypothesized that APOL1 risk variants and HIV carry potential for the induction of the activation of the PDGF pathway in podocytes.

Methods: To determine the effect of APOL1 and APOL1 variants expression, stably expressing Vector, APOL1G0, APL1G1, or APOL1G2 human podocyte (HP) cell lines were developed. To evaluate the effect of HIV expression, pseudo type HIV (NL4-3) or empty vector (control) virus was transduced into APOL1G0/HPs, APOL1G1/HPs and APOL1G2/HPs. After 48 h, RNAs were extracted. cDNAs were amplified with specific primers for PDGF-A, PDGF-B, PDGF-C, PDGF-D, and PDGFRβ.

Results: HIV transduction significantly increased the expression of PDGF-A, PDGF-B, PDGF-C, PDGF-D, and PDGFRβ in podocytes.G0/HPs, G1/HPs, and G2/HPs with or without HIV transduction did not display any change in the expression of PDGF-B, PDGF-C, or PDGF-D, when compared with vector; whereas, G2/HPs in HIV milieu displayed enhanced expression of PDGF-A. Interestingly, both G1/HPs and G2/HPs displayed 10 fold increase in PDGFRβ expression when compared to vector/HPs or G0/HPs.

Conclusions: These findings indicate that PDGFs and their receptor PDGFRβ can be induced by HIV and APOL1 risk variants. The present study could lead to new therapeutic targets for HIVAN.

Assessment of Urinary Liver Type Fatty Acid Binding Protein in Patients of Type 2 Diabetes Mellitus with Early Chronic Kidney Disease
Om Prakash Kalra,[1] Mohit Garg,[1] Ashok Kumar Tripathi,[2] Sunil Agarwal.[1] *[1]Medicine, UCMS & GTB Hospital, Delhi, India; [2]Biochemistry, UCMS & GTB Hospital, Delhi, India.*

Background: Diabetes mellitus is the most common cause of chronic kidney disease (CKD) worldwide. Various markers are being indentified which can detect nephropathy at an earlier stage. Both glomerular and tubular injury play an important role in etiopathogenesis of diabetic nephropathy (DN) and tubular damage preceeds glomerular damage. Tubular markers like urinary neutrophil-gelatin associated lipocalin, urinary liver-type fatty acid binding protein (L-FABP) and kidney injury molecule-1 are newer markers for early kidney injury. In the present study, we assessed the role of urinary L-FABP as a tubular injury marker in DN.

Methods: This was a case control, cross sectional study. Eighty four subjects in the age group 30–60 years of either sex were taken and were divided into three groups: Group I: Healthy controls (n=28) Group II: Type 2 diabetes patients with normoalbuminuria (n=28) Group III: Type 2 diabetes patients with micro/macroalbuminuria (n=28). Detailed history, physical examination, liver and kidney function tests, urine albumin creatinine ratio (ACR) was done. Urinary L-FABP was measured by ELISA (CMIC, Tokyo).

Results: The urinary ACR levels were comparable in group I and II. Subjects in Group III had significantly elevated ACR values. Levels of urinary L-FABP were higher in subjects of group II and III when compared with group I. Values of L-FABP were also higher in group III compared to group II. There was a significant positive correlation found between urinary ACR and urinary L-FABP levels. A significant negative correlation was found between urinary L-FABP and eGFR.

Conclusions: Levels of urinary L-FABP are markedly increased in patients of diabetic nephropathy as compared to healthy controls. Levels were also increased in diabetes patients with normoalbuminuria suggesting early tubular injury in these patients. This suggests that urinary L-FABP may be a promising early marker for detection of diabetic nephropathy.

Neuropilin1 Regulates Pericyte Behavior in Postnatal Kidney
Monika Lucyna Wnuk, Regula Buergy, Werner A. Graber, Valentin Djonov. *Inst of Anatomy, Univ of Bern, Bern, Switzerland.*

Background: Neuropilin1 (Nrp1) is a transmembrane co-receptor implicated in the regulation of endothelial cell migration during angiogenesis. In the adult kidney, Nrp1 is however expressed not only by endothelium but also by pericytes including peritubular pericytes and mesangial cells.

Methods: In order to precisely address the role of Nrp1 in postnatal kidney, two complementary mouse models were used; in the first one, Nrp1 was deleted specifically in pericytes with tamoxifen-inducible NG2Cre line and in the second approach, Nrp1 was blocked with neutralizing antibody (Genentech). In both models, tamoxifen/antibody treatment started at P21.

Results: Mutant mice showed mild proteinuria and/or hematuria at 3 months of age with Nrp1 excision efficiency being around 30% based on colocalization level between Nrp1 and PDGFRb. Kidney histology revealed that it was primarily glomerular basement membrane (GBM) that was affected; mutant mice presented thickened, folded GBM with relatively intact podocyte foot process and endothelial fenestrations. The expression of genes encoding GBM proteins was examined and the deregulation of nidogen1 could be confirmed on protein level. Mutant mice showed additionally dilated capillaries with increased glomerular capillary surface area. Interestingly, these mice had also a tendency for fewer renin stained glomeruli as compared to Cre- controls. Furthermore, mutants had more BrdU-positive interstitial cells. Consistently, mice treated with anti-Nrp1 neutralizing antibody showed hematuria, mild mesangial expansion and GBM abnormalities including nidogen1 deregulation. Interestingly, in both models, male but not female mice were primarily affected. In vitro experiments with primary mesangial human and mouse cell lines showed increased cell proliferation, abnormal spreading and actin reorganization in Nrp1 knock down cells.

Conclusions: This study shows a novel role of Nrp1 in adult kidney pericytes. Future experiments with kidney challange models and measurement of blood pressure will help to further clarify these interesting findings.

Funding: Government Support - Non-U.S.

Development of a Spontaneous, Reproducible and Treatable Kidney Fibrosis Model
Jessica Marie Overstreet, Ming-Zhi Zhang, Raymond C. Harris. *Medicine, Vanderbilt Univ, Nashville, TN.*

Background: Kidney fibrosis in chronic kidney diseases causes gradual loss of kidney functionality. Currently, only a few kidney fibrotic models are available. New kidney fibrotic models are needed. Since our previous studies indicated that activation of epidermal growth factor receptor (EGFR) contributes to the development of renal fibrosis, we have developed a model with selective overactivation of proximal tubule EGFR.

Methods: B6D2 transgenic mice with selective overexpression of an EGFR ligand, human heparin-binding EGF (hHB-EGF) in renal proximal tubule, were generated. Male C57/BL6 homozygous hHB-EGF mice received vehicle (water) or erlotinib (80 mg/kg/day) by daily gastric gavage from 4 to 14 weeks of age.

Results: Kidney cortical hHB-EGF mRNA and protein levels were dramatically higher in homozygous hHB-EGF mice than in heterozygous mice. Profound renal interstitial fibrosis was found in both B6D2 and C57/BL6 homozygous hHB-EGF mice, but not in heterozygous mice, as indicated by histology and increased levels of the pro-fibrotic and fibrotic components (CTGF, α-SMA, collagen I and IV). Homozygous hHB-EGF mouse kidneys also exhibited increased oxidative stress and infiltration of both macrophages and T-lymphocytes. Interstitial fibrosis appeared as early as 4 weeks old. Homozygous hHB-EGF mice had increased kidney EGFR activation (increased phosphorylation of EGFR) and activation of downstream signaling, p-ERK and p-AKT. In addition, there was markedly increased p-Smad 2/3. p-EGFR, p-ERK, and p-Smad 2/3 were all primarily localized to proximal epithelial cells, indicating that hHB-EGF-mediated EGFR activation in proximal epithelial cells is the primary event in the development of interstitial fibrosis. Treatment with erlotinib, an inhibitor of EGFR tyrosine kinase activity, inhibited EGFR signaling pathways and attenuated the development of renal interstitial fibrosis.

Conclusions: These studies suggest that ligand-mediated EGFR activation in renal proximal tubule epithelial cells leads to spontaneous, reproducible, and treatable renal interstitial fibrosis. Therefore, homozygous HB-EGF mice may be a useful renal fibrosis model to test the effectiveness of anti-fibrotic agents.

LPA-LPA$_1$ Signaling Regulates Fibroblast Proliferation and Myofibroblast Differentiation Dependent on Epithelial Cell-Fibroblast Interaction
Norihiko Sakai, Yasutaka Kamikawa, Akihiro Sagara, Yasuyuki Shinozaki, Shinji Kitajima, Akinori Hara, Yasunori Iwata, Miho Shimizu, Kengo Furuichi, Takashi Wada. *Div of Nephrology, Kanazawa Univ, Kanazawa, Japan.*

Background: Renal fibrosis is a common pathway of progressive renal diseases, resulting in renal failure regardless of its cause. The accumulation of fibroblasts and myofibroblasts has been recognized as a hallmark of renal fibrosis. However, the precise mechanisms driving it remain to be determined. We have previously found the lipid mediator lysophosphatidic acid (LPA) and one of its receptors, LPA$_1$, stimulates peritoneal mesothelial cells to induce fibroblast proliferation through connective tissue growth factor (CTGF) production, suggesting the involvement of epithelial cell-fibroblast interaction regulated by LPA-LPA$_1$ signaling in the pathogenesis of organ fibrosis.

Methods: In this study, we focused on the effects of LPA-LPA$_1$ signaling on the interaction between renal tubular epithelial cells (RTEC) and renal fibroblasts (RFB).

Results: The stimulation with LPA induced CTGF expression in both RTEC and RFB in a time- and dose-dependent manner. The induction of CTGF in both cells was suppressed by the treatment with LPA$_1$ antagonist (AM095). In addition to that, LPA-induced CTGF expression in both cells was diminished by the treatment with Rho inhibitor (C3 toxin) and Rho kinase inhibitor (Y27632). In both cells, LPA enhanced the nuclear translocation of myocardin-related transcription factor (MRTF)-A/B and the transcriptional activity of MRTF-serum response factor (SRF), whereas Y27632 treatment inhibited those. The inhibition of MRTF-A/B-SRF pathway by the treatment with siRNA or a chemical inhibitor suppressed CTGF expression in response to LPA. Finally, CTGF derived from RTEC or RFB enhanced the proliferation of RFB and the expression of alpha smooth muscle actin in RFB.

Conclusions: In conclusion, LPA-LPA$_1$ signaling regulates epithelial cell-fibroblast interaction to induce fibroblast proliferation and differentiation into myofibroblasts through CTGF production dependent on Rho/Rho kinase/MRTF/SRF pathway.

TWEAK/Fn14 Signaling Promotes Kidney Disease by Driving Myofibroblast Activation, Inflammation and Vascular Instability
Ivan G. Gomez,[1] Allie M. Roach,[1] Gamze Karaca,[1] Linda Burkly,[1] Jeremy Stuart Duffield.[1] *[1]Research & Development, Biogen, Cambridge, MA; [2]Medicine, Univ of Washington, Seattle, WA.*

Background: We identified Fibroblast growth factor-inducible 14 (Fn14) as a receptor on pericytes, which is strongly upregulated as they differentiate into myofibroblasts *in vivo* in kidney disease. TNF-related weak inducer of apoptosis (TWEAK), a TNF-family

cytokine produced predominantly by myeloid leukocytes has been reported to activate NFκB signaling via Fn14. We discovered that NFκB signaling was activated in myofibroblasts *in vivo* and hypothesized that TWEAK/Fn14 signaling might be an important driver of pathological myofibroblasts in kidney disease.

Results: Fn14 deficiency ameliorates myofibroblast appearance, fibrosis and microvascular injury in the UUO model. TWEAK activates primary murine cultured kidney pericytes through Fn14, inducing proliferation, migration, myofibroblast differentiation and production of pro-inflammatory mediators. In addition, TWEAK/Fn14 signaling further activates established pathological myofibroblast cultures. Transcriptional profiling of TWEAK-stimulated myofibroblasts supports its multifaceted role and has identified TWEAK-response genes, including inflammatory, matrix pathways and vascular destabilizing pathways. TWEAK stimulates non-canonical NFκB pathway, an interferon response, as well as ERK signaling in myofibroblasts.Non-canonical NFκB downstream signaling plays a vital role in myofibroblast responses to TWEAK. The importance of TWEAK signaling in disease progression was evaluated in the mouse Alport model of chronic kidney disease. Anti-TWEAK antibodies preserve organ function and significantly attenuate disease progression.

Conclusions: These findings suggest that targeting the TNF superfamily TWEAK/Fn14 pathway is an approach to modulate myofibroblast activation and a novel way to block both inflammatory and fibrotic aspects of chronic kidney disease.

SA-PO331

Deregulation of Hippo-TAZ Pathway During Renal Injury Promotes Fibrotic Phenotype Rohan Samarakoon,[1] Lucas Falke,[2] Roel Goldschmeding,[2] Paul J. Higgins.[1] *[1]Center for Cell Biology and Cancer Research, Albany Medical Center, Albany, NY; [2]Dept of Pathology, Univ Medical Center Utrecht, Utrecht, Netherlands.*

Background: Hippo pathway is the principal regulator of organ size. Transcriptional co-activator with PDZ-binding motif (TAZ), a nuclear transducer of Hippo pathway, is activated by loss of cellular polarity, tensional forces and soluble factors. TAZ has been implicated in the progression of lung fibrosis and cancer. However, role of Hippo-TAZ pathway in chronic kidney disease (CKD) is unknown.

Methods: We utilized three mouse models of renal injury [ureteral ligation (UUO), aristolochic acid nephropathy (AAN), streptozotocin (STZ)-driven diabetic nephropahty] and TAZ genetic manipulation in HK-2 tubular epithelial cells and NRK-49F renal fibroblasts to investigate role of TAZ in renal fibrosis.

Results: TAZ is activated [as evident by increased nuclear accumulation (4-fold) and expression (2.5-fold) at both in the tubular and interstitial cells and decreased TAZ^{Ser89} phosphorylation] in the UUO kidney compared to contralateral controls. TAZ expression is also upregulated in AAN and streptozotocin (STZ)-induced renal diabetic injury models. TAZ activation correlated with increased pSMAD3 in the fibrotic kidney. TGF-beta1 and Angiotensin II stimulation, moreover, promoted TAZ and pSMAD3 nuclear entry in HK-2 cells suggesting that these cytokines likely disable core Hippo signaling. TAZ stable gene silencing in HK-2 cells, indeed, suppressed TGF-beta1 and Angiotensin II induced CTGF, PAI-1 and fibronectin expression. Stable TAZ overexpression in HK-2 cells promoted epithelial dedifferentiation and proliferative arrest.

Conclusions: Activated during renal injury, TAZ is a novel profibotic effector of TGF-beta1 and Angiotensin II induced phenotypic responses. TAZ nuclear accumulation in response to TGF-beta1 and Angiotensin II is suggestive of cross-talk among Hippo pathway and these cytokines.

Design and Characterisation of Novel BMP Agonists and Antagonists Daniel Crean, Satnam Surae, Finian Martin, Catherine Godson. *UCD; UCD; UCD.*

Background: We have previously reported a role for the Bone Morphogenetic Protein [BMP] antagonist Gremlin as a driver of diabetic nephropathy and fibrosis in both kidney and lung. Bone Morphogenetic Proteins are integral regulators of bone and organ development. BMPs are secreted proteins and signal by associating with membrane bound receptors. The activity of BMP agonists is modulated by a family of secreted protein antagonists, including Noggin, Crossveinless-2 and Gremlin that limit BMP-receptor association by binding to the ligand and thereby inhibiting receptor binding.

Methods: We have analysed BMP-receptor and BMP-antagonist interactions using a newly designed automated pipeline, Protein Complex Tool (PCT). Co-crystal structures of the BMP-BMP receptor and the BMP-antagonist complexes were submitted to PCT and in silico alanine substitution scans were performed to calculate the free energy contribution of each BMP-2, or BMP-7, residue to the stability of the complexes with receptors, BMPRIa (BMP-2 only) and ActRIIa, and antagonists, Crossveinless-2 (BMP-2 only) and Noggin (BMP-7 only).

Results: The free energy calculations identified the key contributions of BMP residues to both binding events and suggested mutations that might generate super-agonist and dominant negative molecules. Further in silico analysis was performed by mutating each residue to each of the other 19 amino acids. From this we identified potential super-agonist and dominant negative mutations for both BMP-2: L51V and N102T (super-agonists) and S88G and L92D (dominant negatives), and BMP-7: E60T, D119I, I124A and K127E (super-agonists) and F117E and V122D (dominant negatives). The super-agonists will bind and activate receptor but will be resistant to binding by antagonist; in contrast, the dominant negatives, bind antagonist but not receptor.

Conclusions: Data will be presented from our investigations of these molecules as potential therapeutic leads for treating fibrotic diseases including DN.

Funding: Pharmaceutical Company Support - ROCHE

SA-PO333

Engineered Growth Factors to Treat Acute Kidney Injury Shawdee Eshghi, Kris Kuchenbecker, Tim Stowe, Matt Onsum. *Silver Creek Pharmaceuticals, San Francisco, CA.*

Background: Acute kidney injury remains a major unmet medical need and economic burden. Currently there are no therapies that act directly on damaged kidney cells to promote survival. At Silver Creek Pharmaceuticals, we are engineering a new class of therapeutics called Smart Growth Factors that act selectively on damaged kidney cells to safely deliver pro-survival signals and restore kidney function.

Methods: We harness the potent pro-survival and mitogenic signaling of growth factors and engineer more desirable drug-like properties, including extended half-life and cell type-specific targeting. Our first SGF, designed to reduce cardiomyocyte death following acute myocardial infarction, has shown positive pre-clinical efficacy and is being prepared for an Investigational New Drug application. We are now designing an SGF to treat acute kidney injury, where apoptosis of proximal tubule cells is a leading mechanism of pathology. We developed an in vitro model of tubule cell apoptosis using hypoxia to screen wild type growth factors for the ability to restore cell viability and promote proliferation. We then used computational models to design SGFs that could maximize pro-survival signaling and targeting in damaged kidney tubule cells.

Results: SGF variants were built, expressed and purified in-house, and screened for their ability to activate prosurvival and proliferative signals selectively in damaged cells using the in vitro hypoxia model. SGFs with favorable rescue ability, selectivity and pharmacokinetics will be tested in a rodent AKI model using bilateral ischemia.

Conclusions: Smart growth factors have the potential to transform the treatment of acute kidney injury, but safely delivering potent pro-survival and mitogenic signals specifically to damaged cells, hopefully leading to better outcomes for this patient population.

SA-PO334

Loss of the Podocyte Glucocorticoid Receptor Exacerbates Proteinuria Julie Goodwin,[1] Xuefei Tian,[2] Shuta Ishibe.[2] *[1]Pediatrics, Yale Univ School of Medicine, New Haven, CT; [2]Internal Medicine, Yale Univ School of Medicine, New Haven, CT.*

Background: Nephrotic syndrome is one of the most common renal diseases in children and podocyte foot process effacement is its histologic hallmark. Glucocorticoids (GC) are the mainstay of treatment. Podocytes express the glucocorticoid receptor (GR) and new evidence suggests that podocyte-specific GC effects may be central to controlling proteinuria.

Methods: Mice with knockout of GR in podocytes were generated by crossing GR fl/fl mice with podocin Cre mice. Proteinuria was induced using both a systemic stimulus (LPS) and a renal-specific insult (nephrotoxic serum (NTS)). Urine protein/creatinine ratios, serum albumin and GBM morphology were assessed in both controls and knockout animals. In vitro, wound healing assays and analysis of stress fiber formation after stimulation with LPS in the presence or absence of dexamethasone (DEX) were performed in primary podocytes isolated from animals of both genotypes.

Results: Podocyte GR knockout mice did not have a phenotype at baseline. Their weight, serum creatinine, serum albumin, urine protein/creatinine ratios and foot process diameter were similar to controls. When challenged with low-dose LPS (12.5 mg/kg, IP), knockout mice developed significantly more proteinuria (2.11 ± 0.77 vs. 0.60 ± 0.21, $p<0.05$, n=5/group) than did controls. Knockout mice also showed greater foot process effacement by EM after LPS (855 ± 157 nm vs. 466 ± 8 nm, $p<0.05$, n=5/group) compared to controls. When mice were treated with NTS, similar results were noted. In vitro, GR knockout podocytes showed fewer and more disorganized stress fiber formation and impaired wound healing after LPS treatment compared to control podocytes. Administration of DEX could rescue the in vitro phenotype in control, but not GR knockout, podocytes.

Conclusions: These results demonstrate that (1) loss of podocyte GR exacerbates proteinuria in two different models in vivo, (2) podocytes lacking GR are more intolerant to injury, and (3) DEX administration ameliorates cellular injury in control, but not GR-deficient, podocytes. We conclude that podocyte GR plays a key role in maintaining the integrity of the slit diaphragm after injury.

Funding: NIDDK Support

SA-PO335

Deletion of Inositol-Requiring Enzyme-1α in Podocytes Disrupts Glomerular Capillary Integrity and Autophagy Daniel Robert Kaufman,[1] Joan Papillon,[2] Takao Iwawaki,[3] Andrey V. Cybulsky.[1,2] *[1]Physiology, McGill Univ, Montreal, QC, Canada; [2]Medicine, McGill Univ, Montreal, QC, Canada; [3]Medicine, Gunma Univ, Maebashi, Japan.*

Background: Inositol-requiring enzyme-1α (IRE1α) is an endoplasmic reticulum (ER)-transmembrane endoribonuclease-kinase, which plays an essential function in extraembryonic tissues during normal development, and is activated during ER stress. IRE1α may be involved in upregulating genes associated with the unfolded protein response and

ER-associated degradation, as well as in the activation of c-Jun N-terminal kinase (JNK)-1, and induction of apoptosis and autophagy. In this study, we address the functional role of IRE1α in podocytes.

Methods: Podocyte-specific IRE1α knockout (KO) mice were produced by breeding mice with loxP sites surrounding exons 20-21 with podocin (NPHS2)-Cre mice. LoxP-mediated excision in glomeruli was confirmed with PCR.

Results: In male mice, deletion of IRE1α in podocytes resulted in albuminuria beginning at 5 months of age, and worsening with time. Electron microscopy revealed focal podocyte foot process effacement in 9 month old male KO mice, as well as microvillous transformation of podocyte plasma membranes and cytosolic vacuolation. By light microscopy, glomerular cross-sectional area (an indicator of hypertrophy) was greater in KO males, compared with control, and capillary lumens occupied a higher fractional area of KO glomeruli, suggesting formation of aneurysms. By immunofluorescence microscopy, WT1-positive cells per glomerulus were comparable in KO and control males. Immunoblotting showed reduced LC3B-2 expression and JNK-1 phosphorylation in KO glomeruli, in keeping with reduced autophagy. There was also a reduction in nephrin maturation in KO glomeruli, suggesting impaired ER function. Finally, expression of IRE1α or IRE1α K599A (dominant inhibitor) in cultured COS-1 kidney cells did not affect ERAD, as monitored by the degradation of the CD3Δ ERAD reporter.

Conclusions: Podocyte-specific deletion of IRE1α leads to albuminuria and morphologic evidence of podocyte injury. Thus, IRE1α is essential to the maintenance of podocyte integrity as mice age. The mechanism may, at least in part, relate to disruption of autophagy in podocytes.

Consistent Downregulation of Autophagy Gene Atg12 Through MicroRNA-192 in Diabetic Nephropathy

Supriya Deshpande,[1] Mitsuo Kato,[1] Mei Wang,[1] Rama Natarajan.[1] *[1]City of Hope; [2]City of Hope; [3]City of Hope.*

Background: Autophagy (Atg) plays a key role in the pathogenesis of kidney diseases, however its role in Diabetic Nephropathy (DN), and particularly in mesangial cells (MC) is not clear. TGF-b1, a key player in the pathogenesis of DN, regulates expression of various microRNAs (miRs) including miR-192. Also, several miRs regulate expression of various Atg genes. We hypothesized that miR-192 plays an important role in Atg regulation in DN.

Methods: Atg gene expression was analyzed in type-2 diabetic *(db/db)* and in STZ-injected type-1 diabetic mice. To analyze the role of miR-192 in Atg regulation, STZ-injected mice were treated with control locked-nucleic-acid (LNA) oligonucleotides (oligos) or LNA oligos targeting miR-192 (anti-miR-192-LNA), and Atg gene expression was analyzed in kidneys. Atg gene expression was also analyzed in kidneys of WT and STZ-injected miR-192 knock-out (KO) mice. The effect of TGF-b1 on Atg gene expression and GFP-RFP-LC3 puncta formation was analyzed using mouse MC (MMC).

Results: Expression of several Atg genes was decreased in kidneys of type-1 and type-2 diabetic mice compared to controls. Treatment with LNA-anti-miR-192 reversed the effect of diabetes on some of the Atg genes. Further, Atg gene expression was not affected in kidneys of diabetic miR-192-KO mice compared to controls. *In vitro* studies using MMC treated with TGF-β also showed a decrease in Atg gene expression compared to control. Transfection of MMC with miR-192 mimic oligos decreased expression of certain Atg genes. In addition, transfection of MMC with a GFP-RFP-LC3 plasmid decreased the average number of RFP-LC3 puncta/cell following TGF-β treatment, and this effect was reversed in MMC from miR-192-KO mice. Of all Atg genes analyzed, Atg12 expression was consistently decreased in these mouse models, and its decrease was reversed by anti-miR-192 LNA oligos as well as in miR-192-KO mice.

Conclusions: These results demonstrate that consistent downregulation of Atg12 through miR-192 contributes to an overall decrease in autophagy and subsequent increase in cellular hypertrophy in response to TGF-b1 in MC and in glomeruli of diabetic mice leading to DN.

SA-PO337

mTOR Dependent Regulation of the Podocyte Metabolic Profile

Tillmann Bork, Wei Liang, Tobias B. Huber. *Renal Div, Univ Hospital Freiburg, Freiburg, Baden-Wuerttemberg, Germany.*

Background: Podocytes play a critical role in the formation and maintenance of the kidney filtration barrier. Previously we have highlighted the role of mTOR signaling as regulator of podocyte adaption, differentiation and size-control. However, the eventual link between podocyte size control and the regulation of podocyte metabolism by mTOR remained elusive.

Methods: Mice models of mTOR hyperactivation (*Tsc1* PcKO) and mTOR loss of function (*Raptor* PcKO) were crossed to a Tomato/eGFP reporter line to efficiently isolate podocytes for primary cell culture studies. Mitochondrial respiration and ATP synthesis were assessed using Seahorse bioanalyzer with specific inhibitors of glycolysis and ß-oxidation.

Results: Lipids are the main source for ATP synthesis due to oxidative phosphorylation in podocytes. Anerobic glycolysis is the dominating pathway to use glucose. Active mTOR signaling pathway massively enhances basal metabolic activity and the capacity for oxidative phosphorylation as well as anaerobic glycolysis.

Conclusions: Podocyte metabolism relies on ß-oxidation of lipids and anerobic glycolysis. mTOR signaling regulates metabolic activity without affecting the preferences for the used metabolic pathways. Targeting the predominant metabolic pathways of podocytes might help to ameliorate diabetic nephropathy or podocyte ageing.

Funding: Government Support - Non-U.S.

Derlin-2 Knockout Mice Unravel an Essential Role for Protein Dislocation in Podocytes

Guohui Ren, Kwi Hye Koh, Jing Li, Changli Wei, Mehmet M. Altintas, Jochen Reiser. *Dept of Medicine, Rush Univ Medical Center, Chicago, IL.*

Background: Protein quality control represents a balance between chaperone-assisted folding and removal of misfolded proteins from the endoplasmic reticulum (ER). Disturbed balance results in ER stress in podocytes that is associated with cellular injury. Derlin-2, a component that nucleates cellular dislocation machinery, has been identified as an important element in skeletal and matrix producing cells.

Methods: Western blot and immunofluorescence staining were used for detection of protein expression. Derlin-2 knockdown or overexpression in podocytes was achieved with transduction of lentivirus containing shRNA or cDNA. Podocyte-specific Derlin-2 knockout mice were generated by crossing Derlin-2-floxed mice with podocin-Cre mice. Autophagy was detected with the conversion of LC3-I to LC3-II. Activation of caspase-12 was measured by cleavage of procaspase-12.

Results: Derlin-2 was expressed in both mouse and human podocytes. Derlin-2 deficiency in podocytes could be compensated for by inositol-requiring enzyme 1 (IRE1) induced autophagy at baseline conditions. However, in situations with induced ER stress owed to adriamycin (ADR) or other compounds, the compensatory response of autophagy was overwhelmed. Meanwhile, caspase-12 mediated apoptosis pathway was activated, and severe cellular injury ensued, leading to heavy proteinuria in podocyte-specific Derlin-2 knockout mice, as compared with wild type C57BL/6J control mice. In contrast, Derlin-2 overexpression in vitro attenuated podocyte injury. Derlin-2 expression was induced in podocytes of patients during focal segmental glomerulosclerosis (FSGS) and diabetic nephropathy (DN) as well as in ADR nephropathy in BALB/cJ mice, streptozotocin (STZ)-induced diabetic mice and BTBR ob/ob DN mice.

Conclusions: Podocytes like osteocytes and chondrocytes emerge from mesenchyme and belong to a group of cells that employ Derlin-2 to guarantee protein quality and minimize ER stress for cellular homeostasis. Overexpression of Derlin-2 may be a mechanism to rescue damaged podocytes. Induction of Derlin-2 expression in vivo may have applications for prevention and therapy of glomerular diseases.

Protein O-GlcNAcylation Is Essential for Normal Podocyte Structure and Function

Shinya Ono,[1] Mako Yasuda,[1] Shinji Kume,[1] Osamu Sekine,[1] Jun Nakazawa,[1] Hisazumi Araki,[1] Masami Kanasaki,[1] Shin-ichi Araki,[1] Daisuke Koya,[2] Masakazu Haneda,[3] Takashi Uzu,[1] Hiroshi Maegawa.[1] *[1]Dept of Medicine, Shiga Univ of Medical Science, Otsu, Shiga, Japan; [2]Div of Diabetology & Endocrinology, Kanazawa Medical Univ, Kahoku-Gun, Ishikawa, Japan; [3]Div of Metabolism and Biosystemic Science, Asahikawa Medical Univ, Asahikawa, Hokkaido, Japan.*

Background: Post-translational modification is essential for normal cell function. The addition of O-linked β-N-acetylglucosamine (O-GlcNAcylation) to proteins is a form of post-translational modification and serves as a nutrient/stress sensor for modulating cell functions. However, little is known about the role of O-GlcNAcylation in podocyte function.

Methods: O-GlcNAc transferase (OGT) is a critical enzyme for O-GlcNAcylation in mammals, and resides on the X chromosome. To examine the physiological role of O-GlcNAcylation in podocytes, we analyzed the renal phenotype of male podocyte-specific *Ogt*-knockout (Podo-OGTKO) mice, which were generated by crossbreeding *Ogt*-floxed mice with podocyte-specific *Cre* mice.

Results: O-GlcNAcylation was immunohistochemically observed in the nuclei of podocytes in wild-type mice, but was completely absent in Podo-OGTKO mice. Podo-OGTKO mice showed normal birth rate and growth up to 32 weeks of age. Proteinuria was first apparent at 8 weeks of age and increased with age up to 32 weeks. Scanning transmission electron microscopy showed disruption of podocyte foot processes in Podo-OGTKO mice after 8 weeks of age. Immunofluorescence showed podocin to have a punctate distribution in Podo-OGTKO podocytes and to be at a reduced level compared with wild-type mice. Furthermore, the numbers of podocytes in 16-week-old Podo-OGTKO mice were significantly decreased compared with wild-type mice. Finally, severe glomerular sclerosis with tubulointerstitial damage was observed in Podo-OGTKO mice at 32 weeks of age.

Conclusions: O-GlcNAcylation of intracellular proteins by OGT is necessary to maintain podocyte numbers and normal foot process structure. Our results provide new insight into podocyte biology.

Identification of Novel Gene Products That Regulate Podocyte Function

Davide Pietro Cina,[1,2] Chengjin Li,[3] Jason Moffat,[4] Susan E. Quaggin.[1,2] *[1]Div of Nephrology, Northwestern Univ, Chicago, IL; [2]Feinberg Cardiovascular Research Inst, Northwestern Univ, Chicago, IL; [3]Tannenbaum-Lunenfeld Research Inst, Mount Sinai Hospital, Torontto, ON, Canada; [4]Donnelly Centre and Banting and Best Dept of Medical Research, Univ of Toronto, Toronto, ON, Canada.*

Background: Podocyte function is linked to the organization of its cytoskeleton and adhesion to the glomerular basement membrane. To identify genes that regulate podocyte function, we designed an *in vitro* genome-wide screen for factors involved in podocyte adhesion to fibronectin, an integrin mediated pathway, or sFLT1/Fc, a heparin sensitive pathway, using a pooled 90000 shRNA library.

Methods: A pool of knockdown podocytes was generated using this library and plated on both substrates for one hour followed by separation of the adherent and floating fractions and deconvolution by illumina sequencing. We developed a stringent method for statistical analysis and 'hit' determination and performed a small-scale validation of this method by interrogating top candidate genes individually. We also performed a larger scale validation using a secondary, focused pooled Cas9 mediated knockout screen.

Results: We identified 121 genes that increased adhesion to fibronectin and 145 genes that increased adhesion to sFLT1/Fc. We also identified 66 genes that decreased adhesion to fibronectin and 106 genes that decreased adhesion to sFLT1/Fc. *DPH1*, *DPH2*, *DPH3* and *DPH4* were in the top ten hits for increased adhesion to both fibronectin and sFLT1/Fc. Stable podocyte knockdown lines for these genes displayed increased adhesion to both substrates. We also generated Cas9 mediated podocyte knockout lines for *DPH1*, *DPH2* and *DPH3,* which displayed increased adhesion and a spreading defect.

Conclusions: We have developed a novel method for identifying genes that regulate podocyte function. Future work will investigate how *DPH1*, *DPH2* and *DPH3* regulate podocyte adhesion, and select novel candidate genes that decrease podocyte adhesion. This unbiased approach will yield a list of genes that broadens our understanding of podocyte physiology and the disease states that perturb this system resulting in kidney disease.

Targeted Deletion of Drp1 in Podocytes Mitigates Mitochondrial Remodeling and Progression of Diabetic Nephropathy Bernard A. Ayanga,[1] Yin Wang,[1] Shawn S. Badal,[1] Farhad R. Danesh.[1,3] *[1]Section of Nephrology, Univ of Texas MD Anderson Cancer Center, Houston, TX; [2]Div of Nephrology, Baylor College of Medicine, Houston, TX; [3]Dept of Pharmacology, Baylor College of Medicine, Houston, TX.*

Background: Diabetic nephropathy (DN) is the most common cause of end-stage kidney disease in the United States. Recent evidence, from our lab and others, suggests that mitochondrial fission may be linked to the pathogenesis of DN and little is known on how mitochondrial fission contributes to the development of DN. Mitochondrial dynamics is regulated by at least three dynamin-related GTPases, including Opa1, mitofusin, and Drp1. Drp1 is an evolutionary conserved protein whose loss results in elongated mitochondria. We have previously reported that Rock1-mediated Drp1 activation leads to increased mitochondrial fragmentation and podocyte apoptosis. We hypothesized that attenuation of Drp1 expression and activity in podocytes may ameliorate features of DN.

Methods: To investigate the role of Drp1 in podocytes, we deployed a genetic and pharmacological approach using a model of Type 2 diabetes (*LepR^{db}*). **First**, we crossed conditional Drp1 (db/m;*Drp1$^{flox/flox}$*) mice with a Podocyte-specific tamoxifen, inducible Cre recombinase to generate diabetic, db/db;Pod-*Drp1$^{f/f}$* mice. **Second**, we employed the Drp1 GTPase activity inhibitor, *Mdivi-1*, to pharmacologically assess the therapeutic potential of targeting Drp1 in diabetic mice.

Results: Both podocyte-specific, *Drp1$^{-/-}$* and pharmacological inhibition of Drp1 by *Mdivi-1* in diabetic mice exhibited significantly attenuated albuminuria, mesangial matrix expansion, increased podocyte numbers, reduced podocyte foot process effacement and attenuated glomerular basement membrane thickening. Ultrastructure analysis revealed significantly elongated mitochondria in *Drp1$^{-/-}$* diabetic mice compared to non-induced diabetic controls. Consistent with our *in vivo* observations, *Mdivi-1* treatment attenuated high glucose induced mitochondrial fission, apoptosis and mitochondrial ROS production in podocytes.

Conclusions: Our Data Suggest that Drp1 as a key regulator of mitochondrial dynamics in podocytes, and point to Drp1 as a potential therapeutic target in DN.

SA-PO342

A Lack of eNOS Leads to Mitochondrial Injury in the Podocytes Shuko Ueda,[1,2] Shota Ozawa,[1,3] Kiyoshi Mori,[1] Katsuhiko Asanuma,[1] Motoko Yanagita,[1,4] Shunya Uchida,[2] Takahiko Nakagawa.[1] *[1]TMK Project, Medical Innovation Center, Kyoto Univ Graduates School of Medicine, Kyoto, Japan; [2]Teikyo Univ School of Medicine, Tokyo, Japan; [3]Pharmacology Research Laboratories II, Mitsubishi Tanabe Pharma Corporation, Saitama, Japan; [4]Nephrology, Kyoto Univ Graduate School of Medicine, Kyoto, Japan.*

Background: Endothelial nitric oxide synthase deficiency was shown to accelerate the progression of glomerular injury in several types of renal disease, but the role of eNOS to podocyte integrity remains unclear.

Methods: In order to examine the role of eNOS in the podocytes, cell morphology and mitochondria were examined by using adult male eNOS knockout mice.

Results: A lack of eNOS caused the glomerular hypertrophy in occasionally accompany with mesangiolysis and glomerular sclerosis. Urinary albumin excretion was also significantly increased in the eNOS knockout mice compared to the wild type mice. Ultrastructural analysis showed that the injured podocytes exhibited the enlarged lysosomes, microvillus formation, pseudocysts and foot process effacement. An increase in oxidative stress was also associated with podocyte injury. With respect to mitochondria, its number was elevated while its size was reduced, suggesting that mitochondrial fragmentation was induced in the podocytes due to eNOS deficiency. While the expressions of several mitochondrial proteins were not altered, the D-17 mutation in mitochondrial DNA was significantly induced in the kidney of eNOSKO mice. Mitochondrial function was also likely impaired by eNOS deficiency as ATP level was significantly reduced in renal cortex of eNOSKO mice. Furthermore, the primary podocytes from eNOSKO mice exhibited the impairment of mitochondrial respiration. Consistently, conditioned medium derived from cultured glomerular endothelial cells lacking NO caused a greater degree of mitochondrial fragmentation and an increase in mitochondrial oxidative stress in the cultured podocytes while such alterations was rescued by an NO donor.

Conclusions: These data suggest that eNOS may be necessary to maintain podocyte integrity, especially mitochondrial function.

SA-PO343

Cytosolic Phospholipase A2 Alpha Regulates G1 Progression Through Modulating Forkhead Box Protein O1 Activity Said Movahedi naini,[1] Gabriel Choukroun,[2] Dirk M. Hentschel,[1] Joseph V. Bonventre.[1] *[1]Brigham and Women Hospital, Renal Division, Boston, MA; [2]Amiens Southern Hospital, Renal Division, Amiens, Picardie, France.*

Background: Mesangial cell (MC) proliferation is characteristic of a number of chronic progressive glomerular diseases. cPLA$_2$α is expressed in MCs and plays a role in cellular proliferation, however the mechanisms involved remain unclear. Here, we show for the first time a novel regulatory role for cPLA$_2$α in the regulation of G1 phase of the cell cycle that is conserved in zebrafish and mammals.

Methods: Mouse embryonic fibroblasts (MEFs) and MCs were derived from *cpla$_2$α-/-* mice. cPLA$_2$α was knocked down in zebrafish using morpholinos (MOs). Cell cycle progression was assessed by flow cytometry in zebrafish larvae and in G$_0$ synchronized cells after stimulation with PDGF. S phase population was assessed in zebrafish and MEFs by BrdU pulse studies. Analysis of the phosphorylation of proteins was carried out by western blot assays using phosphospecific antibodies.

Results: We identified two zebrafish cpla$_2$α genes, termed zcpla$_2$aa and zcpla$_2$ab, with conserved phospholipase activity. In zebrafish and MCs cPLA$_2$α promotes G$_1$ progression via its phospholipase activity and through PGE$_2$ production. PGE$_2$ through the PI3'-K/AKT pathway, promotes FOXO1 phosphorylation and FOXO1 nuclear export. This, in turn, inactivates FOXO1 resulting in upregulation of cyclin D1 and downregulation of p27^{Kip1}, thus promoting G$_1$ progression. These data indicate an evolutionary conserved mechanism between lower vertebrates and mammals. Further, using pharmacological inhibitors, we show that cPLA$_2$α, RAF/MEK/ERK, and PI3'-K/AKT signaling pathways cooperatively regulate G$_1$ progression in response to mitogenic stimulation.

Conclusions: cPLA$_2$α is a critical effector of the G$_1$ phase of the cell cycle through its phospholipase activity. Pharmacological targeting of this enzyme may have important therapeutic benefits in disease mechanisms that involve excessive cell proliferation including progressive acute and chronic glomerulonephritis.

Podocyte Specific Glycogen Synthase Kinase 3 Is Critical for Neonatal Survival and for Renal Function in Maturity Jenny Hurcombe,[1] Abigail Charlotte Lay,[1] Gavin Iain Welsh,[1] Peter W. Mathieson,[1] Satish Patel,[2] Susan E. Quaggin,[3] James R. Woodgett,[2] Richard Coward.[1] *[1]Academic Renal Unit, Univ of Bristol, Bristol, United Kingdom; [2]Samuel Lunenfeld Research Inst, Univ of Toronto, Toronto, ON, Canada; [3]Feinburg School of Medicine, North Western Univ, Chicago, IL.*

Background: GSK3 is a multi-functional serine/threonine kinase existing as two distinct but related isoforms: α and β. Knockout mouse models suggest that the GSK3 isoforms have different and cell type specific functions. This study aims to examine the importance of GSK3 in the podocyte.

Methods: We have used Cre/LoxP technology to generate mice with podocyte-specific ablation of GSK3α and/or GSK3β in development (using the podocin cre driver) and in maturity (using the doxycycline inducible podocin RtTA – tet-o-cre driver).

Results: Mice developmentally lacking either GSK3α or GSK3β specifically in the podocyte are viable with normal life span (up to 2 years) and normal renal histology. In contrast, mice null for both GSK3 isoforms, born at normal Mendelian frequency, die at 10-16 days with massive albuminuria and acidosis. These mice have vacuolated glomeruli and glomerulosclerosis. Knockout of GSK3α and β after full glomerular development, at 4 weeks of age, also results in significant renal disease which develops within 2 weeks of knockdown. It consists of significant albuminuria with renal failure in some mice. Furthermore, there is evidence of a crescentic proliferative glomerulopathy, together with massive fibrosis and glomerulosclerosis. Mechanistically the wnt signalling pathway is up-regulated and β-catenin activated throughout the kidney. Contemporaneous knockdown of β-catenin in the developmental model dramatically improves albuminuria and renal histology but not acidosis or survival indicating the involvement of other pathways. These are currently being investigated through a glomerular transcriptomic approach.

Conclusions: Podocyte specific GSK3 is critical for glomerular and renal function in development and full maturity. Loss of single isoforms can be compensated throughout life but loss of both is catastrophic.

Podocyte Oxidative Stress Coupled with Ubiquitin C-Terminal Hydrolase Deletion Exacerbates Renal Damage Naomi C. Read,[1,2] Chet E. Holterman,[2] Douglas A. Gray,[2] Chris R. Kennedy.[1,2] *[1]Cellular and Molecular Medicine, Univ of Ottawa, Ottawa, ON, Canada; [2]Ottawa Hospital Research Inst, Ottawa, ON, Canada.*

Background: Ubiquitin C-terminal hydrolase L1 (UCHL1) may promote antioxidation by hydrolyzing ubiquitin-thioester bonds on glutathione (GSH) thereby protecting GSH from degradation. Podocyte UCHL1 is upregulated in diseased glomeruli where it may maintain redox balance. *UCHL1*-deleted mice overexpressing podocyte-specific *NOX5* should exhibit exacerbated glomerular damage due to unregulated oxidative stress.

Methods: COS7 cells were infected with AdGFP or AdNOX5 and UCHL1 levels determined by immunoblot. UCHL1 mRNA was quantified by qPCR. *UCHL1*+/- and *NOX5*$^{pod+}$ mice were crossed to generate *NOX5*$^{pod+}$/*UCHL1*-/- mice. Albuminuria (ACR) was measured by ELISA. Renal mass was normalized to tibia length. Glomerular filtration rate (GFR) was assessed by FITC-Inulin. Immunofluorescence with anti-PCNA and anti-renin was performed on renal sections. Blood pressure was determined by tail cuff plethysmography.

Results: UCHL1 protein increased 1.9-fold in COS7 cells infected with AdNOX5 vs. AdGFP-infected controls. Similarly, glomeruli from 12-week-old *NOX5*$^{pod+}$ mice showed limited UCHL1 mRNA induction (1.5-fold). ACR increased in *NOX5*$^{pod+}$/*UCHL1*-/- mice at 12 weeks (40ug/mg) but not in nonTG, *UCHL1*-/- and *NOX5*$^{pod+}$/*UCHL1*-/- mice (24, 28 and 25ug/mg). Renal mass was reduced by 10% in both *UCHL1*-/- and *NOX5*$^{pod+}$/*UCHL1*-/- mice as compared to nonTG mice. Interestingly, GFR was elevated in *NOX5*$^{pod+}$, *UCHL1*-/- and *NOX5*$^{pod+}$/*UCHL1*-/- mice (283, 362 and 352ul/min) vs. nonTG (198ul/min). In *UCHL1*-/- mice regardless of NOX5 expression, hypercellularity was evident in the juxtaglomerular region. However, no differences were found in renin or PCNA expression, suggesting that the increased GFR is independent of the renin-angiotensin system. Blood pressure increased in *NOX5*$^{pod+}$/*UCHL1*-/- mice (121mmHg vs. 113 and 109mmHg for nonTG and *UCHL1*-/- mice), but was not different from *NOX5*$^{pod+}$ mice (127mmHg) at 12 weeks.

Conclusions: *UCHL1*-null mice have altered renal function and mass. When intercrossed with *NOX5*$^{pod+}$ mice, *UCHL1* deletion combined with unchecked oxidative stress promotes filtration barrier damage.

Apolipoprotein L1 Has Diverse RNA and Protein Isoforms and APOL1-B3 Activates Pro-Inflammatory Signaling Hidefumi Wakashiu, Jeffrey B. Kopp. *Kidney Disease Branch, NIDDK, NIH, Bethesda, MD.*

Background: Genetic variants apolipoprotein L1 (APOL1), present in individuals of recent African descent, are strongly associated with glomerular disease, but the molecular mechanisms have not been clarified. APOL1 mRNAs have seven exons, and produce splice variants which are predicted to code for distinct protein isoforms (A, B3 and C). However, it is unknown which isoforms drive glomerular disease.

Methods: We examined mRNA expression by TA cloning and determined protein localization using immunofluorescence (IF) of FLAG-tagged APOL1 in stably transfected cells. Mitochondrial fractions were isolated using a detergent-based method.

Results: Using RNA from human podocytes we cloned a new APOL1 splice variant (B3) that lacks exon 4, which contains the signal sequence of APOL1. APOL1-B3 was specifically recognized by APOL1-B antibody raised in rabbits immunized to exon 2. APOL1-B3 was absent from human serum, but was present in podocytes. Both endogenous and transfected APOL1-B3 partially co-localized with mitochondria in IF study and were detected in mitochondrial fractions by Western blot using either anti-FLAG antibody and APOL1-B antibody. By immunoprecipitation, APOL1-B3 was associated with NLRP12, which is a regulator of pro-inflammatory signaling. IL-1 receptor signaling was enhanced in APOL1-B3 stably transfected HeLa cells, and over-expressed NLRP12 overcame the enhancement of IL-1 receptor signaling by APOL1-B3.

Conclusions: APOL1 mRNA splicing produces multiple protein isoforms including A, B3 and C. APOL1-B3 was associated with NLRP12 and enhanced IL-1 receptor signaling. APOL1 nephropathies may be driven by podocyte inflammation and the TLR and IL-1 receptor signaling pathways may be therapeutic targets.

TNFα Mediated NFAT Activation Causes Podocyte Cholesterol Accumulation in FSGS Christopher E. Pedigo,[1,2] Farah Leclercq,[1,2] Matthias Kretzler,[3] Sebastian Martini,[3] Alla Mitrofanova,[1,2,4] Ximena A. Morales,[1,2] Christian Faul,[1,2] Alexis J. Sloan,[1,2] George William Burke,[4] Alessia Fornoni,[1,2] Sandra M. Merscher.[1,2] *[1]Nephrology, U of Miami; [2]Katz Drug Discovery Center, U of Miami; [3]U of Michigan; [4]Surgery, U of Miami.*

Background: Focal Segmental Glomerulosclerosis (FSGS) is the most common cause of glomerulonephritis in the US and podocyte injury is associated with the development of albuminuria. Tumor Necrosis Factor alpha (TNFα) levels are increased in a subset of patients with FSGS and TNFα alters ATP-Binding Cassette A1 (ABCA1) expression in association with altered cholesterol homeostasis. Treatment strategies for FSGS patients include cyclosporine A (CsA) which directly influences podocyte Nuclear Factor of Activated T-Cells (NFAT) activation. However a potential link between TNFα-NFAT-ABCA1-Cholesterol has not been established. We hypothesized that TNFα causes NFAT mediated lipid dependent podocyte apoptosis in FSGS.

Methods: Differentiated human podocytes were cultured in the presence of TNFa (100ng/ml). Caspase 3 activity was determined in human podocytes. Cyclodextrin (CD) was utilized to deplete cholesterol.

Results: FSGS sera treated podocytes demonstrated increased TNFα expression. Increased TNFα expression correlated with reduced ABCA1 expression in glomerular biopsies from FSGS patients. TNFα treatment of podocytes increased NFAT promoter luciferase activity and RCAN1 mRNA expression. Inhibition with CsA an upstream activator of NFAT prevented downregulation of ABCA1 and increased Caspase 3 activity. TNFα administration in mice caused glomerular NFAT activation and albuminuria that was prevented by CsA. Mice overexpressing podocyte specific constitutively active NFAT developed albuminuria and kidney cholesterol accumulation that was prevented by cholesterol depletion with CD.

Conclusions: TNFα expression is increased in glomeruli of patients with FSGS and in podocytes treated with sera from patients with FSGS. TNFα treatment of human podocytes causes NFAT activation leading to reduced ABCA1 expression and cholesterol accumulation in association with podocyte apoptosis. Our data suggest that treatments targeting the TNFα-NFAT-ABCA1-cholesterol axis may prevent podocyte injury in FSGS.

SA-PO348

Insulin Receptor Isoform A Is Implicated in Podocyte Injury in Diabetic Kidney Disease Alla Mitrofanova,[1,2] Ximena A. Morales,[1] Mayrin Correa-Medina,[1] Christopher E. Pedigo,[1] Farah Leclercq,[1] George William Burke,[2] Sandra M. Merscher,[1] Alessia Fornoni.[1] *[1]Katz Family Drug Discovery Center, Div of Nephrology & Hypertension, Univ of Miami, FL; [2]Dept of Surgery, Univ of Miami, FL.*

Background: Disruption of physiological insulin signaling occurs in podocytes in experimental diabetic kidney disease (DKD). Two isoforms of insulin receptor (IR) have been described that either lack (IRA) or contain (IRB) the 12 amino acids encoded by exon 11. IRA signals primarily through p70S6 kinase and IRB signals primarily through AKT. Podocytes are dependent on functional lipid rafts and associated protein caveolin-1 (Cav1) for proper signaling and survival. We have recently shown sphingomyelin-phosphodiesterase-acid-like-3b (SMPDL3b), which regulates the activity of acid-sphingomyelinase in podocyte lipid rafts, is upregulated in DKD and may contribute to podocyte injury. We tested the hypothesis that SMPDL3b overexpression suppresses IRB signaling and facilitates IRA signaling leading to podocyte hypertrophy and apoptosis.

Methods: Podocytes were treated with insulin (0.1 or 1 nM, 30 min) and samples were used for Western blot analysis. Co-immunoprecipitation experiments (Co-IP) were performed in HEK cells, transfected with 1ug of GFP- or FLAG-SMPDL3b, FLAG-IRA, FLAG-IRB, GFP-Cav1 plasmid. Apoptosis analysis was measured using Caspase-3 Fluorometric Assay kit. Cell surface area was measured by confocal microscopy (OPERA XL).

Results: Podocytes overexpressing SMPDL3b (OE) showed significant increase of IRB/IRA mRNA expression ratio compared to control podocytes (CT) (1.00±0.00 and 0.74±0.05, $p<0.05$). Co-IP demonstrated that both IRA and IRB interact with Cav1. SMPDL3b overexpression augmented IRA/Cav1 interaction and suppressed IRB/Cav1 interaction. OE podocytes showed bigger cell surface area compared to CT (2778.0±246.5 and 2171.0±54.7, $p<0.05$). Insulin stimulation had no effect on the caspase-3 activity in CT podocytes while it induced apoptosis in OE cells (1.19±0.08 and 2.14±0.32, $p<0.05$).

Conclusions: Our data suggest SMPDL3b overexpression in human podocytes impairs IRB signaling leading to increased apoptosis and augments IRA signaling resulting in cell hypertrophy.

Cyclodextrin Improves Renal Function in Experimental Alport Syndrome Ximena A. Morales,[1,2] Alla Mitrofanova,[1,2,3] Christopher E. Pedigo,[1,2] Judith T. Molina David,[1,2] Mayrin Correa-Medina,[1,2] Farah Leclercq,[1,2] Javier T. Varona Santos,[1,2] Gloria Michelle Ducasa,[1,2] Sandra M. Merscher,[1,2] Alessia Fornoni.[1,2] *[1]Div of Nephrology and Hypertension, Dep of Medicine, Univ of Miami, Miami, FL; [2]Peggy and Harold Katz Family Drug Discovery Center, Univ of Miami, Miami, FL; [3]Dep of Surgery, Univ of Miami, Miami, FL.*

Background: Alport syndrome (AS) is an inherited disease caused by gene mutations involved in collagen type IV biosynthesis. No treatments are currently available for AS. 2-hydroxypropyl-β-cyclodextrin (CD) is a cholesterol depleting agent that is now in clinical trials for treating Niemann-Pick disease type C. We have recently reported that CD protects in experimental DKD by reducing cholesterol dependent podocyte damage. We hypothesized that CD improves renal function in an experimental model of AS.

Methods: Collagen Col4a3 knockout (KO) mice were used as a model for AS. Four-week-old Col4a3 (KO) and wild type (WT) female mice were injected subcutaneously with CD (4000 mg/kg) or vehicle (0.9% Saline solution), 3 times per week for 3 weeks. Four groups were analyzed: WT+vehicle (n=4), WT+CD (n=5), KO+vehicle (n=6), and KO+CD (n=4). Body weight and ACR (albumin/creatinine ratio) from urine were determined weekly. Serum creatinine and blood urea nitrogen (BUN) were analyzed by mass spectroscopy and ELISA respectively at treatment initiation and at sacrifice. Perfused kidneys and skin samples at the site of injection were collected for histological analysis (H&E, PAS) and for Oil Red O (ORO) Staining.

Results: H&E staining showed no toxicity at the site of CD injections. No body weight changes were observed during treatment. CD administration reduced glomerular

ORO staining and prevented the development of mesangial expansion in KO+CD group compared to KO+Vehicle. A significant reduction in ACR was observed after 3 weeks of CD treatment in KO+CD compared to KO+Vehicle mice ($p<0.001$), accompanied by a trend in reduced serum creatinine. CD treatment did not affect ACR, renal function or mesangial expansion in WT mice.

Conclusions: Based on these results, we conclude that CD improves renal function in a mouse model for AS and could be a new therapeutic strategy for the treatment of AS patients.

The Glomerular Matrisome in Alport Syndrome Is Altered prior to the Onset of Albuminuria Michael J. Randles,[1,2] Sophie C. Collinson,[1] Jeffrey H. Miner,[3] Rachel Lennon.[1,2] *[1]Wellcome Trust Centre for Cell-Matrix Research, Faculty of Life Sciences, Univ of Manchester, Manchester, United Kingdom; [2]Inst of Human Development, Faculty of Medical & Human Sciences, Univ of Manchester, Manchester, United Kingdom; [3]Renal Div, Washington Univ School of Medicine, St. Louis, MO.*

Background: Alport Syndrome is caused by genetic defects in *COL4A3, COL4A4* or *COL4A5*, but despite this knowledge there are currently no targeted therapies. We aimed to build our basic understanding about the glomerular extracellular matrix (ECM) in Alport syndrome and performed global analysis of composition and ultrastructural imaging in the *Col4a3-/-* mouse.

Methods: Cellular and extracellular matrix (ECM) fractions from wild type and Col4a3-/- glomeruli at 6 and 16 weeks of age were analysed by mass spectrometry (MS) and imaged using serial block face-scanning electron microscopy (SBF-SEM).

Results: MS analysis revealed moderate changes in the composition of glomerular ECM at 6 weeks, even prior to the onset of barrier dysfunction. These included complete absence of type IV collagen a3, α4, α5 and upregulation of type IV collagen a1, a2, α6 and type VI collagen. At 16 weeks more dramatic changes were detected including elevated type IV collagen a1, a2, fibronectin, type I collagen, laminin a2 and fibrinogen chains. Global and pathway analysis of cellular fractions indicated changes in actin regulating proteins at 6 weeks and mitochondrial dysfunction at 16 weeks. SBFSEM demonstrated thickened and irregular glomerular basement membranes with evidence of podocyte protrusions into this ECM.

Conclusions: Our data demonstrate that Alport syndrome progresses with distinct early changes in ECM followed by more profound ECM accumulation, disruption and mitochondrial dysfunction. Enhanced understanding about the pathways that control podocyte cell-matrix adhesion may ultimately inform therapeutic strategies to correct or repair glomerular barrier function in Alport syndrome.

Creation and Analysis of Mouse Models of Human Nephrotic Syndrome Caused by the Laminin b2 (LAMB2) S80R Mutation Steven Daniel Funk, Jeffrey H. Miner. *Renal Div, Washington Univ School of Medicine, St. Louis, MO.*

Background: Most cases of congenital nephrotic syndrome in the first year of life are caused by mutations in 4 genes expressed in podocytes: *NPHS1*, *NPHS2*, *WT1*, and *LAMB2*. *LAMB2* encodes laminin b2, a glomerular basement membrane component critical for glomerular filtration. We previously created transgenic mice using the nephrin promoter to study missense mutations discovered in patients with congenital nephrotic syndrome, including R246Q and C321R, which inhibit laminin-521 secretion and/or induce podocyte ER stress. Here we aimed to characterize a new mutation (S80R) in the LAMB2 polymerization domain that was discovered in a delayed nephrotic syndrome patient; this delay suggests that chronic dysfunction in glomerular filtration may be the pathogenic mechanism.

Methods: In our first approach the S80R mutation was engineered into the rat laminin b2 cDNA and placed under the control of the nephrin promoter; this construct was used to make transgenic mice expressing LAMB2-S80R in podocytes on the *Lamb2-/-* background. In a second approach, we utilized CRISPR/Cas9 and homologous recombination to "knock-in" the S80R point mutation into the endogenous *Lamb2* gene.

Results: Several transgenic mouse lines were characterized as very high, high, and low/mosaic LAMB2-S80R-expressing mouse lines. Surprisingly, high S80R expressers did not exhibit albuminuria up to 1 year of age. The low/mosaic expressers exhibited persistent, low level albuminuria that never progressed into the nephrotic range or overt kidney disease. These observations suggested to us that unregulated transgene expression may compensate for what could be only a mildly pathogenic mutation. We then used CRISPR/Cas9 technology in zygotes to generate LAMB2-S80R knock-in mice that will better mimic endogenous expression of the mutant protein, as in the patient. These are currently being bred for analysis.

Conclusions: The LAMB2-S80R mutation seems to be mild vs. other LAMB2 mutations. S80 is in the laminin N-terminal (LN) domain important for laminin polymer formation. High transgene expression may compensate for S80R-induced polymerization defects, which will be avoided with CRISPR/Cas9-induced, S80R knock-in mutants.

Differential Roles of Cell Surface Proteoglycans in Podocyte-Glomerular Basement Membrane Adhesion Angela C. DiPoto-Brahmbhatt, Deborah J. McCarthy, Kevin J. McCarthy. *Pathology and Translational Pathobiology, LSU Health Sciences Center-Shreveport, Shreveport, LA.*

Background: Cell surface proteoglycans (PG), via their heparan sulfate (HS) chains, work in a cooperative fashion alongside integrins to mediate podocyte (POD)-glomerular basement membrane (GBM) interactions. Results of our previous studies have shown that complete loss of HS at the POD cell surface leads to the development of foot process effacement. Since POD have at least two cell surface HS PG's that are capable of mediating such interactions, the purpose of this study was to determine the effects of selective deletion of the cell surface PG, syndecan-1 (Sdc1) or syndecan-4 (Sdc4) on POD in vivo.

Methods: Frozen tissue sections of kidneys from wild-type (WT), Sdc1, or Sdc4 knockout (KO) mice were immunostained with antibodies against the core proteins of Sdc1 and Sdc4, HS (antibody HS4C3), synaptopodin (SYN), nephrin, and α-actinin-4. To determine the potential for loss of anionic charge associated with HS, 500µm sections of unfixed kidneys were labeled with polyethylenimine (PEI) followed by fixation and processing for transmission electron microscopy.

Results: TEM studies showed that the GBMs of both Sdc1 and 4 KO mice had GBM irregularities, the POD in Sdc4KO mice showing moderate foot process effacement. Immunostaining for HS did not show differences in staining intensity for HS between Sdc1 and Sdc4KO mice. However, PEI labeling showed that the GBMs in Sdc4 KO mice had larger aggregates of PEI than those found in the GBM of Sdc1KO mice. Immunostaining showed that a compensatory increase in Sdc4 expression in Sdc1KO glomeruli or Sdc1 expression in Sdc4KO glomeruli did not occur. The glomeruli of Sdc1 KO mice showed disruption of nephrin organization compared to Sdc4 and WT mice. Immunostaining for α-actinin-4 in both Sdc1KO and Sdc4KO glomeruli was also disrupted compared to control.

Conclusions: The data show that disruption of either Sdc1 or Sdc4 interactions with the GBM does affect the manner by which POD interact with the GBM. Although loss of Sdc4 was associated with the development of foot process effacement, the loss of either Sdc1 or Sdc4 have effects on POD cytoskeletal organization.

ERM Protein Activation by CLIC4 in Glomerular Endothelial Cells Abass Almomany,[1] Mahtab Tavasoli,[1] Laiji Li,[1] John C. Edwards,[2] Barbara J. Ballermann.[1] *[1]Medicine, Univ of Alberta, Edmonton, AB, Canada; [2]Internal Medicine, St. Louis Univ, St. Louis, MO.*

Background: We reported (J. Cell Sci. 2014, 127:5164) that the podocyte-predominant CLIC5A stimulates PI[4,5]P2 production and consequent ERM (ezrin, radixin, moesin) protein phosphorylation (pERM). Activated ERMs link membrane-spanning proteins to cortical actin, and inactive ERMs are unstable. CLIC4, homologous to CLIC5A, is expressed at high levels in glomerular and peritubular capillary endothelial cells (EC), and in proximal tubule brush border and basolateral membranes. CLIC4 deficient mice ($CLIC4^{-/-}$) have fewer glomeruli and a lower peritubular capillary density than wild-type mice (BMC Nephrology 2014, 15:54). Here, we explored whether CLIC4 regulates ERM protein activation, similar to CLIC5A.

Methods: Confocal immunofluorescence (cIF) microscopy was used to visualize CLIC4 and moesin kidney sections. Western blot analysis (WB) was used to study total and cytoskeletal fractions from isolated mouse glomeruli and cultured human glomerular EC cells. In cultured human glomerular EC, CLIC4 was silenced with CLIC4-specific siRNA ± CLIC4 cDNA rescue.

Results: By cIF CLIC4 co-localized exquisitely with moesin in mouse glomerular EC. WB showed that CLIC4 is absent from $CLIC4^{-/-}$ glomerular lysates, and that the ratio of pERM : tubulin is lower in $CLIC4^{-/-}$ than in $CLIC4^{+/+}$ glomeruli (1.28 ± 0.11 vs. 2.26 ± 0.30, respectively, $p < 0.01$, mean ± SD, n=3). Total ERM protein was also reduced, and much less ERM protein was observed in the cytoskeletal fraction of $CLIC4^{-/-}$, compared to $CLIC4^{+/+}$ glomeruli. In cultured human glomerular EC, CLIC4 siRNA reduced CLIC4 protein by >90% and resulted in ERM protein dephosphorylation and dissociation from the cytoskeleton, all rescued by over-expression of CLIC4. CLIC4-induced ERM phosphorylation was abolished by PLC activation with m-3M3FBS, indicating that PI[4,5] P2 dependence.

Conclusions: Hence, CLIC4 co-localizes with moesin in glomerular EC in vivo. Like CLIC5A, CLIC4 promotes ERM phosphorylation in a PI[4,5]P2-dependent fashion. We speculate that defective ERM phosphorylation may be responsible, in part, for the morphological and physiological abnormalities in $CLIC4^{-/-}$ mice.

SA-PO354

Vascular Glycocalyx Syndecan (SDC) 4 Loss Coincides with Albuminuria in Diabetic Nephropathy (DN) Raina D. Ramnath, Amy Russell, Rebecca R. Foster, Gavin Iain Welsh, Andy Salmon, Simon C. Satchell. *Academic Renal Unit, Univ of Bristol, Bristol, United Kingdom.*

Background: The endothelial glycocalyx is a critical determinant of vascular health and a key regulator of vascular permeability. Increasing evidence points to disruption of the endothelial glycocalyx as a contributor to development of albuminuria (albumin in the urine) and eventually DN. TNFα which is important in the development of microvascular disease in diabetes caused a disruption of the glomerular endothelial cells (GEnC)

glycocalyx through shedding of SDC4 and heparan sulphate (HS). We seek to investigate the role of vascular endothelial glycocalyx in DN and determine the mechanisms involved in its disruption in DN.

Methods: DN was induced in DBA2J mice by giving daily intraperitoneal injection of streptozotocin (STZ) at 50mg/kg for 5 days. The mice became hyperglycemic at 2 weeks and significantly albuminuric at 8 weeks post STZ injection.

Results: In DN, SDC4 protein expression was significantly decreased in isolated glomeruli. This was accompanied by a corresponding increase in SDC4 in the circulation and in the urine, suggesting shedding of vascular glycocalyx SDC4. An increase in SDC4 shedding causes a positive feedback mechanism resulting in an increase in SDC4 mRNA synthesis in isolated glomeruli and GEnC. The glycocalyx SDC4 disruption coincides with albuminuria, strongly suggesting that vascular glycocalyx SDC4 damage is likely to contribute to albuminuria in DN. There was a significant elevation in gelatinase matrix metalloproteinase (MMP)2 in glomeruli in DN, suggesting that MMP2 could mediate SDC4 shedding. My in vitro data in human GEnC showed that gelatinase MMP9 was upregulated and resulted in the shedding of SDC4 and HS. This resulted in an increase in BSA permeability across the monolayer.

Conclusions: MMP2,9-mediated shedding of SDC4 is likely to contribute to vascular endothelial glycocalyx disruption and albuminuria observed in DN.Potential therapies targeted at glycocalyx protection will be of benefit not only in DN but also in ameliorating systemic vascular disease in diabetes.

Blood Cell Velocities in Glomerular Capillaries Measured by 2-Photon In Vivo Microscopy Reveal Heterogeneous Blood-Flow Deianira Pedoto,[1,2] Eugenio Gutierrez,[3] Luca Bordoni,[1] Sara Damiano,[2] Francesco Trepiccione,[2] Giovambattista Capasso,[2,4] Sebastian Frische.[1] *[1]Dept of Biomedicine, Aarhus Univ, Aarhus, Denmark; [2]Dept of Cardio-Thoracic and Respiratory Science, Second Univ of Naples, Napoli, Italy; [3]Center for Functionally Integrative Neuroscience, Aarhus Univ, Aarhus, Denmark; [4]Biogem, Ariano Irpino, Italy.*

Background: Theoretical models have shown that the blood-flow within a glomerulus may be heterogeneous and that flow heterogeneity may affect the ultrafiltration coefficient and thus GFR. The aim of this study is to provide experimental data to test these model predictions by measuring glomerular capillary flow velocities by in vivo 2-photon microscopy.

Methods: Male Munich-Wistar rats were intubated, anesthetized with isoflurane, and mechanically ventilated. Blood pressure and heart-rate were monitored. The left kidney was externalized and the rat placed in the 2-photon microscope. Blood plasma was labeled by i.v. injection of 70 kD TexasRed-Dextran. Longitudinal lines in the lumen of capillaries in superficial glomeruli were scanned at a frequency of >700 Hz. The axial movement of single blood cells was measured. 308 different capillaries were analyzed in 17 glomeruli from 5 different rats.

Results: Blood cell velocity was 2.99 μm/ms +/- 0.54. A Gaussian distribution and a Gamma-distribution were fitted to data from 13 glomeruli in which >12 capillaries were studied. C^2-tests (α=0.05) showed 5 of 13 datasets not to follow a Gaussian distribution and 1 of 13 not to follow a Gamma-distribution. The data from all 308 capillaries normalized to the mean of the respective glomerulus did not follow a Gaussian distribution ($P<0.05$). The Gamma-distribution allows an asymmetrical distribution around the mean and provided the best description.

Conclusions: This study provides experimental evidence of heterogeneity and an asymmetric distribution of blood cell velocity in glomerular capillaries. This new experimental evidence calls for refinement of current models of glomerular blood flow heterogeneity and invokes the possibility to investigate the potential regulatory control of the ultrafiltration coefficient by regulation of capillary flow heterogeneity, e.g. by the action of mesangial cells.

Assessment of Exosomes Derived from Mesangial Cells Stimulated with High Glucose Antonio S. Novaes,[1] Fernanda Teixeira Borges,[1] Marcos Dias,[2] Mirian A. Boim.[1] *[1]Medicine, Federal Univ of Sao Paulo, Sao Paulo, SP, Brazil; [2]CIPE - Centro Internacional de Pesquisa, A.C. Camargo Cancer Center, Sao Paulo, SP, Brazil.*

Background: Exosomes and microvesicles (MV) are extracellular vesicles (EV) that play a key role in the intercellular communication and they have been recently involved in many physiological and pathological conditions. EV released by cells contains substances that can modify the function of other target cells. The content of this vesicles include proteins and nucleic acids such as microRNAs (miRNA). This study aimed to ascertain whether high glucose can modify the cargo of the human mesangial cell (HMC)-derived EV.

Methods: EV secreted from HMC were purified by ultracentrifugation serum-free medium and analyzed by electron microscopy. The vesicles size/concentration ratio was determined by the particle tracking using a nanoparticles analyzer (NanoSigth) and the characterization of the exosomes was performed by the presence of a specific marker CD63. Since mesangial cells are an important intrarenal source of the renin angiotensin system (RAS) components, we evaluated the presence angiotensinogen in the exosomes, by Western Blot. The exosomes obtained from control (C-Ex) and HG exposed HMC (HG-Ex) were used to evaluate whether they are able to modify the function of target control HMC. Exosomes were added to the culture medium and 24 hr after, the expression of fibronectin mRNA was estimated by real time PCR.

Results: The vesicles had a mean size of 140 nm and expressed the CD63, specific for exosomes.The amount and size of exosomes were not modified by stimulation with high glucose. It was observed the presence of angiotensinogen in the exosomes, and it was increased in the exosomes derived from HG stimulated HMC. Interestingly, the expression levels of fibronectin was higher in control HCM treated with HG-Ex compared with those treated with C-Ex, indicating that HG-Ex can modify the function of normal HMC.

Conclusions: In conclusion, the exosomes derived from HG stimulated HMC were able to induce fibronectin production in target control cells, and suggest that the intercellular communication through the exosomes may have pathophysiological implications in the diabetic kidney.

Axl Receptor Tyrosine Kinase Is Involved in Proliferation of Human Mesangial Cells Activated by PDGF Qi Bian,[1,2] Joshua Charles Anderson,[1] Xianwen Zhang,[1] Zhi Qiang Huang,[1] Kerstin Ebefors,[4] Jenny C. Nystrom,[4] Stacy D. Hall,[1] Bruce A. Julian,[1] Christopher D. Willey,[1] Jan Novak.[1] *[1]Univ of Alabama at Birmingham, Birmingham, AL; [2]Changhai Hospital, Second Military Medical Univ, Shanghai, China; [3]Univ of Gothenburg, Sweden.*

Background: Proliferation of mesangial cells (MC) is an important feature in many glomerular diseases, including IgA nephropathy (IgAN). Platelet-derived growth factor (PDGF) is a potent stimulator of MC, activating multiple signaling pathways associated with proliferation of MC. Our global kinomic profiling revealed that activity of multiple kinases in MC increased after PDGF stimulation, including tyrosine kinase Axl. As there is limited information on the association of PDGF signaling and activation of Axl in human MC, we studied details of Axl involvement in human MC stimulated by PDGF.

Methods: MC were obtained from a commercial source or isolated from biopsy specimens of patients with IgAN or other glomerular diseases. Quiescent primary human MC were stimulated by PDGF AB in the presence or absence of different inhibitors. MC lysates were analyzed by global tyrosine-kinome profiling using PamStation®12 platform and Western blotting. MC proliferation was measured by BrdU incorporation. The expression and distribution of Axl in MC were assessed by immunofluorescence.

Results: Tyrosine-kinome profiling indicated that PDGF AB increased Tyro3, Abl, and Ltk kinase activities. Further data analyses predicted Axl as one of the key upstream kinases activated in PDGF-AB-stimulated MC. We found that Axl was expressed in all tested primary human MC. PDGF AB stimulated proliferation of MCs; this effect was inhibited by Axl-specific inhibitor R428. Signaling studies revealed that PDGF AB increased phosphorylation of multiple signaling proteins, including Axl, PDGFR-β, Akt1, and ERK1/2. R428 significantly inhibited phosphorylation of Axl and Akt1, and, to a lesser extent, also of ERK1/2 and PDGFR-β. MEK1/2 inhibitor U0126 and PI3K inhibitor LY294002 did not affect phosphorylation of Axl.

Conclusions: Axl is involved in PDGF-induced proliferation of cultured MC through multiple signaling pathways. Targeting Axl may provide a new therapeutic strategy for IgAN.

SA-PO358

Different Effects and Mechanisms of Prostaglandin E2 Receptor Subtypes EP2 and EP4 in TGF-β1 Induced Mesangial Cell Injury Chen Xiao Lan,[1] Yuan Li.[2] *[1]Affiliated Hospital of Nantong Univ; [2]Affiliated Hospital of Nantong Univ.*

Background: To study effects of prostaglandin E2 receptor subtypes 2 and 4 (EP2 and EP4) in mesangial cell injury by transforming growth factor -β1 (TGF-β1) and relevant signal pathways.

Methods: 1. The primary cultures of EP2 gene knockout (EP2-/-), EP4 gene knockout (EP4flox/flox) and wild type (WT) mice mesangial cells were established; 2. grouping: A: ① WT; ② WT +TGF-β1; B: ③ EP2-/-; ④ EP2-/- + TGF-β1; C: ⑤ EP4flox/flox + AD-CRE (EP4KO); ⑥ EP4flox/flox + AD-CRE (EP4KO) + TGF-β1; Group ⑤ and ⑥ respectively take EP4flox/flox+AD-GFP (EP4KO) and EP4flox/flox + AD-GFP (EP4KO) +TGF-β1 as control; 3. the level of PGE2 ,cAMP ,the PKA activity of mesangial cell was tested ; PKA (H89) and ERK (PD98059) inhibitors were used to interdict PKA activity and ERK pathway in WT mesangial cell; EP2 or EP4 receptor agonist were used to pretreat WT MCs.

Results: 1. After TGF-β1 stimulation, expression of FN and CTGF increased; the expression of FN and CTGF in Group EP2KO increased; the expression of FN and CTGF in EP4KO decreased; 3. after TGF-β1 stimulation, the Smad3 phosphorylation level in EP2KO increased; while the Smad3 phosphorylation level markedly decreased in EP4KO; 4. the PGE2 level of WT mesangial cell increased at 12h after TGF-β treatment; 5. the cAMP content in EP2KO was less than that of the control; PKA activity obviously declined; the cAMP content has no obvious changes in EP4KO; after stimulation with TGF-β1, the PKA activity increased; 6. ERK inhibitor blocks the function caused by agonist EP4; while PKA inhibitor block the inhibition function of agonist EP2.

Conclusions: EP2 and EP4 have different regulating effects on injury and renal fibrosis of mesangial cells: EP2 receptor mediated PGE2 induced up-regulation of the level of cAMP and PKA activity, so as to inhibit transduction effects of TGF-β1/Smad3 pathway and reduced the occurrence of injury and fibrosis of mesangial cell; while EP4 may coordinate the promotional effect of mesangial cell injury induced by TGF-β1 by activating phosphorylation ERK pathway, resulting in regulating effects different from that of EP2.

Mesenchymal Stem Cells in the Repair of the Damaged Mesangium: A Step by Step Ultrastructural Account of the Events Taking Place Jiamin Teng. *Pathology and Transitional Pathobiology, Louisiana State Univ Health Sciences Center, Shreveport, LA.*

Background: Not much is known about repairing the damaged mesangium. The use of mesenchymal stem cells (MSCs) to repair the injured mesangium is a rather novel concept. The present study aimed at analyzing the entire process using transmission electron microscopy in an effort to better understand the various steps involved.

Methods: Mesangial cells (MCs) cultured single layer in dish (2D) and on Matrigel (3D), MCs were first cultured to confluent and quiescent for 48 hours. Then they were incubated with glomerulopathic light chains (GLCs) (10 ug/ml) purified from the urine of patients with renal biopsy-proven light chain-related amyloidosis (AL-Am) (n=3) and light chain deposition disease (LCDD) (n=3) for 4 days and subsequently labeled MSCs were added. Samples were collected 10 days after the introduction of the MSCs (day 14) and processed for light and transmission electron microscopy.

Results: MCs revealed evidence of direct damage by the GLCs including apoptosis with apoptotic bodies released. MSCs identified and migrate to areas where cellular damage was present. When MSCs became activated they acquired a "macrophage" phenotype. They then became active in phagocytosing cell debris, apoptotic bodies damaged extracellular matrix and non-extracellular matrix material. Their process of cleaning the damaged mesangium resulted in MSCs full of cellular debris and eventually disposing of the internalized material. After performing this function, they proceeded to differentiate into mature MCs.

Conclusions: MSCs actively clean the injured mesangium by phagositosing apoptotic cells and other material. They do so by transforming into a macrophage phenotype. Once the cleaning process is completed, they differentiate into MCs acquiring their characteristic smooth muscle morphology and functional properties. .The entire sequence of events was documented by transmission electron microscopy providing an added dimension to the understanding of MSCs in the repair of the damaged mesangium.

SA-PO360

Characterization of Circulating APOL1 Complexes and Their Kidney Distribution in African Americans Lijun Ma, Allison Weckerle, James A. Snipes, Dongmei Cheng, Abraham K. Gebre, Mariana Murea, Gregory A. Hawkins, John S. Parks, Barry I. Freedman. *Wake Forest School of Medicine.*

Background: The apolipoprotein L1 gene (*APOL1*) G1 and G2 renal-risk variants associate with non-diabetic nephropathy and cardiovascular disease in African Americans (AAs). Although substantial APOL1 protein is present in the circulation, with enrichment in podocytes compared to other renal cells, little is known about circulating APOL1 protein.

Methods: Total serum APOL1 levels were examined by Western blot in a cohort of healthy AAs who had a 1st degree relative with kidney disease. APOL1 protein complexes were isolated from fast protein liquid chromatography (FPLC) peak fractions and characterized by proteomic analyses. Results were subsequently verified by co-immunoprecipitation and Western blot.

Results: No significant differences were detected in serum APOL1 protein concentration based on *APOL1* genotypes. However, serum APOL1 protein binds to other protein complexes. Non-denaturing gradient gel electrophoresis and FPLC demonstrated that serum APOL1 protein existed in two non-overlapping peaks (12.2nm and 20.0nm in diameter, respectively). The smaller complex was labeled complex A and the larger complex B. Density gradient ultracentrifugation and agarose gel electrophoresis confirmed that neither APOL1 protein complex was associated with HDL or LDL cholesterol. The exposure of APOL1 complex A surface epitopes appeared to be altered by G1/G2 renal-risk variants based on avidity to a specific monoclonal antibody from a non-G1/G2 associated immunogen (p=0.01). APOA1, haptoglobin-related protein (HPR), and complement C3 were present in APOL1 complex A. APOA1, HPR, IgM, and fibronectin were present in APOL1 complex B. In APOL1 complex A, HPR-α was more abundant in those with G1 and G2 renal-risk variants, relative to G0 (GENMOD p=0.04, total N=12). Serum HPR-α was only present in APOL1 complexes. Small amounts of HPR protein were detected in renal tubule cells but not glomeruli, whereas *HPR* mRNA was absent in the kidney.

Conclusions: Results provide unique insights on the composition of circulating APOL1 complexes. The role of circulating APOL1 in kidney and cardiovascular disease in AAs requires further investigation.

Funding: NIDDK Support

SA-PO361

Deep Mapping of the Native Mouse Podocyte Proteome Markus M. Rinschen,[1] Florian Grahammer,[2] Tobias B. Huber,[2] Thomas Benzing.[1] [1]*Internal Medicine, Univ Hospital Cologne, Cologne, Germany;* [2]*Internal Medicine, Univ Hospital Freiburg, Freiburg, Germany.*

Background: The entity of proteins expressed within a podocyte is still not known.

Methods: We performed mass spectrometry based absolute and relative quantification of the proteome of FACS-sorted native mouse podocytes.

Results: We resolved the podocyte proteome at a near-comprehensive resolution (more than 8000 identified proteins). Absolute copy numbers of proteins correlated with copy numbers obtained from deep-sequencing transcriptomic analysis. The dataset indicates agreement between transcriptome and proteome regarding expression of proteins which are mutated in hereditary forms of proteinuria and FSGS in humans. 541 proteins were enriched within podocytes at very high ratios and significance. This study suggests that the podocyte is not only target to inflammatory stimuli such as TNFalpha and IFNgamma, but also several unanticipated other stimuli. In addition, this study delineates podocyte enriched tyrosine kinases, a few of these are drugable. Protein domains significantly enriched in podocyte proteins comprise not only PDZ and Fn3 domains, but also i-set domain, an adhesion domain. The majority of podocyte specific proteins also stain positive for glomeruli in human samples, with a weak correlation between staining intensity and absolute protein abundance measured by MS/MS.

Conclusions: This initial, near comprehensive draft of the podocyte proteome reveals untapped molecules and mechanisms. This dataset will be of benefit to understand podocyte physiology, pathobiology and develop potential therapeutic strategies.

Maternal Obesity Is a Significant Risk Factor for the Development of Diabetic Nephropathy Sarah J. Glastras,[1] Rachel Teh,[1] Michael Chi-Ho Tsang,[2] Hui Chen,[2] Amgad Sawiris,[1] Carol A. Pollock,[1] Sonia Saad.[1] [1]*Dept of Medicine, Kolling Inst, Univ of Sydney;* [2]*Univ of Technology, Sydney.*

Background: Our previous studies have shown that maternal obesity is associated with increased renal injury in offspring. We hypothesised that a second-hit such as diabetes may further exacerbate diabetic nephropathy in offspring exposed to maternal obesity.

Methods: Female C57Bl6 mice were fed either normal or high-fat diet (HFD) for 6 weeks prior to pregnancy, during pregnancy and weaning and their offspring were weaned to chow diet or HFD. At Week 8, the male offspring were randomized to streptozotocin (STZ) 55mg/kg/day for five consecutive days, 100 mg/kg once only or placebo. Weight and glucose levels were tested fortnightly. 24 h urine collection was performed at Week 20 and 30. The kidneys were harvested at Week 32.The renal structure was observed. Gene expression levels of profibrotic, inflammatory and oxidative stress markers were measured by real time PCR and confirmed with protein quantification with Western blot and/or immunohistochemistry.

Results: Offspring of obese mothers had increased fat deposition. Diabetic offspring had reduced weight gain, hyperglycaemia, glycosuria and microalbuminuria. Urinary albumin measurements were highest in diabetic offspring of obese mothers exposed to 5 doses of STZ. The kidneys of the offspring exposed to maternal obesity and induced with diabetes had increased structural damage, renal fibrosis and increased inflammatory changes and markers of oxidative stress when compared to the kidneys of diabetic offspring of normal weight mothers. There was significant intrarenal lipid deposition in obese offspring, exacerbated by maternal obesity and diabetes.

Conclusions: Offspring exposure to maternal obesity accelerates the severity of damage to the kidney caused by diabetes. Fetal programming of renal inflammation and oxidative stress may be a key component to the accelerated risk. Offspring diet has a powerful effect on renal outcome.

SA-PO363

Leucine-Rich Glycoprotein 1 : A Candidate Biomarker for Early Renal Function Decline in Type 2 Diabetes Sona Haku,[1,2] Kouichi Tamura,[1] Jennifer W. Xu,[2] Carla Cavallin,[2] Hiromichi Wakui,[1] Kengo Azushima,[1] Kazushi Uneda,[1] Ryu Kobayashi,[1] Kotaro Haruhara,[1] Michael S. Simonson,[2] Satoshi Umemura.[1] [1]*Dept of Medical Science and Cardiorenal Medicine, Yokohama City Univ Graduate School of Medicine, Yokohama, Kanagawa, Japan;* [2]*Dept of Medicine, Div of Nephrology and Hypertension, Univ Hospitals Case Medical Center and Case Western Reserve Univ School of Medicine, Cleveland, OH.*

Background: Biomarkers that identify patients with type 2 diabetes and early renal function decline may improve our ability to intervene and slow progression to end-stage renal disease. In a Phase I preclinical exploratory study, we tested whether leucine rich glycoprotein-1 (LRG1), a candidate biomarker discovered in *db*/*db* mice, would identify patients with early decline in renal function.

Methods: Patients with type 2 diabetes were recruited into training (n=56) and independent, non-overlapping test (n=37) groups (median baseline eGFR = 80.3 + 29.5 ml/min/1.73m^2). LRG1 was measured in spot urine collections by ELISA, and performance was assessed as area under the receiver operating characteristic curve (AUC) with adjustment for clinical covariates of DKD.

Results: Urine LRG1 was associated inversely with eGFR (r = -0.546, P<0.001) and positively with ACR (r = 0.283, P = 0.034). The AUC of LRG1 for identifying participants with baseline eGFR 90 – 60 was 0.815 + 0.103; in contrast, the AUC of the albumin/creatinine ratio was 0.465 + 0.093 (P < 0.01 versus LRG1). Adjustment for age, sex, race, duration of diabetes, and HbA_{1c} did not alter the AUC for LRG1, and these results were replicated in the test group. In participants with eGFR >= to 60 ml/min/1.73m^2 at baseline, LRG1 predicted a 5-year outcome of eGFR < 60 or ESRD better than ACR (0.702 ± 0.085, P < 0.01 versus ACR, 0.520 ± 0.119).

Conclusions: Taken together, these results suggest LRG1 may identify patients with early renal function decline more accurately than ACR. Evaluation of LRG1 in prospective cohort studies of type 2 diabetes may lead to a better biomarker for identifying and monitoring DKD.

SA-PO364

A Longitudinal Study on Kidney Function, Pathology, and Multiple Urinary Biomarkers in ZSF1 Rat Model of Type II Diabetic Nephropathy Zhi Su, Deborah Widomski, Marian T. Namovic, Diana L. Donnelly-Roberts, Laura Leys, Katherine Salte, Arthur L. Nikkel, Lauren Olson, Ji Ma, Timothy A. Esbenshade, Steve McGaraughty. *Renal Discovery, Abbvie, North Chicago, IL.*

Background: Obese ZSF1 rats display many clinical features of human type II diabetic nephropathy (DN). To further understand this model and to identify relevant biomarkers of disease progression, we followed the development of DN by measuring glomerular filtration rate (mGFR), histopathology, and a variety of urinary and tissue biomarkers over 24 weeks after uninephrectomy (Unx). Correlations between mGFR and individual urinary biomarkers were assessed.

Methods: Male rats (9-week old) underwent either a sham or Unx (right kidney) surgery and were fed a high carbohydrate diet. GFR was measured by transdermal clearance of FITC-sinistrin. Urine samples were collected once every 2-4 weeks for biomarker analysis, and renal tissue was examined for collagen deposition as well as for the levels of key inflammatory and fibrotic genes.

Results: Kidney hyperfiltration was observed (2-3 fold increase in mGFR) in obese rats 2-week after surgery lasting until week 4. The mGFR subsequently declined over time in these rats and was 2-fold lower than control rats by end of study. Compared to lean rats, obese rats also demonstrated time-dependent increases in urinary excretion of protein, KIM-1, L-FABP, NGAL, Cystatin C, Clusterin, Beta2-microglobulin, alpha1-acid glycoprotein, VEGF, MCP-1, TIMP-1, Collagen IV, TGF-b1, and TGF-b2. A significant correlation was found between mGFR and a number of urinary biomarkers (L-FABP, KIM-1, TIMP-1, Clusterin, Cystatin C, and TGF-b2). Kidney fibrosis was significantly elevated by week 12 post surgery and continued to expand in the following weeks. Unx increased the weight and glomerulosclerosis of the remaining kidney and accelerated the decline of mGFR in obese rats during late weeks of observation.

Conclusions: ZSF1 rats showed a progressive increase of fibrosis and loss of mGFR over the 24-week study. A number of urinary biomarkers demonstrated a strong inverse correlation with the time-dependent changes in mGFR. Additionally, Unx significantly increased glomerulosclerosis and loss of GFR in obese rats.

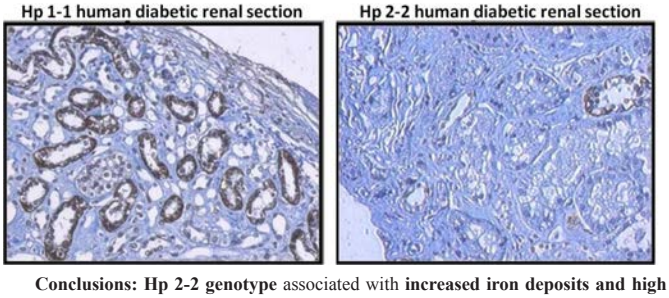
SA-PO365

Haptoglobin 2-2 Genotype Is Associated with Decreased Levels of Vitamin D Receptor (VDR), Klotho and Accelerated Renal Apoptosis in Mice and Humans Diabetic Nephropathy Farid M. Nakhoul,[2] Farber Evgeny,[2] Nadia Thawho,[1] Andy Levy,[3] Inbal Dahan.[1] *[1]Diabetic Nephropathy Lab, Baruch-Padeh Poriya M. Center, Lower Galilee, Israel; [2]Nephrology, Faculty of Medicine In Galilee Bar Ilan Univ, Israel; [3]Vascular Medicine, Technion, Haifa.*

Background: Haptoglobin (Hp) is an antioxidant protein by its ability to binds free hemoglobin (Hb) and prevents heme-iron mediated oxidation. Diabetic mice & humans with different Hp genotype (1-1, 2-2) have a different susceptibility to developed Diabetic Nephropathy (DN) due to impaired Hb clearance and increased iron deposits in the lysosomes of the kidney proximal tubules (PCT). This leading to increased renal oxidative stress and cell damage. Our study proposed a molecular mechanism explaining the influence of Hp genotype, klotho expression on 1-α hydroxylase and active vitamin D/VDR in DN patients.

Methods: Slides from kidney biopsies of DN patients and mice with different Hp genotype (1-1, 2-2) were subjected to Immunohistochemistry staining of iron modified with DAB method, klotho, active caspase 3, vitamin D receptor (VDR) and 1-α hydroxylase, using specific antibodies. Blood samples to Haptoglobin test and ELISA assays.

Results: There were significant increased in iron deposits in the renal PCT of Hp2-2 DM patients. In the PCT of Hp 2-2 mice and patients there was a significant increase expression of active caspase-3 staining that was accompanied with decrease renal expression‹ of VDR, 1α hydroxylase and klotho levels.



Conclusions: Hp 2-2 genotype associated with **increased iron deposits and high levels of PCT apoptosis** Decreased levels of the **anti oxidant klotho and VDR in the renal PCT.** We propose a molecular mechanism explaining the influence of Hp genotype and klotho expression on renal PCT apoptosis in DN patients. These results provide new insights into the **role of Klotho and VDR expression on the pathogenesis of DN in patients with Hp2-2 genotype**.

SA-PO366

Resistance Exercise Training Prevents Kidney Hypertrophy and Increases the Biogenesis Mitochondrial in Diabetic Rats Luciana Jorge,[1] Kleiton Augusto Santos Silva,[1] Rafael Luiz,[1] Rodolfo Rosseto Rampaso,[1] Janaina Paulini Aguiar,[2] Nestor Schor.[1] *[1]Nephrology, Federal Univ of Sao Paulo, Sao Paulo, Brazil; [2]Molecular Biology, Univ of Utah, Salt Lake City, UT.*

Background: Diabetic nephropathy(DN) is a progressive complication arising from diabetes. kidney cell response to injury includes cell division, cell hypertrophy and apoptosis. Increasing evidence indicates that the disruption of mitochondrial bioenergetics and structural change in the kidney may be important in the development and progression of DN. Therefore, is fundamental the understand of a non pharmacological intervention as exercise training to prevent those complications. We investigated the effect of resistance training(RT) on the DN pathogenesis.

Methods: Male Wistar rats were divided into:control(C),control trained(CT),diabetic(D) and diabetic trained (DT). DM was induced by STZ. Trained groups were submitted to a resistance exercise training on Ladder climb (8wk). Urinary volume and proteinuria were evaluated.Tissue weight/tibial lenght ratio was used as kidney hypertrophic index. Expression of P-Akt,P-Mtor,P-AMPK and MFN2 protein was evaluated by western blotting.

Results: RT improved renal parameters in DT group show a decreased urinary vo lume(D=160;DT=120;C=13;CT=14ml),proteinuria(D=45;DT=32;C=18;CT=7 mg/24h) ($p<0.05$).Diabetes resulted in increased hypertrophic index (50%)and RT prevented it.Renal expression of PAMPK and MFN2 was reduced in D group and RT normalized this expression($p<0.05$). Moreover, the renal expression of PAKT and PmTOR were increased in the DM and the RT influence on it($p<0.05$). Histological analysis showed glomerular hypertrophy in D and RT prevent this complication.

Conclusions: RT attenuated progression of diabetic nephropathy; Those improvements could be a result of increased AMPK/MFN2 pathway, an important pathway to biogenesis mitochondrial; and inhibition of AKT/mTOR pathway, responsible for hypertrophic response, demonstrating that those complications were prevented by exercise training. Ours findings demonstrated that RT is an important approach to avoid, both molecular and functional complications in diabetic kidney.Funds from FAPESP,CNPq and CAPES.

SA-PO367

Aerobic Exercise Training Improves Proteinuria and Renal Inflammatory Factors in Rats with Diabetic Nephropathy Rodolfo Rosseto Rampaso, Rafael Luiz, Kleiton Augusto Santos Silva, Luciana Jorge, Edson Andrade Pessoa, Mario luis Ribeiro Cesaretti, Nestor Schor. *Nephrology, UNIFESP, SP, Brazil.*

Background: The objective of this study was to evaluate the effects of aerobic exercise training in controlling the progression of diabetic nephropathy, inflammatory factors, and its possible renoprotective effects.

Methods: Adult male Wistar rats/4 groups, n=8/group: Sedentary controls (C-SED), Diabetes+Sedentary (DM-SED), Diabetes+Exercise (DM-EXE) and control exercise (C-EXE). Diabetes was induced with STZ,50 mg/kg iv. The exercise training were conducted on a treadmill 60min/day, 5 days/week/8 weeks. Weekly certain, maximal exercise test(set at 65-70% of MEtest). Glycemia after post 24 education(24 glycemiapt), MEtest, creatinine clearance/BW(CrCl/BW), arterial pressure(AP), proteinuria(uProt), renal inflammatory factors IL-6, IL-10 and TNF-α were measured. Data as mean ± SD.

Results:

	C-SED	DM-SED	DM-EXE	EXE
glycemiapt (mg/dl)	103±2.03	551±7.03*&	491±5.50*&	83±2.57
uProt (mg/24h)	17±0.88	46±2.05 *#&	18±0.72	16±0.99
CrCL/ (ml/min/ BW)	5.65±0.66	5.02±0.43	4.19±0.37	4.21±0.29
AP (mmHg)	122±1.89	133.88±1.79*#&	122±1.35	121±2.11
Weight (g)	455±6.00	236±14.41*#&	324±9.34*&	387±8.71
MEtest (m/min)	23.2±0.49#&	19.5±0.57*#&	35.1±0.97	37.5±0.57
IL-6 (pg/ml)	541±98	993±40*#&	768±74*&	391±22
IL-10 (pg/ml)	545±86	876±34*#&	654±31*&	453±28
TNF-α (pg/ml)	3.05±0.4	5.18±0.76*#&	4.08±0.22*&	2.32±0.51
P<0.05:*VS C-SED #VS DM EXE &VS C- EXE				

Conclusions: Reductions in blood glucose and AP ~11% comparing DM-EXE vs DM-SED. The DM-EXE controlled weight loss ~40% compared to DM-SED, but did not prevent change in CrCl/BW with this protocol. However, the effect was surprisingly observed EXE reduction in both excretion through uProt ~60% and ~25% in MD-inflammatory factors comparing SED vs DM-EXE. Therefore, preliminary data suggests that aerobic exercise can reduce proteinuria and inflammatory factors in diabetic animals and hence reduce the potential effects caused by diabetic nephropathy and could reduce the progression of renal failure.

SA-PO368

Inhibition of miR-25 Processing Mediated by Mecp2 Phosphorylated by HIPK2 Can Upregulate NOX4 in Early Diabetic Nephropathy
Hyung Jung Oh, Mitsuo Kato, Supriya Deshpande, Mei Wang, Linda L. Lanting, Rama Natarajan. *Diabetes and Metabolism, Beckman Research Inst of City of Hope, Duarte, CA.*

Background: Altered microRNA (miR) levels play key roles in the pathogenesis of diabetic nephropathy (DN), but it is unclear if miR processing is involved. Phosphorylated methyl-CpG binding protein2 (p-MeCP2), known to act as a transcriptional repressor, was recently reported to suppress the processing of several miRs. Homeo-domain interacting protein kinase2 (HIPK2) can bind to and phosphorylate MeCP2. However, it is not known if MeCP2 and HIPK2 are involved in processing and expression of candidate miRs involved in DN.

Methods: p-MeCP2 and HIPK2 staining in kidney sections from 4-week streptozotocin (STZ) injected diabetic and control mice, was studied by immunohistochemistry. Protein, mRNA and miR levels were examined by Western blotting (WB) or RT-qPCRs in TGF-b1- or high glucose (HG)-treated mouse mesangial cells (MMCs).

Results: p-MeCP2 and HIPK2 immunostaining, and their protein levels were significantly higher in renal glomeruli (but not cortex) of STZ mice than control. Moreover, Seven in Absentia Homolog 1 (SIAH1), which mediates proteasomal degradation of HIPK2, was decreased in STZ mice compared with control. Among several regulated miRs, miR-25 and -93 levels were significantly decreased in STZ mice relative to control. The precursors of miR-25 and -93 were also significantly decreased in STZ mice, while conversely, NADPH oxidase4 (NOX4), a target of miR-25 that is associated with renal fibrosis and DN, was significantly increased in STZ mice. Protein levels of p-MeCP2 and HIPK2 were also increased in vitro in TGF-β- or HG-treated MMCs compared to control. Moreover, mRNA levels of the genes mentioned above in vivo were similarly regulated in MMCs in vitro, although only miR-25 and its precursor were significantly decreased in the treated MMCs.

Conclusions: NOX4, a target of miR-25, can be upregulated due to downregulation of miR-25. This occurs via impairment of miR-25 processing by p-MeCP2 phosphorylated by HIPK2 which is stabilized by decrease of SIAH1 in diabetes. These results reveal a novel mechanism for downregulation of key protective miRs during DN progression.

SA-PO369

Ursolic Acid Attenuated High Glucose Induced Podocyte Injury by Increasing Autophagy Level via Inhibition of miR-21 Expression and PTEN/Akt/mTOR Pathway
Qiuling Fan. *Nephrology, The First Hospital of China Medical Univ, Shenyang, Liaoning, China.*

Background: Autophagy played an important role in maintanining podocyte homeostasis. The defective autophagy might contributed to podocyte dysfunction under high glucose condition. In this study, we investigated the effects of ursolic acid (UA) on autophagy and injury of podocyte cultured with high glucose condition.

Methods: Conditionally immortalized murine podocyte were cultured in high glucose, the effect of PI3K inhibitor LY294002 and ursolic acid treatment would be observed. The autophagic inhibitor 3-MA was used to assess the effect of ursolic acid on autophagy in podocyte. The miR-21 expression was detected using RT-qPCR. The activation of PTEN-PI3K/Akt/mTOR pathway, expression of autophagy-associated protein and podocyte associated protein were determined by western blot. Immunofluorescence staining showed the expression of podocyte associated protein and endogenous accumulation of LC3. Autophagosomes were observed using electron microscopy.

Results: In the high glucose condition, high basal level of autophagy in podocyte became defective and defective autophagy facilitated the podocyte injury. miR-21 expression was upregulated, PTEN level was downregulated, PI3K/Akt/mTOR pathway was activated in podocyte cultured with high glucose. Ursolic acid and LY294002 can reduced podocyte injury by increasing autophagy level via inhibition of PI3K/Akt/mTOR pathway. However, LY294002 did not affect the expression of miR-21 and PTEN. Ursolic acid inhibited miR-21 expression and upregulated PTEN level. Downregulation of autophagy with 3-MA significantly suppressed the protective effect of ursolic acid on podocyte.

Conclusions: These data suggested that podocyte injury is associated with defective autophagy level under high glucose condition. Ursolic acid could reduce podocyte injury by increasing autophagy level via inhibition of miR-21 expression and PTEN/Akt/mTOR pathway.

SA-PO370

Hyperglycemic Memory in DN: Effects of Epigenetic Changes of SHP-1 in Podocytes
Farah Lizotte, Benoit Denhez, Andréanne Guay, Pedro Miguel Geraldes. *Medecine, Univ ok Sherbrooke, Sherbrooke, QC, Canada.*

Background: Previous animal and clinical observation suggested that disruption of normal insulin actions is a part of the etiology of diabetic nephropathy (DN). Although, intensive blood glucose control reduced the development of DN, the EDIC study showed that, if not started early, it is not sufficient to prevent DN progression. This hyperglycemic memory phenomenon can be explained by epigenetic changes. Our previous studies demonstrated that SHP-1, a protein tyrosine phosphatase, is elevated in renal cortex of type 1 diabetic mice (Akita) causing insulin unresponsiveness and DN. We hypothesize that epigenetics changes lead to persistent increase of SHP-1 expression despite systemic glucose normalization that triggers to hyperglycemic memory in DN.

Methods: The persistent expression of SHP-1 *in vivo* that contribute to hyperglycemic memory effect was evaluated using diabetic Akita (DM) mice treated with insulin implants after 4 months of diabetes. Mouse podocytes were cultured in normal (5.6 mM; NG), high glucose concentrations (25 mM; HG) or HG prior returning glucose levels to NG for an addition 24-48h (HG+NG).

Results: Urinary albuminuria secretion, GFR, mesangial cell expansion and collagen IV expression were measured and were significantly increased by 2.3 fold, 64%, 58% and 40%, respectively in DM mice compared to non-DM mice and remained elevated despite glucose normalization with insulin implants. SHP-1 expression was increased by 2 fold in renal cortex of DM and DM mice treated with insulin implants. Elevated expression of SHP-1 mRNA, protein and phosphatase activity in HG conditions remained increased in spite returning glucose concentration to NG and associated with insulin actions inhibitions. Evaluation of histone modifications showed that monomethylation of the H3K4 (me1), which is associated with enhanced gene activity, in the promoter region of SHP-1 was increased in HG and remained elevated after returning to NG concentration.

Conclusions: In conclusion, hyperglycemia induces epigenetic changes on SHP-1 promoter causing persistent expression and elevated activity of SHP-1 leading to podocyte unresponsiveness to insulin and DN.

Targeting the Polycomb Repressive Complex Chromatin Remodeling Machinery for Therapeutic Benefit in Diabetic Nephropathy
Letizia De Chiara, Hayley Beaton, Catherine Godson, John Crean. *UCD School of Biomolecular and Biomedical Science, Diabetes Complications Research Centre, Univ College Dublin, Dublin, Ireland.*

Background: Diabetic Nephropathy (DN) manifests as renal microvascular abnormalities, mesangial sclerosis and tubulointerstitial fibrosis as a result of longstanding hyperglycaemia. Emerging evidence indicates that multiple factors involved in the aetiology of diabetes can alter epigenetic mechanisms and regulate susceptibility to microvascular complications.

Methods: Immunoprecipitation, ChIP, Western Blot, miR302 overexpression, luciferase assay.

Results: We have previously identified SMAD3 and EZH2 as part of a context dependent switch enhancing complex that regulates cell fate during fibrotic processes. Here we describe the further characterisation of this interaction and delineate its potential pathogenic significance. Comparative analysis of gene expression data from patients, animals and cell models of diabetic kidney disease revealed a subset of genes that are potentially regulated by the interaction between Smad3 and EZH2, including critical regulators of epithelial fate such as E-Cadherin. Endogenous immunoprecipitation and luciferase assays performed in renal epithelial cells demonstrated that SMAD3 directly binds and recruits EZH2 to the E-Cadherin promoter causing its down-regulation during Epithelial to Mesenchymal Transition. We further demonstrated that this interaction is disrupted by mutating SMAD3 protein sequence. Perturbation of the interaction between SMAD3 and EZH2 was facilitated by viral overexpression of miR302. Human renal mesangial cells transduced with mir302 undergo profound changes in gene expression exhibiting de novo expression of SNAIL and EZH2 and start to express de novo E-Cadherin.

Conclusions: Our results suggest that SMAD3 and EZH2 control the repression of E-Cadherin during DN, opening the possibility for therapeutic manipulation of this nexus during the progression of renal disease. Understanding the processes through which dynamic epigenetic silencing is controlled in adults cells will allow us to address the epigenetic state of acquired disease and whether original states, regenerative in nature, can be restored with therapy.

Effects of DPPIV Inhibitor versus Combined Treatment with DPPIV Inhibitor and ARB on Renal Function in Type 2 Diabetic Mice
Hye Sook Min,[1] Jin Joo Cha,[1] Sung Jin Kim,[2] Kitae Kim,[1] Jung Eun Kim,[1] Jungyeon Ghee,[1] Ji Eun Lee,[3] Hyunwook Kim,[3] Jee Young Han,[4] Young Sun Kang,[1] Dae R. Cha.[1] *[1]Internal Medicine, Korea Univ Ansan Hospital; [2]Nephrology, Sam Hospital, Anyang; [3]Internal Medicine, Wonkwang Univ Sanbon Hospital; [4]Pathology, Inha Univ, Incheon, Republic of Korea.*

Background: Recent evidence has shown that DPPIV is involved in all steps leading to renal fibrosis, such as inflammatory response, cell apoptosis and fibrosis. The aim of our study was to investigate the mechanism and effects of DPPIV inhibitor (DA1229) alone and combined treatment with DPPIV inhibitor and ARB (LC158809) on renal injury in db/db mice.

Methods: The mice were divided into five groups as follows: non-diabetic db/m mice (control), untreated db/db mice, db/db mice treated with DA1229 (300mg/kg/d), db/db mice treated with LC158809 (1.5mg/kg/d) and db/db mice combined treatment with DA1229 and LC158809 for 12 weeks.

Results: 12week HbA1c level was significantly decreased in combined treatment group. Oxidative stress markers were not different from each other. Activity of serum DPPIV was significantly reduced with DA1229. 24h albuminuria significantly decreased with LC158809 treatment at 8 weeks and with DA1229 at 12 weeks in diabetic mice. However, no additive effect on albuminuria was observed with combined treatment. Administration of DA1229 or LC158809 significantly decreased accumulation of ECM protein, TLR4 and NOX4 expressions in glomeruli. No additive effects were observed in combined treatment group. Urinary excretion of nephrin was increased in diabetic mice and was decreased in combined treatment with DA1229 and LC158809. In vitro, DPPIV was expressed on the

podocyte membrane and its expression was activated by angiotensin-II. Nephrin expression in cultured podocyte was attenuated by high glucose and angiotensin-II. This attenuation was recovered with DA1229 treatment, but not with other DPPIV inhibitors.

Conclusions: Our data suggest that renoprotective effects of DA1229 in experimental diabetic mice might be associated with protective effect of podocyte injury. DA1229 might be a potential therapeutic agent to slow the progression of diabetic nephropathy.

SA-PO373

PBI-4425, a Novel Anti-Inflammatory/Fibrotic Compound, Improves Kidney Function and Structure in the Diabetic db/db Mouse Model

Brigitte Grouix, Kathy Hince, François Sarra-Bournet, Liette Gervais, Alexandra Felton, Alexandre Laverdure, William Gagnon, Martin Leduc, Lilianne Geerts, Pierre Laurin, Lyne Gagnon. *ProMetic BioSciences Inc., Laval, QC, Canada.*

Background: Kidney disease associated with diabetes mellitus is a major health problem worldwide. Glomerular injury plays a pivotal role in the development of diabetic nephropathy. PBI-4425 possesses a pleiotropic mechanism of action with anti-inflammatory, antioxidant and anti-fibrotic properties. The aim of this study was to investigate the protective effect of PBI-4425 on kidney function and structure in uninephrectomized (NX) diabetic (db/db) mice.

Methods: Total nephrectomy of the right kidney was performed on day 0 and animals were treated with vehicle or PBI-4425 (100 mg/kg, oral once a day) from day 1 through 105. Kidney function (GFR), kidney mesangium lesions, modulation of gene expression, and serum cytokines were investigated.

Results: GFR assessed by inulin clearance was significantly reduced in NX-db/db mice compared to NX-C57BL/6 negative control mice, and PBI-4425 treatment significantly improved GFR. As shown by PAS staining, NX-db/db mice had larger glomeruli with increased mesangial matrix. Mesangium lesions scores were significantly reduced by PBI-4425 treatment. Gene expression of inflammation, fibrosis, oxidative stress, and extracellular matrix remodeling markers were assessed. Kidney MCP-1, IL-6, Collagen I, iNOS, MMP2, and Timp1 mRNA expression were markedly increased in NX-db/db mice, and PBI-4425 treatment induced a significant decrease of these markers. Glomerular response to injury was accompanied by activation of kidney development-related genes, such as glomerular epithelial protein 1 (GLEPP1); expression of GLEPP1 was significantly increased in NX-db/db mice, and restored to the negative control level following treatment with PBI-4425. Moreover, PBI-4425 significantly reduced serum pro-inflammatory cytokines IL-1β, IL-6, IL-12(p70), as well as TH9-type pro-inflammatory cytokine IL-9.

Conclusions: These results suggest that PBI-4425 offers the potential as a novel therapy for diabetic nephropathy by improving kidney function and structure, and reducing pro-inflammatory and pro-fibrotic markers.

SA-PO374

The Effect of Nox Inhibitor APX-15 on Diabetic Kidney Disease

Jin Joo Cha,[1] Hye Sook Min,[1] Kitae Kim,[1] Jung Eun Kim,[1] Jungyeon Ghee,[1] Hyunwook Kim,[2] Ji Eun Lee,[2] Jee Young Han,[3] Young Sun Kang,[1] Dae R. Cha.[1] *[1]Internal Medicine, Korea Univ Medical College Ansan Hospital, Ansan, Republic of Korea; [2]Internal Medicine, Wonkwang Univ Medical College Sanbon Hospital, Gunpo, Republic of Korea; [3]Pathology, Inha Univ College of Medicine, Incheon, Republic of Korea.*

Background: Excess reactive oxygen species generated by NADPH oxidases (Nox) have been implicated in the inflammatory and fibrotic processes of chronic kidney disease. Recent studies have suggested the importance of renal Nox in the progression of diabetic nephropathy. Therefore, we investigated the effect of a novel NOX-inhibitor APX-15 on diabetic nephropathy in an experimental model of type 2 diabetic mice.

Methods: 8 to 10 week old db/m and db/db mice were treated with APX-15 for 12 weeks. APX-15 was administered by oral gavage at a dose of 60mg/kg/day. To compare the effects of APX-15 with a selective Nox inhibitor, db/db mice were treated with GKT136901 according to same protocol.

Results: APX-15 significantly improved insulin resistance in diabetic mice similar to GKT136901. Oxidative stress measured by plasma 8-isoprostane level was decreased in APX-15 group compared to diabetic control. All lipid profiles, both in plasma and tissues (kidney, fat, liver) improved with Nox inhibition. Nox mRNA expressions in adipose tissue (Nox1, Nox2) and in kidney tissue (Nox4) were downregulated and Nox protein expressions were decreased with APX-15. 24 hour urinary albumin excretion was reduced and creatinine clearance was preserved with APX-15. In diabetic kidney, structural changes were notably attenuated with APX-15. Importantly, mesangial expansion was significantly improved with APX-15, but not with GSK 136901. Kidney PAI-1 and TGF-β expressions were decreased and nephrin expression increased in both APX-15 and GKT136901 groups compared to diabetic control. Additionally, F4/80 infiltrations in the adipose tissue and the kidney were decreased with APX-15.

Conclusions: Our findings suggest that APX-15 may have a better renoprotective effect compared to selective inhibitor GKT136901 in experimental animal model of diabetic nephropathy. Broad Nox inhibition with APX-15 might be a promising therapy for diabetic nephropathy.

SA-PO375

Metabolomics Reveals a Key Role for Fumarate in Mediating NOX4 Activity in Diabetic Kidney Disease

Young-Hyun You,[1] Rintaro Saito,[2] Kumar Sharma.[3] *[1]Medicine, UCSD, La Jolla, CA; [2]Medicine, UCSD, La Jolla, CA; [3]Medicine, UCSD, La Jolla, CA.*

Background: The NADPH oxidase isoform NOX4 has been linked with diabetic kidney disease (DKD), however a mechanistic understanding of the downstream effects of NOX4 remains to be established.

Methods: To clarify the role of increased NOX4, we examined the role of NOX4 in the podocyte-specific NOX4 transgenic mouse. We also treated F1 Akita (DBA/2J × C57BL/6J- *Ins2*^{Akita}) mice with food pellets containing GKT137831, a NOX1/4 inhibitor from week 12 to week 28, and examined the effectiveness of treatment with the NOX1/4 inhibitor on the development of chronic kidney disease (CKD) and on the urine metabolome in a model of progressive DKD.

Results: Podocyte-specific induction of NOX4 in vivo was sufficient to recapitulate the characteristic glomerular changes noted with DKD, including glomerular hypertrophy, mesangial matrix accumulation, GBM thickening, albuminuria, and podocyte dropout. Intervention with a NOX1/4 inhibitor reduced albuminuria, glomerular hypertrophy, and mesangial matrix accumulation in the F1 Akita model of DKD. Metabolomic analysis from the mouse studies revealed that TCA related urinary metabolites were increased in DKD however fumarate levels were uniquely reduced by the NOX4 inhibitor. TCA cycle enzyme fumarate hydratase (FH) reduction has been linked to regulating urine fumarate and indeed, FH was reduced in the diabetic kidney (in mice and human tissue) and the Nox4 inhibitor increased FH levels. Induction of Nox4 both in vitro and in the podocyte-specific NOX4transgenic mouse led to reduced FH levels. The potential role of fumarate to DKD was demonstrated as fumarate was found to stimulate ER stress, matrix gene expression and regulate HIF-1α andTGF-b.

Conclusions: Our data suggest that NOX4 is a major mediator of glomerular dysfunction with diabetes and renal FH is a key enzyme regulated in DKD and targeted by NOX4. Fumarate is a key link that connects metabolic pathways to DKD pathogenesis and may have application to monitor renal NOX4 activity.

The Prostaglandin E2 EP3 Receptor Regulates Diet Induced Obesity

Ryan Patrick Ceddia,[2] Richard M. Breyer.[1] *[1]Div of Nephrology and Hypertension, Dept of Veterans Affairs and Vanderbilt Univ, Nashville, TN; [2]Dept of Pharmacology, Vanderbilt Univ, Nashville, TN.*

Background: Obesity is associated with a number of co-morbidities including diabetes, dyslipidemia and nonalcoholic fatty liver disease. Deletion of the PGE_2 E-prostanoid (EP) 3 receptor in mice has been shown to alter feeding patterns and increase food consumption.

Methods: To further characterize the effects PGE_2-EP3 signaling on diabetes in a setting of diet induced obesity, EP3$^{-/-}$ mice were fed a high-fat diet (HFD; 45% calories from fat) or a control diet (10% calories from fat).

Results: Though no differences in body weight were observed in mice fed control diet, when fed a HFD, EP3$^{-/-}$ mice became heavier relative to EP3$^{+/+}$ mice (41.1±1.10 vs. 32.6±0.98 g; P<0.0001). EP3$^{-/-}$ mice fed HFD had increased epididymal fat mass (1407±177 vs. 2401±167 mg; P<0.0001) and adipocyte size (6350±375 vs. 4330±469 μM^2; P=0.0005) compared to HFD fed EP3$^{+/+}$ mice; paradoxically a relative decrease in both epididymal fat pad mass (P < 0.0001) and adipocyte size (P=0.0055) was observed in the heaviest EP3$^{-/-}$ mice. EP3$^{-/-}$ mice had increased macrophage infiltration (P<0.0001) and necrosis (P < 0.0001) in epididymal fat pads as compared to EP3$^{+/+}$ mice. Adipocytes isolated from EP3$^{-/-}$ mice lacked PGE_2-evoked inhibition of isoproterenol-stimulated lipolysis compared to EP3$^{+/+}$ (1 nM ISO, ±100nM PGE_2; EP3$^{+/+}$: 10.2±1.14 vs. 4.4±1.84, P = 0.0036; EP3$^{-/-}$: 11.8±1.20 vs. 10.3±0.68 nmol glycerol/10,000 cells, P>0.9999). EP3$^{-/-}$ mice fed HFD had ectopic lipid accumulation in skeletal muscle (7.5±1.24 vs. 17.7±1.82 mg triglyceride/mg; P<0.0001) and liver (14.6±2.83 vs. 78.5±13.0 mg triglyceride/mg; P<0.0001), with evidence of hepatic steatosis. When fed HFD, EP3$^{-/-}$ mice became hyperglycemic (107±8.80 vs. 158±7.14 mg/dl; P<0.0001) and hyperinsulinemic (0.598±0.079 vs. 1.55±0.241 ng/ml; P<0.0001) when compared to EP3$^{+/+}$ fed HFD, demonstrating a more severe insulin resistance phenotype in EP3$^{-/-}$ (4.77±0.931 vs. 18.1±3.50 HOMA-IR; P<0.0001).

Conclusions: These results demonstrate that when fed a HFD, EP3$^{-/-}$ mice have abnormal lipid distribution, developing excessive ectopic lipid accumulation and associated insulin resistance.

Resveratrol Activates Renal Expressions of Adiponectin Receptor 1 and 2 in *db/db* Mice

Yaeni Kim, Ji Hee Lim, Min Young Kim, Hyung Wook Kim, Cheol Whee Park. *Div of Nephrology, Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Seoul, Republic of Korea.*

Background: Adiponectin is an adipocyte-derived adipokine that binds to adiponectin receptors (AdipoR) and exhibits antidiabetic effects via activation of AMPK and PPAR-α. Our previous study investigated the renoprotective role of resveratrol by decreasing lipotoxicity and inhibiting mesangial cell glucotoxicity in a manner dependent on the AMPK-SIRT1-PGC1α axis in diabetic mouse model. The common pathway shared by both substances instigated us to explore the favorable effect of resveratrol on renal physiology through the activation of AdipoR.

Methods: Male *db/db* mice at 8 weeks of age were fed resveratrol (20 mg/kg/day) via gavage for 12 weeks. Serum, urine and renal tissue were obtained to analyze for changes in metabolic parameters, molecular levels and renal structure.

Results: Resveratrol treatment showed favorable effects on albuminuria, glomerular matrix expansion and inflammatory cell infiltration. Increased expressions of AdipoR1 and AdipoR2 were observed with increases in phosphorylated AMPK and PPAR-α level. It also ameliorated free fatty acid and triacylglycerol accumulation in the kidney which was related to increases in the phosphorylation of AMPK and the activation of SIRT1-PGC-1α signaling and of the key downstream effectors, the PPARα-Forkhead box O (FoxO)1/FoxO3a-oestrogen-related receptor (ERR)-1α- sterol regulatory element-binding protein 1 (SREBP1)/acetyl coenzyme A carboxylase (ACC). Furthermore, resveratrol increased eNOS phosphorylation and Bcl-2/Bax ratio which were associated with decreased apoptotic cells and oxidative stress as reflected by renal 8-hydroxy-deoxyguanosine (8-OH-dG) and urinary 8-OH-dG and isoprostane concentrations. Resveratrol prevented high-glucose-induced oxidative stress and apoptosis in cultured human glomerular endothelial cells (HGECs) through activation of both AdipoR and subsequent phosphorylation of AMPK and the downstream effectors.

Conclusions: In conclusion, our results suggest that resveratrol exerts its renoprotective effects through activation of both AdipoR which prevent lipotoxicity related apoptosis and oxidative stress in the kidney.

SA-PO378

Oral Treatment with PBI-4547, a Novel Anti-Diabetic and Anti-Fibrotic Compound, Ameliorates Kidney Function and Glomerular Integrity in the Diabetic db/db Mouse Model Martin Leduc, Brigitte Grouix, Kathy Hince, Alexandra Felton, François Sarra-Bournet, Liette Gervais, William Gagnon, Alexandre Laverdure, Mikaël Tremblay, Marie-Pier Cloutier, Pierre Laurin, Lyne Gagnon. *ProMetic BioSciences Inc., Laval, QC, Canada.*

Background: Diabetic nephropathy is the most common complication of longstanding diabetes affecting up to 30% of all diabetic patients, and is the main cause of end-stage kidney disease. This study examined the long-term nephroprotective effects of PBI-4547 in uninephrectomized (NX) diabetic (db/db) mice, a model of type 2 diabetes.

Methods: Total nephrectomy of the right kidney was performed on day 0 and animals were treated with vehicle or PBI-4547 (10 and 50 mg/kg, oral once a day) from day 1 through 105. Kidney function (GFR) and structure (mesangium lesions, glomerular integrity), regulation of pro-inflammatory/fibrotic gene expression in the kidney, as well as serum pro-inflammatory cytokine levels were examined.

Results: Kidney function assessed by GFR was significantly reduced in NX-db/db mice compared to NX-C57BL/6 negative control animals, and PBI-4547 treatment significantly improved GFR in NX-db/db mice. As shown by PAS staining, mesangial matrix accumulation/expansion was prominent in NX-db/db mice compared to the negative control, but was significantly suppressed in PBI-4547-treated NX-db/db mice. Moreover, qPCR analysis of the expression of MCP-1, IL-6, Collagen I, MMP2, Timp1, and iNOS showed that PBI-4547 downregulated diabetes-induced inflammation, fibrosis, oxidative stress, and extracellular matrix remodeling in the kidney. Expression of GLEPP1 was significantly increased in NX-db/db mice, and restored to the negative control level following treatment with PBI-4547. Serum levels of cytokines were measured (multiplex panel). Early/innate TNF-α, IL-1β, and IL-6 cytokines were markedly reduced by PBI-4547, as well as TH1-type IL-12p70, IFNγ, IL-2 cytokines, and TH2-type IL-4, IL-5, IL-13 cytokines. TH9-type pro-inflammatory cytokine IL-9 was also decreased.

Conclusions: These results suggest that PBI-4547 is a potential novel therapy for diabetic nephropathy by improving kidney function and structure, and reducing pro-inflammatory and pro-fibrotic markers.

SA-PO379

Prostaglandin E2 Receptor 3 (EP3) Inhibits Vasopressin-Stimulated Water Reabsorption and Contributes to Diabetic Renal Dysfunction in Mice Ramzi Hassouneh, Rania Nasrallah, Joe A. Zimpelmann, Kevin D. Burns, Richard L. Hébert. *Kidney Research Centre, Cellular and Molecular Medicine, Univ of Ottawa, Ottawa, ON, Canada.*

Background: The early renal manifestations of diabetes are polyuria and reduced urine osmolality (Uosm), and when sustained long-term lead to nephropathy. We propose that these processes are mediated through the interaction of prostaglandin E2 (PGE2) acting via EP3 and the anti-diuretic hormone, vasopressin (VP).

Methods: Global EP3-/- and wild-type (WT) 8wk male C57BL6 mice were injected with vehicle or streptozotocin (STZ) and analyzed after 12wks. Glomerular filtration rate (GFR) was measured by inulin clearance. Aquaporin (AQ) 1/2 and cyclooxygenase-2 (COX-2) were assessed by Western blotting. PAS stain was done to assess renal injury on paraffin sections. 24hr urinary VP excretion rate was quantified. Cortical collecting ducts (CCD) were microdissected for in vitro perfusion and stimulated with VP and sulprostone (SLP; EP3/1 agonist). 3H-inulin was used as a volume marker to measure net water reabsorption (Jv).

Results: EP3-/- STZ show decreased polyuria, hyperfiltration, CCD injury, and VP levels compared to STZ. EP3-/- STZ show increased Uosm compared to STZ. Cortex AQP2 and medulla AQP1/2 are decreased by 50% in STZ and restored to control levels in EP3-/- STZ. Cortex and medulla COX-2 was increased up to 2-fold in STZ, and attenuated in EP3-/- STZ (n=5, P<0.05). VP increased Jv in all groups, and SLP reversed this effect only in WT and STZ. See table.

	WT	$EP_3^{-/-}$	STZ	$EP_3^{-/-}$ STZ
Blood Glucose (mM)	9.03 ± 1	7.79 ± 1	27.5 ± 4*	26.9 ± 4†
Urine Glucose (mM)	2.70 ± 0.2	2.14 ± 0.2	135 ± 0.1*	136 ± 0.1†
Kidney Wt./Tibia (mg/m)	9.56 ± 0.5	10.8 ± 0.4	11.8 ± 0.5*	11.0 ± 0.3
GFR (µl/min)	211 ± 20	240 ± 10	332 ± 10*	269 ± 20†‡
Urine Volume (ml/24hr)	0.570 ± 0.06	0.760 ± 0.07	29.6 ± 2*	19.8 ± 2†
Urine Osmolality (Osm/kg)	1170 ± 90	1170 ± 70	458 ± 7*	536 ± 30†‡
VP Excretion (pg/24hr)	207 ± 80	184 ± 30	2920 ± 300*	1810 ± 300†‡
CCD Area (pixels x10^5)	1.88 ± 0.1	1.74 ± 0.1	4.21 ± 0.2*	3.65 ± 0.2†‡
CCD Cysts (No/image)	0.0333±0.03	0.192 ± 0.1	7.97 ± 1*	5.36 ± 1†‡

Jv	WT	$EP_3^{-/-}$	STZ	$EP_3^{-/-}$ STZ
Baseline	1	1	1	1
VP	1.62 ± 0.1$^{\Delta}$	1.63 ± 0.2$^{\Delta}$	1.65 ± 0.2$^{\Delta}$	1.53 ± 0.1$^{\Delta}$
SLP	1.20 ± 0.1**	1.53 ± 0.2$^{\Delta}$	1.11 ± 0.5**	1.51 ± 0.2$^{\Delta}$

*P<0.05 vs WT, †P<0.05 vs $EP_3^{-/-}$, and ‡P<0.05 vs STZ using 1 way ANOVA with Tukey's post-test. ΔP<0.05 vs Baseline and **P<0.05 vs VP using t-test. N = 5 – 10.

Conclusions: Despite elevated VP levels in STZ, the CCD response to VP stimulation was no different than in WT, while SLP inhibited VP-induced Jv in both groups. In the absence of EP3, the VP-induced Jv was unchanged by SLP, confirming the importance of EP3 in this process. During diabetes, EP3 inhibition of VP-induced Jv may lead to polyuria and a sustained increase of VP, which may be injurious to the kidney.

Effects of Diuretics on SGLT2 Inhibitor-Induced Changes in Blood Pressure and Natriuresis in Obese Rats Suffering from the Metabolic Syndrome Akira Nishiyama, Daisuke Nakano, Wararat Kittikulsuth. *Dept of Pharamacology, Kagawa Univ Medical School, Kagawa, Japan.*

Background: Experiments were carried out to investigate whether diuretics (hydrochlorothiazide + furosemide) impact on the effects of a sodium-dependent glucose co-transporter 2 (SGLT2) inhibitor on glucose metabolism, blood pressure and rate of urinary excretion of sodium in metabolic syndrome SHR/NDmcr-cp(+/+) rats (SHRcp).

Methods: Male 13-week-old SHRcp were treated with: (i) vehicle; (ii) the SGLT2 inhibitor luseogliflozin (10 mg/kg/day, p.o.); (iii) diuretics (hydrochlorothiazide; 10 mg/kg/day + furosemide; 5 mg/kg/day, p.o.); or (iv) luseogliflozin + diuretics for 5 weeks (n = 5–8 for each group). Blood pressure and glucose metabolism were evaluated by a telemetry system and oral glucose tolerance test, respectively.

Results: Vehicle-treated SHRcp developed non-dipper type hypertension (dark- *vs*. light-period mean arterial pressure (MAP): 148.6±0.7 and 148.0±0.7 mmHg, respectively, *P=0.2*) and insulin resistance. Compared with vehicle-treated animals, luseogliflozin-treated rats showed an approximately 4000-fold increase in urinary excretion of glucose and improved glucose metabolism. Luseogliflozin also significantly decreased blood pressure and converted the circadian rhythm of blood pressure from a non-dipper to dipper pattern (dark- *vs*. light-period MAP: 138.0±1.6 and 132.0±1.3 mmHg, respectively, *P<0.01*), which were associated with a significant increase in urinary excretion of sodium. Addition of diuretics did not influence luseogliflozin-induced improvement of glucose metabolism and circadian rhythm of blood pressure in SHRcp.

Conclusions: These data suggest that a SGLT2 inhibitor elicits its beneficial effects on glucose metabolism and hypertension in subjects with metabolic syndrome undergoing treatment with diuretics.

SGLT2 Inhibition Slows the Progression of Diabetic Nephropathy in the db/db Mice Li Tang, Yuanyuan Wu, Yufeng Huang. *Fibrosis Research Laboratory, Div of Nephropathy, Univ of Utah, Salt Lake City, UT.*

Background: It has been shown that SGLT2 inhibitor not only enhanced renal glucose excretion and lowered blood glucose (BG) but also reduced albuminuria in patients with Type 2 diabetes (T2DM). However, the renoprotective effect of SGLT2 inhibition in diabetes has not fully established.

Methods: This study sought to determine whether dapagliflozin, a selective SGLT2 inhibitor, could slow the progression of glomerulosclerosis in the uninephrectomized db/db mouse, a model of T2DM.

Results: Untreated uninephrectomized db/db mice developed progressive albuminuria and glomerulosclerosis between wks 18 and 22, associated with increased renal expression of TGFß1, PAI-1, type IV collagen and fibronectin. Treatment with dapagliflozin (1mg/kg/d) via gel diet from wks 18 to 22 did not affect body weight but reduced BG (from 573.53±21.73 to 371.14±55.02 mg/dL, P<0.05) and HbA1c levels. Of note, treatment with dapagliflozin arrested the increases in albuminuria and markers of glomerulosclerosis seen in db/db mice between wks 18 to 22. Renal expressions of NF-κBp67, MCP-1, Nox4, Nox2, and p47phox and urine TBARS levels, the markers of renal inflammation and oxidative stress, were increased during disease progression in db/db mice. Treatment with dapagliflozin reduced these markers. In addition, db/db mice had markedly increased daily water intake, urine output, urinary sodium and potassium excretion but decreased urinary osmolality. Dapagliflozin had no effects on these measurements. Interestingly, dapagliflozin

ameliorated diabetes-induced glomerular hyperfiltration determined by elevated creatinine clearance rates (2.44±0.55 ml/min in treated db/db vs. 3.72±0.63 ml/min in db/db) and caused a significant reduction in renal RAS activity determined by urinary aldosterone levels (45.5±4.93 vs. 60.9±4.01, µg/24h, P<0.05).

Conclusions: These results suggest that SGLT2 inhibitor not only reduces albuminuria but also slows the progression of the glomerulosclerosis resulting from T2DM by improving hyperglycemia and renal inflammation and oxidative stress. Decreasing glomerular hyperfiltration and negatively regulating renal RAS activity by SGLT2 inhibitor may be also renoprotective.

Effect of SGLT2 Inhibitor Ipragliflozin on Urinary Na Excretion and Body Fluid Volume Takahiro Masuda,[1] Yuko Watanabe,[1] Minami Watanabe,[1] Keiko Fukuda,[1] Akira Onishi,[3] Hermann Koepsell,[2] Volker Vallon,[3] Daisuke Nagata.[1] *[1]Div of Nephrology, Deparment of Medicine, Jichi Medical Univ, Shimotsuke, Tochigi, Japan; [2]Univ of Würzburg, Germany; [3]Univ of California and VA San Diego Healthcare System, San Diego, CA.*

Background: Sodium-glucose cotransporter (SGLT) 2 inhibitors are new antidiabetic drugs that increase urinary glucose excretion (UGE) by inhibiting renal SGLT2. SGLT2 inhibitors may induce body fluid reduction due to the increase in urine volume and Na excretion, but the details remain unclear.

Methods: Spontaneously Diabetic Torii (DM) rat, a non-obese type 2 diabetic model was used in this study. At the onset of diabetes (blood glucose ≥ 250 mg/dl), DM rats and age-matched Sprague-Dawley (non-DM) rats were separated to vehicle (Veh) and 0.01% (in diet) Ipragliflozin (Ipra) group, respectively. After 8 weeks, bioimpedance spectroscopy (ImpediVet) for the assessment of total body water, urine collection and blood tests were performed.

Results: Renal membrane protein expression of SGLT2 was significantly higher in DM rats compared with non-DM rats. Ipra enhanced the expression of SGLT2 in non-DM rats, but not in DM rats. Ipra did not change plasma glucose in non-DM rats (Veh 172±11 vs. Ipra 158±5 mg/dl, P=0.12), but significantly decreased in DM rats (681±21 vs. 361±22 mg/dl,* P<0.05). Ipra increased fractional glucose excretion in non-DM rats (0.3±0.2 vs 31.3±2.1 %*) and DM rats (31.5±1.7 vs. 52.9±3.2 %*). In non-DM rats, Ipra increased urine volume (36±7 vs. 61±5 ml/day*), UGE (0.03±0.01 vs. 4.8±0.2 g/day*), urinary Na excretion (3.0±0.4 vs. 4.2±0.3 mEq/day*), food intake (31±1 vs. 34±1 g/day*) and fluid intake (61±9 vs. 87±8 ml/day*). These parameters were higher in DM rats than in non-DM rats, but Ipra did not significantly change these parameters. Total body water (related to body weight) and fluid balance (fluid intake-urine volume) were similar among the 4 groups.

Conclusions: SGLT2 inhibition did not induce sustained changes in body fluid volume in DM or non-DM rats. In non-DM rats given Ipragliflozin, the increase in fluid intake might maintain fluid balance in response to the osmotic diuresis whereas the natriuresis is likely due to greater food intake.

Up-Regulated Sglt2 Reduces Proximal Tubular Sirt1 and Augments Renal Gluconeogenesis in Early Stage Diabetic Nephropathy Hiroyuki Umino, Kazuhiro Hasegawa, Shu Wakino, Hiroshi Itoh. *Keio Univ.*

Background: We previously reported that high glucose (HG) decreases proximal tubule (PT) **Sirt1** prior to decreasing glomerular Sirt1, which leads to a disruption of tubule-podocyte communication in diabetic nephropathy (DN) (Nat Med 2013). Protein expression levels of **Sglt2** are elevated to compensate for the increased demand for glucose uptake in DN, which causes a rise in intracellular HG in PT. Here, we investigated whether Sglt2-mediated HG down-regulates PT Sirt1.

Methods: Cultured PTs (HK2) were cultivated on a two-chamber-system consisting of an upper chamber equivalent to the ureteral lumen on the apical side of PTs and a lower chamber corresponding to the vascular lumen on the basolateral side of PTs. PTs were cultured with combinations of normal glucose (NG) or HG in each chamber to determine the polarity of HG that affects Sglt2 and Sirt1 expression. We also administered a **Sglt2 inhibitor** (canagliflozin) to 8-week-old db/db mice and analyzed the Sglt2 and Sirt1 expression.

Results: HG in the lower chamber increased Sglt2 and decreased Sirt1 expression, but HG in the upper chamber had no effect. Thus, high blood sugar (BS), but not glucosuria regulates Sglt2 and Sirt1. Furthermore, in db/db mice, high BS also elevated Sglt2 and lowered Sirt1 expression in PTs, as confirmed by immunofluorescence and immunoelectron microscopy, and reduced deacetylation of **Foxa2**, a Sirt1 target. Decreased Sirt1 expression led to an increase in Foxa2 acetylation, which induces **gluconeogenesis**. Results from DNA microarrays and confirmatory real-time PCR using laser-microdissected db/db PTs showed an increase in **Pck1** and **G6Pase** in concert with Sglt2 upregulation and Sirt1 downregulation. However, Sglt2 inhibitors blocked these changes.

Conclusions: Increased Sglt2 expression, already seen in the early stage of DN, forms a **vicious cycle** whereby both **exogenous** HG, mediated by a Sglt2-induced influx of BS, and **endogenous** HG, generated by Foxa2-induced renal gluconeogenesis, reduce PT Sirt1 levels. Decreased Sirt1 acetylates and activates Foxa2, further promoting renal gluconeogenesis, which accelerates this cycle. However, Sglt2 inhibitors can block the HG-induced reduction in Sirt1 levels and prevent DN progression.

Characterization of Aged Mice Lacking SGLT2 Yiling Fu, Falk Bernhard Batz, Akira Onishi, Aleksandra Novikov, Panai Song, Volker Vallon. *Div of Nephrology, UC San Diego & VA San Diego Healthcare System, La Jolla, CA.*

Background: SGLT2 inhibitors have recently been approved in type 2 diabetes and long-term clinical trials are ongoing to further establish efficacy and safety. Humans with familial renal glycosuria due to mutations in SGLT2 do not show signs of general renal tubular dysfunction or other pathological changes, and they seem to have normal life expectancies. Here we compared the phenotype of non-diabetic aged male mice (at 24 months) that lack SGLT2 (*Sglt2*-/-) with their wild-type littermates (WT).

Methods: In awake mice, blood pressure (BP) and heart rate (HR) was measured by an automatic tail-cuff system and GFR by FITC-inulin plasma eliminations kinetics.

Results: Out of initially 11 *Sglt2*-/- and 14 WT, 2 mice per genotype died for unknown reasons before reaching an age of 24 months; thus 9 *Sglt2*-/- and 12 WT mice were analyzed. Consistent with results previously reported in young adult mice (3-5 months): aged *Sglt2*-/- and WT showed similar body weight (33.6±0.6 vs 32.1±0.9 g), blood glucose (105±6 vs 116±10 mg/dl), and GFR (329±36 vs. 370±20 µl/min); *Sglt2*-/- had higher urinary glucose excretion (381±71 vs 5±1 µmol/mg creatinine) associated with higher intake of food (3.8±0.1 vs 3.2±0.1 g/day) and fluid (8.9±0.2 vs 5.1±0.1 ml/day) and smaller adipocytes in subcutaneous and epididymal fat tissue (4790±446 vs 6348±130 and 8093±890 vs 11811±778 µm^2)(each P<0.01); urine pH was similar (6.2±0.1 vs 6.5±0.2) and no bacterial growth detected in bladder urine. Different from previous findings in young adult mice: aged *Sglt2*-/- had modestly higher kidney weight (15.4±0.9 vs 12.6±0.4 µg/g body wt), BP (105±2 vs 95±1 mm Hg) and HR (660±7 vs 625±9 1/min) than WT and lower hematocrit (38.1±1.0 vs 41.3±0.4% (each P<0.01).

Conclusions: Aged *Sglt2*-/- mice show many of the expected phenotypes previously observed in young adult mice, and have preserved GFR and no evidence for ascending bacterial infections. An increase in kidney weight has previously been reported in 7.5 months old *Sglt2*-/- mice. Further analyses aim to better understand the latter findings and the observed modest changes in BP and hematocrit.

Renal Secretion of the SGLT2 Inhibitor Empagliflozin and Rightward Shift in Its Glucosuric Response Curve in Mice Lacking OAT3 Yiling Fu,[1] Akira Onishi,[1] Panai Song,[1] Falk Bernhard Batz,[1] Eric W. Mayoux,[2] Volker Vallon.[1] *[1]Div of Nephrology, UC San Diego & VA San Diego Healthcare System, La Jolla, CA; [2]Boehringer Ingelheim, Biberach, Germany.*

Background: SGLT2 inhibitors, like empagliflozin (EMPA), may reach their target in the brush border of the early proximal tubule through nephron filtration and tubular secretion. The organic anion transporter OAT3 in the basolateral membrane of the proximal tubule contributes to secretion.

Methods: Renal ^{3}H-inulin clearance studies were performed in wild-type (WT) mice to characterize the renal handling of EMPA. EMPA was given in diet for 3 weeks (~30mg/[kg body wt x day]) ± i.p. bolus (10 mg/kg 1 hr before study)). EMPA was determined by LC/MS/MS. Mean fractional protein binding of empagliflozin in mouse plasma is constant over a wide range (up to >=50µM) at 88.1 +/- 0.5%. b) Metabolic cage studies were performed in mice lacking OAT3 and WT littermates; EMPA (0.3-30 mg/kg) or vehicle was applied i.p. together with an oral water load (30 ml/g bw) and the urine quantitatively collected over 3 hours to determine the glucosuric response.

Results: Comparing freely filtered and excreted amounts of EMPA revealed a fractional renal excretion of ~300-500 % for free plasma concentrations in the range of 1-2 nM (with chronic application in diet, which is close to the IC50 for mouse SGLT2) to 20-22 nM (with additional bolus application), indicating that 2/3 or more of the renal excretion of EMPA derived from renal secretion. B) OAT3-/- showed a small but significant rightward shift in the glucosuria response curve to EMPA (ED50 ~6 vs. 3 mg/kg in WT; with significantly lower glucosuria at 1, 3, and 10 mg/kg (P<0.05), whereas vehicle/0.3 mg/kg and 30 mg/kg induced similar minimal and maximal glucosuria, respectively)(n=9-19/dose).

Conclusions: The SGLT2 inhibitor empagliflozin is secreted by the kidney; this may involve OAT3 in the early proximal tubule whose activity is a determinant of the acute glucosuric effect of EMPA.

SGLT Inhibition Significantly Increases Oxygen Consumption of the Medullary Thick Ascending: A Modeling Study Anita T. Layton,[1] Volker Vallon,[2] Aurelie Edwards.[3] *[1]Mathematics, Duke Univ, Durham, NC; [2]Medicine and Pharmacology, Univ of California San Diego, La Jolla, CA; [3]Centre National de la Recherche Scientifique, Paris, France.*

Background: The objective of this study was to investigate how changes in sodium reabsorption in the proximal tubule affect oxygen (O_2) consumption and the metabolic efficiency of the nephron.

Methods: To do so, we developed a detailed mathematical model of solute transport in a short-loop nephron of the rat kidney. Glucose is reabsorbed via sodium-glucose cotransporters (SGLTs) in the proximal tubule, which expresses the isoform SGLT2 in S1-S2 and the isoform SGLT1 in S3. We used the model to investigate the effect of inhibiting SGLT2, a novel treatment for reducing proximal tubule glucose uptake in diabetes, on renal Na^+ transport and renal oxygen consumption (Q_{O2}).

Results: Inhibiting SGLT2 shifts Na^+ transport to downstream nephron segments, possibly increasing their Q_{O2}. Of particular concerns are the S3 segment and medullary thick ascending limb (mTAL), which are at risk for hypoxic injury. Dual SGLT1-SGLT2 inhibition protects the S3 segment, but could further reduce mTAL oxygenation. Model simulations suggest that SGLT2 inhibition substantially increases S3 Q_{O2}. Together with elevated membrane expression of Na-K-Cl cotransporter (NKCC2), SGLT2 inhibition also increases mTAL Q_{O2}. Additionally, we used the model to determine the optimal combination of SGLT1 and SGLT2 inhibition, in terms of suppressing tubular glucose uptake and maintaining sufficiently low S3 and mTAL Q_{O2}.

Conclusions: In conclusion, SGLT inhibition significantly increases oxygen consumption of the mTAL. This research was supported in part by NIH grant DK-89066.

SGLT2 Expression Is Increased in Human Diabetic Nephropathy: SGLT2 Inhibition Decreases Renal Lipid Metabolism, Inflammation and the Development of Nephropathy in Diabetic Mice

Xiaoxin Wang,[1] Jonathan Levi,[2] Yuhuan Luo,[1] Evgenia Dobrinskikh,[1] Almut Grenz,[1] Michal Herman-Edelstein,[3] Uzi Gafter,[3] Avry Chagnac,[3] Hermann Koepsell,[4] Jeffrey B. Kopp,[2] A. Rosenberg,[2] Moshe Levi.[1] *[1]Univ of Colorado Denver; [2]NIDDK; [3]Rabin Medical Center; [4]Univ of Wurzburg.*

Background: The renal sodium gradient dependent glucose transport protein SGLT2 expression is increased in renal biopsies from human subjects with diabetic nephropathy.

Methods: To determine the potential mechanisms of beneficial effects of SGLT2 inhibition in progression of diabetic renal disease we treated db/db mice with a selective SGLT2 inhibitor.

Results: We found that SGLT2 inhibition caused marked decreases in systolic blood pressure, kidney weight/body weight ratio, urinary albumin (745±36 mg/g in db/db vs. 207±5 mg/g in treated db/db, $p<0.001$) and urinary thiobarbituric acid-reacting substances (TBARS). SGLT2 inhibition also a) prevented renal lipid accumulation via inhibition of LPK, SCD-1 and DGAT1, key enzymes that mediate fatty acid and triglyceride synthesis, b) decreased inflammation via inhibition of CD68 macrophage accumulation, and expression of p65, TLR4, MCP-1 and OPN, and c) increased CD73 and decreased adenosine A receptors Adora1, Adora2a, and Adora2b mRNA. These effects were associated with prevention of mesangial expansion, accumulation of extracellular matrix proteins fibronectin and type IV collagen, as well as loss of podocyte markers WT1 and synaptopodin, as determined by quantitative immunofluorescence microscopy.

Conclusions: In summary, our study showed that SGLT2 inhibition modulates renal lipid metabolism and inflammation and prevents the development of nephropathy in db/db mice.

Loss of Angiotensin-Converting Enzyme 2 Alters Glomerular Strucutre in Non Obese Diabetic Mice

Heleia Roca-Ho,[1] Marta Riera,[1] Marta Rebull,[1] Javier Gimeno,[2] Julio Pascual,[1] Maria Jose Soler.[1] *[1]Nephrology, Hospital del Mar-Inst Hospital del Mar d'Investigacions Mèdiques, Barcelona; [2]Pathology, Hospital del Mar, Barcelona.*

Background: ACE2 has been shown to play an important role in diabetic nephropathy (DN). We studied renal morphology and kidney function in non-obese diabetic(NOD) female mice (with spontaneous autoimmune diabetes) carrying a deletion on ace2 gene(NOD.ACE2$^{-/-}$) and NOD.ACE2$^{+/+}$ after 30days of diabetes (DOD). Non obese resistant strain (NOR.ACE2$^{-/-}$ and NOR.ACE2$^{+/+}$) was used as control mice.

Methods: To evaluate kidney function urinary excretion of albumin(UAE) and glomerular filtration rate(GFR) were calculated.UAE was determined on spot urine collections. GFR was measured using clearance kinetics of plasma FITC-inulin after 75min of a single bolus injection on conscious mice (N=6-13 animals/group). Paraffin embedded kidney sections were obtained. 20glomeruli were randomly selected for each animal. To assess renal morphology, PAS staining was performed. The extent of extracellular mesangial matrix was identified by PAS-positive material in the glomerulus and factored by the glomerular tuft area. Area calculations were performed using ImageJ software. To assess podocyte number in glomerular tuft, WT-1 staining was performed.

Results: NOD.ACE2$^{-/-}$ mice showed glomerular area increase, mesangial matrix expansion and podocyte loss as compared to NOR.ACE2$^{-/-}$ age matched mice. UAE was increased in both diabetic NOD mice, without differences among them. Interestingly, GRF was found decreased in NOD.ACE2$^{-/-}$ showing a tendency for GFR decrease as compared to NOD.ACE2$^{+/+}$.

GROUP	UAE (µg Alb/mg Crea)	GFR (µL/min)	GLOMERULAR AREA (µm²)	MESANGIAL AREA (µm²)	PODOCYTE NUMBER
NOR.ACE2$^{+/+}$	17.6±4.0	29.4±4.1	3213.6±226.6	975.3±78.2	12.1±0.5
NOR.ACE2$^{-/-}$	19.9±3.7	29.3±5,1	3220.3±145.7	877.2±47.1	13.8±0.4
NOD.ACE2$^{+/+}$	770.1±270.2 *	54.2±8.3 *	3713.1±107.3	1171.8±43.5 *	11.3±0.7
NOD.ACE2$^{-/-}$	512.0±288.3 **	36.3±6.4	3637.2±164.6 **	1178.0±48.8 **	10.2±1.0 **

* p≤0.05 vs. NOR.ACE2$^{+/+}$

** p≤0.05 vs. NOR.ACE2$^{-/-}$

Conclusions: Glomerular hypertrophy, mesangial matrix expansion and podocyte loss were found in female NOD.ACE2$^{-/-}$ after30DOD.GFR values showed mild decrease in NOD.ACE2$^{-/-}$ compared to NOD.ACE2$^{+/+}$ mice. Our results suggest that ACE2 deletion worsens kidney injury in diabetic NOD mice.

SA-PO389

Ace2 Deficiency Accentuated AngII-Induced Hypertension and Albuminuria in Diabetic Mice

Sergi Clotet-Freixas, Maria Jose Soler, Marta Rebull, Julio Pascual, Marta Riera. *Nephrology, Hospital del Mar-Inst Hospital del Mar d'Investigacions Mèdiques, Barcelona, Spain.*

Background: AngiotensinII (AngII) promote renal vasoconstriction, albuminuria, fibrosis, apoptosis and inflammation. ACE2 deficiency exacerbates hypertension in AngII-infused male mice. However, the effect of ACE2 deletion on diabetic and AngII-infused female mice has not been previously studied.

Methods: We evaluated the effect of AngII infusion in age matched C57BL/6 wild-type (WT) and ACE2KO streptozotocin(STZ)-induced female mice and their respective non-diabetic controls. At week 8 of follow-up, mice were anesthetized and minipumps for AngII infusion (ANGII) were surgically implanted. Sham-operated (SHAM) mice were used as control groups. Study groups: WT-Control(CONT) + SHAM, WT-CONT + ANGII, WT-Diabetic(DB) + SHAM, WT-DB + ANGII, ACE2KO-CONT + SHAM, ACE2KO-CONT + ANGII, ACE2KO-DB + SHAM, ACE2KO-DB + ANGII. Blood glucose, body weight, kidney weight/body weight (KW/BW), heart weight /body weight (HW/BW), systolic blood pressure (SBP) and urinary albumin excretion (UAE) were studied.

Results: Hyperglycemia and reduced BW were observed in all groups given STZ. ACE2 deletion and AngII infusion supposed a modest decrease in body weight in control and diabetic mice. Both, SHAM and AngII-infusedACE2KO diabetic mice showed higher KW/BW as compared to WT.AngII infusion significantly augmented HW/BW and SBP in control and diabetic ACE2KO mice as compared to non-infused mice. Diabetes and AngII infusion were accompanied by increased UAE in all groups. This increase was more pronounced in ACE2KO mice. Within AngII-infused groups, ACE2KO-CONT + ANGII and ACE2KO-DB + ANGII showed significantly higher HW/KW, SBP and UAE than WT-CONT + ANGII and WT-DB+ANGII.

Conclusions: Loss of ACE2 accentuated renal hypertrophy and AngII-induced hypertension, albuminuria and cardiac hypertrophy in diabetic female mice.

Global ACE2 Deficiency Worsens Glomerular Cell Proliferation but Does Not Affect GFR in Diabetic Mice

Jan A. Wysocki,[1] Minghao Ye,[1] Yashpal S. Kanwar,[1] Agnes B. Fogo,[2] Daniel Batlle.[1] *[1]Northwestern Univ; [2]Vanderbilt Univ.*

Background: Alterations in ACE2 have been described in rodent models of diabetic kidney disease and in humans with type 2 diabetes where glomerular ACE2 expression has been found to be decreased similar to findings in diabetic db/db mice. At the tubular level however, ACE2 is increased. To examine the impact of ACE2 deficiency on kidney pathology we developed a model of type 2 diabetes with global ACE2 deficiency. The effect of STZ-induced diabetes on kidney pathology was also examined in ACE2KO mice with two different genetic backgrounds.

Methods: ACE2 deficient db/db mice were generated and backcrossed to the BLKS genetic background for at least 6 generations. The effect of ACE2-deficiency was also studied in WT and ACE2KO mice (C57BL6/J and FVB/N genetic backgrounds) that were rendered diabetic using STZ (2x150mg/kg).

Results: In ACE2 deficient db/db mice, there was a modest but significant reduction in podocyte count (10.3±0.2 vs. 11.1±0.1, $p<0.05$) and an increase in glomerular cellularity (1.81±0.13 vs. 1.06±0.11, $p<0.001$, respectively) but neither GFR (3.0±0.4 vs. 2.4±0.3ul/min/g) nor albumin excretion were significantly different from db/db WT controls. ACE2-deficient db/db mice also exhibited Lacis cell hyperplasia, increase in polar cells and foci of glomerular sclerosis. Glomerular cellularity was significantly increased also in mice with STZ-induced diabetes on the FVB/N but not in the C57BL6/J background as compared to their respective diabetic WT counterparts.

Conclusions: Genetic ACE2 ablation worsens glomerular hypercellularity in diabetic mice whereas GFR and ACR are not significantly altered and other markers of glomerular pathology are minimally affected.

Blood Pressure-Independent Amelioration of Glomerulosclerosis in Diabetic Rats Treated with Dual AT_1Receptor-Neprilysin Inhibition versus AT_1Receptor Blockade Alone Lodi C.W. Roksnoer,[1] Richard Van Veghel,[1] Marian Clahsen - van Groningen,[3] René De Vries,[1] Ingrid M. Garrelds,[1] Usha M. Bhaggoe,[1] Jeanette M. Van Gool,[1] Edith C.H. Friesema,[1] Frank P.J. Leijten,[1] Ewout J. Hoorn,[2] Alexander H. Danser,[1] Wendy W. Batenburg.[1] *[1]Div. Pharmacology and Vascular Medicine, Dept Internal Medicine, Erasmus MC, Rotterdam, Netherlands; [2]Div. Nephrology, Dept Internal Medicine, Erasmus MC, Rotterdam, Netherlands; [3]Dept Pathology, Erasmus MC, Rotterdam, Netherlands.*

Background: Dual AT_1 receptor-neprilysin inhibition (ARNI) has recently been shown to exert beneficial effects on blood pressure (BP), NT-proBNP, and estimated GFR in heart failure patients, compared with AT_1 receptor blockade (ARB) alone. Neprilysin is upregulated in epineural arterioles of diabetic rats. We hypothesized that ARNI improves cardiac and kidney parameters in diabetic TGR(mREN2)27 rats, a model displaying angiotensin II-mediated hypertension.

Methods: Rats were made diabetic with streptozotocin, for 5 or 12 weeks. In the final 3 weeks rats were treated with vehicle, the ARB irbesartan (15mg/kg.day) or irbesartan (15mg/kg.day) + the neprilysin inhibitor thiorphan (0.1mg/kg.day; ARNI). BP was measured by telemetry in the 5-week group only.

Results: Baseline mean arterial BP (MAP) was 157±5mmHg. ARB and ARNI lowered MAP identically over the 3-week period, reaching a maximum reduction of ~50mmHg around day 7. Heart weight/tibia length ratio in 12-week diabetic rats was 17±9% lower after ARNI treatment vs. ARB treatment ($P<0.05$). Proteinuria and albuminuria were observed from 8 weeks of diabetes onwards. ARNI reduced proteinuria more strongly than ARB (-78% vs. -49%, $P<0.05$), and a similar trend was seen for albuminuria. Kidneys of ARNI-treated rats showed less focal segmental glomerulosclerosis than those of ARB-treated rats. At the end of the study, no differences between ARNI- and ARB-treated rats were found regarding diuresis, natriuresis, plasma endothelin-1, vascular reactivity (acetylcholine and endothelin-1 responses), or kidney sodium transporters.

Conclusions: ARNI reduces proteinuria, focal segmental glomerulosclerosis, and cardiac hypertrophy in diabetic TGR(mREN2)27 rats more strongly than ARB, and this occurs in a blood pressure-independent manner.

SA-PO392

Collateral Effects of Atrasentan on Renin-Angiotensin System Lidia Anguiano, Marta Riera, Marta Rebull, Julio Pascual, Maria Jose Soler. *Nephrology, Hospital del Mar-Inst Hospital del Mar d'Investigacions Mèdiques, Barcelona, Spain.*

Background: Endothelin-1 is a vasoconstrictor peptide that has been shown to be increased in diabetic kidney disease. In kidney cortex from obese diabetic mice ACE2 activity is increased whereas ACE activity is decreased. Objective: study the effect of atrasentan, an antagonist of type A endothelin receptor, on renin-angiotensin system (RAS) in obese diabetic mice(db/db) and its respective controls(db/m).

Methods: Diabetic groups: vehicle (VehDB), 10mg/kg/day atrasentan (10DB), 25mg/kg/day atrasentan (25DB), 50mg/kg/day atrasentan (50DB). Non-diabetic groups: vehicle (VehCONT), 10mg/kg/day atrasentan (10CONT). Animals were included in the study at 12weeks of life and treated for 16weeks. Systolic (SBP) and diastolic (DBP) blood pressure and ACE2 and ACE enzymatic activities in serum and kidney were analyzed.

Results: See table. Atrasentan therapy significantly decreased SBP and DBP in non-diabetic mice. Circulating and renal ACE2 activities were significantly increased in VehDB mice as compared to VehCONT. Atrasentan treatment at 25 and 50mg/kg/day reduced circulating and renal ACE2 activities. Circulating and renal ACE activities were decreased in VehDB as compared to VehCONT, with no modulation by atrasentan treatment.

	VehCONT	10CONT	VehDB	10DB	25DB	50DB
SBP(mmHg)	113.5±1.4 *	105.7±1.8 $	97.5±2.5	99.3±2.7	98.4±2.3	104.3±3.4
DBP(mmHg)	85.7±1.4 *	78.6±1.8 $	71.4±2.5	74.5±2.2	72.1±1.8	76.5±2.7
Serum ACE(RFU/µL)	68712.9±4081.5 *	75946.3±4113.2	35634.7±3595.4	34085.8±3239.6	32776.8±3146.4	34412.8±1738.2
Renal ACE(RFU/µg)	3818.6±416.5 *	3692.3±334.5	752.1±94.8	595.2±68.6	696.4±118.7	561.3±101.5
Serum ACE2(RFU/µL/h)	104.3±9.1*	123.9±7.9	144.1±13.5	114.6±7.3	101.5±5.8 *	94.9±2.5 *
Renal ACE2(RFU/µg/h)	535.1±72.0 *	702.6±87.7	1126.9±130.8	816.8±119.6	837.2±65.8 *	837.2±184.8 *

*p<0.05 versus VehDB
$p<0.05 versus VehCONT

Conclusions: Atrasentan prevented the increase of circulating and renal ACE2 in diabetes, indicating a collateral effect by RAS modulation. These results suggest that the beneficial effect of atrasentan in diabetic nephropathy may be related with endothelin blockade and its effect in the non-classic RAS pathway.

SA-PO393

$P16^{ink4a}$ Expression Is Increased *via* 12-Lipoxygenase in High Glucose-Stimulated Glomerular Mesangial Cells and Type 2 Diabetic Glomeruli Yuanyuan Zhang, Fu-zhe Ma, Tao Sun, Wan-ning Wang, Hang Yuan, Zhong-gao Xu. *Nephrology, The First Hospital of Jilin Univ, Changchun, Jilin, China.*

Background: Arachidonic acid-metabolizing enzyme 12-lipoxygenase (12-LO) is involved in glomerular hypertrophy of diabetic nephropathy (DN), in which cyclin-dependent kinase inhibitors (CKIs) play important roles. However, it is unclear whether 12-LO regulates the expression of the CKI $p16^{ink4a}$ in DN.

Methods: Primary glomerular mesangial cells (MCs) and glomeruli isolated from rats were used in this study. The rats were fed a high-fat diet and given low-dose streptozotocin to induce type 2 diabetes. The 12-LO product 12(S)-hydroxyeicosatetraenoic acid [12(S)-HETE] was infused through an osmotic minipump. Enzyme-linked immunosorbent assay, Western blot, and morphometric analyses were performed.

Results: High glucose (HG) increased $p16^{ink4a}$ protein expression in MCs, but this increase was prevented by the 12-LO inhibitor cinnamyl-3,4-dihydroxy-α-cynanocinnamate (CDC). The levels of p-p38MAPK and $p16^{ink4a}$ in MCs were significantly elevated after 12(S)-HETE treatment, whereas the p38MAPK inhibitor SB203580 prevented these increments. Compared with levels in control MCs, marked increases in p38MAPK activation and $p16^{ink4a}$expression were observed in MCs plated on collagen IV, while CDC treatment prevented these changes. Subcutaneous injection of CDC did not affect glucose levels but completely attenuated the diabetes-related increases in 12(S)-HETE content, $p16^{ink4a}$ expression, p-p38MAPK levels, glomerular volume, and kidney/body weight ratio. Compared with levels in controls, $p16^{ink4a}$ and p-p38MAPK in the glomeruli derived from 12(S)-HETE-treated rats were significantly increased.

Conclusions: 12-LO-p38MAPK mediates the upregulation of $p16^{ink4a}$ in HG-stimulated MCs and type 2 diabetic glomeruli, and new therapies aimed at 12-LO inhibition might be beneficial in ameliorating diabetes-induced glomerular hypertrophy.

SA-PO394

The Effect and Mechanism of Probucol on Diabetic Nephropathy Tubulointerstitial Injury via Down-Regulating P66Shc Shi-kun Yang,[1] Xiaoxuan Xu,[1] Chun Hu,[1] Li Xiao,[1] Fuyou Liu,[1] Lin Sun.[1] *[1]Dept of Nephrology, Kidney Inst of Central South Univ, Changsha, Hunan Province, China; [2]Dept of Nephrology, Kidney Inst of Central South Univ, Changsha, Hunan Province, China.*

Background: P66Shc induce mitochondrial ROS overproduction and lead to renal oxidative stress. Probucol has the renal protective effect on the progression of DN. However, the mechanism remains poorly understood.

Methods: ICR mices were divided into control (n=10), DN (n=10), probucol (10mg/kg/d) group (n=10), DMSO group (n=10). The DN model was induced by injection of STZ (40mg/kg body weight) . Probucol was intraperitoneally injected to the mice every other day for 12 weeks after the model was built. Renal lesions and the expression of SIRT1, P300, AcH3, P66Shc, FN were detected by HE, Masson staining, TUNEL, DHE, immunohistochemistry and western-blot respectively.In addition, HK-2 cells were incubated with different concentrations of D-glucose (5, 30mM) with or without probucol, 1mM AICAR or 20uM Dorsomorphin or1uM EX-527 . The expression of P66Shc, SIRT1, P300, AcH3, AMPK, p-AMPK in HK-2 cells were detected by realtime-PCR,Western-blot and immunoflurescence assays. In addition, chromatin immunoprecipitation (ChIP) assay was used for determining the effect of probucol on acetylation of histone of P66Shc gene.

Results: Compared to control, the reduced ECM protin and renal tubular damage were observed in DN mice after treated by probucol. It also decraesed the expressions of P300, P66Shc, FN in the kidney of DN mices. In addition, Probucol can reduce the level of serum creatinine levels, attenuate renal ROS levels and apoptosis ,while boost the expressions of p-AMPK and SIRT1. Furthermore, pretreatment with the selective AMPK inhibitor Dorsomorphin or SIRT1 inhibitor EX-527 could block the inhibitory efficiencies of probucol. The ChIP analysis showed that probucol treatment could decrease the acetylation of histone H3 in p66Shc gene promoter regions (-535 bp to -276 bp) in HK-2 cells induced by high glucose.

Conclusions: Probucol could epigenetically suppress the expression of P66Shc through AMPK-SIRT1-AcH3 pathway, then ameliorate the apoptosis and oxidative injury in HK-2 cells induced by high glucose.

SA-PO395

Macrophages in Type 2 Diabetic Nephropathy Celine Klessens, Malu Zandbergen, Ron Wolterbeek, Jan A. Bruijn, Ton J. Rabelink, Ingeborg M. Bajema, Daphne Thomas-ijpelaar. *Leiden Univ Medical Center.*

Background: Inflammation seems to play a role in type 2 diabetic nephropathy (DN). Therefore, novel therapies focus on inhibition of inflammation to inhibit renal failure in DN. Interstitial macrophages are present in progressive interstitial lesions, however, the role of glomerular macrophages in the development of diabetic glomerular damage remains incompletely understood. In this study we investigated the accumulation of macrophages in glomeruli and interstitium of humans with various stages of DN.

Methods: Kidney samples obtained at autopsy of type 2 diabetes patients (N=88) with histologically proven DN were stained with CD68 and CD163, as global and M2 macrophage markers. As controls, renal autopsy samples of 5 non-diabetic and 18 diabetic

patients without DN were used. Macrophages in 50 glomeruli per sample were counted. Interstitial macrophages were counted semi-quantitatively. Glomerular and interstitial macrophages were correlated to histological and clinical parameters.

Results: Glomerular CD68+ and CD163+ cells were present in all stages of DN according to the histopathological class and did not differ between classes, but the accumulation varied widely. The mean influx of glomerular CD68+ cells over the classes was 4.2 (range 0-19) and the mean influx of glomerular CD163+ cells was 2.1 (range 0-14.74). The mean ratio of CD163/68+ cells amounted 0.5. Glomerular macrophages were also present in the control groups. Renal function was associated with the number of CD68+ cells and CD163+ cells were significantly associated with histological lesions. Interstitial macrophages significantly correlated with clinical parameters like GFR stage and albuminuria.

Conclusions: We showed that macrophages (including anti inflammatory CD163 + macrophages) are present in all stages of DN both in the glomerulus and interstitium. Correlation between clinical data and interstitial macrophages indicates that interstitial inflammation probably influences the progression of DN. In addition, presence of glomerular macrophages in early diabetic nephropathy suggests that they influence the glomerular diabetic damage as well. Therefore, therapies targeting macrophages might be a useful novel therapy in DN.

SA-PO396

Activation of CXCL16/CXCR6 Pathway by Inflammation Accelerates the Progression of Diabetic Nephropathy Zebo Hu, Kun Ling Ma, Yang Zhang, Wu Yu, Bi-Cheng Liu. *Inst of Nephrology, Southeast Univ, Nanjing City, Jiang Su Province, China.*

Background: Diabetic nephropathy(DN)was considered as a chronic inflammatory disease. Inflammation plays critical roles in the progression of DN. This study investigated the role of CXC chemokine ligand 16 (CXCL16)/CXC chemokine receptor 6 (CXCR6) pathway in DN under inflammatory stress and explored its potential mechanisms modulated by purinergic receptor P2X ligand-gated ion channel 7 (P2RX7).

Methods: Diabetic db/db mice were randomly divided into two groups: db/db, and db/db+casein for eight weeks. Casein was subcutaneously injected to induce chronic inflammation. The morphological change of renal pathology and ultra-microstructure were checked by pathological staining and electron microscopy. Lipid accumulation in kidneys was observed by Filiping staining and quantitative assay of intracellular free cholesterol. The expression of CXCL16/CXCR6 pathway, inflammatory cytokine, and fibrotic index related molecules were detected by immunohistochemistry, immunofluorescent staining, and Western Blot.

Results: The 24-hour urinary protein, tubulointerstitial injury, inflammatory cell infiltration, and the protein expression of monocyte chemotactic protein 1(MCP-1), tumor necrosis factor α (TNFα), CD68, a-Smooth muscle actin (α-SMA), and fibronectin (FN) in kidneys of db/db+casein mice were significantly increased compared with the db/db mice. Furthermore, there was significant lipid accumulation, increased protein expression of CXCL16 and CXCR6 and decreased disintegrin and metalloproteinase-10(ADAM10) expression in kidneys of db/db+casein mice compared with db/db mice, accompanied with increased P2X7R expression. Further analysis demonstrated that there was a positive correlation between P2X7R and CXCL16 expression.

Conclusions: Inflammation accelerates tubulointerstitial injury in DN partly through the activation of CXCL16/CXCR6 pathway, which may facilitate inflammation induction and lipid accumulaton in cells. The P2X7R pathway may be involved in the activation of CXCL16/CXCR6 pathway.

SA-PO397

Albumin Glycation Induces Structural Changes That Reduce Proximal Tubule FcRn-Albumin Binding and Reclamation Mark C. Wagner,[1] Jered Myslinski,[1] Shiv Pratap Singh Yadav,[3] George Rhodes,[1] Ruben M. Sandoval,[1] Sudhanshu Kumar,[1] Sarah E. Wean,[1] Fnu Ashish,[3] Bruce A. Molitoris.[1,2] *[1]Nephrology Div, Dept of Medicine, Indiana Univ School of Medicine, Indianapolis, IN; [2]Cellular & Integrative Physiology, Indiana Univ School of Medicine, Indianapolis, IN; [3]CSIR-Inst of Microbial Technology, Chandigarh, India.*

Background: Diabetic nephropathy remains the leading cause of chronic kidney disease (CKD) and ESRD. It results in increased albumin glycation and this is believed to be involved in proximal tubule cell injury and the pathophysiology of interstitial fibrosis and CKD progression.

Methods: To understand the mechanisms we have addressed specific in vitro albumin modifications and their impact on albumin-FcRn binding since proximal tubule FcRn is necessary for transcytosis and reclamation of filtered albumin.

Results: Those studies showed markedly reduced binding to FcRn when albumin was glycated proportional to the level of glycation. To address the mechanism for reduced binding we used SAXS analysis and molecular modeling to determine structural changes. SAXS data analysis revealed significant shape changes occur to albumin upon glycation which affected its binding affinity to FcRn.Our prediction would be that albumins with weaker FcRn binding would have more rapid serum clearance implying increased Pt catabolism via lysosomal degradation. Prior to evaluating modified albumin, control albumin was labeled with multiple fluorophores to determine conjugation ratios and dyes that retained normal pH dependent FcRn binding and would thus permit accurate serum clearance to be evaluated. The results agreed with our prediction and we are presently evaluating the serum clearance for the glycated albumins that have been conjugated to a fluorescent probe.

Conclusions: The data indicate modifications to albumin lead to structural alterations resulting in reduced PT pH dependent FcRn binding, which alters lysosomal catabolism leading to transcytosis and reclamation resulting in a shorter serum half life and may mediate the enhanced interstitial inflammation and fibrosis in diabetic nephropathy.

The Efects of Glucagon-Like-Peptide-1 and Vitamin D on Inflammatory and Histological Changes of Diabetic Nephropathy in db/db Mice Yael Einbinder,[1,2] Sydney Benchetrit,[1,2] Tali Zitman-Gal.[1] *[1]Renal Physiology Laboratory, Dept of Nephrology and Hypertension, Meir Medical Center, Kfar Saba, Israel; [2]Sackler Faculty of Medicine, Tel Aviv Univ, Tel Aviv, Israel.*

Background: Glucagon-like-peptide-1 is a gut incretin hormone that stimulates insulin secretion and may affect the inflammatory pathways involved in type 2 diabetes mellitus (DM). Calcitriol plays an important role in renal, endothelial, and cardiovascular protection. We evaluated the anti-inflammatory and histological effects of GLP-1 and calcitriol in a db/db mice diabetic model.

Methods: C57BL/6 (WT) and BKS.Cg-*Dock7^{m}* +/+ *Lepr$^{db/db}$* (db/db) mice were randomized to: a) WT mice; b) db/db mice (diabetic control group); c) db/db mice+GLP-1 analog (100 nmol/kg); and d) db/db mice+GLP-1 analog +calcitriol (250 ng/kg). Blood glucose levels and weight were evaluated weekly. At the end of the14-week treatment, kidneys were perfused and removed for protein analysis and histology.

Results: Blood glucose levels and weight were significantly higher in db/db mice compared to control WT mice. Blood glucose level was non-significantly lower in the db/db GLP-1 group compared to untreated db/db mice (460.5±83.2 mg/dl vs. 526.3±33.3 mg/dl). GLP-1 treatment significantly up-regulated eNOS protein expression and significantly down-regulated p65 protein expression compared to the db/db control group. Vitamin D did not further improve the beneficial effect observed on protein expression. Kidney VDR protein expression increased only in the vitamin D group compared to the db/db control group. Kidney histology demonstrated beneficial effect of GLP-1 treatment on golmerular hypertrophy in db/db mice at 26 weeks of age but had no significant effect on the severity of mesangial expansion.

Conclusions: In the experimental model of diabetic nephropathy (db/db mice), GLP-1analog treatment improved the protein expression involved in the inflammatory response and significantly ameliorated the glomerular hypertrophy seen in the diabetic control group.

Mineral Metabolism and Interleukin-6: Predictive Risk Factors for Left Ventricular Hypertrophy in Patients with Diabetic Nephropathy Teresa M. Jeronimo,[1] André Fragoso,[1] Filipa Brito Mendes,[1] Ana Paula Silva,[1,2] Ana Pocinho Pimentel,[1] Nelson Tavares,[3] Pedro L. Neves.[1,2] *[1]Nephrology, Centro Hospitalar do Algarve, Faro, Portugal; [2]Dept of Biomedical Sciences and Medicine, Univ of Algarve, Faro, Portugal; [3]Cardiology, Centro Hospitalar do Algarve, Faro, Portugal.*

Background: Left ventricular hypertrophy (LVH) is an important risk factor for cardiovascular disease in patients with diabetic nephropathy (DN) and is an independent predictor of mortality in patients with chronic kidney disease (CKD). The aim of this study was to evaluate the predictive risk factors of LVH in a population of patients with DN.

Methods: The authors analysed the relationship of LVH with gender, body mass index (BMI), systolic blood pressure (SBP), estimated glomerular filtration rate (eGFR), albumin, cholesterol, hemoglobin (Hb), calcium, phosphorus, parathyroid hormone (PTH), urine albumin-to-creatinine ratio (UACR), interleukin-6 (IL-6), hemoglobin A1c (HbA1c) and insulin resistance (HOMA-IR). Descriptive statistics, Student's t-test and logistic regression model were used.

Results: In a cross-sectional study were included 119 type 2 diabetic patients with CKD stages 3 and 4. Patients with LVH had significant lower values of eGFR and albumin, higher levels of UACR, HOMA-IR and IL-6. Phosphorus (odd ratio (OR) = 0.602 (1.075-4.414), p = 0.038), PTH (OR = 1.009 (1.098-3.000), p = 0.004) and IL-6 (OR = 1.264 (1.863-6.719), p = 0.0001) were independently related with LVH.

Variable	Adjusted OR (95% CI)	p-Value
Gender	-1.012 (0.064-2.076)	0.255
Age	0.032 (0.890-1.053)	0.455
BMI	0.170 (0.969-1.448)	0.098
SBP	-0.008 (0.944-1.043)	0.757
eGFR	-0.026 (0.930-1.021)	0.279
Albumin	-0.021 (0.137-7.012)	0.983
Hb	0.242 (0.770-2.106)	0.347
Phosphorus	0.602 (1.075 -4.414)	0.038
iPTH	1.009 (1.098-3.000)	0.044
UACR	-0.001 (0.993-1.006)	0.865
HOMA-IR	0.422 (0.746-3.114)	0.247
IL-6	1.264 (1.863-6.719)	0.0001

Multivariate logistic regression model — risk factors of LVH.

Conclusions: Phosphorus, PTH and IL-6 were independent risk factors of LVH in our diabetic population with CKD stages 3 and 4.

Far-Infrared Therapy Retrieves Pancreatic Beta Cell Function and Survival in a Streptozotocin-Nicotinamide-Induced Type 2 Diabetic Mouse Model

Yung-Ho Hsu,[1] Tso Hsiao Chen,[2] Cheng-hsien Chen.[1,2] *[1]Div of Nephrology, Dept of Internal Medicine, Shuang Ho Hospital, Taipei Medical Univ, Taipei, Taiwan; [2]Div of Nephrology, Dept of Internal Medicine, Wan Fang Hospital, Taipei Medical Univ, Taipei, Taiwan.*

Background: In diabetes, the apoptotic cell death of insulin-producing beta cells leads to insulin deficiency. Recently, we found low-temperature far-infrared (FIR) irradiation increased proliferation and survival of human umbilical vein endothelial cells via promyelocytic leukaemia zinc finger protein (PLZF)-mediated PI3K/Akt activation.

Methods: In this study, we investigate the protective effects of FIR on pancreatic beta cell function and survival in the nicotinamide (NA) and streptozotocin (STZ)-induced type II diabetic mouse model. ells via promyelocytic leukaemia zinc finger protein (PLZF)-mediated PI3K/Akt activation.

Results: The present study showed that FIR therapy decreased non-fasting blood glucose levels and increase blood insulin levels in diabetic mice in a dose-dependent manner. Immunohistochemistry staining revealed that FIR therapy retrieved insulin production of pancreatic beta cells in diabetic mice. But the influence of FIR on blood glucose and insulin levels was not found in NA/STZ-treated PLZF-knockout mice. We also used the insulin-secreting beta cell line RIN-m5f to investigate the protective effects of FIR in vitro. FIR irradiation promoted cell proliferation and inhibited STZ-induced apoptosis in RIN-m5f cells. FIR also induced PLZF nuclear translocation and increased PI3K expression and Akt phosphorylation in RIN-m5f cells. PLZF siRNA transfection inhibited the influence of FIR on RIN-m5f cells.

Conclusions: Our data suggest that FIR therapy retrieves pancreatic beta cell function and survival in diabetic mice via a PLZF-mediated pathway.

Transgenic Mice Overexpressing Human CD39 (ENTPD1) Are Protected from High-Fat Diet-Induced Obesity and Insulin Resistance

Anna U. Brandes,[1] Yue Zhang,[1] Kristina M. Heiney,[1] Simon C. Robson,[2] Bellamkonda K. Kishore.[1] *[1]Internal Medicine, Univ of Utah & VA Med Ctr, Salt Lake City, UT; [2]Internal Medicine, BIDMC, Harvard Univ, Boston, MA.*

Background: CD39 is a vascular ecto-nucleotidase that sequentially hydrolyzes extracellular ATP to ADP and AMP, thus terminating P2 receptor signaling. Previously we reported that deletion of *Cd39* results in hepatic insulin resistance (IR). We also found that deletion of ATP/UTP activated $P2Y_2$-R confers significant protection against high-fat diet (HFD)-induced obesity and IR. Hence, we hypothesized that global overexpression of human CD39 (hCD39), which decreases the availability of extracellular nucleotides should attenuate development of HFD-induced obesity and IR.

Methods: Groups of age-matched adult wild type C57/Bl6 (WT) and syngeneic transgenic (TG) mice globally overexpressing hCD39 were fed regular diet (10% calories as fat; n = 5) or HFD (60% calories as fat; n = 7) with free access to food and water for 10 weeks. Body weights (BW), food and water consumption and urine output were monitored periodically. Glucose tolerance (GTT) and insulin sensitivity (IST) tests were conducted between 8 to 10 weeks.

Results: In response to HFD feeding, both genotypes showed significant increases in BW over the experimental period as compared to their counter parts fed regular diet. However, the gain in BW was significantly less in TG vs. WT mice (mean 21.5 ± 0.3 vs. 15.3 ± 2.0 g, n = 7, p = 0.005). There were no significant differences between the genotypes in the amount of food consumed, nor was there evidence of steatorrhea indicating malabsorption. Fasting blood glucose levels in HFD fed TG mice were 2-fold higher vs. WT mice (179 ± 12 vs. 88 ± 5 mg/dL, n = 7, p = 0.0001). When fed HFD, both genotypes exhibited glucose intolerance, but this was less severe in TG mice. In parallel, insulin sensitivity was significantly better in HFD-fed TG vs. WT mice.

Conclusions: Our results demonstrate that overexpression of hCD39 confers significant protection against the development of HFD-induced obesity and IR, and thus validating the proposition that dominantly deleterious roles are played by extracellular nucleotides in metabolic homeostasis.

Mass Spectrometry Imaging Reveals a Role for Glomerular Sphingomyelin to Suppress AMPK Activity by Stimulating ATP Production in Mesangial Cells

Satoshi Miyamoto,[1,2,3] Cheng-Chih Hsu,[4] Gregory Hamm,[5] Manjula Darshi,[1,2] Jonathan Stauber,[5] Pieter Dorrestein,[1,4] Kumar Sharma.[1,2,3] *[1]Inst of Metabolomic Medicine, Univ of California San Diego, La Jolla, CA; [2]Center for Renal Translational Medicine, Univ of California San Diego, La Jolla, CA; [3]Veterans Affairs San Diego Healthcare System, La Jolla, CA; [4]Therapeutic Discovery Mass Spectrometry Center, Univ of California San Diego, La Jolla, CA; [5]ImaBiotech, MS Imaging Dept, Lille, France.*

Background: We have recently shown that the ATP/AMP ratio is increased in the glomeruli in a mouse model of type 1 diabetes by matrix-assisted laser desorption/ionization mass spectrometry imaging (MALDI-MSI) and may be the basis for reduced AMP-activated protein kinase (AMPK) in diabetic glomeruli. Here, we applied MALDI-MSI to identify a key molecule involved in the regulation of glomerular ATP.

Methods: For MALDI-MSI, 23 weeks-aged male diabetic Akita (C57BL/6J-Ins2^{Akita}) (A), wild type mice (W), and a normal human kidney (H) were used. For cell culture study, murine mesangial cells (MMCs) were treated with sphingomyelin(d18:1/16:0) (SM)-containing liposomes (SL), control liposomes (CL) and vehicle. For ATP measurements, MMCs were transfected with sphingomyelin synthase (SMS)1, 2 or control siRNA before treatment with liposomes.

Results: By MALDI-MSI, we found that SM(d18:1/16:0) was preferentially distributed in the glomeruli in W and H. Importantly, we found that SM is more abundant in glomeruli of A compared with W, and associated with increased SMS1 and 2 in the glomeruli ($p<0.05$). SL stimulated ATP production in MMCs compared with CL ($p<0.01$), and was inhibited by siRNA based inhibition of SMSs. AMPKα activity and PGC1α protein expression were significantly reduced by SL ($p<0.05$). In addition, SL increased glucose consumption and lactate production in high glucose conditions ($p<0.05$) suggesting a role for enhanced glycolysis.

Conclusions: We demonstrate using MALDI-MSI that the accumulation of glomerular SM in type 1 diabetic mice is associated with increased ATP in glomeruli and may contribute to reduced AMPK activity in diabetes. These findings suggest that reduction of SM may lead to novel therapeutic targets for the treatment of diabetic kidney disease.

Chronic Hyperglycemia Activates Authophagy Through an Increased Lysine-63 Linked Ubiquitination: A Candidate Mechanism in the Progression of Tubular Damage in Diabetic Nephropathy

Paola Pontrelli, Annarita Oranger, Mariagrazia Barozzino, Francesca Conserva, Massimo Papale, Matteo Accetturo, Maria Teresa Rocchetti, Giuseppe Castellano, Loreto Gesualdo. *Dept of Emergency and Organ Transplant, Nephrology Unit, Univ of Bari, Italy.*

Background: Chronic hyperglycemia, a key pathogenic factor of diabetic nephropathy (DN), can alters autophagy whose role in tubular cells under hyperglycemic conditions (HG) remains unclear. We reported that lysine63-ubiquitination (K63-Ub) plays a key role in the progression of tubular damage in DN; moreover K63-Ub promotes protein autophagic clearance. Aim of our study was to: evaluate the HG effect in modulating autophagy in tubular cells (HK2); evaluate *in vivo* the autophagy state in patients with diabetes without renal damage and in different DN classes; investigate the K63-Ub role in the modulation of tubular cells autophagy.

Methods: K63-Ub was inhibited in HK2 under HG (30mM) by UBE2v1 silencing, E2 enzyme involved in K63-Ub, or by NSC697923 inhibitor. The expression of the authophagic factor LC3 was detected by western blotting and confocal microscopy. Immunohistochemistry (IHC) and immunofluorescence (IF) were performed on kidney biopsies of 3 control patients, 3 diabetic, 9 DN (classes IIb, III and IV).

Results: HK2 showed a significant increase in LC3 protein after 24h of HG. UBE2v1 silencing completely abolished LC3 induced protein expression after 24h of HG. Confocal microscopy showed the reduction of autophagic vesicles induced by HG in the presence of the K63-Ub inhibitor (NSC697923). IHC on kidney biopsies revealed an increased tubular expression of LC3 in diabetic patients vs controls, that persists in all DN classes and class IV patients showed cytoplasmic accumulation of fused-vesicles. The same tubules with activated autophagy, expressed K63-Ub proteins both in diabetic and in DN patients (IF).

Conclusions: In conclusion, our data demonstrate that chronic hyperglycemia induces an increase in autophagy, linked to the accumulation of K63 ubiquitinated proteins. However, uncontrolled autophagy levels could lead to tubular damage through the generation of intracellular vesicles, bringing to the progression of renal damage in DN patients.

Complexome Profiling of Mitochondrial Respiratory Chain Proteins from Podocytes of Diabetic Mice

Zengchun Ye, Shawn S. Badal, Daniel L. Galvan, Jianyin Long, Farhad R. Danesh. *Section of Nephrology, The Univ of Texas MD Anderson Cancer Center, Houston, TX.*

Background: Mitochondria play essential roles in many aspects of biology, and their dysfunction has been linked to diverse diseases, including diabetic nephropathy (DN). Central to proper mitochondrial function is oxidative phosphorylation (OXPHOS), coordinated by respiratory chain complexes encoded by both nuclear and mitochondrial genomes. Whether alterations in specific OXPHOS complex protein expression/activity contribute to mitochondrial dysfunction in DN remain largely unknown.

Methods: To asses complexome profiles, mitochondria were isolated from podocytes of16-week-olddiabetic (*db/db*) and nondiabetic (*db/m*) mice. Blue Native Gel Electrophoresis (BNE) was coupled with quantitative mass spectrometry (nano-HPLC/ESI/MS/MS) to identify known and unknown macromolecular protein complexes.

Results: We identified a total of 1216 mitochondrial proteins. Complexome profilingrevealed mitochondrial complexes I and III to be markedly reduced in podocytes of *db/db* compared to controls. Consistent with MS results, Complex I activity was significantly reduced in podocytes of *db/db* mice compared to controls. Importantly, we found that the protein expression levels of Ndufb2, Ndufb3 and Ndufb8, all components of complex I, were significantly reduced in podocytes of *db/db* mice. We further validated

our initial results and found that the podocyte-derived mitochondria from diabetic db/db mice display markedly reduced message and protein expression levels of Ndufb8. These changes are coincident with significantly decreased Complex I activity from analogously isolated and processed mitochondria derived from db/db mice.

Conclusions: Our study uncovers a previously unrecognized role of complex I in the pathogenesis of DN. We propose that deficiencies in components of complex I may disrupt complex I assembly, eventually reducing mitochondrial oxidative metabolism of podocytes in diabetic kidney disease. Further genetic studies are currently underway in our laboratory to establish the value and limitations of using Ndufb8 transgenic mice in experimental models of diabetes as a model for targeting mitochondrial dysfunction in DN.

Hyperglycemia and Hyperinsulinemia Increased Cell Proliferation and Regulated DNA Damage/Repair Pathways in Type II Diabetic (db/db) Mouse Samy L. Habib,[1,2] Sitai Liang.[1,2] *[1]Geriatric Research, Education and Clinical CTR, South Texas Veterans Health System, San Antonio, TX; [2]Cellular and Structural Biology, The Univ of Texas Health Science Center, San Antonio, TX.*

Background: The mechanisms by which hyperglycemia and/or hyperinsulinemia activate cell proliferation to regulate the DNA damage/repair pathways and increase renal cell damage in diabetes remain unclear.

Methods: In the current study, we investigated the role of hyperglycemia and hyperinsulinemia in regulating cell survival and cell proliferation to regulate the DNA damage/repair pathways the in type II diabetic (db/db) mouse.

Results: Significant increase in proteinuria, albuminuria, creatinine in 24h urine as well as in serum insulin was detected in db/db mice compared to wild type mice. Cell proliferation was measured by Ki67 staining and PCNA expression in kidney sections of diabetic and wild type mice. Data showed significant increase of Ki67 staining and protein expression of PCNA in kidney of diabetic mice compared to wild type mice. The activity of survival kinase Akt (measured by phospho-Akt at Ser^{473}) was significantly increased and associated with increased activation of mTORC1 (measured by phosphor-p70S6K at Thr^{389}) in kidney cortex of db/db mice compared to wild type mice by Western blot analysis. DNA repair OGG1 and the transcription factor regulates OGG1 (Nrf2) were significantly decreased and associated with increased in oxidative DNA damage (8-oxodG) in kidney homogenate from db/db mice compared to wild type mice. Gel shift analysis shows reduction of Nrf2 binding to OGG1 promoter in nuclear extracts of kidney homogenate of db/db mice compared to wild type mice. A portion of the DNA-protein complexes was significantly decreased in the presence of the Nrf2 antibody indicating that Nrf2 is indeed a component of these complexes.

Conclusions: In summary, our data provide a novel mechanism of increase renal cell damage through decrease binding of Nfr2 to the OGG1 promoter and consequence deficiency in DNA repair that lead to accumulate DNA damage and lead to renal complications under hyperglycemia and hyperinsulinemia condition in diabetic mice.

Spleen Tyrosine Kinase Activation Promotes the Progression of Diabetic Nephropathy in the Early Stage Fei Liu. *Nephrology, West China Hospital of Sichuan Univ, Chengdu, Sichuan, China.*

Background: Inflammation triggered by metabolic disorder has played an important role in the pathogenesis of diabetic nephropathy (DN) in the early stage.The inflammatory cytokines binding to immunoglobulin G Fc receptors (FcgRs) in the surface of cell contribute to the progression of inflammation. It was found in our previous study that there was an increased expression of FcgRs with an immunoreceptor tyrosine-based activation motif (ITAM-FcgRs) in the kidney of diabetic CRP-Tg mouse induced by streptozotocin (STZ). It was also observed that ITAM-FcgRs were increased and spleen tyrosine kinase (SYK) were activated in rat glomerular mesangial cells (GMC) cultured with high glucose. SYK is a cytoplasmic nonreceptor tyrosine kinase and plays critical role in intracellular signal transduction of ITAM-FcgRs. It has been established that activated SYK signal cascade leads to the pro-inflammatory cytokines production in antibody-dependent kidney disease. However, the role of SYK in the progression of DN remains unclear. The present study investigated the potential role of SYK activation in the early stage of DN.

Methods: Diabetes was induced by STZ in Sprague Dawley (SD) rats for assessment of kidney injury at 2, 4, 8weeks by real-time PCR, immunohistochemistry and western blot analysis. In vitro, the pathogenic effect of SYK was observe.

Results: Compared with control, urinary albuminexcretion significantly increased in diabetic SD rats at 2, 4 and 8 weeks after STZ injection. Renal inflammation has been developed with enhanced infiltration of macrophages and T cells, and upregulation of pro-inflammatory cytokines (IL-1β, TNFα) in diabetic rats. Enhanced renal inflammation in diabetic rats caused the increase of SYK phosphorylation and the over-activation of nuclear factor κB (NF-κB) signaling pathway. In vitro, high glucose significantly upregulated pro-inflammatory cytokines (IL-1β, TNFα) via SYK cascade, which further promoted high glucose-mediated renal inflammation.

Conclusions: These findings suggested that SYK may be as "signal switch" to activate NF-κB signaling pathway and promote the progression of renal injury in the early stage of DN.

Smooth Muscle Specific Heavy Chain Ferritin Knockout Mice as a Model of Obesity Vyvyca Walker, Bo Chen, Reny Joseph, Anupam Agarwal. *Nephrology Research and Training Center, Div of Nephrology, Univ of Alabama at Birmingham, Birmingham, AL.*

Background: Ferritin, consisting of heavy (H) and light (L) chain subunits, is a highly conserved ubiquitous protein that safely sequesters iron in a non-toxic form. During the course of our studies to evaluate the role of heavy chain ferritin (FtH) in a model of vascular calcification in CKD, we generated a transgenic mouse using the cre-lox system with smooth muscle cell-specific deletion of FtH ($FtH^{SM22-/-}$). Serendipitously, we discovered the $FtH^{SM22-/-}$ mice gained more weight compared to control "floxed" FtH mice and exhibited features resembling metabolic syndrome.

Methods: To characterize $FtH^{SM22-/-}$ mice as a model of obesity, male $FtH^{SM22-/-}$ mice and $FtH^{SM22+/+}$ control mice were individually housed from 6-28 weeks of age to monitor weight, food intake, and body composition utilizing quantitative magnetic resonance (QMR) imaging. Protein analysis was performed on skeletal muscle and fat to determine expression levels of insulin signaling mediators and iron regulators. RNA analysis of inflammatory markers expressed in white fat was also performed.

Results: At 28 weeks old, $FtH^{SM22-/-}$ mice gained more weight (30.58g ± 2.02 vs. 27.72g ± 1.06 controls) during the observation period and consumed significantly more food starting at 20 weeks of age than the controls. QMR studies revealed that $FtH^{SM22-/-}$ mice had slightly more fat, lean and water mass compared to controls. Protein analyses of skeletal muscle and white fat revealed a loss of GLUT4 expression and iron trafficking proteins, respectively, in transgenic mice. Moreover, there was an increase in tissue iron concentration and gene expression of TNFα in the fat tissue of $FtH^{SM22-/-}$ mice compared to controls. Interestingly, review of publically available microarray data sets (NCBI, GEO data set GDS3876) derived from human samples suggest a significant (~1.5 fold) increase in FtH gene expression in obese individuals compared to lean controls.

Conclusions: Over a third of the adults in the United States are obese. Obesity predisposes individuals to other health risks, including CKD, diabetes, stroke, and cardiovascular disease. Our studies provide a novel mouse model for obesity.

The Induction and Role of p53 in Tubular Cell Apoptosis During High Glucose Treatment and Diabetes Lin Li,[1,2] Zhengwei Ma,[1] Changlin Mei,[2] Zheng Dong.[1] *[1]Dept of Cellular Biology and Anatomy, Georgia Regents Univ, Augusta, GA; [2]Dept of Nephrology, Shanghai Changzheng Hospital, 2nd Military Medical Unversity of PLA, Shanghai, China.*

Background: p53, known as a tumor suppressor, plays a crucial role in the cellular response to various stresses. P53 has been implicated in diabetic kidney disease but its role remains unclear and controversial.

Methods: Kidneys from Akita mice and STZ-treated diabetic mice were collected for in vivo studies. In vitro, renal proximal tubular cells (RPTC) with or without p53 dominant negative (p53-DN) were cultured in medium containing 5.5 mM or 30 mM glucose. Apoptosis was evaluated by morphologic observation, TUNEL, and flow cytometric analysis. The cells were also fractionated to investigate the subcellular redistributions of Bax and cytochrome c. The expression of p53, phosphorylated-p53 and apoptosis-related proteins were examined by western blot, immunohistochemistry/immunocytochemistry and immunofluorescence.

Results: Apoptosis was detected in renal tubules within a few weeks of diabetes, which was accompanied by p53/p-p53 expression. In cultured RPTC cells, high glucose induced apoptosis and p53. In these cells, there were Bax translocation to the mitochondria and cytochrome c release. Interestingly, these changes and apoptosis were attenuate in p53-DN cells. Consistently, they were also suppressed by pifithrin-α, a pharmacological inhibitor of p53.

Conclusions: These results suggest that p53 may be an upstream mediator of tubular cell apoptosis during high glucose treatment and in diabetic kidneys. P53 is induced under these conditions and may activate the mitochondrial pathway of apoptosis.

Mechano-Growth Factor Regulates mTOR and Other Growth Factor Expression in Mouse Mesangial Cells, Enhancing Cell Proliferation and Extracellular Matrix Production: Implications for Diabetic Glomerulosclerosis Yongxin Gao, Leighton R. James, Charles W. Heilig. *Medicine, Univ of Florida College of Medicine-Jacksonville, Jacksonville, FL.*

Background: MGF-S mesangial cells (MC) overexpress Mechano-Growth Factor protein 13.2-fold, with increased GLUT1, glucose uptake, cell proliferation and extracellular matrix (ECM). Here we examined mTOR expression and downstream S6 kinase activation, VEGF and TGF beta1 in our MGF-EV empty vector control MC, MGF-S MC overexpressing MGF, and MGF-AS MC with suppressed MGF.

Methods: Western analyses for selected proteins in cultured MGF-EV, MGF-S and MGF-AS were performed with specific antibodies and band densities normalized to endogenous beta-tubulin. 3H2-Deoxyglucose (3H2-DOG) uptake rates were determined as we have previously published. P<.05 was considered significant in statistical analyses.

Results: MGF-S exhibited persistent stimulation of VEGF expression 1.6-fold the MGF-EV control. mTOR expression increased 7.7-fold vs MGF-EV, leading to activation

of S6 kinase (phospho-S6 kinase) protein 8.7-fold. This increase in mTOR and active S6 kinase correlated with an increased proliferation rate of MGF-S vs. MGF-EV. MGF-AS had suppressed mTOR by 69%, but suppressed active S6 kinase by an insignificant amount. VEGF expression was suppressed 60% in MGF-AS vs MGF-EV. TGF beta1 protein was increased 1.8-fold in MGF-S, and reduced 46% in MGF-AS. GLUT1 protein in MGF-S was increased 7.2-fold, with a 10.6-fold increased 3H2-DOG uptake rate. In contrast, 3H2-DOG uptake was suppressed 85% in MGF-AS vs. MGF-EV. In MGF-S, Type IV collagen (Col-IV) was increased 4.2-fold.

Conclusions: MGF-S MC demonstrate increased mTOR with S6 kinase activation, consistent with their enhanced proliferation rate, while the increased VEGF and TGF beta1 promote Col-IV protein expression. Overexpression of MGF in MC to mimic events in diabetic glomeruli recreates many features of high glucose-exposed MC. MGF-AS MC demonstrate a role for MGF in basal VEGF and TGF beta1 expression.

High Fat and High Sucrose Diet Induce Steatohepatitis That Is Dependent on Fructokinase Takuji Ishimoto,[1] Miguel A. Lanaspa,[2] Shoichi Maruyama,[1] Richard J. Johnson.[2] *[1]Nephrology, Nagoya Univ of Graduate School of Medicine, Nagoya, Aichi, Japan; [2]Renal Diseases and Hypertension, Univ of Colorado Denver, Aurora, CO.*

Background: High fructose intake from added sugars, which are high in Western diet, correlates with the epidemic rise in obesity, metabolic syndrome, nonalcoholic fatty liver disease, and chronic kidney disease. However, the interaction of fructose with high fat intake, which is also rich in Western diet, remains unclear. Here we tested the interaction between fructose and fat, and determined whether if this was dependent on a primary enzyme in fructose metabolism, fructokinase.

Methods: Wild type mice and fructokinase knockout mice (C57BL6/J background, male) were assigned to one of three groups (n = 8–9) respectively, matching mean body weight among the groups. Mice had free access to tap water, and a low fat (11%, LFD), high fat (36%, HFD) or high fat (36%) and high sucrose (30%) diet (HFHSD) for 15 weeks. Urine samples were collected at 13 weeks using metabolic cages. At 15 week, blood was withdrawn, and tissues including kidney and liver were taken after 6 h fasting.

Results: Both wild type mice fed HFD and fructokinase knockout mice fed HFD developed obesity with mild hepatic steatosis without hepatic inflammation compared to mice fed LFD. In contrast, wild type mice fed HFHSD developed more severe hepatic steatosis and low grade inflammation and fibrosis in pathological analysis, but not in fructokinase knockout mice. Increased CD68, TNF-alpha, MCP-1, alpha-smooth muscle actin, and collagen I and TIMP1 expression were found in wild type mice fed HFHSD. These changes were prevented in the fructokinase knockout mice. Meanwhile, there was no significant change of urinary protein and urinary NGAL, and no apparent renal pathological change among groups.

Conclusions: This study demonstrated an additive effect of high fat and high sucrose diet on the development of hepatic fat accumulation. Furthermore, the combination of sucrose with high fat diet may induce steatohepatitis. These results indicates the important role of fructose in the development of fatty liver and nonalcoholic steatohepatitis.

The Succinate Receptor 1 Contributes to Obesity-Induced Type II Diabetes and Chronic Kidney Disease Peter M.T. Deen,[1] Claudia Carmone,[1] Janna A. Van diepen,[3] Joris Hubertus Robben,[1] Ana Carolina Ariza,[1] Olivier Devuyst,[2] Rinke Stienstra.[3] *[1]Physiology, Radboud Univ Medical Center, Nijmegen, Netherlands; [2]Physiology, Univ of Zürich, Zürich, Switzerland; [3]Internal Medicine, Radboud Univ Medical Center, Nijmegen, Netherlands.*

Background: Cell stress-induced release of mitochondrial succinate and activation of its SUCNR1 receptor in the macula densa is essential for type I diabetes mellitus (T1DM)-related renin release and hypertension. Obesity-induced T2DM and Chronic Kidney Disease (CKD) are aggravated by hypertension and go with cell stress in adipose/kidney tissue and macrophages, which express SUCNR1. Here we tested the role of SUCNR1 in obesity-induced T2DM and CKD.

Methods: Wild-type (wt) and SUCNR1-/- mice were fed a low fat diet (LFD; 10%) or high (H) FD (60%). At different weeks, mice were weighed, and subjected to metabolic cages (electrolyte measurements), glucose tolerance tests (GTT). Mice were sacrificed and blood and tissues collected.

Results: Blood succinate was increased in diabetic patients versus healthy controls. Isolated adipose tissue of wt and SUCNR1-/- mice revealed increased succinate release with hypoxia or high glucose. 16 weeks LFD/HFD showed similar body, adipose tissue and kidneys weight gain for both HFD groups, but liver and heart weight gain was reduced in HFD SUCNR1-/- versus wt mice. Starving glucose levels were similarly increased in both HFD groups, but SUCNR1-/- mice had a better GTT response. Inflammatory signals and macrophage infiltration was higher in adipose tissue of wt than SUCNR1-/- HFD mice. Bone marrow derived cells of SUCNR1-/- mice migrated less efficient towards chemotaxic signals from diabetic/hypoxic 3T3 cells. Blood sodium and urine volumes were similarly decreased and eGFR increased in both HFD groups versus LFD controls. However, only HFD wt mice showed albuminuria, elevated collagen IV expression, and some increase in inflammatory gene expression in the kidney.

Conclusions: SUCNR1-mediated chemotaxis of macrophages to affected adipose tissue and, possibly, increased SUCNR1-mediated hypertension, contributes to obesity-induced T2DM and CKD development. If similar in humans, the SUCNR1 may form a novel therapeutic target for T2DM and CKD.

Fluoxetine Disrupts E-Cadherin-Mediated Cell Adhesion and Calcium Homeostasis in Pancreatic β Cells Yun-wen Chen,[1] Huang-Yu Chang.[1] *[1]Pharmacology, National Cheng Kung Univ, Tainan, Taiwan; [2]Pharmacology, National Cheng Kung Univ, Tainan, Taiwan.*

Background: Major depressive disorder (MDD) is a common psychiatric illness and it affects as many as 840 million people.MDD and Type 2 diabetes (T2D) are disorders with mutual risk factors identified in prevalence study reports. Antidepressant treatment could be another critical factor affecting the bidirectional associations between MDD and T2D. Long-term use of selective serotonin reuptake inhibitors (SSRIs), the most commonly prescribed class of antidepressants, is associated with an increased risk of developing T2D. E-cadherin mediated cell-cell adhesion has been linked to diseases such as cancer and diabetes. Loss of cell-cell adhesion in beta cells decreases insulin secretion.

Methods: Here we examine the effects of the SSRI fluoxetine (Prozac®) on beta cell function employing MIN6 cells, a mouse beta cell line, to elucidate the underlying molecular mechanisms.

Results: We showed that fluoxetine treatment significantly reduced glucose stimulated insulin secretion (GSIS). We found that fluoxetine has no effect on the total expression of E-cadherin, but decreased the surface of E-cadherin. Moreover, fluoxetine triggered E-cadherin accumulating in cytosol, mainly localized in Golgi, not in endoplasmic reticulum (ER). Our immunohistochemistry showed that reduction cell surface E-cadherin is due to increased endocytosis. Moreover, ER calcium release and the activation of store-operated calcium entry (SOCE) were suppressed by fluoxetine .

Conclusions: Taken together, the results suggested that the impairment of E-cadherin and calcium homeostasis may be underlying mechanisms by which fluoxetine caused the reduction of GSIS in pancreatic beta cells.

Involvement of Ischemic Condition in the Pathophysiology of Renal Damages in Obesity-Induced Kidney Injury Koji Futatsugi, Hirobumi Tokuyama, Makiko Naitoh, Shu Wakino, Hiroshi Itoh. *Internal Medicine, Keio Univ School of Medicine, Tokyo, Japan.*

Background: We have reported hypertrophic proximal tubules in obese mice which implies an inefficient oxygen supply in this area (Obesity Int, 2012). We examined whether hypoxic condition in proximal tubules are involved the pathogenesis of obesity-induced renal injury. We also test the hypothesis that this injury can be ameliorated by molecular intervention of prolyl hydroxylase domains (PHDs), sensors for tissue oxygen levels that is a crucial molecule for tissue response to hypoxia.

Methods: Tissue hypoxic conditions were assessed by pimonidasole immunostaining. Peritubular capillaries (PTCs) were evaluated by counting CD34 stained vessels.Tamoxifen (Tam)-inducible proximal tubules-specific PHD2 deficient mice were created by crossing $PHD2^{flox/flox}$ mice and Tam-inducible *N-myc downstream-regulated gene-1*-Cre mice on C57BL/6J backgrounds.These inducible conditional knock out (CKO) miceand their wild-type littermates (WT) were fed a high fat diet (HFD) or a low fat diet (LFD) for 12 weeks. The expressions of PHD2 and VEGF were measured by real-time PCR and immunohistochemistry.

Results: The WT mice on HFDmanifested renal histological changes, including cellular enlargement of proximal tubules and a rarefaction of PTCs, which were consistent with more hypoxic area in proximal tubules than in WT mice on LFD. Urinary albumin and NGAL excretion were higher in HFD-fed mice, indicating ischemic tissue damage in proximal tubular area.However, expression of either PHD2 or VEGF was unchanged in HFD-fed WT mice, suggesting the lack of hypoxic tissue response in HFD-fed WT.Injecting Tam to HFD-fed CKO mice downregulated PHD2 in proximal tubules, increased VEGF expression, increased the number of PTCs, decreased hypoxic area, and attenuated proximal tubular damages and albuminuria.

Conclusions: Hypoxic condition due to enlarged cell with vascular rarefaction is evident in the proximal tubular area of obese mice whereas tissue reaction to hypoxic damages failed to properly compensate. The early reduction of PHD2 specifically in the proximal areamay constitute a novel strategy againstthe progression process from an early stage of obesity-induced kidney injury.

Herbal Mixture of Radix Puerariae and Fructus Crataegi Prevents Renal Injury in Type 2 Diabetes via Inhibition of AKT/PI3K Zhengyue Chen.[1,2] *[1]Runliang Diabetes Laboratory, Diabetes Research Center, School of Medicine, Ningbo Univ, Ningbo, China; [2]Div of Nephrology, Ningbo Urology and Nephrology Hospital, School of Medicine, Ningbo Univ, Ningbo, China.*

Background: It has been reported recently that radix puerariae (RP) is one of the best herbal medicines for metabolic diseases, as it has pronounced anti-oxidative effects and helps improving insulin resistance and lowering blood sugar and lipids levels. Fructus crataegi

(FC) also possesses strong antioxidant activity in vitro. The present study was designed to investigate whether RP and FC together (RPFC) can prevent renal injury through a diabetic rat model generated by a high-fat diet and a low-dose streptozotocin (STZ).

Methods: A Type 2Diabetic model was generated by feeding rats with high fat diet followed by injecting a low dose of STZ. Rats were randomly divided into five groups: normal, high fat diet, diabetes mellitus, high fat diet plus RPFC prevention, and diabetes mellitus plus RPFC prevention. RPFC was given to rats daily by intragastric gavage for 3 weeks. The rats were monitored for body weight, blood glucose, oral glucose tolerance, blood insulin and lipids, serum creatinine and urea nitrogen, urinary protein. Renal pathological changes were examined with hematoxylin and eosin staining, periodic acid schiff staining, and Masson trichrome staining. The mRNA and protein levels of α-smooth muscle actin (α-SMA) and collagen IV in the kidney were detected by RT-PCR, Western blot and immunohistochemical staining. The levels of PI3K and AKT were determined by Western blot.

Results: Rats treated with RPFC showed reduced 24 h urinary protein excretion and decreased blood glucose level compared with corresponding vehicle treated rats, but RPFC prevention did not affect blood lipids. Glomerulus mesangial matrix expansion, renal capsule constriction, and renal tubular epithelial cell edema were less severe following RPFC prevention. Moreover, RPFC prevention markedly reduced protein levels of PI3K, AKT, α-SMA and collagen IV in the kidney of diabetic rats.

Conclusions: Combined prevention with RPFC may inhibit the PI3K/AKT pathway in the kidney, thereby preventing renal injury in diabetic rats.

High Protein Diet Markedly Accelerates Diabetic Nephropathy Whilst Nephrectomy Has Minor Effects in the BTBR ob/ob Mouse Model

Anna Granqvist,[1] Karin Nelander,[2] Ann-katrin Andersson,[1] Gerhard Bottcher,[3] Magnus Soderberg,[3] Anette E. Ericsson.[1] *[1]Dept of Bioscience; [2]Discovery Sciences; [3]DSM Pathology Sciences, AstraZeneca R&D, Mölndal, Sweden.*

Background: There is a need for better mouse models that resemble the features of diabetic nephropathy (DN). The obese diabetic BTBRob/ob mouse was recently shown to mimic key features of human DN including progressive proteinuria and glomerular lesions.

Methods: In an attempt to enhance the progression of renal disease further we challenged the model through unilateral nephrectomy (performed at 7 weeks of age) or supplementation with high protein content diet (40%, from 10 weeks of age).

Results: BTBRob/ob mice exhibited hyperinsulinemia and hyperglycemia with elevated HbA1c. The urinary albumin excretion rate (AER) was increased 33-fold in intact and 34-fold in nephrectomised BTBRob/ob at 20 weeks age whereas high protein diet increased AER 332-fold in BTBRob/ob at 18 weeks age compared with lean controls. Plasma creatinine level was lower in intact (median 3.2 μM) and nephrectomised (median 2.9 μM) BTBRob/ob compared with lean controls (median 7.2 μM) at 20 weeks. At 18 weeks age high protein treated BTBRob/ob also had lower creatinine (median 3.2 μM) indicative of hyperfiltration. Morphological assessment of glomeruli demonstrated notable mesangial matrix expansion in BTBRob/ob mice at 20 weeks, which was slightly increased by nephrectomy. High protein diet (up to 24 weeks of age) resulted in a significant aggravation of renal pathology, with increased mesangial expansion as well as subcapsular and interstitial fibrosis. Moreover, the high protein diet increased GBM thickness and decreased the number of podocyte slits per mm GBM.

Conclusions: In conclusion, the BTBRob/ob mouse demonstrated renal injury with marked albuminuria and glomerular morphological alterations. Disease progression was not significantly advanced by nephrectomy and maintained an intact capacity of filtration comparable to lean mice. Using high protein content diet appears to be a straightforward method to aggravate BTBR ob/ob pathology, which enables new end points for efficacy studies and shortens cycle times.

Insulin Stimulates Renal Proximal Tubule Sodium Transport in Overt Type 2 Diabetic Nephropathy

Motonobu Nakamura,[1] Nobuhiko Sato,[1] Masashi Suzuki,[1] Atsushi Suzuki,[1] Haruki Kume,[2] Yukio Homma,[2] George Seki,[3] Shoko Horita.[1] *[1]Nephrology, The Univ of Tokyo Hospital, Bunkyoku, Tokyo, Japan; [2]Urology, The Univ of Tokyo Hospital, Bunkyoku, Tokyo, Japan; [3]Internal Medicine, Yaizu City Hospital, Yaizu, Shizuoka, Japan.*

Background: We have previously shown that the insulin receptor substrate (IRS) 2-dependent stimulatory effect of insulin on renal proximal tubule (PT) transport is preserved in insulin resistant humans without nephropathy, facilitating hypertension in metabolic syndrome (Kidney Int 87:535-42, 2015). Whether this stimulatory effect of insulin is preserved in type 2 diabetes (T2D) with overt nephropathy remains to be determined.

Methods: Cell pH measurement with BCECF was performed to estimate the activity of $Na\text{-}HCO_3$ cotransporter (NBCe1) in isolated PTs from 55 week-old OLETF rats. Compared to control LETO rats, OLETF rats showed extensive mesangial expansion (glomerular injury score 1.6 vs 3.3) and overt proteinuria (1.5 vs 34 mg/mg Creat). NBCe1 activity was also determined in a T2D patient with renal carcinoma who had decreased eGFR (39.2 $ml/min/1.73m^2$), massive proteinuria (2.5 g/g Creat), and histological changes compatible with overt diabetic nephropathy.

Results: The basal NBCe1 activities of OLETF rats and the patient were comparable to those of respective non-diabetic control rats and humans. Furthermore, 10^{-8} M insulin markedly stimulated the NBCe1 activity by 65 % and 104% in OLETF rats and the patient, respectively. While the expression of insulin receptor was moderately reduced by 15%, the expression of IRS1 was severely reduced by 80% in kidney cortex of OLETF rats. However, the expression of IRS2 was completely preserved in kidney cortex of OLETF rats. Insulin-mediated Akt phosphorylation was also preserved in kidney cortex of OLETF rats.

Conclusions: These data indicate that insulin can induce sodium retention via its effect on PT transport even in T2D with overt nephropathy, which may at least partially explain increased cardiovascular risk and volume expansion occasionally associated with intensive glycemic control in T2D CKD patients. On the other hand, the reduced expression of IRS1 in PT could be relevant to enhanced renal gluconeogenesis in T2D.

Modulation of Akt/AS160 Phosphorylation Mediates Insulin Resistance in a Rat Model of Metabolic Syndrome

E. Chepchumba K. Yego, Katherine Kam, Sharma S. Prabhakar. *Internal Medicine, Texas Tech Univ Health Science Center, Lubbock, TX.*

Background: Insulin resistance is the underlying pathophysiologic hallmark of metabolic syndrome (MS) which is most often associated with obesity. While adipokines and inflammatory cytokines have been incriminated in the insulin resistance of MS, the exact underlying mechanisms and signaling processes have not been defined. The current study assessed the molecular mechanisms of insulin signaling in the skeletal muscle in ZSF1 rats which have leptin receptor mutation and phenotypically manifest MS.

Methods: Obese ZSF1 rats were maintained from the 8th week and sacrificed at 24 or 32 weeks and fed on high calorie high fat diet (Purina 5008) while control rats (lean ZSF and SD) were fed normal rat chow. Body weights and water intake were monitored weekly and blood and urine samples were obtained at 8 weeks and at the time of sacrifice for chemistry analysis. Skeletal muscle and fat tissue were also harvested and homogenates were examined for the expression of proteins involved in insulin signaling such as adiponectin and its receptor, insulin receptor substrate 1 (IRS1), Akt and AS160 by western blots.

Results: The obese ZSF1 rats showed full blown MS with obesity, hyperlipidemia, hypertension and hyperglycemia while the lean ZSF and SD rats were normoglycemic. The expression of GLUT 4 was decreased in both skeletal muscle and fat tissue of obese rats. Studies done previously in our lab demonstrated that compared to non-diabetic rats, plasma adiponectin levels were lower in obese ZSF rats and adiponectin expression was decreased in fat tissue but not in skeletal muscle. The expression of adiponectin receptor 1 and insulin substrate receptor1 (IRS1) were similar in all rats. Furthermore, the expression of phosphorylated Akt and AS160 were reduced by 74% and 38% in diabetic obese ZSF1 rats compared to non-diabetic controls.

Conclusions: Our results demonstrate that while GLUT4 expression in insulin sensitive tissues is decreased in obesity mediated diabetes, several intermediary steps in insulin signaling are unaltered. However the most consistent finding was reduced phospho Akt/AS160, which could be a major determinant of insulin resistance in obesity.

Murine Recombinant ACE2 Reduces Renal Fibrosis in Experimental Alport Syndrome (AS)

Eun Hui Bae,[4] Ana Konvalinka,[1] Fei Fang,[1] Xiaohua Zhou,[1] Vanessa R. Williams,[1] John Tran,[1] Xuewen Song,[1] Shao-Ling Zhang,[2] Rohan John,[1] Vaibhav B. Patel,[3] Gavin Oudit,[3] York P. Pei,[1] James W. Scholey.[1] *[1]Univ of Toronto; [2]Univ of Montreal; [3]Univ of Alberta; [4]Chonnam National Univ Medical School.*

Background: ACE2 is a monocarboxypeptidasein the renin angiotensin systemthat catalyzes the breakdown of angiotensin II (AngII) to angiotensin-(1-7) (Ang1-7). We have reported that ACE2 expression and activity in kidney are reduced in experimental Alport Syndrom (AS) but the impact of this finding on disease progression has not been studied.

Methods: Accordingly, we evaluated the effects of murine recombinant ACE2 (mrACE2) treatment in *Col4A3*$^{-/-}$ mice, a model of AS characterized by proteinuria and progressive renal injury. mrACE2 (0.5 mg/kg/day)was administered from 4 -7 weeks of agevia osmotic mini-pump.

Results: Treatment with mrACE2 led to an increased urinary ACE2 excretion, reduced renal AngII level and a correspondingly increased Ang1-7 level in 7-week-old *Col4A3*$^{-/-}$ mice. Pathological structural changes and albuminuria in the mutant mice were both attenuated by mrACE2 administration. mrACE2 ameliorated kidney fibrosis in *Col4A3*$^{-/-}$ mice as shown by decreased expression of profibrotic genes, less accumulation of extracellular matrix proteins and inhibition of the TGF-β signaling activation. Further, the increases in proinflammatory cytokine expression, macrophage infiltration, inflammatory signaling pathway activation and heme oxygenase-1 (HO-1) level in *Col4A3*$^{-/-}$ mice were also reduced by mrACE2 treatment. Lastly, mrACE2 influenced the turnover of renal ACE2, as it suppressed the expression of TNF-α converting enzyme (TACE), a negative regulator of ACE2.

Conclusions: In summary, treatment with mrACE2 alters angiotensin peptide metabolism in the kidneys of *Col4A3*$^{-/-}$ mice and attenuates the progression of AS nephropathy.

SA-PO420

Blockade of CDK9 and Smad3/4 Signaling Reduces Renal Fibrosis in Mice with Unilateral Ureteral Obstruction Jinhua Li,[1] Xinli Qu,[1] Xiaoyun Jiang,[2] John F. Bertram,[1] David J. Nikolic-Paterson.[3] *[1]Dept of Anatomy and Developmental Biology, Monash Univ, Clayton, Vic, Australia; [2]Dept of Pediatrics, The First Affiliated Hospital of Sun Yat-Sen Univ, Guangzhou, Guangdong, China; [3]Dept of Medicine, Monash Medical Centre, Monash Univ, Clayton, Vic, Australia.*

Background: TGF-b1/Smad signalling plays a central role in the pathogenesis of renal fibrosis. Smad3 and Smad4 are pro-fibrotic, while Smad2 is anti-fibrotic. However, these Smads form heterogeneous complexes the functions of which are poorly understood. This study investigated Smad complexes in renal fibrosis in mouse unilateral ureteric obstruction (UUO).

Methods: UUO was established in wild type mice, mice heterozygous or homozygous for Smad3 and/or Smad4 (Smad3/4$^{+/-}$, Smad3$^{-/-}$, Smad4$^{-/-}$). siRNA was used to knock down CDK9. CDK9 activity and Smad3 c-terminal phosphorylation was inhibited by a specific CDK9 inhibitor or a Smad3 inhibitor in cultured mouse renal fibroblasts and in UUO.

Results: Smad3/4$^{+/-}$ mice exhibited substantial protection from renal fibrosis on day 7 UUO, whereas Smad2/3$^{+/-}$ or Smad2/4$^{+/-}$ mice showed only modest protection. Formation of Smad3/Smad4/CDK9 complexes was an early event following UUO in wild type mice, which involved nuclear phosphorylation of the linker regions of Smad3. Smad3 or Smad4 deficiency significantly decreased the formation of Smad4/CDK9 or Smad3/CDK9 complex, Smad3 linker phosphorylation as well as renal fibrosis but at different degrees. In vitro, TGF-b1 stimulation of collagen I promoter activity involved formation of Smad3/Smad4/CDK9 complexes, and over-expression of each component gave additive increases in collagen promoter activity. A CDK9 inhibitor or CDK9 siRNA significantly reduced TGF-b1-induced interaction between Smad3 and Smad4, Smad3 linker phosphorylation and fibrotic response in mouse renal fibroblasts. Co-administration of the CDK9 inhibitor and the specific Smad3 inhibitor achieved better protection from TGF-b1-induced fibrotic response in vitro and renal interstitial fibrosis in UUO.

Conclusions: Our studies suggest that the formation of Smad3/Smad4/CDK9 complex drive renal fibrosis in the UUO model. Formation of this complex represents a novel target for anti-fibrotic therapies.

Genetic Activation of Nrf2 Signaling Protects against Chronic Kidney Disease Roderick J. Tan,[1] Dionysios V. Chartoumpekis,[3] Dong Zhou,[2] Brittney M. Rush,[1] Haiyan Fu,[2] Thomas W. Kensler,[3] Youhua Liu.[2] *[1]Medicine, Univ of Pittsburgh, Pittsburgh, PA; [2]Pathology, Univ of Pittsburgh, Pittsburgh, PA; [3]Pharmacology, Univ of Pittsburgh, Pittsburgh, PA.*

Background: The Keap1/Nrf2 pathway is upregulated in kidney injury, leading to the expression of an array of cytoprotective genes with antioxidant, anti-inflammatory, and detoxifying roles. Keap1 inhibits Nrf2 by sequestering it in the cytoplasm. During oxidative/electrophilic stress, Keap1 undergoes conformational change that renders it inactive and Nrf2 accumulates and enters the nucleus to upregulate target genes. Pharmacologic inducers of this pathway (e.g. CDDO-Me) have harmful off-target effects. Therefore, more specific study of the Keap1/Nrf2 pathway with genetic approaches is necessary to determine its therapeutic potential in chronic kidney disease (CKD).

Methods: Keap1 hypomorphic (HM) mice have lower Keap1 expression and increased Nrf2 activity. We subjected HM and wild-type (WT) mice to two models of CKD: unilateral ischemia followed by 10 days of reperfusion (IR); and unilateral ureteral obstruction (UUO). Kidney injury was assessed with serum creatinine, histology, western blotting and quantitative real-time PCR (qPCR) for injury markers.

Results: Compared to WT, HM mice had increased expression of numerous Nrf2-regulated genes after injury. In IR injury, HM mice were significantly protected from developing CKD, demonstrating decreased serum creatinine and renal fibrotic lesions compared to WT mice. Furthermore, HM mice had lower levels of fibronectin, α-smooth muscle actin, and TGF-β. Inflammation was also suppressed in HM mice, as was pathologic β-catenin signaling, which is known to play a role in CKD progression. Similar results were obtained in the UUO model.

Conclusions: Most studies on the Keap1/Nrf2 pathway examine acute kidney injury or utilize pharmacologic agents with off-target effects. We demonstrate here that genetic enhancement of the Nrf2 pathway is protective in two models of CKD in mice, due to increased expression of cytoprotective genes as well as downregulation of β-catenin signaling. These studies suggest that the Keap1/Nrf2 pathway should remain a promising target in CKD treatment.

Early and Late Treatment with PBI-4050, an Orally Active Anti-Fibrotic Agent, Reduces Fibrosis and Increases Survival of 5/6-Nephrectomized Rats Lyne Gagnon, François Sarra-Bournet, Lilianne Geerts, Brigitte Grouix, Jean-Simon Duceppe, Boulos Zacharie, Pierre Laurin. *ProMetic BioSciences Inc., Laval, QC, Canada.*

Background: PBI-4050, a first-in-class orally active compound which is currently in clinical phase Ib/II in CKD patients, displays anti-fibrotic activities via a novel mechanism of action. In a double-blind ascending dose (400 to 2400 mg) clinical phase I, PBI-4050 was found to be safe and well tolerated up to 2400 mg without any significant side effect. The aim of this study was to investigate the effect of early (Day 21) and late (Day 84) treatment of PBI-4050 on 5/6-nephrectomized rats.

Methods: Sprague-Dawley rats were partially nephrectomized (2/3 of the left kidney) on day 0. On day 7 the right kidney was removed. Oral treatment with PBI-4050 (200 mg/kg, once a day) or vehicle was initiated at day 21 or at day 84, following randomization based on their glomerular filtration rate (GFR) results. GFR was measured at day 21 or day 84 and assessed every 3 weeks up to day 190 (early) or day 128 (late).

Results: Early treatment with PBI-4050 resulted in a significant improvement (up to threefold relative to control) in GFR. It also significantly reduced proteinuria. Histological lesion scores of kidney were also significantly ($p<0.05$) decreased in PBI-4050-treated rats (2.7 ± 1.5) compared to control (3.9 ± 1.4), as determined by HPE, PAS and Masson's trichrome staining. Early treatment with PBI-4050 induced a significant reduction of urine MCP-1 level. Furthermore, early treatment with PBI-4050 reduced the overexpression of fibrotic (TGF-b1, collagen I and α-SMA), pro-fibrotic cytokines (IL-23p19 and IL-6), remodeling (MMP2, SPARC and fibronectin), and oxidative stress (iNOS) markers. Late treatment with PBI-4050 resulted in mild improvement of GFR and serum creatinine level (reduction of 50 mmol/L) but most importantly in an increase in survival (55% non-treated versus 80% with late treatment) at day 128.

Conclusions: These results suggest that PBI-4050 offers the potential as a novel therapy for chronic kidney disease by reduction of fibrosis and may potentially improve residual kidney function in patients with end-stage renal failure.

SA-PO423

Targeting Cardiorenal Connectors Reduces Renal and Cardiac Fibrosis in Experimental Chronic Renocardiac Failure Nynke R. Oosterhuis,[1] Lennart G. Bongartz,[1] Branko Braam,[3] Marianne C. Verhaar,[1] Roel Goldschmeding,[1] Carlo A. Gaillard,[2] Jaap A. Joles.[1] *[1]UMC Utrecht, Netherlands; [2]UMC Groningen, Netherlands; [3]Univ of Alberta, Edmonton, Canada.*

Background: Cardiorenal connectors (CRC) play a major role in progression of organ damage in renocardiac failure (subtotal nephrectomy (SNX) followed by coronary ligation (CL)). We hypothesized that simultaneous inhibition of all CRC would be most effective in reducing cardiorenal fibrosis and functional decline.

Methods: In rats subtotal nephrectomy was followed by coronary ligation (wk 8) [Bongartz, AJP, 2012]. In wk 11 we administered losartan (RAS), or PDTC, tempol and moldisomine (Inflammation-NO/ROS) or all of these plus metoprolol (all-CRC) until wk 16.

Results: Tubulo-interstitial (TI) fibrosis decreased in all treated groups (fig 1A). However, renal function was not significantly affected by any treatment. Systolic dysfunction stabilized in all treated groups, but declined further in vehicle-treated rats (fig 1B). Cardiac fibrosis improved in all treated groups without significant additive effect of targeting all CRC (fig 1C). TI and cardiac fibrosis correlated (fig 1D). Only all-CRC reduced MAP. Diastolic hemodynamics and ventricular and cardiomyocyte size were not affected by any treatment. Reducing TI injury and renal and cardiac CTGF mRNA expression was most effective by targeting all CRC.

Conclusions: Pharmacological targeting of cardiorenal connectors in this model of chronic renocardiac syndrome ameliorated the severity of cardiac and renal fibrosis and prevented further decline in systolic dysfunction.

SA-PO424

Fibroblast Growth Factor 23 Is Synthesised Locally by Renal Proximal Tubular Cells and May Be Pro-Fibrotic Edward Robert Smith,[1] Sven-Jean Tan,[1,2] Stephen G. Holt,[1,2] Tim Hewitson.[1,2] *[1]Dept of Nephrology, The Royal Melbourne Hospital, Melbourne, Victoria, Australia; [2]Dept of Medicine (RMH), The Univ of Melbourne, Melbourne, Victoria, Australia.*

Background: Physiologically, FGF23 synthesis occurs predominantly in bone and regulates mineral handling in the kidney. In Chronic Kidney Disease, circulating levels become grossly elevated and are strongly predictive of disease progression, yet changes in FGF23 are not explained by increased osteocytic synthesis. Since extra-osseous FGF23

production is observed in diseased heart and vascular tissue, and is associated with the activation of pro-fibrotic cascades, the involvement of renal FGF23 synthesis and potential fibrinogenic effects warranted investigation.

Methods: Kidneys were harvested from FVB mice at day 0 or after 3 or 9 days post-unilateral ureteric obstruction (UUO) (n=6). Paraffin-embedded sections were stained for FGF23 and with lectins to identify specific nephron segments. Total RNA was extracted from whole kidney tissue and laser-capture microdissected glomerular and tubular regions, and analysed by qPCR. Rat renal fibroblasts were cultured with exogenous recombinant human FGF23 and stained for α-smooth muscle actin (aSMA) to assess myofibroblast differentiation.

Results: Generalisedlow-level FGF23 protein staining was observed in proximal tubules at day 0, with more intense focal staining at days 3 and 9 post-UUO. Local FGF23 synthesis was confirmed by qPCR of whole kidney extracts, and specifically, in microdissected proximal tubular cells, but not glomeruli. Normalised FGF23 expression increased 11-fold in day 3 UUO relative to day 0 (both $p<0.01$). Treatment of rat UUO fibroblasts with 10ng/mL FGF23 resulted in 4-fold increase in aSMA staining over 72h, equivalent to the effect of 1ng/ml transforming growth factor-b_1 (both $p<0.01$).

Conclusions: Local renal FGF23 synthesis in proximal tubular cells is enhanced by tubulointerstitial injury and may augment myofibroblast differentiation.

Quantitating Intracellular Oxygen Tension in Kidney by Phosphorescence Lifetime Measurement

Yosuke Hirakawa,[1] Imari Mimura,[1] Toshitada Yoshihara,[2] Mako Kamiya,[1,3] Yasuteru Urano,[1,4,5] Seiji Tobita,[2] Masaomi Nangaku.[1] *[1]Graduate School of Medicine, The Univ of Tokyo, 7-3-1 Hongo, Bunkyo-ku, Tokyo, Japan; [2]Dept of Chemistry and Chemical Biology, Gunma Univ, 1-5-1 Tenjincho, Kiryu, Gunma, Japan; [3]PRESTO, Japan Science and Technology Agency, 4-1-8 Honcho, Kawaguchi, Saitama, Japan; [4]Graduate School of Pharmaceutical Sciences, The Univ of Tokyo, 7-3-1 Hongo, Bunkyo-ku, Tokyo, Japan; [5]CREST, Japan Science and Technology Agency, 4-1-8 Honcho, Kawaguchi, Saitama, Japan.*

Background: Hypoxia plays critical roles in the progression of chronic kidney disease, since intracellular reactions to hypoxia depend on intracellular oxygen (O_2) tension. However, existing techniques to detect intracellular hypoxia cannot quantify O_2 tension.

Methods: Phosphorescence lifetime (PL) measurement is reported to be useful to quantitate O_2 tension in vivo, however, most phosphorescent probes distribute extracellularly. Here we used BTPDM1, a lipophilic phosphorescent probe, to quantitate intracellular hypoxia in the kidney. We measured PL in Human Kidney 2 (HK-2) cells and murine kidney after BTPDM1 administration.

Results: We first made a calibration curve between PL and partial pressure of O_2 (pO_2) in HK-2 cells. Then we confirmed that BTPDM1 distributed in tubular cells *in vivo*. Next we measured PL of the murine kidney in normal condition, renal ischemia, hypoxemia and anemia. PL were calculated to be 1.8±0.2μs, 4.0±0.3μs, 2.8±0.2μs, 2.2±0.2μs, respectively. We also investigated chronic kidney damaged model mice of 7 days after 30 minutes unilateral ischemia-reperfusion (I/R) injury of kidney. PL of I/R injured kidney was longer than contralateral kidney (2.2±0.2μs vs 1.8±0.1μs). We also found an increase in pimonidazole adduct protein and a decrease in peritubular capillary density in I/R injured kidneys. We quantitated in vivo intracellular pO_2 by extrapolating the calibration curve in HK-2 cells. The intracellular pO_2 of normal kidney tubule was estimated to be 50mmHg, which was compatible with published value obtained by needle O_2 electrode.

Conclusions: Our novel technique allowed accurate estimation of intracellular O_2 tension of the normal and diseased kidney *in vivo* for the first time.

Resveratrol Increases Expression of Heme Oxygenase-1 via Nrf2 Signaling to Ameliorate Renal Damage by Anti-Complement, Anti-Oxidative, and Anti-Apoptotic Effects in a Murine Model of Membranous Nephropathy

Chia-chao Wu,[1,2] Kuo-cheng Lu.[3] *[1]Div of Nephrology, Dept of Medicine, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan; [2]Dept and Graduate Inst of Microbiology and Immunology, National Defense Medical Center, Taipei, Taiwan; [3]Dept of Medicine, Cardinal Tien Hospital, School of Medicine, Fu Jen Catholic Univ, New Taipei City, Taiwan.*

Background: Idiopathic membranous nephropathy (MN) is an autoimmune-mediated glomerulonephritis and a common cause of nephrotic syndrome in adults. There are limited available treatments for MN. We assessed the efficacy of resveratrol (RSV) therapy for treatment of MN in a murine model of this disease.

Methods: Murine MN was experimentally induced by cationic bovine serum albumin, with phosphate-buffered saline used in control mice. MN mice were untreated or given RSV. Disease severity and pathogenesis was assessed by determination of metabolic and histopathology profiles, lymphocyte subsets, immunoglobulin production, oxidative stress, apoptosis, production of heme oxygenase-1 (HO1) and signalings.

Results: MN mice given RSV had significantly reduced proteinuria and a marked amelioration of glomerular lesions. RSV also significantly attenuated immunofluorescent staining of C3 in the kidney. RSV treatment also reduced the production of reactive oxygen species, cell apoptosis, and upregulated heme oxygenase 1 (HO1). Inhibition of HO1 with tin protoporphyrin IX partially reversed the renoprotective effects of RSV. We show that concentration-dependent induction of HO-1 in E11 podocytes as RSV added. Nrf2 but not AMPK1/2 protein level can be upregulated by RSV. We find that an induction of Nrf2 exists at the HO-1 promoter regions segment #3 and #4 when RSV added. The Nrf2-specific siRNA attenuated the induction of HO1 mRNA by RSV. It suggests that increased Nrf2 at the HO1 promoter leads to elevated HO1 expression when RSV is exposed.

Conclusions: Our results show that RSV increased the expression of HO1 and ameliorated the effects of membranous nephropathy in a mouse model due to its anti-complement, anti-oxidative, and anti-apoptotic effects. RSV appears to have potential as a treatment for MN.

FVB Os/+ Mesangial Cells Exhibit Enhanced mTOR and Growth Factor Expression, Modeling the FVB Os/+ Glomerulosclerosis Mouse

Yongxin Gao, Charles W. Heilig. *Medicine, Univ of Florida College of Medicine-Jacksonville, Jacksonville, FL.*

Background: We previously reported Fvb Os/+ mice which exhibit rapidly progressive glomerulosclerosis beginning within the first 2 weeks after birth. Here we examine primary culture mesangial cells (MC) from FVB Os/+ mice and FVB +/+ control mice to examine the phenotype of FVB Os/+ MC and identify cellular mechanisms which may contribute to glomerulosclerosis (GS) in vivo. FVB Os/+ MC have excess ECM production.

Methods: Primary culture MC were studied between passages 5 -12. Western analyses were performed with specific antibodies against selected proteins to examine mTOR, phospho-S6 Kinase, and growth factor expression important to excess extracellular matrix (ECM) production. GLUT1 glucose transporter expression and 3H2-deoxyglucose uptake rates were also determined. $P<.05$ was considered significant for statistical analyses.

Results: GLUT1 and glucose uptake rate were both increased >2-fold in FVB Os/+ MC vs. FVB +/+ control MC, consistent with their increases in FVB 0s/+ glomeruli. FVB Os/+ MC exhibited slowed proliferation consistent with the Os mutation. FVB Os/+ MC also had increased VEGF (1.6-fold) and TGF beta1 (2.7-fold), which likely contribute to the excess ECM production of these cells. The increased VEGF in vitro simulates increased VEGF in FVB Os/+ glomeruli in vivo. MGF was increased in FVB Os/+ MC (2.7-fold), mimicking increased glomerular MGF in vivo. We previously found MGF stimulates VEGF and TGFß1 in MC. FVB Os/+ MC carry the Os mutation which impairs cell division, explaining their slow proliferation. Consistent with this, phospho-ERK1/2 was reduced 66%. In spite of increased mTOR (3.8-fold) and downstream phospho-S6 kinase (5.2-fold), the cells could not proliferate normally.

Conclusions: FVB Os/+ MC exhibit growth factor expression simulating glomerular growth factor expression in vivo in these mice. MGF expression is increased both in glomeruli in vivo and MC in vitro. MGF is a stimulus to VEGF and TGFbeta1 expression as observed here. These growth factors are associated with excess ECM production in FVB Os/+ MC, despite suppressed Erk1/2, indicating another pathway is important to excessive ECM production.

SA-PO428

Role of Sodium-Glucose Linked Cotransporter-2 Inhibitor in the Kidneys of Salt Sensitive Hypertension

Mikako Hisamichi,[1] Atsuko Ikemori,[1,2] Takeshi Sugaya,[1] Kenjiro Kimura,[3] Yugo Shibagaki.[1] *[1]Div of Nephrology and Hypertension, Dept of Internal Medicine, St. Marianna Univ School of Medicine, Kawasaki, Japan; [2]Dept of Anatomy, St. Marianna Univ School of Medicine, Kawasaki, Japan; [3]Dept of Internal Medicine, Tokyo Takanawa Hospital, Tokyo, Japan.*

Background: Sodium-glucose linked cotransporter-2 (SGLT2) is expressed in the apical side of the proximal tubules and can transport not only glucose but also sodium. Because salt is an aggravated factor for the salt sensitive hypertensive renal injury model, SGLT2 expression may be related to the the progression of renal injury due to salt sensitive hypertension. The aim of this study is to reveal the role of SGLT2 inhibitor in angiotensin II (AII) induced renal injury.

Methods: Male C57/BL6 wild-type mice were divided into three groups: The Ang II group was systemically infused with Ang II for 16 days. The SGLT2 inhibitor (SGLT2-I) group was given an oral dose of the dapagliflozin SGLT2 inhibitor of 1mg/kg/daily in addition to an injection of Ang II. The control group was injected with a vehicle.

Results: In both the Ang II and the SGLT2-I groups, the degree of hypertension, the glycemic levels in blood and the body weight were similar. Renal gene expressions of angiotensinogen and SGLT2 significantly increased in both the AII and the SGLT2-I groups than the control group. Renal gene expression of the angiotensinogen in the SGLT2 inhibitor group tended to be lower than that in the AII group. The degree of macrophage infiltration and urinary albumin levels tended to be lower in the SGLT2-I group than in the AII group. These results suggested that SGLT2 inhibitor may attenuate the renal damage due to salt sensitive hypertension via inhibiting the activation of renal renin angiotensin system.

Conclusions: In conclusion, SGLT2 inhibitor may be a useful treatment of hypertensive renal disease.

SA-PO429

The Renoprotective Effect of Nuclear 1 Factor Related Factor 2 (Nrf2) Activator, Bardoxolone Methyl, in Aldosterone and High Salt-Induced Renal Injury Mikako Hisamichi,[1] Atsuko Ikemori,[1,2] Takeshi Sugaya,[1] Kenjiro Kimura,[3] Yugo Shibagaki.[1] *[1]Div of Nephrology and Hypertension, Dept of Internal Medicine, St. Marianna Univ School of Medicine, Kawasaki, Kanagawa, Japan; [2]Dept of Anatomy, St. Marianna Univ School of Medicine, Kawasaki, Kanagawa, Japan; [3]Dept of Internal Medicine, Tokyo Takanawa Hospital, Tokyo, Japan.*

Background: Activation of nuclear 1 factor related factor 2 (Nrf2) is reported to have anti-oxidant and anti-inflammatory effects. In the aldosterone (Ald) and high salt-induced renal injury model using mice, we previously reported that severe tubulointerstitial damage was provoked by oxidative stress. The aim of this study is to reveal the renoprotective effect of the Nrf2 activator in this model.

Methods: To evaluate the degree of tubulointerstitial damage using the urinary liver type fatty acid binding protein (L-FABP), known as a biomarker of the tubulointerstitial damage, we used human L-FABP chromosomal transgenic (L-FABP$^{+/-}$) mice. Male L-FABP$^{+/-}$mice were divided into three groups: The Ald group received systemic aldosterone infusions via an osmotic minipump and were given 1% NaCl water for 14 days. The Ald-Nrf2 group wasgiven Bardoxolone Methyl of the Nrf2 activator intraperitoneallyat a dose of 10mg/kg/daily in addition to an injection of aldosterone and salt. The control group was given only a vehicle.

Results: The gene expression of MCP-1, the gene expression of RANTES, the gene expression of collagen typeIand type III and the degree of macrophage infiltration were significantly greater in the kidneys of the Ald group compared to those in the control, and renal inflammatory reaction and renal fibrosis were significantly attenuated in the Ald-Nrf2 group. The degree of renal hL-FABP gene expression and urinary hL-FABP levels increased in the Ald group compared to the control and decreased in the Ald-Nrf2 group.

Conclusions: The Nrf2 activator, Bardoxolone Methyl, could attenuate renal oxidative stress induced by aldosterone and high salt, and consequently, renal inflammatory reaction and the production of renal collagen were prevented. Bardoxolone Methyl may be a useful treatment for renal disease.

SA-PO430

Detection of Mesangial Tissue Transglutaminase Activity in Human Kidney Biopsy Specimens Kazuo Takahashi,[1,2,6] Tomohiro Mizuno,[1,2] Takanori Onouchi,[1] Shin'ichi Akiyama,[1,3] Hideki Tatsukawa,[4] Mamoru Kusaka,[1] Tadashi Nagamatsu,[2] Yutaka Tsutsumi,[1] Shoichi Maruyama,[3] Hiroshi Kitamura,[5] Jan Novak,[6] Kiyotaka Hitomi,[4] Yukio Yuzawa.[1] *[1]Fujita Health Univ School of Medicine, Toyoake, Aichi, Japan; [2]Meijo Univ, Nagoya, Aichi, Japan; [3]Nagoya Univ Graduate School of Medicine, Nagoya, Aichi, Japan; [4]Nagoya Univ Graduate School of Pharmaceutical Sciences, Nagoya, Aichi, Japan; [5]NHO Chiba-East Hospital, Chiba, Japan; [6]Univ of Alabama at Birmingham, Birmingham, AL.*

Background: Tissue transglutaminase (TG2) is a protein-cross-linking enzyme that plays an important role in tubulointerstitial fibrosis in animal models of chronic kidney disease and diabetic nephropathy. However, its pathological significance in human glomerular diseases remains unclear. TG2 transforms into catalytically active TG2 through conformational changes. Thus, it is crucial to detect catalytically active TG2 to assess the role of TG2 in human biopsy samples.

Methods: A total of 241 renal biopsy specimens obtained between January 2010 and December 2013 were assessed for TG2 activity by immunofluorescence microscopy with FITC-labeled highly reactive TG2 substrate peptides.

Results: Thirty-five of 65 (56%) patients with IgAN, 23 of 40 (58%) patients with lupus nephritis (LN), and 7 of 11 (64%) patients with secondary IgAN, including 8 IgA vasculitis patients, exhibited mesangial TG2 activity. In contrast, only 7 of 125 (6%) patients with other kidney diseases showed mesangial TG2 activity. IgAN patients with mesangial TG2 activity had higher levels of proteinuria (1.2 *vs*. 0.5 g/day, $P< 0.01$) and a higher mesangial score defined by the Oxford classification (0.53 *vs*. 0.38, $P= 0.03$) than those without mesangial TG2 activity. LN patients with mesangial TG2 activity showed higher presence of hematuria more than 20/hpf (39% *vs*. 0%, $P< 0.001$) and had histological evidence of active lesions more frequently than patients without mesangial TG2 activity (83% *vs*. 35%, $P< 0.001$).

Conclusions: Immune-complex mediated glomerulonephritis such as IgAN, LN, and IgA vasculitis frequently have the active form of TG2 in the mesangial area. This assay for mesangial TG2 activity may represent a useful new diagnostic test.

Renoprotective Effect of Xanthine Oxidoreductase Inhibitor, Topiroxostat, in Hyperuricemic-Induced Renal Injury Atsuko Ikemori,[1,2] Takeshi Sugaya,[2] Mikako Hisamichi,[2] Kenjiro Kimura,[2] Yugo Shibagaki.[2] *[1]Dept of Anatomy, St. Marianna Univ School of Medicine, Kawasaki, Japan; [2]Div of Nephrology and Hypertension, Dept of Internal Medicine, St. Marianna Univ School of Medicine, Kawasaki, Japan; [3]Dept of Internal Medicine, Tokyo Takanawa Hospital, Tokyo, Japan.*

Background: Hyperuricemia is known to be a risk factor of chronic kidney disease. The aim of this study is to reveal the effect of xanthine oxidoreductase inhibitor, Topiroxostat in a model of hyperuricemic renal disease provoked by adenine-containing diet.

Methods: To evaluate the degree of tubulointerstitial damage using urinary liver type fatty acid binding protein (L-FABP) known as a biomarker of the tubulointerstitial damage, we used human L-FABP chromosomal transgenic (Tg) mice. Male Tgmice (n=24) were fed a 0.2% w/w adenine-containing diet. Two weeks later from the start of the diet, renal dysfunction of these mice were confirmed and were divided into the four groups: the adenine group was given only the diet containing adenine. The Febuxostat (Feb) group and the Topiroxostat high (Top-H) or low (Top-L) groups were given the diet containing each Feb (3mg/kg), Top-H (3mg/kg), Top-L (1mg/kg) in addition to adenine for another 2 weeks. Thereafter, adenine-containing diet was stopped, only each medication was continued for additional 2 weeks and the kidneys in each group were removed.

Results: Renal dysfunction, the degree of macrophage infiltration, tubulointerstitial damage and renal fibrosis were significantly attenuated in the kidneys of the Feb, the Top-L and the Top-H groups compared to those in the adenine group. Serum uric acid levels and renal xanthine oxidoreductase activity in the Feb, the Top-L and the Top-H groups were significantly lower than those in the adenine group. Those levels in the Top-H group were significantly lower than those in the Feb group. Urinary excretion levels of L-FABP in both the Top-H and Top-L groups were significantly lower than those in both the adenine and Feb groups.

Conclusions: In conclusion, Topiroxostat attenuated the renal damage induced by hyperuricemia and may be a useful treatment for hyperuricemic renal damage.

Accumulation of Indoxyl Sulfate in Renal Tubular Cells Aggravates Kidney Injury in Rats with 5/6 Nephrectomy Ayano Konagai, Kaori Kikuchi, Ayako Fujieda, Sumie Goto, Hiroko Iijima, Yoshiharu Itoh. *Pharmaceuticals Division, Kureha Corporation, Tokyo, Japan.*

Background: Indoxyl sulfate (IS), a representative uremic toxin, is detected in renal tubular cells of CKD patients and 5/6 nephrectomized rats administrated with IS. It has been suggested that the retention of IS is induced through organic anion transporters in the basolateral membrane of renal tubular epithelial cells and this retention leads to nephrotoxicity. However, the mechanism for IS accumulation in renal tubules remains unclear. To reveal the correlation between IS accumulation and renal dysfunction in 5/6 nephrectomized rats, we investigated the expression of transporters in the apical or basolateral membrane and of markers for renal injury, and a content of IS in renal tubular epithelial cells using a novel antibody against IS.

Methods: To study the serum concentration of IS, we used high-performance liquid chromatography (HPLC) and our newly developed enzyme-linked immunosorbent assay (ELISA). The renal sections from the rats were stained with the antibody for IS. The expression of the transporters in renal tubular cells and the markers for renal injury such as Kidney Injury Molecule-1 (KIM-1) were detected by immunohistochemistry.

Results: Serum level of IS was identified to be increased in the 5/6 nephrectomized rats compared to the normal rats by the newly ELISA. The new system could sensitively detect the low concentration of IS. The value determined by ELISA is in a good correlation with HPLC. Immunohistochemistry showed a significant IS staining in renal sections of the model rats. We found the presence of IS in hypertrophic tubular cells, where the expression of a transporter in the apical membrane mediating IS secretion was decreased, while the expression of a transporter in the basolateral membrane was retained. KIM-1, the marker for early kidney injury, was highly expressed in some tubules, but not in the IS positive cells.

Conclusions: Our findings suggest that IS is accumulated in renal tubular cells at the later stage of renal injury due to unbalance expression of transporters between in the apical membrane and in the basolateral membrane, and this accumulation aggravates kidney injury.

SA-PO433

IL-15 as a Potential New Therapeutic Treatment for Renal Fibrosis L. Lecru,[1] A. Devocelle,[1] V. Le coz,[1] C. Gallerne,[1] S. Ferlicot,[2] A. Durrbach,[1] P. Eid,[1] B. Azzarone,[1] H. Francois,[1] J. Giron-michel.[1] *[1]UMRS Inserm 1197, Villejuif, France; [2]Bicetre Hospital, Kremlin-Bicetre, France.*

Background: The human epithelial cells of various tissues produce interleukine-15 (IL-15), which acts not only on immune cells, but also on epithelial cells, mainly via its anti-apoptotic action. Thus, human and mouse renal tubular epithelial cells (RPTEC) constitutively secrete IL-15. Our group recently reported that IL-15 preserves epithelial phenotype in human kidney tubular cells since IL-15 is sufficient to inhibit EMT commitment of RPTEC. Therefore, the goal of our study is to explore the renoprotective potential of IL-15 *in vitro* and *in vivo* in renal fibrosis.

Methods: Our study sought to examine if IL-15 could inhibit EMT in tubular epithelial cells *in vitro* and therefore ameliorate tubulointerstitial fibrosis using the unilateral ureteral obstruction model (UUO) in mice. We also analyzed IL-15 expression in various human nephropathies.

Results: IL-15 expression decreased in human renal disease and in mice during UUO ($p<0.05$, n=19). IL-15 treatment coupled with its soluble receptor (IL-15/IL-15Rα), prevents interstitial fibrosis during UUO (10.7 ± 1.1% in control group, vs 8.2 ± 0.7% in IL-15 treated mice and 6.4 ± 0.6% in IL-15/IL-15Rα treated mice, $p<0.01$, n=7 mice/group), quantified by Sirius Red and Western Blot, through two different mechanisms. We first found a reduction of macrophages infiltration associated with a decrease of MCP1 expression in IL-15 and IL-15/IL-15Rα treated mice ($p<0.05$, n=7 mice/group). IL-15 also reduced TGFb1-induced EMT *in vitro* on RPTEC and tubular cell line (HK2) ($p<0.05$). This protective effect of IL15 acted through Snail inhibition and C-Jun activation ($p<0.05$). Furthermore, we found a direct inhibition of IL-15 on collagen synthesis, in both HK2 (collagen IV) and myofibroblasts (collagen I and III).

Conclusions: In conclusion, IL-15 can attenuate TGFb1-induced EMT by acting directly through a reduction of collagen synthesis, both on myofibroblast, the main effector of fibrosis, and tubular cell. IL-15 also modulates macrophages infiltration *in vivo* in UUO. Therefore IL-15 could be a novel therapeutic player in renal diseases.

Loss of the Vascular Class 3 Semaphorin, Semaphorin 3G, Leads to Attenuated Fibrosis and Reduced Tubular Injury by Unilareral Ureteral Obstruction in Mice Kana Ide,[1] Yoshiro Maezawa,[1] Shintaro Ide,[1] Christer Betsholtz,[2] Minoru Takemoto,[1] Koutaro Yokote.[1] *[1]Clinical Cell Biology and Medicine, Chiba Univ Graduate School of Medicine, Chiba, Japan; [2]Dept of Immunology, Genetics and Pathology, Uppsala Univ, Uppsala, Sweden.*

Background: Chronic kidney disease (CKD) is a large social health issue, affecting 10-16% of the adults worldwide. In advanced stage of CKD, tubulointerstitial fibrosis occurs and promotes renal failure. Although a number of cell types and secretary factors are known to be involved in the formation of renal fibrosis, its precise mechanisms are still unclear. Semaphorin 3G (Sema3G) belongs to a class 3 family of secreted semaphorin. Class 3 semaphorins binds to neuropillin receptors and plexin coreceptors, showing various biological functions in neural development, angiogenesis, immunological response, and tumorigenesis. In the kidney, Sema3G is expressed in podocytes and endothelial cells of extraglomerular blood vessels. However, its role in renal fibrosis is still unknown.

Methods: To understand the role of Sema3G in renal fibrosis, Sema3G knockout mice and control mice are subjected to unilateral ureteral obstruction (UUO).

Results: Histologically, UUO kidneys does not show obvious difference between controls and Sema3G KO. However, although mRNA expression of Tgfb and Snail, a key regulator of Tgfb-induced fibrosis, increases by UUO in controls, these increases are attenuated in Sema3G KO UUO kidneys (for Tgfb, 55% suppression compared to controls, $P<0.01$). In addition, mRNA expression of Acta2 and Fibronectin, and serum BUN level tend to be reduced in Sema3G KO after UUO. Expressions of inflammatory markers do not show a consistent tendency. Interestingly, increase of a tubular injury marker, Kim-1, after UUO is largely suppressed in Sema3G KO mice (77% suppression compared to controls, $P<0.05$ at day3,95% suppression, $P<0.01$ at day7), suggesting that Sema3G KO mice are protected from tubular injury.

Conclusions: Together, these data demonstrate that endothelial Sema3G acts on adjacent tubular/interstitial cells and promotes fibrosis by UUO. Identification of the mechanism of this interaction would provide new therapeutic targets for CKD and renal fibrosis.

Leukemia Inhibitory Factor Attenuates Tubulointerstitial Fibrosis in Unilateral Ureter Obstruction Sebastian Alexander Potthoff, Fabian Srugies, Lars C. Rump, Ivo Quack. *Nephrology, Medical Faculty - Heinrich Heine Univ Duesseldorf, Duesseldorf, Germany.*

Background: Tubulointerstitial fibrosis is common in chronic kidney disease which is often sustained by chronic inflammation. CD4+ T-cells play an important role in immune response in kidney disease. Leukemia inhibitory factor (LIF), a member of the Interleukin 6 family, and Interleukin 6 (IL-6) play a crucial role in regulating the balance between Th17- and regulatory T-cells (Treg): LIF augments expression of forkhead-box-P3 (Foxp3) leading to Treg, IL-6 induces RAR-related orphan receptor gamma (RORyt) driving Th17 lineage development. Dysregulation or overproduction of Th17 cells result in sustained inflammation. Here, we investigate how LIF influences renal inflammation and tubulointerstitial fibrosis in unilateral ureter obstruction (UUO).

Methods: 6-8-week old male C57BL/6 mice were treated intraperitoneally daily either with LIF (10µg/kgBW; n=7) or PBS (control; n=8) starting 2 days prior to UUO. At day 10 after UUO, kidneys, spleen and paraaortal lymphnodes were extracted.

Results: qPCR from tissue lysates of obstructed kidneys (OB) revealed that NFκB and RANTES as well as collagen1 and TGF-ß were significantly downregulated in LIF treated mice. There was no significant difference between IL17a, IL-1b, MCP1, IL-6, TNFα, PAI1 and PDGFR1. Accordingly, expression of MCP1, NFκB, RANTES and TNFα in the paraaortal lymphnodes were reduced by LIF. IL-1b and IL-6 expression tended to be reduced by LIF but failed to reach statistical significance. CD3+ cells accumulated in obstructed kidneys. LIF significantly reduced renal infiltration of CD3+ cells (OB vs. OB+LIF: 144±6 vs. 115±8; $p<0.01$) and F4/80+ cells. LIF treatment significantly reduced tubulointerstitial fibrosis in obstructed kidneys assessed by Sirius Red morphometry (OB vs. OB+LIF: 10.3±2.4 vs. 5.1±1.2 %-area; $p<0.05$) and collagen1 Western Blot analysis (OB vs. OB+LIF: 0.77±0.12 vs. 0.32±0.09 arbitrary units; $p<0.01$).

Conclusions: These data confirm the critical role of inflammation in UUO. LIF treatment significantly attenuates tubulointerstitial fibrosis by inhibiting pro-inflammatory pathways and T-cell infiltration indicating a possible future treatment option.

Dendritic Cell-Specific Shp-1-Knockout Mice Spontaneously Develop Unique Glomerulo- and Tubulointerstitial Nephritis Mitsuharu Watanabe,[1] Keiju Hiromura,[1] Yoriaki Kaneko,[1] Masato Kinoshita,[1] Yuko Ohishi,[1] Toru Sakairi,[1] Hidekazu Ikeuchi,[1] Akito Maeshima,[1] Hiroshi Ohnishi,[2] Takashi Matozaki,[3] Yoshihisa Nojima.[1] *[1]Dept of Medicine and Clinical Science, Gunma Univ Graduate School of Medicine, Japan; [2]Dept of Laboratory Sciences, Gunma Univ Graduate School of Health Sciences, Japan; [3]Div of Molecular and Cellular Signaling, Dept of Biochemistry and Molecular, Kobe Univ Graduate School of Medicine, Japan.*

Background: Src homology 2 domain-containing protein tyrosine phosphatase-1 (Shp-1) is a nonreceptor-type protein tyrosine phosphatase, which is highly expressed in hematopoietic cells. We have previously reported that dendritic cell (DC)-specific Shp-1 conditional knockout mice (CKO) spontaneously developed pneumonitis and nephritis at around 40 wks of age, together with anti-dsDNA antibody (J Immunol. 2012; 188, 5397). In the current study, we further characterize the renal lesions in the CKO mice.

Methods: CKO mice were generated by mating Shp-1-flox mice and CD11c-Cre mice. Mice were sacrificed at 8, 20, and 40 wks or later.

Results: Compared to control mice, CKO mice showed significantly higher serum creatinine at 40 wks or later. Anti-dsDNA antibody was detected at low levels at 8 wks and markedly elevated at 20 and 40 wks. At 40 wks, CKO mice showed severe proliferative glomerulonephritis and tubulointerstitial nephritis by light microscopy with mesangial IgG and C3 depositions by IF staining. Electron microscopy revealed electron dense depositions in mesangial area, but few in subendothelial or subepithelial area. Immunohistochemical staining showed marked accumulation of DCs ($CD11c^+$), macrophages ($F4/80^+$) and helper T cells ($CD4^+$) at periglomerular and tubulointerstitial area. Infiltration of numerous DCs was also observed within glomeruli. Flow cytometric analysis of the CKO kidney showed the inflammatory cells increased with increasing age. Despite the prominent morphological changes, there was no significant increase of albuminuria, even at 40 wks.

Conclusions: The DC-specific ablation of Shp-1 in mice resulted in development of unique autoimmune glomerulo- and tubulointerstitial nephritis, which is distinct from typical lupus nephritis characterized by wire-loop lesions and heavy proteinuria.

Funding: Government Support - Non-U.S.

TLR4 Mutant Mice Are Protected from Renal Fibrosis following Folic Acid Injection Ana C. Souza,[1] Irina Baranova,[2] Alexander V. Bocharov,[2] Jonathan Street,[1] Xuzhen Hu,[1] Kenneth J. Wilkins,[1] Peter S.T. Yuen,[1] Robert A. Star.[1] *[1]Kidney Diseases Branch, NIDDK, NIH, Bethesda, MD; [2]Clinical Center, NIH, Bethesda, MD.*

Background: Local renal inflammation contributes to interstitial fibrosis (IF). Toll-like receptor 4 (TLR4) drives inflammation/ inflammasome and is expressed on renal epithelial cells (RECs). In the folic acid (FA) model of renal fibrosis there is an acute phase of acute tubular damage and a later phase of IF. To evaluate the role of TLR4 in renal inflammation-fibrosis, we analyzed the degree of inflammation that is dependent on TLR4 in RECs from WT or TLR4 mutant mice subjected to LPS. We further compared IF following FA injection in both strains.

Methods: Primary cultures of RECs isolated from WT or TLR4 mutant mice were incubated for 20h with increasing doses of LPS. Supernatant IL-6 was measured by ELISA. Total RNA was extracted, and RTqPCR performed for IL-6, IL-1β, NLRP3, and GAPDH. Results were normalized by protein content. Exact stratified Wilcoxon test was used for differences. *In vivo*, FA (250 mg/kg IP) was given to 9 wk old TLR4 WT or mutant mice (N=16/group). Day 2 BUN was used as an AKI marker. Mice with [day 2:baseline BUN] ratio above 1.5 were included. At day 14, mice were euthanized and kidneys harvested for IF by Masson trichrome stain. Changes in IF (after adjusting for day 2 log BUN) were analyzed by regression analysis.

Results: LPS dose-dependently increased IL-6 secretion in TLR4 WT RECs , but TLR4 mutant RECs secreted very low levels of IL-6, and IL-6 mRNA expression was 7-fold lower than WT cells. TLR4 mutant RECs expressed less NLRP3 (2-fold), and IL-1β (40-fold). Day2 log BUN was not different between the groups at day 2, and correlated with day 14 IF ($p<0.01$). After adjustment for day2 log BUN, TLR4 mutant mice were protected from IF at day 14 ($p=0.014$). Renal mRNA expression of IL-6, TNF-α, and TGF-β were not different between the strains at day 14.

Conclusions: *In vitro*, TLR4 signaling can stimulate inflammasomes and inflammatory cytokine production RECs. *In vivo*, although TLR4 is not required for the acute phase injury, the TLR4-mutant is protected from interstitial fibrosis, potentially via reduced sensitivity to DAMPs released after acute injury.

SA-PO438

A New Mouse Model of Glomerular Foam Cell Accumulation in Disease

Minseob Eom, Kelly L. Hudkins, Anna Batorsky, Charles E. Alpers. *Dept of Pathology, Univ of Washington School of Medicine, Seattle, WA.*

Background: Foam cells are lipid-laden cells of monocyte/macrophage origin which have a key role in the development of atherosclerosis. Similar foam cells are found in human kidney biopsies in various diseases (e.g. tip and cellular variants of focal segmental glomerulosclerosis (FSGS), diabetic nephropathy, and the interstitium in nephrotic states). The pathophysiologic significance of foam cells in the kidney is poorly understood, in part due to lack of good animal models. We sought to develop a robust animal model for foam cell accumulation in the kidney to test their pathogenic significance.

Methods: Six-week old apolipoprotein E (Apo E)-null C57BL/6 mice were divided into two groups. Group 1: Mice were gavaged daily with 1% hydropropyl methyl cellulose with 0.1% tween 80 (HPMC-Tween) (10ml/kg) for 30 days. Group 2: Untreated age-matched controls. Each organ including kidney was harvested for histologic evaluation. Immunohistochemical stains (IHC) for Mac2 were performed to quantify the state of monocyte/macrophage infiltration and urinalysis was conducted to calculate the urine albumin-creatinine ratio (ACR) and total albumin excretion.

Results: IHC for Mac2 revealed that 83.76% of glomeruli were infiltrated by foam cells in the HPMC-Tween treated group. Most showed several foam cells in each glomerulus. Neither FSGS nor mesangiolysis nor interstitial foam cell accumulation developed in the treated mice despite the prominent glomerular foam cells. Additionally, there was no significant difference in ACR between treated group and control group, although the treated mice revealed a trend of higher urine ACR, compared with pre-treatment urine.

Conclusions: Treated mice developed widespread glomerular foam cells. FSGS, mesangiolysis, or interstitial changes that are features of human renal foam cell injury did not develop within the limited 30 day observation period during which foam cells accumulated. We speculate affected mice may not have had sufficient time to develop sclerosis. Apo E null mice treated with HPMC-Tween has potential to be a good animal model for the studies of the tip and cellular variants of FSGS, for which no good mouse models currently exist.

Aberrant Methylated DNA Regions Lead to Low Activation of CD4⁺ T Cells with a Consequent Imbalance of the Th1/Th2 Polarization in IgA Nephropathy Patients

Fabio Sallustio,[1,2,3] Grazia Serino,[1] Alessandra Dalla Gassa,[4] Claudia Curci,[3] Giuseppe De Palma,[3] Barbara Banelli,[5] Gianluigi Zaza,[4] Massimo Romani,[5] Francesco Paolo Schena,[1,3] Sharon N. Cox.[1] *[1]DETO, Univ of Bari, Bari, Italy; [2]DiSTeBA, Univ del Salento, Lecce, Italy; [3]Consorzio Carso, Valenzano, Italy; [4]Dept of Medicine, Univ of Verona, Verona, Italy; [5]IST, IRCCS San Martino, Genova, Italy.*

Background: The immunoglobulin A nephropathy (IgAN) pathogenesis has a strong genetic component. In this setting, also the DNA methylation could be an important factor influencing the pathology. Aim of our study was the identification of abnormally methylated regions in CD4+T cells of IgAN patients.

Methods: A genome-wide screening of the DNA methylation CD4⁺T cells from 6 IgAN patients and 6 healthy subjects (HS) was performed. Differentially methylated regions have been validated on 40 samples of IgAN and HS by pyrosequencing and functional studies by 5-aza-2'-deoxycytidine and MSP-RT-PCR. The gene expression was verified by RT-PCR. Activation of CD4⁺T cells was studied by BrdU proliferation assays and IL2 and IL4 ELISA.

Results: We found 161 tiling regions, 12 promoters, 12 genes and 5 CpG islands differentially methylated. Three regions differentially methylated included genes involved in the response and proliferation of CD4⁺ T cells. In particular, we identified an hypermethylated region containing the gene codifying for the miR-886 precursor and two hypomethylated regions containing TRIM27 and DUSP3 genes involved in the T cell receptor (TCR) signaling. We showed that these genes were dysregulated due to the aberrant methylation in IgAN patients. Moreover, we demonstrated that the hypermethylation of miR-886 precursor led to a decreased CD4⁺ T cell proliferation following TCR stimulation and to an over-expression of the TGFβ, also regulated by the miR-886 precursor.

Conclusions: We describe, for the first time, some DNA regions abnormally methylated in IgAN patients, some of which including genes involved in the TCR signalling and CD4⁺ T cell response and proliferation. These abnormalities led to a reduced activation of CD4⁺ T cells with a consequent T helper cell imbalance. These findings may play an important role in the pathogenesis of IgAN.

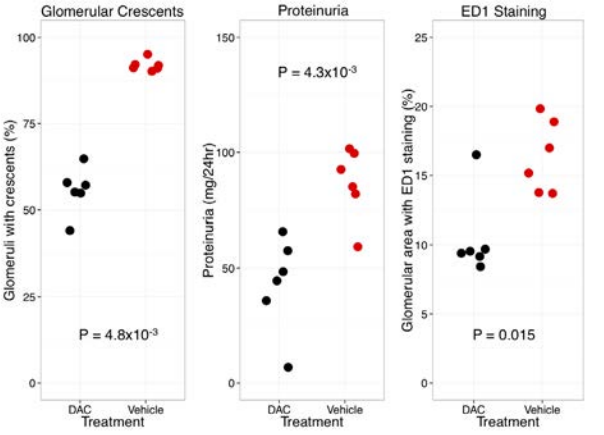
5-Aza-2-Deoxycytidine Reduces Nephrotoxic Nephritis and DNA Cytosine Methylation in Nephritic Glomeruli and Macrophages In Vitro

Thomas Oates,[1] Stephen Paul McAdoo,[2] Charles D. Pusey,[2] H. Terence Cook,[2] Enrico Petretto.[3] *[1]Imperial NHS Trust, London, United Kingdom; [2]Imperial College London, London, United Kingdom; [3]MRC Clinical Sciences Centre, London, United Kingdom.*

Background: Nephrotoxic nephritis (NTN) is a macrophage dependent rat model of crescentic glomerulonephritis (CRGN). We investigated whether DNA cytosine methylation could determine dysregulation of macrophage activity and contribute to CRGN susceptibility, by examining the effect of 5-aza-2'-deoxycytidine (DAC), an inhibitor of DNA methylation, on NTN phenotypes and DNA methylation in both nephritic glomeruli and bone marrow derived macrophages.

Methods: NTN was induced in male WKY rats. 6 rats were treated with intra peritoneal DAC and 6 controls with vehicle only. Treatment was given every three days prior to sacrifice at 10 days and then NTN phenotypes assayed. The effect of DAC on DNA methylation was examined by multiplexed PCR sequencing of bisulfite converted DNA in both nephritic glomeruli from NTN animals, and in WKY bone marrow derived macrophages treated *in vitro* with DAC.

Results: DAC treated animals had fewer glomerular crescents, less proteinuria and less glomerular macrophage infiltration (ED1 staining).



DNA methylation in nephritic glomeruli was decreased across 200 cytosine bases in DAC treated samples compared to controls (P = 0.049, Wilcoxon rank sum test). This decrease was driven by 39 cytosines that showed demethylation in DAC treated animals. *In vitro* sequencing in macrophages showed diverse methylation changes after DAC treatment depending on length of exposure and dose.

Conclusions: These experiments show that DAC treatment had a protective effect on NTN phenotypes in WKY rats with a reduction in DNA cytosine methylation in both nephritic glomeruli and macrophages. These results suggest that DNA methylation may be involved in the pathogenesis of CRGN and may represent a target for intervention.

SA-PO441

Macrophages Present an Essential Source of Anti-Inflammatory Annexin A1 Signals During the Course of Acute Anti-Thy-1.1 Nephritis

Robert Labes,[1] Philipp Dittert,[1] Sebastian Bachmann,[1] Alexander Paliege.[1,2] *[1]Dept of Anatomy, Charité - Universitätsmedizin Berlin, Berlin, Germany; [2]Dept of Nephrology, Charité - Universitätsmedizin Berlin, Berlin, Germany.*

Background: Macrophage subpopulations exert distinctive effects during inflammatory kidney disease and may either aggravate kidney damage or foster renal repair. The anti-inflammatory protein annexin A1 (AnxA1) has been shown to shift macrophage polarization towards the anti-inflammatory M2 phenotype. Cellular sources and regulation of intrinsic AnxA1 signals during renal inflammation remain to be elucidated.

Methods: Adult Wistar rats were injected with anti-Thy-1.1 antibody to induce mesangioproliferative glomerulonephritis and examined after 24h (initiation phase), 5d (proliferation phase), and 15d (resolution phase). Regulation of AnxA1 was studied by qPCR and immunohistochemistry. AnxA1+ cells were characterized by triple labelling immunofluorescence using antibodies against CD68 for monocytes and macrophages, and CD206 for macrophages with M2 polarization. Quantification of immunoreactive cells was performed by cell counting on confocal micrographs.

Results: Induction of anti-Thy-1.1 nephritis caused a rapid increase of renal AnxA1 mRNA levels (24h: +92±16%; 5d: +128±19%; 15d: +78±33% relative to controls; p<.05). Quantitative image analysis revealed a pronounced interstitial accumulation of total, and CD206+ M2 macrophages at d5 (+150±40% and +260±29%; p<.05) and d15 (+378±43% and +600±100%; p<.05) as compared to controls. Triple labelling studies revealed elevated numbers of CD68+/CD206+/AnxA1+ interstitial M2 macrophages at d5 and d15 as compared to controls (+240±27% and +450±80%; p<.05). CD68+/CD206-/AnxA1+ macrophages were increased to a lesser extent (d15: +270±47% relative to controls; p<0.05).

Conclusions: In conclusion, we have shown that AnxA1 expression and protein abundance are significantly increased during the course of anti-Thy-1.1 nephritis. Accumulation of CD206+/AnxA1+ and CD206-/AnxA1+ macrophages at d15 suggests that these cells present a relevant source for anti-inflammatory AnxA1 signals during the resolution phase of renal inflammation. Further studies are needed to establish the characteristics of these cells.

SA-PO442

Reduced Mitochondrial Energy Production in the Kidney Induces Focal Segmental Glomerulosclerosis in Low-Birth-Weight Rats at Adulthood

Toshiyuki Imasawa. *Kidney Center, National Hospital Organization Chiba-East Hospital, Chiba-City, Chiba, Japan.*

Background: Intraglomerular hypertension has been linked with the pathogenesis of focal segmental glomerulosclerosis (FSGS) lesions in low-birth-weight (LBW) -related nephropathy, which is associated with a decreased number of nephrons. However, other mechanisms may participate in the pathogenesis of LBW-related nephropathy. Here, we investigated innate factors that could induce LBW-related nephropathy at adulthood.

Methods: LBW rats (N = 7) were obtained by intraperitoneally injecting pregnant rats with dexamethasone. Normal-birth-weight (NBW) rats (N = 7) were obtained by saline injection. At 4 weeks of age, the left kidney was removed and used for histological analysis and quantitative proteomics (label-free LC-MS). At 9 weeks of age, the right kidney was histologically analyzed.

Results: At 4 weeks of age, glomerular numbers in LBW rats were significantly lower than NBW rats ($p < 0.01$) . However, there were no sclerotic lesions, and neither group showed any other pathological changes at this age. At 9 weeks of age, FSGS lesions were observed in 7.4% of glomeruli in LBW rats, but only 0.5% of glomeruli had lesions in NBW rats. The pathological changes in LBW rats at 9 weeks of age resembled that of human LBW-related nephropathy. Quantitative proteomics using the renal cortex from 4-week-old rats revealed that 685 proteins decreased in LBW rats compared with NBW rats, and among them, 97 proteins (14.2%) were mitochondrial proteins. In such reduced mitochondrial proteins, 12 subunits of OXPHOS, especially of complex III and V, and 15 enzymes of TCA cycle were significantly decreased in LBW rat cortexes ($p < 0.05$). Western blotting revealed the reduced expression of p-AMPK, NRF-1, and TFAM, which are master regulators of mitochondrial biogenesis, in LBW rats at 4 weeks of age.

Conclusions: This is the first report to investigate the innate suppression of mitochondrial energy production in LBW animals. We have shown that in addition to intraglomerular hypertension, innate defects to mitochondrial energy production should induce the formation of FSGS lesions in LBW-related nephropathy at adulthood.

SA-PO443

Chronic Hypoxia Does Not Activate Innate Immunity Neither Promotes Kidney Injury in Normal Rats or Undergoing Renal Ablation 5/6

Lisienny C.T. Rempel, Gizely C.S. Moreira, Thalita F. Nascimento, Camilla Fanelli, Orestes Foresto-Neto, Simone C.A. Arias, Viviane D. Faustino, Claudia R. Sena, Vivian L. Viana, Victor F. Avila, Denise M. Malheiros, Niels O.S. Camara, Clarice K. Fujihara, Roberto Zatz. *Univ of Sao Paulo, Brazil.*

Background: Tissue hypoxia (Hyp) is thought to influence the pathogenesis of chronic kidney disease (CKD), but direct evidence that prolonged exposure to tissue Hyp initiates or aggravates CKD is lacking. We tested this hypothesis by chronically exposing to Hyp normal rats and rats with 5/6 nephrectomy (Nx). In addition, we investigated whether such effect of Hyp would involve activation of innate immunity.

Methods: Adult male Munich-Wistar rats underwent Nx (n=30) or sham surgery (S, n=19). Seven S (S_{nor}) and 13 Nx (Nx_{nor}) rats remained in normoxia, while 12 S rats (S_{hyp}) and 17 Nx rats (Nx_{hyp}) were kept in a normobaric Hyp chamber (12% O_2). Results at 8 weeks (BW, body weight, g; Hb, hemoglobin, g/dL; TCP, tail-cuff pressure, mmHg; Ualb/Ucr, urine albumin/creatinine; KW/BW, kidney/body weight; GSI, glomerulosclerosis index; %INT, % cortical interstitium; MØ, interstitial macrophages, cells/mm^2; renal IL-1β (pg/g); and TLR-4 ($2^{-\Delta\Delta Ct}$).

Results:

	S_{nor}	S_{hyp}	Nx_{nor}	Nx_{hyp}
BW	307±8	285±7[b]	280±6[a]	271±6
Hb	15.6±0.2	18.1±0.6[b]	14.1±0.4	16.6±0.5[b]
TCP	143±2	139±3	195±7[a]	182±5[a]
Ualb/Ucr	0.2±0.1	0.2±0.1	4.9±1.3[a]	3.7±0.6[a]
KW/BW	0.5±0.0	0.4±0.0	0.5±0.0	0.4±0.0[b]
GSI	0.3±0.3	0.3±0.1	9.9±4.9[a]	3.3±0.9[ab]
%INT	0.6±0.2	0.1±0.1	8.4±1.8[a]	4.6±1.2[ab]
MØ	9±3	11±2	76±6[a]	38±7[ab]
IL-1β	2.1±0.5	1.6±0.3	8.8±2.6[a]	4.4±1.2[b]
TLR-4	1.03±0.12	0.93±0.08	2.69±0.30[a]	2.15±0.16[ab]

Mean ± SE, [a]p <0.05 vs. respective S, [b]p <0.05 vs respective Nor.

Exposure to Hyp increased Hb in both S and Nx, but led to no injury or elevation of the renal content of IL-1β or TLR-4 in S. Unexpectedly, Hyp attenuated IL-1β, TLR-4, MΦ, GSI and %INT in Nx.

Conclusions: We found no evidence that chronic Hyp initiates or worsens CKD. Chronic Hyp may be even renoprotective by unclear mechanisms, perhaps involving adaptive molecules. FAPESP/CNPq.

Methylation Decreases Expression of Erythropoietin in Fibrosing Kidney Disease

Ching-chin Yang,[1] Yu-ting Chang,[1] Szu Yu Pan,[2] Yu-hsiang Chou,[1] Yung-ming Chen,[2] Shuei-Liong Lin.[1,2] *[1]Physiology, National Taiwan Univ College of Medicine, Taipei, Taiwan; [2]Internal Medicine, National Taiwan Univ Hospital, Taipei, Taiwan.*

Background: Renal erythropoietin-producing cells remain in atrophic kidneys and are capable of producing erythropoietin in dialysis patients who take the stabilizer of hypoxia-inducible factors. The mechanism of decreased response of renal erythropoietin-producing cells to anemic stimulation in chronic kidney disease remains unclear.

Methods: We use genetically modified mice who report pericytes/myofibroblasts and express pericyte-specific Cre recombinase to perform in vivo study. We also isolate pericytes/myofibroblasts from these mice for in vitro analysis of epigenetic modification and erythropoietin expression.

Results: Here we show that Foxd1+ progenitor-derived;Col1a1-GFP+;PDGFRbeta+ kidney pericytes are erythropoietin-producing cells regulated by hypoxia-inducible factor 2 alpha but decrease such a function upon their transition to myofibroblasts in fibrosing kidney disease. Hypermethylation of erythropoietin 5'-untranslated region is demonstrated and associated with decreased expression of erythropoietin in kidney myofibroblasts. Demethylation with 5-azacytidine or knockdown of upregulated DNA methyltransferase 1 in kidney myofibroblasts is found to increase expression of erythropoietin in fibrosing kidney disease.

Conclusions: These studies demonstrate that epigenetic modifications may provide a molecular basis for decreased response of renal erythropoietin-producing cells to anemic stimulation in fibrosing kidney disease.

SA-PO445

Multiparametric Magnetic Resonance Imaging for Assessing Renal Histopathology in a Mouse Model of CKD

Gunnar Schley,[1] Jutta Janke,[2] Kai-Uwe Eckardt,[1] Tobias Bäuerle,[2] Carsten Willam.[1] *[1]Nephrology and Hypertension, Univ of Erlangen-Nuremberg, Erlangen, Germany; [2]Radiology, Univ of Erlangen-Nuremberg, Erlangen, Germany.*

Background: Multiparametric magnetic resonance imaging (MRI) allows non-invasive assessment of renal pathologies, especially in patients with chronic kidney disease (CKD) as is does not require contrast agent administration. We aimed to establish an imaging protocol for multiparametric MRI in an experimental CKD mouse model and correlate radiological and histopathological parameters.

Methods: CKD was induced in male C57BL/6 mice (n=8) by feeding an adenine-supplemented diet for 3 weeks resulting in deposition of dihydroxyadenine crystals, tubular dilation, capillary loss, tubulointerstitial inflammation and fibrosis. Untreated animals (n=8) served as controls. Kidneys were fixed in paraformaldehyde and subjected to MRI in a 7-Tesla scanner ex vivo. Volumetry of renal cortex and medulla was performed on T2 weighted sequences. MRI parameters (apparent diffusion coefficient (ADC), fractional anisotropy (FA), T1, T2, T2* relaxation times) were determined for 3 regions of interest placed manually in the cortex and outer medulla, compared between CKD and controls kidneys and correlated with (immuno-)histological analyses for crystal density, tissue cellularity, tubular dilation, inflammatory infiltration, fibrosis, and vascularization.

Results: CKD resulted in significant volumetric augmentation of the medulla. T1 times did not differ in control and diseased kidneys, T2 and T2* times were significantly increased in both cortex and medulla, whereas ADC was increased only in the cortex of diseased kidneys in comparison to controls. In contrast, FA was significantly reduced in diseased cortex and medulla. T2 time correlated with the relative area of fibrosis (Spearman's rho 0.71 for cortex, 0.79 for medulla), infiltrated macrophages (0.69, 0.81), and tubular lumen (0.74).

Conclusions: Multiparametric MRI enabled characterization and diagnosis of chronic changes in the presented CKD model and showed correlation of T2 times with fibrosis, inflammatory infiltration, and tubular dilation. These results may help to broaden our understanding of MRI findings in CKD patients.

SA-PO446

Nuclear Magnetic Resonance Based Metabonomic Profiles Produced by Aristolochic Acids: Comparison with Well-Known Tubulotoxic Agents

Marilyn Duquesne,[1,2] Nordinn Rabai,[1] Anne-Emilie Decleves,[2] Coulon Françoise,[3] Eric De prez,[2] Jean-Marie Colet,[1] Joelle L. Nortier.[2] *[1]Lab Human Biology & Toxicology, UMONS; [2]Lab Experimental Nephrology, ULB; [3]Lab Histology, UMONS.*

Background: Aristolochic acids (AA) are powerful nephrotoxic and carcinogenetic products derived from Aristolochiaceae responsible for acute to chronic renal failure and urothelial cancer complications in countries using traditional herbal medicine. Early detection of renal tubular injury could be useful in individuals at risk of exposure to AA.

Methods: The Consortium of Metabonomic in Toxicicology (COMET) has developed predictive models of renal toxicity based on the NMR-based metabonomic evaluation of urine and serum samples collected from rats acutely exposed to various well characterized nephrotoxicants. Using this COMET protocol, we studied the metabonomic urine profile of rats exposed to one sc injection of AA I or II at different dosages (75, 100mg/kg). We then compared it to those obtained with 3 molecules known for their toxicity on the proximal tubule, i.e ifosfamide (Ifo: 7, 70mg/kg), gentamicin (Genta: 40, 400mg/kg) and cisplatin (Cis: 0.5, 5mg/kg), respectively.

Results: Metabonomic results obtained in AA rats demonstrated a urinary increase in metabolites involved in osmoregulation (taurine, betaine, glycine), cell death (lactate) and in reabsorptive capacity of the tubular epithelium (glucose), and a significant reduction of Krebs's cycle components (alpha-ketoglutarate, succinate, citrate), suggesting a mitochondrial injury. The comparison of these AA profiles with those obtained with Ifo, Genta and Cis revealed close similarities in 2D plots. However, the 3D modelization approach showed very close score plots shared by AA, Ifo and Cis and a different behaviour exhibited by Genta samples.

Conclusions: This metabonomic study confirms the mode of action of AA towards the proximal tubule and provides an original signature of induced mitochondrial insult. This approach could bring new insight in understanding the toxicity pathways of AA within the kidney. Moreover, it could be a useful tool of noninvasive screening in populations at risk of AA intoxication.

SA-PO447

Establishment of a 3-Step Method to Obtain the Absolute Number of Nephrons in Mice Xiaogang Chu, Jian-Kang Chen. *Depts of Cellular Biology & Anatomy and Medicine, Georgia Regents Univ, Augusta, GA.*

Background: Low nephron number is implicated in hypertension and kidney disease. Existing methods to determine nephron number have various limitations. While using the Cre reporter mice expressing membrane-Tomato/membrane-Green fluorescent protein (mT/mG) for other studies, we fortuitously noticed that the Tomato fluorescence remarkably visualized all glomeruli in the kidneys, which prompted us to establish a 3-step (Separate-Press-Count) method to obtain the *exact* nephron number in mice.

Methods: One homozygous mT/mG mouse ($232, available from the Jackson Laboratory, Stock Number: 007576) was bred with FVB/NJ mice. This produced ~11 heterozygous pups per litter. After the pups reached 6 weeks of age, they were weighed and euthanized. Each kidney was decapsulated, weighed, and bluntly separated into 35-45 pieces (1-2 mm^3 each) using forceps with non-serrated but blunted tips. Each piece was pressed between a microscope slide with grids and a coverslip, followed by counting of every single glomerulus under a fluorescence microscopy.

Results: The nephron number in male mice ranged from 10421 to 15577 (mean = 12977 ± 2136) for left kidney and 10374 to 15691 (mean = 13271 ± 2414) for right kidney (n=6) while that of female mice ranged from 13890 to 16277 (mean = 15184 ± 993) for left kidney and 14547 to 16165 (mean = 15555 ± 741) for right kidney (n=5). Thus, the mean total nephron number in male mice (25562 ± 4530) is lower than that of female mice (30739 ± 1443). This is still true when expressed as mean nephron number per gram of body weight (N/gBwt): male 1025 ± 179 vs. female 1362 ± 90; n=5-6, p<0.01). 5/6 nephrectomy (Nx) in male mice decreased N/gBwt down to 156 ± 17, increased blood pressure (BP) up to 142 ± 7 mmHg, elevated BUN level up to 292 ± 7 mg/dl, and caused 37.5% mice to die within 2 weeks while the remaining 5/6Nx mice with >241 N/gBwt had 130 ± 8 mmHg BP and 73 ± 25 mg/dl BUN and were still alive even 4 weeks after 5/6 Nx.

Conclusions: We have established a new simple method to count the absolute nephron number and are using it to define the minimum of nephrons per gram of body weight that can maintain the normal blood pressure and kidney function in mice.

New Aspects on the Difference in Permeability Between Proteins and Polysaccharides in the Glomerular Filtration Barrier Carl Mikael Öberg,[1] Joseph J. Groszek,[2] William Henry Fissell,[2] Bengt Rippe.[1] *[1]Dept of Nephrology, Lund Univ, Lund, Skane, Sweden; [2]Nephrology and Hypertension, Vanderbilt Univ, Nashville, TN.*

Background: One of the many unresolved questions regarding the permeability of the glomerular filtration barrier (GFB) is the reason behind the marked difference in permeability between albumin and polysaccharide probe molecules such as Ficoll. The difference in sieving coefficients between albumin and a Ficoll molecule of the same molecular size (~36 Å) is ~2-3 orders of magnitude. Although this large difference in permeability has been attributed mainly to charge effects, we have previously shown that this would require a supraphysiological amount of charge on the filtration barrier, being about ~10 times more than the charge on the albumin molecule (~0.02 C/m^2).

Methods: The classic heteroporous model by Deen, Bridges, Brenner and Myers (Deen et al, AJP Renal Physiology, 1985) was extended by introducing size distributions on the solute molecules, making them flexible in their conformation. Experimental sieving data for Ficoll, both from the rat glomerulus and from precision-made nanopore membranes, were analyzed using the model. The variation in solute size was quantified in terms of the geometric standard deviation (gSD) of the solute size distribution. The (mode) solute radius was assumed to be equal to the SE-radius and the pore size distribution gSD was set to unity.

Results: For the glomerulus (n=7), a gSD for the Ficoll size-distribution of 1.16 (± 0.01) was obtained, along with a small pore radius of 36.1 Å (± 0.5 Å) and a large pore radius of 152 Å (± 7 Å). For the nanopore membranes (n=16), a gSD of 1.24 (± 0.01) was found.

Conclusions: In the current study, we show, for the first time, that a variation of only ~15-17% in the size of the molecule is sufficient to explain the difference in permeability between albumin and Ficoll. In addition, we show that the effects of applying a size-distribution on the solute molecule are only evident when the molecular size is close to the size of the selective elements of the barrier. This is well in line with experimental data, both from the GFB and from synthetic membranes.

Rapid MicroRNA Isothermal Amplification and Detection in Urine for Nephrotic Syndrome and Other Renal Disease Biomarker Discovery Kathrin Gassei, Chandramohan Ishwad, Jacqueline Ho, Abhay N. Vats. *Pediatrics, Childrens Hospital of Pittsburgh, Pittsburgh, PA.*

Background: MicroRNAs play an important role in renal development and are being explored as biomarkers for several renal diseases including nephrotic syndrome (NS). However, miRNA detection assays can be expensive, laborious, and time consuming. We have been developing a fast and reliable assay for microRNAs in urine and report a novel isothermal amplification method. We tested this method [called cross hybridization amplification (CHAMP)] for detection of miR-30a-5p in urine of patients with NS and controls.

Methods: We designed two 20-25 nt primers and a probe specific for miR-30a-5p. Primers were labeled with either Biotin or Digoxigenin on the 3'-end. Synthetic miR targets were developed for miR-30a, miR30b and Let7 microRNAs. Amplification required, Bst DNA polymerase enzyme, and incubation at 65°C for 30-60 min. Assay optimization was performed on urine samples spiked with synthetic miR constructs. Amplification and detection was performed with real-time PCR; gel electrophoresis and later flow devices.

Results: CHAMP was able to amplify and detect miR30a-5p in 60 minutes or less. The primers / probe were specific for miR30a and did not amplify mir30b or let7 microRNA . Appropriate melting curves were obtained for mir30a only. Amplicons were also detected by UV transillumination. The incorporation of Biotin and Digoxigenin in primers allowed the detection on lateral fl ow strips also. The presence of urine did not inhibit the reaction, and unprocessed urine could be used, without the need for RNA isolation. The de-identified urinary samples of 3 patients with steroid resistant NS had mir30a levels that were upto 200 fold higher than controls.

Conclusions: A novel isothermal amplification method (CHAMP) can be used for paid microRNA detection in human urine. It allowed a rapid, sensitive, and highly specifi c amplification and detection of miRNA and is much easier and more cost effective than qPCR or microarray. CHAMP could detect miR-30a-5p, with sensitivity similar to qPCR, without the need for RNA isolation and could be used for biomarker discovery based on micrRNA studies for NS and other renal diseases.

Dominant Negative Etv Expression in Metanephric Mesenchyme Reduces Nephron Endowment: A Model of Low Nephron Number CKD Susanne V. Fleig, Flavia G. Machado, Benjamin D. Humphreys. *Brigham and Women's Hospital, Boston.*

Background: The role of etv4 expression in the ureteric bud during kidney development has been established; however etv4 is also expressed in the metanephric mesenchyme. We asked what role Etv4 plays during nephrogenesis.

Methods: To inhibit etv4 function in the metanephric mesenchyme, we crossed mice with a loxP-flanked dominant-negative etv4 (R26-LoxP-DN-$Etv4^{+/+}$) with metanephric mesenchyme-specific six2-cre mice (Six2-TGC $^{(tg/+)}$); cre-negative littermates served as control.

Results: Six2cre-DN-Etv4 mice express DN-etv4 in the nephron progenitor population starting dpc10.5. Cre-positive mice have lower body weight and fail to thrive. At four weeks, they have a reduced nephron number (24.4 ±2.4 vs. 86.8 ±6.9 glomeruli/section, p<0.0001). They develop kidney failure (at 4 weeks: BUN 103.8±17.8mg/dl vs. 14.1±1.8mg/dl, p < 0.001) and proteinuria (21.29±7.23g Albumin/g Creatinine vs. 0.14±0.03g Albumin/g Creatinine in urine, p<0.05). Their kidneys show all features of chronic kidney failure (protein casts, glomerulosclerosis, fibrosis) and they die at 3-5 weeks of kidney failure.

Conclusions: Etv4 expression in the metanephric mesenchyme is required for normal kidney development, and expression of DN-Etv4 in the six2+ population leads to defective kidney development with reduced nephron number and progressive chronic kidney failure at 3-5 weeks of age. Titration of DN-Etv4 expression in metanephric mesenchyme may provide a novel genetic model for low nephron endowment and progressive CKD.

Funding: NIDDK Support

SA-PO451

NO Depletion by L-NAME Causes Increases in Rat Glomerular Permeability *In Vivo* – Reversal with Tempol and L-Arginine, but Not with the Potent NO-Donor DEA-NONOate Bengt Rippe, Julia Dolinina, Kristinn Sverrisson, Anna Rippe. *Dept of Nephrology, Lund Univ, Lund, Sweden.*

Background: There is increasing evidence that the permeability of the glomerular filtration barrier (GFB) is regulated by a balance between the bioavailability of nitric oxide (NO) and the presence of reactive oxygen species (ROS). It has been postulated that normal or moderately elevated NO levels protect the GFB from permeability increases, while ROS, through reducing the bioavailability of NO, have the opposite effect.

Methods: In anaesthetized Wistar rats, the left ureter was cannulated for urine collection, while simultaneously blood access was achieved. To test the tentative antagonism between NO and ROS, rats were systemically infused with either L-NAME (6 mg/kg/min) or L-NAME together with the superoxide scavenger tempol (1 mg/kg/min), or L-NAME together with L-arginine (290 mg/kg/min). Furthermore, we tested whether the potent NO donator, DEA-NONOate, could reverse the permeability effects of L-NAME. To measure glomerular sieving coefficients (θ) to Ficoll, rats were infused with fluorescein

isothiocyanate (FITC)-Ficoll 70/400 (mol.radius 10-80Å). Plasma and urine samples were analyzed by high performance size exclusion chromatography (HPSEC) for determination of θ for Ficoll repeatedly during up to 2 hours.

Results: L-NAME increased θ for $Ficoll_{70Å}$ from 2.27 (± 1.30) x 10^{-5} to 8.59 (± 2.06) x 10^{-5} (n=6; p<0.05) in 15 min. Tempol (n=6) completely abrogated these increases in glomerular permeability, the θ $Ficoll_{70Å}$ being 7.0 (± 2.1) x 10^{-6} at 15 min, which was also seen with L-arginine. However, DEA-NONOate did not reverse the permeability effects following L-NAME.

Conclusions: NO depletion *in vivo* by L-NAME caused increases in glomerular permeability, which could be reversed by either the ROS antagonist, tempol, or by L-arginine. By contrast, the potent NO-donor, DEA-NONOate, did not ameliorate the permeability effects of L-NAME. It is concluded that moderate levels of elevated NO production act to protect the permeability of the GFB, whereas very high levels of NO, as predicted following systemic DEA-NONOate infusion, may actually be detrimental to the GFB.

SA-PO452

Down-Regulation Of Renal Tubular Wnt/β-Catenin Signaling Induces Tubular Cell Death in Proteinuric Nephropathy Dickson W.L. Wong, Wai Han Yiu, Hao-Jia Wu, Ruixi Li, Kam Wa Chan, Joseph C.K. Leung, Loretta Y.Y. Chan, Kar Neng Lai, Sydney C.W. Tang. *Dept of Medicine, The Univ of Hong Kong/ Queen Mary Hosptial, Hong Kong.*

Background: Persistent proteinuria from any causes is closely associated with chronic kidney disease (CKD) progression. Excessive transglomerular protein trafficking impacts on renal tubular cell injury by triggering tubular cell death. Studies on the role of Wnt/β-catenin signalling in different forms of CKD have yielded discrepant results.

Methods: β-catenin expression was measured in control/ human serum albumin (HSA)-treated human kidney 2 (HK-2) cells and kidney cortical lysates of protein-overloaded mice given 4- or 8- week BSA injection by Western blotting and IHC staining. Genetic knockdown of β-catenin in HK-2 cells was achieved using siRNA transfection. Apoptotic phenotypes were evaluated by qPCR, Western blotting, IHC staining/ activity assay and TUNEL assay.

Results: Upon 4-dayHSA stimulation, protein levels of active nuclear β-catenin in HK-2 cells declined by 67%±0.04 (p<0.05) versus control. Simultaneously, Bax/Bcl-2 gene expression ratio increased significantly. HSA treatment with or without β-catenin siRNA transfection in HK-2 cells up-regulated Bax/Bcl-2 gene expression ratio by 116%±0.2 (<0.05) and 52%±0.2 (p<0.05), respectively. Similarly, TUNEL and caspase-3 activity was also increased by silencing β-catenin. In protein-overloaded mice, dynamic expression of tubular β-catenin was observed, with up-regulation (by 88 %±0.2 *vs.* control animals; p<0.05) at the early stage (4 weeks after BSA injection) and abrogation (24%±0.2; p<0.05) in the late phase (8 weeks after BSA injection). UACR decreased during renal tubular β-catenin overexpression but increased thereafter as tubular β-catenin levels came down. Elevated apoptotic phenotypes were evident in the later phase and associated with up-regulation of NGAL and KIM-1 genetic expressions.

Conclusions: Protein-overload promotes renal tubular apoptosis via abrogation of Wnt/β-catenin signalling *in vitro* and *in vivo*. Funding supports: Hong Kong Society of Nephrology Research Grant (2013), and the National Basic Research Program of China 973 program no. 2012CB517600 (no. 2012CB517606).

SA-PO453

Endothelin-1 Induces Proteinuria by Heparanase-Mediated Disruption of the Endothelial Glycocalyx Marjolein Garsen,[1] Olivia Lenoir,[2] Angelique Rops,[1] Henry Dijkman,[3] Brigith Willemsen,[3] Ton J. Rabelink,[4] Jo H.M. Berden,[1] Pierre-Louis Tharaux,[2] Johan Van der vlag.[1] *[1]Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands; [2]Paris Cardiovascular Research Centre, Inst de la Santé et de la Recherche Médicale, Paris, France; [3]Pathology, Radboud Univ Medical Center, Nijmegen, Netherlands; [4]Nephrology, Leiden Univ Medical Center, Leiden, Netherlands.*

Background: Diabetic nephropathy (DN) is the leading cause of chronic kidney disease in the Western world. Recently, endothelin receptor antagonists (ERAs) have emerged as a novel treatment for DN, but the mechanism underlying the protective effect of ERAs remains unknown. We previously showed that heparanase (HPSE), a heparan sulfate (HS)-specific endoglucuronidase, is essential for the development of DN. Loss of HS expression has been associated with the development of proteinuria. We hypothesize that endothelin-1 signals via HPSE.

Methods: In this study we evaluate the effects of endothelin-1 on HPSE expression and function *in vitro* and *in vivo*.

Results: Endothelin-1 induced HPSE expression in cultured mouse podocytes. Moreover, culture supernatant of endothelin-1-stimulated podocytes increased transendothelial albumin passage, which is HPSE-dependent. Experimental type 1 diabetes in wild type (WT) mice revealed proteinuria and renal damage, accompanied with an increased glomerular HPSE expression and a reduced glomerular HS expression. Proteinuria and renal damage were reduced in the diabetic podocyte-specific endothelin receptor knockout (podETRKO) mice, which showed a normal HPSE and HS expression. Importantly, glycocalyx thickness was reduced after induction of diabetes in the WT mice, but preserved in the diabetic podETRKO mice.

Conclusions: Our data show that endothelin-1 induces HPSE expression in the podocyte in experimental DN. Furthermore, these results suggest that HPSE cleaves HS in the endothelial glycocalyx, which results in a reduced glycocalyx thickness and the development of proteinuria.

SA-PO454

Endothelin-1 Increases Glomerular Permeability in Sickle Cell Mice Malgorzata Kasztan,[1] Chiao-Wang Sun,[2] David M. Pollock.[1] *[1]Cardia-Renal Physiology&Medicine, Univ of Alabama at Birmingham, Birmingham, AL; [2]Biochemistry&Molecular Biology, Univ of Alabama at Birmingham, Birmingham, AL.*

Background: Sickle cell disease (SCD) leads to nephropathy manifested by increased glomerular permeability (P_{alb}) and albuminuria/proteinuria. The endothelium-derived peptide, endothelin-1 (ET-1), with its powerful vasoconstrictor and pro-inflammatory effects mediated primarily through ET_A receptors, is elevated in SCD patients and may contribute to the development of sickle cell glomerulopathy. Therefore, the aim of the study was to determine whether ET-1 contributes to increased glomerular permeability to albumin in SCD and if ET_A receptors blockade ameliorates glomerular damage. Furthermore, because our preliminary studies showed sex differences in the vasoconstrictor response to ET-1 in sickle cell mice the study was designed to determine if sex differences exist in this response.

Methods: Experiments utilized 12 week old humanized sickle cell mice (HbSS) and genetic controls (HbAA) recently developed by the Townes' lab. Ambrisentan (ET_A antagonist), A-182086 ($ET_{A/B}$ antagonist) or vehicle was administrated via drinking water (10mg/kg/day) for 2 weeks. Glomeruli were isolated for direct permeability measurements as a volume response of glomerular capillaries to an oncopressive medium generated by defined concentrations of albumin.

Results: P_{alb} was significantly higher in glomeruli from sickle mice (both in males and females) than control mice (0.50±0.07 and 0.47±0.06 vs. 0.13±0.02 and 0.10±0.2, respectively). Ambrisentan treatment significantly reduced the elevated P_{alb} in glomeruli from male (0.24±0.05 vs. 0.50±0.07) and female (0.20±0.03 vs. 0.47±0.06) HbSS mice. $ET_{A/B}$ receptors antagonism with A-182086 also significantly decreased the P_{alb} in glomeruli from male (0.28±0.06 vs. 0.50±0.07) and female (0.24±0.03 vs. 0.47±0.06) HbSS mice. Treatment with both antagonists did not alter P_{alb} in HbAA mice.

Conclusions: These data support the hypothesis that ET-1 may play an important role in the development of sickle cell nephropathy and support the use of chronic ET_A antagonism as a prospective treatment for sickle cell nephropathy.

SA-PO455

Longitudinal Transcutaneous Glomerular Filtration Rate (GFR) After Uninephrectomy (UNx) in Mice Hiroshi Kojima, Jonathan Street, Ana C. Souza, Peter S.T. Yuen, Robert A. Star. *Renal Diagnostics and Therapeutics Unit, NIDDK, NIH, Bethesda, MD.*

Background: Glomerular filtration rate is a universally accepted measure of global kidney function. Serum filtration markers such as serum creatinine, BUN, or cystatin C have confounding factors, and measuring clearance of "inert" markers requires blood and urine collection, which can be cumbersome in unstable, oliguric patients, and small animals. A new non-invasive method using fluorescently-labeled Sinistrin and a miniaturized fluorescence detector can non-invasively detect plasma disappearance in conscious mice. To determine if the assumptions for plasma disappearance are met, we tested the method in a classic mouse uninephrectomy model with a predictable change (50%) then slow recovery.

Methods: Young male CD-1 mice underwent left UNx at Day 0. Transcutaneous measurement of GFR was performed every 3-4 days until Day 18. Under isofluorane anesthesia, a depilatory was applied to the back, and a miniaturized fluorescence detector (NIC-Kidney; Mannheim Pharma & Diagnostics GmbH, Mannheim, Germany) was fixed on the exposed skin using a double-sided adhesive patch. After background signal was obtained, FITC-Sinistrin was injected intravenously. Data acquisition lasted 60 min. After removing injection artifacts, GFR was calculated using the half-life derived from the rate constant of the single exponential elimination phase of fluorescence-time curve.

Results: All fluorescence measurements decayed as a single exponential, consistent with a stable, single components model and a stable GFR during the time of measurement. Assuming that GFR declined 50% immediately after UNx, GFR gradually increased until 8 days post-UNx, when it plateaued at 75% of normal function.

Conclusions: FITC-Sinistrin plasma disappearance follows single component kinetics at baseline and after UNx, allowing calculation of GFR by single pool kinetics. This technology can easily detect renal hyperfiltration early after UNx.

CHOP Deficiency Impedes Progressive CKD by Inhibiting Proteinuria Zahraa Mohammed-Ali,[1] Chao Lu,[2] Jeffrey G. Dickhout.[1,2] *[1]Medicine, McMaster Univ, Hamilton, ON, Canada; [2]St. Joseph's Healthcare Hamilton, Hamilton, ON, Canada.*

Background: Endoplasmic reticulum (ER) stress occurs due to the accumulation of misfolded proteins in the ER and is associated with proteinuria in chronic kidney disease (CKD). CHOP (GADD153/DDIT3) is a pro-apoptotic transcription factor that is upregulated during ER stress. Increased expression of CHOP has been shown in biopsies of patients with membranous nephropathy and membranoproliferative glomerulonephritis. CHOP deficiency protects against oxidative stress, albuminuria and inflammation in mouse models of acute kidney injury and diabetic nephropathy. Therefore, we hypothesized that CHOP deficiency would influence the development of CKD.

Methods: Our model of CKD combines a uninephrectomy and subcutaneous implantation of a slow release deoxycorticosterone acetate (DOCA) pellet and Angiotensin (Ang) II osmotic infusion pump in C57BL/6 male mice. Mice were also given 1% sodium

chloride in their drinking water. Mice with total CHOP knockdown were used to test the role of CHOP in CKD development. CKD was assessed using blood pressure and 24h total urinary protein and albumin measurements. On day 21 post-implantation, mice were sacrificed and PAS staining was used to evaluate renal intertubular cast formation and glomerular damage.

Results: In response to the CKD model, both $CHOP^{-/-}$ and wild type (WT) mice experienced significant increases in systolic and diastolic blood pressure. However, $CHOP^{-/-}$ mice showed significantly lower proteinuria and albuminuria. In addition, CHOP deficiency significantly decreased intertubular cast formation and glomerular damage in response to the model compared to WT.

Conclusions: CHOP deficiency resulted in a decrease in proteinuria and renal tissue damage. Along with inducing apoptosis, CHOP has been shown to interact with inflammatory pathways resulting in NFκB activation. Further tests will evaluate the effect of CHOP deficiency on inflammatory, fibrotic and apoptotic response in our model. Our findings could lead to the development novel therapeutics to halt the progression of CKD.

Caveolin-1 Is Crucial in the Pathogenesis and Progression of Light Chain Deposition Disease but Not in Al-Amyloidosis Jiamin Teng. *Pathology and Transitional Pathobiology, Louisiana State Univ Health Sciences Center, Shreveport, LA.*

Background: In-vitro models of glomerulopathic light chains (GLCs), including light chain deposition disease (LCDD) and light chain amyloidosis (AL-Am) have provided solid platforms to study the pathogenesis of these disorders and how initiation / progression takes place. C-fos and NF-κB have been found to be important signaling mechanisms in the initiation phase of these two disorders. The role of caveolin-1 in the initiation / progression phases was explored in this study using human and mouse caveolin-1 knock-out (KO) and wild type (WT) mesangial cells (MCs).

Methods: Human and Caveolin-1 KO and WT mouse MCs were grown on dishes (2D) and Matrigel (3D), and incubated with GLCs 10 µg/ml purified from the urine of renal biopsy-proven patients with LCDD and AL-Am. Downstream effects were tested by determining whether c-fos and NF-κB cytoplasmic to nuclear signal translocation occurred and analyzing the presence / absence and amounts of amyloid fibril formation in AL-Am and determining amounts of extracellular matrix production in LCDD.

Results: When LCDD GLCs were incubated with caveolin-1 KO cells, no c-fos or NF-κB cytoplasmic to nuclear migration occurred and there was no increase in the extracellular matrix. In contrast, normal translocation was observed with WT caveolin-1 MCs. In contrast, signal translocation for c-fos or NF-κB was unaffected and similar amounts of amyloid fibril formation occurred when WT and caveolin-1 KO MCs were incubated with AL-Am GLCs.

Conclusions: Caveolin-1 (through activation of c-fos and NF-κB) plays a crucial role in signaling in LCDD and subsequent downstream effects. The absence of caveolin-1 at the surface of MCs abolishes downstream effects in LCDD but not in AL-Am. While amyloid production still occurs when MCs are incubated with Am-AL GLCs, the production of excess extracellular matrix is abolished when LCDD GLCs are incubated with caveolin-1 KO MCs.

Inhibition of TRPC6 Channels Protects against Renal Fibrosis Yueh-lin Wu,[1,2] Jian Xie,[2] Chou-Long Huang.[2] *[1]Taipei Medical Univ Hospital, Taiwan; [2]UT southwestern Medical Center, Dallas, TX.*

Background: Fibrosis is an important process of tissue repair, yet excess leads to organ failure. Transformation of fibroblasts into myofibroblasts is a critical step in fibrosis and requires activation of multiple new genes. Ca2+-permeable TRPC3/6 channels contain NFAT response element in the promoter such that increased Ca2+ entry via TRPC3/6 may, by activating calcineurin/NFAT nuclear signaling cascade, lead to positive feedforward amplification and un-remitting gene expression. We test the hypothesis that TRPC6 is critical for fibroblast-myofibroblast transformation in kidney fibrosis and inhibition of TRPC6 may ameliorate fibrosis.

Methods: Wild type (WT) and Trpc6-null mice (129 SvJ) underwent unilateral ureteric obstruction (UUO) on left kidney and sham operation on contralateral kidney. Ten days after surgery, kidneys were harvested for histological analysis of fibrosis by trichrome staining and for measurement of mRNA expression by quantitative real-time PCR. In separate experiments, WT mice underwent UUO and received injection of TRPC3/6 inhibitor BTP2 (2 mg/kg daily by i.p.) or vehicle for 7 days.

Results: UUO induced a >20-fold increase in mRNA for Trpc6 in UUO kidney vs contralateral sham kidney in WT mice. mRNA for collagen-1, vimentin, cTGF, TGF-b1, and matrix metalloproteases MMP-2 and MMP-9 as well as area for fibrosis measured by trichrome staining were also markedly increased in UUO vs sham kidney. Deletion of Trpc6 resulted in a significant reduction in fibrosis and blunted the increase in mRNA expression of collagen-1, vimentin, cTGF, TGF-b1, MMP-2, and MMP-9 in UUO kidney relative to those in WT mice. Trpc6 deletion did not alter the basal gene expression in sham kidney. Compared to vehicle-treated mice, BTP2 treatment also markedly decreased the measured area of fibrosis and attenuated the increase in expression of fibrosis and pro-fibrotic gene markers in UUO kidney. As in results from Trpc6 deletion, inhibition of TRPC6 by BTP2 had no effect on sham kidney.

Conclusions: Activation of TRPC6 may be critical for myofibroblast transformation in fibrosis. TRPC6 may be a new potential pharmacologic target in treating renal fibrosis.

SA-PO459

Histone Methyltransferase EZH2: A Novel Therapeutic Target for Renal Fibrosis Xiaoxu Zhou, Murugavel Ponnusamy, Evelyn Tolbert, George P. Bayliss, Shougang Zhuang. *Dept of Medicine, Rhode Island Hospital and Alpert Medical School, Brown Univ, Providence, RI.*

Background: EZH2 (Enhancer of Zeste Homolog 2) is a methyltransferase that induces histone H3 lysine 27 trimethylation (H3K27me3) and functions as an oncogenic factor in many cancer types. However, its role in renal fibrogenesis remains to be explored.

Methods: In this study, we studied the role EZH2 in the activation of cultured renal interstitial fibroblasts and development of renal fibrosis in a murine model of unilateral ureteral obstruction as well as mechanisms involved.

Results: Our results showed that EZH2 and H3K27me3 were highly expressed in the cultured renal fibroblasts and the fibrotic kidney from mice with unilateral ureteral obstruction. Pharmacological inhibition of EZH2 with 3-deazaneplanocin A(3-DZNeP) and GSK126, or silencing of EZH2 with its specific siRNA, inhibited serum- and TGFb1-induced activation of renal interstitial fibroblasts in vitro. Administration of 3-DZNeP abrogated deposition of extracellular matrix proteins and expression of a-SMA in the obstructed kidney. Mechanistically, 3-DZNeP inhibited expression of type I TGFb receptor and phosphorylation of Smad3, along with preservation of Smad-7 expression. 3-DZNeP was also effective in blocking phosphorylation of the EGF and PDGFb receptors, and suppressing activation of STAT3 and ERK1/2 signaling pathways in the injured kidney. Moreover, 3-DZNeP treatment abolished injury-induced renal expression of avb6 intergin, Notch1 and Notch3. Finally, EZH2 inhibition increased expression of PTEN, a protein tyrosine phosphatase associated with dephosphorylation of multiple tyrosine kinase receptors, in the kidney after ureteral ligation.

Conclusions: This study has identified EZH2 as an important epigenetic regulator of renal fibrosis and suggested that it could be a novel target for therapeutic interference in chronic kidney disease.

Targeting PHD2 for the Treatment of Anemia and Interstitial Fibrosis in Chronic Kidney Disease Raechel Peralta, Xiaokun Xiao, Melanie Katz, Shuling Guo, Gene Hung, Sue Murray. *Antisense Drug Discovery, Isis Pharmaceuticals, Inc., Carlsbad, CA.*

Background: Anemia is a common manifestation of chronic kidney disease (CKD) and is associated with cardiovascular disease. The predominant cause of anemia in CKD is erythropoietin (EPO) deficiency. EPO is a hormone produced primarily by adult kidneys and is essential for the production of red blood cells. It has been shown in many animal models that EPO protects the kidney against interstitial fibrosis. Prolyl hydroxylase domain protein 2 (PHD2) is a primary regulator of hypoxia-inducible factors (HIFs) that regulate genes involved in cellular adaptation to reduced oxygen availability. When PHD2 is reduced, HIFa is stabilized and upregulates several genes to promote survival in low-oxygen conditions. Systemic PHD2 inactivation has been found to increase renal EPO production and stimulate red blood cell synthesis, which can improve anemia in CKD patients (Minamishima et al, Science 2010).

Results: Using antisense oligonucleotides (ASOs) designed against the PHD2 mRNA, we have demonstrated a 60% reduction of kidney PHD2 expression after 4 weeks of treatment (50 mpk/wk) compared to the saline group. In addition, we observed increases of EPO mRNA expression in the kidney interstitial fibroblasts by RT-PCR (~550-fold) and by in-situ analysis. We sought to demonstrate an improvement in anemia and renal fibrosis using our PHD2 ASO. We developed an adenine-induced mouse model of CKD that demonstrates severe anemia and interstitial fibrosis. After simultaneous administration of the 0.2% adenine diet and the PHD2 ASO (12 mpk/wk) for 12 weeks, we observed significant increases in kidney EPO mRNA (~35-fold) and plasma EPO levels (~12-fold) compared to the control ASO group. Histological analysis showed improved fibrosis based on reduced Sirius Red staining. There were also improvements in anemia based on whole blood analysis of hemoglobin and hematocrit levels.

Conclusions: These data indicate that reducing PHD2 with ASOs may be a viable option for treating CKD patients with severe anemia and renal fibrosis.

Fibronectin Assembly Mediates KIM-1 Induced TGFβ-Dependent Kidney Fibrosis Venkata Sabbisetti, Cuiyan Xin, Sandhya Padmanabhan, Bhargavi Chandrasekar, Akinwande A. Akinfolarin, Joseph V. Bonventre. *Dept of Medicine, Renal Div, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Background: Cell-extracellular matrix interactions play a crucial role in kidney fibrosis. Localized activation of TGFβ is critical for exertion of its cellular effects. Kidney Injury Molecule-1 (KIM-1) is upregulated in dedifferentiated proximal tubular cells (PTECs) following kidney injury and has been shown to induce kidney fibrosis *in vivo*. Here, we report that KIM-1 mediates fibrosis by up-regulating the critical components of the TGFb activation machinery including fibronectin and corresponding integrin receptors. In vivo, blocking fibronectin assembly reduces kidney fibrosis.

Methods: Full-length KIM-1 or the KIM-1 mutant was overexpressed in LLC-PK1 and HEK cell lines and fibronectin and integrin levels were evaluated. Active TGFbwas measured using a bioassay. Mice were subjected to ischemia/reperfusion injury (IRI) or

unilateral ureteral obstruction (UUO). In the UUO model, mice were treated with fibronectin blocking peptide or control peptide to evaluate the effects of inhibition of fibronectin assembly on fibrosis.

Results: KIM-1 expressing PTECs produced significantly increased levels of fibronectin and fibronectin receptors. These increases were abrogated when phosphotyrosine-350 of KIM-1 was mutated or KIM-1 was deleted. KIM-1 expressing cells displayed higher levels of total and activated TGFβ as compared to control cells. In vivo, KIM-1 expressing tubular epithelial cells were characterized by high fibronectin staining after ischemia/reperfusion injury or UUO. Blocking fibronectin assembly with a blocking peptide decreased fibrosis in the UUO model.

Conclusions: KIM-1 induced localized activation of TGFbthrough up-regulation of TGFβ, fibronectin and integrin receptors. Blocking fibronectin assembly reduced fibrosis in response to UUO in vivo. This mechanism can contribute to the fibrosis associated with chronic expression of KIM-1 and may be a common feature of chronic kidney disease. Blocking fibronectin assembly may be therapeutically beneficial to prevent or reduce kidney fibrosis.

Complement Modulation by C1-Inhibitor Hampered Pericyte (PC) to Myofibroblast Trans-Differentiation (TDF) and Vascular Rarefaction in Ischemia/Reperfusion (I/R) Injury

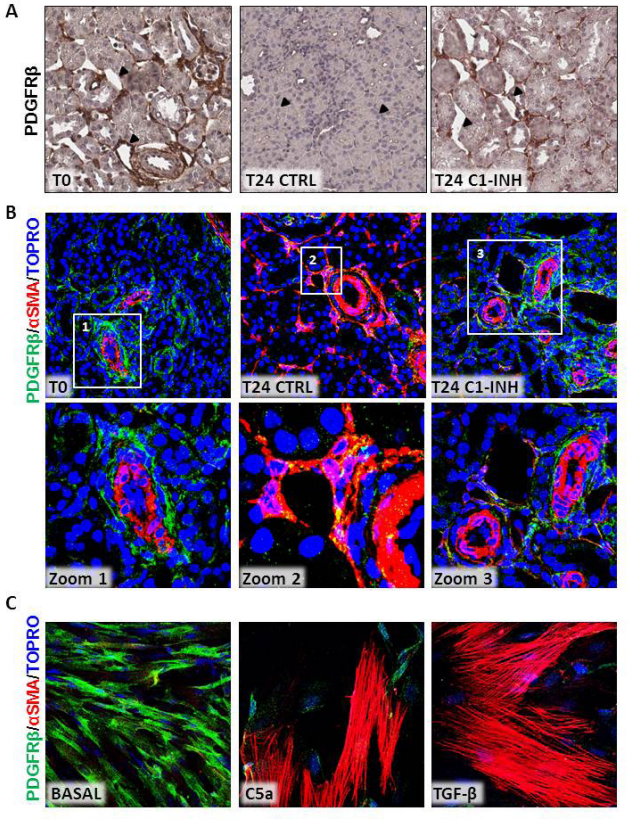
Giuseppe Castellano,[1] Rossana Franzin,[1] Chiara Divella,[1] Alessandra Stasi,[1] Angelica Intini,[1] Margherita Gigante,[1] Marco Fiorentino,[1] G. Lucarelli,[1] M. Battaglia,[1] Giuseppe Grandaliano,[2] Loreto Gesualdo.[1] *[1]Nephrology and Urology Unit, Univ of Bari; [2]Dept Medical and Surgical Science, Univ of Foggia, Italy.*

Background: Preservation of endothelium-Pericyte (PC) interaction is critical to counteract renal fibrosis during chronic kidney disease; no data are available on PC involvement in AKI. We investigated whether Complement might modulate PC activation in I/R.

Methods: Ten pigs underwent to 30 min of renal warm I, followed by 24h of R. Five pigs were treated with C1-Inhibitor (C1-Inh, 500U/Kg). Biopsies were analyzed by IHC and IF for PDGFRβ, Caspase3 and aSMA. FACS, AnnV-IP and IF were performed on human PC (PDGFRβ$^+$ cells) stimulated with C5a (1x10^{-7}M) for 24h in vitro.

Results: I/R injury induced PC to myofibroblasts TDF by reducing PDGFRβ without PC apoptosis (PDGFRβ$^+$/Caspase3$^-$) *in vivo*. TDF was accompanied by a significant decrease in capillary lumen area (**Fig1A** %T0:11.3±2.1;T24:3.9±2.3; p<0.05) and aSMA up regulation (**Fig1B**). C1-Inh preserved PDGFRβ expression in PC and restored peritubular capillary area (T24C1-Inh: 12.06±3.5 vs T24). In accordance, C5a induced PC proliferation and Collagen I production without apoptosis (Ann V-) *in vitro*. C5a induced PC to myofibroblasts TDF, with PDGFRβ down-regulation (**Fig1C**. %Bas: 15.2±3.6; C5a:3.6±2.3; TGFβ:2.08±1.04,p<0.05) and remodeling of aSMA-stress fibers, with contractile phenotype. Finally, C5a significantly up-regulated Id2 factor in PC, which is pivotal for cellular de-differentiation.

Fig.1



Conclusions: Complement might contribute to PC to Myofibroblasts TDF in I/R injury, leading to vascular rarefaction and renal fibrosis. C1-Inh may be an effective strategy to prevent fibrosis development in transplanted kidney.

SA-PO463

Establishment of a Novel Mouse Strain to Trace Erythropoietin Producing Cells at Desired Time Points

Keiichi Kaneko, Motoko Yanagita. *Nephrology, Kyoto Univ, Kyoto, Japan.*

Background: We previously reported that resident fibroblasts including Erythropoietin (Epo)-producing cells were lineage-labeled with myelin protein zero-Cre mouse strain and transdifferentiated into myofibroblasts during fibrosis with concomitant loss of Epo production. However, the previous method could not distinguish between Epo-producing cells and other resident fibroblasts and the behavior of Epo-producing cells remains unclear. Recently, Epo-Cre mice were generated which enabled the lineage tracing of the cells with the history of Epo production. Using the mouse strain, the transdifferentiation of Epo-Cre labeled cells into myofibroblasts during fibrosis has been demonstrated. Because Epo-Cre mice labeled the cells with the history of Epo production from fetal period to adult life, we tried to narrow down the period of labeling and to trace the certain cell population with the current Epo-producing ability at desired time points.

Methods: We generated a novel mouse strain in which inducible form of Cre is knocked-in at the locus of Epo gene (Epo-Cre^{ERT2} mice). Epo-Cre^{ERT2} mice were crossed with R26tdTomato mice. Tamoxifen was administered to activate inducible form of Cre, Cre^{ERT2}.

Results: Epo-Cre^{ERT2} labeled cells were located in the interstitium of the cortical and corticomedullary region of the kidney, and the numbers were increased with the induction of anemia. Epo-Cre^{ERT2} labeled cells expressed PDGFRβ and CD73, suggesting that Epo-Cre^{ERT2} labeled cells are resident fibroblasts and are likely to be Epo-producing cells. After unilateral ureteral obstruction (UUO), Epo-Cre^{ERT2} labeled cells transdifferentiated into myofibroblasts. The ratio of Epo-Cre^{ERT2} labeled cells transdifferentiated into myofibroblasts was 68 % at day 3 and 86 % at day 5 of UUO. The numbers of Epo-Cre^{ERT2} labeled cells were increased 1.9-fold at day 3 and 2.1-fold at day 5 of UUO.

Conclusions: We generated a novel mouse strain and succeeded in labeling Epo-producing cells at desired time points. We demonstrated that Epo-producing cells transdifferentiated into myofibroblasts and were increased in fibrotic kidney. We aim to elucidate the mechanism of injury and repair of Epo-producing cells with this strain, Epo-Cre^{ERT2} mice.

SA-PO464

Role of PI3 Kinase γ in Recruitment of Bone Marrow-Derived Fibroblasts and Development of Renal Fibrosis

Yuanbo Wu, Hua Liang, William E. Mitch, Yanlin Wang. *Medicine, Baylor College of Medicine, Houston, TX.*

Background: Renal fibrosis is a prominent pathological feature of chronic kidney disease leading to progressive loss of renal function. Although activated fibroblasts are responsible for the production and deposition of the extracellular matrix, the origin of activated fibroblasts mediating renal fibrosis remains debatable. Recent studies have shown bone marrow-derived fibroblasts contributed significantly to the pathogenesis of renal fibrosis. We have previously shown that CXCL16 plays a critical role in recruiting bone marrow-derived fibroblasts into kidney. However, the signaling mechanisms are not known. In the present study, we examined the role of PI3 kinase γ (PI3Kγ) in the recruitment of bone marrow-derived fibroblasts and development of renal fibrosis.

Methods: We examined the role of PI3Kγ in the recruitment of bone marrow-derived fibroblasts and the development of fibrosis using a mouse model of folic acid-induced nephropathy in wild-type (WT) and PI3Kγ-knockout (KO) mice in vivo and migration of cultured mouse monocyte treated with CXCL16 in vitro.

Results: Compared with WT mice, PI3Kγ-KO mice exhibited significant preservation of kidney function as measured by serum urea nitrogen and displayed significantly fewer bone marrow-derived fibroblasts dual positive for CD45 and PDGFR-β in the kidney 2 weeks after folic acid treatment. Furthermore, PI3Kγ-KO mice exhibited fewer α-smooth muscle actin (α-SMA) positive myofibroblasts and expressed less α-SMA protein in the kidney following folic acid treatment. Consistent with these findings, PI3Kγ deficiency significantly reduced total collagen deposition and suppressed expression of extracellular matrix proteins (collagen I and fibronectin). In cultured mouse monocytes, CXCL16 activated PI3Kγ and induced transwell migration, which was abolished in the absence of PI3Kγ.

Conclusions: These data indicate that PI3Kγ plays a pivotal role in recruiting bone marrow-derived fibroblasts into the kidney and developing renal fibrosis. Inhibition of PI3Kγ signaling may represent a novel therapeutic strategy for chronic kidney disease.

Inhibition of K-Ras prior to Induction of Acute Kidney Reduces Long-Term Progression to Chronic Kidney Disease in a Murine Model of Aristolochic Acid Nephropathy

Sujit Kumar Saha, Bruce M. Hendry, Claire C. Sharpe. *Dept of Renal Sciences, King's College London, London, United Kingdom.*

Background: Acute kidney injury (AKI) is recognised to be an early harbinger of chronic kidney disease (CKD). We have previously shown that K-Ras expression and activation are up-regulated in renal fibrosis and reducing K-Ras expression can prevent scarring. In this study our aim was to test whether transiently reducing K-Ras expression in the peri-AKI period can reduce progression to CKD.

Methods: CD1 mice received i.p. injections of either 3.5mg/kg Aristolochic Acid (AA) or normal saline on Day 1 and on Day 5. A treatment group were also given a single

subcutaneous injection of 100mg/kg of mouse K-Ras antisense oligonucleotide (ASO) 2 days prior to the first AA injection. A vehicle group was given a subcutaneous injection of saline 2 days prior to the first AA injection. Renal function at multiple time points was assessed through a blood urea nitrogen (BUN) assay. The degree of fibrosis was ascertained through Picrosirius Red (PSR) and Masson Trichrome (MT) staining to quantify collagen deposition. The expression of K-Ras was determined by Q-PCR.

Results: CD1 mice given AA suffered an AKI with a 4.6 fold rise in BUN at Day 12 that returned to baseline by Day 30. However by Day 80, the AA mice had a 57% higher BUN than control mice, demonstrating later onset CKD. AA mice treated with mouse K-Ras ASO pre-AKI suffered a similar AKI but BUN at Day 80 was 48% lower than untreated AA mice and was comparable with healthy controls. PSR and MT staining demonstrated a 5 fold increase in collagen deposition by Day 80 in AA mice which was reduced by 30% in ASO-treated animals. K-Ras expression was consistently unregulated in the untreated AA mice throughout the chronic phase but the transient treatment with ASO prior to the acute injury resulted in normalisation of K-Ras mRNA by Day 80.

Conclusions: Transiently reducing K-Ras expression in the peri-AKI period in a murine model of aristolochic acid nephropathy reduces downstream fibrosis and prevents the decline in renal excretory function. Targeting K-Ras may provide a future therapeutic option for preventing renal fibrosis and CKD following AKI.

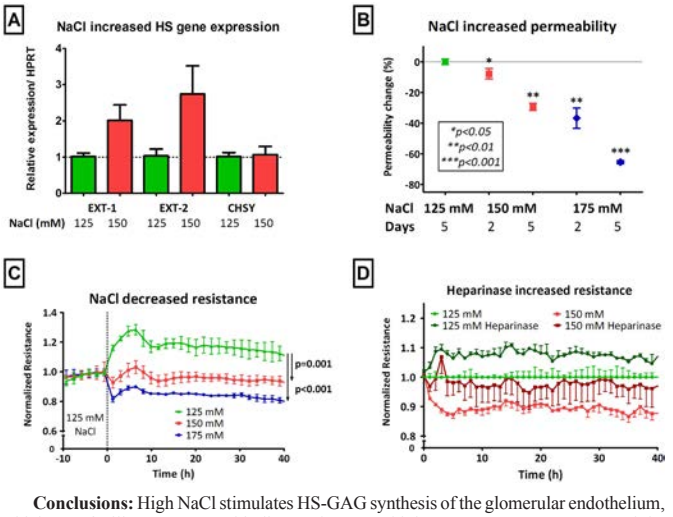
SA-PO466

Non-Osmotic Sodium Storage Affects Glomerular Endothelial Cell Permeability Rik Hg Olde Engberink,[1] Peter Ochodnicky,[2] Simon C. Satchell,[3] Ed van Bavel,[4] Liffert Vogt.[1] *[1]Nephrology, AMC, Amsterdam, Netherlands; [2]Pathology, AMC, Amsterdam, Netherlands; [3]Renal Unit, Univ of Bristol, Bristol, United Kingdom; [4]Biomedical Engineering and Physics, AMC, Amsterdam, Netherlands.*

Background: High dietary NaCl intake may affect glomerular permeability via pressure effects or via direct effects. In this respect, the Na^+ buffering capacity of heparan sulfate glycosaminoglycans (HS-GAGs) in the endothelial surface layer (ESL) is of interest. The objective of this study is to investigate the interplay between Na^+ and HS-GAGs and their effects on glomerular permeability.

Methods: Human glomerular endothelial cell (GEnCi) permeability to macromolecules was tested by measuring FITC-labeled albumin passage. Electrical resistance of a GEnCi monolayer, reflecting ESL Na^+ content, was assessed with the ECIS® system at 4000 Hz. We studied the expression of gene coding enzymes involved in heparan sulfate (EXT-1, EXT-2) and chondroitin sulfate (CHSY) synthesis using real-time qPCR. Measurements were performed at different NaCl concentrations (125/150/175 mM ± HS degradation enzyme heparinise, 0.7 U/mL). We added mannitol to keep osmolality constant.

Results: Relative to 125 mM, EXT-1 and EXT-2 expression was higher after stimulation with 150 mM NaCl while CHSY expression remained unchanged (Fig A). Albumin permeability decreased after 2 and 5-d stimulation with 150 and 175 mM NaCl (Fig B). ECIS experiments showed that NaCl addition led to a concentration-dependent decrease in resistance (Fig C). NaCl did not alter resistance in the absence of cells. Heparinase increased resistance when added to 125 and 150 mM NaCl (Fig D). Mannitol did not alter permeability or resistance.



Conclusions: High NaCl stimulates HS-GAG synthesis of the glomerular endothelium, which may facilitate more Na^+ binding. Subsequent higher ESL Na^+ content may seal the glomerular barrier as suggested by both lower permeability and lower resistance.

SA-PO467

Precision-Cut Human Kidney Slices as a Model to Elucidate the Pathogenesis of Renal Fibrosis Elisabeth G.D. Stribos,[1,2] Theerut Luangmonkong,[2] Annemarie Leliveld,[4] Igle J. de Jong,[4] Willem Van Son,[1] Jan-luuk Hillebrands,[3] Marc Maj Seelen,[1] Harry Van Goor,[3] Peter Olinga,[2] Henricus A.M. Mutsaers.[2] *[1]Dept of Internal Medicine, Div of Nephrology, Univ of Groningen, Univ Medical Center Groningen, Netherlands; [2]Dept of Pharmaceutical Technology and Biopharmacy, Univ of Groningen, Netherlands; [3]Dept of Pathology and Medical Biology, Div of Pathology, Univ of Groningen, Univ Medical Center Groningen, Netherlands; [4]Dept of Urology, Univ of Groningen, Univ Medical Center Groningen, Netherlands.*

Background: Renal fibrosis is a major problem in chronic kidney disease and chronic renal transplant failure. Unraveling the mechanisms underlying the initiation and progression of renal fibrosis is of key importance to identify new therapeutic targets. However, suitable human *ex vivo* models for renal fibrosis are lacking. Here, we explored precision-cut human kidney slices (PCKS) as a model for human renal disease.

Methods: PCKS were prepared from human cortical kidney tissue obtained from tumor-nephrectomies and cultured up to 96h. Morphology, cell viability (ATP levels, LDH leakage) and metabolic functionality (UDP-glucuronosyltransferase and transporter activity) were determined to assess PCKS integrity. Furthermore, inflammation- and fibrosis-related gene expression was characterized. To validate the model, renal fibrogenesis was induced using transforming-growth factor b1 (TGF-b1).

Results: Preparation of PCKS induced an inflammatory tissue response, while long-term incubation (96h) induced fibrogenesis as seen by increased expression of collagen type 1a1 (COL1A1) and fibronectin (FN1). Importantly, PCKS remained functional for more than 48h as evidenced by active glucuronidation and phenolsulfonphthalein uptake. Moreover, treatment with TGF-b1 augmented fibrosis, as illustrated by at least 1.8-fold increase of multiple fibrosis markers including COL1A1, FN1, plasminogen activator inhibitor-1 and α-smooth muscle actin.

Conclusions: After extensive characterization, PCKS appear to be an excellent model to investigate renal pathology *e.g.* renal fibrosis. Moreover, the human origin of PCKS makes this *ex vivo* model very suitable for translational research.

SA-PO468

Centrality of Bone Marrow-Derived Fibroblasts in Magnetic Resonance Imaging Contrast-Induced Systemic Fibrosis Viktor Drel,[2] Catherine Do,[2] Chunyan Tan,[2] Brent Wagner.[1,2] *[1]South Texas Veterans Health Care System, San Antonio, TX; [2]Dept of Medicine, Univ of Texas Health Science Center at San Antonio, San Antonio, TX.*

Background: So–called "nephrogenic" systemic fibrosis is a ghastly sclerotic condition that occurs only in conditions of low renal function (acute kidney injury or severe chronic kidney disease) and gadolinium–based contrast exposure. Nothing is known about the pathobiology.

Methods: Experiments were designed to test if bone marrow from magnetic resonance imaging contrast–treated donors is stimulated to induce fibrosis, and to what degree these cells can be primed to home to affected organs. Male Fisher 344 rats that express human placental alkaline phosphatase (hPAP) were divided into two groups; one served as control, the other treated with pharmaceutical–grade gadodiamide (Omniscan, General Electric) 2.5 mol/kg IP daily, aiming for 20 doses over 4 weeks or evidence of systemic fibrosis. Rats with 5/6 nephrectomies were lethally–irradiated (900 Rad) followed by salvage bone marrow transplant from the control or contrast–treated donors. After an engraftment period, these recipients were divided into control and contrast–treated groups.

Results: Regardless of bone marrow source, contrast–treated recipients demonstrated severe skin fibrosis. Fibronectin was similarly increased by immunofluorescence and immunoblot, but a synergistic effect evident in recipients of contrast–treated animals. The fibroblast precursor ("fibrocyte") markers, CD45RO and procollagen I, were increased in the contrast–treated recipients. Recipients of marrow from contrast–treated donors demonstrated greater dermal CD34 without histologic evidence of fibrosis.

Conclusions: Bone marrow from contrast–treated animals did not induce systemic fibrosis, therefore target organs (such as the skin) appear central to the process. However, given the synergistic effect, "primed" fibroblast precursors do have an increased affinity for diseased lesions. Clinically, this may explain why repeat administrations of gadolinium–based contrast correlate with chronicity.

SOCS2 Plays No Major Role in the Mouse Remnant Kidney Model of Fibrosis Yael Segev,[1] Muhamed Assadi,[1] Ralph Rabkin,[2,3] Daniel Landau.[1,4] *[1]Microbiology and Immunology, Ben Gurion Univ, Beer Sheva, Israel; [2]Research Inst, Veterans Administration Hospital, Palo Alto, CA; [3]Medicine, Stanford Univ, CA; [4]Pediatrics B, Schneider Children's Medical Center, Petach Tikva, Israel.*

Background: SOCS2, a key negative regulator of GH stimulated JAK/STAT5 signaling, is overexpressed in muscle, bone and liver of uremic rats and is presumably a cause of uremic GH resistance and growth retardation. SOCS2 deficient mice are GH sensitive, exhibit gigantism and accumulate collagen in skin, trachea and lungs (Reiser K et al, AJP 2004). Since GH overexpression in mice causes renal fibrosis, we tested whether SOCS2 deletion, by increasing GH sensitivity, accelerates remnant kidney fibrosis.

Methods: Four-week old SOCS2 deficient mice (high growth - HG strain) and normal wild-type mice (N) underwent 5/6 nephrectomy (CRF) or sham operation (SO), forming 4groups: SO-N, SO-HG, CRF-N, CRF-HG. Mice were sacrificed after 3 weeks. IP bovine GH was given 30 min before sacrifice.

Results: Weight gain was reduced significantly in CRF-N versus SO-N. In contrast, growth of CRF-HG increased significantly versus both CRF-N and SO-N. Kidney SOCS2 mRNA, absent in HG mice, was significantly increased in CRF-N Vs SO-N. The degree of renal insufficiency was similar in CRF-N and CRF-HG mice. TGF-β and type IV collagen mRNA levels were increased to the same extent in SO-HG, CRF-HG and CRF-N Vs SO-N. Renal GH receptor mRNA levels were decreased in both CRF groups. GH stimulated STAT5 phosphorylation increased in SO-HG Vs SO-N, decreased in CRF-N Vs SO-N and increased in CRF-HG Vs CRF-N. IL6, SOCS3 mRNA and phospho-STAT3 levels increased similarly in both CRF groups Vs SO controls.

Conclusions: GH induced STAT5 signaling is depressed in remnant kidneys of CRF-N mice but is increased in non-uremic and uremic SOCS2 deficient mutants. Levels of fibrosis-related genes rose similarly in CRF-HG and CRF-N, despite absence of SOCS2 expression in CRF-HG mice. This suggests that SOCS2 does not play a central role in remnant kidney fibrosis. On the other hand, IL6 and its mediators phospho-STAT3 and SOCS3, were elevated in CRF-HG and CRF-N mice suggesting that inflammation may play a role in remnant kidney fibrosis.

β-arrestin2, Downstream of Angiotensin II Type 1 Receptor Biased Signaling Pathway, Plays an Important Role in Renal Fibrosis Yan-Dao Wang, Chen Yu. *Dept of Nephrology, Tongji Hospital, Tongji Univ, Shanghai, China.*

Background: Expect G protein signaling pathway, it is now considered that there is also a β-arrestin pathway in the downstream of G protein-coupled receptors (GPCRs); angiotensin II type 1 receptor (AT1R) belongs to GPCRs and angiotensin II (AngII) is a bi-stimulus to both G protein pathway and β-arrestin pathway;it is important to known which downstream pathway involving in AngII-AT1R-induced renal fibrosis. In this study, we used β-arrestin biased agonist SII ([1-sar, 4, 8-ile]-angiotensin II) to study β-arrestin pathway in renal fibrosis.

Methods: The model of unilateral ureteral obstruction (UUO) was used *in vivo*, and rat kidney fibroblast cell line (NRK-49F) was treated with SII *in vitro*.

Results: 1) SII induced the binding of β-arrestin2 with AT1R, not β-arrestin1. 2) SII increased the synthesis of collagen I and fibronectin in NRK-49F. Transfection of β-arrestin2 siRNA abolished the effect of SII on the accumulation of ECM. Overexpression of β-arrestin2 increased SII-induced ECM synthesis. 3) Candesartan pretreatment abolished collagen I and fibronectin up-regulation induced by SII in NRK-49F. 4) These effects were blocked in the presence of ERK1/2 blocker (PD98059). Transfection of siRNA targeting β-arrestin2 inhibited SII-induced ERK phosphorylation. Overexpression of β-arrestin2 enhanced SII-induced ERK1/2 phosphorylation. 5) The mRNA and protein levels of β-arrestin2 were significantly upregulated in the UUO model.

Conclusions: Our results suggested that AT1R downstream β-arrestin2 pathway, not β-arrestin1, might play a key role in renal fibrosis by forming complexes of β-arrestin2 and AT1R, inducing ERK1/2 phosphorylation and increasing ECM accumulation.

Deletion of ATR, a Master Molecule of DNA Damage Response, in the Proximal Tubule Exacerbates Kidney Injury and Increases Fibrosis Seiji Kishi,[1,2] Takaharu Ichimura,[1,2] Ryuji Morizane,[1,2] Joseph V. Bonventre.[1,2,3] *[1]Renal Div, Dept of Medicine, Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Harvard Stem Cell Inst, Cambridge, MA.*

Background: Impaired response of cells to DNA damage can cause cellular senescence. We have previously implicated the DNA damage response of renal proximal tubule cell (RPTC) in progressive kidney injury and fibrosis. The purpose of this study was to investigate the role of Ataxia telangiectasia and Rad3-related (ATR), a master molecule of the DNA damage checkpoint, in kidney injury and fibrosis.

Methods: RPTC-specific conditional ATR knockout ($ATR^{RPTC-/-}$) mice were generated by crossing ATR floxed ($ATR^{fl/fl}$) mice , $ATR^{+/-}$ mice and tamoxifen-inducible ($SLC34a1\text{-}CreER^{T2}$) mice. We evaluated the role of ATR in susceptibility to cisplatin nephrotoxicity, unilateral ureteral obstruction (UUO) and renal ischemia/reperfusion injury (IRI).

Results: Four days after cisplatin injection, $ATR^{RPTC-/-}$ mice had increased kidney histological damage, increased Kidney Injury Molecule-1 (KIM-1) expression and decreased renal function compared with wild-type mice. Within the first 5 days, 34% of $ATR^{RPTC-/-}$ mice died, while no WT mice died. Increased DNA damage and the number of apoptotic cells were also found in $ATR^{RPTC-/-}$ mice. At 7 days after UUO, when compared with wild-type mice, $ATR^{RPTC-/-}$ mice exhibited increased kidney histological damage, KIM-1 expression, DNA damage markers, and number of apoptotic cells. ATR deletion resulted in increased expression of fibrosis-related genes and increased kidney fibrosis. After IRI there was worse kidney function on day 3 and day 7 in $ATR^{RPTC-/-}$ mice and increased interstitial fibrosis 4 weeks after IRI. Expression of p21, a marker of senescence, was significantly increased in $ATR^{RPTC-/-}$ mice in each of the three models of injury.

Conclusions: ATR activation in the RPTC represents a protective response in acute and chronic kidney disease of various etiologies.

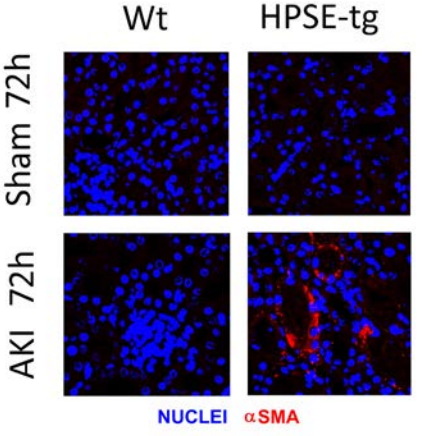
Role of Heparanase in Renal Epithelial-Mesenchymal Transition Induced by Ischemia/Reperfusion Valentina Masola,[1] Gianluigi Zaza,[1] Giovanni Gambaro,[2] Maurizio Onisto,[3] Gloria Bellin,[1] Gisella Vischini,[2] Iyad Khamaysi,[4] Antonio Lupo,[1] Israel Vlodavsky,[5] Zaid Abassi.[5] *[1]Renal Unit, Dept of Medicine, Verona, Italy; [2]Columbus-Gemelli Hospital Catholic Univ, Roma, Italy; [3]Univ of Padova, Padova, Italy; [4]Rambam Medical Center, Israel; [5]Technion, Israel.*

Background: Ischemia/reperfusion (I/R) activates epithelial-mesenchymal transition (EMT) of tubular cells, thus leading to organ fibrosis. Heparanase (HPSE) controls the EMT induced by FGF2 and TGFb. The aim of this study was to evaluate whether HPSE modulates the EMT induced by I/R.

Methods: Tubular cells (HK-2) wt and stably silenced for HPSE were subjected to 24h of hypoxia and 6h of reoxygenation. The cells were also treated with SST0001 (Sigma-Tau Research Switzerland SA), an inhibitor of HPSE. The I/R injury has been reproduced in vivo by clamping the renal arteries for 30 min in transgenic mice over-expressing HPSE (HPSE-tg) and their wt mice. Mice were sacrificed after 48 and 72 h. Gene and protein immunoreactivity of EMT markers (α-SMA, VIM, FN and TGF-β) were evaluated by real-time PCR, WB and IF; histology was assessed by PAS staining.

Results: In vitro; I/R increased the expression of EMT-markers in wt tubular cells but not in HPSE-silenced cells. Similarly, the inhibition of HPSE with SST0001 (Sigma-Tau Research Switzerland SA) in wt cells prevented the development of I/R induced EMT. In-vivo; I/R induced acute tubular necrosis, which was more profound in HPSE-tg than their wt animals. In wt mice I/R-injury increased glomerular and tubular HPSE expression, but did not induce the EMT-markers. In contrast, I/R in HPSE-tg mice remarkably induced the expression of EMT-markers already after 72h.



Conclusions: HPSE is as a crucial factor for the development of EMT induced by I/R. HPSE inhibition may therefore constitute a possible therapeutic approach for the prevention of fibrosis in organ transplantation.

Hydrogen Sulfide Deficiency in the Kidney and Brain in Aging Mice Hak Joo Lee,[1,2] Kavitha lakshmi Satara natarajan,[4] Meenalakshmi M. Mariappan,[1] Denis Feliers,[1] Jeffrey L. Barnes,[1,2] Goutam Ghosh-Choudhury,[1,2] Christopher G. Kevil,[3] Balakuntalam S. Kasinath.[1,2] *[1]Medicine, MC7882, Univ of Texas Health Science Center, San Antonio, TX; [2]Medicine, South Texas Veterans Health Care System, San Antonio, TX; [3]Pathology, Louisiana State Univ, Shreveport, LA; [4]Oklahoma Medical Research Foundation, Oklahoma City, OK.*

Background: Hydrogen sulfide (H2S) is constitutively synthesized by cystathionine γ lyase (CSE) and cystathionine β synthase (CBS). It regulates GFR and tubular transport in the kidney and NMDA receptors in the brain. H2S activates AMPK to inhibit mTORC1 and abrogate matrix protein increment in high glucose treated renal cells (Lee, JBC, 2012). Since mTORC1 is implicated in aging, we surveyed the status of H2S relative to mTORC1 in the organs of aging mice.

Methods: C57B6 mice, immunoblotting, H2S generation and content assays, histopathology, cell culture.

Results: The renal and cerebral CSE and CBS expression, H2S content and generation were reduced in old mice (26-32 mos old, n=6 mice) compared to young mice (4-6 mos old, n=8 mice); such changes were not seen in the heart or the skeletal muscle. Old mice showed increase in renal collagens I, III, fibronectin, parenchymal fibrosis, albuminuria, and rise in serum cystatin C. Signaling analysis showed that aging was associated with renal and cerebral activation of Akt, reduced phosphorylation of AMPK, and activation of mTORC1 manifest as increase in the phosphorylation of p70S6 kinase and 4E-BP1. Since insulin has been implicated in the aging process, we examined insulin regulation of CSE and CBS in renal proximal tubular epithelial (MCT) cells; insulin rapidly reduced CSE and CBS expression and decreased H2S generation. Insulin also promoted the synthesis of fibronectin matrix protein in MCT cells.

Conclusions: Our data show for the first time that the aging kidney and cerebrum share similar changes in H2S metabolism associated with reduced AMPK activity leading

to mTORC1 activation; these pathways could be related to age related changes including fibrosis. Insulin may mediate reduction in CBS, CSE and H2S and contribute to matrix accumulation in the aging kidney.

SA-PO474

The Role of Ergothioneine/OCTN1 in CKD Yasuyuki Shinozaki,[1] Kengo Furuichi,[1] Shinji Kitajima,[1] Akinori Hara,[1] Yasunori Iwata,[1] Norihiko Sakai,[1] Miho Shimizu,[1] Takashi Wada.[1,2] *[1]Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Ishikawa, Japan; [2]Dept of Laboratory Medicine, Kanazawa Univ, Kanazawa, Ishikawa, Japan.*

Background: Chronic kidney disease (CKD) is a strong risk factor for end stage kidney disease, and closely complicates with other organ damages. Organic cation transporter 1 (OCTN1) is known as a specific transporter for ergothioneine (ERGO). ERGO is reported to have a strong antioxidant effect. We hypothesized that OCTN1 function and the reduction of ERGO were closely related to the progression of CKD.

Methods: To evaluate the effects of OCTN1 function in CKD, everted sac method was used in CKD model or control mice. Furthermore, the pathological changes and oxidative stress in the kidney of $OCTN1^{-/-}$ or $OCTN1^{+/+}$ were evaluated in the CKD model mice. Moreover, the amount of ERGO in red blood cells of was measured in CKD patients.

Results: The uptake of ERGO in everted sac significantly decreased in CKD mice than control mice. Interstitial fibrosis, that evaluated by azan stain, sirius red stain, and the content of hydroxyproline of injured kidney, was significantly advanced in $OCTN1^{-/-}$ CKD mice. Moreover, oxidative stress, that assessed by the number of 4-HNE stain positive cell, was exaggerated in $OCTN1^{-/-}$ CKD mice (WT 26.4±9.7, KO 73.8±37.4/mm^2>, $p<0.05$). Correspondingly, the total antioxidant capacity decreased in $OCTN1^{-/-}$ CKD mice. The concentration of ERGO in red blood cells decreased accompanied with CKD stage (G3b:30.0±4.4mg/mL, G4:25.8±5.6mg/mL, G5:14.8±8.1mg/mL, ESKD:5.1±3.9mg/mL).

Conclusions: The uptake of ERGO through OCTN1 decreased in CKD. The reduction of ERGO in CKD may participate in oxidative stress and progression of kidney injury.

SA-PO475

SIRT2-MDM2 Signaling Attributes to Fibroblasts Activation but Not Tubular Epithelial-Mesenchymal Transition During Tubulointerstitial Fibrosis Chun Zhang, Renyu You, Hua Su. *Nephrology, Huazhong Univ of Science and Technology, Wuhan, Hubei, China.*

Background: Renal resident fibroblasts and tubular epithelial cells are the main sources for extracellular matrix producing myofibroblasts during tubulointerstitial fibrosis (TIF). Histone deacetylases (HDAC) inhibitors are shown to have an antifibrogenic effect in skin, liver and lung. Sirtuin 2 (SIRT2), belonging to class III HDAC, mediates p53 deacetylation and subsequently sensitizes the sequestration of p53 by MDM2, thereby resulting in a p53 reduction and cell cycle progression. Up to now it is unclear the role of SIRT2 and its association with MDM2 during renal fibrosis.

Methods: Unilateral Ureteral Obstruction (UUO) animal model was constructed on B57CL/6 mice. In vitro study cultured tubular epithelial cell line NRK-52E (TEC) and renal fibroblast cell line NRK-49F were employed. The expression of SIRT2 and MDM2 was regulated by its pharmacologic inhibitors or transfection of Lentiviral shRNA.

Results: It showed the protein level of SIRT2 was elevated markedly in UUO mice as well as the fibroblasts treated with TGF-b1. Nevertheless, in TECs the abundance of SIRT2 was not altered under TGF-b1 exposure. Additionally, AGK2, a specific SIRT2 inhibitor, attenuated the severity of TIF in UUO mice and the fibroblast activation triggered by TGF-b1. Next in fibroblast we found MDM2, a p53 inhibitor, was upregulated simultaneously under TGF-b1 stimulation. Interestingly, the increased MDM2 level can be minimized by pharmacologic or genetic blocking of SIRT2 which was not interfered by Nutlin-3 (an inhibitor of the interaction between MDM2 and p53). Thus, it indicated SIRT2 regulating MDM2 was p53 independent. Moreover, genetic deletion of MDM2 by shRNA transfection didn't affect the expression of SIRT2, although which could alleviate fibroblast activation.

Conclusions: Our current study suggests that besides p53, SIRT2 also could modulate MDM2 during fibroblasts activation, and targeting SIRT2-MDM2 signaling may be a potential strategy for the treatment of renal fibrosis.

The Role of $cPLA_2$ in Experimental Renal Fibrosis John Ross Montford, Allison M.B. Lehman, Raphael A. Nemenoff, Seth B. Furgeson. *Div of Renal Disease and Hypertension, UC Denver School of Medicine, Aurora, CO.*

Background: Chronic kidney disease (CKD) is characterized by progressive renal fibrosis involving poorly defined signaling events between renal epithelial cells, fibroblasts, and inflammatory cells. Cytosolic phospholipase A2 (cPLA2) is abundant in renal epithelium and inflammatory cells and serves as the rate-limiting enzyme in eicosanoid production. Since eicosanoids regulate many biological processes important in renal injury, we aimed to investigate the role of cPLA2 in the progression of renal fibrosis in a mouse model.

Methods: Wild type (WT) and cPLA2 globally deficient (KO) C57BL/6 mice were subjected to unilateral ureteral obstruction (UUO). In separate experiments WT mice were lethally irradiated and transplanted with either WT bone marrow or cPLA2-deficient bone marrow. We then performed UUO 5-6 weeks after bone marrow transplantation. After UUO, we collected uninjured and injured kidneys for RNA, protein, flow cytometry, and histologic analysis, and preparation of single cell suspensions for flow cytometry.

Results: Compared with WT, cPLA2 KO animals had a 1.5-2.0 fold increase in histologic fibrosis at 14 days after UUO. In addition, the KO animals had elevated levels of mRNA for matrix proteins such as collagen and fibronectin, pro-fibrotic chemokines such as fractalkine, and inflammatory markers such as MCP-1 after UUO as compared with WT animals at 7 days. By flow cytometry, cPLA2 KO animals had significantly more infiltration of CD45+, CD11b positive-Ly6C negative cells than WT animals after UUO. Additionally, adoptive bone marrow transplant from cPLA2 KO mice into WT mice yielded worsening of histologic fibrosis after UUO as compared with transplants derived from WT animals.

Conclusions: Depletion of cPLA2 and/or its products, predominantly from circulating myeloid cells, contribute to the development of experimental fibrosis using a UUO model in mice.

Delayed Administration of Suramin Attenuates Peritoneal Fibrosis in Rats Chongxiang Xiong,[1] Na Liu,[2] Shougang Zhuang.[1] *[1]Dept of Medicine, Rhode Island Hospital and Alpert Medical School, Providence, RI; [2]Dept of Nephrology, Shanghai East Hospital, Tongji Univ School of Medicine, Shanghai, China.*

Background: Peritoneal fibrosis is one of the most serious complications in patients with peritoneal dialysis (PD) and lacks effective treatments. Our recent study showed that treatment with suramin, a compound that inhibits the interaction of multiple cytokines and growth factors with their receptors, attenuated the development of peritoneal fibrosis in a model of peritoneal fibrosis induced by chlorhexidine gluconate (CG). In the current study, we further assessed the therapeutic effect of suramin on the progression of peritoneal fibrosis in this model.

Methods: Rats were given a daily intraperitoneal injection of chlorhexidine gluconate (CG) for 3 weeks to induce peritoneal fibrosis followed by weekly administration of suramin at 20 mg/kg for an additional one or two weeks before kidneys were harvested.

Results: Delayed administration of suramin attenuated peritoneal membrane thickening and collagen fibril deposition occurred after CG exposure. Suramin was also effective in reducing CG-induced expression of a-smooth muscle actin, fibronectin and collagen I. Injury to the peritoneal membrane resulted in increased phosphorylation of Smad-3, a prominent mediator in transforming growth factor –b signaling, and epidermal growth factor receptor (EGFR), a key tyrosine kinase receptor associated with peritoneal fibrosis; suramin treatment blocked their phosphorylation. Similarly, suramin reduced CG-induced phosphorylation of transducer and activator of transcription-3 (STAT3) and extracellular signal-regulated kinase 1 and 2 (ERK1/2), two molecules that mediate profibrotic signal transduction. Moreover, delayed application of suramin suppressed CG-induced expression of several inflammatory cytokines in fibrotic peritoneum.

Conclusions: Our results indicate that suramin treatment inhibits the progression of peritoneal fibrosis via a mechanism involved in suppression of TGF-b1 and EGFR signaling pathways, and suggest that suramin holds a therapeutic potential for treatment of peritoneal fibrosis.

SA-PO478

MDM2 Mediates Tubulointerstitial Fibrosis and Fibroblasts Activation via p53-Independent Pathway Hua Su, Chen Ye, Chun Zhang. *Nephrology, Huazhong Univ of Science and Technology, Wuhan, Hubei, China.*

Background: MDM2 is an E3 ubiquitin ligase which plays essential roles in podocytes and tubular epithelial cells injury or repair by regulating cell cycle and mediating inflammatory process. MDM2 exerts its pathophysiological effects via p53 dependent or independent pathway. However whether MDM2 is implicated in tubulointerstitial fibrosis (TIF) and fibroblasts activation is still unknown.

Methods: Patients with TIF (secondary glomerulonephritis and interstitial nephritis were excluded) were enrolled in this study and Unilateral Ureteral Obstruction (UUO) animal model was constructed on B57CL/6 mice. In vitro study cultured renal fibroblast cell line NRK-49F was employed. The expression of MDM2 and Notch1 was regulated by its pharmacologic inhibitors or transfection of Lentiviral shRNA. PYR-41 was used as an inhibitor of ubiquitin E1 activating enzyme.

Results: Here, we found the abundance of interstitial MDM2 was increased in patients with TIF as well as UUO mice. And interstitial MDM2 mainly originated from (myo) fibroblast. In vitro the expression of MDM2 was upregulated with fibroblasts activation under TGF-b1 stimulation, which was minimized by MDM2 knocking down but not by MDM2-p53 pathway inhibitor---Nutlin-3. Consistently, in UUO mice Nutlin-3 treatment cannot alleviate the interstitial fibrosis. Interestingly, we found Notch1, a molecule positively or negatively affecting the processes of proliferation, differentiation and apoptosis in a context-dependent manner, was reduced in cultured fibroblast treated with TGF-b1 which could be reversed by either genetic deletion of MDM2 or ubiquitin E1 activating enzyme inhibitor. Moreover, although pharmacologic or genetic blocking Notch1 signaling could trigger fibroblast activation it did not affect MDM2's abundance.

Conclusions: Our current study suggests that MDM2-Notch1 signaling pathway, not the classic MDM2-p53 pathway, is involved in fibroblast activation in an ubiquitination dependent manner during tubulointerstitial fibrosis.

Biomarkers of Collagen Type III and VI Turnover Can Predict Poor Recovery of Kidney Function in Kidney Transplant Recipients

Daniel Guldager Kring Rasmussen,[1,2] Signe Holm Nielsen,[1] Federica Genovese,[1] Morten Asser Karsdal,[1] Shengqiang Xia,[2] Martin Tepel.[2] *[1]Nordic Bioscience, Denmark; [2]Univ of Southern Denmark, Denmark.*

Background: Allograft dysfunction is a common complication after renal transplantation (Tx). The turnover of extracellular matrix proteins, collagen type III and type VI, contributes to renal repair mechanisms which accompany allograft dysfunction. Distorted turnover may lead to progressive fibrosis and to loss of renal function. The objective of our study was to evaluate the role of specific collagen type III and type VI cleavage fragments for early allograft dysfunction after kidney Tx.

Methods: 171 incident patients, receiving a kidney allograft were enrolled at Odense University Hospital. Plasma and urine samples were collected at the first postoperative days. C3M and Pro-C6 were measured in samples using novel ELISAs. Early allograft dysfunction was defined as eGFR less than 30 mL per minute per 1.72m² 29 days after Tx. The relative change of plasma creatinine (RCPC) is the difference between plasma creatinine (pCrea) on the preoperative and first postoperative day divided by preoperative pCrea. Follow-up data on pCrea from a subset of patients was available at 6- and 12 months.

Results: Plasma Pro-C6 (pPro-C6) levels were significantly different in patients who received a deceased donor (DD), living donor (LD) and AB0 incompatible (AB0) donor kidney ($p<0.001$). pPro-C6 had a negative correlation with eGFR 29 days post-Tx ($p<0.0001$, $r=-0.35$) and a positive correlation with pCrea at 6- ($p=0.0001$, $r=0.31$) and 12 months ($p=0.0001$, $r=0.32$). With a cut-off of 0.3 for the RCPC, ROC curves showed that plasma Pro-C6 predicted allograft dysfunction ($p<0.0001$, AUC=0.898). uC3M levels were not significantly different in patients receiving a DD, LD and AB0 donor kidney. uC3M levels showed a negative correlation with plasma creatinine at 6- ($p<0.0001$, $r=-0.37$) and 12 months post-Tx ($p<0.0001$, $r=-0.35$). Plasma C3M was associated with plasma CRP ($p<0.0001$, $r=0.62$).

Conclusions: The study indicates that specific collagen type III and type VI cleavage fragments, i.e. C3M and Pro-C6, are both markers for early and late allograft dysfunction after kidney Tx, and reflect the underlying pathophysiology.

SA-PO480

Inhibitory Effect of Proximal Tubular Cells-Derived Neuropilin-1 in TGF Beta Signaling Pathway

Rui Cheng, Xuemin He, Symon Ma, Jian-xing Ma. *Physiology, Univ of Oklahoma Health Sciences Center, Oklahoma CIty, OK.*

Background: Neuropilin-1 (NRP-1)is a co-receptor protein for multiple growth factors including class 3 smaphorins, VEGF, PDGF and TGF-β, and promotes signaling pathway involved in tumor growth, axonal chemorepellents, angiogenesis and liver fibrosis. In contrast, its function in the renal fibrosis has not been defined.

Methods: Primary renal proximal tubular cells (MRPTC) were cultured from *Nrp-1*$^{flox/flox}$ mice. After infection of *Nrp-1*$^{flox/flox}$ cells with adenovirus expressing Cre resulted in NRP1 Knock-out (*Nrp-1*$^{-/-}$) in the primary cells. Human proximal tubular cell line HKC-8, MEF cells and 3T3-L1 cells were used in this study. TGF-β-driven promoter transcriptional activity was measured by luciferase assay.

Results: NRP-1 was down-regulated by TGF-β in HKC8 and up-regulated in MEF cells and 3T3-L1 cells, suggesting the different regulation mechanisms and functions of NRP-1 between proximal tubular cells and fibroblasts. Over-expression of NRP-1 suppressed TGF-β-induced phosphorylation of Smad2/3 and expression levels of fibronectin. HKC-8 cells over-expressing NRP-1 showed significantly decreased levels of both TGF-β receptor I and receptor II. The *Nrp-1*$^{-/-}$ cells showed higher TGF-β-induced Smad2/3 transcriptional activities and expression of fibronectin in *Nrp-1*$^{flox/flox}$ MRPTCs, compared with control adenovirus-infected *Nrp-1*$^{flox/flox}$ MRPTCs.

Conclusions: Proximal tubular cells-derived NRP1 inhibits the TGF beta signaling pathway. NRP1 functions are cell type-specific in the kidney.

The cAMP-epac Pathway Regulates Renal Fibrosis by Promoting Mitochondrial Biogenesis of Tubular Epithelial Cell

Lei Jiang, Junwei Yang. *Center for Kidney Disease, Second Affiliated Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: As a universal second messenger, cAMP inhibits the formation of extracellular matrix in tissue fibrosis. Mitochondrial dysfunction is an early event in real fibrosis, but how it leads to kidney fibrosis and how it is regulated is unclear. In this paper, we investigated the role of cAMP-epac pathway in mitochondrial biogenesis and renal fibrosis.

Methods: Animal models of renal fibrosis was induced by unilateral ureteral obstruction (UUO), chronic Ang II infusion and adriamycin administration. cAMP was given to CD1 mice under UUO by tail vein injection. Rolipram was injected intraperitoneally in CD-1 mice under UUO. A primary tubular epithelial cell (PTC) culture from normal CD-1 mice renal cortex was used. Rolipram, PKA activator, epac activator, PDE4b siRNA, epac siRNA were given to PTC respectively with TGF-b1 stimulation. ATP kit and NAD+/NADH kit were used to evaluate the mitochondrial function. Real-time PCR was used to detect mitochondrial DNA (mtDNA) expression. The morphology of mitochondria was observed by electron microscope.

Results: 1.The level of cAMP was decreased in the fibrotic kidney; 2.PDE4b were upregulated obviously in the kidney under UUO, and the epac not PKA were responsed to fibrosis; 3. Upregulation cAMP by giving PDE inhibitor (rolipram) or cAMP could ameliorate the renal fibrosis and protect mitochondrial structure; 4.Rolipram could stabilize PGC-1a expression and block the mitochondrial dysfunction induced by UUO; 5.TGF-b1 could induced the downregulation of cAMP in PTC. Increasing the level of cAMP in PTC by rolipram, PDE 4b siRNA, epac acitivator or epac siRNA could reduce the damage of PTC under TGF-b1 sitimulation; 6.Rolipram could restore PGC-1a expression, reduce the mtDNA damage and protect the mitochondrial function and structure of PTC under TGF-b1 stimulation.

Conclusions: cAMP-epac pathway is involved in renal fibrosis. Increased cAMP level blocks the progress of renal fibrosis. cAMP promotes mitochondrial biogenesis and restores mitochondrial structure and function of tubular epithelial cell.

Endothelial Cell Thymosin β4 Knock Down Ameliorates Kidney Fibrosis by Reducing Endothelial to Mesenchymal Transition (EndoMT)

Jianyong Zhong,[1,2] Haichun Yang,[1] Agnes B. Fogo.[1] *[1]Dept of Pathology, Microbiology and Immunology, Vanderbilt Univ; [2]Div of Pediatric Nephrology, Vanderbilt Univ, Nashville, TN.*

Background: Thymosin β4 (Tβ4) is a G-actin sequestering protein with effects on angiogenesis, cell migration and matrix. Our previous data showed that exogenous Tβ4 treatment ameliorated matrix accumulation at day 14 after unilateral ureteral obstruction (UUO). In this study, we investigated whether knockdown of Tb4 only on endothelial cells has effects on renal fibrosis.

Methods: We generated inducible endothelial cell Tβ4 knockdown mouse (Tβ4 KD) by mating Tb4 shRNA loxp mice with SCL Cre mice. SCL Cre negative mice were used as control (Cont). Tamoxifen was administrated to induce Tβ4 knockdown (×5, qod, from-8d). Mice were sacrificed at 14 days after UUO.

Results: Peritubular capillary density, assessed by CD31 staining, was significantly decreased in Tβ4 KD mice (Tβ4 KD 2.39±0.11 *vs.* Cont 3.20±0.08 %, $P<0.001$). Peritubular capillary permeability, measured by injecting Evans blue dye in vivo and assessing extravasated dye in the kidney, also was reduced in Tβ4 KD mice (Tβ4 KD 107.01±5.49 *vs.* Cont 161.85±16.32 mg/g KW, $P<0.05$). Tβ4 KD had significantly decreased collagen I, accessed by IHC, vs Cont (Tβ4 KD 15.24±0.57 *vs.* Cont 17.68±0.71 %, $P<0.05$), but no significant change in Sirius red positive area (Tβ4 KD 0.91±0.03 *vs.* Cont 1.14±0.15 %) or total collagen (Tβ4 KD 48.06±5.01 *vs.* Cont 53.50±2.34 mg/mg). Tβ4 KD had less EndoMT (α-SMA$^+$ and CD31$^+$ double positive cells/high power: Tβ4 KD 1.20±0.11 *vs.* Cont 1.74±0.17 $P<0.05$).

Conclusions: We conclude that endothelial cell thymosin β4 knockdown results in impaired peritubular capillary number and function, with reduced collagen I protein in UUO. We speculate that Tβ4 KD in endothelial cells may change endothelial function and modulate EndoMT.

Endostatin and Transglutaminase 2 Are Geronic Proteins Involved in Fibrosis of Aging Kidney

Chi Hua Sarah Lin,[1] Jun Chen,[1] Gail V.W. Johnson,[2] Arthur J.l. Cooper,[1] Zhongtao Zhang,[1] Julianne Feola,[2] Jonathan Shein,[1] Heli Ruotsalainen,[3] Taina Pihlajaniemi,[3] Michael S. Goligorsky.[1] *[1]New York Medical College; [2]Univ of Rochester; [3]Univ of Oulu, Finland.*

Background: Endostatin (EST), the C-terminal fragment of collagen XVIII and a potent anti-angiogenic factor, is highly enriched in aging kidneys. It has also been recently described as an interactive partner of another profibrogenic factor, transglutaminase 2 (TG2), an enzyme cross-linking extracellular matrix proteins. We inquire the possible direct or auxiliary role they may play in the development of renal tubulointerstitial fibrosis of aging.

Methods: Studies were conducted in young and aging wild type mice, mice overexpressing EST and mice kidney of subcapsular injection of TG2 or EST.

Results: In wild type mice, aging kidneys exhibited 2-4-fold increase in TG2 paralleled by the increased cross-linking of extracellular matrix proteins and striped fibrosis. Ex vivo aortic rings embedded in matrigel supplemented with TG2 showed suppressed angiogenesis and proteolytic degradation. Injection of TG2 in the intact kidney produces increased cross-linking within 48h. Transgenic miceoverexpressing EST showed renal interstitial fibrosis already at the young age, suggesting that EST may contributes to interstitial fibrosis in the aging kidney. Moreover, a month-long delivery of EST peptide via implanted minipumps to young mice also showed increased renal fibrosis, which became more robust when superimposed on the early "wound healing" phase of folic acid (FA)-induced nephropathy, a "second hit" model. Upregulation of TG2 and impaired renal function were also apparent in kidneys of mice with EST peptide delivery in combination with FA-induced nephropathy. Moreover, subcapsular injection of TG2 or EST increased the proportion of kidney-resident cells prematurely senescent.

Conclusions: These studies allow us to conclude that kidney fibrosis in aging may represent a natural outcome of deregulated EST and TG2, but more likely it appears to be a result of cumulative renal stresses occurring on the background of elevated geronic proteins, EST and TG2.

Angiopoietin-1 Deficiency Increases Tubulointerstitial Fibrosis Krishnapriya Loganathan,[1] Susan E. Quaggin,[2] Marie Jeansson.[1] *[1]Dept of Immunology, Genetics and Pathology, Uppsala Univ, Uppsala, Sweden; [2]Feinberg School of Medicine, Northwestern Univ, Chicago, IL.*

Background: Renal tubulointerstitial fibrosis is predictive of progressive decline in kidney function, independent of underlying disease. It is characterized by an increase in aSMA+ fibroblasts, myofibroblasts that produce collagen. Identification of factors that regulate the fibrotic response are excellent candidate targets for treatment of kidney diseases. We previously showed that loss of Angiopoietin-1 (Angpt1) in adult mice predisposes to fibrosis in wound healing and diabetic nephropathy. Angpt1 acts through the Tie2 tyrosine-kinase receptor expressed on endothelial cells and a subset of myeloid cells. Here, we test the hypothesis that loss of Angpt1-Tie2 signaling destabilizes endothelial cells and results in an increased fibrotic response.

Methods: To investigate the role of Angpt1 in renal fibrosis we utilized Angpt1 conditional knockout mice in experimental models of renal fibrosis, including unilateral ureter obstruction (UUO) and ischemia/reperfusion injury. Gene and protein regulation of fibrotic markers were investigated at different time points. We also performed lineage tagging experiments using Tie2-Cre and LysM-Cre to better understand the contribution of Tie2+ cells and macrophages to the myofibroblast population in UUO.

Results: Angpt1 deficient mice showed a significant ($p<0.01$) increase in fibrotic area 3days after UUO, 9.7±0.45%, compared to controls, 7.9±0.24%. At the same time point, there was a trend (n.s) towards an increased number of myofibroblasts per field from 15.4±1.8 in controls to 20.1±4.1 in Angpt1 deficient mice. Ischemia/reperfusion experiments are ongoing. In our lineage tagging experiment we found that 18.5±0.03% of myofibroblasts came from the Tie2-lineage whereas the LysM lineage contributed minimally, 2.4±0.005%.

Conclusions: Our results suggest that loss of Angpt1-Tie2 signaling increases tubulointerstitial fibrosis as seen by the increased expression of fibrosis markers in Angpt1 deficient mice. Ongoing work is designed to use other models of fibrosis and to elucidate the mechanism(s).

Inter-Alpha-Inhibitor Heavy Chain5 Interactions Control Fibroblast: Myofibroblast Differentiation John Martin, Timothy Bowen, Soma Meran, Aled O. Phillips, Robert Steadman. *Nephrology, Cardiff Univ, Cardiff, Wales, United Kingdom.*

Background: Fibroblasts are central to CKD through their Transforming Growth Factor-β1 (TGF-β1)-triggered phenotypic transition into contractile, α-smooth muscle actin (α-sma)-positive myofibroblasts. Transition is dependent on an increase in the synthesis and accumulation of a pericellular matrix of hyaluronan (HA) and the HA-dependent co-localisation of CD44 with EGFR. Interactions of HA with hyaladherins, such as inter-alpha-inhibitor (IαI) and the protein product of Tumour necrosis factor-stimulated gene 6 (TSG-6) aid the assembly of this matrix and are also essential for the phenotypic activation of fibroblasts. The mechanisms controlling this effect, however, are not known and are the subject of this study.

Methods: Fibroblasts were incubated for 72 h with 10ng/ml TGF-β1 to become myofibroblasts. RT-QPCR was used to assess mRNA, siRNA was used to knockdown mRNA expression, immunocytochemistry and SDSPAGE:Western Blotting assessed protein levels.

Results: Following TGF-β1 treatment, TSG-6 and α-sma, had different kinetics of induction. Using siCD44 or EGFR inhibitor AG1478 to interfere with the CD44/EGFR-dependent signal initiation prevented differentiation but had no effect on TSG6 expression. TSG-6, however, was essential for differentiation and using monoclonal antibody A38, HA-oligosaccharides, Cobalt, or siBikunin to interfere with the activity of TSG6, all prevented phenotypic change. These results suggested that it was the TSG6/IaI heavy chain (HC) interaction that was necessary for the effect. HC5 was shown to be the principal HC expressed in these cells. HC5 was released by hyaluronidase treatment of the fibroblast cell surface and siCD44, siTSG6 and siBikunin all inhibited the expression of HC5 protein. Finally, HC5 could be deleted on the cell by specific siRNA and this resulted in antagonism of phenotypic change, confirming its role in myofibroblast differentiation.

Conclusions: The mechanisms regulating TSG-6 and HA synthesis, during TGF-β1-dependent induction of myofibroblasts are distinct. TSG-6, however, contributes to the pro-fibrotic response through its catalytic transfer of IαI HC5 to HA leading to the subsequent induction of phenotypic change.

Role of IL-4 Receptor α in Bone Marrow-Derived Fibroblast Activation and Renal Fibrosis Hua Liang, Yuanbo Wu, Yanlin Wang. *Medicine, Baylor College of Medicine, Houston, TX.*

Background: Renal fibrosis is a common pathway leading to progression of chronic kidney diseases. We and others have shown that bone marrow-derived fibroblasts contribute significantly to the pathogenesis of renal fibrosis. However, the signaling mechanisms underlying the activation of bone marrow-derived fibroblasts in the kidney are incompletely understood. We have found that IL-4 and its receptor α (IL4Rα) are induced in the kidney during the development of renal fibrosis. However, little is known about the role of IL-4Rα in the activation of bone marrow-derived fibroblasts and the development of renal fibrosis.

Methods: We examined the role of IL-4Rα in the activation of bone marrow-derived fibroblasts and the development of renal fibrosis using a mouse model of folic acid-induced nephropathy and cultured bone marrow monocytes treated with IL-4.

Results: Compared with wild-type (WT) mice, IL4Rα-knockout (KO) mice exhibited significant preservation of kidney function as measured by serum urea nitrogen and accumulated significantly fewer bone marrow-derived fibroblasts dual positive for CD45 and PDGFR-β in the kidney 2 weeks after folic acid treatment. Furthermore, IL4Rα-KO mice exhibited fewer α-smooth muscle actin (α-SMA) positive myofibroblasts and expressed less α-SMA protein in the kidney following folic acid treatment. Consistent with these findings, IL4Rα deficiency significantly reduced total collagen deposition and suppressed expression of extracellular matrix proteins (collagen I and fibronectin). In cultured bone marrow monocytes, IL-4 activated STAT6 and induced expression of α-SMA and extracellular matrix proteins, which was abolished in the absence of IL4Rα.

Conclusions: Our results have demonstrated that IL4Rα plays an important role in the activation of bone marrow-derived fibroblasts and the development of renal fibrosis. These results indicate that IL4Rα signaling may represent a novel therapeutic target for chronic kidney disease.

Role of Scaffolding Protein JLP in Preventing Renal Fibrosis in Obstructive Nephropathy Qiang Fu, Qi Yan, Qin Zhang, Guohua Ding, Huiming Wang. *Renmin Hospital of Wuhan Univ.*

Background: Renal fibrosis is a common pathologic lesion in the end stage of various progressive kidney diseases, and is characterized by interstitial inflammation, proliferation of myofibroblasts, and progressive accumulation of extracellular matrix(ECM). The JNK-associated leucine zipper protein (JLP) is a crucial scaffolding protein in signals transduction and molecular trafficking. JLP has been found expressed in mouse tissues of brain, lung, spleen, testis, and kidney. We reported here, for the first time, the effects of JLP deficiency on the progression of renal fibrosis in mice model of unilateral ureteral obstruction (UUO).

Methods: *lp* Wild type ($jlp^{+/+}$) and *jlp* deficient ($jlp^{-/-}$) mice were divided into four groups,: $jlp^{+/+}$- and $jlp^{-/-}$-sham-operated groups, $jlp^{+/+}$- and $jlp^{-/-}$-unilateral ureteral obstruction (UUO)-operated groups ($jlp^{-/-}$- UUO group and $jlp^{+/+}$- UUO group). Mice were sacrificed at the days of 7 and 14 to evaluate the fibrosis by Masson and H&E staining. The expression of transforming growth factor-b1 (TGF-b1), α-smooth muscle actin (α-SMA), collagen I(COL-I), and collagen III (COL-III) were assayed by immunohistochemistry staining.

Results: One week after the surgery, more collagen deposition was observed in the renal interstitial area in $jlp^{-/-}$- UUO group than in $jlp^{+/+}$- UUO group. Similar to that, the expression of COL-I and COL-III were significantly increased in the kidney cortices in $jlp^{-/-}$- UUO-operated groups. The expression of TGF-b1 and α-SMA was also significantly higher in $jlp^{-/-}$- UUO-operated group than in $jlp^{+/+}$- UUO group.

Conclusions: Scaffolding protein JLP is critical in preventing renal fibrosis through the mechanism of inhibition TGF-b1 expression and myo-fibroblast induction.

HGF-Producing Cell Sheet Suppress Renal Fibrosis Induced by Unilateral Uretic Obstruction in a Rat Masatoshi Oka,[1] Sachiko Sekiya,[2] Ryoichi Sakiyama,[2] Kosaku Nitta,[1] Tatsuya Shimizu.[2] *[1]Nephrology, Tokyo Women's Medical Univ, Shinjuku, Tokyo, Japan; [2]Tokyo Women's Medical Univ Inst of Advanced Biomedical Engineering and Sciences, Shinjuku, Tokyo, Japan.*

Background: Tubulointerstitial fibrosis is a typical pathological finding in chronic kidney disease (CKD) and is associated with the progression of renal dysfunction. Recently several studies reported to suppress renal fibrosis by transplantation of cells expressing several growth factor, for example EGF, HGF. Cell sheet transplantation is a methodology of cell therapy for regenerative medicine. This technology demonstrated high effective therapy for diseases in other organs, such as cornea, periodontium, esophagus and heart. In this study, we performed to suppress renal fibrosis by local and sustained administration of hepatocyte growth factor (HGF) with HGF-producing cell sheet (HGF sheet) transplantation.

Methods: Human mesothelial cells transfected human HGF gene by lipofection were cultured on temperature-responsive dish for 4 days. When temperature reduced, these HGF-producing cells were detached from dishes as cell sheet without enzyme-treated. We performed unilateral ureteric obstruction (UUO) in nude rat and transplanted the HGF sheet immediately. To compare HGF sheet transplantation with intermittent administration of HGF protein, we also injected HGF protein from tail vein every 24 hours for UUO rat (HGF i.v.). The kidney volume after operation measured with CT every 7 days for 4 weeks.

Results: One week after operation, histologically the positive area of collagen and smooth muscle actin in kidney transplanted HGF sheet was significantly less compared to that in HGF i.v. kidney. Moreover, the kidney volume treated HGF sheet with UUO was significantly less compared to control 4 weeks after operation. And it maintained thick cortex tissues with a lot of glomeruli, tubules and microvessels in the kidney treated HGF sheet.

Conclusions: Local and sustained HGF administration with HGF sheet strongly suppressed renal fibrosis induced by UUO in a rat. Our results suggested that cell sheet therapy may be a promising strategy for renal disease.

Extracellular Matrix Modulates Macrophage Phenotype Profile Astgik Petrosyan,[1] Stefano Da Sacco,[2] Sargis Sedrakyan,[2] Giuseppe Orlando,[3] Matthew Edward Thornton,[1] Brendan Grubbs,[1] Roger E. De Filippo,[1,2] Laura Perin.[1,2] *[1]Univ of Southern California; [2]Children's Hospital Los Angeles; [3]Wake Forest School of Medicine.*

Background: It is known that macrophages play an important role in kidney damage and resolution. An increase in macrophages phenotype type 1 (M1) is known to promote scar formation while an increase in macrophage phenotype type 2 (M2) leads to pro-healing processes. However little is known on how the extracellular matrix (ECM) can direct macrophages toward a specific phenotype acquisition during development, tissue homeostasis and disease.

Methods: Using established protocols we decellularized human adult healthy, adult diseased, and fetal kidneys; monocytes were seeded on the different ECMs and macrophage phenotype switch after 24hrs and 5 days was assessed. Macrophage maturation was tested by evaluating release of IL-10, IFN-γ, TNF-α and IL-4 in the culture media along with qRT-PCR and immunocytochemistry to evaluate expression of M1 (CD80 and CD86) and M2 (CD163, CD16, CD14 and CD200R) phenotypes.

Results: We observed that monocytes cultured on ECMs were able to mature into macrophages and present an increase in M1 marker (CD80) on diseased ECM, an increase in M2 markers (CD163, CD200R) on healthy ECM, and an increase in anti-inflammatory M2 marker (CD16) on fetal ECM, after 24hrs. After 5 days of co-culture there was an overall decrease in gene expression for all markers followed by an increase in media secretion of IL-10 on diseased ECM vs healthy and fetal ECM. Additionally after 5 days higher number of seeded monocytes appear to adhere onto the adult ECM vs the fetal ECM. IFN-γ, IL-4 or CD64 expression was not detected during 24hrs and 5 days. Monocytes capacity to mature into macrophages was confirmed *in vitro* by administration of phorbol myristate acetate (PMA) and 1,25-dihydroxy vitamin D3 with LPS.

Conclusions: This preliminary work suggests that the ECM has the capacity to modulate macrophage phenotype and might contribute to disease progression. Additionally, this model may be used to investigate mechanisms of ECM-dependent macrophage activation during renal disease and regeneration.

SA-PO490

High Salt Diet Induces Blood Pressure Independent Tubulointerstitial Remodeling and Lymphangiogenesis in Rat Kidney Ryanne S. Hijmans, Saleh Yazdani, Gerjan Navis, Jacob van den Born. *Nephrology, Univ Medical Center Groningen, Groningen, Netherlands.*

Background: In chronic kidney disease (CKD), proteinuria is an important cause of tubular activation and progressive tubulointerstitial damage. It has been shown that high salt (HS) intake can aggravate this renal damage. Although earlier studies mainly focused on the blood pressure dependent (BP) effects of sodium on the kidney, recent studies suggest there is a BP independent route as well. A HS diet has been shown to store Na+ in the skin and as a result of binding of Na+ to proteoglycans, the influx of macrophages stimulates the secretion of vascular endothelial growth factor C (VEGF-C). Macrophage-derived VEGF-C has been shown to induce lymphangiogenesis (LA) in the skin. As LA has a role in inflammatory remodeling, we hypothesize that HS diet exerts its BP independent effects on the kidney by inducing LA and renal tubulointerstitial (TI) remodeling. We tested this hypothesis in normal rats, to avoid interference with TI remodeling due to the primary renal disorder.

Methods: Male Wistar rats (n=15) were randomly assigned to one of three study groups. Two groups (both n=5) received a high salt diet of 8% salt, while the control group (n=5) had a normal rat diet. After 2 weeks, one of the two groups on a high salt diet was sacrificed, and the other groups were sacrificed at 4 weeks. The kidneys were stained and quantified for lymphangiogenic, fibrotic and inflammatory markers.

Results: Rats with HS intake showed an increased number of lymph vessels compared to their controls at week 4 ($p<0,06$). ED1+ macrophages also increased in the HS group at week 4 ($p<0.06$). There was a significant increase of myofibroblasts (α-SMA) after 4 weeks in the HS group ($p<0,02$). Except for week 1 ($p<0,05$), the HS groups showed no significant BP differences with their controls at 2, 3 and 4 weeks.

Conclusions: We showed that high salt intake induces tubulointerstitial lymphangiogenesis, inflammation and profibrotic changes in rat kidneys, even when the BP is not significantly different between the groups. This finding supports our hypothesis that HS intake has BP independent effects next to it's well known BP dependent effects in CKD.

Genetic and Epigenetic Analysis of the MicroRNA-200 Family for Association with End Stage Renal Disease Laura Jane Smyth,[1] Gareth J. McKay,[1] Alexander P. Maxwell,[1,2] A.J. McKnight.[1] *[1]Centre for Public Health, Queen's Univ of Belfast, Belfast, Northern Ireland, United Kingdom; [2]Regional Nephrology Unit, Belfast City Hospital, Belfast, Northern Ireland, United Kingdom.*

Background: DNA methylation and miRNA profiles are associated with complex disease and are altered in uremic patients. We evaluated CpG sites, gene expression and SNPs of the miRNA-200 family and their target genes, including exploration of relevant methylation quantitative trait loci (meQTLs).

Methods: Quantitative DNA methylation was extracted from existing epigenome-wide association data (Illumina's 450K Methylation array) for individuals with and without kidney disease (n=407). Following stringent quality control, a total of 14 significant CpG sites were identified within the miRNA-200 family, the most significant of which was cg23651812 (*MIR429*, $P=4.1x10^{-45}$). The top 20 predicted target genes were determined using miRDB for each miRNA (*MIR141*, *MIR200A*, *MIR200B*, *MIR200C* and *MIR429*). Target genes had 308 CpG sites with methylation data; the most significant for *MIR429* were cg11686204 in *ELL2* and cg19038462 in *ZEB1* ($P=4.2x10^{-48}$). RNA-Seq analysis was performed on renal transplant recipients and healthy controls using the Ion Proton™. RNA was selectively depleted for ribosomal RNA and up to 40 million reads were gained per sample. Differential methylation status was associated with expression of miRNA and their corresponding gene targets. Genome-wide SNP data (n=561,233 SNPs; 372 individuals) from the Illumina 660K array was analysed in PLINK with QTL methylation data from the individual miRNA (n=14) and their target genes (n=308) CpG sites.

Results: No genome-wide significant cis-meQTLs were identified for the miRNAs. Two cis-meQTLs were identified for *ZEB2* (rs10200550 and rs4347890), a target gene for *MIR429*. Genome-wide significant results (n=476 SNPs) were obtained for 67 target genes (maximum $P=9.98x10^{-32}$). These genes may influence miRNA regulation.

Conclusions: *CD36*, the top-ranked gene, has previously been linked to kidney disease where it is suggested that it has a prominent role in the development of renal fibrosis. We have provided a genomic map of the miRNA-200 family using novel data in order to assist in determining its association with ESRD.

SA-PO492

A MicroRNA Signature of Epithelial–Mesenchymal Transition in Progression of Chronic Renal Disease Ali Ramezani,[1] Joseph M. Devaney,[2] Akshay Roy-Chaudhury,[1] Richard Scott,[2] Sara Karandish,[1] Susan Knoblach,[2] Jeffrey B. Kopp,[3] Dominic S. Raj.[1] *[1]Div of Renal Diseases and Hypertension, George Washington Univ, Washington, DC; [2]Center for Genetic Medicine Research, CNMC, Washington, DC; [3]NIDDK, NIH, Bethesda, MD.*

Background: Irrespective of the diverse initial causes, progression of CKD is characterized by increasing tubulointerstitial fibrosis. There is a great need for accurate, noninvasive biomarkers for early detection of fibrosis in the kidney and the progression of kidney disease. Recent evidence suggests that miRNAs participate in the fibrotic process in the kidney. The aim of this study was to examine the urinary and circulatory miRNA expression profiles regulating the EMT and whether they are reflected by parallel changes in the pro-fibrotic factors and the progression of kidney disease.

Methods: Blood and urine samples were obtained from 28 patients with CKD. Patients were divided into two groups according to their GFR: GFR<30 and GFR>30. Plasma and urinary levels of two biomarkers of fibrosis, collagens III (PIIINP) and IV, were measured. To analyze the involvement of miRNAs in kidney fibrosis, the plasma and urinary miRNA expression profiles of the patients were analyzed.

Results: Plasma and urine PIIINP and CIV levels were significantly increased in patients with GFR<30. Furthermore, miRNA expression profile of the patients showed 58 downregulated and 60 upregulated miRNAs in urine, and 51 downregulated and 61 upregulated miRNAs in the plasma of the patients with GFR<30 compared with GFR>30. A panel of 4 urine and 6 plasma miRNAs was identified which not only distinguished patients with GFR<30 from GFR>30, but their altered expression were also implicated in the phenotypic changes that occur during EMT and fibrosis. The altered expression levels of these miRNAs were validated in a tubular epithelial cell line, and studies are underway to validate their expression in vivo, in the Alb/TGFβ mouse model.

Conclusions: Plasma and urinary miRNAs are reliable, noninvasive, and inexpensive markers for CKD fibrosis and progression. These miRNA panels warrant study in larger cohorts since plasma- and urine-based assays could provide a more feasible and safer screening compared to biopsy.

SA-PO493

The PR3 Receptor CD177 Is Controlled by Epigenetic Mechanisms Claudia Eulenberg,[1] Sylvia Bähring,[1] Friedrich C. Luft,[1] Ralph Kettritz.[2] *[1]Charité-Buch, Experimental and Clinical Research Center, Berlin, Germany; [2]Nephrology and Intensive Care Medicine, ECRC, Berlin, Germany.*

Background: Proteinase 3 is the major ANCA antigen in granulomatosis with polyangiitis (GPA). PR3-ANCA binding to membrane-PR3 (mPR3) is a key event for neutrophil activation and vascular damage. The neutrophil-specific CD177 receptor enables $mPR3^{high}$ expression on a neutrophil subset ($CD177^{pos}/mPR3^{high}$). ANCA patients show a higher percentage of $CD177^{pos}/mPR3^{high}$ neutrophils compared to healthies, the higher the percentage, the worse the prognosis. We reported previously that CD177 protein and mRNA expression is restricted to $CD177^{pos}/mPR3^{high}$ neutrophils with a random monoallelic mRNA expression pattern. We hypothesized that epigenetic mechanisms control CD177 gene expression.

Methods: Haplotype analysis, genome-wide methylation analysis, chromatin immunoprecipitation (ChIP) analysis and CD177 expression studies were performed in neutrophils and HeLa cells.

Results: Methylation analysis on $CD177^{neg}$ and $^{-pos}$ neutrophils revealed three CpGs in the potential CD177 promotor that were methylated in $CD177^{neg}$, but not in $CD177^{pos}$ cells ($p<0.001$; n=6). ChIP identified an enrichment of the H3K4me3 mark (euchromatin) in the predicted CD177 promotor region in $CD177^{pos}$ neutrophils ($p<0.05$; n=4). This putative promotor region contains a TATA box and binding sites for several transcription factors, including the AP1 family. We established a HeLa cell model that recapitulates the neutrophil situation. We observed CD177 mRNA in PMA-treated HeLa cells. HeLa cells also had euchromatin in the promotor region and CD177 mRNA followed a monoallelic expression

pattern. CD177 mRNA expression was upregulated when we transfected HeLa cells with the AP1 family members c-Jun, c-Fos and c-Ets1. The same AP1 family members bound the putative CD177 promotor region by ChIP experiments in HeLa and neutrophils. HeLa cell treatment with the demethylation agent 5-aza-2'-deoxycytidine led to a biallelic CD177 gene expression. Reporter assays in HeLa cells will further characterize the epigenetic and transcriptional CD177 regulation.

Conclusions: Our data strongly implicate epigenetic mechanisms that are responsible for the generation of distinct CD177/mPR3 subsets.

Application of Human Kidney RNA-seq Expression Quantitative Trait Loci in Chronic Kidney Disease Yi-An Ko, Frank S. Chinga, Nora Ledo, Katalin Susztak. *Renal Electrolyte and Hypertension Div, Perelman School of Medicine, Univ of Pennsylvania, Philadelphia, PA.*

Background: There are more than 5 million sequence variants in humans. Somegenetic variations influence transcript levels and therefore have the ability to interfere with cell and organ function. Such genetic variants are called expression quantitative trait loci (eQTL). The goal of our study was identify such functionally important genetic variants at the genome-wide level.

Methods: This analysis requires the collection of large number of human tissue samples with genotype and transcript level data. Here we used 99 human kidney samples of Central European descents.RNAseq and genotype data was normalized and genotype data was imputed using 1,000 Genome reference data. The association between genotype and transcript levels was performed using Matrix eQTL software and was limited to *cis*-eQTLs where the genetic variant and transcript levels were within 2 megabases distance.

Results: We identified 164 significant target genes (we call these eGenes) and 7590 significant SNPs (eSNPs) that passed the threshold for statistical significance after multiple testing correction using adjusted *p*-values<1.0E-10. Next we compared variants that influence gene expression in the kidney to those that have been published for other organs using the publicly available Genotype-Tissue Expression project (GTEx). Of the 164 eGenes,103 were common between the kidney and other organs, indicating that there are cell type specific and cell type independent eGenes. Using kidney specific epigenome maps, we found that eSNPs were enriched on kidney specific regulatory elements, including promoters and enhancers. We also found a significantly greater overlap between kidney eGenes and polymorphisms that are associated with CKD development, compared to other traits (digestive, nervous, immune system diseases, hematological measurement, cardiovascular, and metabolic disease).

Conclusions: We identified transcript level changes associated with genotypic variations. These results can highlight kidney specific regulatory elements and may also help to identify target genes for polymorphisms associated with kidney function related traits.

RNA Sequencing Reveals Tumor Necrosis Factor α Inducible Protein 6 (*TNFAIP6*) as a Potential Single Gene Classifier of Renal Cell Carcinoma Oystein Solberg Eikrem,[1] Christian Beisland,[1] Andreas Scherer,[2] Arnar Flatberg,[3] Trude Skogstrand,[1] Lea Landolt,[1] Sabine Leh,[1] Karin Margrethe Hjelle,[1] Vidar Beisvag,[3] Hans-Peter Marti.[1] *[1]Dept of Clinical Medicine, Univ of Bergen, Bergen, Norway; [2]Spheromics, Kontiolahti, Finland; [3]Dept of Cancer Research and Molecular Medicine, Univ of Science and Technology, Trondheim, Norway.*

Background: The recent release of a new library preparation kit improved the cDNA library quality from formalin-fixed, paraffin-embedded (FFPE) tissues. In this study we demonstrate the feasibility of next generation sequencing (NGS) of mRNA obtained from FFPE tissues as compared with RNAlater® stored tissues.

Methods: Paired biopsies from tumorous and adjacent non-tumorous tissue of 16 patients with ccRCC were either FFPE or stored in RNAlater® (Qiagen) for £1 year. Total RNA was extracted utilizing the miRNeasy FFPE kit and the miRNeasy micro kit (Qiagen). Sequencing libraries were prepared using the TruSeq RNA Access Library Prep Kit® (Illumina).

Results: The average expression of detected transcripts in both FFPE and RNAlater® datasets correlated with R^2=0.97, and the log2 fold changes of the transcripts which are significantly altered in both datasets (n=1106) correlated with R^2=0.94. A classifier model with TNFAIP6 was developed for the FFPE dataset with a specificity of 100% and sensitivity of 94%; ROC AUC=0.99 (Fig. 1A); only one normal sample was misclassified due to a small admixture of cancer tissue. Classifier validation in an Affymetrix microarray dataset obtained from GEO (GSE53757) showed *TNFAIP6* up-regulation in all tumor stages with both sensitivity and specificity of 94%; ROC AUC=0.98 (Fig. 1B).

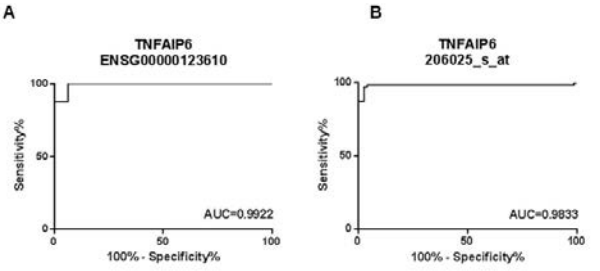

Figure 1: ROC of TNFAIP6. (A) present study, (B) validation in GSE53757 data set.

Conclusions: We describe a potential single gene classifier for ccRCC. Furthermore, NGS in FFPE tissues is feasible and correlates well withRNAlater® stored tissues. Thus, our studies open up novel diagnostic possibilities on archival renal biopsies.

SA-PO496

Gene Expression Based Dissection of Chronic Kidney Disease Traits Pazit Beckerman, Katalin Susztak. *Renal, Electrolyte and Hypertension Dept, Univ of Pennsylvania, Philadelphia, PA.*

Background: Chronic kidney disease (CKD) is a progressive decline in kidney function. There are several manifestations of CKD including glomerular function change, albuminuria, glomerulosclerosis, tubulointerstitial fibrosis and metabolic changes. These traits are strongly correlated but the question remains whether they are driven by identical mechanisms.

Methods: We conducted genome wide transcript level analysis of 95 microdissected human kidney tubule samples. We used transcript level changes as quantitative traits to dissect underlying mechanisms. These samples included subjects with normal eGFR with or without diabetes (DM) or hypertension (HTN), and diseased kidney samples with low eGFR, fibrosis and sclerosis, with or without DM or HTN.

Results: We identified 1430 transcripts with significant linear correlation with eGFR. Pathway analysis indicated significant enrichment for inflammation and metabolism related pathways. Subgroup analysis indicated enrichment for TGFβ and Wnt signaling and ECM receptor interactions only in earlier CKD stages. Our analysis identified 1606 transcripts that correlated with fibrosis and 1803 transcripts correlated with glomerulosclerosis. Similar to the clinical overlap between eGFR and fibrosis, we found that 78% of transcripts were identical. Transcripts that showed correlation with fibrosis but not with eGFR were enriched for inflammation related pathways. On the other hand, metabolism related genes correlated with eGFR but not with fibrosis. There were significant differences between male and female samples as well.

Conclusions: Our transcriptome-based dissection method highlights the relatedness of eGFR and kidney fibrosis, but also indicates potential differences in the underlying mechanisms of the two processes.

Early-Onset, Severe Forms of Hypertension and Cardiovascular Complications Are Associated with *APOL1* G1/G2 Susceptibility Alleles in African Americans Girish N. Nadkarni, Geneviève Galarneau, Stephen B. Ellis, Rajiv Nadukuru, Stuart Scott, Laura Rassmussen Torvik, Abel Kho, Geoffrey Hayes, Jennifer Pacheco, Rex L. Chisholm, Joshua C. Denny, Dan M. Roden, Eimear Kenny, Erwin P. Bottinger. *Electronic Medical Records and Genomics (eMERGE) Network.*

Background: Apolipoprotein L1 (*APOL1*) susceptibility alleles have been associated with kidney disease progression and ESRD in hypertensive African Ancestry (AA) populations. We explored whether these *APOL1* alleles are associated with blood pressure-related traits in AA enrolled in the electronic medical records and genomics (eMERGE) Network.

Methods: Study populations included the Mount Sinai Bio*Me* biobank discovery(dis) cohort(n=5,213) and three EMR-linked biobank replication(rep) cohorts, including Vanderbilt BioVU (n=2,889), Northwestern NUgene (n=613), and Mount Sinai Bio*Me* (n=1,655). *APOL1* single nucleotide polymorphisms (SNPs) rs73885319, rs71785313 and rs60910145 were genotyped in Bio*Me* samples and imputed in BioVU and NUgene samples to determine *APOL1* G1 and G2 risk alleles. Longitudinal phenotypic data were extracted from EMRs. Linear regression models & meta-analyses (METAL) were performed with age, sex, mean BMI, and eGFR as covariates.

Results: Compared with carriers of [0 or 1] *APOL1* G1/G2 risk alleles, carriers of [2] risk alleles were diagnosed with hypertension a mean of 2.5 years (95%CI 1.9-2.9 yrs) earlier in life (P_{dis}=0.04, P_{rep}=3x10^{-4}; Cox hazard); manifested 2-3 mmHg higher systolic BP(SBP) in younger AA (age 20–39) (P_{dis}=0.07, P_{rep}=0.04); and were exposed to more antihypertensive medication classes (P_{dis}=0.11; P_{rep}=3x10^{-4}). Carriers of [2] risk alleles were more likely to manifest concentric left ventricular hypertrophy by echocardiogram (OR(95%CI)=1.52(1.14-2.02); P<0.01) and hemorrhagic cerebrovascular accidents (OR(95%CI)=2.42(1.01-5.97); P=0.05).

Conclusions: *APOL1* G1/G2 susceptibility alleles are associated with early-onset, more severe form(s) of hypertension & with hypertensive complications hemorrhagic stroke

and concentric LVH independent of kidney function & BMI. These results may warrant a shift from kidney-intrinsic to systemic vascular pathomechanisms attributable to *APOL1* G1/G2 susceptibility alleles.

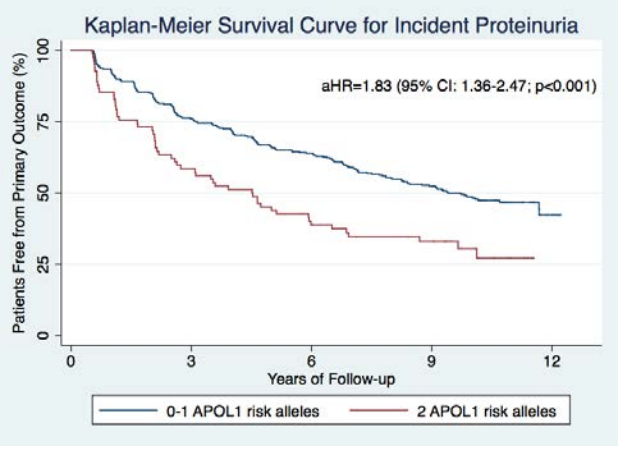
Apolipoprotein L1 (*APOL1*) Gene Variants and Incident Proteinuria: Results from the African American Study of Kidney Disease and Hypertension (AASK) Teresa K. Chen,[1] Carmen A. Peralta,[2] Lawrence J. Appel,[3] Michael J. Choi,[1] Michelle M. Estrella.[1] *[1]Nephrology, Johns Hopkins Univ; [2]Nephrology, Univ of California San Francisco; [3]Medicine, Johns Hopkins Univ.*

Background: *APOL1* gene variants are associated with kidney function decline. Whether these same gene variants are associated with incident proteinuria in the context of pre-existing chronic kidney disease (CKD) is unknown.

Methods: Using the trial and cohort phases of AASK (median follow-up of 6.8 years, maximum follow-up of 12.2 years), we evaluated participants who had hypertension-attributed CKD and who did not have proteinuria at baseline. Cox proportional hazards models were used to estimate the relative hazard of incident proteinuria (defined as a doubling of urine protein-to-creatinine ratio and UP/Cr ³0.22), comparing *APOL1* high-risk genotype (2 risk alleles) vs. low-risk genotypes (0-1 risk alleles). We adjusted for age, gender, baseline GFR, percentage of European ancestry, randomized blood pressure goal (usual vs. low), and randomized blood pressure drug (ramipril vs. metoprolol vs. amlodipine). Effect modification by randomized trial interventions and dietary sodium intake (as estimated by 24-hour urine sodium) was assessed.

Results: Of the 480 participants included in our study, 17% (n=82) had the *APOL1* high-risk genotype. Individuals with the *APOL1* high-risk genotype were 83% more likely to develop incident proteinuria compared to those with the low-risk genotypes (adjusted HR: 1.83; 95% CI: 1.36 to 2.47; p<0.001). The association between *APOL1* and incident proteinuria was not modified by randomized blood pressure goal, randomized blood pressure drug, or dietary sodium intake (p-interaction>0.05 for each).



Conclusions: Among African-Americans with CKD attributed to hypertension but without baseline proteinuria, high-risk variants of *APOL1* are associated with a greater risk of incident proteinuria.

Funding: NIDDK Support, Pharmaceutical Company Support - The AASK trial and cohort were also supported by the following pharmaceutical companies: King Pharmaceuticals, Pfizer, AstraZeneca, GlaxoSmithKline, Forest Laboratories, Pharmacia, and Upjohn.

African Ancestry Specific Alleles Confer Chronic Kidney Disease Risk in U.S. Hispanics Nora Franceschini,[1] Adrienne M. Stilp,[6] Michael F. Flessner,[2] Carmen A. Peralta,[3] Sylvia E. Rosas,[4] Cathy C. Laurie,[6] Holly J. Kramer.[5] *[1]Epidemiology, Univ of North Carolina, Chapel Hill, NC; [2]National Insts of Health, Bethesda, MD; [3]Univ of San Francisco, San Francisco, CA; [4]Harvard Univ, Boston, MA; [5]Loyola Univ, Maywood, IL; [6]Univ of Washington, Seattle, WA.*

Background: Hispanics are a heterogeneous group with varying genetic ancestry. African ancestry can differ in Hispanics by country of origin, and its proportion relates to their risk of chronic kidney disease (CKD).

Methods: We examined the association of African ancestry population-specific risk alleles (*APOL1* and *HBB* rs334 related sickle cell anemia) with CKD in 11,921 Hispanics, aged 18-74 years, recruited in a community-based study in four US centers. *APOL1* G1/G2 alleles were genotyped and rs334 alleles were imputed (rsq=0.83). CKD was defined as an increased urine albumin to creatinine ratio (UACR) (≥ 17 mg/g in men and ³25 mg/g in women), reduced estimated glomerular filtration rate (eGFR) <60 ml/min/1.73 m² based on serum creatinine/cystatin C CKD-EPI equation, or presence of reduced eGFR or an increased UACR. Analyses used generalized linear mixed models that accounted for the sampling strategy and family relatedness, age, sex, diabetes, systolic blood pressure and anti-hypertensive medications, and stratified by Hispanic background.

Results: There were 41% men, and mean age was 46 (SD =14). The prevalence of increased UACR was 14%, reduced eGFR was 4%, and combined CKD outcomes was 16%. Caribbean Hispanics (Cuban, Dominican, Puerto Rican, N=5348) had higher prevalence of 2 *APOL1* risk alleles (1% vs 0.1%) and rs334 allele (2% vs. 0.7%) compared to Mainland Hispanics (Central American, Mexican, South American, N=6,539). *APOL1* alleles were associated with increased UACR ($p=10^{-4}$) and the composite CKD outcome ($p=10^{-4}$), and rs334 was associated with same outcomes (UACR, $p=10^{-7}$; CKD composite outcome, $p=10^{-7}$) among Caribbeans only.

Conclusions: African-specific alleles are associated with CKD in Hispanics, but associations vary by Hispanic background. Medical care providers should be aware of the impact of these genetic variants for CKD risk in Hispanics.

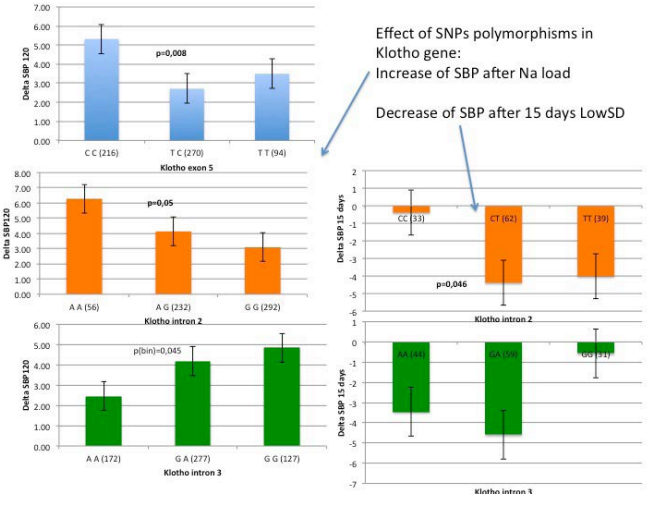
Role of Klotho Genetic Polymorphisms in Salt-Sensitivity: A Link Between Salt and Aging? Chiara Lanzani, Lorena Citterio, Elena Brioni, Simona Delli Carpini, Marco Simonini, Guido Gatti, Elisabetta Messaggio, Paolo Manunta. *Nephrology and Hypertension, San Raffaele Hospital, Milan, Italy.*

Background: Previous data in transgenic mice showed that one-half klotho deficiency resulted in extensive premature aging, increased salt sensitivity and caused salt-sensitive hypertension. Recent gene expression study confirmed the expression oh Klotho in renal distal tubular cells. The aim of this study is to evaluate the role of Klotho polymorphisms in salt sensitivity hypertension.

Methods: Design: study of pressure-natriuresis relationship in essential hypertensive patients, never treated before, naive (NHP) by Acute salt load (NaLoad: 310 mMol in 2 h iv) and low salt diet (Low SD: <100 mEq/die for 15 days). **Methods:** 580 NHP underwent Naload, whereas 137 NHP were compliant to lowSD protocol (of 324 enrolled).

Results: GWA analysis identified 32 SNPs in Klotho gene (restricted to 15 with tagging r^2=0,80). Six of these resulted significantly associated to BP variation after Naload and LowSD. The effect of intron 2 and 3 SNPs genotype on SBP variation after Naload and LowSD are reported in the (figure 1) confirming the similar effect in the two manoeuvres.



Conclusions: These results are the first demonstration of the role of Klotho gene in salt homeostasis and hypertension development and suggest that Klotho polymorphisms affect sodium renal tubular excretion. If confirmed these results propose Klotho as key gene in salt sensitivity and aging.

SA-PO501

Associations Between the Reticulon 1 Gene (*RTN1*) and End-Stage Kidney Disease Jason A. Bonomo,[1] Nicholette D. Palmer,[1] Ying Fan,[2] John C. He,[2] Donald W. Bowden,[1] Barry I. Freedman.[3] *[1]Center for Genomics & Personalized Medicine Research, Wake Forest School of Medicine; [2]Dept of Internal Medicine, Section on Nephrology, Mount Sinai School of Medicine; [3]Dept of Internal Medicine, Section on Nephrology, Wake Forest School of Medicine.*

Background: *RTN1* encodes endoplasmic reticulum stress proteins that have recently been associated with chronic kidney disease. We sought to determine if genetic variants within *RTN1* were associated with end-stage renal disease (ESRD) in African Americans (AAs) and European Americans (EAs) with diabetic (T2D-ESRD) and non-diabetic forms of ESRD.

Methods: We examined the *RTN1* gene region using a published AA T2D-ESRD genome-wide association study (Discovery study; n=922 cases, n=861 controls). Seven single nucleotide polymorphisms (SNPs) with p<0.05 were identified and genotyped in replication samples of AAs with T2D-ESRD (n=1,312) and controls (n=774), as well as

EAs with T2D-ESRD (n=604) and controls (n=1030). SNPs were also investigated in AAs with non-T2D ESRD (n=1,459 AA) and T2D in the absence of ESRD (n=500 AAs, n=620 EAs). Data were adjusted for age, gender, admixture, and the *APOL1* alleles, if applicable.

Results: The top *RTN1* SNPs from the Discovery study underwent replication testing in independent case-control samples of AAs with T2D-ESRD. Replication was observed with three variants and a combined T2D-ESRD analysis (Discovery + Replication study) in AAs yielded p=0.015–3.0x10^{-4} with OR=0.67-0.77 thus showing protection with the minor allele. One SNP, rs12434215, replicated association in EAs with T2D-ESRD (p=0.019, OR=0.69). Nominal associations were observed for SNPs rs12431381 and rs12434215 with non-T2D ESRD in AAs (p=0.014–0.015, OR=0.77). A combined AA all-cause ESRD analysis (n=3,800 cases, n=1,803 controls) demonstrated associations with rs12434215 (p=6.7x10^{-4}, OR=0.73) and rs12431381 (p=7.5x10^{-4}, OR=0.75). Minimal evidence of association between these three SNPs and T2D alone was observed in both AAs and EAs.

Conclusions: These data provides genetic evidence of association between *RTN1* and ESRD in AAs and EAs. Further studies are needed to clarify the signal.

SA-PO502

Interaction of Risk Alleles in Japanese Idiopathic Membranous Nephropathy Kenjiro Honda,[1] Myo Thiri,[2] Koji Okamoto,[3] Kent Doi,[1] Hodaka Suzuki,[4] Tsuyoshi Watanabe,[4] Masaomi Nangaku,[1] Katsushi Tokunaga,[2] Eisei Noiri.[1] *[1]Nephrology and Endocrinology, The Univ of Tokyo, Tokyo, Japan; [2]Dept of Human Genetics, Graduate School of Medicine, The Univ of Tokyo, Tokyo, Japan; [3]Kidney Section, NIDDK/NIH, Bethesda, MD; [4]Depts of Nephrology and Hypertension, Fukushima Medical Univ, Fukushima, Japan.*

Background: Recent studies have reported the association of risk alleles of *PLA2R1* and *HLA-DQA1* with idiopathic membranous nephropathy (IMN) in the European and Chinese populations. However, both close association of the risk alleles and interaction between risk alleles of *PLA2R1* and *HLA* from high-resolution HLA typing among Japanese IMN patients has not been investigated.

Methods: Samples of Japanese biopsy-proven IMN patients (N = 183) and healthy control subjects (N = 620) were collected. Fifteen common variants were selected within *PLA2R1* gene. High-resolution association analysis of single nucleotide polymorphisms (SNPs) within *PLA2R1* and *HLA* alleles in *HLA-A*, *B*, *C*, *DRB1*, *DQB1* and *DPB1* was performed using 53 IMN cases and 420 controls. The significant associations discovered in the first sample set were validated by the second set that comprised of 130 IMN cases and 200 controls.

Results: The strong associations *HLA-DRB1*15:01* (P=7.72 x 10^{-5}, OR=2.9) and *HLA-DQB1*06:02* (P=5.12 x 10^{-4}, OR=2.6) were observed. Additionally, *HLA-Cw*07:04* and *HLA-DRB1*16:02* showed nominal association with IMN, while *HLA-B*07:02*, *HLA-DRB1*04:05* and *HLA-DQB1*04:01* were inversely associated with IMN. The associations did not remain significant after correction for multiple comparisons. In combined data analysis, *HLA-DRB1*15:01* and *HLA-DQB1*06:02* showed stronger association with IMN. In single locus analysis of *PLA2R1*, seven SNPs showed strong associations with IMN. Interaction analysis between *HLA* alleles and *PLA2R1* variants revealed high odds ratio for IMN with both risk alleles.

Conclusions: The associations of *PLA2R1* and *HLA* polymorphisms were identified in Japanese IMN patients. Moreover, *PLA2R1* risk alleles and *HLA* risk haplotype showed additive effects that were stronger than individual odds ratios, indicating the importance of interaction of these two genes in the development of IMN.

Relationship Between rs3760106 Variation of *PRKCB1* Gene and End-Stage Renal Disease in Type 2 Diabetes Mellitus in Chinese Limei Liu,[1] Xiaoxu Ge,[1] Langen Zhuang,[1] Ming Li,[1] Rong Zhang,[1] Feng Wang,[2] Niansong Wang.[2] *[1]Dept of Endocrinology and Metabolism, Shanghai Jiao Tong Univ Affiliated Sixth People's Hospital; [2]Dept of Nephrology, Shanghai Jiao Tong Univ Affiliated Sixth People's Hospital, Shanghai, China.*

Background: To explore the relationship between rs3760106 (C/T) variation of protein kinase C-β gene (*PRKCB1*) and end stage renal disease (ESRD) in type 2 Diabetes mellitus (T2DM) in Chinese.

Methods: 602 type 2 diabetes patients of Shanghai Han origin were recruited, which were divided into DN-ESRD group (n=274) with end-stage renal disease (ESRD) of diabetic nephropathy (DN) and DN-0 group (n=328) without diabetic nephropathy (DN-0). Taqman PCR assay was used to detect the genotypes of rs3760106 variation of *PRKCB1* gene. Genotypic and allelic frequencies and clinical characteristics were compared between two groups, including DN-0 and DN-ESRD groups as well as genotypic groups in DN-0 or DN-ESRD group.

Results: Three genotypes (CC, CT and TT) of rs3760106 were detected. The distribution of the three genotypes of type 2 diabetes patients was in accordance with Hardy-Weinberg equilibrium. There were significant differences in both genotypic and allelic frequencies between DN-0 and DN-ESRD groups ($p < 0.05$ for each). The frequencies of CT+TT genotype and T allele in DN-ESRD group were significantly higher than those in DN-0 group ($p < 0.05$ for each). Patients with risk allele T (i.e. CT and TT genotypes) were at significantly higher risk of developing ESRD (OR = 2.14, 95% CI, 1.18-3.87, $p < 0.05$). After adjusting for confounding variables, i.e., sex, onset age of diabetes and BMI with multi-factorial logistic regression model, this odds ratio (OR) remained significant [OR=1.94 (95% CI, 1.04-3.64)]. Moreover, compared with patients carrying CC genotype, those with CT+TT genotype had significantly higher fasting plasma glucose (FPG) level in DN-0 group ($p < 0.05$) or had an increasing tendency in DN-ESRD group ($p > 0.05$).

Conclusions: *PRKCB1* gene rs3760106 (C/T) is significantly associated with development of ESRD and T allele carriers are at higher risk of developing ESRD than those CC carriers in T2DM in Han Chinese of Shanghai.

The First Genome-Wide Association Study of Diabetic Nephropathy in Korean Type II Diabetes Patients Byeongwoo Kim,[1] Yeong Hoon Kim,[1] Sang Ho Lee,[2] Sunwoo Kang.[1] *[1]Dept of Nephrology, Inje Univ, Busan Paik Hospital, Busan, Korea; [2]Dept of Nephrology, College of Medicine, Kyung Hee Univ, Seoul, Korea.*

Background: It has been suggested that genetic susceptibility plays an important role in the pathogenesis of diabetic nephropathy. Recently, several genome wide association studies (GWASs) suggested that specific polymorphisms of candidate genes were associated with susceptibility to diabetic nephropathy. However, there was weak point in contents of GWAS DNA chip for GWAS. In fact, previous contents of GWAS DNA chip were fixed and did not cover SNPs in exon region and promoter region. In present study, we used the Axiom™ Genome-Wide Human Assay. The contents of assay are selected by researcher and useful to investigate association between several candidate SNPs and specific diseases.

Methods: To investigate whether specific polymorphisms are involved in the development of the diabetic nephropathy, 87 diabetic nephropathy patients and 104 diabetic controls in Korean with type II diabetes were studied. We firstly selected 47,777 genes of homo sapiens in NCBI gene database and searched the SNPs in dbSNP database. And the criteria for selection exonic SNPs, promoter SNPs, and intron SNPs in each gene were following: (1) SNPs with > 10% minor allele frequency (MAF), (2) >0.1 heterozygosity, (3) known genotype frequencies of SNPs in Asian population, (4) SNPs studied in previous study, and (5) unknown SNPs. Finally we selected 378,707 SNPs. Logistic regression models were performed to determine odds ratio (OR), 95% confidence interval (CI), and P value. The analysis were analysis using Helixtree program.

Results: Among 378,707 SNPs, three SNPs (rs3214159 in *ABCC8* gene, rs3747636 in *PIK3C2B* gene, and rs3765156 in *PIK3C2B* gene) showed strongly significant association with diabetic nephropathy ($p<0.00001$).

Conclusions: These results suggest that these significant SNPs may be useful to investigate the development of diabetic nephropathy.

SA-PO505

An Efficient and Comprehensive Strategy for Genetic Diagnostics of All Hereditary Kidney Diseases Lisbeth Silva,[1] M. Lara Besada-Cerecedo,[1] Olaya Lamas-Gonzalez,[1] Patricia Regueiro Casuso,[1] Ana Barcia de la Iglesia,[1] Beatriz Sobrino,[2] Jorge Amigo,[2] Francisco Barros Angueira,[2] Angel Carracedo,[2] Candido Diaz Rodriguez,[1] Miguel A. Garcia-Gonzalez.[1] *[1]Group of Genetics and Developmental Biology of Renal Diseases, Dept of Nephrology, Univ Hospital Complex and Health Research Inst of Santiago de Compostela (IDIS), Santiago de Compostela, A Coruña, Spain; [2]Galician Public Foundation of Genomic Medicine, Santiago de Compostela, A Coruña, Spain.*

Background: Sanger is a traditional and reliable method for sequencing, but next generation sequencing (NGS) has improved genetic diagnosis in a time and cost effective manner. We established and validated a NGS strategy for all hereditary kidney diseases, and compared it with traditional and NGS exome sequencing technologies.

Methods: Based in clinical classification and population prevalence, we generated four panels and test them in 318 patients with renal disease during 2 years of routine clinical assistance: (1) Panel for common cystic disease (8 genes, 129 patients); (2) Panel for common, rare and ultra-rare cystic diseases (72 genes, 48 patients); (3) Panel for glomerular disease (26 genes, 89 patients) and (4) Panel for tubule/interstitial disease (36 genes, 52 patients).

Results: This strategy has shown greater gene coverage, sensibility and specificity considering pseudogenes, compared to two independent NGS exome sequencing strategies (ampliseq n=2 and sureselect n=115). Also, we have developed a bioinformatics algorithm and generated an in-house database identifying a total of 6945 genomic variants (248 frameshift- and 66 nonframeshift- insertion/deletion/substitutions, 44 stopgain; 102 splicing, 807 nonsynonymous SNV, 592 synonymous SNV and 39326 non coding variants) that we have used to classify and re-classify considering every single genetic variant described into the literature. We have identify genetic interaction as the most common lack of positive genetic diagnosis and the major mechanism of phenotypic inter- and intra-familial variability.

Conclusions: Here we describe a novel strategy to anticipate disease and provide complete genetic information for clinical decision-making, in a time- and cost-efficient manner.

SA-PO506

Exome Sequencing as Diagnostic Tool in Daily Clinical Nephrology Practice Ilse M. Rood,[1,2] Dorien Lugtenberg,[1,2] Elisabeth A.M. Cornelissen,[1] Jeroen Schoots,[1] Nicole Van De Kar,[1] Michiel F. Schreuder,[1] Linda Koster-Kamphuis,[1] Jeroen Deegens,[1] Julia M. Hofstra,[1] Tom Nijenhuis,[1] Jack F. Wetzels,[1] Ronald Roepman,[1] Ernie M.H.F. Bongers.[1] *[1]Radboud Center Renal Disorders, RadboudUMC, Nijmegen, Netherlands; [2]Shared first author.*

Background: Next generation sequencing, e.g. exome sequencing (ES), is currently the state of the art technique to identify mutations in genetic diseases. We developed a workflow for implication of ES in daily clinical practice for patients with a suspected hereditary kidney disease. The aim of this study was to analyze the diagnostic yield of this approach in clinical practice.

Methods: We developed a two-tier analysis, in which the first step is a kidney disease gene panel to screen for pathogenic variants in 187 genes, minimizing the change of coincidental findings. If causative mutations are not identified (first step), the complete exome data set was analyzed after additional written informed consent. We analyzed the diagnostic yield of this approach.

Results: From Jun. 2013 till Jan. 2015 we included 74 unrelated patients with kidney disease, defined as glomerular disease (n=34), cystic renal disease (n=16), electrolyte disorders (n=11), renal insufficiency of unknown cause (n=4) and other (n=9). The kidney disease gene panel revealed pathogenic mutations in 11 cases (15%), and likely pathogenic variants in 12 other cases (16%), necessitating follow-up studies. Further analysis of the complete exome data set in 19 patients, revealed candidate genes in 6 patients that are under investigation. In addition, copy number variation analysis revealed a pathogenic deletion in 2 patients (in one patient another pathogenic mutation was also identified in step one). There was 1 coincidental finding necessitating follow up for coloncarcinoma. In 23 patients open exome analysis is currently ongoing. Nine patients refused further analysis.

Conclusions: Currently, in 30 out of 74 patients (41%) (likely) causative mutations or new candidate genes were identified. We conclude that diagnostic exome sequencing is a powerful tool for detecting causative mutations in daily clinical practice without having the limitations of other gene testing approaches (single gene testing/targeted sequencing).

SA-PO507

Atypical Hemolytic Uremic Syndrome Targeted Re-Sequencing Study in a South Italian Cohort of Patients Matteo Accetturo,[1] Anna Zito,[1] E.D. Stea,[1] Maddalena Gigante,[2] Paola Pontrelli,[1] S. Diella,[2] Giuseppe Castellano,[1] M. Giordano,[3] L. Santangelo,[3] Loreto Gesualdo.[1] *[1]Emergency and Organ Transplants, Nephrology Unit, Univ of Bari, Italy; [2]Medical and Surgical Sciences, Nephrology Unit, Univ of Foggia, Italy; [3]Giovanni XXIII Hospital, Italy.*

Background: Atypical hemolytic uremic syndrome (aHUS) is a multifactorial disease due to autoimmune or genetic factors leading to deregulated alternative complement pathway activation. At present 12 genes are associated to aHUS, however 30-50% of patients lack mutations in these genes resulting in still partially obscure genotype-phenotype correlations.

Methods: We enrolled 20 aHUS patients and 2 relatives from Apulia Region, Italy. We performed targeted parallel re-sequencing of the 12 known genes plus ADAMTS13, integrated in the panel for genetic diagnostic routine screening. We analyzed the genotypes, investigating the overlapping with other alternative complement pathway disorders, such as C3 glomerulopathy, Age-related Macular Degeneration (AMD) and drusen. We selected patients for their history of sporadic aHUS. Target enrichment was performed using an Illumina TruSeq Custom Amplicon panel. Sequencing was performed on Illumina MiSeq Desktop Sequencer. All variants were evaluated for their pathogenicity according to CADD, Sift and Polyphen algorithms.

Results: We identified 30 missense and one nonsense variants in known aHUS genes, plus seven missense variants in ADAMTS13. Several combined variants were identified which might explain the different phenotypic nuances of our patients, as well as, in some cases, their signs of other Complement-related diseases. We evidenced that different combination of variants together with different triggering factors result in a phenotypic spectrum encompassing all the Complement-related disease range. Additionally, in presence of some combinations, also other underlying pathologies can act as a triggering background for aHUS.

Conclusions: Our data suggest that (i) ADAMTS13 gene should be routinely sequenced for aHUS (ii) the overlapping with other complement-related diseases is considerable. Mutations should therefore be analyzed in combination, and the high-throughput strategy is the only feasible in this scenario.

SA-PO508

Whole Exome Sequencing (WES) Revealed Underlying Complexity in Genetic Studies of Familial IgA Nephropathy (fIgAN) Xuewen Song,[1] Nicole M. Roslin,[2] Meng Yi Xu,[1] Kairong Wang,[1] Jannel Liu,[1] Bushra Joarder,[1] Amirreza Haghighi,[1] Melody Ren,[1] Mitchell Li Cheong Man,[1] Joseph C.K. Leung,[3] Sydney C.W. Tang,[3] Kar Neng Lai,[3] Andrew D. Paterson,[2] Florent Soubrier,[4] York P. Pei.[1] *[1]Div of Nephrology, Univ Health Network, Toronto, ON, Canada; [2]Program in Genetics and Genomic Biology, Hospital for Sick Children, Toronto, ON, Canada; [3]Div of Nephrology, The Univ of Hong Kong, Hong Kong, China; [4]INSERM, Univ Pierre et Marie Curie Paris 06 (UPMC), Paris, France.*

Background: Diagnosis of familial glomerular diseases may be confounded by non-specific clinical (i.e. hematuria and proteinuria) and/or pathological findings. Indeed, a recent study of familial focal segmental glomerulosclerosis (FSGS) has identified *COL4A3* and *COL4A4* mutations in ~10% of study families [Kidney Int 86:1253-59, 2014]. In the course of studying a cohort of fIgAN, we unexpectedly identified pathogenic mutations in 13 families with non-IgAN glomerular diseases.

Methods: We performed whole exome sequencing (WES) in 109 patients from 54 families all with at least 2 biopsy-proven cases.

Results: Our WES study identified heterozygous/hemizygous pathogenic *COL4A3* (c.1504+1G>A; p.G291R; p.G695R; p.G1054E; p.G1286R), *COL4A4* (p.Q970X; p.G1508A), and *COL4A5* (p.G48R; p.G325R) mutations in 9 families with fIgAN. These mutations occurred at the canonical splice junction or conserved glycine residues and segregated in all affected subjects within family. In two multiplex families, co-existence of thin basement membrane disease (TBMD) with IgAN was also observed in the biopsied subjects in retrospect. Additionally, putative heterozygous pathogenic variants were found in 3 families in the known genes for FSGS (*ACTN4*, c.398-2A>G), CFHR5 nephropathy (*CFHR5*, p.C449fs), and membranous nephropathy (*PLA2R1*, p.C192G) and homozygous mutation in one family in another known gene for FSGS (*ADCK4*, p.S246N).

Conclusions: The presence of other glomerular diseases may confound the diagnosis of fIgAN in some putatively affected subjects ascertained based on urinary findings or even kidney biopsy. Due to its high prevalence in the general population, TBMD may be an important cause of phenocopy that can confound genetic linkage studies in fIgAN.

SA-PO509

Disease Gene Discovery for Familial IgA Nephropathy (fIgAN) by Whole Exome Sequencing (WES) Xuewen Song,[1] Nicole M. Roslin,[2] Meng Yi Xu,[1] Kairong Wang,[1] Jannel Liu,[1] Bushra Joarder,[1] Amirreza Haghighi,[1] Melody Ren,[1] Mitchell Li Cheong Man,[1] Joseph C.K. Leung,[3] Sydney C.W. Tang,[3] Kar Neng Lai,[3] Andrew D. Paterson,[2] Florent Soubrier,[4] York P. Pei.[1] *[1]Div of Nephrology, Univ Health Network, Toronto, ON, Canada; [2]Program in Genetics and Genomic Biology, Hospital for Sick Children, Toronto, ON, Canada; [3]Div of Nephrology, The Univ of Hong Kong, Hong Kong, China; [4]INSERM, Univ Pierre et Marie Curie Paris 06 (UPMC), Paris, France.*

Background: IgAN is the most common primary glomerular disease worldwide. Genome-wide linkage scans have identified multiple susceptibility loci for fIgAN but no disease gene has yet been identified.

Methods: To identify susceptibility genes for fIgAN, we performed WES in 109 patients from 54 families all with >2 biopsy-proven cases and putatively affected members ascertained with persistent hematuria/proteinuria. In 3 multiplex families each with >5 affected cases, we also performed genome-wide linkage scans under a dominant model and focused WES on regions with suggestive linkage. Standard algorithms for sequence alignment, base calling, and QC filtering were applied to identify rare (MAF<1%) deleterious variants of high (i.e. protein-truncating) and moderate (i.e. inframe indels and deleterious non-synonymous missense variants predicted by PolyPhen-2, Sift, Mutation Assessor, CADD_phred, PhylopPMam_avg, and PhylopVert100_avg) impact.

Results: Overall, 99.8% of the targeted exome were covered with a mean depth of 100x. We examined 19 regions with LOD >1 in 3 multiplex families and ~3,000 immunologic candidate genes. We identified 26 candidate genes (i.e. *IFIH1*, *CD33*, *MSH6*, *ERAP2*, *FUT2*, *MMRN1*, *MINA*, *OAS1*, *TLR1*, *RNASEL*, *MARCO*, *THADA*, *BTN1A1*, *PTPRK*, *RELT*, *ERCC1*, *ASB4*, *LCP1*, *HK3*, *ASH1L*, *LTB*, *FES*, *MPO*, *GP1BA*, *BACH2*, and *EMP3*), each with rare deleterious variants affecting 2 or 3 unrelated families.

Conclusions: Our results suggest extensive genetic heterogeneity in fIgAN with many disease genes each contributing to a small proportion of cases. Future studies with expanded sample size will aid selection of the most promising candidate genes for functional studies. Identification of disease genes for fIgAN has the potential to improve diagnosis and treatment.

Funding: Government Support - Non-U.S.

Discovery of New Risk Gene Loci in IgA Nephropathy: Genome-Wide Human Assay Kyung-Hwan Jeong, Tae Won Lee, Sang Ho Lee, Se Yun Kim, Jin Sug Kim, Shin Yeong Lee, Chun-Gyoo Ihm. *Internal Medicine, KyungHee Univ School of Medicine.*

Background: IgA nephropathy(IgAN) is the most common form of glomerulonephritis in Korea. The etiology of IgAN is complex with high genetic heterogeneity. Several genome wide association studies(GWAS) suggested that specific polymorphisms of candidate genes were associated with susceptibility to IgAN. However, previous contents of GWAS DNA chip were fixed and did not cover SNPs in exon region and promoter region.

Methods: We used the Axiom™ Genome-Wide Human Assay by Affymetrix. The contents of assay are useful to investigate association between several candidate SNPs and specific diseases. We firstly selected 47,777 genes of homo sapiens in NCBI gene database and searched the SNPs in dbSNP database. And the criteria for selection exonic, promoter, and intron SNPs in each gene were following: SNPs with>10% minor allele frequency, >0.1 heterozygosity, known genotype frequencies of SNPs in Asians, SNPs studied in previous study, and unknown SNPs. Logistic regression models were performed to determine odds ratio(OR), 95% confidence interval(CI), and P value. The analysis was using Helix tree program.

Results: To investigate whether specific polymorphisms are involved in the development of the IgAN, 182biopsy confirmed IgAN patients and 455 healthy controls were studied. We selected 378,707 SNPs. We carried out genome wide genotyping on customized Axiom™ Genome-Wide Human Assay Among 378,707 SNPs, 19SNPs showed strongly significant association with IgAN(p<0.00001). We identified at rs201580039,rs12219125 and rs55730189 that implicated the genes encoding KLF14(Kruppel-like factor14,7q32.3,OR 8.04,p=4.95x10^{-7}), intergenic region at chromosome 10(OR0.24,p=1.72x$10^{-5}$and unc-51 like autophagy activating kinase 2(ULK2,17p11.2,OR 8.44, p=3.61x10^{-5}) as susceptibility genes. To validate the previous reported susceptibility SNPs of IgAN , we selected and genotyped 19 SNPs. rs660895 of HLA-DRB1 and rs2856717 of HLA-DQB1 were significantly different between two groups.

Conclusions: These results suggest that these significant SNPs may be useful to investigate the development of IgAN.

SA-PO511

Mannan-Binding Lectin 2 Polymorphisms Were Associated with Progression of IgA Nephropathy Yan Ouyang, Jingyuan Xie, Meng Yang, Xiaoyan Zhang, Xiaoxia Pan, Weiming Wang, Nan Chen. *Nephrology Dept, Ruijin Hospital, Shanghai Jiao Tong Univ, School of Medicine, Shanghai, China.*

Background: Our aim is to evaluate whether MBL2 polymorphism associates with progression of IgA nephropathy (IgAN).

Methods: Patients with Primary lgAN were retrospectively recruitd from 2009 to 2013. Renal specimen was semi-quantitative scored according to the Oxford scoring system. Whole coding and promoter regions of MBL2 were sequenced in 101 patients. Then 3 SNPs (rs11003125, rs7096206 and rs7095891) in promoter and 1 SNP (rs1800450) in exon1 of MBL2 were genotyped in other 185 patients by Sanger sequencing. The associations of the 4 SNPs with patients' clinical, pathological and prognostic parameters were analyzed. Serum MBL level was measured by ELISA.

Results: A total Of 286 patients were enrolled, mean age at time of biopsy was 36.37±12.1 years. ESRD was found in 29 patients (10.1%) after a mean follow-up time of 34.80 months. Among the 4 SNPs, only rs1800450, coding the 54th amino acid of MBL, significantly increased the risk of ESRD. More patients with rs1800450-AA (27.3%) progressed to ESRD compared to patients with GA genotype (15.5%) [P=0.326] or GG genotype (6.8%) [P=0.015]. Then all patients were divided into GG group (n=191), GA group (n = 84) and AA group (n=11) based upon genotypes of rs1800450. There were no differences of demographic, clinical and pathological parameters at time of biopsy, except for proteinuria (P =0.028). Interestingly, serum MBL levels in patients with AA genotype (median 0ng/ml) were significant lower than GA genotype (median 243.28ng/ml) [P<0.001] and GG genotype (median 1033.03ng/ml) [P<0.001]. Kaplan-Meier survival analysis showed that mean survival time of AA group (38.90±5.68 months) was significant shorter than GG group (66.01±1.9months) [P=0.173] and GA group (56.37±2.62 months) [P<0.001].Finally, AA independently increased the risk of ESRD (AA vs GG+GA, HR=26.73, 95%CI 4.92-145.30, P<0.001) after adjusted by sex, age and clinical indicators by COX regression analysis.

Conclusions: IgAN patients with rs1800450-A allele have a higher risk of disease progression probably as a result of lower MBL levels in these patients, which may increase the risk of infection.

SA-PO512

ARHGAP32 as a Candidate Gene for Primary Focal Segmental Glomerulosclerosis Guisen Li, Li Wang. *Nephrology, Sichuan Academy of Medical Sciences & Sichuan Provincial People's Hospital, Chengdu, Sichuan, China.*

Background: Focal and segmental glomerulosclerosis (FSGS) is one of common causes of end-stage renal disease worldwide. Previous studies showed that genetic factor played an important role in the pathogenesis of FSGS. The purpose of this study was to identify the candidategene of FSGS in Chinese familial FSGS.

Methods: Total 21 individuals of a FSGS pedigree were involved in this study. Firstly, we screened the known causal mutations of *ACTN4*, *TRPC6*, and *INF2*gene in this pedigree. Then we conducted a genome wide scan for linkage study. And DNA of four members were assayed by whole exome sequencing. The data were filtrated according to the 1000 Genomes Project, ESP6500 and dbSNPinformation, and database with 69 exome sequencing project (without kidney diseases). By PCR sequencing methods, we detected candidate causal mutation. And then, we tested the mutation in other 97 sporadic FSGS patients and 96 normal controls.

Results: No mutation was detected from those exons of *INF2*, *ACTN4* and *TRPC6* in the FSGS pedigree. 8 loci suggested for linkage were identified, and the maximum two-point parametric LOD score of 1.69 was marked by D5S2115. A mutation (c.C1213G, p.L405V) of *ARHGAP32* gene was identified by combination with exome sequencing, genome-wide scan, function prediction of coding proteins. A new mutation (*c.A3559G, p.T1187A*)of ARHGAP32 *gene* was detected in one sporadicFSGS patient from 97 cases and 96 controls. The ARHGAP32 expression was detected in the glomeruli and tubule.

Conclusions: We found a candidate mutation of *ARHGAP32*gene for primary FSGS by combination with whole genome linkage analysisandwhole exome sequencing.

SA-PO513

Targeted Sequencing in Adults with Focal Segmental Glomerulosclerosis Konstantinos Koutroutsos,[1] Jana Vandrovcova,[2] Thomas M. Connor,[1,2] H. Terence Cook,[2] Marina Loucaidou,[1] Tim Aitman.[3] *[1]West London Renal and Transplant Centre, Imperial College NHS Trust, United Kingdom; [2]Imperial College London, United Kingdom; [3]Inst of Genetics & Molecular Medicine, Univ of Edinburgh, United Kingdom.*

Background: Multiple genes underlying focal segmental glomerulosclerosis (FSGS) and/or steroid resistant nephrotic syndrome (SRNS) have been identified. We aimed to investigate the distribution of gene mutations in adult patients with FSGS by targeted sequencing.

Methods: 94 adults with familial or sporadic FSGS were recruited through a single renal unit in England. The mean age at diagnosis was 46.4, and 61 were male. Ethnicity: 42 Caucasian, 24 Afro-Caribbean, 24 South Asian. History of familial renal disease (14), recurrent FSGS in a renal transplant (21). DNA was extracted from whole blood or saliva using standard protocols. An Illumina TruSeq Custom Amplicon Targeted Next Generation sequencing (NGS) panel was designed covering 21 genes for FSGS. NGS sequencing was performed on the MiSeq v3 system. Data were analysed using our standard Mendelian disease pipeline and all variants were confirmed by Sanger sequencing.

Results: 19 rare, non-synonymous coding variants were identified, affecting 16 individuals, including 3 with a family history and 4 with recurrent disease. 14 variants were heterozygous dominant, 3 compound heterozygous, and 2 X-linked recessive. Known pathogenic mutations included *TRPC6* N143S and *NPHS2* R229Q. Control variants were accurately identified in *INF2* R214H, *NPHS2* V180M, and *MYH9* R1932fs. Other variants included *ACTN4* (1), *CD2AP* (4), *INF2* (1), *ITGB4* (3), *MYH9* (3), *NPHS2* (2), *NFX5* (2), *TRPC6* (2), and *WT1* (3); of these 13 were predicted to be pathogenic by SIFT and/or Polyphen2.

Conclusions: We have shown a high frequency of potentially pathogenic variants in our adult population with FSGS. We did not see enrichment for mutation carriers in those with a documented family history or recurrent disease. Targeted NGS allows rapid and inexpensive identification of these gene mutations.

SA-PO514

Family Risk of Acute Kidney Injury Olafur S. Indridason,[1] Snaevar Sigurdsson,[2] Þórir E. Long,[3] Gisli H. Sigurdsson,[4,6] Martin I. Sigurdsson.[4,5] *[1]Div of Nephrology, Landspitali; [2]Decode Genetics, Reykjavik; [3]Dept of Medicine; [4]Dept of Anesthesia, Landspitali - The National Univ Hospital of Iceland; [5]Faculty of Medicine, Univ of Iceland, Reykjavik, Iceland; [6]Dept of Anesthesia, Perioperative and Pain Medicine, Brigham and Women´s Hospital, Boston, MA.*

Background: Previous studies indicate that certain genetic variants may predispose to acute kidney injury (AKI) in critically ill patients but global assessment of heritability and an unbiased genome-wide assessment of acute kidney injury is lacking. The purpose of this study was to assess the familiality of AKI to support a common genetic background.

Methods: We used data from the clinical laboratory at Landspitali – The National University Hospital of Iceland to find all serum creatinine (SCr) measurements over 20 years. We identified each patients highest SCr value and a baseline SCr within the preceding 6 months, defining AKI as a 50% increase in SCr compared to baseline (highest/baseline SCr>1.5). Patients with ESRD and diseases known to result in AKI were excluded. To assess the familial relationship between individuals, we used the Icelandic Genealogy Database that contains reliable genealogy information on the entire Icelandic nation dating back to the year 1650. Familiality of AKI was assessed by calculating the risk ratio of AKI in 1-5th degree relatives of AKI patients, and significance assessed by comparing the risk ratio to the risk ratio in 1000 randomly selected control groups.

Results: We identified 12.807 individuals with AKI. There was a significantly increased risk of AKI in the relatives of AKI patients with 1st-degree relative risk ratio (RR) of 1.26, 2nd-degree relative RR of 1.08, 3rd-degree relative RR of 1.12 (p<0.001 for all). The risk ratio was even higher for the most severe AKI (highest/baseline SCR>3.0), where 1st-degree relative RR was 1.36 (p=0.006), 2nd-degree relative RR was 1.18 (p=0.067) and 3rd-degree relative RR was 1.14 (p=0.06).

Conclusions: Our results suggest a genetic component in the development of AKI and given the relationship between relative risk and the power to map disease genes by linkage analysis, GWAS studies might yield positive results.

SA-PO515

Premature Death in First Degree Relatives of End Stage Renal Disease Patients Rannveig Skrunes,[1,2] Einar Svarstad,[1,2] Anna Reisaeter,[3] Hans-Peter Marti,[1,2] Bjorn Egil Vikse.[2,4] *[1]Dept of Medicine, Haukeland Univ Hospital, Bergen, Norway; [2]Dept of Clinical Medicine, Univ of Bergen, Bergen, Norway; [3]Dept of Transplantation Medicine, Rikshospitalet Oslo Univ Hospital, Oslo, Norway; [4]Dept of Medicine, Haugesund Hospital, Haugesund, Norway.*

Background: Increased risk of end stage renal disease (ESRD) and death in Norwegian living kidney donors has been reported. The majority of donors were related to the recipient. The present study investigates risk of death in first degree relatives of ESRD patients.

Methods: The Norwegian Population Registry has since 1960 registered all Norwegian Citizens. Sibling data are complete for most individuals since 1953. The National Cause of Death Registry has registered causes of death since 1969 and the Norwegian Renal Registry has registered all individuals with ESRD since 1980. The registries were linked. All citizens born in Norway with at least one registered first degree relative were included. A cohort-design was used, ESRD in a first degree relative was the main exposure variable and death and causes of death were the main outcome variables. Adjusted hazard ratios (aHR) were calculated using Cox regression analysis.

Results: 5,217,568 individuals were included, 27,650 had at least one relative with ESRD. 844,407 died during follow-up. aHR for death was 1.14 (95% CI 1.10-1.17) in individuals with a relative with ESRD compared to those without a relative with ESRD. Excluding known hereditary renal disease, aHR decreased to 1.12 (95% CI 1.09-1.16). Cardiovascular death aHR was 1.15 (95% CI 1.10-1.21), of which cerebrovascular death 1.34 (95% CI 1.22-1.47). aHR for death due to non-hereditary renal/ureteric disease was 2.32 (95% CI 1.84-2.94) with renal failure 1.80 (95% CI 1.26-2.56) and primary renal disease 5.88 (95% CI 4.04-8.56) as main contributors. Compared to individuals without a relative with ESRD, death occurred 9 years earlier in individuals who died before the age of 50 and 1 year earlier in individuals who died at age 70.

Conclusions: ESRD in first degree relatives was associated with premature death. Death due to cardiovascular- and non-hereditary renal diseases increased the most.

Identifying Genetic Predictors of Skin Cancer in Renal Transplant Populations Caragh P. Stapleton,[1] Mark Mccormack,[1] Dervla M. Connaughton,[2] Paul J. Phelan,[3] Gianpiero Cavalleri,[1] Peter J. Conlon.[2] *[1]Dept of Molecular and Cellular Therapeutics, Royal College of Surgeons, Dublin 2, Dublin, Ireland; [2]Kidney Centre, Beaumont Hospital, Dublin 9, Dublin, Ireland; [3]Dept of Nephrology, Royal Infirmary of Edinburgh, Edinburgh, NHS Lothian, United Kingdom.*

Background: Renal-transplant recipients have a 33-fold increased risk of developing non-melanoma skin cancer relative to an age-matched non-transplanted individual. Some of this risk can be attributed to factors such as type of immunosuppressant treatment, however much of the risk remains unaccounted for. In this study we set out to map germline genetic variations influencing the development of skin cancer in our cohort of 325 renal-transplant recipients, using a genome-wide association study (GWAS) and candidate gene study design.

Methods: Both logistic regression and survival analysis was applied in our GWAS. Survival analysis was used in our candidate gene study. Multiple robust genetic loci for skin cancer in non-transplant populations have been identified via large GWAS. These genetic predictors of skin cancer (n=21) identified from non-transplant populations were examined to see if they have a higher effect size in renal-transplant recipients compared to the general population.

Results: For the candidate SNP analysis, a nominally significant association was found with a SNP in the *MC1R* gene (p= 0.0157). The variant was found to have the same direction of affect as described in the original study and the odds ratio was higher. The presence of one or more copies of the minor allele caused a significant decrease in time to develop skin cancer post renal transplantation (hazard ratio = 2.06). We found a significant association in our GWAS between time to developing skin cancer post transplantation and a variant in *SPOCK1* ($p = 4x10^{-8}$). We found that heterozygote individuals developed skin cancer 7 times faster than wild type homozygotes.

Conclusions: Associations were found between time to developing skin cancer post-transplantation and the genes *MC1R* and *SPOCK1*. We will be carrying out further testing in other cohorts for validation of results. This work is funded by Irish Research Council for Science, Engineering and Technology.

Genetic Variants in ANCA-Associated Vasculitis: A Meta-Analysis Chinar Rahmattulla,[1] Antien Mooyaart,[1] Daphne Van Hooven,[1] Jan W. Schoones,[1] Jan A. Bruijn,[1] Olaf Dekkers,[1,2] European Vasculitis Genetics Consortium,[3] Ingeborg M. Bajema.[1] *[1]Leiden Univ Medical Center; [2]Aarhus Univ Hospital.*

Background: Genetic factors may influence the pathogenic pathways leading to anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV). We performed a meta-analysis to determine the genetic variants most likely associated with AAV and investigated whether diagnostic and serological subtypes within AAV have distinct genetic backgrounds.

Methods: Studies investigating the association between genetic variants and AAV in humans were searched in PubMed, Embase, and Web of Science. All variants significantly associated with AAV in at least one study and investigated in at least two studies were included. Additionally, data on these genetic variants from the largest GWAS in AAV were included to increase the validity of this meta-analysis.

Results: The literature search yielded 5180 articles. Fifty-three articles investigating 55 genetic variants were included, 31 of which remained associated with AAV in a meta-analysis. These genetic variants were in or near the following genes: *SERPINA1*, *CD226*, *CTLA-4*, *HLA-B*, *HLA-DP*, *HLA-DQ*, *HLA-DR*, *HSD17B8*, *IRF5*, *PTPN22*, *RING1/RXRB*, *RXRB*, and *TLR9*. Moreover, we identified genetic distinctions between granulomatosis with polyangiitis and microscopic polyangiitis and between proteinase 3 ANCA vasculitis and myeloperoxidase ANCA vasculitis. In 79% of the genetic variants, subdivision based on ANCA serotype resulted in higher odds ratios than subdivision based on clinical diagnosis.

Conclusions: This meta-analysis identified 31 genetic variants associated with AAV, supporting a role for alpha-1-antitrypsin, the major histocompatibility complex system, and several distinct inflammatory processes in AAV pathogenesis. Our results indicate that subdivision of AAV based on ANCA serotype has a stronger genetic basis than subdivision based on clinical diagnosis.

SA-PO518

Meta-Analyses of Genetic Associations in New Onset Diabetes After Kidney Transplantation Katherine A. Benson,[1] A.J. McKnight,[1] Alexander P. Maxwell.[1,2] *[1]Centre for Public Health, Queen's Univ Belfast, Belfast, Northern Ireland, United Kingdom; [2]Regional Nephrology Unit, Belfast City Hospital, Belfast, Northern Ireland, United Kingdom.*

Background: New-onset diabetes after transplantation (NODAT) is a serious complication following solid organ transplant. There is evidence of a genetic contribution to this disease and we have previously identified genetic risk factors associated with NODAT following kidney transplantation. These meta-analyses examine the pooled effect of genetic variants associated with NODAT in kidney transplant populations.

Methods: Relevant articles investigating the association between genetic markers and NODAT were identified by means of a database search of PubMed, Web of Science and Google Scholar from 1945 to 2015. Variants replicated in a minimum of three studies were included for analysis. Data was analysed using a random effects model in Review Manager 5.3. The association between identified variants and NODAT was calculated at the per-study allele level, where original studies were concordant with Hardy-Weinberg Equilibrium, to generate overall significance values and effect sizes.

Results: Our literature search returned 4,147 citations. Of the 36 eligible articles identified, 18 genetic variants from 13 genes were included for analysis. Of these, three were significantly associated with NODAT by meta-analysis at the 5% level of significance; *TCF7L2* rs7903146 p=0.01 OR=1.41, 95%CI=1.07-1.85 (n=2967 individuals), *CDKAL1* rs10946398 p=0.006 OR=1.43, 95% CI=1.11-1.85, (n=696 individuals), and *KCNQ1* rs2237892 p=0.0007 OR=0.70, 95% CI=0.54-0.91, (n=1270 individuals).

Conclusions: These meta-analyses identified three genetic variants statistically associated with NODAT. Ideally, these variants should be assessed in less heterogeneous studies with larger numbers of kidney transplant recipients with a carefully defined NODAT phenotype.

SA-PO519

New Prioritization and Burden Analyses of Rare Variants in 208 Candidate Genes Are Questioning the Pathogenicity of Previously CAKUT-Associated Genetic Variants Nayia Nicolaou,[1] Sara L. Pulit,[1] Isaac J. Nijman,[1] Albertien M. van Eerde,[1] Ernie M.H.F. Bongers,[2] Rachel H. Giles,[3] Nine V. Knoers,[1] Kirsten Y. Renkema.[1] *[1]Medical Genetics, UMC Utrecht, Utrecht, Netherlands; [2]Human Genetics, Radboudumc, Nijmegen, Netherlands; [3]Nephrology and Hypertension, UMC Utrecht, Utrecht, Netherlands.*

Background: The leading cause of end-stage renal disease in children is attributed to congenital anomalies of the kidney and urinary tract (CAKUT). Familial clustering and mouse models support the presence of monogenic causes. Genetic testing is insufficient as it mainly focuses on *HNF1B* and *PAX2* mutations that are thought to explain CAKUT in 5-15% of patients.

Methods: To identify novel, potentially pathogenic variants in additional genes, we designed a panel of genes identified from studies on familial forms of isolated or syndromic CAKUT and genes suggested by *in vitro* and *in vivo* CAKUT models. The coding exons of 208 genes were analyzed in 453 patients with CAKUT using next-generation sequencing. Rare truncating, splice-site variants and non-synonymous variants, predicted to be deleterious and conserved, were prioritized as the most promising variants to have an effect on CAKUT.

Results: Previously reported disease-causing mutations were detected. Five variants were fully penetrant causal mutations that improved diagnosis. We prioritized 148 candidate variants in 151 patients, found in 82 genes, for follow up studies. Using a burden test, we found no significant excess of rare variants in any of the genes in our cohort compared to controls.

Conclusions: Thus, in a study that represents the largest set of genes analyzed in CAKUT patients to date, the contribution of previously implicated genes to CAKUT risk is significantly smaller than expected and the disease may be more complex than previously assumed.

SA-PO520

Comparison of Genetic Associations with Different Definitions of CKD Progression in Children Matthias Wuttke,[1] Elke Wuehl,[2] Li Luo,[3] Jayanta Gupta,[4] Bradley Warady,[5] Susan L. Furth,[6] Anna Kottgen,[1] Franz S. Schaefer,[2] Craig S. Wong.[3] *[1]Freiburg Univ, Germany; [2]Heidelberg Univ, Germany; [3]Univ New Mexico; [4]Texas Tech Univ; [5]Children's Mercy, Kansas City; [6]CHOP, Univ Pennsylvania.*

Background: The PediGFR Consortium aims to identify genetic factors associated with pediatric chronic kidney disease (CKD) progression. The optimal definition of CKD progression for testing is unclear. To address this question, we performed genome-wide association studies (GWAS) of two different definitions of CKD progression, slope of the annual change in estimated GFR (eGFR) versus time-to-event (TTE).

Methods: There were >8 million genotyped and imputed markers from 1,122 patients. The calculation of slope was based on 2-41 eGFR values per patient. TTE was a combined primary endpoint of dialysis, transplant, 50% GFR loss or GFR <5 ml/min/1.73m2. Respectively, cox proportional hazards and linear regressions were used for the GWAS of TTE and slope. Both analyses were adjusted for age, sex, principal components and baseline eGFR. For each definition, data were meta-analyzed from five study-/ancestry-specific groups in PediGFR.

Results: For TTE, follow-up time was 1.66-5.0 years (IQR) and an event rate of 34%. For slope, mean slope was -4.2 ml/min/1.73m2. For comparison, we focused on SNPs present in all five groups with a minor allele frequency >0.05, and I2<50%. For TTE, 6 genomic regions contained one or more of such SNPs with p<1E-6, one of which reached genome-wide significance (p<5E-8). Hazard ratios per risk allele ranged from 1.58-1.97. For slope, there were 3 regions with p<1E-6, one of which reached genome-wide significance. All of the 6 TTE variants were nominally associated with slope (one-sided p<0.05), whereas 2 of the 3 slope variants were nominally associated with TTE. None of the loci with p<1E-6 overlapped between the two definitions.

Conclusions: Genetic variants associated with CKD progression differed based on the definition of the phenotype. GWAS of TTE identified more loci at p<1E-6 than slope and these were biologically more plausible based on current knowledge of kidney disease. However, the number of genome-wide significant loci was the same.

SA-PO521

New Candidate Genetic Loci Associated with Pediatric Proteinuria in the CKiD Cohort Sophie Limou,[1] Derek Ng,[2] Kimberly J. Reidy,[3] Robert Woroniecki,[4] Susan L. Furth,[5] Bradley Warady,[6] Craig S. Wong,[7] Jeffrey B. Kopp,[8] Cheryl Ann Winkler,[1] Frederick J. Kaskel.[3] *[1]Leidos Biomedical Research, Inc / NCI-Frederick National Laboratory; [2]Johns Hopkins Bloomberg School of Public Health; [3]Children's Hospital at Montefiore/ Albert Einstein College of Medicine; [4]Stony Brook Univ Hospital; [5]Children's Hospital of Pennsylvania; [6]Children's Mercy Hospital; [7]Univ of New Mexico; [8]NIDDK, NIH.*

Background: Proteinuria is an early marker for chronic kidney disease in adults and children. Here, we sought to identify genetic variants associated with baseline proteinuria in African American children diagnosed with chronic kidney disease from the CKiD cohort.

Methods: We genotyped 140 CKiD participants using the Illumina HumanExome beadchip v1.2 comprising over 250,000 markers, including putative functional exonic variants that were implicated in common metabolic disorders. 81,460 SNPs passed quality control and were tested for association with baseline proteinuria in 129 children with chronic kidney disease by linear regressions adjusted for age, gender, and the first five eigenvectors from the population stratification analysis.

Results: We identified several genetic loci that were significantly associated with proteinuria (P£10^{-8}), as well as new candidate loci (10^{-5}<P<10^{-8}). Among the top hits, we notably revealed kidney-expressed genes that were previously associated with the TGFβ pathway, renal homeostasis, IgA nephropathy, congenital kidney disease, and vascular integrity (*e.g. VAV3*, *STRA6*, and *HDAC7*).

Conclusions: Our study emphasizes the power of unbiased large genetic screenings to discover new factors associated with pediatric kidney conditions. These new results warrant independent replication and functional validation.

SA-PO522

Genotype-Phenotype Analysis in Pediatric Patients with WT1 Glomerulopathy Eujin Park,[1] Yo Han Ahn,[1] Hee Gyung Kang,[1,2] Hye Won Park,[3] IL-Soo Ha,[1] Hae Il Cheong.[1,2] *[1]Dept of Pediatrics, Seoul National Univ Children's Hospital, Seoul, Korea; [2]Research Coordination Center for Rare Diseases, Seoul National Univ Hospital, Seoul, Korea; [3]Dept of Pediatrics, Seoul National Univ Bundang Hospital, Seongnam, Korea.*

Background: The *WT1* gene plays an essential role in urogenital and kidney development and its mutations manifest two different types of glomerulopathies, Denys-Drash syndrome (DDS) and Frasier syndrome (FS). In this multicenter retrospective cohort study, genotype-phenotype correlations in Korean pediatric patients with *WT1* mutations were analyzed.

Methods: During the period from 2001 to 2015, *WT1* mutations were detected in a total of 23 children by genetic screening.

Results: The patients were grouped into FS (n=10, having a mutation in intron 9) and DDS (n=13, having an exon mutation). Nine (69%) DDS patients presented as congenital (CNS) or infantile nephrotic syndrome (INS), while 7 (70%) FS patients presented as steroid-resistant focal segmental glomerulosclerosis. Interestingly, monozygotic twin patients with DDS presented as end-stage renal disease (ESRD) without any previous history of glomerulopathy. Progression to ESRD was noted in 11 (85%) DDS patients at the median age of 0.22 (interquartile range [IQR], 0.07-1.65) years and in 5 (50%) FS patients at age 9.30 (3.25-16.50) years. Five (38%) DDS patients died at age 0.59 (0.27~2.29) years. Disorder of sexual development (DSD) was accompanied in 8 (62%) DDS and 7 (70%) FS patients. Three (13%) patients (2 with DDS and 1 with FS) had diaphragmatic defect/hernia. Five (22%) and six (26%) patients underwent prophylactic nephrectomy and gonadectomy, respectively. Among the rest of the patients, Wilms tumor and gonaldoblastoma developed in 3 DDS patients and 1 FS patient, respectively.

Conclusions: The clinical manifestations and disease course of the Korean patients with *WT1* glomerulopathy were mostly same as those of previous reports. Of note, patients with *WT1* mutations may manifest atypically, i.e., chronic kidney disease without any preceding history of significant proteinuria and/or NS. DSD is common in both in FS and DDS and is a useful diagnostic clue. Prophylactic nephrectomy/gonadectomy is strongly recommended.

SA-PO523

Age of the NPHS2 p. V260E Mutation, a Cause of Childhood Steroid Resistant Focal Segmental Glomerulosclerosis, in the Ancestral Population of Black Africans in Durban, South Africa George W. Nelson,[1] Rajendra Bhimma,[2] Sophie Limou,[1] Jeffrey B. Kopp,[3] Cheryl Ann Winkler.[1] *[1]FNLCR, NCI, Frederick, MD; [2]Univ of KwaZulu-Natal, Durban, South Africa; [3]NIDDK, NIH.*

Background: A study of 44 children with sporadic steroid resistant nephrotic syndrome (SRNS) with focal segmental glomerulosclerosis (FSGS) histology, in Durban, South Africa, revealed that 30% carried two copies of a missense mutation, p. V260E, in the podocin gene, *NPHS2*. This mutation has previously been reported as recessively associated with FSGS in consanguineous families in regions at one time in the Omani empire, suggesting spread with this empire. We speculated that the children in our study might be cryptically related from common descent from a recent ancestor.

Methods: Inheritance of the V260E mutation from two parents with a common ancestor will result in a region of homozygosity surrounding the locus, indicating the overlap of extended haplotypes preserved around the locus. To test for this we genotyped 10 individuals homozygous for the mutation, and 74 individuals homozygous for the wild type variant, with the Illumina exome chip. After QC, this chip provided 1674 markers within 20 megabases (Mb) ofV260E. To predict the distribution of lengths of homozygous regions around the locus as a function of the number of generations between parents and their common ancestor carrying the mutation, we performed 10,000 coalescence simulations of recombination in each generation for n generations from 6 to 48.

Results: Plotting heterozygous and homozygous loci in the region surrounding V260E clearly showed regions of homozygosity around the locus. 8 of the 10 individuals had segments of homozygosity from 1.9 to 3.6 mB. This distribution of lengths is inconsistent with a common ancestor within the last 20 generations.

Conclusions: Cryptic consanguinity does not explain the presence of homozygosity for NPHS2 V260E among Durban children with SR-FSGS. The indicated age of the mutation is inconsistent with introduction by the Omani Empire, which spread in East Africa beginning in the 1690s.

SA-PO524

Genetic Markers Associated with Hemoglobin in the PediGFR Consortium Meredith A. Atkinson,[1] Anna Kottgen,[2] Elke Wuehl,[3] Craig S. Wong,[4] Matthias Wuttke,[2] Franz S. Schaefer,[3] Bradley Warady,[5] Susan L. Furth.[6] *[1]Johns Hopkins Univ; [2]Univ of Freiburg; [3]Heidelberg Univ; [4]Univ of New Mexico; [5]Univ of Missouri-Kansas City; [6]Univ of Pennsylvania.*

Background: Genome-wide association studies have identified genetic variants associated with erythrocyte traits, but associations in children with CKD have not been studied. Our goal was to identify whether single nucleotide polymorphisms (SNPs) are associated with hemoglobin (Hgb) decline in progressive CKD in children.

Methods: Longitudinal analysis of genotype and Hgb in 1,141 European (n=806) or Turkish (n=335) children in the Pediatric Investigation for Genetic Factors Linked to Renal Progression (PediGFR) consortium. With a candidate marker approach, linear mixed-effect modeling for Hgb regressed on time and genotype of 24 previously reported SNPs was performed, stratified by ethnicity. Bonferroni correction was used to account for multiple comparisons.

Results: In Europeans, a nominally significant association between SNPs on the RCL1 (p=0.03), BCL11A (p<0.001), RTBDN (p=0.006), and TFR2 (p=0.007) genes and increased risk for Hgb decline over time was noted. Among Turks, a significant association was seen with SNPs on the RCL1 (p=0.03), KIT (p=0.006), BCL11A (p<0.001), RTBDN (p=0.006), CD164 (p=0.031) and HBS1L/MYP (p=0.031) genes. The RCL1 gene has been associated with MCH. The TFR2 and HBS1L/MYB genes are associated with Hgb; TFR2 mediates cellular iron uptake and HBS1L/MYB is a quantitative trait locus controlling fetal Hgb. The KIT, BCL11A, RTBDN, and CD164 genes are associated with MCV, and have roles in hematopoiesis (KIT and CD164), persistence of fetal Hgb (BCL11A) and retinoid binding (RTBDN). After Bonferroni correction, only the SNP on BCL11A remained significantly associated with Hgb in Europeans and Turks, with marginal significance for SNPs on RTBDN and TFR2 in Europeans and on KIT and RTBDN in Turks.

Conclusions: We confirmed the association of selected genetic variants with decline in Hgb in children with progressive CKD, with differential effects by ethnicity at specific loci. Clarification of the genes involved in susceptibility to anemia has the potential to identify new therapeutic targets.

Cell-Free Hemoglobin and HMOX1 in Sickle Cell Nephropathy

Santosh Saraf,[1] Xu Zhang,[1] Binal N. Shah,[1] Krishnamurthy P. Gudehithlu,[2] Jose A.L. Arruda,[1] Ashok K. Singh,[2] Victor R. Gordeuk.[1] *[1]Medicine, Univ of Illinois at Chicago, Chicago, IL; [2]Nephrology, John H. Stroger, Jr Hospital of Cook County, Chicago, IL.*

Background: Chronic kidney disease (CKD) is observed in over 50% of adults with sickle cell disease (SCD) and hemoglobinuria, a consequence of intravascular hemolysis, is independently associated with CKD stage and its progression. In this study we investigate the mechanistic role of hemoglobinuria and HMOX1, the rate limiting enzyme for heme metabolism, in SCD nephropathy.

Methods: Urinary tubular (kidney injury molecule-1, KIM-1) and glomerular (nephrin) biomarkers of injury were measured in 32 SCD patients by ELISA from the University of Illinois at Chicago (UIC). We then cultured human kidney-2 (HK2) tubular cells with lyophilized hemoglobin (L-Hb) to determine biological responses and expression of candidate genes. We examined the association of CKD with 11 tag SNPs and the GT-repeat polymorphism in HMOX1 in 247 UIC SCD patients and in a separate replication cohort (Walk-PHaSST) of 482 SCD patients.

Results: Urine KIM-1 correlated with increasing urine cell-free hemoglobin concentration (P=0.003), while urine nephrin levels did not. HK2 culture studies showed increasing KIM-1 concentrations in the culture medium (P=0.01), decreasing HK2 cell viability (P=0.01), increased HMOX1 expression (P=0.0001) and protein concentration (P<0.0001) with incremental concentrations of L-Hb. We identified a SNP in HMOX1 (rs743811, MAF=0.14) that was significantly associated with CKD stage (OR 2.8, P=0.0003) and CKD stage ³3 (OR 3.0, P=0.02) in the UIC cohort and with ESRD (OR 9.8, P=0.0004) and CKD stage ³3 (OR 2.3, P=0.04) in our replication cohort. UIC SCD patients with £25 GT-repeats in the promoter region of HMOX1, known to be associated with increased HMOX1 inducibility and activity, had higher estimated glomerular filtration rate (eGFR)(β=9.2, P=0.01).

Conclusions: Cell-free hemoglobin contributes to sickle cell nephropathy through renal tubular injury. A tag-SNP in HMOX1, rs743811, was associated with kidney disease and the presence of shorter (GT)n repeats correlated with increasing eGFR, raising the possibility that altered HMOX1 activity has a critical role in SCD-nephropathy.

Telomere Attrition Is Associated with Renal Replacement Therapy and Immunosuppressive Treatment in End-Stage Renal Disease Patients

Karin Luttropp,[1] Louise Nordfors,[2] Dagmara Mcguinness,[3] Abdul Rashid Tony Qureshi,[2] Peter F. Barany,[2] Peter Stenvinkel.[2] *[1]Dept of Molecular Medicine and Surgery, Karolinska Inst, Stockholm, Sweden; [2]Dept of Clinical Science, Intervention and Technology, Karolinska Inst, Stockholm, Sweden; [3]Inst of Cancer Sciences, Univ of Glasgow, Glasgow, United Kingdom.*

Background: Telomere attrition is a feature of ageing and is accelerated by renal disease. The effects of renal replacement therapy (RRT) and immunosuppressants on telomere length and attrition are unknown. We therefore investigated changes in telomere length during 12 months of RRT and effects of immunosuppressants.

Methods: Telomere length was measured in whole blood DNA from 47 renal transplantation (RTx) and 49 dialysis patients. Data were collected at baseline and after 12 months of RRT. Telomere length determination was performed by qPCR using a Roche Light Cycler LC480. The relative T/S ratio (repeat copy number to single gene copy number) was determined in relation to the control DNA sample. Non-parametric statistical tests were used.

Results: RTx patients had a greater telomere attrition than dialysis patients (p=0.008), despite no significant differences in telomere length at baseline or after 12 months. RTx patients were divided into those receiving azathioprine (n=11) and those receiving mycophenolate (n=32). Mycophenolate-treated patients had greater telomere attrition than patients receiving azathioprine (p=0.007), although telomere length at baseline and after 12 months was not significantly different.

Conclusions: RTx patients have a greater telomere attrition than dialysis patients over the course of 12 months; this may reflect an increased stress associated with the transplantation procedure itself as opposed to dialysis treatment. This raises questions regarding the potential risk of accelerated ageing in RTx, which is commonly considered by be a superior form of RRT. In addition, mycophenolate-treated patients show greater telomere attrition than azathioprine-treated patients. This is currently being investigated further, as it could have clinical implications on the choice of treatment regimen.

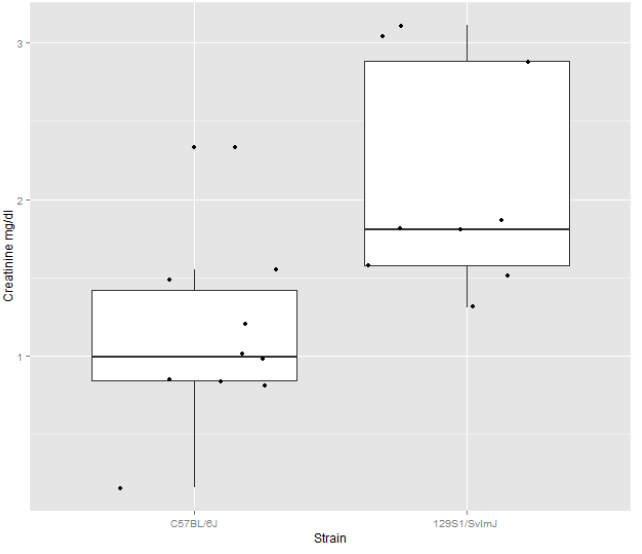
Differences in Susceptibility to Cisplatin Nephrotoxicity Among 8 Mouse Strains

Gabor Bodonyi-Kovacs, Rosa Chan, Thu H. Le. *Renal Div, Univ of Virginia, Charlottesville, VA.*

Background: Cisplatin is a widely used chemotherapeutic agent with remarkable efficacy, but its use is limited by significant nephrotoxicity. Significant differences in susceptibility to nephrotoxicity among individual patients have been noted, but predicting those at risk remains a challenge. To begin to identify genes that play a role in susceptibility to cisplatin nephrotoxicity (CPN), we set out to determine differences in CPN among 8 genetically distinct founder mouse strains of the Collaborative Cross: A/J, C57BL/6J, 129S1/SvImJ, NOD/ShiLtJ, NZO/HlLtJCAST/EiJ,PWK/PhJ, and WSB/EiJ.

Methods: 10-14 week old male mice received ip. injection of 25 mg/kg cisplatin and serum was collected 72 hours later prior to sacrifice. Serum urea nitrogen (BUN) was measured for the 8 strains using a nonenzymatic, colorimetric kit (Arbor Assays) and analyzed by one way ANOVA and two sided t-test. Serum creatinine was measured using an enzymatic, colorimetric kit (Crystal Chem) and analyzed by a two sided t-test for the 2 strains that showed the largest difference in BUN.

Results: The 8 strains differed significantly in their serum BUN values (p=0.042). The number of animals in each group, and the mean and SD of BUN (mg/dl) were as follows: C57BL/6J (n=4) 188.6±9.2, CAST/EiJ (n=3) 207.9±32.7, NOD/ShiLtJ (n=5) 236.7±93.0, PWK/PhJ (n=4) 240.9±27.2, WSB/EiJ (n=5) 254.1±51.6, A/J (n=5) 267.6±62.3, NZO/HlLtJ (n=5) 290.0±50.7,129S1/SvImJ (n=4) 319.5 ±28.3. The biggest differences were seen between the C57BL/6J and 129S1/SvImJ strains, (p = 0.0001). In direct comparison the serum creatinine was significantly different between C57BL/6J (n=10) and 129S1/SvImJ (n=9) strains, (p=0.0047) (Figure 1).



Conclusions: Crosses from "susceptible" and "resistant" mouse strains may enable identification of novel genetic determinants governing individual susceptibility to CPN.

The PAX2-Related SNP rs11190739 Is Associated with Accelerated Loss of GFR in Diabetes Mellitus

Paul R. Goodyer,[1] Melanie Cosgrove,[1] James C. Engert.[2] *[1]Pediatric Nephrology, Research Inst of McGill Univ Health Centre, Montreal, QC, Canada; [2]Genetics, McGill Univ, Montreal, QC, Canada.*

Background: In embryonic kidney, PAX2 is crucial for optimal branching of the ureteric bud and final nephron number. Previous studies show that common polymorphic variants of the PAX2 gene are associated with a 10% decrease in newborn kidney size. Brenner proposed that individuals with suboptimal nephron number might have accelerated loss of GFR in the setting of acquired renal disease in adulthood.

Methods: We used PLINK software to test for an association between PAX2 SNPs and reduced GFR among Caucasians (N=225) entered into the FIND ("Family Investigation of Nephropathy and Diabetes") cohort available through dbGaP. This cohort of adult diabetics consisted of 175 Afro-American, 225 European-American and 257 Mexican Americans with eGFR data 15-25 years after onset of diabetes. Association testing that incorporated a genomic inflation factor, as well as gender and duration as covariates was used. To test Brenner's hypothesis, we tested this PAX2 SNP for an additional association with subtle newborn renal hypoplasia among 225 healthy Caucasian newborns from Montreal. Kidney volume was measured by ultrasonography within the first 3 days of life.

Results: We identified a SNP (rs11190739) in the FIND cohort (MAF=6.5%) that was associated with a 15% decrease in GFR exclusively among European-American diabetics with one or more minor alleles (p=0.022). eGFR (ml/min/1.73m^2) in European Americans was 70.71 for GG individuals, 61.64 for GT, and 41.9 for TT. No association was found between the rs11190739 SNP and eGFR among Afro-American and Mexican-American

subjects. Among healthy Montreal newborns, this same PAX2 SNP (rs11190739) was associated with a 10.2% decrease in newborn combined kidney volume in 14.6% of babies who were heterozygous for this common variant (p=0.036).

Conclusions: Our study provides the first evidence that a common PAX2 variant associated with newborn renal hypoplasia is also associated with decreased eGFR among Caucasians with diabetes mellitus for 15-25 years.

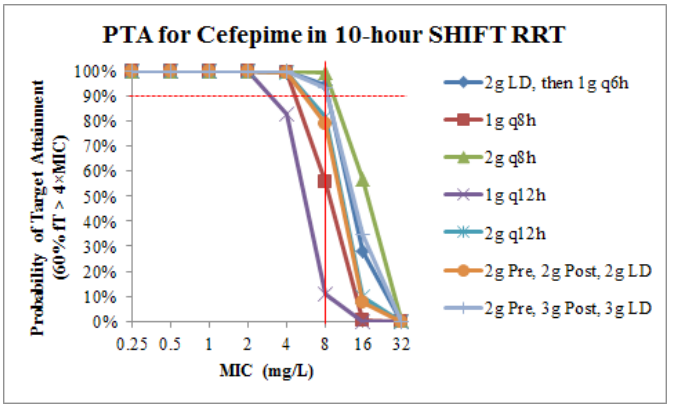
Cefepime Dosing in Modeled Critically Ill Patients Receiving SHIFT Hemofiltration or Hemodialysis Renal Replacement Therapies

Katherine N. Gharibian, Susan J. Lewis, Bruce A. Mueller. *College of Pharmacy, Univ of Michigan, Ann Arbor, MI.*

Background: Cefepime is an antibiotic commonly used in the ICU where acute kidney injury (AKI) is prevalent. SHIFT therapy, a 6-12 hour renal replacement therapy (RRT), also referred to as Prolonged Intermittent Renal Replacement Therapy (PIRRT) or Slow Low Efficiency Daily Dialysis (SLEDD), is increasingly utilized to help treat AKI. However, dosing information for cefepime in critically ill patients receiving SHIFT therapy is currently lacking.

Methods: Using previously-published pharmacokinetic (PK) data and a PK model developed for critically ill patients receiving SHIFT RRT, a series of 5000-subject Monte Carlo simulations were performed for 18 cefepime regimens in 8 scenarios with varying duration (8 & 10 hr), effluent rate (4 & 5 L/hr), modality (HF/HD), and time of SHIFT relative to cefepime doses. Cefepime regimens were evaluated on the probability of attaining a free drug concentration equal to at least the minimum inhibitory concentration (MIC)×4 for ≥60% of the dosing interval during the first 48 hours of therapy. Optimal regimens yielded a probability of target attainment (PTA) ≥90% for MIC values ≤8 mg/L using the smallest total daily dose.

Results: Cefepime 1 g q6 hours with a 2 g loading dose was the only regimen to yield a PTA ≥90% in all 8 SHIFT settings while limiting the total daily maintenance dose to 4 g. This dosing regimen resulted in 48-hour mean trough concentrations >32 mg/L in most subjects.



Conclusions: In PK models of critically-ill subjects receiving 8 or 10 hours of SHIFT RRT, a cefepime dose of 1 g q6 hours with a 2 g loading dose yielded pharmacodynamic target attainment for >90% of the population.

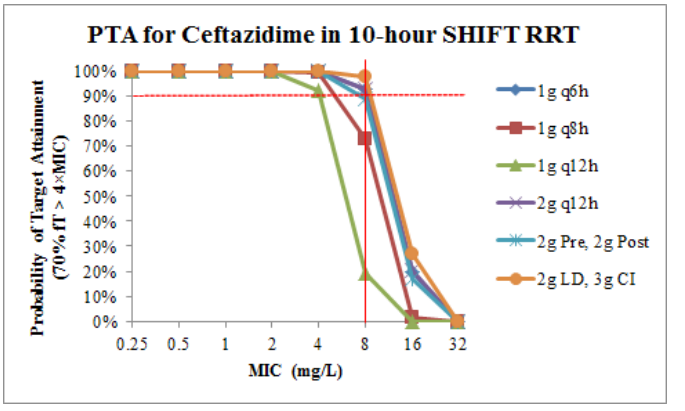
Identification of Optimal Ceftazidime Dosing Regimens in Modeled Critically Ill Patients Receiving SHIFT Renal Replacement Therapy

Katherine N. Gharibian, Susan J. Lewis, Bruce A. Mueller. *College of Pharmacy, Univ of Michigan, Ann Arbor, MI.*

Background: Ceftazidime is an antibiotic commonly used in critically ill patients. Ceftazidime doses of 2 g every 12 hours have been recommended for continuous renal replacement therapies (CRRT), however, no studies have evaluated the optimal dose in patients receiving SHIFT Therapy (NxStage Medical), a 6-12 hr RRT commonly referred to as Prolonged Intermittent Renal Replacement Therapy (PIRRT) or Slow Low Efficiency Daily Dialysis (SLEDD).

Methods: Pharmacokinetic (PK) data compiled from previously-published studies were used to develop models for critically ill patients receiving intermittent hemofiltration (HF) or hemodialysis (HD). Eight models were developed to account for the variability in settings including duration (8 & 10 hr), effluent rate (4 & 5 L/hr), modality (HF/HD), and time of SHIFT relative to ceftazidime dose. Using a series of 5000-subject Monte Carlo simulations, 12 ceftazidime regimens were applied to each model and evaluated for the probability of attaining free drug concentrations equal to or greater than the minimum inhibitory concentration (MIC)×4 for ≥70% of the dosing interval during the first 48 hours of therapy. Optimal regimens yielded a probability of target attainment (PTA) ≥90% for MIC values ≤8 mg/L, the MIC for *Pseudomonas aeruginosa*.

Results: Ceftazidime administered in 4 g total daily doses (2 g q12 hours; 1 g q6 hours) yielded a PTA ≥90% in all 8 RRT models. Continuous infusion of the drug (3 g continuous infusion with a 2 g loading dose) achieved similar PTA values.



Conclusions: Published ceftazidime CRRT doses (2 g every 12 hours) yielded 90% PTA in modeled critically ill patients receiving 8 or 10 hours of SHIFT RRT. Future studies should validate these findings in the clinical setting.

SA-PO531

Use of Monte Carlo Simulation to Determine Optimal Meropenem Regimens in Patients Receiving SHIFT Renal Replacement Therapy

Susan J. Lewis, Katherine N. Gharibian, Bruce A. Mueller. *College of Pharmacy, Univ of Michigan, MI.*

Background: Current antibiotic dosing regimens often result in subtherapeutic concentrations in critically ill patients, but scant pharmacokinetic (PK) data exist to support antibiotic dosing. This study applied Monte Carlo simulations (MCS) to determine the initial meropenem regimen to treat critically ill patients receiving SHIFT Renal Replacement Therapy (RRT), a daily prolonged intermittent RRT.

Methods: Body weight & PK parameter [non-renal clearance, free fraction, volume of distribution & extraction coefficients] estimates with variability were obtained from relevant published studies. Values were randomly selected from the log-Gaussian distribution within the assigned limits to vary individual free meropenem concentration profiles. MCS were performed for 13 meropenem regimens including weight-based and pre- & post-SHIFT dosing, in 4 different SHIFT settings (4L/hour x 10 hours or 5L/hour x 8 hours in hemodialysis or hemofiltration) occurring either at the beginning of or 14-16 hours after meropenem infusion. Probability of target attainment (PTA) was evaluated using a pharmacodynamic target of ≥ 40% free meropenem concentrations above 4 times of the minimum inhibitor concentration (fT≥4xMIC) for *Pseudomonas aeruginosa* (2 µg/mL) for the first 48 hours of therapy. A ≥ 90% of PTA with the smallest daily dose was defined as optimal.

Results: Meropenem regimens using ³2g/day attained ≥ 90% PTA. Meropenem 1g q12h and 1g given pre- & post-SHIFT were optimal regimens for all SHIFT settings. Weight-based regimens did not yield better target attainment than fixed-dose regimens.

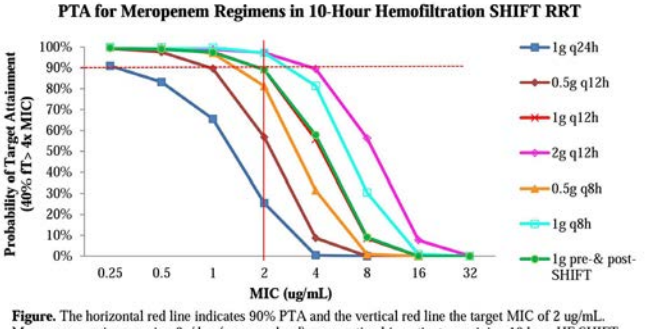

Figure. The horizontal red line indicates 90% PTA and the vertical red line the target MIC of 2 ug/mL. Meropenem regimens using 2g/day (green and red) were optimal in patients receiving 10 hour HF SHIFT

Conclusions: This simulation indicates that meropenem regimens using 2g/day should be used initially to treat critically ill patients receiving 8 or 10 hour SHIFT RRT. These results warrant clinical validation.

Funding: Pharmaceutical Company Support - NxStage Medical Inc.

SA-PO532

Evaluation of Piperacillin/Tazobactam Regimens in Patients with SHIFT Renal Replacement Therapy Susan J. Lewis,[1] Katherine N. Gharibian,[1] Ashita J. Tolwani,[2] William Henry Fissell,[3] Bruce A. Mueller.[1] *[1]College of Pharmacy, Univ of Michigan, MI; [2]Univ of Alabama, AL; [3]Vanderbilt Univ, TN.*

Background: SHIFT Renal Replacement Therapy (RRT) is a prolonged intermittent RRT to treat critically ill patients with acute kidney injury, but lack of antibiotic pharmacokinetic (PK) data in this RRT limits its utility. This study evaluated probability of target attainment (PTA) of piperacillin/tazobactam regimens recommended in critically ill patients receiving SHIFT RRT, using Monte Carlo Simulations (MCS).

Methods: Mathematical PK models were constructed using literature-derived demographic/PK data with known variability. Four daily-SHIFT settings (hemofiltration or hemodialysis with effluent rates of 5L/hour x 8 hours or 4L/hour x 10 hours) occurring at 2 different times relative to drug dose were modeled. PTA of 13 piperacillin regimens (2-4g q6-8h) and 3 tazobactam regimens (0.5g q6h) with intermittent or prolonged infusion (4-hour or continuous) were evaluated. MCS generated free drug concentration profiles for each regimen in the 5,000 virtual patients. Pharmacodynamic targets were ≥ 50% of time free piperacillin concentrations above 4x the minimum inhibitory concentration (MIC) of *Pseudomonas aeruginosa* (16 µg/mL) and ≥ 50% of time free tazobactam concentrations above corresponding threshold (4 µg/mL) for the initial 48 hour-therapy. The optimal regimen required ≥ 90% of PTA for both agents.

Results: The attainment of≥ 90% of PTA required piperacillin 16g/day and tazobactam 2g/day in all SHIFT settings. Prolonged infusion was not superior to intermittent infusion to yield better PTA in patients receiving SHIFT RRT.

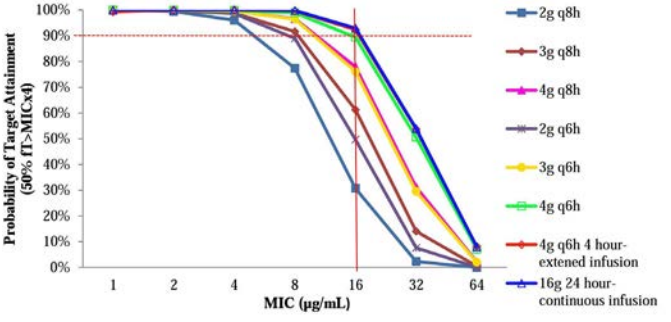

Figure. Predicted target attainment of piperacillin dosing regimens across MICs in patients receiving Daily-SHIFT for the intial 48 hours of antibiotic therapy. The horizontal red line indicates 90% of PTA and the vertical red line the target MIC of 16 ug/mL. A total of 16g/day with intermittent or prolonged infusion was required to attain the pharmacodynamic target successfully (green, red, and blue lines).

Conclusions: Piperacillin/tazobactam 4.5g q6h is recommended for critically ill patients receiving 8 or 10 hour SHIFT RRT. These PK simulation results need to be clinically validated.

SA-PO533

Beta-Blocker Dialyzability in Chronic Hemodialysis Patients Alvin Tieu,[1] Thomas Velenosi,[1] Andrew S. Kucey,[1] Laura Elisabeth Mccuaig,[1] Matthew A. Weir,[1] Brad Urquhart.[1,2] *[1]Dept of Physiology and Pharmacology, Schulich School of Medicine and Dentistry, London, ON, Canada; [2]Dept of Medicine, Div of Nephrology, Western Univ, London, ON, Canada.*

Background: There is a paucity of data available to describe beta-blocker dialyzability. Of the available information, most were obtained prior to implementation of high-flux dialysis membranes. This study aims to characterize the dialyzability of four of the most commonly prescribed beta-blockers in patients undergoing conventional high-flux hemodialysis (HD). Based on physiochemical properties, we hypothesize atenolol and metoprolol to be extensively removed by HD, while bisoprolol and carvedilol to be poorly dialyzed.

Methods: HD patients from the London Health Sciences Centre were recruited for a pharmacokinetic, crossover study. Atenolol (50mg), bisoprolol (5mg), carvedilol (6.25mg) and metoprolol (50mg) were administered separately to each patient over four hemodialysis sessions. Arterial and venous blood samples and total spent dialysate were collected. Beta-blocker concentrations were measured by mass spectrometry, and dialytic clearance was determined by the dialyzer and recovery clearance methods.

Results: Following dialysis, 6.78 mg of atenolol, 0.66 mg of bisoprolol, 0.02 mg of carvedilol, and 1.53 mg of metoprolol were recovered in spent dialysate. These amounts of dialyzed beta-blockers were applied in the recovery clearance method to produce dialytic clearance values of 124.0, 91.5, 1.3, and 150.2 mL/min for atenolol, bisoprolol, carvedilol, and metoprolol, respectively.

Conclusions: Beta-blocker efficacy can be hindered if substantial dialytic clearance occurs. Accordingly, atenolol and metoprolol were extensively cleared by HD, while carvedilol displayed low dialyzability. Contrary to previous literature, our data suggests moderate dialyzability for bisoprolol. With recent studies indicating heightened mortality risk in HD patients prescribed highly-dialyzable beta-blockers, drug dialyzability data is critically important to optimize pharmacotherapy in HD patients. Definitive characterization of beta-blocker dialyzability can allow for determination of post-dialysis supplemental drug doses, or alternative drug therapies.

SA-PO534

Rituximab Exhibits Altered Pharmacokinetics in Patients with Membranous Nephropathy Uma R. Fogueri,[1] Wisit Cheungpasitporn,[2] David Bourne,[1] Fernando C. Fervenza,[2] Melanie S. Joy.[1] *[1]Schools of Pharmacy and Medicine, Univ of Colorado, Aurora, CO; [2]Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: Rituximab (RTX) is an anti-CD20 antibody used in the treatment of glomerular diseases including membranous nephropathy (MN). There is little information about the pharmacokinetics of therapeutic proteins, including RTX in patients with glomerular diseases. The study evaluated rituximab pharmacokinetics in patients with MN from a pilot investigation(Fervenza et.al, 2010).

Methods: Patients with MN (n=20) received 4 RTX weekly IV infusions (375mg/m^2), with a repeat of the identical treatment at 6 months. Patient baseline characteristics were: gender (17M/3F), age (49±13 y), BSA (2.22±0.24 m^2), urinary protein excretion (11.3±4.1 g/d), creatinine clearance (72±33 mL/min). Pharmacokinetic analysis was performed using rituximab plasma concentrations. Comparisons of pharmacokinetic parameters were made between the MN patients and published data from other populations.

Results: The MN population had a favorable reduction in urinary protein excretion 3 months after each RTX treatment course (7339±4114 mg/day and 4131±3441 mg/day, respectively), while creatinine clearance values were similar to baseline (72±31 mL/min and 82±37 mL/min, respectively). Patients with MN exhibited a shortened half-life (T1/2), greater volume of distribution (Vd), and enhanced clearance of RTX vs. previous reports in other patient populations. These characteristics resulted in an exposure (AUC) that was significantly reduced in patients with MN.

	Membranous Nephropathy (N=20)	Follicular Lymphoma (N=22)	Autoimmune Disorders (N=14)
T1/2 (h)	231±143	513 (248-705)	484 (292-859)
Clearance(mL/hr)	29.6±9.5	11.2 (8.4-17.8)	14.5 (8.4-26.2)
Vd (mL)	9722±6877	3850 (3432-4686)	4642 (2266-5786)
AUC (mg h/mL)	31.4±12.7	73.6 (46.3-98.2)	56.9 (31.5-98.2)

Conclusions: The pharmacokinetics of RTX in patients with MN are significantly altered compared to published data from cancer and autoimmune populations. These results suggest shorter T1/2 and lower exposures to RTX in MN may necessitate higher doses and/or changes to dosing frequency in order to elicit an optimal therapeutic effect.

SA-PO535

Eculizumab Treatment Efficiently Prevents C5 Cleavage without C5a Generation In Vivo Elena Volokhina,[1] Grethe Bergseth,[2] Nicole Van De Kar,[1] Lambertus P.W.J. Van den Heuvel,[1] Tom Eirik Mollnes.[2] *[1]Radboud Univ Medical Center, Nijmegen, Netherlands; [2]Nordland Hospital, Bodø, Norway.*

Background: The C5 inhibitor eculizumab has been successfully used to treat atypical hemolytic uremic syndrome (aHUS), however, available data on pharmacodynamics of this medication are limited. Recently, increased generation of C5a in a single patient with HELLP syndrome treated with eculizumab has been reported. Since this observation was unexpected, we aimed to reproduce these data and search for possible explanations for the findings.

Methods: Levels of C5a were analyzed in EDTA plasma samples of aHUS (n=3) patients using three commercial ELISA kits, one of the kits was also used in the HELLP study and other two kits were included as controls. The samples were collected before the first eculizumab dose and then at various time points during treatment.

Results: In line with the report on HELLP patient, the C5a values, measured by one of the commercial ELISA kits, increased significantly in all aHUS patients after the first eculizumab dose as compared to the values obtained before treatment (p=0.016). C5a remained elevated throughout the treatment period. Such increase could not be reproduced by using another two commonly available commercial kits. When eculizumab was added in vitro to normal human serum prior to activation, no generation of C5a was measured by all used kits.

Conclusions: Our data indicate that existing commercial assays require validation for specificity before being used to monitor effect of eculizumab, especially in clinical laboratory practice. This example illustrates how false conclusions can be drawn when based on results from one single commercial assay not satisfactorily validated for the purpose it is used.

SA-PO536

Sensitive, Reliable and Easy-Performed Laboratory Monitoring of Eculizumab Therapy in Atypical Hemolytic Uremic Syndrome Elena Volokhina,[1] Nicole Van De Kar,[1] Grethe Bergseth,[2] Thea J. Van der velden,[1] Jack F. Wetzels,[1] Lambertus P.W.J. Van den Heuvel,[1] Tom Eirik Mollnes.[2] *[1]Radboud Univ Medical Center, Nijmegen, Netherlands; [2]Nordland Hospital, Bodø, Norway.*

Background: Atypical hemolytic uremic syndrome is a severe renal illness caused by complement dysregulation. Treatment with the complement C5 inhibitor eculizumab is effective, but associated with high costs. Laboratory monitoring of these patients with

respect to complement function has not been standardized. The aim of this study was to evaluate novel complement functional assays for their application in routine follow-up of eculizumab-treated patients.

Methods: Complement activity in serum samples was analyzed using Wieslab® complement screen assay. The presence of eculizumab-C5 complexes in serum, EDTA plasma samples and in urine was measured using ELISA. Levels of sC5b-9 in urine were measured using electroluminescent epitope assay.

Results: First, we documented that the Wieslab® complement screen assay showed a sensitivity of 1-2% of C5 activity by adding purified C5 or normal human serum to a C5 deficient serum. Second, we found that all the patient samples obtained during the standard treatment course, were completely blocked for terminal complement pathway activity. Moreover, complement remained fully blocked when intervals between the eculizumab infusions were extended to four weeks. Levels of complexes between eculizumab and C5 were inversely correlated to the complement activity (p=0.01). Third, titrating serum from eculizumab-treated patients into normal serum, revealed that eculizumab was present in excess up to four weeks after infusion. Finally, we showed that increased urine sC5b-9 disappeared after eculizumab treatment.

Conclusions: We demonstrate sensitive, reliable and easy-performed assays to monitor eculizumab-treated patients, which can be used to design individual dosage regimens.

Dose Exposure Relationship of AKB-6548 Is Independent of the Level of Renal Function Akshay Buch, Bradley J. Maroni, Charlotte S. Hartman. *Akebia Therapeutics, Inc., Cambridge, MA.*

Background: AKB-6548 is a novel, once-daily, oral hypoxia-inducible factor prolyl-hydroxylase inhibitor (HIF-PHI) in development for the treatment of anemia in non-dialysis dependent (NDD) and dialysis dependent (DD) chronic kidney disease (CKD). Studies in NDD-CKD patients have shown AKB-6548 produces physiologic increases in erythropoietin, enhances iron mobilization, and produces a dose dependent increase in hemoglobin levels.

Methods: The pharmacokinetics (PK) of AKB-6548 have been evaluated in single and multiple dose studies in healthy volunteers and CKD patients (NDD-CKD and DD-CKD) over a broad range of dose levels. An analysis of results across studies was conducted to assess the potential impact of renal function on selecting the dose levels and dosing regimen in CKD patients. The analyses evaluated dose-linearity in drug exposure, clearance routes of AKB-6548 and its metabolites, as well as the impact of CKD severity and the hemodialysis procedure on drug disposition.

Results: In healthy volunteers, AKB-6548 demonstrated dose linearity and proportionality over single doses of 80-1200 mg and multiple doses of 500-900 mg/day. The PK parameters of AKB-6548 in healthy volunteers, NDD-CKD and DD-CKD patients were similar except for a slightly longer half-life with declining renal function (4.7 hr., 7.9 hr. and 9.1 hr., respectively). A mass balance study (using ^{14}C- labeled drug) in healthy volunteers demonstrated both renal and fecal routes of parent drug and metabolite clearance, supporting use of AKB-6548 in CKD patients without significant differences in drug exposure. Moreover, AKB-6548 was minimally cleared by the hemodialysis procedure and the PK parameters were similar whether AKB-6548 was administered prior to or following dialysis.

Conclusions: The results demonstrate a linear dose-exposure relationship for AKB-6548 over a wide range of doses and support the utility of once-daily dosing and similar dose levels across the spectrum of CKD severity.

Nonclinical Pharmacokinetics and Toxicokinetics of RG-012, an Inhibitor of MicroRNA-21 Being Investigated for Treatment of Alport Syndrome John Stewart Grundy,[1] Kai Liu,[1] Steven Neben,[1] Cindy L. Berman,[2] Deidre Mackenna,[1] Neil W. Gibson.[1] *[1]Regulus Therapeutics, San Diego, CA; [2]Berman Consulting, Wayland, MA.*

Background: RG-012 is a single-stranded chemically modified oligonucleotide being developed to treat patients with Alport syndrome, which is characterized by loss of renal function associated with defects in specific collagen genes expressed in the kidney glomerular basement membrane. RG-012 inhibits miR-21, a microRNA target known to have increased expression in context of kidney stress and associated with renal dysfunction.

Methods: In vitro pharmacokinetic (PK) evaluations of RG-012 conducted during preclinical development included: plasma protein binding, metabolic stability in whole blood and liver lysates, and CYP450 inhibition/induction potential in cryopreserved human hepatocytes. In vivo PK and toxicokinetic (TK) properties of RG-012, and its major active metabolite (RG0005), were determined upon subcutaneous dosing of RG-012 in a set of nonclinical PK, pharmacology, and safety studies in CD-1, SV129, and COL4A3 mice (6.25–450 mg/kg/week) and cynomolgus monkeys (10–225 mg/kg/week).

Results: Both RG-012 and RG0005 were highly bound (≥98%) to proteins in plasma from mice, monkeys, and humans. RG0005 was the only major degradation product seen in whole blood and liver lysates from all three species. RG-012 exhibited little to no potential to inhibit or induce CYP450 enzymes. Upon administration of RG-012, PK and TK properties of RG-012 and RG0005 were consistent across all nonclinical species and were characterized by rapid absorption, dose-dependent plasma exposure, rapid plasma clearance due mainly to extensive tissue distribution, and subsequent slow tissue elimination (half-lives in liver and kidney of ~2–3 weeks). Comparison of plasma and tissue exposure levels (RG-012+RG0005 combined) seen at the NOAEL in cynomolgus monkeys, the most clinically relevant toxicological species, with those achieved at pharmacologically active dose regimens (ED_{50} and ED_{90}) in a COL4A3 mutant mouse model, indicates a therapeutic index (TI) ranging from 3.4 to 25.4.

Conclusions: In conclusion, favorable nonclinical PK/TK properties and TI of RG-012 support initial clinical testing.

Novel Methodology for Assessing Inhibition of MicroRNA-21 by RG-012, a MicroRNA Therapeutic in Development for the Treatment of Kidney Dysfunction in Patients with Alport Syndrome John Rolf Androsavich, Xueqing Liu, Shweta Pandya, Deidre Mackenna. *Regulus Therapeutics, San Diego, CA.*

Background: microRNA-21 (miR-21) is upregulated in animals models with kidney dysfunction and also in patients with chronic kidney disease (CKD). RG-012 is a miR-21 inhibitor entering clinical development for treatment of CKD in Alport syndrome (AS) patients. RG-012 demonstrates activity both as a monotherapy and in combination with the ACE inhibitor ramipril in the Col4A3 deficient mutant mouse model of AS.

Methods: Two distinct methods have been developed to evaluate the ability of RG-012 to inhibit miR-21 in preclinical studies – the polysome shift assay (PSA) and alterations in the expression of miR-21 target mRNAs. The PSA measures direct target inhibition at the level of the physical interaction between microRNA and messenger RNA targets. C57Bl/6 mice were treated subcutaneously with RG-012 at doses ranging from 0.1 to 100 mg/kg. Tissue homogenates were separated using sucrose gradient ultracentrifugation, with microRNAs associating with messenger RNA targets in the heavier polysome fraction. The ability of RG-012 to displace the target miR-21 from the polysome containing fraction was used to assess direct target engagement.

Results: RG-012 demonstrated dose dependent displacement of miR-21 from polysomes in both liver and kidney with a maximum effect reached at dose levels that are efficacious in the Col4A3 mouse models. Loss of miR-21 from the polysomes was specific as levels of Let-7a, a control microRNA to which RG-012 has no complementarity, were unaffected. In the liver, target engagement was also assessed using mRNA derepression of a set of confirmed miR-21 target genes. Here, target gene derepression strongly correlated with polysome displacement. This comparison was not possible in kidney, however, because target genes are not regulated in kidneys in the absence of stress.

Conclusions: RG-012 directly and specifically inhibits miR-21 resulting in its displacement from actively translating polysome complexes and subsequent derepression of messenger RNA targets.

Tacrolimus Pharmacokinetics in Nephrotic Stage Mara Medeiros,[1] Saul Valverde,[1] Luis Velasquez-Jones,[1] Ana M. Hernández,[1] Gilberto Castañeda-Hernández,[2] Guido Filler.[3] *[1]Hospital Infantil de México Federico Gómez, Mexico; [2]CINVESTAV, IPN, Mexico; [3]Children's Hospital, Univ of Western Ontario, Canada.*

Background: While tacrolimus (Tac) therapy is not first-line therapy for childhood nephrotic syndrome, it is often used instead of cyclosporine to ameliorate the side effects. The pharmacokinetics of Tac can be influenced by many conditions, and it has a high plasma protein binding. The Tac pharmacokinetics during relapse and remission of childhood nephrotic syndrome have not been well described.

Methods: We performed 14 pharmacokinetic (PK) profiles (with measurements before and 0.5, 1, 2, 4 and 12 hours post intake) in 7 children with steroid-resistant nephrotic syndrome (SRNS) during relapse and in remission. These data were compared with historical PK data of 161 PK profiles in 87 pediatric renal transplant recipients with measurements before, 0.5,1,1.5,2,3,4,6,8 and 12 hours post intake. Tac levels were measured using the Abbott Tacro II assay. We used descriptive statistics to generate percentiles and compared these with the SRNS patients. We also compared the PK profiles during relapse and remission.

Results: Median age of SRNS patients was 3.2 years. Tacrolimus dose, biochemical values and pharmacokinetics parameters are shown in Table 1. Values as median and interquartile range.

	Baseline	Week 1	Week 16	P value*
Serum albumin (mg/dL)	2.1 (1.4, 2.9)	2.6 (2.4, 3.5)	3.7 (3.6, 3.7)	0.008
Proteinuria (mg/m²/h)	54.5 (28.5, 168)	22 (5, 30)	4.5 (0.46, 30)	0.01
Cholesterol (mg/dL)	281 (229, 506)	286 (236, 383)	165 (137,191)	0.0003
Triglycerides (mg/dL)	182 (115, 430)	173 (120, 276)	90 (49, 126)	0.02
eGFR (ml/min/1.73m²)	114 (92, 349)	92 (91, 130)	85 (73, 120)	0.02
Tacrolimus dose mg/kg/day		0.11 (0.08, 0.12)	0.13 (0.08, 0.15)	0.81
Tacrolimus C0h (mg/dL)		7.9 (3.8, 10.2)	5.3 (3.6, 11.3)	1.0
AUC/Dose (ng*h/ml/mg)		1858 (625, 3172)	3823 (1212, 4790)	0.07
Cmax/Dose [(ng/mL)/[mg/kg/d)]		131 (93, 240)	188 (135, 330)	0.21
Tmax (h)		1 (1, 2)	0.5 (0.5, 2)	0.58
t ½ (h)		9.2 (6.1, 11.3)	8 (6, 12.8)	0.57

The PK profiles were well within the percentiles of the transplant children.

Conclusions: Tac PK profiles are not different in children with nephrotic syndrome during relapse and remission.

SA-PO541

Clinical and Genetic Determinants of Longitudinal Dose-Corrected CNI Exposure in Children After Renal Transplantation Noel Knops,[1] Elena N. Levtchenko,[1] Dirk R. Kuypers.[2] *[1]Pediatric Nephrology, Univ Hospitals Leuven, Leuven, Belgium; [2]Nephrology, Univ Hospitals Leuven, Leuven, Belgium.*

Background: Calcineurin-inhibitors (CNI) have a narrow therapeutic index and dosing is difficult due to inter- and intra-individual variation in pharmacokinetics (PK). Polymorphisms in genes involved in drug metabolism can play a critical role in individual exposure. Data concerning long-term CNI exposure in relation to dose in children are scarce and in general based upon trough levels. We present the longitudinal follow up of 12-hour CNI PK in relation to dose, clinical and genetic factors in a cohort pediatric renal allograft recipients.

Methods: Retrospective single center study in subjects after renal transplantation (age 0-20 yrs) with annual PK assessments (6-point AUC0-12hr) for tacrolimus (Tac) or cyclosporine (CsA). Clinical and laboratory data were retrieved. Analysis of polymorphisms in *CYP3A4, CYP3A5, CYP3A7, POR* and *ABCB1* was performed.

Results: We collected 180 "full" AUCs for Tac, 56 for CsA in 51 kids. Mean age at Tx: 9.9 yrs(1-19); FU after Tx: 4.6 yrs (0-16). Dose-corr. exposure (AUC/ dose in mg/kg) increased with age: 854 (mean) in <5 yrs to 2702 >15yrs); 817 to 1787 ng*hr/ml per mg/kg in Tac and CsA resp. (p< 0.01). Correction for dose per m2 body surface (BS) demonstrated stable dose-corr. exposure for ages <15 yrs, and was higher only for >15 yrs (Tac: <5yrs-15 yrs: 44 (95%CI: 40-48) >15yrs: 73.4 ng hr/ml per mg/m2; CsA: 40 (CI 36-44) vs. 52. *CYP3A5* genotype was an important co-determinant of dose-corr. exposure for Tac (2.1 higher dose-req. in **1* vs **3/3*), but not for CsA. **1* carriers had an attenuated increase in dose-corr.exposure into adulthood (27 vs. 39 in >15yrs; **3/3*: 48 vs. 82 resp.)

Conclusions: Dose-corr exposure according to BS, in contrast to bodyweight, demonstrates stable CNI dose requirements in children <15 yrs. Polymorphisms in *CYP3A5* are important for individual Tac dose requirements and modify the effect of age. CsA is not affected by *CYP3A5*. Our data suggest that CNI dosing per m2 in children after renal transplantation would be less prone to variation in exposure with age and thus preferred. *CYP3A5* genotype only aids in predicting Tac dose requirements.

Sex and Race Influences on Tacrolimus Pharmacokinetics in Renal Transplant Recipients Kathleen M. Tornatore,[1,3] Calvin J. Meaney,[1] Joseph D. Consiglio,[2] Gregory E. Wilding,[2] Shirley Shwu-Shiow Chang,[3] Rocco C. Venuto.[3] *[1]NYS Center of Excellence in Bioinformatics & Life Science; Pharmacy, School of Pharmacy & Pharmaceutical Sciences; [2]Biostatistics, School of Public Health; [3]Medicine, School of Medicine & Biomedical Sciences; Univ at Buffalo, Buffalo, NY.*

Background: Tacrolimus (TAC) is the primary calcineurin inhibitor in immunosuppressive regimens for renal transplant recipients(RTR) and exhibits notable interpatient variability in pharmacokinetics(PK) necessitating therapeutic drug monitoring(TDM). There are limited data that characterize sex and race influences on TAC PK.

Methods: During a 12-hour PK study, we evaluated steady-state TAC trough (C0), area under the concentration time curve 0-12 hours (AUC 0-12) normalized for dose, apparent clearance(CL) and total body weight(TBW) normalized CL using non-compartmental analysis. 65 stable African American (AA) and Caucasians (C) females(F) and males(M) who were greater than 6 months post-transplant and receiving TAC and mycophenolic acid were enrolled. TAC dosage was adjusted using C0 range of 4-9 ng/ml. TAC adverse effects(AE) were evaluated using standardized assessments to generate a cumulative AE score(CAE).

Results: The clinical and PK parameters are summarized below. Total and weight-normalized CL were most rapid with lower dose-normalized AUC in AAF compared to other RTR. Higher CAE was found in female RTR. No sex-race differences were noted for C0 in spite of higher TAC doses in AA.

Mean(SD)	AAF[n=13]	AAM[n=20]	CF[n=16]	CM[n=16]	P Value
eGFR[ml/min/1.73m2]	49.9(17.7)	57.4(13.4)	49.8(11.5)	64.4(16.2)	0.019
TAC dose[mg]	5.0(1.7)	3.7(1.6)	2.7(1.2)	2.2(0.7)	<0.001
TAC C 0[ng/ml]	7.2(1.8)	7.3(1.9)	6.7(1.7)	6.2(1.2)	NS
Apparent CL[L/hr]	40.0(16.8)	28.2(13.3)	22.2(8.9)	21.3(6.7)	0.0003
CL/TBW	0.47(0.23)	0.34(0.20)	0.32(0.15)	0.23(0.07)	0.005
AUC 0-12/Dose[ng.hr/ml/mg]	29.6(12.5)	44.9(25.5)	54.6(25.9)	51.7(16.8)	0.001
CAE Score	0.21(0.06)	0.09(0.06)	0.16(0.09)	0.13(0.06)	<0.001

Conclusions: Sex-race differences in TAC PK contribute to differential dosing requirements in AA vs C. A more individualized approach to chronic TAC immunosuppression integrating sex-race with TDM and a standardized adverse effect assessment may benefit RTR.

SA-PO543

Sex and ABCB1 Haplotype Associations with Tacrolimus Pharmacokinetics in Renal Transplant Recipients Kathleen M. Tornatore,[1,3] Daniel Brazeau,[2] Calvin J. Meaney,[1] Louise M. Cooper,[1] Rocco C. Venuto.[3] *[1]NYS Center of Excellence in Bioinformatics & Life Science; Pharmacy, School of Pharmacy & Pharmaceutical Sciences; [2]GAP-Core Facility; Schools of Pharmacy & Medicine, Univ of New England, Portland, ME; [3]Medicine, ECMC, School of Medicine; Univ at Buffalo, Buffalo, NY.*

Background: Tacrolimus (TAC) is the mainstay calcineurin inhibitor for immunosuppression in renal transplant recipients (RTR). TAC exhibits interpatient variability in pharmacokinetics (PK) attributed primarily to CYP 3A5 isoenzymes and P-glycoprotein (Pgp). Pgp is encoded by the *ABCB1* gene. The common single nucleotide polymorphisms (SNP): *1236C>T (rs1128503), c.2677G>T/A (rs2032582), and c.3435C>T (rs1045642)* have conflicting associations to TAC PK. This study objective evaluated these common SNP as haplotypes in relation to TAC PK.

Methods: During a 12-hr PK study, trough (C0), apparent clearance (CL) and lean body weight (LBW) normalized CL were determined in 29 female and 36 male African American (AA) and Caucasian (C) stable RTR greater than 6 months post-transplant receiving TAC and mycophenolic acid. TAC dosage was adjusted to C0 range of 4-9 ng/ml. The ABCB1 SNPs: *c.1236C>T (rs1128503), c.2677G>T/A (rs2032582), and c.3435C>T (rs1045642)* were assessed. *ABCB1* haplotype associations comparing the primary variant TTT to CGC [wild-type (WT)] relative to TAC PK were computed using the THESIAS program with sex sub-analysis.

Results: TAC C0 ranged from 5-10 ng/ml with no difference between groups in spite of higher doses in AA (P<0.0001). Significant associations of TTT to TAC dose, CL and CL/LBW were noted with sex sub-analysis and summarized as Phenotypic Mean with Confidence Interval (CI) of WT compared to variant in table. These data suggest RTR with TTT variant received lower doses and had slower TAC CL relative to sex.

Mean[SD]	CGC[WT] Phenotypic Mean[CI]	TTT- Phenotypic Mean[CI]	P Value
TAC Dose[mg]	2.4[1.7-3.2]	1.6[0.7-2.5]	0.029
Apparent CL[L/hr]	20.4[14.5-26.3]	13.9[7.9-20.1]	0.023
CL/LBW	0.48[0.37-0.60]	0.35[0.23-0.47]	0.022

Conclusions: The ABCB1 haplotypes provide important insight into interpatient variability in TAC PK post renal transplant and the role of P-gp that is also influenced by sex.

Funding: NIDDK Support, Pharmaceutical Company Support - Astellas Scientific and Medical Affairs, INC

SA-PO544

Pharmacokinetics and Pharmacodynamics of Tacrolimus, and NFAT Regulated Gene Expression in Kidney Transplant Patients Frieder Keller. *Univ Hospital, Ulm, Germany.*

Background: Suppression of genes that are regulated by the nuclear factor of activated T-cells (NFAT) is an effect of calcineurin inhibitors. We correlated the pharmacodynamics to the pharmacokinetics of tacrolimus.

Methods: This study was undertaken in the University Hospitals of Ulm (Frieder Keller) and Heidelberg (Claudia Sommerer, Thomas Giese, Martin Zeier). Tacrolimus trough concentrations (Ctrough) and 1.5 – 2 hours later the peak concentrations (Cpeak) were measured by LCMS. Simultaneously, the NFAT trough effect (Etrough) and the nadir effect (Enadir) were determined. The pharmacokinetic half-life (T1/2) was estimated from peak (Cpeak) and trough concentrations (Ctrough) considering the time distance between steady-state peak and troughs (10.5 – 10 hours). The pharmacodynamic concentration producing the half-maximum effect (CE50) and the Hill coefficient (H) were estimated from trough effect (Etrough) at trough concentrations and from nadir effect (Enadir) at peak concentrations. The two equations were solved by numerical iteration for an estimate of the two unknown parameters (CE50, H).

Results: A total of 10 stable kidney transplant patients were included. The median age was 58 years and the median serum creatinine was 306 mcmol/l. The pharmacokinetics of tacrolimus were estimated with T1/2 = 11 hours, Cl/F = 64 l/h and Vd/F = 480 l. The median value for NFAT was 89% (Etrough) of normal gene expression, and the nadir effect was 43% (Enadir) representing the strongest immunosuppression of basal gene expression. The pharmacodynamics of tacrolimus were estimated with CE50 = 7.7 ng/ml and the Hill coefficient with H = 4.6, respectively.

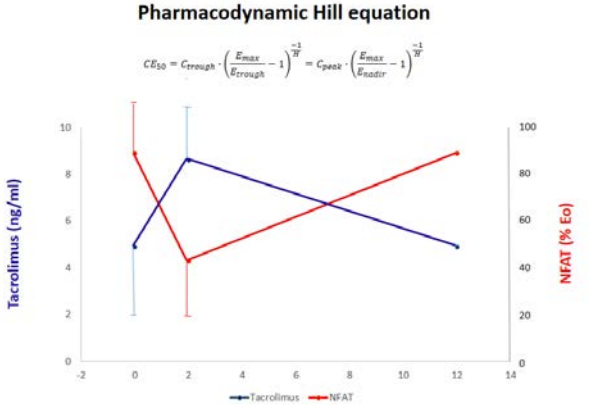

Figure 1: Tacrolimus pharmacokinetics (blue) and pharmacodynamics (red).

Conclusions: While on triple immunosuppression, the NFAT pharmacodynamics indicate a low concentration producing the half-maximum effect and a high Hill coefficient. These findings suggest a narrow trough-to-peak target concentration range of 4.0-to-9.5 ng/ml for tacrolimus.

SA-PO545

2-Sample Iohexol Plasma Clearance: The Clear Choice for Measuring Kidney Function in Rats Mandy E. Turner,[1] Kimberly J. Laverty,[1] Martin Kaufmann,[1] Glenville Jones,[1] Rachel M. Holden,[2] Michael A. Adams.[1] *[1]Biomedical and Molecular Sciences, Queen's Univ, Kingston, ON, Canada; [2]School of Medicine, Queen's Univ, Kingston, ON, Canada.*

Background: The lack of simple and sensitive tools for longitudinal kidney function assessment in rodent models has impeded analysis of CKD onset and progression and the impact of interventions. This study evaluates 2-sample plasma clearance (pCl) of iohexol, a radio-contrast agent, compared to previously validated inulin pCl in rats to estimate GFR.

Methods: Progressive CKD was induced with a 0.25% adenine diet in male Sprague-Dawley rats (N=8). Following serial tail vein injections of iohexol (51.92 mg/kg) and FITC-inulin (2.5 µL/kg of 5% solution), 12 saphenous blood samples were taken from conscious rats over 5 hours, weekly (control, 5 weeks of adenine). Plasma creatinine was measured via the Jaffrey method, FITC-inulin via fluorometry, and iohexol via UPLC-MS. Two reference methods for pCl calculation were used: a 2-compartment model(2 COM) and trapezoidal approximation(TRA) of area under the curve.

Results: Reference methods of inulin PCl agreed well with iohexol pCl.

Reference Clearance	Comparative Clearance	R^2	%Bias/Precision	15% Accuracy
INU TRA	IHX 2-COM	0.86	6.0±16.9	62.6
	IHX TRA	0.93	3.9±10.9	81.4
	IHX 1-COM	0.93	6.8±13.3	69.8
	Cre	0.53		
INU 2-COM	IHX 2-COM	0.93	15.3±12.7	46.5
	IHX TRA	0.96	13.2±12.3	48.8
	IHX 1-COM	0.96	16.2±10.1	51.2
	Cre	0.58		

pCl of iohexol and inulin was significantly decreased, compared to baseline, after one week ($p<0.005$), whereas plasma creatinine concentration was not significantly elevated until the third week ($p=0.02$). Characterization of a 1-compartment model using 2-samples was employed: samples at 30 and 90 min post injection yielded high agreement ($R^2=0.98$) and no significant bias.

Conclusions: Iohexol pCl sensitively and accurately measures an early decline in kidney function, especially compared to creatinine. The 2-sample method for assessing kidney function is straightforward and is therefore suitable for large rat cohorts. This approach will both enable detection of early kidney disease and facilitate concise interpretation of results derived from pre-clinical studies.

SA-PO546

Renal Nitrate Clearance in Chronic Kidney Disease Mark Gilchrist,[1] Jennifer Williams,[2] Richard D'Souza,[2] Miranda J. Smallwood,[1] Lindsay Hayman,[1] Angela C. Shore,[1] Paul G. Winyard,[1] Nigel Benjamin.[3] *[1]NIHR Exeter Clinical Research Facility, Univ of Exeter, Exeter, United Kingdom; [2]Renal Unit, Royal Devon and Exeter Hospital Foundation Trust, Exeter, United Kingdom; [3]Horizon Inst, South Devon Healthcare Foundation Trust, Torquay, United Kingdom.*

Background: Endogenously synthesised nitric oxide(NO) is rapidly oxidised to nitrite and nitrate. These oxidation products can be recycled back into nitric oxide via a complex entero-salivary pathway, thus preserving NO activity. It has previously been shown that 60% of circulating nitrate is excreted in the urine in 48 hours with the fate of the remainder unknown. 24hour urinary nitrate excretion is often used to estimate total body nitric oxide synthesis rates. It is not known what effect declining GFR has on renal nitrate clearance.

Methods: 27 subjects, 14M,13F, median age 70 (range 27-74years) with CKD-EPI eGFR between 9 and 89 were recruited. Following 24hrs low nitrate diet plasma nitrate concentration and 24 hour urinary nitrate excretion were measured to determine renal nitrate clearance using a microplate spectrophotemetric method.

Results: There was a statistically significant correlation between renal nitrate clearance and eGFR: Pearson r = 0.748, $p<0.0001$. There was no relationship between plasma nitrate concentration and eGFR, $p=0.239$, or between plasma nitrate concentration and renal nitrate clearance, $p=0.547$.

Conclusions: As plasma nitrate concentration is unchanged despite diminished renal nitrate clearance at lower eGFRs, we suggest that non-renal clearance is responsible for a greater proportion of nitrate elimination as GFR falls. We conclude that 24 hour urinary nitrate excretion cannot be considered a reliable measure of total body nitric oxide synthesis in CKD. Elucidating the non-renal pathways of loss of the NO storage molecule, nitrate, may lead to novel therapeutic strategies in CKD and cardiovascular disease.

SA-PO547

The Pharmacodynamic Effect of Tenapanor Is Most Pronounced when Administered Before Food in Healthy Volunteers David P. Rosenbaum,[1] Mikael Knutsson,[2] Maria Leonsson Zachrisson,[2] Susanne Johansson.[2] *[1]Ardelyx Inc., Fremont, CA; [2]AstraZeneca R&D, Mölndal, Sweden.*

Background: Tenapanor (AZD1722), a small molecule with minimal systemic availability, is an inhibitor of the Na^+/H^+ exchanger NHE3. Tenapanor acts locally in the gut to reduce absorption of sodium (Na) and phosphate. This study evaluated the effect of food intake on the pharmacodynamics of tenapanor.

Methods: In this open-label, 3-way crossover study (NCT02226783), 18 healthy adults (mean age±SD, 35±11 years; 14 men) completed a randomized sequence of 4-day treatments with tenapanor hydrochloride 15 mg bid: before food (5–10 min before breakfast and dinner); after food (30 min after the start of breakfast and dinner); and at fasting (1 h before breakfast, and 3 h after dinner/1 h before an evening snack). There was a 2-day washout between treatments. All participants received the same meals on the same study days; diet was standardized for Na content.

Results: Stool Na content was higher for tenapanor taken before food than for after food or at fasting, with least-squares mean differences significant in both cases (Table). Differences in urinary Na were not significant. The difference in stool phosphorus (P) content was significant for tenapanor taken before food versus at fasting. The difference in urinary P was significant for administration before food or after food versus at fasting. Stool frequency and consistency were similar across treatments, and there were slightly higher stool weights for administration before or after food, compared with at fasting. There were no serious AEs or discontinuations due to AEs.

Least-squares mean difference (90% CI) in excretion, mmol/day			
	Tenapanor		
	(Before food) – (after food) (n=18)	(After food) – (at fasting) (n=18)	(Before food) – (at fasting) (n=18)
Stool Na	8.8 (3.7,14)	3.0 (−2.0,8.1)	12 (6.8,17)
Urinary Na	0.30 (−11,11)	−6.8 (−18,4.1)	−6.4 (−17,4.5)
Stool P	1.6 (−1.2,4.5)	3.3 (0.45,6.1)	4.9 (2.1,7.7)
Urinary P	−0.24 (−1.9,1.5)	−3.7 (−5.4,−2.0)	−3.9 (−5.6,−2.2)

Conclusions: The pharmacodynamic effect of tenapanor, as judged by stool Na content, was greatest when tenapanor was taken before food. This supports taking tenapanor before meals in future trials.

Triferic Does Not Induce Non-Transferrin Bound Iron or Labile Plasma Iron: *In-Vivo*/*In-Vitro* Correlation

Raymond D. Pratt,[1] Dorine W. Swinkels,[2] Carrie D. Guss,[1] Ajay Gupta.[1] *[1]R&D, Rockwell Medical Inc., Wixom, MI; [2]Radboud Univ Medical Center, Nijmegen, Netherlands.*

Background: Triferic is a complex iron salt approved for administration via hemodialysate to maintain hemoglobin in patients with CKD 5HD. Triferic crosses the dialyzer membrane and binds to transferrin during hemodialysis replacing the obligatory iron losses in HD patients. Serum iron and transferrin saturation (TSAT) values rise after HD and return to the baseline by the start of the next dialysis session.

Methods: A pharmacokinetic (PK) study in healthy volunteers administered up to 10 mg of Triferic iron over 4 hours and up to 20 mg Triferic iron over 12 hours assessed the PK of serum total iron (sFe-total) and transferrin bound iron (TBI). An *in-vitro* study assessed labile plasma iron (LPI). Triferic iron was added to plasma like medium (40 mg/mL human serum albumin) at a concentration range of 0 to 112 mg/dL . In addition, Triferic was added to 5 different human plasma's (TSAT, range 10 - 46%; total iron binding capacity (TIBC), mean: 374 mg/dL, range: 342-446 mg/dL) across a concentration span up to and exceeding 100% TSAT. LPI was measured in the presence of 40 mM ascorbate using dihydrorhodamine (DHR)-123 in the presence of 50 mM deferiprone (DFO) to detect iron- catalyzed radical generation.

Results: In the human PK study, sFe-total and TBI showed an identical PK profile. Non-transferrin bound iron (NTBI), calculated as the difference between SFe-total and TBI, showed no dose dependent increase up to a TSAT of 100%. In plasma like medium, LPI increased with increasing concentrations of Triferic iron. When Triferic was added to human plasma, there was a small increase in LPI observed when iron concentrations were less than 100% TSAT. The mean magnitude of LPI (expressed in concentration units) at approximately 100% TSAT was 5.35 mg/dL (mean 1.4% of the total iron concentration). Once 100% TSAT was exceeded, the LPI increased rapidly.

Conclusions: Triferic rapidly donates iron to transferrin *in vivo* and *in vitro*. In vivo, at TSAT less than 100%, NTBI was minimal. In vitro, the LPI results confirm the lack of redox active iron in plasma until the plasma TIBC is exceeded.

Impact of Tubular Luminal H^+/Organic Cation Antiporter, MATE, on Imatinib-Induced Fluid Retention

Moto Kajiwara,[1,2] Satohiro Masuda.[1] *[1]Dept of Pharmacy, Kyushu Univ Hospital, Fukuoka, Japan; [2]Dept of Research and Development of Next Generation Medicine, Kyushu Univ, Fukuoka, Japan.*

Background: A tyrosine kinase inihibitor, imatinib (IMA) is the first class agent against chronic myeloid leukemia. Although little is known about mechanism involved, more than 50% of imatinb-treated patients suffering from edema. *In vitro* study reported that clinical blood level of IMA inhibits multidrug and toxin extrusion (MATE, SLC47A)-mediated transport of metformine, a hypoglycemic drug. MATE is highly expressed in the brush border membrane of proximal tubular cells mediating the efflux of organic cations, such as metformin, monoamines. The renal dopaminergic system is likely responsible for regulating >50% of net renal salt and water excretion when salt intake increases. In this study, we test a hypothesized that IMA prevents natriuresis by inhibiting MATE-mediated dopamine (DA) secretion into tubule lumen and consequently causes edema.

Methods: C57BL/6 wild type mice (WT) and Mate1 knockout mice (KO) were used. Sodium levels in the urine of mice were measured using an ion-selective electrode. Urinary DA concentration was measured with a liquid chromatography-tandem mass spectrometry.

Results: To determine whether IMA inhibits dopamine uptake by MATE, we examined [^{3}H]DA uptake in HEK293 cells transiently expressed human (h) MATE1, hMATE2-K, and mouse (m) MATE1 in the presence of various concentration of IMA. Uptakes of [^{3}H]DA by those cells were inhibited by IMA in a concentration dependent manner with IC_{50} values (μM) of 1.1, 13.8, and 100.6, respectively. *In vivo* acute saline-loading experiments were performed to examine inhibitory effect of IMA on urinary DA secretion in WT. In IMA-treated WT, the amount of urinary DA and urinary sodium were decreased to 42% and 27% of that observed in vehicle-treated WT, respectively. Consistently, urinary dopamine was almost undetectable in KO. Furthermore, fraction water weight in mice body was significantly increased in IMA-treated WT compared to vehicle-treated WT ($P<0.05$).

Conclusions: IMA prevents natriuresis by inhibiting MATE-mediated DA secretion into tubule lumen and consequently causes edema.

Optimizing Between-Patient Variability in Response to Renoprotective Drugs: Meta-Analysis of Rotation Trials

Sergei Petrykiv,[1] Dick de Zeeuw,[1] Frederik I. Persson,[2] Peter Rossing,[2,3] Hans-Henrik Parving,[3] Gozewijn Dirk Laverman,[1] Hiddo Jan Lambers Heerspink.[1] *[1]Univ Medical Center, Groningen, Netherlands; [2]Steno Diabetes Center, Gentofte, Denmark; [3]Univ Copenhagen, Denmark.*

Background: Individual response to albuminuria lowering intervention is highly variable between patients. To investigate whether uptitrating the dose of drug, changing the mode of intervention (with similar or different drug classes), or lowering dietary sodium intake improves individual response variability, we meta-analyzed individual responses to different modes of anti-albuminuric intervention in non-diabetic and diabetic patients.

Methods: Randomized rotation trials were analyzed to assess correlation of patient-specific responses (n=216 patients) to anti-albuminuric interventions. Included studies (N=20) compared the anti-albuminuric effect of uptitrating the dose of intervention in the RAS (RASi) (N=10 comparisons) and NSAIDs (N=1), rotation within the same class of RASi (e.g. ACEi to ARB; N=5) or NSAIDs (N=1), rotation between RASi and NSAIDs (N=2), and rotation from high to low sodium intake during RASi (N=1). A two stage meta-analysis was performed. First, deeming reression was conducted in each study to assess correlation in response. Individual study results were then meta-analyzed. Albuminuria was measured in 24-hr urine samples.

Results: The albuminuria response to one dose of RASi or NSAID positively correlated with the response to a higher dose of RASi or NSAID, rotation within the same class of RASi or NSAIDs, rotation between RASi and NSAIDS, and rotation from high to low salt intake. Correlations were consistent in diabetic and non-diabetic patients.

	Correlation	P-value
Uptitration dose of RASi or NSAID	0.73	<0.01
Rotation within class of RASi or NSAID	0.54	<0.01
Rotation between RASi and NSAIDs	0.44	<0.01
Rotation high to low salt intake	0.48	<0.01

Conclusions: The correlations observed in this study indicate that patients poorly responding to one dose or mode of albuminuria lowering intervention also respond poorly to other doses or modes of intervention in the RAS. Whether other drugs targeting pathways beyond the RAS improve individual response variability requires further study.

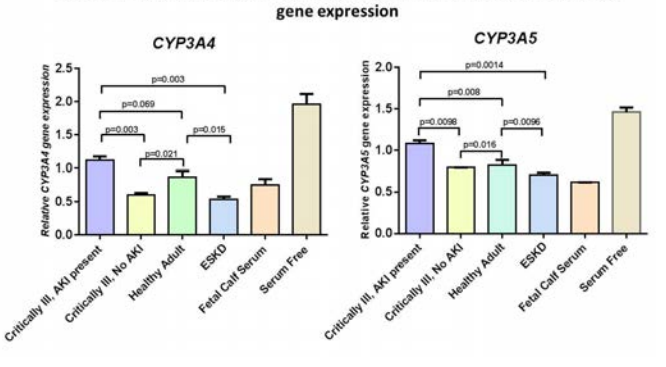
Acute Kidney Injury Serum Upregulates Hepatic Transcription of Cytochrome P450 3A4 and 3A5

Katie Lane,[1] John Dixon,[1] Ekram Nabi,[2] Barbara J. Philips,[1] Iain Macphee,[3] Mark E. Dockrell.[2] *[1]Critical Care, St. George's Univ of London, United Kingdom; [2]South West Thames Inst for Renal Research, United Kingdom; [3]Renal Medicine, St. George's Univ of London, United Kingdom.*

Background: Hepatic drug metabolism by cytochrome P450 3A (CYP) is reduced in end stage kidney disease (ESKD) and acute kidney injury (AKI). The underlying mechanisms are uncertain. Previously we reported suppression of *CYP3A4* mRNA transcription when human hepatocytes (HepG2) were exposed to serum from ESKD patients compared to healthy adults. CYP3A4 and 5 protein concentrations were unchanged. We now investigate whether serum from patients with AKI elicits similar results.

Methods: Serum was collected from critically ill adults with varying AKI severity. Sera from KDIGO 0 (n=15) and KDIGO 3 (n=16) AKI patients were applied individually to HepG2s for 24 h, when cells were lysed. *CYP3A4* and *3A5* gene expression was examined by RT-qPCR. CYP3A4 and CYP3A5 protein expression was examined by Western blotting. The sera were also applied to HepG2 in a pooled fashion, alongside pooled sera from adults with ESKD prior to hemodialysis (n=10) and healthy adults (n=6), to allow comparison with previous data.

Results: AKI serum exposure doubled *CYP3A4* gene expression compared to No AKI serum (p=0.0055 individual and p=0.003 pooled). AKI serum *CYP3A5* mRNA increased approx. 25% compared to No AKI serum (p=0.11 individual and p=0.0098 pooled).



CYP3A4 and 3A5 protein concentrations did not differ after exposure to AKI or No AKI sera (p=0.35, p=0.43).

Conclusions: In contrast to ESKD, hepatocyte exposure to AKI serum upregulates *CYP3A4* and *CYP3A5* transcription compared to No AKI serum. CYP3A4 and 3A5 protein concentrations were unchanged. Further serum analysis will determine whether differences in inflammatory profiles may be responsible. The results underscore the need to view drug metabolism in AKI as distinct from that in ESKD.

SA-PO552

The Effect of Gut-Derived Uremic Toxins on the Expression of Hepatic Drug Metabolizing Enzymes in Chronic Kidney Disease Thomas Velenosi, Alvin Tieu, Andrew S. Kucey, David A. Feere, Brad Urquhart. *Physiology and Pharmacology, Univ of Western Ontario, London, ON, Canada.*

Background: Hepatic drug metabolism is altered in patients with chronic kidney disease (CKD). Previous studies suggest that uremic toxins affect drug metabolizing enzymes in CKD. We hypothesize that gut-derived uremic toxins are involved in the downregulation of hepatic drug metabolizing enzymes and that removal of gut-derived uremic toxins by AST-120 will recover hepatic CYP3A and CYP2C enzyme function and expression in rats with CKD.

Methods: Huh7 human hepatoma cells were treated with various uremic toxins as well as a cocktail of all uremic toxins. Chronic kidney disease was induced in male Wistar rats using 0.5% adenine supplemented into rat chow. Control rats were pair-fed to CKD animals. After 5 weeks, control and CKD animals were further divided and received 8% AST-120 or a control diet. Rats were sacrificed 8 weeks after initiation of the study and plasma and liver tissue were obtained.

Results: Indoxyl sulfate caused a concentration-dependent decrease in Huh7 CYP3A4 expression with an IC50 value of 179.8 ± 20.1 μM. In CKD rats, gut-derived uremic toxins: indoxyl sulfate, p-cresyl sulfate and hippuric acid were significantly increased 4.8-fold, 11.8-fold and 3-fold; respectively, compared to controls. Animals with CKD treated with AST-120 had indoxyl sulfate, p-cresyl sulfate and hippuric acid levels significantly lower than CKD animals and similar to control animals. Hepatic CYP3A2 mRNA expression was significantly decreased by 90% in rats with CKD ($P<0.05$); however, rats with CKD given AST-120 had a 25% recovery in CYP3A2 mRNA expression. Rats with CKD had decreased hepatic CYP2C11 mRNA expression that was not recovered by AST-120.

Conclusions: Uremic concentrations of indoxyl sulfate decreased CYP3A4 mRNA expression in Huh7 cells. AST-120 given to rats with CKD reduced indoxyl sulfate, p-cresyl sulfate and hippuric acid levels similar to control levels. Hepatic CYP3A2 mRNA expression was decreased in CKD and partially recovered by AST-120. AST-120 did not affect the downregulation of CYP2C11 in rats with CKD. Therefore, gut-derived uremic toxins may partially mediate the downregulation of hepatic CYP3A in CKD.

SA-PO553

The Effect of AST-120 on Hepatic and Intestinal Drug Transporter Expression in Chronic Kidney Disease Andrew S. Kucey,[1] Thomas Velenosi,[1] Alvin Tieu,[1] Stephanie E. Nevison,[1] Brad Urquhart.[1,2] *[1]Dept of Physiology and Pharmacology, Schulich School of Medicine and Dentistry, London, ON, Canada; [2]Lawson Health Research Inst, London, ON, Canada.*

Background: Chronic kidney disease (CKD) is the progressive decline in renal function over time. There is a marked reduction in both renal and non-renal drug clearance in CKD. AST-120 is an oral adsorbent that promotes the elimination of gut-derived toxins that accumulate in CKD due to impaired clearance. It is hypothesized that there will be a reduction in the expression of drug transporters in CKD conditions. AST-120 will help recover drug transporter expression in CKD by decreasing uremic toxins that accumulate in CKD.

Methods: In vivo: CKD was induced in Wistar rats by treatment with adenine (0.7%) in standard rodent chow for 7 weeks. Treatment groups received AST-120 in the final 3 weeks to decrease the concentration of uremic toxins. Expression of hepatic and intestinal transporters were determined by real-time PCR. In vitro: Using the human hepatoma cell line Huh7, specific uremic toxins (e.g. indoxyl sulfate, p-cresyl sulfate, CMPF) will be tested to see if they directly impair rosuvastatin transport. Rosuvastatin uptake will be measured with ultra-performance liquid chromatography coupled to mass spectrometry.

Results: Preliminary results have shown that OATP2 expression is decreased by 25% in CKD rat livers compared to control. Treatment with AST-120 causes a significant reduction in the plasma concentration of the uremic toxins indoxyl sulfate and p-cresyl sulfate. AST-120 treatment restores OATP2 expression to control levels.

Conclusions: Decreased hepatic OATP2 expression in CKD will result in reduced clearance of substrate drugs. This could lead to toxicity if a lowered dose is not administered. On average a CKD patient will be co-prescribed 10 different drugs. Clarifying the impact of CKD on drug transporter expression and activity will help guide dosing in this patient population.

SA-PO554

Patient Characteristics and Genetics Contribute to Kidney Function After Cisplatin Therapy Cara A. Chang,[1] Nickie L. Johnston,[1] Madeleine Gomez,[1] Lucas Ellison,[1] Lauren Aleksunes,[2] Steven R. Kleeberger,[3] Daniel Bowles,[1] Cindy L. O'Bryant,[1] Melanie S. Joy.[1] *[1]Skaggs Schools of Pharmacy and Medicine, Univ of Colorado, Aurora, CO; [2]Ernest Mario School of Pharmacy, Rutgers Univ, NJ; [3]NIEHS.*

Background: It is known that kidney function can decline after a single dose of cisplatin necessitating alternate chemotherapeutic regimens. The current study explored the contribution of patient characteristics and polymorphisms in drug metabolism and transport genes relevant to cisplatin kidney disposition on changes to renal function.

Methods: Blood (5mL) was obtained from patients (n=206) who received cisplatin. Genotyping assessments included candidate SNPs in kidney uptake and efflux transporters (*SLC22A2, ABCC2, SLC47A1*) and metabolism pathways (*GSTA1, GSTP1, GGT1*). Genotyping was performed using QuantStudio multiplex assays and coded [0(wt/wt), 1(wt/var), or 2(var/var)]. Glomerular filtration rate (GFR, mL/min/1.73m^2) and changes from pre-cisplatin to the time just prior to the second dose were calculated. Univariate and multivariate analyses were performed using patient characteristics and genotyping results.

Results: Patient demographics (mean±sd) included: age 53±14 y, weight 80±20 kg, BSA 1.9±0.3, Caucasian 90%, gender (50%M/50%F), and cisplatin dose (65±23 mg/m^2). Specific patient characteristics that significantly ($p<0.05$) contributed to a beneficial effect on GFR were non-Caucasian race, baseline GFR, and non-fractionated cisplatin dosing. Genetic variant in *GSTP1*/GST pi-1 variant (rs1695) and wildtypes in *SLC22A2*/OCT2 (rs2279463 and rs3127573) significantly ($p<0.05$) contributed to a beneficial effect on GFR. Variables retained in the final model (R^2 25.25%, $P<0.0001$) were: Change in GFR = 38.983 - 0.1714 (weight) – 0.3685 (baseline GFR) + 5.893 (*GSTP1*; rs1695).

Conclusions: The results from this study demonstrate the combined role of patient characteristics and genetic variants in drug disposition genes on changes to GFR secondary to cisplatin. Appropriate risk stratification based on patient characteristics and genetics may be used to apply precision medicine to reduce the risk of kidney injury from cisplatin and potentially other nephrotoxins.

Influence of Genetic Variations in Fcγ Receptors (FcgR) and Cytochrome P450 (CYP450) Enzymes on Treatment Outcomes in ANCA-Associated Vasculitis (AAV) Divya Indrakanti,[1] Rodrigo Cartin-ceba,[2] Gary S. Hoffman,[3] Cees Kallenberg,[4] Carol Langford,[3] Peter A. Merkel,[5] Paul Monach,[6] Robert Spiera,[7] E. William St. Clair,[8] Ulrich Specks,[2] John H. Stone,[9] Daniel J. Birmingham,[1] Brad H. Rovin.[1] *[1]The Ohio State Univ Wexner Medical Center, Columbus, OH; [2]Mayo Clinic and Foundation; [3]Cleveland Clinic Foundation; [4]Univ of Groningen, Netherlands; [5]Univ of Pennsylvania; [6]Boston Univ School of Medicine; [7]Hospital for Special Surgery; [8]Duke Univ Medical Center; [9]Massachusetts General Hospital.*

Background: The Rituximab in AAV (RAVE) trial compared rituximab (RTX) to cyclophosphamide (CYC) for the treatment of AAV. Using the RAVE cohort we investigated whether known single nucleotide polymorphisms (SNPs) in FcgR or CYP450 enzyme genes were associated with the response to RTX and CYC treatment, respectively.

Methods: SNPs for FcgR (FcgRIIA 491G>A, FcgRIIB 695T>C, FcgRIIIA 559T>G) and CYP450 (CYP2B6 1459 C>T, CYP2C19 681 G>A) were analyzed by direct sequencing of PCR-amplified genomic DNA. Each SNP was tested as a predictor of the primary outcome, complete remission at 6 months, using logistic regression including the covariates baseline BVAS/WG, ANCA type, and new versus relapsing disease. The association of these SNPs with the trial's secondary outcomes, including time to complete remission, time to relapse, and time to B-cell reconstitution, were analyzed by Kaplan-Meier and Cox proportional hazard ratios.

Results: No significant associations were identified between FcgRIIA, FcgRIIB, FcgRIIIA, CYP2B6 or CYP2C19 SNPs and the primary outcome. However, the 491AA genotype of FcgRIIA was associated with a shorter time (183± 47 versus 241± 114 days) to complete remission (n=52, $p<0.001$) in the entire cohort.

Conclusions: None of the SNPs tested influenced response to treatment with RTX or CYC in AAV. The finding that FcgRIIA 491 G>A was associated with a shorter time to complete with both RTX and CYC implies FcgRIIA may be involved in disease pathogenesis and response to therapy.

SA-PO556

The *GSTA1* Polymorphism and Cyclophosphamide Therapy Outcomes in Lupus Nephritis Patients Na Hong Wang, Jun Xue. *Nephrology, Nephrology, Shanghai, China.*

Background: Pulsed low-dose cyclophosphamide (CTX) therapy has become the most effective approaches in improving the clinical outcomes of lupus nephritis (LN) patients. However, variations in CTX therapeutic outcomes in LN patients are incompletely understood.

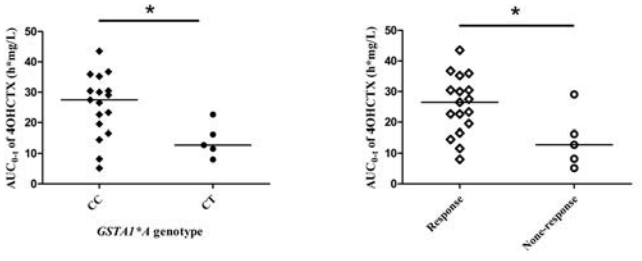
Methods: We investigated the contributions of known allelic variants in *CYP2B6*, *CYP2C19*, *CYP3A5*, *GSTA1,GSTP1*, *ABCC1* and *ABCC4* genes to CTX therapy outcomes

in LN patients.Pharmacokinetics of CTX and 4-hydroxycyclophosphamide (4OHCTX) were obtained from 22 patients randomly enrolled from 77 LN patients and applied to explore the mechanism.

Results: GSTA1, one of detoxification enzymes to CTX, gene polymorphism could greatly influence the therapeutic outcome to CTX treatment in these 77 LN patients. LN patients with a *GSTA1*A* mutation (CT heterozygous) had a risk of none-response (*P* =0.005).

Genotype	No. of patients response	No. of patients none-response	*P*
CYP2B6*4 AA(n=38) GA/GG(n=39)	33 29	5 10	0.25
CYP2C19 GG(n=31) GA/AA(n=46)	24 38	7 8	0.57
CYP3A5 GA/AA (n=40) GG(n=37)	35 27	5 10	0.15
ABCC1/MRP1 CT/TT(n=63) CC(n=14)	50 12	13 2	0.73
ABCC1/MRP1 GG(n=67) GT(n=10)	52 10	15 0	0.20
ABCC4/MRP4 GG(n=35) GT/TT(n=42)	28 34	7 8	1
GSTA1*A CC(n=59) CT(n=18)	52 10	7 8	0.005**
GSTA1*B GG(n=60) GA/AA(n=17)	50 12	10 5	0.30
GSTP1 AA(n=45) GA/GG(n=32)	38 24	7 8	0.39

Pharmacokinetics data indicated that patients with a *GSTA1*A* heterozygous variant had a lower exposure to 4OHCTXcompared to wild-type patients (12.8(9.8, 19.5) h*mg/L *vs.*27.5 (18.1, 32.8) h*mg/L, *P* =0.023), but not CTX. And clinical efficacy was significantly related to higher exposure to 4OHCTX, *P* =0.038).



Conclusions: LN patients with *GSTA1*A* heterozygous genotypes had poor CTX treatment response due to less exposure to activated 4OHCTX. A pharmacogenomic approach using the *GSTA1* SNP may be useful for predicting clinical efficacy to CTX therapy in LN patients, and facilitating individualized therapy.

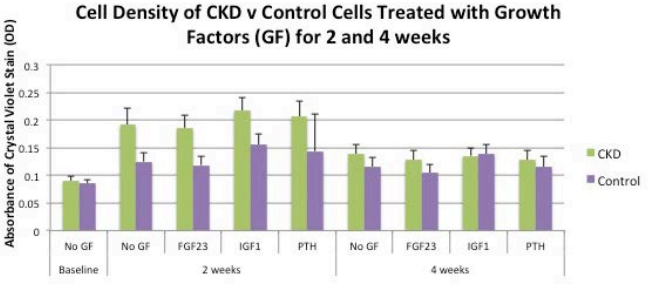
Effect of Growth Factors on Bone Mineralization in Health and CKD

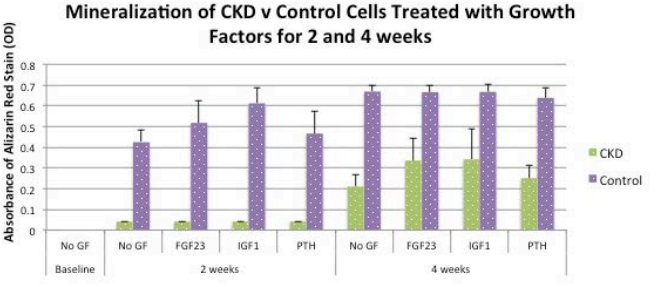
Nadine Khouzam,[1] Renata C. Pereira,[1] Isidro B. Salusky,[1] Richard E. Bowen,[2] Katherine Wesseling-Perry.[1] *[1]Pediatrics, David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]Orthopedic Surgery, David Geffen School of Medicine at UCLA, Los Angeles, CA, United Kingdom.*

Background: Children with chronic kidney disease (CKD) develop unexplained resistance to PTH and GH. Moreover, bone expression of FGF23 is very high in CKD. Data suggest that FGF23 may directly suppress osteoblast maturation and mineralization in mice (Weng JBMR 2009); however, it is not known whether excess expression of this hormone has direct effects on bone cells in CKD. We have previously demonstrated that primary osteoblasts isolated from patients with CKD have defects in maturation and mineralization, even when removed from the uremic milieu. We thus hypothesized that CKD-mediated alterations in osteoblast maturation may contribute to a blunted response to growth factors in pediatric CKD.

Methods: Human osteoblasts isolated from 3 patients with CKD and 3 normal controls were grown to confluence and induced to mineralize. Cells were treated twice weekly with fresh media and 100 nm of PTH, 200ng/mL of IGF1 or 10ng/mL of FGF23 for 0, 2 and 4 weeks. Cell density and mineralization were assessed by staining parallel wells with crystal violet and alizarin red respectively and quantified using spectrophotometry. Results were expressed as the mean (+ SE) in optic density. A mixed model was used to test differences in proliferation between CKD cells and healthy controls and between hormone dosages over time.

Results: Cells from CKD patients mineralized at a slower rate than cells from normal controls (p<0.05). The addition of growth factors did not have a significant effect on the rate of mineralization for the sample size used.





Conclusions: Diminished mineralization is present in CKD; as previously demonstrated in pediatric patients. Further studies are required to assess whether PTH, IGF1 and FGF23 have an effect on mineralization of human osteoblasts.

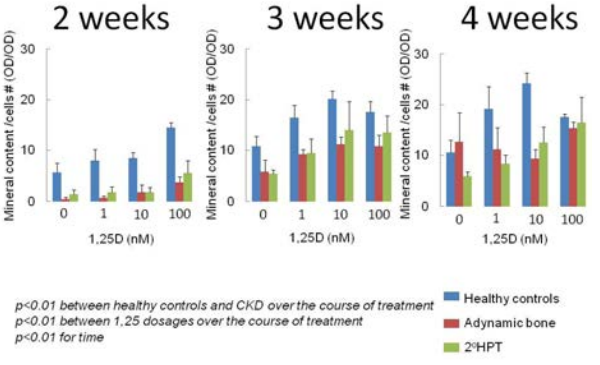
SA-PO558

CKD Induces Intrinsic Alterations in Osteoblast Response to 1,25D

Renata C. Pereira,[1] Nadine Khouzam,[1] Richard E. Bowen,[2] Isidro B. Salusky,[2] Katherine Wesseling-Perry.[1] *[1]Pediatrics, David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]Orthopedics, David Geffen School of Medicine at UCLA, Los Angeles, CA.*

Background: Skeletal mineralization defects are common in pediatric CKD patients. In vivo $1,25(OH)_2$vitamin D (1,25D), the only currently approved therapy for the treatment of 2°HPT in children, fails to normalize skeletal mineralization in these patients. We have recently demonstrated that primary osteoblasts obtained from patients with CKD have altered proliferation, differentiation and mineralization characteristics, suggesting that CKD results in intrinsic changes to osteoblast biology, independent of circulating mineral ion and hormone concentrations.

Methods: To evaluate the interaction between CKD and 1,25D therapy on osteoblast maturation and mineralization, primary human osteoblasts from 3 healthy controls, 3 pediatric dialysis patients with low bone turnover (adynamic bone) and 3 pediatric patients with high bone turnover (2°HPT) were cultured under pro-mineralizing conditions consisting of 10mM β-glycerolphosphate and 100 ug/ml ascorbic acid in the presence of 1,25D at 1, 10, and 100 nM. After 2, 3, and 4 weeks of growth under mineralizing conditions, cells were washed with PBS, fixed with 10% formalin, and stained with2% Alizarin Red S. The amount of mineral content was assessed by measuring absorption of acetic acid-extracted Alizarin Red S dye (at 405 nm) normalized by live cell concentration (as assessed by absorption (at 570 nm) of methanol-extracted Crystal Violet staining obtained from parallel cultures).



Results: 1,25D treatment decreased proliferation and increased mineralization; however, high concentrations were required in cells from CKD patients (**Figure**).

Conclusions: CKD induces osteoblast resistance to 1,25D.

SA-PO559

Fourier Transform Infrared Spectroscopy Crystallinity Indices in Bone from Patients with ADPKD Renata C. Pereira,[1] Berenice Y. Gitomer,[2] Isidro B. Salusky,[1] Diana George,[2] Jason W. Stoneback,[3] Karen B. King,[3] Myles S. Wolf,[4] Michel Chonchol.[2] *[1]Pediatrics, UCLA, Los Angeles, CA; [2]Medicine, Univ of Colorado, Aurora, CO; [3]Orthopaedics, Univ of Colorado, Aurora, CO; [4]Nephrology, Northwestern Univ, Chicago, IL.*

Background: We have previously shown that patients with autosomal dominant polycystic kidney disease (ADPKD) and normal kidney function have a low bone turnover state. This is coupled with increased expression of fibroblast growth factor 23, dentin matrix protein 1 and osteopontin in bone compared to healthy controls. To further characterize the bone defect in ADPKD fourier transform infrared (FTIR) spectroscopy was undertaken.

Methods: ADPKD patients with an average eGFR 111 ml/min/1.73m^2 and normal parathyroid hormone levels underwent standard tetracycline double labeling prior to transiliac crest bone biopsy. FTIR imaging was performed on bone sections from 6 ADPKD patients and 6 age and sex matched healthy historical controls.

Results: The mean (SD) age and eGFR of ADPKD patients were 29±4 yrs and 115 mL/min/1.73m^2, respectively. The sex distribution was 5 males and 1 female. Crystallinity a measure of the size of mineral crystals and the degree of order within the crystals was obtained by FTIR and differed significantly between ADPKD and control samples. The differences were more pronounced in the cortices (1.22 vs. 1.19; p = 0.03) than in the trabeculae (1.19 vs. 1.17; p= 0.48). There were no significant differences in heterogeneity of crystallinity, mineral/matrix, carbonate/mineral, collagen maturity (cross links) or acid phosphate substitution between ADPKD and historical control samples.

Conclusions: We describe for the first time a significant difference in the chemical composition of cortical bone measured by FTIR in patients with ADPKD when compared to historical control bone samples. Bone crystallinity has been associated with bone strength and stiffness, it is thus intriguing to hypothesize that the observed changes may impact bone quality and expression of bone proteins in ADPKD. Future studies that also assess bone strength and elasticity will be required to more fully investigate bone quality in ADPKD.

Late Onset Avascular Osteonecrosis in Renal Transplant Recipients Spyridon Arampatzis, Anita Maurer, Vasileios Devetzis, Uyen Huynh-do. *Nephrology, Hypertension and Clinical Pharmacology, Uni. Hospital Bern, Inselspital, Bern, Switzerland.*

Background: Avascular osteonecrosis (AO) after renal transplantation (RT) is a debilitating skeletal complication. In most studies patients with AO presented within the first 24 months after RT. In order to determine the prevalence and therapeutic outcome of late onset AO (³24 months after RT) we conducted a single-center retrospective study based on radiological/histological confirmed cases.

Methods: We conducted a single-center retrospective study among our RTR with a clinical diagnosis of AO over the past two decades. We evaluated 70 cases with a AO. In 46 patients AO was radiological/histological confirmed and all relevant clinical, radiological and laboratory data were extracted and analyzed.

Results: The average follow-up time was 14 (±8) years after the first RT. The prevalence of AO was 5.4%. Overall, 41 patients showed AO of the femoral head, 23 bilateral AO of the femoral head, 5 of the knee and 5 of other locations, while 43 patients were symptomatic at time of diagnosis. In our cohort 71% presented late onset (³24 months) AO after RT. On average, AO was diagnosed 90 months after RT (SD±78). Furthermore, RTR with late onset were younger at the time of first RT (39±15 years, p<0.01) than the ones with early onset (53±14). A considerably higher cumulative dose of prednisone was administered to patients with late onset of AO prior to their first AO (21±11g vs. early onset 4±1g, p-value <0.001) and a higher percentage of late onset RTR received corticosteroids even prior to their first RT (48%) compared to the group of early onset (15%; p=0.038). Overall, 34% of the patients presented with an advanced stage of AO Ficat III or IV at first diagnosis of AO and 57% needed total hip arthroplasty.

Conclusions: Late onset avascular necrosis represent a corticosteroid related complication, with a particularly high prevalence among young RTR and is associated with significant morbidity. The majority of AO patients have a bilateral manifestation and present with advance structural femur failure resulting in hip replacement.

SA-PO561

Indoxyl Sulfate Exacerbates Low Bone Turnover Induced by Parathyroidectomy in Rats Junya Hirata,[1] Kazuya Hirai,[1] Hirobumi Asai,[1] Masaki Inada,[2] Chisato Miyaura,[2] Hideyuki Yamato,[1] Mie Watanabe-Akanuma.[1] *[1]Kureha Corporation, Tokyo, Japan; [2]Tokyo Univ of Agriculture and Technology, Tokyo, Japan.*

Background: Low-turnover bone disease is one of the bone abnormalities observed in chronic kidney disease (CKD) patients and recognized to be associated with low serum parathyroid hormone (PTH) level and skeletal resistance to PTH. Indoxyl sulfate (IS) is a representative uremic toxin that accumulates in the blood as renal dysfunction progresses in CKD patients. In order to examine whether IS exacerbates low bone turnover, we produced rats with low bone turnover by parathyroidectomy (PTX) and fed these rats a diet containing indole, a precursor of IS, to elevate blood IS level from indole metabolism.

Methods: Male SD rats were underwent PTX. From 2 weeks after PTX, the rats were fed a diet containing 0.5% indole (w/w) for 4 weeks. Serum IS levels and bone metabolism related markers were examined periodically. After the end of indole treatment, histomorphometric analyses in the secondary spongiosa of the femur and measurement of bone mineral density of the tibia were performed.

Results: Histomorphometric analyses revealed significant decreases in both bone formation-related parameters (mineralized surface/ bone surface, bone formation rate/ bone surface) and bone resorption-related parameters (eroded surface/ bone surface, osteoclast surface/ bone surface) in PTX rats. In indole-treated PTX rats, further decreases in bone formation-related parameters were observed. On the other hand, there were no decreases in bone resorption-related parameters in indole-treated PTX rats when compared to the PTX rats. Serum IS levels in indole-treated PTX rats were elevated during the indole treatment period and the levels were similar to those in CKD and dialysis patients.

Conclusions: IS exacerbates low bone turnover through inhibition of bone formation by mechanisms unrelated to skeletal resistance to PTH in rats. Our data suggest that IS may be one of the uremic toxins that contribute to progression of low-turnover bone disease in patients with CKD or on dialysis whose serum IS levels are elevated because of renal dysfunction.

Changes of Marrow Adipocyte Away from Bone Surface After Parathyroidectomy in Patients with Secondary Hyperparathyroidism Aiji Yajima, Ken Tsuchiya, Kosaku Nitta. *Medicine, Tokyo Women's Medical Univ, Tokyo, Japan.*

Background: We've already reported that marrow adipocytes proliferated around bone surface after parathyroidectomy for secondary hyperparathyroidism. However, fibrous volume was reduced near bone surface where adipocytes proliferated after the surgery. In addition, adipocytes may be associated with bone remodeling, because adipocytes suppress the function of osteoblasts. Therefore, the parameters of marrow adipocyte, which are away from bone surface were histomorphometrically measured before and after parathyroidectomy for secondary hyperparathyroidism.

Methods: Sixteen hemodialysis (HD) patients suffering from secondary hyperparathyroidism (Age; 58.4 ± 8.4 years, HD duration; 14.3 ± 6.8 years) were treated by total parathyroidectomy with immediate autotransplantation (parathyroidectomy) and received iliac bone biopsies before and at 1 week (n=4) and at 4 weeks (n=10) after parathyroidectomy. Adipocyte volume per marrow volume (Fa.V/Ma.V;%), adipocyte number per marrow volume (N.Fa/Ma.V;N/mm^2), and mean adipocyte volume (Fa.V/N.Fa (×10^{-3}) mm^2/N) were obtained in the area away from bone surface. If there are so many artifacts in bone marrow, the bone samples were excluded from this research.

Results: Serum intact parathyroid hormone (i-PTH) level was decreased from 1268.8 ± 459.6 to 18.5 ± 7.9 pg/mL. Fa.V/Ma.V was siginificantly increased from 22.4 ± 6.3 to 30.9 ± 8.1 % (P<0.001), N.Fa/Ma.V was also increased from 183.3 ± 48.1 to 217.7 ± 47.1 N/mm^2 (P<0.001), and Fa.V/N.Fa was not changed (1626.9 ± 418.5 to 1668.7 ± 548.1 (× 10^{-3}) mm^2/N) after parathyroidectomy.

Conclusions: The facts substantiate that an acute reduction of PTH induced an increase of adipogenesis. As reported previously, osteoblast surface transiently increased at 1 week after parathyroidectomy, but it acutely decreased at 4 weeks after the surgery. Thease findings mean that undifferentiated stem cells went to the adipogenesis after the acute reduction of PTH in patients receiving HD.

Evaluation of Marrow Adiposity in Patients Pre and Post-Kidney Transplantation: Comparison Between Bone Histomorphometry Mariel Jose Hernandez,[1] Luciene dos Reis,[2] Igor Marques,[2] Fellype C. Barreto,[3] Elias David-Neto,[4] Rosa M.A. Moyses,[2,5] Ezequiel R. Bellorin-Font,[1] Vanda Jorgetti.[2] *[1]Nephrology Div, Univ Central de Venezuela, Caracas, Venezuela; [2]Nephrology Div, Univ de Sao Paulo, Sao Paulo, Brazil; [3]Medical School, Pontifícia Univ Católica, Curitiba, Brazil; [4]Urology Div, Univ de Sao Paulo, Sao Paulo, Brazil; [5]UNINOVE.*

Background: The osteoblasts (Obs) and adipocytes (Ads) derive from the mesenchymal cells (MSCs). An imbalance in the differentiation of Obs and Ads could be decisive to preserve the integrity of bone. We analyzed bone histomorphometry and marrow adiposity in bone biopsies from patients before and after kidney transplantation (KT).

Methods: We compared biochemical parameters and bone histomorphometry data from 23 patients, before and one year after KT, under standard immunosuppressive therapy including glucocorticoids. Adipocytes area (Ad.Ar/T.Ar,%), number (N.Ad/B.Pm,n/mm), and the ratio adipocytes/active osteoblasts (N.Ad/N.AcOb), and adipocytes/total osteoblasts (N.Ad/N.TOb) indexes were measured.

Results: Our patients were young (42.3±2.6 years) and mostly male (14). One year after KT, PTH levels (515.6±424.1 vs. 96± 137.1), bone alkaline phosphatase (98.2±63.9 vs. 37.4± 26.6) and sclerostin (1.1±0.8 vs. 0.5± 0.1) decreased significantly. A significant increase in Ad.Ar/T.Ar (24.3±11.6 vs. 30.6±10.5), N.Ad/B.Pm (37.3±20.6 vs. 47.9±25), N.Ad/N.AcOb (240.4±657.6 vs. 674.6±1192.4) and N.Ad/N.TOb (128.2±362.3 vs. 230.5±642.4) and a decreased osteoblast number/tissue area (22.8±21.9 vs. 5.3±2.8) was observed. In the post-transplant biopsies significant correlation was found between N.Ad/N.TOb and PTH (r=-0.48), trabecular number -Tb.N (r=-0.29) and mineral apposition rate (r=-0.23); as well as between Ad.Ar/T.Ar and bone volume (r=-0.36) and between N.Ad/B.Pm and Tb.N (r=-0.72).

Conclusions: KT improved biochemical findings related to bone mineral disease, however, this condition is also clearly associated with an inverse relationship of the bone

mass and osteogenic cellularity with marrow adiposity, compromising dynamic parameters. MSCs differentiation is competitively balanced; mechanisms that promote one cell fate actively suppress mechanisms that induce the alternative.

SA-PO564

High Marrow Adiposity Is Associated with Low Turnover Bone Disease in Peritoneal Dialysis Patients Fellype C. Barreto,[1] Rodrigo Azevedo de Oliveira,[5] Mariel Jose Hernandez,[6] Ana Clara Simões Flórido Almeida,[1] Luciene dos Reis,[2] Aluizio B. Carvalho,[3] Vanda Jorgetti,[2] Rosa M.A. Moyses.[2,4] *[1]Pontificia Univ Católica do Paraná; [2]Univ de São Paulo; [3]Univ Federal de São Paulo; [4]Univ Nove de Julho, UNINOVE; [5]Univ Federal do Rio Grande do Norte; [6]Univ de Caracas.*

Background: Marrow adiposity has been implicated in the pathogenesis of bone disorders, such as osteoporosis and bone fragility. We sought to investigate the relationship between marrow adiposity and renal osteodysthrophy in peritoneal dialysis patients.

Methods: We analyzed transiliac bone biopsy specimens from 41 peritoneal dialysis patients (age:50.3±10.2 yrs) by quantitative histomorphometry to asses bone and marrow adipocyte parameters. Selected biochemical parameters, such as serum markers of bone turnover and sclerostin, were measured.

Results: Adipocyte area (Ad.Ar), perimeter (Ad.Pm) and percentage of adipocyte volume per marrow volume (Ad.V/Ma.V) correlated positively with age. Diabetic patients had higher marrow adiposity than non diabetic patients (Ad.V/Ma.V= 50±14 vs 39±12%; P=0.009; Ad.Ar=0.19±0.06 vs 0.15±0.05 mm^2;P=0.02). Ad.V/Ma.V demonstrated inverse association with bone specific alkaline phosphatase (r= -0.32;P=0.04) and direct relationship with sclerostin (r=0.38;P=0.01). No association was found between marrow adiposity and dynamic bone hystomorphometric parameters. Interestingly, patients with Ad.V/Ma.V > 41% (median) presented higher percentage of low turnover bone disease (P=0.04) as well as significantly lower bone specific alkaline phosphatase (39.5±27.3 vs 65.3± 28.9 U/L; P=0.006) and higher sclerostin (2.3±0.97 vs 1.6±0.97 ng/mL ;P=0.02) levels than patients below the median.

Conclusions: Increased marrow adiposity seems to be associated to lower osteoblast activity and to low turnover bone disease in peritoneal dialysis patients. The higher marrow fat in diabetic and aged patients might expose them to an increased risk for fracture. Further studies are required to understand the possible contribution of marrow adiposity to the pathogenesis of renal osteodysthrophy.

Role of Wnt10b Signaling in Cinacalcet-Induced Bone Anabolic Effects Cai-Mei Zheng,[1,2] Yung-Ho Hsu,[1,2] Yuh-feng Lin,[1,2] Jia-Fwu Shyu,[1,3] Kuo-cheng Lu.[1,4] *[1]Graduate Inst of Clinical Medicine, Taipei Medical Univ, Taipei City, Taiwan; [2]Dept of Nephrology, Shuang Ho Hospital, New Taipei City, Taiwan; [3]Biology and Anatomy, National Defense Medical Center, Taipei City, Taiwan; [4]Dept of Medicine, Cardinal-Tien Hospital, New Taipei City, Taiwan.*

Background: Chronic kidney disease-mineral bone disorders (CKD-MBD) is important for osteoporosis and bone fractures in CKD patients. Since calcium receptor plays an important role in osteoclast differentiation, we assume that calcimimetic agents(cinacalcet) might have a role in bone remodeling.

Methods: Bone marrow mononuclear cells isolated from rat femur and tibia were induced into osteoclasts by M-CSF and RANKL treatments. Osteoclasts were treated with different doses of cinacalcet. Untreated osteoclasts used as control. The release of Clastokine Wnt10b was measured by ELISA and Western blot. Alizarin red staining was used to evaluate mineralization of osteoblasts co-cultured with osteoclasts. Fluo-4 AM stain was used to determine intracellular calcium changes. Cinacalcet treated and untreated CKD animal models (5/6 nephrectomy) were used to analyse the changes in clastokines and bone mineral density.

Results: In osteoclasts, cinacalcet decrease the TRAP stain reaction. However, ELISA analysis showed increases of Wnt10b expression in supernatant collected from the cinacalcet-treated osteoclasts. Pretreatment of Wnt10b secretion inhibitor, C-59, blocked the increase of Wnt10b induced by cinacalcet. Western blot analysis showed an increase intracellular Wnt10b in the cinacalcet-treated osteoclasts. Culture of osteoblasts with the cinacalcet-treated osteoclasts supernatant showed an increase of mineralization as indicated by alizarin red staining. Intracellular calcium staining is increased in cinacalcet-treated osteoclasts, which demonstrated its effect on osteoclast Wnt 10b release is through intracellular calcium oscillation. Clastokines and bone mineral density (BMD) changes are also noted in CKD rats before and after cinacalcet treatment.

Conclusions: Cinacalcet decrease osteoclastic activity, but increase the secretion of Wnt10b through intracellular calcium oscillation. Cinacalcet also related with certain clastokine and BMD changes in CKD animals.

SA-PO566

Changes of Osteocyte Number in Micropetrosis Area After Treatment of Secondary Hyperparathyroidism Aiji Yajima, Ken Tsuchiya, Kosaku Nitta. *Medicine, Tokyo Women's Medical Univ, Tokyo, Japan.*

Background: Osteocyte number decreased after total parathyroidectomy with immediate autotransplantation (parathyroidectomy) for secondary hyperparathyroidism in hemodialysis (HD) patients (JBMR 2010). Osteocyte number in micropetrosis area and in the other area was measured before and after parathyroidectomt and treatment with cinacalcet hydrochloride (HCL).

Methods: Thirteen HD patients received parathyroidectomy and transiliac bone biopsies before and at 3-9 weeks after parathyroidectomy (Group I). And eight HD patients with secondary hyperparathyroidism were treated by cinacalcet HCL and received bone biopsies before and at 1 year after the treatment (Group II). Osteocyte number in micropetrosis area (N.Ot/Mp.V;N/mm^2) and in the other area (N.Ot/(BV-Mp.V);N/mm^2) were measured before and after the treatment.

Results: Serum intact parathyroid hormone (i-PTH) levels decrease from 1186.5 ± 768.3 to 24.8 ± 8.1 pg/ml after parathyroidectomy. N.Ot/Mp.V was decreased from 159.8 ± 71.2 to 110.1 ± 87.3 N/mm^2 (P<0.001), and N.Ot/(BV-Mp.V) was not changed (from 236.1 ± 69.3 to 262.2 ± 79.3 N/mm^2) after parathyroidectomy (Group I). Serum i-PTH levels decrease from 903.6 ± 503.0 to 212.7 ± 98.1 pg/ml after the treatment with cinacalcet HCL. N.Ot/Mp.V was not changed in both mictropetrosis area (100.1 ± 68.2 to 99.6 ± 76.1 N/mm^2) and in the other area (from 240.1 ± 56.3 to 279.6 ± 88.6 N/mm^2) after the treatment (Group II).

Conclusions: Cinacalcet HCL did not reduce osteocyte number in both micropetrosis area and in the other area, suggesting that this agent improves bone quality by maintaining osteocytic perilacunar/canalicular system. Parathyroidectomy reduces osteocyte number in only the micropetrosis area.

SA-PO567

Trabecular Bone Score in Kidney Transplant Recipients Kyla Lynn Naylor,[1] Lisa M. Lix,[2] Didier Hans,[3] Amit X. Garg,[1,4,5] David N. Rush,[2] William Leslie.[2] *[1]Western Univ; [2]Univ of Manitoba; [3]Lausanne Univ Hospital; [4]London Health Sciences Centre; [5]Inst for Clinical Evaluative Sciences.*

Background: Kidney transplant recipients have altered bone mineral metabolism and are at a higher risk of fracture compared to the general population. There is conflicting evidence regarding the ability of bone mineral density (BMD) to accurately predict fracture. Trabecular bone score (TBS) is a texture measure derived from dual energy x-ray absorptiometry (DXA) lumbar spine images which provides information independent of BMD. We assessed TBS in kidney transplant recipients.

Methods: We included 327 kidney transplant recipients from Manitoba, Canada, who received a post-transplant DXA (median 106 days post-transplant). We matched each kidney transplant recipient (mean age 45 years, 39% men) to three controls from the general population (matched on age, sex, and date of DXA). Lumbar spine (L1-L4) DXA images were used to derive TBS. Non-traumatic incident fracture (excluding hand, foot, and craniofacial) (n=31) were assessed during a mean follow-up of 6.6 years. We used logistic regression to determine predictors of TBS and hazard ratios per standard deviation decrease in TBS to express the gradient of risk for fracture prediction using Cox proportional hazards regression.

Results: Compared to the general population, kidney transplant recipients had a significantly lower lumbar spine TBS (1.41 ± 0.13 versus 1.37 ± 0.13, p<0.001). Multiple logistic regression revealed reduced TBS (lowest versus highest tertile) in kidney transplant recipients compared to the general population (adjusted odds ratio, 2.13 95% confidence interval [CI] 1.47-3.07). TBS predicted fractures in kidney transplant recipients independent of the Fracture Risk Assessment (FRAX) score and spine BMD (adjusted hazard ratio per standard deviation decrease in TBS 1.57, 95% CI 1.07-2.29).

Conclusions: Kidney transplant recipients had abnormal bone texture as assessed by TBS. Lumbar spine TBS was able to predict incident fractures in kidney transplant recipients and may provide novel insights into skeletal fragility in this unique population.

SA-PO568

Low Bone Turnover Disease Is Prevalent 1 Year After Successful Renal Transplantation: A Cross-Sectional Bone Biopsy Study Pieter Evenepoel,[1] Patrick C. D'Haese,[2] Liesbeth Viaene,[1] Geert J. Behets.[2] *[1]Nephrology, Univ Hospitals Leuven, Leuven, Belgium; [2]Pathophysiology, Univ of Antwerp, Antwerp, Belgium.*

Background: Studies evaluating bone histomorphometry in renal transplant recipients are scanty and so far hampered by small sample size and heterogeneity.

Methods: We evaluated bone histomorphometry (according to TMV classification), laboratory parameters of mineral metabolism (including biPTH, FGF23, sclerostin, OPG, sRANKL), biomarkers of bone formation (bsAP) and bone resorption (TRAP5b, NTX), and inflammation (IL6) in an unselected cohort of 60 renal transplant recipients (44 males, age 56±12 yrs) 1 year after successful transplantation (NCT01886950). Standard immunosuppressive regimen consisted of steroids, a calcineurin inhibitor and mycophenolate mofetil. Mean cumulative methylprednisolone dose at 1 year was 1.7 g/d.

Results: Sixty-five % of the patients presented with disturbances in at least one of the TMV parameters. High, normal and low bone turnover disease were observed in 1.7, 45.0, and 53.3 % of renal transplant recipients , respectively. Mineralization was delayed in 17.0 % and bone volume was low in 15.0 %. Patients with persistent

hypercalcemic hyperparathyroidism (n=4, 7%) showed either low or normal bone turnover. Hypophosphatemia was present in 11%. Vitamin D stores were sufficient in 52% (median HydroxyvitaminD 32 ng/ml) . Spearman correlation revealed significant correlations between bone formation rate and biomarkers of bone formation & resorption (direct: bsAP: r0.36, p=0.01; TRAP5b: r0.40, p<0.01; NTX:r0.38, p<0.01) and inflammation (inverse: Il6: r-0.51, p<0.001), but not with mineral metabolism hormones (PTH, FGF23, sclerostin).

Conclusions: Low bone turnover disease is the most prevalent bone disease in renal transplant recipients 1 year after successful renal transplantation. Additional studies are required to clarify underlying pathophysiological mechanisms. PTH, FGF23 and sclerostin do not correlate with histomorphometric parameters and circulating biomarkers of bone turnover.

SA-PO569

Sclerostin Bone Expression and Blood Levels in Patients with Chronic Kidney Disease Stages 2-5 Florence Lima, Marie-Claude M. Faugere, Hanna W. Mawad, Hartmut H. Malluche. *Div of Nephrology, Bone & Mineral Metabolism, Univ of Kentucky, Lexington, KY.*

Background: Sclerostin (Scl) produced by osteocytes (ocy) was found to be increased in blood in early stages of CKD patients (pts) with renal osteodystrophy (ROD). The aim of this study was to establish when blood scl levels and bone expression are increased and how they progress with worsening CKD.

Methods: Fifty pts underwent anterior iliac crest biopsies and blood was drawn at time of biopsy. Kidney function was determined by creatinine clearance using MDRD calculation. There were: 11 CKD-2, 16 CKD-3, 9 CKD 4-5 pts, and 14 healthy aged-matched controls. Scl concentrations in blood were determined by ELISA and scl expression in bone was determined in undecalcified bone sections by measuring number of ocy exhibiting positive scl immunostaining. Measurements were done separately in cortical and cancellous bone. Bone sections were also evaluated by histomorphometry for turnover, mineralization and volume.

Results: Blood scl levels were significantly greater in CKD compared to controls with no differences between stages (P<0.01).

Bone scl expression was significantly higher in cortex of CKD 2-5 pts compared to controls (P<0.01). Scl expression was significantly greater in cortical than in cancellous bone in CKD. In cancellous bone scl expression was higher in CKD; this reached significance in CKD-3 (Figure 1).

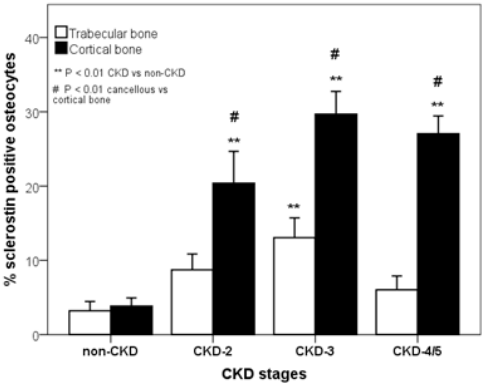

Figure 1. Sclerostin positive ocy per total ocy number in cancellous and cortical bone (mean ± SE).

Scl expression in cortical and cancellous bone correlated with serum scl (rho=0.30, 0.40, rsp; P<0.05). Serum scl correlated negatively with bone formation, activation frequency and osteoblast number (rho=-0.33, -0.38, -0.43, rsp; P<0.05). Scl in bone correlated negatively with trabecular thickness (rho=-0.51; P<0.05), osteoblast and osteoclast surface, and erosion depth (rho=-0.50, -0.52, -0.55, rsp; P<0.01).

Conclusions: These findings ascribe a potential role to scl in the pathogenesis and management of ROD.

SA-PO570

Single Timepoint and Longitudinal Serum Sclerostin Levels as Mortality Predictors in Prevalent Dialysis Patients Lotte Lips,[1] Camiel L.M. de Roij van Zuijdewijn,[1] Marc G. Vervloet,[1] Peter J. Blankestijn,[2] Denis Fouque,[4] Solenne Pelletier,[4] Pieter M. Ter Wee,[1] Menso Jan Nubé,[1] Muriel P. Grooteman.[1] *[1]Nephrology, VU Univ Medical Center, Amsterdam, Netherlands; [2]Nephrology, Univ Medical Center Utrecht, Utrecht, Netherlands; [3]Internal Medicine, Maasstad Hospital, Rotterdam, Netherlands; [4]Nephrology, Centre Hospitalier Univ de Lyon, Pierre Benite, France.*

Background: Currently, data are conflicting whether high serum Sclerostin (sScl) levels, a 22kDa-sized glycoprotein inhibiting bone formation, are positively or negatively associated with mortality. Its concentration may change over time. Therefore, we investigated whether longitudinal sScl levels predict mortality better than a single measurement.

Methods: A post-hoc analysis on data from the CONTRAST study was performed, a RCT comparing online postdilution hemodiafiltration to hemodialysis in prevalent dialysis patients. sScl was measured in a subset of patients. Patients were eligible for analysis if a baseline (T0) and a 6 months (T6) sScl value were available. Hazard ratios (HRs) were calculated within quartiles for sScl level at T0, T6 and for DsScl. All-cause mortality was used as end point. As the interaction between dialysis modality and DsScl was non-significant (p>0.1), pooled estimates are reported. To correct for multiple testing, a two-sided p-value <0.01 was considered statistically significant.

Results: Out of 714 patients, 341 were available for analysis. Baseline characteristics between these groups did not differ. Median sScl at T0, T6 and DsScl was 136.3 pmol/L (interquartile range [IQR] 98.7-186.1), 134.0 pmol/L (IQR 100.4-183.0) and 0 pmol/L (IQR -25 to 15), respectively. sScl values at baseline and T6 were negatively associated with mortality (adjusted HRs highest versus lowest quartile 0.49 [95% CI 0.30-0.81] and 0.48 [95% CI 0.29-0.82], respectively). However, we found no association between DsScl and mortality.

Conclusions: A single timepoint sScl is inversely associated with mortality in our cohort of dialysis patients. sScl change over a six month period does not predict mortality.

SA-PO571

Variation of PTH and Bone Biomarkers in Hemodialysis Patients Pierre Delanaye,[1] Xavier Warling,[1] Martial Moonen,[1] Nicole Simone Smelten,[1] Hans Pottel,[2] Jean-marie H. Krzesinski,[1] Etienne Cavalier.[1] *[1]Univ of Liège, Belgium; [2]Univ of Leuven, KULAK.*

Background: Bone turnover must be monitored in dialysis patients. KDIGO guidelines suggest to measure and follow-up both parathormone (PTH) and bone-specific alkaline phosphatase (b-ALP). Also underlined by the KDIGO, clinical decision should be based on variations (or slopes) (Δ, in%) of these biomarkers, more than on isolated concentrations. In this work, we studied the correlation between DPTH and Δ of different bone biomarkers: P1NP, CTX, TRAP-5b, osteocalcin and sclerostin. Δ were studied at different timings, namely 6 weeks (T6W), 6 months (T6M) and 1 year (T1Y).

Methods: We have prospectively followed the variations of these biomarkers over one year in patients from 3 independent dialysis centers at T6W (n=123), T6M (n=108) and T1Y (n=93). We analyzed DPTH with Δ of bone biomarkers by univariate linear regression. We also categorized patients according to variations reaching the critical difference of the biomarkers at one year. These results were analyzed by Mantel-Haenszel c^2 test.

Results: At T6W, a significant correlation was only found between DPTH and ΔCTX (r=0.38, p<0.0001). At 6M, a significant correlation was found between DPTH and ΔCTX (r=0.38, p<0.0001) and Dosteocalcin (r=0.27, p=0.0049). At T1Y, a significant correlation was found between DPTH and ΔCTX (r=0.47, p<0.0001), DP1NP (r=0.4, p<0.0001), Db-ALP (r=0.29, p=0.0054) and Dosteocalcin (r=0.36, p=0.0004). No correlation was found at T1Y neither between DPTH and DTRAP-5b nor Dsclerostin. The same conclusions were reached when variations reaching the critical differences were considered. Correlations between DPTH and Dbone biomarkers were particularly poor in patients with low PTH levels (as defined by the KDIGO) at baseline. Conclusions remained the same if analysis was restricted to the 93 patients who completed the study.

Conclusions: A concordance between variations of PTH on one hand and variations of CTX, b-ALP, osteoclacin and P1NP on the other hand can be observed in dialysis patients, but only after a long follow-up (at least one year). Variation of bone biomarkers need repeated measures and must not be analyzed on a too short period.

SA-PO572

Intereukin-1 Inhibition, Chronic Kidney Disease-Mineral and Bone Disorder (CKD-MBD), and Physical Function Kristen L. Nowak,[1] Adriana Hung,[2,3] Talat Alp Ikizler,[2] Heather Farmer,[1] Natjalie Salas,[2] Rafia I. Chaudhry,[2] Andrew N. Hoofnagle,[4] Gerard John Smits,[1] Michel Chonchol.[1] *[1]Univ of Colorado Denver; [2]Vanderbilt Univ; [3]VA Tennessee Valley Healthcare System; [4]Univ of Washington.*

Background: Epidemiologic studies have suggested a possible link of chronic systemic inflammation with vitamin D deficiency, intact parathyroid hormone (iPTH), and fibroblast growth factor 23 (FGF23) excess, which are a central features of CKD-MBD. Declining renal function is also associated with worsening physical function, which may be explained by systemic inflammation, CKD-MBD, or both. We hypothesized that inhibiting inflammation with an interleukin-1 (IL-1) trap would improve vitamin D deficiency, iPTH and FGF23 excess, as well as physical function in patients with moderate-to-severe CKD.

Methods: In a two-site, double-blind trial, 42 patients with stage 3-4 CKD were randomized to receive either the IL-1 trap rilonacept (160 mg/week) or placebo for 12 weeks. The following CKD-MBD markers were assessed in serum before and after the intervention: calcium, phosphorus, 25-hydroxyvitamin D (25(OH)D), 1,25-dihydroxyvitamin D ($1,25(OH)_2D$), iPTH, and iFGF23. A battery of tests was also administered in a sub-group (n=22) to assess multiple domains of physical function (endurance, locomotion, dexterity, balance, strength, and fatigue).

Results: Participants were 63±11 years of age, 24% female, 29% Hispanic, mean eGFR 38±13 ml/min/1.73m^2, and mean high sensitivity C-reactive protein (hsCRP) 4.7±4.2 mg/L. Rilonacept effectively reduced systemic inflammation, as evidenced by reduced hsCRP levels (p<0.01). There was no change in serum calcium, phosphorus, 25(OH)D, $1,25(OH)_2D$, iPTH, or FGF23 levels ($p^3$0.41) with IL-1 inhibition. Similarly, rilonacept did not alter locomotion, dexterity, balance, strength, or fatigue ($p^3$0.22). However, endurance (400m walk time) tended to be reduced in the rilonacept (-29 sec) as compared to placebo (-6 sec; p=0.059).

Conclusions: 12 weeks of IL-1 inhibition did not improve circulating markers of CKD-MBD or physical function (although it tended to improve endurance). These results support that inflammation does not directly mediate CKD-MBD or select domains of physical function.

Serum Metabolomic Profiling and CKD-MBD: A New Tool for Bone Turnover Evaluation

Aline Lourenco Baptista,[1] Kallyandra Padilha,[2] Pamella Araujo Malagrino,[2] Gabriela Venturini,[2] Ana Carolina de Mattos Zeri,[3] Janaina Silva Martins,[4] Rodrigo Azevedo de Oliveira,[5] Geuza Dutra,[6] Luciene dos Reis,[1] Vanda Jorgetti,[1] Alexandre Costa Pereira,[2] Rosa M.A. Moyses.[1,6] *[1]Nephrology, USP; [2]Molecular Cardiology, INCOR, USP; [3]LNBio, CNPEM; [4]UEM; [5]UFRN; [6]Master Degree Program, UNINOVE, Brazil.*

Background: Bone biopsy still is the gold standard to assess bone turnover in CKD patients and serum biomarkers are not able to replace histomorphometry. Recently, metabolomics has emerged as a new technique that could potentially improve disease diagnoses and the understanding of pathophysiology. However, as this approach has never been tested in the CKD-MBD scenario we investigated whether a serum metabolomic profile could help us to better predict bone turnover in CKD patients.

Methods: Serum and bone histomorphometry data from hemodialysis (HD, n=51) and peritoneal dialysis patients (PD, n=40) were analyzed. They were classified as high (HT, 49.4%) or low turnover (LT). Metabolomic analysis was done through MRI spectroscopy, followed by identification and quantification of metabolites and PLS-DA. As HD had a completely different metabolome of PD group, we analyzed them separately. In addition, we selected the main metabolites found in each group and searched for the metabolic pathways involved.

Results: The difference between LT and HT was explained by 12 metabolites in HD and 8 in PD ($p = 0.03$ and 0.01, respectively). ROC curve analysis showed that parathormone and alkaline phosphatase were the best predictors for HT, whereas glycerol and glucose were the best predictors for LT in HD and PD, respectively. The main canonical pathways involved were glycine degradation, tyrosine biosynthesis IV and phenylalanine degradation I in HD and creatine-phosphate biosynthesis, pyruvate fermentation to lactate and AMPK signaling in PD group.

Conclusions: In this preliminary analysis, we identified new metabolites that might be used as biomarkers of bone turnover. Moreover, the differences in metabolome between the two dialysis modalities and the different metabolic pathways suggest that the pathophysiological mechanisms involved in the modulation of bone turnover in these patients might be different.

Deletion of the Gene Encoding the Transient Receptor Potential Canonical Type 1 (TRPC1) Channel Produces Hyperparathyroidism, Low Calcitonin (CaT), Hypercalcemia, but Hypocalciuria and Enhanced Bone Mass: Evidence for the Role of TRPC1 in Regulating Intracellular Ca ($[Ca^{2+}]i$) in Target Cells

Bonnie Eby,[1] Alexander Lau,[1] Lindsay J. Barron,[1] Marybeth Humphrey,[1] Leonidas Tsiokas,[2] Kai Lau.[1,3] *[1]Medicine, Univ of Oklahoma, Oklahoma City, OK; [2]Cell Biology, Univ of Oklahoma, Oklahoma City, OK; [3]Medicine, VA Medical Center, Oklahoma City, OK.*

Background: We recently showed that TRPC1 deficiency impairs store-operated Ca entry (SOCE), reduces $[Ca^{2+}]i$, stimulates PTH and causes hypercalcemia. We here evaluated the potential mechanism & consequence.

Methods: We studied male TRPC1 wild-type & null mice by metabolic, clearance (Cl), & micro-CT techniqes. PTH, 1,25 di(OH) vit D (1, 25 D), & CaT were measured by mouse ELISA. We analyzed Ca & P (by published methods) & creatinine (Cre) by HPLC.

Results: Hypercalcemia in null mice emerged at 2 mon & lasted through 21 mon, when last checked. Serum Ca was high in fed & fasted null mice (10.1 vs. 9.4 mg%), excluding gut hyperabsorption. In pg/ml, [PTH] was higher in the null (598 vs. 402), [1,25 D] (301 vs. 308) similar & CaT lower (2.2 vs 2.8). P (6.6 vs. 6.5 mg%) was similar. At 7 mon, femur (105 vs. 84 mg) & hind limb (189 vs. 151 mg) were heavier, but the latter was shorter (34.5 vs. 35.7 mm), implying higher bone density in the null. Urine Ca (1.2 vs 2.2 mg/d), CaCl (14 vs. 26 ml/min) & urine Ca:Cre (1.8 vs. 3.1) were reduced. At 16 mon, urine OH-proline, absolute (400 vs. 734 mg/d) or ratioed to Cre (0.54 vs 0.96), was reduced. At 19 mon, on micro-CT, proximal tibia of null mice had 80 % more bone volume to tissue volume, 37% more trabecular number, 25 % less trabecular spacing, & 3-fold increase in trabecular connectivity density.

Conclusions: 1. TRPC1 deficiency impairs SOCE, reduces $[Ca^{2+}]i$, stimulates PTH, and inhibits calcitonin in their respective glands, producing hypercalcemia independent of 1,25 D or P. 2. Lack of TRPC1 channels produces hypocalciuria in the kidney & reduced bone resoprtion and skeletal PTH resistance in osteoclasts. 3. Our data support the critical role of TRPC1 channels in regulating $[Ca^{2+}]i$ in the many cells where it is ubiquitously expressed.

Role of the Sodium/Calcium Exchanger NCX1 in Osteoclasts

Giuseppe Albano,[1,3,4] Candice Stoudmann,[2,4] Willy Hofstetter,[3] Olivier Bonny,[2,4] Daniel G. Fuster.[1,3,4] *[1]Div of Nephrology, Hypertension and Clinical Pharmacology, Univ of Bern, Bern, Switzerland; [2]Inst of Pharmacology and Toxicology, Univ of Lausanne, Lausanne, Switzerland; [3]Dept of Clinial Research, Univ of Bern, Bern, Switzerland; [4]NCCR Kidney.CH, Univ of Zürich, Zürich, Switzerland.*

Background: Previous studies demonstrated that inhibition or siRNA-mediated knock-down of sodium/calcium exchanger 1 (NCX1) in osteoclasts decreases bone resorption in vitro, indicating a critical role of NCX1 in osteoclast-mediated bone resorption.

Methods: To test the role of NCX1 in osteoclasts in vivo, we generated mice with osteoclast-specific deletion of NCX1 ($NCX1^{DOC/DOC}$). For this purpose, mice with a floxed exon 11 of NCX1 were crossed with mice expressing Cre-recombinase under the influence of the osteoclast specific cathepsin K promoter.

Results: Osteoclasts differentiated from $NCX1^{DOC/DOC}$ mice displayed an 80-90 % reduction of NCX1 protein compared to wild-type mice. NCX1 expression was unaltered in extraosseus tissues in $NCX1^{DOC/DOC}$ mice. NCX2 and NCX3 were present at low levels in wild-type osteoclasts and not upregulated in $NCX1^{DOC/DOC}$ osteoclasts. In vitro RANKL stimulation of bone marrow cells isolated from wild-type and $NCX1^{DOC/DOC}$ mice yielded no differences in osteoclast development and resorptive activity. In addition, at 3 months of age, structural parameters of bone, quantified by high-resolution microcomputed tomography, were not different in $NCX1^{DOC/DOC}$ mice compared to wild-type littermates. To stimulate osteoclast-mediated bone resorption, we performed surgical ovarectomy (OVX) in 12 week old female mice, but OVX-induced bone loss over 12 weeks was similar in WT and $NCX1^{DOC/DOC}$ mice.

Interestingly, however, at 6 months of age, female $NCX1^{DOC/DOC}$ mice had significantly higher bone volume whereas male $NCX1^{DOC/DOC}$ mice displayed reduced bone volume compared to wild-type mice.

Conclusions: Our data indicate that genetically induced deficiency of NCX1 in osteoclast-precursors and mature osteoclasts does not affect osteoclast differentiation and bone resorption in vitro. However, $NCX1^{DOC/DOC}$ mice display an age- and sex-specific phenotype. Additional studies are needed to unveil the underlying mechanisms.

The Impact of a Previously Created AV-Fistula on Radial Bone Mineral Density Measurements in Renal Transplant Recipients

Spyridon Arampatzis, Vasileios Devetzis, Uyen Huynh-do. *Neprhrology, Hypertension and Clinical Pharmacology, Uni. Hospital of Bern, Inselspital, Bern, Switzerland.*

Background: The arteriovenous-fistula (AVF) of the distal radius often remain patent after transplantation. Distal radius is the typical site for peripheral DXA measurements in renal transplant recipients (RTR). Since no data exist concerning the impact of a previously created AVF on peripheral bone characteristics in RTR we evaluated the effect of AVF on bone mineral density (BMD) as mirrored by contralateral differences between forearms and explored the densitometric correlation of distal radius with the tibia as an alternative peripheral measurement site.

Methods: This cross sectional study included 40 renal transplant recipients (RTR) and 40 chronic kidney disease (CKD) patients matched for age, gender and BMI. In addition to relevant demographic, biochemical and clinical aspects we assessed bone characteristics of both forearms, femoral neck and tibia by DXA.

Results: The CKD patients without any AVF, displayed no significant discrepancies concerning BMD in both forearms. In RTR BMD was significantly lower in the AVF forearm in comparison to the contralateral non AVF forearm. This observation was evident at all measured subregions of the AVF radius sides, i.e. at the 1/3 radius (0.710±0.103 vs. 0.727±0.104, p=0.003), ultradistal radius (0.424±0.085 vs. 0.444±0.080, p=0.007) and total radius (0.571±0.090 vs. 0.589±0.090, p=0.001) as well. This significant side-to-side difference was 7.5% at the 1/3 radius, 7.2% at the total radius, and 7.0% at the ultradistal radius, respectively. The BMD intersite analysis between radius and distal tibial showed a strong and highly significant correlation (r= 0.7346-0.875) between corresponding peripheral sites.

Conclusions: In conclusion, a previously placed AVF in RTR exerts a negative impact on the ipsilateral radius resulting in significant side-to-side BMD differences. A strong densitometric association exist between peripheral sites and thus DXA measurements at the tibia can be considered as a valuable alternative site to radius. Longitudinal studies are needed in order to replicated these findings by incorporating methods with higher bone density definition.

SA-PO577

Cortical Bone Analysis in Pre-Dialysis Patients: A Comparison with a Dialysis Population

Catarina Carvalho,[1] Juliana Magalhães,[1] Ricardo Neto,[1] Luciano Pereira,[1] Teresa Adragao,[2] Joao M. Frazao.[1] *[1]Nephrology and Infectiology Research and Development Group, INEB, Porto, Portugal; [2]Nephrology, Hospital Santa Cruz, Lisboa, Portugal.*

Background: ROD presents early in CKD pts. Bone biopsy is the gold-standard diagnostic tool. Cortical bone represents 80% of human bone and is the major determinant of bone strength.

Methods: We evaluated cortical bone histomorphometry in 13 CKD stage 3 and 4 pts, (9 male, age 65.1±10.4, eGFR 23.3±8.3ml/min/m^2, who underwent trans-iliac bone biopsy and compared them to 13 dialysis pts (9 male, 11 on HD, age 52.15±10.2, 55.3±17.6 mo in RRT).

Results: Biochemical values and external cortical bone parameters of both groups shown in table

	Pre-dialysis	Dialysis	p value
PTHi (pg/ml)	157.8±85.9	283.2±187.5	**0.038**
Ca (mg/dL)	9.6±0.4	9.0±0.6	**0.009**
Pi (mg/dL)	3.6±0.8	4.8±2.2	0.087
External Cortical			
Po (%)	12.5±7.9	12.6±6.6	0.973
CtTh (μm)	635.6±323.2	384.6±170.5	**0.023**
OnMS/BS (%)	3.0±5.6	4.1±4.3	0.593
OnBFR/BS (μm3/μm2/y)	1.8±2.4	15.0±15.4	**0.025**
OnOS/BS (%)	23.5±9.4	26.2±10.0	0.506
OnES/BS (%)	9.2±4.5	7.0±8.8	0.463
OnOTh (μm)	6.8±2.3	9.9±5.0	**0.067**
OnAjAR (μm^3/μm^2/day)	0.02±0.03	0.15±0.15	**0.023**

Dialysis pts compared to the pre-dialysis population showed more deranged cortical bone, with decreased cortical thickness, increased osteonal bone formation rate and adjusted apposition rate. In this pre-dialysis population, external cortical porosity positively correlated with both trabecular bone volume and osteoid volume (respectively, r=0.70 and 0.76, p=0.016 and p=0.006). External cortical osteonal BFR correlated negatively with S-calcium (r=-0.88, p=0.021) and positively with trabecular thickness (r=0.88, p=0.021). These findings were not observed in internal cortical suggesting that this is more stable to PTH effects.

Conclusions: In pre-dialysis pts, our findings support that PTH has a modulating effect on both trabecular and cortical bone. As renal disease progresses cortical thinning is more pronounced, eventually contributing to the higher fracture rate. Understanding cortical abnormalities may have implications in the treatment of CKD-MBD.

SA-PO578

Chronic Kidney Disease Severity Is Independently Associated with Deficient Bone Mineralization, Hip Fracture and Post-Fracture Mortality

Farsad Afshinnia,[1] Robert J. Ackermann,[1] Ka kit Wong,[1] Baskaran Sundaram,[2] Panduranga S. Rao,[1] Subramaniam Pennathur.[1] *[1]Univ of Michigan; [2]Thomas Jefferson Univ.*

Background: While decreased bone mineral density (BMD) is associated with fracture in non-chronic kidney disease (CKD) subjects, its utility in CKD has been questioned because of associated renal osteodystrophy. In this study, we aim (a) to estimate prevalence of decreased BMD by CKD severity in a large tertiary care academic medical center (b) test whether CKD severity is independently associated with hip fracture and decreased hip BMD, and (c) ascertain if CKD increases mortality following hip fracture.

Methods: This study is a retrospective cohort of 25109 patients with bone densitometry, clinical and lab values from 2001 to 2013 at the University of Michigan. Deficient mineralization (DM) is defined as BMD£2.5 standard deviation (SD) below the mean peak bone mass of young, healthy adults. Clinical outcomes are all-cause mortality and hip fracture. Logistic regression was used to assess the risk associated with fracture. Cox survival model was used to assess risk of all-cause mortality by stage of CKD in hip fracture.

Results: Mean age was 61 years (SD=14). There were 4700 males (18.7%) and 23215 (92.5%) were Caucasian. There were 20507, 4226, 293, and 83 patients with eGFR≥60, 30-59, 15-29, and <15 mL/min, respectively. There was a graded increase in prevalence of DM at total hip from 6.4% in eGFR≥60 to 27.7% in eGFR<15 mL/min (P<0.001). Hip fracture was observed in 544 patients of which 122 (22.4%) died during follow up. Hip fracture ranged from 1.9% in eGFR≥60 to 9.6% in eGFR<15 mL/min (P<0.001). CKD stage 4 and 5 was independently associated with 2.2 folds higher odds of DM (95% CI: 1.6-3.0, P<0.001) and 1.7 folds higher odds of hip fracture (95% CI: 1.0%-2.7%, P=0.044) as compared to eGFR≥60. In an age and co-morbidity adjusted Cox model, risk of mortality following hip fracture was 6.5-fold (95% CI: 1.8-23.3, P=0.004) higher in eGFR<15 compared to eGFR>60 mL/min.

Conclusions: This study highlights utility of BMD to predict fracture in CKD, underscores the burden of DM on outcomes, and reveals independent higher mortality after hip fracture in end stage kidney disease.

SA-PO579

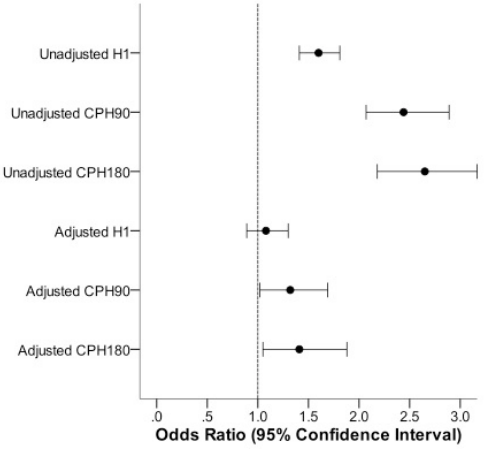
Chronic Hyponatremia Is a Novel Risk Factor for Hip Fracture in Chronic Kidney Disease-Mineral Bone Disease

Sagar U. Nigwekar,[1] Andrew S. Allegretti,[1] Julia Beth Wenger,[1] Juan Carlos Ayus,[2] Ravi I. Thadhani,[1] Ishir Bhan.[1] *[1]Massachusetts General Hospital; [2]Renal Consultants of Houston.*

Background: Risk factors that make skeleton more fragile in chronic kidney disease (CKD) are uncertain. Considering recently reported direct effects of sodium depletion on bone health, we investigated chronic persistent hyponatremia (CPH) as a novel risk factor for hip fractures caused by CKD-mineral bone disease (CKD-MBD).

Methods: Cases for this multi-center case-control study were elderly (>65 years) patients with CKD (eGFR <60 ml/min) with a new hip fracture. Controls (CKD patients with no hip fracture) were matched to cases on age, sex, race and comparative health. Primary exposure was serum sodium <135 mEq/L on at least 2 occasions ≥ 90 days apart within one year preceding hip fracture for cases and within the first year of study entry for controls (CPH90). Secondary exposure definitions were hyponatremia on at least 1 occasion (H1) and hyponatremia on at least 2 occasions ≥ 180 days apart (CPH180). Variables for multivariable logistic regression analyses were identified using stepwise selection.

Results: We analyzed 1,236 cases and 4,515 controls. Mean age of all patients was 84 ± 9 years, 87% were whites, and 39% were females. Serum calcium, phosphate, parathyroid hormone and 25-hydroxy vitamin D levels were similar between cases and controls. Prevalence of CPH90 (21.2 vs. 9.9%, P<0.001), CPH180 (15.5 vs. 6.5%, P<0.001) and H1 (52.7 vs. 41.1%, P<0.001) were higher in cases compared to controls. In analyses adjusted for falls, tobacco use, osteoporosis, eGFR, body mass index, heart failure and medications, CPH90 and CPH180 were associated with increased risk of hip fracture but H1 was not.



Conclusions: CPH is a risk factor for hip fractures caused by CKD-MBD. Mechanistic studies are needed to investigate the effects of CPH on bone turnover, mineralization and volume in CKD.

Follicle Stimulating Hormone Is Associated with Low Bone Mineral Density in Women in Hemodialysis

Priscila Preciado, Enrique Rojas-Campos, Alfonso M. Cueto-Manzano, Benjamin Gomez-Navarro. *Unidad Investigación Médica en Enfermedades Renales, IMSS, Guadalajara, Jalisco, Mexico.*

Background: CKD-BMD associated to sexual hormonal status have not been well evaluated. **Aim**:Assess the association between female hormones (FSH and estradiol) and bone mineral density (BMD) in women in hemodialysis (HD).

Methods: Cross-sectional study in 46 women (20-60 years), at least 3 months in HD in a tertiary care setting between Jan-Jul 2014. Pregnant patients or with steroid medication were excluded. Physical examination and blood markers of sexual hormonal and mineral-bone status were done. A bone densitometry of lumbar spine and non-dominant femur was performed; the results were classified as *normal*, *osteopenia* and *osteoporosis*.

Results: 5 had osteoporosis and 5 had osteopenia in the lumbar spine. In the femur, 2 had osteoporosis and 18 had osteopenia. Comparisons are shown in Table. BMD in lumbar spine was associated to FSH (R^2 0.27; P<0.0001), FSH (OR -0.52 [-0.02 - -0.008]; p<0.0001), on the other hand BMD in femur (R^2 0.30; p =0.001), FSH (OR -0.34 [-0.01 - -0.001]; p=0.02), and CRP were significantly associated (OR -0.32 [-0.02 - -0.001]; P=0.03)

L1 – L4	**Normal (N 36)**	**Abnormal (N 10)**	*p value*
Age (years)	30 ± 8	44 ± 12	**<0.0001**
Phosphorus (mg/dl)	5.9(4.9-7.7)	5.6 (5.3-5.9)	0.53
Calcium (mg/dl)	9.1 (8.0-9.6)	9.3 (9.0-9.6)	0.40
Alkaline phosphatase (U/l)	233 (121-435)	131 (93-232)	0.16
PTHi (pg/ml)	795 (446-1064)	164 (112-456)	**0.001**
Estradiol (pg/ml)	114 (79-244.4)	71 (54 -98)	**0.03**
FSH (pg/ml)	4.8 (4-8.5)	66.07 (7.3-136.4)	**0.001**
C Reactive protein (mg/l)	4.0 (3-9.4)	6.3 (3.0-33.3)	0.62
FEMUR	***Normal (26)***	***Abnormal (20)***	***p value***
Age (years)	31.0 ± 8.4	35.7 ± 12.6	0.18
Phosphorus (mg/dl)	6.2 (4.87-7.7)	5.4 (5.24-6.3)	0.29
Calcium (mg/dl)	8.9 (8-9.4)	9.4 (9-9.62)	**0.03**
Alkaline phosphatase (U/l)	163 (97-316)	223.5 (109-509)	0.38
PTHi (pg/ml)	756 (349-958)	591 (166-1011)	0.67
Estradiol (pg/ml)	133.9 (92.2-244.4)	82.6 (57.4-178.8)	0.14
FSH (pg/ml)	4.78 (4.03-9.13)	7.01 (4.46-5.50)	0.20
C Reactive protein (mg/l)	3.1 (3-7.0)	7.8 (3-32.1)	**0.02**

Conclusions: In women in HD, the higher levels of FSH predicts lower BMD in the lumbar spine, while in the femoral region higher FSH and CRP predicts lower BMD.

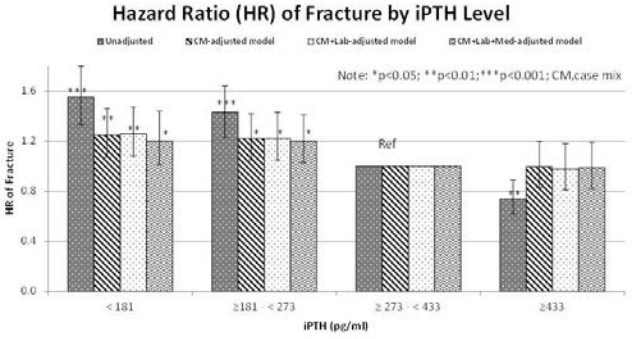
SA-PO581

Time Averaged Intact Parathyroid Hormone Concentration as a Risk Factor For Hip Fractures in Patients on Dialysis Steven Fishbane,[1] Azzour Hazzan,[1] Kenar D. Jhaveri,[1] Lin Ma,[2] Eduardo K. Lacson.[2] *[1]Div of Nephrology, Hofstra North Shore-LIJ School of Medicine, Great Neck, NY; [2]Fresenius Medical Care, North America, Waltham, MA.*

Background: Recent studies found the incidence of hip fractures has increased greatly in patients on dialysis. Most of the increase occurred in patients with characteristics typical of bone frailty, where oversuppression of intact parathyroid hormone (iPTH) could be harmful. Since recent studies have not addressed clinical risk factors, we studied time-averaged iPTH as a risk factor for hip fractures.

Methods: 142,407 prevalent patients of Fresenius Medical Care had hip fractures identified by ICD-9 codes. Four cohorts were constructed: observation periods 2001-2003, 2004-2006, 2007-2009, 2010-2012. For each, the prior year was used to measure exposure. Risks for fractures were analyzed for each cohort and for the combined cohorts. Three models for risk adjustment were created: Case Mix CM-adjusted: age, gender, race, dialysis vintage, and diabetic status, CM+Lab adjusted and CM+Lab+Med adjusted.

Results: For the combined cohorts, unadjusted analyses indicated higher hip fracture risk with with lower iPTH ($p<0.0001$), lower calcium ($p=0.003$), lower phosphate ($p<0.0001$) and lower IV vitamin D ($p<0.0001$). In the fully adjusted model the two lowest iPTH quartiles were significantly associated with greater risk of fractures (HR 1.2, 95% CI 1.01-1.44, $p=0.03$ for lowest quartile, iPTH < 181 pg/ml). Similarly the lowest quartile for calcium was associated with greater risk (< 8.7 mg/dl, HR 1.00-1.37, $p=0.04$). Serum phosphate and iv vitamin D were no longer associated with risk in the fully adjusted model.



Conclusions: In conclusion, we found that that lower time-averaged iPTH and calcium were associated with a greater risk for hip fracture in dialysis patients.

SA-PO582

The Discriminative Ability of Three Fracture Risk Assessment Tools in Hemodiaylysis Patients Ying Qian, An jin Chang, Xiaonong Chen, Nan Chen. *Dept of Nephrology, Ruijin Hospital Affiliated to Shanghai Jiaotong Univ School of Medicine, Shanghai, China.*

Background: The present study aimed to explore factors associated with fractures among hemodialysis patients, and assess the ability of the World Health Organization's fracture risk assessment tool (FRAX) compared with bone mineral density (BMD) and OSTA to discriminate fracture status.

Methods: We enrolled 118 hemodialysis patients in this cross-sectional study. Parameters including serum calcium, phosphate, intact parathyroid hormone, 25 hydroxy vitamin D, alkaline phosphatase were analyzed. Clinical characteristics were also collected. BMD values were tested using dual-energy X-ray absorptiometry at the lumbar spine and hip region. OSTA and FRAX scores were calculated using formula or through the FRAX website. Factors associated with fractures were examined. Discriminative ability of BMD, OSTA and FRAX (non-BMD model and BMD model) in fracture status was assessed with receiver operator characteristic curves (ROC) analysis.

Results: There were 16 (13.56%) fractures in 118 hemodialysis patients. Patients with fractures were significantly older and more osteoporosis. All BMD parameters at hip region (including femoral neck, femoral shaft, and total hip) were notably lower in fracture group than in non-fracture group (0.74 (0.65~0.87) vs 0.82 (0.74~0.96); 0.88 (0.77~1.01) vs 0.99 (0.86~1.14); 0.80 (0.66~0.88) vs 0.88 (0.78~1.00)). There was no difference in clinical characteristics or blood biochemistry levels between the two groups. Areas under ROC curves of BMD, OSTA, FRAX1 (non-BMD model) and FRAX2 (BMD model) were 0.692 (95% CI: 0.600 to 0.774), 0.654 (95% CI: 0.561 to 0.739), 0.917 (95% CI:0.851 to 0.960), and 0.851 (95% CI:0.773 to 0.910), respectively. Either FRAX1 or FRAX2 performed better than BMD and OSTA at identifying patients with fractures ($P < 0.05$). But FRAX2 performed no better than FRAX1 ($P>0.05$). The best cutoff values were 0.91, -3, 7.2%, 3.4%.

Conclusions: Among hemodialysis patients, age and BMD at hip are associated with fracture. FRAX performs better than BMD and OSTA in discriminating fracture status, suggesting its usefulness of fracture risk prediction in hemodialysis patients.

SA-PO583

Teriparatide for Low Bone Mass in Hemodialysis Patients Rikako Hiramatsu, Yoshifumi Ubara, Junichi Hoshino, Kenmei Takaichi. *Nephrology Center, Toranomon Hospital, Tokyo, Japan.*

Background: Fracture rates in dialysis patients are extremely higher than general population. Recently the prevalence of low turnover has greatly increased in dialysis population. Teriparatide would be also beneficial for low turnover dialysis patients with low bone mass. However, there have been only a few reports describing the use of teriparatide in dialysis patients.

Methods: ***Design*** This was a prospective, single-center, observational study. Hemodialysis patients with low iPTH (iPTH<60 pg/mL) coexisting low bone mass determined by lumbar spine (LS) or /and femoral neck (FN) T-score<-2.5 with DXA were eligible and subcutaneous recombinant human $PTH_{1\text{-}34}$ (20 μg teriparatide; Forteo) was injected 3 times per week at the end of each hemodialysis sessions. We analyzed the following parameters, including serum Ca, P, albumin, ALP, iPTH and bone metabolic makers including iP1NP, BAP, OC, and TRACP-5b at baseline and following teriparatide. BMD at LS and FN were measured at baseline, 6, 18 months after treatment. ***Pharmacokinetics*** After the of 24 th administration of teriparatide, we measured the serum teriparatide acetate concentrations.

Results: Five patients (median age; 72 yeas old,median hemodialysis periods; 24 years) were included.After teriparatide injection, BMD of LS as well as FN at 6 months significantly increased from 0.67±0.18 to 0.68±0.19 g/cm^2 and from 0.44±0.08 to 0.48±0.07 g/cm^2 , respectively. Corrected Ca levels significantly decreased at 3 and 6 months with increases in endogenous iPTH in response to lowering of serum Ca. As for bone metabolic markers, percent changes of serum BAP and serum iP1NP levels significantly increased at 3 and 6 months. Conversely, serum TRACP-5b decreased after injection. Throughout this study, there were no fractures. Pharmacokinetics result is shown in Figure 1. There was a peak at 30 minutes at 157.2 pg/mL, and then it rapidly decreased to undetectable level at 240 minutes.

Conclusions: In conclusion, treatment with teriparatide, the dose was 20 μg 3 times/ week, which is smaller than the suggested dose for non dialysis patients, led to increase of BMD at LS and FN. Our data on pharmacokinetic of teriparatide suggested that we can use this agent in normal dose in dialysis patients.

SA-PO584

Restless Leg Syndrome in Hemodialysis Patients: Possible Relationship with Mineral and Bone Metabolism Precil Diego Miranda de Menezes Neves,[1] Ramaiane Aparecida Bridi,[1] Rosa M.A. Moyses,[1,2] Rosilene M. Elias.[1] *[1]Nephrology Div, Univ of São Paulo, São Paulo, Brazil; [2]Nephrology Div, Univ Nove de Julho - UNINOVE, São Paulo, Brazil.*

Background: Restless legs syndrome (RLS) is a movement sleep disorder that is common among patients on hemodialysis (HD) and is associated with cardiovascular morbidity and mortality. The physiopathology of this syndrome is not completely understood, and CKD-MBD may be implicated. We aimed to evaluate the prevalence of RLS in patients on hemodialysis, testing the relationship with CKD-MBD markers.

Methods: Prevalence and severity of RLS were assessed using the International RLS Study Group (IRLSSG) rating scale.

Results: Of the 101 patients (53.5% women) included, RLS was observed in 29 patients (28.7%), with mild, moderate, severe and very severe presentation in 1, 12, 13 e 3 patients, respectively. RLS was more frequent among women (62% vs 38%, p=0.04), and was associated to high phosphate-P (6.0 ± 1.7 vs 5.2 ± 1.7mg/dl, 0.048), lower transferrin saturation-TS (32 ± 16% vs. 46 ± 29%, p=0.019) and a tendency toward high parathyroid hormone-PTH [529 (190, 1017) pg/ml vs. 305 (143, 546) pg/ml, p=0.054]. Logistic regression showed that female gender (HR=2.8, p=0.039), P (HR=1.4, p=0.042) and TS (HR=0.9, p=0.033) were independently associated to RLS. As 22.8% of patients were already submitted to parathyroidectomy, we further categorized PTH as ≥ or <500pg/ml. This new variable was modeled in another regression model, which came out independently associated to a high risk of RLS (HR 3.0, p=0.027). We also compared patients with RLS severe/very severe to those with RLS mild/moderate. The first group presented higher P, and lower serum albumin, iron, and ionic calcium. Finally, multivariable regression showed that severity score was dependent on P and vit D insufficiency (r^2= 0.37).

Conclusions: Besides all traditional risk factor for RLS already described in the general population, CKD-MBD seems to play a role in the pathophysiology of this syndrome in HD patients. It is plausible that the relationship between RLS and CKD-MBD contribute to the increased mortality risk observed in these patients.

SA-PO585

Vascular Smooth Muscle Cells from CKD Rats Have Increased Intracellular Calcium Chad A. Zarse,[1] Mikaela Lee Mckenney,[2] Stacey L. Dineen,[2] Rebecca S. Bruning,[2] Michael Sturek,[2] Neal X. Chen,[1] Sharon M. Moe.[1,3] *[1]Nephrology, IU School of Medicine; [2]Physiology, IU School of Medicine; [3]Roudebush VAMC, Indianapolis, IN.*

Background: CKD vascular smooth muscle cells (VSMC) exhibit phenotypic plasticity which promotes calcification and increases cardiovascular risk. Changes in intracellular calcium (iCa) as CKD progresses may regulate transcription of genes requisite for this process. This study examined iCa homeostasis in early and advanced CKD.

Methods: We studied VSMC freshly isolated from 10 week normal Sprague Dawley (SD) and CKD Cy/+ rats and 35 week normal SD, CKD Cy/+ (~15% nl function), and CKD rats treated with 3% calcium gluconate. (n=6-8 per group). Intracellular calcium was measured with Fura-2 using a ratiometric approach (F360/F380 nm). Basal iCa, sarcoplasmic reticulum (SR) store release, and store-operated calcium entry (SOCE) was assessed. Expression of common calcium regulatory proteins NCX1 and SERCA2a was examined by Western Blot. Results were compared by ANOVA.

Results: Basal iCa levels were lower in 10 week CKD VSMCs compared to NL (0.76±0.02 vs. 0.66±02, p<0.05) however increased 1.5-fold by 35 weeks to become greater than NL (0.98±0.01 CKD, 0.81±0.02 NL, 0.90±0.04 CKD+Ca, p<0.05). SR store release was greater in CKD VSMCs at both 10 weeks (0.45±0.02 vs. 0.37±0.02, p<0.05) and 35 weeks (0.62±0.02 CKD, 0.44±0.03 NL, 0.50±0.03 CKD+Ca, p<0.05). At 10 weeks, SERCA2a expression was greater in CKD rats in part explaining the lower basal iCa levels, however, at 35 weeks SERCA2a and NCX1 were both decreased in CKD rats, consistent with higher iCa levels. There was no difference in SOCE at 10 weeks but by 35 weeks was increased in the CKD+Ca cohort (p<0.05) with a trend toward significance in the CKD cohort (p=0.08), also consistent with higher observed basal iCa levels.

Conclusions: Basal iCa, SR store release, and SOCE increases with progressive CKD at least in part due to changes in expression of the common calcium regulatory proteins SERCA2a and NCX1. The increase in iCa is likely a key mechanism in our previous observations that CKD VSMCs display an osteogenic phenotype, which is known to worsen cardiovascular outcomes.

The Role and Mechanism of Nrf2/HO-1 Pathway in Oxidative Stress-Induced Vascular Calcification in End-Stage Renal Disease In Vitro Li Wang. *Nephrology, Sichuan Academy of Medical Sciences & Sichuan Provincial People's Hospital, Chengdu, Sichuan, China.*

Background: To investigate the mechanism of Nrf2/HO-1 pathway in oxidative stress(OS)-induced vascular calcificationin in end-stage renal disease(ESRD) in vitro, and to explore a new target for the intervention of vascular calcification in ESRD.

Methods: 1. Rat aortic vascular smooth muscle cells(RASMCs) were cultured and divided into 4 groups: the complete medium cultured group, the calcification medium cultured group, the group of complete medium cultured for 42h and then sulforaphane (SFN) cultured for 6h, the group of complete medium cultured for 46h and then H_2O_2 cultured for 2h. Detect nuclear Nrf2 expression in each group by western blot. 2. 4 groups of RASMCs were cultured: the calcification medium cultured group, the group of H_2O_2 pretreated for 2h and then calcification medium cultured, the group of SFN pretreated for 6h and then calcification medium cultured, the group of SFN pretreated for 6h and H_2O_2 pretreated for another 2h, and then calcification medium cultured. Detect the expression of intracellular reactive oxygen species (ROS) by using DCFH-DA probe, and the expression of Nrf2, Heme Oxygenase (HO-1), Runt-related transcription factor 2(Runx2) by western blot.

Results: 1.Nrf2 expression in nuclear was enhanced after SFN and H_2O_2 stimulation. 2. The expression of Nrf2,Runx2 and ROS,but not HO-1, were induced by calcification medium in a time-dependent manner. 3. ROS was significantly reduced after H2O2, SFN, SFN + H2O2 pretreated, and decreased gradually with incubation time (P<0.05). 4. The expression of Nrf2 and HO-1 were induced by SFN, and the expression of Runx2 was inhibited in calcification medium. 5. The expression of Nrf2, HO-1, Runx2 could be induced by H_2O_2, but the expression of Runx2-induced calcification medium decreased gradually within incubation time after H_2O_2 or SFN + H_2O_2 pretreated.

Conclusions: The calcification in RASMCs is associated with the overexpression of endogenous ROS. Overexpression of Runx2 induced by endogenous ROS, but not exogenous ROS, may be inhibited or attenuated by the activated Nrf2/HO-1 pathway.

Matrix Vesicles from Calcifying Vascular Smooth Muscle Cells (VSMC) Have Different MicroRNA (miRNA) Expression from Non-Calcifying VSMC Neal X. Chen,[1] Sarath Chandra Janga,[2] Kalisha O'Neill,[1] Manjunath Siddappa,[2] Jeanette N. Mcclintick,[3] Sharon M. Moe.[1,4] *[1]Nephrology; [2]Biohealth Informatics; [3]Medical and Molecular Genetics, Indiana Univ; [4]Roudebush VAMC, Indianapolis.*

Background: Treating VSMC with high phosphorus induces the production of calcifying matrix vesicles (CaMV) that initiate mineralization within the extracellular matrix of VSMC. MV are similar to exosomes which are known to contain miRNA important in cell-cell communication. We hypothesized that the miRNA expression profile in calcifying MVs (CaMV) would differ from non-calcifying MV (CTLMV) isolated from CKD rats.

Methods: VSMC from CKD rats (n=3) were incubated with control media or high-phosphorus (calcifying media) and MV isolated. Total RNA was isolated from CaMV or CtlMV, miRNA quantified, and MiRNA array was performed using GeneChip miRNA 3.0 Array. We analyzed the miRNA on array that changed at least 2 fold in the comparison groups with a p value of < 0.01 and false discovery rate of < 20%. Bioinformatic target gene prediction was performed using Targetscan and Miranda. CTLMV or calcifying MV were also co-cultured with VSMC to assess the change in calcification.

Results: CaMV increase calcification when added to VSMC compared to CTLMV. The arrays demonstrated 33 increased miRNAs and 17 decreased miRNAs in CaMV vs CTLMV. Real time PCR confirmed the miR-30c expression, known to regulate vascular calcification, is increased in CaMV vs CTLMV. Additional regulatory miRNA identified via target prediction analysis followed by functional enrichment yielded multiple miRNA-mRNA networks. Narrowing the analyses to only those RNA controlled by at least 3 miRNAs identified important miRNAs, including cell signaling pathways known to be involved in vascular calcification: Decreased expression of miRNAs (Ca vs. CTL) that would upregulate target genes involved in PI3 kinase signaling. In contrast, increased miRNA expression in CaMV vs. CTLMV would lead to downregulation of several signaling pathways including MAPK, RAS, mTOR and FOXO.

Conclusions: Calcifying MV contain different miRNAs compared to CTLMV. MiRNAs contained in calcifying MV may be transferred to other VSMC and regulate signaling pathways involved in vascular calcification.

SA-PO588

The Precedence of the Reduced Osteopontin Expression and the Increased Calcium Phosphate Nanoparticle to the Calcification by Phosphate Load with Normal Fasting Glucose in Human Vascular Smooth Muscle Cells Masanori Tokumoto,[1] Shunsuke Yamada,[1,2] Kazuhiko Tsuruya,[3] Takanari Kitazono,[2] Hiroaki Ooboshi.[1] *[1]Div of Internal Medicine, Fukuoka Dental College, Fukuoka, Japan; [2]Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [3]Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.*

Background: It is well-known that vascular calcification (VC) develops in diabetes mellitus patients. On the other hand, malnutrition is also reported to induce VC. Thus, we examined how glucose load affects phosphate (P)-induced calcification in human vascular smooth muscle cells (hVSMC).

Methods: We added P of 1, 1.5, or 2.0 mM in the culture media (DMEM) of hVSMC with normal fasting or high glucose (HG) (100 or 450 mg/dl), although hVSMC are usually cultured with HG. The degree of calcification, the content of calcium P nanoparticle (CPP) in the media, and the expression of both the intrinsic calcification inhibitors and the chondro-osteogenic differentiation markers were examined at Day 1, 7, and 14.

Results: Regardless of P load amount, the degree of calcification was severer with normal fasting glucose at Day 7 and 14. At Day 7, the mRNA expression of Sox9, a chondrogenic differentiation marker, increased by P load and was higher with normal fasting glucose. The content of calcification correlated significantly with the SOX9 mRNA expression at Day 7. At Day 1, the content of CPP increased by P load, and was higher with normal fasting glucose. The SOX9 mRNA expression at Day 7 correlated significantly with the content of CPP at Day 1. At Day 1, the mRNA expression of osteopontin (OPN), a calcification inhibitor, decreased by P load and was less with normal fasting glucose. Moreover, it negatively correlated with the content of CPP at Day 1 and the correlation was more intensive with normal fasting glucose. There was no significant change in the mRNA expression of chondro-osteogenic differentiation markers at Day 1.

Conclusions: In conclusion, P load with normal fasting glucose reduced OPN expression and induced the formation of CPP, followed by the chondrogenic differentiation and calcification in hVSMC.

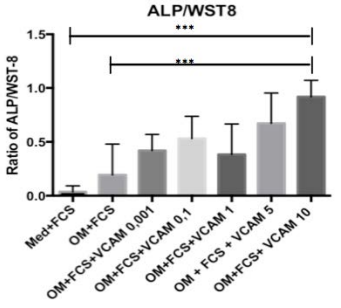
VCAM - 1 and TNF Alpha Induce Vascular Calcification In Vitro Kevin Willy, Ralf Schindler, Daniel Zickler. *Dept of Nephrology and Internal Intensive Care Medicine, Charité Univ Medicine, Berlin.*

Background: VCAM, TNF alpha and soluble TNF alpha receptor 1 (sTNFR1) are elevated in patients with chronic kidney disease (CKD). In previous clinical trials with high cut-off dialysis plasma levels of these molecules and *in vitro* vascular calcification were lowered. Here we assessed the role of sTNFr 1 and VCAM on *in vitro* calcification.

Methods: In human vascular smooth muscle cells (VSCMs) vascular calcification was induced by osteogenic medium (OM). VCAM , TNF-α and sTNFR1 were added. Calcification was quantified by alkaline phosphatase staining and alizarin red staining. Calcification was then normalized to WST – 8.

Results: VCAM enhances vascular calcification *in vitro* in a dose-dependent manner (p<0,0001). TNF-α –induced calcification was effectively inhibited by sTNFR1 (50% reduction of the initial level; p<0,0001). sTNFr1 alone does not promote vascular calcification.



VCAM concentration: 0,001 - 10 µg/mL.

Conclusions: VCAM and TNF alpha promote vascular calcification *in vitro*. Their elimination with high cut-off dialysis or their pharmacological blockade may be advantageous in regard to vascular calcification in CKD.

The Triplehelical Collagen Analog $(GPO)_{10}$ Affects Calcifications of Vascular Smooth Muscle Cells in a Concentration Dependent Manner Uwe Querfeld,[1,2] Nadja Kretzschmar,[2] Christian Freise.[1,2] *[1]Pediatric Nephrology, Charité, Berlin, Germany; [2]Center for Cardiovascular Research, Charité, Berlin, Germany.*

Background: Extensive remodeling of the extracellular matrix and the trans-differentiation of vascular smooth muscle cells (VSMC) contribute to the pathogenesis of vascular calcifications in patients with chronic kidney disease (CKD). Matrix metalloptoteinases (MMPs) are proteolytic enzymes that impact on both of these processes and, thus, represent potential therapeutic targets. We have previously shown that the synthetic collagen analog $(Gly\text{-}Pro\text{-}Hyp)_{10}$ - $(GPO)_{10}$ –impacts the substrate binding and the enzymatic activity/stability of the gelatinases MMP-2 and -9 in a concentration dependent manner [1]. Aim of this study was therefore to investigate potential regulatory functions of $(GPO)_{10}$ in an in- vitro model of arteriosclerotic VSMC calcification.

Methods: Calcifications of murine VSMC were induced by a calcification medium (CM) containing elevated concentrations of calcium and phosphorus with or without the presence of different $(GPO)_{10}$-concentrations. VSMC calcifications were quantified by measuring calcium depositions and ALP-release in the cultures. Effects on MMP-activities were determined by specific substrate assays.

Results: CM-treated VSMC exhibit strong calcifications compared to control. Low $(GPO)_{10}$ concentrations (50-70 nM) massively enhanced calcifications of VSMC and were accompanied by elevated gelatinase activities in VSMC supernatants. In contrast, higher concentrations of $(GPO)_{10}$ (680 nM) blocked CM-induced calcifications of VSMC and reduced gelatinolytic activities in culture supernatants.

Conclusions: Considering the important function of MMP-2 and -9 in VSMC calcification [2], the collagen peptide $(GPO)_{10}$ on the one hand indirectly impacts the VSMC calcification by modulating MMP activities. On the other hand, direct effects of $(GPO)_{10}$ e.g. by interaction with collagen receptors might simulate a "healthy" vessel matrix, which will be investigated in future studies. [1] Ruehl, M., et al., Fibrogenesis Tissue Repair., 2011. 4(1): p. 1. [2] JASN 25: 2014 (SA-OR062, p.95A; TH-PO555, p.233A; FR-PO833, p.562A).

Protective Effects of Epigallocatechin Gallate (EGCG) on Vascular Calcification In Vitro and In Vivo Uwe Querfeld,[1,2] Karoline Websky,[2] Christian Freise,[2] Kerstin Sommer,[2] Ursula Schulz,[2] Veronika Bobb.[2] *[1]Pediatric Nephrology, Charité, Berlin, Germany; [2]Center for Cardiovascular Research, Charité, Berlin, Germany.*

Background: Vascular calcifications are common in patients with chronic kidney disease (CKD). Our preliminary studies indicate that inhibition of matrix metalloproteinases (MMP)-2 and -9 suppresses the development of arterial calcification in uremic rats. Epigallocatechin gallate (EGCG), a polyphenol ingredient of green tea, has strong antiinflammatory properties and inhibitory effects on MMPs. We therefore investigated potential protective effects of EGCG on calcium uptake of vascular smooth muscle cells (VSMC) in vitro and in an animal model of uremia-associated arteriosclerosis in vivo.

Methods: In vitro, calcifications of murine VSMCs were induced by a high phosphate (HP)-medium and cells were treated with different EGCG-concentrations (20-100µg/ml). VSMC calcifications were quantified using the ortho-cresolphthalein-method and proteolytic activities of MMP-2 and -9 in VSMC supernatants were determined by gelatin zymographies. C57BL/6 mice were 5/6-nephrectomized and arterial calcifications were induced by calcitriol (1µg/kg body weight) and a HP-diet (2% phosphate). One cohort (n=10) was additionally administrated 0.02% EGCG in drinking water. Animals were sacrificed after 2 weeks of treatment and aortic calcifications were quantified after von Kossa-staining.

Results: In-vitro, EGCG provoked a dose-dependent decrease of HP-induced calcification (up to 85%) of VSMCs and of proteolytic MMP-2 and -9 activities. *In vivo*, all calcitriol-treated mice had severe arterial calcifications, involving 50% of the arterial wall after only 2 weeks of treatment. EGCG had no significant inhibitory effect on the development of vascular calcifications.

Conclusions: In this "negative experimental trial", EGCG had no beneficial effect in the chosen animal model, which (considering the rapid development of calcifications) may have been too aggressive, thus overriding potential protective effects of EGCG.Encouraged by the positive in vitro results, the effects of EGCG and other polyphenols should nonetheless be further investigated in other animal models of uremia-associated arteriosclerosis.

Mechanism of Calcification by Iron Stimulation in Vascular Smooth Muscle Cells Sayuri Kawada,[1] Yasuyuki Nagasawa,[1] Mutsuki Kawabe,[2] Aritoshi Kida,[1] Mana Yahiro,[1] Tomoko Kimura,[1] Kiyoko Yamamoto,[1] Masayoshi Nanami,[1] Yukiko Hasuike,[1] Takahiro Kuragano,[1] Keiji Nakasho,[2] Hideki Ohyama,[2] Takeshi Nakanishi.[1] *[1]Dept of Internal Medicine, Div of Kidney and Dialysis, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan; [2]Dept of Pathology, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan.*

Background: In CKD patients, atherosclerosis is one of important key factors which determine their prognosis. It was reported the calcification induced by TNF-alpha was related with iron in HUVEC cells by our group. TTo reveal the relationship between calcification in vascular media and iron stimulation using vascular smooth muscle cells.

Methods: The aorta smooth muscle cells were cultured for three weeks. At day 0, we changed the usual culture medium to calcification medium, and TNF-alpha and iron were added to the calcification medium. Calcification in each condition was confirmed by Alizarin staining. And to reveal early mechanism to enhance the calcification by iron and TNF-alpha stimulation, we compared the gene expression profile between each condition in day 1 and day 3 using microarray analysis. We confirmed gene expression of cytokine which had increased in microarray analysis by real-time PCR.

Results: We confirmed both iron and TNF-alpha stimulation enhanced calcification by Alizarin Staining. Moreover, both iron and TNF-alpha stimulation at the same time enhanced calcification more strongly than single stimulation. We picked up a cytokine which had increased with both iron and TNF-alpha stimulation in the microarray analysis as similar as the Alizarin Staining result had shown. We confirmed gene expression of this cytokine by real-time PCR. Gene expression was increased at day1 by stimulation of iron(5.8±3.0 fold change vs control), TNF-alpha (7.8±1.9 fold change vs control) ,and both stimulation(53.1±27.1fold change vs control),synergistically.

Conclusions: Iron stimulation enhanced calcification in vascular smooth muscle cells along with TNF-alpha stimulation. The possibility was suggested that this gene change from the early stage participated in the mechanism that iron promoted blood vessel media calcification.

SA-PO593

Kidney Injury/Repair Stimulates Vascular Disease Through Activin and Systemic Wnt Inhibition Matthew James Williams, Olga A. Agapova, Yifu Fang, Toshifumi Sugatani, Carmen M. Halabi, Keith A. Hruska. *Pediatrics, Nephrology, Washington Univ School of Medicine, Saint Louis, MO.*

Background: We show that the vascular effects of CKD are an interplay of Wnt inhibition and activin induced modulation of Activin receptor (ActRIIA) function resulting in a stimulation of atherosclerosis and vascular calcification.

Methods: CKD with elevated activin and Wnt inhibitors, especially Dkk1, was induced in the mouse models for vascular calcification, lineage tracing, and Alport's. Activin, Dkk1, ActRIIA, psmad 2/3, aklotho and collagen levels were measured by Elisa, RT-PCR and westerns. Vascular smooth muscle cell (VSMC) function was measured by pressure

induced arterial dilatation *in situ*. Cell lineage tracing was performed in Rosa-tdT mice bred to endothelial specific Tie2-Cre mice. Mice harboring Rosa-tdT express tomato red in cells harboring Cre recombinase.

Results: Circulating activin and Dkk1 levels were increased while aklotho levels were decreased by CKD. **In diseased kidneys**, activin was expressed in myofibroblasts, and activin receptor, ActRIIA, signaling through Smad 3 was increased. An ActRIIA ligand trap, RAP-011, inhibited renal pSmad 3, ColA1 expression, urinary protein levels, and Dkk1 levels, and increased tubular epithelial klotho levels. **In the vasculature**, CKD decreased VSMC ActRIIA protein levels, and ActRIIA signaling was decreased along with decreased VSMC differentiation and function. The ActRIIA ligand trap increased VSMC differentiation and inhibited osteoblastic transition and atherosclerotic calcification. In the circulation, the ActRIIA ligand trap decreased Dkk1 levels. CKD induced expression of tomato red in cells of the adventia after two weeks of femoral artery injury in Tek-Cre/Rosa-tdT CKD mice compared to Tek-Cre/Rosa-tdT mice with normal kidney function.

Conclusions: CKD increased circulating free activin levels, decreased VSMC function, stimulated aortic osteoblastic transition and atherosclerotic calcification. Decreasing effects of elevated activin in CKD with an ActRIIA ligand trap, inhibited Smad dependent renal fibrosis, blocked aortic osteoblastic transition, increased VSMC differentiation and decreased vascular calcification.

Transient Azotemic Episode Exacerbates Vascular Calcification in Adenine-Induced Uremic Rats Daisuke Mori,[1] Isao Matsui,[1] Akihiro Shimomura,[2] Yasuo Kusunoki,[1] Sayoko Yonemoto,[1] Masamitsu Senda,[1] Yusuke Sakaguchi,[1] Takayuki Hamano,[2] Yoshitaka Isaka,[1] Hiromi Rakugi.[1] *[1]Geriatric Medicine and Nephrology, Osaka Univ Graduate School of Medicine, Suita, Japan; [2]Comprehensive Kidney Disease Research, Osaka Univ Graduate School of Medicine, Suita, Japan.*

Background: Urea, the final metabolite of amino acids in the body, can carbamylate proteins at lysine residues, and thereby modifies characteristics of proteins irreversibly. Several studies have revealed that functions of proteins are impaired by carbamylation. Acute kidney injury (AKI) is a representative pathological condition that elevates serum urea temporarily. Although AKI is not a perpetual condition, it is well-known that AKI increases subsequent risk of cardiovascular diseases through yet-unknown mechanisms.

Methods: We evaluated the effects of transiently elevated serum urea on vascular calcification (VC). Male Sprague-Dawley rats at age 9 weeks were divided randomly into two groups: cellulose-preload + adenine diet (group C+A) and urea-preload + adenine diet (group U+A). Urea-preloaded group received 10% urea diet from 9 to 13 weeks of age. Cellulose served as a control for urea. After one week of urea-washout period, all rats received 0.75% adenine-containing diet up to 19 weeks of age.

Results: Serum urea levels were 15.87 ± 2.96 mg/dL in cellulose-preloaded group and 39.20 ± 3.74 mg/dL in urea-preloaded group at the end of the preload period. Serum urea levels in urea-preloaded group were normalized to 14.73 ± 1.28 mg/dL during the washout period. At age 19 weeks, rats in group U+A developed severer VC in comparison with the rats in group C+A. Serum creatinine, urea nitrogen, calcium, phosphate, magnesium, albumin, and body weight were not different between the two groups at age 19 weeks. Western blot analysis of the aorta revealed that dietary preload of urea increased carbamylated protein.

Conclusions: Preload of urea exacerbated VC in adenine-induced uremic rats. Protein carbamylation might link urea-preload to VC.

SA-PO595

SNF472 Inhibits Cardiovascular Calcification in Uremic Rats Joan Perelló,[1,2] Carolina Salcedo,[1] Ellen Neven,[3] Geert J. Behets,[3] Pieter H. Joubert,[1] Patrick C. D'Haese,[3] Miquel D. Ferrer.[1] *[1]R&D Dept, Laboratoris Sanifit, Palma, Illes Balears, Spain; [2]Laboratory of Renal Lithiasis Research, Univ of Balearic Islands, Palma, Illes Balears, Spain; [3]Laboratory of Pathophysiology, Univ of Antwerp, Antwerp, Belgium.*

Background: SNF472, an intravenous (i.v.) formulation of phytate, has been shown to inhibit cardiovascular calcification (CVC) in non-uremic conditions. We investigated the pharmacokinetics (PK) and efficacy (inhibition of CVC) of i.v. SNF472 in control and uremic rats.

Methods: The first part of the study was performed with 10 male Wistar rats in which uremia was induced by 10 daily oral (p.o.) administrations of 600 mg/kg adenine followed by p.o. administrations of 300 ng/kg α-calcidol on days 11 and 13. Ten animals received 10 mg/kg and ten animals 50 mg/kg of SNF472 daily as 4-hour i.v. infusions. Blood was collected at days 1 (controls) and 14 (uremic) and plasma SNF472 concentrations were measured at different time points. In an efficacy study uremia was induced as above whilst α-calcidol was administered 3 times/week from day 11 to day 19. Twelve rats received daily 4-hour i.v. infusions of 50 mg/kg SNF472 and twelve rats received saline from day 0 to day 19. At day 19 all surviving animals were sacrificed and blood and tissue samples were collected to measure SNF472 plasma levels as well as calcium content in aorta and heart.

Results: Steady state was reached at 60 minutes in control animals receiving 50 mg/kg SNF472 but not in those receiving 10 mg/kg. Steady state was reached in uremic animals, but with exposures between 3 and 7 times lower than in controls. All the animals in the efficacy study developed uremia as a consequence of the high-dose adenine administration. The exposure to SNF472 in uremic animals was distinctly lower (5-fold for Cmax). SNF472 treatment resulted in a significant reduction in CVC of 80 and 88% in aorta and heart, respectively.

Conclusions: Daily SNF472 4 hour infusions of 50 mg/kg inhibit the development of CVC by up to 88% in a rat adenine model of uremia. These results support further investigation of SNF472 in the treatment of CVC in patients with calcification-related disorders such as calciphylaxis and ESRD patients.

Enzyme Therapy for Vascular Calcification W. Charles O'Neill,[1] Kelly E. Manning,[1] Koba A. Lomashvili,[1] Nelson Hsia,[2] Peychii Lee,[2] Francis T. Danehy,[2] Kim L. Askew,[2] Anthony G. Quinn.[2] *[1]Renal Div, Emory Univ School of Medicine, Atlanta, GA; [2]Synageva Biopharma, Lexington, MA.*

Background: Pyrophosphate (PPi) is a key endogenous inhibitor of hydroxyapatite formation that circulates at levels sufficient to prevent vascular calcification. PPi is produced from extracellular ATP by the ectoenzyme, nucleotide pyrophosphatase pyrophosphorylase 1 (NPP1) and deficiency of this enzyme produces severe fatal medial arterial calcification in humans. Mice lacking NPP1 have undetectable plasma PPi and also develop arterial calcification. We examined whether exogenous NPP1 can increase plasma PPi and prevent vascular calcification in these mice.

Methods: Recombinant proteins containing the extracellular portion of human ENPP1 fused to human IgG1 Fc (ENPP1-Fc) were created and injected into two mouse models of NPP1 deficiency (Enpp1$^{-/-}$ and Enpp1$^{asj/asj}$). NPP1 activity was measured by conversion of [^{32}P]ATP to ^{32}PPi with separation by thin-layer chromatography. Plasma PPi was measured by a radiometric enzyme assay using UDP-[^{14}C]glucose and UDP-glucose pyrophosphorylase.

Results: Intravenous injection of NPP1-Fc (6 mg/kg) into Enpp1$^{-/-}$ mice increased plasma NPP1 activity to a peak of 160 +/- 10% of normal at 4 hours with a decline to 70 +/- 5% of normal by 72 hours. There was no increase in aortic NPP1. Plasma PPi followed a similar pattern, with a peak of 2.2 +/- 0.6 uM at 4 hours declining to 0.21 +/- 0.04 uM at 72 hours (normal: 2.18 +/- 0.33 uM). With subcutaneous injection, plasma NPP1 was 110 +/- 13% of normal and plasma [PPi] was 0.38 +/- 0.14 uM after 48 hours. Subcutaneous injection every 48 hr reduced aortic calcium content 86 +/- 5% ($p<0.001$) after 18 days in Enpp1$^{-/-}$ mice fed a high phosphorus diet, and improved survival at 10 weeks from 15% to 50% ($p<0.001$) in Enpp1$^{asj/asj}$ mice fed a high phosphorus, low magnesium diet.

Conclusions: Administration of NPP1 in NPP1-deficient mice produces an increase in circulating PPi that is sufficient to prevent vascular calcification and increase survival. The ability of Enpp1 fusion proteins to raise PPi levels and inhibit tissue calcification supports the potential to reduce vascular calcification in other calcification-prone states.

SA-PO597

The Risk of Medial Arterial Calcification in Early Chronic Kidney Disease W. Charles O'Neill,[1] Kum Hyun Han,[1,2] Arshad Ali,[1] Ansley O'Neill,[1] Kelly E. Manning.[1] *[1]Renal Div, Emory Univ, Atlanta, GA; [2]Internal Medicine, Dept of Internal Medicine, Inje Univ College of Medicine, Ilsan Paik Hospital, Goyang, Korea.*

Background: Medial arterial calcification is common in advanced chronic kidney disease (CKD) but whether this risk begins in early CKD is unknown. There is also concern that possible benefits of vitamin D and calcium in this group may be offset by potential induction of vascular calcification. We have previously shown that breast arterial calcification is a readily available and specific marker of medial arterial calcification and that its prevalence is increased in advanced CKD.

Methods: From a computerized search of medical records, 446 women with CKD and mammograms were randomly selected. After exclusion of women with renal transplants or other stages of CKD, history of warfarin use, or non-screening mammograms, 333 women with CKD 3 (MDRD formula) were identified and individually matched by age and diabetes status to women with an estimated GFR >90 ml/min/1.73 m^2. Digital mammograms were visually inspected for arterial calcification.

Results: Mean age was 69.5 +/- 0.6 (range: 44-91), mean eGFR was 49.5 +/- 0.4 ml/min/1.73 m2, 20.1% had diabetes, 31.5% were receiving calcium supplements, 31.3% were receiving vitamin D (> 1000 units/d), and 1.8% were receiving an active form of vitamin D. Controls had a mean eGFR of 104.1 +/- 0.7 ml/min/1.73 m2. The prevalence of arterial calcification was the same in CKD 3 patients (35.1%) and controls (33.3%). Dividing the CKD 3 patients by different thresholds of serum creatinine yielded similar results. There was no difference in calcification between patients taking or not taking calcium supplements (36.2% vs. 34.6%), vitamin D (36.2% vs. 34.6%), or both (30% vs. 32.5% with neither). In a logistic regression, only age was a significant determinant of arterial calcification ($p<0.0001$).

Conclusions: The prevalence of medial arterial calcification is not increased in women with stage 3 CKD, indicating that the risk begins at stage 4 CKD. Supplementation of calcium or vitamin D does not increase the risk of medial arterial calcification in these patients.

Deoxycholic Acid (DCA), a Metabolite of Circulating Bile Acids, and Coronary Vascular Calcifications in Chronic Kidney Disease (CKD)
Makoto Miyazaki,[1] Shinobu Miyazaki-anzai,[1] Audrey L. Keenan,[1] Kristen L. Nowak,[1] Jessica B. Kendrick,[1] Geoffrey A. Block,[2] Michel Chonchol.[1] *[1]Univ of Colorado Denver; [2]Denver Nephrology.*

Background: Our group has previously shown that DCA, a metabolite of circulating cholic acid, induces vascular mineralization and osteogenic differentiation in animal models and that circulating levels of DCA are elevated in patients with CKD. We investigated whether increased DCA serum levels are associated with an increase risk for higher coronary artery calcification (CAC) volumes and lower lumbar bone mineral density (BMD) in CKD patients.

Methods: We used stored baseline serum samples in 112 patients with moderate to advanced CKD (eGFR= 20-45 mL/min/1.73m^2) who participated in a randomized-controlled study to examine the effects of phosphate binders on vascular calcification. Circulating DCA levels were assayed using liquid-chromatography-tandem mass spectrometry (LC-MS/MS). CAC volume was obtained using GE-Imatron C150 scanner and lumbar BMD was determined using abdominal computed tomography scans with a calibrated phantom of known density. Linear regression models were used to examine the cross-sectional association between DCA with CAC volume and lumbar BMD.

Results: Participant characteristics were as follows: mean age, 68±11 years; 50% women; 10% black; mean eGFR, 32±8 mL/min/1.73m2; and median DCA 58.4 (IQR 29-112) ng/mL. After adjusting for demographics, co-existing illness, body mass index, eGFR and circulating markers of CKD-MBD including serum calcium, phosphorus, vitamin D, parathyroid hormone and fibroblast growth factor 23, an increase serum DCA level > 58 ng/mL positively associate with CAC volume (ß: 494.84 ± 238.82; p=0.03) and negatively associated with BMD (ß: - 20.35± 9.56; p=0.03).

Conclusions: Higher serum levels of DCA in patients with stage III and IV CKD is independently associated with higher CAC volume and lower lumbar BMD. Larger cohort studies are needed to confirm these findings.

Fibroblast Growth Factor 23 and Fetuin A Levels in Pre-Dialysis Stage 4-5 Chronic Kidney Disease Patients with Aortic Calcification: A Case Control Study
Vijayakumar Theophilus-Sunder, Anna T. Valson, Vinoi George David, Santosh Varughese, Tamilarasi Veerasamy. *Dept of Nephrology, Christian Medical College, Vellore, Tamil Nadu, India.*

Background: Vascular calcification (VC) contributes to the increased cardiovascular mortality seen in CKD. However, not everyone with advanced CKD develops VC, indicating that circulating levels of factors that modulate VC may play a role in determining individual susceptibility towards VC. We aimed to examine this hypothesis by measuring the levels of FGF-23 and Fetuin-A in a group of pre-dialysis CKD Stage 4-5 patients who had documented abdominal aortic calcification (AAC) and an age, gender and eGFR matched group of patients who did not have AAC.

Methods: Out of a pre-existing cohort of 710 patients with CKD Stage 4-5, 28 patients with AAC (Group 1, cases) were compared with an equal number of age, gender and eGFR matched patients without AAC (Group 2, controls) with respect to their demographic and biochemical parameters, including FGF-23 and Fetuin-A. AAC was assessed by lateral abdominal X ray, while Fetuin-A and intact FGF-23 were estimated by ELISA in serum.

Results: Groups 1 and 2 were matched for age (mean age 57.7 and 57.8 years respectively, p = 0.938), gender (84.6% males in both groups) and eGFR (median eGFR 14.5 and 13.1 respectively, p = 0.826), and were not significantly different with respect to risk factors for AAC such as presence and duration of diabetes, hypertension, smoking and obesity. Levels of calcium, phosphorus, PTH, 25 (OH) vitamin D, serum cholesterol, triglycerides, HDL and LDL were also comparable between the two groups. However, median FGF23 levels were significantly higher in Group 1 [25.2, (Q1= 14, Q3=34.2)] compared to Group 2 [12.1 (Q1 = 6.6, Q3 = 14.1), n = < 0.001]. Median Fetuin-A levels were also significantly higher in Group 1 [5.5 (Q1=4.4, Q3=6.5)] compared to Group 2 [4.1 (Q1 = 3.6, Q3 = 5.7, n = 0.034).

Conclusions: Pre-dialysis patients with Stage 4-5 CKD with AAC, had higher FGF-23 and Fetuin-A levels compared to age, gender and eGFR matched patients who did not have AAC. The nature and mechanism of this association between elevated FGF23 and Fetuin-A levels and AAC requires further exploration.

SA-PO600

Lack of Association Between Serum Osteoprotegerin, Osteopontin and Fetuin-A Levels and the Longitudinal Changes in Arterial Stiffness in CKD Patients Undergoing Renin-Angiotensin System Blockade
Cecilie Lyngsø,[1] Marie Frimodt-Moller,[2] Marianne Rix,[2] Anne-Lise Kamper,[2] Svend Strandgaard,[1] Arne Høj Nielsen,[1] Allan Flyvbjerg,[3] Mette Bjerre.[3] *[1]Dept of Nephrology, Herlev Hospital, Herlev, Copenhagen, Denmark; [2]Dept of Nephrology, Rigshospitalet, Copenhagen, Denmark; [3]The Medical Research Laboratory, Dept of Clinical Medicine, Aarhus Univ, Aarhus, Denmark.*

Background: Osteoprotegerin (OPG), osteopontin (OPN) and fetuin-A, have been suggested to participate in the accelerated development of arteriosclerosis seen in patients with chronic kidney disease (CKD). We have previously shown that measures of vascular stiffness were significantly reduced after 24 weeks of treatment with renin-angiotensin system (RAS) blocking agents. The aim of this longitudinal post hoc study was to investigate whether serum levels of OPG, OPN and fetuin-A were associated with these same changes in markers of arterial stiffness found in CKD patients treated with RAS blocking agents.

Methods: Serum OPG, OPN and fetuin-A levels were measured in 57 patients with CKD stage 3-5, mean eGFR 29 ml/min, as a post hoc analysis of data acquired during a 24-week controlled trial in which patients were randomized to treatment with 16 weeks of monotherapy with either enalapril or candesartan followed by 8 weeks of dual blockade. Serum levels were obtained upon study entry and after 16 and 24 weeks of RAS blocking therapy and compared to aortic pulse-wave velocity and augmentation index.

Results: Except for a significant correlation between OPG and central pulse pressure ($p < 0.05$), serum levels of OPG, OPN and fetuin-A did not correlate to markers of vascular stiffness. There were no significant changes in serum levels of OPG, OPN and fetuin-A when monotherapy with enalapril or candesartan was compared to dual blockade.

Conclusions: The present results do not corroborate the use of OPG, OPN and fetuin-A as surrogate markers for vascular stiffness in patients with CKD.

SA-PO601

Hyperuricemia Is Significantly Associated with Coronary Artery Calcification and Vascular Stiffness in Asymptomatic Subjects Undergoing General Health Examination
Ah Ran Choi, Hae Yeul Park, Seok-Hyung Kim, Hoon Young Choi, Sung-Kyu Ha, Hyeong Cheon Park. *Nephrology, Gangnam Severance Hospital, Yonsei Univ College of Medicine, Seoul, Korea.*

Background: Recent studies suggest that hyperuricemia may be associated with increased adverse cardiovascular events even in healthy subjects. Quantity of coronary artery calcium (CAC) correlates with atherosclerotic plaque burden and increased cardiovascular events. This study aimed to determine the relationship between serum uric acid level(sUA) and brachial-ankle pulse wave velocity (ba-PWV), coronary artery calcium score (CACS) as well as other traditional cardiovascular risk factors in asymptomatic subjects.

Methods: We consecutively enrolled 4,703 asymptomatic subjects who underwent ba-PWV and coronary CT angiography as part of a general health examination. A high ba-PWV group, those having increased vascular stiffness, was defined as ba-PWV greater than 1497.5 cm/s (75th percentile). The subjects were stratified into four groups according to sUA.

Results: Mean age of enrolled subject was 52.8 ± 9.4 years, 61 % of the study participants were male. Eight point four percent of the study participants showed CACS greater than 100. The adjusted odds ratio (OR, 95% confidence interval) for the presence of high ba-PWV in the second to fourth sUA quartile vs. first sUA quartile was 1.45 (1.137-1.840, P<0.003), 1.42 (1.081-1.866 P<0.012), 1.66 (1.246-2.218, P<0.001), respectively after adjusting for age, gender, diabetes, hypertension, smoking, body mass index (BMI), estimated glomerular filtration (eGFR), fasting blood sugar (FBS) and calculated LDL. Moreover, subjects with CACS greater than 100 also showed that fourth quartile of sUA was associated with high ba-PWV compared with the first quartile of sUA [OR 2.4, (1.65-3.47, P<0.001)]. Multivariate linear regression analysis demonstrated that old age, male, hypertension, diabetes, BMI, FBS, eGFR and sUA were significantly associated with mean ba-PWV and log transformed CACS.

Conclusions: Our results show that sUA is an independent risk factor for increased vascular stiffness and coronary atherosclerosis in asymptomatic adults undergoing health examination.

SA-PO602

Abdominal Aortic Calcification Score on Plain Radiograph as a Predictor of Coronary Artery Calcification Score on Computed Tomography and T-Score on BMD in Dialysis Patients
Eu Gene Jeong,[1] Su Mi Lee,[1] Young Ki Son,[1] Dongyeol Lee,[2] Hansae Kim,[2] Sung Hyun Son.[3] *[1]Dept of Internal Medicine, Dong A Univ Hospital, Busan, Republic of Korea; [2]Dept of Internal Medicine, Bong Seng Memorial Hospital, Busan, Republic of Korea; [3]Dept of Internal Medicine, BHS Han Seo Hospital, Busan, Republic of Korea.*

Background: Not only coronary artery calcification scores (CACS) on computed tomography (CT) but also several VC scores on plain radiographs can predict cardiovascular events. However, there is no study about the correlation between CACS on CT and VC scores of several sites on plain radiographs. Therefore, we evaluated which VC scores among several VC scores on plain radiographs are a predictor of CACS on CT in dialysis patients. We also investigated the association between VC scores and bone mineral density (BMD).

Methods: We conducted this single center cross-sectional study from March 2013 to September 2014. We checked the plain radiographs of the feet, hands, pelvis, and lateral lumbar spine and estimated the VC scores. CACS on CT and BMD were evaluated. We defined severe CACS as CACS > 1000. FGF-23, fetuin-A, osteoprotegerin (OPG) and receptor activator of NF-κB ligand (RANKL) were analyzed with ELISA.

Results: The mean ages of 61 patients including 38 hemodialysis(HD) and 23 peritoneal dialysis(PD) patients were 58.6±10.2 years. The prevalence rate of significant VC was 75.4% and prevalence rate of severe CACS was 26.2%. The OPG levels were higher in patients with severe CACS(p=0.019) and significant VC(p=0.009). Patients with AAC score≥5 had lower T score of wrist and hip than patients with AAC score<5. CACS is positively correlated with AAC score(r=0.639, p< 0.001), VC score of the hands and pelvis (r=0.494, p< 0.001). AAC score is negatively correlated with T score of wrist(right: r=-0.286, p=0.027) and hip(right: r=-0.259, p=0.045)on BMD. AAC score(B=59.4, C.I.=18.3-100.6, p=0.006) and VC score of the hands and pelvis(B=225.8, C.I.=69.7-381.8, p= 0.006)on plain radiographs were independently associated with CACS on CT.

Conclusions: AAC score among several VC scores on plain radiographs is the most reliable predictor of CACS on CT and T score on BMD in dialysis patients.

SA-PO603

Total Body Multislice Computed Tomography as a Gold Standard of Vascular Calcification Nadia Martin Alemany,[1] Xoana Barros,[1] Jordi Calabia,[1] Juan Baños.[2] *[1]Nephrology, Univ Hospital Dr Josep Trueta, Girona, Spain; [2]Radiology, Inst de Diagnostic per la Imatge (IDI), Girona, Spain.*

Background: Vascular calcification (VC) is a marker of cardiovascular risk in CKD patients. Imbalance of calcium-phosphate parameters and secondary hyperparathyroidism (sHP) has been proposed as inductors of VC. Traditionally VC has been evaluated with Kauppila, Adragao and coronary Agatston scores but they are limited to restricted body areas and may underestimate total VC. We proposed a new method to assess VC in CKD patients with mild sHP based on total body multislice computed tomography (MSCT) without contrast.

Methods: Multicenter transversal study which included incident dialysis patients with mild sHP (PTH >150pg/dL) after signed informed consent. Kauppila and Adragao scores were determinate on abdominal and pelvis/hand X-ray, respectively. Total body area calcification (cm2) was measured by MSCT. Patients with a total calcified area of >150 cm2 were considered calcified. Sensibility and specificity of Kauppila and Adragao scores were calculated considering total calcified body area > 150 cm2 as reference.

Results: We enrolled 22 patients (13 hemodialysis / 9 peritoneal dialysis), 45% diabetics, 62±15 years old. Mean±SD were: phosphorus 4.6±1.5mg/dl, calcium 9.21±0.44mg/dL and parathyroid hormone 278±132pg/dL.They presented mean Kauppila score of 6.9±6.9, Adragao score of 2±3.7 and total calcified area of 112.6±196.7cm^2. 77% patients were calcified, considering positive if overall calcified area was >150cm^2. Diabetics and those with previous cardiovascular events had higher total body calcified area, whereas gender and type of dialysis didn't demonstrate any influence on calcification. Sensibility of Kauppila and Adragao scores were 70% and 30% respectively, whereas specificity of both of them was 100%.

Conclusions: It is possible to evaluate the overall body calcified area in patients with ESRD by multislice computed tomography, which could be considered as a potential gold standard of global vascular calcification in those patients.

SA-PO604

Comparison of Mineral Metabolic Markers and Therapy in Chronic Hemodialysis Patients with Different Degree of Abdominal Aortic Calcification Score Manja Antonic,[1] Saska Lampreht,[1] Zeljka Veceric Haler,[2] Jakob Gubensek,[2] Andrej Drozg.[1] *[1]Dept of Nephrology and Dialysis, General Hospital, Celje, Slovenia; [2]Dept of Nephrology, Univ Medical Centre, Ljubljana, Slovenia.*

Background: The correlations of vascular calcifications with different markers of CKD-MBD and also its therapy are not always consistent across the studies and cross-sectional associations are favoured over long-term analyses. We therefore aimed to evaluate laboratory markers and therapy load over a longer period in chronic hemodialysis patients with different severity of abdominal aortic calcification (AAC).

Methods: In hemodialysis patients AAC was determined by lateral lumbar radiography and quantified by Kauppila score. Patients were divided in two groups according to median AAC score of the whole group. Mean active vitamin D and cinacalcet intake for last 4 years and calcium carbonate for last 10 years (or whole dialysis vintage for those on dialysis for shorter time) and mean mineral metabolism markers (Ca, P, iPTH, CaxP product and alkaline phosphatase (AF) for last 4 years) were compared between the groups.

Results: 20 patients with high AAC score were significantly older (72±9 vs. 59±15 years, p=0.003) and more often diabetic (15% vs. 2%, p=0.04) compared to 19 patients with low score, but there was no difference in dialysis vintage (6.4±4.8 vs. 5.3±4.2 years, p=0.44) or presence of cardiovascular disease. We found no difference in mean calcium carbonate dose (4.1±1.6 vs. 4.4±1.9 g/day, p=0.59) or mean cinacalcet dose (21±26 vs. 12±17 mg/day, p=0.18), but significantly higher mean calcitriol-equivalent dose of active vitamin D (1.7±0.8 vs. 0.9±0.8 mg/week, p=0.03). There was no significant difference in Ca, CaxP product, iPTH or AF, but P was significantly higher (1.6±0.2 vs. 1.4±0.3 mmol/l, p=0.03) in group with high AAC score.

Conclusions: In patients with higher AAC score higher mean active vitamin D dose and higher phosphate levels over a long period of time were found in addition to older age and more diabetes. We find this retrospective analysis important because treatment and laboratory values were evaluated over a prolonged period.

SA-PO605

Influence of the Bone Mineral Disorder on Vascular Calcification Occurrence and Progression in Hemodialysis Patients João Henrique Castro,[1] Pasqual Barretti,[1] Janaina Silva Martins,[2] Rogerio Carvalho Oliveira.[1] *[1]Medical Clinic, Faculdade de Medicina de Botucatu, Botucatu, Sao Paulo, Brazil; [2]Medical Clinic, Univ Estadual de Maringa, Maringa, Parana, Brazil.*

Background: Cardiovascular disease is the main cause of death in hemodialysis patients; vascular calcification (VC) is common among them. The main objective of this study was to evaluate the influence of bone mineral disorders in VC and its progression in a prospective cohort of patients. Secondarily, we intend to identify clinical, laboratory and nutritional predictors of the presence and progression of VC.

Methods: Adult patients undergoing HD for ≥90 days were included. At the beginning of and after 12 months Kaupilla and Adragão methods were used to determin the VC score (VCS); and clinical, hormonal, inflammatory, biochemical, and nutritional markers were measured. Bone biopsy and histomorphometric analysis were performed at the beginning of follow up.

Results: Sixty patients completed the study; of them 41.7 % were male, 43.4% diabetic, and the mean age was 56. 7±13.8 years. At the beginning of the follow-up, 75% of the patients exhibited VC. Age > 60 years (Odds ratio=50.2, 95%CI= 4.1-618,4, p=0.002), FGF23 levels > 3000 Ru/ml (Odds ratio=5.7, 95%CI= 1,00-329, p=0.05), and serum fetuin A >673 g/l (Odds ratio=7.34, 95%CI= 1,26-43,7, p=0.03) were independent predictors of VC. Regarding VC progression age > 60 years (Odds ratio=4.3, 95%CI= 1.003-18.5, p=0.049), serum fetuin A >673 g/l (Odds ratio=6.4, 95% CI= 1.47-27.9, p=0.01), no use of statins (Odds ratio=5.6, 95%CI= 1.13-28.1, p=0.03) were the only independent predictors. Bone turnover and histomorphometric findings were not associate with VC and its progression.

Conclusions: The present study reinforces the role of age, FGF23 levels, use of statins on the VC process and arises a paradoxical effect of serum fetuinA on VC and its progression, which deserves new and more specific investigations.

SA-PO606

Low Bone Mineral Density of Lower Extremities Associates with Coronary Calcification Score in End-Stage Renal Disease Patients Zhimin Chen,[1] Abdul Rashid Tony Qureshi,[1] Bengt Lindholm,[1] Hannes Olauson,[1] Peter F. Barany,[1] Lars Wennberg,[2] Jonaz Ripsweden,[3] Peter Stenvinkel.[1] *[1]Renal Medicine & Baxter Novum, Karolinska Inst, Stockholm, Sweden; [2]Transplantation Surgery, Karolinska Inst, Stockholm, Sweden; [3]Radiology, Karolinska Inst, Stockholm, Sweden.*

Background: Kidney transplantation (Rtx) corrects many abnormalities in uremia but mineral and bone disorders and cardiovascular disease often persevere. We investigated associations between low bone mineral density (BMD) and coronary artery calcification (CAC) in patients (pts) with end stage renal disease (ESRD) undergoing living donor Rtx.

Methods: In 40 pts (aged 44 ± 13 years; 60% male) undergoing living donor Rtx, BMD measurements were made before (n=19), close to (n=40) and after (n=13) RtX and CAC measurements (n=34) were also made close to RtX. BMD was assessed by dual-energy X-ray absorptiometry (DXA) and CAC by computed tomography. We investigated the associations between BMD and CAC (measured at the same time). Logistic regression models were adjusted for age, gender and diabetes.

Results: Altogether 32 % (11/34) pts had CAC Agatston score ≥ 100. CAC associated with age (rho = 0.46, p < 0.01) and diabetes (rho = 0.57, p < 0.001). At baseline, there were significant associations between CAC and BMD of upper extremities (rho= -0.49, p < 0.01), BMD of lower extremities (rho = -0.66, p < 0.001) and BMD of femoral neck (rho = -0.58, p < 0.001). In multivariate analysis adjusted for age, gender and diabetes, BMD of lower extremities remained as significantly lower in pts with CAC scores ≥ 100 (p< 0.05). No significant differences were seen between values of BMD obtained -2.0 [-4.4, -1.1] years before Rtx (n=19) as compared to BMD obtained close to Rtx at -0.1 [-0.7, 0.6] years (n=40) or 2.1 [1.1, 3.3] years after (n=13) RTx. Sex-stratified analyses also showed no significant differences in BMD before, close to and after RTx.

Conclusions: BMD of lower extremities is associated with CAC in ESRD pts undergoing living donor Rtx. No significant changes in BMD were found when comparing values before, close to and after RTx. Further studies are required to elucidate the mechanism(s) linking BMD to CAC score in ESRD pts.

SA-PO607

Association of Vascular Calcification Biomarkers with Peripheral Arterial Disease in Hemodialysis Patients Steven Menez,[1] Michelle M. Estrella,[1] Esther D. Kim,[2] Lucy A. Meoni,[1] Kunihiro Matsushita,[1] Pranav S. Garimella,[3] Stephen M. Sozio,[1] Rulan S. Parekh,[1,2] Bernard G. Jaar.[1] *[1]Medicine, Johns Hopkins Univ, Baltimore, MD; [2]Medicine, Univ of Toronto, Toronto, ON, Canada; [3]Medicine, Tufts Univ, Boston, MA.*

Background: Vascular calcification is common in ESRD patients. We evaluated whether the vascular calcification biomarkers, namely osteoprotegerin (OPG), fetuin A, and matrix Gla protein (MGP) are associated with PAD among incident hemodialysis (HD) patients in the Predictors of Arrhythmia and Cardiovascular Events (PACE) study.

Methods: We performed a cross-sectional analysis among 402 participants in whom these biomarkers were measured at baseline. We defined PAD as ABI <0.9 or >1.4 and or a documentation in the medical record at study entry. Using multivariable logistic regression we evaluated the association of OPG, fetuin A and MGP with prevalent PAD. Sensitivity analysis was performed in persons who had PAD defined only by medical records.

Results: PAD was prevalent in 28% (n=111) of the cohort. Mean age was 55 years, 72% were black. 60% were ever smokers, 58% had diabetes, 37% had coronary artery disease, and 69% hypercholesterolemia. The median OPG and MGP levels were 10.1 pmol/L and 1412 pM, respectively; the mean fetuin A level was 0.51 g/L. Adjusting for age, gender, race, Charlson co-morbidity index, smoking, diastolic blood pressure, mean serum phosphate, and mean dialysate calcium concentration, 1 pmol/L higher OPG was associated with 1.07-fold increased odds of PAD. There was no association of fetuin A or MGP with PAD. In sensitivity analysis, the association of OPG and odds of PAD was similar to the main results.

Association of Vascular Calcification Biomarkers with Odds of PAD		
	Unadjusted OR (95% CI)	Adjusted OR (95% CI)
OPG, per 1 pmol/L higher	1.06 (1.02-1.11)	1.07 (1.01-1.13)
Fetuin A, per 1 g/L higher	0.88 (0.24-3.26)	1.25 (0.27-5.81)
MGP, per 1-log pM higher	0.98 (0.75-1.28)	0.91 (0.66-1.25)

Conclusions: In this population of incident HD patients at high risk of PAD, OPG was significantly associated with odds of PAD. Whether the elevation of OPG is causal to the development of PAD or whether it serves as a marker of disease severity needs to be explored.

Funding: NIDDK Support

SA-PO608

Association of Metabolic Syndrome with Aortic Arch Calcification and Outcome in Non-Diabetic Peritoneal Dialysis Patients Cheng Chia Lee,[1,2] Kun-Hua Tu,[1,2] Ya-chung Tian,[1,2] Ming-Yang Chang,[1,2] Chih-Wei Yang.[1,2] *[1]Dept of Nephrology, Kidney Research Center, Chang Gung Memorial Hospital, Taoyuan, Taiwan; [2]Chang Gung Univ, College of Medicine, Taoyuan, Taiwan.*

Background: Vascular calcification (VC) is now recognized as an important risk factor for mortality in dialysis patients. Previous studies have shown conflicting results regarding the association of the metabolic syndrome (MetS) and mortality in patients on peritoneal dialysis (PD). Despite the controversial definition of MetS in PD patients, the association between MetS and the presence and severity of VC in the non-diabetic PD patients remained unknown.

Methods: We enrolled 277 non-diabetic PD patients into this study. Posterior-anterior chest X-ray were assessed for the aortic arch calcification (AoAC). Frequency of different components and their constellation as MetS were determined according to the modified Adult Treatment Panel III criteria. Using multinomial logistic regression, the factors determine baseline AoAC were analyzed. We used Kaplan Meier analysis to assess the impact of MetS on both mortality and technique failure.

Results: Mean age was 48.4 ± 13 years and 43.1% (n=118) had metabolic syndrome.179 patients were classified as no visible calcification (AoAC grade 0), 51 patients as mild calcification (AoAC grade 1), and 47 patients as moderate to severe calcification (AoAC grade 2+ 3). The adjusted odds ratio for AoAC grade 1 was 3.03 (95% CI: 1.34-6.84) and for AoAC grade 2+3 was 6.25 (95% CI: 2.26-17.27) among patients with MetS as compared with those without MetS. Multivariate linear regression analysis showed that MetS (P <0.001) was independent risk factor for higher inflammation, as denoted by high sensitivity C-reactive protein. Over a mean of 45.9 months of follow-up, 34 patients died. Kaplan Meier analysis demonstrated that the incidence of mortality and technique failure does not differ in patients with and without MetS.

Conclusions: MetS was independently associated with the presence and severity of AoAC but cannot predict mortality or technique failure in non-diabetic PD patients. Nevertheless, non-diabetic PD Patients with MetS warrant more aggressive risk factor management to reduce the risk of VC.

SA-PO609

Increased Peripheral Arterial Calcification in Patients Receiving Warfarin Kum Hyun Han,[2] W. Charles O'Neill.[1] *[1]Renal Div, Emory Univ, Atlanta, GA; [2]Internal Medicine, Inje Univ College of Medicine, Ilsan Paik Hospital, Goyang, Korea.*

Background: Matrix gla-protein is a vitamin K-dependent inhibitor of vascular calcification, and genetic deficiency or inhibition with warfarin produces medial vascular calcification in animals, raising concerns that warfarin may promote vascular calcification in humans. We recently showed that warfarin use is associated with increased breast arterial calcification but whether this is reflective of other arteries or occurs in men as well is unclear. Therefore, we compared the prevalence of calcification in peripheral arteries in patients with and without warfarin therapy.

Methods: A random sample from a computerized search of medical records yielded 430 patients with x-rays performed during or after warfarin therapy. Each was matched to a patient without warfarin exposure based on age and diabetes. Patients with warfarin exposure <1 month, history of ESRD, or serum creatinine > 2.0 were excluded. X-rays were reviewed visually for arterial calcification.

Results: Mean age was 66.9 + 0.8, 41% were males, and 34% had diabetes. The indication for warfarin was atrial fibrillation in 45% and venous thrombosis or embolism in 44%, and mean duration of warfarin was 4.8 yrs (range: 1 month to 38 yrs). 68% were on warfarin at the time of the x-ray and the remainder had been off warfarin for a mean of 2.4 yrs (range: 1 day to 25 yrs). Serum calcium was slightly lower (9.04 +/- 0.03 vs. 9.17 +/- 0.03, p=0.0005) in the warfarin patient but serum creatinine and phosphorus did not differ. Prevalence of arterial calcification was 44% greater in warfarin patients (30.2% vs. 20.9%, p=0.0023) but not on x-rays performed prior to warfarin (26.4% vs. 22.4%, n=156), indicating that the increase was due specifically to the warfarin and not to underlying disease or other patient characteristics. The increase in calcification was seen only after >5 yrs of warfarin and only in the ankle and foot. It was similar in men and women and greatest (2.4-fold) in patients under age 60 (15% vs. 6.3 %, p=0.04).

Conclusions: Warfarin use is associated with lower extremity arterial calcification in both men and women independent of age, diabetes, and other patient characteristics.

Matrix Gla Protein and Vascular Calcification in Patients with End Stage Renal Disease Hannes Olauson,[1] Christian L. Meuwese,[1] Karin Luttropp,[1] Annika Wernerson,[1] Peter F. Barany,[1] Cees Vermeer,[2] Peter Stenvinkel.[1] *[1]CLINTEC, Karolinska Inst, Sweden; [2]VitaK, Maastricht Univ, Netherlands.*

Background: Vascular calcification (VC) is a common and severe consequence of end-stage renal disease (ESRD). Matrix Gla protein (MGP) is a calcification inhibitor expressed by the vasculature that counteracts the development of VC.

Methods: In 84 ESRD patients undergoing LD-Tx at Karolinska University Hospital, biopsies from the inferior epigastric artery were obtained during surgery. Vascular calcification was assessed by von Kossa staining both by manual scoring (0-3) and by semi-automated analysis (%). Total uncarboxylated MGP (t-ucMGP) and dephospho-uncarboxylated MGP (dp-ucMGP) were measured in plasma. Tissue MGP expression was quantified in arterial biopsies by TaqMan rtPCR. DNA methylation of the MGP gene was assessed in peripheral blood from 12 ESRD patients and 12 healthy controls.

Results: 50 patients (59.5%) had low VC scores (0 and 1) and 34 (40.5%) patients high VC scores (2 and 3). Plasma levels of dp-ucMGP were higher in patients with high VC scores compared to patients with low VC scores (2214 [1413-2995] vs. 1701 [1275-2233] pmol/L, p<0.05) and also associated with calcification (%) (Fig 1A: β [95%CI]: 26 [7 to 45] p<0.01). Additionally, calcification (%) associated with arterial expression of MGP (Fig 1B: β [95%CI]: 0.04 [0.02 to 0.06] p<0.0001). t-ucMGP levels were not associated with measures of VC. DNA methylation of the MGP gene was significantly lower in patients with ESRD compared to healthy controls (adjusted p<0.01).

Figure 1

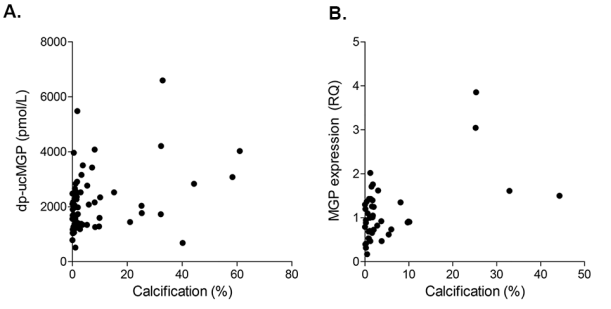

Figure 1. The association between calcification % (as assessed by semi-automated analysis) and A) plasma dp-ucMGP levels, and B) tissue MGP expression.

Conclusions: Tissue and plasma levels of dp-ucMGP were higher in patients with VC versus those without, possibly indicating a compensatory up-regulation of MGP to prevent further progress. The observation that the methylation of the MGP gene was lower in ESRD than in controls suggests that the altered expression could be due to epigenetic regulation.

A Nationally Representative Case Control Study of Calciphylaxis Risk Factors Sagar U. Nigwekar,[1] Sophia Zhao,[1,2] Julia Beth Wenger,[1] Franklin W. Maddux,[2] Jeffrey L. Hymes,[2] Ravi I. Thadhani,[1] Kevin Chan.[1,2] *[1]MGH; [2]Fresenius Medical Care North America.*

Background: Prior studies evaluating calciphylaxis risk factors suffer from sample size limitations and none examine whether characteristics at dialysis initiation predict calciphylaxis risk.

Methods: Data for this matched case control study were derived from hemodialysis (HD) population at the Fresenius Medical Care North America (FMCNA). Cases were identified from FMCNA calciphylaxis prospective database. Controls (HD patients without calciphylaxis) were matched to cases on age, sex, and race. Data on variables at HD initiation were abstracted. Variables for multivariable logistic regression analyses were identified using stepwise selection.

Results: We analyzed 1,025 calciphylaxis cases (52% biopsy-confirmed) and 2,050 controls. Body mass index, diabetes mellitus (DM), serum parathyroid hormone (PTH) level, use of warfarin and phosphate binders were higher whereas serum calcium and active vitamin D use were lower at HD initiation in cases compared to controls.

	Cases (n=1,025)	Controls (n=2,050)	P value
Age,years	54±14	54±14	NA
Sex, female %	67	67	NA
Race, white %	49	49	NA
BMI, kg/m^2	36.3±9.9	30.3±8.5	<0.001
DM, %	61.2	44.4	<0.001
Albumin-corected calcium, mg/dL	8.6±1.3	8.8±1.0	<0.001
Phosphrous, mg/dL	5.1±2.3	4.9±1.7	0.18
PTH, pg/mL (median, IQR)	339 (153, 658)	288 (129, 523)	<0.001
Albumin, g/dL	3.3±0.8	3.5±0.6	<0.001
Warfarin, %	23.3	7.4	<0.001
Active vitamin D, %	70.8	80.9	<0.001
Cinacalcet, %	7.2	4.3	0.06
Phosphate binder, %	65.5	58.5	0.04
Statin, %	44.3	38.0	0.67
Insulin injections, %	25.6	15.5	<0.001

No significant differences were noted for serum phosphorous, dialysate calcium, use of statins and cinacalcet. In DM subgroup, insulin injection use was more common in cases. In multivariable analyses, obesity (OR: 2.55, 95% CI: 1.82-3.59), DM (OR: 2.63, 95% CI: 1.88-3.69), use of warfarin (OR: 3.60, 95% CI: 2.40-5.41) and insulin injections (OR: 1.29, 95% CI: 1.07-1.89) were associated with higher risk. Similar results were noted in analyses restricted to biopsy-confirmed cases.

Conclusions: Obese, diabetic HD patients treated with insulin injections or warfarin are at high risk for calciphylaxis.

Calciphylaxis Quality Improvement Project and Case Series Rohan V. Mehta, Jean Luc Franck, Jason Cobb. *Renal Div, Emory Univ, Atlanta, GA.*

Background: Calciphylaxis (Calcific Uremic Arteriolopathy) is a serious condition characterized by extended length of stays and multiple hospital admissions. The treatment of calciphylaxis can become a burden on the healthcare system especially with the demands on hospital systems to become more efficient.The lengths of stay & 30-day readmission rates are becoming a measure of hospital quality.We developed a multidisciplinary team including nephrologists, hospitalists, dermatologists, hospital administration, nurses, wound care staff, social workers, dieticians, and palliative care.The purpose of the team is to improve the quality of care of our calciphylaxis patients.In development of this quality improvement project we began by examining our baseline patient population.We are reporting our baseline data as a case-series.

Methods: Retrospective chart review of calciphylaxis patients from 2001-2014 in our single center hospital which includes academic and community physicians.Baseline data reported included age, calcium, phosphorus, PTH, albumin, hemoglobin, creatinine, BUN, and the use of warfarin. Treatment options, the length of stay, and number of admissions were reported.

Results: In 20 reported patients, 19 were African-American. Average age was 61 years old. Average calcium levels of 8.8 mg/dl and phosphorus of 5.5 mg/dl. The average PTH was 573, albumin 2.75 gm/dl, hemoglobin of 10.4 gm/dl BUN of 42, and creatinine 6.5 md/dl. 13 patients received hyperbaric oxygen treatment, 9 patients received sodium thiosulfate infusions, and 6 patients received cinacalcet. 11 patients were using warfarin for medical conditions including atrial fibrillation and deep venous thrombosis.The average length of stay was 45 days and 3 admissions per patient.

Conclusions: We reported one of the largest single center and predominant African-American calciphylaxis case series.In comparison to other reported calciphylaxis series our average PTH was lower and a high percentage of our patients were using warfarin at time of diagnosis.Future tasks include testing if the multidisciplinary quality improvement team interventions can improve our patient quality of care and hospital goals such as reductions in length of stay and 30-day readmission rates.

SA-PO613

Calciphylaxis – A Multi-Interventional Treatment Regimen Including Vitamin K Supplementation Might Reduce Mortality in Chronic Kidney Disease Patients Daniel A. Hochfellner,[1] Barbara Binder,[2] Werner Ribitsch,[1] Alexander R. Rosenkranz,[1] Gernot Schilcher.[1] *[1]Clinical Div of Nephrology, Dept of Internal Medicine, Medical Univ of Graz, Graz, Austria; [2]Dept of Dermatology, Medical Univ of Graz, Graz, Austria.*

Background: Calciphylaxis is a rare disease predominantly affecting patients with chronic kidney disease (CKD) with a high mortality mainly due to wound infection. Recently, multimodal therapy schemes including sodium thiosulfate (STS) have been established. The role of a standardized Vitamin K supplementation remains unclear.

Methods: In a retrospective study we evaluated the impact of a standardized, multi-interventional treatment regimen on the mortality of calciphylaxis patients treated at the Clinical Department of Nephrology, Medical University of Graz, Austria between January 2009 and February 2014. Patients were treated with STS, dermatological wound management and high dose supplementation of vitamin K1 (Phytomenadion 30mg/week). The primary endpoint was mortality compared to the present literature. Secondary endpoints included gender distribution, number of biopsy proven cases, analysis of triggering events and time from event to diagnosis. Data were collected from medical records.

Results: 20 patients with newly diagnosed Calciphylaxis at different CKD stages (CKD 5, n= 15; CKD 4, n= 3; CKD 3, n= 1; no CKD, n= 1;) were included. The mortality was 25% versus 52% compared to recent literature. Gender distribution and amount of biopsy proven cases were comparable to other retrospective studies. 12 patients (60%) had a known preceding event such as trauma possibly having triggered development of calciphylaxis. The period from event to diagnosis was 103±94 days. 19 patients (95%) received STS. In contrast to other multimodal therapeutic concepts 95% (19) of our patients additionally received high dose vitamin K supplementation.

Conclusions: In our cohort calciphylaxis was associated with a markedly reduced mortality as compared to published outcome data. We hypothesize that supraphysiological supplementation of vitamin K in addition to thiosulfate therapy and our multi-interventional treatment regimen play an important role in the treatment of calciphylaxis.

SA-PO614

The German Calciphylaxis Registry Vincent Brandenburg,[1] Jürgen Floege,[2] Joanna Korbiel,[1] Markus Ketteler.[3] *[1]Cardiology, RWTH Aachen Univ Hospital, Aachen, Germany; [2]Nephrology, RWTH Aachen Univ Hospital, Aachen, Germany; [3]Nephrology, Klinikum Coburg, Coburg, Germany.*

Background: Calciphylaxis (CUA) is a rare disease and for patients a devastating condition associated with high morbidity and mortality. CUA is characterised by painful, ischemic, partly necrotic skin ulcerations. Pathomorphologically, media calcification of cutaneous arterioles and extracellular matrix remodelling are the hallmarks of CUA. Epidemiology and risk factors are incompletely understood. Referring patients to specialized units is limited due to high disease burden.

Methods: Therefore, we established an internet-based observational registry in 2006 (www.calciphylaxie.de) to allow online notification for pts with CUA. The registry includes a comprehensive data base with 71 parameters concerning patient and laboratory data, clinical background and presentation as well as therapeutic strategies. The diagnosis of CUA is made on clinical and/or histological grounds by the referring physician.

Results: Until Febr 2015 n=253 patients with CUA have been recorded (~ 30 pts/year at constant rate) with a median delay of 28 days after onset: 99% Caucasians, 60% females; 76% HD and 10% PD patients; median age 66 (IQR 61-76) years. Co-medication at the time of diagnosis: 75% ESA, 51% vitamin K antagonists (VKA). Skin biopsy was done in 45%, prior PTex in 12%; major skin lesion in 80% at the legs. Median lab data upon diagnosis of CUA: Alk Phos 113 U/L (IQR 86 - 167); PTH 173 ng/L (IQR 73-390), total calcium 2.20 mmol/L (IQR 2.04-2.36), phosphorus 1.62 mmol/L (IQR 1.28-2.00). Among the most frequently recorded therapeutic procedures were: surgical necrosectomy (plus antibiotics), intensifying dialysis modality, reduction of calcium supply, i.v. sodium-thiosulfat application. Survival was analyzed in a subgroup of 91 pts: Median survival time was 516 days after online notification.

Conclusions: CUA is a rare disease among ESRD pts with high mortality. Therapeutic strategies vary significantly among centers; EBM guidelines are absent. VKA usage appears to be risk factor for CUA in ESRD pts. The German CUA registry is a valuable tool to collect data and may become a basis for a European registry (EuCalNet).

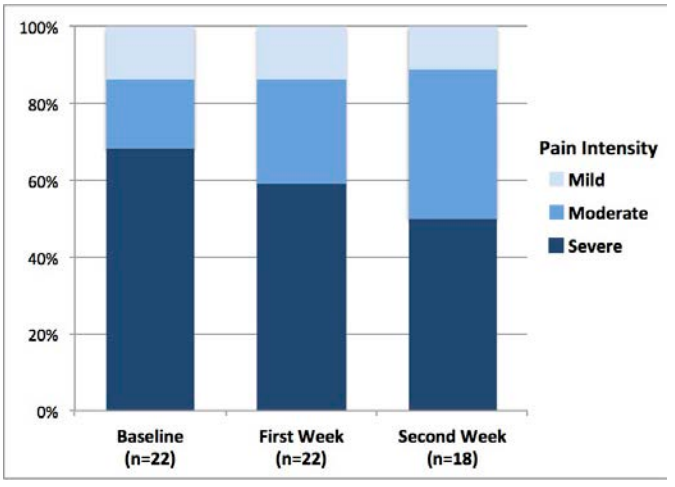
Evaluation of the Effects of Sodium Thiosulfate Treatment on Calciphylaxis Pain Guillermo Ortiz, Joshua Wibecan, Julia Beth Wenger, Ravi I. Thadhani, Sagar U. Nigwekar. *Nephrology Div, Massachusetts General Hospital, Boston, MA.*

Background: Intravenous sodium thiosulfate (STS) is commonly prescribed to treat calciphylaxis, a highly fatal disease that presents with excruciating painful skin lesions. Anecdotal reports suggest that STS may improve calciphylaxis associated pain (CAP) within 2 weeks of initiation; however, systematic evaluation of effects of STS on CAP is lacking.

Methods: This observational study included 22 patients with biopsy-confirmed calciphylaxis who were hospitalized at our center for ≥ 2 weeks during 2012-2014 for newly diagnosed calciphylaxis and were treated with STS. Medical records were reviewed to abstract clinical data including CAP severity (0-10 scale) and analgesic use. CAP scores at baseline, 1-week, and 2-week time-points were noted and classified into mild (1-3),

moderate (4-6), and severe (7-10) categories. Responders were patients who reported ≥ 30% improvement in CAP severity score from baseline during the first 2 weeks of treatment. Predictors of response and association between CAP response during the first 2 weeks of STS treatment and 6-month outcomes (skin lesion status, mortality) were examined in univariate logistic regression analyses.

Results: Median age was 60 years (Range: 52-67), 59% were males, 95% were whites, 55% were on dialysis, 36% had chronic kidney disease not requiring dialysis, and 9% had normal kidney function. Median duration between lesion appearance and STS initiation was 12 weeks (Range: 6-19). There was a trend toward decrease in severe CAP from baseline to 2-weeks (figure 1) despite steady doses of opiate medications. No significant predictors of CAP response were observed and CAP improvement at 2-weeks did not predict 6-month outcomes.



Conclusions: A large prospective trial is needed to ascertain the effects of STS on CAP.

SA-PO616

Long-Term Impact of Strict Blood Pressure Control During CKD on Mortality Risk After ESRD Elaine Ku,[1] Lawrence J. Appel,[2] Jennifer J. Gassman,[2] Miroslaw Smogorzewski,[2] Mark J. Sarnak,[3] David V. Glidden,[1] Chi-yuan Hsu.[1] *[1]UCSF; [2]AASK; [3]Tufts.*

Background: In extended follow-up of the Modification of Diet in Renal Disease (MDRD) study, we reported that strict BP control did not lower risk of ESRD but associated with lower mortality risk after ESRD (HR 0.72 [95% CI 0.58–0.89]) (Ku KI 2015). To further address this issue, we conducted parallel analyses in the African American Study of Kidney Disease (AASK) and *post-hoc* pooled analyses of AASK and MDRD.

Methods: AASK randomized 1094 persons with CKD attributed to hypertension to strict (mean arterial pressure [MAP] <92) versus usual BP control (MAP <102-107 mmHg) between 1995-2001. We ascertained death and ESRD status through 6/2012 via US Renal Data System (USRDS) and Social Security Death Index for 1067 enrollees with non-missing identifiers.

Results: In extended AASK follow-up, 397 cases of ESRD and 475 deaths (208 after ESRD) occurred. The risk for ESRD was 0.94 (95% confidence interval [CI] 0.77-1.14), overall mortality risk was 0.92 (95% CI 0.77-1.10), and risk for death after ESRD onset was 0.92 (95% CI 0.70-1.20) comparing strict versus usual BP arms. Thus, the CI for death after ESRD was wider and included the prior MDRD estimate. In pooled MDRD/AASK analysis (N=1907), the corresponding risk for ESRD (1024 cases) was 0.90 (95% CI 0.80-1.02), overall mortality (N=920) was 0.87 (0.76-0.99), and risk for death after ESRD (N=532) was 0.78 (95% CI 0.75-0.92).

Conclusions: Although AASK analyses did not achieve conventional statistical significance for outcomes of interest, potentially due to inadequate power, pooled results demonstrated a continued association between strict BP control and lower mortality risk after ESRD. These data provide the most persuasive evidence to date that aggressive management of BP prior to ESRD may have a persistent benefit after ESRD onset.

SA-PO617

Obesity, Renin-Angiotensin System Blockade, and Chronic Kidney Disease: A Population-Based Cohort Study Jordana B. Cohen, Alisa J. Stephens-Shields, Michelle Denburg, Amanda Hyre Anderson, Raymond R. Townsend, Peter P. Reese. *Univ of Pennsylvania, Philadelphia, PA.*

Background: Obesity substantially increases the risk of the development and progression of chronic kidney disease. Adipose tissue expresses all of the components of the renin-angiotensin system (RAS), which is an important contributing factor to the high prevalence of hypertension in obese patients, and drives renal hyperfiltration and subsequent glomerular injury.

Methods: We performed a retrospective cohort study using The Health Improvement Network, a primary care database with comprehensive demographic, laboratory, and pharmacologic data from patients in the United Kingdom. We evaluated the effect of time-updated exposure to RAS blockade versus all other antihypertensive medications in obese, hypertensive, non-diabetic patients with normal or mildly reduced kidney function using a Cox proportional hazards model as estimated by pooled logistic regression to assess the hazards of developing a 50% reduction in estimated glomerular filtration rate (eGFR) or end stage renal disease. In addition to adjusting for baseline comorbidities including age, gender, socioeconomic status, cardiovascular disease, and body mass index (BMI), we adjusted for time-varying covariates including systolic blood pressure (SBP), number of antihypertensive medications, use of mineralocorticoid antagonists, and eGFR.

Results: There were 219,701 patients that met inclusion criteria, with a median 4.9 years of follow-up. Median baseline eGFR was 72.6 mL/min/1.73m^2, median SBP was 146 mmHg, and median BMI was 32.8 kg/m^2. 59% of patients were on RAS blockade at baseline, and 69% of patients were on it for at least half the duration of follow-up. Taking into account time-updated exposure, there was a significantly reduced hazard of adverse renal outcomes in patients treated with RAS blockade compared to those treated with other antihypertensive medications (HR 0.93, p<0.01).

Conclusions: This study, conducted in a large real-world cohort of patients with detailed and time-updated data about blood pressure treatment, provides important evidence that RAS blockade may protect against deterioration in renal function among obese, hypertensive, non-diabetic patients.

Distribution and Prognostic Value of Central Blood Pressure in Chronic Kidney Disease Yun Jung Oh,[1] Su Mi Lee,[2] Ji Yong Jung,[3] So Mi Kim,[4] Chungsik Lee.[1] *[1]Dept of Internal Medicine, Cheju Halla General Hospital, Jeju, Republic of Korea; [2]Dept of Internal Medicine, Dong-A Univ Hospital, Busan, Republic of Korea; [3]Dept of Internal Medicine, Gacheon Univ Gil Hospital, Incheon, Republic of Korea; [4]Dept of Internal Medicine, Jeju National Univ Hospital, Jeju, Republic of Korea.*

Background: Central blood pressure (CBP) has been shown to be a better predictor for cardiovascular events and target organ damages than brachial blood pressure. However, little is known about comparative values of CBP and brachial BP in chronic kidney disease (CKD) population. We investigated the distribution of CBP and evaluated the comparative values of CBP and brachial BP for the prediction of renal progression in both CKD and non-CKD population.

Methods: We conduct this study using data from 868 subjects who underwent CBP measurement by the radial artery tonometric method between 2009 and 2013. Demographic and clinical characteristics were obtained from a review of the medical records at the time of CBP measurement. The outcome was renal progression defined as decline of estimated glomerular filtration rate greater than 30% of baseline during the follow-up.

Results: In overall, estimated central systolic BP (cSBP) was higher than brachial systolic BP (bSBP). The cSBP was significantly increased with age in non-CKD group, but such a correlation was not observed in CKD group. In CKD population, high cSBP group with greater than mean cSBP value (³150mmHg) had significantly increased probability of renal progression (P=0.016), while high bSBP (³140mmHg) group did not predict the outcome (P=0.370). In contrast, the predictor of renal progression was high bSBP not cSBP in non-CKD population. In Cox analysis adjusted for covariates, high cSBP remained a predictor of renal progression in CKD population (HR 5.408; 95% CI 1.008-29.030; P=0.049), whereas high bSBP was not a significant predictor in non-CKD population (HR 2.893; 95% CI 0.786-10.650; P=0.110).

Conclusions: The CBP had different correlation with age and clinical significance according to presence or absence of CKD, and the high cSBP was strong independent predictor of kidney disease progression in CKD patients.

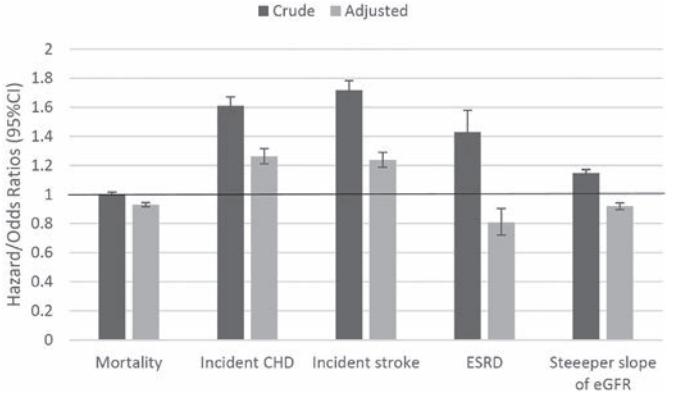
SA-PO619

Clinical Characteristics and Outcomes Associated with Resistant Hypertension in a Large Cohort of U.S. Veterans Csaba P. Kovesdy,[1,2] Miklos Zsolt Molnar,[2] Adriana Hung,[3] Jun Ling Lu,[2] John J. Sim,[4] Robert B. Canada,[2] Elvira Gosmanova,[2] Fridtjof Thomas,[2] Kamyar Kalantar-Zadeh.[5] *[1]VA Medical Center, Memphis, TN; [2]Univ of Tennessee Health Science Center, Memphis, TN; [3]VA Medical Center, Nashville, TN; [4]Kaiser Permanente, CA; [5]Univ of California, Irvine, CA.*

Background: The prevalence of true resistant hypertension (RH), the characteristics of patients with RH and its association with clinical outcomes is unclear.

Methods: From 2,398,778 patients with essential HTN, we identified 95,334 (4%) with RH, defined as: Failure to achieve BP<140/90 mmHg with >=3 antihypertensives (one being a thiazide diuretic) or success with >=4 drugs; excluding measurements when pain score was >5, when interfering medications were prescribed and excluding those with confounding conditions (CKD, secondary HTN, sleep apnea, urinary obstruction, adrenal, thyroid and parathyroid over-activity). We examined associations with mortality, incident CKD, ESRD, steeper slopes of eGFR, incident coronary heart disease (CHD) and stroke in Cox models and logistic regression models adjusted for demographic and socioeconomic factors, comorbidities, BP, and antihypertensives.

Results: The mean SBP/DBP in RH and non-RH patients were 148±22/81±14 vs. 137±19/78±12 mmHg. Compared to non-RH, patients with RH were older (64±11 vs. 62±13), more likely to be black (25 vs. 17%) and had a higher prevalence of DM and CVD. Crude mortality was similar and the incidence of the renal and cardiovascular end points was higher in RH. After full adjustment the risk of CHD and stroke associated with RH remained significant, but the risk of renal outcomes was reversed (Figure).



Conclusions: RH is relatively infrequent (4%) among patients with essential HTN, and is associated with older age and a higher comorbidity burden. Patients with RH have a higher risk of incident CHD and stroke.

SA-PO620

Association of Components of Body Mass Index with Treatment-Resistant Hypertension in Men and Women with Chronic Kidney Disease Toshiyuki Aoki,[1] Yasushi Ohashi,[1] Reibin Tai,[1] Kiyoto Koibuchi,[2] Atsushi Aikawa,[1] Ken Sakai.[1] *[1]Nephrology, Toho Univ School of Medicine, Ohta-ku, Tokyo, Japan; [2]Nephrology, Saiseikai Eastern Hospital, Yokohama, Kanagawa, Japan.*

Background: Treatment-resistant hypertension is a risk for cardiovascular disease and end-stage renal disease. However, the appropriate clinical management strategies remain unclear in patients with CKD. Our objective is to investigate the association of components of body mass index (BMI) with treatment-resistant hypertension in patients with CKD.

Methods: Body fluid composition was measured in 310 patients with CKD from 2005 to 2014, and BMI was separated into 3 components – (a) free water mass consisting of muscle, fat, and minerals, (b) intracellular water (ICW), and (c) extracellular water (ECW). Treatment-resistant hypertension was defined as an office BP of ³130/80 mmHg, despite receiving ³3 antihypertensives including diuretics, or ≥4 drugs usage. The main outcomes were adverse renal outcomes, as defined by a decline of 50% or more from baseline GFR or initiation of renal replacement therapy and cardiovascular events.

Results: The prevalence of treatment-resistant hypertension were 69 male patients (35.4%) and 19 females (16.5%). Patients with treatment-resistant hypertension were more likely to be diabetic, have a higher BMI, GFR, and proteinuria, and to be older especially in women. In the components of BMI, those in men and women tended to have higher ECW content and free water mass, respectively. Higher ECW contents in men and diabetes in relation to higher free water mass in women were independently caused treatment-resistant hypertension. Compared with patients with no treatment-resistant hypertension during a median 743-day follow-up, those with treatment-resistant hypertension had worse adverse renal outcomes (16.2 vs. 6.1 per 100 patient-years, P < 0.001) and cardiovascular events (5.0 vs. 1.6 per 100 patient-years, P < 0.001).

Conclusions: Treatment-resistant hypertension is associated with diabetes in relation to higher free water mass in women and higher ECW in men, which exhibits adverse renal outcomes and cardiovascular events. These findings emphasize the importance of adequate weight and volume status.

SA-PO621

Adherence Assessment in Resistant Hypertension: A Comparison Between Pill Count and Direct Method of High Performance Liquid Chromatography Analysis in Urine Patricia Cardoso Alarcon Hori, Silvana de Barros, Indira Fernandes Braga Azam, Andrea Pio de Abreu, Andrea Cassia Perreira Sforsin, Vanusa Barbosa Pinto, Decio Mion Junior, Giovanio Vieira da Silva. *Nephrology and Pharmacy, General Hospital of Sao Paulo Univ, Sao Paulo, Brazil.*

Background: Poor adherence to antihypertensive therapy is one of possible causes of resistant hypertension. Pill count is currently considered the standard for assessing drug adherence, but as an indirect method, it is inaccurate. The aim of this study was to compare the pill count with the direct method of toxicological urine screening in patients with resistant hypertension.

Methods: Patients with resistant hypertension criteria were included: office blood pressure (BP) above goal (systolic BP> 140mmHg and/or diastolic BP> 90mmHg) taking 3 or more antihypertensive agents of different classes, one of them diuretic, or office BP below goal taking 4 or more classes. Adherence was assessed by direct method of high performance liquid chromatography analysis for antihypertensive drugs or their metabolites in 4 different urine samples, with 30-day interval between them. Simultaneously, pill count was also performed. Patient was considered adherent by direct method if it was found every prescribed agents in at least 3 urine samples. Regarding pill count, patient was considered adherent if he consumed at least 90% of prescribed agents.

Results: 18 patients were selected: 78% women, age 57.5 ± 5.7 years, body mass index 29.3 ± 3.6 kg/m², office mean BP 151/88 ± 20/15 mmHg and 24 hours mean BP by ambulatory blood pressure monitoring 132/85 ± 21/12 mmHg. The average number of antihypertensive agents prescribed was 4.8 ± 0.8 classes per patient. 3 (17%) and 2 (11%) patients were considered adherent by direct method and pill count, respectively. However, the agreement between methods was poor (Kappa correlation coefficient -0.15).

Conclusions: Adherence to therapy in patients with resistant hypertension was very low in both methods. There was no agreement between pill count and direct method. The best method to assess adherence in resistant hypertension is yet to be determined.

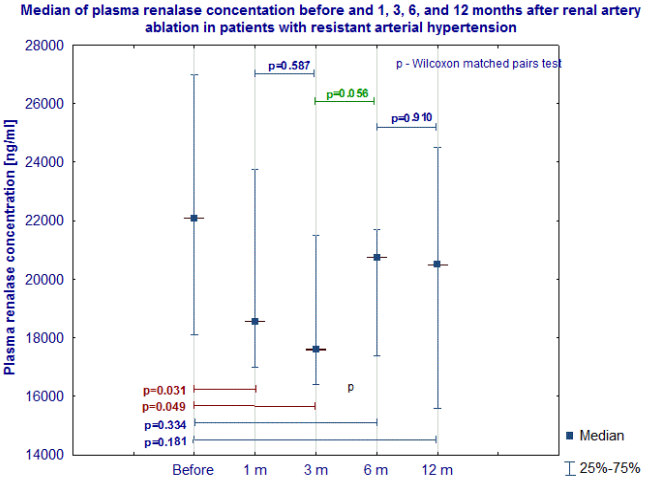
Plasma Renalase Concentration Before and After Radiofrequency Renal Denervation in Patients with Resistant Hypertension: Preliminary Results Marcin Adamczak,[1] Beata Czerwienska,[1] Maciej T. Wybraniec,[2] Michal Lelek,[2] Katarzyna T. Mizia-Stec,[2] Andrzej Wiecek.[1] *[1]Dept of Nephrology, Transplantation and Internal Medicine, Medical Univ of Silesia, Katowice, Poland; [2]1st Dept of Cardiology, Medical Univ of Silesia, Katowice, Poland.*

Background: Renalase is a catecholamine-metabolizing enzyme produced by proximal tubular cells in kidney which is supposed to be involved in blood pressure regulation. The aim of the study was to evaluate plasma renalase concentration after radiofrequency renal denervation (RDN) in patients with resistant arterial hypertension (HTN).

Methods: 19 patients (10 men; median age 56 (48; 57) years; BMI 30.9±4.4 kg/m² and eGFR 89±17.7 ml/min/1.73 m²) with resistant HTN were enrolled in the study. In all patient plasma renalase concentration was measured before and 1, 3, 6 and 12 months after RDN by ELISA method (Cloud-Clone Corp, Houston, USA).

Results: A significant decrease of both office systolic and diastolic blood pressure 6 months after RDN was found (192 ± 31 vs. 177 ± 28 mmHg, p=0.03; 113 ± 23 vs. 99 ± 21 mmHg, p=0.002, respectively). One and 3 months after RDN plasma renalase concentration decreased significantly, with a subsequent return to values comparable with baseline at 6- and 12-month follow-up (median of 22100 vs. 18550 vs. 17600 vs. 20750 vs. 20500 ng/ml respectively; Friedman analysis of variance p=0.054).



Conclusions: 1. RDN leads to the temporary decrease of plasma renalase concentration in patients with HTN. 2. Lower plasma renalase concentrations seems to be a counteract reaction to the antihypertensive effects of RDN.

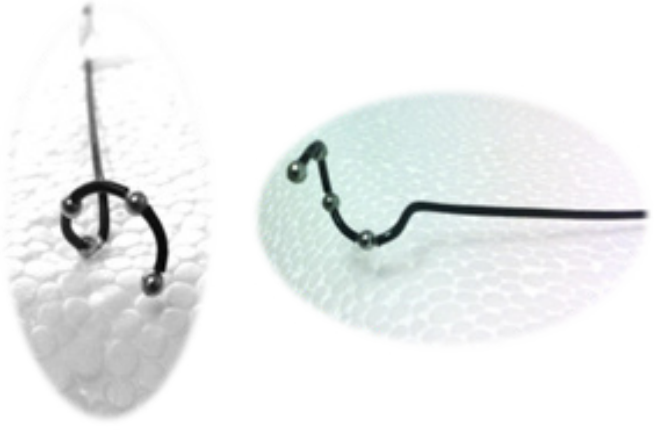
A Non-Vascular Treatment for Resistant Hypertension Richard R. Heuser,[1] Adam Gold.[2] *[1]Cardiology, St. Luke's Medical Center, Phoenix, AZ; [2]Verve Medical, Scottsdale, AZ.*

Background: Systematic arterial hypertension remains the most common and important risk factor for cardiovascular and renal disease. A safe and effective medical device effecting a significant and immediate fall in arterial BP addresses an unmet clinical need. Early clinical experience with the Verve non-vascular device causes an immediate BP drop in patients with resistant hypertension.

Methods: In humans, there is a greater abundance of efferent compared with afferent nerve fibers and the afferent nerves are much less abundant in general and are much less abundant as one goes away from the aorta. In contrast to the widespread distribution of EFFERENT Sympathetic nerve fibers in the kidney, the majority of the AFFERENT Renal Sensory nerves are located in the renal pelvic area. With our first generation device, we treated patients with resistant hypertension. Four patients with resistant hypertension were treated. They had immediate blood pressure drop (Systolic Mean 44mmHg, Diastolic Mean 13mmHg), which was maintained for 3 months. Because of the possibility of calyceal damage noted in follow-up in our animal model, we have redesigned the probe and shortened the duration of therapy.



Results: In over two dozen animals, it appears that we get a similar histopathologic results with our first generation probe without late pelvic or calyceal damage. In our first clinical application of this helical probe, there also is an immediate blood pressure drop.

Conclusions: Unlike other renal denervation treatments, the Verve natural orifice approach appears to treat the afferent nerves and results in an immediate blood pressure drop. More patients will need to undergo treatment to confirm these encouraging results. We will present our first series of resistant hypertensive patients treated with the helical device.

Microparticles Cause Preeclampsia and Kidney Injury by Activation of Inflammasome in the Placenta Shrey Kohli, Berend Heinrich Isermann. *Inst of Clinical Chemistry and Pathobiochemistry, Otto Von Guericke Univ, Magdeburg, Germany.*

Background: Preeclampsia is a hypertensive disorder of pregnancy associated with high morbidity and mortality. Hallmarks of preeclampsia are endothelial damage and functional (e.g. proteinuria) and morphological renal aberrations. The only known remedy against this is the delivery of the placenta. Cell derived microparticles (MP) of different origins are elevated in preeclampsia but their mechanistic relevance is unknown. Preeclampsia is also associated with a pro-inflammatory condition but there are meager mechanistic insights into this as well.

Methods: To address these questions MP (endothelial or platelet derived) were injected into C57/Bl6 pregnant mice and the pregnancy outcome (embryonic survival and growth, placenta morphology) was studied. Morphology of the kidney was studied using PAS staining and electron microscopy. Proteinuria was studied as a measure of renal dysfunction. To address mechanistic questions, inflammasome activation by MP in placenta and trophoblast cells was studied using western blotting and immunohistochemistry. Human trophoblast derived cells and placentas from pregnancies complicated with pre-eclampsia were also studied for activation of inflammasome. NLRP3 and Casp-1 KO mice were used to rescue the mice from disease conditions and establish causality of the mechanism.

Results: MP caused preeclampsia associated with fetal loss and embryonic growth restriction in mice. This was associated with renal damage indicated by proteinuria, glomerular enlargement, thickness of glomerular basement membrane, and podocyte effacement in the kidney. Human and mouse placenta analysis indicated inflammasome activation seen by elevated expression of NLRP3, cleaved casp-1 and IL-1β. The pregnancy outcome and renal function was rescued in NLRP3 and Casp-1 KO mice.

Conclusions: Our results establish that MP are causative of preeclampsia, fetal death, embryonic growth restriction, and renal injury. These pathogenic effects of MP are mechanistically linked with inflammasome activation in the placenta.

Funding: Government Support - Non-U.S.

SA-PO625

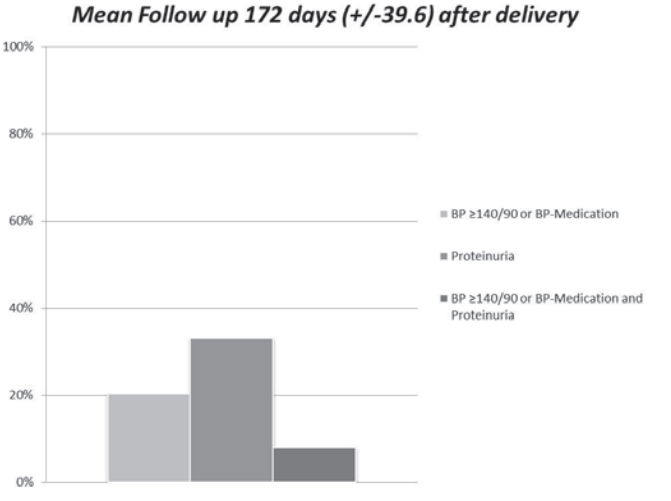
Short Term Sequela of Preeclampsia Michael Yannik Girsberger,[1] Irene Mathilde Hoesli,[2] Michael Dickenmann.[1] *[1]Clinic for Transplantation Immunology and Nephrology, Univ Hospital Basel, Basel, Baselstadt, Switzerland; [2]Dept of Gynaecology and Obstetrics, Univ Hospital Basel, Basel, Baselstadt, Switzerland.*

Background: Data on sequela in the first year after preeclampsia are scarce. We investigated kidney function, blood pressure, proteinuria and urine sediment in women with preeclampsia six month after delivery.

Methods: From January 2007 to July 2014 all women with preeclampsia and 6-moths follow up at the university hospital Basel were prospectively analysed. Preeclampsia was defined as new onset of hypertension (³140/90 mmHg) or worsening hypertension and either proteinuria or signs of end-organ dysfunction. Hypertension was defined as a blood pressure (BP) ³140/90 or the use of antihypertensive medication. Proteinuria was defined as a protein-to-creatinine ratio in a spot urine > 11 mg/mmol. Urine sediment was evaluated by a nephrologist.

Results: 202 women were included. Baseline characteristics are shown in Table 1 and follow up data are shown in Figure 1. The mean time of the follow up visit was 172 days (+/- 39.6) after delivery. The mean blood pressure at follow up was 124/76 mmHg (+/- 14/11, range 116-182/63-110) and the mean serum-creatinine was 61.8 umol/l (+/- 11.6). Mean estimated glomerular filtration rate (CKD-EPI) was 110.7 mml/min/1.73m2 (range 59.7-142.4 mml/min/1.73m2). No active urine sediment (e.g. signs of glomerulonephritis) was observed.

Onset Gestational Week	36+1.75 (+/- 3.9)
Gravida	1.75 (+/- 1.16)
Para	1.41 (+/- 0.78)
Multiple pregnancy (twins, triplets) (27/202)	13.4%
Diabetes before pregnancy (4/201)	1.99%
Gestational diabetes (19/202)	9.4%
Previous hypertension (16/202)	7.9%
HELLP (40/198)	20.2%
Eclampsia (4/198)	2.0%
Severe Preeclampsia (132/197)	67%
Acute Kidney Injury (17/197)	8.6%
Chronic kidney disease (4/201)	1.99%



Conclusions: The findings stress the importance of a close follow up to identify those women who need further care.

SA-PO626

Preeclampsia: Long-Term Effects on Pediatric Neurologic Disability
Alberto Tejedor Jorge, Clara Nicolas, Patrocinio Rodríguez Benítez, Olga Arroyo, Maria Silva, Laura Matesanz, Carmela Mercurio, Manuel Sánchez Luna. *Hospital General Univ Gregorio Marañón.*

Background: Preeclampsia affects up to 10% of pregnancies worldwide and is one of the main causes of fetal morbidity and mortality. Although it has been linked to developmental delay, its long-term effects on neurologic development in children have yet to be sufficiently quantified. Our aim is to evaluate whether the preeclampsia's severity and the therapeutic options used to manage it correlate to the degree of developmental delay in these infants.

Methods: This is an observational and descriptive study performed on a population of 96 women who were diagnosed with preeclampsia at Hospital General Universitario Gregorio Marañón between 2007 and 2014, and their 111 children. To evaluate the mother, we gathered data pertaining to her medical history, renal function markers, and medical management of the preeclampsia. To assess the children, we collected fetal growth measurements, acute fetal distress markers and main diagnoses at birth. We used the Pediatric Disability Inventory in its computerized adaptive test version (PEDI-CAT) to study neurologic development, and the TNO-AZL Preschool children Quality of Life (TAPQOL) to estimate health-related quality of life.

Results: Early-onset and more severe preeclampsias were associated with higher preterm birth and perinatal mortality rates. Preeclampsias with a greater impact on maternal organ function showed a clear correlation to higher periventricular-intraventricular hemorrhage rates in the newborn. In terms of neurologic development, PEDI-CAT percentiles were consistently lower in the Social/Cognitive domain than in other areas. Lower Social/Cognitive percentiles were associated to both lower maternal IgG levels and presence of necrotizing enterocolitis during the neonatal period.

Conclusions: Early-onset preeclampsias have a greater negative impact on both maternal renal function and fetal morbimortality. A connection between preeclampsia and poor social/cognitive outcomes exists that warrants further research, as does the possible link between between preeclampsia, immunity, and autistic features.

SA-PO627

Do Hypertension Providers Inquire About Hypertension in Pregnancy?
Andrea G. Kattah, Vesna D. Garovic. *Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: Hypertensive pregnancy disorders are increasingly recognized as a risk factor for future hypertension and cardiovascular disease. However, knowledge of this risk may be inadequate among internal medicine providers.

Methods: We reviewed all new consults in a 2-month period in a hypertension subspecialty clinic. We determined the frequency with which providers documented a reproductive history, a history of hypertension in pregnancy and known cardiovascular risk factors. We also studied whether there were differences according to gender and level of training of the provider (consultants vs. residents/fellows) using the chi-square test.

Results: There were 102 consults for hypertension in the study period. The majority of consults were by consultants, 55/102 (53.9%), and 23/102 (22.6%) were by female providers. A reproductive history, including number of pregnancies, infertility and/or intent of pregnancy, were documented in 37/102 (36.3%) of notes. Chart review revealed that 85/102 (83.3%) of women had live births, but it was documented in only 31 (36.5%) of notes. Female providers were more likely to document pregnancies (57.9% vs. 30.3%, p=0.03). Of the women who had live births, 15/85 (17.7%) of providers inquired about hypertension in pregnancy and 12/85 (14.1%) inquired about preeclampsia. Other hypertension and cardiovascular risk factor documentation by level of training are shown below.

Risk Factor, n(%)	Resident/Fellow (n=47)	Consultant (n=55)	P-value
Dietary issues	29 (62%)	32 (58%)	0.72
Alcohol Use	37 (79%)	36 (55%)	0.94
Illicit Drug Use	16 (34%)	2 (4%)	**<0.0001**
Smoking	41 (87%)	47 (85%)	0.79
Exercise	27 (58%)	29 (53%)	0.71
Medication-related effects	32 (68%)	31(56%)	0.23
Family History of Hypertension	43 (92%)	38 (69%)	**0.005**
Renal Disease	44 (94%)	41 (75%)	**0.01**
Dyslipidemia	17 (36%)	25 (46%)	0.34
Diabetes	22 (47%)	25 (46%)	0.89
Obstructive Sleep Apnea	22 (47%)	21 (38%)	0.38
Hypertension in Pregnancy*	5/36 (14%)	10/49 (20%)	0.44
Preeclampsia*	5/36 (14%)	7/49 (14%)	0.96

*Only in women with live births

Conclusions: Hypertension specialists rarely document a reproductive history or a history of hypertension in pregnancy, irrespective of level of training. Female providers were more likely to document pregnancies.

SA-PO628

Accuracy of a Spot Urine Protein-to-Creatinine Ratio in Preeclampsia
Roshni Upputalla,[1] Juliet Mushi,[2] Mary King,[2] Belinda Bun Jim,[1] Anjali Acharya.[1] *[1]Nephrology, Jacobi Medical Center/Albert Einstein College of Medicine, Bronx, NY; [2]Obstetrics, Jacobi Medical Center/Albert Einstein College of Medicine, Bronx, NY.*

Background: Correlation between a 24 hour urinary protein excretion with a spot urine protein-creatinine (SP/Cr) ratio in patients with preeclampsia is unclear. Moreover, urinary creatinine excretion is greater in populations such as Africans and non-white Hispanics. We studied the correlation of the SP/Cr ratio with a 24 hour urine protein measurement in this minority population.

Methods: ICD-9 codes of 642.4, 642.5, 642.6, 642.7 representing mild pre-eclampsia to eclampsia were used for data collection. Only 110 women with both 24 urinary protein collection and (SP/Cr) were included in the analysis. Correlation between SP/Cr and 24-hour protein excretion was assessed by Spearman correlation coefficient. The sensitivity and specificity of the SP/Cr ratio at various cut-offs for the prediction of significant proteinuria were estimated with a 95% confidence interval, using the 24-hour urine collection as gold standard. Receiver operating characteristic (ROC) curve analysis was used to determine the best discriminator values of the (SP/Cr) to predict proteinuria above 300 mg/ 24 hr. A P value of 0.05 or< was significant.

Results: The median SP/Cr ratio was 0.30 (interquartile range (IQR) 0.3) while the median 24 hour urine protein was 316.5 mg (IQR 286.8). The overall Spearman correlation was 0.48 (P= .0001). and 0.63 (P = 0.05), 0.59 (P= .01), and 0.45 (P= .0001) for the 1st, 2nd, and 3rd trimesters respectively. At the cut-off value of 0.15 for SP/Cr, the sensitivity and specificity were 91.8% and 75.5% respectively. The cut-off SP/Cr ratio 0.25 was identified as the best threshold to detect a 24 hour protein excretion of 300 mg with a sensitivity and specificity of 75% and 59% respectively. The area under the curve (AUC) by the ROC curve analysis was found to be 0.69.

Conclusions: Even in a minority, inner city population we found significant correlation between the 24 hour protein excretion and the SP/Cr ratio, especially in the 2nd and 3rd trimesters of preeclamptics. Our findings are in line with the literature despite a minority patient population.

SA-PO629

Thiazide Diuretics for Hypertension in Kidney Transplant Recipients Using Tacrolimus
Arthur David Moes, Dennis Alexander Hesselink, Anton H. Van den Meiracker, Robert Zietse, Ewout J. Hoorn. *Internal Medicine, Erasmus Medical Center, Rotterdam, Netherlands.*

Background: Hypertension after kidney transplantation is common and associated with poorer graft and recipient outcomes. Recently, we and others showed that tacrolimus activates the thiazide-sensitive sodium chloride cotransporter to cause hypertension. This suggests that thiazide diuretics may be especially effective drugs in this context, but prospective data are lacking.

Methods: We conducted a non-inferiority crossover trial to compare chlorthalidone (CT, 12.5-25 mg) with amlodipine (AML, 5-10 mg). Patients were invited for ambulatory blood pressure measurement (ABPM) if office BP >140/90 mmHg. Other criteria included eGFR >30 ml/min, proteinuria < 1 g, and no use of glucocorticoids. The treatment periods were randomized, lasted 8 weeks (allowing dose titration after 2 weeks), and were separated by a 2-week wash-out. Background anti-hypertensive drugs were allowed except for other diuretics.

Results: 71 patients underwent initial ABPM of whom 45 patients (63%) with average wake SBP >140 mmHg were enrolled (median 2.6 years after transplantation). 38 patients completed the study (5 patients stopped during CT mainly due to electrolyte disorders vs. 2 during AML, p=0.4). CT and AML both markedly reduced ABPM after 8 weeks (151/85 ± 11/9 to 141/81 ± 12/9 mmHg vs. 151/84 ± 13/9 to 138/79 ± 14/7 mmHg). There was no statistical difference in blood pressure response between the two drugs (p=0.3 by 2-way ANOVA). Dose titration rates were similar (42% for CT vs. 37% for AML, p=0.8). CT decreased eGFR (53 ± 17 to 46 ± 15 ml/min), whereas amlodipine increased it (50 ± 16 to 53 ± 17 ml/min, P<0.001). The first post-CT eGFR returned to baseline (51 ± 17 ml/min). Treatment with CT resulted in less proteinuria (median 14 vs. 19 mg/mmol, p=0.03) and less edema (8 vs. 31%, p=0.02). Regression analysis showed that a higher aldosterone to renin ratio, lower baseline serum potassium, and higher baseline serum bicarbonate predicted a better anti-hypertensive response to CT.

Conclusions: Thiazide diuretics effectively lower blood pressure in kidney transplant recipients using tacrolimus. Thiazides were especially effective in patients with more aldosterone effect.

SA-PO630

The Detrimental Effects of Beta-Blockers on Central Hemodynamic Parameters: A Propensity Score Analysis Remi Goupil,[1] Dominique Dupuis,[1] Stephan Troyanov,[1] Francois Madore,[1] Mohsen Agharazii.[2] *[1]Hopital du Sacre-Coeur de Montreal, Montreal, QC, Canada; [2]CHU de Québec, Hotel-Dieu de Quebec, Quebec City, QC, Canada.*

Background: Central blood pressure (BP) and aortic stiffness are better predictors of the cardiovascular burden than peripheral BP. Beta-blockers (BB) are known to reduce central BP to a lesser extent than peripheral BP, a hypothesized consequence of heart rate (HR) reduction. Therefore, the association between BB use, HR and central hemodynamics indices were studied in the treated hypertensive participants of the CARTaGENE study.

Methods: Using propensity score analyses, BB users (n=605) were matched to controls having similar clinical characteristics with (Model 1) and without (Model 2) adjustment for HR. This resulted in 457 and 510 pairs with adequate balance, except for a different HR in Model 2 (62.5 ± 10.5 vs. 70.4 ± 11.5 bpm, p<0.001).

Results: In Model 1, the difference between peripheral and central systolic BP (DSBP) was 8.3 mmHg (IQR 5.8, 11.6) with BB compared to 9.7 mmHg (7.1, 13.5) without (p<0.001), indicating that for any given peripheral BP, BB use resulted in higher central systolic BP. Pulse pressure amplification, augmentation index and augmented pressure were also less favorable with the use of BB. The different HR in Model 2 further increased the detrimental DSBP observed with BB to 7.9 (5.6, 11.0) vs. 10.6 (8.1, 14.3) without (p<0.001) and was associated with a higher central pulse pressure (46.5 ± 13.0 vs. 43.3 ± 11.3, p<0.001).

	Model 1			Model 2		
Parameters	**No beta-blocker**	**Beta-blocker**	**p-value**	**No beta-blocker**	**Beta-blocker**	**p-value**
Central SBP	120 ± 15	121 ± 16	0.67	118 ± 15	121 ± 17	0.006
ΔSBP	9.7 (7.1-13.5)	8.3 (5.8-11.6)	<0.001	10.6 (8.1-14.3)	7.9 (5.6-11.0)	<0.001
Central PP	45 ± 11	46 ± 13	0.45	43 ± 11	47 ± 13	<0.001
PP amplification	1.3 (1.2-1.3)	1.2 (1.1-1.3)	<0.001	1.3 (1.2-1.4)	1.2 (1.1-1.3)	<0.001
Augmentation Index	29 ± 11	31 ± 11	0.005	27 ± 11	31 ± 10	<0.001
Augmented pressure	13 (9-17)	13 (9-19)	<0.001	11 (7-16)	14 (9-20)	<0.001

Conclusions: This study shows that the unfavorable central hemodynamic profile of BB has both a HR-dependent and a HR-independent component.

Funding: Government Support - Non-U.S.

SA-PO631

Risk of Development of Dementia During Treatment of Hypertension with Different Calcium Channel Blockers Leonid Feldman,[1,2] Shai Efrati,[1,2] Ilia Beberashvili,[1,2] Shlomo Vinker,[2,3] Michal Shani.[2,3] *[1]Assaf Herofeh Medical Center, Israel; [2]Tel Aviv Univ, Israel; [3]Clalit Health Services, Israel.*

Background: Arterial hypertension (HTN) is proved to be a risk factor for development of dementia. Medical treatment of HTN may decrease the risk of dementia. Experimental study pointed to the possibility of difference between different calcium channel blockers (CCB) in their neuro-protective effect. The aim of our study was to evaluate the risk of dementia during treatment of HTN with one of three different CCBs.

Methods: This is a retrospective cohort study based on electronic database of Clalit Health Services, Central District. Study period was 11 years (2002-2012). Inclusion criteria: age 40-75**,** diagnosis of HTN without diagnosis of "Dementia" at the starting point**,** minimal duration of treatment > 30 months with single specific CCB. New diagnosis of dementia was established according to appearance of its diagnostic code in the chronic diseases register or prescription of medication for its treatment – whatever occurred first.

Results: 15,664 patients were included in the study: 3,884 were treated with amlodipine, 2,062 - with nifedipine, 609 – with lercanidipine and 9,109 never received CCBs. The mean age was 60.7 years, 52.9% were females and the mean baseline creatinine was 1.0 mg/dL. 13.4% of patients died during the study period. Dementia developed in 765 (4.9%) patients. Adjusted HR of dementia in patients treated with amlodipine, nifedipine and lercanidipine was 0.60 (p<0.001), 0.89 (NS) and 0.90 (NS).

Conclusions: Treatment of arterial hypertension with amlodipine may be associated with decreased risk of development of dementia in comparison to treatment without CCBs.

SA-PO632

The Association Between Antihypertensive Agents and Postural Blood Pressure Response Using Beat-to-Beat Data: Results from the Irish Longitudinal Study on Ageing Mark N. Canney,[1,2] Matthew Dl O'Connell,[1] Catriona M. Murphy,[1] Mark Alan Little,[2] Conall M. O'Seaghdha,[3] Rose Anne M. Kenny.[1] *[1]The Irish Longitudinal Study on Ageing, Trinity College Dublin; [2]Trinity Health Kidney Centre, Tallaght Hospital Dublin; [3]Dept of Nephrology, Beaumont Hospital Dublin.*

Background: Beat-to-beat blood pressure (BP) measurements provide a dynamic picture of BP behavior during postural change. Impaired BP stabilization after standing is associated with substantial morbidity and mortality. We aimed to define the relationship between class of antihypertensive drug and BP stabilization during an active stand.

Methods: Cross-sectional analysis from The Irish Longitudinal Study on Ageing, a nationally representative cohort study of 8175 adults ≥50 years. Beat-to-beat BP was recorded in participants undergoing an active stand test. We defined grade 1 hypertension according to European Society of Cardiology criteria (systolic BP [SBP] 140-159mmHg ± diastolic BP [DBP] 90-99mmHg). Orthostatic hypotension (OH) was defined as a drop in SBP ³20mmHg ± DBP ³10mmHg. Outcomes were sustained OH (OH throughout the test) and impaired BP stabilization (OH at each 10-second (s) interval during the test [total 110s]). Outcomes were assessed using logistic regression models adjusted for potential confounding variables.

Results: A total of 536 participants with self-report hypertension were receiving monotherapy with a renin-angiotensin-aldosterone-system inhibitor (317), betablocker (89), calcium channel blocker (89) or diuretic (41). Betablockers were associated with increased odds of sustained OH vs untreated grade 1 hypertension (OR 3.4, 95% CI 1.9-6.0). This was evident from 20s (OR 2.3, 95% 1.4-3.7) and remained statistically significant at 110s (OR 2.8, 95% CI 1.6-4.9). Multivariable adjustment did not attenuate the association. No significant association was detected among the other drug classes.

Conclusions: In older hypertensive adults betablocker monotherapy was associated with a >3-fold increased odds of OH compared to subjects with untreated grade 1 hypertension. The effect was evident from 20s after standing and was sustained. This should inform decision-making regarding appropriate choice of antihypertensive agent in older adults.

SA-PO633

Effect of Vitamin D on 24 Hour Ambulatory Blood Pressure: A Randomized, Double-Blind, Placebo-Controlled Clinical Trial Ciaran Joseph McMullan,[1] Lea Borgi,[1] Gary C. Curhan,[1] Naomi D.L. Fisher,[2] John P. Forman.[1] *[1]Renal Div, Brigham and Women's Hospital, Boston, MA; [2]Endocrine Div, Brigham and Women's Hospital, Boston, MA.*

Background: Lower levels of 25-hydroxyvitamin D (25[OH]D) have been associated with an increased risk of hypertension in prospective cohort studies, suggesting that vitamin D might be a modifiable target for the prevention of hypertension. Vitamin D supplementation has also been shown to decrease clinic blood pressure (BP) in some studies.

Methods: We performed a randomized, double-blind, placebo-controlled trial of nonhypertensive participants with body mass index ³25, and 25[OH]D£20ng/mL; subjects were randomized to receive either ergocalciferol 50,000 units or placebo, once a week for 8 weeks. Mean 24 hour BP was measured using 24 hour ABPM at baseline and 8 weeks after starting the study.

Results: By the end of the trial, 29 and 27 participants randomized to receive vitamin D and placebo, respectively, had adequate 24 hour ABPM at both baseline and at 8 weeks. Mean vitamin D levels increased from 14.9 to 30.3 ng/mL in the intervention group and from 14.4 to 17.4 ng/mL in the placebo group. Vitamin D supplementation did not lower BP at 8 weeks; 24 hour systolic BP changed from 120±10 to 122±8 mmHg in the intervention group (p-value=0.29), and from 124±8 to 125±10mmHg in the placebo group (p-value=0.38), with a treatment effect p-value of 0.92.

Conclusions: In this randomized, double-blind, placebo-controlled trial of overweight/obese normotensive individuals, there was no improvement in mean 24 hour blood pressure after repletion of vitamin D. These findings are not consistent with vitamin D being a modifiable target for prevention of hypertension.

Funding: NIDDK Support

SA-PO634

Effect of Uric Acid Lowering on Intrinsic Renal and Systemic Renin Angiotensin System Activity: A Randomized, Double-Blind, Placebo-Controlled Clinical Trial Ciaran Joseph McMullan,[1] Lea Borgi,[1] Gary C. Curhan,[1] Naomi D.L. Fisher,[2] John P. Forman.[1] *[1]Renal Div, Brigham and Women's Hosptial, Boston, MA; [2]Endocrine Div, Brigham and Women's Hosptial, Boston, MA.*

Background: Higher levels of uric acid have been associated with an increased activity of the renin angiotensin system (RAS) in animal models of hypertension and kidney disease. Similarly, individuals with high levels of circulating uric acid have increased renal specific RAS activity measured using renal plasma flow (RPF). However, the effect of lowering serum uric acid on RAS activity in humans is unknown.

Methods: We performed a randomized, double-blind, placebo-controlled trial analyzing the Modifiable Effectors of Renin System Activation Treatment Evaluation (MODERATE). Normotensive individuals with body mass index (BMI) ³25 and uric acid level ≥ 5.0 mg/

dL were randomized to receive either allopurinol 300/600mg, probenecid 500/1000mg, or placebo daily for 8 weeks. Renal specific and systemic RAS activity was measured at baseline and 8 weeks after starting the study.

Results: By the end of the trial, 36, 30 and 41 participants randomized to receive probenecid, allopurinol and placebo, had RAS measurements at baseline and 8 weeks, respectively. Uric acid levels changed from a mean of 5.9, 5.6 and 5.6 mg/dL to 3.9, 3.9 and 5.7 mg/dL in the probenecid, allopurinol and placebo groups, respectively. Renal specific RAS, measured by change in RPF to captopril in high sodium balance, was not improved after uric acid lowering: RPF response to captopril changed from 42.6±38.8 at baseline to 45.3±43.9 mL/min at 8 weeks with probenecid (p-value=0.26), from 40.5±34.9 to 35.1±29.8 mL/min with allopurinol (p-value=0.23), and 37.3±46.9 to 35.9±26.2 mL/min with placebo (p-value=0.70). Similarly, changes in plasma renin activity and plasma angiotensin II levels did not significant change with treatment.

Conclusions: In contrast to animal experiments and observational studies, this randomized, double-blind, placebo-controlled trial found that lowering uric acid had no effect on renal specific or systemic RAS activity.

Funding: NIDDK Support

SA-PO635

Effect of Vitamin D Supplementation on Intrinsic Renal and Systemic Renin Angiotensin System Activity: A Randomized, Double-Blind, Placebo-Controlled Clinical Trial Ciaran Joseph McMullan,[1] Lea Borgi,[1] Gary C. Curhan,[1] Naomi D.L. Fisher,[2] John P. Forman.[1] *[1]Renal Div, Brigham and Women's Hospital, Boston, MA; [2]Endocrine Div, Brigham and Women's Hospital, Boston, MA.*

Background: Disruption of vitamin D signalling in rodents causes activation of the renin angiotensin system (RAS). In humans lower circulating 25[OH]D is associated with increased renal specific RAS activity (measured using renal plasma flow [RPF]); in addition, a small, open label, uncontrolled study found that vitamin D supplementation decreased renal specific RAS activity. However, the effect of vitamin D supplementation on the RAS in humans with vitamin D deficiency has never been examined in a rigorous manner.

Methods: We performed a randomized, double-blind, placebo-controlled trial of normotensive individuals with body mass index ³25 and vitamin D deficiency (25[OH]D £20ng/mL); subjects were assigned to receive either ergocalciferol 50,000 units or placebo, once a week for 8 weeks. Renal specific (assessed by RPF response to captopril in high sodium balance) and systemic RAS activity (plasma renin activity [PRA] and angiotensin II levels [AngII]) were measured at baseline and 8 weeks after starting the study.

Results: By the end of the trial, 43 and 41 participants allocated to receive vitamin D and placebo, completed the study with measurement of renal and systemic RAS activity. Mean vitamin D levels increased from 14.9 to 30.3 ng/mL in the ergocalciferol group and from 14.4 to 17.4 ng/mL in the placebo group. Renal specific RAS did not significantly change after vitamin D repletion: the RPF response to captopril was 33.9±56.1 mL/min at baseline and 35.7±47.7 mL/min at 8 weeks in the ergocalciferol group (p-value=0.26); and was 37.3±46.9 mL/min at baseline and 35.9±26.2 mL/min at 8 weeks in the placebo group (p-value=0.70), with a treatment effect p-value of 0.27. Similarly, vitamin D supplementation had no effect on PRA or AngII levels.

Conclusions: In contrast to animal experiments, observational studies, and open-label uncontrolled interventions, this randomized, double-blind, placebo-controlled trial found no effect of vitamin D supplementation on RAS activity in vitamin D deficient individuals.

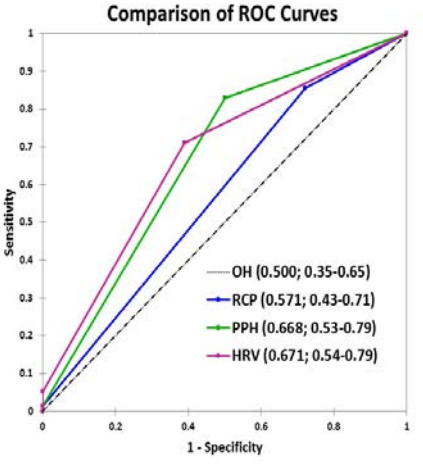
Comparison of Office Orthostatic Blood Pressure and 24-Hour Ambulatory Blood Pressure Measurements in the Prediction of Autonomic Dysfunction Girish Singhania, Rajesh Mohandas, Kawther Farouk Alquadan, Abhilash Koratala, A. Ahsan Ejaz. *Nephrology, Univ of Florida, Gainesville, FL.*

Background: Evaluation of orthostatic hypotension (OH) may involve office orthostatic blood pressure (BP_{OH}) measurements, 24-hour ambulatory BP (ABP) and autonomic reflex screen (ARS). We investigated the predictive performance of BP_{OH} and the variables of ABP, i.e., reversal of circadian pattern (RCP), postprandial hypotension (PPH) and noncompensatory heart rate variability (HRV), to predict autonomic dysfunction as measured by the AUC of the ROC curves.

Methods: Data from previously published study were analyzed. Ninety-four patients were included for analysis. BP_{OH}, RCP, PPH, HRV were investigated for the presence or absence of autonomic dysfunction. Autonomic dysfunction was defined as a CASS (composite autonomic scoring system) score of ³1. Comparisons of the AUCs of the ROC curves of the candidate parameters were performed.

Results: ROCs of candidate parameters are shown in Fig. 1.



The diagnostic performance to predict autonomic dysfunction for HRV was superior to PPH. Both were superior to RCP. RCP was a better predictor of autonomic dysfunction than office BP_{OH}.

Conclusions: Our data suggests that ABP is a reliable, simple and inexpensive predictor of autonomic dysfunction in routine clinical practice.

SA-PO637

Factors Predicting Long Term Renal Prognosis in Malignant Nephrosclerosis Peng Xia, Jiaxin Lang, Yubing Wen, Mingxi Li, Hang Li, Xuemei Li, Xuewang Li, Limeng Chen. *Nephrology, Peking Union Medical College Hospital, Beijing, China.*

Background: This study investigated correlations between kidney pathology and Renin-Angiotensin System(RAS) activation, RAS inhibitor response and prognosis of malignant hypertensive nephrosclerosis(MHN) patients.

Methods: This retrospective cohort study included 82 essential MHN patients from Jan.2003 to Oct.2014 with renal biopsy followed up to May2015. Pathology were evaluated by two pathologists independently. Localized renin expression and peritubular capillaries(PTC) area were evaluated by IHC staining of renin and CD34. Renal replacement therapy, kidney transplant and death were defined as the primary end point.

Results: 87.8% of patients were male with mean age of 34.7±8.8ys. Clinical data showed highest blood pressure(BP)226.6±25.7/152.2±22.0mmHg, serum creatinine(Scr)5.31±3.79mg/dl, proteinuria2.06±1.83g/d(n=68) and mean eGFR21.3±15.1ml/min.1.73m^2. Glomerular Sclerosis Index, tubular atrophy and interstitial fibrosis were 1.51±0.51, 63.7±18.3% and64.0±18.3%. MHN patients has a lower PTC proportion (2.27±0.74%(n=35),3.75±0.79%(n=17), P<0.001) and a higher renin-positive juxtaglomerular apparatus ratio(35.1±17.8%,(n=35),21.2±15.0%(n=17),P=0.008) comparing with glomerular minimal lesion patients. Tubularinterstitial lesions correlated with Scr(r=0.547,P<0.001), eGFR(r=-0.574,P<0.001) and proteinuria(r=0.447,P<0.001). PTC area correlated with Scr(r=-0.675,P<0.001,n=35) and eGFR(r=0.648,P<0.001,n=35). 90.4%patients received RAS inhibitors which was associated with improvements in BP (136.7±9.9/86.8±8.2mmHg,P<0.001),Scr(4.06±2.74mg/dL,P<0.001) and proteinuria (2.26±1.89vs.1.26±0.86g/d,n=45,P<0.001). After 54.1±36.6 months follow up, 1-year and 5-year cumulative renal survival rates were 93%and 65%. RAS inhibitors, BP control and eGFR over 30ml/min·1.73m^2 correlated with longer renal survival by Kaplan-Meier analysis. Cox regression identified RAS inhibitors(RR=0.24,95%CI(0.09,0.62),P=0.004) and CKD stages(RR=4.72,95%CI (1.71,13.03),P=0.003) as independent factors predicting renal outcome.

Conclusions: MHN patients had localized activation of renin and less PTC area. RAS inhibitors benefited patients in BP control, eGFR improvements and long-term renal outcome.

SA-PO638

Office Blood Pressure Monitoring: A Novel Tool for Evaluating Blood Pressure in Children (and Adults) Gianluigi Ardissino,[1] Paolo Marchetto,[1] Francesca Tel,[1] Sara Testa,[1] Ilaria Possenti,[1] Michela Perrone,[1] Luciano Sangaletti,[1] Amelia Ballarino,[1] Stefani Rotondo,[1] Silvia Ghiglia,[1] Franco De luca,[2] Patrizia Salice.[1] *[1]Pediatric Nephrology and Cardiology, Fondazione IRCCS Ca' Granda Policlinico, Milan, Italy; [2]Pediatric Cardiology, Policlinico Univ, Messina, Italy.*

Background: Blood pressure measurement (BPM) is a common procedure in clinical practice but in children (C) obtaining reliable values can be challenging. Casual office BPM, the standard of care, is all but accurate and ABPM may be difficult to perform or even misleading.

Methods: Office Blood Pressure Monitoring (OBPM) was developed at our Center in 2010 for evaluating BP in C with serial and automated BPM (³10 in at least 30 min)

with a standard oscillometric device. BP values are uploaded in a software to calculate the coefficient of variation (CV) after having excluded outlier values (<5th and >95th centile of the recorded values).

Results: Since 2010 a total of 402 OBPMs have been performed but only the 282 in 110 C (59% Males) aged <18 yrs old (IQR 4.8-12.1) with a CV <10% for both syst and diast BP were considered for the analysis. The table compares BP as measured by OBPM with a single BPM (1st and 3rd) and with the mean of the 3 initial measurements (*: p<0.01 vs. others BPMs with student's t test for paired data and c^2).

	Systolic	Diastolic	Patient BP class No. (%)		
	Mean Z score ± sd		Normotensive	Borderline	Hypertensive
1st BP	1.92±1.40	1.62±1.27	70 (24.8)	26 (9.2)	186 (66.0)
2nd BP	1.75±1.40	1.51±1.20	72 (25.5)	36 (12.8)	174 (61.7)
1st, 2nd and 3rd BP (mean)	1.81±1.31	1.55±1.15	75 (26.6)	30 (10.6)	177 (62.8)
OBPM	**1.69±1.30***	**1.48±1.12***	**88 (31.2)**	**37 (13.1)**	**157 (55.7)***

Conclusions: OBPM provides significantly lower BP values, leading to a diagnosis of poor BP control in a smaller number of patients (-10%). Given the lack of a gold standard, the present analysis doesn't demonstrate that OBPM is more reliable then standard procedures however serial BPM have the potential of reducing measurement biases and white coat effect. We recommend the routine use of OBPM for measuring BP in C at risk of hypertension rather then relying upon few measurements.

SA-PO639

A Simple Prediction Score for Incident Hypertension in a Korean Population

Jong-Hwan Jung, Sung Kwang Park, Won Kim, Kyung Pyo Kang, Sik Lee. *Dept of Internal Medicine, Chonbuk National Univ Medical School, Jeonju, Republic of Korea.*

Background: We aimed to develop a simple prediction model for incident hypertension that could help to prevent or delay the onset of hypertension for some patients who did not experience hypertension yet.

Methods: The Korean Genome and Epidemiology Study was used for the model development (n=3533) and internal validation (n=1698). Hypertension was defined when either the systolic and diastolic blood pressures (SBP, DBP) were 140 and 90 mmHg or higher or being treated with antihypertensive medications.

Results: SBP, age and DBP, parental hypertension, obesity, high density lipoprotein (HDL), current smoking and fasting glucose were significantly associated with incident hypertension. Integer scores were assigned to variables based on the magnitude of associations SBP (-2 to 5), age and DBP (-2 to 5), parental hypertension (2), obesity (2), low HDL (2), current smoking (2) and high fasting glucose (2).

	b (se)	Adjusted OR (95% CI)	Assigned score
Systolic blood pressure			
SBP <110	-0.6 (0.2)	0.55 (0.36-0.85)	-2
110 ≤ SBP < 115		1	0
115 ≤ SBP < 120	0.6 (0.2)	1.87 (1.25-2.81)	2
120 ≤ SBP < 125	0.9 (0.2)	2.43 (1.61-3.67)	3
125 ≤ SBP < 130	1.1 (0.2)	2.87 (1.85-4.44)	4
130 ≤ SBP	1.3 (0.2)	3.64 (2.32-5.71)	5
Age and Diastolic blood pressure			
age 40-50 and DBP ≤ 70	-0.8 (0.3)	0.45 (0.27-0.75)	-2
age 50-60 and DBP 70-80		1	0
age 60-70 and (DBP ≤ 70 or DBP 70-80)	0.4 (0.2)	1.44 (1.03-2.00)	2
age 40-50 and DBP ≥ 80	0.9 (0.2)	2.51 (1.65-3.81)	3
age 50-60 and DBP ≥ 80	1.1 (0.2)	3.10 (1.94-4.95)	4
age 60-70 and DBP ≥ 80	1.3 (0.3)	3.53 (2.12-5.88)	5
Parental hypertension	0.4 (0.2)	1.41 (1.05-1.89)	2
Obesity	0.4 (0.1)	1.46 (1.13-1.89)	2
HDL < 40mg/dl	0.2 (0.1)	1.29 (1.01-1.66)	2
Fasting glucose ≥ 126mg/dl	0.6 (0.3)	1.84 (1.03-3.28)	2
Smoking	0.4 (0.1)	1.54 (1.14-2.09)	2

Based on the Youden index, 5 or greater defined a high risk with 76% sensitivity, 72% specificity, 27% positive predictive value and 96% negative predictive value.

Conclusions: This prediction algorithm, weighted towards common modifiable variables, showed good performance characteristics in a Korean population.

SA-PO640

Hemodynamics and Cardiovascular Autonomic Efficiency During Blood Pressure Variations in Hemodialysis

Dan Sapoznikov, Rebecca Backenroth, Dvora Rubinger. *Nephrology and Hypertension Services, Hadassah Univ Medical Center, Jerusalem, Israel.*

Background: Chronic hemodialysis (HD) is associated with hemodynamic instability and with reduced cardiovascular autonomic efficiency (CaE).

Methods: To define hemodynamic changes associated with intradialytic blood pressure variations, beat-to-beat systolic blood pressure (SBP) and interbeat interval (IBI) monitoring using Finometer device and Beatscope software was performed during HD sessions in 69 non-diabetic patients (Pts), age 56±15 y. Cardiac output (CO) and total peripheral resistance (TPR) were calculated using the Modelflow simulation method. Differences in variability indices during SBP periods, 10% above (high) or below (low) the mean SBP were considered representative of CaE.

Results: During low to high SBP periods, two patterns of changes were noted: increased CO and decreased TPR (18 Pts,TPR↓), and relatively stable CO with increased TPR (51 Pts, TPR↑). Low frequency (LF) range variability of SBP and IBI, CO and TPR (median and interquartile ranges) were:

	TPR↓		TPR↑	
	Low-high SBP	p	*Low-high SBP*	p
SBP (mmHg)	109(33)-146(28)	0.001	114(25)-159(31)	0.001
IBI (ms)	830(235)-844(226)	NS	808 (158)-827(177)	NS
sd IBI (ms)^	26(14)-22(10)	NS	23 (17)-24(22)	NS
LF SBP ($mmHg^2$/Hz)	132(140)-146(102)	NS	127(123)-99(160)	NS
LF IBI(ms^2/Hz)	1706(1894)-1118(1593)	NS	1014(2480)-1589(3757)	NS
CO (L/min)	4.20(1.64)-5.95(2.81)	0.001	6.19 (1.90)-6.32(1.41)	NS
TPR(mmHg.s/ml)	1.160(0.359)-0.922(0.412)	0.001	0.808 (0.196)-1.046(0.443)	0.001

^sd: standard deviation

The proportion of Pts with intradialytic hypotension (56%) was significantly higher in TPR↓ than in TPR↑ (28%, p=0.036), while TPR changes were directly correlated with post dialysis SBP (r=0.453, p=0.001) and with sd IBI (r=0.357, p=0.003) in all Pts. There were no differences between groups in other variables.

Conclusions: 1.CaE resetting during HD may be associated with predominant CO and/or TPR variations; the latter are significantly correlated to sd IBI, a strong marker of autonomic activity. 2.Intradialytic hemodynamics may be different in hypotension-prone Pts. These observations are relevant to the pathogenesis of intradialytic hemodynamic instability and of postdialysis hypertension.

SA-PO641

Antihypertensive Medications and Blood Pressure Control in Chronic Kidney Disease: A Cross-Sectional Analysis from the German Chronic Kidney Disease (GCKD) Study

Karl F. Hilgers,[1] Matthias Schmid,[2] Silvia Huebner,[1] Martin Busch,[3] Seema Baid-Agrawal,[4] Anna Kottgen,[5] Georg Schlieper,[6] Claudia Sommerer,[7] Gunter B. Wolf, MHBA,[3] Kai-Uwe Eckardt.[1] *[1]Univ Hospital Erlangen; [2]Univ of Bonn; [3]Univ Hospital Jena; [4]Charite Medical Univ; [5]Univ of Freiburg; [6]RWTH Univ Hospital; [7]Univ Hospital Heidelberg, Germany.*

Background: We reported low rates of blood pressure (BP) control in a large German cohort of patients with chronic kidney disease (CKD). Here, we analyzed the antihypertensive drug therapy to assess the prevalence of resistant hypertension, and to determine associations with control of BP.

Methods: The German Chronic Kidney Disease (GCKD) study is a prospective observational cohort study which enrolled 5217 patients with CKD in Germany. Inclusion criteria were an estimated glomerular filtration rate (eGFR) of 30-60 mL/min×1.73 m2 or overt proteinuria. At enrollment, office BP was measured by trained study nurses, and information on medications was collected from patients.

Results: Office BP was obtained from 5181 participants, 4958 (95 %) were classified as hypertensive (>= 140/90 mmHg or use of antihypertensive medication). In 2410 (49 %) hypertensive patients, BP was controlled (defined as < 140/90 mmHg). Inhibitors of the renin-angiotensin system (RAS; ACE inhibitors, sartans and aliskiren) were the most frequently used antihypertensives (87.4 % of participants), followed by diuretics (61.6 %), beta-blockers (57.7 %) and calcium channel blockers (39.6 %). 81.4 % of hypertensive participants received 2 or more different antihypertensive substances. Of the patients with uncontrolled hypertension, 49.9 % met the definition of resistant hypertension (uncontrolled despite 3 or more antihypertensive substances, including a diuretic). In multivariate analysis, RAS inhibitors were associated with better control of BP (odds ratio 1.48, p<0.001), as were diuretics (odds ratio 1.16, p=0.036).

Conclusions: Resistant hypertension was present in 49.9% of CKD patients whose BP was not controlled. RAS inhibitors were widely used and associated with better odds for controlled BP whereas the use of diuretics was less frequent than expected.

Associations Between Cystatin C Based eGFR, Ambulatory Blood Pressure Parameters, and in-Clinic versus Ambulatory Blood Pressure Agreement in Older Community-Living Adults Tyler Woodell, Jan M. Hughes-Austin, Tiffany Tran, Atul Malhotra, Joseph A. Abdelmalek, Dena E. Rifkin. *UC San Diego.*

Background: Although CKD IV-V has been associated with abnormal ambulatory blood pressure (ABPM) patterns, the associations with milder CKD have not been determined. We examined the relationship between mild chronic kidney disease (measured by cystatin C-based eGFR) and abnormal ABPM (including nocturnal dipping) in healthy older adults. Further, we assessed agreement between clinic and ambulatory blood pressure monitoring.

Methods: 334 older community-living adults had clinic BP and 24-hour ABPM measured. Serum cystatin C levels were used to calculate eGFRcys using the CKD-EPI equation. Multiple linear regression was performed to examine associations between eGFR < 60 ml/min/1.73m2 (CKDcys) and ABPM parameters. Bland-Altman analysis was performed to evaluate agreement between clinic and ambulatory measurements.

Results: Average age was 72. Average eGFRcys was 78 ± 20, and 60 individuals with CKDcys. Compared to those without CKDcys, individuals with CKDcys were older, more likely to have clinic-based hypertension and less likely to be dippers. After multivariate analysis, the presence of CKDcys was significantly associated with lower mean ambulatory diastolic blood pressure (DBP) (-2 mm Hg, p = 0.048), but not with nocturnal dipping or other ABPM parameters. Analyses using creatinine-based eGFR yielded similar results. Clinic systolic blood pressure (SBP) significantly overestimated mean wake time ambulatory SBP; mean difference was 11 mmHg for those without CKDcys (95% limits of agreement -14 to 35 mmHg) and 14 mmHg for those with CKDcys (95% limits of agreement -13 to 41 mmHg); there was no statistically significant effect modification by CKD status.

Conclusions: In older community-living adults, mild CKD as detected by cystatin C was associated with lower ambulatory DBP, but not with dipping status. This result is in contrast to findings with more advanced CKD in other studies and suggests that abnormal ABPM may only emerge at more advanced stages of CKD. The presence of CKD did not affect interpretation of clinic vs. ABPM pressures, although accuracy of clinic SBP was poor in this older cohort.

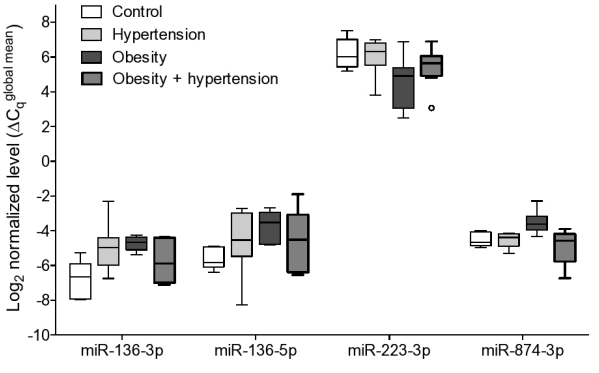
Serum MicroRNA Biomarkers for Obese Children with Hypertension Scott Saint-Amour,[1] Santosh Kumar Patnaik,[2] Sudha Garimella.[1] *[1]Pediatric Nephrology, Univ at Buffalo, Buffalo, NY; [2]Cardiothoracic Lab, RPCI, Buffalo, NY.*

Background: Childhood obesity is a major health problem and 30% of obese children may develop hypertension.There is no clinical method to identify high risk obese children before they develop hypertension. MicroRNAs are non-coding RNAs that are implicated in pathways of inflammation and vascular injury.There has been no characterization of miRNA profiles of obese children with hypertension. This study aims to characterize miRNA profiles as a first step toward evaluating miRNAs as biomarkers for obesity-related hypertension.

Methods: 39 patients ages 3-21 were placed in four cohorts based on presence or absence of obesity and hypertension.Total serum RNA was isolated using miRCURYBiofluids kit Exiqon®, and examined for miRNAs by RT-PCR. C_q values were normalized by the global mean method. Rates of false discovery(FDR) arising from multiple testing were assessed from P values with the Benjamini-Hochberg method.

Results: 69 of 179 examined miRNAs were detected in all samples. MiRNA measurements were globally reduced in sera of obese normotensive Vs. controls. Four miRNAs were identified as differentially expressed between these two groups at FDR <10%, whereas no miRNA was identified as differentially expressed between controls and hypertensive obese. Tukey plots of miRNAs in the cohorts are shown.



Conclusions: Serum levels of four miRNAs appear to be reduced in patients with obesity alone, but not in those with obesity and hypertension. While it is possible that serum miRNA differences were because of variables such as serum lipid content and medications, our study suggests that serum miRNAs have utility in detecting hypertension risk in obese children. This should be validated in a larger study, and the biomarker value of the serum miRNAs correlated with ambulatory blood pressure monitoring data as well as left ventricular hypertrophy.

Funding: Pharmaceutical Company Support - Roswell Park Cancer Institute Support to Dr. Sai Yendamuri in the Cardiothoracic Lab at RPCI was used for this study.

SA-PO644

Effect of Prenatal and Childhood Lead Exposure on Blood Pressure at 4 Years of Age Alison P. Sanders,[1] Katherine Svensson,[1] Chitra Amarasiriwardena,[1] Priyanka Basnet,[1] Ivan Pantic,[2] Adriana Mercado-Garcia,[3] Lourdes Schnaas,[2] Andrea A. Baccarelli,[4] Martha M. Tellez-Rojo,[3] Chris Gennings,[1] Lisa M. Satlin,[1] Robert O. Wright.[1] *[1]Icahn School of Medicine at Mount Sinai; [2]National Inst of Perinatology; [3]National Inst of Public Health; [4]Harvard T.H. Chan School of Public Health.*

Background: Prenatal lead (Pb) exposure occurs during a susceptible period of renal development and may program later life cardiovascular and renal disease.

Methods: Systolic and diastolic blood pressure (SBP and DBP) was obtained using an automated oscillometer from 397 children at 4 years of age in the PROGRESS cohort located in Mexico City. Maternal blood samples were previously collected at the 2nd trimester (2T), 3rd trimester (3T), and at delivery and children's blood samples were collected at birth (cord blood), 1 year, and 2 years of age. Blood lead levels (BLLs) were analyzed via inductively coupled plasma-mass spectrometry. We performed linear regression to examine the associations between longitudinal BLLs and children's SBP, DBP, and pulse pressure (mSBP-μDBP) adjusting for child's age, sex, body mass index, maternal education and environmental tobacco smoke.

Results: Maternal 2T BLLs ranged between 0.7 and 18.8 mg/dL, and 89 (22%) prenatal BLLs were above the CDC guideline level of 5 mg/dL. Increased 2T and 3T BLLs were associated with decreased pulse pressure (p<0.05) and modestly associated with increased DBP (p=0.1).

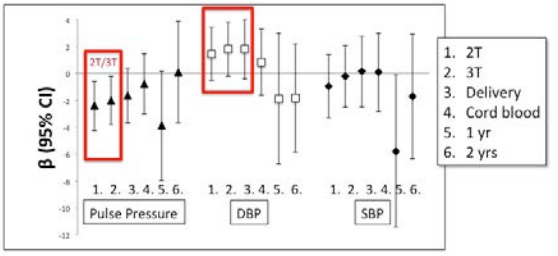


Figure 1. The effect of longitudinal lead exposure on childhood blood pressure at 4 yrs. Estimates (β) and 95% confidence intervals (CIs) were adjusted for child's age, sex, body mass index, as well as maternal education and environmental tobacco smoke.

No significant associations were observed for childhood BLLs and BP. Stratification by sex showed that the effect of prenatal Pb (2T and 3T) on decreased pulse pressure was significant only among females.

Conclusions: Prenatal Pb exposure may contribute to subclinical changes in the developing kidney or cardiovascular system leading to elevated BP in childhood. Future studies will assess if the contributions of early life Pb exposure to BP outcomes persist at later life stages.

Smoking, Microalbuminuria and Renal Function in Essential Never Treated Hypertensive Patients Dimitrios Petras,[1] Vanessa Tzamou,[3] Athanasios Bramos,[4] Panagiota E. Giannou,[1] Stella-Maria Kyvelou,[3] Eva Karpanou,[2] Gregory Vyssoulis.[3] *[1]Nephrology Dept, Hippokration Hospital, Athens, Greece; [2]1st Cardiology Clinic, Onassis Cardiac Surgery Center, Athens, Greece; [3]Hypertensive Unit, 1st Cardiology Clinic, Univ of Athens, Hippokration Hospital, Athens, Greece; [4]Microbiology Dept, Hippokration Hospital, Athens, Greece.*

Background: The aim of the present study was to identify possible differences depending on patient's individual smoking history with renal function and microalbuminuria in essential never treated hypertensive patients.

Methods: The study included 6100 consecutive patients with essential hypertension. In each patient the smoking status has been assessed by means of a standard questionnaire. Each patient had renal profile work up including microalbumin levels, albumin creatinine ratio in 24h urine collection (ACR) and 24h creatinine clearance.

Results: The study population was divided according to the smoking status in three groups: Smokers (n=2350), Ex-smokers (n=663) and Non-smokers (n=3121). Microalbumin and ACR were significantly higher in smokers compared to ex-smokers and non-smokers [(26.3±24.3 vs 23.6±21.7 vs 22.0±20.0, p<0.0001), (31.5±30.2 vs 28.8±29.3 vs 27.4±27.2, p<0.0001), respectively]. There was no significant difference in creatinine clearance among the three groups of smokers (p=NS)

Parameters	Smokers (n=2350)	Ex Smokers (n=663)	Non Smokers (n=3121)	p
Micoralbumin (mg/dl)	26.3±24.3	23.6±21.7	22.0±20.0	0.0001
ACR	31.5±30.2	28.8±29.3	27.4±27.2	0.0001
24h creatinine clearance	122±37.8	121.4±37.1	121.4±36.8	0.914
SBP (mmHg)	162.7±10.3	164.4±9.7	162.4±10.6	0.0001
DPB (mmHg)	101.6±7.2	100.1±8.3	99.6±7.9	0.0001
Age (years)	51.3±12.7	57.1±12.8	55.1±14.2	0.0001
N (males)	1321	437	1506	0.0001

Conclusions: In conclusion, in this retrospective large cohort study of essential never treated hypertensive patients there is a clear association that active smoking is associated with higher microalbumin and ACR levels in these patients.

SA-PO646

Comparison of Salt Taste Thresholds and Salty Usage Behaviors Between Myanmar and Korean Adults Hyungjin Cho.[1] *[1]Div of Nephrology, Dept of Internal Medicine, College of Medicine, Univ of Ulsan, Asan Medical Center, Seoul, Republic of Korea; [2]Div of Nephrology, Dept of Internal Medicine, Jeju National Univ Hospital, Jeju, Republic of Korea.*

Background: Excessive oral salt intake can induce hypertension. According to previous studies, prevalence of hypertension is higher in Myanmar than Korea. We postulated that Myanmar adult had higher salt taste thresholds and eat much saltier food. The aim of this study is comparing of salt taste thresholds and salt usage behavior scores between Myanmar and Korean adults.

Methods: This cross sectional study enrolled the patients who visited volunteer medical service clinic at Ansung in Korea and Hlegu and Bago in Myanmar in August 2014. We measured vital signs, height and weight of each patient and evaluate detection threshold, recognition threshold, salt preference. All patients took urinalysis and checked spot urine Na. They also filled up the salt usage behavior questionnaire.

Results: Total 131 patients were enrolled and 64 of them were Myanmarese and 67 were Koreans. Blood pressure was significantly higher in Myanmar adults than Koreans. Detection threshold, recognition threshold, salt preference, spot urine sodium and salt usage behavior score was also higher in Myanmarese than Koreans.

	Myanmar (n=64)	Korea (n=67)
Detection threshold (%)***	0.102±0.108	0.046±0.026
Recognition threshold (%)**	0.174±0.163	0.103±0.115
Salt preference (%)**	0.44±0.16	0.37±0.10
Spot urine sodium (mg/dL)**	157.7±84.3	117.0±62.1
Salt usage behavior score*	11.4±2.5	10.4±2.4
*p<0.05, **p<0.01, ***p<0.001		

We calculated correlation coefficient between spot urine Na and other parameters that related to salt intake. The salt preference, salt usage behavior score and detection threshold significantly correlated with the spot UNa.

Conclusions: All parameters related to salt intake, such as detection thresholds, the recognition thresholds, salt preference, salt usage behavior score and spot urine sodium concentration, of Myanmarese were significantly higher than those of Korean.

SA-PO647

Relationship Between Circadian Rhythm of Blood Pressure and Intrarenal Arteriolosclerosis Keiji Kono, Hideki Fujii, Kentaro Nakai, Shunsuke Goto, Shinichi Nishi. *Div of Nephrology and Kidney Center, Kobe Univ Graduate School of Medicine, Kobe, Japan.*

Background: Hypertension (HT) is a common complication in chronic kidney disease (CKD) patients. CKD patients often have circadian rhythm disorder of blood pressure (BP). However, the relationship between circadian BP pattern and intrarenal damage remains unclear.

Methods: Ninety patients with glomerulonephritis were included in this study. Patients with diabetes mellitus and prescription for antihypertensive agents were excluded. Clinic BP (CBP) and 24-h ambulatory BP (ABP) measurements were performed in all the study patients, and who were divided into the following four groups; normotension (NT), white coat hypertension (WHT), masked HT (MHT) and sustained HT (SHT). As renal histopathological assessments, we evaluated the percents of sclerotic glomeruli (SG) and interstitial fibrosis (IF), and classified the degrees of intimal thickening of intra-lobular arteries (ILA) and arteriolar hyalinosis (AH) into four grades (none, mild, moderate, severe) in each biopsy specimen.

Results: The prevalence of NT, WHT, MHT and SHT was 60.0%, 3.3%, 23.3% and 13.4%, respectively. In comparison of circadian BP pattern, all-day HT was most prevalent in the SHT group, and nocturnal HT was most prevalent in the MHT group. SG and IF were significantly severe in the SHT group compared to the NT group. As for intrarenal vascular lesions, the MHT and SHT groups had more severe AH compared to the NT and WHT groups, whereas ILA was comparable between all the four groups. Furthermore, we investigated the relationship between intrarenal vascular lesions and clinical characteristics. ILA was significantly correlated with age and renal function, whereas AH was significantly correlated with age, sex, smoking, total cholesterol, HT based on ABP (ABPHT) and HT based on CBP (CBPHT). In multivariate analysis, ILA was significantly correlated with only age, and AH was significantly correlated with age and ABPHT.

Conclusions: Our findings suggest that intrarenal AH was markedly severe not only in the SHT group, but also in the MHT group. Careful ABP monitoring should be recommended in patients with glomerulonephritis.

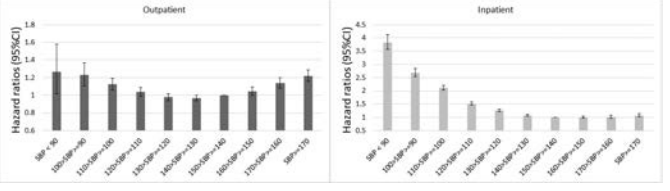
SA-PO648

Association of Inpatient versus Outpatient Systolic Blood Pressure with All-Cause Mortality in Patients with Normal Estimated Glomerular Filtration Rate Osita W. Okechukwu,[1] Miklos Zsolt Molnar,[1] Praveen Kumar Potukuchi,[1] Jun Ling Lu,[1] Fridtjof Thomas,[1] Kamyar Kalantar-Zadeh,[2] Csaba P. Kovesdy.[1,3] *[1]Univ of Tennessee Health Science Center, Memphis, TN; [2]Univ of California, Irvine, CA; [3]VA Medical Center, Memphis, TN.*

Background: Hypertension is associated with worse outcomes, and its treatment of improves mortality and cardiovascular disease. Hospitalized patients undergo frequent BP measurements, and hence hospitalization is an opportunity to diagnose and treat hypertension. However, it is unclear if BP measured as inpatient is associated with outcomes.

Methods: From 3,499,271 US veterans with normal eGFR, we identified 1,113,515 patients with inpatient and outpatient SBP recordings. We examined the association of baseline outpatient SBP, and baseline inpatient SBP (defined as the SBP obtained on the first day of the first hospitalization following cohort entry) with all-cause mortality in Cox proportional hazards analyses. Models included both in- and outpatient SBP and their interaction terms, and were adjusted for age, gender, race, eGFR, comorbidities, socio-economic factors, and antihypertensives.

Results: Low SBP was associated with higher mortality in both settings, but much more so inpatients (Figure). Outpatient SBP >140-149 mmHg was associated with linearly higher mortality (hazard ratio (95%CI) for SBP ³170 mmHg: 1.22 (1.16-1.29), p<0.001), but with less increase in mortality in the inpatient setting, which was only present for SBP ³170 mmHg (HR (95%CI) for SBP ³170 mmHg: 1.08 (1.02-1.14)).



Conclusions: SBP shows markedly different associations in the outpatient vs inpatient setting, with higher blood pressures in the inpatient setting conferring less mortality risk compared to the outpatient setting. Until randomized controlled clinical trials are done, caution is warranted when treating hypertension in hospitalized patients.

SA-PO649

Fibroblast Growth Factor 23 and Sodium-Volume Regulation: FGF23-Response to Sodium Restriction in Essential Hypertensive Subjects and to Long Term Extracellular Volume Reduction in Hemodialysis Patients Francesca Mallamaci, Patrizia Pizzini, Daniela Leonardis, Sebastiano Cutrupi, Rocco Tripepi, Giovanni Tripepi, Carmine Zoccali. *Clin. Epid. and Physiopath. of Renal Dis. and Hypert. & Nephrology, Dialysis, and Transplantation Unit, CNR-IFC & Azienda Ospedaliera, Reggio Calabria, Italy.*

Background: Dietary sodium load causes volume expansion and hypertension in mouse models of FGF23 and αKlotho deficiency. FGF23 also associates with ultrafiltration volume in cross-sectional analyses in hemodialysis (HD) patients (pts) further implicating this bone hormone in extracellular volume regulation.

Methods: 32 uncomplicated essential hypertensives were randomized to a 2-weeks high sodium diet (200mmol/day) or to a 2-weeks low sodium diet (10-20 mmol/day). After 1 week wash out, these treatments were crossed-over. At the end of each diet-period, pts underwent 24h urine sodium, 24h ABPM and serum intact FGF23 measurements. The FGF23 response to UF intensification was assessed in 52 hypertensive HD pts. FGF23 and standardized BP measurements were performed at baseline and after 6 months of UF intensification.

Results: In essential hypertensives, PRA and aldosterone (P<0.01) rose during low sodium. However, FGF23 remained unmodified [low sodium: median 36.2 pg/mL, inter-quartile range (IQR):32.4-44.0; high sodium:33.9 pg/mL, IQR:29.5-41.0; P=0.18]. Changes in FGF23 were unrelated to systolic and diastolic ABPM, heart rate, PRA and aldosterone changes. In hypertensive HD pts, baseline FGF23 was 4062 pg/ml (IQR: 1381-12571). BP during the longitudinal study fell from 144 to 139 mmHg (P=0.02) along with a parallel decline in dry body weight (BW)(from 63.7 to 62.8 Kg) but FGF23 remained unchanged (3688 pg/mL, IQR: 1372-14117,P=0.30). Changes in FGF23 were unrelated (P=0.90) with ongoing changes in dry BW.

Conclusions: Changes in sodium intake that potently activate the renin-aldosterone system do not alter FGF23 in essential hypertensives. Similarly, extracellular volume

reduction by UF intensification does not materially influence FGF23 in hypertensive HD pts. These findings suggest that FGF23 is unlikely to play a role in the response to changes in sodium intake in human hypertension.

SA-PO650

Association of Urinary Albumin Excretion and Salt-Sensitivity of Blood Pressure: Genetic Epidemiology Network of Salt Sensitivity (GenSalt) Study

Jing Chen,[1,2] L. Lee Hamm,[1] Chung-shiuan Chen,[2] Kevin K. Wu,[2] L. Gabriel Navar,[1] Jiang He.[2,1] *[1]Medicine, Tulane School of Medicine, New Orleans, LA; [2]Epidemiology, Tulane School of Public Health and Tropical Medicine, New Orleans, LA.*

Background: Albuminuria is a marker of early kidney injury and associated with risk of hypertension, cardiovascular disease, end-stage renal disease, and premature death. However, it is unknown whether urinary albumin excretion is associated with salt- and potassium-sensitivity.

Methods: We investigated the association between urinary albumin excretion and salt- and potassium-sensitivity of blood pressure (BP) among GenSalt study participants. The GenSalt dietary intervention consisted of a 7-day low sodium diet (51.3 mmol sodium/day), 7-day high-sodium diet (307.8 mmol sodium/day), and 7-day high-sodium diet with potassium supplementation (307.8 mmol sodium/day and 60 mmol potassium/day). Twenty-four hour urinary albumin excretion was estimated at baseline and at the end of each intervention from 100 randomly selected GenSalt participants.

Results: Urinary albumin-to-creatinine ratio (ACR, mg/g) was significantly reduced during low-sodium and potassium-supplementation interventions to 2.26 (1.11, 4.61) and 2.10 (1.46, 4.26), respectively, from a baseline ratio of 2.97 (1.20, 6.40) and increased during the high-sodium intervention to 3.23 (2.15, 5.73) with P for group difference=0.005. One standard deviation higher of baseline log-transformed ACR (2.23 mg/g) was significantly associated with 1.5 (95% CI 0.3, 2.7) mm Hg higher in mean arterial BP (P=0.01) from low-sodium to high-sodium intervention (salt-sensitivity) but not statistically significantly associated with potassium-sensitivity after adjusting for confounding factors.

Conclusions: These data indicate that urinary albumin excretion may be associated with BP salt-sensitivity.

SA-PO651

Effects of Nephrectomy on Blood Pressure and Its Circadian Rhythm

Naro Ohashi,[1] Sayaka Ishigaki,[1] Shinsuke Isobe,[1] Takayuki Tsuji,[1] Akihiko Kato,[2] Hideo Yasuda.[1] *[1]Internal Medicine 1, Hamamatsu Univ School of Medicine, Hamamatsu, Japan; [2]Blood Purification Unit, Hamamatsu Univ School of Medicine, Hamamatsu, Japan.*

Background: Intrarenal renin-angiotensin system (RAS) activation causes disturbance of sodium excretion from the kidney by increasing sodium reabsorption in the tubulus, with resultant blood pressure (BP) elevation and nocturnal hypertension. However, the effects of nephrectomy on BP and its circadian rhythm have not been clarified in the patients who have various renal functions.

Methods: We investigated 25 nephrectomized patients [17 men and 8 women, age: 61.3±14.7 years, chronic kidney disease stage 1 in 3 patients, stage 2 in 7, stage 3 in 5, stage 4 in 1 and stage 5 in 9 (hemodialysis in 8 and peritoneal dialysis in 1)]. Body weight (BW), circulating RAS [plasma renin activity (PRA) and plasma angiotensin II (AngII)] and 24-h ambulatory BP monitoring (ABPM) were examined before and after nephrectomy. We divided the daytime and nighttime for 24-h ABPM using sleep and waking times. Renal function [estimated glomerular filtration rate (eGFR)] was evaluated in non-dialysis patients.

Results: In non-dialysis patients,eGFR after nephrectomy was significantly decreased compared with that before nephrectomy (before nephrectomy, 67.8±23.1 ml/min/1.73m^2 and after nephrectomy, 47.9±16.5 ml/min/1.73m^2; p<0.01). There were no significant differences in the levels of BW, BPs during daytime, nighttime and 24-h periods, and circulating RAS before and after nephrectomy. However, night-to-day (N/D) ratio of systolic BP (SBP) was significantly increased after nephrectomy compared with that before nephrectomy (before nephrectomy, 93.0±6.7% and after nephrectomy, 97.4±7.5%; p=0.032), and the patterns of circadian BP rhythm were also significantly changed before and after nephrectomy (p=0.021). Namely, dipper pattern decreased and nondipper and riser patterns increased after nephrectomy. On the other hand, no significant findings were found in N/D ratio of SBP and the patterns of circadian BP rhythm in dialysis patients before and after nephrectomy.

Conclusions: Nephrectomy has effects on nocturnal hypertension due to the decrease of renal sodium filtration ability, but not absolute values of BP.

Funding: Government Support - Non-U.S.

SA-PO652

Association of Urinary Dopamine and Norepinephrine Excretion with Salt- and Potassium-Sensitivity of Blood Pressure

Jing Chen,[1,2] L. Lee Hamm,[1] Chung-shiuan Chen,[2] Kevin K. Wu,[2] L. Gabriel Navar,[1] Jiang He.[2,1] *[1]Medicien, Tulane School of Medicine, New Orleans, LA; [2]Epidemiology, Tulane School of Public Health and Tropical Medicine, New Orleans, LA.*

Background: Dopamine and norepinephrine may play an important role in regulating sodium and potassium reabsorption in the proximal tubules. It is unknown, however, if urinary dopamine and norepinephrine excretion are associated with salt- and potassium-sensitivity of blood pressure (BP).

Methods: We investigated the association of urinary dopamine and norepinephrine with BP salt- and potassium-sensitivity among Genetic Epidemiology Network of Salt Sensitivity (GenSalt) study participants. The GenSalt dietary intervention consisted of a 7-day low sodium diet (51.3 mmol sodium/day), 7-day high-sodium diet (307.8 mmol sodium/day), and 7-day high-sodium diet with potassium supplementation (307.8 mmol sodium/day and 60 mmol potassium/day). Twenty-four hour urinary dopamine and norepinephrine were estimated at baseline and at the end of each intervention in 100 randomly selected GenSalt participants.

Results: Urinary dopamine (μg/24-h) was significantly (p=0.01) reduced from baseline (191.5±124.2) during high-sodium (157.2±143.2) and high-sodium and potassium-supplementation (149.9±139.7) interventions. Likewise, urinary norepinephrine (μg/24-h) was significantly (p<0.0001) reduced from baseline (38.6±24.3) during high-sodium (24.5±21.4) and high-sodium and potassium supplementation (24.6±24.1) interventions. In addition, one standard deviation higher in urinary dopamine concentration (124.2 μg/24-h) was associated with 1.5 (-2.5, -0.6) mm Hg of mean arterial BP reduction from high-sodium to high-sodium plus potassium supplementation (p=0.001). One standard deviation higher in urinary norepinephrine concentration (24.3 μg/24-h) was associated with 1.4 (0.2, 2.6) mm Hg mean arterial BP increase from low-sodium to high-sodium (p=0.02) and 2.2 (-3.1, -1.3) mm Hg mean arterial BP reduction from high-sodium to high-sodium plus potassium supplementation (p<0.0001).

Conclusions: These data indicate that urinary excretion of dopamine and norepinephrine may play a role in BP salt- and potassium-sensitivity.

Difference of Impact on Cardio-Ankle Vascular Index Among Various Blood Pressure Indexes in Patients with Non-Diabetic Chronic Kidney Disease

Hideo Okonogi, Tetsuya Kawamura, Akira Fukui, Shinya Yokote, Nobuo Tsuboi, Yoichi Miyazaki, Makoto Ogura, Takashi Yokoo. *Div of Nephrology and Hypertension, Dept of Internal Medicine, The Jikei Univ School of Medicine, Tokyo, Japan.*

Background: Several studies reported that pulse pressure (PP) is the predictor of heart and kidney risks. On the other hand, arterial stiffness negatively correlates with renal function, and is the predictor of all causes mortality and mainly cardiovascular events in chronic kidney disease (CKD). Cardio-ankle vascular index (CAVI) is a non-invasive indicator of arterial stiffness, and is not influenced by the blood pressure (BP) at the time of examination. Therefore, we examined the relationship between various BP indexes and CAVI in patients with non-diabetic CKD.

Methods: Fifty-nine patients with non-diabetic CKD, who were diagnosed by first time biopsy, were included. Relationships between various BP indexes and CAVI were analyzed. Then receiver-operating characteristic (ROC) analysis for diagnosis of the presence of high arterial stiffness (CAVI≥9, suggesting the presence of arterial sclerosis) were analyzed.

Results: As a result, systolic BP (SBP) and PP significantly correlated with CAVI (r=0.433, p<0.01 and r=0.624, p<0.01, respectively), while diastolic BP (DBP) and mean BP (MBP) did not correlate with CAVI. The ROC curves for diagnosis of the presence of high arterial stiffness by each BP index showed that SBP, DBP, MBP and PP had an area under the ROC curve (AUC) value of 0.786 (p<0.01), 0.425, 0.614 and 0.906 (p<0.01), respectively. Then, by two-graph ROC analysis, the threshold values of SBP and PP were obtained as 132.4mmHg (sensitivity 71%, specificity 71%) and 55.5mmHg (sensitivity 82%, specificity 82%), respectively.

Conclusions: These results indicated that PP has the most strong impact on arterial stiffness among various BP indexes. PP may affect renal function and cardiovascular risk via increase in arterial stiffness.

SA-PO654

Uric Acid Levels Are Associated with Peripheral but Not Central Blood Pressure Parameters in Normotensive Individuals

Pierre-Luc Lavoie, Stephan Troyanov, Francois Madore, Remi Goupil. *Nephrology, Hopital du Sacre-Coeur de Montreal, Montreal, QC, Canada.*

Background: Uric acid is increasingly recognised as a risk factor for cardiovascular disease. Whether this could be explained by changes in peripheral or central blood pressure (BP) profiles remains controversial. The aim of this study was to assess the association of uric acid levels with peripheral and central hemodynamic parameters in untreated normotensive individuals.

Methods: Of 20,004 CARTaGENE participants, 8,420 were normotensive individuals not treated for hyperuricemia or hypertension with valid pulse wave analysis (46.9% male, 52.6 yo). The associations between uric acid levels and peripheral systolic BP (SBP), pulse pressure (PP) central systolic BP (cSBP), central PP (cPP), pulse pressure amplification (PPA), augmentation index (AIx) and augmented pressure (AP) were tested with linear regressions.

Results: In univariate analyses, uric acid levels were significantly associated with all parameters. In contrast, in multivariate analyses, only SBP and cSBP remained independently associated with uric acid levels. As cSBP is usually highly dependent of SBP, it was further adjusted for peripheral BP, where it was not independently associated with uric acid levels (β coefficient -0.003, p=0.51).

	Univariate		Multivariate [a]	
Parameters [b]	**β coefficient [c]**	**p-value**	**β coefficient [c]**	**p-value**
SBP	0.260	<0.001	0.062	<0.001
PP	0.108	<0.001	-0.004	0.77
cSBP	0.167	<0.001	0.068	<0.001
cPP	-0.027	0.013	0.002	0.89
PPA	0.236	<0.001	-0.005	0.65
AIx	-0.272	<0.001	0.002	0.85
AP	-0.210	<0.001	0.006	0.60

[a] adjusted for gender, age, BMI, diabetes, cardiovascular disease, smoking history, eGFR, fasting glucose, total cholesterol, HDL, TSH, and heart rate.
[b] PPA expressed in 0.01 unit and AIx in %. All others in mmHg.
[c] expressed per 10 umol/L of serum uric acid.

Conclusions: In normotensive individuals, uric acid levels were independently associated with SBP, but not with other hemodynamic parameters. Whether the increased risks associated with uric acid levels are explained by these parameters remains uncertain and needs further study.

Funding: Government Support - Non-U.S.

Blood Pressure Trajectory and Events in the Cardiovascular Health Study

Christopher C. Smitson,[1] Rebecca Scherzer,[1] Michael Shlipak,[1] Mark J. Sarnak,[2] Michelle Odden,[3] Carmen A. Peralta.[1] *[1]UCSF; [2]Tufts; [3]OSU.*

Background: The association of blood pressure (BP) trajectories with clinical events in elders is not well established. The importance of integrating trajectories of systolic (SBP) and diastolic (DBP) is not known.

Methods: Among 4,067 participants in the Cardiovascular Health Study, we used repeated measures from the first 7 years to identify discrete trajectories of SBP, DBP and joint SBP/DBP by latent class analysis. We evaluated independent associations of BP trajectory with all-cause mortality, incident CVD (myocardial infarction, cardiac arrest, stroke or CVD death), and heart failure using multivariable Cox models with follow up beginning after 7th year (median follow-up 9.3 years).

Results: Mean age at 7th year was 78. Considering SBP or DBP separately, trajectory groups were primarily determined by baseline BP, and these were not independently associated with outcomes (all p>0.05). In contrast, three distinct groups were identified using joint SBP/DBP: (1) concordant increasing, (2) discordant (stable SBP and decreasing DBP), and (3) concordant decreasing. Compared with a concordant increasing, a concordant decreasing and discordant trajectory had increased risk of death. Concordant decreasing was also associated with increased risk for incident CVD and HF, compared with concordant increasing. Findings did not differ when we stratified by use of antihypertensives.

	Event Rate per 1000 PY	Multivariable Analysis HR (95% CI)
Mortality		
Concordant Increasing (n=1838)	60.6 (57.1, 64.4)	1 [reference]
Discordant (n=1109)	62.2 (57.6, 67.2)	1.16 (1.03, 1.31)
Concordant Decreasing (n=1120)	83.9 (78.2, 90.1)	1.20 (1.06, 1.36)
Incident CVD		
Concordant Increasing (n=1332)	24.0 (21.4, 26.9)	1 [reference]
Discordant (n=779)	25.2 (21.8, 29.2)	1.16 (0.93, 1.44)
Concordant Decreasing (n=726)	30.6 (26.5, 35.4)	1.26 (1.01, 1.58)
Incident HF		
Concordant Increasing (n=1689)	32.3 (29.5, 35.3)	1 [reference]
Discordant (n=998)	32.6 (29.0, 36.7)	1.00 (0.84, 1.20)
Concordant Decreasing (n=946)	42.2 (37.7, 47.3)	1.18 (0.99, 1.42)

Conclusions: Among community-dwelling elders, distinct BP trajectories were identified integrating SBP and DBP. Decreasing BP is associated with higher risk for adverse outcomes.

Serum Uric Acid and Vascular Stiffness in African Americans with Hypertension

Rajesh Mohandas,[1,2] Xuerong Wen,[2] Jogiraju V. Tantravahi,[1,2] Titte Srinivas,[3] Richard J. Johnson,[4] Mark S. Segal.[1,2] *[1]Nephrology and Hypertension Section, North Florida/South Georgia Veterans Health System, Gainesville, FL; [2]Div of Nephrology, Hypertension & Transplantation, Univ of Florida, Gainesville, FL; [3]Div of Nephrology, Medical Univ of South Carolina, Charleston, SC; [4]Div of Renal Diseases and Hypertension, Univ of Colorado, Denver, CO.*

Background: Elevated serum uric acid levels as well as vascular stiffness is associated with hypertension and cardiovascular (CV) disease. However, how uric acid affects vascular stiffness is not known. We examined the relationship between uric acid and vascular stiffness in a cohort of African American men and women with well-controlled hypertension.

Methods: 120 African-Americans with controlled hypertension were randomized in a double-blind, placebo controlled study to allopurinol (300mg/dl) or placebo for 4 weeks. Vascular stiffness was assessed by augmentation index at baseline and at 4 weeks after allopurinol therapy. Uric acid was characterized as low or high (>7 mg/dL in men and > 6 mg/dL in women).

Results: The mean age was 48.7 ± 8.73 years and majority of the participants were women (71%). Augmentation index was negatively correlated with uric acid at baseline (R= -0.24 p=0.009). The high uric group as compared to the low uric acid group, had a lower augmentation index (9.07 ± 5.52 vs. 11.22 ± 5.23 p=0.03) while the mean BP (119 /75 vs 118/75), age (48.7 vs 48.6), and endothelial function as measured by endoPAT (2.2 vs. 2.2) were similar . With allopurinol therapy there was a drop in uric acid by 2.23 ± 1.4 mg/dl as compared to placebo -0.15 ± 0.9 mg/dl but there were no significant changes in vascular stiffness or endothelial function.

Conclusions: In African Americans with hypertension uric acid is negatively associated with vascular stiffness and short-term therapy with allopurinol does not alter vascular stiffness. These changes are not explained by endothelial function. The mechanistic basis of how uric acid may be protective against vascular stiffness may explain the many conflicting studies on the contribution of uric acid to cardiovascular risk and merits further investigation.

SA-PO657

The Impact of Renin-Angiotensin System Blockers on Renal Sodium Handling: An Analysis of CARTaGENE

Catherine Delmas-Frenette, Stephan Troyanov, Josee Bouchard, Francois Madore, Remi Goupil. *Nephrology, Hopital du Sacre-Coeur de Montreal, Montreal, QC, Canada.*

Background: Renin-angiotensin system blockers (RASB) reduce the effects of angiotensin II, and subsequently aldosterone, leading to vasodilation and natriuresis. The magnitude of the RASB-induced natriuresis compared to diuretics and other anti-hypertensive agents remains uncertain.

Methods: We identified patients treated for hypertension from the prospective CARTaGENE cohort, a random sample of the Quebec population aged 40 to 69, who had available urinary sodium levels. We compared the fractional excretion of sodium (FeNa) between patients on beta-blockers or calcium channel blockers without diuretics (Group 1), on RASB without diuretics (Group 2) and on diuretics (Group 3) with ANOVA and a general linear model adjusting for age, gender, estimated glomerular filtration rate (eGFR), diabetes and peripheral mean arterial pressure (pMAP).

Results: Of the 3828 individuals with treated self-declared hypertension, 155 had urinary measurements. Of these 61% were male, their mean age was 59±8 years, 23% had diabetes and the eGFR and pMAP were 85±14 ml/min/1.73m^2 and 93±11 mmHg. Groups 1, 2 and 3 included 42, 72 and 41 patients, respectively. In unadjusted analyses, patients in Group 1 (0.67±0.33) had lower FeNa than Group 2 (1.02±0.51, p=0.001) and Group 3 (1.25±0.70, p<0.001), while Group 2 had lower FeNa compared to Group 3 (p=0.029). In the adjusted analysis, Group 2 still had higher FeNa than Group 1, but the results were similar to Group 3.

Treatment	Adjusted FeNa (95% CI)	p-value (vs Group 1)	p-value (vs Group 2)
Group 1 (beta-blockers and calcium channel blockers)	0.75 (0.59-0.92)	-	-
Group 2 (RASB)	1.01 (0.88-1.13)	0.049	-
Group 3 (diuretics)	1.19 (1.03-1.36)	0.001	0.22

Conclusions: After adjustment for important covariables, RASB therapy is associated with a natriuresis similar to diuretics and greater than other antihypertensive drugs in hypertensive patients. Whether the degree of natriuresis parallels the blood pressure response to these agents remains to be determined.

SA-PO658

Urine Mitochondrial-DNA Copy Number Identifies Renal Injury in Severe Renovascular Disease Alfonso Eirin,[1] Ahmed Saad,[1] Sandra Herrmann,[1] Hui Tang,[1] Amir Lerman,[2] Stephen C. Textor,[1] Lilach O. Lerman.[1,2] *[1]Divs of Nephrology and Hypertension, Mayo Clinic; [2]Cardiovascular Diseases, Mayo Clinic, Rochester, MN.*

Background: We have previously demonstrated that mitochondrial injury contributes to renal dysfunction in swine renovascular disease (RVD), but its implications in human RVD remain unknown. Fragments of the mitochondrial genome released from dying cells are considered surrogate markers of mitochondrial injury. We hypothesized that RVD would be associated with increased urine mitochondrial DNA (mtDNA) copy numbers.

Methods: We prospectively measured urinary copy numbers of the mtDNA genes COX3 and ND1 by quantitative real-time PCR in essential hypertensive (EH), moderate RVD, and severe RVD patients (based on ultrasound criteria and evident loss of functional tissue), during constant sodium intake and anti-hypertensive regimens, and compared them with healthy volunteers (HV). Systemic levels of the kidney injury molecule neutrophil gelatinase-associated lipocalin (NGAL) were measured by ELISA.

Results: Blood pressure was similarly elevated in EH and RVD, yet serum creatinine and NGAL were higher and estimated glomerular filtration rate (eGFR) lower in RVD versus HV and EH (Table). Urinary COX3 and ND1 were higher in EH and moderate RVD compared to HV, and further elevated in patients with severe RVD (Figure). In RVD patients, urinary COX3 and ND1 directly correlated with NGAL (R^2=0.18, p=0.02 and R^2=0.37, p<0.001), proteinuria (R^2=0.33, p<0.001 and R^2=0.53, p<0.001), and serum creatinine (R^2=0.27, p=0.002 and R^2=0.16, p<0.02) levels, and inversely with eGFR (R^2=-0.11, p=0.05 and R^2=-0.13, p<0.04, respectively).

Conclusions: We found progressive increments in urinary mitochondrial injury markers with increased severity of RVD, implicating mitochondrial injury in kidney damage in human RVD. Mitochondria might represent a novel therapeutic target in RVD.

	HV (n=22)	EH (n=25)	Moderate RVD (n=20)	Severe RVD (n=14)
Age (years)	66.0±9.4	60.8±17.5	69.3±7.2	69.9±8.2

Association Between Urinary Big Angiotensin-25 and Microalbuminuria in Hypertensive Patients Yasuhiro Yamashita,[1] Sayaka Nagata,[1] Yuji Sato,[2] Kazuo Kitamura,[1] Shouichi Fujimoto.[3] *[1]Div of Circulatory and Body Fluid Regulation, Dept of Internal Medicine, Faculty of Medicine, Univ of Miyazaki, Miyazaki, Japan; [2]Dialysis Div, Univ of Miyazaki Hospital, Miyazaki, Japan; [3]Dept of Hemovascular Medicine and Artificial Organs, Faculty of Medicine, Univ of Miyazaki, Miyazaki, Japan.*

Background: In hypertensive patients, albuminuria is a predictive factor for cardiovascular events. Recently, a newly glycosylated angiotensin-related peptide, Big angiotensin-25 (Bang-25), was isolated from human urine (Nagata et al. Biochem Biophys Res Commun 2013), and it was localized to podocytes in kidney tissue. Bang-25 may be involved in the renin-independent pathway for localized angiotensin II generation, and can contribute to diagnosis in organ disorders. Using cross-sectional data, we investigated the relationship between urinary Bang-25 and albuminuria in hypertensive patients.

Methods: We examined the data of 408 hypertensive patients (male 50.5%; mean age 70±10 years, BMI 25±3.7 kg/m², diabetes mellitus 38.0%, and eGFR 72±17 ml/min/1.73m²). We evaluated urinary albumin/creatinine ratio (ACR) and we measured urinary Bang-25 by specific AlphaLISA immunoassay. The association between urinary Bang-25/creatinine ratio and microalbuminuria was analyzed by a multivariate logistic method.

Results: Thirty patients were excluded because of macroalbuminuria (ACR³300 mg/gCr). Of 378 patients, 96 had microalbuminuria (30≤ACR<300 mg/gCr). Patients were then divided by quartiles of Bang-25/creatinine ratio. Older patients, females, lower hemoglobin, lower uric acid, and higher HDL were more prominent in higher Bang-25/creatinine quartiles. After adjusting for age, sex, eGFR, and presence of diabetes, the odds ratios (95% confidence intervals) for microalbuminuria per quartile, calculated using multivariate logistic analysis, were as follows: Q1, reference; Q2, 0.72 (0.33-1.54); Q3, 0.99 (0.49-2.01); and Q4, 2.05 (1.01-4.14).

Conclusions: Higher urinary Bang-25/creatinine quartile was significantly associated with microalbuminuria in hypertensive patients. As Bang-25 is localized to podocytes, it may play some role in the development of albuminuria.

Independent Association of Vitamin D on Endothelial Function: A Randomized, Double-Blind, Placebo-Controlled Clinical Trial Lea Borgi,[1] Ciaran Joseph McMullan,[1] Gary C. Curhan,[1] Naomi D.L. Fisher,[2] John P. Forman.[1] *[1]Nephrology, Brigham and Women's Hospital, Boston, MA; [2]Endocrinology, Brigham and Women's Hospital, Boston, MA.*

Background: In nonhypertensive individuals, lower levels of 25-hydroxyvitamin D (25[OH]D) have been associated with an increased risk of hypertension, and vitamin D deficiency has been associated with endothelial dysfunction in such individuals. However, the effect of vitamin D supplementation on endothelial dysfunction in nonhypertensive individuals has not been examined in a rigorous fashion.

Methods: In this randomized, double-blind, placebo-controlled trial of nonhypertensive, nondiabetic overweight or obese individuals with vitamin D deficiency (body mass index [BMI] ³25 and 25[OH]D£20ng/mL), we assigned subjects to receive either ergocalciferol (50,000 units) or matching placebo, once a week for 8 weeks. Our primary outcome was endothelial-dependent vasodilation (EDV) measured by brachial artery ultrasound at baseline and 8 weeks post-randomization.

Results: By the end of the trial, 46 and 47 participants were allocated to receive ergocalciferol and placebo, respectively. Mean 25(OH)D levels increased from 14.9 to 30.3 in the vitamin D group and 14.4 to 17.4 in the placebo. EDV did not change significantly with either vitamin D repletion (from 6.3±3.6% at baseline to 6.1±4.6% at 8 weeks; p-value=0.78) or placebo (7.9±4.7% to 6.8±4.7%; p=0.17). The treatment effect p-value (comparing the 8-week change with ergocalciferol to the change with placebo) was 0.35.

Conclusions: In this randomized, double-blind, placebo-controlled trial, there was no improvement in endothelial function (measured as EDV) after repletion of vitamin D in overweight/obese non-hypertensive individuals.

Secondary Hypertension, Primary Hyperaldosteronism, and Renal Cell Carcinoma Nicole Piero,[1] Krishnanath Gaitonde,[1,2] Charuhas V. Thakar.[1,2] *[1]Cincinnati VA Medical Center; [2]Univ of Cincinnati.*

Background: Primary hyperaldosteronism (PH) is the most common cause of secondary hypertension. Renal cell carcinoma (RCC) can cause secondary hypertension, but as a renin-mediated process. We describe 5 cases referred for evaluation of PH (uncontrolled hypertension and hypokalemia), incidentally diagnosed with RCC, and the potential role of RCC as a renin-independent mechanism for hypertension.

Methods: At the initial renal visit, average blood pressure (BP) was 167/87 mmHg, with an average of 4 BP meds (no aldosterone blockers). Average serum levels of potassium, sodium and bicarbonate were 3.1, 143 and 30 mmol/L respectively. Average plasma renin activity (PRA) was 0.12 ng/ml/hr, average serum aldosterone (sAldo) was 16.6 ng/dL, with a mean sAldo:PRA of 143.6. In 24-hour urine analysis, aldosterone ranged from 11.8 to 30.2 ng/dL and sodium ranged 82-226 mmol/24 hours. All patients required 1 or 2 aldosterone blocking agents to achieve an average BP of 134/75 mmHg. Upon imaging, 4/5 had adrenal adenomas and all 5 patients had incidental solid renal masses with radiological characteristics of RCC. To date, 3/5 have had renal masses treated with partial/total nephrectomy or cryotherapy; all have confirmed pathology of RCC. All those undergoing RCC treatment were had improved BP with 2/3 having reduced therapy. At presentation these 3 patients had an average BP of 159/87 mmHg and were on an average of 4.6 BP meds; between 5 and 9 months after RCC treatment BP was 133/75 mmHg on average of 4 BP meds; 2/3 able to eliminate aldosterone blockade. 2/3 patients treated for RCC had follow-up biochemical assessment. sAldo:PRA normalized in the patient with partial nephrectomy; whereas it remained elevated in patient treated with cryotherapy.

Conclusions: To our knowledge this is the first case series describing a possible renin-independent, aldosterone-mediated mechanism for secondary hypertension associated with RCC. Although presence of adrenal and renal tumors has been reported, this series describes a physiological link between the two. Whether RCC leads to maladaptive sterol pathways leading to an aldosterone-like action in mediating hypertension requires detailed analysis of RCC tumors.

SA-PO662

Effect of Uric Acid Lowering Agents on Endothelial Function: A Randomized, Double-Blind, Placebo-Controlled Clinical Trial Lea Borgi,[1] Ciaran Joseph McMullan,[1] Gary C. Curhan,[1] Naomi D.L. Fisher,[2] John P. Forman.[1] *[1]Nephrology, Brigham and Women's Hospital, Boston, MA; [2]Endocrinology, Brigham and Women's Hospital, Boston, MA.*

Background: In nonhypertensive individuals, higher levels of serum uric acid have been associated with an increased risk of hypertension, and elevated serum uric acid has been associated with endothelial dysfunction in such individuals. However, the effect of lowering serum uric acid on endothelial dysfunction in nonhypertensive individuals has not been examined thoroughly.

Methods: In this randomized, double-blind, placebo-controlled trial of nonhypertensive, nondiabetic overweight or obese individuals with elevated serum uric acid (body mass index [BMI] ³25 and serum uric acid≥5mg/dL), we assigned subjects to receive one of the following: allopurinol 300mg daily for 4 weeks followed by 600mg daily for 4 weeks; probenecid 500mg daily for 4 weeks then 1000mg daily for 4 weeks; or matching placebo. Our primary outcome was endothelial-dependent vasodilation (EDV) measured by brachial artery ultrasound at baseline and 8 weeks post-randomization.

Results: By the end of the trial, 43, 44 and 47 participants were allocated to receive probenecid, allopurinol and placebo, respectively. Mean serum uric acid levels decreased from 5.9 to 3.6 mg/dL in the probenecid group, from 5.6 to 2.9 mg/dL in the allopurinol group, and were unchanged in the placebo group (5.6 to 5.7 mg/dL). EDV did not change significantly with either probenecid (from 7.6±5.1% at baseline to 8.4±5.2% at 8 weeks; p-value=0.39), allopurinol (from 7.4±6.0% at baseline to 5.9±4.6% at 8 weeks; p-value=0.09) or placebo (6.8±3.8% to 7.1±4.9%; p=0.66).

Conclusions: In this randomized, double-blind, placebo-controlled trial, there was no improvement in endothelial function (measured as EDV) after lowering serum uric acid in overweight/obese non-hypertensive individuals.

Azelnidipine Can Restore the Deceleration Capacity of Heart Rate Variability (DC) In CKD Patients with Preceding Treatment with ARB

Michio Fukuda,[1] Toshiyuki Miura,[1] Yoshiaki Ogiyama,[1] Ryo Sato,[1] Daisuke Fuwa,[1] Hiroyuki Ito,[1] Tetsuhei Matsuoka,[1] Yukako Isobe-Sasaki,[1] Ken Kiyono,[2] Yoshiharu Yamamoto,[3] Junichiro Hayano,[1] Nobuyuki Ohte.[1] *[1]Nagoya City Univ; [2]Osaka Univ; [3]Tokyo Univ.*

Background: Recently, we have hypothesized that DC, novel measure of cardiac vagal modulations, is also attributable to sympathetic nerve activities. Azelnidipine was reported to decrease non-Gaussianity index of HRV (l_{25s}), which can serve as a marker of sympathetic cardiac overdrive.

Methods: In 43 hypertensive patients with CKD under treatment with an angiotensin receptor blocker (ARB), we tested whether 8-week add-on administration of azelnidipine can increase DC. DC was calculated by Bauer's signal processing technique of phase-rectified signal averaging. For reference, the power of high frequency (HF, 0.15–0.40 Hz) obtained from frequency measure of HRV was examined as a conventional indicator of vagal activity.

Results: DC increased (6.17 ± 1.84 to 6.55 ± 1.85, p=0.002) and l_{25s} decreased (0.56 ± 0.15 to 0.50 ± 0.12, p=0.001), while no significant changes were observed in other HR variability measures including HF (p=0.9). Change in DC correlated inversely with the change in l_{25s} decreased (r=-0.38, p=0.01), but not with the change in HF (p=0.8).

Conclusions: Our findings are consistent with the thesis that DC is not a simple measure of vagal activity but a product of complex interplay between sympathetic and vagal nerve activities.

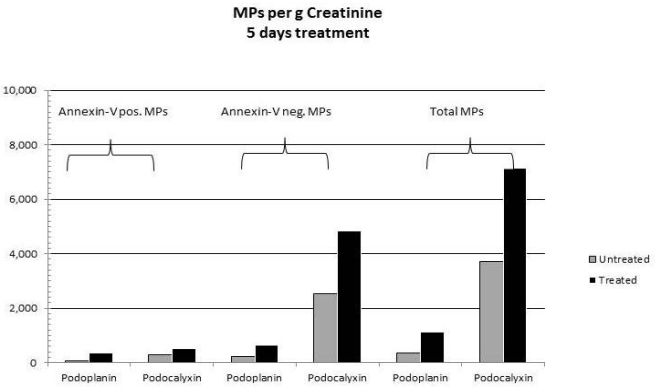
Elevated Levels of Podocyte Derived Urinary Microparticles in Angiotensin II Induced Hypertension

Uta Erdbruegger, Christine Rudy, Sylvia Cechova, Rosa Chan, Joseph C. Gigliotti, Thu H. Le. *Div of Nephrology and HTN, Univ of Virginia Health System, Charlottesville.*

Background: Early and non-invasive biomarkers of kidney damage are needed to identify hypertensive patients at risk for kidney damage. Urinary micropaticles (uMPs) have gained significant attention as potential novel biomarkers for kidney damage, and have already been identified in pre-albuminuric diabetic glomerular injury. These vesicles are less than 1 micron in size and carry markers of the parent cell. We hypothesized that podocyte derived uMPs are elevated in angiotensin II-induced hypertension (HTN).

Methods: Wild-type mice were treated with AII (400ng/kg/min) via mini-osmotic pumps. Untreated WT mice served as controls. Blood pressure was measured with tail-cuff manometry. 24 hour urines were collected after 5 days of AII treatment. Enumeration and phenotyping of MPs was done of podocyte culture supernatant and urine. UMP levels were normalized to urinary creatinine concentration. Podocalyxin(Pcal), podoplanin (Ppla) and annexin 5 (AV) were used as surface markers.

Results: Pcal and Ppla positive MPs as well as AV positive and negative MPs were detectable in supernatant from primary podocyte cultures. Compared to untreated controls (n=3), AII treated mice (n=2) had an increase in systolic blood pressure (SBP) by 33 mmHG (p=0.02). Despite similar urinary albumin/creatinine ratios between groups, there was a trend of higher levels of total numbers of Pcal and Ppla positive MPs in hypertensive mice compared to untreated (see Figure1). In addition, AV negative but Ppla and Pcal positive MPs were also numerically higher in hypertensive mice compared to AV positive uMPs.



Conclusions: In conclusion, podocyte derived urinary MPs are detectable in AII HTN. These findings need to be confirmed in a larger group of animals. Urinary MPs can be potential marker for kidney end-organ damage in HTN.

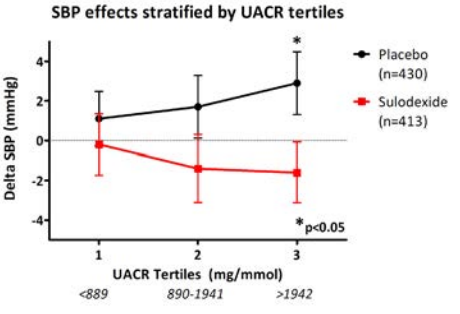
Blood Pressure Lowering Effects of Sulodexide Depend on Albuminuria Severity

Rik Hg Olde Engberink,[1] Hiddo Jan Lambers Heerspink,[2] Dick de Zeeuw,[2] Liffert Vogt.[1] *[1]Nephrology, AMC, Amsterdam, Netherlands; [2]Clinical Pharmacy and Pharmacology, UMCG, Groningen, Netherlands.*

Background: Diabetic patients have a thinner endothelial surface layer (ESL), especially when macroalbuminuria is present**.** Sulodexide, a mixture of glycosaminoglycans (GAGs), increases ESL thickness. Previous data indicate that the ESL is pivotal for BP regulation. In this study, we assessed whether the BP reducing effect of sulodexide is modified by albuminuria severity (a surrogate for the ESL) in type 2 diabetic patients.

Methods: In a post-hoc analysis of the randomized, double-blind, placebo-controlled Sun-MACRO trial, including type 2 diabetic patients with macroalbuminuria and maximal angiotensin II receptor blocker therapy, we studied the BP effects of sulodexide 200 mg/d. We stratified patients in baseline urinary albumin-creatinine ratio (UACR) tertiles. We used ANCOVA to study whether baseline UACR modified the 3-month SBP changes of sulodexide.

Results: Data of 843 patients were available for analysis. Baseline BP was 138/73 mmHg. At 3 months, mean (SEM) SBP change was -0.9 (±0.9) and +1.7 (±0.9) mmHg in the sulodexide and placebo arm, respectively (p=0.037). The SBP reduction was most pronounced in the highest UACR tertile (-1.6 (±1.5) vs 2.9 (±1.6) mmHg; p=0.042). Treatment (p=0.015), baseline SBP (p<0.001), heart rate (p=0.007) and UACR (p=0.007) were associated with SBP change. We found an interaction between treatment and UACR (p=0.047), indicating that sulodexide and placebo differently affected SBP at various UACR levels. Age, eGFR, BMI, Hba1c and lipid profile (i.e., factors influencing ESL thickness) did not modify the treatment effect. The BP differences persisted during the first year of follow-up (p=0.047).



Conclusions: The BP reducing potency of sulodexide is modified by albuminuria severity in type 2 diabetes, indicating that ESL restoration may represent a new target for BP treatment in these patients.

Under-Diagnosis of Hypertension in a Large Cohort of Overweight/Obese Adolescents

Brian William Sykes, Divya G. Moodalbail, Christopher J. LaRosa, Joshua Zaritsky. *Nephrology, Nemours/A.I. duPont Hospital, Wilmington, DE.*

Background: The obesity epidemic in children is strongly associated with increasing prevalence of childhood hypertension (htn) along with heightened risk for cardiovascular morbidity and mortality in adulthood. Therefore we assessed the identification of htn in overweight/obese adolescents cared for by a large healthcare system utilizing an EMR system.

Methods: We performed a retrospective study of patients (pts) in the Nemours Health Care System, aged 12-17 years, with a BMI > 85%ile, and >3 documented BPs > 120/80 in the outpatient setting, between 1/2010 and 12/2014. Pts with established diagnosis of htn (ICD-9 codes 401.XX – 405.XX), renal or heart disease were excluded.

Results: Of the 6604 distinct pts identified, only 255 (3.8%) received a diagnosis of htn during the study period, while 6,349 (96.2%) were undiagnosed. Pts who were undiagnosed had lower BMIs and BPs and were less likely to be African American or have Medicaid and were seen less by Nephrology, Cardiology or Weight management subspecialties compared with those diagnosed with htn (**table**). Additionally undiagnosed pts had fewer abnormal BPs and had a longer interval between their 1st and 3rd abnormal BP compared with those diagnosed with htn.

	Diagnosed HTN (n=255)	Undiagnosed HTN (n=6349)	P-value
Age (years)	13.9±1.6	13.9±1.5	NS
BMI (Z-Score)	2.17 (1.77,2.49)	1.88 (1.47,2.26)	<0.001
SBP (mmHg)	128 (122,134)	126 (122,131)	<0.002
DBP (mmHg)	74 (68,80)	70(65,76)	<0.001
African American (%)	38.0	25.4	<0.001
Medicaid (%)	37.2	29.9	<0.01
Seen by Nephrology (%)	30.1	9.6	<0.001
Seen by Cardiology (%)	53.3	13.8	<0.001
Seen by Weight Management (%)	25.1	8.1	<0.001
Abnormal BPs (n)	6 (4,10)	4 (3,6)	<0.001
Median time between 1st & 3rd BP (days)	251 (110,480)	364 (182,623)	<0.001

Data is presented as Mean±SD or Median (Interquartile range)

Conclusions: In this large cohort of overweight/obese adolescents with htn, the vast majority of pts were undiagnosed and not referred to subspecialists who manage BP monitoring and treatment. Thus it is crucial that future efforts focus on improving detection and early recognition of htn in order to reduce cardiovascular morbidity and mortality in this at-risk population.

SA-PO667

Multidisciplinary Selection of Angioplasty Indications in Atheromatous Renal Artery Stenosis Leads to an Improvement in Blood Pressure, Drug Sensitivity and Renal Function Thomas Fournier,[1] Florence Sens,[1] Olivier Rouviere,[2] Antoine Millon,[3] Laurent Juillard.[1] *[1]Nephrology, Hôpital E.Herriot, Hospices Civils de Lyon, Lyon, France; [2]Radiology, Hôpital E.Herriot, Hospices Civils de Lyon, Lyon, France; [3]Vascular Surgery, Hôpital E.Herriot, Hospices Civils de Lyon, Lyon, France.*

Background: Angioplasty as treatment of atheromatous renal artery stenosis (ARAS) is controversial since 3 large randomised trials (CORAL, ASTRAL, STAR) failed to prove the superiority of percutaneous renal artery angioplasty and stenting (PTRAS) over medical treatment alone (MT). However, since population selection was questionable among other bias, the extrapolation of these results in clinical practice is uncertain.

Methods: ARAS cases were discussed during bi-monthly multidisciplinary meetings gathering nephrologists, radiologists and vascular surgeons from April 2013 to February 2015. For every patient, we compiled clinical, biological and radiological data. We then recorded blood pressure (BP), renal function and treatment evolution after a one-year follow-up.

Results: During 23 months, 52 cases were discussed. Mean age was 69 years. Two thirds of patients had at least 3 cardiovascular risk factors. Mean BP was 161/77 mmHg, despite the use of 2.5 ± 1.1 anti-hypertensive drugs. CKD-EPI was 53mL/min/1,73m2. 31% of patients had a history of pulmonary edema. Collective decisions were PTRAS for 21 patients (40%), MT for 28 patients (54%) and surgery for 3 patients (6%). PTRAS and MT groups were initially comparable (blood pressure, renal function, treatment, comorbidities). In the PTRAS group, a significant improvement at 1 year was observed for BP control (systolic -22.6 +/- 29.3 mmHg; diastolic -10.1 +/- 12.9 mmHg), antihypertensive drug number (-0.8 +/- 0,94) and creatinin (-18.3 +/- 35.4 µmol/L). In the MT group, these improvements were not observed.

Conclusions: The significant improvement observed in the PTRAS could be explained by a better selection of patients who could benefit from PTRAS, based on radiologic data analysis and systematic multidisciplinary approach. Multidisciplinary identification of PTRAS indications leads to a better BP control, a reduction in anti-hypertensive drugs use and an improvement in renal function.

SA-PO668

Comparison of Control Rates Among Recommended Drug Selection Strategies for Initial Therapy of Hypertension Kamel A. Gharaibeh,[1] Stephen T. Turner,[1] Arlene B. Chapman,[3] Rhonda M. Cooper-DeHoff,[2] Julie A. Johnson,[2] Gary L. Schwartz.[1] *[1]Nephrology and Hypertension, Mayo Clinic, MN; [2]College of Pharmacy, Univ of Florida, FL; [3]Nephrology, Univ of Chicago, IL.*

Background: Thiazide diuretics (TD) are recommended for initial therapy of hypertension (HTN). In addition to this TD for all, other recommended strategies for initial drug selection are based on age/race (A/R) criteria or on measures of plasma renin activity (PRA). It is uncertain which of these 3 strategies achieves the highest control rate with monotherapy in stage-I HTN.

Methods: Blood pressure (BP) responses from the Pharmacogenomic Evaluation of Antihypertensive Responses (PEAR) study were used to estimate control rates for each of the 3 strategies: (i) TD (hydrochlorothiazide) for all, (ii) TD for all black subjects and for white subjects aged ≥50 years and a renin-angiotensin system (RAS) blocker (atenolol) for whites aged <50 years (A/R strategy) or (iii) TD for suppressed PRA < 0.6 ng/ml/h and a RAS blocker for non-suppressed PRA ≥ 0.6ng/ml/h regardless of age or race (PRA strategy). In PEAR, adults with stage 1 HTN were treated with either hydrochlorothiazide (n=148 black and 218 white subjects) or with atenolol (n=146 black and 221 white subjects). BP response was assessed in the clinic and by 24-hour ambulatory BP (ABP).

Results: Overall, the PRA strategy was associated with the highest control rate compared to the other strategies: **clinic BP:** 48.9% with PRA strategy, 40.8% with A/R strategy (P=0.0004) and 31.7% with the TD strategy (P<0.0001); **ABP:** 61.3% with PRA strategy, 51.6% with A/R strategy (P<0.0001) and 43.9% with TD strategy (P<0.0001). This was also true for each racial subgroup: **clinic BP:** in whites: 50.3% with PRA strategy, 40.6% with A/R strategy, P=0.002 and 25.4% with the TD strategy P<0.0001; in blacks: 46.7% with PRA strategy, and 41.1% for the other 2 strategies, P=0.08, **ABP:** in whites 63.5% with PRA strategy, 50.9% with A/R strategy, P<0.0001 and 38.2% with TD strategy, P<0.0001; in blacks 57.9% with the PRA strategy, and 52.6% with the other 2 strategies P=0.099.

Conclusions: Compared to TD or A/R, the PRA strategy for initial drug selection in stage I HTN was associated with the highest control rate.

Primary Hyperaldosteronism: An Inner City Hypertension Clinic Experience! Ewalola A. Ijaduola, Srijan Shrestha, Islamiyat J. Babs animashaun, Jeffrey D. Wallach, Sudhanshu Jain. *Nephrology, Harlem Hospital Center, New York, NY.*

Background: Primary Hyperaldosteronism (PA) has historically been regarded as a rare disorder. Recent studies have shown a widely variable prevalence. We screened for PA in the Hypertension(HTN) Clinic at Harlem Hospital in patients with predominantly African-American and Hispanic ethnicities.

Methods: Retrospective cross-sectional study of patients seen at Harlem HTN Clinic between January 2008 to November 2013. The inclusion criteria were patients seen with completed aldosterone and renin levels. The exclusion criteria were patients on spironolactone prior to the laboratory studies or with incomplete data. Prevalence was measured as number of patients with both an Aldosterone/Renin ratio >20 and an Aldosterone level >15ng/dl as a ratio of total number of patients tested.

Results: A total of 268 patients who had plasma aldosterone and renin activity obtained was reviewed. Of these, 8 patients had incomplete data and were excluded. 220 of the remaining 260 patients in the study were black, while 40 patients were Hispanic. Notably, 43/260, or 16.5% of the patients were found to have met biochemical criteria for PA. About half, 22/43 or 51% of the patients had CAT Scans showing adrenal adenomas. Additionally, one patient had bilateral enlarged adrenal glands consistent with adrenal hyperplasia, 10 had CAT scans with no evidence of an adrenal mass, while the remaining 10 patients had no abdominal imaging. In the 43 patients who met biochemical criteria for PA, 34 patients were black, 16 of which (47%) had CT evidence of adrenal adenoma while 1 patient had bilateral hyperplasia. Of the 9 Hispanic patients, 6 (67%) had CT evidence of adrenal adenoma. Overall, the prevalence of PA was 34/220 (15.4%) in African-American patients and 9/40 (22.5%) in Hispanic patients.

Conclusions: Our study suggests a higher than anticipated prevalence of PA in African-American and Hispanic patients in Harlem, NYC, based on selective screening with plasma aldosterone and plasma renin activity. In addition adrenal adenomas were present by CT scan in at least 50% of cases, potentially treatable with surgery. Thus,adequate screening of patients for PA is essential, especially in minorities.

HIV-2 and Chronic Kidney Diseases (French HIV-2 Cohort ANRS CO5) Jerome Tourret,[3,4] Aissatou Paye,[1] Marine Naudin,[1] Roland Tubiana,[3,4,5] Philippe Genet,[6] Diane Descamps,[2,7,8] Francoise Brun-Vezinet,[2] Catherine Fagard,[1] Genevieve Chene,[1] Sophie Matheron,[2,7,8] The french Anrs co5 cohort.[1] *[1]INSERM U897, Univ Bordeaux, France; [2]AP-HP Hôpital Bichat, France; [3]AP-HP Hôpital Pitié Salpêtrière, France; [4]UPMC, Univ Paris 06, France; [5]INSERM UMR 1136, France; [6]Hôpital Argenteuil, France; [7]Univ Paris Diderot, France; [8]IAME, INSERM UMR 1137, France.*

Background: The link between HIV-2 and chronic kidney diseases (CKD) has not been studied. We describe the prevalence of CKD and their risk factors in people living with HIV-2.

Methods: All patients included in the HIV-2 French national cohort with 2 creatinine measurements at least 3 months apart were included. Glomerular filtration rate was estimated by MDRD formula and used to categorize CKD according to the NKF classification. Risk factors were determined by uni and multivariate analyses using a Cox model which included the main known risk factors for CKD and the main characteristics of HIV infection.

Results: Out of 1048 patients, 737 had 2 creatinine measurements. Their characteristics did not significantly differ from those of the total cohort: mean age (SD) was 50 (11) years, 62% of the patients were females, and 80.1% originated from sub-Saharan countries. On average, HIV-2 infection was diagnosed 12.8 (6.8) years before last creatinine measurement. Prevalence of CKD stage ³2 was 39.8% and that of chronic kidney failure (stages ³3) was 7.2%. Univariate analysis revealed that age (HR=1.06, $p<10^{-4}$), HIV stage (HR=3.1, $p<10^{-4}$ for CDC stage C), HIV-2 plasma viral load (HR=1.9 for each increment of $\log_{10}$(copies/ml), $p<10^{-3}$), and CD4 count (HR=3.12, $p<10^{-2}$ if <100/mm³) were risk factors for chronic

kidney failure. HIV stage A (HR=0.3, $p<10^{-4}$) had a protective effect. Multivariate analysis revealed that age (HR=1.05, p=0.002) and CDC stage A (HR=0.35, p=0.01) were risk and protecting factors, respectively.

Conclusions: The prevalence of CKD in this very large cohort of people living with HIV-2 seems to be comparable to what is known in literature for people living with HIV-1. HIV-2 infection parameters determine most of the kidney risk. The role of ARV exposition remains to be taken into account.

Effect of Nephropathy on the Frequency of Cardiac Dysautonomia in HIV Patients Syed Rizwan Bokhari,[1] Syed Hunain Riaz,[2] Qurrat-ul-ain Abid,[2] Hafiz I. Ahmad,[1] Muhammad Zaman Khan Assir,[2] Fahmina Ashfaq,[2] Kashif Saleem.[2] *[1]Dept of Nephrology, Allama Iqbal Medical College/ Jinnah Hospital, Lahore, Pakistan; [2]HIV Clinic, Jinnah Hospital, Lahore, Pakistan.*

Background: Dysfunction of autonomic nervous system including Cardiac Dysautonomia (CD) is seen in a variety of conditions like diabetes mellitus, adrenal insufficiency and renal failure. CD is well documented in patients with renal dysfunction/ CKD. Prevalence of renal dysfunction (HIV Nephropathy) is high in our population of HIV positive patients, but the effect of HIV nephropathy on the frequency of CD has not been previously studied. We conducted this study to determine the effect of HIV Nephropathy on the frequency of CD.

Methods: This cross sectional study was conducted at HIV Clinic in collaboration with the Department of Nephrology Jinnah Hospital Lahore. A total of 47 HIV positive patients were enrolled; 13 (28%) with nephropathy and 34 (72%) without nephropathy. Patients underwent 5 tests for cardiac autonomic dysfunction including resting tachycardia, abnormal heart rate response to deep breathing, abnormal Valsalva ratio, abnormal 30:15 ratio and postural hypotension. Patients with 2 or more abnormal tests were considered positive for CD.

Results: Of 47 patients, 39(83%) were male, 5(11%) female and 3(6%) were transgender with median age of 31 years (range 19-56 years). The median CD4 count was 339 (range 39-797) and 96% (n=45) patients were on highly active anti-retroviral therapy (HAART). The median duration of HIV was 12 months (range 1-56) and median duration of HAART was 11 months (range 0-49). CD was seen in 42 (89%) patients. Seventeen (36.2%) patients had 2, 18(38.3%) had 3, 6 (12.8%) had 4 and 1 (2%) had 5 abnormal tests. The frequency of CD was comparable among patients with and without nephropathy [92% (12 out of 13) vs 88% (30 out of 34), respectively; p value=1]. The presence of CD had no correlation with CD4 count, degree of renal impairment, treatment regimen and duration on HAART.

Conclusions: There was high frequency of CD in our population of HIV patients and it was independent of presence or absence of nephropathy, CD4 count and duration of anti-retroviral therapy.

SA-PO672

Glomerular Filtration Rate Estimating Equations Using Beta-Trace Protein and Beta-2 Microglobulin in Chronic Kidney Disease Lesley Inker, Hocine Tighiouart, Josef Coresh, Meredith C. Foster, Amanda Hyre Anderson, Gerald J. Beck, Gabriel Contreras, Tom Greene, Amy Karger, John W. Kusek, James P. Lash, Julia Lewis, Jeffrey R. Schelling, Sankar D. Navaneethan, James H. Sondheimer, Tariq Shafi, Andrew S. Levey. *Chronic Kidney Disease Biomarkers Consortium.*

Background: Beta-trace protein (BTP) and beta-2-microglobulin (B2M), like cystatin C (Cys), are novel serum filtration markers that have stronger associations with adverse outcomes than serum creatinine (Cr). However, comparisons of BTP and B2M to Cr and Cys as filtration markers are limited by the absence of rigorously developed GFR estimating equations.

Methods: Using a pooled database of three populations with CKD (N=3551, mean measured GFR using iothalamate [mGFR] 48 ml/min/1.73m^2), we developed equations to estimate mGFR using Cr, Cys, BTP or B2M. Equations were developed in 2/3 of the population and tested in the remaining 1/3.

Results: The table shows the coefficients included in each equation and the performance of the equations in the validation dataset compared to established CKD-EPI Cr-Cys equations.

Performance of GFR estimating equations in the validation dataset

Description	IQR(95%CI)	1-P_{30}(%)(95%CI)
BTP age, sex*	15.0 (14.1, 15.9)	23.6 (21.3, 26.1)
B2M*	12.9 (12.2, 13.8)	18.4 (16.2, 20.8)
BTP-B2M*	12.1 (11.4, 13.0)	15.5 (13.3, 17.7)
CKD-EPI Cr age, sex, race*	11.6 (10.9, 12.4)	16.4 (14.2, 18.6)
CKD-EPI Cys age, sex*	11.4 (10.6, 12.4)	16.9 (14.9, 19.1)
CKD-EPI Cr-Cys age, sex, race	9.3 (8.7, 10.1)	11.3 (9.5, 13.2)
Average of CKD-EPI Cr-Cys + BTP-B2M	10.2 (9.5, 11.0)	9.6 (8.0, 11.4)

IQR, interquartile range of mGFR-eGFR. 1-P_{30},% of estimates >30% of mGFR. Bias is not shown as it is expected to be near zero, since both the development and the validation dataset are random samples of the total dataset. *p<0.001 for difference of 1-P_{30} from CKD-EPI Cr-Cys equation

Conclusions: BTP and B2M are less influenced by age, sex and race than Cr or Cys but did not improve precision (IQR) or errors (1-P30), even when averaged with Cr-Cys equation. CKD-EPI BTP and B2M equations provide tools for future study in their associations with mGFR and risk and adverse outcomes, but further study is required before clinical use.

Estimation of Glomerular Filtration Rate P.C. Pham,[1] Ruchika Bhasin,[1] Afsaneh Haftbaradaran,[1] Eileen C. McCann,[1] Solomon C. Huang,[1] Saman Sarani,[1] Anita Kamarzarian,[1] Golriz Jafari,[1] P.T. T. Pham.[2] *[1]Div of Nephrology and Hypertension, Olive View-UCLA Medical Center, Sylmar, CA; [2]Kidney Transplant, UCLA Medical Center, Los Angeles, CA.*

Background: Estimations of glomerular filtration rates (GFR) based on routine 24 hour urine collections have been replaced by relatively accurate equations derived from large epidemiological studies. Nonetheless, equations including Modification Diet in Renal disease-4 and 6 variables (MDRD-4, -6) and Chronic Kidney Disease-Epidemiology Collaboration (CKD-EPI) are known to have wider variations in predicting GFR among patients with relatively good kidney function. As renal clearance of any solute is dependent on its presence in the plasma and not whole blood, we suspect that varying hemoglobin/ hematocrit (Hct) may play an important role in the actual clearance of solutes. We aim to determine if adding the plasma factor PF (1 - Hct/100) to MDRD-4, -6, or CKD-EPI equations can improve the accuracy of determining actual GFR.

Methods: This is a retrospective pilot study where the most recent 200 existing 24-hour urine collections obtained with creatinine concentrations as recorded by the Olive View-UCLA Medical laboratory are collected for analysis. Only 24-hour urine collections with concurrent measurements of complete blood count and chemistry 7 are included. To minimize poor 24 hour collections, only samples with urine creatinine ranging between 15-25 mg/kg body weight/day are used. PF is added as an inverse multiplication factor to MDRD-4 and 6-variables and CKD-EPI equations to assess for variations when correlated with actual 24 hour urine collections.

Results: 90 out 200 samples met inclusion criteria. Albeit small, when each of the aforementioned equation was adjusted for PF, R^2 variation improved. MDRD-4: unadjusted R^2=0.836 to adjusted R^2 = 0.853, MDRD-6, R^2=0.811 to 0.813, CKD-epi, R^2=0.746 to 0.747.

Conclusions: Adding PF to MDRD-4, MDRD-6, and CKD-EPI equations reduced variations when correlated to 24 hour urine collections. Of interest, PF appears to improve MDRD (derived for CKD patients where anemia is prevalent) variations better than CKD-EPI. Large-scale reevaluation of eGFR estimates with consideration for PF is warranted.

SA-PO674

Interest of Cystatin C in the Evaluation of Glomerular Filtration Rate in Type 2 Cardio-Renal Syndrome Delphine Kervella,[1,3] Sandrine Lemoine,[2,3] Florence Sens,[1,3] Eric Pouliquen,[1,3] Laurence Dubourg,[2,3] Fitsum Guebre-egziabher,[1,3] Laurent Juillard.[1,3] *[1]Nephrology, Hôpital Edouard Heriot, Hospices Civils de Lyon, Lyon, France; [2]Renal Function, Hôpital Edouard Heriot, Hospices Civils de Lyon, Lyon, France; [3]Univ Claude Bernard Lyon 1, Lyon, France.*

Background: In patients suffering from type 2 cardio-renal syndrome (CRS2), glomerular filtration rate (GFR) is overestimated with creatinine based formulae, leading to the misclassification of these patients in chronic kidney disease stages. As cystatin C is less dependent from muscle mass than creatinine, the aim of this study was to determine if estimation of GFR based on cystatin C offers a better evaluation of renal function than creatinine-based estimations in patients with CRS2.

Methods: GFR measured by Inulin clearance (measured GFR, mGFR) in 50 patients with CRS2 was compared to estimations of GFR (eGFR) with CKD EPI (Chronic Kidney Disease Epidemiology Collaboration) formulae based on creatinine (CKD EPI), cystatin (CKD EPI_{CYST}) and cystatin and creatinine (CKD $EPI_{CYST\text{-}CREAT}$). We calculated absolute bias (eGFR-mGFR) and accuracy 30% for each formula.

Results: Mean mGFR is 26.5±11.5 mL/min/1.73 m². eGFR are 41.5±20, 32±15 and 35±14.5 mL/min/1.73 m² with CKD EPI, CKDEPI_{CYST} and CKD $EPI_{CYST\text{-}CREAT}$ respectively .

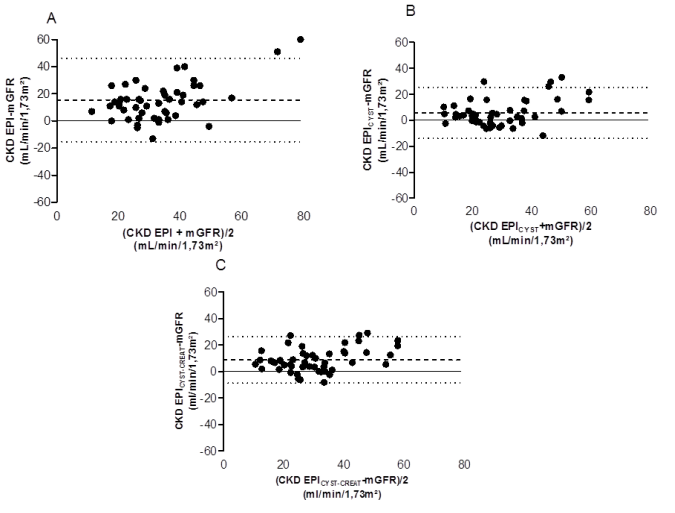

Figure 1. Bland and Altman plots of CKD EPI_I (A), CKD EPI_{CYST} (B), and CKD $EPI_{CYST\text{-}CREA}$T (C).
Thick dashed line represents mean bias between eGFR and mGFR, thin dashed lines represent limits of agreement 95% of mean bias.

These values of eGFR are significantly different from mGFR. Mean absolute bias are 15.4, 5.7 and 8.8 mL/min/1.73 m² and accuracies 30% are 30%, 68% and 48% respectively. The accuracy of CKD EPI_{CYST} is significantly higher than the accuracy of CKD EPI.

Conclusions: Glomerular filtration rate is strongly overestimated with creatinine-based CKD EPI formula in CRS2 patients as previously described. CKD EPI formula based on cystatin C offers a better evaluation of GFR in this population. The high prevalence of malnutrition in this population can explain these results.

SA-PO675

Creatinine Level in Capillary Blood: A New Tool for Instant Estimation of Glomerular Filtration Rate Maurice Laville,[1] Solenne Pelletier,[2] Denis Fouque.[1] *[1]Nephrologie, Univ de Lyon, Pierre Benite, France; [2]Nephrologie, Hospices Civils de Lyon, Pierre Benite, France.*

Background: Serum creatinine is the most used endogenous marker to estimate glomerular filtration rate (eGFR) in clinical practice. A handheld device (StatSensor®, Nova Biomedicals) allows to measure creatinine level in capillary blood. The aim of the study was to assess the accuracy of GFR values (eGFR) estimated from capillary blood creatinine level (CBCr), as compared with GFR values simultaneously measured by a gold standard method (mGFR) in patients with CKD.

Methods: The study included 79 adult patients (36 men, 43 women) who underwent renal function tests. The consent form contained information on the procedure and on the later use of the information for research. Inulin clearance was performed using a continuous infusion of inulin, and urine collections by periods of 30 min. Blood tests were done in the middle of each period of urine collection. Measurements of polyfructosan concentrations were performed using an enzymatic method. Inulin clearance was calculated in each period to obtain the average, and normalized to 1.73 m2 body surface area. A drop of capillary blood was collected from a finger simultaneous to the first and the last blood sampling for inulin measurement. The drops were deposited on a test strip including enzyme reagents and inserted into the SatSensor® device. Reading was done at 30 sec. eGFR was calculated from CBCr with the CKD-EPI equation and the average of the 2 values was taken as eGFR. To assess the performance of CBCr-derived eGFR, the mean absolute bias (eGFR - mGFR) and the correlation coefficient (R2)were calculated.

Results: Mean age was 54 ±17 years, and mean BMI was 25± 5 kg/m2.Mean value of mGFR was 61 ±27 ml/min/1.73 m2. Mean bias was -5.2 ml/min/1.73 m2. On correlation analysis, there was no significant difference between the 2 methods (correlation coefficient 0.86 [0,7;1,01].

Conclusions: Estimation of GFR using instant measurement of capillary blood creatinine level and CKD-EPI formula provides consistent results as compared with a gold standard method for GFR measurement, and could be used for screening and self-assessment purposes.

SA-PO676

Renal Function Estimated with Different Formulae and Mortality in the INCIPE Cohort: Results After 8 Years Follow-up Pietro Manuel Ferraro,[1] Antonio Lupo,[2] Giovanni Gambaro.[1] *[1]Div of Nephrology, Catholic Univ of the Sacred Heart, Rome, Italy; [2]Div of Nephrology, Univ of Verona, Verona, Italy.*

Background: Chronic kidney disease is a known risk factor for adverse outcomes. Its presence and severity is usually ascertained with formulae to estimate renal function based on serum creatinine and/or cystatin C. We analyzed whether renal function estimated with different formulae has a differential association with mortality.

Methods: The INCIPE cohort is a sample of the Italian population enrolled in 2006-07, with follow-up data available up to 2014. CKD stages were defined as GFR ≥90, 89-60, 59-45 and <45 mL/min based on the following formulae: Cockcroft-Gault (CG), Cockcroft-Gault normalized to body surface area (nCG), abbreviated MDRD (MDRD), 6-variables MDRD (MDRD-6), CKD-EPI calculated with serum creatinine (EPI-Cr), with serum cystatin C (EPI-Cys), and with both serum creatinine and cystatin C (EPI-CrCys). CKD stage was then included in a Cox proportional hazards model together with age, body mass index, sex, high blood pressure, diabetes, dyslipidemia, previous cardiovascular disease, smoking status and albuminuria. Harrell's c statistics with 95% confidence intervals (CI) were then calculated and compared for each formula.

Results: The final sample included 2,916 participants, all caucasians, 47.4% males, with an average age at enrollment of 59.9±11.4 years. Participants contributed a total of 22,514 person-years of follow-up (median follow-up 7.9 years) during which 198 death events occurred. Overall, the models were highly predictive of mortality

	Harrell's c	95% CI
CG	0.818	0.788, 0.848
nCG	0.818	0.788, 0.848
MDRD	0.820	0.791, 0.849
MDRD-6	0.819	0.789, 0.848
EPI-Cr	0.818	0.789, 0.848
EPI-Cys	0.826	0.797, 0.856
EPI-CrCys	0.821	0.791, 0.850

The GFR-Cys model performed significantly better than MDRD-6 (difference in c-statistics of 0.008, 95% CI 0.001, 0.015; p=0.034), whereas all the other models performed similarly.

Conclusions: Our study suggests that CKD defined with the CKD-EPI cystatin C formula shows a better prediction of mortality after accounting for a large number of potential risk factors.

SA-PO677

Do the BIS Equations Better Predict Death in Older Women? Muna T. Canales,[1,2] Terri L. Blackwell,[3] Areef Ishani,[4,5] Brent C. Taylor,[4] Allyson Hart,[6] Rebecca Beyth,[1,2] Kristine E. Ensrud.[4,5] *[1]Malcom-Randall VAMC; [2]Univ of Florida; [3]California Pacific Medical Center; [4]Minneapolis VA Health Care System; [5]Univ of Minnesota; [6]Hennepin County Medical Center, Minneapolis, MN.*

Background: KDIGO 2012 guidelines recommend use of the CKD-EPI equations to estimate GFR except when there are alternate equations that may perform better for certain populations such as older adults. The BIS equations were specifically developed in an aged population, but their performance when compared to the CKD-EPI equations to predict mortality in older adults is unclear.

Methods: We conducted a prospective study of 1289 community-dwelling elderly women (≥72 years old) enrolled in the Study of Osteoporotic Fractures (SOF) who had both serum cystatin-C(cysc) and creatinine(SCr) measured at Year 10(1992-1994). We used Cox proportional hazards regression and net reclassification improvement(NRI) to compare the ability of the BIS2 (cysc & SCr-based), CKD-$EPI_{cr,cysc}$, BIS1 (SCr-based), and CKD-EPI_{cr} expressed as 4 eGFR categories (≥75, 60-74, 45-59, <45) to predict death. For NRI analyses, reference equations were CKD-$EPI_{cr,cysc}$ for BIS2 and CKD-EPI_{cr} for BIS1.

Results: The mean age was 79.5±4.6 years; 89% were white. Mean BMI was 27±5 kg/m^2. Mean follow-up time was 9±4 years. % eGFR<60 was: CKD-EPI$_{cycs,cr}$ 33%, BIS2 48%, CKD-EPI$_{cr}$ 24% and BIS1 49%. When compared to eGFR≥75 and after adjustment for age, race, BMI, HTN & DM, eGFR<45 by BIS2 was associated with a 2.1-fold greater risk of death (95% CI 1.5-3.0) vs 1.9-fold for eGFR <45 by CKD-EPI$_{cr,cysc}$ (95%CI 1.5-2.5); BIS1 eGFR<45 was associated with a 1.6-fold greater risk of death (95% CI 1.1-2.1) vs 1.8-fold for eGFR <45 by CKD-EPI$_{cr}$ (95% CI 1.4,2.4; p trend <0.001 across categories for each equation). In category-based NRI analyses neither of the BIS definitions materially changed discrimination of mortality risk when compared to CKD-EPI equations.

Conclusions: In this cohort of older community-dwelling women, the BIS equations identified a greater proportion of participants as having CKD. With respect to mortality risk prediction, the BIS equations did not perform better than current CKD-EPI equations recommended by KDIGO 2012.

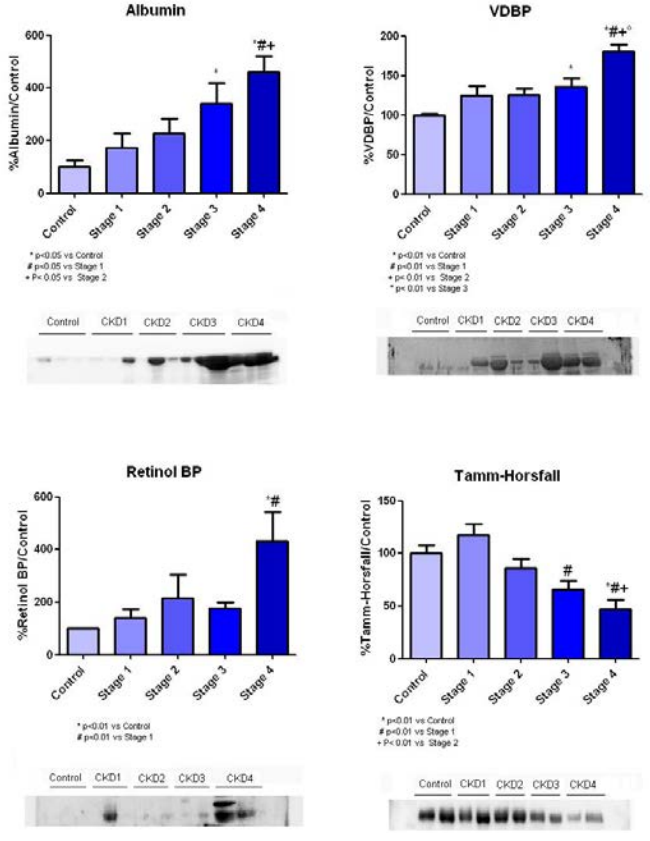
Canine Chronic Kidney Disease: New Protein Biomarkers and Treatment with Human Umbilical Cord Mesenchymal Stem Cells

Camila Eleuterio Rodrigues,[1] Jose Manuel Condor Capcha,[1] Talita R. Sanches,[1] Douglas Caragelasco,[2] Cinthia Martorelli,[2] Fernanda Chacar,[2] Priscila Queiroz Gouveia,[1] Irene L. Noronha,[1] Marcia Kogika,[2] Lucia Andrade.[1] *[1]Div of Nephrology, School of Medicine; [2]Dept of Veterinary Internal Medicine, Univ of Sao Paulo, Brazil.*

Background: There are few strategies to prevent the progression of renal disease in humans or animals. In canine chronic kidney disease (cCKD), as in human CKD, proteinuria correlates with CKD progression, although there are no established urinary protein biomarkers. cCKD has become more common, dogs routinely being euthanized upon reaching the advanced stages. Mesenchymal stem cells (MSCs) have proven renoprotective in rodent CKD models. Here, we aim to characterize the roles that urinary excretion of albumin (Alb), Tamm-Horsfall protein (THP), vitamin D-binding protein (VDBP) and retinol-binding protein (RBP) play in cCKD and to determine whether human umbilical cord MSC (huMSC) administration slows its progression.

Methods: We performed Western blotting for urinary exosomal expression of Alb, THP, VDBP and RBP in cCKD stage 1-4 dogs (n=10/stage) and control dogs (n=10). We evaluated huMSC phenotypes with flow cytometry and immunocytochemistry. We randomized CKD stage 3 dogs to receive i.v.-injected placebo (n=5) or 10^6 huMSC/kg (n=6). We measured serum creatinine (SCr), serum urea (SUr) and the urinary protein:creatinine ratio (UPC) monthly for a year.

Results: Alb, THP, VDBP and RBP correlated significantly with cCKD progression.



Over the study period, UPC decreased in treated dogs (2 excluded for external causes) and increased in control dogs (-25.46±29.63 vs. 81.93±25.56%, p<0.05); SCr and SUr did not differ between the groups (183.6±236.2 vs. 32.02±68.69 and 48.3±31.7 vs. 45.3±62.2%, respectively); treated dogs presented less proteinuria.

Conclusions: Our findings broaden perspectives for CKD treatment. Supported by FAPESP.

SA-PO679

Validation of the Urine Total Protein-To-Creatinine Ratio-Based Chronic Kidney Disease Risk Classification: A Secondary Analysis

Hiroyuki Yamamoto,[1] Kyoko Yamamoto,[1,2] Yutaro Nishi,[1] Kyoko Takeda,[1] Hiroko Izumo,[1] Yasuhiro Komatsu.[1] *[1]St. Luke's Int'l Hospital, Tokyo, Japan; [2]Tohoku Univ Graduate School of Medicine, Sendai, Japan.*

Background: The most recent Japanese chronic kidney disease (CKD) guideline states that patients without diabetes should be classified using the total urine protein-to-creatinine ratio (PCR) instead of the urine albumin-to-creatinine ratio (ACR); however, validation of the PCR is still required. This study was conducted to validate the PCR-based CKD risk classification compared with the ACR-based classification and to explore more accurate methods for classification, focusing on relatively early CKD patients.

Methods: We conducted a secondary analysis using two previous datasets with diabetic or cardiovascular patients who were classified into CKD stages A1-A2 and G1-G3b. We assessed the CKD stage and risk classification of each patient according to the estimated glomerular filtration rate and the ACR- or PCR-based classification method. Then, various candidate PCR values were utilized as the cut-off values between stages A1 and A2. Cohen's kappa statistics were calculated to evaluate the agreement between each classification method.

Results: In total, 860 patients (131 from the diabetic clinic and 729 from the cardiovascular clinic) were enrolled. Using the cut-off value recommended in the current guideline (PCR 0.15 g/gCr), the misclassification rates in these populations were 26.0% and 16.6%, respectively; the misclassifications were primarily caused by underestimation. The kappa statistics achieved 0.56 (95% confidence interval, 0.45-0.69) and 0.72 (0.67-0.76), respectively. Using PCR values of 0.08-0.10 g/gCr as the cut-off value improved the misclassification rates and kappa values.

Conclusions: Current PCR-based CKD classification method leads to underestimation of risk classification in outpatient setting.

Beta-Trace Protein as Renal Marker in Older Adults – Results from the Berlin Initiative Study

Natalie Ebert,[1] Olga Jakob,[2] Jan Bartel,[3] Markus van der Giet,[1] Mirjam Schuchardt,[1] Christine A. White,[4] Elke Schaeffner.[1] *[1]Nephrology, Charité, Berlin, Germany; [2]Epidemiology and Biostatistics, Charité, Berlin, Germany; [3]Labor Limbach, Heidelberg, Germany; [4]Nephrology, Queen's Hospital, Kingston, ON, Canada.*

Background: It has been shown that GFR estimation based on b-Trace Protein (BTP), a relatively novel biomarker, is reliable and might serve as an alternative in kidney transplant recipients. Whether BTP-based eGFR equations can be applied in older adults is not known.

Methods: BTP has been analysed by immunonephelometry with N-Latex® bTP Assay on a BN ProSpec® System, Siemens, Germany. Analysis was done in 570 participants of the Berlin Initiative Study (mean age: 78.5 yrs) who underwent iohexol clearance measurement (mean mGFR: 60.3 mL/min/1.73m^2). The following 3 currently available eGFR equations were used: Pöge (BTP): GFR = 47.17 ×BTP$^{-0.7933}$, Pöge (BTP/Crea): GFR = 974.31 × BTP$^{-0.2594}$ × creatinine$^{-0.647}$ and White (BTP/Crea): GFR=167.8 × BTP$^{-0.758}$ × creatinine$^{-0.204}$ × (0.871 if female). Comparison of BTP estimating equations with mGFR was done for determination of bias (mGFR-eGFR), precision (SD) and accuracy (P10, P30).

Results: The boxplot includes median and eGFR range calculated with the 3 GFR-equations. Mean eGFR was 100,3 for Pöge (BTP), 62,7 for Pöge (BTP/Crea) and 86,2ml/min/1.73m^2 for White (BTP/Crea).

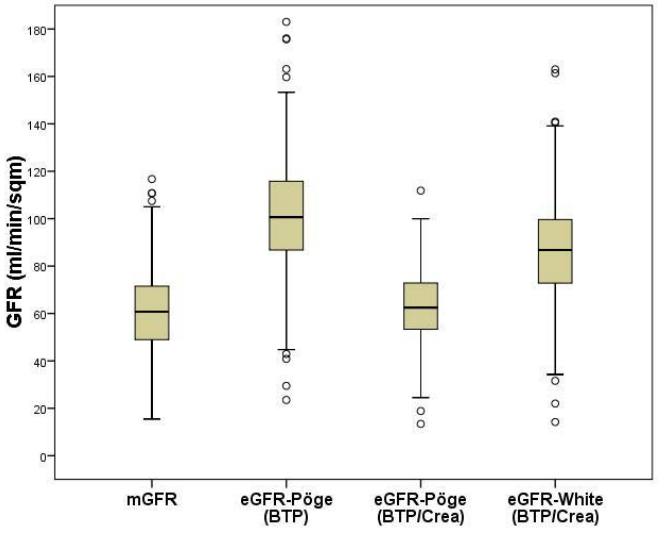

Table 1 shows bias, precision and accuracy for all 3 equations compared to mGFR.

	Mean Bias (ml/ min/1.73m^2)	SD of Differences	Mean Percentage Bias (%)	SD of perc. Bias	P10 (%)	P30 (%)
Pöge, BTP	40.0	15.5	71.4	32.4	1.2	5.8
Pöge, BTP/ Crea	2.40	10.4	6.68	18.6	45.0	87.9
White, BTP/Crea	25.9	13.0	46.0	24.4	3.3	25.7

Conclusions: Currently available eGFR equations that were developed for adult kidney transplant recipients are not applicable in non-transplanted elderly patients. Further research is necessary to evaluate whether BTP is a useful renal marker for older adults.

Funding: Private Foundation Support

SA-PO681

Galectin-3, Possible Useful Biomaker in Predicting Chronic Kidney Disease in Hepatitis C Positive Patients Hany Refaat, Haitham Ezzat, Amr Mohab. *Nephrology Dept, Ain Shams Univ, Cairo, Egypt.*

Background: Galectin-3, a profibrotic mediator, is involved in mechanisms of tubulointerstitial fibrosis and CKD progression. Data regarding its predictive value of CKD development in Hepatitis C patients is scarce.

Methods: In this Cohort study**,** we measured the level of Galectin-3 in the sera of 80 Hepatitis C positive patients. Patients were stratified into two groups: Forty hepatitis C positive patients with normal kidney function (Group I), and 40 hepatitis C positive patients with CKD (Group II). Galectin-3 concentration was also measured in 10 healthy individuals, as a control group (Group III). Other laboratory investigations were done which included hemoglobin level, serum creatinine, eGFR by MDRD equation, ALT, AST, INR, serum albumin, serum bilirubin and CRP titre. We correlated galectin-3 concentrations with demographic and biochemical parameters in all groups.

Results: 30 females (33.3%) and 60 males (66.7%) were included in the study with mean age 47.6±5.3 years.Plasma levels of Galectin-3 were highest in group II (22.1±5 ng/ml) when compared to group I (15 ±2.4 ng/ml) and group III (9.7±2.5 ng/ml) ($p<0.001$). Also CRP titre was highest in group II (10.1±1.5 mg/L), when compared to group I and III (2.5±0.9 mg/L and 2.3±1.1 mg/L respectively) ($p<0.001$). There was positive correlation between Galectin-3 level and CRP titre in both group I and II ($p<0.001$). Moreover, in group II, Galectin-3 level was positively correlated with serum creatinine ($p<0.001$), while inversely correlated with eGFR ($p<0.001$). There was no correlation between serum Galectin-3 level, and INR, ALT, AST and serum albumin in both group I and II.

Conclusions: In hepatitis C positive patients, galectin-3 concentrations increased with progressive renal impairment. Galectin-3 levels were not correlated with liver functions, suggesting the predictive value of galection-3 for CKD development in hepatitis C positive patients.

SA-PO682

Chronic Kidney Disease: Long Term Prevalence Trends and Influence of Modifiable Risk Factors Stein I. Hallan,[1] Marius Altern Øvrehus,[2] Solfrid Romundstad,[2] Dena E. Rifkin,[1] Arnulf Langhammer,[2] Joachim H. Ix.[1] *[1]UCSD, La Jolla, CA; [2]Faculty of Medicine, NTNU, Trondheim, Norway.*

Background: Prevalence of chronic kidney disease (CKD) is high worldwide, and it has been increasing in the US. However, less strict treatment goals for hypertension have recently been suggested despite increasing prevalence of obesity and diabetes.We aimed to determine whether CKD prevalence is increasing in Norway, evaluating the influence of changing prevalence of CKD risk factors on CKD prevalence, and compared findings to corresponding US data.

Methods: We included general population based participants from the Nord-Trøndelag Health Studies (HUNT), Norway: 65237 from HUNT2 (1994-96) and and 50586 from HUNT3 (2006-08). eGFR and u-ACR based on fresh blood and 3 urine samples were used to diagnose CKD. Thorough quality-control and comparisons of methods over time excluded analytical drift. We used attendance weights used to avoid responder bias.

Results: Total CKD prevalence remained stable in Norway 1996-2007 (11.3%-11.1%, p=0.42) but increased in subjects >75 years (36.6%-39.3%, p=0.014). eGFR <60 ml/min/1.73m2 increased (4.5%-4.8%, p=0.033) while albuminuria >30mg/g decreased (7.9%-7.4%, p=0.034). The most important contributors were a strong blood pressure decline during this 10 years period, more physical activity and lower cholesterol; without these improvements 2.8, 0.7 and 0.6 percentage-point higher CKD prevalence would have been expected, respectively. In contrast, the prevalence of diabetes and obesity increased moderately, but diabetics received more intensive preventive therapy, and the proportion of diabetic patients with CKD decreased substantially (33.4%-28.6%, p=0.002). In contrast, published US data indicate a stronger increase in obesity and diabetes, and physical activity was low and not improving. Access to effective care was also suboptimal for a substantial group of the population.

Conclusions: In contrast to the US where CKD prevalence has been increasing, it remained stable over a 10 year period in Norway, likely due to substantial improvements in blood pressure, lipids and physical activity despite modestly increasing diabetes and obesity.

SA-PO683

Natural Progression of Chronic Kidney Disease in Optimally Managed Patients on the Maximum Conservative Management Pathway Suzanne H. Forbes, Kieran Mccafferty, Muhammad M. Yaqoob. *Nephrology, Royal London Hospital.*

Background: The natural progression of advanced chronic kidney disease (CKD)/ end-stage renal disease (ESRD) managed in a specialist palliative care nephrology clinic setting is unknown.

Methods: We conducted an observational study of all patients with advanced CKD undergoing predialysis counselling between 2009-2014 in a single UK center. All patients who opted for conservative management were followed up prospectively in a specialist conservative care clinic and their clinical phenotype and renal outcomes recorded. Change in eGFR was noted in those patients whose eGFR was<10, with 2 or more serum creatinine estimations taken more than 2 months apart.

Results: We prospectively studied 354 patients with median length of follow-up 452 days (165-769). Median eGFR at referral was 8ml/min (7-9). Demographics are shown.

Age	78 (73-84)
Gender	M - 62% F - 38%
Diabetes	Yes - 62% No - 38%
Ethnicity	Caucasian - 39% South Asian - 37% Black - 14% Other - 10%
Cause of CKD	Diabetes - 38% Renovascular (including hypertension) - 24% Urological - 9% GN - 5% Other - 4% Unknown - 20%
Previous Modality	Nephrology/Low Clearance Clinic - 92% Failing Transplant - 2% Unknown to Service - 6%
Death (n)	209
Cause of Death n (%)	Cardiac - 16 (8) Sepsis - 13 (6) Stroke - 2 (1) Unknown - 38 (18) Other - 12 (6)
Age at Death	80 (75 - 85)
Time to Death (days)	276 (103 - 555)

Fall in eGFR in ml/min/year was 3.9 (1.8-8). Neither baseline eGFR (p=0.13) nor presence of diabetes (p=0.72) affected this rate of decline. Time to death from eGFR 10ml/min was 276 days.

Conclusions: In this first longitudinal study of conservatively treated patients with advanced CKD, variable rate of decline of eGFR ranging between 1.8-8ml/year led to death of 55% of the cohort within the median follow up period of 15 months. Reassuringly the majority of patients died at their preferred place of terminal care (home/hospice) and were registered as deaths due to ESRD. Over 50% of patient's eGFR decline was less than 4 ml/min per year which could translate into a life expectancy of >1 year without dialysis in these exceedingly frail individuals. Prospective study is ongoing to determine the quality of life of these patients treated conservatively.

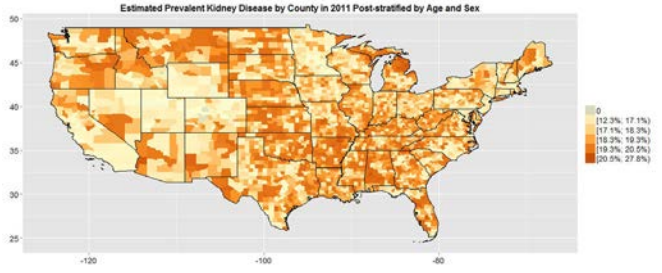
SA-PO684

Estimating County-Level Prevalence of Chronic Kidney Disease (CKD) in the United States Sai Hurrish Dharmarajan,[1] Jennifer L. Bragg-Gresham,[1] Hal Morgenstern,[1] Yi Li,[1] Neil R. Powe,[2] Delphine S. Tuot,[2] Deborah Rolka,[3] Sharon Saydah,[3] Rajiv Saran.[1] *[1]Univ of Michigan, Ann Arbor, MI; [2]Univ of California, San Francisco, CA; [3]Centers for Disease Control and Prevention, Atlanta, GA.*

Background: The prevalence of adult CKD in the US, estimated from 2005-2012 national survey data, is about 13%; however, those surveys are not designed to provide estimates for small regions. Applying a Bayesian multi-level model (BMLM), we estimated adult CKD prevalence in US counties using national and state surveys.

Methods: Data on self-reported CKD and risk-factors were obtained from (i) the National Health and Nutrition Examination Survey (NHANES 2005-2012; n=20,831), and (ii) the Behavior Risk Factor Surveillance System (BRFSS 2011; n=506,467); NHANES also provided CKD laboratory data. CKD was defined as estimated glomerular filtration rate 15-60 ml/min/1.73m2 or urinary albumin-to-creatinine ratio >30mg/g. As BRFSS does not include laboratory data, CKD for each person in the BRFSS was multiply imputed using a logistic regression model trained on NHANES data. A BMLM that effectively borrows information from neighboring counties was then fit to each imputed dataset to produce 10 sets of county-level estimates of CKD prevalence. These estimates were combined to obtain a final prevalence estimate for each county.

Results: Estimated county-level prevalence of CKD ranged from 12.3 to 27.8% (median: 18.8%) in 2011 (see map).



The standard deviation of these estimates ranged from 0.8 to 7%, and the coefficient of variation ranged from 5 to 32% of the estimate, suggesting good statistical precision.

Conclusions: We believe this is the first attempt to estimate CKD prevalence in U.S. ccounties. Our approach yields estimates with improved statistical precision for small counties, and is being used to study geographic variation in CKD burden across the U.S.

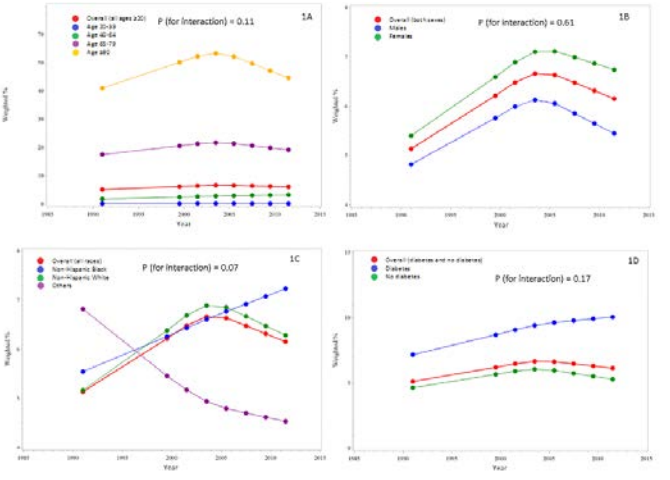
Overall CKD Prevalence in the U.S. Has Stabilized in Recent Years Daniel P. Murphy,[1] Charles E. McCulloch,[1] Feng Lin,[1] Tanushree Banerjee,[1] Jennifer L. Bragg-Gresham,[2] Mark Eberhardt,[3] Meda E. Pavkov,[3] Rajiv Saran,[2] Neil R. Powe,[1] Chi-yuan Hsu.[1] *[1]UCSF [Drs. CY Hsu and NR Powe are Co-Senior Authors]; [2]Univ of Michigan; [3]CDC.*

Background: ESRD incidence rates in the U.S. have stabilized recently. We sought to better understand trends in CKD prevalence since 2003-2004.

Methods: We examined data on adults from the National Health and Nutrition Examination Surveys from 1988 through 2012. We determined prevalence of stage 3-4 CKD (CKD-EPI equation eGFR 15-59 mL/min/1.73m^2) overall and by age, sex, race, and diabetes strata. We examined crude prevalence and adjusted prevalence for age, sex, race, and diabetes mellitus (diagnosed and undiagnosed). Restricted cubic splines were used to model trends. The years 2003-4 (last years with published literature) were compared to 2011-12 (most recent years of available data).

Results: Consistent with the published literature, we saw a rise in CKD prevalence from the late 1990s to the early 2000s. But since around 2003-4, adjusted and unadjusted prevalence of CKD have stabilized (Figure). This temporal trend was observed across age (p for interaction=0.11), sex (p=0.61) and racial-ethnic subgroups (p=0.07; although the trend in non-Hispanic blacks appeared to differ); and did not differ by diabetes status (p=0.17). There was no difference in overall stage 3-4 CKD prevalence comparing 2003-4 and 2011-12 (p=0.25). Similar trends were seen with an expanded definition of CKD to include persons with higher eGFRs but albuminuria or used the MDRD equation.



Conclusions: Over the last decade in the U.S., there has been stabilization in the overall prevalence of stage 3-4 CKD, with a possible exception in blacks. This is contrast to what has been reported by prior studies analyzing older data but consistent with the observed stabilization of overall ESRD incidence. Efforts should be continued to implement reno-protective measures, especially in blacks.

SA-PO686

Global Prevalence of Chronic Kidney Disease Categories 3-5 – A Systematic Review Tazeen H. Jafar,[1] Pryseley Nkouibert Assam,[1,2] Fahad Javaid Siddiqui,[1] Shreyasee S. Pradhan,[1] Edwin S.Y. Chan.[2] *[1]Duke-NUS Graduate Medical School, Singapore; [2]Singapore Clinical Research Inst.*

Background: Chronic kidney disease (CKD) has become a leading contributor to the global burden of disease. We performed a systematic review of published studies to estimate the global prevalence of CKD categories 3-5 defined by estimated glomerular filtration rate (eGFR) less than 60 ml/min/m^2.

Methods: PubMed, EMBASE and Scopus were searched for studies published in English from 2003 to 2013 reporting prevalence of CKD categories 3-5 in the general population. Studies were included if they (1) sampled from the general adult population, (2) assessed CKD using CKD-EPI or MDRD Study equations; (3) not on renal replacement therapy.

Results: A total of 13,081 studies were considered, of which 566 studies from 54 countries assessed prevalence of CKD, and 284 studies were in unselected general population. The global prevalence of CKD accounting for clustering among all adults aged 20 years or older are shown in table below

CKD Category (C)	Countries	Studies	CKD Prevalence (95% CI)	Expected Number of Individuals with CKD (Millions) (95% CI)
C 3 to 5 (eGFR <60 ml/min/1.73m2)	41	264	7.0 (5.2 to 9.3)	335.0 (249.0 to 446.0)
C 3 to 5 (20 to 65 yrs)	29	66	3.9 (2.1 to 7.2)	154.4 (80.0 to 289.0)
C 3 to 5 (65 + yrs)	25	58	28.9 (19.3 to 41.1)	229.6 (154.4 to 328.0)
C 3 only (eGFR 30-59 ml/min/1.73m2)	27	86	6.2 (4.2 to 9.3)	332.8 (220.9 to 446.0)
C 4 only (eGFR 15-29 ml/min/1.73m2)	18	50	0.3 (0.2 to 0.4)	14.4 (11.5 to 17.2)
C 5 only (eGFR <15 ml/min/1.73m2)	15	29	0.1 (0.1 to 0.2)	5.2 (3.8 to 7.2)

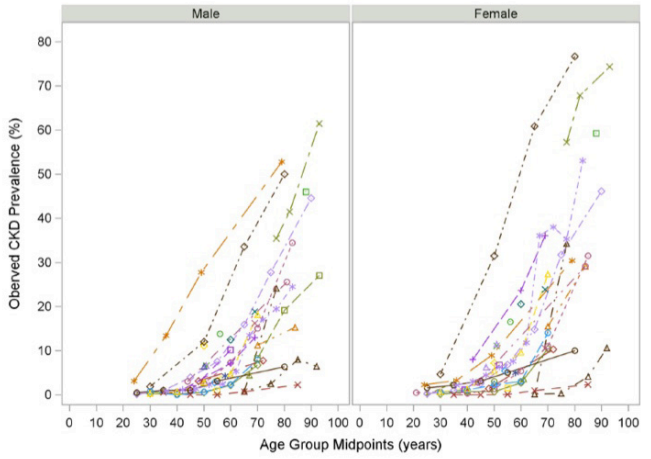

Figure shows the association of age with CKD categories 3-5. Sensitivity analysis revealed consistent CKD prevalence (6.9%) for all 566 studies.

Conclusions: Clinically significant CKD is high both in younger and older adults globally. Our findings call for institution of urgent public health efforts for CKD prevention and management.

SA-PO687

Prevalence of Chronic Kidney Disease with Diabetes and Glomerulonephritis in China Luxia Zhang, Jinwei Wang, Ming Hui Zhao. *Renal Div, Dept of Medicine, Peking Univ First Hospital, Beijing, China.*

Background: Diabetes is the leading cause of end stage kidney disease worldwide, while glomerulonephritis is thought to be the predominant cause in developing countries. However, the surging prevalence of diabetes in developing countries such as China may have substantial impact on the spectrum of chronic kidney disease.

Methods: A national in-patient database involving 19.5 million patient-records was used. Diagnoses of chronic kidney disease with diabetes (DM-CKD) as well as with glomerulonephritis (GN-CKD) were extracted from International Classification of Diseases-10 codes of the discharge diagnoses. Furthermore, a general population-based, national representative sample of 47 204 participants was used. Identification of DM-CKD and GN-CKD was based on laboratory tests and the questionnaire inquiring about medical history. Then the prevalence of DM-CKD and GN-CKD was compared among both hospitalized population and general population.

Results: Among 19.5 million hospitalized patients, 1.19% and 0.79% were identified as with DM-CKD and with GN-CKD, respectively. Compared with GN-CKD, DM-CKD was associated with 7.2% (95% confidence interval [CI] 6.4-8.0%), 5.4% (95%CI 4.7-6.0%) and 59% (95%CI 46-73%) increase of costs, length-of-stay and in-hospital mortality, respectively. For general population, the prevalence of GN-CKD is also exceeded by that of DM-CKD at 0.84% (95%CI 0.68-1.00%) and 1.23% (95% CI 1.06-1.41%), respectively. The estimated number of DM-CKD patients in China was 20.1 million.

Conclusions: Our study indicates that DM-CKD surpassed GN-CKD in both hospitalized population and general population, which marked a transition of kidney disease spectrum in China. Furthermore, DM-CKD is associated with substantial increased healthcare resources utilization and increased risk of in-hospital mortality.

SA-PO688

Prevalence of Chronic Kidney Disease on the U.S.-Mexico Border: Role of Acculturation Jonathan Michael Starkey,[1] Kristina Vatcheva,[2] Susan P. Fisher-Hoch,[2] Joseph B. Mccormick.[2] *[1]Inst for Translational Sciences, Univ of Texas Medical Branch, Galveston, TX; [2]Univ of Texas School of Public Health, Houston, TX.*

Background: Mexican-Americans are the dominant Hispanic group in the US and face significant health disparities, including end-stage renal disease, diabetes and obesity. We characterize the quantity and associations of chronic kidney disease (CKD) in Cameron County, TX where almost 90% of the population is Hispanic and is predominantly zero or first generation Mexican-American.

Methods: The Cameron County Hispanic Cohort (CCHC) is a random sample of the Hispanic population on the southernmost point along the US-Mexico border. 1,777 participants with baseline serum creatinine measurements from 2003-2014 are included in this cross-sectional study. The glomerular filtration rate (eGFR) is estimated from serum creatinine and CKD is defined as eGFR < 60 mL/min/1.73 m^2 . The weighted prevalence of CKD is estimated. A multivariate model of factors associated with CKD outcome.

Results: The prevalence of CKD is 6.0% in the CCHC and estimates the prevalence in Cameron County, TX. Stratified by gender, the prevalence in men and women is 6.9% and 4.9%, respectively. Multivariate analysis reveals significant associations of country of birth (OR 2.14, 95% CI [1.02, 4.46] for those born in the US), hypertriglyceridemia (OR 2.72, 95% CI [1.41, 5.239]) and granulocyte count (OR 1.345, 95% CI [1.058, 1.708]) with CKD status after adjusting for age, gender, diabetes status, cardiovascular disease history, hypertension, smoking history, obesity, LDL and statin use.

Conclusions: The prevalence of CKD in the CCHC is higher than previous national estimates in Hispanics or Mexican-Americans. The data suggest that acculturation, triglycerides and inflammation are associated with CKD in Hispanics living on the US-Mexico border. More research is needed in Mexican-Americans to investigate CKD in this growing minority population.

Validation of the Kidney Failure Risk Equation in Manitoba Reid Whitlock,[1,2] Paul Komenda,[1,2,3] Claudio Rigatto,[1,2,3] Allison Dart,[1,3,4] Joe A. Bueti,[3,4] Randy Walld,[1] Navdeep Tangri.[1,2,3] *[1]Community Health Sciences, Univ of Manitoba, Winnipeg, MB, Canada; [2]Nephrology, Seven Oaks Hospital, Winnipeg, MB, Canada; [3]Medicine, Univ of Manitoba, Winnipeg, MB, Canada; [4]Nephrology, Health Science Centre, Winnipeg, MB, Canada.*

Background: Patients with chronic kidney disease (CKD) are at risk for progression to kidney failure. We previously developed the Kidney Failure Risk Equation (KFRE) to predict the progression of CKD to kidney failure in patients referred to nephrologists. This study aims to validate the KFRE in an unreferred population in Manitoba, and to determine risk thresholds for clinical decision-making.

Methods: We included patients from the Diagnostic Services of Manitoba database with an eGFR < 60 ml/min/1.73 m^2 and a urinary albumin creatinine ratio measured between October 1, 2006 – March 31, 2007. Five year kidney failure risk was predicted using the 4-variable KFRE and compared with treated kidney failure events from the Manitoba Renal Program database. Sensitivity and specificity for KFRE thresholds (3% and 10% over 5 years) were then compared to eGFR thresholds (30 and 45 ml/min/1.73m^2).

Results: 1,512 patients were included and 151 developed kidney failure over the 5-year follow-up period. The 4-variable KFRE more accurately predicted kidney failure when compared to eGFR alone (AUROCs 0.90 [95% confidence interval (CI) 0.88-0.92] for KFRE vs. 0.78 [95% CI 0.74-0.83] for eGFR). At a risk threshold of 3 % over 5 years, the KFRE had a sensitivity of 97 % and a specificity of 62 %.

Conclusions: The KFRE is highly accurate at predicting 5-year risk of kidney failure in a population based sample of Manitobans with CKD Stages 3 to 5. Integration of the 4-variable KFRE into laboratory information systems should be considered.

Funding: Private Foundation Support

SA-PO690

A Risk Prediction Model of End-Stage Renal Disease in Type 1 Diabetes Using Urine MCP-1 as an Alternative Biomarker of ACR Masayuki Yamanouchi, Monika A. Niewczas, Natalia Z. Nowak, Andrzej S. Krolewski. *Genetics & Epidemiology, Joslin Diabetes Center, Boston, MA.*

Background: There is a great need to develop risk prediction models to recruit patients at high risk of end-stage renal disease (ESRD) for clinical trials in patients with type 1 diabetes. We developed two models to predict progression of CKD 3 and 4 to ESRD in 5 years in patients with type 1 diabetes: "ACR model" that consists of patient's age, eGFR, HbA1c and ACR, and "Urine MCP-1 model" that consists of the same markers but replacing ACR with urine MCP-1.

Methods: We identified 285 patients with type 1 diabetes and impaired renal function (eGFR: 15-60 ml/min/1.73m^2) from Joslin Proteinuria Cohort that was followed for 7 to 18 years to ascertain ESRD. We focused on the events within 5 years from enrollment. For the ACR model, the Cox model identified four baseline variables: age, eGFR, ACR, and HbA1c for the final model. For the urine MCP-1 model, urine MCP-1, age, eGFR and HbA1c were identified by the Cox model. Assigned point scores corresponded to each coefficient.

Results: 5-year risk of ESRD in the study group was 40.5%. In the ACR model, the variable with highest magnitude was eGFR<30, 4 points; followed by ACR >300, 2 points; HbA1c >7.5, 1 point; and age <45 years, 1 point, while in the urine MCP-1 model, the variable with highest magnitude was eGFR<30, 2 points; followed by urine MCP-1 >545, 1 point; HbA1c >7.5, 1 point; and age <45 years, 1 point. The model with urine MCP-1 performed almost equal to the model with ACR (C statistic of 0.702 (0.556-0.831) vs. 0.719 (0.574-0.845)). Although the number of patients who developed ESRD in the high risk group in the urine MCP-1 model is smaller than in the ACR model, the incident rate of ESRD in the high risk group in the urine MCP-1 model was much higher than in the ACR model (291/1000 vs. 196/1000, p<0.001).

Conclusions: Using the risk score with urine MCP-1, we can identify a subgroup of patients at very high risk of ESRD.

A Reliable Formula to Estimate 24-h Urine Sodium Excretion from Morning Fasting Urine in Patients with Chronic Kidney Disease Se Yun Kim,[1] Ho Jun Chin,[2] Sejoong Kim,[2] Dong Ki Kim,[3] Suhnggwon Kim,[3] Jung Hwan Park,[4] Sung Joon Shin,[5] Bum Soon Choi,[6] Chun Soo Lim,[7] Sang Ho Lee.[1] *[1]Kyung Hee Univ Hospital, Seoul, Korea; [2]Seoul National Univ Bundang Hospital, Seong-Nam, Korea; [3]Seoul National Univ Hospital, Seoul, Korea; [4]KonKuk Univ Hospital, Seoul, Korea; [5]Dongguk Univ Ilsan Hospital, Goyang, Korea; [6]Seoul St. Mary's Hospital, Seoul, Korea; [7]Seoul National Univ Baramae Medical Center, Seoul, Korea.*

Background: Estimated 24 hour urine sodium excretion based on spot urine has been proposed to replace 24 hour urine collection in epidemiologic studies. However, estimated sodium excretion has not been verified whether it is useful in patients with chronic kidney disease (CKD) as well as in interventional study. The aim is to evaluate the estimated sodium excretion in prospective low salt diet education study (ESPECIAL) cohort.

Methods: New formula was developed from baseline data of 228 CKD patients of ESPECIAL cohort using a multivariate linear regression and compared with previous three formulas from healthy population (Kawasaki, INTERSALT, Tanaka) and one from CKD patients (Nerbass) for the prediction of 24 hour sodium excretion after ARB treatment and low salt diet education.

Results: Among previous reported formulas, the estimation by Tanaka's formula showed the smallest bias (estmated 144.3±46.5 vs. measured 154.1±69.6 mEq/day), but weak correlation (r=0.34). We developed new formula with improved bias (estimated 154.0±39.7 mEq/day) and correlation (r=0.56). New formula also showed the best correlation (r=0.57) with smallest bias (estimated ± mEq/day) even after ARB treatment, which did not showed significant change of measured sodium excretion(156.3±70.6 mEq/day). Intensive low salt diet education elicited the significant decrease of measured sodium excretion (121.2±59.4 mEq/day). Although new formula also showed best correlation, any of formulas did not predict the amount of the decrease of measured sodium excretion.

Conclusions: We developed more reliable formula for estimating urine sodium excretion for CKD patients. However, our data suggests estimated sodium excretion could be applied for epidemiological study rather than low salt intervention study.

SA-PO692

Evaluation of Glycated Albumin for Glycemic Monitoring in Diabetic Nephropathy Yang Fei, Ying Fan, Yumei Liu, Niansong Wang. *Dept of Nephrology and Rheumatology, Shanghai Jiaotong Univ Affiliated the Sixth Hospital, Shanghai, China.*

Background: Glycated albumin(GA) has been now widely used for the evaluation of blood glucose in diabetic nephropathy(DN) patients. However, the effect of proteinuria on GA should be taken into account, especially in patients with advanced DN.

Methods: A total of 621 diabetic nephropathy patients from year 2009 to 2014 were enrolled in the study. According to the 24h urinary protein(UP) output, subjects were divided into 3 groups defined as (1) microalbuminuia: UP=30-300mg/24h, (2) moderate albuminuria: UP=300-1000mg/24h, (3) macroalbuminuia: UP>1000mg/24h).

Results: In all DN patients, the related factors of GA were fasting blood glucose(FBG), postprandial blood glucose(PBG), body mass index (BMI) and 24h UP. The multivariate regression equation was GA = 0.254FBG + 0.347PBG-0.341 BMI-1.306UP, (R2=0.375). There was no correlation between GA and 24h UP in DN patients with micro or moderate albuminuria. However, GA was found to be much lower and negatively correlated with 24h UP in DN patients with macroalbuminuria. Therefore, adjusted GA (adjGA) was applied for those subjects, taking 24h UP, serum albumin (SA) and the ratio of normal albumin metabolism days to total albumin metabolism days into account. adjGA=mGA×(1+3.75×UP/SA). As a result, GA value was increased after adjustment in DN macroalbuminua group. The adjGA was also found only correlated with FBG and PBG, and had no relation with 24h UP and SA.

Conclusions: In diabetic nephropathy patients, blood glucose, serum albumin and 24h urinary protein output may serve as important factors for the evaluation of GA on glycemic level. GA tended to be underestimated in DN patients with macroalbuminuria. The adjGA may be a better way to objectively evaluate glycemic status in patients with advanced DN.

SA-PO693

Fat Mass, Lean Body Mass and Serum Filtration Markers in Adults in the United States: The National Health and Nutrition Examination Survey (NHANES) Meredith C. Foster,[1] Julie K. Bower,[2] Josef Coresh,[3] Roger A. Fielding,[4] Lesley Inker,[1] Andrew S. Levey.[1] *[1]Tufts Medical Center; [2]The Ohio State Univ; [3]Johns Hopkins Univ; [4]Tufts Univ.*

Background: Established serum filtration markers are influenced by body composition (creatinine by muscle mass, cystatin C by fat mass) but limited data exist evaluating associations of these markers with body composition assessed using a gold-standard measurement approach. Our aim was to examine the association of body composition quantified using dual energy X-ray absorptiometry (DXA) with serum creatinine and cystatin C in US adults.

Methods: We conducted a cross-sectional analysis in 4378 adults age 18+ years from NHANES 1999-2002. Body composition included total lean mass and total fat mass; body mass index (BMI, kg/m^2) was included for comparison. Associations of natural log-transformed creatinine and cystatin C with body composition measures were evaluated using multivariable linear regression, stratified by age. Analyses were weighted to account for the NHANES design with multiple imputation for missing DXA data.

Results: Lean mass was associated with higher serum creatinine in in all age groups whereas higher fat mass was associated with higher creatinine in adults age 65+ (**Table**). Lean mass and fat mass were associated with higher serum cystatin C across all age groups; associations of lean mass with cystatin C were not significant with additional adjustment for fat mass.

Table: Association of body composition with serum creatinine and cystatin C by age group, NHANES 1999-2002

	Ln(Creatinine)		Ln(Cystatin C)	
	Beta	p-value	Beta	p-value
Age 18-39 (48% women; mean age 29 yrs, lean mass 50.9kg, fat mass 25.4kg, BMI 26.8kg/m^2)				
Fat Mass (per 5 kg)	-0.006	0.08	0.014	<0.001
Lean Mass (per 5 kg)	0.010	0.03	0.017	<0.001
BMI (per 5 kg/m^2)	-0.007	0.3	0.027	<0.001
Age 40-64 Years (52% women; mean age 50 yrs, lean mass 51.5kg, fat mass 29.5kg, BMI 28.7kg/m^2)				
Fat Mass (per 5 kg)	-0.002	0.6	0.025	<0.001
Lean Mass (per 5 kg)	0.009	0.02	0.024	<0.001
BMI (per 5 kg/m^2)	-0.003	0.7	0.043	<0.001
Age 65+ Years (58% women; mean age 74 yrs, lean mass 45.5kg, fat mass 28.4kg, BMI 27.7kg/m^2)				
Fat Mass (per 5 kg)	0.009	0.05	0.024	<0.001
Lean Mass (per 5 kg)	0.021	0.002	0.022	0.002
BMI (per 5 kg/m^2)	0.024	0.006	0.048	<0.001

Note: Models adjusted for age, sex, and race/ethnicity. Abbreviations: BMI, body mass index; SE, standard error. Unweighted N by age group: 18-39, N=953; 40-64, N=1435; 65+ N=1990

Conclusions: Fat mass and lean mass are differentially associated with creatinine and cystatin C in US adults. Findings in younger adults suggest that observed associations may reflect the impact of body composition rather than kidney function on serum marker levels. Further work is needed to determine how the observed associations are influenced by GFR and body composition simultaneously and the impact of fat and lean mass on CKD prevalence estimates.

Funding: Private Foundation Support

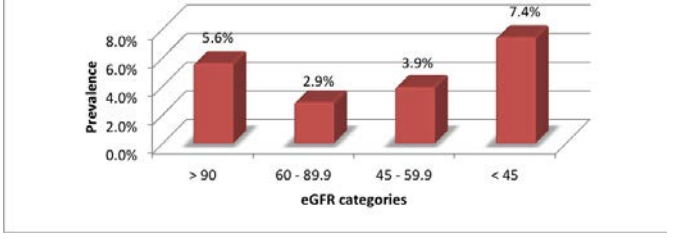
SA-PO694

Associations of the Levels of Kidney Function with Protein-Energy Wasting Syndrome Are Independent of Serum CRP and Bicarbonate Xiaorui Chen,[1] G. Wei,[1] Robert E. Boucher,[1] Dominique Ferranti,[1] Michel Chonchol,[3] Kalani L. Raphael,[1] Srini Beddhu.[1,2] *[1]U of Utah; [2]VA SLC; [3]UC Denver.*

Background: Inflammation and metabolic acidosis are putative causative factors of protein-energy wasting (PEW) in CKD. Therefore, we examined whether serum CRP and bicarbonate levels attenuate the associations of CKD with PEW in 11,834 adult (age > 20 yrs) participants in the 1999-2004 National Health and Nutrition Examination Survey (NHANES).

Methods: PEW syndrome was defined as the presence of at least one criterion in two out of three categories: serum chemistry (albumin < 3.25 g/dl or cholesterol < 100 mg/dl), body weight (BMI < 20 kg/m^2 or unintentional wt loss > 10% over 1 yr), and muscle mass (body fat % < 10% or MAMC < 10% of 50th percentile of reference population). Using eGFR 60 to 89 ml/min/1.73 m^2 as the reference, the odds of PEW in ≥ 90, 45-59 and < 45 ml/min/1.73 m^2 groups were examined in logistic regression models using svy suite in STATA 13.

Results: Mean age was 46.0 yrs, 50.3% were male, 9.5% were black. The prevalence of PEW syndrome had a U shaped association with the level of kidney function.



Compared to the reference group, both eGFR ≥ 90 and < 45 groups had nearly two-fold increased odds of PEW. This was not attenuated after adjusting for serum CRP or bicarbonate.

eGFR (ml/min/1.73m^2)	PEW syndrome OR (95% CI)	
	Model 1*	Model 2§
60 – 89.9	Ref	Ref
≥ 90	1.95 (1.41, 2.68)	1.86 (1.36, 2.55)
45 – 59.9	1.11 (0.70, 1.76)	1.17 (0.72, 1.90)
<45	2.09 (1.05, 4.13)	2.33 (1.10, 4.97)

* adjusted for age, gender, race, education, smoking, alcohol use, MI, CHF, stroke, diabetes, lung disease and cancer
§ Above + serum CRP and serum bicarbonate

Conclusions: PEW syndrome is highly prevalent in those with lower kidney function. This appears independent of inflammation and serum bicarbonate. Further studies are warranted to determine the mechanism of PEW syndrome in the CKD population.

Awareness and Perceived Risk of CKD Among African American Patients with CKD Raquel C. Greer,[1] Yang Liu,[1] Jessica M. Ameling,[1] Deidra C. Crews,[1] Patti Ephraim,[1] Lisa A. Cooper,[1] L. Ebony Boulware.[2] *[1]Johns Hopkins Univ; [2]Duke Univ.*

Background: African Americans (AAs) are disproportionately affected by CKD with greater prevalence of advanced disease and poorer control of CKD risk factors. Patients' awareness of CKD may facilitate engagement in self-management behaviors to modify CKD risks.

Methods: As part of a baseline assessment for a randomized controlled trial, we characterized CKD awareness and perceived risk of CKD among AAs with uncontrolled hypertension and CKD (eGFR 15-60 ml/min/1.73m^2 or UACR^{3}30mg/g). We assessed patients' self-reported CKD awareness ("Do you have a kidney problem or chronic kidney disease?"; yes or no response) and degree of perceived likelihood ("How likely do you think it is that you could develop kidney problems or kidney failure in the next 10 years?"; not likely versus slightly, moderately, or very likely response) and perceived concern of developing CKD ("How concerned are you about developing kidney problems in the next 10 years?"; not concerned versus slightly, moderately, or very concerned response). We constructed multivariable models to assess patient characteristics independently associated with patients' CKD awareness and perceived CKD risks.

Results: Among 52 AA patients with CKD, the mean age was 58 years, 67% were female, 67% had diabetes, 15% had coronary artery disease, 40% had eGFR<60 and 60% had albuminuria alone. The majority (n=37, 71%) of patients were not aware of their CKD. Among these, 27% (n=10) considered themselves unlikely to develop CKD and 19% (n=7) were not concerned about developing CKD. CKD awareness was greater among patients with an eGFR<60 (vs. eGFR≥60) (adjusted percentages (AP) [95% CI]: 50% [19-81%] and 19% [reference], respectively; p=0.05. Conversely, patients with diabetes reported less CKD awareness than those without diabetes (AP [95% CI]: 53% [reference] and 10% [2-38%], respectively; p=0.008). Perceived risk of CKD did not vary by patient characteristics.

Conclusions: Among AA patients with uncontrolled hypertension and CKD, awareness of CKD was low, with some patients unconcerned about developing CKD in the future. Strategies to improve recognition of CKD risks among AAs at high CKD risk are needed.

SA-PO696

Discussions About CKD Between African Americans with High CKD Risks and Their Primary Care Physicians Raquel C. Greer,[1] Debra L. Roter,[1] Yang Liu,[1] Jessica M. Ameling,[1] Deidra C. Crews,[1] Patti Ephraim,[1] Lisa A. Cooper,[1] L. Ebony Boulware.[2] *[1]Johns Hopkins Univ; [2]Duke Univ.*

Background: Routine primary care visits provide an important opportunity for primary care physicians (PCPs) to discuss CKD risk modification with patients at high risk, but the frequency of patient-physician discussions about CKD is unknown.

Methods: In a randomized controlled trial of African American (AA) patients with uncontrolled hypertension, we analyzed audio-recorded encounters between patients and their PCPs using the Roter Interaction Analysis System to characterize the occurrence of CKD discussions (e.g., discussion of kidney disease, eGFR, creatinine, or albuminuria) and patient-physician communication patterns (e.g., patient-centeredness, the degree to which the discussion focused on the patient's psychosocial and lifestyle context) during routine primary care visits. In multivariable logistic regression models, we assessed patient, visit, and communication characteristics independently associated with the presence of CKD discussions among all patients and among those with CKD (eGFR<60ml/min/1.73m^2 or UACR^{3}30mg/g).

Results: Among 124 patients, the mean age was 58 years, 69% were female, 48% had diabetes, 35% had CKD (mean eGFR 83). The average visit length was 22 minutes. Patients and PCPs discussed CKD in 47% of visits and discussions more frequently occurred among patients with CKD (vs. without CKD) (66% and 36% respectively, p=0.002). Discussions were less common [Odds Ratio (95% CI)] in visits of patients ≥ age 60 (vs. <60) [0.3 (0.1-0.8)] or with higher eGFR [0.96 (0.95-0.98), per ml/min/1.73m^2], and more common when visits were more (vs. less) patient-centered [2.4 (1.0-5.8)] or when diabetes was (vs. was not) discussed [3.7 (1.5-9.4)]. Patient gender, comorbid disease, and visit length did not predict discussions. Among patients with CKD (n=44), CKD discussions were also less common among patients ≥ age 60 [0.1 (0.2-0.9)] or with higher eGFR [0.96 (0.92-1.0)].

Conclusions: AA patients at high risk of CKD and their PCPs discussed CKD in fewer than half of routine primary care visits. Efforts to improve the occurrence of CKD discussions during routine primary care encounters are needed.

SA-PO697

Primary Care Utilization Is Associated with Reduced Mortality Among Older Adults With CKD Raquel C. Greer,[1] Hsien-Yen Chang,[1] Gerard Fenton Anderson,[1] Bernard G. Jaar,[1] Craig Pollack,[1] Nae-Yuh Wang,[1] Lawrence J. Appel,[1] L. Ebony Boulware.[2] *[1]Johns Hopkins Univ; [2]Duke Univ.*

Background: Routine primary care visits provide opportunities to identify and manage patients' CKD risk factors and to provide preventative care. It is unclear how primary care utilization impacts clinical outcomes among older adults with CKD.

Methods: We quantified the association between primary care utilization and ESRD incidence or mortality among older US adults with CKD (in 2005-2006) using Medicare claims. We assessed (in 2006) patients' primary care utilization (no visit vs. at least one), other care utilization (nephrology care [no visit vs. at least one], the total number of ambulatory evaluation and management (E &M) visits with any type of provider), and patients' comorbid conditions and sociodemographics. We used standard and cause-specific (accounting for competing risk of death) Cox proportional hazard models overall and stratified by age (65-74, 75-84, or ≥ 85 years) to estimate hazard ratios (HRs) for ESRD or mortality.

Results: Among 106,765 patients, most (79%) had at least one primary care visit in 2006, and 21% had at least one nephrology visit. The median number of ambulatory E&M visits was 10. Compared to patients with no primary care visits, patients with at least one visit were younger (78 vs. 80 mean years, p<0.001), less likely African American (10 vs. 14%, p<0.001), and had a greater prevalence of diabetes (46 vs. 42%, p<0.001), hypertension (88 vs. 78%, p<0.001), or coronary artery disease (74 vs. 72%, p<0.001). Over 4 years of follow-up, 4,264 patients developed ESRD and 45,059 died. Primary care utilization was not associated with ESRD incidence. However, compared to patients with no primary care visits, patients with at least one visit had a lower risk of death [HR (95%CI): 0.73 (0.72-0.75)] overall and in age stratified models.

Conclusions: Primary care utilization was not associated with lower ESRD risk, but it was associated with a lower risk of death among older adults with CKD. Efforts to improve the engagement of primary care providers in the care of patients with CKD represent an important strategy to improve the health of this high risk population.

SA-PO698

Routine Use of Health Care Among High-Risk African Americans at Risk of CKD Clarissa Jonas Diamantidis,[1] Nrupen Anjan Bhavsar,[1] Julia J. Scialla,[1] Clemontina A. Davenport,[1] Rasheeda K. Hall,[1] Crystal C. Tyson,[1] Mario Sims,[3] Tara Smith Strigo,[1] Neil R. Powe,[2] L. Ebony Boulware.[1] *[1]Medicine, Duke Univ, Durham, NC; [2]Medicine, UCSF, San Francisco, CA; [3]Medicine, Univ of Mississippi Medical Center, Jackson, MS.*

Background: Engagement in routine health care (RHC) is a key strategy to decrease health inequities among African Americans (AAs) at high risk of developing CKD or CKD complications. We examined demographic, attitudinal and socio-cultural factors associated with RHC among high-risk AAs at risk of CKD incidence or progression.

Methods: We quantified the prevalence of RHC (physical exam <1 year prior) use among AA Jackson Heart Study (JHS) baseline participants (from 2000-2004) with hypertension (HTN) or diabetes. We identified demographic, attitudinal (e.g., perceived discrimination, anger and hostility, stress, trust in health providers) and educational (i.e., CKD awareness) factors independently associated with RHC use. Those missing demographic or attitudinal data were excluded.

Results: Of 5301 JHS participants, 1152 met inclusion criteria. Most (n=909, 79%) reported RHC use. Rates of RHC were similar in those with and without CKD (22% vs. 23%). Participants not using RHC (vs. using) were more likely to be < 55 years of age (51% vs 37%), male (43% vs. 30%), without HTN (9% vs. 5%), tobacco users (38% vs. 29%), and uninsured (14% vs. 9%), all p<0.05. Participants not using RHC less frequently reported trust in their health provider (80% vs. 95%), more frequently reported difficulty obtaining health services (17% vs. 8%), and less frequently reported provider satisfaction (91% vs. 98%), all p<0.05. In multivariable models, not using RHC was associated with age <55 (OR 1.75 [95% CI 1.25-2.5], male sex (OR 1.55 [1.12-2.16]), < HS diploma (OR 1.63 [1.12-2.34]), no HTN (OR 2.14 [1.13-4.1]), lower provider trust (OR 3.27, [1.61-6.65]) and less anger and hostility (OR 1.53, [1.1-2.1]).

Conclusions: Among high-risk AAs in the JHS, younger participants and males were less likely to use RHC. Those with low trust were also less likely to use RHC. Efforts to address health risks among high-risk AAs should target those using less RHC and consider attitudinal barriers to RHC.

SA-PO699

Development of a Question Prompt Sheet for Patients with Chronic Kidney Disease Swati Lederer,[1,2] Michael J. Fischer,[1,2] Howard S. Gordon,[1,2] Anuradha Wadhwa,[2] Subhash Popli,[2] Elisa J. Gordon.[2,3] *[1]Jesse Brown VAMC and Univ of Illinois, Chicago, IL; [2]Hines VA Hospital, Hines, IL; [3]Northwestern Univ, Chicago, IL.*

Background: Patients with chronic kidney disease (CKD) commonly have unmet information needs. Greater patient participation in healthcare discussions can address these needs, and is associated with improved health outcomes. A question prompt sheet (QPS), a list of questions to prompt discussion, has been shown to increase patient participation in other chronic disease discussions; however, no QPS has been developed for CKD patients.

Methods: We conducted a 2-phase cross-sectional study involving semi-structured telephone interviews to develop a QPS targeted to patients with moderate CKD. Patients with an estimated glomerular filtration rate <60ml/min/1.73m^2, on dialysis, or with a transplant were recruited from a single VA nephrology clinic. Phase 1 interviews included 17 open-ended questions assessing patients' CKD information needs. Responses were qualitatively analyzed to generate an initial 67-item QPS. Phase 2 participants reviewed a pre-mailed QPS to rate the importance of asking each question on a 5-point Likert scale, provide open-ended feedback, and rate their willingness to use a CKD-QPS. Question item responses were analyzed to refine and reduce QPS questions.

Results: A total of 76 patients completed interviews (phase 1: n=32, phase 2: n=44). Most were male (96%), non-Hispanic white (68%), and mean age was 66 years. Patients desired more information about CKD, particularly regarding self-care techniques, dialysis/transplant, and CKD complications. The final QPS tool included 37-questions divided into 10 CKD subtopics (i.e., CKD definitions, causes, impact, monitoring, labs, self-care, treatment, dialysis, transplant, managing comorbid conditions). Most patients (91%) reported being 'completely' or 'very' willing to use a CKD-QPS in future doctor visits.

Conclusions: CKD patients have unmet information needs and wish to use a CKD-QPS. Further research is needed to assess whether our CKD-QPS effectively addresses patients' information needs, enhances doctor-patient communication, and improves health outcomes.

SA-PO700

Medication Burden and Safety in Veterans with Chronic Kidney Disease

Swati Lederer,[1,2] Michael J. Fischer,[1,2] Zhiping Huo,[2] Katie Suda,[2] Kevin Stroupe.[2] *[1]Jesse Brown VAMC and Univ of Illinois Hospital, Chicago, IL; [2]Hines VA Hospital, Hines, IL.*

Background: Veterans are at exceptionally high risk for chronic kidney disease (CKD) and other chronic health conditions. Pharmacologic treatments are a core aspect of CKD disease management. We characterized medication burden and safety and their relationship to CKD severity among elderly Veterans.

Methods: Using national VA databases, we included all female and a random 10% sample of male VA healthcare users who were >65 years old. We characterized the average number of medications, frequency of contraindicated medications, and occurrence of concerning drug-drug interactions. CKD was defined by estimated glomerular filtration rate (eGFR) in 2008 and classified according to conventional eGFR-based severity groups. A non-CKD comparison was used (eGFR >=60 ml/min/1.73m^2). Medications were identified in calendar year 2009 from VA utilization data and Medicare Part D claims.

Results: Among a final cohort of 96,317 Veterans, 47% had CKD (mean age=79.8, male=81%, non-black=93%, hypertensive=90%, diabetic=33%). Mean medication number increased with CKD severity: 8.5(eGFR >=60), 9.6 (eGFR 30-59), 11.7 (eGFR15-29), 12.5 (eGFR <15). After adjusting for demographic characteristics, CKD stage 3, 4, and 5 took 1.3, 3, and 3.6 more medications, respectively, compared to the non-CKD group (p-value<0.0001). Contraindicated medications were often prescribed to patients with an eGFR<30ml/min/1.73m^2 and included bisphosphonates (5%) and nonsteroidal anti-inflammatory drugs (4%). Concerning drug-drug interactions with an eGFR<60ml/min/1.73m^2 included: sedatives-opioids (3.8%), ace inhibitor-angiotensin receptor blocker (1.6%), statins-diltiazem or verapamil (5.1%).

Conclusions: Greater severity of CKD was independently associated with an increasing number of medications among elderly Veterans. Medications that were contraindicated in CKD and concerning drug-drug interactions were commonly prescribed. Increased awareness and interventions are needed to improve medication management and safety in Veterans with CKD.

Funding: Veterans Administration Support

SA-PO701

Illicit Drug Use and Chronic Kidney Disease in an Urban Population

Tessa Kimberly Novick,[1] Anika Alvanzo,[1] Yang Liu,[1] Alan B. Zonderman,[2] Deidra C. Crews.[1] *[1]Johns Hopkins Univ, Baltimore, MD; [2]National Inst on Aging, NIH, Baltimore, MD.*

Background: Opioid and cocaine use have been associated with risk of ESRD in retrospective studies, however, the association of illicit drug use with chronic kidney disease (CKD) has not been well-examined in prospective studies. Our objective was to determine the association of illicit drug use with reduced kidney function, albuminuria and rapid kidney function decline (KFD) among a cohort of urban-dwelling adults.

Methods: Our study included 2,286 Healthy Aging in Neighborhoods of Diversity across the Life Span (HANDLS) study participants who are community-dwelling African American and white adults from 12 neighborhoods in Baltimore MD. We used logistic regression to examine whether opioid or cocaine use (defined as ≥ 5 lifetime uses of either drug) was associated with baseline reduced eGFR (<60 ml/min/1.73m^2 by CKD-EPI), baseline albuminuria (albumin-to-creatinine ratio >30mg/g) or rapid KFD (eGFR decline of >3% per year over a median of 4.7 years of follow up).

Results: Participants' mean age was 48 years, 57% were African American, 15% reported opioid use, and 22% reported cocaine use. Those reporting illicit drug use (opioid or cocaine) were more likely to be male, African American, living in poverty and/or uninsured; and tobacco use, problem drinking, and hepatitis B and/or C infection were more prevalent among illicit drug users than non-users (P <0.01 for all variables). Our adjusted models included those variables above, and age, diabetes and hypertension. A total of 5.3% of illicit drug users had reduced eGFR compared to 5.0% of non-users (NS). A total of 5.9% of illicit drug users died during follow-up compared to 3.8% of non-users (P 0.03).

Outcome	N for analysis	N events	Opioid Users vs Non Opioid Users Adjusted Odds Ratio (95% CI)	Cocaine Users vs Non Cocaine Users Adjusted Odds Ratio (95% CI)
Reduced eGFR	2286	115	2.7 (1.5, 4.9)	1.4 (0.9, 2.3)
Albuminuria	1652	190	1.2 (0.8, 1.7)	1.8 (1.3, 2.5)
Rapid KFD	1665	245	0.9 (0.6, 1.3)	0.9 (0.7, 1.3)

Conclusions: Illicit drug use was associated with prevalent reduced eGFR and albuminuria, but not rapid KFD. Illicit drug use may be an important risk factor for CKD in urban populations.

A Tailored, Interactive Mobile Health Communication Application for Patients with Chronic Kidney Disease: Development and Feasibility Assessment

Yali Cao. *Nephrology, China-Japan Friendship Hospital, Beijing, China.*

Background: Chronic kidney disease (CKD) is an increasingly common chronic condition whose prognosis can be improved by patient involvement and self-management. Patient involvement can be fostered by web-based Interactive Mobile Health Communication Applications (IMHCAs) combining health information with decision support, social support and/or behavior change support. Tailoring content and tone of IMHCAs to the individual patient's needs might improve their effectiveness.

Methods: A tailored, IMHCAs was developed by collaborative profession (nephrologist, nurse, research fellow, web developer). The effectiveness and usage of the tailored IMHCA were tested against the control arm without access to this IHCA in a small–scale single-blinded randomized trial. The content covers information on CKD, its complications and sequelae, and its treatment options including health behavior and dietary guidance. In the intervention group the content is delivered in dialogue form, tailored to relevant patient characteristics (the stage of CKD and the Etiology). Eighty patients (forty patients at each arm) with stage 3-5 CKD were enrolled in the study. The data were collected directly after the first visit, and at 3-month follow-up.

Results: There were no difference between the two groups as to the age, gender, CKD stage and blood pressure. Three months after system use, participants using the tailored system displayed significantly more knowledge(P=0.001), better blood pressure compliance rate (P=0.02) and improved dietary behavior, mainly regarding low protein and enough calories (P=0.003).

Conclusions: This is the first tailored IMHCAs in China. Our data demonstrated that implementation of IMHCAs into standard practice is feasible.Suggested developments will augment reported strengths to inform ongoing testing in the wider China network of units.

SA-PO703

Evaluation of Clinical Pharmacy Services in the Management of Kidney Disease

Calantha K. Yon, Chai L. Low. *Pharmacy, Veterans Affairs San Diego Healthcare System, San Diego, CA.*

Background: Chronic kidney disease (CKD) and end stage renal disease (ESRD) place a significant burden on healthcare systems and is the focus of national health initiatives. Management of CKD requires a multidisciplinary approach to maximize outcomes. Studies support the impact of clinical pharmacists (CP) in medication management, but studies demonstrating the significance of a CP as part of a multidisciplinary approach to management of AKI and CKD/ESRD are lacking. This study evaluates the effectiveness of pharmacy services in the setting of a multidisciplinary approach to the management of AKI and CKD/ESRD.

Methods: Interventions by a CP in the inpatient setting were collected from 12/1/2010 to 11/1/2011 as part of Nephrology Consults. Interventions were categorized as: drug interaction, dose/frequency adjustment, untreated diagnosis, adverse reactions, duplication of therapy, and other. Cost avoidance from these interventions were calculated. Outpatient pharmacy patient encounters were monitored from 1/1/2008 to 12/31/2014 as patient visits or interventions in hemodialysis (HD), peritoneal dialysis (PD), erythropoietin stimulating agent (ESA) clinic, and renal access clinic. CPs were involved in the management of anemia, hypertension, immunizations, mineral bone disease, transplant, dialysis related infections, pharmacokinetic drug monitoring, medication reconciliation and patient counseling.

Results: Most of the 440 inpatient interventions were dose adjustments for renal function and medication therapy for untreated diagnoses during AKI. Inpatient interventions by a CP resulted in $706,911 in cost avoidance. HD and PD encounters by a CP increased from 241 in 2008 to over 1,400 since 2011. Patient visits in the ESA/anemia clinic increased from 185 in 2008 to near 300 in 2014. Encounters in the renal access clinic increased from 19 in 2008 to near 300 in 2014.

Conclusions: The expansion of pharmacy services in nephrology at Veterans Affairs San Diego Healthcare System has resulted in the improvement in the quality of care provided to patients with AKI, CKD or ESRD with significant cost avoidance. Clinical pharmacists play a significant role in the multidisciplinary approach to the management of CKD/ESRD.

SA-PO704

Views and Practice Patterns of Dialysis Medical Directors Towards End-of-Life Decision Making for Patients with End-Stage Renal Disease
Enrica Fung,[1] Nathan Samuel Slesnick,[2] Manjula Kurella Tamura,[1,3] Brigitte Schiller.[2] *[1]Stanford Univ, Palo Alto, CA; [2]Satellite Healthcare, San Jose, CA; [3]Geriatric Research and Education Clinical Center, Veterans Affairs, Palo Alto, CA.*

Background: Nephrologists frequently engage in end-of-life decision making for patients with end-stage renal disease (ESRD). Patients with ESRD report infrequent end-of-life discussions and nephrology trainees report feeling unprepared for end-of-life decision making, but the views of dialysis medical directors have not been studied. Our objective is to understand dialysis medical directors' views and practice patterns on end-of life decision making for patients with ESRD.

Methods: We administered questionnaires to dialysis medical directors during medical director meetings of three different dialysis organizations in 2013. Survey questions corresponded to recommendations from the Renal Physicians Association clinical practice guidelines on initiation and withdrawal of dialysis.

Results: There were 121 medical director respondents from 28 states. The majority of respondents felt "very prepared" (66%) or "somewhat prepared" (29%) to participate in end-of-life decisions and most (80%) endorsed a model of shared decision-making. If asked to do so, 70% of the respondents provided prognostic information "often" or "nearly always". For patients with a poor prognosis, 36% of respondents would offer a time-limited trial of dialysis "often" or "nearly always", while 56% of respondents would suggest withdrawal from dialysis "often" or "nearly always" for those with a poor prognosis currently receiving dialysis therapy. Patient resistance and fear of taking away hope were the most commonly cited barriers to end-of-life discussions.

Conclusions: Views and reported practice patterns of medical directors are consistent with clinical practice guidelines for end-of-life decision making for patients with ESRD but inconsistent with patient perceptions.

Funding: NIDDK Support

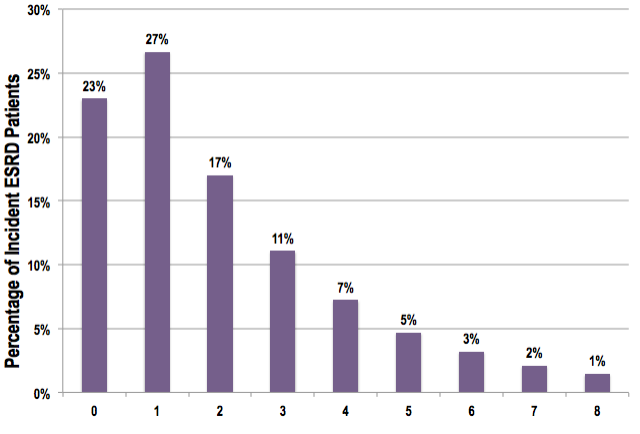
SA-PO705

Emergency Department Utilization Among United States ESRD Patients
Brendan P. Lovasik, Rebecca H. Zhang, Taylor A. Melanson, Stephen O. Pastan, Rachel E. Patzer. *Emory Univ, Atlanta, GA.*

Background: Single center studies suggest that ESRD patients have a high rate of emergency department (ED) utilization, with 0.9-2.4 ED visits/patient-year. Prior studies show that ESRD is a stronger risk factor for ED use than heart failure, lung disease, or cancer. However, ED utilization among a national ESRD patient population has not been examined.

Methods: We examined a cohort of 788,162 incident adult ESRD patients in the United States Renal Data System from 2005-2011. ED utilization was identified using CPT codes 99281-5 (Severity Levels 1-5) and 99291 (Critical Care) by American College of Emergency Physicians guidelines. ED and hospital admission, diagnosis, and procedures were obtained from the USRDS and Medicare Physician/Supplier and Inpatient databases for Medicare Part A/B claims.

Results: In the first year of ESRD diagnosis, 1,143,372 ED visits were observed for 480,176 unique ESRD patients. 77% of ESRD patients used the ED within the first ESRD year at an average of 2.69 ED visits/patient-year. The national range was 1 to 172 ED visits per year with median 2 visits (interquartile range 1-4 visits) and 95th percentile 8 visits.



The top 5% of patients accounted for 80.4% of ED visits, and 7 patients utilized the ED over 100 times in their first ESRD year. Nearly half (46.0%) of ED visits were coded as a Severity Level 5, with 9.6% coded as Critical Care emergencies. 15.4% of ESRD patients in the ED were admitted to the hospital, with vascular access infection, pneumonia, and congestive heart failure as most common indications.

Conclusions: This study is the first to our knowledge to describe ED utilization in a national sample of ESRD patients. Compared to the national average, ESRD patients have higher ED use (2.69 vs. 0.4) and hospital admission rates (15.4 vs. 11.9%). Comprehensive understanding of ED utilization will aid development of outpatient and ED interventions.

SA-PO706

Impact of Evidence-Based Clinical Care on Major Adverse Clinical Events in Patients with Clinically Significant Proteinuria: A Population-Based Retrospective Cohort Study
Julius Oluoch Okel,[1] Bilal Qarni,[1] Timothy Olusegun Olanrewaju,[2] Aminu K. Bello.[1] *[1]Univ of Alberta; [2]Univ of Ilorin, Nigeria.*

Background: Proteinuria is an important prognostic marker for cardiovascular (CV) and renal events. Most studies of quality of care (QoC) in chronic kidney disease (CKD) have focused on other markers for risk stratification and outcomes. We hypothesized that in proteinuric CKD, markers of good quality care will be associated with lower risk of adverse clinical outcomes (all-cause mortality, all-cause hospitalization, CV and renal outcomes).

Methods: We used a population-based cohort of patients with significant proteinuria (albumin:creatinine ratio (ACR) ≥60 mg/mmol, protein:creatinine ratio (PCR) ³100 mg/mmol or protein ³3+ on dipstick) to evaluate current patterns of evidence-based care and association with outcomes. Markers of good quality care were defined as nephrology referral, relevant laboratory testing and appropriate medication use (ACEi/ARBs; statins). Participants were followed from their index date until March 2009 for outcomes of all-cause mortality, hospitalization, CV and renal events.The associations between quality of care markers and outcomes were estimated using Cox proportional hazards models.

Results: Of the 71, 660 with atleast 1 or 2 proteinuria measurements, 16,204 (22.6%) had significant proteinuria. At follow-up, receipt of good quality care [1) timely referral, 2)HbA1c testing, 3)use of ACEi/ARBs and 4) use of statins] was associated with reduced risk of mortality: 0.67 (0.59-0.75), 0.52 (0.46-0.59), 0.68 (0.62-0.74), and 0.63 (0.57-0.69), and all-cause hospitalization: 0.85 (0.69-0.93), 0.65 (0.59-0.72), 0.93 (0.87-0.99), and 0.82 (0.77-0.88) respectively. There were no statistically significant associations with the risk of CV and renal events.

Conclusions: This study examined the link between evidence-based treatment and clinical outcomes in an especially high-risk population with CKD. Good quality care impact on mortality risk and reduced risk of hospitalization. The impact of QoC on renal and cardiovascular events is less clear. The findings would justify future interventions to increase uptake of such treatments in patients with proteinuric CKD.

SA-PO707

***APOL1* Risk Alleles and Risks of Cardiovascular Disease in Children with Focal Segmental Glomerulosclerosis (FSGS)**
Robert Woroniecki,[1] Derek Ng,[2] Sophie Limou,[3] Cheryl Ann Winkler,[3] Kimberly J. Reidy,[4] Mark Mitsnefes,[5] Craig S. Wong,[6] Bradley Warady,[7] Susan L. Furth,[8] Jeffrey B. Kopp,[9] Frederick J. Kaskel.[4] *[1]Stony Brook Children's Hospital, Stony Brook, NY; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, NY; [3]NCI, NIH, FNL, Frederick, MD; [4]Einstein/Children's Hospital at Montefiore, Bronx, NY; [5]Cincinnati Children's Hospital, Cincinnati, OH; [6]Univ of New Mexico, Albuquerque, NM; [7]Children's Mercy Hospital, Kansas City, MO; [8]Univ of Pennsylvania, Philadelphia, PA; [9]NIDDK, NIH, Bethesda, MD.*

Background: APOL1 renal risk alleles are a major cause of glomerular disease in African Americans (AA). It is controversial as to whether individuals with high risk (HR) APOL1 genotypes (2 risk alleles) are at risk for atherosclerotic heart disease, and association with left ventricular hypertrophy (LVH) has not been explored. It is unclear whether children with focal segmental glomerulosclerosis (FSGS) and HR APOL1 are at increased cardiovascular risk.

Methods: Self-identified AA children with FSGS in CKiD study cohort were genotyped for APOL1 renal risk variants: G1 (rs73885319, S342G) and G2 (rs71785313, NY388-389 deletion), and compared to non-AA children with FSGS; none with HR.

Results: Of 79 children with FSGS, 36 were non-AA, and 25 were AA with HR APOL1. Compared to non-AA, children with HR APOL1 developed FSGS at a later age, 11.5 (IQR: 9.5, 12.5) vs 6 (IQR: 2.5, 11) years, p=0.005. There were no differences in GFR, hemoglobin, iPTH, calcium-phosphate product, or CRP. HR APOL1 subjects had a higher prevalence of uncontrolled hypertension (52% vs 28%, p=0.06) and a lower prevalence of nephrotic range proteinuria (13% vs 43%, p=0.02). Subjects with HR APOL1 had higher left ventricular mass index (41 [28, 53] vs 30 [27, 33] g/m2.7, p=0.01) and a higher prevalence of LVH (53% vs 12%, p=0.009) compared to non-AA children with FSGS.

Conclusions: Children with FSGS and HR APOL1 have later onset kidney disease and are at higher risk for cardiovascular disease than non-AA.

SA-PO708

Trends in Burden of Out-of-Pocket Expenses in United States Adults with Kidney Disease from 2002-2011
Mukoso N. Ozieh,[1] Kinfe Gebreegziabher Bishu,[2] Clara E. Dismuke,[2] Leonard Egede.[2] *[1]Nephrology, MUSC; [2]Center for Health Disparities Research, Internal Medicine, MUSC, Charleston, SC.*

Background: High out-of-pocket (OOP) burden negatively impacts healthcare access and outcomes. Studies examining high OOP burden in the general population exists however no studies has examined OOP healthcare burden in people with kidney disease (KD). This study examined trends in high OOP healthcare in people with KD while concurrently evaluating the impact of insurance status and income category on high OOP burden.

Methods: We analyzed 2,966 adults aged 18-64 years with kidney disease using the Medical Expenditure Panel Survey-MEPS. Individuals with KD were identified with Clinical Classification Codes: 156 - nephritis, nephrosis, renal sclerosis; 157 - acute and unspecified renal failure; 158 - chronic renal failure; 160 - calculus or urinary tract and; 161

- other diseases of kidney and ureters. OOP burden was calculated by dividing total family OOP spending on healthcare in a given year by the family's self-reported pretax income for that year. A person with KD is considered to have high OOP burden if the family total OOP spending on healthcare exceeds 10% of the family income. We used t-test to examine the mean changes from the bench mark year (2002/2003) to the subsequent time periods.

Results: Mean annual total family OOP spending was highest for prescription drugs over the years. Compared to the privately and publicly insured, uninsured status in people with KD was associated with high mean annual total family OOP spending. Of the 2,966 adults with KD, 19% faced a high OOP burden from 2002-2011. Overall, the proportion of people with high OOP fell by 10 percentage points from 2002/2003 to 2010/2010. The proportion of poor/near poor people and uninsured with high OOP was as high as 52% and 30% respectively in 2002/2003 but fell to about 25% and 27% respectively in 2010/2011.

Conclusions: Trends in high OOP burden in people with KD has decreased over time however people with kidney disease in the US still experience high OOP burden. Policies to reduce high OOP in people with KD could significantly impact KD outcomes.

SA-PO709

Health Disparities and Increased Risk of Developing End Stage Renal Disease in Patients with Chronic Kidney Disease Alejandro Pepen Romero, Ritika Sharma, Candace D. Grant, Ronak Patel, Monika Wadhwani, Vladimir Liberman, Shanza Mujeeb, Sairah Sharif, Shayan Shirazian, Nobuyuki (Bill) Miyawaki, Joseph Mattana. *Medicine, Winthrop-Univ Hospital, Mineola, NY.*

Background: Health disparities occur in groups of people that experience suboptimal health care based on their social, economic, and/or environmental disadvantage. Identifying how these disparities affect the risk of chronic kidney disease (CKD) progression to end stage renal disease (ESRD) can hopefully lead to a reduction in these health inequities and improve clinical outcomes for all CKD patients. We examined health disparities and the risk of ESRD using patient-specific and community-specific variables.

Methods: We studied a cross-section of 623 patients with stage 3 and 4 CKD and estimated their 2- and 5-year risk of ESRD using the method of Tangri et al. (JAMA 2011; 305:1553–1559). The U.S. Census Bureau Community Survey was used to obtain patient zip code-specific data including percent foreign born, percent below the poverty level, median household income, and percentage graduating high school. We did a multivariable generalized linear analysis on the outcome variables of the 2 and 5 year risk of ESRD.

Results: Lower household income was associated with a higher risk of ESRD at 2 and 5 years ($p<0.05$). There was a trend towards a higher risk of ESRD amongst patients from zip codes with higher poverty rates and lower education levels. Being single, including by divorce and separation but not by being widowed, was associated with a significantly higher risk of ESRD. We also found that patients on Medicaid and patients with private insurance or self pay had a significantly higher ESRD risk compared to those on Medicare.

Conclusions: Our findings suggest that there are substantial health disparities related to CKD and the risk of ESRD. Some of these disparities are patient-specific but others appear to be related to variables associated with the community where they reside. This suggests that evaluation of patient-specific as well as community-specific variables might help to better individualize CKD care and improve our ability to identify and treat the patient at increased risk of developing ESRD.

SA-PO710

Impact of Timely AV Fistula Placement on Resource Utilization After Initiation of Dialysis Edwin J. Anand,[1] Kabir Jalal,[3] Laura L. Argauer,[2] Brian M. Murray,[1] Pradeep Arora,[4] Rocco C. Venuto.[1] *[1]Medicine, SUNY at Buffalo, Buffalo, NY; [2]Computer Task Group, Buffalo, NY; [3]Epidemiology, SUNY at Buffalo, Buffalo, NY; [4]Medicine, VA Medical Center, Buffalo, NY.*

Background: Maintenance dialysis is ideally initiated in the outpatient setting with a permanent access. This requires advance planning and of care between nephrologists, and access surgeons. The costs associated with 'crash' initiation of dialysis is anticipated to be high. In this observational study, we studied the hospitalization rates and costs of care in the 12 months following dialysis initiation between patients who started dialysis in an ideal manner versus sub optimally.

Methods: Claims and laboratory data from a large, regional insurance company covering half a million patients between January 2001 and May 2014 were reviewed. 32,121 patients were identified to have CKD (at least one eGFR <60 ml/min/1.73 m^2). Of these, 422 patients developed ESRD during the observed period. We defined a 'crash' if the first instance of dialysis was in an inpatient setting, provided they had atleast one eGFR value indicative of CKD before their first dialysis. Univariate and multivariate analyses were performed to analyze the effect of 'crash' on hospitalization and costs for 12 months following initial dialysis.

Results: 422 patients were started on dialysis in the above period. 257 patients (61%) had a crash start of dialysis. 86 patients (20%) had a fistula prior to dialysis. Compared to patients who did not crash, patients who crashed were older ($p<0.0001$), had a higher hospitalization rate in the one year period ($p=0.0089$). Multivariate analysis confirmed that patients who crashed had a significantly higher hospitalization rate in the one year following dialysis ($p=0.0067$). Patients with a fistula in place prior to dialysis experienced fewer hospitalizations ($p=0.0377$). Cost in the first year was also higher in patients who had a 'crash' without a fistula ($p=0.0181$). The cost advantage of having a fistula decreased with increasing age (0.0402).

Conclusions: Dialysis 'crash' results in increased morbidity and resource utilization. Coordination of care and timely access creation should reduce hospitalization and costs.

SA-PO711

DASH Diet Accordant Foods in the Homes of Urban African Americans at Risk for CKD Deidra C. Crews,[1] Yang Liu,[1] Edgar R. Miller,[1] Patti Ephraim,[1] Jessica M. Ameling,[1] Kimberly Gudzune,[1] Lisa A. Cooper,[1] L. Ebony Boulware.[1,2] *[1]Johns Hopkins U., Baltimore, MD; [2]Duke U., Baltimore, MD.*

Background: The Dietary Approaches to Stop Hypertension (DASH) diet is recommended for the treatment of hypertension, especially among African Americans (AAs). Many barriers may hinder urban AAs from following the DASH diet, putting them at increased risk of poor health outcomes, including CKD.

Methods: In a randomized trial of urban AAs with uncontrolled hypertension, we assessed (via interview and home inspection) the presence of DASH diet accordant foods and full-sized kitchen appliances needed to prepare DASH meals. We examined factors associated with having DASH diet accordant foods or needed appliances using logistic models adjusted for age, sex, food insecurity (skipping meals due to lack of money), income, literacy, diabetes, obesity, CKD (eGFR<60 or albuminuria) and comorbid disease (Charlson Index).

Results: Among 159 participants, mean age was 57 yrs and 74% were female. Only 14.5% had 5 of the DASH food categories in their homes (fruits, vegetables, low fat dairy, whole grains, plant proteins). Over 80% had full-sized ovens and refrigerators.

DASH Accordant Foods in Home	N (%) Participants
Fresh or frozen vegetables	131 (82%)
Fresh or frozen fruits	93 (58%)
Low fat dairy	48 (30%)
Whole grains	102 (64%)
Plant proteins	129 (81%)

Participants with CKD (vs without) had lower odds of having fresh fruits (adjusted odds ratio, 95% confidence interval: 0.40, 0.18-0.86). Younger age (yr increments) and annual income <$30K (vs ≥$30K) were associated with lower odds of having whole grains (0.96, 0.93-0.99 and 0.28, 0.11-0.72, respectively). Younger age was associated with lower odds of having plant proteins (0.94, 0.90-0.99). Persons with low literacy (<3rd grade level versus higher) had lower odds of having an oven (0.15, 0.04-0.52) and lower odds of a full-sized refrigerator in their homes (0.12, 0.02-0.59).

Conclusions: The homes of urban AAs at high risk for CKD were often lacking either foods or needed appliances required for DASH meals. The lack of these items was associated with CKD, younger age, low income and/or low literacy. Interventions to improve DASH adherence in this high-risk group should consider these factors.

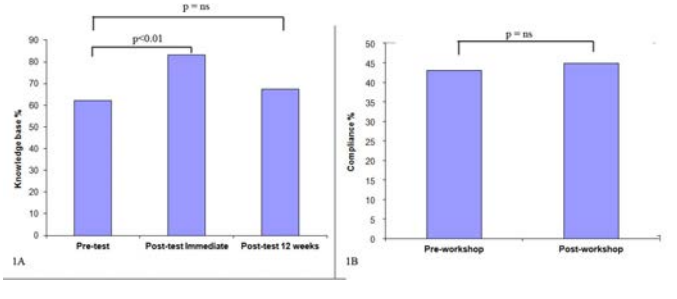
SA-PO712

ABCD of CKD Management Among Internal Medicine Residents: Are Interactive Workshops and Web-Based Tools Useful? Swati Arora, Richard J. Marcus, Khaled Nashar, Bhavna Chopra, Jia Zhang, Gargi Davda, Emad Sedki, James B. Reilly, Kalathil K. Sureshkumar. *Nephrology and Hypertension, Allegheny General Hospital, Pittsburgh, PA.*

Background: Chronic Kidney Disease (CKD) is under-recognized and suboptimally managed especially in primary care setting. We aimed to evaluate the impact of interactive workshops and web-based tools in improving CKD management among internal medicine residents.

Methods: A pre-test assessed knowledge in areas of CKD diagnosis, anemia (A), bone-mineral disease (B), control of BP (C) and degree of proteinuria (D). Interactive workshop on ABCD of CKD lasting 90-minutes was conducted over 5 weeks along with access to self-developed online CKD management resource (www.nephromania.com). Post-test was conducted at workshop conclusion and 12 weeks later. Assessment for post-intervention CKD care improvement was done through chart review.

Results: Among 98 participating residents, 25% utilized the online resource and 62% found it very helpful with majority bookmarking it on smart phones. KDOQI guidelines awareness, recognition of CKD diagnosis and complications were respectively 22%, 70% and 75% on pre-test, 98%, 93% and 90% on immediate post-test ($P<0.001$), declining to 86%, 77% and 74% at 12-weeks. Aggregate scores are shown in Figure 1A. Practice patterns measured through chart-review (n=94) to assess compliance with CKD guidelines over next 3 months failed to show change (figure1B).



Conclusions: Our study showed effectiveness of targeted interactive workshops to improve recognition of CKD and its complications. Intelectualizing the taught concepts by residents did not translate to improved patient care. Declining retention of core concepts at 12-week testing indicates the need for ongoing reinforcement sessions. Continued education including online resourses utilization is warranted as opposed to annual core-lectures provided by most training programs.

SA-PO713

Evaluating Progress of Healthy People 2020 Chronic Kidney Disease Objectives: Are We There Yet? Asel Ryskulova,[1] Lawrence Agodoa,[2] Paul W. Eggers,[2] Kevin C. Abbott.[2] *[1]NCHS, CDC; [2]NIDDK, NIH.*

Background: Chronic Kidney Disease (CKD) is a significant public health problem in the U.S. and a major source of disability, poor quality of life, and premature death for those afflicted. CKD and End-Stage Renal Disease (ESRD), the final stage of the CKD, exact a high economic price. In 2012 ESRD costs exceeded $49 billion dollars including 34 billion (about 20%) of total Medicare expenditures. An estimated 11.5% of adults ages 20 or older had physiological evidence of CKD determined from data collected through the 2001-06 National Health and Nutrition Examination Survey (NHANES). Each year in the United States, more than 115,000 people are diagnosed with ESRD.

Methods: Reflecting the importance of CKD, 24 CKD objectives area were included in the Healthy People 2020 (HP2020) national health goals to reduce new cases of CKD and related complications, disability, death, and economic costs. CKD objectives are focused on improving cardiovascular care in patients with CKD; increasing the proportion of patients with CKD and diabetes who received recommended evaluation and treatment; reducing death rate and percentage of U.S. population with CKD; and increasing CKD awareness in persons with impaired renal function. All CKD objectives are measurable, having at least one data point from national data systems including the NHANES, National Death Index, and U.S. Renal Data System.

Results: In 2015, 14 objectives had met their target (n=9) or showed improvement (n=5). Six objectives showed little or no significant change. Two objectives: increase the proportion of persons with diabetes and CKD who received recommended medical treatment with angiotensin-converting enzyme inhibitors or angiotensin II receptor blockers, and increase the proportion of patients receiving a kidney transplant within 3 years of ESRD**,** moved away from the target. The remaining 2 objectives were not evaluated as they were informational with no target set. Disparities persisted by sex, race/ethnicity, and SES status.

Conclusions: The presentation will cover the most recent national and state data for selected CKD objectives and provide an overview of the HP2020 and data search using the HP2020 website.

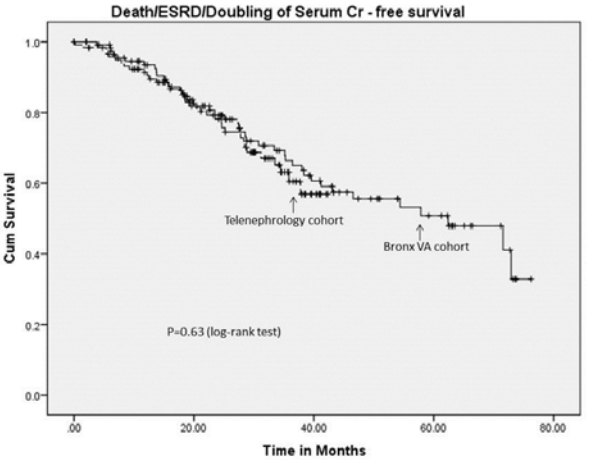
SA-PO714

Telenephrology for the Remote Management of Chronic Kidney Disease (CKD): A Retrospective Cohort Study Rajeev Rohatgi,[1,2] Judy K. Tan,[2] Anita Mehrotra.[2] *[1]Medicine, James J. Peters VAMC, Bronx, NY; [2]Medicine, Icahn School of Medicine, New York, NY.*

Background: Veterans with CKD who live in the Hudson Valley Veterans Affair Medical Center (HVVAMC) catchment area travel to the Bronx VAMC for nephrology care. Analysis of the no-show and cancellation frequencies for these renal appointments exceeded 50%, likely due to the distance between HVVAMC and the Bronx (60 miles).

Methods: We hypothesized that patients managed via a telenephrology service, where patients visit their local VA and are evaluated remotely via videoconference by a Bronx VA nephrologist, would exhibit comparable clinical outcomes and visit compliance as in-person renal care. In a retrospective observational study, the clinical outcomes of CKD patients enrolled in telenephrology (n=117) and the Bronx VA nephrology clinic (n=121) from 2008-14 were compared.

Results: Characteristics of the groups were similar (initial creatinine [Cr], eGFR, distribution of CKD stage, urine protein) except for race and probable cause of CKD. Prior to the telenephrology service, 53.1% of scheduled visits of HVVAMC patients to the Bronx VAMC renal clinic were either cancelled or "no-shows" and this was reduced to nearly half (29.2%) after instituting telenephrology ($p<0.001$). Moreover, the frequency of attending appointments was greater in the telenephrology (70.8%) vs. Bronx VA cohort (61.8%) which was driven by a greater frequency of cancelled visits in the Bronx VA (27.9%) vs. the telenephrology group (15.8%). The incidence of a composite outcome of doubling of Cr, ESRD and/or death was similar between both groups (Figure 1). The change in blood pressure and eGFR from baseline to 1 year was also similar.



Conclusions: Telenephrology is not inferior to in-person care for the management of CKD and may be superior for visit compliance. Application of this technology is a promising method to deliver care to CKD patients.

Funding: Veterans Administration Support

SA-PO715

Engaging Urban African Americans at Risk for CKD in Discussions About Their Diet Deidra C. Crews,[1] Debra L. Roter,[1] Raquel C. Greer,[1] Yang Liu,[1] Patti Ephraim,[1] Jessica M. Ameling,[1] Kimberly Gudzune,[1] Lisa A. Cooper,[1] L. Ebony Boulware.[1,2] *[1]Johns Hopkins U., Baltimore, MD; [2]Duke U., Durham, NC.*

Background: Patient-physician discussions about diet are recommended in primary care to decrease patients' health risks, including CKD. However, little is known about the frequency of diet discussions or factors influencing them among African Americans (AAs) at increased CKD risk.

Methods: In a randomized trial of urban AAs with uncontrolled hypertension, we audio-recorded patients' routine visits with their primary care physicians (PCPs) at the first visit following enrollment. We transcribed audio recordings, and quantified the frequency of patient-physician discussions about diet during visits. We marked transcripts for discussions of 36 dietary terms (e.g. sodium, weight, sweets). We also assessed patterns of patient-physician communication, including patient centeredness (degree to which the discussion focused on the patient's psychosocial and lifestyle context), during each encounter using the Roter Interaction Analysis System. We identified factors independently associated with discussions of diet using logistic regression.

Results: Among 127 participants, mean age was 58 years and 70% were female. Average PCP visit lasted 25 minutes. Diet was discussed in 73% of visits, but only included discussion of the Dietary Approaches to Stop Hypertension (DASH) diet in 12%, weight/obesity in 36%, and cholesterol in 39% of visits. Independent predictors of diet discussions (odds ratio, 95% confidence interval) were patient centeredness score ratio (7.5, 1.3-41.9), annual income (3.8, 1.4-10.5 comparing ≥$10k vs <$10k), and visit length (1.07, 1.02-1.1 for each minute increment). Patient age, gender, literacy, comorbid disease burden, obesity, diabetes nor CKD status predicted discussions.

Conclusions: Discussions of diet in primary care were frequent, and they were more likely to occur when visits were longer, were centered on patient priorities, and were attended by patients with incomes ≥$10k. Diet discussions focused on various topics, but infrequently on the recommended DASH diet or other key aspects of dietary modification. Improvements in the content of diet discussions among African Americans at risk for CKD may be needed.

Funding: NIDDK Support, Other NIH Support - NHLBI

SA-PO716

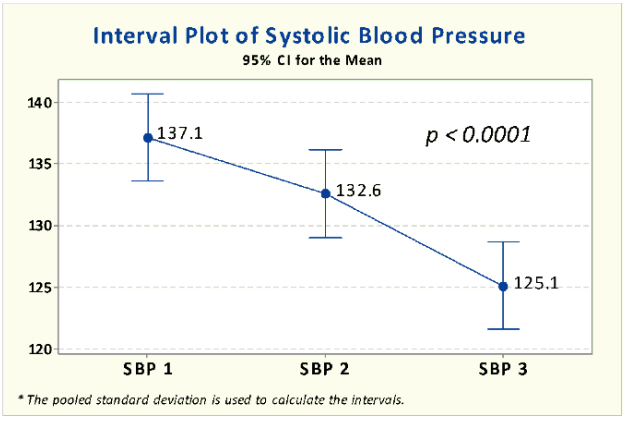
Tele-Nephrolog: A Feasible Way to Improve Access to Care for Patients with Kidney Disease Who Reside in Underserved Areas Marco A. Ladino Avellaneda, Desiree Garcia, Joslyn Wiley, Jose M. Cardona-Guzman, Alejandro Valdes, Alberto J. Sabucedo, Roberto J. Echeverri. *Dept of Medicine/Div of Nephrology, Miami VAMC/Univ of Miami, Miami, FL.*

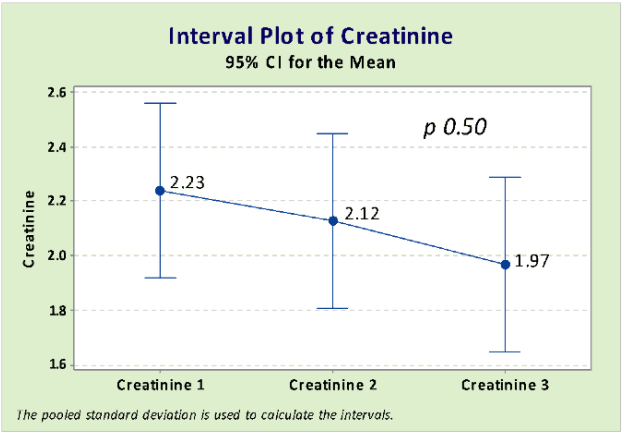
Background: The Miami VA Healthcare System serves veterans in three South Florida counties: Miami-Dade, Broward and Monroe, with an estimated veteran population of 175,000. To overcome geographical barriers and facilitate the access to nephrology evaluations, we implemented Provider-Patient Tele-Nephrology using secured videoconferencing.

Methods: A retrospective and descriptive study design was used to evaluate the effect of the Tele-Nephrology clinic intervention. Multiple clinical indicators were included in the analysis: blood pressure control, stabilization of the renal function and electrolyte/metabolic control. 101 patients that were evaluated in the clinic between 2013-2015 were included and the indicators were collected retrospectively.

Results: 101 patients were included, 95% male (n=96) and 5% female (n=5). The mean age was 65.5 years. 50 patients had Chronic Kidney Disease (CKD) stage III (49.5%), 14 patients had CKD stage IV (13%0, 8 patients had CKD stage II (7.9%). A one-way analysis of variance analysis (ANOVA) between subjects was conducted and showed that the effect

of the Tele-Nephrology clinic interventionon reducing blood pressure was statistically significant (systolic blood pressure P-value <0.0001). Renal function stabilized but the creatinine changes over time were not statistically significant (P-value: 0.50).





The potassium showed a significant improvement in this sample (P-value: 0.0076). Phosphorous and bicarbonate did not show a statistically significant improvement (p-value 0.79 and 0.91).

Conclusions: With the tele-nephrology clinic intervention we were able to effectively improve blood pressure and stabilize renal function in patients with kidney disease who reside in underserved areas.

SA-PO717

Impact of Exercise Counseling on Physical Function in Chronic Kidney Disease Clara Bohm,[1] Mara McAdams-DeMarco,[2] Navdeep Tangri,[1] Brett M. Hiebert,[1] Leroy J. Storsley,[1] Lawrence J. Cheskin,[2] Claudio Rigatto.[1] *[1]Univ of Manitoba; [2]Johns Hopkins Univ.*

Background: Few studies have investigated the effect of exercise counseling on physical function (PF) in chronic kidney disease (CKD). Using retrospective, quasi-experimental pretest-posttest non-equivalent control group design, this study investigated the effect of attending a real-world exercise counseling clinic (ECC) on PF in individuals with CKD.

Methods: Individuals with any stage of CKD registered with the Manitoba Renal Program from Jan. 1, 2011 to Dec 1, 2014 were eligible for inclusion. The exposed group (EC) included individuals who attended ECC. The control group (CG) included individuals who did not attend ECC, but participated in an observational frailty study. *Primary Outcome*: Change in Short Physical Performance Battery score (SPPB) at 1 year. Ranging from 0-12, lower SPPB represents worse PF. *Secondary Outcomes*: Change in health-related quality of life (HRQOL) at 1 year using EQ5D-3L; 2. Change in physical activity (PA) at 1 year using HAP and PASE. *Analysis*: Mann Whitney U, Independent T and Chi-square tests used for group comparisons.

Results: Of 194 individuals in EC and 216 in CG eligible for 1-year follow-up, 73 (37%) in EC and 72 (33%) in CG were assessed. At baseline, mean age was lower in EC (60 years) as compared to CG (68 years); p<0.01. Median SPPB scores at baseline and follow-up were significantly different between groups, but change in SPPB over time was not.

Group	N	Baseline SPPB (IQR)	Follow-up SPPB (IQR)	Mean Change in SPPB (SD)
EC	73	11 (9-12)	11 (9-12)	-0.2 (2.0)
CG	72	10 (8-11)	9 (6-11)	-0.6 (2.2)
P-value		p = 0.01	p = 0.01	p = 0.32

Subgroup analysis of individuals with eGFR < 30 ml/min or on dialysis reduced the differences in age and SPPB between groups, but demonstrated no significant difference to change in SPPB over time. HRQOL did not change significantly between groups. Proportion of individuals with improved PA over 1-year was 36% and 38% in EC and CG, respectively (p=0.82).

Conclusions: In this study, an exercise counseling clinic had no significant effect physical function as measured by SPPB at 1-year, suggesting that exercise counseling alone is inadequate to improve physical function in CKD.

SA-PO718

Ideal and Actual Support of Renal Replacement Therapy Modality Selection Patients with Chronic Kidney Disease: A Nationwide Survey in Japan Shiho Kosaka,[1] Shinichi Nishi,[2] Yugo Shibagaki,[3] Junichi Hoshino,[4] Kazuo Takahashi,[5] Yukiko Katagiri,[1] Chika Murayama,[1] Yuka Funaki.[1] *[1]Sophia Univ, Tokyo, Japan; [2]Kobe Univ Graduate School of Medicine, Kobe, Japan; [3]St. Marianna Univ Hospital, Kawasaki, Japan; [4]Toranomon Hospital, Tokyo, Japan; [5]Fujita Health Univ School of Medicine, Toyoake, Japan.*

Background: Optimal renal replacement therapy (RRT) selection supports for chronic kidney disease (CKD) patients are essential to improving post-therapy outcomes. We aimed to investigate how and when modality selection supports for patients with CKD are used by nephrologists in Japan, through a nationwide questionnaire survey of nephrologists.

Methods: A questionnaire was mailed to 1903 board-certified nephrologists of Japanese Society of Nephrology. Questionnaireitems targeting support for modality selection examined the following points: establishment of an RRT modality selection (RRT-MS) clinic, ideal and actual disease stage at which RRT-MS explanation is discussed, timing of RRT initiation, and type of specialist discussing RRT-MS with patients.

Results: The valid response rate was 12.3% (234/1903). Ninety-four out of 234 responding nephrologists (40.9%) had clinics dedicated to RRT-MS. Modality selection was most frequently discussed at CKD stage 4 (53.0%), stage 3b (22.8%), and stage 3a (13.4%). Nephrologists considered stage 3b (32.5%), stage 3a (19.5%), most ideal for discussing RRT-MS; a significant difference was therefore found between ideal and actual timing of RRT-MS discussion. Timing (by eGFR) of access placement of hemodialysis (HD) and peritoneal dialysis (PD) was significantly earlier in patients of RRT-MS clinics than in those of conventional clinics (HD, 12.3/14.1; PD, 12.6/14.9 mL/min/1.73 m^2). Regarding types of specialists, nurses most frequently supported patients in RRT-MS (67.1%); however, this may be partly explained by the fact that nephrologists are required to commit more specialiststo supporting patients for RRT-MS.

Conclusions: A gap between ideal and actual timing of discussion of RRT-MSwith patients in Japan was identified. To promote appropriate timing of RRT-MS among CKD patients, early and multidisciplinary support systems should be structured.

Funding: Government Support - Non-U.S.

SA-PO719

Primary Care Physicians' Perceived Barriers and Facilitators to Care of Older Adults with Kidney Failure Not on Dialysis Helen Tam-Tham, Brenda Hemmelgarn, Chandra Mary Thomas, Karen Fruetel, Robert R. Quinn, Kathryn M. King-Shier. *Univ of Calgary, AB, Canada.*

Background: Primary care physicians are important care providers for older adults with kidney failure, but how they perceive and practice conservative (non-dialysis) care has not been studied. We undertook a qualitative study to describe barriers, facilitators, and possible enhancements of conservative care in the community for these older adults.

Methods: Semi-structured telephone interviews were conducted with primary care physicians from southern Alberta, Canada. Participants were identified by a snowball sampling strategy and purposively sampled based on sex, age, and rural/urban location of clinical practice. All participants managed at least 1 patient ≥75 years with kidney failure (eGFR <15ml/min/1.73m^2 for at least 3 months, not on dialysis) over the past year. Transcripts were analyzed thematically by conventional content analysis.

Results: Twenty-seven primary care physicians participated in this study (55.6% of participants were male, 55.6% of participants were aged 40 to 60 years, and 51.9% of participants practiced in the primary care setting for greater than 20 years). Perceived barriers to conservative care included: managing expectations of kidney failure for patients and their families, optimizing medical management of conservative care, and negotiating provider roles and responsibilities of co-management. Facilitators for care included: establishing patient and their family expectations of care early, preserving continuity of care, and utilizing a multidisciplinary team approach. Primary care physicians also identified suggestions for enhancement of conservative care in the community, including direct telephone access by primary care physicians to conservative care clinicians, treatment decision aids for patients and their families, and a conservative care clinical pathway for primary care providers.

Conclusions: We found important barriers and facilitators to conservative care by primary care physicians in the community. Further investigation of potential strategies that remove barriers and enable facilitators is required to improve the quality of conservative care in the community.

Asking Patients If They Are Aware of Their Chronic Kidney Disease: Does the Question Matter? Delphine S. Tuot, Yunnuo Zhu, Alexandra Velasquez, Juan Maciel Espinoza, Celia Mendez, Tanushree Banerjee, Chi-yuan Hsu, Neil R. Powe. *Univ of California San Francisco.*

Background: Awareness of chronic kidney disease (CKD) is low, even among patients with advanced disease. Increasing awareness to 11.7% is a Healthy People 2020 goal. The National Health and Nutrition Examination Survey (NHANES) measures CKD awareness using the question "Have you ever been told by a doctor or other health professional that you had weak or failing kidneys (excluding kidney stones, bladder infections, or incontinence)?" The framing of this question may influence responses. We sought to compare its sensitivity/specificity to different questions as well as to awareness of other chronic conditions.

Methods: We administered a questionnaire to 220 English, Spanish and Cantonese-speaking adults who received primary care in a public healthcare delivery system. We obtained demographic data, screened for health literacy and ascertained patient awareness about chronic health conditions, including CKD, diabetes, hypertension and hyperlipidemia. CKD awareness was measured using the NHANES question and additional ones, asking if patients had been told about "kidney disease", "protein in the urine", "kidney problem", or "kidney damage". Health conditions were verified by medical record review.

Results: In our diverse study population (9.6% White, 40.5% Black, 36.4% Hispanic, 12.0% Asian), mean age was 58, mean eGFR was 47 ml/min/1.73m^2 and 47% had low health literacy. Sensitivities of each CKD awareness question were: 26.7% for "kidney damage", 28.0% for "kidney disease", 33.5% weak or failing kidneys" (NAHNES), 36.2% for "protein in the urine" and 40.6% for "kidney problem". Specificities ranged from 88.2% to 97.7%. Combining all 5 questions yielded a sensitivity of 61.1% and a specificity of 79.6%. This was comparable to awareness of hyperlipidemia (68.8%) but was lower than awareness for hypertension and diabetes (89.6% and 94.3% respectively). Sensitivities were lower in patients with low health literacy.

Conclusions: CKD awareness is low compared to other chronic diseases. Nevertheless, by using more sensitive combinations of questions to ascertain CKD awareness, we have likely reached the Healthy People 2020 goal.

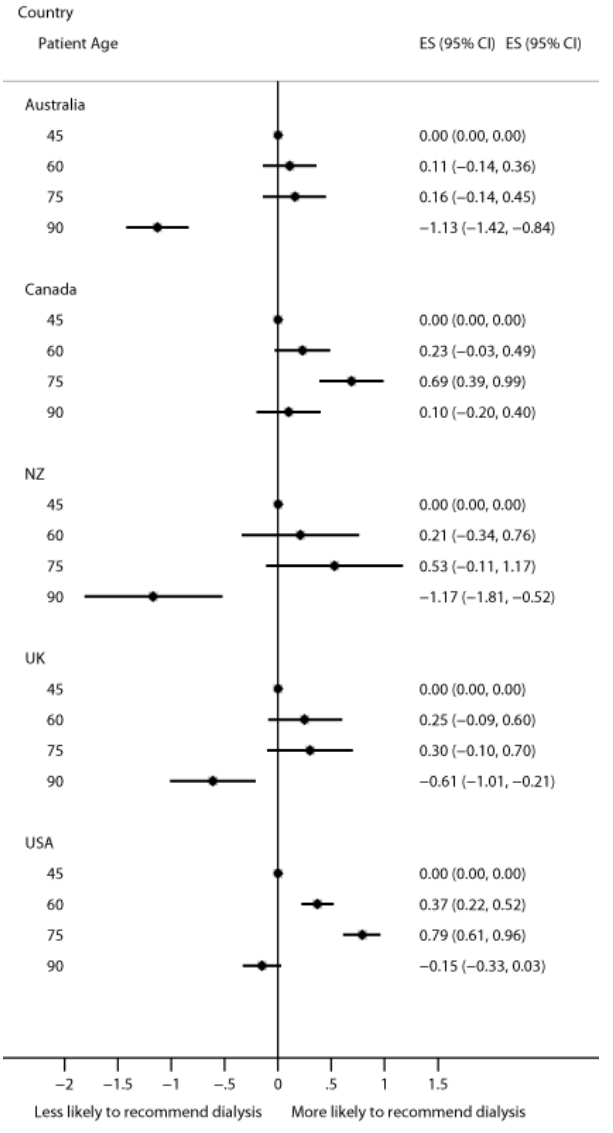
SA-PO721

The Effects of Age and Symptoms on Recommendations to Initiate Dialysis Michael Walsh, Rajnish Mehrotra, Carmel M. Hawley, Marcello Tonelli, Clare I. Castledine, Stephen P. McDonald, Peter Margetts, Darin Treleaven, Vicki Levidiotis, K. Scott Brimble. *McMaster Univ.*

Background: The extent to which patient characteristics influence Nephrologists' recommendations regarding initiation is unclear. We conducted an international survey to examine the effect of country on recommendations to initiate dialysis.

Methods: Nephrologists from Australia, Canada, New Zealand, the UK and the US were surveyed by email. The survey included clinical vignettes that varied patient characteristics. The recipient scored the likelihood they would recommend initiating dialysis on an 8-point modified Likert scale anchored at 1 (definitely would not) and 8 (definitely would). Results were analysed using mixed-effects regression.

Results: 771 nephrologists were included. The degree to which patient age was associated with recommending dialysis varied by country ($p<0.001$ for interaction) (Figure 1). For a given level of GFR, only nephrologists from Canada ($p<0.001$) and the US ($p<0.001$) were more likely to recommend dialysis for patients age 75 than those aged 45. Conversely, nephrologists from Australia ($p<0.001$), New Zealand ($p<0.001$) and the UK ($p=0.003$) were less likely to recommend dialysis for patients aged 90 than those age 45. All nephrologists were more likely to recommend dialysis as symptoms increased but this association was less pronounced in the US and Australia ($p<0.001$ for interaction). Patient comorbidities, nephrologists' years in practice, and practice type were not associated with recommendations.



Conclusions: For patients at a given eGFR, other characteristics such as age and symptom burden influence nephrologists' recommendations to initiate dialysis but the extent of this influence differed substantially between nephrologists in different countries. Further research is required to understand the effect of these differences on patients and health systems.

SA-PO722

The Association of Community Health Indicators with Late Nephrology Referral in Patients Reaching End-Stage Renal Disease in the U.S. Jung-Im Shin, Mari Palta, Micah R. Chan, Brad C. Astor. *Univ of Wisconsin School of Medicine and Public Health, Madison, WI.*

Background: Late nephrology referral in patients reaching end-stage renal disease (ESRD) is associated with inadequate preparation for dialysis and poorer clinical outcomes after renal replacement therapy (RRT). Previous studies have focused on individual-level factors to identify patients at higher risk of late nephrology referral. Environmental and socioeconomic conditions of communities in which patients live may also impact nephrology referral patterns.

Methods: We assessed the association of community health indicators with late nephrology referral in 587,574 patients reaching ESRD, using the data from United States Renal Data System (USRDS) from 2005-2012. An overall community health risk score was calculated using 35 community-level factors based on 1) health outcomes, 2) health behaviors, 3) access and quality of care, 4) socioeconomic factors, and 5) physical environment, using County Health Rankings data from University of Wisconsin Population Health Institute. Late nephrology referral was defined as the first encounter with a nephrologist occurring < 6 months before RRT initiation. Multilevel logistic regression models adjusted for individual characteristics, including demographics, cause of ESRD, body mass index, comorbidities, and insurance and employment status.

Results: The prevalence of late nephrology referral was 47.8%. A significant dose-response relationship of community risk score with late nephrology referral was found, with an adjusted odds ratio of 1.52 (95% CI: 1.36-1.71) for the highest versus lowest risk communities.

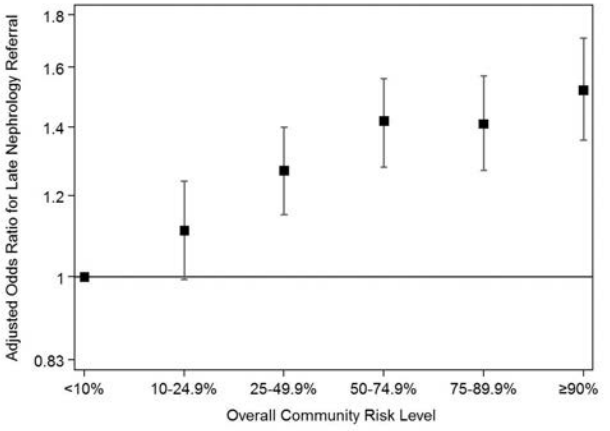


Figure 1. Adjusted odds ratio for late nephrology referral, by overall community risk level.

Conclusions: Higher community risk is significantly associated with late nephrology referral, independent of individual-level factors. Community risk may be an important consideration for developing interventions to improve access to pre-ESRD nephrology care.

SA-PO723

Assessment of Quality of Care Received by Patients with Predialytic Chronic Kidney Disease Seen at a Philippine General Medicine Out-Patient Clinic – Experience at a Government Training Hospital

Rizza Ann B. Lio. *Section of Nephrology, Univ of the Philippines-Philippine General Hospital, Manila, Philippines.*

Background: In a country with limited access to dialysis and transplantation such as the Philippines, it is imperative to recognize patients with early stage CKD and aggressively intervene in a timely fashion to prevent ESRD and death. The objective of this study is to evaluate the quality of care (QoC) of patients with predialytic CKD seen at a general medicine clinic.

Methods: This was a retrospective study which reviewed the medical records of 276 patients with CKD Stages 3-4 who have at least 1 year of consult. Patients who were admitted for critical illness, and are on dialysis were excluded. For each QoC parameter, percentage of patients who received the appropriate care were reported. For the QoC correlates, Mann-Whitney U Test, Kruskal-Wallis Test or regression analysis was done.

Results: The mean QoC score for this study is 58.36% (± 23.7%) and the average annual GFR decline is 3.92 mL/min/1.73m^2.

	Percentage Achieved
CKD Monitoring	
Diagnosis	72.83
Staging	39.13
Monitoring of GFR	97.10
Monitoring of Proteinuria	54.35
Cardiovascular Care	
BP Control	70.29
Glycemic Control	69.6
Dietary Modification	
Salt Restriction	82.25
Protein Restriction	30.43
Anemia Monitoring	51.81
Metabolic Bone Disease	
Baseline Calcium	66.67
Baseline Phosphate	44.93
Baseline Alkaline Phosphatase	10.51
Acidosis	70
Drug Safety	83.33
Nephrology Referral	55.47
TOTAL	58.36

In majority of patients, physicians failed to deliver CKD-specific management strategies such as proteinuria monitoring, protein restriction, anemia and metabolic bone disease recognition. Nephrology comanagement is associated with a better quality of care (85.9 vs. 48.6, p <0.001) and a lower GFR decline (1.64 vs. 4.7 mL/min/1.73m^2; p <0.001).

Conclusions: The study confirmed that there are significant gaps and challenges as well as opportunities for improvement in the delivery of quality health care to our patients. There is a need for education to improve the knowledge of primary care physicians in CKD management in consideration to the limited number of nephrologists in the country.

SA-PO724

Chronic Kidney Disease (CKD) Patients' Understanding of Renal Replacement Therapy (RRT) Options: Early Findings from the U.S. CKD Outcomes and Practice Patterns Study (CKDopps)

Laura H. Mariani,[1,2] Charlotte Tu,[1] Brian Bieber,[1] Elodie Speyer,[1] Jarcy Zee,[1] Hal Morgenstern,[2] Benedicte Stengel,[3] Bruce M. Robinson,[1] Francesca Tentori.[1,4] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Univ of Michigan, Ann Arbor, MI; [3]Inserm UMR1018, France; [4]Vanderbilt Univ, Nashville, TN.*

Background: Current KDIGO guidelines indicate that kidney failure patients should receive information on all RRT modalities, including conservative management.Even when education is provided, patients' understanding of such a complex topic may be limited. We report the perspective of US participants in the first year of CKDopps.

Methods: CKDopps is a new international prospective cohort study that enrolls adult advanced CKD patients in national samples of nephrology clinics in the US, Brazil, France, and Germany and follows patients through the dialysis transition period. As of early 2015, 245 US participants with eGFR<30 mL/min/1.73m^2 completed a self-administered questionnaire including their understanding of, education on, and preferences for RRT options.

Results: The median age of patients was 71; 43% were male and 57% had diabetes. 66% of patients reported they received no education about treatment options for kidney failure; 20% said they received one-on-one education; and 14% participated in a class. 34% recalled that in-center hemodialysis (HD) was discussed as a treatment option, and less than 25% recalled their doctor discussing peritoneal dialysis, home HD, conservative management, or transplantation. 58% of participants reported they did not know if transplantation was an option for them. Nearly 3 out of 5 participants did not know what RRT option they would choose if their kidneys failed.

Conclusions: Understanding of RRT options was poor among CKDopps participants in the US. Though the responses may not necessarily reflect information that was actually provided by their nephrology clinic teams, our results indicate that current educational strategies fail to adequately communicate key messages on RRT.

Statin Prescribing Among U.S. Ambulatory Outpatient Visits for Patients with CKD

William A. Janes,[1] Talar Markossian,[1] David J. Leehey,[2] Benjamin Ling,[1] Nicholas Burge,[2] Vinod K. Bansal,[1] Julia Koval,[1] Ivan Pacold,[1] Kevin Stroupe,[2] Holly J. Kramer.[1] *[1]Loyola Univ Chicago; [2]Hines VA Medical Center.*

Background: Approximately 1 in 3 adults with CKD is at high risk of developing cardiovascular disease (CVD). Recent lipid management guidelines agree that statins alone should be used for CVD prevention via lipid lowering. However, lack of congruent recommendations for statin use in adults with CKD may lead to low utilization of statins in this population at high risk for CVD.

Methods: Outpatient visit data during years 2006 to 2010 were obtained from the National Ambulatory Medical Care Survey to determine the frequency of statin prescriptions among outpatient visits for adults age ≥50 years with non-dialysis stage 1-5 CKD based on ICD9 codes. Drug type (particular statin or other cholesterol lowering drugs type) was determined by the generic code recorded in the survey data. The analysis accounted for the complex survey design and utilized the sampling weight, cluster and strata statements so that results are generalizable to US outpatient ambulatory visits during years 2006-2010.

Results: A total of 2262 visits were included with patients being 48% white, 54% male and mean age of 69.6 years. 52% visits were covered by Medicare. Overall, 43% and 31.5% of visits for non dialysis CKD stage 3-5 and stages 1-2, respectively, included a statin prescription with simvastatin being the most commonly prescribed statin. Table 1 shows the prevalence of statin prescription in all patients with non-dialysis dependent CKD by provider type for the outpatient visit.

Clinician Type	% Visits (standard error) with Statin Prescribing for Adults age ≥50 years with non-dialysis CKD by prescriber type
Internal Medicine/Family Practice	35.6 (0.05)
Cardiology	46.8 (0.10)
Nephrology	45.4 (0.13)
Advanced Nurse Practitioner	40.6 (0.16)
Physician Assistant	7.7 (0.04)

Conclusions: These results suggest that the rate of prescription of statins in CKD patients is suboptimal and differs by the provider who cares for the patient with CKD. Lack of CVD preventive care may impact overall CVD risk in patients with non-dialysis dependent CKD.

SA-PO726

Patients' Knowledge of Their Chronic Kidney Disease Stage and Education About Kidney Failure Prevention – The CKD-REIN Cohort

Benedicte Stengel,[1] Celine Lange,[2] Briançon Serge,[2] Luc Frimat,[3] Denis Fouque,[4] Maurice Laville,[4] Christian Jacquelinet,[2] Bruce M. Robinson,[5] Ziad Massy,[1,6] Christian Combe.[7] *[1]Inserm U1018-CESP UVSQ, Villejuif; [2]Agence Biomedecine; [3]CHU Nancy; [4]CHU Lyon; [5]Arbor Research Collaborative for Health, Ann Arbor; [6]A.Paré - APHP; [7]CHU Bordeaux, France.*

Background: Patient knowledge about their CKD stage and how to prevent kidney failure is important to reduce ERSD risk through better adherance to treatment and lifestyle changes. We report primary findings about CKD knowledge among patients seen by nephrologists in France.

Methods: We used baseline data from the CKD-REIN study, a prospective cohort of patients with CKD stage 3 and 4 in a national sample of 40 nephrology clinics. Information was collected from patient interview and self-administered questionnaire.Comparisons between stages were adjusted for age and gender.

Results: Median age was 68[60-76] and 56% were men. About 80% reported knowledge that their kidney function was low. Patients were more likely to know their creatinine level (~40%) than GFR or CKD stage. For each question, knowledge increased slightly from stage 3 to stage 4. Education about how to prevent kidney failure was uncommon (£10%)

	Answers	Stage 3	Stage 4	p
Patient Interview		**n=1,107**	**n=925**	
Has a doctor ever told you your kidney fonction was low?	Yes	77%	82%	0.002
Do you know your creatinine level ?	Yes	39%	43%	0.04
Do you know your GFR level ?	Yes	18%	27%	<0.001
Do you know your CKD stage ?	Yes	32%	34%	0.1
Patient questionnaire		**n=944**	**n=749**	
Have you attended a class or received one-on-one education about the prevention of kidney failure?	Yes, a class Yes, one-on-one	4% 4%	10% 9%	<0.001
During the past year, how many times have you see the nephrologist ?	None 1 or 2 ≥3 times	2% 72% 26%	2% 48% 50%	<0.001

Conclusions: Most CKD patients seen by nephrologists are aware that they have low kidney function, but their knowledge of disease severity is low. Very few received education about prevention of kidney failure. While the precise impact of these gaps in knowledge on CKD outcomes requires further investigation, the findings highlight the need to more effectively educate CKD patients about its potentially serious consequences.

Funding: Pharmaceutical Company Support - Amgen, Baxter, Fresenius, GSK, Lilly, MSD, Sanofi, Government Support - Non-U.S.

SA-PO727

The Cost-Effectiveness of Primary Screening for Chronic Kidney Disease in Rural and Remote First Nations

Thomas W. Ferguson,[1] Navdeep Tangri,[1,2] Matthew T. James,[3] Zhi Tan,[3] Claudio Rigatto,[1,2] Paul Komenda.[1,2] *[1]Community Health Sciences, Univ of Manitoba, Winnipeg, MB, Canada; [2]Medicine, Univ of Manitoba, Winnipeg, MB, Canada; [3]Medicine, Univ of Calgary, Calgary, AL, Canada.*

Background: Chronic Kidney Disease (CKD) is a risk factor for cardiovascular disease, early mortality, and kidney failure. We have shown that the burden of CKD in First Nations (FN) populations in Manitoba is similar to that in diabetic and hypertensive populations. The cost-effectiveness of screening for CKD and subsequent treatment in FN or other high-risk indigenous populations has not yet been described.

Methods: We constructed a Markov model comparing screening in adult FN (age 18+) for CKD by both proteinuria and estimated glomerular filtration rate (eGFR) to usual care from the perspective of the publicly funded Canadian health care payer. Patients were assigned an initial risk classification based on urine albumin-to-creatinine ratio and eGFR using the Kidney Disease Improving Global Outcomes (KDIGO) heat map. We obtained screening tests results on 1346 adult participants from the First Nations Community Based Screening to Improve Kidney Health and Prevent Dialysis (FINISHED) initiative. Our analysis was further stratified into communities accessible by road and communities accessed by air travel. Our primary outcome of interest was the incremental cost per quality-adjusted life-year (QALY).

Results: Overall crude prevalence of CKD in FN was 26.7%. Screening for CKD was associated with an ICER of $33,500/QALY in comparison to usual care. Restricting the model to screening in the remotest air access communities (prevalence of CKD 36.0%), this ratio fell to an ICER of $16,180/QALY. In less remote road access communities (CKD prevalence 18.4%) this ICER was $63,780/QALY. Primary model drivers included the cost of dialysis, assumed treatment effectiveness, and rates of progression towards kidney failure.

Conclusions: Targeted screening for CKD in rural and remote First Nations is likely cost-effective (< $50,000/QALY). These findings may be translatable to other high-risk indigenous groups with elevated rates of CKD and kidney failure and warrant further research.

SA-PO728

Getting a Diagnosis of Chronic Kidney Disease: Despite Fears, Patients Want to Know Early

Julie A. Wright Nunes,[1] Meghan Roney,[2] Eve Kerr,[3] Akinlolu O. Ojo,[1] Angela Fagerlin.[1,2,3] *[1]Internal Medicine, Univ of Michigan, Ann Arbor, MI; [2]Center for Bioethics and Social Sciences in Medicine, Univ of Michigan, Ann Arbor, MI; [3]Center for Clinical Management Research, VA Ann Arbor Healthcare System, Ann Arbor, MI.*

Background: Little is known about patient perspectives related to getting a diagnosis of chronic kidney disease (CKD). This information could help providers optimize diagnosis messaging at the point of care.

Methods: Using root/cause analysis and quality function deployment we conducted semi-structured patient interviews. Adult patients with established non-dialysis CKD were interviewed between January-October 2014. Interviews were audiotaped and transcribed. Content analysis was done with Dedoose, a qualitative software package.

Results: 49 patients completed interviews. Mean (SD) age was 63 (14) years, 50% were male, 80% were Caucasian and 84% had CKD Stage 3-5. Key themes emerged from a total of 786 statements: 1) Reaction to diagnosis (160 statements) 2) Barriers to accepting diagnosis (61 statements) and 3) Expectations of diagnosis communication (122 statements). 45% of patients felt fearful after getting a CKD diagnosis - most often related to perceived threats of future dialysis and death. Barriers to diagnosis acceptance included disbelief because of lack of symptoms and lack of prior familiarity with CKD. Despite fear and denial the majority of patients (63%) desired early diagnosis communication by their providers, i.e. at earliest stages of identification. Consistent terminology and disease explanations by providers across the care continuum were perceived as critical to effective communication and diagnosis delivery, yet patients expressed frustration at inconsistent terminology/explanations.

Conclusions: Our findings emphasize that patients learning of a CKD diagnosis can experience fear, but they also prefer early communication of diagnosis. More work is needed to set uniform diagnosis terminology for patients with CKD across the care continuum.

Funding: NIDDK Support

SA-PO729

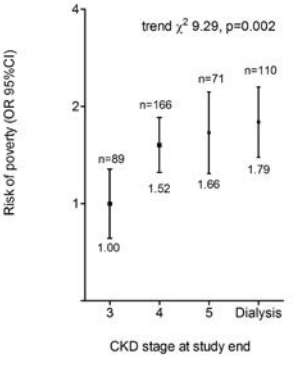
The Impact of Chronic Kidney Disease on Household Income: Does Health Affect Wealth?

Rachael L. Morton,[1,3] Alan Cass,[2] Borislava N. Mihaylova.[3] *[1]Univ Sydney, Australia; [2]Charles Darwin Univ, Australia; [3]Univ Oxford, United Kingdom; [4]On behalf of SHARP Collaborators.*

Background: The impact of progressive chronic kidney disease (CKD) on household income is unclear. We sought to determine whether CKD severity and non-fatal adverse events were associated with a fall into poverty.

Methods: Prospective cohort study among participants with moderate-to-severe CKD randomized into the Study of Heart and Renal Protection (SHARP) with information on household income at study entry and study end (median follow-up 5 years). Household income recorded as: High (> twice the participating country median); Medium-high (> the median, but < twice the median); Medium-low (< the median, but > half the median); and Low (< half the median income, i.e. poverty). Logistic regression models with socio-demographic factors, smoking, prior diseases, severity of CKD, income category at entry and incident non-fatal events (myocardial infarction, stroke, incident cancer, initiation of dialysis, kidney transplantation) were used to determine a fall into poverty, defined as a move into the lowest household income category.

Results: 2914 SHARP participants were included in the analysis; 933 of these were in poverty at screening and a further 436 (22% of the remaining) moved into poverty by study end. In addition to black ethnicity, low educational attainment, single adult household and low income category at baseline, CKD severity was a significant predictor of a fall into poverty.



Those who received kidney transplant were less likely to fall into poverty (OR 0.48, 95%CI 0.31-0.72). Non-fatal adverse events were not significantly associated with a fall into poverty.

Conclusions: Patients in advanced stages of CKD are at an increased risk of falling into financial hardship. Kidney transplantation may have a role in reducing the risks of household poverty due to CKD.

Funding: Government Support - Non-U.S.

SA-PO730

Healthcare Expenditures for Non-Dialysis Dependent Kidney Disease Compared to Other Chronic Diseases Christina Small,[1] Holly J. Kramer,[1] Karen A. Griffin,[1] David J. Leehey,[1] Vinod K. Bansal,[1] Kavitha Vellanki,[1] Talar Markossian.[1] *[1]Loyola Univ Chicago; [2]Hines VA Medical Center.*

Background: There is a paucity of literature comparing the expenditures of kidney disease with other common costly chronic diseases in the United States. Our study compares the U.S. healthcare expenditures of non-dialysis dependent kidney diseases to several other chronic conditions.

Methods: This study used the 2012 Medical Conditions and Consolidated Data files from the Medical Expenditure Panel Survey administered by the Agency for Healthcare Research and Quality. Analyses included adults age ≥ 21 years with one of the following conditions: kidney disease, stroke, cancer, or a combination of the three (multichronic). Non-dialysis dependent kidney disease included any ICD9 code for kidney related conditions while chronic kidney disease (CKD) included only ICD9 code "585". Analyses of calculated healthcare expenditures accounted for the complex survey design and incorporated the sampling weights so that estimates represent healthcare expenditures for the 2012 adult U.S. population (~313.4 million). Out of pocket healthcare expenditure burden was defined as the ratio of out of pocket healthcare expenditure to total person-level income for the year 2012.

Results: The mean age for non-dialysis dependent kidney disease and CKD was 56.5 and 65.9 years, respectively. Table 1 shows the median total and out of pocket healthcare expenditure values and mean out of pocket healthcare expenditure burden for kidney disease, CKD and other chronic conditions.

Chronic Condition	Median Out of Pocket Expenditures, $ (range)	Median Total Expenditures $(range)	Mean Out of Pocket Expenditures Burden %
CKD	862 (38-13,915)	22, 919 (1,782-189,893)	9.5
Any kidney disease	795 (0-42,034)	6,351 (0-262,189)	5.0
Cancer	760 (0-54,698)	8, 528 (0-147,533)	5.2
Stroke	790 (0-79, 313)	7,606 (0-212, 886)	5.2
Multiple Chronic Conditions	824 (2-5,711)	16, 323 (992-276, 047)	6.0

Conclusions: Healthcare expenditures including out of pocket costs are higher for non-dialysis dependent CKD compared to other chronic medical conditions. Policy efforts should focus on reducing the healthcare cost burden for patients with kidney disease.

SA-PO731

Smartphone-Based Self-Management System for Chronic Kidney Disease: Results from a Single Centre Prospective Trial Stephanie W. Ong,[1,2] Sarbjit Vanita Jassal,[1] Akib Uddin,[3] Kelly Min,[1] Joseph A. Cafazzo,[3] Alexander G. Logan.[1] *[1]Nephrology, Univ Health Network, Toronto, ON, Canada; [2]Pharmacy, Univ Health Network, Toronto, ON, Canada; [3]Centre of Global eHealth Innovation, Univ Health Network, Toronto, ON, Canada.*

Background: Following user-centric design principles we developed a smartphone-based self-management support system for patients with advanced CKD. The patient interface focuses on 4 behavioral elements over which they have direct control: monitoring BP at home, self-assessment of symptoms, managing medications and tracking laboratory results. The main objectives of this 6-month prospective study were to determine acceptability,measured by system adoption and adherence, and assess effectiveness by measuring pre and post changes in BP,medications, labs and self-management behaviors.

Methods: We tested the mobile app system in 10 renal clinics at a single academic renal center in Toronto. The 47 enrolled patients were instructed at a regular clinic visit on the use of the mobile app.The clinical team independently received information on the mobile app system's operation.

Results: 61% of participants were non-smartphone owners. All had more than one chronic condition and on average were on 10 to 15 medications. Most were over the age of 50 with the greatest representation in the age group 55-64. >80% of the users achieved more than the recommended 80% adherence rate to mobile app use.27% with normal clinic BP readings were discovered to have 'masked' hypertension on home BP monitoring. By the end of the study the SBP fell by 6.8 ± 20.4 mm Hg ($p<0.05$) and DBP, by 0.9 ± 9.1 mmHg. Out of 250 medication reviews,49% required intervention from the clinical team, such as altering drug dosing. Due to the short study duration and infrequency of lab testing,there were no changes in pre and post laboratory test results. On exit, patients and clinicians felt the mobile app helped engage and empower patients in their CKD care.

Conclusions: The mobile app was acceptable and suggests improvements in BP management and medication error prevention. This offers early evidence to supporting innovative use of mobile technology in CKD management and strongly support evaluating its use in a larger clinical.

SA-PO732

Potentially Preventable Hospitalization Among Patients with Chronic Kidney Disease and High Inpatient Use Paul E. Ronksley, Braden J. Manns, Marcello Tonelli, James Wick, Brenda Hemmelgarn. *Univ of Calgary, Calgary, AB, Canada.*

Background: While prior studies have observed high rates of hospitalization among patients with chronic kidney disease (CKD), little attention has been given to those with high inpatient use. We explored clinical characteristics, patterns of hospital use, and potentially preventable acute care encounters among hospitalized patients with CKD.

Methods: We identified all adults (³18 years) with an eGFR<60 mL/min/1.73m2 in Alberta, Canada between Jan 1 and Dec 31, 2009, excluding those with prior kidney failure. Patients with CKD were linked to administrative data to capture clinical characteristics and frequency of hospital encounters, and followed until death or end of study (Dec 31, 2012). Patients with 1 or more hospital encounters were categorized into 3 groups: persistent high use (upper 5% of inpatient use (³3 encounters/yr) in 2 or more years), episodic high use (upper 5% in 1 year only), or non-high use (lower 95% in all years). Within each group we described patient characteristics and calculated the proportion of potentially preventable hospitalizations as defined by 4 CKD-specific ambulatory care sensitive conditions (ACSC); heart failure, hyperkalemia, volume overload, malignant hypertension.

Results: During a median follow-up of 3 years, 57007 patients had 118671 hospitalizations of which 1.7% of patients were persistent high users of hospital services, 12.3% episodic high users, and 86.0% non-high users. Persistent high users were often younger, male, First Nations, living in rural areas, and had higher levels of comorbidity compared to episodic and non-high use groups. Overall, 24804 (20.9%) CKD-related ACSC encounters were observed in the cohort. The proportion of ACSC encounters were higher in persistent high users (29.1%) compared to episodic (27.3%) and non-high users (17.3%) ($p<0.01$). The majority of the encounters were attributed to heart failure and hyperkalemia in all groups.

Conclusions: A substantial proportion of hospitalizations among patients with CKD and high inpatient use are ACSC-related. These findings suggest opportunities to reduce inpatient use and cost by focusing on strategies to improve community-based care for this subset of patients.
